Abstract

AIM: The utility of serum alpha-fetoprotein (α -FP) in the detection of hepatocellular carcinoma (HCC) is questionable. Very high circulating levels of nociceptin/orphanin FQ (N/OFQ), a ligand for a novel opioid receptor, have recently been reported in HCC. The aim of this study was to assess the role of plasma N/OFQ in the diagnosis of HCC arising in patients with liver cirrhosis.

METHODS: Plasma N/OFQ levels were measured by ELISA in 58 patients (28 HCC and 30 liver cirrhosis) and in 25 healthy controls. The values were correlated with clinical and laboratory features including α -FP. Spearman index, biserial correlation coefficient, non parametric combination (NPC) test and discriminant stepwise analysis were used for statistical evaluation of data.

RESULTS: The upper normal limit of nociceptin was 122 pg/mL. Plasma levels above this cut-off were found in 21.4% of patients with HCC, in 23.3% of those with cirrhosis and in 8% of healthy subjects. α -FP serum levels > 200 ng/mL were found in 46.4% of the patients with HCC and in none of those with cirrhosis. No correlation was found between N/OFQ levels and any of the clinical and laboratory features, including α -FP. By NPC test, HCC and cirrhotic patients were different with regard to α -FP ($P = 0.000$) but not in terms of nociceptin ($P = 0.595$). By point biserial correlation, HCC presence was positively correlated with α -FP ($r_{pb} = 0.52$, $P = 0.000$) but not with N/OFQ ($r_{pb} = 0.16$, $P = 0.157$). In a discriminant analysis, α -FP was significant in the Wilks test ($Y = -0.709 + 0.03 \alpha$ -FP) and properly classified

81% of all patients and 61% of HCC. N/OFQ had lower sensitivity, specificity and predictive values than α -FP.

CONCLUSION: Nociceptin is increased in patients with chronic liver disease, independently of the presence of HCC, although the underlying mechanism has yet to be clarified. We conclude it is not a useful marker for HCC.

INTRODUCTION

Nociceptin/orphanin FQ (N/OFQ) is a 17-aminoacid neuropeptide with selective binding affinity for a novel opioid receptor-like 1 (ORL1/NOP). N/OFQ is synthesized in the neurons of the central and peripheral nervous system and is present in the blood and in the cerebrospinal fluid. The N/OFQ/NOP system has been implicated in a variety of biological functions at both central and peripheral levels: pain modulation, immunity, memory, learning, feeding, locomotion, thermoregulation and activities of the gastrointestinal, cardiovascular, renal and respiratory systems^[1,2]. However, its precise biological role in humans has not been fully defined. The presence of N/OFQ/NOP has also been reported in human neuroblastoma cell-lines^[3]. N/OFQ is detectable in the blood and high circulating levels have been reported in incidences of acute and chronic pain, where they are correlated with the duration of symptoms^[4]. In Wilson disease, probably in relation to altered catabolism caused by liver and/or brain deposits of copper^[5], and in cirrhosis of the liver^[6] slightly increased circulating levels of N/OFQ have recently been found. Moreover, very high

levels have been reported in patients with hepatocellular carcinoma (HCC) suggesting that plasma N/OFQ level might represent a specific marker for HCC^[6].

HCC is the leading cause of death in patients with cirrhosis of the liver^[7]. The most commonly used serological marker for HCC surveillance, alpha-fetoprotein (α -FP), has highly variable sensitivity and specificity^[8] while the diagnostic utility of other markers, such as des- γ -carboxyprothrombin^[9], human hepatocyte growth factor^[10], and serum chromogranin-A^[11] remains unclear.

The aim of this study was to investigate the utility of plasma N/OFQ levels in the diagnosis of HCC in patients with liver cirrhosis.

MATERIALS AND METHODS

Patients and healthy subjects

Fifty-eight consecutively observed patients, 28 with HCC and 30 with liver cirrhosis, and 25 healthy members of the medical staff were included in the study. Informed written consent was obtained from patients and healthy controls. The diagnosis of HCC was based on imaging findings and/or histological confirmation. The diagnosis of liver cirrhosis was clinical and/or histological. The demographic and clinical characteristics of the populations studied are shown in Table 1.

Parameters examined

Clinical features (age, gender, etiology, Child-Pugh score, HCC size, presence of pain) and laboratory parameters as reported in Table 2 (plasma N/OFQ, serum α -FP, blood glucose, blood urea, serum creatinine, K, Na, Ca, bilirubin, aspartate aminotransferase, alanine aminotransferase, gamma glutamyl transpeptidase, alkaline phosphatase, lactic dehydrogenase, creatine phosphokinase, amylases, cholinesterase, albumin, erythrocyte sedimentation rate, C-reactive protein, fibrinogen, international normalized ratio, hemoglobin, red blood cells, white blood cells, platelets) were evaluated through statistical analysis.

N/OFQ assay

Blood drawn from fasting subjects between 7.30 and 9.30 AM was collected in tubes containing K-EDTA. Aprotinin was immediately added to inhibit proteases. Plasma samples, stored at -80°C for less than one month, were loaded onto C-18 containing Sep-columns (Phoenix Europe GmbH, Karlsruhe, Germany), washed with 0.1% trifluoroacetic acid, eluted with 60% acetonitrile in 1% trifluoroacetic acid and freeze-dried. ELISA assay of N/OFQ was performed using a commercially available kit (Phoenix Europe GmbH, Karlsruhe, Germany). Briefly, the lyophilized samples reconstituted with assay buffer were placed in microwells, together with rabbit anti-orphanin FQ serum and biotinylated peptide. After 2 h incubation at room temperature, streptavidin-horseradish peroxidase was added followed by a 1 h incubation. After washing, 100 μ L of substrate solution was added and the reaction was terminated after 1 h with 100 μ L of 2N HCl. Absorbance was read at 450 nm and results were compared to a standard curve ranging from 10 to 100.000 pg/mL.

Table 1 Clinical-Demographic characteristics of the populations studied

	HCC	Cirrhosis	Controls
Number of patients	28	30	25
Mean age \pm SD (yr)	70 \pm 4.8	65.3 \pm 11.1	35.4 \pm 13.9
Male/Female	20/8	21/9	10/15
Etiology <i>n</i> (%)			
HCV	24 (85.8)	15 (50)	
HBV	-	3 (10)	
Alcohol	2 (7.1)	8 (26.7)	
Cryptogenic	2 (7.1)	4 (13.3)	
Child - Pugh score <i>n</i> (%)			
A	22 (78.6)	19 (63.3)	
B	6 (21.4)	7 (23.3)	
C		4 (13.3)	
Patients with pain (%)	4 (14.3)	5 (16.6)	6 (24)
HCC diameter min-max (cm)	1.2-12.5		

HCV: Hepatitis C virus; HBV: Hepatitis B virus; HCC: Hepatocellular carcinoma.

Statistical analysis

Correlations among the variables studied were calculated using non-parametric Spearman index and biserial correlation coefficient^[12], as appropriate. Differences between groups were evaluated using the Non Parametric Combination Test, NPC^[13]. $P < 0.05$ was considered as statistically significant. Variables discriminating the groups of patients were identified with discriminant stepwise analysis (Wilks test and Classification results)^[14]. The upper normal limit of N/OFQ was defined as the 95th percentile of the values in healthy controls. Software packages used were Methodologica S.R.L. (2001) for non-parametric analysis NPC test, Confidence Interval Analysis (CIA) Windows version 2.0 (2000) for sensitivity and specificity evaluation, and SPSS, Windows 11.0 (2001) for correlation index and discriminant analysis.

RESULTS

The upper normal limit of N/OFQ was 122 pg/mL. Plasma levels above this cut-off were found in 6 patients with HCC (21.4%), in 7 patients with cirrhosis (23.3%) and in 2 healthy subjects (8%). α -FP serum levels > 200 ng/mL, reported in the literature as highly suggestive for HCC^[20], were found in 13 patients with HCC (46.4%) and in none of the patients with cirrhosis (Figure 1).

In all the groups, N/OFQ levels were not correlated with any of the demographic-clinical features nor with the laboratory parameters mentioned in the materials and methods section. In particular, N/OFQ levels were not correlated with α -FP levels.

The NPC test showed that patients with HCC and patients with cirrhosis were significantly different with regard to α -FP ($P = 0.000$), but not according to N/OFQ levels ($P = 0.595$). Point biserial correlation showed that HCC presence was positively correlated with the levels of α -FP ($rpb = 0.52$ $P = 0.000$) but not with those of N/OFQ ($rpb = 0.16$ $P = 0.157$). Within the discriminant

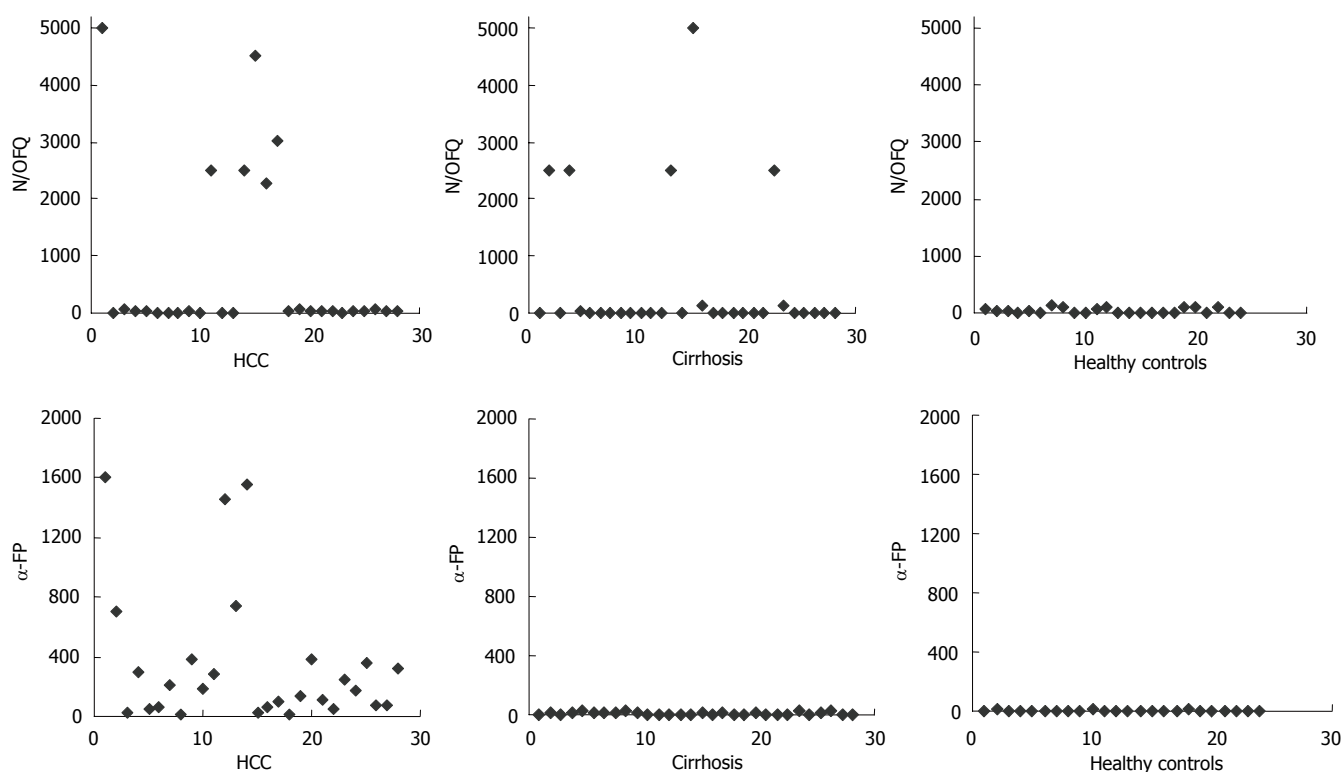

Figure 1 N/OFQ (pg/mL) and α -FP (ng/mL) values in patients with HCC, with cirrhosis and in healthy controls.

Table 2 Laboratory parameters included in the statistical analysis

Mean values \pm SD	HCC	Cirrhosis	Controls

Table 3 Diagnostic accuracy tests

	N/OFQ		α -FP	
Sensitivity % (CI)	21.4	(0.06 - 0.36)	46.4	(0.29 - 0.64)
Specificity % (CI)	76.7	(0.61 - 0.91)	100	(0.88 - 1.00)
Positive predictive value % (CI)	46.2	(0.19 - 0.73)	100	(0.77 - 1.00)
Negative predictive value % (CI)	51.1	(0.36 - 0.65)	66.7	(0.52 - 0.78)
Positive likelihood ratio (CI)	0.92	(0.35 - 2.40)	∞	(4.01 - ∞)
Negative likelihood ratio (CI)	1.02	(0.77 - 1.35)	0.53	(0.33 - ∞)

analysis, the Wilks test showed that only α -FP was significant in the model ($Y = -0.709 + 0.03 \alpha$ -FP). The classification of results demonstrated that α -FP properly classified 81% of all patients and 61% of patients with HCC. Sensitivity, specificity and predictive values of N/OFQ and α -FP in the diagnosis of HCC are reported in Table 3.

DISCUSSION

HCC is the third leading cancer-related cause of death worldwide^[15]. In western countries, HCC arises in cirrhotic livers with an annual incidence of 3%-5%. Early detection of HCC allows optimal application of curative treatments. The increased survival, after radical treatment in the last decade, recommends surveillance for detection of early HCC in cirrhosis^[16]. Ultrasonography plays a key role in the detection of HCC but its sensitivity for small

nodules is low^[17] and other imaging techniques, such as CT and MRI, are too expensive for screening programs. An elevation in serum α -FP is associated with HCC but it is also elevated in non-hepatic malignancies^[18] and in hepatitis^[19]. Although the diagnostic accuracy of serum α -FP is highly variable in the reported series depending on the cut-off level^[20], it remains the most commonly used serological marker for HCC surveillance. The diagnostic value of other markers proposed so far, such as des- γ -carboxyprothrombin^[9], human hepatocyte growth factor^[10], serum chromogranin-A^[11], is not well defined. It has recently been published that plasma levels of N/OFQ are very high in all patients with HCC, including those with normal α -FP^[6]. With the aim to define if plasma N/OFQ values represent an indicator of HCC even in absence of increased α -FP, we studied circulating N/OFQ and α -FP levels in patients with liver cirrhosis, with and without HCC, comparing the diagnostic value of the two markers.

Mean N/OFQ values were higher both in patients with liver cirrhosis alone and in those with HCC than in controls, but did not differ significantly between the two patient groups, with a similar percentage of values above the normal range. On the other hand, mean α -FP levels in HCC patients were higher than in cirrhotics, with a higher percentage of values > 200 ng/mL. The NPC test showed significant differences between patients with and without HCC with regard to α -FP but not for N/OFQ. Such data are in accordance with the results of Szalay *et al.*^[6] with respect to the increase in plasma N/OFQ values seen in cirrhotic patients, but do not confirm the unique finding of extremely elevated values in the entire population with HCC. Since the demographic and clinical features, including size of the tumor and presence of pain, are similar among the patients enrolled in the two studies, we are not able to suggest any explanation other than possible genetic differences for the discordant results.

Receptors for N/OFQ are normally present in the liver as shown by detection of mRNA for the ORL1/NOP receptor^[21]. Therefore, an increase in plasma N/OFQ values in some patients with chronic liver disease, with and without HCC, might be due to the chronic liver disorder with a reduced ability to bind N/OFQ.

Transcription of the N/OFQ gene is enhanced by estrogen^[22], therefore another explanation for the increase of N/OFQ plasma levels in cirrhotic livers, independently of the presence of HCC, might be the increase of estrogen hormones, common in patients with advanced liver disease.

A higher N/OFQ content has been shown in HCC tissue as compared to tumor-free liver tissue in one patient with PBC^[23] and in rats with experimentally induced tumors^[24], suggesting that the HCC cells might produce N/OFQ or give signals for neuronal production. However, we were not able to find any correlation between plasma N/OFQ levels and tumor size, in agreement with the finding of Szalay *et al.*^[6].

Peripheral blood neutrophils express and secrete N/OFQ following degranulation^[25]; N/OFQ stimulates chemotaxis^[26] and is present at sites of inflammation, such as synovial exudates^[25]. However, in this study, we were not able to correlate the amounts of circulating N/OFQ with

any of the inflammatory indices (erythrocyte sedimentation rate, C-reactive protein, peripheral leukocytes, fibrinogen, platelets).

It has been demonstrated that N/OFQ plays a role in the perception of pain, inhibiting the release of various neurotransmitters, including pain related peptides^[27,28]. However, no correlation between plasma values of N/OFQ and the presence of pain in any of the groups studied was found.

When we compared the diagnostic utility of N/OFQ and α -FP in HCC, α -FP had better sensitivity (46% *vs* 21%), better specificity (100% *vs* 77%), higher positive predictive value (100% *vs* 46%) and negative predictive value (67% *vs* 51%).

In conclusion, from our experience, N/OFQ cannot be recommended as a marker for early detection of HCC in patients with liver cirrhosis. α -FP is very specific when a high cut-off (200 ng/mL) is adopted but its sensitivity is low. N/OFQ is increased in patients with chronic liver disease, independent of the presence of HCC, although the underlying mechanism needs to be clarified. In the diagnosis of HCC, further research is needed in order to find serum markers more sensitive than α -FP.

Abstract

AIM: To study whether CCR5 Δ 32 mutation was associated with viral infection and severity of liver disease.

METHODS: Two hundred and fifty two histologically proven, chronic HCV patients (mean age: 41 ± 14 years; M/F: 164/88) were genotyped. PCR based genotyping of 32 bp deletion at the CCR5 locus was done. Four-hundred and eight matched healthy controls were studied to assess susceptibility to HCV infection. To assess correlation of immune gene polymorphism with severity of HCV related liver disease, patients with chronic HCV infection were divided into those with a fibrosis score of ≤ 2 (mild) or > 2 (severe) and histological activity index (HAI) of ≤ 5 or > 5 . For correlation between CCR5 Δ 32 mutations and response to therapy, 129 patients who completed therapy were evaluated.

RESULTS: The majority (89.4%) of the patients were infected with genotype 3. The frequency of homozygous CCR5 Δ 32 mutants was comparable to HCV patients as compared to the healthy controls (0.7% vs 0%, $P = 0.1$). Further more, the frequency of CCR5 Δ 32 mutation was comparable in patients with mild or severe liver disease.

INTRODUCTION

HCV is the only known positive stranded RNA virus that causes persistent long-life infection in humans. Hepatitis C virus is an important cause for chronic liver disease and hepatocellular carcinoma in a proportion of patients with persistent infection. The mechanisms of chronicity and progression of liver disease are probably multifactorial and involve a rather complex interplay between the virus and the host. There has been a surge of interest in studying various immunomodulatory genes to answer these questions.

Hepatitis C virus being a hepatotropic virus requires the recruitment of virus specific T cells to the liver for viral clearance. Chemokines and interaction with their receptors may regulate the selective recruitment of primed Th-1 cells to the site of inflammation. It has been proposed that the immune response in chronic hepatitis C is compartmentalized, with a predominantly Th-2 or Th-0 response in the periphery and a Th-1 response in the liver^[1-5]. In contrast, patients who clear the virus have a predominant peripheral Th-1 response. Moreover, differences in chemokine receptor expression between Th-1 and Th-2 cells might explain their selective recruitment to tissue. In particular, lymphocytes infiltrating HCV infected liver express high levels of the chemokine receptor (CCR5) and CXCR4.

chemokine receptor (CXCR3). The CC chemokine macrophage inflammatory protein (MIP)-1 α (CCL3), MIP-1 β (CCL4) and RANTES (CCL5) are important in immune surveillance. These chemokines bind to their corresponding receptors CCR1 and CCR5. Both these receptors are preferentially expressed on lymphocytes with a Th-1 cytokine secretion pattern. Chronic hepatitis C virus infection has been shown to lead to reduced surface expression of CCR1 and CCR5 on peripheral blood T lymphocytes^[6] and more so, on CD8 lymphocytes. While the mechanism of altered chemokine receptor expression and chemokine responsiveness is still not clear, reduced expression would probably lead to a decrease in T lymphocyte migration in response to MIP-1 α , MIP-1 β and RANTES in chemotaxis assays.

The Δ 32 mutation of the CCR5 gene was reported to be associated with inflammatory bowel disease by some but not all authors^[7]. Furthermore, a negative correlation with susceptibility to rheumatoid arthritis has been described^[8,9]. In contrast to these weak or contradicting correlations, the Δ 32 mutation was found to be of paramount importance for protection against HIV infection. The β -chemokine receptor CCR5 appears to be the major co-receptor for entry of macrophage-tropic and non-syncytium-inducing (NSI) variants of HIV^[10]. A 32 bp deletion mutation (Δ 32) of the CCR5 gene encodes a non-functional protein. Homozygosity for the Δ 32 deletion makes the CD4 T cells resistant to infection from NSI virus strains or delay HIV-1 disease progression in CCR5 Δ 32 heterozygotes.

There is a controversy related to the role of CCR5 Δ 32 mutation in susceptibility to HCV infection and disease progression. Woitas *et al* have suggested that a genetically determined loss of CCR5 gene expression is linked to chronic HCV infection and high viral load^[11]. On the other hand, a recent study by Promrat *et al* has shown that reduced expression of CCR5 and RANTES may lead to reduced hepatic inflammation and 59029 -G/A to improved response to interferon therapy in chronic hepatitis C^[12]. Hellier *et al* also suggested a possible role of CCR5 Δ 32 polymorphism in the outcome of HCV infection^[13].

The present case-control association study was undertaken to identify whether CCR5 Δ 32 mutation is associated with HCV disease progression and severity. We also compared the allele frequencies defined by CCR5 Δ 32 mutation in HCV patients with a control group of healthy individuals in order to identify a possible association with susceptibility to disease.

MATERIALS AND METHODS

Patients

Two hundred and fifty two patients with histologically proven chronic HCV infection were studied. The *inclusion criteria* were evidence of chronic hepatitis on liver biopsy and HCV RNA positivity on two occasions at baseline. The HCV RNA was detected as described elsewhere^[14]. HCV genotyping was performed with the reverse hybridization line probe assay (LIPA; Innogenetics, Ghent, Belgium). Patients were *excluded* if they had hepatitis B virus (HBV) or HIV infection, history of heavy alcohol consumption

(> 80 g/d for > 5 years), positivity for antinuclear or anti smooth muscle antibody (in 1:80 dilution), autoimmune liver disease, thyroid disease, diabetes mellitus or malaria. The Institutional Ethical Committee approved the study protocol. An informed consent was obtained for enrolling the patients. The clinical and biochemical assessment of the patients was done according to the study protocol. The histological examination of liver biopsies was done according to the modified Knodell scoring system^[15].

Patients received either 3 million IU of IFN α 2b daily for 24 to 48 wk. A group of patients received pegylated IFN- α 2b (1 to 1.5 μ g per wk) for either 24 or 48 wk depending on viral genotype. All patients received ribavirin given orally (patients with < 65 kg received 800 mg/d and 65-85 kg received 1000 mg/d). Outcome of treatment was classified as follows: End Therapy Response (ETR): patients with undetectable HCV RNA at the end of treatment; Sustained Virological Response (SVR): patients with undetectable HCV RNA 6 mo after the end-of-treatment; Non-Response (NR): failure to achieve viral clearance at the end-of-treatment or 6 mo there after.

Controls

Unrelated healthy adult subjects, with no previous history of liver disease and negative for HBV and HCV infection were included as controls. A total of 408 healthy subjects were included as controls. Both patients and control groups included Hindus, Muslims, and Christians. Patients and controls were prospectively matched for ethnic group.

DNA extraction and PCR- based genotyping of allelic variants

Genomic DNA was extracted from whole blood using a commercially available kit. The CCR5 Δ 32 deletion mutation was detected by PCR based techniques as mentioned elsewhere^[16]. Primers amplified 2 fragments of 200 bp and 172 bp corresponding to wt and deleted CCR5 alleles. Primer sequences were CCR5L-5' TTA AAA GCC AGG ACG GTC AC 3' CCR5R-5' GAC CAG CCC CAA GAT GAC TA 3'. Cycling conditions were 96°C for 5 min, followed by 30 cycles at 94°C for 30 s, 58°C for 30 s, and 72°C for 30 s. A final extension step of 72°C for 10 min was applied. Amplified fragments for the CCR5 locus were resolved in 2% agarose gel electrophoresis and visualized by ethidium bromide staining.

DNA sequencing

The CCR5 Δ 32 mutation was confirmed by sequencing. For DNA sequencing, ABI PRISM Dye Terminator Cycle Sequencing Ready Reaction Kit (ABI) was used.

Correlation of immune gene polymorphism and persistence of HCV infection

To study whether persistence of HCV infection is linked to immune gene polymorphism, patients with chronic HCV infection were compared with healthy controls.

Correlation of immune gene polymorphism and severity of HCV related liver disease

To study whether immune gene polymorphisms influence the course of HCV related liver disease, patients were

categorized on the basis of the stage of ALT levels (< 60 or ≥ 60 IU/L), hepatic fibrosis and histological activity index (HAI). Patients were divided into those with a fibrosis score of ≤ 2 (mild) or > 2 (severe) and with a necroinflammatory score of ≤ 5 (mild) or > 5 (severe).

Statistical analysis

The frequencies of CCR5Δ32 mutant allele were compared between patients with chronic HCV infection and controls by Chi-square test. Categorical variables were analyzed with χ^2 or Fisher's exact test. Two-sample *t*-tests were used to compare means for continuous variables and for non-normally distributed continuous variables, non-parametric test, Wilcoxon Mann-Whitney-U test was used for comparison of median values. Univariate analysis was used to assess associations between the various allelic variants and severity of liver disease.

Hardy-Weinberg equilibrium was tested by comparing expected and observed genotype frequencies by χ^2 -test. The distribution of genotypes between the patients and healthy controls were compared by contingency table analysis.

For all tests, a 2-tailed *P* < 0.05 was considered significant. The analysis was performed by using statistical software SPSS 12.0 software (SPSS, Chicago, IL).

RESULTS

Demographic profile

Two hundred and fifty two patients with chronic hepatitis C were studied. The baseline characteristics of the cases and controls in the study group are summarized in Table 1. The most common source of HCV infection was blood transfusion.

Table 2 Allele frequency of CCR5 variants in chronic HCV patients and healthy controls

CCR5	HCV Patients (<i>n</i> = 252)	Healthy Controls (<i>n</i> = 408)	<i>P</i> value
Wt/wt	247 (98%)	405 (99.3%)	0.07
Δ32mt carrier	5 (1.9%)	3 (0.7%)	0.3
Wt/Δ32	3 (1.2%)	3 (0.7%)	0.2
^a Δ32mt/Δ32mt	2 (0.7%)	-	0.1

^aThe patients were genotype 1.

Viral genotype

HCV genotypes could be determined in 209 of the 252 (82.9%) patients. The predominant viral genotype was genotype 3a/3b. One hundred eighty seven (89.4%) patients had genotype 3, 17 (8.1%) had genotype 1, one patient had genotype 2 and 4 patients had genotype 4 (Table 1). No significant difference was observed in immune gene polymorphism and patients with different viral genotypes.

Distribution of CCR5 allelic variants

The frequency of CCR5Δ32 mutations in HCV patients and controls is shown in Table 2. Two hundred and forty seven (96.6%) HCV patients and 405 (99.3%) healthy controls had CCR5 wt/wt homozygosity. 3 (1.2%) of 252 patients had heterozygous and 2 (0.7%) had homozygous Δ32 mutations; overall 5 (1.9%) of the HCV patients had Δ32 mutant alleles. On the other hand, none of the healthy controls had a homozygous Δ32mt/Δ32mt pattern. Three healthy controls exhibited heterozygosity (Table 2). The difference between the patients and the controls was comparable but not significant. CCR5Δ32/Δ32 was present in HCV genotype 1 patients. Patients carrying CCR5Δ32 (CCR5Δ32 homozygote and heterozygote) mutation had no significant difference in the serum ALT level, degree of hepatic inflammation, fibrosis score and viral genotype compared with those patients who had wild type CCR5. All the allelic variants were in Hardy-Weinberg equilibrium.

Relation to serum alanine aminotransferase

We also used the mean serum ALT concentrations as an indicator of the activity of liver disease. However, no significant difference was observed for any of the genetic markers in patients with normal or without raised ALT (data not shown).

Relation to liver histology: Fibrosis and Histological inflammation

When patients were categorized based on the severity of hepatic fibrosis, 162 patients had mild and 90 patients had severe hepatic fibrosis. The frequency of CCR5Δ32 mutations was comparable in patients with mild or severe liver disease (*P* = NS) and it did not correlate with the severity of the liver disease (Table 3). Similarly CCR5Δ32 mutations did not correlate with histological severity

Response to therapy

Table 4 depicts the response pattern of the patients

Table 3 Correlation of Immune Gene Polymorphism and histological severity of HCV Related Liver Disease in Univariate analysis

Liver histology	CCR5-Genotype			P
	wt/wt	wt/ Δ 32	Δ 32/ Δ 32	
Fibrosis				
≤ 2 (n = 162)	154 (98%)	1 (0.6%)	2 (1.2%)	NS
> 2 (n = 90)	88 (97.8%)	2 (1.2%)	0	
HAI				
≤ 5 (n = 162)	170 (98.3%)	1 (0.6%)	2 (1.2%)	NS
> 5 (n = 90)	77 (97.5%)	2 (2.5%)	0	

enrolled in the study. When patients were categorized on the basis of the response pattern, no difference was observed in the distribution of alleles with respect to response rate. Of 252 patients, 129 patients received antiviral therapy. Eighty six patients had attained sustained virological response, 34 patients were non-responders while 7 patients relapsed after discontinuation of therapy and one patient developed decompensation and discontinued the therapy. Two patients who were CCR5 Δ 32/ Δ 32, did not receive therapy. There was also no difference in the response pattern among the heterozygotes.

DISCUSSION

Host genetic factors encoding for gene products, which are likely to be involved in the immune response following HCV infection, are likely to influence the disease susceptibility and progression. It has been demonstrated by studies which correlated polymorphisms or mutations of genes encoding for HLA subtypes^[17-19], tumor necrosis factor^[20-22], interleukin 10^[23] or chemokine receptor 5 (CCR5) with disease susceptibility or treatment outcome in HCV.

In our population 1.9% (5/252) HCV patients were carriers of the CCR5 Δ 32 mutation as compared to 0.7% (3/408) of the general population. This refers to both homozygous and heterozygous mutations combined. Since the frequency of these mutations is rather low it is difficult to make definite statistical analysis between various groups. The reason for the variance in our results compared to the earlier studies is not easy to explain. This could probably be because the frequency of these mutations is rather low, thus it is difficult to make definite statistical analysis between various groups. An earlier study from India has reported a single heterozygote for CCR5 Δ 32 mutants^[24]. However, the group had only genotyped 150 normal healthy individuals for the presence of Δ 32 allele. We had adequate number of controls (n = 408). Woitas *et al* had observed a higher frequency of CCR5 Δ 32 homozygotes in chronic HCV patients^[11]. In the present study, we observed a 0.7% occurrence of CCR5 Δ 32 mutants in chronic HCV patients but none in healthy controls, however the difference was not significant.

Apart from the sample size, a plausible explanation for these divergent results might be the differences in comorbidity of patients in the studies by Woitas and Nguyen^[11,25], who had a substantial proportion of patients with haemophilia and/or concomitant hepatitis B. In the present study

Table 4 Response patterns in HCV patients genotyped for CCR5

Response		CCR5-Genotype			P
		wt/wt	wt/ Δ 32	Δ 32/ Δ 32	
IFN+ Riba/	Responders	86	1	-	NS
Peg IFN+ Rib	Non-responders	34	1	-	NS
	Relapsers	7	-	-	NS

patients with haemophilia, hepatitis B or HIV were carefully excluded. Moreover, we did not detect elevated aminotransferase levels in carriers of the Δ 32 mutation, which might also be due to the small number of homozygous carriers of the Δ 32 mutants in the present study^[26].

CCR5 Δ 32 mutants did not increase the likelihood of a more severe liver disease in our patients due to HCV infection (Table 3). Table 5 gives an overview of the published data in chronic HCV patients genotyped for CCR5 Δ 32 mutation. As shown in Table 5, the correlation of CCR5 Δ 32 mutations with histological severity is controversial. Significant associations were found between CCR5 Δ 32 and reduced portal inflammation and milder fibrosis^[13]. Liver inflammatory activity was found to be significantly reduced in Jewish Israeli patients infected with the hepatitis C virus carrying the CCR5 Δ 32 allele^[32]. Heterozygosity for CCR5 Δ 32 has been shown to be significantly associated with lower hepatic inflammatory scores^[26]. However, other studies failed to find an association of CCR5 Δ 32 mutations with the histological severity.

Table 5 also shows distribution of viral genotypes in the published data for CCR5 Δ 32 mutation. It is known that the distribution of genotypes could be dependent on geographical distribution and possibly susceptibility. In all the previous studies, the associations have been studied primarily in the population of HCV patients infected with genotype 1. It might be possible that this could influence the susceptibility and severity of liver disease and could have led to variations in the results. The present study is the first study which has looked into the role of CCR5 Δ 32 mutation in genotype 3.

In the study population, nearly 161 of 182 (88.4%) patients in whom genotyping could be done, had genotype 3 infection. Most studies from the Indian subcontinent have reported similar frequency of genotype 3^[34]. HCV 3a is a hepatitis virus strain that responds better to interferon IFN- α therapy than other HCV strains. IFN- α induces the production of CCL3, a CCR5 ligand, in the liver. It is thus possible that CCR5 is involved in a cascade of events or recruitment of immune cells, which negatively regulate the production of IFN- α in the liver. Loss of CCR5 expression due to CCR5 Δ 32 mutation could affect the course of hepatitis C, probably by interfering with cellular immune response. It has been suggested that CCR5 Δ 32/ Δ 32 mutant has no expression of CCR5 on the cell surface and henceforth is an ineffective HCV-specific immune response resulting in an immune imbalance to Th-1→Th-2 response^[27].

It is therefore important to study the role of CCR5 Δ 32 mutation with response to therapy. Ahlenstiel *et al* have shown that response rates to interferon-alpha monotherapy are reduced in hepatitis C virus infected patients

Table 5 Analysis of published data in chronic HCV patients genotyped for CCR5Δ32 mutation

carrying the CCR5Δ32 mutation^[28]. It is difficult to comment on the role of CCR5 mutations in HCV infection with genotype 3 in our population, since this is the most common genotype. Also, we had 0.7% allelic frequency of CCR5Δ32 and since 98% of HCV patients had CCR5 wt/wt, speculating a higher SVR in 3a genotype is not possible. Our patients had received combination therapy of interferon/pegylated interferon and ribavirin. However it has been suggested that the interferon and ribavirin combination treatment may overcome this negative effect of CCR5Δ32^[28]. Thus, in population a infected with genotype 3 HCV, CCR5Δ32 mutations do not influence the response to combination therapy with interferon and ribavirin.

In conclusion, our results indicate that CCR5Δ32 mutation does not influence the susceptibility and severity of liver disease in chronic hepatitis C patients. Moreover, CCR5Δ32 mutation does not influence the response to therapy.

Abstract

AIM: To test the feasibility of delivering a plasmid encoding IL-15 as a DNA vaccine adjuvant for improving the immune responses induced by hepatitis B virus core gene DNA vaccine.

METHODS: We used RT-PCR based strategies to develop IL-15 expression constructs. We first confirmed that the gene could be expressed in *Escherichia coli* due to the poor expression of IL-15. Then the bioactivity of IL-15 plasmid expression product was identified by CTLL-2 proliferation assay. One hundred micrograms of DNA from each of the IL-15 eukaryotic expressed plasmid and the recombinant plasmid harboring DNA encoding the 144 amino acids of the N-terminus of HBV core gene (abbreviated pHbc144) was used to co-immunize C57 BL/6 mice. The titer of anti-HBcIgG was detected by ELISA and the antigen-specific CD8⁺ T cells (CD8⁺IFN- γ ⁺ T cells) were detected by intracellular cytokine staining at different time points.

RESULTS: After co-immunization by pIL-15 and pHbc144 DNA vaccine the antigen-specific CD8⁺ cells of mice increased gradually, the first peak of immune response appeared 14 d later, then the number of antigen-specific CD8⁺ T cells decreased gradually and maintained at

a steady level in 3 mo. After boosting, the number of antigen-specific CD8⁺ T cells reached the second peak 10 d later with a double of the 1st peak, then the number of antigen-specific CD8⁺ T cells decreased slowly. IL-15 as a gene adjuvant had no significant effect on humoral immune responses induced by hepatitis B virus core gene DNA vaccine, but increased the memory antigen-specific CD8⁺ T cells induced by hepatitis B virus core gene DNA vaccine.

CONCLUSION: DNA vaccine constructed by HBc Ag 1-144 amino acid induces effective cell immunity, and cytokine plasmid-delivered IL-15 enhances the longevity of CD8⁺ T cells.

INTRODUCTION

The final goal of a vaccine is to make body acquire long-term and effective protection. However the long-term and effective protection depends on the quality and quantity of memory T cells. IL-15 mRNA is constitutively expressed by various cells and tissues such as placenta, skeletal muscle, kidney, epithelial cells, synovial cells, and macrophages^[1]. IL-15 is essential for CD8⁺ memory T-cell generation and maintenance, and is involved in the maintenance of antigen-specific memory CD8⁺ T cells. The number of memory-type (CD44^{high}Ly6C) CD8⁺ T cells increases significantly in the periphery lymphoid tissue of IL-15 Tg mice, producing IL-15, while the number of antigen-specific memory CD8⁺ T cells declines in IL-15⁻ and IL-15R⁻ deficient mice^[2].

IL-15 has attracted great attention because of its important effect on memory CD8⁺ T cells^[3-5]. This report describes the IL-15 mRNA extraction from

human peripheral blood mononuclear cells (PBMCs) and the molecular cloning of IL-15. We demonstrated that recombinant IL-15 was expressed in *Escherichia coli* and showed bioactivity in COS cells. Our results suggest that IL-15 plasmid has effect on the memory phase of cellular immune response induced by HBc DNA vaccine, indicating that plasmid IL-15 functions as a candidate adjuvant and can be used in for vaccine or immunotherapeutic studies.

MATERIALS AND METHODS

Mice

Female C57BL/6 mice at the age of 6-8 wk were purchased from Shanghai Sippr-Bk Company and allowed to acclimate for at least 2 wk prior to use. The mice were housed in laminar airflow cages with free access to food and water *ad libitum*. Analyses of specimens from those animals revealed no evidence of exposure to viral, bacterial or parasitic pathogens during these studies.

Plasmids and peptides

The HBcAg-expression plasmid pHbC144 was constructed by inserting a gene encoding hepatitis B core antigen N' end 144 amino acid into a vector (pcDNA3, Invitrogen), driven by the cytomegalovirus (CMV) immediate early promoter. The secreted HBcAg could be detected in the supernatant of cell culture transiently transfected with pHbC144^[6]. Anti-HBc could be detected in the serum of Balb/c mice, which were injected with pHbC144 DNA plasmid.

The HBV core Ag peptides were synthesized and generously provided by Dr. Rafi Ahmed (Emory University, GA).

Cell culture

PBMCs were isolated from peripheral blood of healthy volunteers by density gradient centrifugation over Ficoll. Fresh whole blood was drawn, heparinized and gently mixed with one volume of RPMI1640. The diluted blood was layered over Ficoll and centrifuged at 800 g, for 20 min at 4°C. PBMC were collected from the interface between the plasma and the density gradient solution. After being washed in PBS, PBMCs were resuspended in RPMI 1640 supplemented with 5 mg/mL LPS, 200 mmol/L L-glutamine, 10% FCS, 20 mmol/L Hepes, 100 U/mL penicillin, and 100 µg/mL streptomycin, at a final cell concentration of 5×10^6 /mL. Then the PBMCs were cultured in 24-well plates for 6 h.

RT-PCR and cDNA cloning of Interlukin-15

RNA extraction as well as RT-PCR analysis were performed as previously described^[7]. Briefly, total RNA was purified using Trizol (Invitrogen Life Technologies) following the manufacturer's instructions. A 4 µg aliquot of total cellular RNA was reverse transcribed using random hexanucleotide primers and the Superscript II preamplification system (Invitrogen Life Technologies). One-tenth of the cDNA obtained was amplified in a 20-µL reaction, using 1 U of Pfu DNA Polymerase ExpandTM High Fidel-

ity PCR System (Boehringer Mannheim) and the reagents provided with the preamplification system. Thirty-five cycles of PCR amplification were performed at 94°C for 2 min, at 60°C for 1 min and at 72°C for 1 min; followed by a final extension at 72°C for 7 min. Ten microliters of the reaction products was analyzed on 1% agarose gel. The primer sequences are sense: 5'-GCGG4ATTCATGAGAATTTTCGAAACCACATTTGAG-3'; antisense: 5'-GCGCTCGAGAATCAATTGCAATCAAGAAGTGT-3'. The amplified cDNA was ultimately digested with *EcoR* I and *Xho* I and cloned into pcDNA3 and pET2c. The sequences of the IL-15 DNA insert were verified by sequencing with the dideoxy chain termination method (Bioasia Co., Shanghai). Sequences were analyzed by Vector NTI Suite software package (InfoMax).

Expression of recombinant protein

Escherichia coli strain BL21(DE3) (Novagen) was transformed by the pET2c-IL-15 plasmid. The detailed protocol for production of fusion proteins was as follows. *E. coli* cells were grown to absorbance 0.6 at 600 nm, then expression was induced with 0.4 mmol/L isopropyl-D-thiogalac-toside for 4 h at 37°C. The bacterial cells were harvested, the cell pellet was suspended in 50 mL MTPBS lysis buffer (150 mmol/L NaCl, 16 mmol/L NaH₂PO₄, 4 mmol/L Na₂HPO₄, pH 7.3, 1% TritonX-100) per liter of culture volume. The cells were sonicated three times, 10 s each time (Sinifer cell disrupter B-30; Branson Sonic Power), and centrifuged at 15 000 g for 10 min at 4°C. The supernatant was collected for SDS-PAGE and Western blotting.

Western blotting

E. coli cells were cultured for an indicated period of time, lysed by adding 2X Laemmli SDS sample buffer and boiled for 5 min in a water bath. The proteins were resolved by 15% SDS-PAGE and transferred to a polyvinylidene difluoride membrane (Immun-blot PVDF; Bio-Rad). Non-specific binding sites were blocked by incubating the blot in blocking buffer (5% nonfat dry milk in wash buffer) for 1 h at room temperature. The blot was washed three times (5 min each time) with wash buffer (0.5% Tween 20, 200 mmol/L NaCl, and 50 mmol/L Tris, pH 7.5), and incubated with the appropriate primary Ab overnight at 4°C. The blot was then washed three times (5 min each time) and incubated with the corresponding secondary Ab-HRP conjugate for 1 h at room temperature. The blot was washed three times again (5 min each time), and proteins were detected.

CTLL-2 proliferation assay

For CTLL-2 bioassays, COS cells were transfected with 30 µg of IL-15 expression constructs following a standard calcium-phosphate-mediated transfection protocol^[7]. For these studies roughly $2-3 \times 10^5$ adherent COS cells/well were transfected in six-well 35-mm plates. After 24 h, the medium was replaced with fresh complete DMEM, supernatants were harvested 72 h after the transfection for assay.

Aliquots (100 µL) of the supernatant and serial two-

Figure 1 Immunization schedule of pHbc144 and pIL-15 plasmid.

fold dilution were added to 96-well microtiter plates containing 1×10^5 CTLL-2 cells in a final volume of 200 μ L. The cultures were incubated for 18 h at 37°C and pulse-labeled for another 6 h with 0.5 μ Ci [3 H] thymidine. Thymidine incorporation was quantified by liquid scintillation spectrometry^[8] (BD). A standard curve was plotted from proliferation induced by standard murine rIL-2.

Immunization and sample collection

Plasmids were amplified in *Escherichia coli* and plasmid DNA was purified by using anion exchange column (Endo-free plasmid purification kit, Qiagen, Chatworth, Calif) according to the manufacturer's instructions. The plasmid DNA was dissolved in sterile physiological saline, and the final concentration was 1 μ g/mL.

C57BL/6 (H-2^b) mice were vaccinated at the age of 6-8 wk by injection of DNA in 0.9% saline (w/v), into the quadriceps of each hind limb as previously described^[9]. Injection volume was 50 μ L per leg and total DNA dose was 50 μ g per leg. On d 30, all mice were booster-immunized with the same DNA. On d 0, 8, 14, 30, 90 after priming and d 90 after boosting, blood samples were collected from each mouse by orbital bleeding (Figure 1). Serum was separated from each blood sample and used for measurement of the anti-HBcAb titer. On the other hand, mouse blood was obtained using heparin as an anticoagulant. The blood was diluted with RPMI 1640. PBMCs were obtained by density gradient centrifugation over HIS-TOPAQUE-1083 (Sigma), washed three times with RPMI 1640 and counted afterward. The spleens were removed for the measurement of cytokine production.

Detection of anti-HBcIgG and subclasses

Anti-HBc antibody was titrated with ELISA kit (Shanghai Infectious Diseases' Hospital). Each serum sample was made in a series of three-fold dilution. Goat anti-mouse IgG-HRP conjugate (The Binding Site Limited Co, England) was used as the secondary antibody and O-pheylene-diamine (OPD) was used as a substrate. The plates were read with Titerec Multiskan MCC/340 at A_{450} . The wells with an absorbance of ≥ 0.1 (above background, 0.020) were scored as positive.

Intracellular cytokine staining and flow cytometric (FCM) analysis

For intracellular cytokine detection of IFN- γ , PBMCs and single suspension of splenocytes were plated in a 96-well plate (Costar) at a density of 1×10^6 cells/well in a final volume of 200 μ L. Cells were stimulated with peptides for 5 h. Brefeldin A (final concentration 2 μ g/mL) was added to the cultures during stimulation. At the end of the

Figure 2 Electrophoretogram of PCR products. The human IL-15 coding sequence (GenBank U14407) was RT-PCR amplified from human PBL mRNA stimulated with LPS.

incubation, the cells were washed twice and stained for 30 min at 4°C with phycoerythrin (PE)-conjugated anti-mouse CD8 (BD Bioscience) in FACS buffer [2% FCS, 0.1% sodium azide in phosphate buffered saline (PBS)]. Cells were collected, washed and incubated in permeabilization buffer for 20 min on ice. The permeabilized cells were washed and stained with fluorescein isothiocyanate (FITC)-conjugated anti-mouse IFN- γ (BD PharMingen, San Diego, CA) for 30 min. Cells were washed, fixed with 2% (w/v) paraformaldehyde, and acquired with a FACSCalibur flow cytometer (Becton Dickinson, Boston, MA). Forward and side scatters were collected on a linear scale, while the PE and FITC signals were collected on a 4-decade log scale. Overlaps of emission spectra were electronically compensated. The debris were eliminated using the threshold on forward scatter and 100 000 events were acquired with CellQuest software (BD, Biosciences).

Statistical analysis

Statistical analyses of data were performed using SPSS 10.0 for windows (SPSS, Inc., Chicago, IL).

RESULTS

cDNA cloning

PBMCs were isolated from peripheral blood of healthy volunteers by density gradient centrifugation over Ficoll. A total of 5×10^5 PBMCs were transferred into 24-well plates and cultured for 6 h with 5 μ g/mL LPS. RNA extraction and RT-PCR were performed (Figure 2). The complete human IL-15 cDNA (GenBank accession No. U14407) was 518 bp long and was comprised of 146 bp signal peptide (IL-15sp) and a IL-15 mature peptide gene sequence (IL-15mp).

Amplified cDNA was ultimately digested with *Eco*R I and *Xba* I and cloned into pCDNA3. The sequences of IL-15 DNA insert were confirmed and this plasmid was named pIL-15.

For generation of the IL-15 prokaryotic expression construct, the IL-15 mp coding sequence was PCR amplified from pIL-15. The resulting fragments were digested with *Eco*R I and *Xba* I and cloned into pET2c named pET-IL-15 (data not shown).

Expression of IL-15 in *Escherichia coli*

Escherichia coli strain BL21(DE3) (Novagen) was transformed by the pET-IL-15 plasmid. After induction by

Figure 3 SDS-PAGE and Western blotting of recombinant polypeptides. M: polypeptide molecular marker; lane 1: BL21; lane 2: pET32c; lane 3: pET-15 uninduced; lane 4: pET-15 induced.

IPTG and temperature, the supernatant of bacteria lysates was taken for SDS-PAGE and Western blotting. IL-15 fragments could be expressed in pET-32c vector and its molecular weight was M_r 26 000 (Figure 3).

Production of IL-15 by COS cells

The IL-15 was cloned into the pcDNA3 vector with CMV promoter (Invitrogen) and transfected into COS cells. Forty-eight hours after transfection, the COS supernatants were collected and subjected to CTLL-2 proliferation assay. CTLL-2 cell ^3H -TdR cpm was related to the dilution fold of the COS supernatant. When the dilution fold of transfection supernatant increased, the incorporation of ^3H -TdR cpm decreased. The incorporation ^3H -TdR cpm of pIL-15-transfected COS supernatant was higher than that of vector-transfected COS supernatant (Figure 4). So we could detect IL-15 activity in the supernatants of COS cells transfected with pIL-15.

Kinetics of antigen-specific CD8 responses following DNA vaccination and cytokine expression profiles of antigen-specific T cells

Both primary and memory antigen-experienced CD8^+ T cells rapidly upregulated cytokine production after encountering cells displaying their cognate peptide ligand in association with a major histocompatibility complex class I molecule. We used ICCS to identify cytokine-producing HBc-specific CD8^+ memory T cells directly *ex vivo* after DNA inoculation prior to this study, but it was unclear how quickly these responses developed when IL-15 as a gene adjuvant was coinjected with HBc DNA vaccine. Therefore, we used ICCS to directly enumerate antigen-specific effector CD8^+ T cells in the spleens of mice at various time points after DNA immunization (pHBc144 and/or pIL-15). The average percentage of peptide-specific CD8^+ T cells detected in three mice analyzed at each time point for each mode of immunization is shown in Figure 5A.

Seven days after-immunization, antigen specific CD8^+ T cells were present at a frequency of less than 0.1% in all of the vaccinated mice (both pHBc144 + pcDNA3 group and pHBc144 + pIL-15 groups), and therefore accurate

Figure 4 IL-15 bioactivity in supernatants of cells transfected with pIL-15 expression plasmid. COS cells were transfected with pIL-15 (\blacktriangle) expression constructs or vector pcDNA3 (\times), and the supernatants were collected 72 h after transfection. The supernatants were tested by CTLL-2 bioassay to measure IL-15 bioactivity. IL-2 (5×10^3 U/mL) was used as a positive control.

analysis of IFN- γ production was not possible (Figure 5A). By d 14, $2.64\% \pm 1.07\%$ of the HBcAg specific CD8^+ T cells primed by pHBc144 + pIL-15 DNA vaccination secreted IFN- γ , and at 30 d after-immunization, $0.39\% \pm 0.21\%$ of the antigen-specific cells were positive. A similar transition was observed in CD8^+ T cells primed by pHBc144 + pcDNA3 DNA vaccination ($2.26\% \pm 2.50\%$ on d 14 and $0.42\% \pm 0.06\%$ on d 30). Thus, the cytokine expression patterns of HBcAg-specific T cells were similar regardless of the pIL-15 immunization.

These proportions decreased gradually, by d 90 post-priming, $0.48\% \pm 0.36\%$ of the antigen-specific CD8^+ T cells induced by pHBc144 in pIL-15 co-immunized group secreted IFN- γ , while $0.16\% \pm 0.04\%$ of the antigen-specific CD8^+ T cells in pHBc144 and pcDNA3 co-immunized group were IFN- γ^+ CD8^+ T cells (Figure 6).

After being boosted, the HBc Ag specific T cells expanded rapidly, and by d 90 post-boost the specific memory cells could still be detected, sustaining a higher level than that for the first response. On d 90 after boosting, $0.28\% \pm 0.04\%$ of the antigen-specific CD8^+ T cells induced by pHBc144 in pIL-15 co-immunized group secreted IFN- γ , while $0.11\% \pm 0.04\%$ of the antigen-specific CD8^+ T cells in pHBc144 and pcDNA3 co-immunized group were IFN- γ^+ CD8^+ T cells (Figures 6A and B).

Kinetics of HBcAg specific CD8^+ T-cells in the circulation induced by DNA vaccine

For examining the kinetics and distribution of antigen specific CD8^+ T-cells in the non-lymphoid tissue induced by DNA vaccination, we separated the lymphocytes from blood. The kinetics of HBcAg-specific CD8^+ T cells in the circulation stimulated with pHBc144 showed a similar pattern with that of the spleen (Figure 5). However the number of HBcAg-specific CD8^+ T cells in PBMCs was lower than that in the spleen at the same time point. Eight days after DNA vaccination, HBcAg-specific CD8^+ T cells were detectable. By d 14 the number of IFN- γ^+ CD8^+ T cells in PBMCs reached the peak and then dropped gradu-

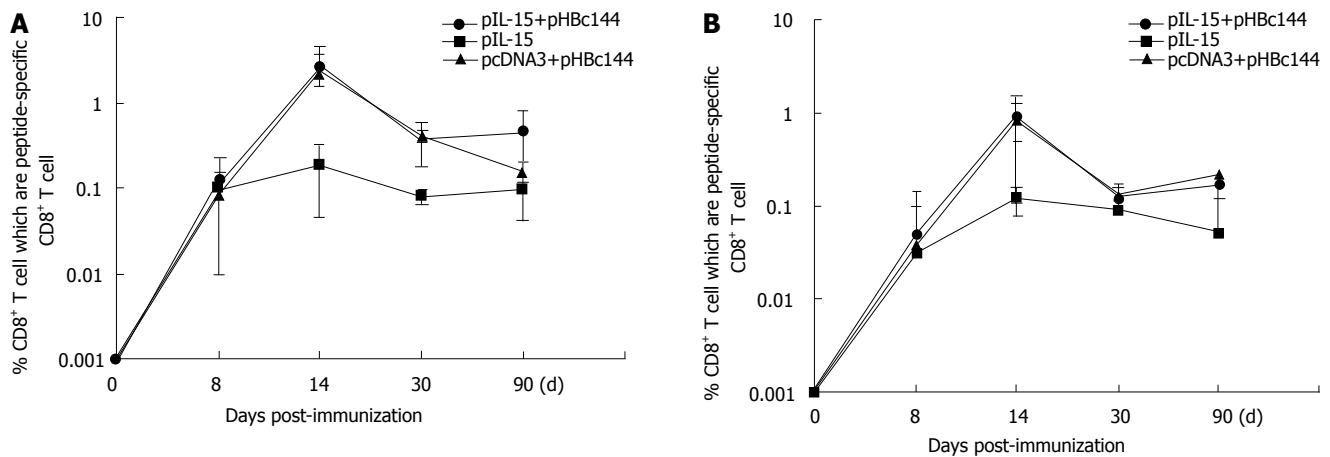

Figure 5 Kinetics of antigen-specific CD8⁺ T-cell response in spleen (A) and PBMCs (B) following DNA immunization. Mice were immunized with pHBc144 plasmid DNA or vector DNA intramuscularly. At various time points, splenocytes and PBMCs were harvested, stimulated for 5 h with specific peptide, double stained with anti-CD8a-PE and anti-IFN- γ -APC. A total of 1×10^5 events were acquired by a flow cytometer. The indicated values on the lines of the figure (plotted on a log₁₀ scale) reflect the percentage of peptide-specific CD8⁺ T-cells to total CD8⁺ T-cells in the spleens or PBMCs (about three mice/group at each time point). The cut-off value was 0.1%.

Mice were injected with 100 μ g of pIL-15 or pHBc144 or both pIL-15 and pHBc144 plasmids intramuscularly. Single-cell suspensions were prepared. Cells were stained with anti-CD4-APC and anti-CD8-PE. The stained cells were analyzed with a FACScan. The data from each group at each time point represent the mean \pm SD ($n = 3$). (A) the total CD4 and CD8 in the spleen. (B) the total CD4 and CD8 in the PBMC.

ally. These proportions decreased gradually until d 90 post-priming, 0.17% \pm 0.05% of the antigen-specific CD8⁺ T cells induced by pHBc144 in pIL-15 co-immunized group secreted IFN- γ , while 0.22% \pm 0.01% antigen-specific CD8⁺ T cells in pHBc144 and pcDNA3 co-immunized group were IFN- γ ⁺ CD8⁺ T cells.

On d 90, after boosting, 0.20% \pm 0.13% of the antigen-specific CD8⁺ T cells induced by pHBc144 and pIL-15 co-immunized group secreted IFN- γ , while 0.12% \pm 0.13% antigen-specific CD8⁺ T cells in pHBc144 and pcDNA3 co-immunized group were IFN- γ ⁺ CD8⁺ T cells (Figure 5B, Figure 6 C and D). The antigen-specific memory cells still could be detected directly *ex vivo* in the circulation on d 90 post-boost (Figure 5B, Figure 6D).

HBcAg specific CD4/CD8 in spleen and PBMCs induced by HBcDNA vaccine

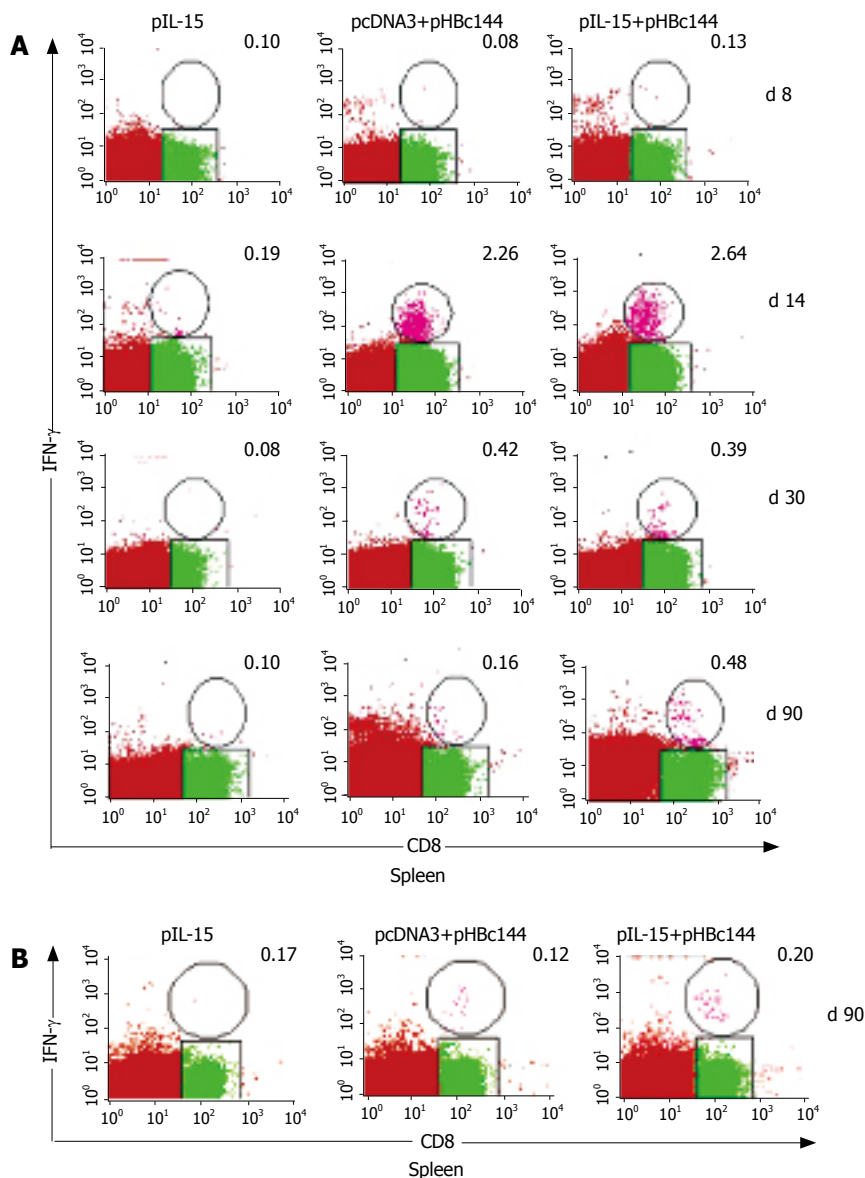

At the same time point, we checked the total CD4⁺ and

CD8⁺ cell percentage (Table 1), IL-15 had no big effect on the ratio of CD4⁺ and CD8⁺.

HBcAg specific humoral response induced by DNA vaccine

The HBcAg specific humoral immune response induced by pHBc144 was detected by ELISA for anti-HBc antibody in serum. The plates were read with Titerek Multiskan MCC/340 at A_{450} . The wells with an absorbance of ≥ 0.1 (above background, 0.020) were scored as positive.

Four weeks after the first pHBc144 immunization, all mice underwent anti-HBc seroconversion. The mean titer of anti-HBc IgG in pHBc144 + pIL-15 group reached $2^{9.81} \pm 2^{0.9}$ on d 30. After being boosted, the mice produced a higher titer of anti-HBc IgG ($2^{9.81} \pm 2^{0.9}$) than that of the primary response, and anti-HBc maintained at that level ($2^{9.81} \pm 2^{0.9}$) on d 90. The titer of anti-HBc IgG2a in pHBc144 + pIL-15 group ($2^{9.81} \pm 2^{0.9}$) was slightly higher

than that of pHBc144 + pcDNA3 group ($2^{8.22} \pm 2^{0.9}$), but there was no significant difference ($P > 0.05$).

DISCUSSION

IL-15 plays a pivotal role in the development, survival, and activation of NK cells, NK-T cells and cytokine release various subsets of T and B cells^[10-12]. IL-15 maintains the homeostasis of memory phenotype CD8⁺ T cells^[13]. The IL-15 response to infectious agents, such as viruses and other intracellular organisms, may represent a critical element in the host defense against these pathogens. Optimized IL-15 in combin with HIV-1gag DNA constructs results in a significant enhancement of Ag-specific CD8⁺ T cell proliferation and IFN- γ secretion, and strong induction of long-lived CD8⁺ T cell responses^[14]. pDNA encoding IL-15 is capable of elevating survival rates of HSV-1-infected mice when coinjected with 1 μ g of gB pDNA^[15]. IL-15 has been reported to have a profound effect on the augmentation of CD8⁺ T cell response against murine *T. gondii* infection^[16]. *Toxoplasma*-specific CD8⁺ T cell immunity in mice is depleted over time, but can be rescued by IL-15 treatment. These findings suggest that IL-15

may be useful as an immune adjuvant given with vaccination to enhance its biologic efficacy.

IL-15 is predominantly regulated posttranscriptionally at the level of translation and translocation. Although Northern blot analysis can reveal widespread constitutive expression of IL-15 mRNA in a variety of tissues such as placenta, skeletal muscle, kidney, lung, heart, fibroblasts, epithelial cells, and monocytes, it is difficult to demonstrate IL-15 in supernatants of many cells that express such mRNA. This discordance between IL-15 mRNA expression and IL-15 protein production is regulated by multiple elements including 12 upstream AUGs of the 5' UTR, a 48-aa signal peptide, and the C-terminus of the mature protein. The IL-15 signal peptide is an important factor in the negative regulation of IL-15 protein expression. There are two alternative leader peptides, one with 48 aa and the other with 21 aa^[17]. IL-15 associated with a short 21-aa signal peptide is not secreted but stored intracellularly, appearing in nuclear and cytoplasmic components^[18]. The long 48-aa isoform of the signal peptide might function as a negative regulator of IL-15 generation. The total quantity of IL-15 generated (the sum of IL-15 retained within the cells) increases 17- to 20-fold when the IL-15

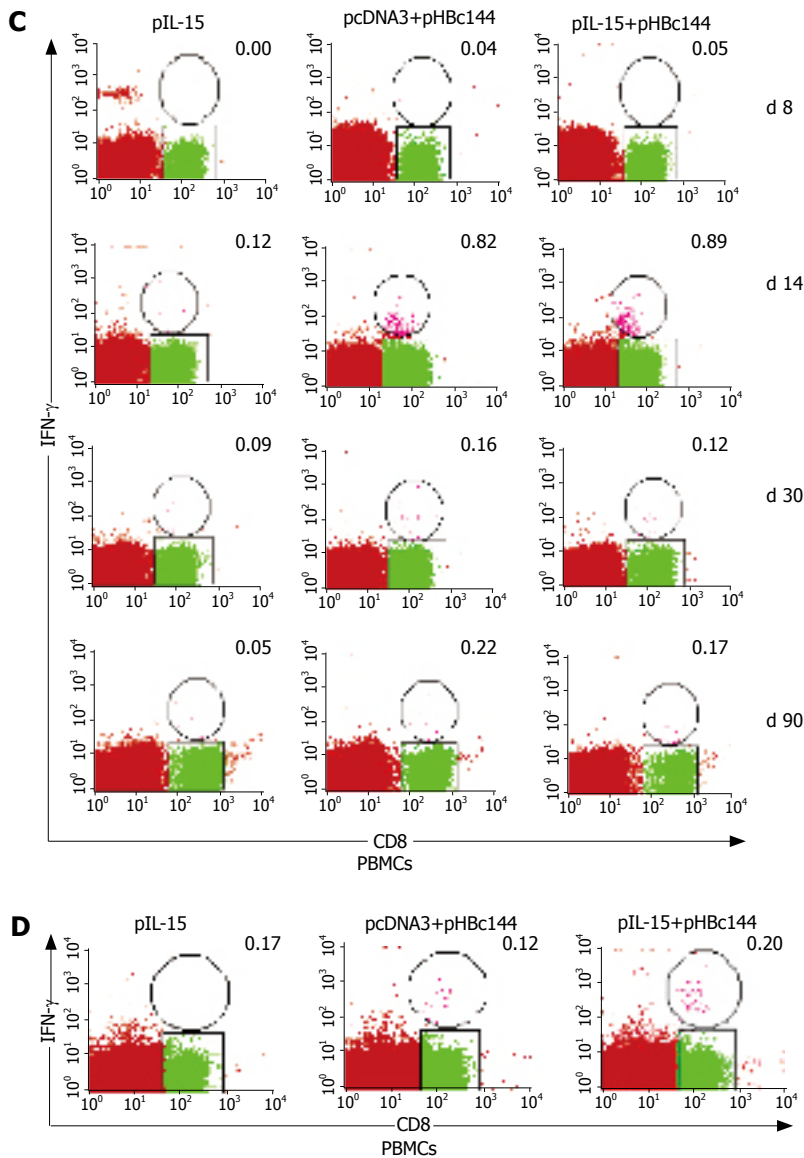

Figure 6 Percentages of HBe specific CD8⁺ T cells in the spleen after primary (A) and secondary immunization (B) and in PBMCs after primary (C) and secondary immunization (D) detected by ICCs directly ex vivo at various time points. C57BL/6 mice were immunized with pHBc144 DNA or pIL-15 DNA and boosted at d 30 later. The splenocytes and harvested at various time points. Then the cells were cultured for 5 h in the absence or presence of the HBcAg peptide and double stained with anti-CD8a-PE and anti-IFN- γ -APC. CD8⁺IFN- γ ⁺ cells are enclosed in ovals, and the numbers in the upper right quadrants represent the percentage of CD8⁺IFN- γ ⁺ cells to total CD8⁺ T cells. The data from each group at each time point represent mean \pm SD ($n = 3$). Naive mice were used as negative controls. The cut-off value was 0.1%.

signal peptide is replaced by that of IL-2. Parallel studies showed that the quantity of IL-2 secreted is reduced 40- to 50-fold when COS cells are transfected with the reciprocal construct in which the IL-2 signal peptide is replaced with that of IL-15. Furthermore, after the IL-15 signal peptide is replaced with that of CD33^[19], translation and secretion increase, supporting the view that IL-15 expression is controlled posttranscriptionally at the level of translation and secretion.

We cloned the classical 48-aa signal peptide isoform of IL-15 (LSP-IL-15). When COS cells were transfected with the wild-type construct^[19], the quantity of IL-15 protein was very low (360 pg per 200 000 cells). Moreover, in most cases it was difficult to demonstrate IL-15 in the culture supernatants. We could not detect IL-15 protein in culture supernatants by Western blot after transfecting COS cells with our construct (data not shown). We therefore sub-

cloned the LSP-IL-15 cDNA into expression vector and let it translate in *E. coli*. Western blot analysis showed a Mr 26 000 fusion protein, which was identified with NCBI sequence.

The IL-15 associated with the long 48-aa signal peptide enters the endoplasmic reticulum where it was glycosylated. Nevertheless, IL-15 is secreted after trafficking through the Golgi, yielding a cytokine with a fully processed signal peptide. We measured the biological function of the construct by detecting the IL-15 in the supernatant of transfection.

Meazza *et al.*^[20] and Onu *et al.*^[17] found that IL-15 is not secreted when IL-15 SP is employed. Nevertheless, Waldmann *et al.*^[21] assessed cultures from COS cells transfected with the wild-type IL-15 coding sequence at 120 h and found that at least 90% of the IL-15 protein (though at low levels) can be identified in the culture

supernatants, and 10% is retained within the cells, as evaluated by sensitive ELISA assays. Our result is consistent with that of Waldmann *et al.* Although in COS cells transfected with IL-15 expression construct, the levels of IL-15 protein synthesized and secreted were very low (3 logs less than those obtained with a comparable IL-2 construct), LSP-IL-15 could secrete in the supernatant of COS cells transfected with IL-15 expression construct and have bioactivity, and can induce CTLL-2 cell proliferation. This difference between the different studies may be due to the fact that the CTLL-2 strain cannot respond to IL-15.

To determine if the IL-15 plasmid has many effects on the humoral and cellular immune response, especially CD8⁺ T cell response induced by DNA vaccination, splenocytes and PBMCs from the pIL-15 and HBcAg DNA vaccine co-immunized mice were evaluated for IFN- γ expression on antigen-specific CD8⁺ T cells and anti-HBc IgG in serum was detected at each time point. We selected them for the DNA plasmid format because they are inexpensive, noninfectious and can be readily optimized to enhance immunogenicity and protective efficacy. Furthermore, DNA vaccines can induce robust and durable CD8⁺ T cell responses, and can be used to deliver a large number of CTL epitopes^[22]. Our results showed that pIL-15 had no effect on anti-HBc IgG induced by pHbC144. Although antigen-specific CD8⁺ T cells reached a peak on d 14 after priming, pIL-15 had no effect on antigen-specific CD8⁺ T cells in splenocytes or PBMCs induced by HBcAg DNA vaccine. pIL-15 could increase the percentage of antigen-specific CD8⁺ T cells induced by HBcAg DNA vaccine on d 90 after priming and boosting. These two time points belonged to memory phase of immune response.

The existence of the basic effector Th1 and Th2 subsets is now well accepted, and used to plan therapeutic and vaccine strategies. Th1 cells produce interleukin 2 (IL-2), interferon γ and lymphotoxin (LT), whereas Th2 cells produce IL-4, IL-5, IL-6, IL-9 and IL-13^[23]. The function of Th1 and Th2 cells correlates well with their distinctive cytokines. Th1 cells are involved in cell-mediated inflammatory reactions. Several Th1 cytokines activate cytotoxic and inflammatory functions, while Th1 clones induce delayed-type hypersensitivity (DTH) reactions; and IFN- γ is commonly expressed at sites of DTH reactions. Th2 cytokines promote antibody production, particularly IgE responses, and also enhance eosinophil proliferation and function. Accordingly, Th2 cytokines are commonly found in association with strong antibody and allergic responses. Unfortunately, we did not evaluate the effect of IL-15 on antigen specific Th1 cells induced by HBc DNA vaccine. But our results showed that IL-15 had no effect on the ratio of CD4⁺ and CD8⁺.

Chronic HBV infection is one of the most common infectious diseases worldwide and leads to a high morbidity and mortality due to the development of liver cirrhosis and cancer. Virus persistence is believed to be due to an insufficient antiviral Th cell and CTL response of the host^[24]. Effective HBV-specific CD8⁺ T cell responses have been proven to inhibit virus replication independently of liver damage^[25,26].

During HBV replication, the nucleocapsid or core particle recruits into the pregenomic RNA and viral reverse transcriptase, and provides the template on which the surface envelope components assemble. Recombinant Mr 21 000 (P21) core protein self-assembles into 28-nm particles representing the native hepatitis B core Ag (HBc Ag)^[27]. Since it plays a central role in nucleocapsid formation and pregenomic viral RNA packaging, HBV core antigen represents another interesting target for DNA-based vaccine, although less data are available on DNA immunization to core antigen protein compared to the envelope protein. DNA-based immunization of mice to the HBV core has been shown to efficiently prime specific antibody and cytotoxic-T-lymphocyte responses^[28].

Interferon is one of the most effective drugs for chronic HBV infection^[29]. Experiments with HBV transgenic mice suggest that intrahepatic secretion of antiviral cytokines, such as IFN- γ and TNF- α by CTLs and Kupffer cells can interrupt the HBV life cycle without lysis of infected hepatocytes. The rapid reduction of HBV-DNA before hepatocellular damage in acute infections in chimpanzees and humans suggests that a similar non-cytolytic mechanism is, at least in part, responsible for inhibition of viral replication during natural infection^[30].

In conclusion, DNA vaccine constructed by HBc Ag 1-144 amino acid induces effective cell immunity, cytokine plasmid-delivered IL-15 enhances CD8⁺ T cell longevity, IL-15 is a possible candidate adjuvant for HBV DNA vaccine.

Abstract

AIM: To design a hand-assisted laparoscopic approach in an attempt to provide an option for laparoscopic resection of abdominal large viscera.

METHODS: A 5-6 cm incision (for HandPort) and 2 trocars were employed. The main vessel of the target organ was taken as a "core", and all tissues around the core were taken as peripheral structures. The peripheral structures were dissected first, and the core vessels were treated last. Twenty-six patients underwent laparoscopic deroofing of the hepatic huge cysts, resection of the segments lying at the outer edge of the liver (segments 2 to 6), splenectomy, hemicolectomy, ileocectomy and subtotal gastrectomy with HandPort device, harmonic scalpel, or Ligasure.

RESULTS: The duration of the procedure was within 2 hours. Blood loss amounted to 8-120 mL. The conversion rate was 3.8% (1/26). All patients had uneventful postoperative courses with less pain, earlier oral intake, and faster recovery, compared with conventional surgery.

CONCLUSION: This method combines the advantages of both open and laparoscopic techniques, achieving better hemostasis effect, shortening the operative time, and is beneficial to the patients.

INTRODUCTION

Since Mouret performed the successful laparoscopic cholecystectomy in 1987, new frontiers have opened for minimally invasive surgery^[1], and has been expanded to more extensive procedures such as resection of the abdominal large viscera^[2-4]. The minimally invasive surgery is superior to conventional open surgery because it offers significant benefits to the patients including much shorter incision, less pain and faster recovery. Despite instrumentation has dramatically improved over the past decade, laparoscopic resection of abdominal large organ still has several concerns regarding the safety, technical difficulties, rapidity and complications such as bleeding, injury to major adjacent structures, which affect the short-term and long-term outcomes^[5].

In an effort to largely simplify and shorten the procedure, provide an easier, safer approach, and decrease patients' postoperative pain and stay, we have designed a method for laparoscopic resection of abdominal large viscera. Usually, several 5-12 mm trocars are placed in the abdominal wall in laparoscopic surgery. However, there must be 5-6 cm port for extraction of a resected specimen in removal of abdominal large visceral organ. From "1 port + 2 trocars" as the minimal invasive wounds, we used a quick and safe hand-assisted laparoscopic technique for resection of abdominal large viscera, by taking advantages of both open and laparoscopic techniques.

MATERIALS AND METHODS

Patients

From May 2001 to December 2002, 26 patients, 15 males and 11 females with a mean age of 61.8 years (range 42-71 years), underwent hand-assisted laparoscopic surgery involving resection of liver, spleen, colon, jejunum, ileocecum, stomach and gallbladder, including 2 emergency operations: a 71 year-old female had uncontrolled bleeding from multiple diverticulosis of ascending colon, and another 54 year-old female suffered from carcinoma of terminal ileum associated with ileus. The procedure was carried out endocorporeally and extracorporeally, by means of the HandPort system (Smith & Nephew Inc. Andover, Massachusetts), harmonic scalpel (HCS 15 and HCS C5, Ethicon, Endo-surgery, Cincinnati, Ohio. Ultra shears 5 mm instrument, US Surgical, Tyco Healthcare) or Ligasure (10 mm Atlas, Vallylab, Boulder, Tyco Healthcare). All procedures were performed with the patients in the

Table 1 (HALS) operations and indicating diseases (26 cases)

Cases	Operations	Indicating diseases
1-2	Left lateral segmentectomy	Hepatitis B-related cirrhosis supervened hepatocellular carcinoma (HCC), hepatic cavernous hemangioma
3	S 6 segmentectomy	Hepatitis B-related cirrhosis supervened HCC
4	S 5 and 6 segmentectomy	Hepatitis B-related cirrhosis supervened HCC
5	S 5, 6 and partial 4 segmentectomy + cholecystectomy	Hepatitis B-related cirrhosis supervened HCC
6	Partial S 4 segmentectomy	Hepatic cavernous hemangioma
7-11	Deroofing of the hepatic huge cysts	The 4, 6, 7, 8 segmental hepatic cysts; the 4, 5, 6, 7, 8 segmental hepatic cysts; the 5, 6, 7 segmental hepatic cysts (2); the 5, 6, 7 segmental hepatic cysts with calcification of cystic wall
12-15	Right hemicolectomy	Carcinoma of the ascending colon (3) ¹ Multiple diverticulosis of ascending colon with massive hemorrhage
16	Left hemicolectomy + partial jejunectomy	Carcinoma of the splenic flexure of colon with metastasizing to liver and jejunum,
17	Left hemicolectomy	² Carcinoma of the sigmoid with metastasizing to left ureter and common iliac artery
18-19	Ileocectomy	¹ Carcinoma of the terminal ileum with ileus, multiple diverticulosis of the ileocecum and chronic appendicitis
20-21	Splenectomy	Idiopathic thrombocytopenic purpura, carcinoma of pancreatic body and tail
22-25	Subtotal gastrectomy	Duodenal ulcer (2), gastric ulcer, gastric ulcer with massive hemorrhage
26	Half gastrectomy + cholecystectomy	Diverticulitis of duodenum and gall stone

supine position, rotated appropriately, or with rolls under the flank of the appropriate side. The operations and indicating diseases are listed in Table 1.

The location of HandPort device was preferred to be directly over or close to the main (core) vessels of the target organ, in order to provide direct visualization to transect the core vessels or dissect the radical lymph nodes. The location of ports and positioning of the operator are listed in Table 2.

Before placement of HandPort device

A 5-6 cm abdominal incision was performed, before placement of HandPort device to allow for introduction of the hand to assist in placing two trocars, similar to placement of abdominal drains in open surgery, and also to allow the hands to perform abdominal exploration. If the dissection preceded the resection, the following procedures were done under direct vision, including mobilizing intraperitoneal adhesion, dissecting the peripheral structures, or placing a loop for occlusion of

hepatic hilar pedicles, in case of emergency use.

Following placement of HandPort device

The HandPort device was placed, with the abdomen insufflated under a pressure of 13-14 mmHg. The left hand was reintroduced. While exposing and retracting or pulling tissues with the hand, the peripheral structures including adhesions, peritoneum, ligaments, omentum, mesentery, as well as the hepatic parenchyma around the “core” pedicles were dissected by harmonic scalpel or Ligasure, occasionally by combined use of electrocoagulation without any laparoscopic suture or ligation.

Treatment of the core vessels finally

Once the target organ was mobilized, its core vessels were treated openly through the port incision by conventional open technique or vascular endo-stapler, as the location of the port incision was most direct over or close to the core vessels of the target organ.

Among our patients, a 71 year-old woman suffered

Figure 1 A: F, falciform ligament; P, portal pedicles; L, lateral segment; B: Dissecting from top to bottom till down to core vessels; C: Dissecting from bottom to top till up to core vessels; D: Transecting core vessels openly using an endo-stapler.

Table 3 Indications for conventional surgery (25 cases)

Cases	Operations	Indications
1-2	Left lateral segmentectomy	Hepatitis B-related cirrhosis supervened HCC, hepatic cavernous hemangioma
3-6	Deroofing of the hepatic huge cysts	Right hepatic huge cysts (4)
7-8	Hepatic S 5 and 6 segmentectomy	Hepatic cavernous hemangioma, hepatitis B-related cirrhosis supervened HCC
9-10	Hepatic S 6 segmentectomy	Hepatitis B-related cirrhosis supervened HCC, hepatic cavernous hemangioma
11	Hepatic S 5 segmentectomy + cholecystectomy	Hepatitis B-related cirrhosis supervened HCC
12-13	Splenectomy	Splenic infarction, splenic cysts
14-17	Right hemicolectomy	Carcinoma of the ascending colon (3), multiple polyps of ascending colon
18	Left hemicolectomy	Carcinoma of the descending colon
19-20	Ileocectomy	Carcinoma of the terminal ileum, multiple diverticulosis
21-25	Subtotal gastrectomy	Duodenal ulcer(2), ¹ gastric ulcer with bleeding, gastric ulcer, diverticulitis of duodenum with bleeding

¹Emergency operation.

¹One of the 26 patients converting to open operation was not included. Statistical comparison was performed using the Independent-Samples *t*-Test ($P < 0.001$).

from hepatitis B-related cirrhosis supervened HCC and arrhythmia. She had had an open partial gastrectomy 5 years ago due to leiomyoma of stomach. She underwent hand-assisted laparoscopic left lateral segmentectomy. The HandPort incision of 6 cm in length was located at the previous wound scar at the right upper transrectus abdominis (the previous incision of 18 cm in length). The strategy of the procedure was to treat the portal pedicles of the left lateral segment as core vessels. First, the adhesions between wound peritoneum and omentum, liver and stomach were dissected. A loop was then placed around hepatic hilar pedicles, in case of requiring interrupting hepatic afferent blood flow. Two trocars for camera and harmonic scalpel were introduced by the open method of making abdominal drains. Following placement of HandPort system, the left hand was reintroduced and the target segment retracted. Ligament attachments of the left lobe were divided until the left lateral segment was completely freed, as shown in Figure 1A. The peripheral

parenchyma around the core vessels was dissected from top toward bottom down to the core vessels (portal pedicles) with a harmonic scalpel (HCS 15 from Ethicon, Cincinnati) (Figure 1B). Then, dissection switched from the bottom toward top up to the core vessels. The core vessels were completely freed (Figure 1C). Finally, the core vessels were transected by a vascular endo-stapler through the port incision openly (Figure 1D). The resected specimen was extracted immediately. There was no active blood oozing from the resected raw surface of the liver, which was covered with absorbable hemostasis gauze. The blood loss was less than 60 mL, without temporary inflow occlusion during operation. There was no need for abdominal drain. The resected left lateral segment was 15 cm × 8 cm × 4 cm.

RESULTS

Twenty-six patients underwent uneventful operation courses. One patient was converted to open procedure because his left ureter and common iliac artery were invaded by the sigmoid cancer. The conversion rate was 3.8% (1/26). The length of the procedures was under 2 hours (range 30 min-2 h). The operative blood loss was between 8 to 120 mL. There were no postoperative complications except that a 70 year-old man with chronic pulmonary emphysema and carcinoma of ascending colon, who underwent hand-assisted laparoscopic right hemicolectomy, developed 2 split stitches at the wound because of a violent cough on the 2nd postoperative day, and another patient had a wound stitch reaction. After operation, all patients felt less pain, resumed earlier oral intake of food, and faster recovery, compared with 25

consecutive corresponding cases of conventional surgery. The data are summarized in Tables 3 and 4.

DISCUSSION

Compared with full minimal laparoscopic large organ resection, an incision is often required for extraction of the resected specimen. In fact, there are often “1 port + more than 2 trocars” abdominal wounds in full minimal laparoscopic large viscera resection. By use of currently available tools including HandPort system, harmonic scalpel, Ligasure[®], we designed “1 port + 2 trocars” specific HALS for safe and quick resection of large abdominal visceral organs.

This technique can be of real significance in avoidance of vascular bleeding during removal of the target organ, because the final step is transection of the core vessels. There is no need for worrying about bleeding as the staplers are taken off. Furthermore, a hand inside the abdomen can play an important role in preventing or controlling bleeding. On the contrary, for total laparoscopic operation, which were several times higher in blood loss and longer in operative time, the unmanageable bleeding has become the main cause to convert to open surgery. Total laparoscopic operation does not equal to the minimally invasive surgery. The minimally invasive surgery presents not only the minimal abdominal wound, but also the minimal surgical intervention and complications including bleeding, injury to major adjacent structures, conversion to open surgery and operative time. The technique we employed is by all means the small ports to accomplish the big organ resection with minimal surgical stress, better hemostasis and shorter operative time, and faster recovery of the patients.

An excellent combination of laparoscopic and open techniques for hemicolectomy

Hand-assisted laparoscopic hemicolectomy by this technique is presumed to be an excellent approach combining advantages of laparoscopic and open surgeries. The procedure includes: (1) Laparoscopically, the distal peripheral structures are mobilized by harmonic scalpel or Ligasure with hand-assistance; (2) Conventionally, the mobilized target colon is long enough to be extracted through the optimal base retractor of HandPort system, through which the major core vessel pedicles are transected, or the radical lymph nodes are dissected under direct vision, then the specimen is removed and delivered to prevent port side “seeding”; (3) Extracorporeally, end to end coloileostomy or colocolostomy is performed by sutureless biofragmentable anastomosis ring (BAR), or single layer anastomosis.

In our series, the HALS wound length of 5-6 cm (mean 5.3 cm) was much shorter than the open surgical wound length of 16-33 cm (mean 22.5 cm). Other studies have reported full laparoscopic wound length of 8.5 cm^[7]. The operative time in our group was under 2 h. In addition, previous studies revealed mean operative times for full laparoscopic colectomy, converted procedures, right, and sigmoid resection were 164, 203, 121 and 177 min, respectively^[8].

Advantages over full laparoscopic splenectomy

Our specifically designed HALS in splenectomy has advantage over total laparoscopic splenectomy. First, through the small incision port, the gastrosplenic ligament was dissected as much as possible by open technique before pneumoperitoneum. Second, after placement of the HandPort device, a hand into the abdomen assisted harmonic scalpel or Ligasure to dissect the rest ligaments. It seemed the spleen was retracted by hand with more safety. It also provided better exposure, easier and faster performance than other instruments. Third, splenic pedicle was transected by endo-stapler laparoscopically, or through the small incision with open visualization. Lastly, the resected specimen was extracted immediately after removal of the spleen. However, in full laparoscopic splenectomy with about 4 trocars, the specimen is bagged, one port incision is extended, and the spleen is broken into pieces, and then delivered.

A definite advantage in terms of HALS in hepatectomy

Our study demonstrates HALS in resection of the segments lying at outer edge of the liver (segments 2 to 6) can be performed with ease, safety and rapidity. Placement of the hand into the abdomen plays an important role, because there is no ideal instrument available for grasping the liver but the hand, which acts as a comparatively atraumatic grasping clamp and retractor providing good exposure, and also allows for fingers to identify major pedicles after finishing parenchymal division with Ligasure or harmonic scalpel. The major pedicles are transected using vascular endo-stapler under direct vision through the small incision, and the specimen is delivered at once without breaking.

Advantages over full laparoscopic subtotal gastrectomy

First, the greater and lesser omentum are dissected using this technique much easier and quicker. Second, the stomach is transected and gastrojejunostomy is performed by using open staplers, which are much easier, quicker, more reliable, and less expensive than using endo-staplers in full laparoscopic subtotal gastrectomy. Third, a big and hard duodenal ulcer like the one in our cases is not the indication for full laparoscopic technique, because such duodenal ulcer can neither be transected, nor can the stump be closed with staplers.

The design of the approach for HALS in resection of abdominal large viscera is based on the minimal abdominal wound “1 port + 2 trocars”, as well as the minimal surgical intervention, combining the laparoscopic benefits with the advantages of a conventional open technique. Even though the target organs include parenchymatous and hollow viscera, the rules of resection are the same, which allow for first dissecting the peripheral structures, and finally transecting the core vessel pedicles. This technique is minimal in access, safe, and rapid in laparoscopic resection of abdominal large viscera.

Abstract

AIM: To observe the therapeutic effects of liposome-encapsulated adriamycin (LADM) on hepatoma in comparison with adriamycin solution (FADM) and adriamycin plus blank liposome (ADM + BL) administered into the hepatic artery of rats.

METHODS: LADM was prepared by pH gradient-driven method. Normal saline, FADM (2 mg/kg), ADM+BL (2 mg/kg), and LADM (2 mg/kg) were injected *via* the hepatic artery in rats bearing liver W256 carcinosarcoma, which were divided into four groups randomly. The therapeutic effects were evaluated in terms of survival time, tumor enlargement ratio, and tumor necrosis degree. The difference was determined with ANOVA and Dunnett test and log rank test.

RESULTS: Compared to FADM or ADM + BL, LADM produced a more significant tumor inhibition (tumor volume ratio: 1.243 ± 0.523 vs 1.883 ± 0.708 , 1.847 ± 0.661 , $P < 0.01$), and more extensive tumor necrosis. The increased life span was prolonged significantly in rats receiving LADM compared with FADM or ADM+BL (231.48 vs 74.66 , 94.70) ($P < 0.05$).

CONCLUSION: The anticancer efficacies of adriamycin on hepatoma can be strongly improved by liposomal encapsulation through hepatic arterial administration.

Key words: Adriamycin; Liposome; Hepatoma

INTRODUCTION

Adriamycin (ADM) is extensively used to treat patients with hepatocellular carcinoma (HCC). *In vitro* studies have verified that the cytotoxic effect of ADM depends on the concentration and duration of exposure^[1]. Unfortunately, intravenous administration (iv) of a high-dose ADM is often associated with acute toxicity, such as myelosuppression, immunosuppression, and dose-cumulative cardiotoxicity. As a result, drug concentrations in hepatomas are limited. During the past few years, many researchers have reported on drug delivery systems for cancer chemotherapy that aim at the specific targeting of antitumor agents to tumor cells or tumor tissues, thus enhancing the efficacy of chemotherapy as well as reducing its toxicity^[2]. Among them, liposomes have drawn much attention for their excellent bioavailability, biodegradability, and targeting, characteristically, to the reticuloendothelial system (RES), especially the liver and spleen^[3].

On the other hand, liver primary tumors receive approximately 90% of their blood supply from the hepatic artery. Therefore, transhepatic arterial chemotherapy (TAC) is now widely recognized as an effective means for the treatment of HCC. With TAC, a much higher drug concentration in the tumor-residing zone can be achieved. It was reported that administration of ADM via the hepatic artery (ia) was able to increase the tumor ADM concentration three-fold compared to intravenous (iv) administration^[4]. In patients with cancers, the ia administration of ADM reduced the plasma AUC by about 30%^[5]. On the basis of these evidences, we hypothesized that a further significant therapeutic effect could be expected by combining TAC and liposome techniques. The current study was carried out to observe the therapeutic effects of liposome-encapsulated adriamycin (LADM) on hepatoma in comparison with the treatment results of adriamycin solution (FADM) and adriamycin plus blank liposome (ADM + BL) administered into the hepatic artery in rats.

MATERIALS AND METHODS

Liposomal adriamycin (LADM) preparation and characterization

Large unilamellar vesicles (LUVs) were prepared by the extrusion method described by Hope *et al*^[6]. Appropriate amounts of lipid mixtures (EPC/Chol, 55:45 mol/mol) in chloroform were dried under a stream of nitrogen gas to form a homogeneous lipid film. The trace amount of solvent was then removed under vacuum overnight. The lipid film was hydrated in a low pH citrate buffer (pH 4.0, 300 mmol/L) by vortex mixing. The resulting multilamellar vesicles (MLVs) were frozen/thawed (liquid nitrogen/55°C) 5 times and extruded 10 times at 55°C through two stacked 100 nm polycarbonate filters (Nuclepore) employing an extrusion device (Lipex Biomembranes, Inc., Vancouver, BC, Canada). ADM was then encapsulated by pH gradient-driven method as described previously^[7].

The final product looked like a reddish, semitransparent, colloidal solution. Under electron microscope, LADM showed a global, regular contour with homogeneous size and distribution. The average 120 nm diameters of the liposomes were determined by quasi-elastic light scattering (QELS) using a Nicomp 370 submicrom particle sizer (Santa Barbara, CA, USA) as shown in Figure 1. EPC and Chol were quantified by high performance liquid chromatography (HPLC) method (Table 1). HPLC analysis was performed using a Perkin Elmer HPLC with a PE 200 LC pump, a PE ISS 200 Advanced LC sample Processor, PE 900 Series Interface and an Evaporative Light Scattering Detector (ELSD, Shimadzu). A YMC, PVA 5 m normal phase column was used in this study. The chromatograph was run in a gradient mode at a flow rate of 1 mL/min with the following program, where solution A contained chloroform-isopropanol (50:50, v/v) and solution B contained chloroform-isopropanol-water (36:55:9, v/v).

The drug-to-lipid ratio was 0.25. The drug-embedding ratio was more than 98%. Encapsulation efficiency was calculated as the percentage of ADM incorporated into liposomes relative to the initial amount of ADM in solution as shown in the equation below. The free ADM was separated by elution over a Sephadex G-50 column. Then the free ADM and liposomal ADM were determined by HPLC.

$$\text{Encapsulation efficiency (\%)} = \frac{(\text{adriamycin/lipid})_{\text{Encapsulated}}}{(\text{adriamycin/lipid})_{\text{total}}} \times 100$$

The liposomal particle sizes were identical before and after drug loading, and ADM encapsulated liposomes were very stable at room temperature for three days. There was no significant leakage of ADM from liposomes. Just before use, normal saline was added to adjust the final concentration of total ADM to 1.0 mg/mL. Free ADM (FADM) was prepared by dissolution of ADM in normal saline at the same concentration.

Animals and anesthesia

Sixty male Wistar rats weighing 230-270 g (mean, 250 g) were provided by Laboratory Animal Center of Fourth

Figure 1 The particle size of prepared liposome with EPC/Chol at 55:45 molar ratio by the extrusion method. The average diameters were determined by QELS.

Table 1 Detailed solvent gradient program for analysis of EPC and Chol by HPLC

Time (min)	0-3	3-11	11-11.5	11.5-30
A%	100	0	0	100
B%	0	100	100	0

Solution A: Chloroform-isopropanol (50:50, v/v); Solution B: Chloroform-isopropanol-water (36:55:9, v/v). EPC: egg phosphatidyl choline; Chol: Cholesterol.

Military Medical University and randomly divided into 4 groups, 15 in each. Sumianxin (Changchun Agricultural Pastoral University) was used as anesthetic.

Establishment of hepatoma model

One milliliter of suspension containing 10^7 Walker-256 (W256) carcinosarcoma cells (Shanghai Medical Industrial Institution) was injected into the thigh muscle of a carrier rat (not included in experimental rats). One week after inoculation, a palpable tumor was found at the injection site. Viable tumor tissue was excised under sterile conditions and soaked in 20 mL of Hanks balanced salt solution. Tissue was cut into approximately 1 mm × 1 mm × 1 mm fragments. Experimental rats were anesthetized with intramuscular injection of Sumianxin at 0.2 mL/kg. Median incision beneath the metasternum was made and the liver was exposed. The tumor fragment was implanted into the left liver lobe.

Administration through hepatic artery

On the 7th d after tumor implantation, all animals received laparotomy again. The longest (a) and shortest (b) diameters of the tumor were measured. The tumor volume was calculated as

$$\frac{a \times b^2}{2}$$

By cannulation method described previously^[8], normal saline (NS), FADM, LADM, or ADM mixed with blank liposomes (ADM+BL) were injected into the hepatic artery of rats in groups 1-4 respectively. The dose of ADM in each formulation was 2.0 mg/kg body weight. The concentration of ADM was 1.0 mg/mL.

Assessment of therapeutic effect

Tumor growth inhibition: Seven days later, all rats received the third laparotomy. The longest (a) and shortest (b) diameters of the tumor were measured again and the tumor volume after drug administration was calculated. The tumor volume ratio (TVR) was calculated as

$$\text{TVR} = \frac{\text{Tumor volume after administration}}{\text{Tumor volume before administration}}$$

Tumor necrosis degree: Seven random rats in each group were killed and anatomized. Hepatoma was removed completely and fixed in 10% formalin. Three 5 μm thick sections from each tumor were sliced on the maximal transverse plane and mounted on glass slides overnight at room temperature. After HE staining, the sections were examined under microscope. According to the percentage of necrosis area, tumors were graded according to the following criteria: I, 0%-30%; II, 30%-70%; III, 70%-100%.

Increased life span: Survival time of the remaining 8 rats in each group was recorded. The mean survival time of NS group was reckoned as control. Increased life span (% ILS) was calculated as

$$\% \text{ILS} = \left(\frac{\text{Mean survival of treated group}}{\text{Mean survival of control group}} - 1 \right) \times 100\%$$

Statistical analysis

SPSS 10.0 for windows was used for statistical analysis. Statistical significance was tested by ANOVA and Dunnett test for tumor growth inhibition, log rank test for survival time. $P < 0.05$ was considered statistically significant.

RESULTS

Tumor growth inhibition

No difference in tumor volume was found among the four groups before treatment ($P > 0.05$, Table 2). After treatment, the tumor grew rapidly in rats which received NS. The mean tumor volume was 31.55 times greater than that before treatment. Metastases were observed in about half of these rats. In contrast, the rate of tumor growth lowered apparently in rats which received FADM or ADM + BL ($P < 0.01$). No difference between FADM and ADM + BL was observed ($P > 0.05$). The slowest tumor growth was found in rats which received administration of LADM. The mean tumor volume ratio on the 7th day after LADM infusion was 1.243. Statistics indicated that LADM produced a further significant tumor inhibition, as compared with FADM or ADM + BL ($P < 0.01$). In addition, no metastasis was found in rats receiving LADM.

Tumor necrosis degree

Under microscope, W256 tumor cells of rats that received NS showed extensive proliferation and active mitoses. Small areas of necroses were observed in the center of tumor tissue accompanied with a few inflammatory cells (Table 3). Moderate to severe necroses were found in tumors of rats that received FADM or ADM+BL. Grade III of tumor necroses was found in 4 of 7 tumors after

Table 2 Tumor volume (V) and tumor volume ratio (TVR) after treatment (mean \pm SD)

% ILS : Increased life span. ^a $P < 0.05$ vs FADM, ADM + BL; ^b $P < 0.01$ vs NS.

administration of LADM, including 2 cases of complete tumor necrosis.

Increased life span

Compared with the survival time (11.88 d) of control rats, survival time was greatly prolonged in rats that received LADM (mean, 39.38 d), or FADM (mean, 20.75 d), or ADM+BL (mean, 23.13 d) (Table 4). LADM prolonged the life span by 231.48%, which was significantly longer than FADM (74.66%) and ADM + BL (94.70%) ($P < 0.01$).

DISCUSSION

Hepatocellular carcinoma (HCC) is by far the third most common cause of cancer mortality throughout the world, especially in the Asian-Pacific region, and its incidence continues to increase. On the other hand, HCC has a high expression rate of multi-drug resistance gene (MDR1) and consequently high levels of P-glycoprotein (P-gp), resulting in its insensitiveness to most chemotherapeutic drugs^[9]. Few agents show response rates (RRs) above 20%. ADM is one of the most successful anticancer agents to date for the treatment of HCC. Early phase II trials and case series

reported RRs ranging from 25% to 100% with single-agent ADM^[10]. However, despite its excellent antitumor activity, ADM has a relatively low therapeutic index, and its clinical utility is frequently limited due to acute and chronic toxicities such as myelosuppression, immunosuppression, and dose-cumulative cardiotoxicity. A retrospective analysis of three phase III trials of patients treated with ADM in combination with other cytotoxic agents or radiation therapy demonstrates that ADM-associated cardiac events may occur more frequently and at lower cumulative doses than previously reported^[11]. Encapsulation of ADM into liposomes may minimize the side effects and enhance the antitumor efficacy by altering its pharmacokinetics and biodistribution pattern. Growing evidence supports the use of LADM as a substitute for ADM to increase the therapeutic index by maintaining the antitumor efficacy while improving the safety profile^[12,13]. After intravenous (iv) administration, LADM is predominantly uptaken by the reticuloendothelial system (RES), especially by the liver and spleen^[14].

The results of our experiments demonstrated that the antitumor activity of ADM could be markedly enhanced when the drug was encapsulated in liposomes and administered into the hepatic artery. Equivalent or similar effects could not be obtained using FADM or ADM + BL. Compared with FADM or ADM + BL, LADM produced a more significant tumor inhibition and more extensive tumor necrosis. The average tumor volume on the 7th day after treatment with LADM was 0.105 cm³, about 70% of 0.149 cm³ of the volume after treatment with FADM. The survival time of rats that received LADM was evidently increased. Compared with saline controls, LADM prolonged the life span by 231.48%, which was significantly longer than FADM (74.66%) and ADM + BL (94.70%).

The likely explanations for the improved therapeutic activity of LADM are as follows. First, W256 carcinosarcoma proliferated rapidly with abundant vasculogenesis, which strongly increased the uptake of LADM by tumor tissues after ia administration. In addition, the deformity of tumor vessels caused significant retention of LADM in tumor tissues. Secondly, it has been testified that the cytotoxic effect of ADM depends on the concentration and duration of exposure^[1]. Increasing ADM concentration in tumor cells or slowing its elimination could certainly enhance its antitumor efficacy, both of which could be met after ia administration of LADM. Thirdly, encapsulating the drug into liposomes might modify its distribution pattern in tissues. After being administered into rats, liposomes were taken up selectively by RES, such as the liver, spleen, and bone marrow^[14]. Accumulation of biodegradable liposomes with associated drugs in Kupffer cells would create a gradient of drug concentration for a massive and prolonged diffusion of the free drug towards neoplastic tissues. Fourthly, the tiny size of the liposome could increase its contact areas significantly, which might result in an apparent improvement in its bioavailability.

We did not include iv administration in the present

experiment because the ia route is much more efficient than iv in the treatment of liver malignancies. Different from the liver parenchyma, which receives more than 70% of its blood supply from the portal vein and the rest from the hepatic artery, hepatoma receives approximately 90% of its blood supply from the hepatic artery. The uniqueness of liver blood supply determines the major difference between the two routes of administration. The difference does not warrant repeat comparison in our study.

Our experiments support the hypothesis that the therapeutic effect of TAC could be dramatically enhanced by combination with nanotechnology. We conclude that liposomes can be used as a promising drug carrier in TAC for the treatment of liver primary and metastatic tumors.

Abstract

AIM: To detect microsatellite instability (MSI) in patients with hereditary nonpolyposis colorectal cancer or ordinary hereditary colorectal cancer and to provide criteria for screening the kindreds with hereditary nonpolyposis colorectal cancer at molecular level.

METHODS: MSI was detected in the specimens from 20 cases with HNPCC, 20 cases with ordinary hereditary colorectal cancer and 20 cases with sporadic colorectal cancer by means of polymerase chain reaction-single strand conformation polymorphism.

RESULTS: The positive rate of MSI was 85% (17/20) in HNPCC group, 40% (8/20) in ordinary hereditary colorectal cancer group and 10% (2/20) in the sporadic colorectal cancer group respectively. The differences were significant. The mean ages of the three groups were 43.6, 52.2, and 61.8 years respectively, which increased gradually. The incidence of right hemicolon cancer was 64.7%, 37.5%, and 0% respectively, which decreased gradually and had significant difference. The expression ratio of BAT26 and BAT25 was 94.1% respectively, which was highest in the 5 gene sites studied. The incidence of poorly differentiated adenocarcinoma was 70.6% in HNPCC group among high frequency microsatellite instability (MSI-H), which was higher than the other two groups, which had 50% and 50% respectively.

CONCLUSION: The incidence of MSI-H is higher in HNPCC group. The detection of MSI is simple and economical and has high correlation with the clinicopathologic feature of HNPCC and can be used as a screening method to detect the germ line mutation of the mismatch repair gene.

INTRODUCTION

Hereditary nonpolyposis colorectal cancer (HNPCC) is an autosomal dominant inheritance syndrome, with a penetrance as high as 70%-80%^[1], and accounts for about 5%-15% of all colorectal cancer^[2]. The molecular genetic basis of the disease is germ line mutation of the mismatch repair (MMR) gene, which causes failure of the DNA MMR system to repair errors that occur during the replication of DNA and results in alterations in the length of simple, repetitive microsatellite sequences and so called microsatellite instability (MSI). MSI may reflect the mutation of the MMR gene indirectly and can be used as a means of screening gene mutation of the MMR gene^[3,4]. Recently, studies showed most patients with HNPCC have MSI^[5,6] and the ratio is higher than that of patients with sporadic colorectal cancer^[7,8]. In the current study, we tested microsatellites of the former paraffin-embedded tissue by the method of polymerase chain reaction-single strand conformation polymorphism (PCR-SSCP) of the Chinese patients who fulfilled the criteria for HNPCC and ordinary hereditary colorectal cancer and tested its application value in the clinic.

MATERIALS AND METHODS

Patients

HNPCC group (group A): 20 patients (12 men, 8 women, mean age 48 years, range 32-70 years) who fulfilled the criteria for HNPCC of Chinese people^[9] were selected and their family histories were obtained by follow-

Figure 1 Positive results of MSI. (arrowhead indicates positive results). M: normal DNA; N: normal tissue; T: cancer tissue.

Figure 2 Negative results of MSI (results of 3 pairs are all negative). M: normal DNA; N: normal tissue; T: cancer tissue.

up study. Among them 9 cases were with carcinoma of ascending colon, 2 cases with carcinoma of transverse colon, 1 case with carcinoma of descending colon, 2 cases with carcinoma of sigmoid colon and 6 cases with carcinoma of rectum.

Ordinary hereditary colorectal cancer group (group B): 20 patients (13 men, 7 women, mean age 61 years, range 30-83 years) who fulfilled the criteria for ordinary hereditary colorectal cancer of Chinese people^[10] were selected. Among them 5 cases were with carcinoma of ascending colon, 3 cases with carcinoma of transverse colon, 1 case with carcinoma of descending colon, 2 cases with carcinoma of sigmoid colon and 9 cases with carcinoma of rectum.

Sporadic colorectal cancer group (group C): 20 patients (10 men, 10 women, mean age 65 years, range 42-80 years) who were diagnosed with colorectal cancer by pathology and with no family history were selected. Among them 5 cases were with carcinoma of ascending colon, 4 cases with carcinoma of sigmoid colon and 11 cases with carcinoma of rectum.

Methods

For MSI analysis, normal and tumor tissues of the three groups were embedded with paraffin, 4-5 slides of tissue with thickness of 4 μ m were sliced and stained with HE. Normal and tumor tissues were selected with microscopy. They were transferred to the EP tubes which contained 150 μ L cell lysates. Then DNAs of the normal and tumor tissues were extracted with DNA extraction kit. The primers of the 5 microsatellite loci of HNPCC (BAT26, BAT25, D2S123, D5S346 and D17S250) were selected according to recommendation of the international cooperation organization (Table 1). The primers were synthesized by TAKARA Company.

The reaction system: It was consisted of a total volume of 25 μ L with 3 μ L template DNA, 0.5 μ L forward and reverse primers, 10 \times Buffer 2.5 μ L, dNTP 2.0 μ L, TaqE 0.2 μ L, DMSO 1.0 μ L, ddH₂O 15.3 μ L. The PCR program started with a 95°C denaturation for 5 min, then at 94°C for 40 s, 53°C for 30 s followed by 35 cycles of annealing at 72°C for 1 min, and extension at 72°C for 40 s, finally an extension at 72°C for 10 min. The PCR products were analyzed by electrophoresis on 1.5% agarose gels containing ethidium bromide.

Detection of MSI: Single strand conformation polymorphism (SSCP) was used to analyze MSI. The PCR products

of normal and tumor tissues were mixed with the same volume of alkaline buffer, then started with 97°C denaturation for 10 min and put in the mixture of water and ice for 5 min. Then electrophoresis was performed vertically on the 10% nondenaturing polyacrylamide gel (constant power; 60 W) for about 4 h. When the indicating straps reached the inferior margin of the gel or the tracer agent disappeared, silver staining, coloration, fixation and termination were performed. When the film dried 24 h later, the imaging was observed.

Results assessment: MSI was defined by the presence of novel bands following PCR amplification of tumor DNA, which were not present in PCR products of the corresponding normal DNA. If more than 2 of them showing positive results, it was defined as high frequency microsatellite instability (MSI-H), and if only 1 of them showing positive result, it was defined as low frequency microsatellite instability (MSI-L), and if none of them showing positive result, it was named microsatellite stable (MSS).

RESULTS

The results of detection of MSI are shown in Figures 1 and 2. and Tables 1 and 2.

The relationship among MSI-H, mean age of the patients and the sites of cancer are shown in Table 3.

The ratio of every locus occupying in the MSI-H is shown in Table 4.

The clinical pathological characteristics of colorectal cancer are as follows: in the 17 cases with MSI-H of group A, 7 cases had multiple cancers, among which 4 cases were with multiple cancers simultaneously, 3 cases were with multiple cancers at different times. As to groups B and C, none of the patients were with multiple cancers. There were 70.6% (12/17) of poorly differentiated adenocarcinoma in group A, which was more than that of groups B (50%, 4/8) and C (50%, 1/2).

DISCUSSION

Microsatellites are long stretches of apparently redundant DNA between genes by 2-6 nucleotides tandemly arrayed, within which repetitive sequences may be found. Repetition of two bases(CA/GT) is most common. Under normal conditions, the repetitive sequence is constant but

MSI-H: high frequency microsatellite instability; MSI-L: low frequency microsatellite instability; MSS: microsatellite stable.

highly polymorphic and is an ideal mark for localization of genes. Cells lacking normal DNA mismatch repair acquire mutations that change the length of nucleotide repeat sequences, termed microsatellite instability (MSI). MSI is the pattern of manifestation of MMR and has a close relationship with HNPCC^[11,12], therefore the mutation of MMR results in the incidence of MSI. About 70%-90% of the patients with HNPCC had MSI and only 10%-15% occurred in patients with the sporadic colorectal cancer. Although the Amsterdam Criteria (the International Collaborative Group established in 1991) is now used as the diagnostic criteria for HNPCC clinically, its determination depends mainly on family history and clinical symptoms and cannot reflect the true morbidity of the disease and predict the occurrence of HNPCC. Therefore the detection of mutation of MMR genes has become the golden standard for diagnosis of HNPCC. However, the MMR gene is very large, it has no mutational hot spot, and the cost of detection is expensive, thus it cannot be used as a routine means for screening of HNPCC family at present. As a phenotype of MMR gene mutation, MSI can be used as criterium for detection of HNPCC, especially in patients whose family history is not complete and who do not fit the criteria of HNPCC clinically. Therefore, DNA is extracted from the tumor tissue for detection of MSI. When a patient of MSI-H is diagnosed, detection of MMR gene should be done. As to the choice of loci of the microsatellite instability, 5 loci of microsatellite are used for PCR amplification according to the recommendation of the International Collaborative Group and the International Cancer Research Institute and the Collaborative Group of the Chinese Genetic Colorectal Cancer. However, number of the microsatellites detected is not constant, from less than 3 loci to more

Table 3 Relationship among MSI-H, mean age of the patients and the sites of cancer (%)

Group	n	MSI-H	Mean age (yr)	Right hemicolon	Left hemicolon
A	20	17 (85)	43.6	11 (64.7)	6 (35.3)
B	20	8 (40)	52.2	5 (62.5)	3 (37.5)
C	20	2 (10)	61.8	0 (0)	2 (100)

Table 4 Ratio of every locus occupying in the MSI-H (%)

Locus	Positive ratio of MSI-H	Positive ratio of MSI
BAT26	94.1 (16/17)	85 (17/20)
BAT25	94.1 (16/17)	90 (18/20)
D2S123	64.7 (11/17)	55 (11/20)
D5S346	52.9 (9/17)	50 (10/20)
D17S250	35.3 (6/17)	40 (8/20)

than 100 loci. The criteria for the number and ratio of the positive locus of MSI tumor are not uniform. Therefore the results of many different researchers could not be compared with each other.

In this study, we amplified 5 loci of microsatellite by PCR according to the criteria of the International Collaborative Group and the International Cancer Research Institute and found the positive ratio was as high as 85% for MSI-H patients with HNPCC, which is in accordance with other research. We found the 5 loci were ideal for detection of MSI of HNPCC patients. It reflected the mutation of MMR gene objectively and could be used as a reliable indicator for screening of HNPCC family just before gene sequencing. If other loci were selected, the type of MSI could be decided by the percentage of positive locus, and MSI-H could be diagnosed when the percentage of positive loci was more than 30%-40% while MSI-L was diagnosed when the percentage of positive loci was less than 30%. As to which loci should be selected, there are a variety of viewpoints. Some scholars think 1-2 microsatellite loci are enough. Hoang^[13] believes BAT26 has high correlation with MSI, and their concordance rate is very high. Because the detecting process is relatively simple, Stone^[14] detected MSI from tumor specimen using BAT26 directly and recommended that it should be used more extensively. Our study found the positive rate of BAT26 was as high as 94.1%, indicating its high sensitivity for MSI-H detection. At the same time, the positive rate of BAT25 was also 94.1%. Their annealing temperature was close to each other and could be carried out in the same reaction system. The combined application of BAT26 and BAT25 may elevate the specificity of the experiment.

Moreover, our research found that about 40% of the patients with ordinary hereditary colorectal cancer were classified as MSI-H, although it was lower than that of the HNPCC group, it was higher than that of the sporadic colorectal cancer group (the positive rate was 10%), suggesting that about 30% of the patients with ordinary hereditary colorectal cancer had the characteristics of HNPCC. Whether these patients were potential HNPCC

patients needs further study. MSI has been shown to have a close relationship with the onset age of the patients in many recent studies. MSI-H shows good consistency with early onset of age. Edmonston^[15] found that the patients whose onset of age was less than 41 years were all MSI-H positive, and the youngest onset age of MSI-H was less than 26 years. Terdiman^[16] found that in the different HNPCC families, the final diagnosis age of MSI-H was young and there were more family members with HNPCC than other families, and the ratio of multiple cancers or other HNPCC-related cancer increased. Our research revealed that the mean onset age of MSI-H in the HNPCC group was 43.6 years, which was younger than that of the ordinary hereditary colorectal cancer group (52.2 years) and the sporadic colorectal cancer group (61.8 years). The incidence of multiple cancers or other HNPCC-related cancers of HNPCC group was higher than other groups. In addition, MSI had a close relationship with the sites of carcinoma. The carcinoma of MSI-H, either of HNPCC or of sporadic colorectal cancer, was all likely to occur at the proximal half of a colon. Just as Altonen's study showed^[17], 62% of the tumors occurred at the proximal hemicolon of the patients with HNPCC while 38% occurred at the distal hemicolon, suggesting that MSI had a close relationship with cancer of right hemicolon and may play a fundamental role in the pathology of cancer of right hemicolon. Our research found the incidences of right hemicolon cancer of the HNPCC group and the ordinary hereditary colorectal cancer group were 64.7% and 62.5% respectively, which were higher than those of left hemicolon cancer. There was no cancer of right hemicolon found in the sporadic colorectal cancer group, because the occurrence of rectum cancer was higher in North China and the bias was related with the cases selected. Our research suggests that MSI had high correlation with the clinical and pathological characteristics of the HNPCC.

At present, there have been few reports about MSI in typical cases of Chinese people and no clinical data about MSI in patients with ordinary hereditary colorectal cancer. Our research demonstrates that the incidence rate of MSI-H in patients with HNPCC, the mean onset age, the site of carcinoma occurrence, and the clinical and pathological characteristics of patients with HNPCC are all different from that of patients with sporadic colorectal cancer. Ordinary hereditary colorectal cancer is a special type between HNPCC and sporadic colorectal cancer. It has partial characteristics of HNPCC but is not the same as HNPCC and has many differences from sporadic colorectal cancer. Whether it has a special molecular genetic mechanism needs further study. In addition, the survival rate of patients with HNPCC is higher than that of patients with sporadic colorectal cancer, which is due to the early diagnosis of some patients with HNPCC^[18,19]. Recently, studies reported that MSI induced by abnormal expression of MMR may affect the therapeutic effect of chemotherapy and the prognosis of patients with colorectal cancer^[20-22]. Therefore, as an important screening method for HNPCC, MSI has a promising prospect in clinical application.

Abstract

AIM: To observe the pharmacokinetics and pharmacodynamics of rabeprazole and compare serum gastrin concentrations in different CYP2C19 genotype groups.

METHODS: The CYP2C19 genotype status of Chinese Han healthy volunteers was determined by polymerase chain reaction-restriction fragment length polymorphism method. Twenty *H. pylori*-negative healthy subjects voluntarily participated in the study. They were divided into the following three groups: homozygous extensive metabolizers (homEM), heterozygous extensive metabolizers (hetEM) and poor metabolizers (PM). After they orally received rabeprazole 20 mg once daily in the morning of d 1 and d 8, blood samples were collected at various time-points until 24 h after administration and intragastric pH values were monitored for 24 h by Digitrapper pH. Serum gastrin concentrations were measured by radioimmunoassay. Serum concentrations of rabeprazole were measured by high performance liquid chromatography.

RESULTS: The mean AUC values for rabeprazole after a single and repeated doses were significantly different between the homEM and PM groups, but not between the homEM and hetEM, or the hetEM and PM groups. No significant differences in intragastric pH medians were observed among the three different genotype groups after a single dose or repeated doses. The ratio of pH medians between d 1 and d 8 ranged from 84% to 108%. The mean gastrin AUC values were also different among the three genotype groups, with a relative ratio of 1.0, 1.2 and 1.5 after a single dose and 1.0, 1.5 and 1.6 after repeated doses in the homEM, hetEM and PM

groups, respectively. The gastrin AUC values among the three different genotype groups showed no significant difference either after a single dose or repeated doses. The subject who had lower intragastric acidity showed higher serum gastrin levels and concentrations of rabeprazole.

CONCLUSION: In Chinese Han healthy people, the pharmacokinetics of rabeprazole are dependent on the CYP2C19 genotype status, but acid-inhibitory efficacy of rabeprazole and the gastrin level are not influenced significantly.

<http://www.wjgnet.com/1007-9327/12/4750.asp>

INTRODUCTION

CYP450 2C19 is a genetically determined enzyme. Its phenotypes are either poor metabolizer (PM) or extensive metabolizer (EM)^[1,2] in the general population. When CYP2C19 is the main metabolism enzyme of a drug, the pharmacokinetics and pharmacodynamics of the drug are different between PMs and EMs. Rabeprazole (RPZ), a kind of the newer proton pump inhibitors (PPIs), has been reported to be metabolized mainly *via* a non-enzymatic pathway, with only minor CYP2C19 and CYP3A4 involvement. The pharmacokinetics of RPZ are expected to be less influenced by the CYP2C19 phenotype than those of omeprazole^[3-6]. However, it is not clear whether the pharmacokinetics and pharmacodynamics of RPZ depend on the CYP2C19 genotype status in Chinese Han people. On the other hand, it is well known that gastrin is secreted from G cells in the antrum of the stomach^[7], and an inhibition of gastric acid secretion by PPIs can stimulate gastrin release from G cells^[8]. Until now, little is known about the kinetics and pharmacodynamic effect

of RPZ on gastrin levels with respect to the polymorphic CYP2C19 in Chinese Han people. Therefore, in the present study, we observed the metabolic characteristics and pharmacodynamics of RPZ and serum gastrin levels after the single and 8-d repeated doses in the different CYP2C19 genotype groups. It showed that acid-inhibitory efficacy of rabeprazole and the gastrin levels were not influenced significantly by CYP2C19 genotype.

MATERIALS AND METHODS

Subjects and CYP2C19 genotypes

Twenty healthy male subjects who were negative for *H. pylori* infection were enrolled in the study. None of the subjects consumed alcohol or smoked, and none had taken any drugs at least 4 wk before or during the study. The protocol was approved in advance by the ethic committee of Anhui Medical University. Written informed consent was obtained from each of the subjects before participation in the study.

Genomic DNA was extracted from leucocytes of each individual using a commercially available kit (Promega, USA). The genotyping of CYP2C19, including CYP2C19*wt, CYP2C19*m1 and CYP2C19*m2, was performed by polymerase chain reaction and restriction fragment length polymorphism (PCR-RFLP)^[9]. The age of the subjects ranged from 20 to 23 years and body weight from 57 to 63 kg. Subjects were genotypically classified into the following three groups: homozygous extensive metabolizer group (homEM, $n = 7$), heterozygous extensive metabolizer group (hetEM, Wt/m1, $n = 4$; Wt/m2, $n = 2$) and poor metabolizer group (PM, m1/m1, $n = 7$).

Study protocol

Subjects were initially screened for *H. pylori* infection by a serological test (Dot-immunogold kit, Lanbo Bio-Tech Institute, China) and ¹³C-urea breath test. Each healthy volunteer received 20 mg RPZ (Pariet, Eisai Co. Ltd, Tokyo, Japan) orally for 8 d. The medications were taken once daily at 8:00 am. The 24-h intragastric pH monitoring and the measurement of plasma concentration of RPZ and gastrin level were performed on d 1 and d 8. Blood samples were collected before and 0.5, 1, 1.5, 2, 3, 5, 7, 10, 12, 24 h after administration on d 1 and d 8. After collection, the blood samples were immediately centrifuged at 4000 r/min for 10 min. One hundred microliter 1% diethylamine solution was added to the 1 mL plasma sample for determination of the concentration of RPZ. All samples were stored at -80°C until assayed. Plasma levels of RPZ were measured by high performance liquid chromatography^[10,11]. Serum gastrin levels were measured using radioimmunoassay (Gastrin-RIA kit, North Bio-Tech Institute, China).

Intragastric pH measurement

After overnight fasting, a glass electrode was inserted transnasally and placed about 5 cm below the cardia. The electrode was calibrated with standard buffers (pH 1.07 and 7.01) before recording the pH with a Digitrappher pH (Medtronic). Intragastric pH recordings started after the oral dose of RPZ at 8:00 am on d 1 and d 8. Two standard

Table 1 AUC of RPZ 20 mg after a single and repeated doses

	AUC ^a (μg/L per h) d 1	AUC ^a (μg/L per h) d 8
homEM	1150.24 ± 327.34	1445.28 ± 205.16
hetEM	1539.42 ± 190.29	1640.91 ± 249.51
PM	2015.38 ± 588.88	2495.61 ± 738.61

^a $P < 0.05$ homEM vs PM.

meals (noon, 18:00 pm), prepared at the hospital, were provided for each subject.

Pharmacokinetic analysis

Pharmacokinetic analysis was performed in a model-independent manner, and non-compartmental kinetic parameters (AUC) were calculated with 3P87 software. The area under concentration-time curve (AUC) for RPZ and gastrin in serum was shown from zero to 24 h (AUC₀₋₂₄).

Statistical analysis

The data are given as mean ± SD in all analyses. Differences in AUC and intragastric pH values between three genotype groups were compared using one-way analysis of variance (ANOVA) combined with the least significant method (LSD). To determine whether the gastrin concentrations and AUC values were increased from a single dose to repeated doses, the paired *t*-test was used. Statistical calculations were performed by SPSS 10.0 software. *P* value of less than 0.05 was considered to be statistically significant.

RESULTS

CYP2C19 genotype and AUC of RPZ

The mean AUC of RPZ is shown in Table 1. The mean AUC values for RPZ after a single dose differed among the three genotype groups, with a relative ratio of 1.0, 1.3 and 1.8 in the homEM, hetEM and PM groups, respectively. The mean AUC values for RPZ after repeated doses also differed among the three groups, with a relative ratio of 1.0, 1.1 and 1.7 in the homEM, hetEM and PM groups, respectively. The mean AUC values for RPZ after a single and repeated doses were significantly different between the homEM and PM groups, but not between the homEM and hetEM, or hetEM and PM groups. No significant change in the mean AUC values for RPZ from a single dose to repeated doses was observed in any of the three genotype groups.

CYP2C19 genotype and 24-h intragastric pH

The median intragastric pH value of the PM group was the highest, followed by that of the hetEM group, with that of the homEM group being the lowest (Table 2). No significant differences in intragastric pH values were observed among the three groups after a single dose and repeated doses of RPZ for 8 d. No significant changes in intragastric pH values from single to repeated doses were observed in the three genotype groups. The ratio of intragastric pH median after a single dose and that after repeated doses ranged from 84.5% to 107.4%, indicating that the metabolism of RPZ after a single dose could

Table 2 Median (interquartile range) 24 h pH after a single and repeated doses of RPZ 20 mg

	HomEM	HetEM	PM

attain maximum acid-inhibitory efficacy.

CYP2C19 genotype and serum gastrin level

The 24-h mean serum gastrin concentration-time profiles are given in Figure 1. The mean serum gastrin concentration in PMs was significantly higher during all time periods than that in EMs. The mean serum gastrin AUC values in hetEMs observed after a single and repeated doses were between that of homEMs and PMs. The mean gastrin AUC values differed between the three genotype groups, with a relative ratio of 1.0, 1.2 and 1.5 after a single dose and 1.0, 1.5 and 1.6 after repeated doses in the homEM, hetEM and PM groups, respectively (Table 3). The gastrin AUC values among the three genotype groups showed no significant differences after a single dose and repeated doses of RPZ 20 mg. Significant increments in gastrin AUC values from a single dose to repeated doses were observed in the three different genotype groups.

As shown in Tables 1, 2 and 3, the subjects who had the lowest intragastric acidity showed the highest serum gastrin levels and the concentrations of RPZ.

DISCUSSION

PPIs, such as omeprazole and rabeprazole, have been used widely in the treatment of acid-related diseases. Studies have found that CYP2C19 is a major enzyme for the metabolism of PPIs in the liver^[12], and the inhibitory effects of PPIs are associated with the genotype of CYP2C19. The *in-vitro* human liver microsomal and *in-vivo* human pharmacology studies have shown that the metabolic profile of RPZ differs somewhat from other PPIs. RPZ is metabolized mainly *via* a nonenzymatic reduction to rabeprazole thioether^[12-14], and CYP2C19 and CYP3A4 are partially involved in the metabolism of RPZ^[12-14]. In addition, it has been shown that RPZ has a more rapid and powerful onset of pharmacological action^[15]. Yasuda^[10] found that the AUC for RPZ is not significantly increased after repeated doses. Our results showed that the AUC for RPZ after a single dose exceeded 80 percent of that after

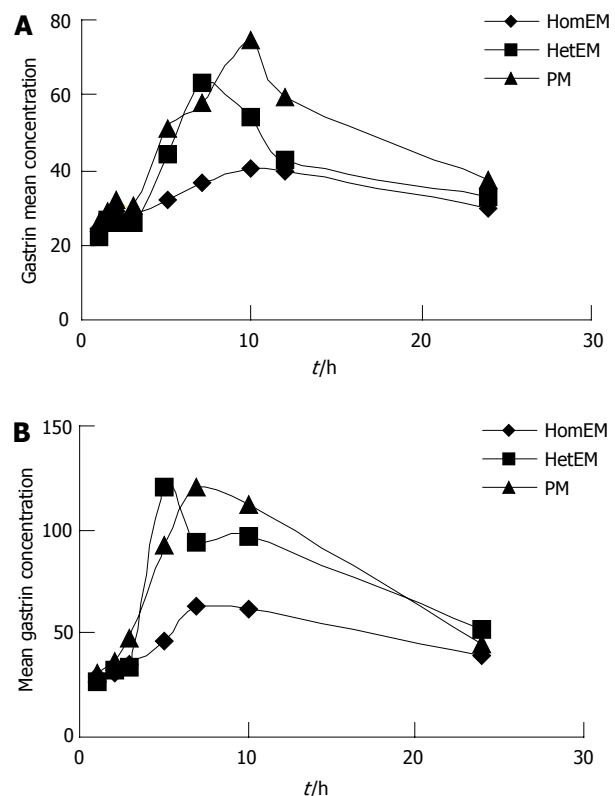

Figure 1 Mean serum gastrin concentration-time curve after a single dose (A) and repeated doses (B) of rabeprazole 20 mg.

repeated doses, and the gastric pH values after a single dose reached 84.5 to 107.4 percent of those after repeated doses. These findings suggest that the human body could absorb RPZ well, and RPZ could attain better acid-inhibitory efficacy.

Horai^[16,17] reported that CYP2C19 genotypic differences affect metabolism and pharmacokinetics of RPZ, and influence the gastric pH values and gastrin level in plasma. However, the majority of researchers^[3-6] believe that the acid-inhibitory efficacy and metabolism of RPZ are not dependent on the CYP2C19 genotype status. In our study, the acid-inhibitory efficacy and the gastrin level of rabeprazole were not influenced. This is supposed to be related with the small sample size of our study, as the number of subjects enrolled in each group was small. Ieiri^[18] reported that the mean AUC values for rabeprazole differed among the three genotype groups, with a relative ratio of 1.0, 1.7 and 3.8 in the homEM, hetEM and PM groups, being significantly related with genotype status. However, we found the AUC for RPZ was different markedly only between homEMs and PMs. Moreover, the intragastric pH, the best or most direct pharmacological index when using PPIs, had no significant differences among the three genotype groups after a single dose. After repeated doses of RPZ, the intragastric pH and AUC for RPZ were not affected by the CYP2C19 genotype status either. As for the discrepancy between the pharmacokinetics and pharmacodynamics of RPZ, we hypothesized that the acid inhibitory effect of RPZ was powerful and rapid, even in the homEM group.

When a PPI inhibits acid secretion, plasma or serum gastrin levels will be increased according to the degree

of acid inhibition, and serum gastrin concentration correlates well with gastric acid suppression^[19]. Therefore, plasma or serum gastrin concentration could be viewed as an indirect marker of the pharmacodynamic effects^[20]. Ieiri^[18] reported that the intergenotypic difference in the gastrin AUC was seen after the first dose of RPZ, and the AUC of serum gastrin on d 8 differed significantly between homEMs and PMs. However, in our study, no significant difference in the mean gastrin AUC was observed among the three genotype groups on d 1 and d 8, nor were significant differences in the median gastric pH levels found. We presume that the intergenotypic difference in serum gastrin AUC was synchronized with that in median gastric pH, which are consistent with the findings by Furuta^[8]. Previous studies indicated that serum gastrin concentrations returned to normal shortly after the antisecretory treatment with RPZ was discontinued^[21,22]; however, this phenomenon seems to be in conflict with the longlasting action of PPIs^[23]. Therefore, serum gastrin concentrations might not accurately reflect PPI-induced changes in intragastric pH, when PPIs were used in the different CYP2C19 genotype groups.

In conclusion, our study investigated mainly the pharmacodynamic and pharmacokinetic effect of rabeprazole on serum gastrin levels in association with different CYP2C19 genotypes. The acid-inhibitory effects of RPZ are independent of the CYP2C19 genotype status as well as the pharmacokinetic characteristics in the human body. Although the median gastric pH by RPZ treatment is related with the serum gastrin level, there is no significant difference between the different CYP2C19 genotype groups. RPZ is not only an effective proton pump inhibitor for treating the acid-related disease, but also does not affect serum gastrin level in association with CYP2C19 genotype status.

Abstract

Sarcoidosis is a systemic disease of unknown aetiology that may affect any organ in the body. The gastrointestinal tract however is only rarely affected outside the liver. Symptoms may be non-specific. Irritable bowel syndrome (IBS) is a common diagnosis. The recognition of IBS is aided by the use of the Rome II criteria - in the absence of organic disease. We describe the first case of a patient with gastric sarcoidosis who presented with IBS symptoms but subsequently responded to immunosuppressive therapy.

INTRODUCTION

Sarcoidosis is a systemic disease of unknown aetiology characterised by the presence of non-caseating epithelioid granulomas. The lungs, eyes and skin are the most commonly affected organs^[1]. Liver involvement is well recognised but symptomatic involvement of the gastrointestinal (GI) tract occurs in less than 1% of

cases^[2-6]. Presenting GI symptoms in order of frequency are abdominal pain, haematemesis, nausea and vomiting and weight loss^[1,2,4-6]. This observation is only based on the case reports and case series that have been reported^[2,4-6]. Irritable bowel syndrome (IBS) is a common diagnosis and the symptom based Rome II criteria may be used to support the diagnosis^[7]. However it is essential when investigating patients who present with IBS type symptoms that organic disease is excluded^[7]. We describe the first case of a patient with gastric sarcoidosis who presented with IBS symptoms but subsequently responded to immunosuppressive therapy.

CASE REPORT

A 27 year old Caucasian man presented to the respiratory physicians with chest discomfort and 'flu-like symptoms' in 1983. A plain radiograph of the chest showed bilateral hilar lymphadenopathy and left middle zone infiltrates. Gallium scanning and a positive Kveim test confirmed the diagnosis of pulmonary sarcoidosis. Remission was achieved with oral steroids. Apart from a chronic irritable cough, he had no recurrence of his respiratory symptoms over the following 22 years. His previous annual serum angiotensin converting enzyme (ACE) and a recent high resolution computed tomography (CT) of the chest was normal.

He presented to a gastroenterology department with a 6-mo history of upper/central abdominal pain relieved on defaecation. There was a change in frequency of bowel movement - he now opened his bowels less than three times per week (prior to this presentation he opened his bowels daily). The stool varied between normal and pellet-like. He described bloating, distension and tenesmus. There was no weight loss or any other sinister symptoms. His symptoms fulfilled the Rome II criteria for constipation predominant IBS. His inflammatory markers (ESR and CRP) were normal. Further investigations including an upper GI endoscopy, colonoscopy, ultrasound and CT of the abdomen were all normal. The diagnosis of IBS was suggested but the patient still had concerns about the cause of his symptoms. With the consent of the clinicians from the initial centre the patient sought a second opinion. Although he had no pulmonary symptoms, (apart from a chronic cough) we wondered if his IBS symptoms could be due to gastrointestinal sarcoidosis. Further investigations in our centre showed a raised serum ACE level of 67 IU/mL (Range 18-55 IU/mL). In addition,

Figure 1 Gastric antrum viewed from mid body of stomach showing widespread erythematous changes consistent with gastritis.

Figure 2 Gastro-oesophageal junction showing polypoid lesion.

Figure 3 Gastric antral biopsy (HE x 400 magnification) showing surface epithelium on the left of the image. The glands are displaced by a central granuloma formed from loosely aggregated epithelioid histiocytes, with a few surrounding lymphocytes.

Figure 4 Biopsy of polypoid lesion at gastro-oesophageal junction showing glandular tissue with active chronic inflammation and reactive epithelial changes (HE x 200 magnification).

he also had a positive IgG antigliadin antibody and a serum IgA of 0.52 G/L (0.8-4.0 G/L) but negative IgA antigliadin and anti-endomysial antibody (EMA). We performed a gastroscopy, which showed antral erythema (Figure 1) and a polypoid lesion at the gastro-oesophageal junction (Figure 2). Duodenal biopsies were normal. Biopsy of the antrum revealed granulomas consistent with sarcoidosis (Figure 3). Biopsy of the polypoid lesion showed chronic inflammatory cell infiltrate only (Figure 4). His CLO test was negative and there was no evidence of *H. pylori* or alcohol-acid fast bacilli in any of the biopsy specimens.

Oral prednisolone initially achieved some symptomatic benefit, but he responded subjectively to a short course of intravenous hydrocortisone. During this time his serum ACE normalised and he was discharged on 30 mg prednisolone. He has subsequently had an octreotide scan showing no activity in the stomach (whilst on prednisolone) and was started on oral azathioprine with progressive resolution of his GI symptoms.

DISCUSSION

Sarcoidosis of the GI tract is rare but when involved the stomach is the commonest site. Gastric granulomas have coincidentally been reported in up to 10% of patients with pulmonary sarcoidosis^[8,9]. However, whether the presence of gastrointestinal sarcoid accounts for GI

symptoms is controversial. Previous investigators have described endoscopic and radiological findings of peptic ulceration, inflammation and gastric outlet obstruction^[2,3,5,10-12]. Diagnosis is achieved by biopsy confirming the presence of granulomas without evidence of any other granulomatous disorders. One series of 67 patients with sarcoidosis described 7.5% of patients as having abdominal pains at diagnosis. Further evaluation revealed 15% had liver involvement (biopsy proven) and 36% had luminal GI disease; reflux oesophagitis (21%), IBS (10%) and inflammatory bowel disease (4.5%)^[13]. Both reflux and irritable bowel syndrome symptoms are frequent amongst the general population, however, this study suggests that the presence of such symptoms may require investigation. The optimal approach would be upper GI endoscopy and biopsy of any abnormal areas.

This is the first reported case of a patient who fulfilled the Rome II criteria for IBS but was subsequently found to have gastric sarcoidosis. Although we performed antigliadin antibodies (and EMA) to exclude coeliac disease-IgG antigliadin lacks specificity and has previously been reported in association with gastrointestinal sarcoidosis^[14,15]. If we had not performed antral biopsies having seen macroscopic evidence of inflammation, then the diagnosis may have been missed. It is possible that in our case both gastric sarcoid and IBS co-exist. We believe that this is unlikely given the symptomatic and serological response to immunosuppression^[16,17]. In addition, a normal

octreotide scan whilst on prednisolone (with no areas of increased uptake) also suggests remission and further corroborates our view^[16].

In conclusion, we report the first case of gastric sarcoid presenting with Rome II criteria for IBS. Our case suggests that patients with suspected functional GI symptoms in the presence of pulmonary sarcoid, may have sarcoidosis of the GI tract. It is imperative that the endoscopist is aware of this possibility and performs a biopsy of any macroscopically abnormal areas. By taking this approach patients with symptomatic GI sarcoid may benefit from early diagnosis and symptomatic relief with prednisolone or immunosuppressive therapy.

Abstract

A 29-year-old nurse with a hepatitis C virus (HCV) infection caused by needle-stick injury was treated with interferon-beta starting about one year after the onset of acute hepatitis. The patient developed acute hepatitis C with symptoms of general fatigues, jaundice, and ascites 4 wk after the needle-stick injury. When these symptoms were presented, the patient was pregnant by artificial insemination. She hoped to continue her pregnancy. After delivery, biochemical liver enzyme returned to normal levels. Nevertheless, HCV RNA was positive and the pathological finding indicated a progression to chronicity. The genotype was 1b with low viral load. Daily intravenous injection of interferon-beta at the dosage of six million units was started and continued for eight weeks. HCV was eradicated without severe adverse effects. In acute hepatitis C, delaying therapy is considered to reduce the efficacy but interferon-beta therapy is one of the useful treatments for hepatitis C infection in chronic phase.

INTRODUCTION

Needle-stick injury is a major cause of acute hepatitis C in health care workers^[1]. Acute infection of hepatitis C virus (HCV) frequently progresses to chronic hepatitis, which leads to liver cirrhosis and to hepatocellular carcinoma^[2]. Preventing the progress to chronicity is necessary, and several treatment strategies of interferon therapies were reported^[3,4,5,6]. Early phase treatment is recommended in order to obtain a sustained virological response (SVR)^[5]. On the other hand, optimal timing of treatment is controversial because self-limited hepatitis exists in 15%-30% of acute hepatitis C^[7]. Several predictive factors of the spontaneous clearance of HCV were reported but these have not been confirmed in larger numbers and well-designed prospective studies. As wait & see strategy to expect the spontaneous viral clearance, it was reported that 8 to 12 wk of delaying therapies obtained more than 90% of SVR rate, however, a delay by one year reduced the rate^[7,8]. We report a case of acute hepatitis C infection caused by needle-stick injury just before pregnancy. After delivery, the patient achieved a SVR by treating with interferon-beta in the chronic phase of acute hepatitis C.

CASE REPORT

Patient

The patient was a 29-year old Japanese woman. She was a clinical nurse. She had a missed abortion at the age of 26. She admitted occasional alcohol intake but she did not receive blood transfusions or operations.

Present illness

She encountered a skin puncture on the hand from a needle contaminated with blood from a patient with chronic hepatitis C on September 15th, 2001. She became pregnant through artificial insemination on October 2nd. She felt general fatigue from October 16th. Her attending physician pointed out the abnormal liver function tests, and then she was referred to Sendai City Medical Center at October 19th. On admission, liver function tests indicated elevated aspartate aminotransferase (AST; 549 IU/L, normal 12-30 IU/L) and alanine aminotransferase (ALT; 870 IU/L, normal 8-35 IU/L) activities. Total bilirubin (1.0 mg/dL, normal 0.2-1.2 mg/dL), albumin (39 g/L, normal 42-53 g/L), and prothrombin time (PT; 93%)

Table 1 Laboratory findings at October 19th

WBC	6530 / μ L	T-Bil	1.0 mg/dL	HCV-Ab	positive
Hb	13.0 g/ μ L	D-Bil	0.7 mg/dL	HCV-RNA	> 850 kIU/L
Plt	200 $\times 10^3$ / μ L	Total protein	71 g/L	HCV genotype	1b
PT	93%	Albumin	39 g/L	HAV IgM	negative
AST	549 IU/L	BUN	6.4 mg/dL	HBs-Ag	negative
ALT	870 IU/L	Creatinine	0.5 mg/dL	HBs-Ab	negative
LDH	497 IU/L	Na	140 mEq/L	IgM HBc-Ab	negative
ALP	181 IU/L	K	4.0 mEq/L	EBV IgM	negative
γ -GTP	259 IU/L	Cl	106 mEq/L	HSV IgM	negative
ChE	94 IU/L	Glucose	92 mg/dL	CMV IgM	negative

WBC: white blood cell; Hb: hemoglobin; Plt: platelet; PT: prothrombin time; AST: aspartate aminotransferase; ALT: alanine aminotransferase; LDH: lactate dehydrogenase; ALP: alkaline phosphatase; γ -GTP: gamma glutamyl transpeptidase; ChE: choline esterase; T-Bil: total bilirubin; D-Bil: direct bilirubin; BUN: blood urea nitrogen; HCV: hepatitis C virus; HAV: hepatitis A virus; HBs-Ag: hepatitis B virus surface antigen; HBc-Ab: hepatitis B virus core antibody; EBV: Epstein-Barr virus; HSV: herpes simplex virus; CMV: cytomegalovirus.

indicated that hepatic functional reserve was maintained (Table 1). Anti-HCV antibody which was negative before the pregnancy, converted to positive, and HCV RNA test revealed high viral load with genotype 1b. Therefore, she was diagnosed with acute hepatitis C. A small amount of ascites was detected on the surface of the liver by ultrasound imaging.

She hoped for continuation of the pregnancy, thus, conservative medical management was performed and liver function tests improved (Figure 1). After that, HCV RNA decreased below detection sensitivity of the routine quantitative method (Cobas Amplicor HCV Monitor test, Roche Diagnostic Systems, Branchburg, NY, USA) although remaining positive with qualitative method (Cobas Amplicor HCV test, Roche). On June 17th, 2002, she delivered safely. Liver function tests were within normal ranges but HCV RNA still remained positive. At this point, spontaneous viral clearance was not expected, thus, she was admitted to our hospital to receive anti-viral therapy on September 9th 2002.

Physical findings at administration

Physical examination revealed: height 158 cm; weight 54 kg; blood pressure 118/64 mmHg; body temperature 36.3°C; and clear consciousness. The bulbar conjunctiva was not icteric. No peripheral edema, vascular spider, and flapping tremor were observed.

Laboratory findings

The result demonstrated normal liver function, no evidence of coagulopathy, anemia, or thrombocytopenia. HCV RNA indicated 1.0 kIU/L, which was under detection sensitivity previously.

Pathology

A liver biopsy specimen taken before anti-viral therapy demonstrated chronic hepatitis with mild activity without fibrosis. Swollen Kupffer cells were seen in diastase-periodic acid-Schiff preparations (Figure 2).

Figure 1 Clinical course of an acute hepatitis C patient receiving interferon-beta (IFN- β). MU, million units.

Clinical course

After informed consent was obtained, the patient received six million units of interferon-beta (Mochida Pharmaceutical Co., Ltd., Tokyo, Japan) by intravenous drug injection daily for eight weeks. She developed a daily fever after the initiation of treatment but recovered in a brief period of time. Other adverse effects were not seen during the treatment. HCV RNA became negative two weeks after the initiation of treatment (Figure 1). ALT increased in slight degree but improved after the end of the treatment (Figure 1). HCV RNA negativity and normalization of ALT level were sustained for 40 mo after the end of interferon treatment.

DISCUSSION

In Japan, 85% of hepatocellular carcinoma patients are associated with chronic HCV infection^[9]. Thus, to inhibiting the progression of acute HCV infection to chronicity is very important for the prevention of

Figure 2 Microscopic pathological findings. **A:** (HE, x 4) and **B:** (HE, x 10) showed inflammatory change with mild activity; **C:** (Elastica-Masson staining, x 4) showed slight fibrotic change.

hepatocellular carcinoma. Recently, as the cause of post-transfusion hepatitis, HCV infection decreased to extremely low levels because of the establishment of diagnostic methods such as HCV-antibody or HCV RNA detection^[10]. However, acute hepatitis C still exists by needle-stick injury in health care workers^[11]. Interferon therapy has been indicated for acute hepatitis C for many years but the strategies were controversial in the points of optimal timing of starting therapy, treatment regimen, duration of interferon injection, and management of self-limited patients. Therefore the standard therapy for acute hepatitis C has not been established.

Treatment regimen varies with the times and institutes. Interferon-beta was indicated in the early 1990's^[11]. Interferon-alpha based therapies have been widely indicated, doses were 3-6 million units, durations were 24-52 wk, and recently, combination with ribavirin and pegylated-interferon were reported^[12].

Jaekel *et al* reported that they treated acute hepatitis C with interferon-alpha (5 million units, thrice weekly for 20 wk) and obtained virological response in 98% of cases, thus, they suggested early treatment immediately on diagnosis^[5]. On the other hand, self-limited hepatitis was reported in 15%-30% of acute hepatitis C^[7]. Identifying the patients who recover spontaneously is important because interferon therapy involves considerable adverse effects, compromises patients' quality of life for long-term treatment, and is highly expensive. Predictable factors of self-limited acute hepatitis C were reported. Female gender^[6], younger age^[13], and the lack of complications such as human immunodeficiency virus infection^[14] were reported as host factors. HCV genotype 3 and 2 were reported as virological factors^[15]. Clinical features during the acute phase of infection as symptomatic disease^[6] and fast and continuous decline in viral load were reported with a lower rate of chronicity^[7]. Hofer *et al* reported that mean duration of spontaneous recovery from acute HCV infection was 77 d from infection and 35 d from the onset of symptoms^[7]. Gerlach *et al* reported that they treated acute hepatitis C patients who could not obtain spontaneous viral clearance within 12 wk by interferon-alpha based therapy (3-5 million units, thrice weekly for 14-61 wk) and that the overall virological response was 91% of cases^[6]. A meta-analysis indicated that delaying therapy by 60 d after the onset of symptoms did not reduce the efficacy of treatment^[16]. Wedemeyer *et al* defined the course of acute hepatitis C virus infection as five phases which were: phase A, post-exposure; phase B, asymptomatic viremic patients with normal ALT, two to six weeks post-exposure before the onset of symptoms;

phase C, acute hepatitis with ALT elevation and symptoms; phase D, spontaneous recovery or partial tolerization; phase E, chronic hepatitis after more than six months of infection^[17]. Nomura *et al* reported that the SVR to 24 wk of interferon-alpha was 100% when therapy was initiated in acute hepatitis phase, but fell to 53% if treatment was applied in chronic phase^[8], though it seems a much high rate to be compared with the SVR rate of conventional interferon monotherapy in chronic hepatitis C.

In our case, we initially expected spontaneous recovery because the patient was of female gender, younger age, because she developed symptoms of jaundice and ascites, and because a fast and continuous decline in viral load was observed. However, HCV RNA level remained at 1.0 kIU/L on year after the onset of the infection. Also liver biopsy indicated the progress to chronic hepatitis. The patient desired to complete the treatment in a short period of time because she has recently completed delivery and she wanted to spend the time with her child and to breastfeed the child, thus we treated her with interferon-beta for eight weeks and obtained the SVR.

Interferon-beta therapy is a useful treatment for acute hepatitis C in chronic phase and is superior to interferon-alpha based therapy with regard to treatment duration. Further studies are necessary to clarify the efficacy of this therapy for acute hepatitis C.

Abstract

The presence of vermiform appendix in inguinal hernia is rare and is known as Amyand's hernia. We report an Amyand's hernia, where the appendix was found in a right inguinal hernia in one male cadaver aged ninety two years.

Key words: Amyand's hernia; Appendix; Inguinal hernia

Anagnostopoulou S, Dimitroulis D, Troupis TG, Allamani M, Paraschos A, Mazarakis A, Nikiteas NI, Kostakis A. Amyand's hernia: A case report. *World J Gastroenterol* 2006; 12(29): 4761-4763

<http://www.wjgnet.com/1007-9327/12/4761.asp>

INTRODUCTION

Inguinal hernia may display very unusual sac contents. Ovary, fallopian tube, urinary bladder, incarcerated bladder diverticula, large bowel diverticula with the form of diverticulitis or abscess, Meckel's diverticulum (Littre hernia) or foreign bodies (e.g., fishbones) have been rarely reported^[1-3]. The presence of the appendix within an inguinal hernia has been referred to as "Amyand's hernia" to honour Claudius Amyand, surgeon to King George II. Amyand was the first to describe the presence of a perforated appendix within the inguinal hernial sac of an eleven-year old boy and performed a successful transherniotomy appendectomy in 1735^[4,5].

CASE REPORT

In a male cadaver, 92 years old, at the time of death, a right inguinal hernia was recognized during a student descriptive anatomy laboratory. The medical history of the patient included arterial hypertension that had been treated for the past twenty years and the right inguinal hernia (without herniotomy) that had existed for the past ten years. The deep fascia, the external oblique aponeurosis and the spermatic cord were identified, as well as the hernial sac. Upon opening the hernial sac, the vermiform appendix was found free within, without adhesions to the sac (Figure 1, Figure 2, Figure 3). Macroscopically, the vermiform appendix was 8 cm in length with a maximum diameter of 0.9 cm. Histological examination did not reveal any pathological alterations (Figures 4A and B).

DISCUSSION

A hernia is defined as the protrusion of a viscus or part of a viscus through the walls of its containing cavity. The presence of the appendix within an inguinal hernial sac is referred to as "Amyand's hernia" and is an uncommon condition. The incidence of having a normal appendix within the hernial sac varies from 0.5% to 1%, whereas only 0.1% of all cases of appendicitis present in an inguinal hernia, underscoring the rarity of the condition^[6,7]. The majority of the reported cases present with the features of an obstructed or strangulated inguinal hernia. Even acute appendicitis or perforation of the appendix within the sac simulates perforation of the intestine within the hernia, and does not have specific symptoms or signs. Due to these facts it is very difficult to reach a clinical diagnosis of Amyand's hernia preoperatively. In fact, the diagnosis is made intraoperatively as the patient undergoes surgical exploration for a complicated inguinal hernia. A preoperative computed tomography scanning of the abdomen could be helpful for diagnosis, but this is not a routine practice after the clinical suspicion of a complicated inguinal hernia^[8]. However, one case of a three-month old boy has been reported in which a right-sided sliding appendiceal inguinal hernia was diagnosed preoperatively with sonography^[9].

The occurrence of herniated appendices is mostly reported in a right inguinal hernial sac, probably as a consequence of the normal anatomical position of the appendix and also because right sided inguinal hernias

Figure 1 Right inguinal hernial sac.

Figure 2 Inguinal hernia with vermiform appendix at the opening of the sac.

Figure 3 Appendix in inguinal hernia.

are more common than left sided hernias^[10]. An extensive literature search revealed three reported cases of left sided Amyand's hernia^[11-13]. The occurrence of left sided Amyand's hernia may be associated with the presence of a situs inversus or malrotation as an underlying cause. An abdominal computed tomography scan or X-ray examination should be performed to exclude these entities^[14].

Most of the published cases have been reported as appendicitis incarcerated in a hernia. It is difficult to determine whether a primary visceral inflammation, which could be referred to as appendicitis, is the pathological

Figure 4 Pathological examination of the appendix found in inguinal hernia. **A:** HE x 100; **B:** HE x 400.

mechanism, or if the primary event is strangulation of the herniated appendix, leading subsequently to ischemic necrosis and secondary inflammation^[15]. The presence or absence of inflammation of the appendix is a very important determinant of appropriate treatment. If inflammation of the organ and incipient necrosis are present, a transherniotomy appendectomy should be performed. The presence of pus or perforation of the organ is also an absolute contraindication to the placement of a mesh for hernia repair. Associated intra-abdominal abscesses, if present, may be dealt with either percutaneously or by open drainage. The majority of the authors agree that a normal appendix within the hernial sac does not require appendectomy, and that every effort should be made to preserve the organ found in the hernia sac for an uneventful postoperative course^[16,17].

Finally, we conclude that the presence of the appendix in an inguinal hernial sac, referred to as "Amyand's hernia", is an uncommon entity. Despite its rarity, the fact that the majority of such cases present as a complicated inguinal hernia, making preoperative diagnosis difficult, demands that surgeons consider this condition in their differential diagnosis and so they are able to offer appropriate treatment.

Abstract

The triple A or Allgrove's syndrome is an autosomal recessive disorder characterized by the triad of achalasia cardia, alacrima and ACTH resistant adrenocortical insufficiency. Mutations of the Achalasia-Addisonianism-Alacrima-Syndrome (*AAAS*) gene on chromosome 12q13 are associated with this syndrome. We report an Indian family where two siblings were homozygous for a known mutation of the *AAAS* gene and presented with the classical triad of symptoms. The mother and the brother were heterozygous and asymptomatic. The affected siblings had iron deficiency anemia and the younger sister had pes cavus and palmoplantar keratosis. Neurological symptoms were absent in both affected children. Recognition of this syndrome can lead to early treatment of adrenal insufficiency and genetic counselling.

INTRODUCTION

Allgrove's syndrome, also known as the triple A syndrome is characterized by the triad of adrenal insufficiency, achalasia cardia and alacrima^[1]. Ever since its first description in 1978, more than 70 cases have been reported in the literature. The condition is associated with impairment of the central, peripheral and autonomic nervous systems, suggesting that it is

a result of a mutation in a pleiotropic gene. Other reported abnormalities include palmoplantar hyperkeratosis, short stature, osteoporosis and microcephaly^[2-4]. Progression of neurological symptoms has been reported with worsening of peripheral neuropathy, dementia, long tract degeneration, dysarthria and ataxia^[5,6].

Pathological studies from esophageal myomectomy specimens of children afflicted with Allgrove's syndrome show fibrosis of the intermuscular plane and absent myenteric ganglia^[3]. Neuronal NO synthase has also been found to be deficient and could explain the poor relaxation of the lower esophageal sphincter (LES). Necropsy has been carried out in one of the pairs of original siblings published, which reveals atrophy of the adrenal cortical zona fasciculata and zona reticularis and absence of ganglion cells and nerve fibers in the lower esophagus^[1].

This syndrome has been mapped to a novel gene on chromosome 12q 13 near the type II keratin gene cluster, and the gene is designated as the Achalasia-Addisonianism-Alacrima-Syndrome gene (the *AAAS* gene)^[7]. There is a great deal of variability of symptoms and severity between patients with the same *AAAS* mutation, implying variable expression of this mutated gene.

This report describes the clinical presentation of two affected siblings with Allgrove's syndrome and analyses the mutations in the immediate family.

CASE REPORT

A seventeen year old young lady presented along with her fifteen year old younger sister with identical symptoms of dysphagia, excessive fatigue and skin pigmentation. The elder sibling had been symptomatic for eight years and her sister for seven years respectively. Both had progressive difficulty in swallowing and regurgitation of food at the time of presentation. They had extreme tiredness and fatigue. The mother had noticed progressive pigmentation in both her daughters. The younger sibling had several episodes of sporadic abdominal pain and vomiting. Their milestones had been normal and they had attained menarche and thelarche normally. Their parents were non-consanguineous and their father had expired following an accident. One elder sister had died of meningitis at nine years of age and on questioning the mother, she mentioned the daughter having similar facial hyperpigmentation. A brother was asymptomatic at 16 years of age. Examination of both patients revealed normal blood pressure and heart rate with no postural changes. Both sisters had facial and palmar hyperpigmentation. The younger sibling had bilateral

Table 1 Summary of clinical features and laboratory investigation in both siblings with Allgrove's syndrome

Variable	Elder sibling	Younger sibling
Dysphagia	Present	Present
Generalized pigmentation	Present	Present
Abdominal pain	Absent	Present
Decreased lacrimation	Present	Present
Postural hypotension	Absent	Absent
Palmoplantar keratosis	Absent	Present
Temporal optical pallor	Present	Present
Hemoglobin (mg%)	6.8	8.1
Albumin (mg%)	4.2	4.2
Pre-Synacthen cortisol (µg/deciliter)	3.94	3.37
Post-Synacthen cortisol (µg/deciliter)	5.16	4.1
Barium swallow	Aperistaltic dilated esophagus	Aperistaltic dilated esophagus
LES pressure on manometry (mmHg)	45	60

palmo-plantar keratosis and pes cavus. The conjunctiva and oral cavities of both sisters were dry. Schirmer's test confirmed decreased lacrimation. Both were noted to have bilateral temporal pallor of optic discs.

Hemogram showed iron deficiency anemia in both sisters. Biochemical tests and chest X ray were normal. Barium swallow showed dilated esophagus and absent peristalsis in both sisters. Esophageal manometry done to confirm the diagnosis showed elevated LES pressures (45 mm and 60 mm respectively), poor relaxation to swallow and absent body peristalsis consistent with achalasia. Serum 8 am cortisol was 3.94 µg/deciliter and 3.37 µg/deciliter in both sisters respectively and post Synacthen values were 5.16 µg/deciliter and 4.10 µg/deciliter respectively, consistent with Addison's disease. The clinical features and laboratory investigations are summarized in Table 1.

The confirmation of achalasia, Addison's disease, history of dry eye in both siblings, palmo-plantar hyperkeratosis in one sister and positive family history pointed to a clinical diagnosis of Allgrove's syndrome. Molecular testing for the *AAAS* gene causing Allgrove's syndrome was initiated to confirm the diagnosis. Blood samples from the patients, their mother and unaffected brother were taken after consent for *AAAS* gene analysis. Replacement therapy with corticosteroids and mineralocorticoids dramatically improved the symptoms in both the sisters. They have been advised to make frequent follow-up visits at the clinic.

MUTATION ANALYSIS

DNA was extracted using standard protocols. Coding sequences including exon-intron boundaries were amplified from genomic DNA and sequenced as reported previously^[8]. Sequencing of the coding regions and exon/intron junctions of the *AAAS* gene in the two sisters revealed a homozygous splice mutation in exon 1, resulting in a frameshift after glycine at amino acid position 14 and a premature stopcodon (G14fs). This is the result of the transversion C to A at nucleotide position 43, forming a new

premature splice donor site after G at nucleotide position 40 with a consecutive loss of the following 83 bp from exon 1. The mother is a heterozygote and so is the brother. Thus it verified the carrier status of the unaffected family members. This gene mutation analysis confirmed the diagnosis and helped in genetic counselling.

DISCUSSION

Triple A syndrome (Allgrove's syndrome) is an autosomal recessive genetic disorder occurring due to mutations in the *AAAS* gene, resulting in phenotypic manifestations of achalasia, addisonianism, alacrima and variable symptoms of progressive neurological involvement. Using positional cloning, the product of the *AAAS* gene, designated ALADIN for alacrima, achalasia, adrenal insufficiency neurological disorder, was identified as a protein belonging to the WD repeat family^[9]. Proteins belonging to this family have a wide functional diversity in that they are involved in signal transduction, RNA processing, vesicular trafficking, cytoskeleton assembly and cell division control^[10].

The ubiquitous expression of *AAAS* is in accordance with the multisystemic character of the disorder and the predominant occurrence in the adrenal gland, gastrointestinal and nervous structures is in line with the tissues mainly affected in triple A syndrome. Various mutations have been described in patients from European, North African, Asian and American populations^[8]. Ours is the first report of mutations in the *AAAS* gene in an Indian family with Allgrove's syndrome. The transversion of C to A at nucleotide position 43 results in a markedly truncated protein, and it has been reported and confirmed that the mutation caused the disease^[8].

Genotypic-phenotypic correlations have not been consistent in Allgrove's syndrome^[11]. We noted similarities in presentation in both these siblings. However, palmoplantar keratosis and pes cavus was present in only the younger sister despite both siblings having the same mutation. There are reports of patients presenting without hypoadrenalism, which is the hallmark of this syndrome^[12]. From a large series of patients it has been seen that frameshift, stop codon and functionally significant mutations are likely to lead to a more severe phenotype, most probably occurring by a loss-of-function effect of the mutated protein^[13]. Future studies need to focus on functional analysis of this mutated gene in order to comprehend the myriad presentations of the Allgrove's syndrome.

ACKNOWLEDGMENTS

We acknowledge the cooperation of the patients and their immediate relatives for providing the samples.

<http://www.wjgnet.com/1007-9327/12/4767.asp>

TO THE EDITOR

I read with a great interest the paper by Gonzalez-Roldan *et al*^[1]. The authors reported on the pattern expression of TREM-1 during sepsis and major abdominal surgery as compared to healthy controls and concluded that TREM-1 expression increased on the surface of monocytes after surgery. Several points deserve consideration. First, no data related to TREM-1 expression on neutrophils is provided. Second, of the 7 surgical patients, only 4 had both pre- and post-surgery cytometry analysis. Among these 4 patients, 2 displayed a decrease of TREM-1 expression after surgery. Therefore, it seems quite hazardous, based on these data, to conclude that TREM-1 increases after major

uncomplicated surgery, reflecting a systemic inflammatory response.

The other question that arose from this study is related to the determination of the TREM-1 splice variant (svTREM-1). First, it is still unknown whether this variant is translated or not^[2]. Anyway, the soluble form of TREM-1 is not believed to be related to this variant^[3]. The authors observed an increase of the svTREM-1 mRNA after surgery or during sepsis. By using the described primers, one could also expect to see a PCR product corresponding to the natural form of TREM-1^[3]. Unfortunately, such a product is not reported. Finally, it is rather disappointing not to see any measurement of plasma sTREM-1 in these patients in order to better characterise the “inflammatory” patients and the septic ones^[4].

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (WJG, *World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly journal of more than 48 000 circulation, published on the 7th, 14th, 21st and 28th of every month.

Original Research, Clinical Trials, Reviews, Comments, and Case Reports in esophageal cancer, gastric cancer, colon cancer, liver cancer, viral liver diseases, etc., from all over the world are welcome on the condition that they have not been published previously and have not been submitted simultaneously elsewhere.

Indexed and abstracted in

Current Contents/Clinical Medicine and Science Citation Index-Expanded, *Index Medicus*, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, Nature Clinical Practice Gastroenterology and Hepatology, CAB Abstracts and Global Health.ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

Published by

The WJG Press

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297 mm × 210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, acknowledgements, References, Tables, Figures and Figure Legends. Neither the editors nor the Publisher is responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part without the written permission of both the authors and the Publisher. We reserve the right to put onto our website and copy-edit accepted manuscripts. Authors should also follow the guidelines for the care and use of laboratory animals of their institution or national animal welfare committee.

Authors should retain one copy of the text, tables, photographs and illustrations, as rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for the loss or damage to photographs and illustrations in mailing process.

Online submission

Online submission is strongly advised. Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/index.jsp>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. Authors encountering problems with the Online Submission System may send an email you describing the problem to wjg@wjgnet.com for assistance. If you submit your manuscript online, do not make a postal contribution. A repeated online submission for the same manuscript is strictly prohibited.

Postal submission

Send 3 duplicate hard copies of the full-text manuscript typed double-spaced on A4 (297 mm × 210 mm) white paper together with any original photographs or illustrations and a 3.5 inch computer diskette or CD-ROM containing an electronic copy of the manuscript including all the figures, graphs and tables in native Microsoft Word format or *.rtf format to:

Editorial Office

World Journal of Gastroenterology

Editorial Department: Apartment 1066, Yishou Garden,
58 North Langxinzhuan Road,
PO Box 2345, Beijing 100023, China
E-mail: wjg@wjgnet.com
<http://www.wjgnet.com>
Telephone: +86-10-85381901
Fax: +86-10-85381893

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using a word-processing software. All submissions must be typed in 1.5 line spacing and in word size 12 with ample margins. The letter font is

Tahoma. For authors from China, one copy of the Chinese translation of the manuscript is also required (excluding references). Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was accomplished, disclosure of any financial support for the research, and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (removing all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s) and full family name.

Abstract

An informative, structured abstract of no more than 250 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipments, and the experimental procedures should be included. RESULTS: The observatory and experimental results, including data, effects, outcome, etc. should be included. Authors should present *P* value where necessary, and the significant data should accompany. CONCLUSION: Accurate view and the value of the results should be included.

The format of structured abstracts is at: <http://www.wjgnet.com/wjg/help/11.doc>

Key words

Please list 6-10 key words that could reflect content of the study mainly from *Index Medicus*.

Text

For most article types, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include in appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both.

Illustrations

Figures should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. No detailed legend should be involved under the figures. This part should be added into the text where the figures are applicable. Digital images: black and white photographs should be scanned and saved in TIFF format at a resolution of 300 dpi; color images should be saved as CMYK (print files) but not as RGB (screen-viewing files). Place each photograph in a separate file. Print images: supply images of size no smaller than 126 mm × 76 mm printed on smooth surface paper; label the image by writing the Figure number and orientation using an arrow. Photomicrographs: indicate the original magnification and stain in the legend. Digital Drawings: supply files in EPS if created by freehand and illustrator, or TIFF from photoshops. EPS files must be accompanied by a version in native file format for editing purposes. Existing line drawings should be scanned at a resolution of 1200 dpi and as close as possible to the size where they will appear when printed. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes of atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...

Tables

Three-line tables should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each table. No detailed legend should be included under the tables. This part should be added into the text where the tables are applicable. The information should complement but not duplicate that contained in the text. Use one horizontal line under the title, a second under the column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. ^a*P*<0.05, ^b*P*<0.01 should be noted (*P*>0.05 should not be noted). If there are other series of *P* values, ^c*P*<0.05 and ^d*P*<0.01 are used. Third series of *P* values can be expressed as ^e*P*<0.05 and ^f*P*<0.01. Other notes in tables or under illustrations should be expressed as ¹*F*, ²*F*, ³*F*; or some other symbols with

a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, etc. in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions are included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should code the references according to the citation order in text in Arabic numerals, put references codes in square brackets, superscript it at the end of citation content or the author name of the citation. For those citation content as the narrate part, the coding number and square brackets should be typeset normally. For example, Crohn's disease (CD) is associated with increased intestinal permeability^[1,2]. If references are directly cited in the text, they would be put together with the text, for example, from references [19,22-24], we know that...

When the authors code the references, please ensure that the order in text is the same as in reference part and also insure the spelling accuracy of the first author's name. Do not code the same citation twice.

PMID requirement

PMID roots in the abstract serial number indexed by PubMed (<http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed>). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information of the journal citations is very important. Through reference testing system (<http://www.wjgnet.com/cgi-bin/index.pl>), the authors and editor could check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in ASP file so that the readers can read the abstract of the citations online immediately.

Style for journal references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). Title of the cited article and italicized journal title (Journal title should be in its abbreviation form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634]

Note: The author should test the references through reference testing system (<http://www.aushome.cn/cgi-bin/index.pl>)

Style for book references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

- 16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those that are linked with a hyphen and the difference between the two numbers at two sides of the hyphen is more than 5. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered as inappropriate references. Authors should not cite their own unrelated published articles.

Statistical data

Present as mean \pm SD or mean \pm SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as γ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p*(B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 $24.5 \mu\text{g/L}$; CO₂ volume fraction, 50 mL/L CO₂ not 5% CO₂; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format about how to accurately write common units and quantum is at: <http://www.wjgnet.com/wjg/help/15.doc>

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further mention.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kbo I*, *Kpn I*, etc.

Biology: *H pylori*, *E coli*, etc.

SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. Author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, the final check list for authors, and responses to reviewers by a courier (such as EMS) (submission of revised manuscript by e-mail or on the *WJG* Editorial Office Online System is NOT available at present).

Language evaluation

The language of a manuscript will be graded before sending for revision.

(1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing; (4) Grade D: rejected. The revised articles should be in grade B or grade A.

Copyright assignment form

Please download CAF from <http://www.wjgnet.com/wjg/help/9.doc>.

We certify that the material contained in this manuscript:

Ms:

Title:

is original, except when appropriately referenced to other sources, and that written permission has been granted by any existing copyright holders. We agree to transfer to *WJG* all rights of our manuscript, including: (1) all copyright ownership in all print and electronic formats; (2) the right to grant permission to republish or reprint the stated material in whole or in part, with or without a fee; (3) the right to print copies for free distribution or sale; (4) the right to republish the stated material in a collection of articles or in any other format. We also agree that our article be put on the Internet.

Criteria for authorship: The *WJG* requests and publishes information about contributions of each author named to the submitted study. Authorship credit should be based on (1) direct participation in the study, including substantial contributions to conception and design of study, or acquisition of data, or analysis and interpretation of data; (2) manuscript writing, including drafting the article, or revising it critically for important intellectual content; (3) supportive work, including statistical analysis of data, or acquisition of funding, or administration, technology and materials support, or supervision, or supportive contributions. Authors should meet at least one of the three conditions. The *WJG* does not publish co-first authors and co-corresponding authors.

We hereby assign copyright transfer to *WJG* if this paper is accepted.

Author Name in full (Full names should be provided, with first name first, followed by middle names and family name at the last, eg, Eamonn MM Quigley). Handwritten names are not accepted.

Author Name in abbreviation (Family name is put first in full, followed by middle names and first name in abbreviation with first letter in capital, eg, Quigley EMM). Handwritten names are not accepted.

Final check list for authors

The format is at: <http://www.wjgnet.com/wjg/help/13.doc>

Responses to reviewers

Please revise your article according to the comments/suggestions of reviewers. The format for responses to the reviewers' comments is at: <http://www.wjgnet.com/wjg/help/10.doc>

Abstract

Nuclear magnetic resonance spectroscopy allows the study of cellular biochemistry and metabolism, both in the whole body *in vivo* and at higher magnetic field strengths *in vitro*. Since the technique is non-invasive and non-selective, magnetic resonance spectroscopy methodologies have been widely applied in biochemistry and medicine. *In vitro* magnetic resonance spectroscopy studies of cells, body fluids and tissues have been used in medical biochemistry to investigate pathophysiological processes and more recently, the technique has been used by physicians to determine disease abnormalities *in vivo*. This highlighted topic illustrates the potential of *in vitro* magnetic resonance spectroscopy in studying the hepatobiliary system. The role of *in vitro* proton and phosphorus magnetic resonance spectroscopy in the study of malignant and non-malignant liver disease and bile composition studies are discussed, particularly with reference to correlative *in vivo* whole-body magnetic resonance spectroscopy applications. In summary, magnetic resonance spectroscopy techniques can provide non-invasive biochemical information on disease severity and pointers to underlying pathophysiological processes. Magnetic resonance spectroscopy holds potential promise as a screening tool for disease biomarkers, as well as assessing therapeutic response.

INTRODUCTION

The nuclear magnetic resonance (NMR) phenomenon was first reported in 1946^[1] and has since been widely used by the scientific and medical communities. The 2003 Nobel Prize for Medicine was jointly awarded to Professor Sir Peter Mansfield and Professor Paul Lauterbur for their work on clinical NMR, and this serves to underline the impact on the medical community of the utility of this technique with all its diverse applications (www.nobel.se/medicine/laureates). In this highlight article, we explain the background to NMR and discuss various clinical studies that are relevant to the liver and the biliary system, with particular emphasis on *in vitro* applications that have analyzed body fluids, such as bile, or tissue obtained from liver biopsies.

NMR is a non-invasive and non-selective technique, allowing the study of molecular composition and structure. NMR forms the basis of magnetic resonance imaging (MRI) methodologies, which have been developed using whole body magnets. Spatial localization using magnetic field gradients has enabled very detailed images of the human body to be obtained. *In vivo* NMR spectroscopy studies can be performed as an adjunct to clinical MRI, as part of the same examination. Longitudinal studies can be readily undertaken using both of these MR applications. The term magnetic resonance spectroscopy (MRS) is used in this highlight topic to denote *in vivo* and *ex vivo* clinical NMR spectroscopy studies, and also encompasses *in vitro* NMR spectroscopy, performed in the laboratory at very high magnet field strengths.

AN OVERVIEW OF MR SPECTROSCOPY

Although a detailed knowledge of the physical principles that govern NMR is not essential for appreciating the scope of NMR applications, it is often helpful to have some understanding of some of the basic concepts that underlie these methodologies. The NMR technique

exploits the behavior of atomic nuclei in an externally applied magnetic field. Magnetic resonance occurs because of the quantum mechanical property of “spin”, which is intrinsic to certain atomic nuclei. Examples of such nuclei of clinical relevance include hydrogen-1 (^1H), carbon-13 (^{13}C), fluorine-19 (^{19}F), phosphorus-31 (^{31}P) and chlorine-35 (^{35}Cl). Such nuclei can be imagined to act like small bar magnets in a magnetic field by ‘lining up’ with or against the field, and can be excited by irradiation with non-ionizing radiofrequency (rf) energy. During relaxation following excitation, rf signals are generated which contain information regarding the magnetic environment experienced by each nucleus, and therefore about the molecules in which they exist. The resulting signals, the “free induction decay”, are detected by a receiver coil and can be expressed as a frequency spectrum by the mathematical process of Fourier transformation. The relative frequency position of a metabolite signal, its chemical shift, is dependent on the locally experienced magnetic field and therefore the local chemical environment. Consequently, each nucleus type within a molecule has a characteristic chemical shift. Hydrogen-1 (^1H) and phosphorus-31 (^{31}P) are the two nuclei most commonly used for biological studies, as they are ubiquitous in nature (^1H = 99.985%, ^{31}P = 100% natural abundance).

Metabolic significance of clinical MR spectroscopy

Jacobson and colleagues^[2] used MRS to examine the effects of hydration of DNA in 1954. Current investigations include both *in vitro* MRS studies on tissue samples or body fluids and *in vivo* whole-body MRS studies.

In vitro MRS studies include the analysis of body fluids (such as plasma, urine or bile), extracts of tissue, or small biopsy-sized specimens of intact tissue. *In vivo* MRS is more difficult to perform and is characterized by poorer resolution of metabolites than *in vitro* MRS. This is due to factors such as the lower magnetic field strengths used for *in vivo* MRS clinical studies and also to the effects of magnetic susceptibility and patient motion. The typical magnetic field strength is 1.5–3.0 Tesla (T) for clinical MRS studies and 11.7–18.8 T for *in vitro* MRS studies.

In vitro MRS can detect and characterize a range of metabolic components simultaneously, even if their chemical identities are unknown at the time of analysis. *In vitro* MRS studies therefore provide a comprehensive metabolic profile of the low molecular weight components in biofluids and tissues, reflecting levels of endogenous metabolites involved in key cellular pathways, which indicate the physiological and pathophysiological status. The technique can also provide a profile of exogenous agents, including xenobiotics and their metabolites, and give an indication as to their effects on endogenous compounds^[3]. For such reasons, *in vitro* MRS has become one of the most successful and popular techniques for biofluid analysis over the past 10 years^[4].

It is relevant to consider *in vitro* MRS applications to the liver in the context of metabolite findings from both *in vivo* ^{31}P and ^1H MRS studies of patients with liver disease, who have been examined using whole body MRI/MRS

techniques. *In vivo* hepatic MRS studies have been primarily used in the research environment and have generally utilized ^{31}P MRS^[5], because ^1H MRS is technically more challenging^[6,7]. *In vivo* ^{31}P MRS gives information on cell turnover and energy state and has been used to grade patients with chronic liver disease^[8] and to aid in diagnosis and treatment response in patients with cancer^[9]. On the other hand, *in vivo* ^1H MRS allows quantification of intra-hepatocellular lipid (IHCL) levels, and therefore has been utilized recently to quantify the extent of steatosis in patients with fatty liver^[10,11].

Representative hepatic ^1H and ^{31}P MR spectra are illustrated in Figures 1–4. *In vitro* ^1H and ^{31}P MR spectra of liver tissue are illustrated in Figures 1 and 3, and these can be compared and contrasted with *in vivo* hepatic ^1H and ^{31}P MR spectra illustrated in Figures 2 and 4. An *in vitro* ^1H MR spectrum is dominated by contributions from water and IHCL. If the signal from water is suppressed using specific NMR methodologies, then more detailed contributions from IHCL can be observed along with resonances from choline-containing compounds (Cho) (Figures 1A–C). These data compare with the *in vivo* hepatic ^1H MRS spectrum, which allows quantification of water and IHCL (Figure 2B).

In vitro ^{31}P MR spectroscopy of liver tissue (Figure 3) allows characterization of resonances from phospholipid

Figure 2 **A:** A transverse image through the abdomen showing the two voxel positions used to study regional variation in hepatic fat content; **B:** Typical proton magnetic resonance liver spectra from three volunteers showing progressive degrees of fatty infiltration. Spectrum (a) shows a liver with minimal fatty infiltration (1.0%), spectrum (b) shows a liver with moderate fatty infiltration (10.2%), and spectrum (c) shows a liver with severe fatty infiltration (74.9%). Resonances from water and IHCL-(CH₂)_n- can be clearly identified. Values refer to the peak area of the IHCL peak with reference to the water peak after correcting for T₁ and T₂. IHCL: intrahepatocellular lipids. Reproduced from Thomas *et al* Gut 2005; 54: 122-127, with permission from the BMJ Publishing Group.

cell membrane precursors, including phosphocholine (PC) and phosphoethanolamine (PE), adenosine monophosphate (AMP) and glycolytic intermediates, such as glucose-6-phosphate. Cell membrane degradation products, including glycerophosphorylcholine (GPC) and glycerophosphorylethanolamine (GPE) and mobile phospholipids from the endoplasmic reticulum can also be identified. Depending on how the tissue is collected it is also possible to quantify contributions to the spectrum from inorganic phosphate and various nucleoside triphosphates (NTP). Such spectral resolution is difficult to achieve *in vivo*, and therefore a typical *in vivo* hepatic ³¹P MR spectrum (Figure 4) consists of six dominant, composite resonances, arising from: (1) the phosphomonoester region (PME), which are mainly cell membrane precursors and sugar phosphates; (2) inorganic phosphate (Pi); (3) phosphodiester (PDE), which are mainly cell membrane degradation products, but also signal from mobile phospholipids contained in mitochondria and (4-6) three resonances from NTP, which are chiefly composed of adenosine triphosphate (ATP), but contain contributions from uridine triphosphate, guanosine triphosphate and cytosine triphosphate^[12].

Changes in the PME and PDE metabolites indicate

Figure 3 Typical proton decoupled *in vitro* ³¹P MR spectrum of perchloric acid extracted normal liver tissue. **A:** Full spectrum; **B:** PME and PDE regions. PME: phosphomonoesters; PDE: phosphodiester; NTP: nucleotide triphosphates; NDP: nucleotide diphosphate; PE: phosphoethanolamine; PC: phosphocholine; GPE: glycerophosphorylethanolamine; GPC: glycerophosphorylcholine; PCr: phosphocreatine; MDP: methylene diphosphonate. Reproduced from Taylor-Robinson *et al* Gut 1998; 42: 735-743, with permission from the BMJ Publishing Group.

modifications in rates of cell membrane synthesis, breakdown, cell death and regeneration, associated with increasingly rapid cell growth, turnover and development^[13]. Thus, these important phosphorus-containing molecules are intricately involved in the cellular processes linked to cellular destruction, turnover and malignant transformation.

MRS also provides important insights into dynamic metabolic changes in the diseased liver. However, unlike most liver function tests, the information obtained is not dependent on blood flow. Furthermore, most standard liver function tests also depend on measurements of plasma components, rather than assessing markers at the site of disease. Recent studies on hepatitis C suggest that the MRS technique may be useful in monitoring response to treatment with interferon and ribavirin^[8].

Methodology for *in vitro* MR spectroscopy

Sample preparation of body fluids requires routine clinical documentation to ensure that the relevant patient details are adequately controlled or accounted for, including time of sample collection and drug use history. It may be necessary to dilute or buffer the sample, or alternatively to document and account for any spectral changes relating to

Figure 4 Typical ^{31}P magnetic resonance spectrum from the liver of a healthy volunteer (TR 10000 ms). PME: phosphomonoester; Pi: inorganic phosphate; PDE: phosphodiester; NTP: nucleoside triphosphate; ppm: parts per million. pH or concentration.

Sample storage should not cause a change in metabolite profile. Therefore storage temperature and conditions should be considered, and whether a change in sample temperature alters metabolite profile, for example during a freeze-thaw process^[14,15].

Immediately prior to data collection, a known amount of a NMR standard can be added for NMR referencing and quantification. For example, sodium trimethylsilyl- $[\text{2H}_4]$ propionate (TSP) is routinely used as a reference compound for ^1H MRS application. If the sample is required to be uncontaminated by any NMR reference compound for any further analysis, then either a reference compound can be placed in a capillary tube within the sample or an external standard is used.

The temperature of NMR data acquisition is under spectrometer control, so the sample temperature should be specified and constant throughout the study protocol. Many studies are performed at 25°C , but it may be necessary to study intact cells at lower temperatures to minimize the effects of ongoing cellular changes.

MR data acquisition includes adjusting the magnetic field homogeneity within the sample (a process known as 'shimming'). Data averaging is generally required, so as to improve the signal-to-noise ratio in the spectrum. Data can be acquired using pulse-collection methods or one- or two-dimensional NMR data collection protocols^[16]. The water signal is generally suppressed using saturation techniques and/or spin-echo methods, in order to more readily observe the metabolite signals^[17]. Intact tissue specimens may be analyzed using conventional solution MR spectroscopy techniques, by simply placing the biopsy sample within a NMR tube or by chemically extracting aqueous or lipid soluble fractions of the tissues. Studying intact tissue specimens directly within a conventional NMR tube has the disadvantage that magnetic field inhomogeneities within the sample do limit the achievable spectral resolution, but has the advantage that sample preparation is minimal and the sample remains intact and available for further analysis by other complementary techniques. Tissue extract studies have the advantage that

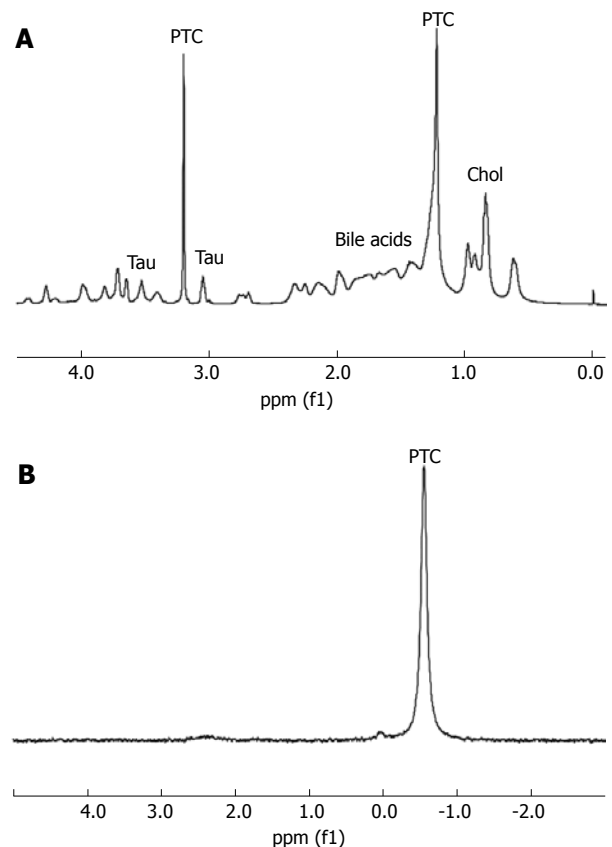

Figure 5 A: ^1H nuclear magnetic resonance spectrum of bile collected at laparoscopic cholecystectomy, after a history of recurrent cholecystitis. The spectrum has no contamination from contrast agents. The major peaks are assigned to phosphatidylcholine (PTC), bile acids, cholesterol (Chol), taurine (Tau) and the reference, sodium trimethylsilyl- $[\text{2H}_4]$ propionate (TSP); B: Corresponding ^{31}P nuclear magnetic resonance spectrum. The major peak is assigned to PTC. ppm, Parts per million. Reproduced from Khan SA, Cox IJ, Thillainayagam AV, Bansil DS, Thomas HC, Taylor-Robinson SD. Proton and phosphorus-31 nuclear magnetic resonance spectroscopy of human bile in hepatopancreaticobiliary cancer. *Eur J Gastroenterol Hepatol* 2005; 17: 733-738, with permission from Lippincott Williams & Wilkins, Inc.

the sample which is finally available for MRS study that has taken place after the extraction process, has become homogeneous so that the spectral peaks are well defined. However, the obvious disadvantages include the total destruction of the sample, the additional influence of metabolite solubilities in the extract medium and the relatively large amount of tissue required (upwards of 100 mg). The recently introduced method of magic angle spinning (MAS) MRS can overcome the limitations of both of the above techniques^[18].

Magic angle spinning (MAS) MRS

The line-broadening effects in an intact semi-solid are caused by constraints on molecular motion from cellular architecture, chemical shift anisotropy and dipolar couplings, and these can be reduced by spinning the sample at an angle of 54.7° to the main magnetic field, known as the 'magic angle'. While such MAS MRS techniques have been used for many years in the NMR spectroscopy study of true solids, MAS MRS has only recently been applied to the study of intact tissue^[18]. A distinct advantage is that a MAS MR spectrum can be obtained from as little as 2

mg tissue and the tissue remains sufficiently intact to allow subsequent histological or genetic analysis^[19].

As in conventional MRS studies, accurate determination of metabolite concentrations is pivotal to the success of tissue MAS MRS studies. A number of factors need to be considered for metabolite quantitation in MAS MRS, including possible leakage of metabolites during washing of biopsies prior to analysis^[15], temperature at which the spectrum is acquired and appropriate choice of reference standard. The question of how to define a standard for quantitation is particularly important. For example the tissue water signal measured from a proton spectrum without water presaturation, may be used as an internal standard. Silicone rubber, for example, provides a useful external standard. Alternatively peak area ratios can be used to compare different spectra, but this has limitations as with *in vivo* MRS studies. For example, not only can changes in absolute concentrations be missed by the use of metabolite ratios, but an increase in the area of one peak can have the same result on the area ratio as a decrease in the other. Therefore, relying on the ratio of signal areas may mask metabolite differences inherent in the spectra.

APPLICATIONS OF *IN VITRO* MR SPECTROSCOPY IN LIVER DISEASE

Cellular bioenergetics

Owing to the ubiquity of phosphorus-containing moieties in energy metabolism, ³¹P MRS has been used to assess energy states in living systems^[20]. However, the rapid degradation of phosphorylated nucleotide intermediates *ex vivo*, such as adenosine triphosphate (ATP) and adenosine diphosphate (ADP), has made snap-shot *in vitro* assessment difficult, although efforts have been made to minimize the ischemic time. Oxidation of these metabolites can occur at harvesting, snap freezing, thawing and during tissue extraction. In order to obtain metabolically useful information, the samples should be snap-frozen as soon as possible. In order to eliminate the need for the extraction of aqueous and lipid fractions, MAS MRS techniques could be used but data collection may need to be done at 4°C to minimise further metabolic reactions during data collection.

An alternative methodology to assess bioenergetics is to use an *in vitro* perfusion system. Applications have included the effects of normoxia and anoxia in rat livers^[21], the response to cyanide intoxication^[22] and the response of damaged liver to fructose loading^[23].

Tumours

³¹P and ¹H MR spectra from aqueous soluble metabolites in extract of liver tumours of different types (hepatocellular carcinoma, colorectal metastases and secondary lung carcinoma) have been compared with samples from normal liver tissue and from histologically normal liver of the tumour host^[24]. A significant increase in phosphoethanolamine (PER), phosphocholine (PC), taurine and lactate has been reported, with a reduction in GPE glycerophosphorylethanolamine (GPE) and glycerophosphorylcholine (GPC) in tumours, compared to normal liver controls^[24]. In addition, the spectral changes identified by ³¹P MRS in

tumour tissue have been seen at a lesser magnitude in the tumour host tissues^[24].

Hepatic ³¹P MRS has been translated to the *in vivo* setting by Cox and colleagues and others^[25]. The observed hepatic *in vivo* MR spectrum demonstrated a significantly raised PME/PDE ratio in tumour compared to controls. These peaks are thought to comprise increased PE and PC, and decreased GPE and GPC respectively, as elicited by *in vitro* analysis of tissue extract^[24].

In vitro ¹H MRS in conjunction with a statistical classification strategy has been used by Soper and colleagues to differentiate histologically normal liver, cirrhotic nodules and hepatocellular carcinoma^[26]. Multivariate and pattern recognition techniques enable all data points to be incorporated into the analysis, no matter whether the metabolites comprising the spectral peaks have been identified. In this study, cirrhotic nodules were distinguished from hepatocellular carcinoma in 98% of cases^[26].

Chronic liver disease

Initial hepatic MRS studies of chronic liver disease focused on cirrhosis of varying aetiologies. Human livers with histologically proven cirrhosis have been assessed using *in vitro* ³¹P NMR spectroscopy^[7]. Spectra from these patients with end-stage liver disease, all of whom had tissue obtained at the time of liver transplantation, showed significant elevations in phosphoethanolamine (PE) and phosphocholine (PC) and significant reductions in glycerophosphorylethanolamine (GPE) and glycerophosphorylcholine (GPC), when spectra were compared with those from histologically normal livers. Whether the patient had compensated or decompensated disease did not significantly alter the spectra obtained. Further work^[27] by the same authors correlated such *in vitro* findings with ³¹P MRS *in vivo* and these studies suggest a potential clinical utility for *in vivo* MRS as an addendum to a standard MRI protocol in staging of the end-stage liver disease in patients that are being imaged for surveillance of hepatocellular carcinomas.

More recently, *in vivo* hepatic ³¹P MRS has been used to stratify inflammation and fibrosis caused by hepatitis C virus, compared to histological staging from standard liver biopsy^[8]. The PME/PDE ratio was found to be elevated in mild, moderate/severe fibrosis and cirrhosis compared to normal, healthy volunteers. These changes have been thought to represent increased cell membrane turnover, although differences between means for each group were statistically significant, there was some overlap between the patient groups^[8]. While histology remains the gold-standard, sampling error is inherent in the technique and it has been postulated that hepatic MRS could potentially provide a more accurate representation of the disease process, owing to the fact that it provides metabolite information from most of the liver^[8]. Further studies directly correlating *in vivo* and *in vitro* MRS findings are awaited in this context.

While *in vivo* hepatic ³¹P MRS has been shown to correlate closely with disease severity in hepatitis C, its availability as a technique is not widespread. *In vivo* hepatic ¹H MR spectroscopy would be more generally applicable on standard MRI scanners. Cho and colleagues have used this

technique to stratify chronic hepatitis compared to histology^[28]. They were able to detect differences between groups, but the signal-to-noise ratio was low and assignment of the spectral peaks is open to debate^[29]. A rational approach would be to identify the change in spectral peaks *in vitro*, using ¹H MAS MRS, prior to translating the technique to the *in vivo* setting. With this in mind, Martínez-Granados and colleagues performed ¹H MAS MRS on needle biopsies of liver tissue from 16 patients with chronic hepatitis or cirrhosis and one specimen from autopsy, nominated a “normal” control. High quality spectra were obtained and a number of metabolites assigned to previously unidentified peaks. Data collection was carried out at 4°C to minimize tissue degradation. Differences in signal intensities between disease states and “normal” liver were noted, particularly increases in mobile fatty acids and glycogen in the former. However, the “normal” liver was harvested 24 h post mortem, so assumptions of metabolic normality are questionable^[30].

Hepatic steatosis

The intrahepatocellular lipid (IHCL) component of lipid extracts from steatotic liver specimens as assessed by ¹H MR spectroscopy has been calibrated with *in vivo* MR spectroscopy measurements to estimate the lipid volume fraction in fatty liver disease^[31]. There is an agreement with CT estimations but histomorphometry appears to underestimate the fat volume in samples. Szczepaniak and colleagues used localised *in vivo* ¹H MRS in 2349 patients to assess the hepatic triglyceride content and estimated the prevalence of hepatic steatosis in the study group as 33.6%^[32]. Further MRI studies *in vivo* have demonstrated a close relation between hepatic steatosis and body adiposity, and a close correlation between MRI estimation of adiposity and histological assessment in two of these patients^[11]. Although studies have shown a close association between *in vivo* estimates and biopsies, *in vitro* MRS assessment of lipid content in liver biopsies by MAS MRS would allow direct comparison with histology, reducing the effect of sampling error^[33].

Orthotopic liver transplantation

Liver transplantation is used as a definitive therapy for acute hepatic failure, severe chronic liver disease and some cases of hepatocellular carcinoma. Demand for donor livers is high and suboptimal specimens may be used. At present there is no reliable non-invasive method to assess the viability of livers between organ harvesting and implantation. A program of research to address these problems demonstrates translational techniques from animal models *in vitro* to the clinical environment.

In vitro and *ex vivo* MRS studies of animals have established a model, which follows human organ harvesting and storage protocols^[34,35]. Rapid reductions in ATP levels, readily measured by *ex vivo* ³¹P MRS have been seen in a pig model compared to rodent models and levels could be replenished by hypothermic reperfusion^[34]. Now that MR probes have been designed to fit within organ retrieval boxes, clinical studies of organs within a transplant program are required^[36].

In a preliminary study, Duarte and colleagues used *in vitro* ¹H MAS MRS to assess biopsies taken at three time-points from six livers, before removal from donors, during cold perfusion and following implantation into the recipient^[33]. The biopsies with the highest concentration of peaks reflecting fatty acyl chain (triglyceride) resonances were also identified as those also estimated to have the highest fat content on histological analysis. Other metabolites were identified, including glycerophosphocholine (GPC), which were reported to decrease from pre- to post-transplant^[33]. However, in further studies such spectral changes need to be correlated with a range of clinical endpoints, including the premorbid clinical history of the liver donor, the pre-transplantation clinical history and nutritional status of the recipient, the subsequent post-transplantation liver function tests, pre-and post-transplantation indices of nutrition in the recipient and ultimately, the final clinical outcome.

Moving towards using MRS as a non-invasive methods for assessing graft dysfunction following transplantation, Taylor-Robinson and colleagues used correlative *in vitro* MRS of liver biopsy material and *in vivo* whole-body clinical hepatic ³¹P MRS to examine chronic ductopenic rejection of human liver allografts and noted an increased PME/NTP metabolite ratio reflecting associated altered phospholipid metabolism^[37]. The study also included electron microscopy of liver tissue and the alteration in the phospholipid component was judged to be related to a change in biliary phospholipid excretion in these cholestatic patients^[37]. Such an increase in the *in vivo* PDE resonance, seen in the *in vivo* hepatic MR spectrum is not a specific finding in patients with chronic allograft rejection, because a similar, albeit less marked change has been found in patients with primary biliary cirrhosis and obstetric cholestasis^[38,39].

Iron studies

Iron overload may be a result of iatrogenic causes such as multiple blood transfusions in beta-thalassaemia, or of metabolic causes such as hereditary haemochromatosis, and is commonly associated with liver dysfunction. At the current time, hepatic iron stores are still usually estimated using liver biopsy with the associated risks that this procedure carries, but are readily studied by MR, since paramagnetic iron compounds cause magnetic inhomogeneities, which shorten the nuclear relaxation time^[40,41]. However, imaging is difficult on account of rapid relaxation caused by these iron moieties. In addition, use of different MR sequences is required and equipment may require recalibration. Relaxometry allows measurement of relaxation times and provides information as to iron-proton interactions. An *in vitro* approach allows direct quantification of iron following MR analysis^[42]. *In vivo*, Wang and colleagues demonstrated single voxel MRS measurement of T₂ in liver iron overload that correlates strongly with iron quantification from biopsy and overcomes the difficulty of lack of detectable signals in conventional MRI^[43]. Furthermore, Gandon and colleagues have proposed the use of a liver to muscle intensity ratio, which is transferable between equipment and sequences^[44].

Gene therapy

Gene therapy offers the opportunity to replace defective genes in phenotypically abnormal tissue with recombinant genes. Integration into the host cell genome allows expression of the desired protein. However, methods of conveying the gene to the required location and monitoring delivery and expression are required. Viral vectors and non-viral means such as naked DNA, liposomes and molecular conjugates have all been used. Expression varies with time and between tissues. MR techniques using MR spectroscopy and/or MR imaging, offer non-invasive methods of monitoring expression^[45,46]. As in drug monitoring techniques where a MR detectable moiety or metabolite is linked to the active drug, genes expressing markers may be combined with the therapeutic gene. Phosphoarginine produced by the enzyme arginine kinase in *Drosophila*, but not present in mammalian skeletal muscle, is expressed in mouse skeletal muscle and detected by ³¹P MRS following injection of an adenovirus vector^[47]. The expression in neonatal mice could continue for up to eight months. This demonstrates elegantly the principle of 'marker metabolite' using xenogenetic material. This principle has been demonstrated *in vitro* using a hepatocyte cell line^[48]. Hepatocytes do not express creatinine kinase so phosphocreatine has not been seen on the hepatic MR spectrum. Integration of the cytoplasmic creatine kinase into hepatocytes *in vitro* could lead to detection of phosphocreatine by ³¹P MRS, raising the possibility that combined with a hepatotropic gene delivery system, gene expression may be monitored *in vivo* through a MR-visible marker.

APPLICATIONS OF *IN VITRO* NMR SPECTROSCOPY IN BILIARY DISEASE

Introduction

Bile is predominantly an aqueous solution containing numerous constituents. Bile acids (BA), phosphatidylcholine (PTC) and cholesterol are the predominant lipid components of bile. Other components include electrolytes, organic anions (bilirubin), plasma proteins, hepatocyte proteins, peptides and amino acids, nucleotides, heavy metals and vitamins, xenobiotics and toxins^[49]. In health the concentration of these biliary constituents is tightly controlled.

Primary bile acids such as chenodeoxycholic acid (CDCA) and cholic acid (CA), and secondary bile acids such as lithocholic acid (LCA) and deoxycholic acid (DOCA) are conjugated with the amino acids taurine and glycine and secreted as sodium or potassium salts into the biliary canaliculi via the ABC biliary transporter proteins^[50]. Phosphatidylcholine, the predominant biliary phospholipid, is synthesized in hepatocytes and transported into the biliary canaliculi by the flippase multidrug resistant protein 3 (MDR3)^[51]. Its main function is to form mixed micelles with primary and secondary bile acids and cholesterol essential for the emulsification of fats. More recently it has been shown to be cytoprotective to the biliary epithelium^[52]. Cholesterol is solubilized by the formation of vesicles with PTC or mixed micelles with bile salts and PTC.

Sampling of bile for diagnostic purposes has become a common clinical practice since the introduction of endoscopic retrograde cholangiopancreatography (ERCP). Bile research has advanced in the last decade mainly as a consequence of the alarming rise in incidence of biliary tract cancer (cholangiocarcinoma)^[53-55].

Advanced cytological techniques such as digital image analysis and fluorescence *in situ* hybridization (FISH) of bile are being used to improve the diagnostic accuracy of cholangiocarcinoma in certain experimental units^[56]. More recently proteomic analysis of cholangiocarcinoma bile has identified 87 unique proteins including several novel proteins whose functions are unknown and a large number of proteins not previously described in bile^[57]. Advances in molecular research and imaging technologies have vastly improved the diagnostic sensitivity and specificity in this area but there is still a clear need to identify novel, highly sensitive and specific biomarkers for fluid-based detection of biliary tract cancer, as well as other diseases of the biliary tree. Metabolic profiling of bile using *in vitro* MRS is a valuable experimental tool for the identification of such early biomarkers of the disease.

Bile physiology by MRS

The majority of MRS studies on bile have been carried out using ¹H MR spectroscopy. The hydrophobic association of conjugated bile acids and biliary lipids in micelles has been confirmed in early MR studies^[58]. Bile acids have also been quantified in both animal and human bile using *in vitro* ¹H MRS. Rat bile studies with ¹H MRS have derived peak assignments for C-18 methyl proton of bile acids at 0.7 ppm and the C-19 at 0.9 ppm, while the taurine moiety of taurine-conjugated bile acids resonated at 3.1 ppm and 3.5 ppm, respectively^[59]. Conjugated bile acids in human gallbladder bile have been quantified using two dimensional MR^[60]. Amide (-NH) proton resonances in glycine- and taurine-conjugated bile salts are in the region of 7.8-8.1 ppm^[60].

More recently, ¹H MRS has demonstrated cholesterol in human bile that can be differentiated from other lipid components in bile^[61]. It has also been utilized for studying the effects of cholesterol on the fluidity of human gallbladder bile as well as for quantifying micellar PTC concentrations^[61,62].

³¹P NMR spectroscopy has been used to quantify phospholipids in red cell membranes and in model bile salts^[63]. Such ³¹P MRS studies have shown higher concentrations of PTC and Pi in gallbladder bile compared to canalicular bile^[64].

MR spectroscopy of bile in disease

The biliary epithelium is exposed to numerous constituents of bile. Bile acids, PTC and cholesterol are of particular importance in disease if the cytoprotective mechanism of cholangiocytes is disrupted^[65]. Biliary disease has a major effect on biliary composition as the level of cellular function determines the production and biochemical constituents of bile. Biliary composition of these lipids also varies in cholestatic diseases of the liver and malignancy of the biliary tree. Current applications of

MRS in biliary disease include assessment of bile content in cholesterol gallstones, rejection in liver transplantation, primary biliary cirrhosis and biliary tract malignancy, as well in biliary excretion of xenobiotics^[64,66-69].

MRS has been used to assess the distribution of biliary lipids between vesicles and micelles, which is believed to have a role in gallstone disease, and there is evidence that cholesterol from vesicular aggregates may be responsible for the deposition of cholesterol stones in the gallbladder^[70]. Changes in the pattern of fatty acids of PTC with an increase of arachidonic acid have also been observed in bile from patients with gallstones^[71]. Fusion and aggregation of phospholipid-cholesterol vesicles which form liquid crystalline droplets leading to nucleation of cholesterol monohydrate crystals are thought to be responsible for the formation of cholesterol gallstones^[70]. A selective reduction in biliary phospholipids has been suggested to be responsible for cholesterol gallstones in certain populations^[72].

Initial ³¹P MRS studies on bile from patients with primary biliary cirrhosis have shown reduced levels of PTC and Pi when compared to bile from healthy volunteers^[64], but the significance of these findings still remains to be determined in more extensive studies.

In vitro MRS has also been demonstrated to effectively identify and quantify xenobiotic metabolites in human and animal bile. Dioxins have been identified in biliary-cannulated rodents^[67].

In vitro ¹H MRS analysis of bile has also been applied in human liver transplantation in an attempt to assess donor liver integrity. Melendez and colleagues studied twenty-four hepatic bile samples from eight liver donors^[69]. The livers from two donors were steatotic on histological analysis, while the rest were normal. ¹H MRS analysis could show more intense PTC resonances in bile from steatotic donor livers, compared to bile from histologically normal donor livers. Seventeen hepatic bile samples from four recipients collected immediately after donor liver reperfusion were also analyzed by ¹H MRS and showed bile from donor livers with good early graft function had a progressive increase in the bile acid peaks which represents restoration of bile flow. When compared to grafts with early graft dysfunction, the relatively reduced bile acid peaks in these spectra suggested slow recovery of bile secretion. In this study a total quantification of bile acids was not feasible due overlapping signals from other biliary lipids, notably cholesterol and PTC^[69].

Our preliminary studies have revealed differences in phospholipid metabolites that may help distinguish between malignant and non-malignant causes of pancreaticobiliary obstruction. A reduced PTC resonance was seen in the bile from the majority of patients with hepatobiliary cancer compared to bile from patients with non-malignant indications for ERCP. This preliminary observation was confirmed by significant differences in the peak area ratios of PTC, referenced to the TSP standard in the ¹H MR spectra ($P = 0.007$)^[68].

Nishijima and colleagues have observed a lactate peak in bile spectra from patients with hepatic and biliary malignancy but not in bile from patients with non-malignant disease or bile from healthy controls^[73]. The

significance of this finding has yet to be determined in larger studies, where the collection and storage of bile for analysis are performed according to uniform protocols without potential contamination from ERCP contrast agents or the uncertainty of a long storage time that may lead to lactate accumulation.

FUTURE STUDIES

Although MRS is primarily a research tool and its use to study hepatobiliary disease is a relatively new area, the ability of both *in vivo* and *in vitro* MRS to provide quick, repetitive, and non-invasive assessments of organ function raises several possible future development areas, including non-invasive diagnosis and staging of disease.

In vitro MRS holds a particular promise in the metabolic profiling of body fluids, such as urine, plasma and bile to pinpoint the potential disease mechanisms and to assess the response of the body to treatment regimens. This is of particular relevance when patients are having *in vivo* MRS studies, since an *in vivo/in vitro* correlation of the metabolite profile obtained may highlight disease processes and inform further genetic profiling studies^[39].

Several clinical areas may be of potential interest. In the oncology field, phospholipid profiling to assess changes by *in vivo* ³¹P MRS may be useful in monitoring responses to the treatment of hepatic tumors, with co-temporaneous *in vitro* MRS analysis of plasma and urine. For example, chemoembolization of hepatic tumors has been found to correlate with a decrease in PME and increase in ATP concentrations using *in vivo* hepatic MRS^[74].

Correlative *in vitro* MRS of body fluids and *in vivo* hepatic MRS techniques can also be applied to chronic liver disease to monitor liver fibrosis and progression towards cirrhosis. With increasing prevalence of alcohol-related liver disease, obesity-related liver disease (non-alcoholic hepatitis or NASH) and viral hepatitis, such as hepatitis C in particular, a reliable and repeatable monitoring system is required that obviates the morbidity and mortality associated with liver biopsy. *In vivo* and *in vitro* MRS may hold some of the answers to this, but further, larger scale studies are required to assess the true utility of these techniques with respect to other methodologies, such as microbubble contrast-enhanced ultrasound, ultrasound elastography and use of serological markers of fibrosis^[75,76].

Future technical advances will boost the clinical potential of *in vivo* MRS, for example improving the delineation of multi-component signals, such as PME and PDE, with proton decoupling^[77]. Increasing magnetic field strengths for *in vivo* studies may also provide better signal-to-noise and increased resolution, and 3T magnets are becoming steadily more available. Furthermore, *in vivo* ¹H MRS may find a role in monitoring hepatic lipid content in interventional treatment studies of patients with non-alcoholic fatty liver disease in the future. *In vivo* ¹³C MRS for measurement of lipid metabolism, glycogen storage and gluconeogenesis looks promising for the future, but current sensitivity issues mean that this capability is currently confined only to a few centers^[78-80]. *In vitro* MRS will find a correlative role in this context for screening plasma and urinary metabolites.

With respect to *in vitro* applications in bile, the ratio of taurine to glycine conjugates of bile acids and conjugated to unconjugated bile acids varies in hepatobiliary disease, and it has been widely accepted that elevated levels of bile acids in hepatocytes are toxic, leading to cholestasis^[65]. More recently, the role of bile acids in cholangiocytes has been highlighted. *In vitro* studies on bile acids has demonstrated that they can act as ligands for the epidermal growth factor receptor on cholangiocytes and *via* the mitogen-activated protein kinase cell signalling pathway, leading to disordered cell cycling and cholangiocyte proliferation^[81]. The measurement of bile acids is therefore necessary for an understanding of the pathophysiology of these diseases. *In vitro* MRS may find a useful role in screening bile in this context.

It is true that the significance of *in vivo* MRS needs to be assessed in larger studies with greater numbers of patients with various hepatobiliary diseases. Correlative *in vitro* NMR spectroscopy will help to elucidate some of the conundra. Trials in large populations in well-defined clinical settings are needed to determine if both *in vivo* and *in vitro* MRS can provide independent diagnostic and prognostic indices in management.

ACKNOWLEDGMENTS

Some of the studies outlined were funded by the British Medical Research Council (MRC grant G99001978). Philips Medical Systems (Cleveland, Ohio, USA) are thanked for support of the magnet systems at the Robert Steiner MRI Unit, Hammersmith Hospital, Imperial College, London. We thank Adrian Lim, Shahid Khan and Nayna Patel for useful discussions.

Abstract

Inflammatory bowel diseases (IBD), such as Crohn's disease (CD) and ulcerative colitis (UC), are chronic inflammatory autoimmune conditions of the gastrointestinal tract. Other organs, such as the eyes, skin and articulations, are often affected and IBD may be accompanied by other diseases of autoimmune origin. There is no single etiological factor responsible for the onset of IBD. Recent advances in genetics and in the molecular mechanisms of the proteins coded by these genes have given rise to a new vision in understanding these complex diseases. Activation of specific genes that affect antigen presentation and the handling of cells by innate immunity may lead to autoimmunity with the consequent activation of the major histocompatibility complex (MHC) and multiple cytokines involved in the regulation of acquired immunity. In this review IBD is described as a constellation of diseases that can best be classified as barrier diseases. This vision, developed by Kiel in Germany, includes the idea that changes in our environment due to the westernization of civilization have not been met with adaptation of the innate immune system, and this has given rise to autoimmune diseases. These diseases affect 1-5 of 1000 individuals and represent a major burden on the national health systems of many countries on different continents. On a world scale, a major challenge is to generate interventions to prevent the development of these diseases in Asia, Latin America and Africa.

INTRODUCTION

In less than five years after the discovery of the first gene involved in susceptibility to Crohn's disease (CD), the initial concept that CD is a multifactorial and polygenic disease has been consolidated^[1,2].

Although the detailed functions of the *NOD2* or *CARD15* gene of chromosome 16 is not entirely clear, their relationship to intestinal flora, Toll receptors (TLR), and other intra-cytoplasmatic receptors of the NOD family together with their relation with NF- κ B, has made clear that the innate immune response is of paramount importance in the pathogenesis of CD^[3-5].

Two years ago it was suggested that the relationship between *TLR-2* and *NOD2* genes could explain the balance between activation of superficial receptors of the epithelial and dendritic cells to stimulate the production of NF- κ B and *NOD2* as inhibitors in order to prevent chronic disease^[6-8]. According to this concept, individuals with mutations in the *CARD15* gene are not able to control the intestinal inflammation and this induces a TH1 immune response^[9]. Recently, however, mutations in the terminal N of the gene in a region rich with leucine repeats have been transfected into the *NOD2* region of mice^[10]. Surprisingly, when these mice are challenged with muramyl dipeptide (MDP) they generate considerable production of NF- κ B and IL-1 β ^[10]. Also the transfection of these mutations in HEK293 cells results in increased transcription of TNF- α , which suggests that different genes contribute to susceptibility to the disease and differences in manifestations of CD^[11].

The fact that *NOD2* is preferentially expressed in Paneth cells in the ileocaecal region probably explains the strong association between these mutations and this disease localization^[12,13]. This region is rich in defensins, which are natural antibiotics that contribute to the mucosal barrier and innate immunity^[14]. It is also now known that patients with mutations in the *CARD15* gene also have less α -defensins. This defect probably contributes to the role of intestinal flora in inducing and/or maintaining inflammation^[15]. Preliminary results of a study carried out by the Stange group in Germany suggest that defensin deficiency is genetically determined. The defensin family is more complex and richer than originally described and its distribution varies within the gastrointestinal tract. The β -defensins are localized in the colon and defective β -defensins could contribute to the colonic localization of IBD^[16]. It is also possible that different defensins may be specific to CD and UC variations^[17].

These observations demonstrate the fine-tuning of

molecular biological responses of the gastrointestinal tract and the complexity of interactions among different genes on different chromosomes. Another example of complexity is gene polymorphisms of the gene inhibitor of plasminogen (PAI-1) in combination with *CARD15* mutations have an influence in the development of CD. Those patients who have mutations of *CARD15* and carry the *PAI-14G/4G* genotype develop a stricturizing phenotype (OR, 4.64; 95% CI, 1.26-17.05)^[18].

Despite the well-demonstrated and replicated role of *CARD15* mutations in the susceptibility for CD in the majority of Caucasian populations^[19-23], no mutations have been found in Asian^[24-27] and in several European populations. In Scotland, Ireland, Galicia, Sweden and Finland the carriership of mutations in the *CARD15* gene is less frequent^[28-32]. An interesting phenomenon was recently reported in monozygotic twins. In Sweden, the number of carriers of these mutations was as low as in the general population^[32]. However, in Denmark 40% of the monozygotic twins carried *CARD15* mutations, which was a higher rate than in the Danish population with CD^[33]. This corroborates the observations in Finland where the 1007fs allele frequency was higher in familial CD than in non-familial cases with CD (10.9% *vs* 3.5%; *P* < 0.01)^[30]. These observations underscore the incidence of genetic variability and the importance of studying healthy controls in the general population.

RELEVANCE OF OTHER GENES

Several other genes on other chromosomes are involved in determining susceptibility to CD. Two interesting genes, one on chromosome 5 and one on chromosome 10, contribute to the new vision of the genetics of CD. On chromosome 5, the SLC22A4/SLC22A5 haplotype codes for molecules involved in cationic transport, other solutes and carnitine (OCT-1 y OCT2)^[34-36]. In some populations, an epistatic interaction has been found to exist between the *CARD15* mutations and the 250 KB region of 5q31^[37,38]. The other interesting gene in this context is the *DLG5* on chromosome 10, which is a gene that is important in the scaffolding of the epithelial cell^[39,40].

The 250 KB region of 5q31 and the HLA region of 6p21 contain several genes that are of paramount importance in the regulation of the immune response and probably contribute to the phenotype of the patient with IBD. The *HLA-DRB1*0103* allele is associated with UC and with the colonic localization of CD^[41,42].

Carriers of *HLA-DRB1*0103*, *B*35* and *B*27* have higher risk for arthralgias/arthritis in some of the greater articulations and *HLA-B*44* carriers are at higher risk for symmetric poly-arthritis^[43,44].

A meta-analysis of 1068 CD patients has also implicated the genes described above in the development of CD and this study identified other regions of potential relevance on chromosomes 2q, 3q, 17q and 19q^[45].

THE CONTRIBUTION OF GENETICS TO A NEW VISION

In the new vision of CD, several genes are involved in the

maintenance of the intestinal barrier, such as scaffolding genes (*DLG5*^[46]), genes involved in the transport of key molecules for the homeostasis or exclusion of toxins (*SLC*^[47] and *MDR1*^[48,49]), genes involving the sensing of bacteria, both on the surface (TLR, CD14) and intracytoplasmatically (*CARD15*, *CARD4* and *CARD8*^[50-52]). Whether a specific gene for regulating permeability exists, as has been suggested on chromosome 19, remains to be demonstrated. The combination of gene rich regions of chromosome 5 and 6 involved in regulating the immune response may contribute to the phenotype of the disease.

In summary, in less than a decade the genetics of IBD has evolved from epidemiology to molecular biology, and from observational studies to functional studies. The challenge for the coming years is the discovery of gene-gene interactions and gene-environment interactions.

A delineation of phenotypes based on genetic and molecular mechanisms will improve diagnoses and more accurate prognoses. This knowledge, together with advances in the understanding of the phenomenon of tolerance and the disruption of this mechanism in the understanding of chronic inflammation of the gastrointestinal tract, will lead to the design of better and novel therapeutic strategies. This should be the basis for effective drug development in addition to increasing knowledge generated by pharmacogenetics and pharmacogenomics.

Regarding the role of the environment in those individuals with a genetic susceptibility, new findings on epigenetic effects from long-term follow-up in monozygotic twins will open a new area of investigation. Investigators at the Spanish National Cancer Centre (CNIO) in Madrid have shown that older monozygotic twins exhibited differences in their overall content and genomic distribution of 5-methylcytosine DNA and histone acetylation. These epigenetic changes affect their gene-expression patterns and may explain the well-known disease discordance in these cases of monozygotic twins^[53].

Abstract

Genetic epidemiology researches such as twin studies, family-clustering of hepatitis B virus (HBV) infection studies and ethnic difference studies have provided the evidence that host genetic factors play an important role in determining the outcome of HBV infection. The opening questions include which human genes are important in infection and how to find them. Though a number of studies have sought genetic associations between HBV infection/persistence and gene polymorphisms, the candidate gene-based approach is clearly inadequate to fully explain the genetic basis of the disease. With the advent of new genetic markers and automated genotyping, genetic mapping can be conducted extremely rapid. This approach has been successful in some infectious diseases. Linkage analysis can find host genes susceptible to HBV and is of great clinical importance.

INTRODUCTION

Hepatitis B virus (HBV) infection is a serious global health problem, with 2 billion people infected worldwide, and 350 million suffering from chronic HBV infection. HBV infection results in 500 000 to 1.2 million deaths per year

caused by chronic hepatitis, cirrhosis, and hepatocellular carcinoma and is the 10th leading cause of death worldwide^[1]. The mechanisms of persistent HBV infection are not fully understood, but they seem to involve several aspects and the genetic component, in particular, is still controversial^[2]. Early studies by Blumberg *et al*^[3] have also suggested a recessive mode of inheritance for HBV viral persistence, but this is perhaps an oversimplification giving the more recent advances in knowledge of the effect of maternal viral infection and the transmissibility of the virus^[4].

Generally, exposure to HBV can cause a broad spectrum of infection^[5]. Ninety to ninety-five percent of adults infected with HBV can eliminate the virus and only 5%-10% of them become chronic HBV carriers, 20%-30% of chronic HBV carriers develop chronic hepatitis B (CHB) and 5% of them develop liver cirrhosis and hepatocellular carcinoma in a long term of disease course. Some rare cases result in a fulminant infection in which the liver is rapidly overwhelmed and ultimately fails. What factors determine why one develops a life-threatening infection, whereas another carries HBV as a harmless commensal or limits the infection to a clinical trivial episode? There is evidence that host genetic factors play an important role in determining the outcome of HBV infection^[6,7].

EPIDEMIOLOGY EVIDENCE FOR HUMAN GENETIC SUSCEPTIBILITY TO PERSISTENT HBV INFECTION: TWINS, FAMILY-CLUSTERING OF HBV INFECTION AND ETHNIC DIFFERENCES

Twin studies

Studies of susceptibility to diseases in identical and non-identical twins are extremely useful in evaluating the importance of inherited vs environmental factors in disease susceptibility^[8]. If the concordance rates for infection and clearance of HBV are significantly higher in monozygotic (MZ) than in dizygotic (DZ) twins, the process of HBV infection and persistence is more genetically decisive. Lin *et al*^[9] studied 289 pairs of MZ twins, 102 pairs of DZ twins and 375 pairs of age-sex-matched singleton controls and found that there is a significant difference in the concordance of HBV infection between MZ and DZ twins and controls, suggesting that the genetic influence occurs in response to HBV infection. Xu *et al*^[10] also found that not only the concordance rate of infection, but the concordance of clinical phenotype and serological

patterns between MZ and control groups is significantly different, indicating that genetic factors influence not only susceptibility to infection but also clinical outcome.

Genetic factors not only influence host response to HBV infection, but also affect the response to HB vaccine. Hohler *et al.*^[11] prospectively studied and vaccinated 202 twin pairs with a combined recombinant HBsAg vaccine and found that the heritability of anti-HBs immune response is 0.61, which means that 60% of the phenotypic variance of responsiveness to HB vaccine can be explained by genetic effect and 40% by environmental effect.

Family-clustering of HBV infection

Most of us do not inherit single-gene diseases. We all, however, inherit slightly different variants of each of our pairs of 30 000 genes. These differences may determine whether we are more or less likely to develop particular health problems or diseases than other people. Genes are shared within families. Because we inherit genes from our parents, a parent who has inherited a particular gene mutation generally means that each child has a fifty-fifty chance of having the same mutation. In fact, many cases of diseases not showing the clear inherited patterns of single-gene diseases, show family clustering patterns that are due, at least in part, to genetics. Substantial genetic epidemiology studies indicate that HBV spreads in families. The familial occurrence of HBV infection has been well established in some ethnic groups. Ohbayashi *et al.*^[12] have reported 3 Japanese families in which 36 of the 54 members are HBsAg positive. Of these, some are healthy carriers while others have liver cirrhosis and hepatocellular carcinoma. Similar observations have been reported in American^[13], European^[14] and Asian^[15,16] continents.

This observed familial clustering may stem from inherited defects in specific genes, from shared environmental exposures among family members or from interaction between specific genetic and environmental factors. If a trait has a genetic basis, the relatives of affected individuals will be affected more frequently than the relatives of unaffected people, and the prevalence of disease decreases from monozygotic (MZ) twin to the first-, second- and third-degree relatives. If the disorder has an environmental basis only, the possibility of infection in each family member is equal^[17]. Tong *et al.*^[18] reported that HBV markers are detected more frequently in blood relatives than in non-blood relatives of the index cases in family. Wang *et al.*^[19] also showed that HBsAg carrier rate decreases in the order of the first, second and third degree relatives, indicating that it is the defect gene shared by family members that produces the epidemiological characteristics of family-clustering HBV infection.

Ethnic differences

Another method used to investigate the role of host genetics in infectious diseases is to look for differences in clinical disease and immune response between different ethnic groups having equal exposure to the same pathogen. Carrilho *et al.*^[20] determined the frequency of HBV markers of genetically related (consanguineous) and non-genetically related (non-consanguineous) Brazilian families of Asian

origin and Western origin and found that the occurrence of HBsAg is significantly higher ($P < 0.0001$) in family members of Asian origin (81.8%) than in those of Western origin (36.5%), which is in line with the high HBsAg prevalence in Asian countries and the relatively low HBsAg prevalence in Western countries^[21]. Though the Asians live in Brazil, a country with a low HBsAg prevalence, and the environment has changed, disease-related genes remain shared within the ethnic group, indicating that Asians possess the HBV susceptible gene(s). This is why they are more susceptible to HBV.

Tong *et al.*^[18] tested family members of Asian and non-Asian patients for HBV markers, and found that Asian family members have a significant increase in HBsAg (34% higher) and antibodies to HBsAg or to hepatitis B core antigen (50% higher) compared with the non-Asian family members. Moreover, birthplace, either in Asia or in United States, does not influence the frequency of antigenemia. In China, the prevalence of HBsAg is 19.1% in Mongoloid populations^[22], and 10% in Chinese Han populations in the same area. These studies have provided important insights into the fact that different ethnics in the same region have different HBV epidemiological characteristics and the same races in the different region share the same prevalence of HBV markers, indicating that genetic factors may play a role in maintaining the frequency of HBV infection and persistence. Moreover, molecular epidemiology study has identified several genetically determined differences between races.

Taken together these epidemiological data provide strong evidence for a genetic predisposition to HBV infection and raise the questions of which human genes are important in infection and how to find them.

TWO METHODS USED TO IDENTIFY HBV SUSCEPTIBLE GENES

Analysis of the human genome has focused primarily on variations that occur between people in their DNA sequence^[23]. Because these differences contribute to the differences in our susceptibility to developing specific diseases, naturally occurring genetic variations in the human genome are frequently found (about every 3 to 500 bp) most often in the form of a change from one base to another, namely a single nucleotide polymorphism (SNP)^[24]. Other common forms of variation include microsatellite where a short sequence, usually a dinucleotide repeat is bound, so that one person might have 10 and 12 copies of the repeating motif and others have 9 and 11 copies. If the repeating sequence is longer, the motif is known as a minisatellite^[25]. They are widely used to determine similarities and differences of human and hunter disease-related genes. Because this kind of genetic variations often varies between individuals (i.e., it is highly polymorphic), microsatellites are particularly informative in the genetic sense^[26]. Analysis of genetic susceptibility to HBV infection aims to link these DNA variations (the genotype) with a particular HBV infection (the phenotype). HBV infection and clearance are complex traits^[27], meaning that the genetic contribution to them is not inherited in a

Table 1 Gene polymorphisms associated with clearance of HBV infection

simple Mendelian manner and several polymorphic genes exert effects on the outcome^[28]. Many possible approaches to mapping the genes underlying complex traits fall broadly into two categories: candidate gene- based association studies and genome-wide linkage studies^[29].

Association studies

Association studies compare the frequency of alleles or genotypes of a particular variant between disease cases and controls to link the genotype with the particular phenotype. Such studies are widely used to investigate inflammatory and infectious diseases. Repeat sequences, such as those of microsatellites, lend themselves less well to association studies because they are intrinsically unstable and may undergo considerable mutations over successive generations and disease-modifying polymorphisms may have arisen many hundreds of generations previously. SNPs, on the other hand, are stable, common and increasingly amenable to high throughput automated genotyping. A number of studies have sought genetic associations between HBV infection/persistence and gene polymorphisms (Tables 1 and 2).

The huge variation in clinical response to identical infecting pathogens is due to the combined effects of genetic variation both in the infecting pathogen and in the infected host^[44]. Its ability to mount an effective immune response to infection is a powerful evolutionary selection pressure, contributing to human genetic diversity. The advantage of a flexible immune response, allowing an efficient response to diverse pathogens without damage to the host, is reflected in marked genetic variability of immune-related genes among (both in DNA sequence and in protein structure) in the entire human genome^[45].

The prototype region for genetic association studies is the human leukocyte antigen (HLA) loci involved in antigen processing and presentation. HLA associated with infections such as AIDS^[46], tuberculosis^[47], leprosy^[48], malaria^[49] and persistence of hepatitis-C virus^[50] has been well-described. This is most obvious within the HLA region, where functional variation has arisen as a strategy to combat pathogen antigenic diversity. Indeed in HBV infection, maximal HLA variation appears to

have a direct protective effect, individuals with the most different alleles at class II HLA loci have the slowest HBV disease progression and the lowest mortality (a “heterozygous advantage”)^[51]. Conversely, lack of HLA diversity (a “homozygous disadvantage”) may increase the susceptibility to HBV infection among isolated communities^[52]. The extensive linkage disequilibrium across some HLA regions makes it difficult to localize specific disease-associated polymorphisms, although the HLA allelic association has allowed identification of critically pathogenic epitopes in some diseases^[39], which might act as potential vaccine candidates.

Disease associations involving loci outside the HLA region are also valuable in identifying the functional molecular basis underlying infectious disease resistance. For example, HIV uses various chemokine receptors as cofactors for CD4 binding to gain entry into human leukocytes. A functional polymorphism of the chemokine receptor CCR5, which is essential for HIV entry into macrophages, results in a truncated nonfunctional protein that confers highly significant protection against HIV susceptibility in the homozygous state and slows disease progression in heterozygotes^[53,54]. Chang *et al*^[38] have developed the association between CCR5 and HBV infection, though the biological process and significance in HBV infection need to be further studied.

Shortcoming of association studies in susceptible gene hunting

The number of studies seeking to identify genes that influence susceptibility to persistent HBV infection has greatly increased since we entered the “post-genomic” era. These studies are fuelled by the unlimited availability of

Table 3 Successful linkage analysis in infectious diseases

Diseases	Location of predisposing genes	Reference
<i>H pylori</i>	IFNGR1	[60]

Leprosy	10p13, 6q25	[68, 69]

SNPs, the relative ease of performing genotyping assays based on PCR technology, and the desire to identify major disease susceptibility gene(s). Literature is now littered with unreproducible genetic association studies that confuse the readers and have an understandable impact on the willingness of editors to accept further manuscripts for publication^[27]. *Nature Genetics* published an editorial in 1999 that set out a list of criteria for genetic association studies^[55]: plausible biological context, rigorous phenotypic selection (case selection), independent replication, rigorous genotyping, low *P* values, appropriate statistical analysis, and transmission disequilibrium test. Up to now, few candidate genes can fully meet the criteria.

Candidate gene-based association studies rely on having predicted the identity of the correct gene or genes, usually on the basis of biological hypotheses or the location of the candidate within a previously determined region of linkage^[56]. Even if these hypotheses are broad (for example, involving the testing of all genes in the insulin-signaling pathway), they will, at best, identify only a fraction of genetic risk factors for diseases in which the pathophysiology is relatively well understood. When the fundamental physiological defects of a disease are unknown, the candidate-gene approach is clearly inadequate to fully explain the genetic basis of the disease^[29]. In 2004, *Hepatology* editor appealed for less hypothesis-driven association studies that result in a negative or weak correlation^[27].

Linkage studies

Linkage is the tendency for genes and other genetic markers to be inherited together because of their location near one another on the same chromosome. Linkage studies classically seek to identify microsatellite markers that are inherited more commonly than expected by siblings who have the disease of interest ("affected sibling pairs")^[57]. Genetic linkage analysis is a powerful tool to detect the chromosomal location of disease genes^[58]. A linkage study is to use a large number of families to look for regions of linkage to a disease, which suggest the presence of loci containing genes that may predispose to this disease. Linkage studies have the advantage of making no supposition about which genes might be involved in a disease, in that they merely identify stretches of chromosome around the microsatellite markers and can be used to examine the entire genome (a "whole genome screen")^[58].

With the advent of new genetic markers and automated genotyping, genetic mapping can be conducted extremely

rapid^[28,59]. This approach has been successful in some infectious diseases (Table 3), but no report on such similar scans for HBV viral persistence is available. Recently a research team of Xi'an Jiaotong University has collected 327 HBV-infected subjects of 32 family pedigrees from a remote village (data not published), which makes it possible to find chromosome regions containing determinant(s) of persistent HBV infection. Their results will be reported soon.

CLINICAL IMPLICATION OF GENETIC STUDIES OF HBV INFECTION

Studies of the genetic determinants for HBV susceptibility can reveal fundamental data concerning the human immune system. The ultimate goal of such studies is the identification of critical immunologic mechanisms in the disease process to develop specific therapeutic interventions. As the precise immune deficiency is identified, it may be possible to "bypass" the identified immune deficiency with a specific therapy.

A specific genetic defect has been identified in rarer single gene defects, which may offer preconception genetic counseling to affected families. In complex diseases it might ultimately be possible to identify patients whose risk factors make them candidates for targeted therapies. Once the genotypic markers for a poor outcome of HBV infections are found, they in combination with rapid genotyping technology may allow more intensive therapies for those patients who are at the greatest risk of poor outcome and death^[70,71]. The potential to target drug treatment, both in terms of identifying patients most likely to benefit clinically and in terms of predicting those who are susceptible to either favorable or adverse pharmacologic outcome, is of great importance. It is conceivable that in the future our understanding of host genetics will largely influence our therapeutic response to HBV-infected patients and determine our choice of both preventive and curative interventions.

Abstract

Crohn's disease (CD) is a multifactorial disorder of unknown cause. Outstanding progress regarding the pathophysiology of CD has led to the development of innovative therapeutic concepts. Numerous controlled trials have been performed in CD over the last years. However, many drugs have not been approved by regulatory authorities due to lack of efficacy or severe side effects. Therefore, well-known drugs, including 5-ASA, systemic or topical corticosteroids, and immunosuppressants such as azathioprine, are still the mainstay of CD therapy. Importantly, biologicals such as infliximab have shown to be efficacious in problematic settings such as fistulizing or steroid-dependent CD. This review is intended to give practical guidelines to clinicians for the conventional treatment of CD. We concentrated on the results of randomized, placebo-controlled trials and meta-analyses, when available, that provide the highest degree of evidence. We provide evidence-based treatment algorithms whenever possible. However, many clinical situations have not been answered by controlled clinical trials and it is important to fill these gaps through expert opinions. We hope that this review offers a useful tool for clinicians in the challenging treatment of CD.

INTRODUCTION

Crohn's disease (CD) is a chronic bowel disease charac-

terised by a relapsing inflammatory process. It can affect any part of the gastrointestinal tract and is associated with discontinuous, transmural lesions of the gut wall. The current working hypothesis suggests that CD results from an aberrant immune response towards fecal bacteria in a genetically susceptible host^[1].

While medical treatment of the acute flare is successful in most patients, one of the most difficult tasks in general medicine is to treat complications such as strictures, abscesses, fistulae and chronic disease activity. In this review, we describe the conventional treatment of CD depending on different clinical situations, such as an acute flare, maintenance of remission, fistulizing or chronically active disease behaviour.

Apart from the below discussed medical and surgical treatment of CD, other factors including changes in lifestyle should be recommended. Herein, probably the most important aspect is smoking cessation. Smoking has shown to be a risk factor for CD relapse after medically or surgically induced remission^[2] and is associated with the need for higher doses of corticosteroids and immunosuppressants^[3]. Importantly, a prospective trial showed that only one year of smoking cessation leads to a more benign course of disease with a lower rate of relapses^[4]. This trial also showed that the ability to quit smoking clearly depended on the physician's role. So the conventional treatment of CD should start, if necessary, with convincing the patient to quit smoking.

ACTIVE DISEASE

Definition

The activity of CD can be assessed clinically, endoscopically or by other indices^[5]. The most established way is through the BEST activity index (CDAI), where symptoms and objective criteria such as anemia and body weight are included^[6]. Index values of 150 and below are associated with quiescent disease; values above that indicate active disease, and values above 450 are seen with extremely severe disease. In addition other diagnostic values such as blood sedimentation rate, C-reactive protein (CRP) and thrombocytes should also be taken into account. Endoscopic inflammatory evaluation, however, is not necessary in every exacerbation of the disease but might offer important information with respect to disease localisation. This is especially important for the use of topically acting agents such as budesonide in terminal ileal or right colonic CD. Exacerbation of CD through infectious agents should always be considered and

Table 1 Drugs for the treatment of CD

Drug	5-ASA (mesalamine or sulfasalazine)
Dosage	3.2-4 g/d
Indications	Mild to moderately active disease, postoperative maintenance
Important side effects	Headache, nausea and abdominal pain, often during treatment with sulfasalazine (in up to 45% of patients); thrombopenia; interstitial nephritis, pancreatitis;
Monitoring	Liver function, full blood count and especially renal function
Pregnancy	Suggested to be safe in conventional doses

excluded if possible.

In addition, the American College of Gastroenterology has defined the different disease activities in clinical practise as follows^[7]: mild to moderately active disease is defined as “ambulatory patients able to tolerate oral alimentation without manifestation of dehydration, toxicity (high fevers, rigors, prostration), abdominal tenderness, painful mass, obstruction or > 10% weight loss. In contrast, moderate to severe disease applies to patients that have failed to respond to treatment for mild to moderate disease or those with more prominent symptoms such as fever, significant weight loss, abdominal pain or tenderness, intermittent nausea or vomiting (without obstructive findings), or significant anemia. Severe disease refers to patients with persisting symptoms despite the introduction of steroids as outpatients, or individuals presenting with high fever, persistent vomiting, evidence of intestinal obstruction, rebound tenderness, cachexia, or evidence of an abscess.

5-ASA

No debate has been as longstanding and controversial as whether the use of 5-ASA containing drugs in CD is justified or not. Numerous studies regarding this aspect have been performed over the last 25 years. However, data from current studies do not clearly support either point of view. Different study designs and drug dosages have been used that make comparison of the results rather difficult.

Sulfasalazine is the original compound in this class consisting of 5-ASA linked by an azo-bond to sulfapyridine, which is split off in the colon. Therefore efficacy of sulfasalazine was expected to be limited to colonic disease. Furthermore up to 50% of patients are not able to tolerate sulfasalazine due to nausea, headache, vomiting and epigastric pain. These side effects are suggested to be caused by the sulfapyridine moiety. Therefore, other 5-ASA formulations (mesalamine formulations and the pro-drugs olsalazine and balsalazide) without sulfapyridine have been introduced into the market with different pharmacodynamic and pharmacokinetic profiles (Table 1). These different preparations are therefore suggested to be non-interchangeable.

Sulfasalazine: Sulfasalazine has been shown to be significantly better than placebo in randomized clinical trials in inducing remission in active CD^[8-10]. Subgroup analyses suggested that patients with only colonic disease seem to

benefit the most from sulfasalazine therapy^[8,9], whereas patients treated previously with prednisone failed to respond^[8]. Sulfasalazine has not shown to have steroid-sparing properties^[9,11]. Since 5-ASA was identified to be the active moiety in sulfasalazine, other 5-ASA containing formulations (such as mesalamine) have been tested in CD.

Mesalamine: Different pharmacological preparations allow release of the active drug in different parts of the intestine. Therefore mesalamine, in contrast to sulfasalazine, may also be used in CD including small bowel CD. However, studies on the induction of remission in active CD with mesalamine yielded conflicting results. In total, six placebo-controlled trials with varying dosages of mesalamine have been performed to date. Two earlier studies did not detect a benefit of mesalamine over placebo in inducing remission^[12,13]. Tremaine and colleagues observed a significantly greater number of patients that responded (defined as either a decrease of CDAI ≥ 70 or CDAI < 150), but this benefit was rather small (9 patients with mesalamine treatment *vs* 4 patients in the placebo group). However, no significant differences were found when clinical remission (defined as CDAI < 150) was analyzed^[14]. Singleton and colleagues conducted three different trials with mesalamine (Pentasa) that were recently combined in a meta-analysis although two of the three trials were never published in full^[15]. This analysis found a statistically significant benefit of mesalamine over placebo. However, this benefit was rather small (CDAI reduction of 18 points for the intention-to-treat-analysis).

In summary the clinical benefit of mesalamine in the treatment of active CD seems to be rather low. However, mesalamine is well tolerated and has a favourable side effect profile compared to sulfasalazine. The latter factor is probably the main reason why mesalamine is significantly used more often compared to sulfasalazine although data from randomized trials are in favor of sulfasalazine. Furthermore, many patients with mild to moderately active disease try a more harmless drug at first before taking corticosteroids.

Budesonide

The introduction of the topically-acting steroid budesonide has become a very potent alternative in the treatment of patients with CD located in the terminal ileum or right colon. Due to rapid metabolism by cytochrome P-450 enzymes in the liver, budesonide has less systemic bioavailability than systemic corticosteroids. A recent meta-analysis combined the data from 5 published studies investigating budesonide in comparison to placebo, 5-ASA and systemic corticosteroids^[16]. A significant advantage of budesonide in inducing remission was observed in comparison to placebo (odds ratio of 1.85) and mesalamine (odds ratio of 1.73). Accordingly, a patient is 73% more likely to achieve remission with budesonide than mesalamine. Corticosteroids induced remission even more often as compared to budesonide with an odds ratio of 0.87, but in patients with mild and moderate disease (CDAI 200-300), no difference in remission rates was found. Treatment with budesonide was associated with similar side effects compared to mesalamine and placebo. Importantly, fewer side effects, such as acne, moon face

Table 2 Drugs for the treatment of CD

Drug	Systemic corticosteroids (prednisone equivalent) or budesonide
Dosage	Corticosteroids: 30-60 mg/d or 1-1.5 mg/kg per day; Budesonide: 9 mg
Indications	Corticosteroids: moderate to severe disease. Budesonide: terminal ileal and right colonic disease in mild to moderate disease, low dose budesonide eventually for maintenance therapy
Important side effects	Weight gain, hypertension, fluid retention, myopathy, mood changes, infections, glaucoma, skin changes including acne, adrenal suppression. Long term side effects: osteoporosis, cataract, aseptic bone necrosis
Pregnancy	Lower doses seem to be relatively safe
Comments	Avoid long-term use

Table 3 Drugs for the treatment of CD

Drug	Azathioprine (6-mercaptopurine)
Dosage	2-2.5 mg/kg (1-1.5 mg/kg)
Indications	Maintenance, chronically active disease, steroid-refractory and steroid-dependency, fistulae, concomitant therapy with infliximab;
Important side effects	Pancreatitis, bone marrow suppression, allergic reactions, drug hepatitis, nausea, malaise, bacterial and viral infections; in patients intolerant to azathioprine due to gastrointestinal symptoms, 6-mercaptopurine is suggested (not in side effects such as pancreatitis and bone marrow suppression)
Monitoring	Liver function, lipase and full blood count biweekly for the first three months, if normal then every three months throughout therapy
Pregnancy	Should be avoided, although available studies suggest a potential use especially in patients where maintaining remission is essential
Comments	Entire therapeutic efficacy is observed mostly after 2-4 mo; consider testing for thiopurine methyltransferase (TPMT) genotypes to identify patients with high-risk of bone marrow suppression; consider metabolite monitoring for adequate dosing; ensure adequate birth control; allow 3 mo time before pregnancy or conceiving

and osteoporosis, were observed compared to systemic corticosteroids. The recommended dose of budesonide is 9 mg/d and should be tapered 3 mg every 2-4 wk unless a maintenance therapy with budesonide is suggested (see below).

Systemic corticosteroids

For moderate to severe CD, and especially if therapy with 5-ASA has failed, systemic corticosteroids are the treatment of choice (Table 2). Corticosteroids are fast and effective and induce remission in approximately 70% of patients. In active CD, corticosteroids have been shown to be superior to sulfasalazine, azathioprine and placebo^[8,9]. No dose finding studies have yet been performed. Reported doses range from 30 mg/d to 1 mg/kg per day, however most clinicians start with 60 mg/d, although it seems to be favourable to apply a body weight dependent dosage (1 mg/kg). Tapering should be performed

Table 4 Drugs for the treatment of CD

Drug	Methotrexate
Dosage	25 mg/wk i.m., if remission is achieved reduce to 15 i.m. (or s.c.)
Indications	Maintenance, chronically active disease, steroid-refractory and steroid-dependency, fistulae
Important side effects	Nausea, abdominal pain, diarrhea, stomatitis; hepatitis, liver fibrosis; hypersensitivity pneumonitis
Monitoring	Liver function and full blood count monthly for the first two months, if normal then every two months throughout therapy
Pregnancy	Strictly prohibited
Comments	Entire therapeutic efficacy is observed mostly after 2-4 mo; consider folic acid supplementation with 2.5-5 mg/d; ensure adequate birth control; allow 3 mo time before pregnancy or conceiving

according to improvement of clinical symptoms and is usually done in steps of 5-10 mg/wk. At lower dosages, tapering might be reduced to 2.5-5 mg/wk. Whether i.v. application has an advantage over oral in severe acute flares is not clear, although it is frequently used when oral treatment has not been effective.

Azathioprine/6-Mercaptopurine

The most commonly used immunomodulators are the thiopurines, 6-mercaptopurine and its prodrug azathioprine (Table 3). Numerous clinical trials studied the efficacy of these immunomodulators in active CD. The most convincing data were obtained in the early trial by Present and colleagues where 67% vs 8% of the patients in the 6-mercaptopurine group vs placebo, respectively, achieved remission^[17]. However, other trials did not observe a significant difference in the use of azathioprine compared to placebo^[8,18]. Despite these conflicting data, a meta-analysis reported an odds ratio of 3.09 favoring azathioprine/6-mercaptopurine therapy over placebo^[19] to induce remission. In addition, a recent Cochrane analysis reported an overall response in active CD of 54% vs 33% for azathioprine vs placebo, respectively^[20].

Thiopurines are slow acting drugs and an effect can be observed after 2-3 mo. Thus thiopurines are less frequently used to induce remission in an acute exacerbation but rather to maintain remission. However, they have been shown to have steroid sparing properties^[19,20] and furthermore the combination of prednisolone and azathioprine has shown to be superior over prednisolone monotherapy^[21]. Therefore it is suggested to add azathioprine to corticosteroids in severe CD.

Methotrexate

In the pivotal trial by Feagan and colleagues, methotrexate given intramuscularly 25 mg once a week was more likely to induce remission compared to placebo (Table 4). In addition, steroid-sparing properties were noted^[22]. However, side effects were more common with methotrexate therapy than with placebo. Other studies using low dose methotrexate did not show a significant benefit^[23,24]. In addition, no benefit was observed when high intravenous methotrexate was compared to oral

Table 5 Drugs for the treatment of CD

Drug	Metronidazole
Dosage	10-20 mg/kg
Indications	Mild to moderately active disease; fistulae (usually prolonged treatment)
Important side effects	Nausea, metallic taste in the mouth, coating of the tongue, peripheral neuropathy
Monitoring	See side effects
Pregnancy	Long term treatment not yet evaluated, short term treatment appears to be safe

Table 6 Drugs for the treatment of CD

Drug	Ciprofloxacin
Dosage	1-2 g/d
Indications	Mild to moderately active disease, fistulae
Important side effects	Taste disturbance, gastrointestinal events, tendopathies
Monitoring	Generally well tolerated, see side effects
Pregnancy	Probably safe

azathioprine^[25]. Like azathioprine/6-mercaptopurine, intramuscular methotrexate is only rarely used to treat an acute exacerbation of CD but is used more frequently in chronic active CD^[26]. Importantly, side effects with methotrexate, specifically liver dysfunction, are common and need to be monitored. In addition, methotrexate is contradicted during pregnancy and should be used very cautiously in women of child-bearing potential.

Antibiotics

Although antibiotics are frequently used to treat CD, this practice is not supported by strong evidence from randomized trials. However, increasing knowledge of the importance of mucosal bacteria for the pathogenesis of CD gives a good rationale for investigating antibiotic approaches^[27]. In addition, distinguishing an acute flare from an infectious gastroenteritis/colitis can be difficult. Thus antibiotics provide a therapeutic alternative, which might benefit both an acute flare and a gastrointestinal infection. However, further studies are warranted to establish the role of antibiotics in the treatment of CD and at this time they cannot be recommended as standard therapy.

Metronidazole: Metronidazole (20 mg/kg per day) has been shown to be superior over placebo in reducing the CDAI but not with respect to the induction of remission^[28] (Table 5). Furthermore, this benefit was only seen in patients with colonic or ileocolonic disease, whereas no benefit was found with disease location in the ileum. Similar findings were reported from another trial where few patients with colonic involvement showed an improvement^[29]. Another study reported no benefit *vs* placebo^[30]. Compared to sulfasalazine, a cross over study reported no difference in the first 4 mo. However, in the cross over design, patients switched to metronidazole showed an improvement of CDAI, whereas in the sulfasalazine group this was not the case^[31,32].

Table 7 Drugs for the treatment of CD

Drug	Infliximab
Dosage	5 mg/kg per infusion; usually started at wk 0, 2, and 6 and then repeated every 8 wk if necessary
Indications	Chronically active disease, steroid-refractory and steroid-dependency, maintenance, fistulae
Important side effects	Nausea, headache, abdominal pain, infections, sepsis; infusions reactions (early or delayed), reactivation of tuberculosis
Monitoring	Vital signs around infusion
Pregnancy	Unknown
Comments	Exclude tuberculosis before infusions, consider concomittant use of immunosuppressants (azathioprine) to reduce antibody formation

Ciprofloxacin: Ciprofloxacin is often used in a clinical routine, especially in combination with metronidazole (Table 6). Ciprofloxacin was significantly better compared to placebo in inducing remission in a smaller trial^[33] and was shown to be similarly effective compared to mesalazine^[34]. In contrast, corticosteroids resulted in higher rates of clinical remission compared to ciprofloxacin and metronidazole^[35]. In patients with chronically active disease on budesonide, the addition of metronidazole and ciprofloxacin was not superior over budesonide monotherapy, although in patients with colonic CD a trend towards a significant benefit was observed^[36].

Infliximab

Infliximab is a chimeric IgG1 monoclonal antibody against TNF- α (Table 7). Apart from inhibiting TNF- α , recent data suggest that the induction of apoptosis in T cells through infliximab might be an important mechanism of action^[37]. Infliximab has shown to be superior over placebo in inducing remission in patients with moderate to severe CD resistance to standard therapy^[38]. In this trial, after four weeks 33% of patients went into remission after one single infliximab infusion as compared to 4% of the patients given placebo.

Summary: Treatment of active CD

In mild and moderately active CD, 5-ASA or budesonide may be used as first line therapy, despite the limited efficacy of 5-ASA shown in randomized, placebo-controlled trials. The presently available budesonide preparations are only efficacious in disease primarily located within the terminal ileum or right colon. In non-responders, systemic corticosteroids should be used. Severe CD should be treated with systemic corticosteroids. If corticosteroids given orally do not lead to improvement, intravenous application should be considered since enteral absorption might be decreased due to severe intestinal inflammation. Enteral nutrition should also be added particularly in malnourished patients (see below chapter on nutrition for details). If an infectious complication is suspected, the additional therapy with antibiotics (e.g. ciprofloxacin plus metronidazole) might be beneficial. The combination of systemic corticosteroids and azathioprine is superior to prednisolone monotherapy and this combination might be beneficial in severe cases. In patients

refractory to corticosteroids, treatment with infliximab should be considered. Surgery might be necessary in patients with severe and refractory CD not responding to above mentioned strategies. Intravenous cyclosporin and tacrolimus should only be used in selected severe and refractory cases.

MAINTENANCE OF REMISSION

Maintaining a medically or surgically induced remission of disease is one of the most important but yet most difficult therapeutic goals in the treatment of CD. Maintenance therapy in CD is characterized as treatment with only a few available drugs, moderately high rates of efficacy and frequent side effects. In total, 40%-70% of CD patients will experience a symptomatic relapse in 1 year after a medically or surgically induced remission^[8,9]. Silverstein and colleagues reported that a surgically induced remission lasts a mean of 766 d whereas a non-surgically induced remission lasts only 120 d indicating that a surgically induced remission is more stable^[39]. It was frequently recommended that the indication for a relapse-preventing therapy should be based on the prospective risk of an individual patient to relapse. Although the estimation of risk for relapse, based on the phenotype or genotype, is still controversial, single well known risk factors like smoking, frequent relapses in the past, a chronic active disease *etc.* have been described. To stop smoking is a very important therapeutic goal^[2,40]. Systemic corticosteroids should not be used for maintaining remission due to lack of efficacy and severe long-term side effects. Since randomized, placebo-controlled trials suggest a different approach in medically or surgically induced remissions, we will handle them separately.

Medically induced remission

5-ASA: Numerous randomized, placebo-controlled studies, including four meta-analyses, have attempted to establish a role for 5-ASA in the maintenance of remission. Different study regimens and durations were performed and a substantial number of trials included only small numbers of patients. The two most recent meta-analyses failed to show a benefit for mesalamine over placebo in the maintenance of medically induced remission^[41,42]. However, the preferable side effect profile of 5-ASA, especially mesalamine compared to azathioprine/6-mercaptopurine or methotrexate, is probably the reason why mesalamine is still used frequently to maintain a medically-induced remission. Many clinicians therefore try to maintain remission with mesalamine at least one time, especially in young women of childbearing potential. In addition many patients are in favour of trying a rather harmless drug at first for long-term therapy.

Azathioprine/6-Mercaptopurine: Azathioprine/6-mercaptopurine is the treatment of choice for patients with high risk of relapse. The effectiveness of azathioprine has been described in a recent meta-analysis including five randomized, placebo-controlled trials. In addition, a steroid-sparing effect was observed^[43]. No clear direction has been given as to when to start the treatment with azathioprine/6-mercaptopurine. The following indications are most

commonly accepted: frequent flares (more than two per year), chronically active disease, and steroid dependence (e.g. if two attempts of tapering steroids have failed). The thiopurines are slow acting drugs and an effect is usually observed after 2-3 mo with approximately 90% of patients responding within the first 4 mo^[17].

An earlier open study suggested that azathioprine is no longer effective after 3.5 years^[44]. In contrast, the same group reported, in a very recent placebo-controlled trial, that azathioprine is still effective with prolonged use^[45]. However, a small increase in the frequency of malignancy, especially lymphoma, cannot be excluded in the long term treatment with azathioprine/6-mercaptopurine^[46,47]. This must be weighed against the improved quality of life due to both drugs for patients with CD.

Methotrexate: The potential of methotrexate to induce remission was investigated in a study by Feagan and colleagues. Herein the patients who had achieved remission after weekly 25 mg intramuscularly were randomized to 15 mg methotrexate or placebo. Methotrexate was found to be significantly better than placebo in maintaining remission^[26]. However, side effects were more significant than placebo. Methotrexate has not been studied in surgically or medically induced remission by other drugs (e.g. corticosteroids). In summary, methotrexate is suggested to be the alternative to azathioprine/6-mercaptopurine in the maintenance of remission. It has also shown to have steroid-sparing properties with the mean time to respond at about 2 mo.

Budesonide: Lower doses of budesonide (3 or 6 mg) have also been studied for their potential to be effective in the maintenance of remission. Although earlier meta-analyses have not shown that budesonide was superior over placebo^[16,48], a recent randomized, placebo-controlled trial found a trend towards a longer quiescent disease in budesonide treated patients compared to placebo^[49]. In this trial, no significant difference in total adverse events or corticosteroid-associated events was demonstrated between placebo and budesonide. In addition, a very recent paper by Sandborn and colleagues combined the data of four double-blind, placebo-controlled trials with identical protocols analyzing the efficacy of 6 mg budesonide. Budesonide was shown to be effective for prolonging the time to relapse and for significantly reducing the rates of relapse at 3 and 6 mo but not at 12 mo. Herein no difference in the frequency of adverse events and glucocorticosteroid associated side effects between budesonide and placebo was found^[50]. Thus, the current data suggest that budesonide at a dosage of 6 mg seems to have the effect of prolonging remission in CD in terminal ileal or right colonic disease. Budesonide might thus offer a potential alternative in the maintenance of a medically-induced remission, especially in steroid-dependent patients.

Infliximab: Two studies have shown that infliximab is effective in maintaining remission in CD^[51,52]. In the Accent I trial, infliximab was shown to be superior over placebo in the maintenance of remission in CD patients that responded to one single infusion of infliximab. Herein, about 20% of patients in remission after the first infusion of infliximab were maintained in remission for one year with repeated infusions every eight weeks^[52]. Infliximab

was also shown to have steroid-sparing properties. Repeated infusions of infliximab should thus be considered for chronically active or steroid-dependent patients where standard immunosuppressants are not effective or where surgical interventions are not considered. However, repeated infusions of infliximab are costly and data on long-term safety, including the occurrence of malignancies, are limited. Infliximab has been shown to lead to mucosal healing, which was associated with reduced surgical interventions and lower hospitalization rates^[53]. However, at this time it is debated whether mucosal healing is an important goal in CD therapy. Further studies are warranted regarding this matter. The development of antibodies against infliximab is frequently found and is associated with reduced efficacy and increased numbers of infusion reactions. The concomitant use of immunosuppressants has been shown to reduce the incidence of antibody formation^[54].

Summary: Maintenance after medically induced remission

After a medically-induced remission, maintenance therapy should be initiated based on the individual situation. No medical therapy may be considered in patients with low risk of relapse. However, in patients with high risk for relapse (frequent relapses, colonic involvement and severe disease behaviour), therapy with azathioprine or 6-mercaptopurine should be initiated. In patients with terminal ileal or right colonic disease, low-dose budesonide might offer an alternative especially in steroid-dependent patients. In patients who are not responding or are intolerant to azathioprine/6-mercaptopurine, therapy with methotrexate may be used. If not successful, patients should be considered for maintenance treatment with infliximab.

Postoperative CD (surgically-induced remission)

About 75% of CD patients will require surgery within the first 20 years after the onset of symptoms^[55,56]. In addition, recurrence rates after surgical resection are high: after the first resection, up to 80% of patients show an endoscopic recurrence within the first year although most patients are not symptomatic^[55-57]. Furthermore, up to 20% have clinical symptoms and 5% require another surgical intervention within the first year. After 5 years, about 50% of patients have a clinical relapse. Systemic corticosteroids and budesonide are not effective in preventing postoperative relapse^[58-61], whereas methotrexate, ciprofloxacin and infliximab have not been studied for this indication. Various risk factors for postoperative recurrence have been described but most of these risk factors have not been studied in a prospective manner. Currently smoking is the most consistently described risk factor for postoperative relapse^[40,62]. In addition, Rutgeerts and colleagues showed that preoperative disease activity and endoscopic lesions at the neoterminal ileum within the first year after surgery are also associated with higher risk for postoperative recurrence^[57]. In addition, a recent study suggested that CD patients with CARD15 mutations have a higher risk of postoperative relapse compared to patients without mutated CARD15. Thus genotyping for CARD15 mutations might offer a potential alternative to identify patients with high risk of postoperative relapse^[63]. Further

studies are warranted to consider this approach.

5-ASA: As opposed to the controversial discussion about the efficacy of 5-ASA in the treatment of CD, the results on the prevention of postoperative recurrence are quite solid. Camma and colleagues described in a meta-analysis a risk reduction of 13.1% by mesalamine treatment compared to placebo^[41]. A more recent placebo-controlled trial reported that mesalamine did not significantly affect the postoperative course of CD, but some relapse-preventing effect was found in patients with isolated small bowel disease^[64]. In summary, 5 ASA is the only treatment with an evidence-based relapse preventing effect after a surgically induced remission and is therefore recommended according to recent guidelines^[65].

Azathioprine/6-Mercaptopurine: The two largest studies regarding the effect of azathioprine/6-mercaptopurine to prevent postoperative recurrence were recently published. In the first trial, Hanauer and colleagues compared 6-mercaptopurine at the low fixed dose of 50 mg/d to mesalamine 3 g/d and placebo after ileocolic resection^[66]. There was a significant benefit of 6-mercaptopurine compared to placebo in preventing clinical and endoscopic recurrence over two years. However, this study has been criticized since it was underpowered and also had a high drop-out rate of patients. Ardizzone and colleagues observed no benefit of azathioprine at standard dosing (2 mg/kg) in preventing clinical relapse after two years in comparison to mesalamine^[67]. In summary, although none of these studies offer robust data to support the use of azathioprine/6-mercaptopurine in the prevention of postoperative recurrence, many clinicians use these drugs for this indication.

Antibiotics: In a randomized, placebo-controlled trial a significant decrease was observed in the incidence of severe endoscopic recurrence with metronidazole treatment as compared to placebo after ileal resection^[68]. In addition, metronidazole therapy statistically reduced the clinical recurrence rates at 1 year. Metronidazole is still only rarely used on this occasion since long term intake is not tolerated by most patients due to side effects such as metallic taste, nausea and peripheral neuropathy. Ciprofloxacin has not been studied in a randomized, placebo-controlled trial regarding the prevention of postoperative recurrence. Rifaximin, which is a non-absorbable drug with good tolerability covering most Gram-positive and Gram-negative bacteria, might offer a very promising alternative since long term application is tolerated much better^[69]. At the moment, although frequently used in clinical practice, none of these antibiotics will be considered standard therapy until more controlled trials provide clear results.

Rutgeerts and colleagues investigated the efficacy of ornidazole, a nitroimidazole antibiotic, for the prevention of clinical recurrence after curative ileocolonic resection in a recent placebo-controlled trial. They found that ornidazole significantly reduced the clinical and endoscopic recurrence rate at 1 year compared to placebo. However, significantly more patients in the ornidazole group dropped out of the study because of side effects. In summary, these data indicate that ornidazole might offer a therapeutic alternative in preventing postoperative recurrence^[70].

Summary: Treatment of postoperative CD

No standard treatment algorithm prevents postoperative relapse. Despite the controversial discussion on its efficacy, mesalamine over a period of two years is recommended as the treatment of choice in the prevention of postoperative relapse. However, many patients who undergo surgical resection have already been treated with mesalamine so that alternative regimes should be initiated. Although robust data are lacking, most clinicians use azathioprine/6-mercaptopurine at standard dosing in patients with higher risk of postoperative relapse. To estimate the risk of clinical relapse the diagnosis of endoscopic lesions at the anastomosis 6 mo after resection may be used. Azathioprine/6-mercaptopurine may be started if severe or moderate lesions at the anastomosis are found^[71]. Although this regime has never been studied in a randomized trial, it seems to be a reasonable approach. Antibiotics, such as metronidazole or ornidazole, might offer a potential alternative although the long term use is limited due to side effects. In addition, prospective studies investigating infliximab in this setting are warranted.

COMPLICATIONS IN CD**Fistulizing disease behaviour**

The treatment of fistulizing CD remains probably the most difficult clinical challenge. Treatment is complicated since very few drugs have proven efficacy whereas most agents used in CD therapy (5-ASA, systemic corticosteroids, budesonide) are ineffective. Fistulae are reported to occur in up to 50% of patients after 20 years of disease^[72]. Especially enterocutaneous and enterovaginal fistulae have a severe impact on the quality of life of CD patients. Enterovesical fistulae require surgical intervention due the potential development of an urosepsis. Perianal fistulae are the most common form and are often complicated by an abscess where surgical drainage must be performed. Since complete long term closure of fistulae cannot be achieved in many patients with the available therapies, reduction of fistula drainage and closure of part of the fistulae have been accepted therapeutic goals. Apart from medical treatment approaches as discussed below, surgical interventions such as fistulotomy and insertion of non-cutting setons should be part of the management. A close cooperation between the gastroenterologist and the surgeon is required.

Azathioprine/6-Mercaptopurine: Robust data summarized in the meta-analysis by Pearson^[19] show a positive effect of azathioprine/6-mercaptopurine on fistula closure with an odds ratio of 4.44 (CI 1.50-13.20). Thus azathioprine/6-mercaptopurine is the basis of long-term treatment of fistulae.

Methotrexate: No randomized trial has been performed using methotrexate to investigate the healing of fistulae. However, retrospective data showed complete or partial response in 56% (9/16) of patients^[73]. Methotrexate might thus be considered as the alternative agent to azathioprine/6-mercaptopurine.

Antibiotics: A small uncontrolled study reported a clinical response to metronidazole in 20 out of 21 patients and complete healing after maintenance treatment in 10 out of

18 patients. A follow-up study demonstrated that dosage reduction was associated with exacerbation of fistulae in all patients and healing was again achieved if the drug was reintroduced^[74]. Ciprofloxacin alone showed an improvement in 7 out of 10 patients treated with up to 1.5 g over three months^[75]. Although controlled clinical trials are lacking, the combination of metronidazole and ciprofloxacin is often initiated.

Infliximab: Infliximab offers robust data from randomized, placebo-controlled trials in the treatment of enterocutaneous fistulae. In the first trial by Present and colleagues, three infusions of infliximab at 0, 2, and 6 wk resulted in complete healing of enterocutaneous fistulae in 55% of patients compared to 13% in the placebo group^[76]. Data from the ACCENT 2 trial showed that infliximab maintained healing of enterocutaneous fistulae in 36% patients who responded to the initial three infliximab infusions^[77]. However, it was shown that healing of fistulae needed repeated infusions, which is similar to the experiences observed in a clinical routine. In summary, data from controlled clinical trials suggest that infliximab might be the most potent drug in the treatment of CD fistulae. Three infusions with a dose of 5 mg/kg at wk 0, 2, and 6 are recommended as standard for the treatment of fistulizing CD.

Cyclosporin A: Cyclosporin A offers an effective alternative treatment for CD fistulae. There are numerous uncontrolled trials that describe a mean initial response in 83% of patients with discontinuation of treatment leading to frequent relapses (reviewed in ref. [78]). However, cyclosporin A toxicity can be dramatic, including renal failure, and thus application should be performed only in centers with expertise. Continuous infusions of 4 mg/kg per day is required and concentrations of 300-400 ng/mL should be maintained^[78]. Dosing can be switched to oral if patients respond to intravenous cyclosporin.

Tacrolimus: A recent placebo-controlled trial showed that tacrolimus at a dose of 0.2 mg/kg was more effective than placebo in improvement of fistulae (defined as closure of $\geq 50\%$ of draining fistulas). However, no difference was observed with respect to fistula remission as defined by closure of all fistulas and maintenance of that closure for at least 4 wk. In addition, adverse events such as headache, increased serum creatinine levels, and insomnia were found significantly more often in the tacrolimus group^[79].

Summary: Treatment of fistulizing CD

No standardized treatment algorithm exists in the medical treatment of fistulizing CD. Importantly, effective management requires good collaboration between the gastroenterologist and the surgeon in both simple and complex fistulae. Azathioprine/6-mercaptopurine are the basis of fistulae treatment. Antibiotic combination therapy, preferable with metronidazole and ciprofloxacin, can be considered over a period of 2-3 mo especially if an abscess might be suspected to occur. In patients with complex fistulae including underlying rectal inflammation not improving from above mentioned strategies, a three dose therapy regimen with infliximab should be applied. If patients respond, therapy with azathioprine and infliximab might be necessary to maintain fistula healing. In refractory cases, therapy

with cyclosporine and tacrolimus should be considered.

Chronic active disease

Various definitions of chronic active disease exist and thus results from clinical trials in this complicated group of patients are rather difficult to interpret. The German consensus conference on the treatment of CD describes chronic active disease as the persisting or recurrent occurrence of symptoms over more than 6 mo despite standardized therapy^[65]. Patients with chronic active disease should thus be treated first with azathioprine/6-mercaptopurine or alternatively with methotrexate. If patients do not respond or are intolerant to these approaches, infliximab should be given. Due to severe long-term side effects, systemic corticosteroids should be avoided. 5-ASA is not effective in chronically active CD.

Steroid-dependent disease

Steroid-dependency is a frequently observed phenomenon in CD and it is defined as the need for corticosteroids to maintain a patient in stable remission after two unsuccessful attempts to withdraw steroids within the last six months. About 28%-44% of patients will become steroid-dependent after an initial course of corticosteroids^[80,81]. Long term use of corticosteroids should be avoided due to severe side effects such as osteoporosis, diabetes and hypertension. Prophylaxis of osteoporosis with calcium and vitamin D should be applied. Similar to patients with chronic active disease, azathioprine/6-mercaptopurine is the treatment of choice and methotrexate is the alternative agent to avoid long term steroid therapy. Two meta-analyses reported a steroid-sparing effect for azathioprine^[20,43] and the same properties were observed for methotrexate^[26]. In addition, infliximab has also been shown to have steroid-sparing properties and thus should also be considered as an alternative^[52].

Steroid-refractory disease

Patients with persisting clinical activity under continuing therapy with corticosteroids at a dose greater than 1 mg/kg per day are described as steroid-refractory. This clinical situation occurs in about 20%-30% of patients treated with corticosteroids^[8,9,80]. Only a few drugs have been tested in this situation: azathioprine/6-mercaptopurine and methotrexate have shown to be effective in steroid-refractory patients^[20,26,43]. In addition, infliximab offers a therapeutic alternative^[52]. However, if medical therapy fails in severe cases, surgical interventions such as colectomy might be necessary.

Gastroduodenal CD

Symptomatic involvement of stomach and duodenum is a rare phenomenon observed in about 4%-5.5% of patients^[82,83]. Endoscopic and histologic involvement might be found in up to 40% of patients^[84-86]. Due to the low frequency of patients with symptomatic gastroduodenal involvement, however, randomized, placebo-controlled trials are not available. Combination therapy with high dose acid suppression (proton pump inhibitors) and standard therapy of CD are usually used. Corticosteroids^[87], azathioprine^[88,89], and infliximab^[90] have been reported to

be effective in selected patients. However, many patients with obstructive symptoms caused by strictures will have to undergo surgical interventions such as gastroduodenal or gastrojejunal bypass, even performed laparoscopically. Gastroduodenal bypass has been reported to result in a good outcome in up to 87% of patients^[91].

Fibrostenotic disease behaviour

CD is often complicated by fibrostenotic strictures that can be located within the whole gastrointestinal tract. Strictures can remain clinically asymptomatic over years until the intraluminal caliber causes obstruction. However, it is often difficult to differentiate between an inflammatory or fibrostenotic stricture. Ultrasound and MRI with the possibility to visualize mucosal blood flow are helpful in differential diagnosis. Before initiating surgical interventions, many clinicians try at least one attempt of medical treatment for strictures suggested to have an inflammatory component. Corticosteroids are most commonly used in this clinical situation. Fibrostenotic strictures will not respond to medical therapy. Endoscopic balloon dilatations, stricturoplasty or resections are required in most cases.

ROLE OF NUTRITION IN CD

Prevention and treatment of malnutrition

During an acute flare of CD, undernutrition with weight loss, protein deficiency and specific deficiencies in vitamins, minerals and trace elements are commonly found. Malnutrition is mainly caused by anorexia, increased intestinal losses and systemic inflammation. In children and adolescents a decrease in growth velocity may occur, secondary to inadequate nutrition and steroid therapy. The relevance and extent of these deficiencies vary according to the site and extent of the diseased intestine as well as disease activity. In active CD, an improvement in nutritional status cannot be achieved by nutritional counselling alone but oral nutritional supplements or tube feeding leads to improvement of the nutritional status^[92,93]. Both malnutrition and growth retardation require enteral nutrition (EN).

The use of oral nutritional supplements or tube feeding should also be taken into account in the perioperative setting. An increased frequency of postoperative complications has been shown in undernourished patients with CD^[94], with undernutrition being defined as weight loss and/or plasma albumin levels below 35 g/L. Although specific data concerning the effect of perioperative nutrition in CD are lacking, there is a considerable body of evidence on the effect of perioperative nutrition in general gastrointestinal surgery and preoperative nutritional support is therefore recommended in malnourished patients^[95]. A prospective study showed that a preoperative oral supplementation with a formula enriched with arginine, omega-3 fatty acids, and RNA was associated with reduced postoperative infections and shorter lengths of hospital stay^[96]. Supplementation of specific deficiencies may be crucial. Iron deficiency is most common and should be treated with oral or i.v. iron supplements. Vitamin D and calcium should be supplemented in patients

on steroid therapy and patients treated with sulfasalazine are at risk to develop Vitamin B12 deficits.

Treatment of active disease

EN is also effective in the treatment of an acute flare in CD with approximately 60% of all patients reaching remission. In children, active disease frequently leads to growth retardation and enteral nutrition is therefore the treatment of choice. In adults, however, treatment with corticosteroids is more effective as shown by a recent meta-analysis^[97]. Enteral nutrition as sole therapy for acute CD is indicated mainly when treatment with corticosteroids is not feasible; e.g. due to intolerance or refusal. Combined therapy (enteral nutrition and drugs) is indicated in undernourished patients as well as in those with inflammatory stenosis of the intestine. If active CD is treated with systemic corticosteroids in combination with EN and supplementary EN is continued after the active phase, it prolongs the relapse free interval^[98].

Total parenteral nutrition is no better than enteral nutrition in the therapy of active CD and should therefore be restricted to patients with a contraindication to or intolerance of enteral nutrition^[99]. EN in subileus and high grade stenosis does require special caution. A documented stenosis however is not a contraindication to EN *per se*^[100].

EXTRAINTESTINAL MANIFESTATIONS

CD is much more than a bowel disease since it can affect almost every other organ of the body. We will describe only briefly the most common extraintestinal manifestations (EIMs) and the recommended therapeutic approaches. The treatment of most extraintestinal manifestations has not arisen from randomized clinical trials but more from experiences and case reports and thus remains often nonempirical. With respect to all EIMs, a collaboration with rheumatologists, dermatologists and especially ophthalmologists should be part of the therapeutic regimen. The basis of treatment of EIMs is to obtain remission since it will positively affect the course of the particular extraintestinal manifestation, especially if symptoms occur parallel to exacerbation of the disease.

Arthritis

Joint involvement is the most frequently found extraintestinal manifestation in CD, which can be separated into axial and peripheral involvement. Peripheral involvement can be subdivided into a pauciarticular, large joint arthropathy, and a bilateral symmetrical polyarthropathy^[101]. Axial involvement can result in sacroiliitis or ankylosing spondylitis. Placebo-controlled trials have shown that sulfasalazine is effective in the treatment of ankylosing spondylitis^[102,103]. Furthermore physiotherapy is important. A low dose of corticosteroids (usually no more than 10 mg/d) can be a therapeutic option. Nonsteroidal anti-inflammatory drugs (NSAIDs) and COX-II-inhibitors might lead to pain relief but should be avoided since they might exacerbate CD. Many patients need analgetics to control symptoms. The use of tramadol or metamizol is preferable. Due to the experiences with rheumatoid arthritis, methotrexate might be offered as an

alternative. In the same respect, infliximab has shown to be very effective^[104,105].

Erythema nodosum, pyoderma gangrenosum, ocular involvement, PSC

Erythema nodosum is the most common skin manifestation in conjunction with active CD and usually responds to therapy with corticosteroids. Severe or refractory cases have been shown to respond to infliximab^[106]. In pyoderma gangrenosum, corticosteroids are the treatment of choice, even applied by the intravenous route in refractory cases. Topical therapy should be considered as an adjuvant to systemic therapy. However, a recent study reported healing of pyoderma gangrenosum after infliximab treatment in all 13 patients^[107]. These results suggest that infliximab might be considered as the treatment of choice for pyoderma gangrenosum, especially in refractory cases. An ocular manifestation such as iridocyclitis or anterior uveitis should be treated with topical steroids and cycloplegics. A case with improvement of uveitis after infliximab treatment was recently reported^[108]. Considering primary sclerosing cholangitis (PSC), although more frequently seen in ulcerative colitis, an earlier study showed that ursodeoxycholic acid (UDCA) at a dose of 10-15 mg/d can result in significant liver enzyme improvement^[109]. However, a recent 5-year, placebo-controlled trial of high-dose UDCA (17-23 mg/d) failed to show benefit for UDCA on survival or the prevention of cholangiocarcinoma in PSC^[110]. Taking all published studies into consideration, Olsson and colleagues conclude that there is, if at all, only a very limited effect of UDCA in PSC. PSC is associated with the occurrence of cholangiocarcinoma where liver transplantation seems to be the only curative approach.

CONCLUSION

Based on the currently available data from randomized, placebo-controlled trials, including meta-analyses, we describe the conventional treatment of Crohn's disease. This conventional approach suggests a step-up approach usually in the order of 5-ASA, corticosteroids, immunosuppressants and usually infliximab in refractory or severe cases including fistulizing disease behaviour. In contrast, a more aggressive form of treatment (bottom-down) has been recently proposed. This regimen starts out early at diagnosis of CD with the combination of biologicals (infliximab) in combination with immunosuppressants (azathioprine). Studies are warranted to elucidate the role of this new therapeutic approach in comparison to the standard therapy algorithms. Furthermore the value of mucosal healing and its effect on the course of CD, including its potential to reduce complications, surgical interventions and hospitalisation rates, should be evaluated in upcoming studies.

The past years have resulted in enormous new insights into the pathophysiology of CD with respect to molecular genetics, mucosal bacteria and immunology. Now it is time to translate these findings into newer therapeutic concepts. Numerous agents, especially biologicals, have been tested but most of them have not been introduced

into the market due to low efficacy or severe side effects. Apart from infliximab, other TNF α -antagonists, such as adalimumab or CDP870, might offer a potent alternative in the future. However, apart from evidence-based medicine, CD therapy will always be an individualized therapy. In addition, many patients construct their own therapeutic regimen, especially after long term disease. Such approaches might be effective in individual situations, although they do often not stand the criteria of evidence-based medicine. Moreover, many clinical situations are complex and might never have been studied in randomized, placebo-controlled trials. Therefore, the treatment of CD frequently requires individual decisions and creativity despite a very good basis of evidence-based therapies.

Abstract

Theories explaining the etiopathogenesis of inflammatory bowel disease (IBD) have been proposed ever since Crohn's disease (CD) and ulcerative colitis (UC) were recognized as the two major forms of the disease. Although the exact cause(s) and mechanisms of tissue damage in CD and UC have yet to be completely understood, enough progress has occurred to accept the following hypothesis as valid: IBD is an inappropriate immune response that occurs in genetically susceptible individuals as the result of a complex interaction among environmental factors, microbial factors, and the intestinal immune system. Among an almost endless list of environmental factors, smoking has been identified as a risk factor for CD and a protective factor for UC. Among microbial factors, no convincing evidence indicates that classical infectious agents cause IBD, while mounting evidence points to an abnormal immune response against the normal enteric flora as being of central importance. Gut inflammation is mediated by cells of the innate as well as adaptive immune systems, with the additional contribution of non-immune cells, such as epithelial, mesenchymal and endothelial cells, and platelets.

<http://www.wjgnet.com/1007-9327/12/4807.asp>

INTRODUCTION

It is fair to state most disease entities that still pose major clinical and therapeutic challenges are ones where the exact etiology remains obscure and the mechanisms of tissue injury appear to be exceedingly complex. This certainly seems to be the case for the two main forms of inflammatory bowel disease (IBD); i.e., Crohn's disease (CD) and ulcerative colitis (UC). It is now clear that CD and UC represent two distinct forms of chronic inflammation of the gastrointestinal tract and, as such, have different causes and different pathogenic mechanisms. Still, the factors underlying the appearance of both CD and UC are roughly the same, and include a temporal association with progressive changes in the environment, an intrinsic genetic predisposition, the existence of a rich enteric flora, and an abnormal immune reactivity which is ultimately responsible for damaging the gut and causing clinical manifestations. Even though the categories of underlying factors are roughly the same, there are variations in each category as well as differences in how the underlying factors interact. The end result is two related but distinct disorders named CD and UC. In this review, differences and similarities of the etiopathogenic factors in each form of IBD will be briefly illustrated and discussed.

ENVIRONMENTAL AND GENETIC FACTORS

A remarkable change in the types of diseases affecting humans has occurred during the last century, most remarkably so in the Western world. The most common illnesses responsible for morbidity and mortality have shifted from infectious to chronic inflammatory and neoplastic diseases. This shift has been best documented in Western countries^[1], but the same phenomenon is now occurring in other parts of the world. The emergence of chronic autoimmune and inflammatory diseases, including IBD, throughout the world is closely linked to social and economical progress. This was initially noted in Northern Europe and North America but, after the Second World War, the same phenomenon occurred in the rest of Europe, Japan and South America. Most recently, the emergence of IBD is also being observed in the Asian Pacific Region^[2].

The "hygiene hypothesis" has been proposed as the probable underlying reason for the switch from infectious to chronic inflammatory diseases, and it postulates that there has been a fundamental lifestyle change from one with high microbial exposure to one with low microbial

exposure^[3]. A relative lack of microbial antigens early in life would lead to a less educated and weaker immune system, not equipped to properly handle new challenges later on in life and generating an ineffective immune response that is prolonged because it is powerless to eliminate the offending agent.

There are innumerable environmental modifications that can be ascribed to the hygiene hypothesis, including better housing, safer food and water, improved hygiene and sanitation, vaccines, the widespread use of antibiotics, lack of parasites, fewer infections, and better but selective nutrition. While contributing to the progressive decline of infectious diseases, at the same time these changes may have contributed to create a surge in allergic and autoimmune diseases^[4]. A variety of environmental factors are considered risk factors for IBD, including smoking, diet, drugs, geography and social status, stress, the enteric flora, altered intestinal permeability and appendectomy^[5]. Among them, cigarette smoking is the strongest example of the influence of the environment on IBD. Remarkably, smoking has a completely opposite effect on CD compared to UC, indicating that distinct pathogenic mechanisms underlie each form of IBD^[6]. Smoking is a recognized risk factor for CD, increasing the frequency of disease relapse and need for surgery, and its discontinuation improves the disease course^[7]. Cessation of smoking, however, increases the risk of UC, suggesting a protective role in this form of IBD^[8]. Other environmental agents associated with IBD are oral contraceptives and nonsteroidal anti-inflammatory drugs (NSAIDs). These agents have also been investigated as having a cause-and-effect relationship with CD or UC. A direct causal relationship has not been found, but women taking oral contraceptives have twice the risk of developing CD than those not taking contraceptives^[9]. In the case of NSAIDs there is a clear association with IBD, and patients in clinical remission have a higher risk of relapse if they use NSAIDs^[10].

Although the epidemiological evidence linking environmental factors to IBD is fairly solid, it is widely believed that no environmental factor alone can directly cause CD or UC, and an intrinsic disease predisposition must also be present. Such predisposition depends on genetic susceptibility, and a number of established or potential susceptibility genetic loci have been identified in IBD. This topic will be discussed in greater depth in another chapter of this issue of World Journal of Gastroenterology.

MICROBIAL FACTORS

Pathogens

It is possible that classical infectious agents are the cause of IBD, but current evidence supporting this hypothesis is rather weak. Over the years, several microorganisms, such as *Listeria monocytogenes*, *Chlamydia trachomatis*, *Escherichia coli*, *Cytomegalovirus*, *Saccharomyces cerevisiae*, as well as others, have been proposed as having an etiologic role. In particular, *Mycobacterium paratuberculosis* as the agent of CD has received and continues to receive considerable attention. This bacterium is the cause of Johne's disease, a chronic granulomatous ileitis in ruminants that closely resembles

CD. *M. paratuberculosis* was initially isolated from a few CD tissues^[11], but follow up studies trying to confirm its presence by histological examination, attempts to culture it from tissue homogenates, search for its genome in intestinal tissues with highly specific probes, and assessment of serum antibodies have all yielded conflicting or inconclusive results. Moreover, controlled trials have failed to show a beneficial effect of antituberculous therapy in CD patients^[12]. One of the last bacteria to be linked to CD is an adherent-invasive strain of *E. coli* which is specifically associated with ileal CD^[13], but its potential etiologic role, if any, remains unclear.

The finding of paramyxovirus-like particles in CD endothelial granulomas led to the suggestion that CD could be a form of chronic vasculitis caused by the persistence of the measles virus in the mucosa^[14]. Based on epidemiological and serologic data, an association between perinatal measles and an increased probability to develop CD was hypothesized^[15], but subsequent studies failed to confirm this association. Importantly, the overall decline of measles infection accompanied by the concomitant rise of CD during the last few decades speaks against an etiologic role of measles in CD.

Commensal bacteria

In contrast to the dwindling evidence that CD or UC are infectious diseases, evidence continues to mount that the indigenous commensal flora of the gut is the target of the immune response in IBD^[16]. A large body of data from animal models of IBD indicates that the normal enteric flora is needed to develop experimental colitis. In fact, gut inflammation only arises in animals kept in a conventional but not a germ-free environment^[17], supposedly because an immune response directed against enteric bacteria is essential to disease pathogenesis^[18]. Thus, the paradigm "no bacteria, no colitis" was created to underscore the central role of the intestinal microbiota in IBD pathogenesis. This paradigm is supported by a variety of clinical observations in IBD patients. There is an increased number of bacteria in close contact with the mucosa in IBD patients^[19]; IBD lesions occur preferentially in segments with the highest concentrations of bacteria (the ileo-cecal valve and the colon); surgical diversion of the fecal stream prevents reappearance of CD whereas restoration of the fecal flow induces disease recurrence^[20]; modulation of the enteric flora with antibiotics and probiotics attenuates inflammation. In addition, pouchitis develops in a considerable proportion of UC patients, and is associated with a dysbiosis caused by the contact of the once near sterile small bowel mucosa with a rich colon-like flora repopulating the pouch soon after proctocolectomy^[21].

Finally, most IBD patients show an enhanced systemic and mucosal immunological reactivity against gut bacterial antigens. Among these, based on serum antibody titers, bacterial flagellin has been recently reported as a dominant antigen in CD^[22], apparently defining a population of patients with complicated CD^[23]. It has been proposed that this immune reactivity is the consequence of a 'loss of tolerance' towards the autologous enteric flora, resulting in an inappropriate immune response in the mucosa which is manifested by the chronic inflammatory process typical

of CD and UC^[24]. Under normal circumstances there is an intimate interaction between commensal intestinal bacteria and the immune system^[25], and this complex crosstalk is under the control of immune tolerance^[26]. Why tolerance is lost and an abnormal response to otherwise normal gut bacteria develops in IBD is still not entirely clear. However, the recent discovery that CD is genetically associated with mutations of the NOD2/CARD15 gene, whose product is a bacteria-recognizing cytoplasmic protein, points to defective mechanisms of bacterial sensing as the link between the gut flora and the altered immune response found in IBD^[27].

CELLULAR FACTORS

The most common type of reaction that the body mounts against external or internal offending agents is inflammation. The gut is particularly susceptible to inflammation as indicated by the fact that, and even under normal circumstances, there is a baseline degree of “physiological inflammation” in the mucosa. This is caused by a tightly controlled immune response directed at an enormous array of dietary and microbial antigens, and it is translated by the presence of an abundant number of leukocytes in the lamina propria^[28]. The ultimate goal of an effective inflammatory response is to eliminate the offending agent(s) and then disappear once the cause of inflammation has been eradicated. If inflammation persists and becomes chronic, it represents an inappropriate response that almost invariably leads to lingering injurious effects resulting in anatomical and functional abnormalities. Both CD and UC are typical chronic inflammatory processes of the gut which, by definition, are due to abnormalities of the intestinal immune system. Fortunately, major advances have occurred during the past three decades in our understanding of the cellular and molecular mechanisms mediating mucosal immunity and the alterations that lead to chronic gut inflammation^[29].

Adaptive immunity

Abnormalities of intestinal immunity in IBD began to be described several decades ago in regard to the main effector cells of adaptive immunity; e.g., T- and B-cells. Initially, it was discovered that the production of antibodies, particularly IgG antibodies, in the systemic as well as mucosal compartments was drastically increased and that the relative proportions of immunoglobulin classes and subclasses were altered as a consequence of chronic gut inflammation^[30-32]. In parallel with these studies, the possibility that some of these antibodies were true autoantibodies directed at self-components of the gut began to be explored. A series of studies suggested that IgG1 antibodies against a structural protein of colonocytes were selectively produced in UC, but not in CD, and could underlie the pathogenesis of this condition^[33]. Until now, however, definitive proof for the existence of classical, tissue injury-inducing autoantibodies in UC is still missing. With the recognition of T-cells as central effector cells and their soluble mediators as key modulators of immunity, the focus of immune investigation in IBD shifted to T helper (Th) cell subsets and the soluble mediators they

produce. A large number of cytokine abnormalities have been described, including pro-inflammatory and immunoregulatory molecules^[34]. In CD, intestinal CD4+ T cells produce large amounts of INF- γ and display marked overexpression of the Th1-cell-specific transcription factor, T-bet^[35], while mucosal macrophages produce large amounts of IL-12 and IL-18^[36,37]. Additionally, CD mucosal T-cells are resistant to apoptosis and cycle faster than control cells^[38,39]. In contrast, in UC nonclassical CD1d-restricted NK T-cells produce increased amounts of IL-13, and mucosal T-cells produce more IL-5, cycle slower and die more than control cells^[39-41]. Based on these observations, it is now generally accepted that the two main forms of IBD are associated with distinct immune profiles which are classified as a fairly typical Th1 response in CD and an atypical Th2 response in UC.

More recently, the study of adaptive immune abnormalities in IBD has been focusing on possible defects of immunoregulation. Different types of immunoregulatory cells exist, the best defined being CD4 + CD25 high T-cells, which are critically important in preventing autoimmunity and suppressing excessive immune reactivity^[42]. In IBD there is a contraction of this regulatory cell pool in the blood and only a moderate expansion in the inflamed intestine, suggesting the presence of insufficient regulation during active disease^[43].

Innate immunity

With the discovery of an association of a group of CD patients (those with small bowel and stricturing disease) with mutations of the NOD2/CARD15 gene, whose product is found in cells mediating innate immunity (primarily macrophages and dendritic cells) and recognizes the bacteria-derived component muramyl dipetide (MDP)^[44,45], a surge of interest in the role of innate immunity in IBD has occurred. Dendritic cells are scarce in the gut mucosa, but form a heterogeneous population of potent antigen-presenting cells pivotal to the balance between tolerance and active immunity and controlling the type of response - inflammatory or not - that follows detection of commensal bacteria^[46]. In IBD, mucosal dendritic cells are activated, express increased levels of the toll-like receptors (TLR) 2 and TLR4- which mediate recognition of bacterial products - and CD40, and produce more IL-12 and IL-6^[47]. All of these phenotypic and functional features indicate a prominent role of dendritic cells in IBD pathogenesis. Epithelial cells are also involved in innate immunity. Interestingly, ileal Paneth cells also express the NOD2 protein, and their production of mucosal α -defensins is decreased in CD patients with NOD2 mutations, perhaps leading to an impaired resistance against enteric microorganisms and eventually contributing to bacteria-induced inflammation^[48].

Another crucial component of innate immunity is the TLRs, cell surface molecules that detect microbial infection and trigger antimicrobial host defense responses^[49]. TLRs are abundantly expressed on the surface of monocytes, macrophages, and dendritic and epithelial cells and, in addition to recognizing pathogenic microorganisms, are essential to identify the commensal microflora and maintain intestinal homeostasis^[50]. Alterations of TLR3 and

TLR4 expression by intestinal epithelial cells have been described in IBD, suggesting the possibility that abnormal bacterial sensing contributes to disease pathogenesis^[51]. Because both NOD2 and TLRs are involved in innate immunity and recognition of and response to bacteria, much attention has been recently devoted to their biological interrelationship and the possibility of functional abnormalities in IBD, and CD in particular. Monocyte-derived macrophages of CD patients carrying homozygous mutations of NOD2 show clear-cut defects of IL-1 β and IL-8 production upon activation by MDP or TNF- α ^[52]. Moreover, the synergism between MDP and TLR ligands that causes a substantial upregulation of TNF- α and IL-1 β production in normal peripheral blood mononuclear cells is lost using cells from CD patients with double mutant genotypes^[53]. Thus, these preliminary reports point to the existence of generalized major defects of innate immune responses mediated *via* pattern recognition receptors in CD.

Nonimmune cells

Other cell types participate in the chronic inflammatory response of IBD, including epithelial, mesenchymal and endothelial cells, and platelets, which actually exert many of the functions traditionally attributed to classical immune cells, such as cytokine production or expression of MHC class II antigens.

Initial evidence that intestinal epithelial cell (IEC) function may be altered in IBD was acquired when immunohistochemical studies showed that IEC inappropriately expressed the class II antigens HLA-DR in actively inflamed mucosa of UC and CD patients^[54]. Later on, after the demonstration that normal IECs have antigen-presenting capacity and preferentially stimulate CD8+ suppressor T-cells, a report showed that IEC from IBD mucosa fail to induce such cells and instead activate CD4+ T-cells, and thus potentially amplify intestinal inflammation^[55]. More recently, IBD IECs were reported to inappropriately express members of the B7 family of co-stimulatory molecules^[56], a finding suggesting possible alterations in B7-ICOS costimulatory pathways in IBD. These reports, together with the above-mentioned altered expression of TLRs in IBD^[51], provide support for the notion that IECs have a role in IBD pathogenesis, but to fully understand their functional relevance will require additional investigation.

The involvement of fibroblasts in IBD has been traditionally viewed as one restricted to production in the extracellular matrix and the pathogenesis of a common and serious complication; e.g., intestinal fibrosis^[57,58]. However, fibroblasts are also involved in gut injury because they represent a major source of matrix metalloproteinases (MMPs), a family of proteolytic enzymes directly responsible for tissue destruction during inflammation^[59,60]. Of special importance is the observation that interaction with activated T-cells is a major pathway of fibroblast activation and MMP production, a phenomenon that links together fibroblast function, adaptive immunity, and gut tissue injury^[61]. In reality, the functional interaction of mucosal fibroblasts with the surrounding microenvironment is physically more complex and functionally more important than previously recognized. A

recent report showed that activation of fibroblasts through the CD40 pathway induces the upregulation of cell adhesion molecules and production of chemokines which, in turn, induce the migration of T-cells through local microvascular cells^[62]. Therefore, mucosal fibroblasts must also be considered as active rather than passive participants in IBD pathogenesis.

Endothelial cells play an essential role in inflammation due to their central "gatekeeper" function, which controls the quality and quantity of leukocytes that transmigrate from the vascular into the interstitial space. This process is complex and is mediated by a number of molecules, including cytokines, chemokines and adhesion molecules. A key observation that opens the whole field of functional vascular biology in IBD is that human intestinal microvascular endothelial cells (HIMEC) isolated from CD and UC mucosa exhibit a significantly higher cytokine-mediated leukocyte binding capacity compared to HIMEC from normal mucosa^[63], a phenomenon secondary to their chronic exposure to the inflammatory milieu of the IBD mucosa^[64]. Increased leukocyte adhesion by IBD HIMEC is apparently due to their deficient production of inducible nitric oxide (NO) synthase^[65]. This also causes a microvascular endothelial dysfunction in IBD due to a loss of NO-dependent dilation that may lead to reduced perfusion, poor wound healing, and maintenance of inflammation^[66].

The role of platelets in IBD has been known for quite some time, but primarily because of their involvement in thrombotic events which are relatively common in CD and UC patients^[67]. However, platelets have increasingly acquired a strong immunological connotation through the demonstration of their initiator or amplificatory role in immunity and inflammation, which is mostly mediated through the CD40/CD40 ligand pathway^[68]. Platelets exist in an activated state in the peripheral circulation of IBD patients, and the elevated levels of soluble CD40 ligand present in their systemic circulation are mostly of platelet origin, apparently due to platelet activation in the inflamed intestinal microvascular bed^[69]. More importantly, recent studies have shown that platelets trigger a CD40-dependent inflammatory response in the microvasculature of IBD patients^[70], thus closely linking this unique cell type to the process of IBD pathogenesis.

CONCLUSIONS

Since the recognition of IBD as a perplexing and challenging clinical entity, the investigation of its pathogenic mechanisms has gone through repeated cycles of new hopes, new knowledge, and new realities. Infectious, allergic, dietary, psychosocial, environmental, microbial, vascular, metabolic, immune and other based theories have been put forward, most of them to be rebuked, if not ridiculed^[71]. At the moment, we appear to have settled down on a unifying but still wide-ranging hypothesis that IBD results from complex interactions between evolving environmental changes induced by society's progress, a still undefined number of predisposing genetic mutations, an incredibly complex gut microbiota that may be constantly varying, and the intricacies of

individual immune systems^[72]. The ability to integrate all these various components into a single cohesive and logical pathway of disease that explains all aspects of IBD appears still a bit distant at the moment. On the other hand, if we look back at where we stood only two or three decades ago, the progress achieved in our understanding of IBD pathogenesis and the way it has changed our approach to therapy is just short of spectacular.

Abstract

The objective of this report is to give an overall view of the epidemiological, clinical, diagnostic and therapeutic features of Cytomegalovirus (CMV) infection in inflammatory bowel disease (IBD). A review of published reports on this topic was carried out, with particular attention paid to the selection of patients included in studies and the diagnostic methods employed. CMV is frequently associated with IBD. In some cases, CMV infection is associated with a poor outcome but it is not clear which patients are more likely to be affected and in which stage of the disease. The use of anti-viral therapy in IBD is controversial and an empirical study with controls is needed. The natural history of CMV infection related to the development and treatment of IBD has not been clarified but it is important to take it in consideration because of the possibility of viral persistence in the immunocompromised host and viral interaction with the immune system.

INTRODUCTION

Cytomegalovirus (CMV) is a member of the Herpesviridae

family, which includes Epstein -Barr virus (EBV), Herpes Simplex virus types 1 and 2 (HSV-1,2), Varicella- Zoster virus, and Human Herpes virus types 6 and 7 (HHV-6,7). Similar to infection with other viruses in the family, primary infection with CMV results in the establishment of a persistent or latent infection, due to the ability of the virus to remain integrated in the DNA of host cells. The sign of a viral infection is a cytopathic effect shown by the presence of large nuclear and cytoplasmic inclusions, represented by aggregates of replicating CMV nucleoprotein cores. To avoid recognition and destruction by CD8+T lymphocytes, the virus develops the ability to evade the immune system by several mechanisms. CMV produces some proteins, such as US2, US3 and US11, that inhibit the presentation of viral antigens to T cells, blocking the class I MHC in the endoplasmic reticulum or in the cytosol. It also produces homologues to class I MHC proteins and may compete for binding and presentation of viral antigens. Once the viral DNA remains undisturbed in the infected cells, subsequent reactivation can occur in response to several stimuli, such as immunosuppressant therapy or chemotherapy^[1]. The down-regulation of the cell surface markers acts on interferon-alpha/beta dependent responses by affecting several levels of IFN signal transduction and a transcription activation pathway. CMV infection leads to the activation of Nuclear Factor kappa B (NF-κB) and its translocation to the nucleus, promoting the expression of cytokines, chemokines and cellular adhesion molecules. These mechanisms are also present in inflammatory bowel disease (IBD) where there is activation of several pro-inflammatory cytokines (such as IFN-gamma), the transcription of which is regulated through nuclear transcription factors (such as Nuclear Factor kappa B) and through a signal transducer and activator of transcription (STAT family).

CMV AND IBD

The role of CMV in IBD is reviewed considering the following issues: diagnostic methods to detect the virus, prevalence of CMV in IBD according to patient selection, clinical characteristics, outcome for patients with IBD and superimposed CMV infection, role of antiviral therapy and natural history of CMV in IBD patients.

Diagnostic method

Results differ based on diagnostic method. Serology is

useful in checking for previous virus exposure and for identifying patients at risk. Since gross appearance is non-specific, a diagnosis is based on the histopathological identification of viral-infected cells in biopsied tissues, using appropriate staining Haematoxylin and Eosin (HE), Immunohistochemistry (ICH), by a dedicated pathologist. Cytomegalic cells have been revealed that are 2-or 4 fold larger (25-35 μm) than surrounding cells, containing a basophilic intranuclear inclusion (8-10 μm) that is eccentrically placed and is sometimes surrounded by a clear halo, giving it an "owl's eye" appearance. These cells also show a thickened nuclear membrane, frequently associated with smaller granular intracytoplasmic inclusions.

Intranuclear inclusions were observed in epithelial, endothelial, stromal and smooth muscle cells.

In the gastrointestinal tract, "atypical" inclusions were also found^[2]. Biopsies taken from the mucosa near or within the ulcer provided greater detection of the virus. IHC is more sensitive than HE.

The CMV pp65-antigenemia assay as Polymerase Chain Reaction (PCR) DNA amplification is a sensitive, specific and rapid method for the early diagnosis of CMV infection based on immunocytochemical detection of a virus protein (pp65) in the nuclei of peripheral blood polymorphonuclear leukocytes. The advantage of this method is an early and rapid response possibility but this technique does not permit the distinction between an asymptomatic infection and an active disease. Viral load quantification may permit the observation of the infection course. PCR is a very sensitive test for the detection of CMV. In solid organ transplant patients, CMV detection can persist for months using qualitative PCR assays, despite effective antiviral therapy. Therefore, the precise amount of CMV DNA may be better determined with virological monitoring. In addition to studies using quantitative PCR in renal transplant recipients, studies on peripheral blood leukocytes suggest a cut-off of > 1000 copies/100 000 leukocytes, indicative of the development of symptomatic CMV infection after transplant^[3]. A slow or absent decline in CMV DNA after the beginning of ganciclovir therapy could be an early indicator of drug resistance^[4]. A PCR positive assay after ganciclovir therapy, irrespective of resolution of clinical signs and symptoms, might be an indicator that therapy should be continued^[5]. Mendez *et al*^[6] analyzed the early diagnosis of CMV infection using four sets of primers that were able to amplify different regions of the CMV genome. The authors demonstrated that a specific primer directed to the HIND III-X fragment region is the most sensitive primer for the early detection of CMV DNA in peripheral blood leukocytes (PBLs), providing detection 17 d before the onset of the symptoms. *In situ* hybridization and qualitative PCR in colonic biopsies seem to offer the greatest accuracy^[7-9] in detecting the virus.

Quantitative PCR (viral-load) in cells from the colon^[10] showed a high positive-predictive value for detecting disease and for monitoring therapeutic response. A qualitative and quantitative PCR assay for CMV DNA has been performed on human faecal specimens from immunocompromised patients^[11,12].

Patient selection method

The reports on prevalence of CMV are extremely varied in regard to patient selection methodology. There is no study that gives an overall prevalence of CMV in IBD patients. Most of the studies have been carried out using a selected patient group (severe colitis, steroid-resistant colitis, urgent colectomy for colitis, patients with active disease) and different diagnostic methods were used as well for different patient group (e.g., histology, ICH, antigenemia, electron microscopy, *in situ* hybridization). Prevalence has been reported to range from 0.5 to 100% (Table 1).

Severe colitis: A group in Italy^[13] studied the prevalence of CMV using rectal biopsies and HE staining, immunoperoxidase staining for CMV antigens and antigenemia pp65 (a buffy-coat preparation) on the peripheral leukocytes. The study was performed prospectively in a consecutive series of hospital admissions without waiting for a possible response to conventional therapy, in order to determine the prevalence of CMV in severe consecutive episodes of colitis. The results showed virus prevalence overall in patients with active IBD (21%). On the basis of these results the authors suggested performing a flexible proctoscopy (without air insufflation) with rectal biopsies in patients hospitalized for severe colitis flare-up, together with antigenemia on peripheral leukocytes, to determine whether the simultaneous detection of virus both in the colon mucosa and in the peripheral blood may be interpreted as the pathogenic cause.

Khishore^[14] used serology, HE and PCR for CMV DNA to study a heterogeneous population, including patients with severe colitis. Thirty-six patients had severe colitis, with 8 patients (22%) shown to be CMV positive based on colonic biopsies. Moreover, the author identified clinical variables associated with a higher risk of CMV infection in IBD. These factors included female gender, pancolonic disease with active inflammation at histology, and azathioprine treatment. Using antigenemia, Wada^[15] reported a prevalence of 34%, while Vega^[16] reported a result of 3% in a retrospective study that used HE and ICH results.

Severe steroid-resistant colitis: Cottone *et al*^[17] showed that the prevalence of CMV, studied using HE and ICH and antigenemia, was 36%. Kambham^[18] obtained a similar result, using HE and ICH on colonoscopic biopsy specimens, detecting CMV in 4 of 15 steroid-resistant patients (26%). Pofelsky^[19], using PCR, showed a higher prevalence (60%) compared to previous reports, and an overall prevalence of viral DNA in the colon of 38%. However, there was a poor correlation between colonic and peripheral viral load which suggests a role of local inflammation in the colon. The genotype detected was gB1, which possibly has a particular colonic tropism. On the contrary, Papadakis^[20], in a retrospective study on 1895 patients, showed a low rate of 0.5% prevalence. He suggested a pathogen role for the virus based on the prompt response and clinical improvement found with antiviral treatment.

Urgent colectomy for colitis: These patients represent a subgroup in which IBD is more severe and, therefore, a higher prevalence of CMV is expected. Six studies

Table 1 Prevalence data according to population and methodology of the study

Author (year of publication)	Population characteristics	Diagnostic assay	Study type	Prevalence
Criscuoli (2004)	42 pts with severe colitis	HE-ICH on rectal biopsy + antigenemia pp65	prospective	21%
Kishore (2004)	63 pts with severe colitis (36 steroid resistant)	Serology-HE and qualitative PCR	prospective	16% 22%
Wada (2003)	47 pts with severe colitis	Antigenemia	prospective	34%
de Saussure (2004)	64 pts with active colitis	Serology-viremia-antigenemia- HE-ICH	prospective	1.5%-6%
Vega (1999)	267 active colitis	HE-ICH	retrospective	3%
Pofelski (2005)	48 pts severe colitis	Quantitative PCR on colonic biopsies	retrospective/ prospective	38% 60%
Kambham (2004)	40 pts steroid resistant (25 operated on for colectomy)	HE-ICH	retrospective	Overall 25% Operated on pts 24%
Papadakis (2001)	1895 steroid resistant pts	HE	retrospective	0.5%
Cottone (2001)	19 Steroid resistant pts	HE-ICH on rectal biopsy + antigenemia pp65	prospective	36%
Maconi (2005)	77 pts operated on for colectomy	HE-ICH on surgical specimen	prospective	22% overall 27% steroid resistant
Takahashi (2004)	69 surgical specimen of IBD pts	HE-ICH on biopsy and surgical specimen	retrospective	11.5%
Alcalá (2000)	39 pts operated on for colectomy	HE + ICH	retrospective	18%
Eire-Brook (1986)	26 pts operated on for colectomy	Light and electron microscopy- ICH	retrospective	11.5%
Cooper (1977)	46 pts operated on for colectomy	HE	retrospective	13%
Rahbar (2003)	23 pts with IBD (13 UC-10 CD)	ICH+ <i>in situ</i> hybridization	prospective	92/100%
Wakefield (1992)	50 pts with IBD (29 CD-21 UC)	qualitative PCR	prospective	66/81%

(two older studies using HE and four recent studies using ICH) have been reported on surgical specimens from patients with colitis who were not responsive to medical therapy^[6,21-25]. These studies showed an overall prevalence (11.5%-27%) that is similar to reports in other studies. In the subgroup of steroid-resistant patients, Kambham and Maconi reported a similar prevalence of 25%-27%.

Patients with active disease: Rahbar^[7] has estimated virus prevalence in intestinal biopsies from IBD patients both using ICH and *in situ* hybridisation. The latter showed detection in over 90% of ulcerative colitis (UC) patients, and in 100% of patients with Crohn's disease (CD). Since the presence of the virus does not necessarily mean active infection, the authors looked at viral replication by CMVea (early antigen) and CMVla (late antigen) by immunohistochemistry, and they obtained a similar result (85% *vs* 100% for UC *vs* CD, respectively) using CMVea.

Other authors have used an immunoperoxidase technique, using a monoclonal antibody against CMV, to demonstrate early CMV infection in cells of colonic specimens in cases showing few cytopathic cells at histological examination. On the contrary, the DNA *in situ* hybridization technique was less helpful in establishing a diagnosis of early infection^[8].

A study that used PCR showed positive detection in about 66% of CD patients, 81% in UC patients, and 29% in controls^[9].

CMV and acquired immunodeficiency syndromes or immunosuppressive therapy

The gastrointestinal system is a common site of CMV infection, especially in AIDS patients. Any tract can be affected, with preference to oesophagus and colonic mucosa (especially right colon) rather than ileum, considering the pouch mucosa are morphologically similar

to colon mucosa^[26]. The syndrome begins with a watery diarrhoea due to an inflammatory response, that quickly turns into bloody diarrhoea due to ulcerative changes in the colonic mucosa. The endothelial cells are a site of CMV detection both in a latent state and active replication state^[27]. This explains why CMV vasculitis is a common manifestation of viral disease localized in different organs (bowel, retina, brain) and that vascular damage is responsible for thrombosis^[28] and atherosclerosis. In the bowel, vasculitis may cause ischemia and transmural necrosis with an increased risk of toxic megacolon and perforation.

A recent meta-analysis^[29] on the outcome of CMV colitis in an immunocompetent host reviewed 44 cases (of which 16 had coexisting immune-modulating morbidities such as diabetes, malignancy or renal failure). The conclusion of this analysis was that CMV colitis is found more frequently in elderly patients in whom the disease had a severe course and where there was a high mortality rate. On the contrary, younger patients (< 55 years) had a significant rate of spontaneous recovery, with 42% of patients diagnosed with subsequent IBD after resolution of CMV infection. Ng^[30] carried out a retrospective analysis on patients without apparent causes for immunodeficiency but who were mainly elderly and were admitted to hospital with bloody diarrhoea. The mortality rate reported was 40% which was thought to be related to co-morbidity.

IBD and superimposed CMV infection: When the syndrome appears with a pre-existing inflammatory disease, IBD may be more aggressive. The clinical outcome of IBD with superimposed CMV is not well understood. The first report about the possible role of cytomegalovirus in IBD dates to 1961 when Powell^[31] described a case of ulcerative colitis and cytomegalic inclusion disease. After many sporadic reports over the last decade, the topic has

regained attention due to more frequent publications of case-reports or small series studies in which the virus provided a worsening prognosis influence, sometimes promoting disease initiation or otherwise acting as a bystander^[9].

The coincidental detection of primary CMV infection at the first appearance of IBD is reported in some case-reports^[32,33], underlining the ability of CMV proteins to enhance pro-inflammatory cytokines that are able to maintain a local colonic inflammation with an immune response. In other conditions the latent virus could exacerbate^[34-36] pre-existing colitis after immunosuppressive situations. Experimental studies have shown that highly proliferating cells, like those in the granulation tissue, around inflammation or in ulcer depth, are easily objects of CMV infection. In this situation the virus could reach the mucosa by monocytes and then colonize the mucosa, acquiring particular affinity for the inflamed mucosa.

This is evidenced by the fact that super-infection with pre-existing colitis causes worsening of symptoms, with a severe course of disease that rarely strikes suddenly, with high prevalence of toxic megacolon and surgical intervention^[10,11,33]. In this case, since steroids or immunosuppressive therapy can lead to the flare-up of CMV infection, the outcome for patients with an acute attack is likely to be poor. A case of disseminated (whole gastrointestinal tract, skin and central nervous system) CMV infection has been reported in Crohn's disease after anti-TNF therapy^[37]. The mechanism of dissemination is likely to be related to vascular damage that allows a viral circulation within the shed endothelial cells.

The literature contains many case reports of CMV infection in steroid-naïve patients or immunocompetent hosts with IBD. Rachima^[38] reported two cases of CMV infection diagnosed by high titres of IgM antibodies to CMV (solid-phase enzyme immunoassay) but without histological detection on colonic biopsies. A high prevalence of CMV IgG antibody in patients with ulcerative colitis, compared to normal controls and to patients with active Crohn's disease, permits the hypothesis of a possible role for the virus to exacerbate the inflammatory disease and therefore its pathogenicity. Although clinically significant CMV infection occurs in individuals with acquired immunodeficiency syndrome or due to immunosuppressive therapy, the same inflammatory disease could be considered a booster of viral infection with local factors, even without previous immunosuppressive therapy.

Antiviral treatment: A review of the literature does not affirm that antiviral treatment is mandatory when CMV is detected in biopsy specimens or in peripheral blood, however, some authors are favourable to the use of antiviral treatment^[2-9]. Eddleston^[39] proposes the consideration of antiviral therapy in immunocompetent patients with multiple organ disease, taking into consideration the poor prognosis with widespread CMV disease. Pfau considers Ganciclovir as a beneficial treatment that significantly decreases the mortality rate and the request for surgery. Eire-Brook considers CMV as a bystander and refuses to allow any antiviral treatment during an acute flare-up of IBD.

It is difficult to draw conclusions about the role of antiviral therapy on the basis of the available evidence. Se-

vere steroid-resistant colitis is the setting in which the role of antiviral therapy should mainly be considered. According to some reports, antiviral therapy treatment was useful, whereas in others it was useless. A controlled study is necessary to answer this question, however a large number of patients would be needed for such a trial and it would therefore be necessary to involve many centres using homogeneous diagnostic methods.

Natural history of CMV infection: No studies have reported on the natural history of CMV infection. It is not known whether the virus remains in the colon after an acute attack or spontaneously disappears. It is also not known whether there is a high incidence of relapse when the virus remains in the colon. Furthermore, it is not clear whether the virus plays a role in risk for cancer and lymphoma of IBD. For many years, the involvement of Human Herpes Virus (EBV, HHV-8) has been well known in the pathogenesis of some tumours, while there is little knowledge about the potential oncogenetic role of CMV.

A study performed using ICH, *in situ* hybridisation and PCR on pathological specimens of colorectal polyps, adeno-carcinomas and normal mucosa, reported an immunoreactivity of at least 80% in the colorectal polyps and carcinoma both for an immediate early gene product (IE1-72) and for a delayed early gene product (pp65), and acid nucleics. Moreover, detected cyclo-oxygenase -2 in the same site of virus detection may play an important oncogenetic role in the development of human colorectal cancer. The virus could activate cellular proto-oncogenes, kinases and transcription factors implicated in tumour-cell survival pathways^[40].

On the contrary, a more recent study^[41] using similar methods did not find nuclear immunoreactivity for CMV proteins and DNA, but found focal cytoplasmic positivity in normal colonic mucosa as well, demonstrating no evidence of association. Adani^[42] reported a case of severe ulcerative colitis with superimposed colonic CMV infection without peripheral involvement that was associated with colorectal high-grade B-cell non Hodgkin's lymphoma (MALT type). More frequent association is reported between CMV pneumonitis and non-Hodgkin's lymphoma. Both cases were associated with previous immunosuppressive treatment, which is a well-known promoting factor.

CONCLUSION

In general the role of CMV in IBD remains unclear. On the basis of the current evidence, in our opinion, in active severe IBD CMV, if is detected in the colonic biopsies together at the presence of antigenemia, should be treated with antiviral drugs. There is certainly a pathogenic role of CMV in immunosuppressed transplant patients and in patients with AIDS where treatment is mandatory.

Abstract

Crohn's disease (CD) and ulcerative colitis (UC) are chronic inflammatory bowel diseases (IBD) that often involve organs other than those of the gastrointestinal tract. These nonintestinal affections are termed extraintestinal symptoms. Differentiating the true extraintestinal manifestations of inflammatory bowel diseases from secondary extraintestinal complications, caused by malnutrition, chronic inflammation or side effects of therapy, may be difficult. This review concentrates on frequency, clinical presentation and therapeutic implications of extraintestinal symptoms in inflammatory bowel diseases. If possible, extraintestinal manifestations are differentiated from extraintestinal complications. Special attention is given to the more recently described sites of involvement; i.e. thromboembolic events, osteoporosis, pulmonary involvement and affection of the central nervous system.

INTRODUCTION

Crohn's disease (CD) and ulcerative colitis (UC) are the main entities of chronic inflammatory bowel diseases (IBD). Although in most cases the gastrointestinal tract is

mainly affected, both ulcerative colitis and Crohn's disease are systemic disorders that often involve other organs. These nonintestinal affections are termed extraintestinal symptoms and may not always coincide with the underlying bowel disease. Extraintestinal disease can involve almost every organ system. The organs most commonly involved include the skin, eyes, joints, biliary tract and lungs. Some symptoms, such as oral lesions, gallstones, pancreatitis, nephrolithiasis and amyloidosis, are more associated with CD than with UC. Other symptoms, e.g. skin and eye manifestations, are equally seen in both CD and UC.

Several factors may be responsible for extraintestinal organ involvement in IBD and sometimes it can be difficult to differentiate the true extraintestinal manifestations (EIMs); i.e. primary systemic affection by the disease itself, from secondary extraintestinal complications of the disease, caused for example by malnutrition, chronic inflammation or side effects of therapy. Some of these EIMs may not correlate with disease activity (primary sclerosing cholangitis and ankylosing spondylitis) but in general EIMs tend to follow the clinical course of IBD and may have a high impact on quality of life, morbidity and even mortality in these patients.

The reported frequency of EIMs in patients with IBD varies from 6%-47%^[1-4]. The development of one EIM appears to increase the susceptibility of developing other EIMs. An overlap of EIMs is particularly observed with peripheral arthritis, erythema nodosum, affection of the biliary tract and the eyes, in concordance with the hypothesis of a common pathogenic pathway. Some authors discuss an autoimmune reaction towards an isoform of tropomyosin (Tropomyosin related peptide), which is expressed in eye (non-pigmented ciliary epithelium), skin (keratinocytes), joints (chondrocytes), biliary epithelium and the gut^[5,6].

The high concordance in EIMs in siblings and first degree relatives with IBD^[7] suggests a common genetic background. Crohn's disease and ulcerative colitis are polygenic disorders and certain susceptibility genes in the major histocompatibility complex (MHC) region on chromosome 6 seem to be linked to EIMs in IBD. In CD, extraintestinal co-morbidities are more commonly observed in patients with HLA-A2, -DR1 and DQw5, whereas in ulcerative colitis, the genotypes HLA-DRB1*0103, B*27 and B*58 are linked with EIMs involving the joints, skin and eyes^[8-10]. Fifty to eighty percent of IBD patients with ankylosing spondylitis are

HLA*B27 positive^[11]. Furthermore, in UC the haplotype HLA B8/DR3 is associated with primary sclerosing cholangitis (PSC) and may also be linked to other autoimmune diseases (e.g. celiac disease, autoimmune hepatitis, myasthenia gravis)^[12]. Interestingly, the NOD2 gene in CD seems to be associated not only with ileal disease in CD but also with sacroileitis^[13].

In the following, an overview of the involvement of the different organ systems in IBD will concentrate on frequency, clinical presentation and therapeutic implications. In some cases, a differentiation of extraintestinal *manifestations* and extraintestinal *complications* will be given. Besides the classical extraintestinal manifestations, such as skin, joints, eyes and the hepatobiliary system, special attention will be given to the rarer, more recently described involvements, such as thromboembolic events, osteopenia and osteoporosis, pulmonary involvement and affection of the central nervous system.

MUSCULOSKELETAL MANIFESTATIONS

Joint manifestations are the most common EIMs in IBD and occur in approximately 20%-30% of patients^[3,14]. Males and females are equally affected. Symptoms may range from arthralgia only to acute arthritis with painful swollen joints. Both peripheral arthritis and axial arthritis can occur.

Peripheral arthritis

Peripheral arthritis in IBD is quite distinct from specific forms of arthritis since there is little or no joint destruction, and tests for rheumatoid factor, antinuclear antibody and LE factor are negative. The prevalence of all forms of peripheral arthritis is reported to be between 5%-10% in UC and 10%-20% in CD, respectively^[6,15], not considering asymptomatic patients under medical treatment. There are two types of peripheral arthritis in IBD^[15] that should be distinguished from unspecific myalgia or arthralgia:

Type 1 (pauciarticular) arthritis affects less than five large joints (predominantly of the lower limbs) and the swelling is acute and often self-limiting. Type I arthritis is related to disease activity of the underlying bowel disease. The mean duration is 5 weeks; some 25%-40% of patients will have recurring arthritis. Type 2 (polyarticular) arthritis is a symmetrical polyarthritis, frequently involving five or more of the small joints (e.g. knuckle joints). Its course is independent of disease activity and may last for several months.

The etiology of peripheral arthritis in IBD is thought to be a combination of genetic predisposition and exposition to luminal (bacterial) bowel contents. Type 1 IBD arthritis is associated with HLA-DRB1*0103, HLA-B*27 and HLA-B*35, whereas type 2 IBD arthritis is associated with HLA-B*44 and MHC class I chain-like gene A, which is a non classical HLA gene located near the HLA-B on chromosome 6^[8,10,16]. The site of intestinal inflammation is of particular interest concerning the pathogenesis of joint inflammation since CD patients with colonic involvement are at higher risk of developing arthritis than those with

isolated small bowel disease. Furthermore the incidence of new joint complications significantly decreases after ileocecal resection (even when corrected for the time spent in remission after surgery), suggesting that bacterial overgrowth proximal to the ileocecal valve plays an important role in the pathogenesis of extraintestinal joint inflammation^[6].

The diagnosis of peripheral arthritis in IBD is made clinically since radiographic findings do not show erosions or deformities. In persisting disease, a positive rheumatic factor should be excluded. In acute swelling, septic arthritis, fistulating arthritis or gout may be excluded by joint aspiration.

Treatment: Type 1 arthritis is related to disease activity and therefore therapy of the underlying IBD is the treatment of choice. Especially in patients with relapsing arthritis (HLA-DRB*0103), 5-ASA treatment should be switched to sulfasalazine, thereby taking advantage of the antiarthritic effect of sulfapyridine to minimize the risk of relapse. In addition, symptomatic treatment is often sufficient. For analgetic therapy, NSAID's and COX-2 selective inhibitors should be avoided, if possible, due to their potential to activate the underlying IBD^[17]. In severe cases, symptoms relief can be achieved by intra-articular steroid injection. Type 2 IBD arthritis generally requires long-term treatment. In persisting disease, sulfasalazine should be initiated at an initial dose of 2 × 500 mg per day, increasing the daily dose by 1000 mg every two weeks towards the maximum dose of 3 × 1500 mg or until symptoms improve. If not effective despite 12 wk of continuing treatment, immunosuppression with methotrexate (7.5 mg po once weekly) should be started. The dose can be increased by 2.5 mg steps in monthly intervals up to the maximum dose of 25 mg per week. Concomitant folic acid (5 mg po 24 h following methotrexate) is recommended to reduce side effects. Systemic corticosteroids may be necessary to control symptoms.

Axial arthropathies

The axial arthropathies are not associated with disease activity of IBD. Spondylitis occurs in 1%-26% of patients with IBD and males are more often affected than females. Both progressive ankylosing spondylitis and sacroiliitis (sometimes asymptomatic) may occur. Plain radiographs of the sacroiliac joints show uni- or bilateral sclerosis and/or erosions. The diagnostic gold standard is magnetic resonance imaging (MRI) with a high sensitivity in detecting sacroiliitis even in the absence of symptoms.

Ankylosing spondylitis

Ankylosing spondylitis (AS) affects the vertebral column by progressive ankylosis of the vertebral facet joints and the sacroiliac joint (Figure 1). The prevalence of AS in IBD (1%-6%) is higher than in the general population (0.25%-1%)^[18]. In contrast, the association with HLA*B27 is considerably weaker than in idiopathic AS with only 50%-80% of IBD patients being positive for HLA B*27 compared to 94% in the general population^[11]. Again, bacteria and gut inflammation seem to play an important role in the pathogenesis of AS.

Figure 1 X-ray thoracic spine demonstrating ankylosing spondylitis (Bechterew's disease) with syndesmophytes/bamboo spine in a patient with CD.

Interestingly, ileocolonoscopy in patients with idiopathic spondylarthropathies reveals ileal inflammation in more than two thirds of patients^[19].

The clinical course of AS in IBD is similar to idiopathic AS, and disease progression leads to increasing immobility of the spine resulting in ankylosis (bamboo spine). Secondary to reduced chest expansion, poor lung expansion with fibrosis and dilatation of the aortic root can occur. AS is associated with peripheral arthritis in about 30% of patients and with uveitis in 25% of patients.

Treatment: There is no causative treatment and therefore physical therapy is of particular importance to maintain mobility of the spine. In the absence of active IBD, NSAID are the drugs of choice, otherwise acetaminophen or tramadol are preferred. Steroid injection (MRI-guided) into the sacroiliac joint may be an option in patients with severe low back pain^[20]. Sulfasalazine may be used, but is more effective in associated peripheral arthritis. The first line immunosuppressant in patients with AS and IBD is methotrexate. Anti-TNF-strategies should be reserved for severe cases. Experience is limited to small case series, but improvement of both spondylarthropathy and active bowel disease has been reported in CD with infliximab^[21-23]. Etanercept is effective in spondylarthropathies^[24,25] but the efficacy in CD has not yet been demonstrated.

Isolated sacroiliitis

It may occur in patients with IBD but most patients are asymptomatic and the disease is non-progressive. Prevalence depends on the radiological method used and varies from 18% in plain radiographs and 32% in CT imaging to 52% in radioisotope scintigraphy. Isolated sacroiliitis seems not to be associated with HLA*B27^[6]. Asymptomatic HLA*B27 negative patients with normal spinal mobility do not require specific treatment.

Osteoporosis

Patients with IBD have an increased risk of developing osteoporosis, associated with fragility fractures and morbidity. The overall prevalence of osteoporosis in IBD is approximately 15% but is more prevalent with older age; the overall relative risk of fractures is 40% greater when compared to the general population^[26,27]. Vertebral fractures often occur spontaneously or after minimal

trauma and it is estimated that only one-third of vertebral fractures come to clinical attention^[28]. X-ray images of the spine most commonly show wedge or compression deformities. A variety of studies have demonstrated both decreased bone mineral density (BMD) in patients with IBD^[29-38], and increased rates of bone loss when followed longitudinally^[34,39,40] in comparison to healthy controls. The current Gold standard for measuring bone mass is dual-energy X-ray absorptiometry (DEXA)^[41].

The pathogenesis of osteoporosis in IBD is multifactorial. Important pathogenetic factors in IBD include the cumulative steroid dose, hypogonadism induced by IBD (absence of menstrual period in women), malabsorption of calcium and vitamin D, low body mass index and disease activity/elevated inflammatory cytokines^[42]. Other risk factors are previous fragility fracture, a positive family history, concomitant liver/endocrine disease (hyperthyroidism, hyperparathyroidism), immobilization and life style risk factors (smoking, excessive alcohol intake, physical inactivity). The multifactorial pathogenesis of bone loss in IBD makes it difficult to assess the importance of each single contributing factor. The results of a study from Norway indicate that disease activity and corticosteroid therapy are the most important factors involved in bone loss in CD patients^[43]. However, it remains unclear whether the bone loss is related to the disease or to its treatment.

Biochemical markers of bone turnover (e.g., osteocalcin, bone specific alkaline phosphatase, carboxyterminal propeptide procollagen type 1, urinary deoxypyridinoline, pyridinoline, carboxyteleopeptide of type I collagen, N-telopeptide cross-linked type I collagen) do not correlate sufficiently with current BMD for routine use^[30,33,35,44-46] and should be confined to research studies^[26].

Treatment: Few IBD patients are receiving optimal bone-sparing therapy, highlighting the importance of increasing awareness of osteoporosis in managing these patients^[38]. Preventing bone loss should begin with an attempt to limit corticosteroid-induced bone loss. This can be done by minimizing the corticosteroid dosage, substituting with budesonide when appropriate^[47,48], administering other steroid-sparing immunomodulators once corticosteroid dependence becomes evident, or by prescribing additional agents that enhance bone health. The administration of calcium and vitamin D^[49] appears to maintain or enhance bone mass^[26]. Bisphosphonates are of unclear additional benefit to the majority of patients who are at low fracture risk. In a small trial in Denmark, one year of daily alendronate treatment p.o. improved BMD in the spine^[50]. Bisphosphonates (etidronate, risedronate, alendronate) are effective in preventing bone loss in steroid treated patients, but only few patients with IBD have been included in these trials^[51-54]. Nasal or s.c. calcitonin can be considered as an alternative treatment approach when bisphosphonates are contraindicated or poorly tolerated. Testosterone replacement should be considered in hypogonadal men^[26], estrogen replacement in postmenopausal women^[55].

Osteomalacia

Osteomalacia is a rare complication of IBD, most likely occurring in patients with severe CD and multiple

intestinal resections^[56], resulting from prolonged and severe vitamin D deficiency. Though both osteoporosis and osteomalacia result in low BMD, apart from elevated bone alkaline phosphatase levels, osteomalacia can only be distinguished from osteoporosis by bone biopsy.

Joint complications in IBD

Complications involving the joints should always be considered and have to be distinguished from sterile joint inflammation, since steroid treatment can cause osteonecrosis (avascular necrosis of the bone). Patients on immunosuppressive therapy are at increased risk of septic arthritis. In CD, fistulization may cause bacterial infection of the iliosacral joint. Rarely a psoas abscess can cause septic hip arthritis.

MUCOCUTANEOUS MANIFESTATIONS

Erythema nodosum, pyoderma gangraenosum and oral ulceration are the most common cutaneous manifestations in IBD and are usually related to disease activity but sometimes may take an independent course. All patients presenting with IBD should be examined for cutaneous manifestations.

Erythema nodosum

It is the most common skin manifestation in IBD affecting up to 15% of CD patients, with a female predominance^[1,6,14]. Erythema nodosum (EN) affects the subcutaneous fat (septal panniculitis), causing tender erythematous nodules usually located on the shins (Figure 2). EN normally heals without ulceration and the prognosis is good. The clinical picture is typical and biopsy rarely is required for diagnosis. The etiology of EN is unknown, however there is a genetic association with a distinct HLA region on chromosome 6 (HLA-B^[9]). EN characteristically parallels intestinal disease activity. There is an association with other EIMs such as arthritis and uveitis^[14,15]. Treatment of the underlying bowel disease usually results in improving EN lesions and at least 25% of EN will heal spontaneously. There is no specific treatment for EN, but symptomatic therapy should comprise pain medication and oral steroids may be given in severe cases. Immunosuppressive treatment is not necessary. In the absence of active bowel disease, other causes of EN, such as sarcoidosis or post-streptococcal infection, should be taken into consideration.

Pyoderma gangrenosum (PG)

Pyoderma gangrenosum occurs in 0.5%-2% of both patients with UC and CD and may take a course independent of disease activity (Figure 3). Conversely, 36%-50% of patients with PG suffer from IBD. PG appears as a tender erythematous papule evolving into a livid pustule with central necrosis and subsequent ulceration, occurring in single or multiple lesions. The ulcer often has a irregular outline and is sharply demarcated with a heaped-up mushy violaceous border, surrounded by a erythematous zone (Figure 1). Often minor trauma, needle stitches or biopsy can induce new PG lesions

Figure 2 Erythema nodosum in a patient with CD.

Figure 3 Pyoderma gangrenosum in a patient with CD.

(pathergy phenomenon). PG lesions have a predilection for the lower limbs but may occur in any area of the skin, sometimes even as peristomal ulcers^[57]. The diagnosis of PG is made clinically; nevertheless skin biopsy of the border of the ulcer may be performed to rule out vasculitis or infection. There are no pathognomonic histologic features, generally revealing only diffuse neutrophilic infiltration and dermolysis.

PG is the most severe skin manifestation in IBD. PG is painful and often persisting despite adequate therapy. Without treatment, PG can last for years and ulcers may spread. Therefore, aggressive and early treatment is required. Local wound care consists of dressings, mild débridement of necrotic material and eschar (continuous wet saline compressions, topical enzymatic ointment, hydrocolloid dressings similar to common ulcer treatment). Topical tacrolimus has also emerged as potentially useful therapy^[58]. First line systemic treatment in PG is high dose prednisolone. Intravenous pulse therapy over three days is highly effective. Careful tapering should be started with clinical improvement. In steroid dependent or steroid refractory (no improvement within 5 d) cases, immunosuppressive therapy should be initiated. In mild cases a combination of steroids with dapsone has been successfully used with an initial dosage of dapsone 100 mg po/d, gradually increasing to 200-300 mg/d^[59]. In more severe cases cyclosporine or tacrolimus are effective. Steroid dependent patients require immunosuppressive treatment with azathioprine/6-mercaptopurine. A variety of other treatments (thalidomide, topical cromoglycate,

Figure 4 Sweet syndrome: papulosquamous exanthema in a patient with UC.

clofazimine, plasmapheresis, granulocyte apheresis, hyperbaric oxygen) have been reported anecdotally. Surgical intervention should be avoided, if possible, since it may induce pathergy. In resistant cases infliximab at a dose of 5 mg/kg has been used successfully^[59,60]. PG often takes a prolonged course, but in general will be controllable with medical therapy. About 35% of patients will experience relapsing PG.

Oral ulcerations

Oral aphthous ulcers occur in at least 10% of patients with UC and 20%-30% with CD and rapidly resolve once remission is achieved. Stomatitis, as an adverse event of methotrexate therapy, should be taken into account.

Miscellaneous skin lesions

Many other skin affections have been described in patients with IBD, such as Sweet's syndrome (neutrophilic dermatosis)^[61] (Figure 4), leukocytoclastic vasculitis, psoriasis, epidermolysis bullosa acquisita, and cutaneous polyarteriitis nodosa. Since these diseases have been mainly reported as single case reports, they probably occur coincidentally rather than as a true EIM. Angular cheilitis in nearly 8% of patients with CD often is a sign of iron deficiency.

EYE MANIFESTATIONS

Two to five percent of patients with IBD experience ocular manifestations^[62]. The manifestations range from conjunctivitis to more significant inflammation, including iritis, episcleritis, scleritis and anterior uveitis. Mild cases of conjunctivitis may be diagnosed clinically, but in other cases early referral to an ophthalmologist is important for accurate diagnosis.

Episcleritis

Episcleritis is less common in UC than in CD, presents as an infection of the ciliary vessels and an inflammation of the episcleral tissues and does not affect visual acuity. Inflammation episodes tend to occur in association with active bowel disease. Successful treatment consists of both

topical corticosteroids and treatment of the underlying bowel disease. Scleritis affects deeper layers of the eye and can cause lasting damage if untreated.

Uveitis

Uveitis is less common than episcleritis and occurs in 0.5%-3% of patients. It does not affect visual acuity unless it involves the posterior segment. Uveitis frequently presents bilaterally, is insidious in onset and chronic in duration. It is more common in females and may not parallel bowel disease activity. On slit-lamp examination uveitis presents as a perilimbal edema and "inflammatory flare" in the anterior chamber. Conjunctival vessel injection and corneal clouding may also be seen. An acute episode of uveitis can lead to permanent damage of the eye with iris atrophy, lens deposits or synechiae. More aggressive therapy may be necessary, especially when the posterior chamber is affected. Prompt diagnosis and therapy with topical and systemic steroids is crucial and sometimes intraocular injections of corticosteroids may be necessary. Steroid treatment should be continued for four weeks before tapering if uveitis is under control. Iridospasm is relieved by topical mydriatic eyedrops. Successful treatment for IBD-associated uveitis with infliximab was first described in one CD patient having a suitable extraintestinal constellation (uveitis and sacroileitis)^[63]. In rheumatoid arthritis with severe refractory uveitis, infliximab was effective but with an unexpected high rate of side effects^[64].

Ocular complications in IBD include keratopathy and night blindness resulting from malabsorption of vitamin A. Cataract development is a severe side effect of steroid therapy, therefore regular ophthalmologic examination should be considered. Rare eye manifestations are retinal vascular disease (central vein occlusion or vasculitis), peripheral corneal ulcers, corneal infiltrates and central serous chorioretinopathy with bullous retinal detachment.

HEPATOBIILIARY MANIFESTATIONS

Primary sclerosing cholangitis

In UC, the main hepatic EIM is primary sclerosing cholangitis (PSC), a chronic inflammatory disease of the biliary tree, occurring in approximately 3% of all patients (Figure 5). The diagnosis is made by endoscopic or magnetic resonance cholangiography, showing beading, irregularity, and stricturing of intrahepatic and extrahepatic ducts. Histology ranges from obliterating concentric fibrosis of the bile ducts to chronic inflammatory infiltrates in the portal tracts resulting in interface hepatitis. Low titres of autoantibodies against smooth muscle, parietal cells, and nuclear antigens are common, and high titres of autoantibodies to neutrophils (p-ANCA)^[65], showing a perinuclear pattern of staining, have been described. The majority (70%) of patients have the HLA-DR3, B8 haplotype.

Treatment

Ursodeoxycholic acid has been suggested to delay disease progression^[66]. Although not avoiding the progression of liver disease, ursodeoxycholic acid has been demonstrated

Figure 5 ERC demonstrating primary sclerosing cholangitis in a patient with CD.

to exhibit chemopreventive effects and reduce the risk of colorectal dysplasia in ulcerative colitis^[67,68]. This is of importance since patients with UC and concomitant PSC have a significantly higher risk of developing colorectal neoplasia compared with patients having UC only^[69]. PSC is seen as a premalignant condition for the development of cholangiocarcinoma as well.

Early symptomatic treatment of cholestasis is mandatory to avoid septic complication and consists of endoscopic dilatation with or without stent insertion. PSC is slowly progressive and independent of the course of UC, developing the complications of portal hypertension and chronic liver failure. For end-stage liver disease, liver transplantation remains an option.

PSC may occur in 4% of patients with CD as well, usually in those with colonic disease. Inflammatory changes of the small ducts show a normal cholangiogram and pericholangitis on liver biopsy^[70].

Hepatobiliary complications

Gallstones are frequent in patients with CD, of which 25% develop gallstones mainly due to malabsorption of bile salts from the inflamed terminal ileum. Abnormalities of liver function (elevated serum aminotransferase and alkaline phosphatase) are common in patients with malnutrition, sepsis, and fatty liver due to severe attacks of IBD. These correlate with disease activity and return to normal once remission is achieved. Factors favouring fatty infiltration of the liver in severely ill patients are poor nutrition and often concomitant steroid therapy.

PANCREATIC MANIFESTATIONS

There is an increased risk for acute as well as chronic pancreatitis in IBD^[71-73] documented by a multitude of case reports and case series.

Acute pancreatitis

Especially in cases of acute pancreatitis, it may be difficult to determine the true incidence of EIM^[74]. Many drugs in IBD treatment have the potential to induce acute pancreatitis (e.g. salicylates, azathioprine and 6-mercaptopurine, rarely corticosteroids). Drug-induced pancreatitis typically occurs within the first weeks after

commencing drug-therapy^[75], the course is usually mild and resolves quickly after discontinuing the drug. Especially in CD regional inflammatory complications due to duodenal/papillary involvement or biliary complications should be considered. Nevertheless, after excluding extra-intestinal complications, an increased risk for idiopathic pancreatitis remains in patients with IBD (1%-1.5%) that should be considered as true extra-intestinal involvement.

Pancreatic autoantibodies have been found in up to 40% of CD patients^[76]. In contrast to earlier reports^[77] the prevalence seems to be increased in both CD and UC patients as well as in first-degree relatives^[78]. The relevance for disease is still unclear, however. In a series with 64 antibody-positive CD patients the proportion suffering from exocrine insufficiency was 27% compared to 8% in antibody negative patients^[79]. Further studies are needed to show whether these antibodies, apart from their diagnostic relevance for IBD, actually play a role in pathogenesis and whether they can help to identify patients at risk of developing an EIM involving the pancreas.

Chronic pancreatitis

Endoscopic retrograde pancreatography (ERP) is still the most sensitive and specific test for chronic pancreatitis. There are several reports on intrapancreatic duct changes in patients with IBD^[80,81]. Pancreatic function has been investigated as well. In the study of Heikius, the exocrine function was found to be decreased in only 4% of patients using the secretin test. These results are consistent with two other studies that diagnosed exocrine insufficiency in a minority of IBD patients only^[73,82]. In all studies, chronic alcohol ingestion as a potential cause for chronic pancreatitis had been excluded. The pathogenesis of chronic pancreatitis in patients with IBD remains unclear. Since there has only been one documented case of pancreatic granuloma in Crohn's disease^[83], pancreatitis has been considered to be caused by circulating inflammatory mediators rather than directly-involved pancreatic tissue. As discussed above, autoantibodies against pancreatic tissue may play a role in the development of exocrine insufficiency.

THROMBOEMBOLIC EVENTS

Patients with IBD are at increased risk of developing thromboembolic complications. The incidence of deep vein thrombosis and pulmonary embolism is increased and is a major cause of mortality in IBD. Venous thrombembolism is more common than arterial embolism. Conventional risk factors, such as prolonged immobilization, hospitalization, sepsis, surgery or invasive procedures, contribute to this increased risk especially in active or complicated IBD. In severe disease, thrombocytosis and increased concentrations of many clotting factors that behave as acute phase proteins, lead to a procoagulatory status. The majority of IBD patients with thromboembolic events have active disease^[84]. However, a recent study demonstrated nicely that IBD, as such, is a risk factor for thromboembolic events. Comparing patients with IBD, rheumatoid arthritis and celiac disease to age and sex-matched controls, they found that patients

with IBD have a 3.6-fold increased risk of experiencing thromboembolic events in contrast to the other chronic inflammatory diseases that have no increased risk^[85].

There is no consistent evidence that inherited thrombophilia is associated with IBD. The main established genetic risk factors have not been found to be increased in IBD^[86-88]. In more than half of patients with thrombosis, no predisposing factor is evident^[86]. Therefore, screening for these risk factors seems to be justified only in the case of a personal or a family history of thromboembolism. Hyperhomocysteinemia, more common in IBD patients than in controls, is associated with an increased risk of thromboembolism as well. To date it is controversial if polymorphisms in the methylenetetrahydrofolate reductase (MTHFR) gene leading to hyperhomocysteinemia are more frequent in IBD patients compared to healthy controls^[87,89,90]. Lack of Vitamin B6, B12 or folate or the use of folate-inhibiting drugs (methotrexate, sulfasalazine) can contribute to acquired hyperhomocysteinemia.

Corticosteroid treatment may cause a hypercoagulable state with increased risk of thrombosis, but systemic data pointing towards a significant association is missing. In general, all hospitalized patients with IBD should receive low-dose heparin for thromboprophylaxis unless there is severe bleeding.

MANIFESTATIONS OF THE KIDNEYS AND THE URINARY TRACT

Glomerulonephritis

There are several reports on glomerulonephritis in patients with IBD. Many kinds of histology and clinical course, ranging from minimal change nephropathy to rapidly progressive glomerulonephritis, have been described^[91-94]. A true extraintestinal manifestation is difficult to prove, however, and the combination of glomerulonephritis and IBD may well be coincidental.

Interstitial nephritis and tubular proteinuria

Again, it is difficult to make a distinction between EIM and side effects of medication. Single cases of interstitial nephritis have been reported in IBD. At least one case of granulomatous interstitial nephritis has been attributed to underlying CD^[95], thus interstitial nephritis may represent a EIM of IBD. Medication, especially therapy with aminosalicylates, may cause interstitial nephritis as well. However, surveillance data from France^[96] and the UK^[97] report a low incidence of renal impairment under salicylate therapy. An additional, large epidemiologic study recently demonstrated that renal impairment is attributed to severity of the underlying IBD rather than to 5-ASA treatment^[98]. This is in accordance with the fact that the frequently observed tubular proteinuria in IBD is related to disease activity and not dependent on 5-ASA treatment^[99-101]. The clinical relevance of this proteinuria remains to be determined.

Renal and urinary complications

In patients with CD, uric acid and oxalate stones are common. Due to fat malabsorption luminal calcium is

bound to free fatty acids. Lack of free calcium results in increased oxalate absorption, hyperoxaluria and formation of renal oxalate stones. Hyperoxaluria may cause chronic tubulointerstitial nephritis as well. Prevention treatment of oxalate stones consists of low oxalate diet and supplementation of oral calcium (1-2 g/d). The risk for uric acid stones is increased with volume depletion (e.g. due to diarrhoea, ileostomy) and a hypermetabolic state in critically ill patients. Prevention of uric acid stone recurrence consists of hydration and oral urinary alkalization.

A rare complication is renal amyloidosis (AA-Amyloidosis) due to chronic inflammation; it mainly occurs in CD and is rarer in UC. Systemic AA amyloidosis is caused by extracellular deposition of fragments of the circulating acute-phase-plasma protein (SAA). Usually the mean duration between onset of the underlying chronic disease and the occurrence of amyloidosis is at least 15 years. The diagnosis is confirmed by detection of amyloid (Congo red staining) deposits in tissue (rectum biopsy, abdominal fat aspiration). Progression of amyloidosis can be stopped by controlling inflammation. Additional genitourinary complications may be caused by (enterovesical) fistula formation, perivesical abscesses, cystitis and obstructive uropathy.

PULMONARY MANIFESTATIONS

Various pulmonary manifestations have been reported in IBD including small and large airway dysfunction as well as obstructive and interstitial lung disorders. Case reports do not show a uniform picture of disease. Various entities including bronchial hyperreagibility, bronchitis and bronchiectasis, inflammatory tracheal stenosis, interstitial pneumonitis as well as bronchiolitis obliterans organizing pneumonia (BOOP) have been described. The respiratory symptoms usually follow the onset of the IBD. Sometimes pulmonary disease, especially serositis, correlates with IBD activity. Parenchymal lung disease often develops independently of disease activity. Interestingly, colectomy seems to be a risk factor for developing pulmonary symptoms with a frequent postoperative onset^[102,103].

Recently, a large population-based Canadian study reported airway disease as the most common concomitant chronic disease in patients with CD and second most common in patients with UC^[3]. Patients with CD and with UC were more likely, 30%-40% and 50%-70% respectively, than controls to have asthma^[3]. The high frequency of pulmonary involvement in IBD probably reflects the commonality of bronchus-associated and gut-associated lymphoid tissue^[104]. Subclinical lung involvement is much more common than apparent respiratory symptoms, reported in as many as 30%-60% of patients with CD. Bronchoalveolar lavage reveals alveolitis in as much as 50% of CD patients without any clinical respiratory symptoms^[105] and abnormal pulmonary function tests have been reported in 42% of IBD patients without respiratory symptoms compared to only 3% in controls^[106]. Interestingly, these changes persist during remission.

Persistent airway inflammation can result in airway narrowing, dependent on the localization, resulting in

tracheal stenosis, bronchiectasis or bronchiolitis obliterans. In fact, the majority of patients with IBD-related respiratory manifestations present with chronic bronchitis or bronchiectasis^[102]. Chest X-rays are often unspecific; high resolution chest CT scanning may demonstrate bronchial wall thickening, dilated airways, branched opacities due to mucoid impaction^[107]. In lung biopsy nonspecific inflammation, small airway fibrosis and sometimes granulomatous bronchiolitis have been reported^[108,109]. The most common interstitial lung disease associated with IBD is bronchiolitis obliterans organizing pneumonia (BOOP)^[102]. Chest X-ray reveals patchy focal opacities or diffuse infiltrates, while CT scanning often demonstrates pleural-based opacities and air bronchograms. Typical granulomatous interstitial lung disease in Crohn's disease is rare and may mimic sarcoidosis with the occurrence of noncaseating granulomas and elevated CD4/CD8 ratios in bronchoalveolar lavage fluid^[110-112]. Apart from airway inflammation and interstitial lung disease other pulmonary manifestations of IBD include serositis^[113]. Serositis occurs as exudative pleural effusion pericarditis, pleuropericarditis and myocarditis^[107].

Complications

Pulmonary parenchymal involvement may be related to IBD, but also may be induced by drugs (e.g. mesalazine, sulfasalazine, methotrexate). Many cases of drug-induced pulmonary complications in IBD patients have been reported. Salicylates of all kinds can induce different types of interstitial lung disease, such as BOOP and granulomatous lung disease. The pulmonary toxicity of 5-aminosalicylic acid (5-ASA) is less common than with sulfasalazine, but pulmonary infiltrates, sometimes eosinophilia or BOOP may develop as well^[102,114,115]. Pulmonary infiltrates with eosinophilia (PIE syndrome) can occur with or without the use of sulfasalazine or mesalamine^[116]. Chest X-rays often show peripheral infiltrates typical of chronic eosinophilic pneumonia and laboratory values reveal eosinophilia. Methotrexate treatment may cause serious hypersensitivity pneumonitis or pulmonary fibrosis. Chest X-rays show diffuse alveolar or interstitial infiltrates.

Especially if patients receive combination immunosuppression, the possibility of opportunistic pulmonary infections should be taken into account.

Treatment

It is unclear whether asymptomatic patients should receive therapy at all. However, it should be born in mind that IBD patients carry an increased mortality risk due to pulmonary disease^[117-119]. Depending on the type of pulmonary complication, inhaled or systemic steroid therapy may be effective. In various forms of airway inflammation, inhalatory steroid therapy (e.g. beclomethasone up to 1200 µg/d) is generally effective, with large airway inflammation being more responsive than bronchiolitis. Patients with bronchiectasis are less likely to respond to inhaled steroids and may require oral steroids. In severe airway inflammation with upper airway obstruction, such as subglottic involvement, intravenous

steroids may be required. Interstitial lung disease usually requires systemic steroids; e.g. prednisolone 0.5-1.0 mg/kg per day for a longer period of time, usually months, depending on the clinical course.

CARDIAC MANIFESTATIONS

Pericarditis or perimyokarditis with or without an effusion have been described in a few case reports on patients with active IBD. Again, it may be difficult to rule out drug toxicity since salicylates are potential culprits. However, in the Canadian population-based study, both patients with CD and UC were at an increased risk of developing pericarditis in comparison to healthy controls^[3]. Age-adjusted prevalence ratios were 3.07 in CD and 3.33 in UC, respectively, although the numbers were small^[120].

NEUROLOGICAL MANIFESTATIONS

The association of autoimmune neurological disorders and IBD has long been hypothesized, especially for multiple sclerosis^[121-125]. Furthermore there are some sporadic reports of neuropathies in IBD such as optic neuritis^[126], peripheral neuropathies^[127] and (subclinical) sensorineural hearing loss^[128,129]. MRI studies have shown clinical nonapparent cerebral white matter lesions in patients with IBD^[130]. A recent retrospective cross-sectional study evaluated the risk of patients with IBD to develop either multiple sclerosis, optic neuritis or demyelinating disease in the pre-anti-TNF- α -era^[131]. The authors found a small but significant association of IBD with these demyelinating diseases (OR 1.67). The risk was not found to be related to the use of steroids and/or immunosuppressive therapy with thiopurines. These results are of special interest in the light of recent reports on new unexpected adverse events of biological agents.

Recently, alarming reports on the development of progressive leucoencephalopathy under treatment with natalizumab, an antibody directed against $\alpha 4$ -integrin, have resulted in stopping all ongoing trials with this substance^[132,133]. Similar observations exist on the anti-TNF α -therapeutic agents infliximab, etanercept and adalimumab^[134-136] and have led to additional safety warnings concerning the use of these drugs. To date, patient numbers are too small to draw final conclusions but these agents may well accelerate the preexisting risk for demyelinating disorders in IBD patients.

Metronidazole, often used in fistulizing CD, can cause polyneuropathy if given as long term treatment. Nutritional deficiencies (Vitamin B12) should always be taken into consideration and looked for especially in long-lasting and severe disease.

SUMMARY

In conclusion, IBD are systemic disorders and not restricted to the intestine. Recent reports on the involvement of new organ systems emphasize that almost every site of the body can be affected by the inflammatory process. The possibility of contributing

Table 1 Extraintestinal symptoms in inflammatory bowel disease

Extraintestinal manifestations	Extraintestinal complications
Musculoskeletal diseases	
Peripheral Arthritis	Drug-induced osteoporosis and osteonecrosis
Ankylosing spondylitis	Bacterial infection of joints (fistulization, immunosuppression)
Isolated sacroiliitis	Septic arthritis
Metastatic Crohn's disease	
Mucocutaneous diseases	
Erythema nodosum	Anal fissures
Pyoderma gangraenosum	Fistulas
Aphthous stomatitis/oral ulceration	
Psoriasis?	Acrodermatitis enteropathica (Zinc deficiency)
Epidermolysis bullosa acquisita?	Purpura (Vitamin C and K deficiency)
Sweet Syndrome?	Glossitis (Vitamin B or Zinc deficiency)
Erythema exsudativum multiforme?	Hair loss (protein deficiency)
	Brittle nail (protein deficiency)
	Perlèche (Iron deficiency)
	Candidiasis (Zinc deficiency, immunosuppression)
	Mucositis/stomatitis (methotrexate)
	Drug-induced rash, allergic exanthema
	Moon-face, acne, stretch marks, skin atrophy (steroid treatment)
Ocular diseases	
Anterior Uveitis	Night blindness Vitamin A deficiency
Conjunctivitis	Kerathopathy Vitamin A deficiency
Iritis	Opportunistic infections (immunosuppressants)
Skleritis/Episcleritis	
Hepatobiliary diseases	
Primary sclerosing cholangitis	Gall stones in Crohn's disease
Granulomatous Crohn's hepatitis	Fatty liver
Autoimmune chronic active hepatitis?	
Biliary cirrhosis?	
Pancreatic diseases	
Acute pancreatitis	Drug-induced pancreatitis (5-ASA, azathioprine)
Chronic pancreatitis, exocrine insufficiency	Biliary pancreatitis in Crohn's disease
	Duodenal involvement in Crohn's disease
Blood and vascular diseases	
Thrombembolic events	Anemia (Iron-, folate-, vitamin B12-deficiency)
Autoimmune hemolytic anemia?	Thrombocytosis, leucocytosis
Thrombocytopenic purpura (Moscowitz Syndrome)?	Hypercoagulation: venous thrombosis, thrombembolism
Renal diseases	
Tubular proteinuria	Nephrolithiasis (oxalate stones, uric acid stones)
Glomerulonephritis?	Local affection involving the urethro-genital system
	Acute interstitial nephritis (drug related SASP, 5-ASA)
Interstitial nephritis?	Drug-induced renal insufficiency (5-ASA, SASP, cyclosporine)
	Renal amyloidosis
Bronchopulmonary diseases	
Chronic bronchitis/bronchiolitis/bronchiectasis	Drug-induced hypersensitivity pneumonitis
Acute laryngotracheitis/tracheal stenosis	Drug related pulmonary fibrosis (methotrexate)
Bronchiolitis obliterans organizing pneumonia	Drug-induced pleuritis
Pleuritis/serositis	Opportunistic infections (immunosuppression)
Cardiac diseases	
Pericarditis	Drug-induced pericarditis (5-ASA)
Myocarditis?/perimyocarditis	
Neurological diseases	
Demyelinating diseases including multiple sclerosis	Peripheral neuropathy (Vitamin B12 deficiency)
Optic neuritis, sensorial hearing loss	Drug-induced leucoencephalopathy (natalizumab, infliximab)
Myasthenia gravis?	Drug-induced polyneuropathy (metronidazole)

disease complications, especially through the side effects of treatment, should always be born in mind. The distinction between disease and treatment side effects can be extremely difficult and may sometimes be impossible. Recent reports on multiple organ involvement, including the central nervous system, point out the importance of an increased awareness for these potential problems. In addition, these data provide additional warning concerning the use of the new biological treatment strategies. These agents have to be prescribed with care since long term experience with toxicity is limited.

Abstract

AIM: To analyze the characteristics of epidemiological, clinical and survival patterns among patients with carcinoma of the stomach.

METHODS: We retrospectively studied the characteristics of 186 gastric adenocarcinoma patients at Ahwaz Jundishapur University Hospitals (AJSUH) from September 1, 1996 to September 1, 2002. All the patients had histopathologically-confirmed malignancy. Demographic variables, family history of gastric cancer (GC), clinicopathologic characteristics and treatment-related variables were analyzed. Univariate analysis was performed with the log-rank test and multivariate analysis with Cox regression. $P < 0.05$ was considered statistically significant.

RESULTS: Male to female ratio was 2.6:1. The mean age was 60.6 years and 14% of the patients were younger than 40 years. Adenocarcinoma, gastric lymphoma, and gastric metastasis were found in 94.5%, 2.3%, and 3% patients, respectively. There was an average of 6-mo delay between the initial symptoms and the diagnosis. Among adenocarcinoma groups, intestinal type was the commonest (55.9%) and the distal third was the most common localization (88.4%). One hundred and thirty-four patients (72.1%) were males. Thirty-one patients (17%) had a family history of GC. Surgery was performed in 90% of patients (non-curative).

CONCLUSION: The epidemiological features of GC in south Iran mimic those in high-risk areas. There is a higher frequency of GC in young patients at our institution. Patients are detected and treated after a

INTRODUCTION

Gastric cancer (GC) remains the third most common malignancy in the world^[1]. The pattern and incidence of GC vary widely in different parts of the world. Costa Rica and Japan have the first and second highest rates in the world with a rate of 77.5 and 50.5/100 000 persons, respectively^[2,3]. Gastric cancer is the most common malignancy in Iran and its incidence is particularly high in the Ardabil Province in the northwest of the country. In this province, the age standard incidence rate is 49.1 and 25.4/100 000 persons per year in males and females, respectively. The cause of the high incidence of GC in this geographical region is unknown^[4,5].

The epidemiology of GC has been widely studied in the Western world as well as in Japan^[6-9]. However, only few scattered reports from the developing world have been published^[10-14]. There is a lack of good descriptive data on GC from the Middle East countries, where both cancer registration and prevalence of risk factors are relatively unknown. Because of the decreasing trend taking place in the Western world as a result of possibly socio-economic development and its consequences, it is important to gain an insight into what is happening in other parts of the world such as in the Middle East. This prompted us to report the epidemiological and clinicopathological features of gastric malignancy in Khuzestan, southwest of Iran in comparison to other countries whenever possible. This

could assist in the better understanding of the important risk factors, which contribute to the development of GC. This also gives a clue about whether or not screening programs are needed in our region.

MATERIALS AND METHODS

We retrospectively analyzed the clinicopathologic characteristics of 186 gastric adenocarcinoma patients who were admitted to or operated upon at Ahwaz Jundishapur University Hospitals (AJSUH) from September 1, 1996 to September 1, 2002. Age, sex, method of operation, size of lesion, location of cancer in the stomach and stage were analyzed in patients, retrospectively. Histologically confirmed primary gastric malignancy was found in 186 patients, including 177 patients with adenocarcinoma, 5 patients with primary gastric lymphoma (PGL), and 3 patients with malignant gastric metastasis. All available endoscopy reports were reviewed. At the entry, clinical symptoms, demographic data and medical history were recorded and gastroscopy was performed to establish the endoscopic diagnosis and status of *H pylori* infection. During the examination of biopsy specimens from the stomach, silver or modified Giemsa staining and histological examinations were performed to establish the diagnosis and status of *H pylori* infection.

Patients and/or family members were contacted. Gastric adenocarcinoma was classified into intestinal type (IT), diffuse type (DT) or mixed type according to the histological criteria of Lauren^[15]. Tumor staging in each patient was based on clinical information, preoperative radiological investigations, operative findings and pathological examination. The staging was made in accordance with the TNM system^[16].

Clinicopathologic data were compared using the χ^2 and Fisher's exact tests. $P < 0.05$ was considered statistically significant.

RESULTS

During the study period, 186 patients with GC were identified, 127 (68.3%) patients were males with a male to female ratio of 2.6:1. The peak incidence was in the age group of 60-69 years (40%), followed by the age group of 50-59 years (16%). Approximately 14% of the patients were younger than 40 years and 6% of the patients were younger than 30 years. The mean age for the whole group was 63 years (range 21-91 years). Table 1 shows the age distribution in the patient groups.

Features of the patients are summarized in Table 2. There was an average of 6-mo delay (range 1-13 mo) between the initial symptoms and diagnosis.

Carcinomas were located most frequently in the lower third of the stomach, accounting for 88.5% (165/186) of all patients. Table 3 shows the distribution of various histological types of gastric adenocarcinoma according to the sites that were affected. One hundred (53.5%) and eighty-six (46.5%) patients lived in urban and rural areas, respectively. The histopathology of gastric biopsy showed *H pylori*-associated chronic active gastritis in 166 (88.9%) patients.

Table 1 Age distribution in patient groups

Age (yr) group	Male patients (n) %		Female patients (n) %	
1-10	0	0	0	0
10-19	0	0	0	0
20-29	4	2.15	7	3.76
30-39	15	8	7	3.76
40-49	11	6	6	3.2
50-59	20	11	10	5.4
60-69	50	27	24	12.9
70-79	19	10	6	3.2
≥ 80	7	3.7	0	0
Total	126	67.9	60	32

Table 2 Features of the studied patients

Signs and symptoms	Patients (n)	%
Abdominal pain	93	50
Weight loss	23	12
Dyspepsia	91	48.8
Nausea, vomiting	74	40
Abdominal mass	4	2
Anorexia	182	97.7
Dysphagia	30	16
Gastrointestinal bleeding	26	14
Ascites	28	15
Constipation	5	2.5

Table 3 Distribution of gastric adenocarcinomas according to their site n (%)

Histopathological type	GEJ and gastric cardia	Gastric corpus and antrum	Total
Intestinal type adenocarcinoma	24 (12.9)	80 (43.1)	104
Diffuse type adenocarcinoma	14 (7.5)	60 (32.3)	74
Gastric lymphoma and metastasis	0 (0)	8 (4.3)	8
Total	38 (16.7)	148 (79.9)	186

GOJ: Gastro-esophageal junction.

According to TNM staging, the proportions of stages I A, I, II + III, and IV in the studied groups were 0% (0/186), 28% (53/186), and 71% (133/186), respectively (Table 4).

DISCUSSION

Gastric cancer is the most prevalent malignancy in Iran. If GC is diagnosed at an early stage, patients can have a highly favorable prognosis and avoid extended surgery, which may produce complications, especially in the elderly people. However, the symptoms of GC are non-specific and vague, when symptomatic patients experience epigastric pain and discomfort and definitive symptoms such as weight loss or obstructive symptoms and metastases that often impede curative radical resection. Additionally, the results of GC treatment do not differ

Table 4 TNM stage and methods of operation in patient groups

Stage (TNM) and methods of operation	Patients (n)	%
I	0	10
II	20	10.8
III	33	17.5
IV	133	71
Curability		
Curative resection	15	8
Palliative resection	95	51
No resection	76	41
Type of resection		
Total and subtotal gastrectomy	70	37.6
Distal gastrectomy	14	7.5
Other resections and palliative operation	26	14

markedly from the past results though there are improved surgical techniques and adjuvant treatments. Researchers have shown that the prognosis of GC has not changed in the past 20 years^[9,17]. The only method that is likely to improve the survival rates is early detection of GC. Our patients tended to present late as evidenced by the fact that there was a long interval between the onset of symptoms and presentation. There was an average of 6-mo delay (range 1-13 mo) between the initial symptoms and the diagnosis.

This is not due to the insufficient current endoscopic services, but due to the fact that many people in our area who have dyspeptic symptoms visit non-specialist physicians who either prescribe medications for long term treatment or use drugs in order to ameliorate the pain. Subsequently, some of these patients whose cause of dyspepsia is cancer present with late stage GC or one of its complications. In addition, the elderly people usually fail to make use of the available medical services. However, general practitioners should be more liberal in referring patients for endoscopy and resist the temptation to treat dyspeptic patients with anti-ulcer therapy without endoscopy, especially in elderly people and in patients with alarming signs. Open access endoscopy, greater efforts in patients' education and improvement of the diagnostic technical skills may improve the early detection of GC.

According to TNM staging, the proportions of stages I A, I, II + III, and IV in the studied groups were 0% (0/186), 28% (53/186), and 71% (133/186), respectively. Approximately more than two-thirds of the patients were diagnosed with advanced GC.

These results re-emphasize that GC symptoms are non-specific and need an early screening examination. A public screening system for gastric cancer has not yet been introduced in Iran and in our area.

Gastric cancer is the most common malignancy in Iran and its incidence is particularly high in the Ardabil Province in the northwest of the country^[12,13,18]. In this province, the age standard incidence rate is 49.1 and 25.4/100 000 persons per year in males and females, respectively.

The cause of the high incidence of gastric cancer in our country is unknown.

The following two factors may play a role. First, the rapid change in dietary habits constitutes a risk factor.

Vitamin C-rich fresh vegetables and fruits, starch and natural unprocessed wheat products are the major constituents of Iranian food. However, canned food, hot spices, pickles and animal proteins are now dominating the Iranian menu.

Fermentation of foods involves the production of nitrosamine. This compound has been implicated as a risk factor for GC in many studies and frequent consumption of fermented food may be a risk factor for GC in our region because our people use such compounds most often.

However, to further investigate the association between fermentation and GC, more comprehensive and detailed data are required. Salt has been indicated as a risk factor for GC in many previous studies. Since the use of salt and fermentation in our regional food preparations is strongly inter-related, we are unable to clearly separate the independent effects of the two variables.

It is known that the environmental risk factors for GC are dietary in origin^[19,20].

In our region the incidence of *H pylori* infection (> 80%) is high and there is a substantial incidence of reflux disease. In addition, 30% people smoke, < 5% people drink alcohol and 60% people have a body mass index > 25^[21].

Most resections are done with palliative intent. The low rate of gastrectomy with "curative" intent could be explained by the high proportion of patients with advanced GC at presentation.

Patterns of GC in our area are similar to those reported from high-risk regions worldwide^[22]. In our study, the male to female ratio was 2.6:1, the peak incidence was in the age group of 60-69 years (40%), followed by the age group of 50-59 years (16%). Approximately 14% of the patients were younger than 40 years and 6% of the patients were younger than 30 years. The mean age of the whole group was 63 years (range 21-91 years). Among our study groups intestinal type (IT) adenocarcinoma was the commonest histological subtype (56%).

IT adenocarcinoma was more common than DT adenoma (1.65: 1) and distal location was more frequent than the proximal one (4.77:1) (Table 1).

In Western countries, PGL and metastasis are represented only in 2%-5% of gastric malignancies^[23]. It was 4.3% in our series, which was lower than 9% from neighboring Iraq^[24], and 14%-22% from Saudi Arabia^[11,25]. During the past three decades the site of PGL in the Middle East has changed. Small intestinal involvement has become less common and gastric involvement more frequent. This varying pattern seems to be environmental in origin. The ratio of PGL to gastric adenocarcinoma among our patients was 0.045, which is similar to the western series^[26].

In conclusion, several symptoms of GC are non-specific. The majority of identified gastric adenocarcinoma patients are symptomatic, and have a lesser chance of being cured by operation and a lower survival rate. The patients with dyspeptic symptoms and alarming signs should be referred to earlier diagnostic endoscopy. Improvements in diet and food storage and control of *H pylori* infection, by indirect means such as improving the

general sanitary conditions or by direct interventions such as eradication are likely to offer great potentials for the prevention of GC in this area.

Although this study has highlighted the pertinent epide-miological and clinicopathological features of gastric malignancy in Khuzestan Province in Iran, further studies are needed to evaluate the environmental risk factors, incidence, the treatment outcomes and survival rate.

ACKNOWLEDGMENTS

The authors would like to thank the medical and nursing staff of Emam and Golestan hospitals for their help in conducting this study and the faculty of Medicine of Jundishapur University, for their encouragement and support.

cluster was undetectable in uninfected HepG2 cells.

CONCLUSION: HepG2 cell line is not only susceptible to HCV infection but also supports its replication *in vitro*. Expression of HCV structural proteins can be detected in infected HepG2 cells. These cells are also capable of shedding viral particles into culture media which in turn become infectious to uninfected cells.

Abstract

AIM: To establish a cell culture system with long-term replication of hepatitis C virus (HCV) genome and expression of viral antigens *in vitro*.

METHODS: HepG2 cell line was tested for its susceptibility to HCV by incubation with a serum from a patient with chronic hepatitis C. Cells and supernatant were harvested at various time points during the culture. Culture supernatant was tested for its ability to infect naïve cells. The presence of minus (antisense) RNA strand, and the detection of core and E1 antigens in cells were examined by RT-PCR and immunological techniques (flow cytometry and Western blot) respectively.

RESULTS: The intracellular HCV RNA was first detected on d 3 after infection and then could be consistently detected in both cells and supernatant over a period of at least three months. The fresh cells could be infected with supernatant from cultured infected cells. Flow cytometric analysis showed surface and intracellular HCV antigen expression using in house made polyclonal antibodies (anti-core, and anti-E1). Western blot analysis showed the expression of a cluster of immunogenic peptides at molecular weights extended between 31 and 45 kDa in an one month old culture of infected cells whereas this

INTRODUCTION

The lack of an efficient cell culture system or a readily available small animal model has hampered the development of therapies for hepatitis C virus (HCV) infection. The chimpanzee is the only animal that is susceptible to hepatitis viral infections, but its endangered status and financial considerations limit its widespread use in viral hepatitis research. Despite these difficulties, recent introduction of heterologous cDNA expression systems^[1] and subgenomic replicons^[2] have allowed researchers to study various aspects of the viral life cycle and examine novel antiviral therapies. Also, among the surrogate animal models that have been developed are mouse liver repopulated with human hepatocytes and transgenic mice expressing hepatitis antigens^[3-5]. For reasons that are not evident, infection of primary hepatocytes and established cell lines with hepatitis viruses have not only produced poor viral replication and low viral yields but have also suffered from poor reproducibility^[6]. The entry of virus into a cell, followed by productive viral replication, depends on both viral and host cell proteins. Only differentiated cells may express the latter. Thus, studies of HCV and HBV infectivity initially used

primary hepatocytes from humans or chimpanzees. One group infects human fetal hepatocytes with HCV-infected serum^[7]. The viral replication is quite low and detectable only by RT-PCR amplification. Using this technique, another group showed an increase in the number of HCV+ strands by d 5, indicating that these hepatocytes support viral replication. Similarly, yet another group showed that adult primary human hepatocytes could be infected with HCV in culture conditions that support long-term cultures of hepatocytes for at least 4 mo^[8]. Under these culture conditions, viral positive-strand RNA was first detectable by PCR after 10 d of infection, and the viral RNA titer increased in culture media during a 3-mo culture. This group also demonstrated *de novo* synthesis of negative-strand viral RNA. Culture supernatants from HCV-infected hepatocytes could transmit infection to naive hepatocytes, indicating the production of infectious viral particles. However, the efficiency of viral infection is unpredictable and does not correlate with viral RNA titers. Addition of polyethylene glycol to the primary hepatocyte cultures maintained in the presence of 20 g/L dimethylsulfoxide markedly increases the infection of HBV^[9] but not HCV^[10]. HCV is lymphotropic, and peripheral blood mononuclear cell cultures support HCV replication^[11]. However, the level of viral replication is very low^[12]. Because primary hepatocytes are difficult to grow in cultures, some researchers have attempted to infect immortalized hepatocytes and hepatoma cell lines. Ikeda and colleagues^[13,14] used PH5CH, a nontumorigenic, immortalized human hepatocyte cell line, to assess the infectivity of HCV positive sera. There was an increase in the HCV sense -strand RNA during the first 12 d of culture, and the viral RNA remained detectable for at least 30 d after infection. Nucleotide sequence determination of the HCV genome in the hypervariable region 1 showed that there is a shift toward the limited HVR-1 population, indicating strong selection for HCV variants during the infection^[13]. Furthermore, IFN γ inhibits the viral replication in these cells^[14]. Recently, Guha *et al*^[5] reported that *in vitro* cell culture models can at best demonstrate the infectivity of the virus but are not suitable to study viral life cycle because of the very low levels of viral replication. These systems could be used in evaluating drugs for antiviral activity or inhibition of HCV infection. Also, Horscroft *et al*^[15] have summarized the recent development of HCV replicon cell culture system and its use in anti-HCV drug discovery. In the present study, we tested the susceptibility of HepG2 cell line to HCV and established an infection cell model that could support HCV long-term replication *in vitro*. The presence of both sense- and antisense-RNA strands and expression of viral core and envelope proteins in infected cells as well as the ability of these cells to exocytose infectious viral particles into culture media suggests that the current cellular model allows study of HCV life cycle.

MATERIALS AND METHODS

HEPG2 cell culture

Caucasian male *Homo sapiens* (human) hepatocellular

carcinoma cell line (HepG2; ATCC, HB-8065, Manassas, USA) was used to establish the *in vitro* HCV replication. HepG2 culturing and infection were carried out according to the protocols described by Seipp *et al*^[10]. HepG2 cells were maintained in 75 cm² culture flasks (greiner bio-one GmbH, Germany) containing Dulbecco's modified Eagle's medium (DMEM) supplemented with 4.5 g/L glucose and 10 g/L L-glutamine (Bio Whittaker, a Combrex Company, Belgium) containing 100 mL/L fetal calf serum (FCS; Biochrome KG Berlin Germany), 10 g/L antibiotics (penicillin/streptomycin; Biochrome KG, Berlin, Germany) and 1 g/L antimycotic (fungisone 250 mg/L; Gibco-BRL life Technologies, Grand Island, New Y). After adding all supplements the medium is called complete. The culture medium was renewed by a fresh medium every 3 d, and cells were subcultured (6-10 d).

In summary the medium was discarded, the adherent cell layer was shortly treated with trypsin-EDTA (2.5 g/L; Sigma, Deisenhofen, Germany) to remove the left traces of trypsin inhibitors from the FCS contained in the medium. After discarding, 1.0 mL of fresh trypsin-EDTA was added onto the cells and flasks were kept either at room temperature or at 37°C (5-15 min) to observe the detachment of cells from the flask wall. To avoid extended proteolytic effect of trypsin on the detached cells complete medium was added to inhibit the enzyme activity. Cells were spun down at 400 g for 2 min, resuspended in 1 mL of complete medium, the exact count of cells was recorded in 50 μ L aliquot after mixed with equal volume of trypan blue (5 g/L; BiochromKG, Berlin, Germany.) using a hemocytometer (Right Line; Sigma, Deisenhofen, Germany). A total of 3×10^6 cells were suspended in 10 mL complete medium and incubated at 37°C in 5% CO₂.

Viral inoculation and sample collection

Cells were grown for 48 h to semi-confluence in complete medium, washed twice with FCS -free medium, then inoculated with a serum sample (500 μ L sense and 500 μ L FCS-free DMEM/ 3×10^6 cells) obtained from HCV infected patients (RT-PCR and antibody positives). The HCV genotype in the used sera was previously characterized as genotype 4 based on the method described by Ohno *et al*^[16]. The viral load in the used serum was quantitated by real time PCR and the average copy number was 290×10^6 copies/L. After 90 min, DMEM containing FCS was added to make the overall serum contents 100 mL/L in a final volume of 8 mL including the volume of human serum used for infection as mentioned above (0.04483 copies/cell). Cells were maintained overnight at 37°C in 5% CO₂. On the next day, adherent cells were washed three times with culture medium to get rid of the remaining infection serum and incubation was continued in complete medium containing 100 mL/L FCS with regular medium changes. The viral infection in HepG2 cells throughout the culture duration was assessed qualitatively by sodium dodecylsulphate polyacrylamide gel electrophoresis (SDS-PAGE) and Western blotting of viral antigens, RT-PCR amplification of sense and antisense strands and quantitatively by real time PCR.

Flow cytometric analysis of intracellular staining of HCV core antigen in infected HEPG2 cells

The intracellular staining of HCV core antigen in infected HepG2 cells was quantified by using a fluorescence activated cell sorting (FACS) based assay. Intracellular staining labeling was performed by direct immunofluorescence. HepG2 cells (collected after addition of trypsin) were centrifuged and supernatants were removed. Cell pellets were washed 4 times with PBS. For intracellular staining, cells were incubated with 4% paraformaldehyde for 10 min and 0.1% Triton X-100 in Tris buffer (pH 7.4) for 6 min. After washed with PBS, cells were incubated with FITC-labeled F(ab)₂ portion of HCV core antibody (at 1:2000 dilution) for 30 min at 4°C. Cells were washed with PBS containing 1% normal goat serum and suspended in 500 µL and analyzed by flow cytometry (FACS Calibure, BD). Mean fluorescence intensity was determined using Cell Quest software (Becton Dickinson).

Flow cytometric analysis of labeled E1 antigen on surface of infected HEPG2 cells

The surface staining of HCV E1 antigen in infected HepG2 cells was quantified by using a fluorescence activated cell sorting (FACS) based assay. Surface labeling was performed by direct immunofluorescence. HepG2 cells collected after trypsinization were centrifuged and supernatants were removed. Cell pellets were washed 4 times with PBS. Cells were incubated with FITC labeled HCV E1 antibody (at 1:1500 dilution) for 30 min at 4°C. Cells were washed 3 times with PBS containing 10 mL/L normal goat serum and suspended in 500 µL PBS and analyzed with flow cytometry (FACS Calibure, BD). Mean fluorescence intensity was determined using Cell Quest software (Becton Dickinson).

Western blot analysis of HCV antigens in HEPG2 cells

Uninfected and infected HepG2 cell lysates were subjected to sodium dodecylsulphate polyacrylamide gel electrophoresis (SDS-PAGE)^[17] through 40 g/L stacking and 160 g/L resolving gels in 0.75 mm-thick vertical slab gels. Cell lysate samples were diluted at 1:25 in PBS, mixed with the sample buffer (0.125 mol/L Tris base, 40 g/L SDS, 2% glycerol, 100 g/L mercaptoethanol, and 1 g/L bromophenol blue as a tracking dye) and immediately boiled for three min. A mixture of reference proteins was run in parallel. Gels were then stained with Coomassie blue. Western blotting was performed as follows: resolved samples separated by SDS-PAGE were electro-transferred onto nitrocellulose membranes (0.45 mm pore size). On the next day, membranes were cut into individual strips each of 0.3 mm width. Strips were washed 3 times with PBS-3 g/L T each for 5 min and blocked against non specific binding at room temperature for 1 h in PBS-3 g/L T-10 g/L bovine serum albumin (BSA). Strips were washed 3 times as above and incubated with diluted first antibody (infected human serum at 1:100, or anti-core/envelope rabbit antibodies at 1:500) in PBS-3 g/L T at room temperature for 2 h. After washed 3 times, strips were incubated with diluted peroxidase-labeled second antibodies (anti-human IgG/IgM mixture at 1:5000 in PBS-3 g/L T for previously treated strips

with human sera or anti-rabbit IgG at 1:1000 in PBS-3 g/L T for those treated with rabbit anti-core/envelope antisera. Both antibodies were from Jakson Immuno Research Laboratories; Dianova, Hamburg, Germany) for 2 h at room temperature. Visualization of immune complexes on the nitrocellulose membrane was done by developing the strips with 0.01 mol/L PBS (pH 7.4) containing 50 mg diaminobenzidine (Sigma; Deisenhofen, Germany) and 100 µL of 30 mL/L hydrogen peroxide.

Isolation and extraction of RNA from serum and HEPG2 cells

Isolation and extraction of RNA from serum and HEPG2 cells were performed as reported in our previous study^[18]. Briefly, cells were precipitated and washed in the same buffer to remove adherent viral particles before lysis in 4 mol/L guanidinium isothiocyanate containing 25 mmol/L sodium citrate and 0.5% sarcosyl and 0.1 mol/L b-mercaptoethanol. Cellular RNA was extracted using the single-step method described originally by Chomczynski and Sacchi^[19].

PCR of genomic RNA strands of HCV

Reverse transcription-nested PCR was carried out according to Lohr *et al*^[20] with few modifications. Retrotranscription was performed in 25 mL reaction mixture containing 20 units of AMV reverse transcriptase (Clontech, USA) with either 400 ng of total PBMC RNA or 3 mL of purified RNA from serum samples (equivalent to 30 mL serum) as template, 40 units of RNasin (Clontech, USA), a final concentration of 0.2 mmol/L from each dNTP (Promega, Madison, WI, USA) and 50 pmol of the reverse primer P1 (for sense strand) or 50 pmol of the forward primer P2 (for anti-sense strand). The reaction was incubated at 42°C for 60 min. and denatured at 98°C for 10 min. Amplification of the highly conserved 5'-UTR sequences was done using two rounds of PCR with 2 pairs of nested primers. The first round amplification was done in 50 mL reaction containing 50 pmol from each of P2 forward primers and P3 reverse primers, 0.2 mmol/L from each dNTP, 10 µL from RT reaction mixture as template and 2 units of Taq DNA polymerase (Promega, USA) in 1 × buffer supplied with the enzyme. The thermal cycling protocol was as follows: 1 min at 94°C, 1 min at 55°C and 1 min at 72°C for 30 cycles. The second round amplification was done as the first round, except for use of the nested reverse primer P4 and forward primer P5 at 50 pmol each. A fragment of 172 bp was identified in positive samples. Primer sequences are as follows: P1: 5' ggtgcacggtctacgagacctc 3'; P2: 5' aactactgtcttcacgcagaa 3'; P3: 5' tgctcatgggtgcacggtcta 3'; P4: 5' actcggtagcagctcgcg 3'; P5: 5' gtcgacgtccaggaccc 3'. To control false detection of negative-strand HCV RNA and known variations in PCR efficiency^[21,22], specific control assays and rigorous standardization of the reaction were employed as previously described^[20]. These specific control assays were cDNA synthesis without RNA templates to exclude product contamination, cDNA synthesis without RTase to exclude Taq polymerase RTase activity, cDNA synthesis and PCR step done with only the reverse or forward

Figure 1 Establishment of an *in vitro* infection experiment of HepG2 cells with serum of a HCV genotype 4-infected patient and monitoring success of infection by nested RT-PCR amplification of viral sense and minus strands. The patient was confirmed to be infected with HCV as demonstrated by nested RT-PCR amplification of viral positive strand in the serum (lane 1), and both viral positive and negative strands (lane 2 and lane 3 respectively) in the peripheral blood mononuclear cells. After infection of the cells with the patient sera (see the detailed method in the materials and methods), cells were carefully washed and nested RT-PCR was carried out on the last wash to make sure that the culture medium contained no more viral RNA and results showed no amplified products (lane 5). At this stage we were sure that any detection of viral RNA within the cells could reflect successful viral adsorption and penetration. Three days after infection, RNA was extracted from both cells and their supernatant and nested RT-PCR for detection of both viral strands was carried out and results showed the presence of the sense strand in the cells (lane 6) but not in the supernatant (lane 7). The antisense strand was neither present in the cells nor in the supernatant (lanes 8, 9). Lane 4 is molecular weight standard DNA marker (ϕ -X-174/HaeIII; Q-BIOgene, Germany).

primer to confirm no contamination from mixed primers. These controls were consistently negative. In addition, cDNA synthesis was carried out using only one primer followed by heat inactivation of RTase activity at 95°C for 1 h, in an attempt to diminish false detection of negative-strand prior to the addition of the second primer.

RESULTS

Establishment of HCV HEPG2 cells in culture

Success of infection was monitored by nested RT-PCR amplification of viral sense and antisense (minus) strands (Figure 1). To confirm the infection of HCV in a patient with chronic active hepatitis whose serum was used in infection of HepG2 cells, nested RT-PCR amplification of viral sense strand in the serum (lane 1) and both viral sense and antisense strands (lane 2 and lane 3 respectively) in peripheral blood mononuclear cells were demonstrated. The viral load was quantified in patient's serum as 2.9×10^5 using real time PCR method (results not shown). After infection of the cells with the patient's sera, cells were carefully washed and nested RT-PCR was carried out on the last wash to make sure that the cell wash contained no more viral RNA (lane 5). At this stage we were sure that any detection of viral RNA within the cells could reflect successful viral binding and entry. Three days after infection, RNA was extracted from cells and culture media. Nested RT-PCR was carried out for detection of both viral strands. Results shown in Figure 1 displayed the presence of sense RNA strand in the cells (lane 6) but

Figure 2 Monitoring of active viral replication at regular time intervals post infection of HepG2 cells. RNA was extracted from infected cells and infectious supernatants and their passages at 1, 2 and 4 wk post infection and nested RT-PCR was carried out for detection of both viral strands. Results showed the presence of both viral strands in RNA extracted from cells 1 wk post infection (lanes 1, 2) but only the sense strand was detectable in the supernatant at this time point (lane 3) while the antisense strand was absent (lane 4). At 2 and 4 wk post infection, both viral strands were detectable in both cells and supernatant. Lanes 6-9 show the presence of both sense and antisense strands in both cells and supernatant at 4 wk post infection. Lane 5 shows molecular weight standard DNA marker (ϕ -X-174/HaeIII; Q-BIOgene, Germany).

not in the culture media (lane 7). The negative strand was neither present in the cells nor in the culture media (lanes 8, 9).

Monitoring of active viral replication at regular time intervals after infection of HEPG2 cells

RNA was extracted from infected cells and infectious supernatants and their passages at 1, 2 and 4 wk post infection and nested RT-PCR was carried out for detection of both viral strands (Figure 2). Results showed the presence of both viral strands in RNA extracted from cells 1 wk post infection (lanes 1, 2) but only the positive strand was detectable in the supernatant at this time point (lane 3) while the negative strand was undetectable (lane 4). At 2 and 4 wk post infection, both viral strands were detectable in both cells and supernatant. Lanes 6-9 show the presence of both sense and antisense strands in both cells and supernatants 4 wk post infection. Results at 2 wk were not demonstrated.

Monitoring infection of HEPG2 cells using culture medium from primary infected cells by nested RT-PCR

After incubation of HepG2 cells with infectious medium presumably containing exocytosed viral particles from primary infected cells, *de novo* infected cells were carefully washed to get rid of any viral traces and the last wash was checked for presence of viral RNA using nested RT-PCR which produced no amplified products (Figure 3, lane 1). RNA was extracted from infected cells as well as their culture media at 3 d, 1 wk, 2 wk and 4 wk post co-incubation with the infectious medium and subjected to nested RT-PCR to check the presence of either or both viral strands (Figure 3). After 3 d the cells contained only sense viral strand (lane 2) while the anti-sense strand was undetectable (lane 3). The supernatant contained neither strand (lanes 4, 5). After 1 wk post infection,

Figure 3 Monitoring infection of HepG2 cells using culture medium from primary infected cells by nested RT-PCR. After incubation of HepG2 cells with infectious medium presumably containing exocytosed virions from primary infected cells, cells were carefully washed to get rid of any viral traces and the last wash was subjected to RNA extraction followed by nested RT-PCR. Results showed no amplification of positive strand products (lane 1). RNA was extracted from infected cells and supernatants at 3 d, 1, 2 and 4 wk post co-incubation with the infectious supernatant and subjected to nested RT-PCR to check for the presence of each viral strand. At 3 d the cells contained only the positive viral strand (lane 2) but the negative strand was undetectable (lane 3). However, the supernatants contained none of the strands, only primers used could be seen (lanes 4, 5). Lane 6 is molecular weight standard DNA marker (ϕ -X-174/HaeIII; Q-BIOgene, Germany). At 1 wk post infection, both sense and antisense strands were detectable in the RNA extracted from the infected cells (lanes 7, 8), whereas the supernatant contained only the sense strand (lane 9) but not the antisense strand (lane 10). At 2 and 4 wk, RNA extracted from infected cells as well as the supernatants contained both positive and negative strands. Results of amplification for both positive and negative strands for cellular RNA are shown (2 wk, lanes 11, 12) and (4 wk, lanes 13, 14).

Figure 4 **A:** Single parameter histogram for flow cytometric analysis of surface staining of HCV E1 gene expression on the infected HepG2 cells after one hour incubation. HepG2 cells were incubated with PBS (**A1**) (uninfected) or with HCV positive serum (**A2**) (infected) for 1 h incubation. Cells were harvested and stained with FITC labeled HCV anti-E1 antibody as described in materials and methods; **B:** Dot histogram for flow cytometric analysis of surface staining of HCV E1 gene expression on the infected HepG2 cells after 24 h incubation. HepG2 cells were incubated with PBS (**B1**) (uninfected) or with HCV positive serum (**B2**) (infected) for 24 h incubation. Cells were harvested and stained with FITC labeled HCV anti-E1 antibody; **C:** Overlap histogram for flow cytometric analysis of surface staining of HCV E1 gene expression on the infected HepG2 cells after one week incubation. HepG2 cells were incubated with PBS (uninfected) or with HCV positive serum (infected) for one week incubation. Cells were harvested and stained with FITC labeled HCV anti-E1 antibody; **D:** Overlap histogram for flow cytometric analysis of intracellular staining of HCV core gene expression in the infected HepG2 cells after 3 d incubation. HepG2 cells were incubated with PBS (uninfected) or with HCV positive serum (infected) for 3 d incubation. Cells were harvested and stained with FITC labeled HCV anti-core antibody. Labeled cells were analyzed with flow cytometry (FACS Calibure, Becton Dickinson).

both sense and antisense viral strands were detectable in infected cells (lanes 7, 8), whereas the supernatant contained only the sense strand (lane 9) while the antisense strand was undetectable (lane 10). After 2 and 4 wk post infection, RNA extracted from infected cells as well as their supernatants contained both positive and negative strands. Results of amplification of both positive and negative strands from cellular RNA at 2 and 4 wk are presented in lanes 11-14. Results of the nested RT-PCR on the supernatant at the same time points were not demonstrated since they were identical to those obtained from the cells. However, culture supernatant from infected HepG2 cells was used to infect naïve (uninfected) cultured

HepG2 cells and we found that these HepG2 cells were infected as detected by RT-PCR (Data not shown).

Flow cytometric analysis of surface and intracellular staining of HCV antigen expression in infected HEPG2 cells

Flow cytometric analysis showed that HCV core and E1 antigens were detected on surface and inside of the infected HepG2 cells. Figures 4A-C show the percentage of anti E1 positive staining on the surface of HepG2 cells after 1 h (4%) and 24 h (7.6%) and one week (12.5%) of incubation of HepG2 cells with positive HCV serum sample. Core protein was detectable in 5.7% of cells after

Figure 5 Testing translation of viral E1 in supernatant and lysates of HepG2 cells infected with HCV from 1 mo culture by Western blot analysis. Supernatant (strip 1) and lysates (strip 2) of HepG2 cells infected with HCV were subjected to Western blot analysis, hybridization with the anti-E1 antibody clearly showed the expression of a cluster of immunogenic proteins at molecular weights localized between 31 and 45 kDa. This cluster was undetectable on the strip immobilized with uninfected HepG2 cell lysates (strip 3).

24 h, and increased to 13.5% of cells after 3 d. Figure 4D shows the intracellular staining of core antigen using F(ab)₂ portion of the core antibody after infection of 3 d.

Western blot analysis of HCV viral antigen expression in infected HEPG2 cell lysates

When supernatant (Figure 5, strip 1) and lysates (strip 2) of HepG2 cells infected with HCV were subjected to Western blot analysis, hybridization with the anti-E1 antibody could clearly show the expression of a cluster of immunogenic peptides at molecular weights extended between 31 kDa and 45 kDa over 1 mo period. This cluster was undetectable on the strip immobilized with uninfected HepG2 cell lysates (strip 3).

DISCUSSION

Although knowledge of the molecular biology of HCV has progressed rapidly, our understanding of viral replication and pathogenicity is still hampered by the lack of reliable and efficient cell culture systems. To achieve a reliable *in vitro* system we need to obtain a biological status wherein viral-host interactions mimic exactly what happens naturally *in vivo*, since both viral and host factors make up together the overall outcome of the pathogenetic pathways. The reasons for using HepG2 cells in the current study include the great similarity in biosynthetic pathways between primary hepatocytes and HepG2 cells^[23]. Also the later cells contain LDL and CD81 receptors which are known to mediate HCV entry into cells^[24]. Validity of HepG2 cells in propagating HCV has been reported by other laboratories^[25]. The viral component of the model has several alternative strategies. Subgenomic or genomic replicons have been used in elucidating the replicative machinery of the virus^[26] but could not mimic the actual viral replication cycle and shedding of the virus to the culture medium. Despite the extremely robust *in vivo* replication rate of HCV using genomic replicons, efforts to propagate the virus in cell culture have been frustratingly unsuccessful^[27]. Thus the viral replication but not the biologically relevant infectious viral particles can be demonstrated by such approach. In the present study we utilized infectious serum with native viral particles presumably containing the full length viral RNA genome in infecting HepG2 cells *in vitro*. The recent understanding

of the HCV molecular biology demonstrates that both 5' and 3' untranslated regions of the viral RNA genome play a pivotal role in translation of viral proteins *via* interaction with cellular factors including eukaryotic initiation factor 3 eIF3^[35], 40S ribosomal subunit^[28] and poly pyrimidine tract binding (PTB)^[29] protein. Besides, it has been shown that intra genetic viral interactions such as NS4a/NS5a are required for key pathways in HCV life cycle. In the current study, the use of infectious viral particles containing intact RNA genome could guarantee the presence of the necessary elements involved in translation of polyprotein precursor and viral replication. We have presented several lines of evidence that the cell model described herein maintains HCV life cycle. A minor fraction of cells (4%) had a detectable viral envelope on cell surface as early as one hour after incubation. This fraction steadily increased to 7.6% in 24 h and 12.5% after one week. E1 protein reached detectable levels by Western blotting analyses at both intracellular and extra cellular compartments after one month. *De novo* synthesis of RNA minus strand was detected inside HepG2 cells as early as one week post infection and appeared in the medium one week later. However, the detection of the replicative intermediate (antisense strand HCV RNA) is thought to be reasonable for assessment of HCV replication. Because detectable HCV structural proteins in cells after infection may represent the residue of the inoculated virus after releasing the viral genome to cytoplasm, it is necessary to demonstrate that HCV structural proteins detected in the infected cultures are newly synthesized rather than residuals of viral inoculum. Interestingly, the core protein was only detectable in 5.7% of cells after 24 h and increased to 13.5% of cells after 3 d, indicating that such observed increase in core expression reflects part of *de novo* synthesized structural viral proteins. The ability of culture medium to transmit viral particles to new cells later in one month culture with concomitant detection of core (results not shown) and envelope proteins as well as detection of sense and antisense RNA strands suggest that infected HepG2 cells reach a state of equilibrium after one month of infection. Other cellular models for HCV propagation can transmit viral particles to naïve cells^[30]. We assume that this approach brings our *in vitro* system to become closer to native viral infection status occurring *in vivo*. The expression of different viral antigens agrees with the earlier reports that liver and blood cells from infected patients do support these expressions^[11,31-35]. Our observation that HCV RNA detection was intermittent during early days post infection agrees with previous reports on infection experiments^[7,10,33], a finding which has led the investigators to suspect the consistency of viral replication and gene expression in these cell models.

In conclusion, we report an *in vitro* system of cultured HepG2 cells infected with HCV particles. These cells support viral replication and gene expression. The consistent expression of viral proteins and the ability of culture medium to transmit the virus to new cells make this model optimum for studying HCV life cycle, screening for anti HCV drugs and testing the efficacy of therapeutic antibodies.

Abstract

AIM: To study expression of tissue factor (TF) in pancreatic cancer and its role in the development of thromboembolism.

METHODS: TF expression was studied in eight human pancreatic carcinoma cell lines by Northern blot and indirect immunofluorescence. Expression of alternatively spliced TF (asTF) was assessed by RT-PCR. In addition, TF expression was determined by immunofluorescence in pancreatic tissues of 19 patients with pancreatic adenocarcinoma (PCa), 9 patients with chronic pancreatitis (CP) and 20 normal controls. Plasma samples (30 PCa-patients, 13 CP-patients and 20 controls) were investigated for soluble TF levels and coagulation activation markers [thrombin-antithrombin III complex (TAT), prothrombin fragment 1 + 2 (F1 + 2)].

RESULTS: All pancreatic carcinoma cell lines expressed TF (8/8) and most of them expressed asTF (6/8). TF expression at the protein level did not correlate with the differentiation of the carcinoma cell line. All but two pancreatic cancer tissue samples stained positive for TF (17/19). In all samples of CP weak staining was restricted to pancreatic duct cells, whereas only a few subendothelial cells were positive in 9/20 of normal controls. TF and TAT levels in PCa patients

were significantly elevated compared to controls whereas elevated F1 + 2 levels did not reach statistical significance compared to controls. In CP patients TAT and F1 + 2 levels proved to be significantly elevated compared to controls, although TAT elevation was less pronounced than in PCa patients.

CONCLUSION: We conclude that in addition to the upregulated expression of TF on the cell membrane, soluble TF might contribute to activation of the coagulation system in pancreatic cancer.

INTRODUCTION

Cancer patients are highly susceptible to thromboembolic complications. These thromboembolic complications include venous and arterial thrombosis, migratory thrombophlebitis, pulmonary embolism and disseminated intravascular coagulation (DIC). Idiopathic deep vein thrombosis may be the first clinical manifestation of an occult malignancy and the cancer risk is particularly increased within the first twelve months after the diagnosis of thromboembolism^[1].

Patients with idiopathic venous thrombosis have been recognized to have a three to four fold increased likelihood of harboring malignancies^[2,3]. Cancer patients have a two to eight fold higher risk of dying after an acute thrombotic event than patients without cancer^[4-6]. Furthermore, pancreatic cancer is associated with the highest risk for thromboembolism with an estimated risk ratio of 10^[7].

Although the first description of an association of malignant disease with thrombotic events dated back as early as 1865, the underlying mechanisms are poorly understood^[8].

Tissue factor (TF) is a key element in the initiation of the extrinsic coagulation cascade. Binding of activated factor VII to TF results in the activation of factor IX and X ultimately leading to thrombin formation which generates fibrin from fibrinogen and activates platelets^[9]. TF is a 49-kD transmembrane glycoprotein belonging to the cytokine receptor family group 2 and contains 263 amino acid residues. Procoagulant activity of TF is tightly regulated at the transcriptional level and the natural inhibitor tissue factor pathway inhibitor (TFPI) can inhibit uncontrolled activation of coagulation. Recently, a variant of TF was identified which results from alternative splicing of the primary RNA transcript. Alternatively spliced TF (asTF) proves to be biologically active^[10,11].

Constitutive TF expression is demonstrated predominantly in the brain, lung, placenta, cerebral cortex and kidney^[12,13]. Aberrant expression of TF, the principal initiator of blood coagulation, has been postulated to contribute to thrombosis in cancer patients.

Various tumor entities are shown to express TF, including glioma^[14], breast cancer^[15,16], non-small cell lung cancer^[17,18] and pancreatic cancer^[19,20].

The present study was designed to systematically investigate the expression of TF by pancreatic carcinoma cells *in vitro* and *in vivo*. Specifically, we focused on the following questions: Do ductal pancreatic adenocarcinoma cells express TF and is the expression intensity related to the degree of tumor differentiation? Is the expression of TF restricted to pancreatic carcinoma cells? Does expression of TF adversely affect blood coagulation in patients as analysed by coagulation activation markers? Is clinical thromboembolism in these patients related to plasma coagulation activation?

MATERIALS AND METHODS

Cell lines

Eight human pancreatic carcinoma cell lines were studied for TF expression: AsPC-1, BxPC-3, Capan-1, Capan-2, PaCa-2, PaCa-3, PaCa-44, and PANC-1. The cell lines have been previously studied and characterized^[21-23]. The grading of the tumor cell lines as assessed by electron microscopy^[21] is listed in Table 1. The expression of asTF was assessed in eight pancreatic cancer cell lines (AsPC-1, BxPC-3, Capan-1, Capan-2, PaCa-44, PANC-1, NP9, NP29), in two colorectal carcinoma cell lines (DLD-1 and SW48), in the cervical cancer cell line HeLa and in fibroblasts.

Cells were grown in their respective medium (usually RPMI-1640) supplemented with 10% fetal calf serum. For serum deprivation, cells were seeded in tissue culture flasks and incubated with medium containing 10% fetal calf serum for 24 h, then washed twice with sterile PBS, and finally incubated with serum-free medium.

Northern blot

RNA was extracted from exponentially growing cell lines as described earlier^[22]. Twenty μ g of total RNA was analysed by formamide agarose gel electrophoresis and Northern blotting^[22]. Blots were hybridized to a TF cDNA

Table 1 Tissue factor expression in eight human pancreatic adenocarcinoma cell lines in relation to the histological differentiation determined by northern-blot analysis (RNA level) and by indirect immunofluorescence (protein level)

	Grade	RNA	Protein
Capan-1	I	1 ¹	2
Capan-2	I - II	3	2
AsPC-1	I - II	3	3
BxPC-3	II	3	2-3
PANC-1	II - III	1	1-2
PaCa-2	II - III	1	2-3
PaCa-3	III	1 ¹	3
PaCa-4	III	1	1-2

¹ Positive only in the absence of fetal calf serum.

probe^[24] and subsequently to a ribosomal cDNA control probe (S138). The 1.4 kb TF-specific insert was labelled with 32P-dATP yielding 5-7 $\times 10^8$ cpm per μ g DNA. Filters were hybridized with 1-2 $\times 10^6$ cpm/mL hybridization mix at 42°C overnight, washed with 2 \times SSC at 37°C for 30 min and 0.5 \times SSC at 55°C for 10 min, dried, and exposed to Kodak XAR film using Kronex lightning enhancer screens. Films were evaluated semiquantitatively according to an established rating. A minimal or no signal representing densitometric measurements < 0.100 was rated 0; a weak signal equivalent to densitometric values 0.100 to 1.0 was rated 1; a signal equivalent to densitometric values 1.0 to 5.0 was rated 2, and a signal equivalent to densitometric readings > 5.0 was rated 3^[21,22].

RT-PCR

For detection of concomitant expression of TF and asTF, cells were washed with PBS. After complete removal of the PBS, 350 μ L buffer RLT (RNeasy Mini Kit; Qiagen, Hilden, Germany) plus β -ME (10 μ L/mL) was pipetted directly onto the cells. The lysate was processed further according to the manufacturer's recommendations. Isolated total RNA (1 μ g, determined photometrically) was reverse transcribed using Superscript II reverse transcriptase (Invitrogen; Karlsruhe, Germany) and oligo-dT primers. The resulting cDNA was amplified in separate tubes using Hot Star Taq (Qiagen; Hilden, Germany). Used primers are listed in Table 2. Oligonucleotides corresponded to TF nucleotides 221-244 and 1013-1036, respectively. TF and asTF were discriminated on a 2% agarose gel as bands of 815 and 656 bp, respectively. The cycling parameters are as follows: initial denaturation and Taq polymerase activation at 94°C for 15 min, cycling (33 \times) at 94°C for 45 s, 50°C for 45 s and 72°C for 45 s and a final extension at 72°C for 5 min.

Immunofluorescence

Tumor cell lines grown on glass slides, cryostat sections of pancreatic carcinoma, chronic pancreatitis, and of normal pancreatic tissue were fixed in acetone at -20°C for 10 min and immunostained by indirect immunofluorescence. The primary mouse monoclonal antibody against TF was clone 5G9^[25]. Staining was performed on at least two separate preparations for all tissue sections or cell lines. Staining intensity was graded semiquantitatively as described before^[21,22]: a negative staining was rated 0, weakly positive 1, moderately positive 2, and strongly positive 3. This referred to the overall staining intensity. If there were focal positive spots, it was documented separately. Appropriate controls were included throughout this investigation.

Pancreatic tissue

Forty-eight tissue samples were available for further investigation: 19/30 samples from patients with pancreatic carcinoma and 9/13 samples from patients with chronic pancreatitis. Twenty normal tissue samples were obtained from organ donor pancreata^[26]. After surgical removal the tissue sample was immediately snap frozen in liquid nitrogen. Five micrometer thick sections were stained with hematoxylin and eosin for histological examination^[27].

Patients

The study population comprised 30 patients with pancreatic ductal adenocarcinoma (PCa). Thirteen patients with chronic pancreatitis (CP) and 30 healthy subjects (co) served as controls. Clinically overt thromboembolic events were noted in four patients.

With patients' written informed consent citrate-anticoagulated blood was drawn on the first day of hospitalization prior to the administration of medications potentially interfering with the coagulation system. Platelet-free plasma aliquots were stored at -80°C .

All patients underwent extensive diagnostic work-up including abdominal ultrasound, contrast-enhanced computed tomography and magnetic-resonance tomography, respectively. Suspected thromboembolic manifestations were investigated by doppler ultrasound and when necessary with computed tomography and angiography.

Coagulation studies

Separate plasma aliquots obtained from patients were quickly thawed and utilized for the following commercially available assays according to the instructions provided by the manufacturers. TF antigen concentration was measured using the Imubind[®] Tissue Factor ELISA kit (American Diagnostics, Greenwich, CT, USA). Thrombin-anti-thrombin III complex (TAT) was quantitated employing the Enzygnost[®] TATmicro enzyme immunoassay (Behring, Frankfurt, Germany). Prothrombin fragment 1 + 2 (F1 + 2) was evaluated using the Enzygnost[®] F1 + 2 kit (Behring, Frankfurt, Germany).

Statistical analysis

Plasma levels of TF, F1 + 2 and TAT are expressed as the means \pm SD. Statistical significance was calculated using the two-sided Mann-Whitney test. A *P*-value of < 0.05 was considered statistically significant.

RESULTS

Expression of TF in pancreatic carcinoma cell lines

All of the eight human pancreatic carcinoma cell lines expressed TF (Table 1, Figures 1, 2, 3A and B). Expression at RNA-level could be modulated in part by serum depletion (Figure 1). All lowly differentiated cell lines (grade II and II-III) exhibited weak TF expression determined by Northern-blot analysis, whereas three of the four highly differentiated cell lines (grade I, I-II and II) were found to have a strong TF expression at the RNA level. In contrast, no clear correlation between differentiation and TF protein levels could be demonstrated by immunofluorescence (Table 1).

Expression of asTF in pancreatic cancer cell lines

In addition to TF, the majority of studied pancreatic carcinoma cell lines (6/8) expressed asTF (Figure 2). Furthermore, asTF expression could be demonstrated in the colorectal carcinoma cell lines DLD-1. The colorectal

Grade 3	4	0	0
Grade 2	7	0	0
Grade 1	6	9*	0
Negative	2	0	11

¹P = 0.027 vs controls; ²A few positively stained epithelial duct cells;

³Expression restricted to subendothelial cells.

carcinoma cell line SW48, the cervical cancer cell line HeLa and fibroblasts did not express asTF.

Expression of TF in pancreatic tissue

Of the 19 pancreatic carcinoma tissue samples nearly all (17/19) were positive for TF (4/19: grade 3, 7/19: grade 2, 6/19: grade 1) and only two were negative (Table 3, Figure 3C). The amount of TF expression in tumor tissue did not correlate with the grading of the tumor (Table 3).

All tissue samples obtained from chronic pancreatitis demonstrated positive staining of epithelial pancreatic duct cells (Table 3, Figure 3D). However, staining intensity was rated weakly in these cases. Nearly half of all normal control tissue samples exhibited only weak staining of a few subendothelial cells (9/20) (Table 3).

Plasma concentrations of TF in patients with pancreatic cancer and healthy controls

TF plasma concentrations in 30 patients with pancreatic cancer were significantly enhanced versus 30 healthy controls (288 ± 41.4 ng/L vs 139 ± 9.7 ng/L, $P = 0.005$) (Figure 4).

Coagulation studies

Plasma levels of TAT in patients with pancreatic carcinoma (PCa) were more than twenty-times higher than in normal controls (89.4 ± 38.8 µg/L vs 4.0 ± 3.5 µg/L, $P = 0.002$). Interestingly, they were also significantly enhanced

Figure 5 Plasma concentrations of thrombin-antithrombin complex (TAT) in patients with pancreatic cancer (PCa), chronic pancreatitis (CP) and healthy controls (Co). Bars indicate means and standard deviation.

Figure 6 Plasma concentrations of prothrombin fragment 1 + 2 (F1 + 2) in patients with pancreatic cancer (PCa), chronic pancreatitis (CP) and healthy controls (Co). Bars indicate means and standard deviation.

in patients with chronic pancreatitis (CP) versus healthy controls (45.1 ± 37.9 µg/L vs 4.0 ± 3.5 µg/L, $P = 0.001$) (Figure 5). However, higher levels in PCa patients compared to CP patients did not reach statistical significance.

Plasma levels of prothrombin F1 + 2 proved to be higher in patients with pancreatic adenocarcinoma although not reaching statistical significance (1.16 ± 1.56 nmol/L vs 0.75 ± 0.34 nmol/L, $P = 0.16$), whereas significant elevation of F1 + 2 was observed in patients with chronic pancreatitis versus controls (1.46 ± 1.23 nmol/L vs 0.75 ± 0.34 nmol/L, $P = 0.005$) (Figure 6). There was no correlation between the plasma levels of

¹ Staging according to UICC; ² Results from immunohistochemistry, i.e. immunofluorescence for TF; ³ TF was focally positive; nd: not determined.

TAT or F1 + 2 and the extent of TF expression in the pancreatic tumor tissue (data not shown). However, there was a strong correlation between TAT and F1 + 2 plasma levels ($P < 0.05$).

Patients with pancreatic cancer and thromboembolic complications

Four of the TF-positive patients had thrombosis, as revealed by doppler ultrasound, computed tomography and/or angiography (Table 4). All patients with thrombosis had a stage 4 pancreatic carcinoma. In two cases TF plasma levels were available which were increased by a factor of 2 and 2.8, respectively, compared to the mean value of TF plasma levels in healthy controls.

DISCUSSION

Our study proved expression of TF by epithelial tumor cells in pancreatic adenocarcinoma *in vitro* and *in vivo*. In patients with pancreatic cancer, a hypercoagulable state could be confirmed by increased concentrations of the TAT in conjunction with elevated TF plasma levels. Four patients expressing TF in their tumors developed clinically overt thromboembolism.

The presence of a malignant disease dramatically increases the risk for thromboembolic events. Immobility, indwelling catheters, surgical procedures and chemotherapy represent risk factors rendering cancer patients for thromboembolism^[28]. In addition, direct activation of the coagulation cascade by cancer cells is considered a key feature of the well-established increased risk for thrombotic events. TF plays a central role in activating coagulation and enhanced expression is implicated in diseases with enhanced thrombotic features like cancer^[29], atherosclerosis^[30], sickle cell disease^[31] and sepsis^[32].

We analyzed the expression of TF in eight well characterized cell lines of ductular adenocarcinoma^[23]. Without exception all showed TF expression at RNA and protein levels. Highest RNA levels were found in the well-differentiated cancer cell lines (Capan-2, AsPC-1, BxPC-3). However, in relation to differentiation no clear correlation of TF expression could be observed at the protein level. The fact that the amount of TF protein levels did not strictly correspond to RNA levels suggests that posttranscriptional regulation might be of importance in TF expression. We could not confirm the finding of Kakkar that expression of TF was most prominent in poorly differentiated tumors^[20].

In addition to expression of TF, the majority of studied pancreatic carcinoma cell lines expressed the recently characterized asTF^[10,11]. This splice variant contains the extracellular domain of TF, but lacks the transmembrane and cytoplasmatic domain. Exon 4 is spliced directly to exon 6 leading to a frameshift so that the translated peptide comprises residues 1-166 of the extracellular domain of TF and a unique C terminus (residues 167-206). AsTF proved to have full pro-coagulant activity. The expression of asTF might contribute to systemic hypercoagulopathy in pancreatic cancer.

Corresponding to the TF expression in pancreatic carcinoma cell lines we demonstrated, in the majority of tissue specimens of patients with pancreatic cancer, TF expression in tumor cells, which showed a high variability in the expression rate determined by immunofluorescence. Recently, upregulated TF expression in colorectal cancer cells was ascribed to *K-ras* mutations^[33]. As mutations in the *K-ras* oncogene are an early event in the development of pancreatic cancer and as these mutations are found in the majority of pancreatic cancer patients, mutational activation of *K-ras* might have a contributory role in upregulated TF expression^[34]. Further studies are warranted to clarify whether inactivation of the tumor suppressor gene PTEN and hypoxia are involved in enhanced TF expression in pancreatic cancer as it was recently demonstrated in glioblastoma^[35]. Lately, Nitori and co-workers determined TF expression in pancreatic cancer by immunohistochemistry and found an association of high TF expression with metastasis and a low survival rate^[36].

To our knowledge this is the first report demonstrating an enhanced TF expression in tissues of patients with chronic pancreatitis which was confined to pancreatic duct cells. This was a surprising result as tissue of chronic pancreatitis patients was initially intended to be included in the study to serve as a negative control. Previous data have shown that the exposure of endotoxin, tumor necrosis factor (TNF)- α and interleukin (IL)-1 results in upregulation of TF expression *in vitro*^[37-40]. Proinflammatory cytokines secreted by the inflammatory infiltrate in chronic pancreatitis might be an explanation for the upregulated TF expression^[41]. In contrast, only weak staining of a few subendothelial cells was found in control tissue specimens. Upregulated TF expression in the tissue of chronic pancreatitis patients might have a contributory role in the development of thrombotic events, which is a well-known complication in chronic pancreatitis.

TF plasma concentrations in patients with pancreatic cancer were found to be more than twice as high than in normal controls which might stem from asTF or from TF-containing microparticles and from TF which is secreted by activated leukocytes, respectively^[42-44]. Further studies are needed to prove that the source of TF in the plasma of patients with pancreatic cancer is the tumor itself.

In parallel to enhanced TF expression, markers of thrombin formation (TAT, F1 + 2) were elevated in the plasma of patients with pancreatic cancer and chronic pancreatitis. A procoagulatory state in patients with chronic pancreatitis might facilitate the generation of portal and splenic vein thrombosis, which is commonly seen in this patients' group.

Four patients with pancreatic cancer had concurrent venous thrombosis or pulmonary embolism. TF expression was highly variable but all patients had a stage 4 carcinoma. Apparently the tumor load and tumor progression is a more powerful prognostic marker for thrombotic complications than TF expression in pancreatic cancer. This is in accordance with data showing that the stage of colorectal cancer most consistently correlates with the risk for thromboembolism^[45].

In this study we focused on TF expression, taking into account that undoubtedly multiple factors modulate hypercoagulable state.

Tissue factor pathway inhibitor (TFPI) is an important factor limiting the effects of TF. In a recent study low levels of TFPI were associated with an increased risk of venous thrombosis^[46]. Mice deficient of TFPI exhibited an increased rate of thrombosis and accelerated atherosclerosis^[47]. Both pancreatic carcinoma and chronic pancreatitis produce a rich stroma^[48]. We demonstrated that epithelial tumor cells can synthesize and deposit extracellular matrix proteins in pancreatic carcinoma^[21,49]. Fibronectin itself which is expressed by pancreatic tumor cells^[21] is capable of activating the coagulation cascade^[50].

In addition to its haemostatic potential, the TF expression by tumor cells has implications in tumor biology^[51,52]. Belting and coworkers have shown that TF directly promotes angiogenesis through protease-activated receptor-2 (PAR-2) signaling^[53]. Upregulation of the urokinase receptor in pancreatic cancer by TF enhances tumor invasion and metastasis^[54]. Pancreatic carcinoma cells possess a functioning thrombin receptor, and stimulation with thrombin representing the product of the coagulation cascade causes cell proliferation^[55]. Furthermore, thrombin has a proangiogenic function^[56,57].

In summary, enhanced TF expression in pancreatic adenocarcinoma in conjunction with elevated TF plasma levels might have a crucial role in hypercoagulopathy, resulting in thromboembolism.

Abstract

AIM: To investigate whether, or how, DA-9601, which is a new gastroprotective agent, inhibits TNF- α -induced inflammatory signals in gastric epithelial AGS cells.

METHODS: Cell viability was determined by MTT assay. IL-8 and CCL20 promoter activities were determined by a luciferase reporter gene assay. NF- κ B-dependent transcriptional activity was determined by I- κ B α degradation, NF- κ B p65 nuclear translocation and a luciferase activity assay. IL-8 and CCL20 gene expression and protein secretion were determined by RT-PCR and an enzyme-linked immunosorbent assay (ELISA). Total and phosphorylated forms of mitogen-activated protein kinases (MAPKs) were determined by Western blot.

RESULTS: Treatment of AGS cells with DA-9601 reduced

TNF- α -induced IL-8 and CCL20 promoter activities, as well as their gene expression and protein release. TNF- α also induced NF- κ B-dependent transcriptional activity in AGS cells. In contrast, in cells treated with DA-9601, TNF- α -induced NF- κ B activity was significantly blocked. Although all three MAP kinase family members were phosphorylated in response to TNF- α , a selective inhibitor of p38 kinase SB203580 only could inhibit both NF- κ B-dependent transcriptional activity and IL-8 and CCL20 production, suggesting a potential link between p38 kinase and NF- κ B-dependent pathways in AGS cells. Interestingly, DA-9601 also selectively inhibited p38 kinase phosphorylation induced by TNF- α .

CONCLUSION: DA-9601 blocked TNF- α -mediated inflammatory signals by potentially modulating the p38 kinase pathway and/or a signal leading to NF- κ B-dependent pathways in gastric epithelial cells.

INTRODUCTION

Artemisia asiatica has been frequently used in traditional Asian medicine for the treatment of diseases such as inflammation, cancer and microbial infection. Along this line, a novel antipeptic formulation prepared from the ethanol extracts of *A. asiatica*, namely DA-9601 (StillenTM), has been reported to possess anti-oxidative and anti-inflammatory activities in experimentally induced

gastrointestinal damage as well as hepatic and pancreatic lesions^[1-4]. DA-9601 is now on the market in South Korea and will be on sale in other Asian countries in the near future. However, despite studies in animals and humans, the detailed cellular mechanism of the pharmacologic actions of DA-9601 is largely unknown.

Chemokines are potential mediators that in many cases can act as a signal for the emigration of blood cells. The C-X-C chemokines are considered the most important mediators for the accumulation of granulocytes^[5,6]. One member of this cytokine family, chemokine interleukin-8 (IL-8), has been shown to be elevated in gastric biopsy samples of patients with *H. pylori*-associated gastritis^[5], and is considered to be an important mediator for the initiation of host innate immunity by recruiting granulocytes^[7]. On the other hand, CCL20 is a recently described C-C chemokine (also known as a liver- and activation-regulated chemokine or macrophage inflammatory protein 3 α) that was first identified by screening the GenBank database of expressed sequence tags for novel chemokine molecules^[8]. CCL20 is also expressed in gastric epithelial cells, upregulated by infection with *H. pylori*, and implicated in the initiation of host adaptive immunity by regulating recruitment of dendritic cells^[9], effector memory T cells and B cells via CCR6^[10]. Given their potential importance in inflammatory responses, these two chemokines may be good target systems in evaluating the anti-inflammatory efficacy of potential pharmacologic drugs in gastric epithelial cells.

In the current study, we primarily investigated whether TNF- α induces IL-8 and CCL20 genes, as well as their protein products, in human gastric epithelial AGS cells. Although TNF- α is a candidate factor for involvement in inflammation-mediated gastric mucosal injury, the mechanisms of action for this cytokine on gastric epithelial cells are still poorly understood. We next analyzed where DA-9601 acted in the TNF- α -induced inflammatory cascade.

MATERIALS AND METHODS

Reagents and Antibodies

DA-9601 (Lot No. DA-9601-L-07) with 0.42% of active ingredient, eupatilin^[11], was extracted from *A. asiatica* and supplied to this study after HPLC analysis in Dong-A Pharmaceutical Co. Ltd., (Yongin, South Korea)^[12]. Alkaline phosphatase-conjugated rabbit anti-goat IgG, and p-nitrophenyl phosphate tablets, dimethyl sulfoxide, phosphate-buffered saline (PBS), 3-(4, 5-dimethylthiazol-2-yl)-2, 5-diphenyltetrazolium bromide (MTT) were purchased from Sigma Chemical Co. (St. Louis, MO). Recombinant human TNF- α goat anti-human IL-8 polyclonal antibody, mouse anti-human CCL20 monoclonal antibody (clone 67310.111), and goat anti-human CCL20 polyclonal antibody were obtained from R&D Systems Inc. (Minneapolis, MN). Rabbit anti-human IL-8 polyclonal antibody was from Endogen Inc. (Woburn, MA). Antibodies against p38 kinase, c-Jun N-terminal kinase (JNK), extracellular signal-regulated kinase (ERK), and the antibodies specific to the phosphorylated forms

(pp38, Thr180/Tyr182; pJNK, Thr183 Tyr185; pERK1/2, Thr202/Tyr204) were purchased from Cell Signaling Technology, Inc. (Beverly, MA). SB203580, SP600125, PD98059 and PDTC were purchased from Calbiochem (La Jolla, CA). Anti-human I- κ B α was from Santa Cruz Biotechnology (Santa Cruz, CA).

Report gene construction

IL-8 promoter-luciferase reporter vector (pGL3-pIL-8) was obtained from Dr. J.-S. Chun in Gwangju Institute of Science and Technology (Korea). The CCL20 promoter from -1905 to +30 was amplified from 100 ng of human genomic DNA by PCR under standard conditions with the following primers (restriction sites underlined) pCCL20_forward (*SacI*) 5'-ATACCGAGCTCGGCCAGTCTGGTCTCGAACT-3'; pCCL20_reverse (*HindIII*) 5'-ATACCAAGCTTCTTTAATCAATATTGCAGTT-3' and cloned into the pGL3-basic plasmid (Promega, Mannheim, Germany) to generate pGL3-pCCL20 luciferase vector. pGL3-pCCL20 was sequence verified with an ABI3700 sequencer (ABI, Foster City, CA) before use.

Cell culture

Human gastric epithelial AGS cells and human kidney epithelial 293T were obtained from the American Type Culture Collection (ATCC). The cells were cultured at 37°C in a 5% CO₂ atmosphere in RPMI-1640 supplemented with heat-inactivated 10% fetal bovine serum (FBS; GibcoBRL) and appropriate antibiotics.

Cell viability assay

Cellular viability was evaluated by the reduction of MTT to formazan. A stock solution of MTT was prepared in phosphate-buffered saline (PBS), diluted in RPMI 1640 medium, and added to cell-containing wells at a concentration of 0.5 mg/mL after the culture medium was first removed. The plates were then incubated for 4 h at 37°C in 5% CO₂. At the end of the incubation period, the medium was aspirated, and the formazan product was solubilized with dimethyl sulfoxide. Absorbency was measured on a multiscan reader with a 570 nm wavelength filter.

IL-8 and CCL20 Measurement

The concentration of IL-8 or CCL20 in culture supernatants from AGS cells was measured by a previously described method^[12,13]. In brief, 96-well microtiter plates (MaxiSorp™, Nunc, Denmark) were coated with 2 μ g/mL of goat anti-human IL-8 (R&D Systems) or mouse anti-human CCL20 (clone 67310.111; R&D Systems) in 50 μ L PBS at 4°C overnight. All further steps were carried out at room temperature. After washing three times with PBS, non-specific binding sites were blocked by incubation with 150 μ L PBS, 1% BSA and 0.05% Tween 20/well for 2 h. After three washes with PBS, 50 μ L of samples or standards were added and incubated for 2 h. As a second antibody, 0.5 μ g/mL polyclonal rabbit anti-human IL-8 (Endogen) or polyclonal goat anti-human CCL20 (R&D Systems) was added and incubated for 2 h. As a third antibody, alkaline phosphatase-conjugated monoclonal mouse anti-rabbit IgG (for IL-8) or rabbit anti-goat IgG

(for CCL20) was diluted in 50 μ L PBS 0.1% BSA and 0.05% Tween 20 to 1:50000 and incubated for 2 h. Finally, alkaline phosphatase substrate *p*-nitrophenyl phosphate (Sigma) was added at a concentration of 1mg/mL in 0.1 mol/L glycine buffer, pH 10.4, containing 1 mol/L MgCl₂ and 1 mol/L ZnCl₂. After overnight incubation, plates were read at 405 nm on a microplate reader (Molecular Devices Corp., Sunnyvale, CA). The detection limit of the ELISA was 30 pg/mL.

RNA Isolation and RT-PCR

AGS cells (5×10^6) were grown in 60-mm culture dish and were incubated for 16 h in a fresh medium containing stimuli as indicated. After discarding the growth medium, total RNA was isolated from cells using easy Blue (iNtRON Biotechnology, Daejeon, Korea), following the manufacturer's instructions. Reverse transcription of the RNA was performed using AccuPower RT PreMix (Bioneer, Daejeon, Korea). One microgram of RNA and 20 pmol primers were preincubated at 70°C for 5 min and transferred to a mixture tube. The reaction volume was 20 μ L. cDNA synthesis was performed at 42°C for 60 min, followed by RT inactivation at 94°C for 5 min. Thereafter, the RT-generated DNA (2-5 μ L) was amplified using AccuPower[®] RT PreMix (Bioneer, Korea). The primers used for cDNA amplification were: 5'-ATGACTTCCAA GCTGGCCGTGGCT-3' (sense) and 5'-TCTCAGCCCT CTTCAAAACTTCTC-3' (antisense) for IL-8^[14]; 5'-ATG TGCTGTACCAAGAGTTTG-3' (sense) and 5'-TTACAT GTTCTTGACTTTTTTACTGAGGAG-3' (antisense) for CCL20^[15]; 5'-CGGAGTCAACGGATTTGGTCGTAT-3' (sense), 5'-AGCTTCTCCATGGTGGTGAAGAC-3' (antisense) for GAPDH^[12]. Amplification conditions were denaturation at 94°C for 30 s, annealing at 56°C for 30 s, and extension at 72°C for 30 s for 30 cycles. The expected PCR products were 289 bp (for IL-8), 291 bp (for CCL20), and 306 bp (for GAPDH). PCR products were subjected to electrophoresis on 1.2 % agarose gel and were stained with ethidium bromide.

Assessment of NF- κ B-p65-EGFP nuclear translocation

AGS cells were seeded at 5×10^5 in a 4-well plate 1 d before transfection (50% cell confluency). Cells were transfected with serum- and antibiotics-free RPMI 1640 medium containing 4 μ g/mL Lipofectamine 2000 reagent (Invitrogen) and 1.6 μ g/mL of NF- κ B p65-EGFP vector (provided by Prof. Rainer de Martin, Department Vascular Pharmacology and Thrombosis Research, University of Vienna, Austria). After 5 h of incubation, medium was replaced with RPMI 1640 medium containing 10% FBS and antibiotics. Cells were allowed to recover at 37°C for 20 h and subsequently were stimulated as indicated in the text or figures. Fluorescence images were observed under the Olympus microscopy (Melville, NY).

Cell extract preparation and Western blot analysis

For the analysis of phosphorylated or total protein levels of mitogen-activated protein kinases (MAPKs) and the I- κ B degradation, stimulated cells were rinsed twice with ice-cold phosphate-buffered saline and then lysed in ice-

cold lysis buffer (50 mmol/L Tris-HCl, pH 7.4, containing 150 mmol/L NaCl, 1% Nonidet P-40, 0.1% SDS, 0.1% deoxycholate, 5 mmol/L sodium fluoride, 1 mmol/L sodium orthovanadate, 1 mmol/L 4 nitrophenylphosphate, 10 g/mL of leupeptin, 10 μ g/mL of pepstatin A, and 1 mmol/L 4-(2 aminoethyl) Benzenesulfonyl fluoride). Cell lysates were centrifuged at 15000 rpm for 20 min at 4°C, and the supernatant was mixed with a one-fourth volume of 4 \times SDS sample buffer, boiled for 5 min, and then separated through a 12% SDS-PAGE gel. After electrophoresis, proteins were transferred to a nylon membrane by means of Trans-Blot SD semi-dry transfer cell (Bio-Rad, Hercules, CA). The membrane was blocked in 5% skim milk (1 h), rinsed, and incubated with primary antibody (for phosphorylated MAP kinases or I- κ B) in TBS containing 0.05% Tween 20 (TBS-T) and 3% skim milk overnight at 4°C. Excess primary antibody was then removed by washing the membrane four times in TBS-T, and the membrane was incubated with 0.1 μ g/mL peroxidase-labeled secondary antibody (against rabbit) for 1 h. Following three washes in TBS-T, bands were visualized by ECL[™] Western Blotting Detection reagents and exposed to X-ray film.

Transient transfection and luciferase activity assay

For transient transfections, AGS cell and 293T Cells were seeded at 5×10^5 in a 12-well plate 1 d before transfection (90%-95% cell confluency). Cells were transfected with serum- and antibiotics-free RPMI 1640 medium containing 4 μ g/mL Lipofectamine 2000 reagent (Invitrogen) and 1.6 μ g/mL of NF- κ B, IL-8 (provided by Professor J.-S. Chun, Gwangju Institute of Science and Technology, Gwangju, Korea), or CCL20 luciferase reporter constructs. After 5 h of incubation, medium was replaced with RPMI 1640 medium containing 10% FBS and antibiotics. Cells were allowed to recover at 37°C for 20 h and subsequently were stimulated as indicated in the text or figures. Cell lysates were prepared and assayed for luciferase activity using Luciferase Assay System (Promega, Madison, WI), according to the manufacturer's instructions.

RESULTS

TNF- α induces IL-8 and CCL20 gene expression and protein release in AGS cells

One of the key molecules mediating the gastric mucosal inflammation is the cytokine TNF- α ^[16]. We therefore first examined whether TNF- α induces inflammatory signals in AGS cells. We were primarily interested in two chemokines; i.e., IL-8 and CCL20, because these proteins play central roles in the evocation of host innate and adaptive immunity^[10,17]. Treatment of AGS cells with TNF- α markedly induced IL-8 and CCL20 secretion (Figure 1). The effect of TNF- α was concentration-dependent in the range of 0-10 ng/mL, as assessed by ELISA and RT-PCR. We chose 5 ng/mL of TNF- α for the following experiments as this concentration is enough for maximal induction of IL-8 and CCL20 (Figure 1A and C). Time-dependent experiments revealed that treatment with TNF- α led to rapid induction of IL-8 and CCL20 mRNAs (about 4 h after stimulation) while their

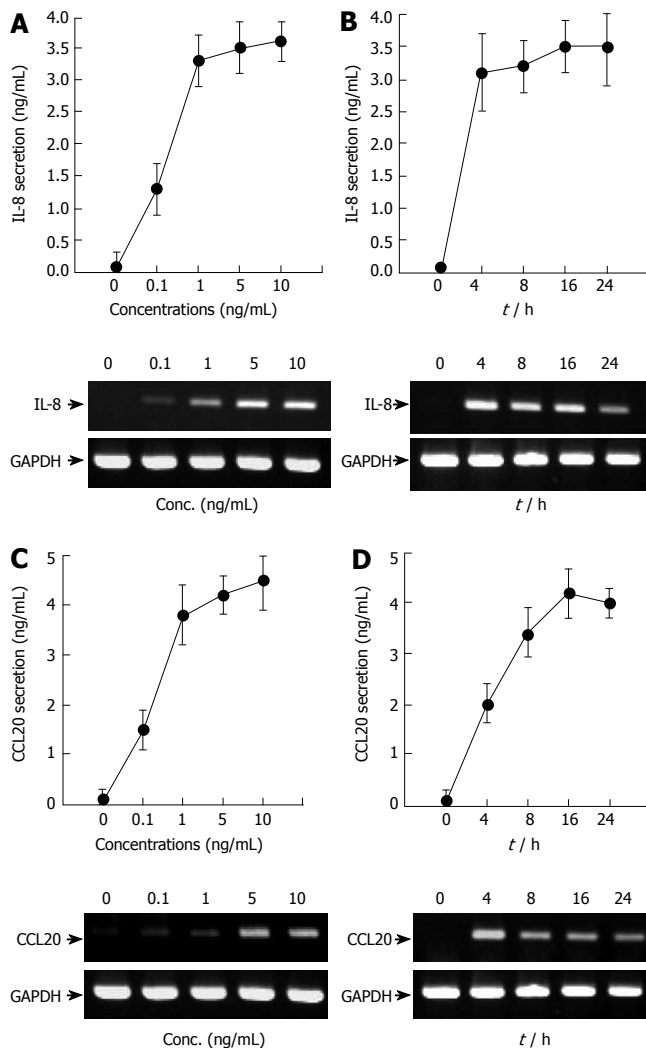

Figure 1 TNF- α induces IL-8 and CCL20 secretion and mRNA accumulation in AGS cells in a time- and dose-dependent manner. (A and C) AGS cells (5×10^5 /well) were treated for 16 h with the indicated concentrations of TNF- α (0-10 ng/mL). After incubation, the supernatants were collected, and the levels of IL-8 (A) and CCL20 (C) were determined by ELISA (top). At the same time, the cells were collected and the expression of two chemokines was determined by RT-PCR (bottom). (B and D) AGS cells (5×10^5 /well) were treated with TNF- α (5 ng/mL) for the indicated time points (0-24 h). IL-8 and CCL20 secretion and mRNA accumulation were determined as described above. For ELISA, results are expressed as means \pm SD of three independent experiments.

protein secretions were slightly delayed (about 16 h after stimulation) in AGS cells. Overall, we conclude that AGS cells produce IL-8 and CCL20 in response to TNF- α .

DA-9601 inhibits TNF- α -induced IL-8 and CCL20 gene expression and protein release in AGS cells

According to previous reports the main effect of DA-9601 is associated with cell death or apoptosis in the rat model of cerulein-induced pancreatitis^[1]. To test preliminarily whether DA-9601 affects viability of human gastric epithelial AGS cells, we performed a MTT assay. The concentrations that ranged from 0 to 100 μ g/mL of DA-9601 showed no toxic effects on AGS cells at 16 h of incubation, while higher concentrations of DA-9601 (>100 μ g/mL) induced delayed cytotoxicity after 24 h (Figure 2A and data not shown). There were no detectable apoptotic nuclei in DA-9601 (0-100 μ g/mL)-treated cells, as verified

Figure 2 DA-9601 inhibits the expression and secretion of CCL20 in AGS cells. (A) AGS cells (1×10^5) were treated with various concentrations of DA-9601 (0-100 μ g/mL) for 16 h. Quantitative analysis of cell viability was determined by the MTT assay (mean \pm SD, $n = 3$). (B) Cells (5×10^5) were pretreated with various concentrations of DA-9601 (0-100 μ g/mL) for 1 h, and then the cells were further incubated for 8 h with TNF- α (5 ng/mL). Levels of IL-8 and CCL20 mRNAs were determined by RT-PCR. (C) Cells (5×10^5) were pretreated with various concentrations of DA-9601 (0-100 μ g/mL) for 1 h, and then the cells were further incubated for 16 h with TNF- α (5 ng/mL). IL-8 and CCL20 protein levels were determined by ELISA. These data are representative of three independent experiments.

by DAPI staining (data not shown).

RT-PCR revealed that DA-9601 (0-100 μ g/mL), which alone did not induce any significant changes, significantly attenuated TNF- α (5 ng/mL)-dependent expression of IL-8 and CCL20 mRNA in human AGS cells (Figure 2B). Addition of DA-9601 dramatically reduced TNF- α -induced IL-8 and CCL20 secretions as well in a dose-dependent manner (Figure 1C). The concentration of 100 μ g/mL of DA-9601 maximally inhibited the secretion of both chemokines; i.e., IL-8 and CCL20 (Figure 1C). However, as this concentration revealed weak cytotoxicity after 24 h of treatment (data not shown), we therefore chose 50 μ g/mL of DA-9601 for the following experiments, unless otherwise indicated.

DA-9601 inhibits TNF- α -induced IL-8 and CCL20 promoter activities in both HEK293T cells and AGS cells

To investigate whether the inhibition of both chemokine secretions by DA-9601 is due to the direct down-regulation of promoter activity, we performed the luciferase reporter gene assay for IL-8 and CCL20 promoters. As shown in Figure 3, treatment with TNF- α significantly induced IL-8 and CCL20 promoter activities (promoter-dependent luciferase signals) in both HEK293T cells and AGS cells.

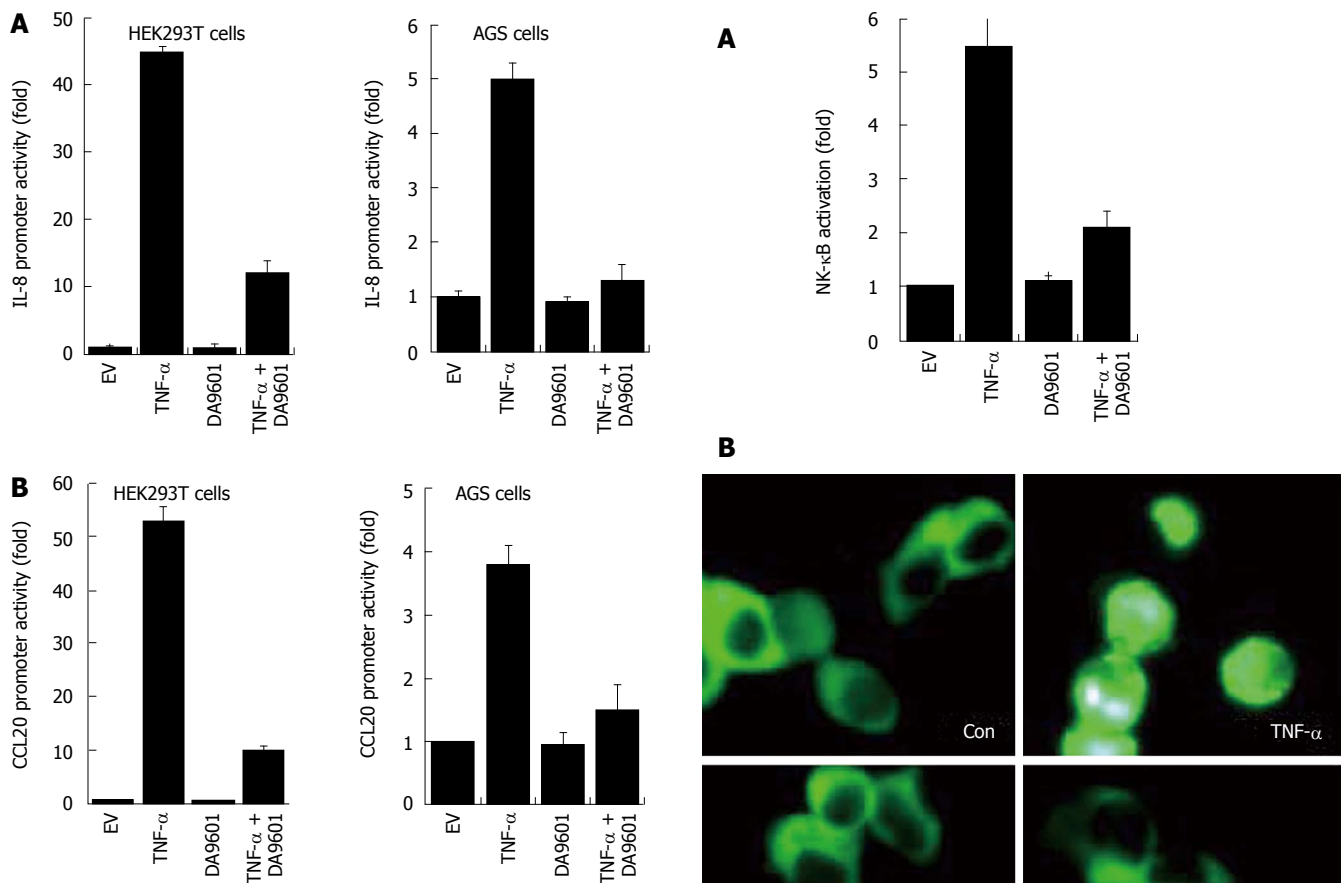

Figure 3 DA-9601 blocks IL-8 and CCL20 promoter activities in HEK293T and AGS cells. HEK293T (left) and AGS (right) cells were transfected with pGL3-pIL-8 (A) or pGL3-pCCL20 (B) luciferase vectors. After 24 h of incubation, cells (1×10^5) were pre-treated for 1 h with DA-9601 (50 μ g/mL) and stimulated for additional 16 h with medium alone or medium containing TNF- α (5 ng/mL). At the end of incubation, cells were lysed, and the relative luciferase activity was measured using Luciferase Assay System. Results are expressed as means \pm SD of three independent experiments.

However, pre-incubation of these cells with DA-9601 (50 μ g/mL) dramatically reduced TNF- α -induced promoter activities in both cell types, suggesting that DA-9601 inhibits IL-8 and CCL20 expressions and secretions *via* direct or indirect modulation of promoter activities.

DA-9601 inhibits TNF- α -induced NF- κ B activity in both HEK293T cells and AGS cells

Several recent studies have demonstrated that gene expression of both IL-8 and CCL20 is NF- κ B dependent^[18-21]. This led us to examine whether DA-9601 can inhibit NF- κ B activity in TNF- α -treated AGS cells. We therefore examined the NF- κ B activation by measuring NF- κ B-dependent transcriptional activity, NF- κ B p65 nuclear translocation, and I- κ B α degradation. As shown in Figure 4A and B, incubation of AGS cells with DA-9601 for 24 h significantly decreased TNF- α -induced luciferase activity. We next measured nuclear translocation of the NF- κ B p65 subunit. To this end, AGS cells were transfected with NF- κ B-p65-EGFP vector for 24 h, and then the cells were further treated with DA-9601 (50 μ g/mL), TNF- α (5 ng/mL), or DA-9601 (1 h before TNF- α treatment) plus TNF- α . As shown in Figure 3C, DA-9601 significantly inhibited nuclear translocation of NF- κ B p65

Figure 4 DA-9601 blocks NF- κ B activity in AGS cells. **A:** AGS cells (1×10^5) were transfected with NF- κ B luciferase reporter vector (0.8 μ g/well). After 24 h of incubation, cells (1×10^5) were pre-treated for 1 h with DA-9601 (50 μ g/mL) and stimulated for additional 16 h with medium alone or medium containing TNF- α (5 ng/mL). At the end of incubation, cells were lysed, and the relative luciferase activity was measured using Luciferase Assay System; **B:** AGS cells (1×10^5) were transfected with p65-EGFP vector (0.8 μ g/well). After 24 h of incubation, cells were pre-treated for 1 h with DA-9601 (50 μ g/mL) and stimulated for 1 h with medium alone or TNF- α . Nuclear translocation of p65-EGFP was observed under the fluorescence microscope (original magnification, 200 X); **C:** AGS cells (5×10^5) were incubated with TNF- α (5 ng/mL) for the indicated time points (0-240 min) (top) or were pretreated with medium alone or with DA-9601 (50 μ g/mL) for 1 h, and incubated with TNF- α for 30 min (bottom). The cell lysates were blotted with antibodies specific for the I- κ B α and β -actin.

subunit after 1 h of TNF- α treatment. We finally tested

Figure 5 TNF- α induces phosphorylation of MAPKs in AGS cells. AGS cells (5×10^5 cells/well) were incubated for various times (0–240 min) with TNF- α (5 ng/mL). Protein extracts were prepared at the indicated time points, and then the levels of phosphorylated or total MAPKs (ERK1/2 (top), p38 kinase (middle), and JNK/SAPK (bottom)) were determined by Western blotting using specific antibodies. The arrows indicate the position of specific immunoreactive bands corresponding to distinct MAPKs.

Figure 6 SB203580 blocks NF- κ B-dependent transcriptional activity in AGS cells. AGS cells (5×10^5) were transfected with NF- κ B luciferase reporter vector (0.8 μ g/well). After 24 h of incubation, cells were pre-treated for 1 h with PD098059 (20 μ mol/L), SB203580 (10 μ mol/L), SP600125 (2 μ mol/L), and PDTC (10 μ mol/L); the cells were stimulated for additional 16 h with medium alone or medium containing TNF- α (5 ng/mL). At the end of incubation, cells were lysed, and the relative luciferase activity was measured using Luciferase Assay System. Note, $^aP < 0.05$, significantly different from control ($n = 4$).

whether DA-9601 inhibits I- κ B α degradation in TNF- α -treated AGS cells. Treatment with TNF- α rapidly induced I- κ B degradation (about 15 min) which later recovered slightly (> 240 min) (Figure 4C). However, pre-incubation of AGS cells with DA-9601 (1 h) significantly inhibited TNF- α -induced I- κ B α degradation (Figure 4B). Taken together, we conclude that DA-9601 inhibits IL-8 and CCL20 expressions and their protein releases, presumably by acting at the site or upstream of NF- κ B-dependent pathways.

p38 kinase plays a crucial role in TNF- α -induced NF- κ B activity as well as CCL20 production in AGS cells

Previous reports demonstrated that three structurally-related mitogen-activated protein kinases (MAPKs) play crucial roles in a variety of systems involving TNF- α ^[22–24]. We therefore asked whether TNF- α leads to phosphorylation of the MAPK subfamilies in AGS cells. As shown in Figure 5, treatment with TNF- α (5 ng/mL) rapidly induced phosphorylation of all three MAPK subfamilies. The maximal phosphorylation levels

Figure 7 Effects of MAPK modulators on IL-8 and CCL20 release by TNF- α in AGS cells. AGS cells (1×10^5) were pre-treated for 1 h with or without selective MAPK inhibitors (PD098059, 20 μ mol/L; SB203580, 10 μ mol/L; SP600125, 2 μ mol/L). The cells were then further incubated for 16 h with TNF- α (5 ng/mL). Levels of IL-8 and CCL20 protein were determined by ELISA. These data are representative of three independent experiments.

were achieved as early as 15 min in all MAPKs after TNF- α treatment, and thereafter the levels were gradually decreased. Interestingly, however, among three MAPK blockers used, the selective p38 kinase inhibitor SB203580 (10 μ mol/L) could only inhibit TNF- α -induced NF- κ B-dependent promoter activity (Figure 6). As expected, treatment with PDTC (10 μ mol/L) also inhibited NF- κ B-dependent promoter activity (Figure 6). These results suggest a functional cross-talk between p38 kinase and NF- κ B-dependent signaling system, and further suggest that p38 kinase acts upstream of NF- κ B activation, thereby inhibiting IL-8 and CCL20 promoter activities in AGS cells.

To further confirm that p38 kinase is involved in chemokine production, AGS cells were incubated with three MAPK inhibitors prior to TNF- α treatment and then the production of IL-8 and CCL20 was measured by the ELISA method. As expected, treatment with SB203580 significantly inhibited IL-8 and CCL20 production induced by TNF- α (Figure 7). The selective inhibitor of the MEK1 pathway PD098059 also inhibited IL-8 and CCL20 production in TNF- α -treated AGS cells, while it had no effect on NF- κ B-dependent transcriptional activity (Figure 6). These results may suggest that, in terms of IL-8 or CCL20 production, ERK1/2 is not coupled with NF- κ B-dependent pathways but may act at a post-transcriptional level.

DA-9601 inhibits p38 kinase phosphorylation, but shows little effect on ERK and JNK in AGS cells

An important question raised at this point was whether DA-9601 also inhibits p38 kinase phosphorylation induced by TNF- α . To test this, AGS cells were treated with DA-9601 for 1 h, and then the cells were further incubated for 15 min with TNF- α (5 ng/mL). The phosphorylation levels of all three MAPKs were determined by Western blot analysis. Surprisingly, while having no effect on both ERK1/2 and JNK1/2, DA-9601 specifically and

Figure 8 DA-9601 selectively attenuates TNF- α -mediated phosphorylation of p38 kinase in AGS cells. Cells (5×10^5 cells/well) were pretreated for 1 h with medium alone or medium containing DA-9601 (50 μ g/mL). Then, the cells were stimulated for 15 min with or without TNF- α (5 ng/mL). The cell lysates were blotted with antibodies specific for the phosphorylated or total forms of ERK1/2, p38 kinase, and JNK/SAPK, and visualized using a peroxidase-conjugated secondary antibody and the ECL system.

significantly inhibited p38 kinase phosphorylation induced by TNF- α (Figure 8). These results strongly suggest that DA-9601 inhibits TNF- α -induced chemokine production as well as secretion via a direct or indirect inhibition of p38 kinase activity. Further, these results suggest that DA-9601 inhibits NF- κ B-dependent transcriptional activity presumably by blocking the p38 kinase signaling system.

DISCUSSION

In this study we analyzed the effect and mechanism of action whereby DA-9601 modulates the production of two chemokines; i.e., IL-8 and CCL20, in human gastric epithelial AGS cells. IL-8 is one of the key molecules that is involved in innate immunity, and is known to be elevated in gastric biopsy samples of patients with *H. pylori*-associated gastritis^[5]. In contrast, it was generally accepted that gastric epithelial cells do not produce the cytokines that are essential components of host adaptive immunity. However, recent study has shown that they do produce CCL20 upon infection with *H. pylori*^[9], thereby suggesting that CCL20 is also involved in gastric mucosal immunity. The present results demonstrate that AGS cells do produce both IL-8 and CCL20 chemokines in response to TNF- α stimulation. This evidence extends the current view and suggests that gastric epithelial cells may also have a critical function by inducing mucosal innate immunity as well as adaptive immunity.

The use of natural anti-inflammatory products provides an attractive and safe alternative to modulate inflammatory disorders. *A. asiatica* has been widely used for centuries in traditional Asian diets and medications without any serious side effects. Also, the standardized ethanol extract (DA-9601) of this medicinal plant has been shown to have strong antioxidative and anti-inflammatory effects in experimental animal models, such as esophageal mucosal damage^[25,26], ethanol-induced gastritis^[4], and cerulin-induced pancreatitis^[1]. However, the mechanisms of action of DA-9601 *in vitro* and *in vivo* are still unclear. Our data indicate that TNF- α -mediated expression of chemokine genes in gastric epithelial cells is blocked by DA-9601 treatment. The mechanism of action of DA-9601 involves blockade of NF- κ B activation, in agreement with previous studies using a mouse skin model^[27]. To further define the mechanism by which NF- κ B activity is inhibited by

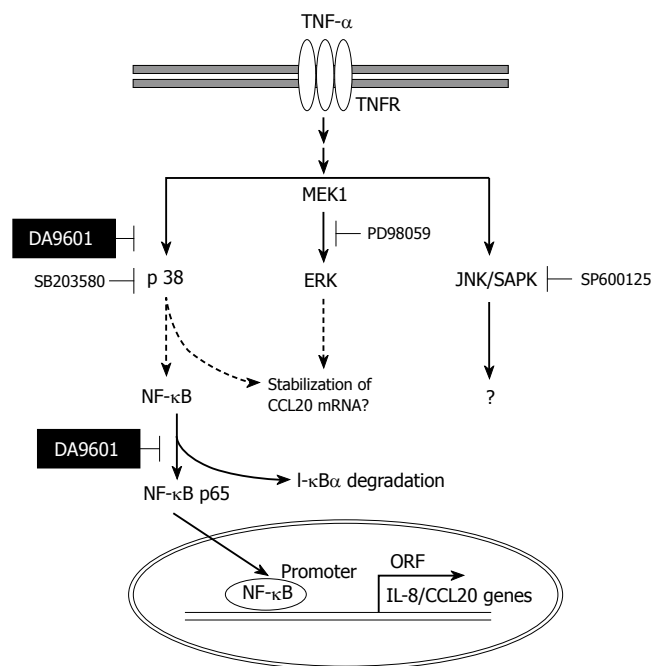

Figure 9 Hypothetical mechanism of action of DA-9601 on TNF- α -induced CCL20 expression in AGS cells. TNF- α induces activation of three MAPKs. Among three MAPKs, however, activation of p38 kinase involves in NF- κ B signaling system. DA-9601 may inhibit NF- κ B directly or indirectly through the inhibition of p38 kinase pathway. See text for discussion.

DA-9601, we investigated molecular relationships between MAPKs and NF- κ B. We found that SB203580, a selective inhibitor of p38 kinase, blocked NF- κ B activity, thereby suggesting that p38 kinase may be functionally linked with NF- κ B. In this regard, it is particularly interesting to note that DA-9601 could block activation of both p38 kinase and NF- κ B in AGS cells. This suggests that DA-9601 does not directly block the NF- κ B-dependent signaling system, but instead, it may indirectly inhibit NF- κ B through the inhibition of p38 kinase pathways. Accordingly, several lines of evidence have suggested that p38 kinase lies upstream of NF- κ B^[28-30]. It is also interesting that PD098059, the upstream inhibitor of ERK1/2 pathway, had no effect on TNF- α -induced NF- κ B activity, while it significantly blocked IL-8 and CCL20 production. These results suggest that the ERK1/2 pathway is not involved in the regulation of promoter activity but may participate in the stabilization of chemokine genes, as demonstrated by other reports^[12,31].

Although DA-9601 has substantial anti-inflammatory or anti-oxidative effects, the structural identity of its active component(s) remains to be elucidated. Eupatilin, one of the major pharmacologically active ingredients of *A. asiatica*, may share its anti-inflammatory^[32] or anti-oxidative effects^[33] with DA-9601. However, our unpublished results demonstrated that eupatilin has no significant effect on TNF- α -induced IL-8 expression and secretion, while it has strong protective (anti-oxidative) effect for AGS cells from hydrogen peroxide-induced cellular damage (data not shown). This implies that DA-9601 may also have other active ingredient(s) that selectively inhibit(s) cytokine-induced expression or release of IL-8 and CCL20 proteins

as well as other inflammation-related proteins.

Collectively, the data obtained in the present study are compatible with the schematic representation in Figure 9. DA-9601 has an anti-inflammatory potential based on its blocking effects on TNF- α -induced IL-8 and CCL20 production. The inhibition by DA-9601 appears to be mediated through the inhibition of promoter activity as well as the NF- κ B-dependent signaling system. Inhibition of p38 kinase by SB203580 blocked NF- κ B activity, suggesting that p38 kinase is functionally linked with NF- κ B and lies upstream of NF- κ B. More interestingly, DA-9601 inhibited activation of both the p38 kinase and NF- κ B-dependent systems. This suggests that DA-9601 inhibits NF- κ B directly or indirectly through the inhibition of the p38 kinase pathway. Additional studies will be required to clarify the upstream signal transduction pathways that might be affected by DA-9601.

Abstract

AIM: To observe the effects of augmenter of liver regeneration (ALR) on Kupffer cells and to determine whether ALR promotes hepatocyte proliferation induced by Kupffer cells.

METHODS: Kupffer cells and hepatocytes were cultured *in vitro* and various concentrations of recombinant rat ALR (rrALR) were added. ³H-thymidine, BrdU and ³H-leucine incorporation was determined in cultured Kupffer cells and hepatocytes, in hepatocytes conditioned by Kupffer cells, and in associated medium. rrALR was labeled by iodination and used to determine its binding activity by Scatchard analysis in Kupffer cells and primarily cultured rat hepatocytes.

RESULTS: rrALR stimulated DNA replication in Kupffer cells and protein synthesis both in cells and in medium in a non-concentration-dependent manner. The effect was significant at the concentration of 1 µg/L ALR. However, rrALR had no effect on primarily cultured hepatocytes, when hepatocytes were cultured with the Kupffer cell medium conditioned by ALR, DNA replication and protein synthesis in hepatocytes increased significantly at the concentration of 1 µg/L ALR. When the ALR concentration was increased, its effect on hepatocyte proliferation decreased to the basal level. Scatchard analysis indicated the presence of a single class of high affinity receptors with a dissociation constant (*K_d*) of 0.883 nmol/L and a maximum binding capacity (*B_{max}*) of 126.1 pmol/g protein in the rat Kupffer cells.

CONCLUSION: ALR can promote hepatocyte proliferation induced by Kupffer cells, which is associated

INTRODUCTION

Liver regeneration requires various factors promoting cellular proliferation. Among these, augmenter of liver regeneration (ALR)^[1], a novel cytokine, similar to the hepatic stimulator substance^[2], has been shown to be mainly involved in the process of liver regeneration. ALR was cloned by Hagiya *et al*^[1] from the weanling rat liver in 1994. Subsequently, Giorda *et al*^[3] and Yang *et al*^[4] cloned the cDNA of human ALR. It was found that rat, mouse, and human ALR genes (and protein products) are highly conserved, homologous and preferentially expressed in testis and liver^[3]. ALR and the *Saccharomyces cerevisiae* homologue Erv 1p are members of the new ALR/Erv 1 protein family^[5-7]. Experiments and clinical research demonstrated that ALR could specifically promote hepatocyte proliferation and rescue liver failure^[8-13]. The specific molecular impact of ALR on liver regeneration still remains unclear. Wang *et al*^[14] have identified and characterized the receptor for human ALR on rat hepatocytes, and they found that human hepatoma cells *via* their specific receptor ALR may initiate a corresponding cytoplasmic signal transduction. But it was also reported that ALR promotes liver regeneration by inhibiting the activity of hepatic natural killer (NK) cells^[13] and rat ALR (rALR) has no effect on primary rat hepatocytes *in vitro*^[15], suggesting that ALR may likely exert its biological effect by using hepatic non-parenchymal cells. Kupffer cells, the resident liver macrophages, have been implicated as the primary source of inflammatory factors but may also be the source of important growth

factors and cytokines that initiate cellular recovery and regeneration^[16,17]. The protective role of Kupffer cells in hepatic injury by promoting liver regeneration has been recently emphasized^[18-20], but the relationship between ALR and Kupffer cells in liver regeneration has not been investigated. Here we report the existence of ALR receptor in Kupffer cells and show the fact that ALR promotes hepatocyte proliferation induced by Kupffer cells.

MATERIALS AND METHODS

Isolation and primary culture of rat hepatocytes

Hepatocytes were isolated from male Sprague-Dawley rats (weighing 180-250 g, provided by Animal Center of Chinese Academy of Sciences) by *in situ* perfusion of the liver with collagenase (0.5 g/L type I CLSI, Sigma) as described previously^[21]. The viability of the cells was determined by trypan blue exclusion. Preparations with their viability greater than 85% or higher were used. The cells were suspended in Williams' medium E (Sigma) containing 100 mL/L fetal calf serum, 2 mmol/L L-glutamine, 7 mg/L insulin and 10 mmol/L HEPES, plated in 24-well plates (0.125×10^6 cells/well), and incubated in an atmosphere of 95% air and 5% CO₂ at 37°C. The medium was renewed after incubated for 3 h and cells were used for experiments after an overnight incubation.

Preparation of Kupffer cells

Kupffer cells were prepared from the livers of male Sprague-Dawley rats (200-224 g) as described previously^[22]. Briefly, following the collagenase (type IV from 0.25 g/L clostridium histotikum, Sigma)/protease (type XIV from 0.5 g/L streptomyces griseus, Sigma) digestion of liver and removal of hepatocytes and cell debris by low speed centrifugation, Kupffer cells and endothelial cells were purified from other non-parenchymal cells by density gradient centrifugation using 300 g/L metrizamide. Finally Kupffer cells were isolated by a centrifugal elutriation procedure^[22]. The viability of Kupffer cell preparation was greater than 95% as determined by trypan blue exclusion. Kupffer cells were suspended in Williams' medium E containing 100 mL/L heat-inactivated fetal calf serum, 5 MU/L penicillin and 5 g/L streptomycin and plated in 24-well culture plates at a density of 1×10^6 cells/well, then plated in 48-well culture plates at a density of 0.5×10^6 cells/well and incubated in an atmosphere of 95% air and 5% CO₂ at 37°C. The medium was renewed after incubated for 3 h and cells were used for experiments after an overnight incubation.

Determination of the effects of Kupffer cells-conditioned medium on hepatocytes

Kupffer cells were washed and placed in serum-free Williams' medium E containing 0.1% bovine serum albumin (BSA, Sigma) and the test ALR concentrations (control, 1, 10, 100 and 1000 µg/L). After 24 h, the medium was filtered (0.2 µm, Gibco) and transferred to the cultured hepatocytes. Hepatocytes were incubated for

24 h with the test agents, the medium was conditioned by Kupffer cells, and various determinations were then made.

³H-thymidine incorporation assay: Determination of DNA replication

Kupffer cells or hepatocytes were rinsed twice with Hanks' buffered saline solution (HBSS), and placed in serum-free Williams' medium E containing 1 g/L BSA and the test ALR concentrations (control, 1, 10, 100 and 1000 µg/L) for 24 h. After the medium was aspirated from Kupffer cells or hepatocytes, a fresh medium containing 37 MBq/L ³H-thymidine (Amersham Pharmacia Biotech, USA) was added to the culture wells. Following an incubation of 4 h at 37°C, the cells were washed with ice-cold HBSS containing 0.1% BSA, treated with 10% ice-cold trichloroacetic acid (TCA) for 10 min, and washed once with TCA followed by 95% ethanol. The cells were then digested with 5% sodium dodecyl sulfate (SDS) at 60°C for 25 min. The liquid was transferred into scintillation vial, and washed once more with 0.5 mL 0.5% SDS. The radioactivity was determined using 5 mL β-scintillation solution.

³H-leucine incorporation assay: Determination of protein synthesis

Kupffer cells or hepatocytes were stimulated for 24 h as in the ³H-thymidine incorporation assay. After the medium was aspirated, a fresh medium containing 37 MBq/L ³H-leucine (Amersham Pharmacia Biotech, USA) was added to the culture wells. Following an incubation of 4 h at 37°C, the medium aspirated from Kupffer cells or hepatocytes was transferred to 1.5 mL Eppendorf tubes, BSA (finally 5%) and TCA (finally 5%) were added for 15 min, centrifuged at 12900 r/min for 20 min at 4°C, washed three times with 5% ice-cold TCA. Then 200 µL 0.1mol/L NaOH was added to dissolve the pellet, pH was adjusted with 0.1 mol/L HCl, the liquid was transferred to the scintillation vial. The cells were washed with ice-cold HBSS containing 1 g/L BSA, treated with 100 g/L ice-cold TCA for 10 min, and washed once with TCA followed by 95% ethanol. The cells were then digested with 5% SDS at 60°C for 25 min. The liquid was transferred to scintillation vial, and washed once with 0.5 mL 0.5% SDS, the radioactivity was determined using 5 mL β-scintillation solution.

BrdU incorporation assay

Cells were plated in 12-well plates, serum-starved, and stimulated as described previously in the ³H-thymidine incorporation assay. After 24 h of stimulation, the cultures were incubated with BrdU labeling reagent (Dako) diluted at 1:1000. Cells were rinsed and fixed for 30 min at room temperature with acetic alcohol (90% ethanol, 50 mL/L acetic acid, 50 mL/L distilled H₂O). Endogenous peroxidase was blocked by incubation in 1% H₂O₂ in methanol for 20 min at room temperature. Cells were washed in PBS and incubated for 15 min in 1.5 mol/L HCl at 37°C, and extensively washed in PBS. Cells were then incubated in anti-BrdU antibody (mouse IgG, Sigma) diluted at 1:40 in PBS containing 1% BSA for 1 h at 37°C and washed in PBS. Cells were incubated in anti-mouse secondary antibody (goat anti-mouse IgG, Sigma) diluted

Figure 1 Effects of ALR on proliferation of Kupffer cells and hepatocytes. **A:** DNA replication; **B:** BrdU-positive nuclei. KC: Kupffer cells; HC: Hepatocytes; KC to HC: Hepatocytes conditioned by Kupffer cells. $^aP < 0.05$ vs control, $n = 3$.

at 1:100 in PBS, and 10 g/L BSA for 30 min at room temperature followed by washing. Cells were incubated in ABC solutions for 30 min at room temperature, washed and incubated in 50 mmol/L Tris (pH 7.6) for 5 min, then the 3, 3'-diaminobenzidine solution was added. Three areas in each well were counted for a total of about 1000 cells. Proliferation was indicated as a percentage of labeled nuclei.

¹²⁵I- recombinant rat ALR binding to cultured kupffer cells and primary hepatocytes

Recombinant rat ALR (rrALR) was expressed in *Escherichia coli* and prepared with high purity ($> 95\%$) as described previously^[23]. rrALR was radioiodinated with the chloramines-T methods^[14,24]. Briefly, 15 μ L of 50 mmol/L sodium phosphate buffers (pH 7.0) and 18.5 MBq/L sodium ¹²⁵I (Amersham Pharmacia Biotech, USA) were added to a siliconized tube containing 5 μ g of rrALR. The reaction was started by adding 10 μ L of chloramine-T reaction using 20 μ L of ending solution (50 nmol/L N-acetyl-L-tyrosine, 0.01 mol/L sodium phosphate buffer). ¹²⁵I-rrALR was separated from free iodine by gel filtration on a column (20 cm \times 11.0 cm) of Sephadex G-25 (Amersham Pharmacia Biotech, USA) equilibrated with PBS and 1 g/L BSA. The fractions containing ¹²⁵I-rrALR were pooled. The assay was performed as described previously^[14,23]. Kupffer cells and rat hepatocytes were washed in HBSS (containing 20 mmol/L HEPES, 1.3 mmol/L CaCl₂, 0.5 mmol/L MgCl₂, 1% BSA, pH 7.0), and pre-incubated in the presence of the same buffer for 30 min at 25°C. After equilibration was achieved in this medium, 0.3 mL containing 12.5 pmol/L-3200 pmol/L ¹²⁵I-rrALR with or without 5 μ mol/L unlabeled rrALR (saturation binding) was incubated for 3 h at 25°C with

constant shaking. The cells were washed 4 times with ice-cold PBS and digested with 0.5 mL 0.75 mol/L NaOH for 30 min at 37°C, and the radioactivity in the digest was determined in a gamma-counter (cpm). Specific binding of ¹²⁵I-rrALR was calculated as the difference between cell-associated radioactivity in the presence and absence of unlabeled rrALR.

Statistical analysis

The values are presented as mean \pm SD of triplicate determinations. Each experiment was repeated at least three times. Student's *t*-test was employed for statistical comparison of the paired samples. $P < 0.05$ was considered statistically significant.

RESULTS

Effects of ALR concentration on Kupffer cells

³H-thymidine incorporation assay showed that rrALR stimulated DNA replication in Kupffer cells in a non-concentration-dependent manner (Figure 1A). The significant effect was observed at the concentration of 1 μ g/L ALR, the DNA replication increased to 144.2% as compared to the control (117 ± 11.7 Bq/well *vs* 81.2 ± 6.7 Bq/well, $P < 0.05$). Following the increase of added ALR concentration, DNA replication began to decrease, but was still higher than that in the control ($P < 0.05$). Being consistent with the ³H-thymidine incorporation assay, cell labeling by BrdU increased to 36% from a basal level of 24% at the concentration of 1 μ g/L ALR ($P < 0.05$, Figure 1B, Figure 2). Similar to the DNA replication, ALR also produced a non-concentration-dependent transforming of protein synthesis both in Kupffer cells and in associated medium, but the significant effect was observed at the

Figure 3 ^3H -leucine incorporation assay. **A:** Kupffer cells and associated medium; **B:** Hepatocytes and associated medium; **C:** Hepatocytes conditioned by Kupffer cells and associated medium. $^aP < 0.05$ vs control, $n = 3$.

lowest concentration of 1 $\mu\text{g/L}$ ALR tested (Figure 3A). The effects in cells and associated medium elevated to 182.6% and 275.3%, respectively, as compared to those in the control (cells: 147.5 ± 19.6 Bq/well vs 80.8 ± 5.9 Bq/well, $P < 0.05$; associated medium: 198.0 ± 46.1 Bq/well vs 71.9 ± 7.5 Bq/well, $P < 0.05$). Following the increase of added ALR concentration, protein synthesis in associated medium decreased, but was still higher than that in the control ($P < 0.05$, Figure 3A).

Effects of ALR concentration on hepatocytes

ALR did not cause any significant change in DNA replication and protein synthesis in hepatocytes or in associated medium (Figures 1A and B, Figure 2, Figure 3B).

Effects of the medium conditioned by Kupffer cells with ALR on hepatocyte proliferation

Stimulation of hepatocytes with the medium conditioned by Kupffer cells with ALR increased DNA replication and protein synthesis at the lowest concentration of 1 $\mu\text{g/L}$ ALR tested, to 174.3% (^3H -thymidine incorporation, Figure 1A) or 180% (BrdU labeling, Figure 1B, Figure 2), 146.2% (in cells) and 210.7% (in associated medium) (Figure 3C) respectively, as compared to that in the control (DNA replication: 48.4 ± 3.5 Bq/well vs 27.8 ± 4.7 Bq/well in ^3H -thymidine incorporation, 18.0% vs 10.0% in BrdU labeling; protein synthesis: 70.5 ± 5.7 Bq/well vs 48.2 ± 9.2 Bq/well in cells, 80.7 ± 15.0 Bq/well vs 38.3 ± 2.5 Bq/well in associated medium, $P < 0.05$).

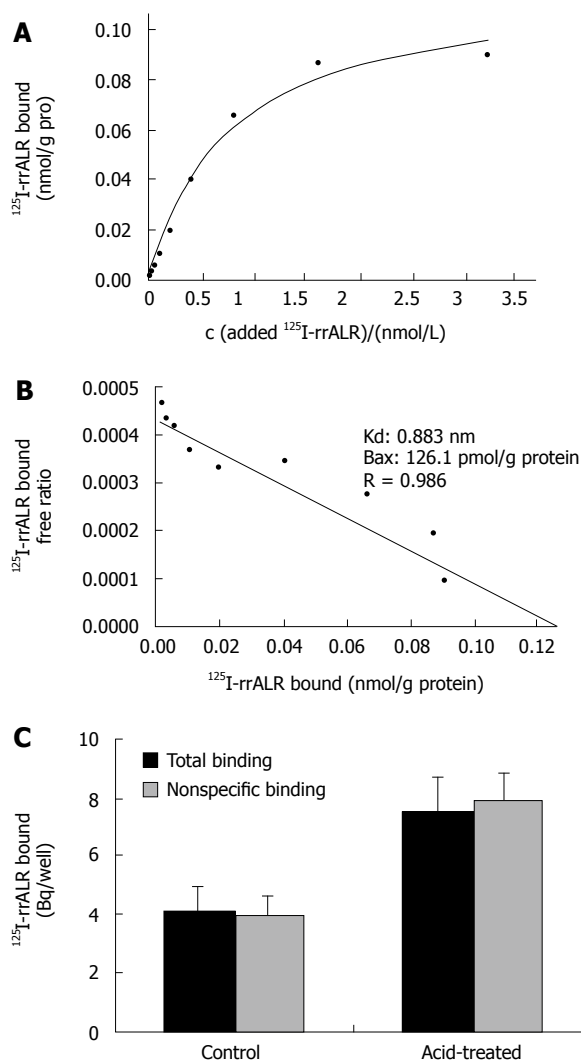

Figure 4 ^{125}I -rrALR binding assay. **A:** Saturation curves of ^{125}I -rrALR binding to its receptor on Kupffer cells; **B:** Scatchard plot of the ALR receptor on Kupffer cells; **C:** Binding of ALR to cultured hepatocytes (mean \pm SD, $n = 3$).

well vs 48.2 ± 9.2 Bq/well in cells, 80.7 ± 15.0 Bq/well vs 38.3 ± 2.5 Bq/well in associated medium, $P < 0.05$). But with the increase of added ALR concentration, the medium conditioned by Kupffer cells with ALR produced a concentration-dependent inhibition of DNA or protein synthesis in hepatocytes, the significant effect was observed at the highest concentration of 1000 $\mu\text{g/L}$ ALR tested (DNA: 28.9 ± 5.8 Bq/well, Figure 1A; protein synthesis: 33.9 ± 9.0 Bq/well in cells, 29.3 ± 8.9 Bq/well in the medium, Figure 3C).

^{125}I -rrALR binding assay

Typical saturation curves of ^{125}I -rrALR binding to cultured Kupffer cells are shown in Figure 4A. Specific binding of ALR was saturated at about 1.5 nmol/L. Scatchard analysis resulted in a rectilinear plot (Figure 4B), thereby suggesting the presence of a single class of high affinity binding sites, namely the existence of a receptor of ALR on Kupffer cells. The ^{125}I -rrALR binding capacity to cultured Kupffer cells was 126.1 ± 22.3 pmol/g protein, the affinity of the receptor was 0.883 ± 0.056 nmol/L.

However, similar to Gandhi *et al*^[23], no receptor for

ALR was found on hepatocytes by radioligand binding analysis. To investigate the possibility that ALR receptors on hepatocytes are down-regulated, the acidic medium, a procedure known to dissociate bound peptide ligand from its receptors, was used to treat cultured hepatocytes as previously described^[21,22], but it did not unmask any specific binding of ALR yet (Figure 4C).

DISCUSSION

Previous studies have revealed that ALR appears to be an important regulator of liver regeneration. Recently, emphasis has been placed on ALR molecular mechanisms underlying liver regeneration. Many advances have been gained in murine and human experiments. For instance, Yang *et al*^[4] have cloned the cDNA of human ALR (hALR) from human fetal liver lysates encoding 125 amino acids and 15KD in molecular weight. hALR could stimulate proliferation of cultured hepatocytes as well as hepatoma cells *in vitro* and rescue acute hepatic failure *in vivo*. ALR exerts its hepatrophic activities through paracrine and autocrine pathways. Wang *et al*^[14] have demonstrated the existence of hALR specific receptor on the surface of primary hepatocytes and hepatoma cells. Through the ALR receptor, ALR stimulates hepatocyte proliferation by activating the mitogen-activated protein kinase cascade (MAPK signaling pathway)^[25]. The existence of ALR in nuclei and cytosol of liver tissues further implicates that ALR has intracellular function in hepatocytes^[26]. In immunohistochemical studies, Thasler *et al*^[27] found that hALR is mainly expressed both in normal and in impaired hepatocytes. Even though there exist many inconsistent issues, Gandhi *et al*^[23] have failed to show any specific rALR receptor in hepatocytes. Hagiya *et al*^[11] and Yu *et al*^[12] reported that rat ALR has no effect on primary rat hepatocytes *in vitro* and that the expression of ALR is absent in normal hepatic tissues^[15]. The existence of contrary results together with the mechanism of inhibiting hepatic NK activity to promote liver regeneration suggests that it is possible for ALR to exert its bioactivities by interacting with other cytokines or with hepatic non-parenchymal cells on hepatocytes.

In this study, we showed the presence of high affinity receptors of ALR on hepatic Kupffer cells, and found that ALR could stimulate proliferation of Kupffer cells, suggesting that ALR stimulates hepatocyte proliferation by activating Kupffer cells, which may improve our understanding of the molecular mechanism of the biological action of ALR and its effect on liver regeneration. ³H-thymidine and ³H-leucine incorporation assay and BrdU labeling demonstrated that ALR stimulated DNA and protein synthesis of Kupffer cells in a non-concentration-dependent manner and had no effect on primary hepatocytes. But with the medium conditioned by Kupffer cells, ALR promoted hepatocyte proliferation. Similar to this study, Chen *et al*^[28] reported that when hepatocytes are co-cultured with Kupffer cell supernatant only activated by LPS, hepatocyte DNA and protein synthesis are increased significantly. Recently Armburst *et al*^[19] reported that the early gene expression

of hepatocyte growth factor in Kupffer cells after carbon tetrachloride (CCl₄) treatment may be an important event in the early phase of liver regeneration. Together with the finding about the entry of ALR into Kupffer cells by immunolabelling^[23], these events suggest that the medium containing some kind of hepatocyte growth factors coming from Kupffer cells conditioned by ALR and secreting into the medium, can regulate hepatocyte proliferation. The increased ³H-leucine incorporation showed the protein synthesis both in Kupffer cells and in associated medium. What kind of protein is needed should be further studied. The foregoing studies have tested acute reactant cytokines such as interleukin-6 (IL-6) and tumor necrosis factor (TNF)- α originated mainly from activated Kupffer cells which are the chief growth factors in hepatocyte proliferation *in vivo*^[17,29-33]. Since TNF- α and IL-6 are involved in the initiation of liver regeneration, we assume that ALR, like LPS, may activate Kupffer cells by unknown means and then mediate Kupffer cell-dependent release of TNF- α and IL-6, triggering hepatocyte proliferation. The ALR receptor on Kupffer cells can elucidate the effect of ALR on Kupffer cells in part. Here, the high affinity receptor for ALR on Kupffer cells can be identified by ¹²⁵I-ALR binding assay. When ALR binds to the cell surface receptor, Kupffer cells are activated and then release various cytokines initiating liver regeneration. The binding effect is saturable. When an excess amount of unlabeled ALR is added, it could replace the cell surface sites to which ALR has bound. It was reported that ¹²⁵I-ALR is found to have the similar molecular weight and biological activity as the unlabeled ALR, and that iodination does not change the characteristics of natural ALR, suggesting that ¹²⁵I-ALR can be used for identification of ALR receptor^[14]. As for the specificity of this binding, further researches need to be done. In our study, as the concentration of ALR was added to 1000 μ g/L, the effect of ALR-dependent-Kupffer cells on hepatocyte proliferation was inhibited, suggesting that Kupffer cells have a dual function as a regulator in liver regeneration. Responding to the immoderate proliferation effect of hepatocytes, Kupffer cells exert their inhibitory effects by releasing growth inhibiting factors. Transforming growth factor(TGF)- β is the most obvious candidate because it has been shown *in vivo* models that TGF- β could antagonize TNF- α actions and induce apoptosis, constraining the amount of hepatocyte proliferation^[34-36].

Similar to the study by Gandhi *et al*^[23], no receptor for rALR was found on hepatocytes in our study, which may interpret the inability of rALR to exert a mitogenic effect on hepatocytes *in vitro*. To investigate the possibility that ALR receptors on hepatocytes are down-regulated, the acidic medium, a procedure known to dissociate bound peptide ligand from its receptors was used to treat cultured hepatocytes, but it did not unmask any specific binding of ALR. At the same time, there is evidence that hepatocytes synthesize and secrete ALR^[23,37]. A further finding showed that hepatic ALR levels decreased while circulating ALR levels increased 12 h after 70% hepatectomy, suggesting that the release of stored ALR from hepatocytes rather than the accelerated synthesis increases the circulating

ALR level^[28].

How should these events be put together? We hypothesize that under pathological or biological circumstances of liver regeneration such as partial hepatectomy or weaning livers, activated Kupffer cells release various cytokines initiating liver regeneration, and that the receptor of ALR on hepatocytes (assuming its existence) and ALR which are constitutively expressed and stored in hepatocytes in an inactive form beforehand, are released from the cells in an active form by unknown means, then ALR exerts its hepatrophic activities through paracrine and autocrine pathways such as binding to Kupffer cells or the inhibition of hepatic NK cells to promote hepatocyte proliferation. To prevent excess hepatocyte proliferation, anti-hepatotrophic growth factors such as TGF- β are produced.

In conclusion, the mechanisms of liver regeneration are involved in complicated interactions of various cytokines and cells^[29,37]. Kupffer cells contain high affinity receptors for ALR on cell surfaces, by which ALR promotes hepatocyte proliferation. Further studies focusing on the examination of the specificity of receptors on Kupffer cells are needed.

Abstract

AIM: To explore the expansion and differentiation of hepatocytoid cell induced from myeloid mesenchymal stem cell (MSC) *in vitro*, in order to find suitable resource of hepatocytes for bioartificial liver or liver transplantation.

METHODS: The rat myeloid MSC was isolated and divided into three groups which were cultured by Friedenstein method, and then were induced by culture fluid, culture fluid plus cholestatic serum and culture fluid plus hepatocyte growth factor (HGF), respectively. Hepatocytoid cell as well as expression of CK18 and AFP was observed by immunohistochemistry.

RESULTS: After the induction for 21 d, hepatocytoid cell was observed, and its expression of CK18 and AFP was detected by immunohistochemistry in MSC cultured with cholestatic serum. Furthermore, on the 35th d, albumin mRNA was expressed in the cell, suggesting the inducing effect was similar to that by HGF.

CONCLUSION: Rat myeloid MSC can differentiate into hepatocyte lineage under appropriate condition. This method is easy to operate.

INTRODUCTION

Over the past few years, great progress has been made in the research of stem cell. It has been proved that some stem cells in bone marrow can differentiate into various kinds of cells. Therefore, through culturing myeloid stem cells *in vitro*, and providing suitable conditions, these cells can be induced to generate and differentiate into other cells. There have been some reports that application of cytokines such as hepatocyte growth factor (HGF), fibroblast growth factor-4 (FGF-4) might promote myeloid stem cells to proliferate and differentiate into hepatocytoid cell. However, the cytokines are costly. This study was to explore a convenient way to induce myeloid mesenchyme stem cell (MSC) into hepatocytoid cell *in vitro*.

MATERIALS AND METHODS

Materials

One-month-old Wista rats were provided by the Animal Center of Tongji Medical College, Huazhong University of Science and Technology. Rat recombinant hepatocyte growth factor (HGF) (R&D Co.), Dulbecco's minimum essential medium (DMEM) (Gibco), fetal bovine serum (FBS, Hyclone), N-2-hydroxyethylpiperazine-N'-2'-ethanesulfonic acid (HEPES), galactose solution of insulin, transferrin and selenite (ITS) (Sigma), nicotinamide, trypsinase (Gibco), proline (Wuhan Lingfei Bio. Co.), alpha fetoprotein (AFP) monoclonal antibody (MoAb) (Santa Cruz Co.), cytokinin 18 (CK18) MoAb, biotin labeled Ab, diaminobenzidine (DAB), streptavidin peroxidase (S-P) (Beijing Zhongshan Co.), deoxy-ribonucleoside triphosphate (dNTPs), Pyrotest Taq enzyme (Bao Bio Ltd. Co.), Bio-11-dUTP (Huamei Biotech Co.), Deion formamide, salmon sperm DNA (Sigma), fluorescein isothiocyanate (FITC) labeled antibiotin (Boshide) and albumin primer 5'ATACACCCAGAAAGCACCTC3', 5'CACGAATTGTGCGAAGTC AC3' (Shenggong Co) were prepared.

Methods

Isolation and culture of myeloid MSC: According to the literature^[1], rat femurs were separated under aseptic condition. The myeloid cell, after doused and blew out from the bone with culture fluid (5 mL DMEM + 10% FBS), was added to the culture fluid to make cell suspension. Then the culturing was begun with the supplementation of fluid of DMEM, 10% FBS, 100 U/

mL penicillin and 100 U/mL streptomycin, at 37°C, in 50 mL/L CO₂ environment. On the third day non-adherent cell was removed and the remaining cells were allowed to grow. On the 10th d the confluent cells were trypsinized and passaged. When the laminating cell with typical cellular appearance was observed, 0.25% trypase was added for digestion for 5-10 min and then the whole medium was added to terminate the digestion. When the inoculation density was $1 \times 10^4/\text{cm}^2$, the nutrient medium was added and the serial subcultivation was begun. The above procedure was repeated to passage for every 3-4 d.

MSC differentiation potency detection: The third generation MSC was inoculated onto 6-well culture plate (density: $5 \times 10^4/\text{mL}$), and the induction culture fluid (0.05 g/L vitamin C, 40 ng/mL dexamethasone, 10 mmol/L β sodium glycerophosphate) was added. Then the cell was passaged for every 4 d. On the 15th d autoclaved coverslips were put into the media and 3 d later the coverslips were taken out and were stained by alkaline phosphatase.

Cholestatic serum preparation: Male rats with weight of 400 g were anesthetized with Pentothal and their abdomens were degermed. After the abdominal cavities were opened, their choledochuses were ligated and then the bellies were sutured. Given normal feed for 10 d, those rats were dissected again at abdomen to obtain blood from inferior caval vein. The serum was separated and preserved in refrigerator at -40°C.

Group division: Three groups, including MSC culture group (only with culture fluid), MSC cultured with cholestatic serum (5%) group and MSC cultured with HGF (0.5 mg/mL) group, were divided. The culture fluid composed of DMEM, 10% FBS, 15 mmol/L HEPES, 10 mmol/L niacinamide, 1 mmol/L vitamin C, 10^{-7} mol/L dexamethasone, 1 mg/mL galactose, 30 $\mu\text{g}/\text{mL}$ proline, ITS and antibiotics. All the cells were inoculated onto 6 well culture plate and allowed to creep on the plate coverslips custodited with polylysine (0.025%). The morphology of the cell was observed on the 7th, 14th, 21st and 35th d according to the literature^[1] and during those days the coverslips were taken out and fixed with paraform (4%) for 30 min.

Detection methods: The expression of CK18 and AFP by the cells was detected by immunohistochemistry and S-P method, with PBS instead of 1st-antibody in negative control. The albumin expression was detected by *in situ* hybridization. Biotin random primer labeling method was applied as albumin labeling probe.

RESULTS

Observation of cell growth condition

Growth condition of MSC culture group: The primary cells adhered to the wall after cultured for 48 h, and the adhered cells increased gradually afterward. After 3 passages, on the 14th d, the cells showed uniform morphology (Figure 1) like fibroblast and grew as grass bunch or whirlpool.

Figure 1 After 3 passages, on the 14th d, the cell showed uniform morphology: fusiform shape or polygon shape, like fibroblast and grew as grass bunch or whirlpool (100 ×).

Figure 2 Growth condition of MSC cultured with cholestatic serum. **A:** Cultured with cholestatic serum for 7 d, peripheral cell of the clone showed cuboidal morphology, which is characteristic of hepatocytes (100×); **B:** Cultured with cholestatic serum for 35 d, all MSCs showed cuboidal morphology, which is characteristic of hepatocytes (100×).

Figure 3 Growth condition of MSC cultured with HGF. **A:** Cultured with HGF for 7 d, peripheral cell of the clone showed cuboidal morphology, which is characteristic of hepatocytes (100×); **B:** Cultured with HGF for 35 d, all MSCs showed cuboidal morphology, which is characteristic of hepatocytes (100×).

Growth condition of MSC cultured with cholestatic serum group: From the 35th d, the cell shape changed from fusiform to polygon and the proportion of the polygon cell increased with time. Meanwhile, the cell proliferation was also slowed. These phenomena appeared first in the periphery of the cell clone, and gradually extended into the whole cell clone (Figure 2).

Growth condition of MSC cultured with HGF group: The characteristics of the cell in this group were similar to that in MSC cultured with cholestatic serum group (Figure 3).

MSC identification

After induced by vitamin C, dexamethasone and β sodium glycerophosphate, respectively, the cells gradually changed to different morphological forms, like triangle, fusiform and polygon. With the prolongation of culturing time, the cell population increased and cell volume enlarged. On the 15th d, the cell endochylema was full and the cells connected with each other with ecphyma. Alkaline phosphatase staining showed positive (Figure 4). This verified that the cells isolated were MSCs.

Expression of CK18 and AFP

Expression of AFP by the cell was observed on the 14th d and expression of CK18 was detected on the 21st d in MSC cultured with cholestatic serum. And these two

Figure 4 MSC identification. **A:** Induced by vitamin C, dexamethasone and β sodium glycerophosphate, MSC differentiated into osteoblast (200 \times); **B:** Alkaline phosphatase stain showed positive (400 \times); **C:** Alkaline phosphatase stain negative control (100 \times).

Figure 5 Expression of CK18 and AFP. **A:** Cultured with cholestatic serum for 14 d, MSC expressed AFP by S-P method (100 \times); **B:** Cultured with HGF for 14 d, MSC expressed CK18 by S-P method (100 \times); **C:** Negative control (100 \times).

manifestations could still be observed on the 35th d. As comparison, MSC cultured with HGF also showed the same distinction but the other groups did not show the feature (Figure 5).

Expression of albumin

Albumin was expressed both in MSC cultured with cholestatic serum and MSC cultured with HGF groups, but the former was more significant (Figure 6).

DISCUSSION

There are two approaches to isolate MSCs including whole-bone marrow method^[2] and density gradient centrifugation method^[3]. The former, by which we employed in this experiment, is to purify MSCs by removing the non-attached cells when culture fluid is changed, according to the different adhering capabilities of stem cell. The latter is by adherently culturing mononuclear cell, based on the conception that different cell component in myeloid has different density. Nowadays, some new techniques have been developed to isolate MSCs, such as flow cytometry and immunomagnetic beads method. However, those

Figure 6 Expression of albumin. **A:** Culture with cholestatic serum for 35 d, expression of albumin was confirmed by in situ hybridization (FITC dyeing) (400 \times); **B:** Culture with HGF for 35 d, expression of albumin was confirmed by in situ hybridization (FITC dyeing) (400 \times).

new methods, being costly and technically difficult, have defect of inhibiting proliferation after sorting. So we preferred the whole-bone marrow method to purify MSC in this experiment, although the cells were of inadequate uniform, and heterogeneous in population.

Up to now, there has been no agreement on the phenotypical characterization of a “pure” population of human MSC despite the panoply of surface antigens reported to be expressed on MSC^[4-6]. Therefore, identification of MSC has been a puzzle. In 1999, Pittenger *et al*^[4] isolated MSC from human flank bone marrow and proved that MSC is pluripotent stem cell in that it could be induced into osteoblast, chondrocyte and lipocyte. Thus, through analyzing the differentiation phenotype during culturing, we could identify MSC. In our experiment, it was observed that osteoblast cytoplasm was basophilic and AKP stain positive. Because the osteoblast was the unique cell in differentiated MSC population, it proved the existence of MSC.

Recently, Verfaillie *et al*^[7] demonstrated that multipotent adult progenitor cells (MAPCs) from rat, mouse and human could differentiate into functional hepatocytes. They detected that the cells could synthesize urea, albumin and amylin, possess activity of cytochrome P450, adsorb α -low-density lipoprotein and did not have carcinogenesis process. It was not clear whether the MSCs we isolated included MAPCs; nevertheless, the cell could excrete CK18, AFP and albumin, which functions were similar to that of hepatocytes. AFP and CK18 are the characteristic proteins expressed during hepatocyte development. In addition, the method we used was convenient, easy to perform, not expensive and the cell still maintained cleavage and differentiation activity after numerous generations, thus it has wide application value in future.

Many investigations^[8] have revealed that bone marrow stem cell (BMSC) or purified hepatic stellate cell (HSC) can differentiate into hepatocytes. To find a suitable inducing condition has become a research hotspot lately. From the results of our study, it could be inferred that the induction of MSC by the cholestatic serum was probably through humoral signal pathway. The likely mechanism is as follows: after the choledochus was ligated, acute hepatic necrosis developed, and the liver was atrophy with a large amount of ascites in abdominal cavity; then hepatocyte growth promoters such as HGF, EGF and FGF were produced; and the cholestatic serum containing those cytokines might promote differentiation of MSC.

The concentration of cholestatic serum in our study,

50 mL/L, with coincidence to the literature^[9,10] had a good effect to induce hepatocytoid cell to secrete CK18, AFP and albumin. But the constituent of cholestatic serum, being complicated and with individual variation could not be detected precisely; therefore it needs further exploration to define ingredients of the cholestatic serum, and moreover, to verify the function of synthesis and secretion, as well as metabolism and non-carcinogenesis nature of the induced hepatocytoid cell. Bone marrow stem cells represent a safe and accessible source of stem cells, and the use of MSCs provides a potential treatment approach for severe liver diseases.

Abstract

AIM: To discuss the use of mycophenolate mofetil (MMF) as an immunosuppressant in steroid resistant rejection after liver transplantation.

METHODS: The clinical records of 260 adult patients who underwent living donor liver transplantation (LDLT) were reviewed. Tacrolimus and methylprednisolone were used for primary immunosuppression. Acute rejection was first treated with steroids. When steroid resistance occurred, the patient was treated with a combination of steroids and MMF. Anti-T-cell monoclonal antibody was administered to patients who were not responsive to steroids in combination with MMF.

RESULTS: A total of 90 (35%) patients developed acute rejection. The median interval time from transplantation to the first episode was 15 d. Fifty-four patients were steroid resistant. Forty-four patients were treated with MMF and the remaining 10 required anti-T-cell monoclonal antibody treatment. Progression to chronic rejection was observed in one patient. Bone marrow suppression and gastrointestinal symptoms were the most common side effects associated with MMF use. There was no significant increase in opportunistic infections.

CONCLUSION: Our results demonstrate that MMF is a potent and safe immunosuppressive agent for rescue therapy in patients with acute rejection after LDLT.

Key words: Tacrolimus; Rejection; Liver transplantation

INTRODUCTION

In the majority of transplant centers worldwide, the standard primary immunosuppressive regimen after liver transplantation is based on calcineurin inhibitors (CNIs) and steroids^[1]. CNIs exhibit a broad spectrum of nonimmunologic side effects, including renal dysfunction, arterial hypertension, and diabetes mellitus^[2]. Despite its potent immunosuppressive effect, acute cellular and chronic rejection can still occur in patients taking CNIs, even when appropriate CNI blood trough levels are maintained^[1].

Mycophenolate mofetil (MMF), an enzyme in the guanine nucleotide synthetic pathway, inhibits the proliferation of both B and T lymphocytes^[3]. MMF is now accepted as a promising immunosuppressant for liver transplantation. Previous reports have described its efficacy as a CNI-sparing drug to reduce CNI-related toxicity in long-term survivors^[4-16]. In contrast, the role of MMF in the immediate posttransplant period is unclear^[17-19]. Here, we describe our experience using MMF for patients complicated with steroid-resistant acute rejection after living donor liver transplantation (LDLT).

MATERIALS AND METHODS

Patients

A total of 260 LDLTs (140 men and 120 women; age range: 18-67 years) were performed at the University of Tokyo Hospital between January 1996 and July 2005. The median postoperative follow-up period was 28 mo (range 1-115 mo). The most common indication was virus-related liver cirrhosis ($n = 112$) secondary to hepatitis C virus infection ($n = 78$) or hepatitis B virus infection ($n = 34$), followed by immune-mediated liver cirrhosis ($n = 74$), including primary biliary cirrhosis ($n = 56$), autoimmune hepatitis ($n = 9$), and primary sclerosing cholangitis ($n = 9$).

The range of pre-operative aspartate transaminase, total bilirubin, and serum creatinine levels were 19-308 IU/L, 4-400 mg/L, and 2-44 mg/L, respectively. The

POD: Postoperative day.

median score for model of end-stage liver disease was 13 (range, 4-34).

Operative and postoperative care

Our surgical technique for recipient and donor surgery is described elsewhere^[20]. All patients received tacrolimus (FK, Prograf, Astellas Pharma Inc., Tokyo, Japan) and methylprednisolone as primary immunosuppressants (Table 1). When there were FK-related adverse events^[21], FK was converted to cyclosporine A (CsA). The cytomegalovirus (CMV) status of the patient was monitored by pp65 antigenemia assay and CMV infection was defined by the presence of more than 5 antigen-positive cells/50 000 white blood cells. Fungal status was monitored by (1-3)-beta-D-glucan assay and antigen assays. Systemic fungal infection was defined as a positive polymerase chain reaction assay or positive culture with the existence of infectious foci. Systemic bacterial infection was defined as a positive culture from the bloodstream or infectious foci.

Management of rejection

Acute rejection was initially suspected by biochemical evidence of deteriorating liver function. After vascular or biliary complications were excluded, liver biopsy was performed to obtain concrete pathologic evidence of rejection. The diagnosis of acute rejection was based on internationally accepted histologic criteria^[22]. Our primary treatment for acute rejection was to administer high-dose methylprednisolone (20 mg/kg per day), followed by a gradual dose reduction with the CNI trough level around the upper range of our regimen. When there was no improvement in serum liver function tests, a second biopsy was obtained to confirm the diagnosis of steroid-resistant rejection. In these cases, oral MMF was initiated at the dosage of 3 g three times a d per mo, and then gradually tapered off within 2 to 6 mo. No reduction of CNIs and methylprednisolone was performed when the recipient was under MMF and after treatment with MMF. Anti-T-cell monoclonal antibody (OKT3, Ortho-Biotech Corporation, Raritan, NJ, USA) was used as a tertiary strategy for steroid-resistant refractory rejection under MMF and steroid recycle treatment.

Statistical analysis

Patients complicated by acute rejection were divided into

Table 2 Outcome of patients with acute rejection stratified by the rescue treatment

Group	<i>n</i>	CMV antigenemia <i>n</i> (%)	Systemic infection <i>n</i> (%)	Mortality <i>n</i> (%)
Steroid	36	14 (39)	5 (14)	7 (19)
Steroid + MMF	44	18 (41)	4 (9)	2 (5)
OKT3	10	7 (70)	4 (40)	4 (40)
Total	90	39 (43)	13 (14)	13 (14)

CMV: Cytomegalovirus; MMF: Mycophenolate mofetil.

three groups: patients treated with one-time steroid therapy ($n = 36$), those receiving MMF administration ($n = 44$), and those eventually treated with OKT3 ($n = 10$). Inter-group comparisons were performed using the chi-square test or Fisher's exact test for categorical variables. A P value of less than 0.05 was considered statistically significant.

RESULTS

Outcome

A total of 90 out of 260 patients developed acute rejection (35%, 90/260). The median interval time from transplantation to the primary episode of acute cellular rejection was 15 d (range 5-637 d). Fifty-four patients presented with steroid-resistant rejection and were treated with a second steroid recycle in combination with MMF. The median duration of MMF administration in these 54 patients was 74 d (range 36-182 d). Of the 54 patients who received MMF, 10 had refractory acute rejection requiring the use of OKT3. The median interval between the addition of MMF and the use of OKT3 was 5 d (range 2-8 d). Among the patients treated with OKT3, two required the additional use of basiliximab (Simulect, Novartis Pharma, Tokyo, Japan). Chronic rejection was observed in one patient (0.04%, 1/260) who eventually required re-transplantation. Graft failure due to uncontrollable acute rejection was experienced in one patient (0.04%, 1/260) who died 49 d after LDLT, despite the combined use of MMF, OKT3, and basiliximab.

Outcome stratified by treatment

Mortality and systemic bacterial/fungal infections were significantly higher in the patients treated with OKT3 than in the other groups ($P = 0.02$ and 0.04 , respectively). The incidence of positive CMV antigenemia tended to be higher in the patients treated with OKT3, although the difference was not statistically significant (Table 2).

Side effects of MMF

MMF-associated side effects were observed in 11 patients (20%), bone marrow suppression in 9 patients (17%), and gastrointestinal symptoms in 2 patients (4%). A dose reduction of MMF and granulocyte colony stimulating factor administration was sufficient for all the patients with bone marrow suppression. Gastrointestinal symptoms disappeared spontaneously under the use of MMF. Cessation of MMF was not necessary due to adverse effects.

DISCUSSION

The results of our study together with those of other studies^[17,19] demonstrate that MMF can influence the course of steroid-resistant acute rejection. The main advantage of MMF rescue therapy is the option of continuing the therapy^[19]. MMF therapy can be continued in selected patients on an outpatient basis. Rejection rescue therapy with OKT3, anti-thymocyte globulins, and anti-lymphocyte globulin, in contrast, permits only limited use for a short period of time.

Another advantage of MMF is that adverse events related to MMF are infrequent and often mild, which allows for long-term administration when required. In our series, bone marrow suppression and gastrointestinal symptoms were the most common adverse events of MMF. These episodes were easily reversed by dose reduction. MMF was not associated with a significantly increased risk of opportunistic infections. These results are compatible with previous reports^[5,7,11].

LDLT theoretically offers an immunologic advantage when the donors are related to the recipients^[23]. The overall incidence of acute rejection, however, is similar between LDLT and deceased donor liver transplantation. Our series demonstrated that the overall incidence of steroid-resistant acute rejection was 21%, which was unexpectedly high because LDLT recipients have been reported less likely to develop steroid-resistant or chronic rejection^[24]. The 'immunologic advantage' of LDLT might be smaller than previously expected.

In conclusion, the results of our retrospective study suggest that treatment with MMF might be indicated for selected patients with acute rejection and demonstrate the high clinical value of MMF for secondary immunosuppressive therapy after LDLT.

Abstract

AIM: To discuss the efficacy of endoscopic mass screening for gastric cancer.

METHODS: The data used in this study were the results of mass screening programs for gastric cancer in Niigata City from 2002 to 2004. The number of participants was 35089 in 2002, 34557 in 2003 and 36600 in 2004. The finding ratio referred to the final diagnosis of gastric cancer after a double check of endoscopic files and histological findings. The costs of identifying one case of gastric cancer were calculated based on the total expense for each screening program and additional close examinations.

RESULTS: From the analysis of individual screening program with endoscopy, individual screening program with X-ray (ISX) and mass screening program with photofluorography (MSP) in reference to the finding ratio of gastric cancer, endoscopic examination was the best for detecting early gastric cancer, the finding ratio was 0.87% in 2004, approximately 2.7 and 4.6 times higher than those of the ISX and MSP groups. In addition, this novel method was the cheapest means regarding the cost of identifying one case of gastric cancer, which was estimated to be 1608000 Japanese yen in 2004.

CONCLUSION: Endoscopic mass screening is a promising method and can be effectively applied if a sufficient number of skilled endoscopists become available to staff the system and if city offices support it.

Key words: Mass screening; Gastric cancer; Endoscopy; Cost effectiveness

INTRODUCTION

Gastric cancer is recognized worldwide as the second leading cause of cancer mortality^[1]. In Japan, non-cardia gastric cancer still remains the major cause of cancer death, although recently the mortality rate has begun to decrease^[2]. With reference to this change, it has been reported that early detection of gastric cancer may contribute to decreases in the mortality rate^[3,4].

Japan has carried out ongoing programs to prevent gastric cancer death by mass X-ray screening methods to detect gastric cancer in its early stages^[4,5]. In recent years, endoscopy has been applied instead of X-ray as the initial mass screening method in several cities in Japan, and endoscopic mass screening has been utilized in Niigata City since 2003. The efficacy of endoscopic mass screening is discussed herein.

It is known that the finding ratio of early gastric cancer with endoscopy is higher than that with X-ray^[6], making endoscopy a highly effective screening method^[7]. There are, however, cost problems related to applying endoscopic mass screening^[6,7]. Endoscopic screening is more expensive than direct X-ray screening (ordinary upper GI) in the Japanese medical system. Although the balance is approximately 3400 Japanese yen, because of financial problems in city offices, at the start of the present study, the costs for the two screening procedures were decided to be the same for a while.

MATERIALS AND METHODS

Subjects

The data used in this study were the results of mass screening programs for gastric cancer in Niigata City from 2002 to 2004. The number of participants was 35089 in 2002, 34557 in 2003 and 36600 in 2004. As employees have their own mass screening system of Japan, nonemployees participated in these mass screenings. All screening participants aged 40 or over could choose one of the three programs utilizing endoscopy (ISE), direct X-ray (ISX) and photofluorography (MSP: indirect X-ray

with a small sized film) each.

Analysis

The finding ratio referred to the final diagnosis of gastric cancer after a double check of endoscopic files and histological findings. The costs of identifying one case of gastric cancer with each method were calculated based on the total expense for each screening program and additional close examinations.

Every citizen participates in some type of a medical insurance program, which enables all Japanese have access to medical services for next close examinations at the same costs. X-ray examination of suspected gastric cancer in ISX and MSP groups showed that the patients with suspected lesion could be referred to the endoscopists to receive endoscopy with biopsy for getting a final histological diagnosis. We included these close examination fees in addition to the screening fee for cost analysis. In ISE group the costs of endoscopic screening and additional biopsy at the same time (if needed) were also counted.

RESULTS

Finding ratio

In 2004, the finding ratio in the ISE group was 0.87%, approximately 2.7 and 4.6 times higher than those of the ISX and MSP groups respectively and the rate of early gastric cancer in the ISE group was the highest among the three groups.

Cost analysis

The cost of identifying one case of gastric cancer was estimated to be 1 608 000 Japanese yen in ISE, 4 177 000 Japanese yen in ISX, and 3 290 000 Japanese yen in MSP in 2004. In the same condition of ordinary medical fee for endoscopic examination, the cost of ISE increased to 1 998 000 Japanese yen.

These results indicated that endoscopic mass screening was the best and cheapest means for detecting and identifying gastric cancer. The results of each mass screening are shown in Table 1.

DISCUSSION

To decrease cancer death, early detection and subsequent surveillance are necessary^[8]. Although eradication of *H pylori* infection is the most effective, the incidence of gastric cancer would remain high for several decades to come^[9]. Endoscopic mass screening for gastric cancer is effective in identifying cancer in its early stages^[6], but endoscopic screening is more expensive than direct X-ray screening in the Japanese medical system. In this study our cost analysis showed that even if we applied ordinary examination fee for endoscopic mass screening, this novel approach was still the most superior method in cost-effectiveness for finding gastric cancer patients.

On the other hand, endoscopic mass screening is practically not appropriate for wide application due to the limited number of skilled endoscopists^[6]. In Niigata City, however, we fortunately have enough endoscopists who have the title of authorized specialists as a board-certified member to examine more than 10 000 cases yearly, making it feasible to adopt an endoscopic screening system.

In mass screening systems for gastric cancer, endoscopic examination is a promising method and can be effectively applied if a sufficient number of skilled endoscopists become available to staff the system and if city offices support it.

ACKNOWLEDGMENTS

The authors thank Dr. Kazuei Ogoshi for his assistance and advice in managing the endoscopic mass screening programs and interpretation of the results.

Abstract

AIM: To determine the clinical, analytical and endoscopic factors related to ischemic colitis (IC) severity.

METHODS: A total of 85 patients were enrolled in a retrospective study from January 1996 to May 2004. There were 53 females and 32 males (age 74.6 ± 9.4 years, range 45-89 years). The patients were diagnosed as IC. The following variables were analyzed including age, sex, period of time from the appearance of symptoms to admission, medical history, medication, stool frequency, clinical symptoms and signs, blood tests (hemogram and basic biochemical profile), and endoscopic findings. Patients were divided in mild IC group and severe IC group (surgery and/or death). Qualitative variables were analyzed using chi-square test and parametric data were analyzed using Student's *t* test ($P < 0.05$).

RESULTS: The mild IC group was consisted of 69 patients (42 females and 27 males, average age 74.7 ± 12.4 years). The severe IC group was composed of 16 patients (11 females and 5 males, average age of 73.8 ± 12.4 years). One patient died because of failure of medical treatment (no surgery), 15 patients underwent surgery (6 after endoscopic diagnosis and 9 after peroperative diagnosis). Eight of 85 patients (9.6%) died and the others were followed up as out-patients for 9.6 ± 3.5 mo. Demographic data, medical history, medication and stool frequency were similar in both groups ($P > 0.05$). Seriously ill patients had less hematochezia than slightly ill patients (37.5% vs 86.9%, $P = 0.000$). More tachycardia (45.4% vs 10.1%, $P = 0.011$) and a higher prevalence of peritonism signs (75% vs 5.7%, $P = 0.000$) were observed in the severe IC group while the presence and intensity of abdominal pain were similar between two groups. Two patients with severe IC had shock when admitted. Regarding analytical data, more seriously ill patients were found to have anemia and hyponatremia

than the mildly ill patients (37.5% vs 10.1%, $P = 0.014$ and 46.6% vs 14.9%, $P = 0.012$, respectively). Stenosis was the only endoscopic finding that appeared more frequently in seriously ill patients than in slightly ill patients (66.6% vs 17.3%, $P = 0.017$).

CONCLUSION: The factors that can predict poor prognosis of IC are the absence of hematochezia, tachycardia and peritonism, anemia and hyponatremia and stenosis.

INTRODUCTION

Ischemic colitis (IC) is the most frequent form of vascular alterations in the digestive system. It occurs mainly in the elderly with pluripathology when there is no major vascular occlusion as a result of reduced blood flow responsible for the colon's needs, and is conditioned by many factors^[1].

Clinical presentations vary from mild and limited forms not needing medical treatment to fulminant trans-mural colonic necrosis which may lead to death of patients. The variability in presentations of IC makes epidemiologic research difficult in the general population. The most frequently observed symptoms are abdominal pain and hematochezia^[2].

If IC is clinically suspected, its diagnosis can be established by colonoscopy. The most frequent locations are the splenic flexure, the descending colon and the sigmoid colon, although any segment of the colon can be affected^[3].

Evolution of IC in patients depends on the severity of the presentation. Most mildly affected patients are asymptomatic after medical treatment. Severely affected patients and those that have strictures need to undergo surgery and have a higher morbidity and mortality rate.

The possibility of establishing prognostic factors promptly is of great importance in deciding the best therapeutic strategy for each case. However, only a few

studies on the possible relation of etiological, pathogenic and clinical factors with the progression to colitis are available^[1,3-11].

This study was to review the clinical, biological and endoscopical data of ischemic colitis patients admitted to our hospital and to discover the prognostic factors that determine the evolution of ischemic colitis.

MATERIALS AND METHODS

Patients

A total of 85 patients who were admitted to our hospital from January 1996 to May 2004 and diagnosed with ischemic colitis were retrospectively analyzed. The diagnosis was suspected based on the clinical and X-ray findings and confirmed by the endoscopic and histologic results or the exploratory laparotomy findings. The patients with ischemic colitis secondary to vascular surgery, thromboembolism of the mesenteric artery and/or rectocolonic tumour were excluded.

Methods

The clinical variables including age, sex, period of time from the onset of symptoms to admission and colonoscopy, personal medical history (especially cardiovascular and metabolic history), medication taken regularly, previous stool frequency, symptoms at onset (general well being, abdominal pain, and hematochezia) were analyzed. The exploration signs on admission including hemodynamic state, especially peripheral collapse (systolic blood pressure < 90 mmHg with signs of decreased peripheral blood flow and high blood pressure (systolic blood pressure > 140 mmHg and/or diastolic blood pressure > 90 mmHg) and abdominal exploration, mainly signs of peritoneal irritation such as rigidity and rebound tenderness (Blumberg's sign) were evaluated.

The usual biological, hematological and biochemical parameters obtained on admission were also analyzed. The normal ranges of values provided by our hospital laboratory were used for the qualitative analysis of the main blood test parameters (basic hemogram and biochemical markers).

The endoscopic and laparoscopic results were described identifying the segment of the affected colon. The colon was divided into ascending colon (superior mesenteric artery) and descending colon (inferior mesenteric artery) according to the artery responsible for each segment, sigmoid and descending colon, transverse colon and ascending colon according to the location.

Patients were divided in two groups: severe ischemic colitis patient group (who needed surgery or died in the episode), and mild ischemic colitis patient group (good evolution with medical treatment). Medical treatment included fasting, symptomatic treatment, hydro-electrolytic correction and support, and use of wide spectrum antibiotics.

Statistical analysis

Data were introduced and analyzed using SPSS version 11.0. Qualitative variables were analyzed with the chi-

square test (Fisher's correction when necessary) and the parametric data were analyzed with the Student *t* test for independent groups. Variables with *P* < 0.1 in the univariate analysis were submitted to logistic regression analysis. *P* < 0.05 was considered statistically significant.

RESULTS

Patients

The study included 85 patients (53 women and 32 men) with an average age of 74.6 ± 9.4 years (range 39-89 years). The main risk factor was high blood pressure which was present in 55 patients (64.7%), followed by other cardiovascular diseases (37.6%), diabetes (29.4%), chronic obstructive pulmonary disease (11.8%) and chronic renal insufficiency (1.2%). Previous cardiovascular illness was confirmed in 80% of the patients. Medications taken during the 15 d before the diagnosis of ischemic colitis were registered: antihypertensive medication (64.7%), nonsteroidal antiinflammatory drugs (NSAID) (35.3%), diuretics (25.9%), anticoagulants (3.5%) and cardiotoxic drugs (2.4%). Chronic constipation was confirmed in 52 out of 71 patients (73.2%), while regular laxative intake was verified in 39 out of 66 patients (59.1%). The main symptoms that motivated medical attendance were abdominal pain (72/85 patients, 84.7%) and hematochezia (66/85 patients, 77.6%). Immediate physical exploration revealed that two patients suffered from shock at admission (systolic blood pressure < 90 mmHg), while 47.5% of the patients had high blood pressure. Abdominal exploration was compatible with peritonism (positive Blumberg's sign) in 16 cases (18.8%).

The diagnosis was established by endoscopy with biopsies (73 patients) and surgery (12 patients). A conventional abdominal ultrasound was performed in 43 patients (50.6%) and a CT-scan was done in 19 patients (22.4%) prior to endoscopy and/or surgery.

The lesions were distributed depending on their locations: descending colon in 66 patients (77.6%), splenic angle in 10 patients (11.8%), transverse colon in 4 patients (4.7%) and ascending colon in 4 patients (4.7%).

Mild ischemic colitis was found in 69 patients (81.2%) including 27 men and 42 women with an average age of 74.7 ± 8.6 years (range 45-89 years). All the patients improved after medical treatment. The severe ischemic colitis patient group was consisted of 16 patients (18.82%) including 5 men and 11 women, with an average age of 73.8 ± 12.4 years (range 39-85 years). One patient died due to failure of the medical treatment, while 15 patients underwent surgery (6 patients who were diagnosed by colonoscopy deteriorated despite medical treatment and 9 patients were directly diagnosed during surgery). Eight patients (9.6%) died. The rest of the patients were followed up at the out-patient clinic for an average period of 9.6 ± 3.5 mo (1-72 mo).

Severity prediction factors

The comparative analysis of mild and severe IC showed no statistically significant differences with respect to age, sex, past medical history, previous medication, stay in hospital,

Table 1 Clinical characteristics of the patients with ischemic colitis

	Total <i>n</i> = 85	Mild <i>n</i> = 69	Severe <i>n</i> = 16
Age (yr)	74.6 ± 9.4	74.7 ± 8.6	73.8 ± 12.4
Sex (M/F)	32/53	27/42	5/11
Hospital stay (d)	8.5 ± 6.8	8.0 ± 5.5	10.4 ± 10.9
HBP, <i>n</i> (%)	55 (64.7)	48 (69.6)	7 (43.8)
Diabetes, <i>n</i> (%)	25 (29.4)	20 (29)	5 (31.3)
Cardiovascular illness, <i>n</i> (%)	32 (37.6)	26 (37.7)	6 (37.5)
CRF, <i>n</i> (%)	1 (1.2)	1 (1.4)	0 (0)
COPD, <i>n</i> (%)	10 (11.8)	6 (8.7)	4 (25)
Constipation, <i>n</i> (%)	52 (61.2)	42 (60.9)	10 (62.5)
Hematochezia, <i>n</i> (%)	66 (77.6)	60 (87)	6 (37.5) ^b
Abdominal pain, <i>n</i> (%)	72 (84.7)	57 (82.6)	15 (93.8)
Peritonism, <i>n</i> (%)	16 (18.8)	4 (5.8)	12 (75) ^b
Systolic BP (mmHg)	142.01 ± 28.3	145.2 ± 28.8	128.4 ± 22.2
Diastolic BP (mmHg)	77.7 ± 13	79.2 ± 13.3	71.2 ± 9.5
Heart rate	82.2 ± 16.2	80.1 ± 13.9	93.5 ± 22.3 ^a

^a*P* < 0.05, ^b*P* < 0.01. Hronic renal failure, COPD: Chronic obstructive pulmonary disease.

stool frequency and location of the lesion in the intestine (Table 1).

Regarding the clinical presentation of the illness, statistically significant differences were observed between the two groups. Hematochezia was most frequently seen in the mild IC patient group compared to the severe IC patient group (86.9% *vs* 37.5%), while signs of peritonism were mostly found in the severe IC patient group compared to the mild IC patient group (75% *vs* 5.7%, *P* < 0.001). No differences were observed in the presence and intensity of abdominal pain (Table 1).

On admission, tachycardia (heart rate > 90 b/min) was found most frequently in the severe IC patient group compared to the mild IC patient group (45.4% *vs* 10.1%, *P* < 0.008). The average blood pressure (systolic and diastolic) was higher in the mild IC patient group than in the severe IC patient group (145.2 ± 28.8 mmHg and 79.2 ± 13.3 mmHg *vs* 128.4 ± 22.2 mmHg and 71.2 ± 9.5 mmHg, *P* < 0.05). However, the number of patients with high blood pressure was similar in both groups. The two patients suffering from shock at admission had severe IC (Table 1).

Biological parameter analysis showed that there were statistically significant differences between the two groups in haemoglobin (normal 120-160 g/L), platelet (normal $130 \times 10^9/L$ - $400 \times 10^9/L$) and glycemia (3.9-6.2 mmol/L) values, and similar results in the rest of the parameters (Table 1). Patients with severe IC had anemia most frequently (haemoglobin < 120 g/L) when compared to patients with mild IC (37.5% *vs* 10.1%, *P* = 0.012) and hyponatremia (serum sodium < 136 mmol/L) (46.6% of the severe *vs* 14.9% of the mild, *P* = 0.012).

No statistically significant differences were observed with respect to the endoscopic lesions (erythema, edemas, hematomas, ulcers and fibrin deposits) except for the strictures which were more frequent in the severe IC patient group (66.6% *vs* 17.3%, *P* = 0.017).

Logistic regression analysis showed that hematochezia was a weak predictor of mild IC (OR = 0.09, IC95% = 0.026-0.308, *P* = 0.000), while signs of peritonism (OR = 48.7, IC95% = 10.6-222.1, *P* = 0.000), tachycardia (OR = 7.36, IC95% = 1.71-31.5, *P* = 0.007), anemia (OR = 5.31, IC95% = 1.47-19.08, *P* = 0.010) and hyponatremia (OR = 4.98, IC95% = 1.47-16.8, *P* = 0.010) were associated with severe IC.

DISCUSSION

Ischemic colitis is a well defined illness that is frequently found in elderly patients and is generally associated with clinical or therapeutic situations. The true incidence in the general population or in groups of patients with specific illnesses is not well known because it depends both on the ability of physicians to suspect the diagnosis and on the thoroughness of the diagnostic process. It was reported that the incidence is 6.1 to 47 in 100 000 inhabitants/year^[12]. No systematic studies have established the association between ischemic colitis and cardiovascular pathology, chronic obstructive pulmonary disease, use of different medications and all circumstances responsible for a reduction in blood flow. Our patients had a high prevalence of these factors.

Observational and meta-analysis studies that point to a relationship between IC and irritable bowel syndrome and their treatment with antagonists of 5-HT₃ receptors have recently been published^[13-16]. Whether they are different stages of the same process remains unclear. Treatment sequelae or the final consequence of an altered phenomenon that was previously considered functional has to be explained.

Another predisposing factor for IC may be constipation, probably due to the increased colonic luminal pressure which is responsible for worse blood flow in the colonic wall. All these factors, in addition to the progressive aging of the population, make us presume a future increase in its incidence. The diagnostic and therapeutic strategies need to be further studied.

Clinical presentation in ischemic colitis varies from mild forms that heal after medical treatment to severe forms with complete necrosis of the colonic wall requiring surgery and/or leading to death of patients. In general, the first symptoms of IC are hematochezia and abdominal pain as confirmed in our series.

Clinical, biological and/or endoscopic factors capable of promptly discriminating both groups of patients can be used to take the most appropriate therapeutic steps. Few studies have evaluated this aspect of IC^[8-11].

Out of all the clinical parameters evaluated in our patients, that standing out as a possible predictor for the evolution of IC is only hematochezia. As a clinical presentation, it can protect the patient from severe IC, because in our study it was significantly more frequent

in the mild forms. The presence of tachycardia and peritonism on physical exploration (in our study significantly more frequent in the severe forms of IC) is possibly an expression of the hemodynamic instability and the colonic trans-mural injury, which could lead to perforation and subsequent peritonitis.

The only biological parameters are anemia and hyponatremia which were more frequent in severe forms of IC in our study.

In our series of patients, we did not find a relationship between the evolution of IC and the anatomical location of the lesions, regardless of the diagnostic method applied (endoscopy or surgery), which is different from that disclosed by other authors^[9].

In this study, we found no relationship between age, sex and the subsequent evolution of IC as in other studies^[8-9]. Pla *et al*^[11] and Barouk *et al*^[10] reported that they have established a worse prognosis in elderly patients. There are also incongruent results with regard to the relationship of the medical history of patients and the severity of IC. Medina *et al*^[9] reported that there is no relationship, while others^[8,10-11] reported that high blood pressure is a predisposing factor for the worse evolution of the illness.

The mortality of our patients was almost 10% and all the patients suffered from severe IC, differing greatly from that (66%) reported in the literature^[17].

In conclusion, ischemic colitis is an illness that should be considered in any elderly patients with clinical and therapeutic risk factors, such as abdominal pain and/or hematochezia. The mortality rate of ischemic colitis is still high. We hold that it is necessary to carry out prospective and controlled studies in order to clearly detect the factors that predict the evolution form and find the best therapeutic approach.

<http://www.wjgnet.com/1007-9327/12/4879.asp>

Abstract

AIM: To evaluate the prevalent topical therapeutic modalities available for the treatment of acute radiation proctitis compared to formalin.

METHODS: A total of 120 rats were used. Four groups ($n = 30$) were analyzed with one group for each of the following applied therapy modalities: control, mesalazine, formalin, betamethasone, and misoprostol. A single fraction of 17.5 Gy was delivered to each rat. The rats in control group rats were given saline, and the rats in the other three groups received appropriate enemas twice a day beginning on the first day after the irradiation until the day of euthanasia. On d 5, 10, and 15, ten rats from each group were euthanized and a pathologist who was unaware of treatment assignment examined the rectums using a scoring system.

RESULTS: The histopathologic scores for surface epithelium, glands (crypts) and lamina propria stroma of the rectums reached their maximum level on d 10. The control and formalin groups had the highest and mesalazine had the lowest, respectively on d 10. On the 15th d, mesalazine, betamethasone, and misoprostol had the lowest scores of betamethasone.

CONCLUSION: Mesalazine, betamethasone, and misoprostol are the best topical agents for radiation proctitis and formalin has an inflammatory effect and should not be used.

INTRODUCTION

Acute radiation proctitis is a major clinical complication of pelvic irradiation^[1,2]. Rectum is exposed to high dose irradiation during radiotherapy of the rectal, cervical and prostate malignancies. The rate of complications, which decrease life quality, has been reported as high as 10%-15%^[3,4].

The problem of radiation proctitis leads to prophylaxis studies. Sukralfat^[5-9], anti-inflammatory agents^[6,9], mesalazine^[5] have been shown to be histopathological ineffective in clinical prophylaxis studies. In spite of the clinical comparative studies of these drugs there is no agreement on the therapy protocol^[8,10-12].

There are several therapy modalities used for the protection and treatment of acute radiation proctitis and consequent chronic sequelae, including diet^[13], sucralfate^[14,15], antiinflammatory agents like mesalazine^[15,16], corticosteroids^[5,10], formalin^[17,18] and misoprostol^[3,6]. However these medical approaches are not sufficiently effective and have only a limited benefit. The search for a more effective therapy should be continued.

The pathological features of irradiation begin in hours. Morphologic changes include loss of columnar shape, and nuclear polarity of enterocytes, epithelial degeneration, ulceration, nuclear pyknosis and karyorrhexis, crypt disintegration, mucosal edema, absent mitosis, crypt abscesses with prominent eosinophilic infiltrates^[19].

The aim of this study was to compare the most prevalent topical therapeutic modalities used for acute radiation proctitis in a standard rat radiation proctitis model^[20].

MATERIALS AND METHODS

Animals

Female Sprague Dawley rats weighing 230-285 g at the age of 6 wk were obtained from the Institute for Experimental Medicine, Istanbul University. All animals were acclimatized for 7 d prior to experimentation in the laboratory of the

Table 1 Grading of histological changes on microscopic examination

Structure	Characteristic
Surface epithelium	Loss of cellular height/flattening of cells Cellular inflammatory infiltrate
Glands (crypts)	Luminal migration of epithelial nuclei Loss of goblet cells Mitotic activity Cryptitis (migration of segmental neutrophils through the crypt wall) Eosinophilic crypt abscesses Loss of glands Atrophy of glands Distortion of glands
Lamina propria	Inflammation Edema Congestion of blood vessels

The abnormalities were assessed as normal (score = 0) or abnormal, ranked according to severity and arranged in quartiles.

mentioned institute, which was maintained at $22 \pm 2^\circ\text{C}$ and a relative humidity of $55 \pm 10\%$ in a constant 12 h dark/light circle. The rats were housed in standard wire cages and fed with standard rodent chow and UV sterilized tap water. The approval of the Ethical Review Committee of the Faculty was obtained and the experimental procedures in this study adhered to the Declaration of Helsinki for the care and use of laboratory animals.

After irradiation each animal was weighed and examined every 2 d until the end of the experiment. Five groups (30 rats in each group) were used. Groups were defined as follows. Rats in control group were anesthetized, restrained and taped by the tail and legs on an acryl plate, irradiated and given saline enemas. Rats in mesalazine group were irradiated, and given mesalazine enemas (Salofalk, Ali Raif, Istanbul, Turkey)^[21]. Rats in formalin group were irradiated, and given formalin enemas (4%)^[22]. Rats in betamethasone group were irradiated, and given betamethasone enemas (Betnesol, Glaxo-Wellcome, Hamburg, Germany)^[13]. Rats in isoprostol group were irradiated, and given misoprostol enemas (5 $\mu\text{g/kg}$)^[23]. The enemas, which were prepared in 1 mL volume at body temperature, were given twice a day beginning on the first day after irradiation until the euthanasia day. The enemas were applied with a soft feeding tube and then the anus was temporarily closed with digital compress for five minutes.

Irradiation

Each rat was anesthetized using sodium pentobarbital intraperitoneally (40 mg/kg). Then 3 to 4 rats at a time were restrained and taped by the tail and legs on an acryl plate at a supine position. Lead shielding (5 half value layer) was used to cover the rat except for a 3 cm \times 4 cm area of lower pelvis containing 2 cm length of rectum in the middle of the field. Irradiation was delivered with a cobalt-60 apparatus, the γ energy was 1.25 MeV, and a distance of 80 cm from the source to the surface was used. Dose rate of the irradiation was 121.49 Gy per min and 17.5 Gy in a single fraction was delivered to each rat. Ten rats from

Table 2 Comparison of the histopathological scores of the rectal specimens with regard to the euthanasia days (mean \pm SD)

	5 th d	10 th d	15 th d
Control	7.40 \pm 3.89	39.20 \pm 3.58 ¹	35.40 \pm 2.27
Mesalazine	5.60 \pm 3.41	11.40 \pm 3.37	22.40 \pm 2.37
Formalin	10.0 \pm 4.50	38.20 \pm 3.61 ²	37.00 \pm 2.26 ²
Betamethasone	3.20 \pm 1.03	20.60 \pm 3.41	18.20 \pm 4.32
Misoprostol	4.40 \pm 1.71	20.80 \pm 2.70	23.6 \pm 2.80 ²

¹ Two specimens were excluded; ² One specimen was excluded.

each group were selected randomly for gross and macroscopic examination and euthanized on d 5, 10, and 15. Two 5 mm segments of the rectum which was 1 cm proximal to anus were excised, fixed in 10% neutral buffered formalin solution and processed by routine techniques. Each specimen was stained with hematoxylin and eosin and examined under a light microscope by a pathologist who was unaware of treatment assignment.

The rectums were evaluated microscopically using a slightly modified scoring system reported by Hovdenak *et al*^[7] by a pathologist who was blinded to the groups and the euthanasia days of specimens. A total of 13 characteristics of three mucosal structures (surface epithelium, glands, and lamina propria stroma) were used. The abnormalities of the 13 parameters were assessed as normal (score = 0) or abnormal, and ranked according to severity and arranged in quartiles: 1 = mildly abnormal; 2 = moderately abnormal; 3 = markedly abnormal; 4 = severely abnormal.

Statistical analysis

Results were presented as mean \pm SD. Relationship between the groups was assessed using analysis of variance. Tukey or Tamhane's test was chosen to test for equality of variances. *P* values less than 0.05 were considered statistically significant.

RESULTS

There was no death during the study. For determination of the acute radiation injury and the response to the local therapy, 10 rats from each group were euthanized on d 5, 10 and 15 after the irradiation. The rats were apparently healthy until the day of sacrifice excluding three rats (2 in control group and 1 in formalin group), which "looked" ill and showed symptoms of diarrhea on the 10th d. The rectums of the rats were removed and examined grossly and histopathologically. Tissues from five specimens (including the three mentioned above) had severe damage and were inappropriate to be scored. They were thus excluded from the study.

The five samples excluded were two from control group on the 10th d due to the ischemic necrosis of the rectal mucosa, one from formalin group on the 10th d due to massive mucosal infarct, one from formalin group on the 15th d due to lymphocytic colitis, one from isoprostol group on the 15th d due to lymphoid hyperplasia and submucosal edema (Table 1).

Figure 1 Sum of the histopathologic scores regard to the euthanasia days. 1: control group; 2: mesalazine group; 3: formalin group; 4: betamethasone group; 5: misoprostol group. The differences in the mean scores of all groups, but the formalin group on the 10th and 15th d and betamethasone group on the 10th and 15th d were statistically significant.

The mean histopathologic scores of the specimens are shown in Table 2.

On the 5th d the formalin group had the highest scores, followed by the control group. Mesalazine, betamethasone and misoprostol groups had the lowest scores. Table 2 gives the statistical comparison of the scores. There was no difference between control and formalin groups. The mesalazine, betamethasone and misoprostol groups had no difference between each other either. The control group had significantly higher scores than betamethasone group ($P = 0.039$). The formalin group had higher scores than the mesalazine, betamethasone and misoprostol groups ($P = 0.028$, 0.0001 and 0.003 , respectively).

On the 10th d the control and formalin groups had the highest scores, followed by misoprostol, betamethasone and mesalazine groups (Table 2). The scores of the control and formalin groups were higher than those in the misoprostol, betamethasone and mesalazine groups ($P = 0.0001$). There was no difference between control and formalin groups. The mesalazine group had the significantly lowest scores ($P = 0.0001$). There was no statistically significant difference between misoprostol and betamethasone groups.

On the 15th d, the scores of formalin and control groups were the highest (Table 2). Misoprostol, mesalazine and betamethasone groups had lower scores. The formalin and control groups had significantly higher scores than the other groups ($P = 0.0001$). There was no difference between mesalazine and misoprostol groups. The betamethasone group had the lowest scores ($P = 0.0001$ for the control and formalin groups, and $P = 0.044$ for the misoprostol group).

The sum of the histopathologic scores on the euthanasia days are presented on Figure 1. The inflammatory processes of the control, formalin and betamethasone groups reached a maximum score on the 10th d and decreased on the 15th d. Since inflammation of the mesalazine and misoprostol groups increased on the 10th and 15th d, the scores of the last group were higher. The mean scores of all groups, except for the formalin group and the beta-

Figure 2 Cryptitis, loss of cellular height/flattening of cells, nuclear debris in the crypt lumen and mononuclear leukocyte infiltration on lamina propria (HE X 125).

methasone group on the 10th and 15th d, were significantly different.

DISCUSSION

The aim of this study was to compare the histopathologic effects of formalin therapy with the most common agents used for radiation proctitis^[4,12,18,24-26]. The consequential correlation between acute injury, which is common and usually self-limiting and chronic sequela has been demonstrated^[27,28].

With a controlled radiation proctitis animal model, the four most widely used therapeutic approaches were studied in a blinded histopathologic comparison. This standard model has two handicaps: the impossibility to examine the same individual over the time and the relation of the pathologic scores to the clinical symptoms. To deal with these problems, we used groups of simultaneously sacrificed rats and a pathological scoring system obtained from a clinical study^[7]. The chosen model was justified with comparison to the clinical series from the pathological point of view in regard to the duration after irradiation and the optimal dose for the human disease. The protective dose of various medications has been determined to be 17.5 Gy in single fraction^[20,29].

The acute pathological findings on the rectal mucosa are reported to persist for two weeks^[20,29]. An edema of the lamina propria was observed in a first couple of days, cryptitis and crypt abscesses were found on d 4 and 5, ulcers and regenerative processes could be determined on d 9 and 10, the mucosa was healed and then the chronic sequelae like fibrosis of the lamina propria arose on d 15^[7].

It was reported that the pathological differences in the 10th d groups are more obvious^[7]. Cryptitis (Figure 2) and crypt abscesses (Figure 3) are the predominant characteristics of acute radiation toxicity. Two specimens of the control group showed mucosal ischemic necrosis. Two specimens of the formalin group showed mucosal infarct. One specimen of the misoprostol group showed crypt hyperplasia. The mean and sum mucosal and glandular pathologic scores of the formalin group were close to those of the control group. Betamethasone and misoprostol groups had statistically significant low scores.

Figure 3 Crypt abscess and nuclear debris in a crypt lumen (HE X 310).

The pathological process, determined with necrosis and edema of the mucosa and focal mucosal ulcers continued till the 15th d in euthanized animals of control and formalin groups. Betamethasone group showed the lowest pathologic scores on the 15th d.

The mucosal cytokines IL-1 β , IL-2, IL-6 and IL-8 have been reported to play a significant role in the etiology of radiation-induced proctoprocitis^[30]. Mesalazine and betamethasone with cytokine suppressive effects have a curative outcome on this immunology-based disease, parallel to our results. The present study showed a solely descriptive basis of the histopathology, which determines the need and extent of the clinical therapy. The immunological contribution of the disease and the effect of therapeutic approaches need to be clarified.

It should be noted that two specimens were excluded from the study, one formalin group specimen on the 15th d due to lymphocytic colitis, one misoprostol group specimen on the 15th d due to lymphoid hyperplasia and submucosal edema. Since lymphocytic colitis, lymphoid hyperplasia and submucosal edema were encountered over the whole rectal wall of the two specimens from the same animal, the scoring of them was thus impossible. Mistol has radiation protective and tissue regenerating effects, but its mechanism of action is not fully understood^[8]. We showed that it could contribute to the healing process after irradiation.

Rectal formalin therapy has serious side effects like worsening of colitis, rectal pain, anal stenosis, rectal ulcers and anal incontinence^[4]. These side effects have been reported even in series with good clinical results^[5,14]. These effects are in accordance with our histopathologic findings.

In conclusion, formalin should not be used in order to avoid its toxic effects on mucosa. Mesalazine and betamethasone can be used for local therapy with no major superiority between each other. Controlled randomized prospective clinical trials are required to determine the best management of this disease.

Abstract

AIM: To evaluate possible risk factors for the spread of hepatitis C infection and to analyze the characteristics of the epidemiological and clinical patterns among the patients with hepatitis C infection.

METHODS: During a five-year period a cross-sectional study was conducted among HCV positive individuals referred to the Ahwaz Jundishapur University Hospitals (AJSUH) and Hepatitis Clinic from 1 Sept 1999 to 1 Sept 2003. The control group consisted of first time blood donors referred to the Regional Blood Transfusion organization. Enzyme-linked immunosorbent assay and recombinant immunoblot assay anti-hepatitis C virus (HCV) tests were performed for two groups. Positive serum specimens were retested using polymerase chain reaction (PCR) for HCV RNA. Risk factors were evaluated using a questionnaire. Reported risk factors among infected subjects ("HCV-positive") were compared to those of subjects never exposed ("HCV-negative") to HCV.

RESULTS: A total of 514 subjects were studied for HCV, of which 254 were HCV-positive and 260 HCV-negative donors comprised the control group. Mean age of the patients was 28.4 (Std 15.22) years. HCV-positive subjects were more likely to be of male gender (63% versus 37%). Transfusion 132 (52%), non-intravenous (n-iv) drug abuse and iv drug abuse 37 (14.5%), haemodialysis 25 (10%), receiving wounds at war and

extramarital sexual activities (2.4%), tattooing (3.6%) were found to be independent risk factors of being HCV-positive. No apparent risk factors could be demonstrated in 29 (11.2%) of the positive cases.

CONCLUSION: Our data indicate that a history of transfusion and iv drug abuse and haemodialysis are important risk factors for HCV infection in our area and that more careful pretransfusion screening of blood for anti-HCV must be introduced in our blood banks. Improvements in certain lifestyle patterns, and customs in this area may be essential to prevent transmission of the infection.

INTRODUCTION

Hepatitis C virus (HCV) infection is responsible for considerable morbidity and mortality worldwide. HCV is a leading cause of liver failure and liver transplantation in adults. Identified risk factors for HCV infection include intravenous (IV) drug use, exposure to infected blood products, and intranasal drug use^[1]. High-risk sexual activity [multiple sexual partners, history of sexually transmitted disease (STD)], tattooing, and skin piercing have also been suggested to be associated with increased risk for HCV^[2]. In addition, mother-to-infant transmission has been demonstrated^[3,4], but the possibility of other transmission routes has not been thoroughly explored. With the use of RT-PCR or bDNA techniques, HCV RNA has been detected in many systemic fluids other than blood, including peritoneal fluids, seminal and vaginal secretion, urine, and feces. These observations, however, have not been confirmed by all investigators^[5]. The possibility of HCV replication in the mosquito alimentary tract has recently been demonstrated, but the epidemiological importance of this has not yet been

determined^[6]. The rate of HCV infection differs in particular countries. The prevalence in developed countries amounts to 0.2%-2.2%, while in developing countries it reaches 7%. In some regions or risk group the rate of occurrence may be as high as 30%-90%. In Iran, according to the latest data, it is estimated that between 0.12-0.89 percent of the general population present anti-hepatitis C virus antibodies, which corresponds to as many as 0.5 million chronic carriers^[7,8].

Risk factors associated with HCV infection may be specific to a country or region^[9]. Few data are available about the risk factors associated with HCV infection in our area. Hepatitis C is a common health problem in South-West of Iran, and needs proper attention to alleviate the suffering of the people. It is essential to assess the magnitude of the problem, which will help us in understanding the dynamics of its transmission and can be utilized to guide screening procedures as well as provide insight into the control and prevention of the disease.

Herein, we report results of our cross-sectional analyses of risk factors for HCV infection in our community in Khuzestan Province, South-West of Iran conducted during a five year period.

MATERIALS AND METHODS

During a five-year period a cross-sectional study was conducted among HCV positive individuals referred to the Ahwaz JundiShapour University Hospitals (AJSUH) and Hepatitis Clinic from 1 Sept 1999 to 1 Sept 2003. On the basis of a specially designed protocol, standard commercially available tests and physical examinations were performed. The analysis included data of medical history, physical examination and periodic evaluation clinically and serologically.

All subjects were evaluated using a face-to-face questionnaire about demographic (gender and age) and socioeconomic (education) aspects, parenteral exposure to blood or blood products, social and sexual behavior, occupational exposure, intravenous drug use, tattooing, acupuncture, surgery, previous hospitalization and parenteral administration of drugs, personal history of jaundice or hepatitis or history of these diseases in the cases' and controls' families. The control group consisted of first time blood donors referred to the Regional Blood Transfusion Organization. None of the control group subjects were HBsAg positive, HIV-positive or have any signs or symptoms of hepatitis.

Enzyme-linked immunosorbent assay (Organon/Teknica UB/HCV EIA) and recombinant immunoblot assay anti-hepatitis C virus tests were performed for two groups. Positive serum specimens were retested using polymerase chain reaction (PCR) for HCV RNA.

None of our patients showed any signs of HBV infection, or any other cause of acute or chronic liver disease, such as HAV, EBV, CMV infections, auto-immune diseases, alcohol and drug abuse, α 1-antitrypsin deficiency, Wilson's disease, or hemochromatosis. HBsAg, anti-HBc were determined by IMx analyzer (Abbott Lab., Abbott Park, IL, USA). HBsAg, anti-HBc were determined by IMx analyzer (Abbott Lab., Abbott Park, IL, USA).

Table 1 Demographic features and symptoms and signs of liver disease of the patients enrolled into the study

Variable	HCV positive (<i>n</i> = 254)	
	<i>n</i>	%
Sex		
Male	160	63
Female	94	37
Age group (yr)		
< 20	81	32
20-29	82	32.5
30-39	56	22
40-59	26	10
> 60	9	3.5
Total	254	100
Symptoms		
RUQ Pain	142	56
Malaise	93	36.6
Dyspepsia	58	22.8
Signs		
Splenomegaly	25	9.8
Jaundice	12	4.7
Hepatomegaly	8	3.1
Elevated serum ALT level	168	66
HIV positive	3	1.2

Reported risk factors among infected subjects ("HCV-positive") were compared to those of subjects never exposed ("HCV-negative") to HCV. Consent for an interview was taken from each participant, who was assured about the confidentiality of his information. Controls were briefed about the known modes of HCV transmission. The institutional Ethics Review Committee approved the study protocol.

Statistical analysis

Collected data were coded, analyzed and computed, using the Statistical Package for Social Sciences (SPSS) version 10 (SPSS Inc., Chicago, IL, USA). Simple statistics such as frequency, and standard deviation were used. We conducted a multivariate logistic regression analysis to identify factors associated with HCV infection. Chi-square and Student's *t*-tests were used for comparison.

RESULTS

A total of 514 subjects were studied for HCV, of which 254 were HCV-positive and 260 HCV-negative donors comprised the control group. Mean age of the patients was 28.4 (SD 15.22) years. Of the 254 patients, 225 (88.6%) had identifiable risks of exposure to HCV infection.

HCV-positive subjects were more likely to be of male gender (63% *vs* 37%). Transfusion 132 (52%), non-intravenous (n-iv) drug abuse and iv drug abuse 37 (14.5%), haemodialysis 25 (10%), receiving wounds at war and extramarital sexual activities 6 (2.4%), tattooing (3.6%) were found to be independent risk factors of being HCV-positive. The mean age was significantly younger in patients with transfusion (13.4 years) than the mean age of all the patients (28.4 years, *P* = 0.004), mainly those with thalassemia and received regular blood transfusion. No

Table 2 Risk factors possibly associated with HCV-positive in patients group

Variable	HCV-negative (n = 260)		HCV-positive (n = 254)	
	n	%	n	%
Risk factor				
Blood transfusions	6	2.3	132	52
Intravenous drug use	0	0	37	14.5
Extramartial sexual activities	1	0.4	3	1.2

Receiving wounds at war	0	0	3	1.2
Endoscopy	14	5.4	1	0.4
Unknown	224	86.1	29	11.2
Total	260	100	254	100

apparent risk factors could be demonstrated in 29 (11.2%) of the positive cases.

The demographic features and the background characteristics of the patient population are displayed in Table 1. Differences in the distribution of risk factors were compared between the HCV positive and negative groups, with similarities observed for educational level, economic status, and residency.

Transfusion ($P < 0.002$), intravenous drug use ($P < 0.005$) and hemodialysis ($P < 0.008$) were the only three variables with a statistically significant correlation with the presence of HCV infection on univariate analysis. There were no other statistically significant differences between the HCV positive and HCV negative control group in terms of demographic characteristics or topic areas associated with HCV infection/transmission such as extramarital sexual activities, tattooing, endoscopy, surgical and dental procedures (Table 2).

DISCUSSION

Chronic HCV infection represents one of the major public health problems in Iran and according to the annual IBTO internal reports, it is estimated to be less than 0.2%^[8,10]. Approximately 20%-30% of patients with chronic HCV infection will progress to cirrhosis^[11], which can be further complicated by hepatic decompensation and development of hepatocellular carcinoma(HCC)^[12,13].

In this study, 254 anti-HCV-positive patients between 1999 and 2003 were investigated. The ages of these patients, at the time of data analysis, ranged from 7 to 68 years with a mean age of 28.4 years. Our study included 160 males and 94 females, with a male:female ratio of 1:7. This male preponderance in HCV-infected patients was also reported by others^[14,15].

Our study indicated blood transfusion was the leading risk factor for HCV acquisition in our patients as 52% of them were diagnosed with chronic haemolytic anemias, mainly thalassemia and received regular blood transfusion. It should be emphasized that these cases most probably,

had contracted the infection before testing for HCV antibodies was performed routinely. Screening for HCV has been a routine for all blood donors since 1995 in Iran^[8]. Although it is not clear whether all the HCV-positive subjects in our study population with a positive history of transfusion had had their transfusion before 1995, the date of transfusion was not determined in our study. Therefore, more careful pretransfusion screening of blood for anti-HCV must be introduced in our blood banks.

Injection drug users (IDUs) constitute the largest group of persons at high risk for acquiring HCV infection in developed countries^[14,15]. Intravenous drug use was the second most frequent risk factor for HCV acquisition in our patient group (14.5%) and all of them were male, which is consistent with other reports. The male patients tended to have a history of IDU, whereas, female patients tended to have a history of transfusion^[16,17]. The data on route of drug administration were based on selfreporting. One must always consider the possibility that injection drug use is underreported and that some of the HCV infection among the non-injection drug users (NIDUs) may have actually occurred through injection of drugs^[18,19]. Although it is certainly possible that some of the NIDUs in this study may have injected drugs and become infected with HCV *via* injection of drugs, it does not appear that underreporting of injection drug use is a viable explanation for the results of this study.

As reported in several studies, HCV infection is a significant health problem in dialysis units in our country with a high prevalence rate (13.2%) among this population^[20]. It was reported that blood transfusion and duration of dialysis treatment are important risk factors for HCV infection in patients on haemodialysis^[21,22]. The more units transfused, the higher the risk for HCV infection.

Besides, we cannot exclude the possibility of nosocomial transmission of the virus over time in this group. This is supported by the fact that 8.8% of infected patients in this population had no history of blood transfusion. Patient-to-patient transmission was prospectively shown in some incidence studies in hemodialysis patients^[17]. Some strategies to reduce the risk of HCV infection in patients on hemodialysis such as early screening of patients for anti-HCV, reduction of transfusion by the use of erythropoietin or screening with more sensitive methods to detect HCV; and reducing the duration of the hemodialysis period by early transplantation should be considered in this group.

No apparent risk factors could be demonstrated in 29 (11.2%) of the positive cases (called sporadic infections), which is similar to those reported previously^[17]. In sporadic infections with no apparent risk factors, other routes of transmission and other factors, such as use of the same razor or tooth brush, or careless dressing of cuts and wounds or the family environment, where the infection risk increases along with exposure time should be noted^[24]. Another possible explanation for this percentage of sporadic infections is failure of the questioning process in our study. We found no significant relationship between sex, previous endoscopy, receiving wounds at war, marital status with the risk of HCV infection as independent risk

factors in our cases in comparison with controls.

Although the serological, epidemiological and possible risk factors of HCV infection here obtained were related to a small population, this study was justified by the lack of information about HCV infection in Khuzestan Province, South-West of Iran. Other limitations of the study are linked to the difficulties inherent in self-reporting of behaviors such as sexual activity and drug use. It is also possible that the patients receiving blood transfusion in the study may not be representative of the population of Khuzestan Province. Genotyping was not performed in our studied cases due to limitations in our area but the genotypes of HCV were investigated in Iranian patients with histologically proven chronic hepatitis, genotype (1a) has been identified in the majority of the patients^[25].

In conclusion, we provide epidemiologic features of hepatitis C and its risk factors in Khuzestan Province in South-West of Iran. These data are useful for understanding the risks of transfusion, hemodialysis, and other lifestyle patterns that predispose people to a number of HCV risk factors. These findings could be utilized to primary prevention program focused on identified risk factors, may help curtail the spread of HCV infection in this and other similar settings in developing countries. These results suggest that further study on the mode of transmission of hepatitis C should focus on patients who deny intravenous drug use or apparent risk factors. This information contributes to our understanding of the worldwide prevalence of hepatitis C. It demonstrates the importance to continue this study in order to establish routine procedures that can be applied to the screening and confirmation of the diagnosis, as well as to provide an applied methodology for the epidemiological investigation of the virologic profile of HCV-infected patients.

ACKNOWLEDGMENTS

We thank the medical and nursing staff of Emam and Golestan hospitals for their help in the conduct of this study and the faculty of Department of Medicine of Joundishapoor University, for their encouragement and support. The authors sincerely thank the participants of the study. The authors also thank Mrs Shahnaz Shahid zadeh for her excellent assistance.

Abstract

AIM: To compare the effectiveness of triple, standard quadruple and ampicillin-sulbactam-based quadruple therapies for *H pylori* eradication in a comparative three-armed randomized clinical trial.

METHODS: A total of 360 *H pylori*-positive patients suffering from dyspepsia and aging 24-79 years with a median age of 42 years were enrolled in the study and randomly allocated into the following three groups: group A ($n = 120$) received a standard 1-wk triple therapy (20 mg omeprazole b.i.d., 1000 mg amoxicillin b.i.d., 500 mg clarithromycin b.i.d.); group B ($n = 120$) received a 10-d standard quadruple therapy (20 mg omeprazole b.i.d., 1000 mg amoxicillin b.i.d., 240 mg colloidal bismuth subcitrate b.i.d., and 500 mg metronidazole b.i.d.); group C ($n = 120$) received the new protocol, i.e. 375 mg sultamicillin (225 mg ampicillin plus 150 mg sulbactam) b.i.d. (before breakfast and dinner), instead of amoxicillin in the standard quadruple therapy for the same duration. Chi-square test with the consideration of $P < 0.05$ as significant was used to compare the eradication rates by intention-to-treat and per-protocol analyses in the three groups.

RESULTS: The per-protocol eradication rate was 91.81% (101 patients from a total of 110) in group A, 85.84% (97 patients from a total of 113) in group B, and 92.85% (104 patients from a total of 112) in group C. The intention-to-treat eradication rate was 84.17% in group A, 80.83% in group B, and 86.67% in group C. The new protocol yielded the highest eradication rates by both per-protocol and intention-to-treat analyses followed by the standard triple and quadruple regimens, respectively. However, the differences were not statistically significant between

the three groups.

CONCLUSION: The results of this study provide further support for the equivalence of triple and quadruple therapies in terms of effectiveness, compliance and side-effect profile when administered as first-line treatment for *H pylori* infection. Moreover, the new protocol using ampicillin-sulbactam instead of amoxicillin in the quadruple regimen is a suitable first-line alternative to be used in regions with amoxicillin-resistant *H pylori* strains.

INTRODUCTION

H pylori is responsible for the majority of peptic ulcer diseases and its eradication leads to the cure of such diseases, thereby eliminating the need for surgical treatment. Eradication of *H pylori* is indicated in the management of dyspepsia in patients under the age of 45 years without alarm symptoms (the 'test and treat' strategy) and also serves as a preventive treatment in precursor lesions of gastric cancer.

According to the Maastricht 2 guidelines, first-line eradication is triple therapy with the use of a proton-pump inhibitor b.i.d., 1 g amoxicillin b.i.d., and 500 mg clarithromycin b.i.d. In the case of penicillin allergy, 500 mg metronidazole b.i.d. is substituted for amoxicillin. When first-line *H pylori* eradication fails, a second-line treatment of quadruple therapy, with a proton-pump inhibitor b.i.d., colloidal bismuth subcitrate q.i.d., 500 mg metronidazole t.i.d., and 500 mg tetracycline q.i.d. is recommended.

Antibiotic resistance is the main cause of failure for *H pylori* eradication and beta-lactamase produced

by resistant *H pylori* strains is a possible mechanism underlying the ineffectiveness of an amoxicillin-based triple or quadruple therapy^[1]. Of the 153 clinical isolates of *H pylori* found in a previous study, 71.9% are resistant to amoxicillin, 77.8% to metronidazole, and 39.2% to both^[2]. The resistance rate to clarithromycin is currently 2%-30%^[3]. Consequently, new treatment modalities have recently emerged to overcome antibiotic resistance^[4]. However, comprehensive comparisons of the effectiveness of traditional and new treatment modalities are lacking in the literature.

Antibacterial activities of beta-lactamase inhibitors such as clavulanic acid and sulbactam have been demonstrated in a number of *in vitro* studies^[5,6]. However, using clavulanic acid associated with amoxicillin has not significantly increased the *H pylori* eradication rate *in vivo*^[7,8]. The aim of this study was to compare the effectiveness of the following therapeutic regimens (triple therapy, standard amoxicillin-based quadruple therapy, ampicillin-sulbactam-based quadruple therapy) in eradicating *H pylori* in a three-armed randomized clinical trial for the first time.

MATERIALS AND METHODS

Patients and medications

A total of 360 *H pylori*-positive patients suffering from dyspepsia and aging 24-79 years with a median age of 42 years were enrolled in the study. *H pylori* status was determined by rapid urease test at entry. After giving written informed consent, the patients were randomly allocated into three groups: group A ($n = 120$) received a standard 1-wk triple therapy (20 mg omeprazole b.i.d., 1000 mg amoxicillin b.i.d., 500 mg clarithromycin b.i.d.); group B ($n = 120$) received a 10-d standard quadruple therapy (20 mg omeprazole b.i.d., 1000 mg amoxicillin b.i.d., 240 mg colloidal bismuth subcitrate b.i.d., and 500 mg metronidazole b.i.d.); group C ($n = 120$) received 375 mg sultamicillin (225 mg ampicillin plus 150 mg sulbactam, purchased from Pfizer SA, Case Postale, 8048 Zurich, Switzerland) b.i.d. (before breakfast and dinner), instead of amoxicillin in the standard quadruple therapy for the same duration. *H pylori* eradication was confirmed by C¹⁴-urea breath test following 6 wk from the end of therapy.

All patients were contacted periodically, asked about the occurrence of possible side effects, and appropriate guidance was provided when needed. Those who were lost to follow up, or used antibiotics in the time period between the end of therapy and post-treatment urea breath test, or could not complete the treatment course because of severe side effects, were excluded in the per-protocol analysis.

Statistical analysis

The study was a three-armed randomized clinical trial with groups A, B and C including 110, 113 and 112 patients for the final statistical analysis (per-protocol analysis). In addition, intention-to-treat analysis was also performed. Chi-square test was used to compare the eradication rates by intention-to-treat as well as per-protocol analyses in the three groups. $P < 0.05$ was considered statistically significant.

Table 1 Demographic and clinical data of patients who completed the treatment

	Group A (Triple therapy)	Group B (Quadruple therapy)	Group C (New protocol)
Patients (n)	110	113	112
Male, n (%)	57 (52)	60 (53)	62 (55)
Female, n (%)	53 (47)	53 (47)	50 (45)
Age range (yr)	28-79 (median 41)	24-47 (median 39)	31-68 (median 47)
Minor side effects, n (%)	6 (5)	5 (4)	12 (11)
Overall eradication (n)	101	97	104
Intention-to-treat (%)	84.17	80.83	86.67
Per-protocol (%)	91.81	85.84	92.85

RESULTS

Five patients in group A, 3 in group B, and 4 in group C were lost to follow up. Four patients in group A, 2 in group B, and 4 in group C used antibiotics in the time period between the end of therapy and post-treatment urea breath test. One patient in group A and 2 in group B discontinued the regimen due to severe allergic reactions. Minor side effects were experienced by 6 patients in group A (vomiting, skin rash and abdominal pain), 5 patients in group B (vomiting, skin rash and pruritis) and 12 patients in group C (vomiting, diarrhea, headache, skin rash and abdominal pain).

Demographic and clinical details of the patients remaining in the three groups are shown in Table 1. The per-protocol eradication rate was 91.81% (101 patients from a total of 110) in group A, 85.84% (97 patients from a total of 113) in group B, and 92.85% (104 patients from a total of 112) in group C. The intention-to-treat eradication rate was 84.17% in group A, 80.83% in group B, and 86.67% in group C. The new protocol yielded the highest eradication rates by both per-protocol and intention-to-treat analyses followed by the standard triple and quadruple regimens, respectively. However, the differences were not statistically significant between the three groups. They were also not significantly different in the occurrence of minor side effects, either.

DISCUSSION

We opted to prescribe antibiotics for ten days because 4- and 7-d regimens have been unsuccessful in Iran^[9]. In this study, the eradication rates for the triple, standard quadruple and ampicillin-sulbactam-based quadruple therapies were not significantly different. Occurrence of serious side effects necessitating termination of therapy was negligible in all three groups. Minor side effects were well tolerated among all three groups and occurred infrequently with almost the same frequency. Diarrhea and headache occurred in group C only, but other side effects were experienced in all groups.

Some recent studies have compared the efficacy of triple versus quadruple therapy, and a recent meta-analysis

has assessed these studies^[10]. Eradication rates were not significantly different among patients receiving triple or quadruple therapy. The duration of therapy (7 vs 10 d) did not significantly change the results, either. Triple therapy given for a 10-d period achieved an intention-to-treat eradication rate of 79% compared with 77% for a 7-d period. Quadruple therapy on the other hand gave an intention-to-treat eradication rate of 83% for a 10-d period and 80% for a 7-d period^[10]. The eradication rates by intention-to-treat analysis among patients receiving either triple or quadruple therapy in this study were almost similar to those obtained previously^[4,10,11].

A previous preliminary study by the authors using ampicillin-sulbactam instead of amoxicillin in 10-d standard quadruple therapy on 26 patients has yielded a 92% eradication rate by per-protocol analysis which was well tolerated among patients (unpublished data). The present study is the first randomized clinical trial to evaluate the efficacy of the new protocol and to compare it with standard triple and quadruple therapies in a relatively large number of patients. Although not statistically significant, the new protocol seems to be more effective than traditional protocols.

H. pylori infection has a high prevalence rate of about 90% in Iran, which emphasizes the importance of having an effective regimen to eradicate *H. pylori*^[12]. The metronidazole-based standard triple therapy regimen has been unsuccessful in *H. pylori* eradication, yielding an eradication rate of only about 55% compared with about 90% in other countries^[13,14]. This is because metronidazole-resistant *H. pylori* strains are rather common in Iran as well as in other developing countries^[9,15]. The high prevalence of metronidazole-resistance in Iran could be explained by the frequent use of metronidazole to treat various infections, thereby promoting antibiotic resistance in *H. pylori*.

On the other hand, 7.4% of *H. pylori* isolates in Iran have been reported to be resistant against amoxicillin and higher resistance rates of up to 29% have been reported in other developing countries^[15,16]. Therefore, the use of ampicillin-sulbactam instead of amoxicillin in the quadruple therapy regimen, leading to an eradication rate of 92.85% by per-protocol and 86.67% by intention-to-treat analysis in this study, may be useful against metronidazole- and amoxicillin-resistant *H. pylori* strains in developing countries like Iran. Consequently, there would be no need to exclude metronidazole (because of antibiotic resistance), which is an inexpensive and widely available anti-*H. pylori* agent in developing countries.

Since the present study did not show the effectiveness of the new combination on ampicillin-resistant strains, we should bear in mind that some of the resistant strains do not act through beta-lactamase but rather penicillin binding proteins (PBPs)^[17]. Perhaps *in vitro* study of ampicillin-resistant strains using ampicillin-sulbactam combination can help answer whether the combination is effective against the resistant strains.

In conclusion, the results of this study provide further support for the equivalence of triple and amoxicillin-based quadruple therapies in terms of effectiveness, compliance

and side-effect profile when administered as a first-line treatment for *H. pylori* infection. Moreover, the new protocol using ampicillin-sulbactam instead of amoxicillin in the quadruple regimen is a suitable first-line alternative to be used in regions with amoxicillin-resistant *H. pylori* strains.

Abstract

AIM: To evaluate whether multiple determinations of intramucosal pH (pHi) in acute pancreatitis (AP) patients could provide additional information of the disease severity during early hospitalization.

METHODS: Twenty-one patients suffering from acute pancreatitis were monitored by gastric tonometry in the first 72 h after hospital admission.

RESULTS: In the survivor group ($n = 15$) the initially low pHi values returned to normal level ($\text{pHi} \geq 7.32$) within 48 h (median pHi: d 1: 7.21; d 2: 7.32; d 3: 7.33). In contrast, pHi values in the non-survivor group ($n = 6$) were persistently either below or in the low normal range (median pHi 7.12; 7.12; 7.07 respectively), but pHi differences between the two groups reached significance only after 24 h ($P < 0.01$). Mucosal acidosis detected at any time during the monitored period was associated with the emergence of single or multiple organ dysfunction ($P < 0.01$).

CONCLUSION: Prolonged gastric mucosal acidosis was associated with remote organ dysfunction and failure in Acute Pancreatitis, however, correlation with the fatal outcome became significant only 24 h after admission. Due to its non-invasive nature gastric tonometry may supplement the pro-inflammatory markers to achieve a multi-faceted monitoring of the disease.

INTRODUCTION

Necrotizing acute pancreatitis (AP) is currently recognized as a two-phase systemic disease, where the early phase (within the first two weeks) is characterized by sterile pancreatic necrosis and concomitant development of systemic inflammatory response syndrome (SIRS). If the patient survives the early MODS, the disease may progress to a second phase with the development of infected pancreatic necrosis and septic complications associated with multiple organ failure (MOF)^[1].

Since an abundance of Gram negative bacteria^[2] and other pathogens of gastrointestinal origin are commonly detected in pancreatic infections, the gut is considered to be the main source of pancreatitis related septic complications^[3]. This is in accordance with experimental data suggesting that bacterial translocation through the damaged gut barrier is the most important mechanism for the contamination of pancreatic necrosis^[4]. Recent evidence indicates that in case of host stress and low availability of intestinal luminal nutrition, non-pathogenic commensal intestinal bacteria can rapidly switch on virulence genes and mount a toxic offensive for their survival. Therefore, when highly virulent traits of enteric bacteria emerge by virulence phenotype switching, gut-derived sepsis may be more likely to occur in severe AP^[5].

Severe AP associated intestinal mucosal dysfunction may be the consequence of several deleterious local and systemic factors, such as disturbance of perfusion (ischemia-reperfusion phenomenon), oxidative stress during systemic inflammatory response syndrome, absence of mucosal feeding during parenteral nutrition, etc. This will eventually lead to metabolic failure in the gut, inducing intramucosal acidosis. Measurement of gastric intraluminal pCO_2 by

balloon tonometry and calculation of intramucosal pH (pHi) provides a quantitative indicator of the adequacy of intestinal milieu. Several studies have confirmed the value of pHi as a predictor of morbidity and mortality in the critically ill^[6].

Gastric tonometry has been applied in human acute pancreatitis, however, the available clinical data are limited. The aim of this study was to analyze the relationship between intramucosal acidosis and AP associated complications (remote organ dysfunction and infection) with special attention to the outcome of the disease.

MATERIALS AND METHODS

Patients

The Ethics Committee of Semmelweis University Medical School has approved the study protocol, and written informed consent was obtained from each patient.

Gastric tonometry is generally considered to be useful in critically ill patients therefore the enrollment into this study was focused on patients hospitalized for suspected severe acute necrotizing pancreatitis. For control purposes patients with moderate and mild severity of pancreatitis were also included. The diagnosis of AP was based on laboratory findings and imaging studies (abdominal ultrasound and/or computer tomography) in association with the typical clinical picture. Exclusion criteria were as follows: pancreatitis associated with pancreatic cancer, history of recurrent AP within 3 mo, chronic, post-traumatic or post-operative pancreatitis, childhood, pregnancy, as well as administration of immune suppressive drugs (including steroids) in the previous one month. Twenty-one patients suffering from acute pancreatitis were enrolled; they were either admitted to the surgical intensive care unit (ICU) or to general surgical ward, all of them were monitored by gastric tonometry for the first three days. The end point of the study was the outcome of the disease. Based on this two groups were created in a retrospective fashion; patients with fatal outcome were enrolled in Group 1, whereas patients who survived were enrolled in Group 2.

All patients were treated according to the usual AP protocols adjusted to their current condition. Initial management was conservative. During the acute phase, the therapy consisted of adequate fluid replacement through a central venous catheter with hemodynamic monitoring, and assistance of respiratory or renal function if needed. A modified nasogastric tube was inserted to keep the stomach empty and measure intraluminal pCO₂. Analgesics were given as required to all patients, and they received proton pump inhibitor (PPI) (2 × 40 mg omeprazole intravenously) to prevent stress ulcers. Prophylactic antibiotics (ofloxacin/metronidazole or imipenem) were administered as soon as the presence of necrosis was evident, or CRP value was over 150 mg/L. Surgical intervention was performed when infected necrosis was diagnosed (2 cases), or if the patient's condition deteriorated despite intensive medical therapy (1 case). In one case laparoscopic cholecystectomy was performed after the patient's recovery from AP.

All patients were monitored by gastric tonometry at least twice daily during the first three days of hospitalization. Attending clinicians did not use the pHi values to guide the patients' management.

Gastric Tonometry

Gastric tonometry was performed using a semi-automated method^[7] according to the modification of the original technique described by Fiddian-Green *et al*^[8]. A tonometry tube (Tonometrics™ 16F Catheter, Datex-Ohmeda Division, Instrumentarium Corp., Helsinki, Finland) was inserted into the lumen of the stomach via the nasogastric route. This catheter is a nasogastric tube with an additional smaller diameter conduit equipped with a CO₂ permeable silicone balloon attached to the tip. The balloon was inflated with room air and its line was connected to a bedside CO₂ monitor (Tonocap™ Monitor, Datex-Ohmeda). Gastric intraluminal pCO₂ pressure was measured after an equilibration period, and actual pHi was automatically calculated using additional data (arterial pH, arterial pCO₂) obtained from the patient's arterial blood samples. Since it is generally presumed that systemic metabolic acidosis confounds the interpretation of gastric pHi, all the pHi values were excluded from analysis where systemic metabolic acidosis was present. We have applied the simplified gastric pHi measurement protocol proposed by Bonham *et al*, where the daily lowest pHi value was used to characterize the mucosal condition^[9]. Routine PPI administration has been employed to improve the accuracy of mucosal pCO₂ measurements^[9], since gastric acid secretion blockade prevents the spurious elevation of luminal pCO₂ (resulting from the artifactual carbon-dioxide accumulation due to the reaction of bicarbonate with acid derived H⁺-s). Mucosal acidosis was diagnosed if pHi ≤ 7.32 (the generally accepted cut off value^[11]).

Laboratory investigations

Serum amylase and lipase activities were measured by the standard spectrophotometry method (reagents from Boehringer Diagnostics, Mannheim, Germany), where the upper limit of normal values was 220 U/L and 190 U/L respectively. Acute pancreatitis was diagnosed if serum amylase level exceeded 600 U/l. CRP was determined routinely by immunoturbidimetric assay (Orion Diagnostica, Espoo, Finland); the upper limit of normal value was 10 mg/L.

Statistical analysis

All data were presented as: median (range). Statistical analysis was performed using the Mann-Whitney *U*-test. Results were considered significant if *P* values were < 0.05.

RESULTS

Twenty-one patients with acute pancreatitis (6 women and 15 men) were involved in the study with a median age of 60 (29-77) years. The overall mortality rate was 6 of 21. There were no significant differences between the non-survivor (Group 1) and survivor (Group 2) groups in median age, gender and duration of symptoms before hospital admission. Ranson's and modified Glasgow scores showed no significant differences between the two groups, in contrast, APACHE II scores were significantly higher in the non-survivor group from the second day after admission. Ethanol was the leading etiological factor in the first group, whereas biliary origin in the second (Table 1).

In the non-survivor group 3 of the 6 patients died

Table 1 Clinical characteristics of the patients investigated in this study

	Group 1 non-survivors (n = 6)	Group 2 survivors (n = 15)	P value
Age (yr) ¹	69 (41-77)	52 (29-69)	0.22
Sex ratio (M/F)	5/1	10/5

¹ Values are represented as median (range). APACHE: Acute Physiology and Chronic Health Evaluation. ² No CT scan or autopsy proven data of necrosis was available.

within the first 3 d (two patients due to cardiorespiratory failure, whereas the third one due to early MOF). Three other patients deceased later (on d 9, 17, 18 respectively), all of them developed sepsis and late MOF (Table 1.) Bacteria responsible for fatal septic complications were Klebsiella, Staphylococci, Enterococci, and unidentified Gram-positive cocci.

In the survivor group local complications (peripancreatic fluid collection, necrosis) evolved in 5 of 15 patients (Table 1), and remote organ dysfunction (circulatory, pulmonary) was observed in 6 cases. Blood culture positivity was observed in 8 of 15 patients. Klebsiella, Enterobacter, Pseudomonas aeruginosa, Staphylococci and alpha hemolytic Streptococci were identified in the samples.

At the time points when the tonometry measurements were performed, serum CRP levels were significantly higher in Group 1. Other inflammatory markers, such as white blood cell counts, and the manifestations of the systemic metabolic disturbances as reflected by the daily lowest arterial pH and actual base excess values did not differ significantly between the two groups (Table 2).

Using our pH_i measurement protocol there were neither failures of tonometer placement, nor tonometer related complications.

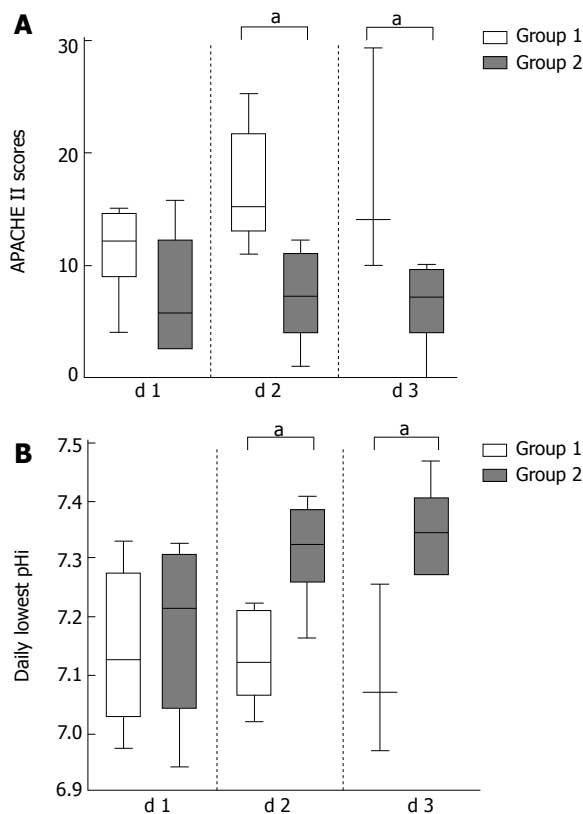

In general, the daily lowest pH_i values were permanently below 7.32 in the non-survivor group (Group 1), whereas pH_i was normal, or only temporarily low in the survivor group (Group 2). The pH_i value differences between the two groups did not reach statistical significance on the first hospital day (Figure 1); in contrast, on the second and third days pH_i values in non-survivors became significantly lower (pH 7.12 and 7.07 respectively), than those of the survivors (Figure 1).

If the relationship between the daily lowest pH_i values and the APACHE II scores of the corresponding day were

analyzed, the non-survivor group was characterized by a day-by-day decrease of pH_i, which was associated with the expected rise in the APACHE II scores. Conversely, the originally subnormal pH_i values of the survivor group have returned to the normal range with a corresponding decrease in the APACHE II scores (Figure 1).

We have found that assessment of the daily lowest pH_i value was able to predict the development of non-infectious complications of acute pancreatitis. Prolonged mucosal acidosis -reflected by constantly subnormal pH_i values- was associated with the development of MODS and fatal outcome. In contrast,

Figure 2 Evaluation of the predictor capacity of pHi values, if single measurements are considered.

Figure 3 Dynamics of the daily lowest pHi values in relation to the different outcomes of acute pancreatitis. In the survivor group (Group 2) pHi data were sorted to reflect the emergence or absence of MODS. In the absence of MODS pHi values stayed close to the physiological range, returning from the initial depression to normal by d 3. In patients with MODS initial pHi values were considerably lower, but a return to normal values was detectable. In the non-survivor group (Group 1) each patient developed MOF, therefore values were sorted to reflect the early or late appearance of this complication. All pHi values continued to stay at subnormal levels from the day of admission, and never returned to normal. (Values represent median and range).

in this study low pHi values were unsuitable to predict infections (Figure 2).

We have also analyzed the dynamics of the daily lowest pHi values from the viewpoint of the development of multiple organ dysfunction/failure (Figure 3). The pHi data in the survivor group were subdivided to represent the emergence or absence of MODS. By definition, MODS in this group was responding to treatment, therefore it was transient in nature. The pHi data curve in the subgroup with the absence of remote organ dysfunction characteristically started slightly below the normal value and returned to normal level by d 3. In contrast, in the subgroup of patients with remote organ dysfunction the curve started low, but similarly, a return to normal values was noted.

Since in the non-survivor group (Group 1) each patient developed MODS with deterioration into MOF (not responding to treatment), the values were sorted to reflect the early or late appearance of this complication. Although such review of the data had limited statistical power (due to the low number of cases), it could be concluded that all pHi values -irrespective of the early or late emergence of MODS/MOF- stayed at subnormal levels from d 1 and never returned to normal.

DISCUSSION

In this study we have shown a strong correlation between

persistent low gastric mucosal pHi and therapy resistant MOF associated with severe AP. This finding is in accordance with the original results of Bonham *et al*^[9]. They suggested that if the lowest pHi -measured at any time during the hospitalization- was below the 7.25 cut-off value, such severe mucosal acidosis was predictive of mortality in AP.

In a study by Juvonen *et al*^[12] pHi values generally did not discriminate mild AP from the severe form, but the pHi values measured at 48 h were significantly lower in the severe patient group. Our data showed that the course of gastric pHi alterations was indeed of considerable interest, since not only in mild cases, but also in patients with responsive severe disease, the originally low values returned to the normal range. This was in sharp contrast with the persistently subnormal pHi values characterizing the therapy resistant MOF cases. With respect to the early predictive capacity of gastric tonometry, however, pHi values at the time of admission did not prognosticate the outcome.

Recent advances in the comprehension of intestinal mucosal pathophysiology in AP deserve further comments. Previous studies used a somewhat simplistic framework of low-flow state and regional perfusion failure as being responsible for the development of mucosal acidosis and the related complications.

Bonham's group proposed that a mucosal ischemia-reperfusion injury was the culprit of gut barrier failure in

AP. Soong *et al*^[13] emphasized the role of hyperinflammation in the pathomechanism of mucosal injury, since peak endotoxin concentrations were detected before pH_i fell to its lowest level. Mucosal acidosis correlated with the consumption of endotoxin core IgM antibodies as a reflection of antecedent circulating endotoxin exposure. Hynninen *et al*^[14] have found that intramucosal acidosis in severe AP was concomitant with, or rapidly followed by increases in circulating cytokines (IL-6, IL-8, and IL-10), but they could identify no correlation between endotoxemia and low pH_i.

It can be suspected that further -yet unexplored- elements may influence the mucosal integrity in AP including nitric oxide dependent vasoregulatory imbalance^[15], mucosal oxidative stress, up-regulation of cellular adhesion molecules, and activation of adherent polymorphonuclear leukocytes with consecutive, destructive oxygen free radical production, as well as alteration of intestinal bacterial virulence^[16,17]. Consequently, acidic gastric pH_i should not be considered as a simple sign of the splanchnic bed hypoperfusion, but rather as a more complex pathophysiological representation of the involvement of the gut in SIRS, evolving together with the stress related alteration in the intestinal milieu.

Although our concept of mucosal barrier failure and bacterial invasion has been enriched by new details recently, the information concerning the general well-being of the mucosa provided by gastric tonometry still seems to be of value in cases of severe AP. Cumulating evidence suggests, however, that on the other side of the mucosal barrier (i.e. in the blood and tissues) a relative immune-deficient state evolves independently from mucosal acidosis in the late course of the disease. The exaggerated SIRS is followed by compensatory anti-inflammatory response syndrome (CARS) leading to immune deactivation^[18], in which the activation induced cell death (AICD) of polymorphonuclear leukocytes^[19] may be an important constituent.

The additive effects of these key elements may well represent the decisive step towards sepsis, and indeed, gastric tonometry will reflect the mucosal part only. (Despite the apparent mucosal dysfunction detected in our severe AP cases, a statistically significant association between low pH_i values and infectious complications could not be established in this study.)

In conclusion, intramucosal pH values showed characteristic, time dependent alterations distinguishing mild acute pancreatitis from the severe form, but detection of mucosal acidosis at admission did not improve outcome prediction. The complex sequence of pathophysiological events responsible for the development of intramucosal acidosis and septic complications is not fully elucidated in acute pancreatitis. However, future investigations should continue to benefit from gastric tonometry as a non-invasive adjunct in monitoring the intestinal mucosal function during the course of the disease.

Abstract

AIM: To evaluate the association among hepatic fibrosis, serum iron indices, and hepatic iron stores in patients with Chronic Hepatitis C (CHC).

METHODS: Thirty-two CHC patients were included in our study. The histological degree of fibrosis and inflammation activity was assessed according to the Metavir system. The serum iron indices including ferritin, iron and transferrin saturation were measured. Hepatic iron deposition was graded by Perls' stain.

RESULTS: The CHC patients with severe hepatic fibrosis ($n = 16$) were significantly older than CHC patients with mild fibrosis ($n = 16$) ($P = 0.024$). The serum iron indices, increased serum iron store and positive hepatic iron stain were not significantly different between the two groups. In multivariate logistic regression analysis, the age at biopsy was an independent predictor of severe hepatic fibrosis (Odds ratio = 1.312; $P = 0.035$). The positive hepatic iron stain was significantly associated with the values of alanine aminotransferase (ALT) ($P = 0.017$), ferritin ($P = 0.008$), serum iron ($P = 0.019$) and transferrin saturation ($P = 0.003$). The ferritin level showed significant correlation with the value of ALT ($r = 0.531$; $P = 0.003$), iron ($r = 0.467$; $P = 0.011$) and transferrin saturation ($r = 0.556$; $P = 0.002$).

CONCLUSION: Our findings suggest that the severity of hepatitis C virus (HCV)-related liver injury is associated with patient age at biopsy. Both serum iron indices and hepatic iron deposition show correlation with serum indices of chronic liver disease but are not related to

INTRODUCTION

Elevations in serum iron, ferritin and transferrin saturation are common in patients with chronic hepatitis C (CHC), as are mild increases in hepatic iron concentration. It has been reported that up to 40%-46% of patients has elevated serum iron, ferritin, or transferrin saturation level^[1,2]. Although the degree of iron deposition is usually mild, histological evidence of liver iron accumulation can be observed in 10%-42.1% of patients with CHC^[2-4]. Increased amounts of iron in the liver may promote the progression of liver disease by adding oxygen free radicals that increase oxidative stress^[5,6]. Iron overload is responsible for liver damage through the generation of reactive oxygen species leading to lipid peroxidation and alteration of the cellular membrane^[7]. Therefore, iron overload may play a role in the pathogenesis of some chronic liver diseases, especially when iron is combined with other hepatotoxic factors such as virus, free fatty acid, and alcohol^[8]. In addition to the production of oxidative stress, the iron may enhance the rates of viral replication and impair the host immune system^[6]. Despite these observations, the exact role of iron overload in patients with CHC remains unclear.

Factors that increase the risk of progression of hepatitis C virus (HCV)-associated hepatic fibrosis include older age at infection, male sex, alcohol abuse, and concurrent viral infection, particularly with human immunodeficiency virus or hepatitis B virus^[9]. The influence of viral load and genotype on the pathogenesis of liver disease is not completely resolved. Most studies have reported that HCV RNA level has no relation to the activity of liver disease^[10]. There are 6 major HCV genotypes. The most types are type 1a, 1b, 2a, 2b in Taiwan and about 65% of HCV

infections are type 1b^[11]. In early studies, HCV genotype 1b was found to be associated with a more severe liver disease^[12]. However, the association between genotype 1b and a more severe liver disease had not been found in studies with adjustment for the confounding factors^[10,13].

Whether the degree of hepatic iron deposition in patients with CHC affects the natural history of the disease remains to be determined. The aim of this study was to assess the association among hepatic fibrosis and serum iron indices, hepatic iron stores in patients with CHC. This study was also performed to assess the other potential factors related to the severity of hepatic fibrosis in these patients, including age, gender, liver enzyme tests, viral load and genotype of HCV. We had adjusted for the other confounding factors, such as alcohol abuse, obesity, and concurrent human immunodeficiency virus or hepatitis B virus infection.

MATERIALS AND METHODS

CHC patients

The patients with CHC were collected at our outpatient department since October 2003. CHC was diagnosed by alteration in liver enzymes persisting for more than 6 mo associated with positive HCV antibody. Patients with potentially secondary causes of iron overload were excluded, including alcohol abuse (ethanol consumption > 20 g/d), ribavirin therapy, and multiple transfusions. The body mass index (BMI) of the patients was not over 27 kg/m². Co-infection with human immunodeficiency virus or hepatitis B virus was also excluded. Serum levels of ceruloplasmin were within normal range. Serological tests for autoimmune hepatitis (anti-nuclear antibody, anti-smooth muscle antibody) and for primary biliary cirrhosis (anti-mitochondrial antibody) were negative.

Serological evaluation

The serum aspartate aminotransferase (AST) and alanine aminotransferase (ALT) were determined by using an Olympus 5000 analyzer. The upper limit of normal for ALT is 34 IU/L. HCV antibody was detected by a commercially available enzyme-linked immunosorbent assay (AxSYM. ABBOTT Diagnostic Corporation, USA). The iron status of each patient was evaluated by biochemical tests. Serum iron (normal range, 60-160 µg/dL) was measured by the colorimetry and ferritin (normal range: 18-274 ng/mL in men and 6-283 ng/mL in women) was measured by a commercially available enzyme-linked immunosorbent assay (AxSYM. ABBOTT Diagnostic Corporation, USA). Transferrin saturation was calculated as (the serum iron divided by the TIBC) × 100%. The increased serum iron store was defined by transferrin saturation > 50% and/or ferritin > upper normal limit.

Hepatic fibrosis stage

The hepatic specimens were obtained with the SURECUT needle by ultrasonography-guided biopsy of liver. The degree of fibrosis and inflammation activity was assessed according to the Metavir system^[14]. The Metavir system scores both necroinflammatory changes on a 4-point scale

of 0 to 3 and fibrosis on a 5-point scale from 0 to 4.

Hepatic iron deposition

The histological assessment of hepatic iron stores was revealed by Perls' stain on liver biopsy specimens^[15]. Hepatic iron deposition was graded on a scale from 0 to 4. Perls' stain is also called Prussian Blue reaction. It is used to demonstrate ferric iron and ferritin. This is not a true staining technique rather, it is a histochemical reaction. The protein is split off by the hydrochloric acid, allowing the potassium ferrocyanide to combine with the ferric iron. This forms the ferric ferrocyanide or Prussian Blue.

Viral load of HCV

The viral load of HCV was checked according to the Cobas Amplicor HCV Monitor Test, version 2.0, Roche Diagnostics. It is based on five major processes: specimen preparation; reverse transcription of the target RNA to generate complementary DNA (cDNA); polymerase chain reaction (PCR) amplification of target cDNA using HCV specific complementary primers; hybridization of the amplified products to oligonucleotide probes specific to the targets; and detection of the probe-bound amplified products by colorimetric determination.

Viral genotype of HCV

The most viral genotypes of HCV are type 1a, 1b, 2a, 2b in Taiwan. We used the method of type-specific PCR to analyze the viral genotype of HCV. Based on variation in nucleotide sequence within restricted regions in the putative C (core) region of HCV, four groups of HCV had been illustrated^[16]. They were types 1a, 1b, 2a and 2b. The method depended on the amplification of a C gene sequence by PCR using a universal primer (sense) and a mixture of four type-specific primers (antisense). HCV types were determined by the size of the products specific to each of them. The primers of first round PCR were 5'-CGAAAGGCCTTGTGGTACTG-3' and 5'-ATATACCCCATGAGGTCGGC-3'. The primers of second round PCR were sense primer 104: 5'-AGGAAGACTTCCGAGCGGTC-3' and four antisense primers. They were antisense primer 132: 5'-TGCCTTGGGGATAGGCTGAC-3', antisense primer 133: 5'-GAGCCATCCTGCCCCACCCA-3', antisense primer 134: 5'-CCAAGAGGGACGGGAACCTC-3' and antisense primer 135: 5'-ACCCTCGTTTCCGTACAGAG-3'.

Statistical analysis

Data were summarized as mean ± SD. Data were compared between groups on the basis of hepatic fibrosis stage. Categorical variables were compared with the chi-square test or Fisher's exact test as required. Continuous variables were compared between groups by using the unpaired *t*-test. The Mann-Whitney test was used when it was appropriate. Independent factors related to hepatic fibrosis severity were assessed by using multivariate logistic regression analysis. Correlations among selected variables were assessed by the Spearman correlation coefficient. The *P* < 0.05 was statistically significant.

Table 1 Demographic and laboratory data of 32 patients with CHC

Variable	Total population (<i>n</i> = 32)	Severe fibrosis (<i>n</i> = 16)	Mild fibrosis (<i>n</i> = 16)	<i>P</i>
Age (yr)	56.47 ± 10.92	60.75 ± 6.50	52.19 ± 12.85	0.024
Sex (male:female)	15 : 17	8 : 8	7 : 9	0.723
AST (IU/L)	105.47 ± 56.18	119.31 ± 55.75	91.63 ± 54.82	0.167
ALT (IU/L)	163.03 ± 102.99	167.81 ± 102.15	158.25 ± 106.95	0.798
Iron (μg/dL)	155.07 ± 43.27	149.50 ± 33.00	160.27 ± 51.71	0.513
TIBC (μg/dL)	356.97 ± 48.38	351.50 ± 41.23	362.07 ± 55.18	0.566
Transferrin saturation (%)	43.63 ± 11.69	42.51 ± 7.85	44.68 ± 14.62	0.621
Ferritin (ng/mL)	291.19 ± 213.72	329.41 ± 222.08	255.53 ± 206.72	0.362
Increased serum iron store	14 (43.75%)	8 (50.00%)	6 (37.50%)	0.476
Positive hepatic iron stain	4 (12.50%)	1 (6.25%)	3 (18.75%)	0.600
Viral genotype (1:2)	22 : 6	12 : 2	10 : 4	0.648
Viral load (× 10 ⁶ copies/mL)	4.94 ± 6.26	6.39 ± 8.16	3.48 ± 3.22	0.231

CHC: Chronic hepatitis C; AST: Aspartate aminotransferase; ALT: Alanine aminotransferase; TIBC: Total iron binding capacity. Data are expressed as mean ± SD or patients number (percentage). Transferrin saturation was calculated as serum iron divided by TIBC × 100%. The increased serum iron store was defined by transferrin saturation > 50% and/or ferritin > upper normal limit.

RESULTS

Thirty-two patients fulfilling inclusion criteria were studied. The demographic and laboratory data of the patients are summarized in Table 1. The mean age of the 32 patients was 56.47 ± 10.92 year-old. Fourteen patients (43.75%) had increased serum iron stores and only four patients (12.5%) had positive hepatic iron stain. In the four patients, three patients were grade one and one patient was grade two on Perls' stain. Of 32 patients, 16 patients showed severe hepatic fibrosis (stages 3 or 4) and 16 patients had mild fibrosis (stages 0, 1 or 2) on histology.

The CHC patients with severe hepatic fibrosis were significantly older than the CHC patients with mild fibrosis (60.75 ± 6.50 *vs* 52.19 ± 12.85 year-old; *P* = 0.024). The other variables showed in Table 1, including gender, liver enzyme tests, serum iron indices, increased serum iron store, positive hepatic iron stain, viral load and genotype of HCV, were not significantly different between patients with severe and mild hepatic fibrosis. In multivariate logistic regression analysis, the age at biopsy was still an independent predictor of severe hepatic fibrosis (Odds ratio = 1.312; *P* = 0.035) (Table 2).

We stratified our data according to patient sex because women may have lower serum iron markers than men. All the serum iron indices and hepatic iron stain were not associated with severe hepatic fibrosis in men and women, respectively. Univariate analysis across grades of histological inflammation activity also did not show a significant association between inflammation activity and any of the serum iron indices or the presence of hepatic tissue iron, age, gender, liver enzyme tests, viral load and genotype of HCV (data not shown).

The positive hepatic iron stain was significantly associated with the values of ALT (*P* = 0.017) and all the

Table 2 Multivariate logistic regression analysis of independent predictors of severe hepatic fibrosis

Variable	Odds ratio	95% CI	<i>P</i>
Age	1.312	1.020-1.688	0.035
Male gender	14.138	0.835-239.266	0.066
Increased serum iron store	0.834	0.081-8.595	0.879
Positive hepatic iron stain	1.584	0.067-37.349	0.775
Viral load	1.412	0.923-2.161	0.112

CI: Confidence interval; ALT: Alanine aminotransferase. The increased serum iron store was defined by transferrin saturation > 50% and/or ferritin > upper normal limit. The ALT and viral genotype were eliminated in multivariate backward logistic regression analysis. We forcibly add the two factors increased serum iron store and positive hepatic iron stain into the analysis.

Table 3 Univariate analysis of demographic and laboratory data in relation to hepatic iron stain

Variable	Positive hepatic iron stain (<i>n</i> = 4)	Negative hepatic iron stain (<i>n</i> = 28)	<i>P</i>
Age (yr)	52.50 ± 9.04	57.04 ± 11.19	0.446
Sex (male:female)	3 : 1	12 : 16	0.319
AST (IU/L)	141.50 ± 99.94	100.32 ± 47.89	0.473
ALT (IU/L)	275.00 ± 172.18	147.04 ± 82.23	0.017
Iron (μg/dL)	210.50 ± 45.11	146.20 ± 36.55	0.019
Transferrin saturation (%)	62.34 ± 10.71	40.64 ± 8.80	0.003
Ferritin (ng/mL)	591.23 ± 119.70	243.19 ± 184.65	0.008

Data are expressed as mean ± SD. AST: Aspartate aminotransferase; ALT: Alanine aminotransferase. Transferrin saturation was calculated as (the serum iron divided by the TIBC) × 100%.

Table 4 Correlations with ferritin levels among laboratory data, hepatic inflammation and fibrosis scores

Variable	ALT	Iron	Transferrin saturation	Inflammation score	Fibrosis score
Spearman coeff	0.531	0.467	0.556	-0.085	0.317
<i>P</i>	0.003	0.011	0.002	0.659	0.094

ALT: Alanine aminotransferase. Transferrin saturation was calculated as (the serum iron divided by the TIBC) × 100%.

three serum iron indices, including ferritin (*P* = 0.008), iron (*P* = 0.019) and transferrin saturation (*P* = 0.003) (Table 3). The ferritin level had significant correlation with the value of ALT, iron and transferrin saturation in Spearman correlation test (*P* = 0.003, 0.011 and 0.002, respectively). Nonetheless, no significant correlation was found between ferritin and grade of inflammation activity or stage of hepatic fibrosis severity (Table 4).

DISCUSSION

It has been recognized for more than 30 years that iron stores may be increased in alcoholic liver disease^[17]. In nonalcoholic steatohepatitis, 58% of patients has elevated serum iron indices and in some cases increased hepatic iron stores^[18]. In order to prevent the effect of

the potential confounding factors in hepatic iron stores, we carefully excluded patients that had alcohol abuse (ethanol consumption > 20 g/d), BMI over 27 kg/m², previous ribavirin therapy and multiple transfusions. The lower rate of positive hepatic iron stain (12.5%) may partly be due to the stringent selection criteria used in our study. In our previous study, we showed that the HFE mutations associated with hereditary hemochromatosis were infrequent in Taiwan and they may not contribute to iron accumulation in CHC patients even when serum iron overload was observed in more than one third of these patients^[19]. Therefore, we didn't exclude the few CHC patients with HFE mutations in our study.

Although the iron-related oxidative stress may play a role in the pathogenesis of CHC, the association between serum iron markers, hepatic iron stores, and hepatic fibrosis stage remains controversial. Previous studies had evaluated the potential impact of hepatic iron store on CHC but they had produced discordant results. Three studies had found that hepatic iron tissue deposition was associated with severe hepatic fibrosis in patients with CHC^[20-22]. Despite the association, they did not found a correlation between the amount of hepatic iron store and the fibrosis score. The absence of dosing effect suggests that there is a cut-off point at which all patients are more likely to have severe fibrosis, and all patients with values above this level have an equal risk regardless of the quantity of tissue iron concentration^[20]. In other words, there is a threshold effect, and once present, increasing hepatic iron does not correlate with increasing fibrosis^[22]. The other studies had proposed the discordant conclusions. No association was observed between the presence of hepatic iron deposition and fibrosis score in these reports^[23-26]. In our study, significant iron that was detectable histologically was also unrelated to the severity of hepatic fibrosis. It is well established that a heavy iron overload per se can cause hepatic fibrosis, as observed in patients with hereditary hemochromatosis. In a semi-quantitative evaluation of hepatic iron in patients with CHC, most had minimal or mild deposits^[25]. Our study had the similar results. In the four patients with positive hepatic iron stain, three patients were grade one and one patient was grade two on Perls' stain. This may be the reason why the hepatic iron stain was not associated with severe hepatic fibrosis in our study. Mild degree of hepatic iron deposition may not reach the threshold at which iron will enforce hepatic injury.

In the present study we did not find any association between serum iron indices or hepatic iron stain and degree of hepatic fibrosis or inflammation activity in patients with CHC. However, our study had showed that hepatic iron stain was associated with altered ALT values and serum iron indices. The ferritin levels also showed correlation with ALT values and the other two serum iron indices. That is, the biochemical injury of liver can be predicted by tissue or serum iron contents but the histological damage can't. This is consistent with the finding that the decline in serum AST and ALT values after phlebotomy is not associated with a change in histological activity of inflammation or fibrosis^[27]. The mechanism by which iron accumulates in some patients with CHC is

unclear. Whether this iron accumulation is cause or result of liver injury is unknown. Previous studies had reported a positive correlation between serum ferritin concentration and ALT level in patients with CHC^[1,28]. Since serum iron index correlated significantly with the value of ALT, it was likely that the excess iron could be related to its release from destroyed hepatocytes as a result of liver injury associated with HCV. This suggested that iron parameters in patients with CHC acted either as markers of the chronic inflammatory state or cytolytic liver activity but did not directly reflect the progression of hepatic fibrosis. Furthermore, the tissue iron contents did associate with the all serum iron indices in our study. In other words, ferritin, iron and transferrin saturation were all excellent predictors for presence of hepatic iron in patients with CHC.

Our study found that older age at biopsy was associated with severe hepatic fibrosis in patients with CHC. This suggested that hepatitis C infection may somehow become more fibrogenic with advancing host age. This is in accordance with previous studies showing that severity of HCV-related liver injury can be predicted by patient age^[23,24,29]. The mechanism underlying this association is unknown. The possible explanations might include immune factors, increased fibrogenesis, or decreased fibrolysis^[9]. The ability of hepatocytes to regenerate or the state of activated hepatic lipocytes alters with age and thus gives rise to increased fibrosis^[29]. Nonetheless, these speculations are unproven yet. Our data allow a conclusion that CHC will place an increasing burden on health care services in the next decades as the population with CHC ages.

Our study do have a potential limitation. In two large-scale studies, age at onset of infection had been identified as predictive factor of progression in CHC^[13,30]. Since the time of onset of infection derived from clinical history may not be reliable, we had omitted this variant in our study.

In conclusion, the severity of HCV-related liver injury is associated with patient age at biopsy. Significant iron deposition in the liver is uncommon in CHC patients. Both serum iron indices and hepatic iron deposition show correlation with serum indices of chronic liver disease but are not related to grade and stage of liver histology. The viral load and genotype of HCV are also not associated with hepatic fibrosis severity and inflammation activity. Our study conclusions suggest that patients with CHC should be treated as early as possible. Our findings do not support the role for iron depletion therapy by phlebotomy in patients with CHC, including those with elevated serum iron indices or positive hepatic iron stain.

Abstract

AIM: To investigate the histological and ultra-structural characteristics of liver graft during different of warm ischemia time (WIT) in rats and to predict the maximum limitation of liver graft to warm ischemia.

METHODS: The rats were randomized into 7 groups undergoing warm ischemia injury for 0, 10, 15, 20, 30, 45 and 60 min, respectively. All specimens having undergone warm ischemia injury were investigated dynamically by light and electron microscopy, and histochemistry staining. After orthotopic liver transplantation (OLT), the recovery of morphology of liver grafts after 6, 24 and 48 h was observed.

RESULTS: The donor liver from non-heart-beating donors (NHBD) underwent ischemia injury both in the warm ischemia period and in the reperfusion period. Morphological changes were positively related to warm ischemia injury in a time-dependent manner during the reperfusion period. The results demonstrated that different degrees of histocyte degeneration were observed when WIT was within 30 min, and became more severe with the prolongation of WIT, no obvious hepatocyte necrosis was noted in any specimen. In the group undergoing warm ischemia injury for 45 min, small focal necrosis occurred in the central area of hepatic lobule first. In the group undergoing warm ischemia injury for 60 min, patchy or diffused necrosis was observed and the area was gradually extended, while hepatic sinusoid endothelial cells were obviously swollen. Hepatic sinusoid was obstructed and microcirculation was in disorder.

CONCLUSION: The rat liver graft undergoing warm ischemia injury is in the reversible stage when the WIT is within 30 min. The 45 min WIT may be a critical point of rat liver graft to endure warm ischemia injury. When the WIT is over 60 min, the damage is irreversible.

INTRODUCTION

In the past 40 years, liver transplantation has achieved a great success and has become the most effective method to treat the end-stage hepatic diseases. Liver transplantation is developing rapidly as a result of perfect perioperative care and widespread applications of potent immunosuppressants. However, there is an obvious problem of donor organ shortage, especially in countries where the "brain-death" cases have not been legitimated. At present, a high percentage of liver grafts comes from non-heart-beating donor (NHBD) in these countries. Under these circumstances, liver grafts unavoidably encounter a period of warm ischemia injury and undergo further injuries in preservation and reperfusion process^[1-3]. Poor quality of liver grafts is considered an important risk factor greatly reducing the liver transplantation effectiveness^[4-6]. Clinical practice suggests that the warm ischemia time (WIT) should not be longer than 5 min^[7], and 10 min of WIT may be the upper limit. According to this, many donor livers are useless, thus aggravating the problem of donor liver shortage. This study was to observe the changing patterns of histological structure and ultrastructure of liver graft undergoing warm ischemia injury.

MATERIALS AND METHODS

Animals and grouping

Two hundred and ten healthy male adult Sprague-Dawley (SD) rats weighing 250-300g (Experimental Animal Center at Sun Yat-Sen University) were used in the study. The mean weight of recipient rats was slightly heavier than that of donor rats. According to WIT, 210 SD rats were randomly divided into seven groups. The duration of WIT was 0, 10, 15, 20, 30, 45 and 60 min respectively. Forty-two SD rats (6 each group) were used for the observation of warm ischemia injury. The other 168 were divided into 7 subgroups. Orthotopic liver transplantation (OLT) was performed in each group according to the predetermined WIT, 12 as donors and 12 as recipients. Histological, histochemical and ultrastructural changes were observed 6, 24 and 48 h respectively after reperfusion. Specimens taken from the right hepatic lobe of rats were divided into 4 types, one for routine olefin sections after fixation in formalin solution, one for glycogen staining after fixation in Gendre solution, one for enzyme histochemical staining after quick freezing in liquid nitrogen and one for ultrathin sections.

Establishment of animal model

Warm ischemia injury was induced by clamping the basilar part of the heart and blocking the thoracic aorta of the donor animals after the donor rat received 0.2 mL heparin sodium solution (1250 U heparin sodium) *via* dorsum of penis vein to establish the non-heart-beating donor model. Then the liver graft was dissected. The liver was then perfused *in situ* through the abdominal aorta with 20 mL chilled lactic acid Ringer's solution (50 U/mL heparin sodium) and stored in a bath of cold lactate Ringer's solution before transplantation. Immediately prior to the portal vein clamping, orthotopic liver transplantation was performed as previously described^[8] with minor modifications^[9]. The cold ischemia time (CIT) was 50 ± 3.5 min and the anhepatic period was 20 ± 2.5 min.

Observation indexes and methods

Specimens were fixed in formalin solution, routine 4-6 μ m paraffin sections were stained with HE for light microscopy.

Specimens were disposed by the typical ultra-histology methods, and the sections were observed under transmission electron microscope and scanning electron microscope.

Hepatic glycogen was stained by PAS reaction after the fresh specimens were fixed in Gendre's solution for 6 h. Tetrazolium blue, PPDA, magnesium activation were respectively adopted to observe the activities of SDH, CO and ATPase on 5-6 μ m thick cryo-sections.

RESULTS

Observation under light microscope

Histological structure changed slightly when WIT was shorter than 30 min. Cytoplasm loosening, cell edema, focal vacuole degeneration were noted when WIT was over 30 min, especially in the lobule center area. Leukocyte

Figure 1 Cytoplasm loosening, cell edema, focal vacuole degeneration after reperfusion (10 \times 10) in the group undergoing warm ischemia injury for < 30 min (A); obvious cell edema, ballooning-like degeneration after reperfusion (40 \times 10) in the group undergoing warm ischemia injury for 30 min (B); focal necrosis around central lobule area after reperfusion (10 \times 10) in the group undergoing warm ischemia injury for 45 min (C); plaque-like area necrosis after reperfusion (40 \times 10) in the group undergoing warm ischemia injury for 60 min (D).

infiltration was noted in the portal area and acidophilus was obvious in some hepatocytes. The above pathologic changes aggravated when WIT was prolonged to 60 min. Cell degeneration was diffuse or extended to a focal area, even lipid degeneration could be seen. The degree of degeneration was dependent on the duration of WIT, but necrosis could hardly be observed under light microscope. After 6 and 24 h reperfusion, injury to liver graft became severer and hepatocytes presented with obvious edema and some ballooning degeneration in the group undergoing warm ischemia injury for 30 min (Figures 1A and B). Focal like necrosis could be noted in the lobule center area in the group undergoing warm ischemia injury for 45 min (Figure 1C), the change aggravated when WIT was prolonged. Forty-eight hours after reperfusion, hepatic injury resumed gradually in the group undergoing warm ischemia injury for < 45 min. Hepatocytes presented with plaque or diffused necrosis and the pathologic change was irreversible in the group undergoing warm ischemia injury for 50 min (Figure 1D).

Observation under electron microscope

The structure of mitochondria and endoresticule was normal when WIT was shorter than 15 min (Figure 2A). Mitochondria became swollen, density of basal plasma was reduced, endoresticule was enlarged and glycogen particles were reduced in the group undergoing warm ischemia injury for 30 min. Mitochondria crista became fuzzy and pale in the group undergoing warm ischemia injury for 45 min. While fuzzy or ruptured mitochondria crista, vacuole degeneration and broken endoresticule were noted in the group undergoing warm ischemia injury for 60 min. Six hours after reperfusion, damage to liver graft became severer and 24 h after reperfusion, mitochondria became swollen and basal density reduction was aggravated, but glycogen particles increased in the group undergoing warm ischemia injury for < 30 min (Figure 2B). Mitochondria became swollen, vacuole was

Figure 2 Swollen mitochondria, ruptured crista, rough endoplasmic reticulum degeneration ($\times 15000$) in the group undergoing warm ischemia injury for 30 min (A); phanero-swollen mitochondria and nuclear chromosome margination, and karyopyknosis after reperfusion ($\times 10000$) in the group undergoing warm ischemia injury for 45 min (B and C); significant swollen mitochondria, crista extinction, nuclear membrane rupture, karyolysis and karyorrhexis after reperfusion ($\times 5000$) in the group undergoing warm ischemia injury for 60 min (D).

Figure 3 Cytoplasmic blebs and irregular endothelial sieve plate in some sinusoids after reperfusion (scanning electron microscope $\times 6000$) in the group undergoing warm ischemia injury for 45 min (A); apoptosis and necrosis of hepatocytes after reperfusion ($\times 8000$) in the group undergoing warm ischemia injury for 60 min (B); cytoplasmic blebs, reticular cellulose and hemocytes after reperfusion (scanning electron microscope $\times 6000$) in the group undergoing warm ischemia injury for 60 min (C); bleb or ballooning like swollen endothelial cells, blocked sinusoids and irreversible microcirculation disturbance after reperfusion ($\times 5000$) in the group undergoing warm ischemia injury for 60 min (D).

degenerated, and rough endoreticule was broken, apoptosis of hepatic and endothelial cells was increased with chromosome margination, karyopyknosis and karyorrhexis in the group undergoing warm ischemia injury for > 30 min (Figures 2C and D). Endothelial gaps were enlarged, the sieve plate was mingled, some endothelial cells broke off, and therefore, some sinusoids were blocked with cytoplasmic bleb accumulation in the groups undergoing warm ischemia injury for 45 and 60 min (Figure 3A). Forty-eight hours after reperfusion, swollen mitochondria resumed gradually, glycogen particles increased obviously in the group undergoing warm ischemia injury for < 45 min. Mitochondria were extended with crista turbulence, vacuole, membrane rupture, and cell apoptosis and necrosis (with karyopyknosis, karyorrhexis and karyolysis) could be noted in the group undergoing warm ischemia injury for 60 min. The above changes were irreversible (Figure 3B). Most endothelial cells underwent necrosis and shedding, many hepatic sinusoids were full of cytoplasmic blebs, reticular fibrosis and hemocytes (Figure 3C). Under scanning electron microscope, endothelial cells presented with bleb or ballooning like degeneration, sinusoids were blocked, thus the microcirculation underwent irreversible disturbance (Figure 3D).

Histochemical observation

Our previous study has demonstrated that hepatic glycogen begins to reduce when WIT is prolonged to 30 min and the activities of SDH, CO and ATPase begin to decrease when WIT is longer than 45 min^[10]. The above changes were positively related to WIT in a time dependent manner during reperfusion in this study. PAS reaction and enzyme activities showed a recovering potency in the groups undergoing warm ischemia injury for 15 and 30 min. The liver graft underwent an irreversible injury and

no evident recovery potency was found after implantation in the groups undergoing warm ischemia injury for 45 and 60 min.

DISCUSSION

How to evaluate the quality of liver grafts and how to ascertain the safety time limit for warm ischemia of liver grafts remain to be solved since warm ischemia injury affects the outcome of liver transplantation. Western transplantation community does not consider much of warm ischemia injury because their liver grafts are mainly taken from “brain-death” donors. Liver transplantation has become an effective management in the treatment of end-stage liver diseases, while the shortage of donor liver is a critical limiting factor for liver transplantation, thus people have begun to reconsider the marginal organ source like NHBD since 1990s^[11-13]. Some laboratory studies support a controversial 60 min WIT limitation^[14-16], but different experimental animals, warm ischemia models and experiment conditions may cause arguments about the WIT limitation. The argument about the WIT limitation has led to a worldwide investigation on warm ischemia-reperfusion injury^[17,18].

In the present study, we observed the changes of histological structure and ultrastructure of liver grafts during different WIT. Cellular edema and vacuole degeneration could be noted in warm ischemia period. The pathologic changes were aggravated with the prolongation of WIT, but necrosis was absent. Hepatocyte vacuole degeneration was due to swollen mitochondria and outstretched endoreticule. Glycogen-absorbed vacuole also could be seen. Under electron microscope, pathologic

changes were reversible, only part of cells underwent irreversible changes such as necrosis (with karyopyknosis, karyorrhexis and karyolysis) and apoptosis. However, liver grafts from NHBD underwent injuries both in the warm ischemia period and in the reperfusion stage. The degree of injury in the reperfusion stage was positively related to the duration of WIT. Histochemical observations showed that hepatic glycogen began to reduce when WIT was prolonged to 30 min. The activities of SDH, CO and ATPase began to decrease when WIT was longer than 45 min. The above changes were positively related to WIT in a time-dependent manner during the reperfusion period. PAS reaction and enzyme activities showed a recovering potency in the groups undergoing warm ischemia injury for 15 and 30 min. The liver graft underwent irreversible injury and no evident recovery potency was found after implantation in the groups undergoing warm ischemia injury for 45 and 60 min.

In conclusion, the pathologic changes of liver grafts undergoing only warm ischemia injury are reversible when WIT is shorter than 60 min, but the damage to liver graft would aggravate at the reperfusion stage, suggesting that rat liver grafts undergoing warm ischemia injury are in the reversible stage when WIT is within 30 min. The 45 min of WIT may be a critical point of rat liver grafts to tolerate warm ischemia injury and when WIT is prolonged to 60 min, the damage is irreversible.

Abstract

Polycythemia is a known paraneoplastic manifestation of hepatoma, but only in the presence of alpha-fetoprotein (AFP). We present a case of polycythemia in the absence of AFP, and suggest concurrent alpha-1-antitrypsin deficiency as the cause for breaking this rule. We also suggest a reason for the apparent constant conjunction between polycythemia and AFP in hepatoma.

INTRODUCTION

Polycythemia is a known paraneoplastic manifestation of hepatoma, but only in the presence of alpha-fetoprotein (AFP). We present a case of polycythemia in the absence of AFP, and suggest concurrent alpha-1-antitrypsin deficiency as the cause for breaking this rule. We also suggest a reason for the apparent constant conjunction between polycythemia and AFP in hepatoma.

CASE REPORT

A 79-year-old man was referred for dizziness with a history of benign prostatic hypertrophy and cholecystectomy. He was taking finasteride and ranitidine. He was an ex-smoker with a forty-pack year history and had never drunk alcohol heavily. Clinical examination was unremarkable but for a smoothly enlarged liver. Full blood count revealed polycythemia (haemoglobin 176 g/L, haematocrit 0.527), with a normal platelet count and white cell count. Chest X ray and ECG were normal. Oxygen saturation was 96% on air.

Abdominal ultrasound revealed a normal spleen and a 47 mm × 57 mm × 49 mm mass in the right lobe of the liver posteriorly, which was compressing the inferior vena cava. A CT scan demonstrated a well-defined rounded mass in the hilum of the liver with a mixed attenuation pattern, consistent with either hepatocellular carcinoma (HCC) or haemangioma. Serum AFP [8 µg/L (normal 0-16)], liver function tests, and hepatitis serology were normal, except IgG antibodies to hepatitis A. MRI of the liver suggested HCC as a more likely diagnosis than haemangioma. With normal AFP and liver function tests, a biopsy of the lesion was carried out. The histology confirmed HCC with adjacent cirrhosis.

He was referred to a specialist centre and further imaging confirmed extra hepatic disease with intra-abdominal and mediastinal lymphadenopathy. There was local vascular invasion but no peritoneal dissemination. A further liver biopsy found underlying fibrosis and DPAS (diastase periodic acid Schiff) positive globular material in the hepatocytes, consistent with alpha-1-antitrypsin (AAT) deficiency. Because of vascular involvement he was deemed unsuitable for surgery and was entered into a trans-arterial embolisation versus chemoembolisation trial.

DISCUSSION

Hepatocellular carcinoma can present with various paraneoplastic manifestations including polycythemia, hypercholesterolemia, hypoglycemia and hypercalcemia^[1]. Our case is unique as it demonstrates an unreported phenomenon: HCC with polycythemia, but normal serum AFP. Polycythemia is strongly related to tumour burden and AFP, and is usually associated with markedly raised serum AFP levels^[2,3].

Polycythemia is only partly due to increased erythropoietin production, as raised serum erythropoietin can be present in up to 23% of HCC patients^[4], yet polycythemia is found only in approximately 1% of patients. This implies that erythropoietin production may be necessary, but is certainly not sufficient for polycythemia, and other factors must be implicated.

One such factor may be the expression of the erythropoietin receptor. This is upregulated by Ephrin-A1, a ligand for the Eph (erythropoietin producing hepatocellular) receptor tyrosine kinase^[5]. Ephrin-A1 expression upregulating the erythropoietin receptor and thus resulting in the appearance of polycythemia would explain the constant conjunction hitherto reported in HCC between polycythemia and AFP, as there is a strong correlation between the presence of AFP in HCC with the expression of Ephrin-A1, which is known to induce AFP^[5].

We therefore suggest that the association between polycythemia and raised AFP previously noted in HCC is because both arise from the expression of Ephrin-A1.

Our patient's normal AFP (despite his polycythemia) may be related to his AAT deficiency. Previous reports demonstrated high serum AFP levels in neonates with neonatal hepatitis, either idiopathic or due to extrahepatic biliary atresia. However, AFP is not raised in those infants with neonatal hepatitis and AAT deficiency. It was postulated that this is because alpha-1-antitrypsin is a rate limiting factor in the production of AFP^[6]. To our knowledge, the possibility of AAT deficiency resulting in normal AFP in HCC in adults has not been raised.

Abstract

An estimated 300 million people worldwide suffer from chronic hepatitis C with a prevalence of 0.8%-1.0% of the general population in Canada. An increasing pool of evidence exists supporting the use of pegylated-interferon (pegIFN) and ribavirin combination therapy for hepatitis C. We report a 49-year old male of North American aboriginal descent with chronic hepatitis C (genotype 2b). Biopsy confirmed that he had cirrhosis with a 2-wk history of left eye pain and decreased visual acuity. He developed retinal vein thrombosis after 16 of 24 wk of pegIFN- α 2a and ribavirin combination therapy. He was urgently referred to a retinal specialist and diagnosed with non-ischemic central retinal vein occlusion of the left eye. PegIFN and ribavirin combination therapy was discontinued and HCV RNA was undetectable after 16 wk of treatment. Hematologic investigations revealed that the patient was a factor V Leiden heterozygote with mildly decreased protein C activity. Our patient had a number of hypercoagulable risk factors, including factor V Leiden heterozygosity, cirrhosis, and hepatitis C that alone would have most likely remained clinically silent. We speculate that in the setting of pegIFN treatment, these risk factors may coalesce and cause the retinal vein thrombosis.

Zandieh I, Adenwalla M, Cheong-Lee C, Ma PE, Yoshida EM. Retinal vein thrombosis associated with pegylated-interferon and ribavirin combination therapy for chronic hepatitis C. *World J Gastroenterol* 2006; 12(30): 4908-4910

INTRODUCTION

An estimated 300 million people worldwide suffer from chronic hepatitis C with a prevalence of 0.8%-1.0% of the general population in Canada^[1]. In the last 10 years, dramatic advances have been made in the treatment of this common chronic condition. The pegylated-interferon (pegIFN) and ribavirin combination therapy has been shown to result in sustained virologic response rates of 46%-77%, depending on viral genotype^[2]. Evidence has also emerged regarding the utility of interferon in cirrhotic hepatitis C treatment with reduced rates of both hepatocellular carcinoma and improved survival^[3-5]. With the growing enthusiasm amongst patients and physicians alike, in favour of treatment as a result of the increasing pool of evidence supporting the use of interferon-based regimens, its adverse effects need to always be recognized and periodically reviewed.

Although interferon or pegIFN therapy can affect any organ system, the most commonly reported side effects include flu-like symptoms such as fever, chills, myalgia, fatigue, diarrhea, nausea and vomiting. Central nervous system disturbances including depression, suicidal ideation, confusion and mental status changes can occur, especially in patients with pre-existing histories. Hematologic side effects, including anemia, thrombocytopenia, and neutropenia, require ongoing monitoring. The reported withdrawal rates due to adverse effects, in studies examining interferon-based combinations are 7%-8%^[2,6].

We report a case of central retinal vein thrombosis in a cirrhotic hepatitis C patient during pegIFN and ribavirin combination treatment.

CASE REPORT

A 49-year old male of North American aboriginal descent, with chronic hepatitis C (genotype 2b) and biopsy confirmed cirrhosis, presented with a 2-wk history of left eye pain and decreased visual acuity, after a 16-24 wk course of therapy with pegIFN- α 2a at a dose of 180 μ g per week injected subcutaneously and 800 mg ribavirin per day (Pegasys, Hoffmann-La Roche, Mississauga, ON, Canada). His past medical and family histories were negative for any thrombophilia. Specifically, he had no

Figure 1 Normal fundus in the right eye (A) and marked venous tortuosity and scattered retinal hemorrhages in the left eye (B).

Figure 2 Left eye angiogram. A: Early phase image revealing delayed venous filling; B: Late phase image revealing leakage of fluorescein in the macula.

history of superficial or deep venous thrombosis and no history of thromboembolic events. Prior to the initiation of treatment, he had no evidence of decompensated liver disease and his serum alanine aminotransferase (ALT) was 256 U/L (upper limit of normal < 50U/L). Abdominal sonographic imaging revealed a cirrhotic liver with mild splenomegaly. Serial blood work performed at 4 and 8 wk of treatment revealed that his serum ALT levels were 67 U/L and 45 U/L (normal < 55 U/L), respectively. There were no complications associated with the treatment regimen prior to his presentation at 16 wk. One week following the onset of left eye pain and decreased visual acuity, he was assessed by an optometrist who prescribed eyeglasses. Due to the continued symptoms he presented to our hepatitis clinic, two weeks after the initial onset of symptoms. He was urgently referred to a retinal specialist and diagnosed with non-ischemic central retinal vein occlusion of the left eye (Figure 1). Fluorescein angiogram revealed delayed venous filling (Figure 2A) and associated macular edema (Figure 2B). Visual acuity at presentation was 20/20 in the right eye, and 20/70 in the left eye. PegIFN & ribavirin combination therapy was discontinued and the HCV RNA after 16 wk of treatment was undetectable.

Subsequent hematologic investigations to look for a hypercoagulable condition revealed heterozygosity for factor V Leiden, and a mildly decreased protein C activity at 0.49 U (lower limit of normal 0.65 U), confirmed by repeat testing. Antithrombin III and protein S levels were within normal limits but at the lower range with values of 0.72 U and 0.66 U, respectively (lower limits of normal for antithrombin III and protein S, 0.70 and 0.65 respectively). Cryoglobulins and the lupus anticoagulant were negative. Six months following the onset of our patient's left eye pain, his visual deficit remained unchanged.

DISCUSSION

Interferons comprise a group of pleiotropic proteins with anti-viral, anti-inflammatory, and anti-angiogenesis characteristics. Interferons are also multifunctional immunoregulatory cytokines with effects at various points in the cytokine cascade, likely accounting for their immunostimulatory effects^[7]. Due to their various mechanisms of action, interferons are well recognized to cause a variety of side effects as previously mentioned. From an ophthalmologic standpoint, there have been few reported cases of retinal vein thrombosis in patients treated with interferon or pegIFN. We are aware of only three reports in the medical literature^[8-10]. Of these, two of the reports describe this rare complication in cirrhotic patients being treated for hepatitis C^[9,10].

Regarding the potential thrombogenic properties of interferon, Guyer *et al.*^[11] in a 1993 paper reporting retinopathy, have suggested that IFN therapy may cause immune complex deposition in the retinal vasculature and leukocyte infiltration, leading to retinal ischemia, congestion, and hemorrhage. Interferon therapy has also been reported to induce a number of thrombogenic autoantibodies, including cryoglobulins, anti-nuclear, anti-smooth muscle, anti-liver-kidney microsomal, anti-thyroglobulin, and anti-phospholipid antibodies, which are thought to play a role in the pathogenesis of a hypercoagulable state^[10].

In our patient, the causative role of pegylated-interferon therapy in inducing a hypercoagulable state that results in the retinal vein occlusion is strong given the temporal occurrence. However other risk factors may also have contributed. Considering the key role of the liver in coagulation, cirrhosis results in various impairments via multiple mechanisms: quantitative and qualitative

platelet defects, decreased production of coagulation and inhibitor factors, vitamin K deficiency, synthesis of abnormal clotting factors, decreased clearance of activated factors by the reticuloendothelial system, hyperfibrinolysis, and disseminated intravascular coagulation. The natural inhibitors of coagulation, antithrombin III, protein C and protein S, were at low to borderline levels of activity in our patient. Nevertheless, it is important to note that plasma activity of inhibitors between 50% and 70% alone, is not associated with increased thrombotic events in cirrhotics, possibly because of the proportional impairment of procoagulants^[12].

As part of the post diagnostic thrombophilic workup, our patient was found to be a heterozygote for the factor V Leiden mutation. Normally, factor V circulates in plasma as an inactive cofactor, awaiting activation by thrombin. Its inactivation requires protein C-mediated cleavage at arginine 306 and arginine 679. Genotypically, a point mutation in the gene-encoding factor V results in a missense mutation. The gene product, called factor V Leiden, which is not susceptible to cleavage by activated protein C, is inactivated more slowly and therefore confers an increased risk of venous thrombosis. The prevalence of heterozygosity for factor V Leiden is 5%-6% and is the most common inherited thrombophilia^[13]. The lifetime risk of thrombosis in heterozygotes compared to patients with no defect has been found to range 2.2-4.9^[14,15].

The hepatitis C virus itself has been found to induce a variety of potentially thrombogenic antibodies such as cryoglobulins, anti-nuclear, anti-smooth muscle, anti-cardiolipin and anti-phospholipid antibodies^[16]. Since the envelope proteins of cytomegalovirus and herpes viruses have been reported to function as a source of procoagulant phospholipid, one could speculate that the hepatitis C envelope could also have procoagulant activity^[17].

Our patient had a number of hypercoagulable risk factors that alone, most likely would have remained clinically silent. We speculate that in the setting of pegIFN treatment, these risk factors may coalesce and result in the retinal vein thrombosis. It is interesting that the three cases of retinal vein thrombosis described by Nadir *et al*^[10] were being actively treated for hepatitis C with pegIFN, but were also found to have primary defects contributing to a hypercoagulable state including protein S deficiency, hyperhomocysteinemia, heterozygosity for factor V Leiden, anti-phospholipid and anti-cardiolipin antibodies. Therefore we conclude that pegIFN treatment is an important risk factor for the development of retinal vein thrombosis, however based on our case and those described in the literature, other underlying risk factors may also need to be present. We emphasize that retinal vein thrombosis is still a rare complication, and we would not advocate the routine thrombophilic work-up of patients being considered for pegIFN treatment. However, the diagnosis needs to be considered in any patient on pegIFN presenting with decreased visual acuity or eye pain and any patient on pegIFN therapy presenting with manifestations of a thrombotic episode needs to undergo further hematologic investigation.

Abstract

We described a 59-year-old male patient who underwent liver transplantation in 1989 for hepatocellular carcinoma (HCC) complicating hepatitis B virus (HBV) cirrhosis. In 2001 (12 years after liver transplantation), he developed a lung metastasis of HCC without intrahepatic recurrence and the resection was done. In July 2003, he was symptom free without any recurrence. HCC metastasis can develop even after a very long time of liver transplantation. Many HCCs grow slowly, and the growth rate of recurrent tumors in patients receiving immunosuppressive therapy is significantly greater than that of those who do not receive immunosuppressive therapy.

INTRODUCTION

Hepatocellular carcinoma (HCC) is the fifth most common cancer in the world and the third cause of cancer-related death^[1]. Cirrhosis mainly caused by hepatitis B and C viruses (HBV and HCV) constitutes the main risk factor for HCC with an yearly cumulative incidence of 3%^[1].

Liver transplantation is claimed to simultaneously cure the tumor and the underlying cirrhosis in selected patients. The 5-year survival rate can be achieved in 75% of optimal candidates for liver transplantation (single nodule < 5 cm or up to three nodules < 3 cm in diameter) with a recurrence rate below 15%^[1,2]. For patients with a single resectable HCC complicating cirrhosis, an alternative strategy is to offer resection first and then liver transplantation, if the tumor recurs or if the liver function deteriorates (salvage OLT)^[3].

However, the rate of HCC recurrence is high even after liver transplantation^[4]. The most frequent sites of recurrence of HCC after OLT are the lung (with a frequency of 51%) and the liver allograft (46%)^[4,5]. The great majority of cancer recurrences appear within 5 years of liver transplantation.

We described a 59-year-old male patient who underwent liver transplantation in 1989 for HCC complicating HBV cirrhosis. In 2001 (12 years after liver transplantation), he developed a lung metastasis of HCC without intrahepatic recurrence and the resection was done. In July 2003, he was symptom free without any recurrence.

CASE REPORT

A 59-year-old man developed deep fatigue and jaundice in May 1986. His serum alanine aminotransferase was 145 IU/L (normal < 40 IU/L) and tests for serum HBsAg, HBeAb, and HbeAb were positive, HBV-DNA was undetectable by hybridization assay. A liver biopsy showed cirrhosis. Serum level of alpha-feto-protein was 200 ng/mL (normal ≤ 15 ng/mL). Imaging studies (computerized tomography and ultrasound) showed a nodule (2 cm in diameter) in segment V with typical features of HCC.

In February 1987, segment V was resected. Histological examination confirmed a 2-cm nodule of HCC with a pseudo-capsule characterized by a sclerotic tissue with an intravascular extension of the tumor. After the intervention, alpha-feto-protein decreased to 20 ng/mL.

In December 1988, alpha-feto-protein raised to 100 ng/mL. Ultrasound and arteriography revealed nodules in the segments IV and VIII. The patient received three cures of chemoembolization (from December 1988 to March 1989) and 3 MU interferon thrice a week for 3 mo until liver transplantation, in order to make serum HBV-DNA negative. In August 1989, orthotopic liver transplantation was performed. Histological examination of the implanted liver showed micronodular cirrhosis without any evidence of neoplasia. He was given cyclosporin (18 mL/d),

Figure 1 A 2-cm polylobulated and homogeneously dense lung nodule in the upper left lobe with no calcifications.

prednisone (20 mg/d) and azathioprine (150 mg/d). During the following 2 mo (October 1989), he was treated with cyclosporin (10 mL/d), prednisone (15 mg/d), and azathioprine (50 mg/d). During the following 14 mo (October 1990), he was treated with cyclosporin (0.6 mL/d), prednisone (10 mg/d), and azathioprine (50 mg/d).

During the following years, he had a 4-mo evaluation. Transaminase, alpha-feto-protein and imaging studies (ultrasound and thoraco-abdominal CT) did not show any sign or symptom of HCC recurrence. Rejection and opportunistic infections did not occur. He did not receive HBsAb immunoglobulins and had no reactivation of HBV infection.

In July 2001 (143 mo after liver transplantation), CT scan revealed a 2-cm isolated nodule in the upper left lung lobe, which was polylobulated and homogeneous without calcification (Figure 1). Alpha-feto-protein increased for the first time to 105 ng/mL. He was treated with prednisone (4 mg/d) and azathioprine (50 mg/d). In May 2002 (153 mo after liver transplantation), an atypical resection of the upper left lobe was performed. Histological examination showed poorly differentiated HCC metastasis. After the intervention, alpha-feto-protein returned to its normal level (3.5 µg). Repeated biochemical and imaging examinations did not show any recurrence in the lung, liver or other organs.

At the last follow-up visit (167 mo after liver transplantation and 14 mo after lung resection), he was symptom free. Thoraco-abdominal CT scan did not show any recurrence (July 2003) and serum alpha-feto-protein was 2 ng/mL (normal \leq 15 ng/mL).

DISCUSSION

Recombinant interferon- α (IFN- α) treatment prior to liver transplantation does not seem to reduce the rate of HBV infection; a residual infectivity may persist even in the absence of detectable serum HBV-DNA by standard method and its role in the carcinogenetic process cannot be eliminated^[6].

The 5-year survival rate can be achieved in 75% of optimal candidates for liver transplantation (early HCC, single nodule < 5 cm or up to three nodules < 3 cm in diameter) with a recurrence-free survival rate of

Table 1 HCC recurrence after liver transplantation

	Number of patients	Recurrence (%)	Pulmonary metastasis (%)	Mean delay (mo)
Yokoyama, 1991 ^[9]	100	43 (43/100)	12 (12/100)	34
Ferris, 1996 ^[4]	124	28 (35/124)	14 (18/124)	18
Wallis March, 1997 ^[10]	214	40 (71/214)	11 (23/214)	24
Total	438	34 (149/438)	12 (53/438)	25

92%^[7]. Most recurrent tumors arise during the first 2 years after resection, which might be explained by the multicentric nature of HCC in cirrhotic livers rather than by intrahepatic metastasis. The multifocal nature of HCC was examined in the livers from patients undergoing liver transplantation. Certain histological findings in the implant, such as the presence of capsular and microvascular invasion, are considered as signs of a more aggressive tumor associated with a greater incidence of recurrence^[8].

When recurrence after liver transplantation occurs, the most frequent sites are lungs (51%), liver allograft (46%), and lymph nodes (43%). Ferris *et al*^[4] have reported a mean interval of 18 mo.

In the three major studies^[4,9,10] involving HCC, the recurrence rate is 34% in 438 patients after liver transplantation (Table 1).

In a great majority of cases, recurrence of HCC occurs within 5 years of liver transplantation. The longest time to recurrence described in the literature is 124 mo^[4]. To our knowledge, the time between liver transplantation and recurrence is the longest in our case (12 years, 143 mo).

An active approach to the management of resectable pulmonary metastasis from HCC is justified in selected patients, which can permit a prolonged survival^[11]. Most pulmonary metastases of HCC are multiple and not amenable to surgical resection. If any solitary pulmonary metastasis encountered is resectable, the patient should undergo surgery.

The selection of patients with early HCC is the main factor affecting HCC recurrence after liver transplantation. At this early stage of tumor development, there are no other factors that have prognostic values. In patients from Western countries, the progression of HCC is usually slow and is related to tumor size^[12]. The mechanism for late recurrence of HCC remains unclear and some hypotheses have been proposed such as intraoperative surgical manipulation^[12], embolization of tumor cells via the hepatic veins before or during liver transplantation, which can result in the trapping of micrometastasis within the capillary network of the lungs and immunosuppressive therapy potentiating macroscopic growth of nodules^[5].

The effect of long-term immunosuppressive therapy on tumor growth in patients with HCC is unknown. It has been suggested that while many HCCs are growing slowly, the growth rate of recurrent tumors in patients receiving immunosuppressive therapy is significantly greater than that in those who do not receive immunosuppressive therapy, indicating that immunosuppressive therapy plays a major role in tumor recurrence after liver transplantation^[9].

In fact, it has been shown that the risk of recurrence in patients who continue to receive corticosteroids may be as much as four times higher than that in patients who stop receiving corticosteroids soon after the liver transplantation^[2,6].

In our case, immunosuppressive therapy seemed to be well balanced, because the patient had neither rejection nor opportunistic infections.

In conclusion, HCC metastasis can develop even after a long time of liver transplantation. A systematic long-term follow-up is necessary. In case of single lung metastasis without any other localization, it is possible to resect it, allowing to prolong the survival of the patient. It is very important to maintain vigilance after liver transplantation, because the risk of recurrence exists for a long time after liver transplantation.

Immunosuppressive therapy, one of the possible key factors in controlling the response to neoplasm, can reduce the treatment time^[13] and achieve immunologic tolerance and reduce the use of immunosuppressive drugs^[12].

Abstract

A 36-year-old Philippine woman presented with dark urine and yellow sclera. Endoscopic retrograde cholangiopancreatography (ERCP) confirmed dilatation of the intrahepatic bile ducts and also showed an irregular stricture of the common hepatic duct at the liver hilum. Histological examination of biopsies from the bile duct revealed epithelioid cell granulomas and caseous necrosis. Tubercle bacilli were then detected on polymerase chain reaction (PCR) testing of the bile, giving the diagnosis of biliary tuberculosis. Although microbiological cure was confirmed, the patient developed cicatricial stenosis of the hepatic duct. She underwent repeated treatments with endoscopic biliary drainage (EBD) tubes and percutaneous transhepatic biliary drainage (PTBD) tubes, and the stenosis was corrected after 6 years. We present a case of tuberculous biliary stricture, a condition that requires careful differentiation from the more common malignancies and needs long-term follow-up due to the risk of post-treatment cicatricial stenosis, although it is rare.

INTRODUCTION

The more common benign causes of biliary stenosis are

postoperative cicatricial stenosis and complications of chronic pancreatitis, duodenal papillitis, and congenital biliary dilatation, whereas tuberculous lesions, such as tuberculosis (TB) of the biliary lymph nodes, pancreatic TB, and biliary TB are rare. In this paper, we report a case of biliary TB causing obstructive jaundice and cicatricial stenosis after oral anti-tuberculosis therapy.

CASE REPORT

The patient was a 33-year-old female of Philippine origin. She presented with dark urine, yellow sclera, and malaise. She had lived in Japan for 3 years when she was admitted to our hospital. Her father and brother had a past history of pulmonary TB. She received no past treatment for TB. When she visited a local doctor in May 1998 for symptoms of dark urine and yellow sclera, she was found to have mild hepatic dysfunction and was thus referred to our hospital with suspected acute hepatitis. Viral, drug-induced, and auto-immune hepatitis were excluded, and she was treated with watchful anticipation as an outpatient. Abdominal ultrasound then revealed dilatation of the intrahepatic bile ducts and multiple intrahepatic hypodense areas, and the patient was admitted to our hospital for further investigation in February 1999. Admission findings included: height 154 cm, weight 54 kg, and body temperature 36.4°C. Her blood pressure was 112/62 mmHg, heart rate was 64 beats/min, and she had a sinus rhythm. Conjunctiva was not anemic or jaundiced. No superficial lymph nodes were palpable. Abdomen was flat and soft. The liver, spleen or masses were not palpable without abdominal pain or tenderness. Full blood examination revealed that she had mild anemia (117 mg/L; normal: 125-170 mg/L) and an elevated erythrocyte sedimentation rate (66 mm/h; normal: <10 mm/h). Serum biochemistry showed elevated biliary enzyme γ -glutamyltranspeptidase (201 IU/L; normal: 12-70 IU/L). Tumor markers CA19-9 (100 KU/L; normal: <37 KU/L) and PIVKA-II (43 AU/L; normal: <10 AU/L) were elevated. Abdominal ultrasonography (US) showed the hepatic parenchyma to be uniform and slightly hypertrophic, with dilatation of the intrahepatic ducts and multiple hypoechoic masses (Figures 1A and B). Abdominal computed tomography (CT) scans confirmed intrahepatic ductal dilatation and multiple hypodense lesions in the liver, some with microcalcifications. The early contrast phase images showed slight enhancement of the periphery of the lesions, while the late phase images showed uneven enhancement

Figure 1 Ultrasonography findings of the liver. **A:** Dilatation of the intrahepatic ducts and a hypoechoic mass in the right lower anterior segment; **B:** A heterogeneous mass in the inner left segment.

Figure 2 Abdominal computed tomography (CT). **A:** Plain CT images show intrahepatic ductal dilatation, micro-calcifications, and multiple hypodense lesions in the liver; **B:** Contrast CT image (early phase) shows clearly delineated hypodense lesions; **C:** Late phase CT image shows slightly enhanced hypodense lesions.

of the peripheral and central areas. Lymphadenopathy was seen both at the liver hilum and at the origin of the splenic artery (Figures 2A-C). Intraductal ultrasonography (IDUS) showed soft tissue masses at the liver hilum of the hepatic duct (Figure 3A), and circumferential thickening of the common hepatic duct (Figure 3B). Endoscopic retrograde cholangiopancreatography (ERCP) revealed that the common hepatic duct was narrowed over a 2 cm section, and the hepatic ducts were clumped and irregular at the liver hilum, with strictures of the feeding branches from each section of the liver (Figures 4A and B). Histopathological examination of endoscopic biopsy specimens from the common hepatic duct at the liver hilum revealed granulomas with epithelioid cells (Figure 5A), whereas a biopsy specimen from a hepatic mass showed very mild atrophy and marked dilatation of the hepatic sinuses, with large foci of caseous necrosis surrounded by epithelioid granuloma (Figure 5B). Repeated bile cytodiagnosis showed no malignancy. Cholangiography showed irregular strictures of the intra and extra hepatic biliary ducts. So hepatic secondaries from malignant neoplasia were mostly suspected, but the

Figure 3 Endoscopic ultrasonography (EUS). **A:** Soft tissue masses at the liver hilum of the hepatic duct; **B:** Circumferential thickening of the common hepatic duct.

Figure 4 Endoscopic retrograde cholangiopancreatography examination. **A:** The common hepatic bile duct was narrowed over a 2 cm section, and strictures and irregularities of the hepatic bile duct at the liver hilum were revealed; **B:** The hepatic ducts at the liver hilum were clumped with strictures of the feeding branches from each section of the liver.

biopsies and bile cytodiagnosis did not show malignancy. Then the differential diagnosis could include primary biliary sclerosis (PSC), drug-induced cholestasis, and HIV-associated cholangiopathy. Serum ALP was normal with no obvious elevations in liver enzymes. Also serum anti-mitochondrial antibody and peripheral anti-neutrophil cytoplasmic antibody (pANCA), and smooth-muscle antibody did not elevate. Symptoms of inflammatory bowel disease, particularly ulcerative colitis did not present. She took no medicine and her serum HIV was negative. The biopsy findings of caseous necrosis and epithelioid granulomas, and bile polymerase chain reaction (PCR)-confirmed tubercle bacilli, led to the diagnosis of biliary TB. Tuberculin test was also strongly positive. Triple anti-tuberculosis therapy, comprising 400 mg isoniazid (INH) daily, 750 mg ethambutol (EB) daily, and 450 mg rifampicin (RIF) daily, was administered for 7 mo. Microbiological cure was confirmed in October 1999, with phlegm, gastric juice, bile, and feces negative for *Mycobacterium tuberculosis*. In December 2000, 14 mo after the completion of anti-tuberculosis treatment, the patient became febrile and jaundiced. Endoscopic retrograde cholangiography (ERC) demonstrated cicatricial stenosis of the common hepatic duct at the liver hilum. Because of the tight stricture at the liver hilum, and narrowing of many intrahepatic bile ducts, transpapillary stent placement was abandoned, and percutaneous transhepatic biliary drainage (PTBD) was performed instead (Figure 6A). Although she subsequently

experienced repeated bouts of pyrexia and jaundice due to ascending cholangitis, the stenosis improved gradually, and fistularisation was achieved in July 2001 (Figure 6B). By February 2003, only two 7 Fr pigtail catheters were required for endoscopic biliary drainage (EBD) tube placement (Figure 6C). Two years later (in January 2005), a further bout of cholangitis made the patient febrile but not jaundiced, and no stenoses were detected on ERC (Figure 6D), so the EBD tubes were removed. She developed biliary stones in April of the same year, which was not detected before. However, EBD tube was reinserted and follow-up was continued at the time of writing this paper.

DISCUSSION

Benign biliary strictures fall into two etiological groups: traumatic (post operative, blunt, or penetrating injury) and nontraumatic (sclerosing cholangitis, recurrent pyogenic cholangitis, chronic pancreatitis, Mirizzi syndrome). The site and number of strictures depend on the cause. TB is

a rare cause of biliary obstruction. Hepatobiliary TB may be caused by three ways: spread of caseous material from the portal tracts into the bile ducts (most often), secondary inflammation-related tuberculous periportal adenitis, and spread of caseous material through the ampulla of Vater and ascending along the common bile duct. Hepatobiliary TB can be classified into 3 types: miliary hepatic TB, hepatic tuberculoma, and biliary TB^[1]. The majority are the miliary TB type. Hepatic tuberculoma requiring differentiation from hepatoma is relatively rare. Biliary TB is even more uncommon, and no cases of biliary TB causing obstructive jaundice due to biliary stenosis have been reported in Japan. A Pub Med search of papers published after 1985 has yielded 16 reported cases of biliary TB causing obstructive jaundice^[2-13] (Table 1). In each case, irregular stenosis of one or more bile ducts was seen on ERC, these findings differing considerably from those in cases of TB of the biliary lymph nodes or pancreatic TB, where obstructive jaundice is caused by extramural compression of the common bile duct (CBD). Differentiation from malignant neoplasia was often extremely difficult, and in 11 of the 16 cases laparotomy was performed without having excluded malignancy, and a preoperative diagnosis of TB was achieved through biopsy or PCR in only 5 cases. In 1 case, although the diagnosis of TB had been made, choledochoduodenostomy was required due to multiple strictures. 2 cases were complicated by biliary stones, and cicatricial restenosis occurred in the same cases following medical treatment. The bile duct might have been severely damaged by repeated inflammatory reactions and have become irreversibly scarred. One case had a postinflammatory stricture for nearly 2 years^[6] and one case required stent changes every 6 mo at the issue^[10]. And only 2 cases were

Figure 6 ERC following anti-tuberculosis therapy showing marked irregularity of the hepatic ducts and strictures of common hepatic duct. **A:** PTBD tubes were inserted via the B8 and B3 branches; **B:** The PTBD tube from the B5 branch was inserted into the common bile duct; **C:** EBD tubes were inserted into both hepatic lobes; **D:** The strictures of the hepatic ducts were recanalized.

with radiological evidence of pulmonary tuberculosis and one case with hepatic calcification, so TB must be considered in the differential diagnosis of any bile duct obstruction, particularly in patients from areas where TB is prevalent.

Biliary TB is a condition with no specific clinical findings and is usually diagnosed through biopsy or the detection of tubercle bacilli. The detection rate through culture is 0%-10%^[14]. However, even if epithelioid granulomas are identified, differentiation from conditions such as hepatic sarcoidosis or inflammatory bowel disease is important. Sarcoid granulomas are similar to TB granulomas, although in the former foreign body-type giant cells are seen in addition to Langhans giant cells, and foci of necrosis are rarely seen. In this case, acid-fast bacilli were not detected by culture or microscopy, and *Mycobacterium tuberculosis* was only detected through PCR testing of the bile. Since PCR testing for *Mycobacterium tuberculosis* is extremely sensitive,

it should be used extensively. Although favourable results can be achieved by medical therapy with repeated stenting of the bile ducts, long-term follow-up is required due to the risk of post-treatment cicatricial stenosis.

Abstract

A 75-year-old man was admitted to our hospital with a diagnosis of liver metastases from colon cancer. He underwent right hemicolectomy for cecal cancer eight years ago, and had a metastatic liver tumor in segment 8 (S8), which was surgically resected about 4 years after the initial operation. Histopathological examination of the resected specimens from both operations revealed a well-differentiated adenocarcinoma with mucinous carcinoma. Four months after the second operation, computed tomography demonstrated a low-density lesion at the cut surface of the remnant liver. Although it was considered to be a postoperative collection of inflammatory fluid, it formed a cystic configuration and increased in size to approximately 5 cm in diameter. With a tentative diagnosis of a recurrence of metastatic cancer, partial hepatectomy of S8 was performed. Histological examination of the resected specimens also revealed mucinous adenocarcinoma, which had invaded into the biliary ducts, replacing and extending along its epithelium. Immunohistochemically, the tumor cells were positive for cytokeratin (CK) 20, but negative for CK7. Therefore, the tumor was diagnosed as a metastatic adenocarcinoma from colonic cancer. Liver metastases of colorectal adenocarcinoma sometimes invade the Glisson's triad and grow along the biliary ducts.

INTRODUCTION

Liver metastases can occur in 25%-35% of patients with colorectal carcinoma^[1], and surgical resection has become accepted as a reasonable treatment for patients with liver metastases. However, because of their propensity to spread along epithelial surfaces, liver metastases of colorectal carcinoma sometimes invade the Glisson's triad^[2]. Therefore, in contrast to hepatocellular carcinoma (HCC), bile duct invasions of liver metastases from colorectal carcinoma are seen in about 10%-12% of resected liver metastases^[3,4]. On the other hand, cystic formation caused by mucin producing metastatic tumor from colorectal cancer has only rarely been reported. Here, we report a case of mucin producing liver metastases with intrabiliary extension that was difficult to distinguish from benign cystic change.

CASE REPORT

A 75-year-old man was admitted to our hospital with a liver tumor. He underwent right hemicolectomy following a diagnosis of cecal cancer in January, 1994. Histological examination of the resected specimens revealed a well-differentiated adenocarcinoma with mucinous carcinoma, which invaded the subserosal layer and metastasized to regional lymph nodes. Four years after his initial operation, he underwent partial hepatectomy of segment 8 (S8) due to a diagnosis of metastatic liver tumor on June 22, 1998. Histopathological examination of the resected specimens revealed a well-differentiated adenocarcinoma with mucinous carcinoma, similar to cecal cancer. The tumor invaded only the bile duct, but surgical margin was negative for cancer. Four months after his second operation, abdominal computed tomography (CT) revealed a low-density lesion at the cut surface of the liver. Initially, it was considered to be a postoperative collection of inflammatory fluid. Through the continuous observation using periodical CT scans, the low-density lesion gradually formed a cystic mass over two years, but little change was found in size. Two years later, the mass increased in size

Figure 1 A low-density lesion at the cut surface of the liver in December, 1998 (A) and two years later, the mass increased in size to approximately 5 cm in diameter (B).

Figure 2 A low-density cystic tumor in S8 with local dilatation of the IHBD (arrows). The tumor was bordered by the diaphragm (arrow heads).

Figure 3 A low intensity signal on T1-weighted (A) and a high intensity signal on T2-weighted (B) images. The edge of the tumor was slightly enhanced by gadolinium, while the inside was heterogeneous (C).

to approximately 5 cm in diameter (Figure 1). Cytological examination from ultrasonography (US)-guided fine needle aspiration biopsy revealed it to be class III, indicating a borderline malignancy.

On admission, the patient exhibited no abnormal findings upon physical examination. Complete blood counts and serum chemistries were within normal limits. Among tumor markers, serum carcinoembryonic antigen (CEA) levels and alpha-fetoprotein (AFP) levels were within normal limits. The indocyanin green retention rate after 15 min (ICG R15) was 16.0%. Abdominal CT revealed a low-density cystic tumor of S8 that measured about 4 cm × 5 cm in size, with local dilatation of intrahepatic bile ducts (IHBD). The tumor was bordered by the diaphragm (Figure 2). Abdominal magnetic resonance imaging (MRI) revealed a tumor with a low intensity signal on T1-weighted images and a high intensity signal on T2-weighted images (Figures 3A and B). In addition, the edge of the tumor was slightly enhanced by gadolinium, while the inside was heterogeneous (Figure 3C). Magnetic resonance cholangiopancreatography (MRCP) revealed local dilatation of IHBD. Based upon these examinations, one of the differential diagnoses was biloma at the cut end of the previous hepatectomy. To further investigate the content of the tumor, US-guided biopsy was performed. An aspirated sample contained a small volume of yellow and clear fluid, but bile was not found. Histological examination of the biopsy

specimens revealed a mucinous adenocarcinoma. Finally, the tumor was judged to be a recurrence of metastatic cancer with invasion to the IHBD. There was no evidence of metastasis in any other organs or in regional lymph nodes. The patient was considered to be a candidate for surgery. On March 13 in 2002, he underwent the third operation. When the peritoneal cavity was entered, there was no evidence of peritoneal dissemination, enlarged lymph nodes or ascites. The tumor was located in the liver in S8 adhering to the diaphragm and was about 4 cm in diameter, as measured by US. US was also performed to indicate a sufficient surgical margin of at least 15 mm. The tumor was resected using intermittent clamping of the primary branch of Glisson's triad (Pringle's procedure). When we cut the regional Glisson's triad, mucinous bile was found at the cut end of the bile duct. The portal vein was intact. According to the preoperative informed consent, partial resection of the liver in sub-segment 8 and the diaphragm was performed. Histological examination of the resected specimens revealed a well-differentiated mucinous adenocarcinoma, which was consistent with the metastatic lesion from colon cancer. The tumor extended along the lumen of the biliary ducts, replacing the non-neoplastic epithelium (Figure 4). The peripheral bile ducts were obstructed by the cancer cells, and the cut end of the bile duct was positive for cancer. The tumor invaded only the abdominal side of the diaphragm and was not apparent on the thoracic side. Immunohistochemically, the tumor

Figure 4 Macroscopic finding (A), well-differentiated mucinous adenocarcinoma (B) similar to cecal cancer (C), extension of tumor cells along the lumen of the biliary ducts with the non-neoplastic epithelium replaced (D). (B) HE, $\times 100$; (C) HE, $\times 100$; (D) HE, $\times 18$.

Figure 5 Immunohistochemically, tumor cells positive for CK 20 (A), but negative for CK7 (B), normal epithelial cells of IHBD positive for CK7 (arrow). (A) $\times 100$; (B) $\times 100$.

cells were positive for CK 20, but negative for CK7 (Figure 5). Thus, we diagnosed it as a recurrence of metastatic adenocarcinoma from cecal cancer.

Three months after the hepatectomy, the patient exhibited a recurrence at the cut surface of the residual liver. He and his family did not hope further surgery. Although he received chemotherapy using 5-FU for the local recurrence, he died 2 years and 9 mo after the second hepatectomy.

DISCUSSION

Liver metastases occur in 25%-35 % of patients with colorectal cancer^[1]. Surgical resection has become a recognized curative treatment^[1,5,6]. However, the rate of intrahepatic recurrence has been reported to range from 16% to 28%^[5,7], and 9%-25% of these arise at the surgical margin^[8,9]. Okano *et al*^[3] reported that 42% of patients who have undergone hepatectomy for colorectal

liver metastases exhibit bile duct invasion, 12% of which exhibit macroscopic invasion. Among these metastases, an intrabiliary extension pattern is rare. Kubo *et al*^[4] reported that 3.7% of resected colorectal liver metastases are extended predominantly along the bile duct without forming an extrabiliary mass. The prognosis of patients with macroscopic bile duct invasion is better than that of patients with microscopic intraluminal invasion, which tends to aggressively involve the Glisson's triad^[3,4].

In the present case, we initially considered the cystic lesion to be a post-operative collection of inflammatory fluid. However, the lesion turned out to be a cystic tumor including mucin produced by the remnant cancer cells. Cancer cells and mucin obstructing the IHBD, caused dilatation of the peripheral bile ducts. Microscopically, about 10% of metastatic tumors from colorectal carcinoma exhibit mucinous features^[2]. Furthermore, the frequencies of incidence of localized IHBD dilatation caused by metastatic liver cancer and cystic degeneration of metastatic tumor have been reported to be 6%^[10] and 2%-4%, respectively^[11,12]. Therefore, the present case was considered to be a very rare case and preoperative diagnosis could not be confirmed by imaging examination alone. On the other hand, it is known that cholangiocellular carcinoma (CCC) is often accompanied with dilatation of the IHBD, because intrahepatic CCC exhibits bile duct extension, either through infiltration into the periductal tissues or appearing as a cast-like growth into the ductal lumen^[13]. Furthermore, CCC sometimes exhibits mucin production. Thus, the growth of colorectal metastases with bile duct invasion can be indistinguishable from that of less aggressive CCC, and it is sometimes difficult to make a differential diagnosis histologically. To discriminate liver metastases from primary CCC, immunostaining for CK7 and CK20 can be very useful. A CK20-positive and CK7-negative pattern is highly characteristic of liver metastases from colorectal cancer, compared with most

adenocarcinomas including CCC that are usually CK20-negative and CK7-positive^[14-16]. In the present case, this immunohistochemical finding allowed us to make a definite diagnosis.

Our patient has survived for more than two-years, in spite of local recurrence. This may be a consequence of the less aggressive features of this tumor, which exhibits macroscopic bile duct extension^[3,4]. However, because this invasion pattern tends to make the cut ends positive for cancer cells, it appears that it is necessary to examine the cut end of Glisson's triad by stamp cytology or frozen section pathology. Actually, during the 2nd hepatectomy, mucinous bile was found in the bile duct. However, since the tumor was a metastatic colorectal cancer rather than a CCC, partial hepatectomy was a procedure of choice for us. For colorectal metastases, we usually perform partial hepatectomy with a sufficient margin rather than anatomical resection if possible. Recently, Pawlik *et al*^[9] reported that the width of a negative surgical margin does not affect survival, recurrence risk, or site of recurrence. However, after having experienced our present case, anatomical hepatic resection may be a treatment of choice for metastatic liver tumor with bile duct extension to avoid the potential for a positive surgical margin. Further studies are necessary to develop a suitable surgical procedure for this unusual pattern of liver metastasis.

Abstract

A 77-year-old man on systemic chemotherapy against postoperative bilateral multiple lung metastases of malignant solitary fibrous tumor of the pleura suffered from pruritus and jaundice. Blood examination showed elevated levels of hepatobiliary enzymes. Abdominal computed tomography showed a tumor with peripheral enhancement in the pancreatic head, accompanied with the dilatation of intra- and extra-hepatic bile ducts. He was diagnosed as having obstructive jaundice caused by a pancreatic head tumor. The pancreatic head tumor was presumably diagnosed as the metastasis of malignant solitary fibrous tumor of the pleura, because the findings on the pancreatic head tumor on abdominal CT were similar to those on the primary lung lesion of malignant solitary fibrous tumor of the pleura. The pancreatic tumor grew rapidly after the implantation of metallic stent in the inferior part of the common bile duct. The patient died of lymphangitis carcinomatosa of the lungs. Autopsy revealed a tumor that spread from the pancreatic head to the hepatic hilum. Microscopically, spindle-shaped cells exhibiting nuclear atypicity or division together with collagen deposition were observed. Immunohistochemically the pancreatic head tumor cells were negative for staining of α -smooth muscle actin

INTRODUCTION

Solitary fibrous tumor of the pleura (SFTP) is a neoplasm derived from mesenchymal cells located in the submesothelial lining of the pleural space, predominantly composed of spindle-shaped cells in combination with collagen deposition^[1]. SFTP comprises approximately 5% of primary pleural tumors following malignant mesothelioma^[2]. Seven percent to 13% of SFTPs are considered to be malignant neoplasms, of which 41% to 63% recur in the pleura or lung or metastasize to the liver, brain, spleen, adrenal gland and other organs^[1,2]. However, no metastasis to the pancreatic head with obstructive jaundice has been reported. Here, we report the first case of obstructive jaundice caused by a secondary pancreatic tumor from malignant SFTP.

CASE REPORT

The patient was a 77-year-old Japanese man. In July 2001, he was found to have an extrapleural tumor projecting from the right diaphragm by mass screening chest roentgenography. Partial resections of the right diaphragm and lower right lobe of the lungs were carried out in July 2002,

Figure 1 An extrapleural tumor projecting from the right diaphragm observed on chest roentgenography.

Figure 3 Multiple nodular lesions in the bilateral lung fields observed on chest computed tomography (CT).

Figure 2 Spindle-shaped cells exhibiting nuclear atypicality or division together with collagen deposition (hematoxylin and eosin staining) (A), tumor cells negative for SMA (B) or CD117 (c-kit) (C) and positive for vimentin (D), CD34 (E) and CD99 (F) on histological examination.

because of the rapid tumor growth (Figure 1). The tumor in the resected specimens was composed of nonorganized, spindle-shaped cells exhibiting nuclear atypicality or division together with collagen deposition. Immunohistochemical staining showed that the tumor cells were negative for α -SMA or CD117 (c-Kit) but positive for vimentin, CD34 and CD99 (Figures 2A-F). He was diagnosed as having a solitary fibrous tumor of the pleura (SFTP).

In September 2003, multiple metastases were found in the bilateral lung fields and he received systemic chemotherapy with gemcitabine (GEM) and cisplatin (CDDP). Two courses of chemotherapy with GEM and CDDP temporarily reduced the tumor size in the lung.

In mid-April 2004, he experienced pruritus and showed

Figure 4 The pancreatic head tumor not detected by preoperative abdominal CT (A), a 25 mm \times 17 mm tumor in the pancreatic head detected by abdominal CT with its periphery enhanced by contrast material in the delayed phase (B) and dilatation of intra- and extra-hepatic bile ducts observed (C).

skin jaundice. He was found to have liver dysfunction. He was admitted to our hospital for further evaluation and treatment.

His medical history before 2001 was uneventful. He had a history of daily alcohol intake for 50 years and daily smoking for 40 years.

On the day of admission, he was alert. His body temperature was 35.4°C. His bulbar conjunctiva and skin were icteric. There was a surgical scar on his right lateral thorax. His liver was soft and palpable 3 cm below the umbilical margin. No tumor was palpated in the abdomen. A moveable and elastic tumor 2 cm in diameter was palpable in his right buttock.

The levels of hepatobiliary enzymes and bilirubin were elevated. The levels of tumor markers including carcino-embryonic antigen (CEA) and pancreatic cancer-associated antigen-2 (DUPAN-2) were normal (Table 1). Multiple

Figure 5 A marked stenosis of the inferior part of the CBD observed on cholangiography via a PTBD tube (A), an obstruction from inferior part of CBD to the confluence of the right and left extrahepatic bile ducts involving the whole stent on reperformed cholangiography (B) on microscopic examination.

Figure 6 Macroscopic findings on autopsy. A dissected (120 mm × 30 mm × 20 mm) tumor spreading from the pancreatic head to the hepatic hilum and involving bilateral hepatic ducts. White arrow shows the pancreatic head tumor and black arrow shows the metallic stent.

nodular lesions were observed in the bilateral lung fields by chest computed tomography (CT) (Figure 3). By abdominal CT, a tumor (25 mm × 17 mm) with its periphery enhanced by the contrast material in the delayed phase, was observed in the pancreatic head (Figure 4B). This tumor was not detected by preoperative abdominal CT in 2002 (Figure 4A). The dilatation of intra- and extra-hepatic bile ducts was also observed. Intra-abdominal lymph nodes were not swollen (Figure 4C). Because the radiological findings observed with or without contrast material were similar to those observed in the primary pleural tumor, he was diagnosed as having obstructive jaundice presumably caused by a secondary pancreatic head tumor from malignant SFTP. Percutaneous transhepatic bile duct drainage (PTBD) was performed to improve his jaundice. Cholangi-

ALP	1860 IU/L		
γ-GTP	612 IU/L		

ography via a PTBD tube showed marked stenosis of the inferior part of the common bile duct (CBD) (Figure 5A). No atypical cell was observed in the bile collected by the tube.

Because of the bilateral multiple lung and right-buttock tumors, which were considered to have metastasized from the pleura, pancreatoduodenectomy was no longer an indication for treatment.

Thus, a metallic stent was implanted in the inferior part of CBD as a palliative treatment. The levels of hepatobiliary enzymes became normal after the implantation. However, in July 2004, he suffered from fever and jaundice with elevated levels of hepatobiliary enzymes. Abdominal CT demonstrated obstruction of the stent and dilatation of the intrahepatic bile ducts. Furthermore, an obstruction from the inferior part of CBD to the confluence of the right and left extra-hepatic bile ducts involving the whole stent was observed when cholangiography was performed again (Figure 5B). Although a drainage tube was reinserted in the anterior and lateral branches of the intra-hepatic bile ducts, he developed lymphangitis carcinomatosa and died of respiratory failure.

Autopsy was performed with informed consent. Multiple tumors were observed in the bilateral lung. A solitary tumor (25 mm × 15 mm × 15 mm) was observed in his right buttock. A large tumor (120 mm × 30 mm × 20 mm) spread from the pancreatic head to the hepatic hilum and involved bilateral hepatic ducts (Figure 6).

Microscopically, spindle-shaped cells exhibiting nuclear atypicity or division together with collagen deposition were observed (Figure 7A). Immunohistochemically, tumor cells of the pancreatic head were negative for α-SMA or CD117, but positive for vimentin, CD34 and CD99 (Figures 7B-F). These findings were consistent with those on malignant SFTP resected in July 2002.

DISCUSSION

Malignant SFTP recurs in the pleura or lung or metasta-

Figure 7 Spindle-shaped cells exhibiting nuclear atypicity or division together with collagen deposition (hematoxylin and eosin staining) (A), tumor cells negative for SMA (B) or CD117 (c-kit) (C) and positive for vimentin (D), CD34 (E) and CD99 (F) on histological examination. These findings are consistent with those on malignant solitary fibrous tumor of the pleura, resected in July 2002.

sizes to the liver, brain, spleen, adrenal gland and other organs *via* a blood-borne pathway^[1-3]. This present patient was considered to have a pancreatic head tumor having metastasized from a malignant SFTP for the following reasons. Multiple metastatic lesions in the bilateral lung and a growing subcutaneous tumor were observed and the findings on the pancreatic head tumor by abdominal CT were similar to those on the primary lung SFTP. The tentative diagnosis was confirmed by the histopathological and immunohistochemical findings on autopsy.

Secondary pancreatic tumor is rare. Nakamura *et al*^[4] reported that the incidence of secondary pancreatic tumor is approximately 6% in autopsy studies and increases to approximately 15% in cases of malignant tumors. The lung is the second most common primary site (18%) of secondary pancreatic tumor^[4,5]. The histopathological types of this tumor are large cell carcinoma, small cell carcinoma, adenocarcinoma and squamous cell carcinoma^[4-7]. Malignant SFTP has never been reported as a cause of secondary pancreatic tumor to date.

In general, secondary pancreatic tumor is caused by blood-borne metastasis, lymphatic metastasis and tumor infiltration from adjacent organs or peritoneal seeding. The secondary pancreatic tumor of this present patient was considered to be caused by blood-borne metastasis because no metastasis in regional lymph nodes was observed during operation or on autopsy, but multiple metastatic lesions in the bilateral lungs and a subcutaneous metastatic tumor in the right buttock were observed.

Although radiation therapy and chemotherapy have been performed against malignant SFTP in addition to resection, they could not achieve sufficient therapeutic efficacy^[2]. On the other hand, GEM monotherapy or combination therapy with CDDP is effective against malignant mesothelioma^[8].

Chemotherapy with GEM and CDDP, which is effective for patients with malignant mesothelioma, was selected for this patient because the treatment of malignant SFTP with metastasis was not authorized, and both malignant mesothelioma and SFTP originated from the pleura. However, the tumor grew more rapidly even after chemother-

apy. Forty-one percent to 63% of malignant SFTPs recur locally or metastasize to other organs^[1,2] and 23% of these patients die within 24 mo of diagnosis^[9]. Therefore, the establishment of an effective anti-tumor therapy against malignant SFTP is desired.

The leading drug for the novel therapy is imatinib mesylate, which is effective against gastrointestinal stromal tumors (GISTs)^[10]. In half of the patients with malignant SFTP, tumor cells have been found positive for c-kit^[11]. Therefore, imatinib mesylate, which inhibits kit-tyrosine kinase, may be a promising drug for molecular-target-based therapy. This hypothesis should be verified in future studies.

In summary, we report a rare case of obstructive jaundice caused by a secondary pancreatic tumor from malignant SFTP. Pancreatic metastasis may adversely affect the prognosis of malignant SFTP. Therefore, abdominal images and the levels of hepatobiliary enzymes should be examined regularly.

Abstract

Villous adenomas of the bile ducts are extremely uncommon. We describe a 58-year-old man presenting with clinical signs and laboratory findings of acute pancreatitis and obstructive jaundice. Preoperative investigation demonstrated a dilated papillary orifice with mucus exiting (fish-mouth sign) and a filling defect in the distal common bile duct. He underwent a modified Whipple operation and histological examination of the surgical specimen showed villous adenoma with rich secretion of mucus.

INTRODUCTION

Villous adenomas are benign epithelial lesions with malignant potential, which are usually encountered in the colon, less commonly in the small bowel or the ampulla of Vater, and extremely uncommonly in the bile ducts^[1]. Since Saxe *et al* first reported a case of villous adenoma of the

common bile duct (CBD) in 1988, a total of 17 cases have been reported so far in the literature^[1-17].

We present what is to our knowledge, the first case of a mucin-secreting CBD adenoma presenting as acute pancreatitis due to mucus hypersecretion and showing the endoscopic finding of "fish-mouth" in the papilla of Vater.

CASE REPORT

A 58-year-old man was admitted to the department of Internal Medicine complaining for upper abdominal pain radiating to the back, nausea and vomiting during the last six hours.

Physical examination demonstrated a well nourished man who appeared jaundiced. The abdomen was soft but revealed tenderness in the epigastrium and a movable, firm, non-tender mass in the right upper quadrant, which was felt to be a distended gallbladder. Previous medical history included a 3-mo period of dyspepsia. The patient did not mention previous episodes of fever or weight loss. He had never been abroad, was not on any drug or alcohol abuse and had no history of serious illness.

Laboratory investigations showed a total serum bilirubin level of 51 $\mu\text{mol/L}$ (normal range 0-3 $\mu\text{mol/L}$), direct bilirubin level of 39 $\mu\text{mol/L}$, alkaline phosphatase level of 548 U/L (normal range < 120 U/L), alanine transaminase level of 143 U/L (normal range < 45 U/L) and serum amylase level of 1720 U/L (normal range < 30 U/L). The hemogram revealed hemoglobin and hematocrit of 142 g/L and 44.6%, respectively, while white blood cell count was 16 100 /mm³. On abdominal ultrasound and CT the pancreas was edematous, the gallbladder was distended without calculi and the CBD was found to be dilated (12.5 mm), with a nonshadowing tissue mass in its distal end. The patient was treated conservatively with resolution of symptoms.

On seventh day, an endoscopic retrograde cholangiopancreatography (ERCP) was performed and demonstrated a patulous papillary orifice of the major papilla (fish-mouth sign) with mucus exuding from it (Figure 1), a normal pancreatogram and a 2 cm \times 1 cm intraluminal filling defect in the distal CBD (Figure 2).

A sphincterotomy was performed and in order to rule out the presence of stone, a balloon was inserted, but nothing was retrieved. A subsequent lithotripter-basket extraction took a fragment tissue out and a 8.5-French Cotton-Leung type plastic stent of 7 cm was placed.

Figure 1 Endoscopic view showing a dilated papillary orifice exiting mucus.

Figure 2 ERCP demonstrating an intraluminal filling defect in the distal common bile duct. A 8.5Fr stent has been placed.

Figure 3 Surgical specimen showing that the tumor consists of tall, columnar, pseudostratified epithelial cells with elongated or round atypical nuclei. Some of the cells contain large amounts of mucin within the apical cytoplasm (PAS X 400).

Because the histological examination of the retrieved tissue showed that the main mass was a villous adenoma, the mass was thought to be resectable with safety margins. The patient subsequently underwent a modified Whipple procedure. The histopathological examination of the specimen demonstrated that the tumor consisted of finger-like villous or papillary processes containing central thin cords of lamina propria lined by a neoplastic epithelium. The epithelial cells were tall columnar, pseudostratified with elongated or round atypical nuclei. Some of the cells contained large amounts of mucin within the apical cytoplasm. Focally goblet cells lied within the epithelium (Figure 3). No signs of hyperplasia or adenoma of the pancreas were observed in the specimen.

The patient recovered uneventfully and remains in good general condition, six months after discharge.

DISCUSSION

Adenomas of the bile ducts are divided into papillary adenomas, pedunculated adenomas and sessile adenomas, according to the gross configuration of the tumors^[18]. This classification replaced an earlier classification of papillomas and adenomas. Villous adenomas are thus classified as frond-like sessile adenomas^[3]. Histologically, however, adenomas are classified into tubular, tubulovillous and villous adenomas.

The most common site for villous adenomas in the biliary tree is the CBD. These adenomas usually develop in the distal aspect of the CBD^[18]; they are histologically similar to villous adenomas in the ampullary region, gallbladder and intestine and should probably be considered having similar biological behavior. The adenoma to carcinoma sequence is well accepted in the colon and most likely also applies in the ampullary region, gallbladder and bile ducts^[19].

Of note, in reviewing the reported cases^[1-17] of bile duct villous adenomas, the clinical picture includes painless jaundice, pruritus, upper abdominal pain, cholangitis and dyspepsia. The tumors rarely grow large enough to become palpable because of their site. The degree of jaundice has been described to fluctuate in some reports, which may be attributable to a ball valve effect of the tumor. Preoperative diagnosis or diagnosis without operation was possible in 6 out of 17 cases, mainly in recently reported cases, reflecting the current sophisticated diagnostic and therapeutic techniques of the biliary tract and pancreas. Abdominal US and CT demonstrated dilation of the CBD and an intraductal tumor but were not capable of specifying any further the nature of the lesion. The absence of gallbladder calculi, as well as the absence of acoustic shadowing of the CBD mass in the patients, made the possibility of the lesion being calculus unlikely. In addition, in the absence of gallbladder sludge, sludge in the CBD is unusual. Moreover, differentiation of a villous adenoma from other nonshadowing solid lesions, such as blood clots, nonshadowing calculi, lipomas, fibromas, or carcinoid tumors on the basis of US and CT findings is difficult^[5]. Echoendoscopy is a well proven technique with higher image resolution and greater diagnostic sensitivity than conventional imaging methods and would be useful to identify the nature of the lesion and exclude an invasive component.

It must be emphasized that two cases of coexisting biliary tract and intestinal polyps have been reported^[20,21]. It has been proposed that bile duct adenomas are part of the spectrum of generalized gastrointestinal polyposis. Some authors^[20-23] have suggested that upper gastrointestinal surveillance of patients with familial adenomatous polyposis should routinely include imaging of the biliary tract.

Our case is both unique and challenging in that the CBD adenoma had close resemblance to intraductal papillary mucinous tumors (IPMT) of the pancreas. More specifically, it was composed of secreting cells, with hypersecretion of mucin. The hypersecreted viscous mucin led to obstruction of the papillary orifice, thus increasing the pancreatic intraductal pressure and activating the cascade of mechanism of pancreatitis. Moreover, the "fish-mouth" sign in the major papilla is an endoscopic finding

which has been discussed in mucin-secreting pancreatic tumors. As both lesions are encountered premalignant, complete resection of both of them is considered mandatory. Therefore, we suggest that the term IPMT of the bile ducts could be used to describe this rare condition.

In conclusion, our case reflects the need to consider a wide differential in patients presenting with acute pancreatitis and jaundice, especially in the absence of cholelithiasis and alcohol abuse.

Abstract

The authors report their experience about 8 cases of intrabiliary rupture of hepatobiliary hydatid disease, and add an algorithm for treatment. To our opinion, the use of diagnostic and therapeutic endoscopic retrograde cholangiopancreatography (ERCP) in the management of hepatobiliary hydatid disease was not stated properly in their proposed algorithm. According to the algorithm, the use of ERCP and related modalities was only stated in the case of postoperative biliary fistulae. We think that postoperative persistent fistula is not a sole indication, there are many indications for ERCP and related techniques namely sphincterotomy, extraction, nasobiliary drainage and stenting, in the treatment algorithm before or after surgery.

Özaslan E. Therapeutic endoscopic retrograde cholangiopancreatography and related modalities have many roles in hepatobiliary hydatid disease. *World J Gastroenterol* 2006; 12(30): 4930-4931

<http://www.wjgnet.com/1007-9327/12/4930.asp>

TO THE EDITOR

We have read with great interest the article titled "Intrabiliary rupture: an algorithm in the treatment of controversial complication of hepatic hydatidosis"^[1]. The authors reported their experience about 8 cases of intrabiliary rupture of hepatobiliary hydatid disease, and added an algorithm for treatment. To our opinion, the

use of diagnostic and therapeutic endoscopic retrograde cholangiopancreatography (ERCP) in the management of hepatobiliary hydatid disease was not stated properly in their proposed algorithm. According to the algorithm, in a case of preoperative suspicion of intrabiliary rupture due to various reasons, such as cystic content in common bile duct (CBD), dilated CBD and obstructive jaundice, surgery was proposed without prior to ERCP. The use of ERCP and related modalities was only stated in the case of postoperative biliary fistula. Many reports^[2-4] including ours^[5,6] are published in English literature about the use of ERCP in the management of hydatid disease. Our former report^[5] has reviewed a total of 294 cases, after collecting 273 cases in 26 articles and 6 abstracts from literature and adding 21 cases of our own experience. Considering the current literature^[7,8] and our experience, we think that postoperative persistent fistula is not a sole indication, there are many indications for ERCP and related techniques namely sphincterotomy, extraction, nasobiliary drainage and stenting, in the treatment algorithm before or after surgery.

ERCP in the preoperative period^[2] I - defines the cystobiliary relationship to help in surgery planning, II - permits evaluation of acute conditions like cholangitis and obstruction so that subsequent surgery can be performed on an elective basis, III - may give permanent cure specifically in cases of frank intrabiliary rupture if evacuation of biliary tract and cystic cavity is manageable, and IV - when combined with preoperative endoscopic sphincterotomy may decrease the incidence of the development of postoperative external fistulae. While the first three statements have been studied extensively, the fourth statement may warrant further studies to clarify the criteria of selection of appropriate cases. The only study regarding this issue performed by Galati *et al*^[7], reported a significant decrease in postoperative fistulae in cases that underwent selective preoperative ERCP (3.8% versus 7.4%).

ERCP in the postoperative period^[2] I - can help to clarify the causes of ongoing or recurrent symptoms or laboratory abnormalities, II - may help to resolve the obstruction or cholangitis due to residual material in biliary ducts, III - may provide the chance to manage postoperative external biliary fistulae, and IV - may be a realistic solution for secondary biliary strictures^[8].

Since hydatid disease is a serious public health problem despite the use of various kinds of preventive measures,

we greatly appreciate every kind of studies regarding the issue to solve the controversions. Endoscopic therapy should be incorporated into the other treatment options including surgery, percutaneous measures and chemotherapy with benzimidazole compounds. The exact place of each therapeutic modality in a particular case should be decided on the basis of expanding current literature.

ACKNOWLEDGMENTS

Acknowledgments to Reviewers of *World Journal of Gastroenterology*

Many reviewers have contributed their expertise and time to the peer review, a critical process to ensure the quality of *World Journal of Gastroenterology*. The editors and authors of the articles submitted to the journal are grateful to the following reviewers for evaluating the articles (including those were published and those were rejected in this issue) during the last editing period of time.

Takeshi Azuma, Associate Professor

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (WJG, *World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly journal of more than 48 000 circulation, published on the 7th, 14th, 21st and 28th of every month.

Original Research, Clinical Trials, Reviews, Comments, and Case Reports in esophageal cancer, gastric cancer, colon cancer, liver cancer, viral liver diseases, etc., from all over the world are welcome on the condition that they have not been published previously and have not been submitted simultaneously elsewhere.

Indexed and abstracted in

Current Contents/Clinical Medicine and Science Citation Index-Expanded, *Index Medicus*, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, Nature Clinical Practice Gastroenterology and Hepatology, CAB Abstracts and Global Health.ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

Published by

The WJG Press

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297 mm × 210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, acknowledgements, References, Tables, Figures and Figure Legends. Neither the editors nor the Publisher is responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part without the written permission of both the authors and the Publisher. We reserve the right to put onto our website and copy-edit accepted manuscripts. Authors should also follow the guidelines for the care and use of laboratory animals of their institution or national animal welfare committee.

Authors should retain one copy of the text, tables, photographs and illustrations, as rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for the loss or damage to photographs and illustrations in mailing process.

Online submission

Online submission is strongly advised. Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/index.jsp>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. Authors encountering problems with the Online Submission System may send an email you describing the problem to wjg@wjgnet.com for assistance. If you submit your manuscript online, do not make a postal contribution. A repeated online submission for the same manuscript is strictly prohibited.

Postal submission

Send 3 duplicate hard copies of the full-text manuscript typed double-spaced on A4 (297 mm × 210 mm) white paper together with any original photographs or illustrations and a 3.5 inch computer diskette or CD-ROM containing an electronic copy of the manuscript including all the figures, graphs and tables in native Microsoft Word format or *.rtf format to:

Editorial Office

World Journal of Gastroenterology

Editorial Department: Apartment 1066, Yishou Garden,
58 North Langxinzhuang Road,
PO Box 2345, Beijing 100023, China
E-mail: wjg@wjgnet.com
<http://www.wjgnet.com>
Telephone: +86-10-85381901
Fax: +86-10-85381893

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using a word-processing software. All submissions must be typed in 1.5 line spacing and in word size 12 with ample margins. The letter font is

Tahoma. For authors from China, one copy of the Chinese translation of the manuscript is also required (excluding references). Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was accomplished, disclosure of any financial support for the research, and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (removing all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s) and full family name.

Abstract

An informative, structured abstract of no more than 250 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipments, and the experimental procedures should be included. RESULTS: The observatory and experimental results, including data, effects, outcome, etc. should be included. Authors should present *P* value where necessary, and the significant data should accompany. CONCLUSION: Accurate view and the value of the results should be included.

The format of structured abstracts is at: <http://www.wjgnet.com/wjg/help/11.doc>

Key words

Please list 6-10 key words that could reflect content of the study mainly from *Index Medicus*.

Text

For most article types, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include in appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both.

Illustrations

Figures should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. No detailed legend should be involved under the figures. This part should be added into the text where the figures are applicable. Digital images: black and white photographs should be scanned and saved in TIFF format at a resolution of 300 dpi; color images should be saved as CMYK (print files) but not as RGB (screen-viewing files). Place each photograph in a separate file. Print images: supply images of size no smaller than 126 mm × 76 mm printed on smooth surface paper; label the image by writing the Figure number and orientation using an arrow. Photomicrographs: indicate the original magnification and stain in the legend. Digital Drawings: supply files in EPS if created by freehand and illustrator, or TIFF from photoshops. EPS files must be accompanied by a version in native file format for editing purposes. Existing line drawings should be scanned at a resolution of 1200 dpi and as close as possible to the size where they will appear when printed. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes of atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...

Tables

Three-line tables should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each table. No detailed legend should be included under the tables. This part should be added into the text where the tables are applicable. The information should complement but not duplicate that contained in the text. Use one horizontal line under the title, a second under the column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. ^a*P*<0.05, ^b*P*<0.01 should be noted (*P*>0.05 should not be noted). If there are other series of *P* values, ^c*P*<0.05 and ^d*P*<0.01 are used. Third series of *P* values can be expressed as ^e*P*<0.05 and ^f*P*<0.01. Other notes in tables or under illustrations should be expressed as ¹*F*, ²*F*, ³*F*; or some other symbols with

a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, etc. in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions are included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should code the references according the citation order in text in Arabic numerals, put references codes in square brackets, superscript it at the end of citation content or the author name of the citation. For those citation content as the narrate part, the coding number and square brackets should be typeset normally. For example, Crohn's disease (CD) is associated with increased intestinal permeability^[1,2]. If references are directly cited in the text, they would be put together with the text, for example, from references [19,22-24], we know that...

When the authors code the references, please ensure that the order in text is the same as in reference part and also insure the spelling accuracy of the first author's name. Do not code the same citation twice.

PMID requirement

PMID roots in the abstract serial number indexed by PubMed (<http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed>). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information of the journal citations is very important. Through reference testing system (<http://www.wjgnet.com/cgi-bin/index.pl>), the authors and editor could check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in ASP file so that the readers can read the abstract of the citations online immediately.

Style for journal references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). Title of the cited article and italicized journal title (Journal title should be in its abbreviation form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634]

Note: The author should test the references through reference testing system (<http://www.aushome.cn/cgi-bin/index.pl>)

Style for book references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those that are linked with a hyphen and the difference between the two numbers at two sides of the hyphen is more than 5. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered as inappropriate references. Authors should not cite their own unrelated published articles.

Statistical data

Present as mean \pm SD or mean \pm SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as γ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p*(B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4 \pm 2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5 μ g/L; CO₂ volume fraction, 50 mL/L CO₂ not 5% CO₂; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format about how to accurately write common units and quantum is at: <http://www.wjgnet.com/wjg/help/15.doc>

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further mention.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kbo I*, *Kpn I*, etc.

Biology: *H pylori*, *E coli*, etc.

SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. Author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, the final check list for authors, and responses to reviewers by a courier (such as EMS) (submission of revised manuscript by e-mail or on the *WJG* Editorial Office Online System is NOT available at present).

Language evaluation

The language of a manuscript will be graded before sending for revision.

(1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing; (4) Grade D: rejected. The revised articles should be in grade B or grade A.

Copyright assignment form

Please download CAF from <http://www.wjgnet.com/wjg/help/9.doc>.

We certify that the material contained in this manuscript:

Ms:

Title:

is original, except when appropriately referenced to other sources, and that written permission has been granted by any existing copyright holders. We agree to transfer to *WJG* all rights of our manuscript, including: (1) all copyright ownership in all print and electronic formats; (2) the right to grant permission to republish or reprint the stated material in whole or in part, with or without a fee; (3) the right to print copies for free distribution or sale; (4) the right to republish the stated material in a collection of articles or in any other format. We also agree that our article be put on the Internet.

Criteria for authorship: The *WJG* requests and publishes information about contributions of each author named to the submitted study. Authorship credit should be based on (1) direct participation in the study, including substantial contributions to conception and design of study, or acquisition of data, or analysis and interpretation of data; (2) manuscript writing, including drafting the article, or revising it critically for important intellectual content; (3) supportive work, including statistical analysis of data, or acquisition of funding, or administration, technology and materials support, or supervision, or supportive contributions. Authors should meet at least one of the three conditions. The *WJG* does not publish co-first authors and co-corresponding authors.

We hereby assign copyright transfer to *WJG* if this paper is accepted.

Author Name in full (Full names should be provided, with first name first, followed by middle names and family name at the last, eg, Eamonn MM Quigley). Handwritten names are not accepted.

Author Name in abbreviation (Family name is put first in full, followed by middle names and first name in abbreviation with first letter in capital, eg, Quigley EMM). Handwritten names are not accepted.

Final check list for authors

The format is at: <http://www.wjgnet.com/wjg/help/13.doc>

Responses to reviewers

Please revise your article according to the comments/suggestions of reviewers. The format for responses to the reviewers' comments is at: <http://www.wjgnet.com/wjg/help/10.doc>

Abstract

Vascular endothelial growth factor (VEGF) is a potent secreted mitogen critical for physiologic and tumor angiogenesis. Regulation of VEGF occurs at several levels, including transcription, mRNA stabilization, translation, and differential cellular localization of various isoforms. Recent advances in our understanding of post-transcriptional regulation of VEGF include identification of the stabilizing mRNA binding protein, HuR, and the discovery of internal ribosomal entry sites in the 5'UTR of the VEGF mRNA. Monoclonal anti-VEGF antibody was recently approved for use in humans, but suffers from the need for high systemic doses. RNA interference (RNAi) technology is being used *in vitro* and in animal models with promising results. Here, we review the literature on post-transcriptional regulation of VEGF and describe recent progress in targeting these mechanisms for therapeutic benefit.

INTRODUCTION

The growth of any tissue *in vivo* relies on the adequacy of its vascular supply. Moreover, the notion of tumor

angiogenesis, first advanced by Folkman in the early 1970s, posits that the growth of any tumor beyond 1-2 cubic centimeters depends on the growth of new blood supply^[1]. In cases of insufficient vasculature, tissues become depleted of oxygen and nutrients, leading to the secretion of angiogenic factors^[2]. These factors, which include hormones, interleukins, insulin, and growth factors, spur the ingrowth of new blood vessels. Vascular endothelial growth factor (VEGF) is one such key regulator of angiogenesis. It is a secreted mitogen and the most potent angiogenic factor, specific to endothelial cells and highly expressed in areas of active angiogenesis such as solid tumors.

The upregulation of VEGF expression in response to hypoxia plays a crucial role in tumor angiogenesis. Though it is not itself an oncogene, VEGF is upregulated in tumorigenesis and is important in blood vessel formation in solid tumors^[3]. VEGF levels correlate with tumor progression and invasion, and a high VEGF level in colorectal carcinoma has been found to be an independent prognostic factor for long-term survival^[4,5].

Hypoxic induction of VEGF appears to occur both by transcriptional activation and through stabilization of VEGF mRNA, which is otherwise labile in normoxic conditions. Transcriptional activation of VEGF relies largely on binding to the hypoxia inducible factor-1 (HIF-1), a heterodimeric basic helix-loop-helix protein that activates transcription of the human erythropoietin gene in hypoxic cells^[6]. HIF-1 binds to a sequence in the 5'-flanking region of the VEGF gene called the hypoxic response element (HRE)^[7-9]. Several other molecules have been implicated in the transcriptional control of VEGF. *Sp1* stimulates transcription by binding to G/C-rich boxes present on the VEGF promoter^[10]. *AP-1* is a dimeric transcription factor of the leucine zipper family that is composed of jun/jun or jun/fos subunits. Hypoxia, oxidative stress, and cytokines may increase VEGF expression through the synthesis of jun and fos proteins and increased AP-1 binding activity. A number of other transcription factors also contribute to VEGF induction and regulation, including Stat-3^[11].

Alternative splicing

In humans there are five alternatively spliced isoforms of VEGF, each is named for the number of amino acids along its length (VEGF 206, -189, -165, -145, 121). While varying amounts of each VEGF isoform mRNA can be generated to produce certain or all isoforms of VEGF^[12],

each is predicted to have a characteristic extracellular localization based on biochemical differences. The larger isoforms bind neuropilin, matrix, and cell surface heparin proteoglycans, and are thought to act locally. The smaller isoforms do not display the heparin proteoglycan binding region and may diffuse to sites distant from the site of synthesis^[13,14].

Post-transcriptional Regulation

A body of evidence is growing rapidly to demonstrate that post-transcriptional regulation of VEGF is critically important in the fine-tuned response required for both physiologic and malignant expression. The importance of post-transcriptional regulation of VEGF is based upon several key observations about the intrinsic nature of the VEGF mRNA. First, the mRNA is labile under conditions of normal oxygen tension^[15]. Second, the 5' UTR of the VEGF mRNA possesses features that make efficient ribosome scanning and initiation of translation unwieldy.

Lability

Whereas the average half-life of eukaryotic mRNAs is 10-12 h, the half-life of VEGF mRNA is less than one hour^[16]. In 1995, Ikeda and colleagues first reported that although VEGF levels were elevated in cells cultured in hypoxic conditions, transcriptional activation alone could not account for the increase in VEGF mRNA levels. Nuclear run-on assays demonstrated upregulation of VEGF transcription under hypoxia that was apparent after three hours, and persisted after fifteen hours of incubation. VEGF mRNA levels were 8-10 times higher than baseline, and this persistent elevation of VEGF could only be explained by increased stability of the mRNA. They concluded that hypoxia could lengthen the half-life of VEGF mRNA by 2-3 fold^[7].

The effect of stabilization is mediated by the RNA-binding protein HuR. Steitz and colleagues first established the association between mRNA degradation and HuR, a member of the Elav family of proteins found in *Drosophila*^[17]. Beginning with the observation that some mRNAs are targeted for rapid degradation by the presence of AU-rich elements (AREs) in the 3' UTRs, it was determined that HuR exhibits affinity for AREs, and levels of HuR correlate with *in vitro* mRNA degradation^[18].

In VEGF, it was observed that the increase in mRNA stability coincided with the binding of a protein to an ARE, forming an RNA-protein complex in a hypoxia-inducible fashion^[16]. Using a tumor cell line lacking the wild type von Hippel-Lindau tumor suppressor gene and in which VEGF mRNA is constitutively stabilized, this RNA-protein complex was found to be constitutively elevated^[19]. The protein was later identified as the HuR protein^[15]. Inhibition of HuR expression by antisense sequences was found to inhibit the hypoxic stabilization of VEGF mRNA, demonstrating its critical role in post-transcriptional stabilization of VEGF expression. However, total cellular steady-state HuR was not altered by hypoxia, raising the possibility that HuR is a component of a hypoxia-inducible complex whose other components are regulated by oxygen tension^[15].

HuR probably has a function as a nuclear-cytoplasmic shuttle as well. It is predominantly localized to the nucleus, where it likely binds newly-transcribed VEGF mRNA and transports it to the cytoplasm and protects it from the ARE-mediated degradation pathways^[20].

Recent studies have suggested HuR and VEGF mRNA localize to the cytoplasm in response to cellular stress^[21]. Upon hypoxic stress, HuR is found to be localized to the cytosol and bound to target mRNAs, preventing their decay. New experiments using double labeling immunofluorescence show that VEGF and HuR colocalize to the nucleus during hypoxia^[22,23]. The nuclear role of VEGF mRNA, if any is unclear. Further studies to more clearly delineate the intracellular localization of VEGF mRNA and HuR are warranted.

The mechanism by which HuR protects VEGF from degradation has been further investigated. One hypothesis is that RNA binding proteins confer stability by binding directly to destabilizing sequences and making them unavailable to endonucleases. Goldberg and colleagues suggest that RNA-stabilizing factors may localize to a distinct binding site and thereby change the secondary or tertiary structure of the RNA, making a specific site unavailable to endonucleolysis. In support of this hypothesis, a 40 bp region adjacent to the HuR-binding site in the VEGF stability region has been identified that is susceptible to ribonucleases in the absence of HuR^[24].

HuR's importance in carcinogenesis is underlined by a report Lopez de Silanes and colleagues^[25]. Using a nude mouse model and the RKO colorectal cancer cell line, they reported that tumors modified to overexpress HuR grew significantly larger than controls, and conversely, tumors modified to repress HuR expression grew smaller. Whether this effect was brought about through stabilization of VEGF mRNA is yet unknown.

IRES

Internal ribosomal entry sites (IRESs) were first discovered in picornaviruses in which they initiate translation of naturally uncapped viral mRNA. Eukaryotic mRNA, however, possesses a 7-methylguanosine cap in the 5'UTR that is critical in the canonical model of translation. In this model, the eukaryotic initiation factors (eIFs) recognize and bind the 5' cap, and unwind the secondary structure of the 5'UTR, thereby making it sterically feasible for ribosomes to scan through the 5' UTR and translate the mRNA beginning at the AUG start codon^[26].

However, perhaps 3%-5% of all cellular mRNAs are translated by a mechanism independent of the 5' cap structure^[27]. Most of these mRNAs are likely to contain an internal ribosome-entry site (IRES) in the 5' untranslated region (UTR), as the ability to maintain efficient translation without utilizing the 5' cap-dependent mechanism relies on the presence of one or several IRESs. IRESs are typically found in mRNAs that possess unusually long 5'UTRs, greater than -300 nt, which consequently have significant secondary structure^[28]. In eukaryotes, IRES-mediated translation bypasses the canonical initiation step by directly recruiting ribosomes to the start codon without the need for the 5' mRNA cap structure or the eukaryotic initiation

factor (eIF) complex^[28,29].

The eIF-4F complex is one of the key mediators of ribosome recruitment in cap-dependent translation and the eIF-4E subunit of this complex can be rate-limiting^[2]. Under normal cellular conditions, eIF-4E is bound to its binding protein 4E-BP1 and translation is limited by the availability of the unbound fraction of eIF-4E^[30]. When 4E-BP1 is phosphorylated, eIF-4E is released and becomes available to bind mRNA and participate in the eIF-4F complex. This phosphorylation is instigated by the downstream effects of various mitogenic pathways. Hypoxia, however, has the opposite effect, increasing the binding of eIF-4E with 4E-BP1, which may mediate the global decrease in protein synthesis seen in stressed cells^[31].

Several observations about the 5' UTR of VEGF mRNA led to the hypothesis that it may contain IRES elements. First, cap-dependent translation of VEGF is cumbersome because the 5' UTR (1038 bp in humans) is much longer than typical eukaryotic 5' UTRs (~300 nt) and does not allow efficient ribosomal scanning. Second, it has a high G+C content, predisposing it to form stable secondary structures. Third, the 5'UTR contains a short open reading frame with in-frame initiation and termination codons^[32]. Furthermore, in order to maximize its effect, translation of VEGF must be upregulated during periods of stress such as cellular hypoxia, when cap-dependent protein synthesis is globally inhibited.

In 1998, VEGF mRNA was shown to possess two IRES sites (IRES A and B) in the 5' UTR^[32-34]. IRES A is contained in a 293nt segment just upstream from the AUG codon and is believed to control translation initiated at the AUG codon^[35]. IRES B is contained in the early portion of the 5' UTR^[33]. These two sites appear to bind different proteins, and the cellular milieus in which each functions optimally are not well understood.

IRES-mediated translation *in vivo* and *in vitro* yields a distinct isoform of VEGF, called "Large VEGF" or "L-VEGF." Whereas initiation mediated by the 5' cap and IRES A is at the AUG start codon it shares with cap-dependent translation, the initiation of the L-VEGF isoform occurs at an upstream CUG start codon (nt 499) within the 5'UTR. The L-VEGF isoform contains an N-terminal extension of 180 a.a., which is cleaved to yield a C-terminal peptide that is nearly identical to VEGF 189. This N-terminal extension is highly conserved through human, bovine, and murine cells, but whether it has any function is unknown^[36].

Inquiry into the control of IRES A has uncovered a complex model of translational regulation. The five classic isoforms (excluding L-VEGF) are the translation products of five distinct mature mRNAs; each of these mature mRNAs is the product of alternative splicing of the transcription product or pre-mRNA. Bornes and colleagues have reported that differences in exon content of the differentially spliced mRNA can lead to preferential activity of one IRES or the other^[35].

Though it is becoming clear that the IRES mechanism in VEGF translation is a plausible pathway in normal physiology, it remains debatable whether this pathway plays a significant role in tumor angiogenesis. The controversy relies on the observation that there is a correlation

between eIF-4E and protein synthesis in malignancy. This correlation has been demonstrated in breast carcinomas, head and neck squamous cell carcinomas, soft tissue sarcomas, and colon carcinoma^[37-40], and is bolstered by the observation that cells that over-express eIF-4E increase secretion of VEGF by greater than 100-fold^[41]. Therefore, it is conceivable that VEGF production in transformed cells relies on the cap-dependent pathway as well, though this has not been definitively demonstrated.

Whether hypoxia is a sufficient stimulus to induce IRES activity, or if other mitogenic stimuli can trigger internal ribosomal entry remains unknown. In a study comparing the IRES elements of VEGF, hypoglycemia was seen to significantly activate IRES activity^[42]. In both transformed and benign cells, the balance between IRES and cap-dependent translation in VEGF requires further investigation.

Deranged expression of the *c-myc* oncogene is associated with many human malignancies, as its over-expression promotes cell growth and angiogenesis^[43]. This effect is in part due to the fact that *myc* over-expression increases secretion of VEGF^[44]. The mechanism behind this increase was recently described by Mezquita and colleagues^[45]. They demonstrated that *myc* interacts with VEGF mRNA to upregulate initiation of translation capable of bringing about a 10-fold increase in VEGF production. They observed no increase in eIF activity and attribute the translational upregulation to VEGF-specific increase of translation initiation, either through *c-myc* or VEGF directly.

Implications for Tumor Angiogenesis

In 1993, Kim and colleagues reported that anti-VEGF antibodies had a strong inhibitory effect on the growth of several tumor types in nude mice. Since then, anti-VEGF therapies to target angiogenesis have gained further attention. Investigators have reported inhibited tumor growth with other anti-VEGF applications including antisense nucleotides, anti-receptor antibodies, soluble VEGF receptors, and a retrovirus-delivered Flk-1 mutant.^[46-49] A recent phase three FDA trial demonstrated improved survival when patients with metastatic colorectal cancer were treated with a humanized monoclonal anti-VEGF antibody (bevacizumab) in combination with standard chemotherapy (irinotecan, 5-FU, and leucovorin), resulting in FDA approval. The FDA has also approved its use in non-small cell lung cancer. Bevacizumab is being tested in several other tumor models with and without adjunctive traditional chemotherapy agents.

Anti-angiogenic therapies have targeted the normal endothelial cell's ability to respond to angiogenic factors, either by primarily inhibiting endothelial cell proliferation or by using antibodies to prevent angiogenic factors from activating endothelial cells^[50]. However, some investigators have observed resistance to this therapy due to the ability of tumor cells to upregulate the expression of VEGF and thereby negate the anti-angiogenic effect^[51]. There is further evidence suggesting that high tumor levels of VEGF may promote tumor survival^[52].

One potential anti-angiogenic strategy is to silence gene expression of angiogenic factors at the mRNA level.

While antisense oligonucleotides have been used for this strategy, the high concentration required and non-specific effects have limited this approach. First described in *C. elegans*, RNA interference (RNAi) is a process in which double stranded RNA (dsRNA) is processed by the enzyme Dicer, resulting in short interfering RNAs (siRNA) 21-25 nucleotides in length^[53,54]. These siRNA molecules are incorporated into an RNA-induced silencing complex (RISC) that binds complementary target mRNAs, leading to their degradation^[55,56].

There is great potential for using RNAi technology in therapeutic applications that target critical signaling pathways involved in cancer, due to its high specificity for targeted genes and its potency at low concentrations. However, relatively few studies have examined the use of RNAi technology to suppress VEGF production.

In 2003, three reports proved the concept. Filleur and colleagues used a rat fibrosarcoma model and systemically delivered siRNA to achieve a 66% decrease in tumor size when compared to controls^[57]. Reich and colleagues used direct injection of anti-VEGF siRNA to decrease choroidal neovascularization in laser-induced retinal injury in the rat^[58]. A plasmid-based siRNA delivery system driven by a Pol III promoter was used by Zhang and colleagues to show isoform-specific knockdown of VEGF^[59].

These three experiments provided the conceptual basis for two further experiments to demonstrate the efficacy of RNAi inhibition of VEGF. In 2005, Yoon and colleagues injected HT1080 fibrosarcoma cells stably transfected with anti-vegfr siRNA into the subcutaneous tissue of rats. They reported substantial decrease in tumor volume and vessel density in resected specimens^[60]. In the same year, Kwon and colleagues described a bi-level approach to silencing VEGF. In their experiment, they combined zinc finger-mediated repression of transcription with RNAi technology to achieve knockdown of VEGF of over 90%^[61].

The critical problem with RNAi-based therapy is one of delivery. Whereas *in vitro* transfection of cells is easily accomplished using lipid-based solution, *in vivo* targeting of the siRNA molecules to cancer cells is far more challenging. Systemic delivery of naked siRNA is problematic as the drugs localize poorly and the degree of dilution is often unacceptable^[62]. Though synthetic vectors offer several advantages such as their relative safety and the ease of incorporating target-specific ligands, there are significant barriers to their effective use that have not yet been overcome^[63]. Viral vectors may offer specific advantages as well^[64].

CONCLUSION

Although much has been learned about VEGF since its discovery in 1989, much more remains to be understood. First, the relevance of hypoxic stabilization of VEGF mRNA must be established in the settings of both neoplasia and normal physiologic conditions. Does our current understanding of hypoxic stabilization provide a sufficient explanation with regard to tumor angiogenesis? Are there other mitogenic factors that can overwhelm the cell's innate response to hypoxia? Second, the balance between

cap-dependent and IRES-mediated translation must be elucidated. What are the factors that mitigate the switch from cap-dependent to IRES-mediated translation? Finally, it is clear that post-transcriptional regulation of VEGF has profound clinical implications with regard to targeting tumor angiogenesis. Will RNAi technology prove to be an efficacious therapeutic modality? If so, how will we deliver the drug to achieve a safe, durable, and clinically significant outcome? It will be a challenge for coming years to determine how best to exploit these molecular mechanisms for our patients' benefit.

Abstract

The term Hereditary Non-Polyposis Colorectal Cancer (HNPCC) is a poor descriptor of the syndrome described by Lynch. Over the last decade, the term has been applied to heterogeneous groups of families meeting limited clinical criteria, for example the Amsterdam criteria. It is now apparent that not all Amsterdam criteria-positive families have the Lynch syndrome. The term HNPCC has also been applied to clinical scenarios in which CRCs with DNA microsatellite instability are diagnosed but in which there is no vertical transmission of an altered DNA mismatch repair (MMR) gene. A term that has multiple, mutually incompatible meanings is highly problematic, particularly when it may influence the management of an individual family. The Lynch syndrome is best understood as a hereditary predisposition to malignancy that is explained by a germline mutation in a DNA MMR gene. The diagnosis does not depend in an absolute sense on any particular family pedigree structure or age of onset of malignancy. Families with a strong family history of colorectal cancer that do not have Lynch syndrome have been grouped as 'Familial Colorectal Cancer Type-X'. The first step in characterizing these cancer families is to distinguish them from Lynch syndrome. The term HNPCC no longer serves any useful purpose and should be phased out.

INTRODUCTION

A fundamental concept in the successful practice of medicine is the recognition of a disease as a distinct entity defined by a clearly recognizable set of clinico-pathological features. Only by recognizing and diagnosing a specific disease is it possible to develop and apply an effective policy of disease management. The recognition of a distinct clinico-pathological entity does not depend on a full understanding of the underlying etiology providing that the appearance and natural history of a disease are sufficiently characteristic to set it apart from all other diseases. Many forms of cancer would fall into this category. The same arguments apply to complex syndromes, though many of these are in fact explained on the basis of a specific and heritable genetic abnormality.

A good example of a hereditary cancer syndrome due to a single gene defect is the autosomal dominant condition familial adenomatous polyposis (FAP) caused by germline mutation of the tumor suppressor gene *APC*^[1]. For many years Henry Lynch and associates drew attention to a second form of familial colorectal cancer (CRC)^[2,3]. Initially, this was believed to encompass two separate syndromes. Lynch I syndrome (or Hereditary Site-Specific Colon Cancer) applied to families with colon cancer only, while Lynch II syndrome (or Cancer Family Syndrome) included families with extra-colonic malignancies in addition to colon cancer. In 1985 Lynch introduced the term 'hereditary non-polyposis colorectal cancer' (HNPCC) to encompass Lynch syndromes I and II^[4]. In 1991 there was further unification with the inclusion of the Muir-Torre syndrome (CRC with associated sebaceous neoplasms) within HNPCC^[5]. Lynch viewed HNPCC as a syndrome characterized by an autosomal dominant pattern of inheritance, early onset of malignancy with a predilection for the proximal colon, multiple CRCs, the absence of premonitory lesions (e.g. adenomas), and the occurrence of cancer in certain extracolonic sites, notably endometrium and ovary.

The concept of a second major form of familial CRC to rival FAP was received with general skepticism, being either ignored, dismissed as an exceedingly rare disease or the chance clustering of a common disease, or interpreted as the result of a shared environmental exposure^[6]. A breakthrough came with the publication of

a series of clinico-pathological investigations conducted in Finland that fully supported the observations of Lynch^[7,8]. It was also shown that CRCs associated with HNPCC had particular histological features^[9,10]. These included poor differentiation, abundant mucin secretion and marked lymphocytic infiltration. Additionally, CRCs developed within adenomas and it was inferred that HNPCC adenomas were more likely to undergo malignant transformation and within a shorter timeframe than conventional adenomas^[9,11,12].

By the 1990s, cancer family clinics and registries for hereditary malignancy were beginning to collect and describe families with the features identified by Lynch and others. In order to standardize clinical and basic research it was suggested in 1991 by the International Collaborative Group on HNPCC that families should only be described as having HNPCC if they met strict criteria, known as the Amsterdam criteria (Table 1)^[13]. Initially it was thought that the Amsterdam criteria would be highly specific for HNPCC. Nevertheless, the term HNPCC and the associated diagnostic criteria soon generated problems and confusion that have continued to this day.

THE TERM HNPCC

The term HNPCC implies a familial aggregation of CRC developing in the absence of polyps. However, patients with HNPCC have adenomas that may sometimes be multiple and frequently present with extra-colonic malignancy. For example, a patient with HNPCC could present with endometrial cancer, multiple adenomas and no family history of cancer. By restricting the Amsterdam criteria to CRC, it rapidly became evident that the criteria lacked sensitivity. The Amsterdam II criteria (Table 1) were developed to allow particular cancers that presented in extra-colonic sites to be substituted for colorectal cancer, notably of endometrium, small intestine and pelviureter^[14]. When the genetic mechanism underlying HNPCC was eventually discovered (see below) it became apparent that even the Amsterdam II criteria lacked sensitivity. Clinical definitions were therefore relaxed in a variety of ways in different geographical regions in order to avoid missed diagnoses^[15-18]. Indeed, single instances of HNPCC might be found as a consequence of new mutation, non-penetrance within small families, denial of family history, non-paternity, or adoption. These new definitions of HNPCC were not used merely to standardize research but were also employed as diagnostic tools for labeling families as having HNPCC. In summary, the term HNPCC was not only a misleading descriptor but came to encompass multiple clinical definitions while nevertheless being applied to families as a specific diagnostic label.

DNA MISMATCH REPAIR

In 1993, soon after the introduction of the Amsterdam criteria, the underlying mechanism for HNPCC was discovered. Most examples were shown to be caused by germline mutation in one of two DNA mismatch repair (MMR) genes: *MSH2* or *MLH1*^[19-22]. *MSH6* was implicated less frequently but showed a stronger association with

Table 1 Amsterdam I and II criteria and Bethesda (revised) guidelines

Term	Criteria	Reference
Amsterdam I ¹	Three 1 st degree relatives with CRC Two generations affected One family member below age 50 yr Exclude familial adenomatous polyposis	Vasen <i>et al</i> , 1991 ^[13]
Amsterdam II ¹	As for Amsterdam I except that CRC may be substituted by cancer of endometrium, small bowel, or pelviureter	Vasen <i>et al</i> , 1999 ^[14]
Bethesda (revised) ²		Umar <i>et al</i> , 2004 ^[44]
1	CRC below age 50 yr	
2	Multiple CRC or HNPCC-related cancers ³	
3	CRC with MSI-related histology ⁴ , < 60 yr	
4	CRC or HNPCC-related cancer in at least one 1 st degree relative, < 50 yr	
5	CRC or HNPCC-related cancer in at least two 1 st or 2 nd degree relatives, any age	

¹All criteria must be met; ²Any criterion (1-5) can be met; ³Includes cancer of endometrium, small bowel, pelviureter, biliary tract, stomach, ovary, pancreas, and brain (mainly glioblastoma multiforme); ⁴Tumor infiltrating lymphocytes, Crohn-like reaction, mucin/signet ring cell differentiation, medullary growth pattern.

endometrial cancer^[23]. The MMR genes were shown to be tumor suppressor genes. Following inactivation of the wild-type allele, MMR proteins would no longer be expressed resulting in a failure to repair DNA mismatches occurring as spontaneous errors during DNA replication^[24]. This failure applied most particularly within non-encoding tracts of repetitive DNA called microsatellites but could also disrupt tumor suppressor genes with short repetitive tracts within their encoding regions, for example (and in decreasing order of frequency) *ACVR2*, *PTHLH*, *TGFbetaRII*, *MARCKS*, *MSH3*, *TCF4*, *RAD50*, *CASP5*, *BAX*, *RIZ*, *MBD4*, *MSH6*, *BLM*, *IGF2R*, *PTEN*, *AXIN2*, *WISP3* and *CDX2*^[25]. Deficiency of MMR therefore resulted in the distinct phenotype described as the mutator phenotype or, more specifically, as DNA microsatellite instability (MSI)^[26,27].

In addition, therefore, to its distinctive clinico-pathological features, the diagnosis of HNPCC could now also be suggested through the demonstration of DNA MSI and/or through the loss of expression of DNA MMR proteins, once monoclonal antibodies to these proteins became commercially available^[28,29]. The corollary that MMR deficiency was a specific biomarker for the syndrome was not however correct^[30]. This is because one of the DNA MMR genes, namely *MLH1*, may be inactivated through hypermethylation of its promoter region^[31]. Through this acquired epigenetic mechanism most CRCs with MSI present sporadically and not as a result of a germline mutation. Nevertheless, in families with the clinico-pathological features of HNPCC, the demonstration of MMR deficiency in one or more tumors is a very strong indicator of a germline mutation in a MMR gene (though not 100% specific, see below). In

summary, it was now possible to precisely demarcate and therefore diagnose HNPCC on the basis of the distinctive combination of clinical, pathological and molecular phenotype.

LACK OF SPECIFICITY OF CLINICAL CRITERIA FOR HNPCC

It was initially assumed that the Amsterdam criteria would be highly specific but not necessarily sensitive for HNPCC. However, the advent of testing for MSI showed that this assumption was not correct. In families meeting the Amsterdam criteria but in which CRCs did not show evidence of MSI, the classical clinical and pathological features of HNPCC were lacking^[32]. Compared with Amsterdam criteria families in which CRCs showed MSI, the non-MSI-positive families comprised fewer affected subjects and CRCs were less likely to be proximally located, show mucinous or poor differentiation, be associated with positive lymph nodes, or have diploid DNA content^[32]. CRCs were also less likely to be multiple or to present at a young age^[32]. Additionally, when subjects from non-MSI-positive families were colonoscoped, they were more likely to have adenomas but the adenomas were less likely to be advanced than in MSI-positive families^[33]. Despite these different clinicopathological findings, families continued to be diagnosed as having HNPCC merely on the basis of meeting the Amsterdam or similar clinical criteria^[34-36].

At this point the question arises whether the term 'HNPCC' is the most appropriate label for a specific hereditary cancer syndrome caused by a germline mutation in a DNA MMR gene. Henceforth, for the purposes of this discussion and in accordance with a recent suggestion^[6], the term 'Lynch syndrome' will be applied to the specific form of hereditary malignancy caused by germline mutation of a DNA mismatch repair gene. The term 'HNPCC' will be used merely to indicate that certain clinical criteria suggestive of a hereditary basis for CRC (excluding FAP) have been met. Families meeting one of the several clinical definitions of HNPCC may or may not have Lynch syndrome. There are three reasons why families may meet the Amsterdam criteria and yet not have the Lynch syndrome. In the first place, CRC is a common disease. Within a large sibship the finding of two affected siblings and one parent with CRC could occur by chance, even when one subject was diagnosed with CRC at the age of 49 years. Indeed, one would be appropriately skeptical of the diagnosis of Lynch syndrome if the other two affected subjects were diagnosed in their seventies or eighties. The labeling of a family with the diagnosis of Lynch syndrome on the basis of the preceding findings would be unwise, even though no 'rule' is being broken. A second reason is the possible clustering of low- or intermediate-risk genes within a family. The third reason is the possibility of family clusters occurring through known (e.g. attenuated FAP^[37] or *MYH* polyposis^[38]) or unknown high-risk genes. Although the lack of specificity of the Amsterdam criteria was first mooted in 1995^[32], recognition that families meeting the criteria are clinically heterogeneous has come about only comparatively

recently. For example, four recent studies have highlighted the lack of features of Lynch syndrome in Amsterdam criteria positive families that lack evidence of DNA MMR deficiency^[39-42]. Features of particular note are the older age of onset of CRC, the reduced penetrance among relatives, the lack of predilection for the proximal colon, the lack of lymphocytic infiltration, the lack of extra-colonic malignancies, and the higher frequency of colorectal adenoma^[39-42].

DIAGNOSIS AND MANAGEMENT OF LYNCH SYNDROME

The discussion above has outlined how over the last decade the Amsterdam or similar clinical criteria have often been the mainstay in reaching a purported diagnosis of Lynch syndrome. While larger, multi-case families with the classical spectrum of early onset colorectal and extra-colonic malignancies were probably diagnosed correctly in most cases using this approach, the diagnosis is less likely to have been correct in families meeting only the minimum set of clinical criteria. The effective management of Lynch syndrome includes informing and counseling affected and at-risk subjects, but this can only happen after the correct diagnosis has been reached and not before. Fortunately, a reliable working diagnosis of Lynch syndrome can usually be reached through the analysis of tissue samples prior to the discovery of a pathogenic germline mutation. Apart from confirming the diagnosis of cancer, evaluation of tissue samples provides both morphological and molecular evidence of tumorigenesis driven by defective DNA mismatch repair, the molecular hallmark of Lynch syndrome. The use of immuno-histochemistry to detect loss of expression of DNA MMR proteins can even identify the likely genetic cause and thereby simplify the ultimate diagnostic step of genetic screening^[28,29].

As noted above, the Amsterdam criteria were established to provide a standard definition of HNPCC presenting within the setting of high-risk cancer family clinics and registries. The Bethesda guidelines were developed as a guide for testing MMR status in CRCs that presented in the population setting (Table 1)^[43,44]. Family history, age at onset of malignancy, and pathology features were utilized as independent markers and in a way that would not only identify new cases of possible Lynch syndrome but would also exclude late-onset CRCs with MSI. The latter would in most instances be sporadic MSI-positive CRCs explicable by age-related methylation of *MLH1*. On this basis, the utilization of the Bethesda guidelines in order to diagnose Lynch syndrome should be more sensitive than the Amsterdam criteria and, through the inclusion of MMR testing within the algorithm, more specific^[45,46].

The Bethesda guidelines highlight the importance of pathology review. This has not always been used in achieving a diagnosis of Lynch syndrome despite the fact that the attempt to arrive at an exclusively clinical definition of Lynch syndrome has been described as a 'search for the impossible'^[47]. There are three reasons for this over-reliance on limited clinical features: (1) The Amsterdam criteria were initially thought to be highly stringent and

therefore specific for Lynch syndrome, (2) It is easier and cheaper to reach the diagnosis using clinical features alone, and (3) It has been argued that both MSI testing and immuno-histochemistry are genetic tests that should not be undertaken without the consent of the patient. With respect to the last, MSI testing and immuno-histochemistry are diagnostic tests capable of demonstrating an acquired and tumor-specific alteration that is indicative of but not conclusive with respect to germline status. Mismatch repair deficiency may be acquired exclusively at the somatic level, for example through methylation of a DNA mismatch repair gene (see above). Like all diagnostic tests of tumor phenotype, the results of MSI testing do not stand alone but must be interpreted in the light of all the available clinical and pathological features.

Because the term HNPCC was introduced as an alternative to the eponymous Lynch syndrome before that condition was fully characterized and explained on the basis of a set of genes with closely related function, it came to be applied in an overly broad sense to any form of CRC that appeared to be inherited but was not FAP (or the other rarer precancerous polyposes). However, it is not possible to use a term that has different and mutually exclusive meanings without generating confusion. The following two sections describe additional scenarios in which the term HNPCC (implying Lynch syndrome) has been used inappropriately.

GERMLINE HEMI-ALLELIC METHYLATION OF *MLH1*

Extrapolating from the Bethesda guidelines (see above), an early-onset CRC that shows MSI is likely to occur in the setting of Lynch syndrome. In 2002, Gazzoli *et al* identified an early onset CRC in which one *MLH1* allele showed methylation^[48]. Intriguingly, the same allele was also methylated in the subject's lymphocytes. By elegantly exploiting the existence of a common polymorphism in the promoter region of *MLH1*, Gazzoli *et al* were able to show that the second or wild-type *MLH1* allele had been lost in the CRC. They therefore introduced the concept of germline hemi-allelic methylation of *MLH1* as a cause of HNPCC^[48]. However, they were skeptical of the possibility that a methylated allele could be transmitted vertically from an affected subject to offspring and suggested that the phenomenon was both rare and sporadic. Miyakura *et al* discovered four additional examples of early onset MSI-positive CRC associated with germline hemi-allelic methylation of *MLH1*^[49]. Although the patients were ascertained through cancer family clinics they did not have family histories suggestive of Lynch syndrome. They were merely young and some were affected with multiple tumors consistent with Lynch syndrome. Again, Miyakura *et al* did not infer that germline hemi-allelic methylation of *MLH1* could be transmitted vertically^[49].

Suter *et al* arrived at a different conclusion with respect to germline hemi-allelic methylation of *MLH1* (which they termed 'epimutation')^[50]. They documented two additional subjects carrying an *MLH1* epimutation who also met clinical criteria indicative of a diagnosis of

HNPCC. Additionally, the epimutation was present in spermatozoa of one of the affected subjects. The latter finding was not only consistent with a germline defect but also provided evidence for transmission of the defect to offspring. The authors therefore advanced the concept of *MLH1* epimutation as a new cause of HNPCC (implying Lynch syndrome) in which there was vertical transmission of a methylated *MLH1* allele^[50]. Nevertheless, it may be questioned if epimutations can in fact be inherited. While germline hemi-allelic methylation was indeed demonstrated in single members of two families that met certain clinical criteria for HNPCC, this is hardly surprising since the search for the epimutation was conducted exclusively in members of families registered in cancer family clinics. This ascertainment bias aside, it is now abundantly clear (see discussion above) that when a family happens to meet a particular clinical definition of HNPCC this does not automatically prove the existence of a heritable cause of cancer that is due to an altered DNA MMR gene^[32,39-42]. It is true that one of the affected subjects showed methylation of *MLH1* within spermatozoa, but this was in less than 1% of spermatozoa^[50]. Even if such a sperm succeeded in fertilizing an ovum, subsequent clearance of methylation during early embryogenesis would negate the effects of vertical transmission of the affected allele.

The same authors who advanced the concept of the heritability of *MLH1* epimutation subsequently demonstrated the *de novo* origin of germline hemi-allelic methylation of *MLH1* in a male subject who was shown to have inherited the methylated allele from his mother in whom the same allele was not methylated^[51]. These authors nevertheless continued to claim that *MLH1* epimutation was 'weakly' heritable^[51]. The fact that genetic alterations may be passed from parent to child and result in syndromes of familial cancer associated with early onset of disease and multiple neoplasia is a dismal truth for affected families and presents multiple problems with respect to the provision of medical solutions that are ethical, compassionate and effective. Therefore, the labeling of a form of cancer as heritable should be backed up by good evidence. The existing evidence does not support the heritability of germline hemi-allelic methylation of *MLH1*.

SERRATED POLYPS, DNA METHYLATION AND HNPCC

In 1997 a family was described as having HNPCC but did not meet the Amsterdam I or II criteria^[52]. There were four siblings in a sibship of six with a total of eight CRCs between them. The initial CRCs presented at the ages of 44, 27, 44 and 55 years (eldest to youngest sibling respectively) and an offspring of the second eldest developed a gastric cancer at the age of 29 years. Gastric cancer is linked to Lynch syndrome but is not included in the Amsterdam II criteria. MSI testing using four markers was initially performed on the CRCs from the eldest and third eldest siblings and all four markers were unstable in both CRCs^[52]. Overall, therefore, the features were consistent with a diagnosis of Lynch syndrome. Only one of the colectomy specimens, a right

hemicolectomy performed on the youngest sibling for two metachronous CRCs, was available for detailed study at the time of surgery. The pathology was atypical for Lynch syndrome insofar as there were five tubular adenomas, seven hyperplastic polyps and seven mixed polyps. The hyperplastic polyps and mixed polyps were noted to be larger than the adenomas^[52]. In retrospect, the correct diagnosis would now be hyperplastic polyposis^[53]. The smaller CRC showed conspicuous lymphocytic infiltration, instability at three of three microsatellite markers, and was arising from a mixed polyp. The large CRC was mucinous and showed instability at two of three microsatellite markers. One of the offspring of this subject had developed a tubulovillous adenoma and two hyperplastic polyps at around the age of 40 years and a second was found to have multiple hyperplastic polyps after the report was published. Overall, it was inferred that this family had Lynch syndrome but that there was a modifying genetic factor in the youngest sibling giving an unusual phenotype^[52]. Nevertheless, no germline mutation in a DNA mismatch repair gene has been found in this family.

Now, in retrospect, it is possible to suggest a simpler and more plausible mechanism underlying this Lynch syndrome-like family. In 2005, a paper described a series of eleven Lynch syndrome-like families in which some CRCs were MSI-high but others had low-level MSI or were microsatellite stable (MSS)^[54]. A more consistent finding across the CRCs and polyps in these 'MSI-variable' families was mutation of the oncogene *BRAF* and methylation of *MINT31*^[54]. In addition, many subjects had advanced serrated polyps and two had hyperplastic polyposis. Based on these observations it was suggested that an inherited predisposition to acquired DNA methylation within somatic tissues could give rise to a 'serrated pathway syndrome'^[54]. Should *MLH1* be implicated then one might observe the development of CRCs that were MSI-high. This would only apply to a subset of CRCs, but could by chance, as in the case of the family described in 1997^[52], affect all CRCs tested within a single family.

What is the evidence for an inherited predisposition to CRCs with DNA methylation? In a family cancer clinic-based study that excluded families with the Lynch syndrome, subjects with CRCs showing the CpG island methylator phenotype (CIMP) had a 13-fold increased risk of having a first degree relative with cancer (not necessarily CRC) as compared with subjects without CIMP-positive CRC^[55]. A hospital-based study could not confirm this finding but removed families meeting a clinical definition for HNPCC^[56]. The latter exclusion clearly introduced a major bias since not all families meeting a clinical definition for HNPCC in fact carry a germline defect in a DNA MMR gene (see above). This is another example of how a loose definition of HNPCC can be confounding.

An inherent difficulty in establishing whether genetic factors may explain CIMP is the lack of an agreed definition of CIMP. It is clear, however, that mutation of *BRAF* co-segregates with extensive CIMP and may therefore be used as a surrogate for high-level CIMP. In a large population-based study, CRCs were stratified on the basis of *BRAF* mutation and DNA MSI status^[57]. In the larger subset of MSS CRCs, the odds ratio for having a

positive family for subjects with *BRAF* mutation-positive CRCs was 4.23 (95% CI = 1.65-10.84) (as compared with subjects with *BRAF* mutation-negative CRCs). The same finding was not observed in patients with MSI-high CRCs^[57]. However, this is not surprising since the subjects with MSI-high CRCs that lacked *BRAF* mutation were relatively young and many would be expected to have Lynch syndrome.

In summary, it is likely that genetic mechanisms will be found to at least partially explain the evolution of CIMP-positive CRCs and to account for a subset of families that may mimic Lynch syndrome but in whom both colorectal polyps and cancers show extensive DNA methylation and frequent mutation of *BRAF*.

LYNCH SYNDROME VARIANTS

The more clearly one defines Lynch syndrome, the simpler it becomes to distinguish the syndrome from clinical scenarios that provide close mimicry. In the preceding two sections we encountered different clinical situations in which there was diagnosis of CRCs with DNA MSI and an inappropriate label of HNPCC. The essential feature of Lynch syndrome is that it is a *hereditary* disorder that is explained by a *germline mutation in a DNA MMR gene*. DNA MSI is a useful diagnostic hallmark but is not requisite for the diagnosis. Some mutations in DNA MMR repair genes may be tumorigenic but may not result in the mutator phenotype^[58]. DNA MMR repair genes are multifunctional and certain mutations may be deleterious because they disrupt cell-cycle checkpoint control and/or apoptosis^[59]. These variants may be associated with lower penetrance and a milder clinical phenotype but should probably be regarded as variants of Lynch syndrome. Mutations in the DNA MMR gene *PMS2* may result in a syndrome that is inherited as an autosomal recessive trait^[60]. The combination of very early onset malignancy involving brain, colon and other sites has been described as Turcot syndrome and linked with bi-allelic mutation of *PMS2* in a small number of families^[60,61]. Drawing a distinction between Turcot syndrome and Lynch syndrome becomes difficult given the fact that *PMS2* mutation has also been linked with autosomal dominant patterns of inheritance^[62,63] while certain *MLH1*, *MSH2* and *MSH6* mutations may give rise to an autosomal recessive trait^[61,64]. Individuals with homozygous MMR gene mutations may show features of neurofibromatosis with café-au-lait spots. This has been associated with somatic mutation of the neurofibromatosis type-1 gene^[65]. The preceding examples could be considered as variants of Lynch syndrome. However, clinical scenarios in which CRCs with MMR deficiency occur in the absence of a vertically transmissible genetic alteration in a MMR gene should not be termed Lynch syndrome.

CONCLUSION

The term HNPCC is a poor descriptor of the syndrome described by Lynch. Over the last decade, the term has been applied as a specific diagnostic label to families meeting a multiplicity of clinical criteria. A subset of

Table 2 Conditions and clinical scenarios that may mimic Lynch syndrome

Attenuated Familial Adenomatous Polyposis ^[37] (polyps may not be numerous)
MYH polyposis ^[38] (polyps may not be numerous)
Juvenile polyposis ^[66] (polyps may not be numerous and may be adenomatous)
Germline mutation of <i>TGFβRII</i> ^[67] and <i>AXIN2</i> ^[68] (is not associated with DNA MSI)
Hereditary mixed polyposis syndrome ^[69] (polyps may not be numerous and may be adenomatous)
Hyperplastic polyposis ^[53] (polyps may not be numerous and may be adenomatous)
Serrated Pathway Syndrome ^[54] (polyps may not be numerous and may be adenomatous and CRCs may show DNA MSI)
Germline hemi-allelic methylation of <i>MLH1</i> ^[48-51] (multiple, early onset cancers with Lynch syndrome spectrum and having DNA MSI)
Lynch syndrome variants ^[61,65] (autosomal recessive Turcot syndrome due to <i>PMS2</i> mutation)
Familial Colorectal Cancer-Type X ^[40] (Amsterdam criteria met but Lynch syndrome and conditions listed above have been excluded)

these families will not carry a germline mutation in DNA MMR gene and will not show the clinical and pathological phenotype associated with the Lynch syndrome. Such families may meet or even exceed the Amsterdam criteria despite lacking evidence for a germline defect in a DNA mismatch repair gene. It has been suggested that these families be grouped as 'Familial Colorectal Cancer Type-X'^[40]. The term HNPCC has also been applied to clinical scenarios in which CRCs with DNA MSI are diagnosed but in which there is no vertical transmission of an altered DNA MMR gene. A diagnostic term that has multiple mutually incompatible meanings is problematic. This becomes particularly evident when extrapolating from a diagnostic label to the management of an individual family.

The Lynch syndrome is best understood as a *hereditary predisposition to malignancy* that is explained by a *germline mutation in a DNA MMR gene*. The diagnosis does not depend in an absolute sense on any particular family pedigree structure or age of onset of malignancy. If present, these are merely useful clinical pointers that have been accorded undue importance when considered in isolation of other facts. No simple set of clinical criteria can serve as a diagnostic label for Lynch syndrome. At the same time, the careful appraisal of clinical, pathological and molecular features can achieve an accurate working diagnosis prior to the demonstration of a pathogenic germline mutation in a DNA mismatch repair gene. To paraphrase a recent recommendation with respect to the term HNPCC: 'Clarification of the genetic basis and full phenotypic expression of this disease mandates a more clinically useful name that gives consideration to non-colonic cancers and unifies the diagnosis around germline mutation in a DNA MMR gene. The term Lynch syndrome is proposed for the autosomal dominant disease caused by a germline mutation in a DNA MMR gene'^[6]. However, in adopting the term Lynch syndrome in place of HNPCC one must also distinguish Lynch syndrome from the numerous clinical scenarios that give rise to close mimicry. By separating and naming these clinical

entities (Table 2) one can begin to undo the considerable confusion that has been generated by the arbitrary use of the imprecise term HNPCC.

Abstract

Hepatic stimulator substance (HSS) has been referred to as a liver-specific but species non-specific growth factor. Gradient purification and sequence analysis of HSS protein indicated that it contained the augmenter of liver regeneration (ALR), also known as hepatopoietin (HPO). ALR, acting as a hepatotrophic growth factor, specifically stimulated proliferation of cultured hepatocytes as well as hepatoma cells *in vitro*, promoted liver regeneration and recovery of damaged hepatocytes and rescued acute hepatic failure *in vivo*. ALR belongs to the new Erv1/Alr protein family, members of which are found in lower and higher eukaryotes from yeast to man and even in some double-stranded DNA viruses. The present review article focuses on the molecular biology of ALR, examining the ALR gene and its expression from yeast to man and the biological function of ALR protein. ALR protein seems to be non-liver-specific as was previously believed, increasing the necessity to extend research on mammalian ALR protein in different tissues, organs and developmental stages in conditions of normal and abnormal cellular growth.

INTRODUCTION

In 1975, La Brecque and Pesch first referred to the existence of a polypeptide, named hepatic stimulator substance (HSS), in the liver cytosol of weanling or adult partially hepatectomized rats^[1]. HSS was able to specifically stimulate hepatocyte proliferation and support liver regeneration in an organ specific but species non-specific manner^[1-2]. Since then a number of studies examined HSS levels of toxicity on animal models of liver regeneration after partial hepatectomy and post induced liver injury *in vivo*^[3,4] and *in vitro*^[5]. Subsequently, the effect of this growth factor in acute^[6-11] and chronic^[12] liver injury and decreased hepatocyte proliferative capacity^[13,14] has been reported in different animal models. A novel growth factor, obtained through progressive purification (831 000x) of the crude HSS extract, was named Augmenter of Liver Regeneration (ALR)^[15-20]. ALR, as well as HSS, did not affect quiescent hepatocytes but enhanced the liver proliferative response to hepatectomy in rats^[1,16,21] and dogs^[22] and prevented atrophy increased cell renewal caused by portacaval shunt (Eck's fistula) in dogs^[23,24]. ALR recently has been the subject of intense investigation. Several different approaches have led to the identification of the respective genes from yeast, rat, mouse, and human. This review deals with the molecular biology of ALR, examining cloning of the ALR gene and its protein product from yeast to man. The biological function of this protein product is also described.

ALR GENE AND PROTEIN FROM YEAST TO MAN

Yeast scERV1

The yeast scERV1 gene was the first and best-characterized gene of a new family found in a large number of lower and higher eukaryotes^[25-28] and in the genome of some double-stranded DNA viruses^[29-31]. This gene encodes a small protein of 189 amino acids (22 ku) having a complex influence on different aspects of mitochondrial biogenesis^[32-34] and is essential for the survival of yeast^[28]. Further studies have shown that the protein (Erv1p) was essential for normal mitochondrial morphology and for the stable maintenance of these organelles. In addition, Erv1p was identified as the first FAD-linked sulfhydryl oxidase from yeast^[34]. The enzymatic activity was located at the 15 ku carboxy-terminal domain of the Erv1p with the conserved Cys-X-X-Cys sequence motif (CXXC motif). This frag-

ment was able to bind FAD and to catalyze the formation of disulfide bonds but was no longer able to form dimers like the complete protein^[35]. Last but not least, analysis of the complete genome sequence from *S. cerevisiae* revealed a second yeast gene with homologies and structural similarities to scERV1. This gene was termed scERV2. Its protein product (Erv2p) had a length of 196 amino acids and exhibited 30% identical amino acid residues with Erv1p in the highly conserved carboxy-terminal part of the polypeptides. However, the complex expression pattern and the high degree of variability found in the amino-terminal regions of the scERV1 and scERV2 proteins, as well as the differences found between them, indicated that the gene products might have diverse functions at different locations and critical times of cellular development^[30].

Rat ALR

Hagiya *et al* in 1994, first discovered and cloned ALR in rat and then in human and mouse, proposing also its identity with HSS or hepatopoietin (HPO)^[25]. They cloned and sequenced the rat ALR gene, which was considered to encode rat HSS^[25]. They also presented evidence that ALR protein (Alrp) was acting as a homodimer and reported that the expression of the 1.2 kb gene transcript was elevated in rat testis and liver. The 1.2 kb cDNA included a 299 bp 5' untranslated region, a 375 bp coding region and a 550 bp 3' untranslated one. The rat Alrp consisted of 125 amino acids and its molecular weight was calculated to be 15 ku, which is consistent with its electrophoretically determined molecular weight under reducing conditions. The molecular weight of the purified native Alrp was calculated to be 30 ku under nonreducing conditions. The 125 amino acid sequence deduced from the rat ALR cDNA presented as 50% homologous to the polypeptide encoded by the scERV1, which is essential for oxidative phosphorylation, vegetative growth and life of the yeast *S. cerevisiae*^[25]. The same investigators, in supplementary experiments, found a single nucleotide (G) insertion at cDNA position 266, which did not alter the results of recombinant Alrp of 125 amino acids that was originally identified. On the other hand, additional G engendered two other in-frame ATG initiation sites, which were 5' to the initiation site of the Alrp they had previously reported, thus raising the possibility of additional ALR variants^[36]. Furthermore, the cloning and sequence analysis of rat genomic DNA of ALR revealed that the gene consisted of 3 exons and 2 introns and was 1508 nt long^[37]. An ALR pseudogene was also found in the rat genome, implying the existence of an ALR multigene family. The length of the pseudogene was calculated to be 442 nt^[37]. The amino acid sequence homology between the rat ALR and its pseudogene proved to be 88.8%^[38]. The crystal structure of recombinant rat Alrp has been determined to 1.8 Å. The structure revealed a unique FAD binding motif, a region containing side chain rings in a stacked parallel orientation, as has recently been reported in Erv2p, and an extensive salt bridges network being unique to ALR. The abundance of disulfide and salt bridges provides the Alrp molecule with a rigid structure and probably accounts for Alrp's thermostability and resistance to some denaturants^[39].

Mouse ALR

The mouse ALR gene was cloned and characterized by Giorda *et al* in 1996^[26]. It was shown that the protein coding portion of the mouse ALR gene contained 3 exons. The first of them consisted of the 5' untranslated sequence and the initial 18 bases after the ATG translation initiation codon. The second exon contained 198 bases and the third one consisted of the remaining portion of the protein coding sequence. Moreover, the ALR gene mapped to mouse chromosome 17, in a region syntenic with human chromosome 16^[26].

Human ALR

Giorda *et al* also published the cDNA sequence of human ALR^[26]. At the same time, Yang *et al* cloned the cDNA of human HPO by functional screening of a fetal liver cDNA library demonstrating that human HPO was identical to human ALR^[40]. The cDNA of human ALR encoding 125 amino acids presented identity of 87% with rat ALR and of 42% to yeast scERV1^[40]. The human ALR gene was located on chromosome 16, at the cytogenetic band 16p13.3-p13.12, in the interval containing the locus for polycystic kidney disease (PKD1)^[27]. The cloning and sequence analysis of human ALR genomic DNA revealed that it consisted of 3 exons and 2 introns. It was 1813 nt long, coding a protein of 125 amino acid residues. A comparison of human and mouse genomic DNA demonstrated that the 3 exons were similar in length but different in their 5'-UTR, introns and 3'-UTR in length^[41,42]. Lu *et al* isolated a variant of ALR from hepatic-derived cells with a length of 205 amino acids, characterizing a novel isoform of HPO cDNA encoding a 205 amino acid open reading frame (ORF). This was named HPO-205 to distinguish it from the previously described HPO, which lacked the N-terminal 80 amino acids^[43].

Therefore, two forms of the human Alrp were found to be present in hepatocytes. The shorter protein consisted of 125 amino acids (15 ku) and lacked the amino terminus and the longer protein had 205 amino acids (23 ku). The 15 ku of Alrp existed only in the nucleus and the 23 ku Alrp was mainly located in the cytosol, probably because they are synthesized from the same mRNA using different initiation codons^[44]. Moreover, under normal conditions, the full-length 23 ku mammalian Alrp is predominant and localized in the mitochondrial intermembrane space^[45]. As a result, ALR could be dimerized at a protein level and its gene could be alternatively spliced at the transcriptional level. Both might contribute to the existence of various Alrp complexes in hepatocytes^[44].

Recent studies reported successfully cloning the genes encoding proteins that interact with Alrp, such as metallothionein and albumin, which might be related to the transportation process of Alrp in the circulation. Selenoprotein-P, an anti-oxidant protein, might also be related to Alrp function, as well as other ALR-binding proteins, such elongation factor 1- α , transitional endoplasmic reticulum ATPase, carboxypeptidase N 83 ku chain, complete factor H related 3, and NADP dehydrogenase, which are known to play important roles in energy metabolism^[46].

Table 1 Augmenter of liver regeneration from yeast to man

	Homo Sapiens (Human)	Mus Musculus (Mouse)	Rattus Norvegicus (Rat)	Saccharomyces cerevisiae (Yeast)
Description	Augmenter of liver regeneration (ALR)/growth factor, erv1 (<i>S. cerevisiae</i>)-like (augmenter of liver regeneration) (GFER)/hepatic regenerative stimulation substance (HSS)/hepatopoietin (HPO)	Augmenter of liver regeneration (Alr)/growth factor, erv1 (<i>S. cerevisiae</i>)-like (augmenter of liver regeneration) (Gfer)	Augmenter of liver regeneration (ALR)/growth factor, erv1 (<i>S. cerevisiae</i>)-like (augmenter of liver regeneration) (Gfer)	<i>Saccharomyces cerevisiae</i> ERV1 (scERV1)/flavin-linked sulfhydryl oxidase localized to the mitochondrial intermembrane space, has a role in the maturation of cytosolic iron-sulphur proteins; ortholog of human hepatopoietin (ALR)
Genomic Location	Chromosome: 16 Cytogenetic: 16p13.3-p13.12	Chromosome: 17 Cytogenetic: 17 A3.3	Chromosome: 10 Cytogenetic: 10q12 Genetic: 17 10.0 cM	Chromosome: VII
Peptide Length	205 aa (23 ku) 125 aa (15 ku)	198 aa	125 aa (15 ku)	189 aa (22 ku)
Protein Function	In liver regeneration and spermatogenesis	In liver regeneration and spermatogenesis	In liver regeneration and spermatogenesis	Essential for the biogenesis of mitochondria, cell viability and for vegetative growth
Protein Subunit	Homodimer/Heterodimer	Homodimer	Homodimer	Homodimer
Protein Similarity	Belongs to ERV1/ALR family	Belongs to ERV1/ALR family	Belongs to ERV1/ALR family	Belongs to ERV1/ALR family
Percentage of similarity to human		85.6% [The comparison with human is based on nucleic acid (GeneCard for GFER)] 87.20% [The comparison with human is based on amino acid sequence (UniGene)]	85.87% [The comparison with human is based on nucleic acid (GeneCard for GFER)] 85.60% [The comparison with human is based on amino acid sequence (UniGene)]	52.85% [The comparison with human is based on nucleic acid (GeneCard for GFER)] 46.85% [The comparison with human is based on amino acid sequence (UniGene)]
Subcellular Location	Nucleus (15 ku) Cytosol (23 ku) Mitochondrial intermembrane space (23 ku)	Mitochondrial intermembrane space	Cytosol Mitochondrial intermembrane space	Cytosol Mitochondrial intermembrane space

The ALR gene promoter has also been studied and might represent a novel architecture for core promoters. It was TATA-less and spanned position -54 to +42 relative to the transcriptional start point. Specifically, it did not contain the TATA box, a consensus A/T rich sequence [TATA (A/T) A (A/T)], which was located -25-30 nucleotides upstream of the transcriptional start site and was recognized by the TATA binding protein subunit of TFIID. TFIID is a transcription factor that was needed to bring about the initiation of transcription by RNA polymerase II and nucleated the formation of the pre-initiation complex. In addition, the core promoter of ALR consisted of a functional initiator (Inr) and three CTGGAGGC tandem repeat elements, which were found surrounding the Inr, with all of them participating in Inr-dependent transcription. The Inr contains a pyrimidine (Y) rich core sequence [YYA+1N (T/A) YY] encompassing the transcription site. The initiator flanking element, lying either upstream or downstream from the Inr, was found to be present in many Inr-containing genes. Both the initiator and at least one of the repeats were able to bind to specific nuclear factors^[47].

The similarities and differences between the structure and function of the ALR gene and its protein product in the four most important and closely related species (yeast, mouse, rat and human) are displayed in Table 1.

BIOLOGICAL FUNCTION OF ALRP

Characterization of human Alrp as a structural and functional homologue for yeast Erv1p

Alrp and Erv1p belong to a protein family, members of which are found in lower and higher eukaryotes from yeast to man^[25-28] and even on the genome of some double-stranded DNA viruses^[29-31]. They have essential functions in the biogenesis of mitochondria, the cell division cycle, and in the development of organs such as liver and testis in higher eukaryotes^[48]. The carboxy terminus of the human Alrp was characterized as a structural and functional homologue for yeast Erv1p^[27]. Especially, Lisowsky *et al* found four major similarities at the amino acid residues of carboxy termini of Erv1p and human Alrp, concluding a conservation of structure and function^[27]. However, Hofhaus *et al* showed that the conserved carboxy terminus of mammalian and yeast proteins were functionally interchangeable between distantly related species such as yeast and man^[49]. On the other hand, the amino terminal parts of the proteins displayed a high degree of variability and significant differences even among closely related species^[49]. Specifically, Hofhaus *et al* first revealed that the yeast protein contained a leader sequence for mitochondrial localization whereas the human protein is not detectable inside the mitochondria. Moreover, they noted that, in yeast only, one form of scERV1 was found

whereas in human cells two protein isoforms were present. Therefore, these two significant differences in the amino termini between Erv1p and human Alrp suggested that the human Alrp did not appear to be functional in yeast^[49].

The enzymatic activity of Alrp as sulfhydryl oxidase

The Alrp/Erv1p family belongs to flavin-linked sulfhydryl oxidase participating in disulfide bond formation^[35,50]. Lisowsky *et al* identified the enzymatic activity of rat and human Alrp as sulfhydryl oxidases by their ability to oxidize thiol groups in a protein substrate, the presence of FAD moiety in the carboxy terminal domain and the formation of dimers *in vivo*^[50]. In general, the sulfhydryl oxidase proteins contain a conserved CXXC motif in the carboxy terminal domain and a non-covalent FAD, which are vital for their catalytic activity^[51-53]. The conserved CXXC motif in the carboxy terminus most likely represents the redox-active site of the enzyme, sharing significant homologies with human growth regulator quiescin Q6^[52] and yeast Erv1p^[35]. It was also reported that the two vicinal cysteines directly interact with bound FAD for the redox reaction. Furthermore, sulfhydryl oxidases form dimers *in vivo* and catalyze the formation of disulfide bonds with the reduction of molecular oxygen to hydrogen peroxide according to the following reaction: $2RS-H + O_2 \rightarrow RSSR + H_2O_2$ ^[51-53].

An interesting new aspect for mitochondrial sulfhydryl oxidase activity and the formation of disulfide bonds was the recent finding of a direct correlation between the electron transport chain and the formation of disulfide bonds in *E. coli*^[54,55]. A very recent study on the fundamental behavior of the short form of the human Alrp suggested that this flavoenzyme might not necessarily function as sulfhydryl oxidase in the mitochondrial intermembrane space but might be coupled with the respiration chain *via* mediation of cytochrome *c* and without the generation of hydrogen peroxide observed in oxidase reactions. Thus, cytochrome *c* should be considered as a potential oxidant for ALR *in vivo*^[56].

The presence of a specific receptor for Alrp and modes of Alrp signaling

Wang *et al* showed the existence of an Alrp receptor on rat hepatocytes and human hepatoma cells with a molecular weight of about 75 ku, presenting with high affinity and specificity, reversibility and saturation^[57]. Alrp binds the receptor in cell membranes initiating a corresponding signal transduction pathway and mediating its biological function on hepatocytes. This function includes specific phosphorylation and dephosphorylation of important proteins in the process of liver regeneration^[57].

Yang *et al* showed that recombinant human HPO/Alrp (125 amino acids, 15 ku) could stimulate proliferation of hepatocytes as well as hepatoma cells *in vitro*, promoting regeneration and recovery of damaged hepatocytes and ameliorating acute hepatic failure *in vivo*. Such observations support the contention that Alrp is a hepatotrophic growth factor^[58,59].

It was shown that HPO/Alrp was able to stimulate hepatocyte proliferation by two signaling pathways. In the

first pathway, extracellular HPO autocrined from hepatocytes and hepatoma cells activated the mitogen-activated protein kinase (MAPK) signaling pathway *via* binding to an ALR receptor. Specifically, Alrp triggered MAPK activation and proliferation in hepatoma cell lines through the induction of tyrosine phosphorylation of epidermal growth factor receptor (EGFR)^[60].

In the second signaling pathway, intracellular Alrp interacted with Jun activation domain-binding protein 1 (JAB1), triggering the activating protein-1 (AP-1) transcriptional activity in a MAPK independent manner, for immediate early response when its intracellular levels were increased with post-partial hepatectomy or liver injury^[61]. JAB1 is the fifth subunit of COP9 signalosome (CSN), being a co-activator of c-Jun/AP-1 transcription factor, which enhances the binding capacity of c-Jun-containing AP-1 complex to their DNA consensus sites and increasing the transactivation of an AP-1 dependent promoter. It was shown that Alrp enhanced the increased phosphorylation level of c-Jun through JAB1 but had no effect on the expression of transfected c-Jun or endogenous c-Jun N-terminal kinase or on phosphorylation of c-Jun N-terminal kinase^[61]. Furthermore, recent studies elucidated a novel relationship of intracellular Alrp with the whole protein complex CSN, suggesting a possible linkage between CSN and liver regeneration^[62]. As a consequence, the CSN complex could represent an intracellular signal platform, where signals from the extracellular or intracellular environment are coordinated with transcriptional activation and with the regulation of the related functions of cells.

Chen *et al* presented a molecular link between the enzymatic redox function of HPO/Alrp and its role as a cytokine^[63]. They displayed the necessity of cysteine residues in the CXXC catalytic centre for the intracellular potentiation of AP-1 activity. As mentioned before, Alrp interacted with JAB1 to trigger AP-1 transcription activity by phosphorylation of c-Jun in a MAPK independent fashion. This effect depended on the integrity of the CXXC enzyme active site, which could provide a novel intracellular signaling pathway shortcut by redox regulation. This implied that the enzymatic activity of Alrp might be a key regulator in the intracellular mediation of the AP-1 pathway through JAB1. On the other hand, they provided evidence that the extracellular cytokine activity of Alrp did not associate with the redox CXXC motif and consequently with its sulfhydryl oxidase activity^[63].

Recently, Li *et al* demonstrated that ALR and macrophage inhibitory factor (MIF) could be considered as a pair in the course of signaling transduction^[64]. Their results showed an interaction between ALR and MIF and led to the alteration of their effects on AP-1 activity. Especially, on the one hand, the binding of MIF to JAB1 was inhibited by ALR and on the other hand the potentiation of the ALR on AP-1 activity through JAB1 was inhibited by MIF. Thus, the activity of AP-1 may be determined by the coordination and balance between ALR and MIF concentration *in vivo*. This balance is crucial for the maintenance of both homeostasis and normal development of cells and tissues. In this sense, ALR serves as physiological counter-regulatory mediator that counteracts the suppressive effect of MIF^[64].

Alrp biological activity

Previous studies have demonstrated that different forms of Alrp may be associated with different localizations and cellular functions^[26,49,65]. Specifically, a 15 ku Alrp fragment appeared to regulate mitochondrial gene expression by inducing the transcription and translation of the nuclear-encoded mitochondrial transcription factor A (mtTFA)^[66]. Polimeno *et al* found that Alrp administration induced a significant increase in mitochondrial gene expression and of nuclear-encoded mtTFA. This increase was associated with enhanced cytochrome content and oxidative phosphorylation capacity of rat liver-derived mitochondria^[66]. It has also been suggested that hepatotrophic factors, such as Alrp, play an important role in liver regeneration and might mediate their activities by regional regulation of natural killer (NK) cells. However, NK cells in liver appeared to have specific cytotoxicity against regenerating hepatocytes. A recent study revealed that *in vivo* administration of Alrp induced inhibition of hepatic NK cytotoxic activities in the population of mononuclear leukocytes infiltrating rat liver but not in those derived from spleen or peripheral blood. These data suggested that Alrp might act as an immunosuppressant agent localized to the liver^[67]. Moreover, Tanigawa *et al* suggested that Alrp production in the liver was enhanced during acute liver disease, especially in the initial stage^[68]. It was also suggested that Alrp might protect against failure of regeneration by inhibiting hepatic NK cell activity in acute liver disease^[68]. It was also demonstrated that Alrp acted as an immunoregulator by controlling, through interferon-gamma (IFN- γ) levels, the mtTFA expression and lytic activity of liver-resident NK cells. The exogenous administration Alrp in intact rats induced a reduction of IFN- γ in liver-resident NK cells, while the administration of IFN- γ in 70% of partially hepatectomized rats was followed by a significant reduction of both mtTFA expression and liver regeneration. These results demonstrated a direct link between Alrp and IFN- γ , implying IFN- γ as the main mediator of Alrp biological activity both as growth factor and immunoregulator^[69]. Recent studies discussed a constructed yeast expressive vector of ALR and this was expressed in yeast cells in order to further study the biological function and mechanism of recombinant human ALR as a regulatory factor that specifically stimulates hepatic cell regeneration. This successful expression of ALR in yeast cells may pave the way for the study of clinical use and provided a good tool for further research in this field. Their results also suggested that ALR enhanced liver regeneration not only through an indirect pathway; i.e. immune regulation, but also through a direct pathway^[70-71].

Recently, an ALR recombinant plasmid was constructed and tested for therapeutic effects on rat hepatic fibrosis. Specifically, the results of this study revealed that the ALR recombinant plasmid could decrease the degrading capacity of collagen types I and III, which were regarded as important parameters reflecting the metabolism of collagen. The ALR recombinant plasmid could also decrease the deposition of the extracellular matrix and the expression of tissue inhibitors of metalloproteinase-1 (TIMP-1) in pathological liver tissue and thus reverse the hepatic fibrosis induced by porcine serum administration^[72].

In addition, the full-length mammalian Alrp (23 ku) was largely located in the mitochondrial intermembrane space and performed the export of iron/sulfur (Fe/S) clusters from the mitochondrial matrix, contributing to the biogenesis of cytosolic Fe/S proteins and to cellular iron homeostasis. Especially, Fe/S cluster components of the mitochondrial matrix preassembled and packaged Fe/S clusters, which could then be transported into the cytosol, a process possibly involving the ABC transporter Atm1p/ABC7^[45]. Cytosolic and nuclear Fe/S proteins have important regulatory functions as enzymes or transcription factors. Therefore, participation in the assembly of cytosolic Fe/S proteins appears to be the primary essential task of mitochondrial full-length Alrp^[45]. This function is crucial for all eukaryotic cell types, whereas the proposed role of 15 ku Alrp as a hepatotrophic factor is restricted to liver cells and it may be effective only after liver damage. This indicates that Alrp, like other redox-active proteins and sulfhydryl oxidases, may have diverse functions in the regulation of cell growth and differentiation^[20,48,57,60,65].

Klissenbauer *et al* first characterized full-length Alrp as intratesticular sulfhydryl oxidase, a new enzyme with expression regulated during spermatogenesis^[73]. Mitochondrial localization of full-length Alrp was of special interest for spermatogenesis because it was known that morphological and functional changes in mitochondria were associated with this highly complex cytodifferentiation process. They also observed the greatest amounts of this protein in spermatogonia and early spermatocytes. Expression levels of Alrp did not correlate with synthesis of components of the respiratory chain, indicating that the full-length Alrp in the mitochondria of spermatogonia and spermatocytes had another possible function in addition to its role in oxidative phosphorylation during sperm cell differentiation^[73].

CONCLUSION

ALR is novel growth factor, related to HSS, participating in the regulation of liver regeneration. With the availability and description of the ALR gene and gene product, a range of questions could be addressed about the cellular mechanisms in which this growth factor participates. At the molecular level, cloning of human ALR cDNA has been completed, but transcription and post-transcriptional regulation, based on the genomic structure of ALR, remains unclear. Transcription and post-transcriptional regulation are among the most important steps in the regulation of human gene expression. Therefore, it is important and essential to investigate the structure of human ALR genomic DNA. Contrary to previous belief, variable RNA expression in nonhepatic tissues suggests that ALR is not restricted to liver tissue, as was also suggested for HSS, but could be expressed in other cell types under appropriate circumstances. It is known that Alrp acts as a FAD-linked sulfhydryl oxidase belonging to the new Erv1p/Alrp family and is the only intratesticular sulfhydryl oxidase detected in the mitochondrial intermembrane space. Possible functions of sulfhydryl oxidases and other redox-active proteins in the regulation of cell growth, differentiation, changes in mitochondrial and cellular morphology, and in the formation of the

extracellular matrix have already been proposed. This indicates that Alrp, like other redox-active proteins and sulfhydryl oxidases, might have diverse functions. Additionally, limited data are available on the secreted Alrp bound to a specific receptor on the hepatocyte membrane and initiation of a signal transduction pathway and mediation of its biological effect on hepatocytes. Further studies should examine the distribution of human Alrp receptors on hepatocytes and on other cell types. The secretory pathway should also be further investigated because Alrp does not contain a typical signal peptide sequence evident of its primary structure. Moreover, Alrp production, expression regulation, secretion-transportation and importance, and also its genetic function, need to be further delineated. As a consequence, there is a necessity to extend studies on mammalian Alrp to different tissues, organs and developmental processes in conditions of normal and abnormal cellular growth. It is clear that the multiple functions of Alrp are biologically and physiologically complicated and need further study.

Abstract

AIM: To determine the incidence of Epstein Barr virus associated gastric carcinoma (GC) in Brazil and compare the expressions of apoptosis related proteins and nitric oxide synthases between EBV positive and negative gastric carcinoma.

METHODS: *In situ* hybridization of EBV-encoded small RNA-1 (EBER-1) and PCR was performed to identify the presence of EBV in GCs. Immunohistochemistry was used to identify expressions of bcl-2, bcl-xl, bak, bax, p53, NOS-1, NOS-2, and NOS-3 proteins in 25 EBV positive GCs and in 103 EBV negative GCs.

RESULTS: 12% of the cases of GC (25/208) showed EBER-1 and EBNA-1 expression. The cases were preferentially of diffuse type with intense lymphoid infiltrate in the stroma. EBV associated GCs showed higher expression of bcl-2 protein and lower expression of bak protein than in EBV negative GCs. Indeed, expressions of NOS-1 and NOS-3 were frequently observed in EBV associated GCs.

CONCLUSION: Our data suggest that EBV infection may protect tumor cells from apoptosis, giving them the capacity for permanent cell cycling and proliferation. In addition, EBV positive GCs show high expression of constitutive NOS that could influence tumor progression and aggressiveness.

INTRODUCTION

Gastric carcinoma (GC) is one of the most common malignant tumors in the world, although its incidence has gradually declined in recent years. In Brazil, gastric cancer remains a prevalent neoplasm with high mortality, ranked as the third highest cause of cancer-related deaths^[1].

The correlation between Epstein-Barr virus (EBV) infection and GC is well known. EBV infection is found in 2%-16% of GCs^[2-4]. However, the pathogenic role of EBV infection in GCs remains uncertain and little is known regarding the molecular characteristics of these tumors.

Apoptosis is a biological phenomenon of critical importance in the regulation of a number of physiological and pathological situations, such as cancer development. In general, it is thought that viral infection and its associated proteins protect against apoptosis, which would normally cause cancer regression^[5]. Among the genes that regulate apoptosis are the members of the bcl-2 family. Expression of bcl-2 protein in gastric tumor cells is frequent and may differ according the histological type^[6]. There are few studies that compare the relationship between EBV infection in gastric carcinomas with apoptosis related protein expression^[7-9].

Nitric oxide (NO) is a short-lived biomolecule with various biological functions. It is an important bioactive agent and signaling molecule that mediates a diverse array of actions such as vasodilatation, neurotransmission, and iron metabolism. NO is also involved in the multi-step process of carcinogenesis by mediating DNA damage, inducing angiogenesis, and suppressing immune responses^[10]. It has been demonstrated that low concentrations of NO can protect tumor cells against apoptosis^[11]; alternatively, high concentrations of NO

can induce tumor cell death^[12]. This small molecule is a product of the conversion of L-arginine to L-citrulline by nitric oxide synthases (NOS). There are two groups of NOS, inducible (iNOS or NOS-2) and constitutive (nNOS or NOS-1 and eNOS or NOS-3). Recent studies have examined the expression and activity of NOS in human cancer^[13,14]. In gastric carcinomas, many studies addressed the issue, and most of them showed an increased activity and expression of NOS in tumor tissue when compared with normal gastric mucosa^[15-18].

To the best of our acknowledgement, the relationship between NOS expression and EBV related gastric cancer has not been investigated. Thus, the aim of the present study is to determine the prevalence of EBV infection in GCs in a Brazilian population and investigate the expression of apoptosis related proteins and nitric oxide synthases in EBV positive and EBV negative gastric carcinomas.

MATERIALS AND METHODS

Materials

Two hundred and eight gastric carcinomas, surgically resected from 1995 to 1998, were analyzed for EBV status using in situ hybridization and PCR. To compare EBV positive and negative carcinomas, we selected 103 EBV negative GC, which were samples that were previously studied for expression of apoptosis related proteins and NOS. The cases were reviewed, and representative formalin-fixed, paraffin-embedded blocks from the tumors were selected. Clinicopathological findings were obtained from surgical records and pathology reports. New paraffin sections were stained with hematoxylin and eosin (H&E), and they were assessed independently by two pathologists (MDB & FAS). Histologically, the tumors were classified according to Lauren's classification system in intestinal or diffuse types^[19]. Also we graded the amount of lymphoid infiltrate within or between the tumor cells as minimal/mild or moderate/intense.

In situ Hybridization (ISH)

Sections (5-6 μ m thick) on glass slides were prepared for ISH with a fluorescein-conjugated oligonucleotide probe for EBER-1 (Novocastra, Newcastle- Upon- Tyne, U.K.). Briefly, after deparaffinization and dehydration the sections were treated with proteinase K (Sigma, St. Louis, MO) for 15 min at 37°C. After washing and dehydration, the FITC-conjugated probe was applied and hybridized overnight at 37°C. The hybridization was further detected by rabbit anti- FITC antibody conjugated with alkaline phosphatase (Novocastra) for 30 min at room temperature. The slides were counterstained with a light Mayer's haematoxylin. Negative controls had no EBER-1 probe applied.

Immunohistochemistry

Sections (5-6 μ m thick) from the same tumor blocks, used for EBER detection, were immunohistochemically analyzed using the standard streptavidin- biotin- peroxidase method. The staining was done using the microwave antigen retrieval technique (95°C for 30 min in citrate buffer pH 6.0)

for all antibodies. Sections were incubated with antibodies against p53 (DO-7, 1:100, Dako, Copenhagen, Denmark), Bcl-2 (124, 1:50, Dako, Copenhagen, Denmark), Bax (bax, 1:50, Dako, Copenhagen, Denmark), Bcl-xl (bcl-xl, 1:50, Dako, Copenhagen, Denmark), Bak (bak, 1:400, Dako, Copenhagen, Denmark), NOS-1 (nNOS, 1:200, Transduction Laboratories, USA), NOS-2 (iNOS, 1:40, Transduction Laboratories, USA), and NOS-3 (eNOS, 1:50, Transduction Laboratories, USA) at 4°C overnight. After reagenting them with biotinylated secondary anti-mouse antibodies, the antigen-antibody reactions were visualized using streptavidin-horseradish peroxidase conjugate (Dako LSAB Kit, Los Angeles, CA). The peroxidase activity was localized by 0.05% 3, 3'-diaminobenzidine and 0.03% hydrogen peroxide in Tris- buffered saline. The slides were counterstained with Mayer's hematoxylin. The percentage of positively stained tumor cells in each tumor section was blinded evaluated by counting at least 1000 cells in 10 randomly selected high-power fields. Brown staining for p53 protein was located in nuclei; staining for bcl-2, bcl-xl, bak, bax, NOS-1, NOS-2, and NOS-3 protein was located in cytoplasm. The section was considered as expressing the protein if cellular staining was $\geq 5\%$ ^[5].

PCR studies for EBV

The DNA of cancerous tissues from 25 patients with EBV positive gastric carcinomas was obtained from paraffin-embedded surgical blocks. The DNA was extracted by prolonged proteinase K digestion. Briefly, after deparaffinization with xylene and rehydration in ethanol, the tissue was resuspended in 300 μ L of SDS-Proteinase K solution (1% SDS; 9 mmol/L Tris-HCl, pH 9.0; 2.25 mmol/L EDTA; 56.5 mmol/L NaCl; 1 μ g/ μ L Proteinase K (invitrogen) and incubated at 48°C for 48 h. Each 12 h, 20 μ L of 20 μ g/ μ L Proteinase K were added. After extraction with an equal volume of phenol-chloroform, the aqueous layer was transferred to a new tube and the DNA was precipitated by the addition of 2 μ L of 20 mg/mL glycogen, 100 μ L of ammonium acetate (7.5 mol/L) and 800 μ L of 100% ethanol followed by incubation overnight at -20°C. After centrifugation, the DNA was resuspended in 50 μ L of water. PCR was performed in a reaction final volume of 25 μ L, containing 10 μ L of DNA; 2.5 μ L of 10 \times PCR buffer; 1.5 μ L of 25 mmol/L MgCl₂; 2 μ L of 2.5 mmol/L dNTP mix; 1 μ L of 10 μ mol/L EBNA1F and EBNA1R primers; and 0.3 μ L of Taq DNA polymerase. The following thermal cycle conditions were used: 94°C for 5 min, 35 cycles of 94°C for 30 s, 60°C for 45 s, and 72°C for 45 s. After the last cycle, a final extension at 72°C for 7 min was carried out. The sequences of the primers were: EBNA-1F (5'-GTCATCATCATCCGGGTCTC-3') and EBNA-1R (5'-TTCGGGTTGGAACCTCCTTG-3'). The amplified products were visualized by electrophoresis in 8% polyacrylamide gels.

Statistical analysis

Statistical comparison among groups was performed using χ^2 test and Fisher's exact test when appropriate. *P* values less than 0.05 were considered statistically significant.

Table 1 Comparison of clinicopathological data between EBV positive and EBV negative gastric carcinomas

	EBV positive gastric carcinomas (n = 25)	EBV negative gastric carcinomas (n = 103)	P value
Gender			NS
Male	20 (80%)	68 (66%)	
Female	5 (20%)	35 (34%)	
Age: range(mean) ¹	35-78 (60.5)	25-84 (61.2)	NS

¹ Age in years; LN: Lymph node; NS: Not significant.

RESULTS

EBER-1 expression and EBNA-1 products were visualized in 25 out of 208 (12%) cases of gastric carcinomas (Figure 1A).

The clinicopathological characteristics of EBV positive and negative GCs are given in Table 1. The male/female ratio in patients with EBV positive GCs and those with EBV negative GCs was 4:1 and 2:1, respectively, and no difference was seen in the average age at 60.5 and 61.2 years, respectively. 68% of EBV positive GCs were in the body and cardia and 32% of them were in the antrum. In the group of EBV negative GCs, 80% were in the body and cardia and only 20% of them were in the antrum, showing predilection for the body and cardia region in both groups. Regarding histological type, 18 of 25 (72%) EBV positive GCs were diffuse type and 7 (28%) were intestinal. 60% of EBV negative GCs were intestinal type and 41 of 103 (40%) were diffuse, resulting in a strong association between histological type and EBV infection in gastric carcinomas ($P < 0.01$). EBV associated GCs also correlated with tumor infiltrating lymphocytes. 19 of 25 (76%) EBV positive GCs showed marked lymphoid stroma evenly distributed with the malignant epithelial cells (Figure 1B). In the EBV negative GCs only 30% of the cases showed marked lymphocytic infiltration ($P < 0.01$). Metastases in lymph nodes were found in 18 of 25 (72%) EBV positive GCs and in 60 of 103 (59%) EBV negative cases. This difference was not statistically significant.

Immunohistochemical results

Table 2 shows the pattern of protein expression in EBV positive and negative GCs. P53 protein expression was observed in the nucleus of the tumor cells with a uniform staining (Figure 1C). 11 of 25 (44%) EBV positive GCs and 55 of 103 (51%) EBV negative GCs were positive for

Table 2 Apoptosis related proteins expressions in EBV positive and EBV negative gastric carcinomas n (%)

	EBV positive gastric carcinoma (n = 25)	EBV negative gastric carcinoma (n = 103)	P value
P53			NS
Positive	11 (44)	55 (54)	
Negative	14 (56)	48 (46)	
Bcl-2			< 0.05
Positive	7 (28)	11 (11)	
Negative	18 (72)	92 (89)	
Bcl-x			NS
Positive	22 (88)	96 (93)	
Negative	3 (12)	7 (7)	
Bak			< 0.05
Positive	11 (44)	71 (69)

Bax			NS
Positive	24 (96)	88 (86)	
Negative	1 (4)	15 (14)	

p53 and no difference was observed between the groups. Expression of bcl-2 protein was observed in 28% of EBV positive GCs and in only 11% of the EBV negative GCs (Figure 1D), showing a statistically significant correlation between EBV status and bcl-2 expression in GCs ($P < 0.05$). The rates of the bcl-xl and bax expressions in EBV positive and negative GCs were 88% and 93%, and 96% and 86%, respectively (Figures 1E and 1F). None of the differences were statistically significant. Bak expression was lower in the EBV positive GCs than in EBV negative tumors (Figure 1G) and it was detected in 11 of 25 (44%) EBV positive GCs, and in 71 of 103 (69%) EBV negative GCs. This difference was statistically significant ($P < 0.01$).

NOS were observed in the cytoplasm of the tumor, epithelial, endothelial, smooth muscle and inflammatory cells. For final analysis, we scored the expression of these enzymes only in the tumor cells (Figures 1H, 1I, and 1J). NOS expressions were significantly different in EBV positive and negative GCs. Overexpression of constitutive forms of NOS (NOS-1 and NOS-3) were more frequently observed in EBV positive than in EBV negative GCs ($P < 0.01$). The majority of GC cases were negative for an inducible form of NOS (NOS-2), independently of EBV status. Comparisons of NOS expressions and EBV status are shown in Table 3.

DISCUSSION

The relationship between Epstein-Barr virus and various epithelioid diseases has already been demonstrated. Involvement of EBV has been described in the etiopathogenesis of not only the nasopharyngeal carcinoma but other carcinomas as well, including gastric carcinomas^[20-22].

It is estimated that EBV infection can be found in about 10% of GCs worldwide, especially those with marked lymphocytic infiltration^[23-27]. We observed EBV infection in 12% of GCs. Previous studies showed the

Figure 1 A: Gastric carcinoma showing strong positivity of EBER-1 in nuclei of the malignant cells (*in situ* hybridization, 400 x); B: Overview of gastric carcinoma with clusters of tumor cells separated by prominent lymphoplasmacytic infiltrate (H&E, 400 x); C: p53 nuclear immunopositivity in gastric carcinoma cells (400 x); D, E, F, G: Immunohistochemical staining for bcl-2, bcl-xl, bax and bak. The cytoplasm of the malignant cells shows irregular brown positivity (400 x); H, I, J: NOS-1, NOS-2 and NOS-3 immunohistochemical staining in tumor epithelial cells, showing a high intensity of staining in the cytoplasm (400 x).

incidence of EBV infection in Brazilian GCs ranging between 5%-11.32%^[28-30]. Some reports described the presence of EBV and its products as restricted on the carcinoma cells^[31-33], whereas others found this virus in the precursor epithelial lesions as well as in the lymphoid cells^[2,7]. In our study the virus was detected in the neoplastic cells but not in the normal, dysplastic gastric epithelium, or in inflammatory cells. This finding indicates that EBV affects the gastric epithelium at a late stage of the multistep process of gastric carcinogenesis.

The role of EBV in neoplastic transformation of gastric epithelial cells is not completely understood. It has been suggested that EBV positive GCs display specific clinicopathological features compared with EBV negative GCs. EBV associated GCs had been characterized by male predominance, preferential location in proximal stomach, and a high prevalence of diffuse types^[2,34-36]. In our series, EBV positive GCs were frequently seen in males, in the body and cardia region, and in diffuse carcinomas in agreement with previous reports. Indeed we observed a strong association between EBV infection and lymphoid stroma. The presence of marked lymphoid infiltrate has already been demonstrated and there is growing evidence that extensive lymphocyte infiltration is a consistent characteristic of EBV positive carcinomas and correlates with less aggressive behavior, although no additional information is available regarding follow-up of the patients in the present study.

Molecular analysis of EBV positive carcinoma has been shown to have distinct characteristics including different chromosomal aberrations^[37], different and lower frequencies of microsatellite instability^[35] and allelic loss^[38], and more CpG methylation^[39]. However, studies have focused on the relationship between EBV and oncogenes or tumor suppressor genes in EBV associated GCs, but no conclusive results have been reported^[15,7,9,40,41]. In this study, expression of apoptosis related proteins and nitric oxide synthases was examined in EBV associated and EBV negative gastric carcinomas. In this report, we observed a correlation between bcl-2 and bak expressions and EBV status. Bcl-2 protein expression was observed more frequently in EBV positive than in EBV negative GCs. On the other hand, positivity for bak protein was more common in EBV negative than in EBV positive GCs. It is already known that the balance between anti-apoptotic and pro-apoptotic members of the bcl-2 family genes determine the outcome of patients with tumors. Bak protein is shown to induce cell death, while bcl-2 can protect cells from apoptosis. Previous reports indicated that EBV infection may protect tumor cells from apoptosis inducing expression of the anti-apoptotic proteins^[41]. Our results showed additional information and confirm that EBV infection and apoptosis related proteins interact to negatively influence apoptosis, through high expression of bcl-2 and low expression of bak in gastric tumor cells. Bax and bcl-xl protein expressions were found in both EBV positive and negative GCs and there was no statistical difference between the groups.

There is some indication that EBV modulates and mutates p53 for its own survival^[42], however earlier reports showed contradictory results^[8,38,43]. In turn, p53

Table 3 NOS expression in EBV positive and EBV negative gastric carcinomas *n* (%)

	EBV positive gastric carcinoma (<i>n</i> = 25)	EBV negative gastric carcinoma (<i>n</i> = 103)	<i>P</i> value
<i>NOS1</i> (<i>nNOS</i>)			< 0.05
Positive	23 (92)	69 (67)	
Negative	2 (8)	34 (33)	
<i>NOS2</i> (<i>iNOS</i>)			NS
Positive	5 (20)	31 (30)

<i>NOS3</i> (<i>eNOS</i>)			< 0.05
Positive	18 (72)	36 (35)	
Negative	7 (28)	67 (65)	

gene mutations are rarely identified in EBV associated carcinomas^[44]. The obtained results in our study showed disturbed function of p53 in almost all cases of EBV positive and EBV negative GCs. Although p53 expression seemed to be slightly lower in EBV positive GCs, that difference was not statistically significant. These results indicated that abnormalities in p53 observed in GCs are independent of EBV infection.

It has been reported that nitric oxide synthases are present in human tumor cell lines and solid tumor tissues^[14,16,45-47]. Increased NOS expression has been observed in different tumors tissues when compared with normal tissues^[14,48,49].

To the best of our knowledge, this is the first report showing NOS expression is associated with EBV infection gastric cancer. In EBV positive GCs, NOS-1 and NOS-3 proteins were more frequent positive in tumor cells than NOS-2. The results agree with previous data that showed higher activity of constitutive rather than inducible NOS in human gastric tumors^[15]. In a recent study, the authors demonstrated significantly high NOS-3 expression in gastric tumors and a directly relationship with tumor angiogenesis and the overall aggressive biology of gastric cancer^[50]. Our study showed higher NOS-3 expression in EBV positive GCs than in EBV negative GCs. Increasing evidence suggests that NOS-3 expression, although constitutive, can be regulated by various hormones, cytokines, and growth factors, and by genetic alterations, such as oncogene activation and tumor suppressor inactivation^[51-54]. Our data indicate that EBV infection and its products can affect the regulation of this enzyme resulting in elevated NO production. It has been showed that elevated NO production enhances the growth of some tumors through the suppression of anti-tumor immune responses^[55-57].

NOS-2 expression was decreased in the whole group of gastric tumors in our study. This feature has been demonstrated by immunohistochemistry in other tumors and there is a possible relationship between loss of NO and carcinogenesis^[15,16]. However, many publications showed elevated NOS expression and increased activity in gastric cancer^[58-60]. Although the mechanisms for the antiviral action of NO have not been clarified, the multiplicity of host enzymes it targets makes it possible

that multiple alterations in host cell proteins are involved. An apparent role of NO in inhibiting EBV reactivation from latency was demonstrated in a study using gastric cells lines in culture^[61]. This finding led us to propose that EBV latency can be directly and/or indirectly associated with NOS gene expression and also lead us to postulate that NO might also be an important factor in the host EBV relationship. Our data suggest that the increased expression of NOS-1 and NOS-3 in EBV positive GC renders a major contribution to high activity of NOS in this specific group of tumors.

In conclusion, it is clear that EBV is associated with gastric carcinomas. EBV positive GCs have a distinct protein expression profile, as well as distinct clinicopathological features. This present data suggest that EBV infection may protect tumor cells from apoptosis, giving them the capacity for permanent cell cycling and proliferation. Indeed, EBV positive GCs have high expression of constitutive NOS, which might be associated with tumor progression or aggressiveness. A larger number of cases and long-term follow-up are necessary to further investigate this possibility.

Abstract

AIM: To investigate the dynamic alteration of telomerase expression during development of hepatocellular carcinoma (HCC) and its diagnostic implications in liver tissues or peripheral blood mononuclear cells for HCC.

METHODS: Dynamic expressions of liver telomerase during malignant transformation of hepatocytes were observed in Sprague-Dawley (SD) rats fed with 0.05% of 2-fluoenyacetamide (2-FAA). Total RNA and telomerase were extracted from rat or human liver tissues. The telomerase activities in livers and in circulating blood were detected by a telomeric repeat amplification protocol-enzyme-linked immunosorbent assay (TRAP-ELISA), and its diagnostic value was investigated in patients with benign or malignant liver diseases.

RESULTS: The hepatoma model displayed the dynamic expression of hepatic telomerase during HCC development. The telomerase activities were consistent with liver total RNA levels ($r = 0.83$, $P < 0.01$) at the stages of degeneration, precancerosis, and cancerization of hepatocytes. In HCC patients, the telomerase levels in HCC tissues were significantly higher than in their adjacent non-cancerous tissues, but liver total RNA levels were lower in the former than in the latter. Although the circulating telomerase of HCC patients was abnormally

expressed among patients with chronic liver diseases, the telomerase activity was a non-specific marker for HCC diagnosis, because the incidence was 15.7% in normal control, 25% in chronic hepatitis, 45.9% in liver cirrhosis, and 85.2% in HCC, respectively when absorbance value of telomerase activity was more than 0.2. If the value was over 0.6, the incidence was 60% in HCC group and 0% in any of the others ($P < 0.01$) except in two cases with liver cirrhosis. However, the combination of circulating telomerase with serum alpha-fetoprotein level could increase the positive rate and the accuracy (92.6%, 125 of 135) of HCC diagnosis.

CONCLUSION: The overexpression of telomerase is associated with HCC development, and its abnormality in liver tissues or in peripheral blood could be a useful marker for diagnosis and prognosis of HCC.

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common and rapidly fatal malignancies worldwide^[1], and has been ranked as the 2nd cancer killer in China, particularly in the eastern and southern areas, including the inshore area of the Yangtze River^[2]. Major risk factors for HCC in these areas are exposure to aflatoxin B1 (AFB1) and infection with hepatitis viruses (HBV and HCV)^[3]. Its prognosis is poor and early diagnosis is of utmost importance^[4]. Treatment options are severely limited by the frequent presence of metastases. Although serum alpha-fetoprotein (AFP) is a useful tumor marker for the detection and monitoring of HCC development, the false-negative rate with AFP level alone may be as high as 40%

for patients with small size HCC. If hepatocyte-specific mRNAs are detected in the circulation, it is possible to infer the presence of circulating, presumably malignant liver cells and to predict the likelihood of haematogenous metastasis^[5-7]. The use of telomerase assay for cancer diagnosis might be possible because telomerase is expressed in malignant lesions but rarely in normal somatic cells^[8].

Telomerase, an RNA-dependent DNA polymerase, can maintain the telomeric length by acting as a reverse transcriptase^[9]. In humans, tumor cells escape programmed cell senescence through reactivation of telomerase^[10]. These immortalized cells can compensate for telomeric shortening at each cell division, leading to progressive neoplastic evolution^[11]. Telomerase re-expression is found in 85% of human malignant tumors^[12]. The expression of telomerase is important to cell proliferation, senescence, immortalization and carcinogenesis^[13]. However, early expression and kinetic alteration of hepatic telomerase during development of HCC remain unclear. The objectives of this study were to observe the dynamic expression of liver telomerase in rat hepatoma model induced by oral administration of 0.05% of 2-fluorenylacetamide (2-FAA), and investigate the telomerase activities in liver tissues and peripheral blood mononuclear cells (PBMCs) by a telomeric repeat amplification protocol-enzyme-linked immunosorbent assay (TRAP-ELISA), as well as its diagnostic implications for HCC in patients with benign or malignant liver diseases.

MATERIALS AND METHODS

Hepatoma rat models

Forty-two closed colony male Sprague-Dawley (SD) rats weighing 120-160 g were obtained from the Experimental Center of Medical Animals, Nantong University, China, and divided randomly into 7 groups, one group ($n = 6$) as normal control and 6 experimental groups ($n = 6$ in each group). All rats were housed under bio-clean conditions at a temperature-controlled ($22^{\circ}\text{C} \pm 2^{\circ}\text{C}$) environment with a 12-h light/dark cycle and 55% humidity. The control group was given basal foodstuffs and the feed of experimental rats contained 0.05% 2-FAA (Sigma, USA). Rats were then monitored daily of survival and weight loss, recorded of their clinical signs and sacrificed at different stages of hepatoma development. One group of the experimental rats and one control rat were killed in every two weeks. All surgical procedures were conducted under deep ether anaesthesia. Blood was drawn from rat's heart. The livers were collected, and histological examination was performed with hematoxylin and eosin (HE) staining. All procedures performed on the rats were conducted in accordance with the Guidelines for Experimental Animals approved by the Animal Care and Use Committee of Nantong University, China.

Patient selection and human HCC tissues

All patients with liver diseases came from the Affiliated Hospital, Nantong University, China. We evaluated 135 HCC patients (103 males and 32 females, age between 35-76 years, mean 49). Ninety-five patients (70.3%)

had a history of cirrhosis, and 52 (38.5%) had a history of chronic hepatitis. Moreover, 85.2% (115/135) were hepatitis B surface antigen (HBsAg) carriers, 10.4% (14/135) had antibodies to hepatitis C virus (anti-HCV, second-generation antibody) and 8.9% (12/135) had antibodies to hepatitis G virus by an enzyme-linked immunosorbent assay (ELISA), respectively. Other cases studied included 80 patients with chronic hepatitis (CH, 58 males and 22 females), 37 patients with liver cirrhosis (LC, 30 males and 7 females), and 70 healthy individuals (35 males and 35 females, mean age 35 years) with negative hepatitis B virus markers (HBsAg, HBcAb, and HBV-DNA) and anti-HCV, and normal levels of serum alanine aminotransferase (ALT) from the Nantong Central Blood Bank as normal controls (NC). The venous blood of patients and normal controls were collected with heparin anticoagulant and stored on ice. The diagnosis of HCC and viral hepatitis was based on the criteria proposed at China National Collaborative Cancer Research Group^[14] and the China National Viral Hepatitis Meeting^[15], respectively.

Fifteen specimens of HCC and their corresponding non-tumor tissues as self-control were obtained from HCC patients who had undergone curative hepatectomy. These specimens were immediately frozen in liquid nitrogen and kept at -85°C . All specimens were hepatocellular cancer confirmed by pathological examination. Eleven non-cancerous tissues from those patients were atypical proliferation. The patients' ages ranged between 31-64 years (mean 51.3 years). There were 12 specimens with a tumor size larger than 3 cm, and 3 specimens smaller than 3 cm.

Isolation of total RNA

Fifty mg of each liver tissue (rat liver, human HCC, and their self-controlled non-tumor tissues) was homogenized with a Polytron homogenizer after the addition of 1.0 mL of TRIzol reagent (Promega). Then 0.2 mL of chloroform was added into the tubes, mixed by vortexing for 15 s, and placed at -20°C for 5 min. Samples were centrifuged at 12000 r/min for 15 min at 4°C . The supernatants were collected, and equivalent isopropanol was added and then they were put into another tube and mixed gently, placed at -20°C for 15 min, then centrifuged at 12000 r/min for 15 min at 4°C . The supernatants were removed, the RNA pellets were washed twice with 0.5 mL of 75% ethanol, mixed and centrifuged at 8000 r/min for 8 min at 4°C . The RNA pellets were air dried 5 min at room temperature and reconstituted in 20 μL of RNase-free DEPC water and incubated at 60°C for 10 min. The purity and concentration of the RNA was estimated by the ratio of absorbance readings at 260 and 280 nm, with an A_{260}/A_{280} ratio between 1.8 and 2.0 indicating sufficient purity. RNA samples were kept frozen at -85°C until use.

Separation of PBMCs

Five milliliters of peripheral blood were collected with heparin anticoagulant from each patient. Ficoll (2.5 mL) was added to each sample. After centrifugation at 2000 r/min for 20 min, the PBMCs were collected from the Ficoll/plasma interface. Then they were washed three times in normal saline and pelleted by using low-speed cen-

trifugation. The cells were collected at 2×10^5 /tube, then stored at -85°C for telomerase assays.

TRAP reaction

A commercial telomerase TRAP-ELISA kit (Boehringer Mannheim), based on TRAP introduced by previous methods^[16], was used to assay telomerase activity in all specimens. Fifty mg liver tissue or 2×10^5 cells were suspended in 200 μL lysis reagent and incubated for 30 min, then centrifuged at 16000 r/min for 20 min at 4°C . Positive control cell extract was from immortalized telomerase-expressing human kidney cells (293 cells). Negative control cell extract was as follows: heat-treatment of the cell extract for 10 min at 65°C prior to the TRAP reaction. The supernatant was removed to other EP tubes and kept frozen at -85°C . Telomeric repeats were added to a biotin-labeled primer for 30 min at 25°C during the first reaction. The mixture was incubated at 94°C for 5 min to induce telomerase inactivation, then subjected to 30 PCR cycles of 94°C for 30 s, 50°C for 30 s, and 72°C for 90 s, and finally at 72°C for 10 min. The PCR products were used for analysis of telomerase activity and gel electrophoresis.

Telomerase detection

An aliquot of the PCR product was denatured and hybridized to a digoxigenin-(DIG)-labeled, telomeric repeat-specific detection probe. The resulting product was immobilized *via* the biotin labeled primer to a streptavidin-coated microtiter plate. The detection probe and the hybridization conditions have been optimized to obtain the highest specificity and sensitivity. The immobilized PCR products were then detected with an antibody against digoxigenin (anti-DIG-POD) that was conjugated to peroxidase. Finally, the probe was visualized by use of peroxidase metabolizing tetramethyl benzidine (TMB) to form a colored reaction product. The absorbance (A) of the samples was measured at 450 nm (reference wavelength 620 nm) within 30 min of addition of the stop reagent. Telomerase activities were expressed according to absorbance difference (ΔA) between sample and negative control.

Telomerase by TRAP silver staining

Fifteen microliters of the PCR products were loaded to 12% polyacrylamide gel and resolved by electrophoresis at 160-180 V for 1-2 h. Then the gel was immobilized to 10% ethanol for 5 min, soaked in 1% AgNO_3 for 5 min, dyed in silver dye solution for 10 min, and then in developing dye for 10 min. The amplified products were of heterogeneous length and created a ladder pattern of bands each representing the addition of a hexanucleotide telomeric repeat by telomerase, and photographed by Delphin-Doc Digital Imaging System (Wealtec, USA). All samples were done in duplicate and the reproducibility was confirmed.

Statistical analysis

The livers of experimental rats according to pathological examination were divided into 4 groups: degeneration of hepatocytes (Exp-1), precancerosis of hepatocytes (Exp-2), cancerization of hepatocytes (Exp-3), and normal controls (Con). The telomerase activities in

¹ One rat died during the experimental process; 2-FAA: 2-fluoenylacetamide.

PBMCs were investigated in patients with HCC, chronic hepatitis (CH), liver cirrhosis (LC), and normal controls (NC). Human HCC tissues were divided into cancerous and their non-tumor (non-HCC) groups. Levels of telomerase and total RNA were expressed as mean \pm SD. Differences between groups were assessed by the Student's *t* test or the χ^2 test, and the Fisher's exact probability test. Probability values less than 0.05 were considered significant.

RESULTS

Histopathological findings

The pathological changes of experimental rat livers with HE staining are shown in Table 1. The rats were administered with 0.05% of 2-FAA for two weeks. The appearance of livers turned to be grey-yellow and scabrous. The hepatocytes showed granular degeneration. Most of normal liver tissue structures remained. A few of hyperplastic oval cells, and the tendency toward nodule formation were seen at the early stage of hepatoma development. At the end of four weeks, precancerous lesions appeared in half of liver tissues. Histologically, normal liver follicles existed in most areas but hyperplastic small round cells or oval cells or hyperplastic nodules were found locally. After the 6th wk, all livers progressed into canceration stage. The structures of liver lobules were completely destroyed, and necrosis was spread over the whole livers. Large numbers of small oval cells, and cancer nests were observed. The histological features of livers showed diffuse patchy necrosis and high degree differentiation of HCC.

Expression of telomerase during rat hepatoma development

The dynamic expression of liver telomerase in rat hepatocyte degeneration (Exp-1), hepatocyte precancerosis (Exp-2), and hepatocyte cancerization (Exp-3) groups during development of hepatomas in comparison with controls (Con) are shown in Figure 1. After rats were given 2-FAA, the specific activities (ΔA /mg protein) of liver telomerase were significantly higher than that of controls ($P < 0.01$) at the stage of hepatocyte degeneration, kept rising at the stage of hepatocyte precancerosis, and peaked at the formation stage of hepatoma. Telomerase activities were consistent with the levels of liver total RNA ($r = 0.83$,

$P < 0.01$) at the different stages of hepatoma development of rats (Figure 2).

Expression of telomerase in human liver tissues

The levels of total RNA and telomerase expression in different human liver tissues are shown in Figure 3. The concentrations of liver total RNA and telomerase were $12.40 \pm 7.34 \mu\text{g/mg}$ liver protein and $18.25 \pm 15.02 \text{ A}/\mu\text{g RNA}$ in HCC tissues, and $53.77 \pm 52.02 \mu\text{g/mg}$ liver protein and $8.16 \pm 6.22 \text{ A}/\mu\text{g RNA}$ in their non-cancerous tissues, respectively. The expression of total RNA in HCC tissues was significantly lower than that in their non-cancerous tissues ($P < 0.01$); however, the expression level of telomerase was significantly higher in HCC tissues than in their non-cancerous tissues ($P < 0.05$). Stronger positive expression of telomerase was presented in HCC tissues and not in their non-cancerous tissues (Figure 4).

Significance of telomerase in PBMCs

There were different telomerase activities of PBMCs in NC, CH, LC and HCC, but the activities in HCC were significantly higher than in others ($P < 0.01$, Figure 5). The

samples were regarded as telomerase-positive if the difference in absorbance (Table 2) was greater than $0.2 \Delta\text{A}$. The incidence of telomerase expression was 15.7% in NC, 25% in CH, 45.9% in LC, and 85.0% in HCC (sensitivity 68.4% and positive predictive value 75.7%), respectively. The incidence of telomerase was significantly higher in

Sen: Sensitivity; Spe: Specificity; Pos: Positive; Neg: Negative; Acc: Accuracy.

HCC group than in any of other groups (*P* < 0.01). If the value rose up to 0.6 ΔA , the incidence of telomerase was 60% in HCC (sensitivity 98.3% and positive predictive value 97.6%), and 0% in any of other groups (*P* < 0.01) except two cases with liver cirrhosis (Table 3). For combined diagnostic values of telomerase and AFP for HCC, the AFP concentration in HCC patients was 1765 ± 1705 $\mu\text{g/L}$ and the positive rate was 70% for a cutoff value of AFP level 200 $\mu\text{g/L}$. Total AFP detection in combination with telomerase activity could increase the accuracy of HCC diagnosis (92.6%).

DISCUSSION

Carcinogenesis of hepatocytes is a multi-factor, multi-step and complex process and has many characteristics, such as fast infiltrative growth, metastasis in early stage, high malignancy, and poor therapeutic efficacy^[17]. Probably HBV infection is merely a carcinogenic factor, and is not related to the growth, infiltration and metastasis of HCC^[18]. It is increasingly clear that oncogenesis is driven by the activation of telomerase, a ribonucleoprotein complex that adds telomeric repeats (hexanucleotide 5'-TTAGGG-3') to the ends of replicating chromosomes. Telomerase is a ribonucleoprotein composed of an essential RNA and a few proteins. It is expressed in embryonic cells and in adult male germ line cells, but is undetectable in normal somatic cells except proliferative cells of renewable tissues. Although the precise processes leading to HCC are still unknown, progression to a cancerous state does require the accumulation of a series of genetic alterations.

To understand the mechanisms and alterations of telomerase expression during carcinogenesis of hepatocytes, rat hepatoma models were induced with chemical carcinogen (2-FAA), and telomerase expression was studied at the different stages of degeneration, precancerosis, and cancerization of hepatocytes (Table 1).

Although the histopathological examination found the oval cells and non-differentiation in morphology at the early stage of hepatoma, telomerase was significantly expressed in livers (Figure 1). This has raised two possibilities: (1) telomerase may be an important target for therapy aiming at controlling cell growth^[19,20]. Telomerase activation in the critical step of tumor progression during hepatocarcinogenesis might be regulated only by hTERT, whereas increased telomerase activity in tumor progression might be regulated by both hTERT (reverse transcript) and hTERT (RNA component)^[21-23]; (2) histological examination in combination with telomerase activity could increase the accuracy of diagnosis at early stage and help the staging of HCC development.

The predominant mechanism for telomere stabilization in tumor cells is the activation of the telomere-synthesizing enzyme telomerase. Both of liver telomerase activity (Figure 1) and total RNA increased (Figure 2) during hepatoma progression. This may be relevant to the cytotoxic effects of liver cells in resisting carcinogenic effect of 2-FAA. In the meantime, the telomerase level of liver tissues and sera of the experimental groups were obviously higher than the normal control group (*P* < 0.01), indicating that the oval cells could express telomerase and secrete it into blood. Telomerase activities increased continuously and reached the highest level in the experimental groups, and livers of the experimental groups in the 6th wk were seen to have canceration. Rat hepatoma is an aggressive malignancy. Both total RNAs and telomerase activity increased during HCC progression. Moreover, in the following weeks, the liver tissues continued to synthesize telomerase, which remained at a high level. These results suggest that the strong enhancement of telomerase activity may be a critical step in hepatocarcinogenesis, although the exact mechanism is not clear.

Telomerase is highly activated in human tumor tissues, whereas it is not activated in primary cell strains and tumor-adjacent tissues^[24,25]. With cell division, telomerase is activated. The cells with positive telomerase activity become immortalized and further develop to carcinoma cells^[26,27]. The telomerase activities in HCC and their surrounding non-tumor tissues were detected by TRAP-ELISA in this study. The telomerase expression in HCC was negatively correlated with differentiation, but was not related to tumor size or histological grade. The expression level of telomerase was significantly higher in HCC tissues than in their corresponding non-cancerous tissues (*P* < 0.05, Figure 3A). Stronger positive expression of telomerase was present in HCC and not in their non-cancerous tissues (Figure 4). No relationship could be observed between the enhancement of telomerase activity and liver total RNA in human HCC tissues (Figure 3B). In China, major risk factors for HCC are exposure to aflatoxin B1 (AFB1) and infection by hepatitis viruses, especially HBV. HBx, encoded by HBV, could block the function of *p53*, resulting in genome unstabilization. Activation of telomerase could make liver cells immortalized, and microvascularization could provide nutrition for their growth and promote metastasis^[17,28]. These two factors may induce carcinogenesis and have a key role in occurrence, development, infiltration and metastasis of HCC. They

may also have notable clinical values in diagnosing and treating HCC in early stage.

Telomerase was strongly activated in HCC, while weakly activated in CH and LC. Progressive shortening of telomeres during hepatocellular carcinogenesis was found from normal liver to CH to LC to HCC. The average telomere length of HCC was significantly and consistently shorter than that of adjacent CH or LC. The possible sequel of telomere shortening in regenerative, non-cancerous liver lesions (CH and LC) is that it may eventually lead to reactivation of telomerase, which in turn may contribute to the malignant conversion to HCC. Telomerase may be expressed in lymphocytes^[29,30]. Lymphocytic infiltration may occur during tumor necrosis, thus the telomerase activity we measured included a proportion generated by lymphocytes and might be overestimated. Almost all HCCs are preceded by CH and/or LC. There were different degrees of telomerase activities of PBMCs in NC, CH, LC and HCC, but the telomerase activities of HCC were significantly higher than others (Figure 5, Table 2). In addition, combined diagnostic values of telomerase and AFP for HCC were investigated in this study. Detection of telomerase activity in combination with serum AFP could increase the accuracy of HCC diagnosis.

These genetic changes may lead to senescence of hepatocytes occurring in patients with advanced liver diseases probably as a result of degeneration and the subsequent regeneration of hepatocytes^[31,32]. Although the mechanisms of carcinogenesis in chronic liver diseases are not known, recessive mutations may result in the reactivation of telomerase and stabilization of telomere length, as well as fixation of the additional mutations required for invasiveness and metastasis^[33,34]. Moreover, the patients with telomerase-positive HCC show poorer prognosis than those with telomerase-negative tumors. Clinically although the diagnostic specificity of hepatoma is high, the positive rate of telomerase is at present much lower than that from animal model studies, and the number of bands does not coincide with that of human being either^[35]. In addition, the cause of human hepatoma is associated with many factors. Telomerase could become a valuable marker for HCC diagnosis if the sensitivity of detection method is improved^[36]. Further research should focus on mechanisms of carcinogenesis by HCV and HBV, development of early detection and more effective treatments. Better understanding of HCC related to hepatitis viruses should also be a major concern in future studies.

Abstract

AIM: To identify and analyze the differentially expressed proteins in normal and cancerous tissues of four patients suffering from colon cancer.

METHODS: Colon tissues (normal and cancerous) were homogenized and the proteins were extracted using three protein extraction buffers. The extraction buffers were used in an orderly sequence of increasing extraction strength for proteins with hydrophobic properties. The protein extracts were separated using the SDS-PAGE method and the images were captured and analyzed using Quantity One software. The target protein bands were subjected to in-gel digestion with trypsin and finally analyzed using an ESI-ion trap mass spectrometer.

RESULTS: A total of 50 differentially expressed proteins in colonic cancerous and normal tissues were identified.

CONCLUSION: Many of the identified proteins have been reported to be involved in the progression of similar or other types of cancers. However, some of the identified proteins have not been reported before. In addition, a number of hypothetical proteins were also identified.

Gam LH, Leow CH, Man CN, Gooi BH, Singh M. Analysis of differentially expressed proteins in cancerous and normal

INTRODUCTION

Colorectal cancer is a worldwide public health concern and also a frequent cause of mortality and morbidity in developed, developing and industrialized countries^[1]. The incidence of colon cancer increases exponentially with age. Environmental factors and host immunological characteristics could contribute to initiation and progression of the disease^[2]. Colorectal cancer is among the best characterized cancers with regard to the genetic progression of the disease^[3].

The ability to obtain maps of the protein content of cells provides a basis for comparison of the protein expression in normal and cancer cells. This capability becomes especially important for mapping the changes that occur during cancer progression. In the transformation process, changes in protein expression may result in expression of proteins at elevated or reduced levels^[4-6]. When a cell transforms from normal to malignant, changes in protein expression ultimately are reflected in the phenotype of the cell. It is also important to map the differences between different stages of cancer and between different cancer samples at the same stage of progression in order to understand the pathways involved in these processes. Ultimately, identification of important proteins involved in the transformation process may lead to the identification of early markers for detection of specific types of cancers and their treatments^[7].

In the present study, proteins from normal and cancerous colon tissues were extracted in three separate fractions. The mapping of a protein profile in each fraction was carried out individually. This approach eases the comparison of protein expression in normal and cancerous tissue as it reduces the total proteins present in each fraction. Using this method, we believe that proteins from different compartments of the cells were extracted in sequential order, where the aqueous soluble proteins were first extracted followed by non-aqueous soluble proteins consisting of proteins with moderate to extreme hydrophobicity. The proteins analyzed in this study were extracted from human tissue specimens (both cancerous and normal). In proteomics study, analysis of cancerous

tissue has advantages over analysis in established cancer cell lines, as the latter may not represent the actual expression of proteins.

MATERIALS AND METHODS

Tissue specimen collection

Normal and cancerous colonic tissues were collected from patients with colon cancer. The specimens were provided by Hospital Pulau Pinang. Normal tissue was taken from the mucosal layer of the normal colon adjacent to the tumor tissue. Both the normal and cancerous tissues were confirmed by hospital pathologists. Ulceration or infected colon cancers were exclusion criteria for the study. The tissues were collected after informed consent had been obtained from the patients. The patients had different grades of colorectal cancer as shown in Table 1. The tissues were cut into similar sizes, weighed and immediately stored at -70°C until analyzed.

Well-differentiated adenocarcinoma refers to the less aggressive type of cancer where the cancerous tissues more closely resemble the normal tissue under histopathological examination, whereas moderately differentiated adenocarcinoma refers to moderately aggressive cancer cells.

Tissue lysis and sequential extractions

The tissues were defatted and an equal weight of tissues (normal and cancerous) was determined and subjected to analysis. The deep-frozen colon tissue specimens were disrupted by grinding in a liquid nitrogen-cooled mortar until the specimens became powder-form. The powder form-like tissues were divided into aliquots in separate eppendorf tubes. Sequential extraction of protein using three protein extraction buffers was carried out. These extraction buffers were prepared according to Molloy *et al*^[8] with modifications. The extraction procedures are described in the following sections.

Tris extraction buffer

The constituent of Extraction Buffer 1 (S1 buffer) is 40 mmol/L Tris. 1000 µL of S1 buffer was added to 500 mg of homogenized tissue. The mixture was vortexed for 30 seconds and centrifuged at 20°C with the speed of 12000 r/min for 8 min. The supernatant was collected in aliquots (50 µL) and kept at -70°C. The pellet was thoroughly washed with S1 buffer before being subjected to the second step in the sequential extraction.

Solution two extraction buffer

The extraction Buffer 2 (S2 buffer) contained 8 mol/L Urea, 50 mmol/L DTT, 40 g/L CHAPS, 2 mL/L Carrier ampholytes (pH 3-10) and 2 mg/L Bromophenol Blue. The recovered pellet was washed twice again with the T1 solution, and was then vortexed, centrifuged and the supernatant was discarded. After washing, a volume of 1000 µL S2 solution was added to the pellet. The mixture was then vortex for 30 s and then centrifuged at 20°C with the speed of 12000 r/min for 8 min. The supernatant was collected in aliquots (50 µL) and kept at -70°C. The pellet was thoroughly washed with the same extraction buffer before being subjected to the third step in the sequential

Table 1 Clinical and pathological data of patient tissue specimens

Patient #	Age	Gender	Race	Cancer stage	Cancer grade
MMN	77	Female	Malay	Stage IV	Well differentiated adenocarcinoma
LKH	66	Male	Chinese	Stage II	Moderately differentiated adenocarcinoma
CCH	55	Male	Chinese	Stage IV	Moderately differentiated adenocarcinoma
NSC	55	Female	Chinese	Stage III	Moderately differentiated adenocarcinoma

extraction.

Solution three extraction Buffer

The extraction Buffer 3 (S3 buffer) contained 5 M Urea, 2 mol/L Thiourea, 50 mmol/L DTT, 20g/L CHAPS, 20 mL/L Triton, 2 mL/L Carrier ampholytes (pH 3-10), 40 mmol/L Tris and 2 mg/L Bromophenol Blue. The recovered pellet from S2 extraction was washed twice with S2 buffer, it was then vortexed, centrifuged and the supernatant was discarded. After washing, 1000 µL of S3 buffer was added to the pellet. The mixture was vortexed for 30 s and then centrifuged at 20°C with the speed of 12000 r/min for 8 min. The supernatant was collected in aliquots (50 µL) and kept at -70°C. The pellet was then discarded.

Sample preparation and electrophoresis

The preparation of protein samples for SDS-PAGE separation was carried out by adding 200 mL/L of sample buffer (0.5 mol/L Tris-HCl, 100 mL/L glycerol, 20 mg/L SDS, 100 mg/L Coomassie blue) to each fraction (5 µL) and vortexed for 30 s. The samples (normal and cancerous) and the protein molecular weights markers were then loaded into individual wells of SDS-polyacrylamide gel using a syringe. Electrophoresis was performed using a vertical electrophoresis slab gel apparatus at a constant voltage of 200 volts throughout the electrophoresis process. Electrophoresis was terminated when the dye front was 2 to 3 mm away from the bottom edge of the gel for both experiments. The gel was stained with Coomassie blue.

In-gel digestion

The SDS-Polyacrylamide gel was washed thoroughly in 100 mmol/L NH₄HCO₃ and the differentially expressed protein bands from either normal or cancerous colonic tissues were then excised from the gel. In-gel digestion was performed using trypsin according to Gam and Aishah^[9] with slight modification. The gel pieces were first excised and shrunk by dehydration in acetonitrile. The solvent was then discarded and the gel pieces were dried in a vacuum centrifuge. A volume of 10 mmol/L dithiotreitol (DTT) in 100 mmol/L NH₄HCO₃ that was sufficient to cover the gel pieces was added and the protein was reduced

for 1 h at 56°C. After cooling to room temperature, the DTT solution was replaced with the same volume of 55 mmol/L iodoacetic acid in 100 mmol/L NH_4HCO_3 . After 45 min incubation at ambient temperature in the dark with occasional vortexing, the gel pieces were washed with 50-100 μL of 100 mmol/L NH_4HCO_3 for 10 min, dehydrated with acetonitrile, rehydrated in 100 mM NH_4HCO_3 and dehydrated in the same volume of acetonitrile. The liquid phase was removed and the gel pieces were dried in a vacuum centrifuge. The gel pieces were swollen in digestion buffer containing 50 mmol/L NH_4HCO_3 , 5 mmol/L CaCl_2 , and 12.5 ng/ μL of trypsin in an ice-cold bath. After 45 min, the supernatant was removed and replaced with 10 μL of the same buffer but without trypsin to keep the gel pieces wet during enzymatic cleavage at 37°C overnight. Peptides were extracted from the gel matrix by adding 15 μL of 20 mmol/L NH_4HCO_3 , vortexed and incubated at room temperature for 10 min and the supernatant was recovered after a brief spin. This was followed by adding (1 to 2 times the volume of gel pieces) 50 mL/L formic acid in acetonitrile:water mixture (70:30), vortex and incubated for 20 min at room temperature. It was then spun down and the supernatant was recovered. These steps were repeated 3 times. Pooled extracts were dried in a vacuum centrifuge and stored at -70°C. Each of the pooled extracts (peptides) was added with 30 μL of deionized water. Then, they were centrifuged at 500 r/min for 5 min at 15°C. The extracts were then subjected to LC/MS/MS analysis.

Mass spectrometric analysis

A volume of 5 μL of the sample was injected into a RPC-column (C_{18} 300 Å, 5 μm , 1 mm \times 150 mm) connected to a Hewlett Packard HPLC. A capillary pump was used to pump the mobile phase at 20 $\mu\text{L}/\text{min}$ flow rate, the linear gradient used was 5% B to 95% B in 65 min. Mobile phase A was 500 $\mu\text{L}/\text{L}$ formic acid in deionized water and B was 500 $\mu\text{L}/\text{L}$ formic acid in ACN. The HPLC was interfaced to an ion trap mass spectrometer. The dry gas temperature was 300°C, dry gas flow rate was of 8.0 L/min, nebulizer pressure of 30.0 psi. The above parameters were used subsequently for acquiring MS data. The peptides were ionized using electrospray soft ionization technique (ESI).

The experimental method was made up of one experimental protocol consisting of 2 scan events. The first scan event was a full scan MS and the second was the data dependent MS/MS scan which is dependent on the results of the first scan event. The most intense ion in a MS scan will be automatically isolated and excited to MS/MS scan. The parameters set for data dependent scan (MS/MS scan) were default collision energy (voltage) = 1.15 V, charge state = 2, minimum threshold = 3000 counts, and the isolation width = 2 m/z.

Mascot protein identification

The protein was identified using Mascot Protein Database Search engine. The Peptide Mass Tolerance was set as ± 2 u and ± 0.8 u was set for the Fragment Mass Tolerance. Only 1 missed cleavage was allowed. This software is available at www.matrix-science.com. Matches were computed using a probability-based Mowse score defined as $-10 \times$

Figure 1 Proteins profiles of normal and cancer colon tissues from four different patients. The proteins were extracted using in S1 buffer. RESULTS

Figure 1 shows the protein profiles of protein extracted using S1 buffer from normal and cancerous colon tissues of four different patients. Diagram 1 shows the consistent protein bands for both normal and cancerous tissues. The thick lines represent the protein bands that were expressed in all four tissues and the faint lines represent the protein bands that were expressed in three of the four patients. The distinct bands that were only detected in one particular tissue are ignored, as it may not represent the proteins that are involved in cancer formation. In colon cancer tissues, the protein bands that were expressed in all the four patients were at 190 ku, 177 ku, 160 ku, 48.8 ku, 39 ku, 35 ku, 27 ku, 26 ku and 24 ku. However, a protein band at 11 ku was detected in three of the four patients. In normal colon tissues, protein bands at 190 ku, 110 ku, 48.8 ku, 43 ku, 36.3 ku, 35 ku, 26 ku and 17 ku were found in all the patients' tissues while protein bands at 78 ku, 27 ku and 24 ku were found expressed only in three patients. When comparing cancerous and normal tissue, it is clear that some of the proteins were differently expressed between the two types of tissues.

Figure 2 shows the profiles of proteins extracted using S2 buffer from both normal and cancerous colonic tissues.

Figure 3 Proteins profiles of normal and cancer colon tissues from four different patients. The proteins were extracted using in S3 buffer. N: Normal colon tissues; C: Cancer colon tissues; M: Marker; Lanes 1 and 2: MMN samples; Lanes 3 and 4: LKH samples; Lanes 5 and 6: CCH samples and Lanes 7 and 8: NSC samples. Diagram 3 shows the consistent protein bands found in the normal and the cancer tissues of the figure.

Diagram 2 represents the consistent protein bands that were expressed in the tissues analyzed. For the cancerous tissues, the protein bands at 76 ku, 38 ku, 32 ku and 25 ku were consistently expressed in all the cancerous tissues analyzed while protein bands at 65 ku, 18 ku and 12 ku were only found in the tissues of three of the four patients. For the normal tissues, the bands at 180 ku, 65 ku, 38 ku, 32 ku and 25 ku were found in the tissues of all four patients while only one band at 12 ku was detected in the tissues of three patients. Most of the proteins extracted from cancerous tissues using S2 buffer were found at the low molecular weight region, in the range of 35 ku to 10 ku. In contrast, relatively few protein bands from normal tissues were detected in this region and those that were detected were present at low protein intensity.

Figure 3 shows the protein profiles of proteins extracted using S3 buffer from normal and cancer colon tissues of the four patients. Diagram 3 represents the

consistent protein bands expressed in the four tissues analyzed. Protein bands at 38 ku, 27 ku, 23 ku 20 ku and 17 ku from cancerous tissues were found in all four patients whereas only the band at 65 ku was found in three of the four patients. Normal tissues of the corresponding patients displayed bands at 38 ku, 27 ku and 20 ku whereas tissues from three patients were found to express consistent bands at 150 ku, 100 ku, 65 ku, 46 ku and 35 ku. The protein band at 65 ku was detected at the highest intensity compared to the other bands and it was uniquely expressed in all the patients except for patient #MMN, which was the only patient diagnosed with well differentiated adenocarcinoma cancer. Thus, its expression is probably related to the cancer grade. Nevertheless, this may just be an ambiguous assumption as only one patient with well differentiated cancer grade was analyzed. When comparing the protein profiles of protein extracted from tissues using S3 buffer, it is obvious that the expression of

Table 3 Unique proteins extracted in S1, S2, S3 buffers from colon tissues

SWISS-PROT accession number	Unique proteins (Normal tissues)	SWISS-PROT accession number	Unique proteins (Cancer tissues)
P32119	Peroxisomal protein 2 precursor	Q9BX84	LTRPC6 channel kinase 6
Q03001	Bullous pemphigoid antigen 1 precursor	Q9AVW8	DNA-directed RNA polymerase II largest chain EC 2.7.7.6

		S31975	14-3-3 protein epsilon

low molecular weight proteins (below 37 ku) in cancerous tissues was greater than that of the normal tissues.

Table 2 shows the list of proteins detected, with a total of 15 and 24 down-regulated and up-regulated proteins identified from normal and cancerous tissues, respectively. Table 3 shows the unique proteins that were identified from normal and cancerous tissues.

DISCUSSION

The sequential protein extraction technique consists of three types of protein extraction buffers, namely the S1 buffer, S2 buffer and S3 buffer. The S1 buffer is used mainly to extract aqueous soluble proteins, such as cytosolic proteins and nuclear proteins while the S2 and S3 buffers were used to extract proteins with intermediate to extreme hydrophobicity. The constituent of S2, which is made up of chaotropic agents and other reagents may disturb rugged protein-protein interaction found among structural, cytoskeletal proteins and aggregating proteins^[10]. However, the combination of urea and thioureas in S3 was used to enhance the solubility of membrane proteins^[8]. The extraction buffers were always used in the orderly sequence of S1 followed by S2 and then S3. The use of sequential protein extraction buffers was first suggested by Molloy *et al.*^[8] for separation of protein mixtures using 2D-gel electrophoresis. However, in our present study, the extracted proteins were separated using the SDS-PAGE technique, whereby direct comparison of protein profiles from tissues of four different patients was carried out.

In general, use of sequential extraction buffers is beneficial to this study because proteins were extracted according to their increasing hydrophobic strength, which may imply that proteins from different cellular compartments were extracted in different fractions. This method not only allows the analysis of proteins according to their localization in the cells but also reduces the number of proteins extracted in each fraction, which provides better resolution of proteins and their visualization in SDS-PAGE.

The protein profiles of the proteins extracted using the S1 and S2 buffers are significantly different, however the protein profiles of proteins extracted using S2 and S3 showed only slight differences. The significant variation between the protein profiles of S1 and S2 can be explained by the vast difference in the property of the proteins extracted, where S1 buffer extracts proteins only solubilize in aqueous solution while S2 buffer extracts the non-

aqueous soluble proteins. The protein profiles displayed by proteins extracted using S2 and S3 also showed a certain degree of variation as S3 buffer was used to enhance the solubility of more stringent proteins from the tissue^[11].

The differentially expressed proteins in each of the gels were then subjected to further analysis and the identity of each protein was analyzed using LC/MS/MS. Proteins were identified using the Mascot protein search engine on the basis of peptide mass matching^[12] with redundancy of post-translational modification and proteolysis. The definition of “up-regulated”, “down-regulated” and unique proteins in this study are solely dependent on their existence in SDS-PAGE. When analyzed using Quantity one software (BioRad), the intensity of the bands for up-regulated proteins was more intense in cancerous as compared to normal tissues while the “down-regulated” proteins were the proteins that were more intense in normal as compared to cancerous tissues. However, some of the intense protein bands in SDS-PAGE were found to contain more than one type of protein. Therefore, for the up-regulated and down-regulated protein bands, both the protein bands of the identical molecular weight from normal and cancerous tissues were excised and subjected to LC/MS/MS analysis. The proteins that were detected in both tissues were then quantified by their peptides’ peak areas in selected ion chromatogram analysis. The proteins present in one tissue and not the other are reported as unique proteins.

A total of ninety-five proteins were identified from the protein bands indicated earlier for both the normal and cancerous tissues. However, some of these proteins were of serum origin, due to the embedded blood vessels in the tissues, and these proteins were excluded from the protein list. Furthermore, some of the proteins were represented by more than one band as described by heterogeneity. The heterogeneous proteins were mainly derived from structural, transport and enzyme subunits such as Actin, gamma-enteric smooth muscle, Desmin, Vimentin, Keratin, type I cytoskeletal 10, Cytoskeletal 9, and Triosephosphate isomerase EC 5.3.1.1. Phosphorylation, glycosylation and limited proteolytic activities have been considered as major modification of proteins and they therefore affect the mobility of the modified proteins in SDS-PAGE^[13-15].

The structural proteins were mostly extracted from the cancerous tissues using the S3 buffer. The majority of the structural proteins identified belongs to the cytokeratin family. Williams *et al.*^[16] reported that cytokeratin expressing tumor cells contain cytokeratins 8 and 18, but not

cytokeratin 19 or vimentin. The roles of cytokeratins are commonly known to encompass both structural and signaling capabilities. In the present study, cytokeratin 18 was found in cancerous colon tissues in S3 buffer extracts. The expression of cytokeratin 18 in colonic cancerous tissues is consistent with those reported by Leong *et al*^[17]. In contrast, the expression of cytokeratin 18 was found reduced in malignant tumors of prostate carcinoma compared to benign prostatic hyperplasia^[4]. The expression of cytokeratins is sometimes used as an indicator of the behavioral changes of a tissue. For instance, in breast tissue, cytokeratin 8 has been reported to be the major receptor for plasminogen on breast cells^[18].

Vimentin is expressed at higher levels in the low-secreting variant. It is present in many cell lines, but normally absent from differentiated cells. Thus, lower vimentin expression in the high secretors may be indicative of a more differentiated phenotype^[19]. In our present study, vimentin is a down-regulated protein found in S1 buffer extracts. Williams *et al*^[16] has reported that the absence of vimentin in colon cancer tissue is due to its correlation with cytokeratin 19 or other cytokeratin expressions. However, Birchmeier *et al*^[20] and Seshadri *et al*^[21] reported no unequivocal correlation between a gain of vimentin and poor prognosis with primary tumors.

Hypothetical proteins were extracted in all three extraction buffers from both normal and cancerous colonic tissues. Generally, hypothetical proteins are defined as the proteins that were not described at the protein level, but were predicted from cDNA sequences^[22]. As shown in Table 2, a series of hypothetical proteins were identified. Afjelhi-Sadat *et al*^[23] suggested that the hypothetical proteins may serve as marker or protein vaccine candidates. Particularly when the hypothetical protein is found in cancerous tissue exclusively, it can be considered as novel and of pivotal importance. Some of the hypothetical proteins were detected as heterogeneous proteins suggesting the post-translational nature of the proteins.

Peroxiredoxin 2 is a type transport protein and it was extracted in the S1 buffer as a unique protein in normal tissues. Peroxiredoxin 2 is part of the peroxidase family, which are proteins that have been known to connect with cell proliferation, differentiation and apoptosis.

Fibrinogen is a type of channel protein and its role was reported to be supporting the binding of growth factors and promoting the cellular responses of adhesion, proliferation, migration during angiogenesis and tumor cell growth^[24]. Fibrinogen was detected in the S2 buffer of cancerous tissues. The presence of fibrinogen in cancer cells was demonstrated to affect the progression of tumor cell growth and metastasis on the basis that fibrinogen alters the ability of breast cancer cells to migrate^[24]. In addition, fibrinogen was also found present in lung cancer following the detection of elevated plasma fibrinogen levels in advanced stages of the disease^[25] and the localization of fibrinogen in tumor tissue^[26,27]. There are also reports of the deposition of fibrinogen on the surfaces of tumor cells and lymphocytes^[28,29]. In primary and metastatic tumor^[30], the presence of fibrinogen was regarded as an adverse event leading to tumor

development. Yamaguchi *et al*^[31] reported that lung cancer was developed through induction of hyperfibrinogenemia.

Transgelin (SM22-alpha) is a cytoskeletal-binding protein that was isolated in S1 buffer as a down-regulated protein. Maguire *et al*^[32] has reported that loss of transgelin expression is an indication of early tumor progression and the authors suggested that transgelin may serve as a diagnostic marker for breast and colon cancer. We found that the expression of transgelin in cancerous tissue is much lower than that of normal tissue. Other cytoskeletal-binding proteins that were detected in S1 buffer extract were Bullous pemphigoid antigen 1 precursor and Skeletal muscle beta-tropomyosin.

Some of the enzymes that play important roles in metabolic pathways and are essential for energy production were detected as up-regulated protein in S1 buffer. These enzymes include triosephosphate isomerase and LTRPC6 channel kinase 6. LTRPC6 channel kinase 6 is an essential ion channel and serine/threonine-protein kinase is crucial for magnesium homeostasis. It plays an important role in epithelial magnesium transport and in the active magnesium absorption in the gut and kidney.

Sodium/potassium-transporting ATPase alpha-4 chain was detected as the up-regulated protein in S3 buffer. It is an integral membrane protein that is located in the cell membrane^[33]. It catalyzes the hydrolysis of ATP coupled with the exchange of sodium and potassium ions across the plasma membrane.

Carbonate dehydratase is also the up-regulated protein detected in S1 and S2 buffer, it is a zinc-containing enzyme that catalyses the reversible hydration of carbon dioxide, which is significant in the transport of CO₂ from the tissues to the lungs. It was reported that over expression of the zinc enzyme carbonic dehydratase is observed in certain human cancers^[34]. Its expression was reported to be elevated in the renal cancer cells as compared to the surrounding normal kidney tissue^[35].

DNA-directed RNA polymerase II largest chain is the DNA-RNA binding protein that was detected as unique protein in S1 buffer extract of cancer tissues. It was also reported in human brain tumors^[36].

Proteins 14-3-3 are the protein-binding proteins that were isolated in the S1 buffer as unique proteins from colon cancer tissue. Protein 14-3-3 plays a role in the regulation of signal transduction protein pathways implicated in the control of cell proliferation, differentiation and survival^[37]. This protein was reported to play multiple roles in maintaining cell survival^[38,39]. Friedman *et al*^[40] has reported that protein 14-3-3 in three different isoforms was expressed up to 1.7 fold in the colon tumors as compared to normal colon tissue.

Alpha-1-antitrypsin is an endopeptidase inhibitor protein that was isolated as a unique protein in S1 buffer from normal tissue only. In individuals who lack this inhibitor protein, the protease destroys the membrane system, leaving the colon and rectum vulnerable to colorectal cancer development^[41]. The main role of alpha-1-antitrypsin is in defense against elastase damage that occurs in the lung under normal physiology conditions^[42]. Alpha-1-antitrypsin was detected in patients with lung cancer^[43] and was used as a cancer marker for cervical

cancer^[44]. Contrary to our finding, Friedman *et al.*^[40] reported the detection of alpha-1-antitrypsin in colon cancer.

ATP (GTP)-binding protein is ATP-binding protein that was detected as down-regulated protein in S2 buffer. It is a mitochondrial membrane protein.

Kinesin is a motor activity protein that was detected as an up-regulated protein in S2 buffer extract. It is a microtubule-associated force-producing protein that may play a role in organelle transport^[45]. This protein was also reported in breast cancer tissue^[46]. Kinesin-like protein 2 is an immunogenic breast cancer antigen^[47]. In addition, kinesin-like protein 2 was also reported in pancreatic cancer^[48].

ACTG1 is another type of motor activity protein that was detected as an up-regulated protein. It is a protein involved in the formation of filaments, which is the major component of the cytoskeleton^[49]. Its existence in colorectal cancer was also reported by Vadlamudi and Shin^[50]. Alteration of cytoskeletal proteins may have an important role in cancer initiation or progression. Mutations affecting four major cytoskeletal components have now been identified in human neoplastic cells. Chou *et al.*^[51] postulated that mutated cytoskeletal genes may be members of a class of oncogenes, which are fundamentally different from both the nuclear-acting and growth factor/receptor/protein kinase-related types of oncogenes.

In this study, a number of the differentially expressed proteins extracted from the normal and cancerous colonic tissues were identified. Amongst the proteins identified, some of the proteins have their roles identified in similar or other types of cancers. There are also a series of hypothetical proteins with unknown functions. Some of these proteins have their primary location at the cell membrane, which may serve as potential antigens for drug-targeted therapy or as candidates for vaccines against colon cancer. These proteins are under further investigation in our laboratory.

ACKNOWLEDGMENTS

We would like to thank the Ministry of Science, Technology and Innovation in Malaysia for providing the grant to carry out this project. We also want to extend our gratitude to the Ministry of Health in Malaysia for providing tissue specimens for the analysis.

Abstract

AIM: To study the anti-tumor effect of caffeic acid phenethyl ester (CAPE) and the influence of CAPE on β -catenin associated signaling pathway in SW480 colorectal cancer (CRC) cells.

METHODS: SW480 cells were treated with CAPE at serial concentrations. The proliferative status of cells was measured by methabenzthiazuron (MTT) assay. Cell cycle and cell apoptosis were analyzed using flow cytometry (FCM). Western blotting assay was used to evaluate the protein level of β -catenin, c-myc and cyclinD1. β -catenin localization was determined by indirect immunofluorescence.

RESULTS: CAPE displayed a strong inhibitory effect in a significant dose- and time-dependent manner on SW480 cell growth. FCM analysis showed that the ratio of G0/G1 phase cells increased, S phase ratio decreased and apoptosis rate increased after SW480 cells were exposed to CAPE for 24 h. Pretreatment of SW480 cells with CAPE significantly suppressed β -catenin, c-myc and cyclinD1 protein expression. CAPE treatment was associated with decreased accumulation of β -catenin protein in nucleus and cytoplasm, and concurrently increased its accumulation on the surface of cell membrane.

CONCLUSION: CAPE can inhibit SW480 cell proliferation by inducing cell cycle arrest and apoptosis. Decreased β -catenin and the associated signaling pathway target

INTRODUCTION

Caffeic acid phenethyl ester (CAPE) is a phenolic antioxidant. As an active component of propolis, CAPE has many biological and pharmacological functions including immunoregulation, anti-inflammatory, antiviral, antibacterial and antitumor activities. Several studies have demonstrated that CAPE has antiproliferative effect, apoptosis-inducing effect in various tumor cells *in vitro*^[1-4] and *in vivo*^[5,6]. CAPE also inhibited the development of azoxymethane-induced aberrant crypts in the colon of rats^[7]. Furthermore, a number of studies reported that CAPE elicits apoptosis and suppresses the growth of transformed cells, and the cytotoxicity of CAPE to transformed cells is sensitive and selective^[8-10]. Multiple molecular mechanisms seem to be involved in the tumor suppressive effects of CAPE. It was reported that CAPE could inhibit NF κ B and induce apoptosis *via* Fas signal activation in human breast cancer MCF-7 cells^[11]. Additionally, Carrasco *et al*^[12] found an 85% decrease in nuclear localization of the p65 subunit of NF-kappa B. While in C6 glioma cells, the tumor suppressor proteins P53 and p38 mitogen-activated protein kinase (p38 MAPK) are involved in CAPE-induced apoptotic cell death^[13].

Colorectal cancer (CRC) is the third most common cancer and the fourth most frequent cause of cancer death worldwide. Recent studies have indicated that in most of CRC, there are aberrant β -catenin associated signaling pathways^[14]. The β -catenin associated signaling pathway

plays critical roles in cell proliferation and differentiation, and the β -catenin is the central component in the pathway. Aberrant β -catenin associated signaling pathway, which generally results from inactivating mutation of adenomatous polyposis coli (APC) or activating mutation of β -catenin, leads to the accumulation of β -catenin in the nucleus of cells, which is subsequently complexed with T-cell factor (TCF) and promotes transcription of a variety of target genes, such as c-myc, cyclinD1, ultimately leading to cell aberrant proliferation and tumor formation. Dysregulation of β -catenin associated signaling and hence β -catenin expression is believed to be central to the early stages of sporadic colorectal carcinogenesis in humans^[15-17]. Therefore, control of β -catenin and/or control of the downstream target gene expression represents an opportunity for rational colorectal cancer therapy.

Here we report the anti-tumor effect of CAPE in association with β -catenin associated signaling in SW480 colorectal cancer cells. These studies have important implications for CAPE to be used as a potential therapeutic agent for colorectal cancer.

MATERIALS AND METHODS

Chemicals

CAPE, dimethyl sulphoxide (DMSO), PI, metha-benzthiazuron (MTT), mouse anti-human β -catenin, c-myc, cyclinD1 and β -actin monoclonal antibody were purchased from Sigma-Aldrich (USA). RPMI-1640 medium, fetal calf serum and trypsin-EDTA were purchased from Hyclone (USA). FITC and horseradish peroxidase-conjugated secondary antibody were obtained from Pierce Biotechnology (USA). Annexin-V and PI double staining kit and Tripure were purchased from Roche (Germany). Protein assay kits were obtained from Bio-Rad Labs (USA). Enhanced chemiluminescence (ECL) system was purchased from Amersham Life Science (UK). CAPE was dissolved with DMSO and adjusted to final concentrations with culture medium prior to use.

Cell culture

The human CRC cell line SW480 was purchased from the American Type Culture Collection (ATCC). The cells were cultured in RPMI-1640 medium supplemented with penicillin G (100 U/mL), streptomycin (100 μ g/mL) and 10% fetal calf serum. Cells were grown at 37°C in a humidified atmosphere of 50 mL/L CO₂ and were routinely subcultured using 0.25% (w/v) trypsin-EDTA solution.

MTT assay

The logarithmically growing SW480 cells were plated into a 96-well plate at a density of 4×10^3 cells/well. After 24 h, the cells were treated with CAPE at designated concentrations (2.5, 5, 10, 20, 40 and 80 mg/L) for 24, 48, 72 and 96 h, respectively. Control wells were treated with 0.1% DMSO alone. Then, 20 μ L MTT (5 g/L) was added to each well and incubated for an additional 4 h, and then culture media were discarded followed by addition of 0.15 mL DMSO and vibration for 10 min. The absorbance was measured at 490 nm. The inhibitory rates (IR) were calcu-

lated as follows: IR (%) = [(1-absorbance of the treated wells)/(absorbance of the control wells)] \times 100%. The 50% inhibitory concentration (IC₅₀) value was determined using CalcuSyn software.

Flow cytometry analysis

Cell density was adjusted to $0.3-1.0 \times 10^7$ cells/mL. Cells were serum-starved for 24 h and then treated with different concentrations of CAPE (2.5, 5 and 10 mg/L) for 24 h. Then the cells were harvested with trypsin-EDTA to produce a single cell suspension. The cells were pelleted by centrifugation and washed twice with phosphate-buffered saline (PBS). Then, the cell pellets were resuspended in 0.5 mL PBS and fixed in 5 mL ice-cold 70% ethanol at 4°C. The fixed cells were spun down by centrifugation and the pellets were washed with PBS. After resuspension with 1 mL PBS, the cells were incubated with RNase A (20 mg/L) and PI (50 mg/L) and shaken for 1 h at 37°C in the dark. The stained cells were analyzed using a FACScan flow cytometer in combination with BD analysis II software (Becton Dickinson).

Annexin-V and PI double-staining flow cytometry analysis

The cells were treated and harvested in the same way as mentioned above. Analysis of apoptosis was performed using the Annexin-V and PI double staining kit according to the manufacturer's protocol. After treatment with CAPE, the cells were immediately analyzed by flow cytometry. The apoptotic cells were localized in the right lower quadrant of a dot-plot graph by using Annexin-V-fluorescein versus PI.

Western blot analysis

Cells were placed in serum-free medium with or without CAPE (2.5, 5 and 10 mg/L) for 24 and 48 h, then were lysed in solubilization buffer containing sodium dodecyl sulfate (SDS) and β -mercaptoethanol. After centrifugation, the supernatant was collected and the protein concentration determined by the BioRad DC kit. Equal amounts of protein (50 μ g) in each sample were resolved in 10% SDS polyacrylamide gel electrophoresis (SDS-PAGE) and transferred to a polyvinylidene difluoride (PVDF) membrane. After blocked with 2% skim milk, the membranes were incubated with primary antibodies at appropriate dilution (β -actin, 1/1000; β -catenin, c-myc and cyclinD1, 1/500) overnight at 4°C. Horseradish peroxidase-conjugated secondary antibody was diluted 1/5000 and incubated for 1 h at 20°C. Immunoreactive proteins were detected with an ECL system, and light emission was captured on Kodak X-ray films. Product bands were quantitated by scanning densitometry.

Indirect immunofluorescence

SW480 cells grown on glass coverslips were treated for 48 h with CAPE (2.5, 5 and 10 mg/L) or an equivalent dilution of DMSO, under standard culture conditions as described above. Then cells were washed with PBS and fixed with methanol for 20 min. Incubation with monoclonal anti- β -catenin antibody (1:200) was carried out overnight at 4°C. This was followed by incubation with FITC-

Figure 1 Effect of CAPE on SW480 cell proliferation. SW480 cells were treated with CAPE at indicated concentrations for 24, 48, 72 and 96 h. The cell viability was determined by MTT assay.

Figure 2 Effect of CAPE on SW480 cell cycle distribution. The percentage of cells in each phase of the cell cycle, G₀/G₁, S, and G₂/M was determined by FCM after cells were treated with indicated concentrations (2.5, 5 and 10 mg/L) of CAPE for 24 h. ^a*P* < 0.05 vs the control group, treated with vehicle, DMSO only.

conjugated secondary antibody (1:200) for 1 h at room temperature. Omission of the primary antibody was used as a negative control. Images were collected using laser scanning confocal microscopy.

Statistical analysis

Data were expressed as mean \pm SD. Analysis of data was performed using one-way ANOVA. *P* < 0.05 was considered statistically significant.

RESULTS

Effect of CAPE on cell proliferation

SW480 cells were treated with various concentrations (2.5, 5, 10, 20, 40 and 80 mg/L) of CAPE for 24, 48, 72 and 96 h, respectively. Then the cell viability was measured by MTT assay. CAPE showed a significant dose-dependent and time-dependent inhibition of cell growth (Figure 1). The IC₅₀ value for CAPE at 24, 48, 72 and 96 h after treatment was 20.27, 11.38, 6.15 and 5.44 mg/L, respectively.

Effects of CAPE on cell cycle progression

In order to examine the effects of CAPE on cell cycle progression, SW480 cells were treated with designated concentrations of CAPE for 24 h. The distributions of cells in each of the cell cycle phases were determined by FCM. As shown in Figures 2 and 3, the percentage of cell

Figure 3 Flow cytometry analysis of SW480 cells following 24 h incubation with CAPE (A) 0 mg/L, (B) 2.5 mg/L, (C) 5.0 mg/L, (D) 10 mg/L.

Figure 4 Effect of CAPE on SW480 cell apoptosis. After treated with CAPE at indicated concentrations for 24 h, the SW480 cell apoptosis rates were analyzed by Annexin-V and PI double-staining flow cytometry. ^a*P* < 0.05, ^b*P* < 0.01 vs the control group.

population of the G₀/G₁ phase significantly increased, while those in S and G₂/M phase decreased. CAPE caused cell cycle arrest in G₀/G₁ phase in a dose-dependent manner.

Effect of CAPE on apoptosis

After SW480 cells were exposed to CAPE at various concentrations (2.5, 5 and 10 mg/L) for 24 h, Annexin-V and PI double-staining flow cytometry analysis showed that the apoptosis rates were 9.1% \pm 0.7%, 15.23% \pm 0.6% and 21.1% \pm 1.44%, respectively, which were significantly higher than that in the control group (3.7% \pm 0.9%). CAPE induced apoptosis of SW480 cells in a dose-dependent manner (Figures 4 and 5).

Effect of CAPE on the expression of β -catenin, c-myc and cyclinD1

To investigate the mechanisms underlying CAPE induced apoptosis, we examined the effect of CAPE on the expres-

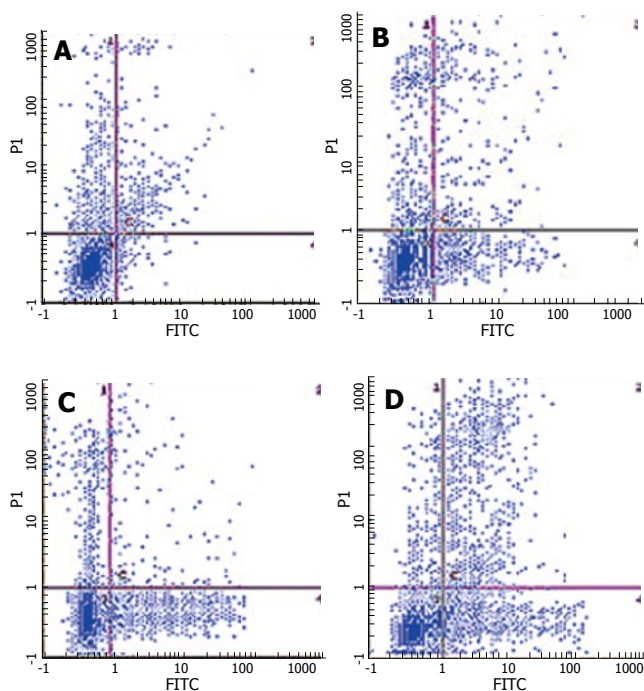

Figure 5 Annexin-V and PI double-staining flow cytometry analysis of SW480 cells following 24 h incubation with CAPE (A) 0 mg/L, (B) 2.5 mg/L, (C) 5.0 mg/L, (D) 10 mg/L.

Figure 6 Western blot analysis of β -catenin, c-myc and cyclinD1 protein expression in SW480 cells following 24 and 48 h incubation with indicated concentrations of CAPE. β -actin served as a loading control.

sion of β -catenin signaling pathway related genes. After SW480 cells were exposed to CAPE (2.5, 5 and 10 mg/L) for 24 and 48 h, Western blot analysis showed that CAPE significantly suppressed β -catenin protein expression in a dose and time-dependent manner. CAPE treatment after 48 h markedly decreased the expression of c-myc and cyclin D1, two of the β -catenin associated signaling pathway target genes (Figure 6).

Indirect immunofluorescence studies of β -catenin localization in SW480 cells revealed that CAPE treatment decreased the accumulation of β -catenin protein in nucleus and cytoplasm, and concurrently increased its accumulation on the surface of cell membrane (Figure 7).

DISCUSSION

Propolis has been used since ancient times in folk

Figure 7 Indirect immunofluorescence analysis of β -catenin protein localization in SW480 cells following 48 h incubation with CAPE (A) 0 mg/L, (B) 10 mg/L.

medicine. Researches indicate that propolis exhibits immunoregulation, anti-bacterial, anti-inflammatory and anti-tumor activities^[18-20]. As an active component of propolis, CAPE is receiving much attention in the medical research community because of its potential for the treatment of a number of disorders, including cancer. Recent studies demonstrated that CAPE has antiproliferative and apoptosis-inducing effects in various tumor cells. An *in vivo* study showed that CAPE decreased the growth of the xenografts of C6 glioma cells in nude mice^[6]. Also, dietary intake of CAPE decreased tumor formation in the enterocytes of the Min/+ mouse^[21].

In the present study, we investigated the effect of CAPE on cell proliferation, cell cycle and apoptosis of SW480 CRC cells. Our data demonstrated that CAPE treatment could significantly inhibit cell growth in a dose- and time-dependent manner, along with induction of G₀/G₁ arrest and apoptosis in SW480 cells.

Multiple molecular mechanisms seem to be involved in the tumor suppressive effect of CAPE. Recently, it was reported that CAPE could inhibit NF κ B, inducing apoptosis *via* Fas signal activation in human tumor cells^[11,12]. Hung *et al*^[22] reported that down-regulation of Mcl-1 gene expression and activation of caspase-8 are associated with CAPE-triggered cell apoptosis. Moreover, tumor suppressor proteins P53 and p38 MAPK play a prominent role in the CAPE-induced apoptotic cell death in C6 glioma cells, which might contribute to the anti-tumor effect in these cells^[13].

Our results suggest that the anti-tumor effects of CAPE on SW480 cells are associated with down-regulation of the β -catenin associated signaling pathways. β -catenin plays a dual role in cells. It is a structural component of cell-cell adherent junctions as well as a key player in β -catenin associated signaling pathway^[23]. The signaling function of β -catenin is particularly important in colorectal cancer since mutations of APC or tumor-associated mutations of β -catenin lead to its stabilization^[24,25]. Here we showed that CAPE treatment inhibited β -catenin in a dose-dependent manner in SW480 cells. More interestingly, CAPE changed the localization of β -catenin in cells. As shown in Figure 7, nuclear accumulated β -catenin in SW480 cells mainly relocalized on the cell membrane at cell-cell contacts after CAPE treatment. Two of target genes of the activated β -catenin associated signaling pathways have been reported to be c-myc and cyclin D1^[26,27]. Oncogenes c-myc and cyclinD1 are a kind of effector protein of the karyomitosis signal, which can trigger and regulate the transcription of the genes related with pro-

liferation. They are frequently overexpressed in several human tumors, including colorectal cancer. Our results showed that CAPE treatment markedly decreased the expression of c-myc and cyclinD1. This indicates that CAPE induced cell cycle arrest and apoptosis might be associated with down-regulation of β -catenin associated signaling pathways.

In summary, we have shown that CAPE can inhibit the growth of human SW480 colorectal cancer cells by inducing cell cycle arrest and apoptosis. Decreased β -catenin and the β -catenin associated signaling pathway target gene expression might mediate the anti-tumor effects of CAPE. These findings have strong implications for CAPE as a potential therapeutic agent for colorectal cancer.

Abstract

AIM: To find the relationship between hepatitis B virus (HBV) and hepatocytes during the initial state of infection by cDNA microarray.

METHODS: Primary normal human hepatocytes (PNHHs) were isolated and infected with HBV. From the PNHHs, RNA was isolated and inverted into complement DNA (cDNA) with Cy3- or Cy5- labeled dUTP for microarray analysis. The labeled cDNA was hybridized with microarray chip, including 4224 cDNAs. From the image of the microarray, expression profiles were produced and some of them were confirmed by RT-PCR, immunoblot analysis, and NF- κ B luciferase reporter assay.

RESULTS: From the cDNA microarray, we obtained 98 differentially regulated genes. Of the 98 genes, 53 were up regulated and 45 down regulated. Interestingly, in the up regulated genes, we found the TNF signaling pathway-related genes: LT- α , TRAF2, and NIK. By using RT-PCR, we confirmed the up-regulation of these genes in HepG2, Huh7, and Chang liver cells, which were transfected with pHBV1.2 \times , a plasmid encoding all HBV messages. Moreover, these three genes participated in HBV-mediated NF- κ B activation.

CONCLUSION: During the initial state of HBV infection, hepatocytes facilitate the activation of NF- κ B through up regulation of LT- α , TRAF2, and NIK.

INTRODUCTION

Human hepatitis B virus (HBV) is a causative agent for liver diseases such as cirrhosis and hepatocellular carcinoma (HCC)^[1]. Chronic infection of HBV affects approximately 800 million people and is the principal cause of chronic liver diseases^[2]. Moreover, HBV carriers have a much higher frequency of developing liver cancer than uninfected people^[3].

HBV has a small, partially double-stranded DNA genome. After viral infection of hepatocytes, the partially double-stranded DNA genome converts into covalently closed circular DNA (cccDNA) in nuclei^[4-7]. Several kinds of viral transcripts are then produced by the host RNA polymerase. The transcripts encode for viral polymerase, viral oncogene HBx protein, and viral structural proteins such as surface proteins and core proteins^[3].

Many efforts have been made to investigate the process of liver disease by HBV. Traditional techniques such as Northern blot and reverse transcription polymerase chain reaction (RT-PCR) for identification of genes differentially expressed by HBV infection have shown limited success, because only one gene or at best a handful of genes can be studied in one experiment. However, complementary DNA (cDNA) microarray allows the study of several thousands of genes at one time. To evaluate the relationship between HBV infection and liver diseases, recent studies have analyzed the gene expression profiles at tissue level. In these studies, the effects of HBV infection are analyzed by cDNA microarray analysis of HCC tissue samples^[8-10]. Through the analyses, many differentially expressed genes can be identified^[11]. The analyses, however, have mainly focused on the gene expression profiles of already transformed cells or long-term infected HBV hepatocytes. Therefore, these analyses mostly stem from the analysis of the end result of pathogenesis of HBV in hepatocytes rather than the analysis of ongoing pathogenesis of HBV infection in hepatocytes. In this report, however, we focused on the gene expression profile analysis of the early stage HBV infection, thereby excluding factors such as responses to host immune surveillance. To mimic the early

stage HBV infection of hepatocytes, we isolated primary normal human hepatocytes (PNHHs) and the cells were infected with HBV in culture. These conditions were chosen as they could represent the most similar conditions to those *in vivo*, except for the absence of other types of cells such as immunocytes. Therefore, gene expression profiles in this report could show the result of interaction only between HBV and PNHHs. In this study we have identified 45 down-regulated genes and 53 up-regulated genes.

MATERIALS AND METHODS

Construction

pHBV1.2 \times , a plasmid which provides all HBV transcripts, was used to infect PNHHs as previously described^[12]. This construct was similar to that as described by Guidotti *et al.*^[13]. Mammalian expression vector for NIK and NIK DN (aa 624-947) was provided by DV Goeddel (Turarik Inc.)^[14], for TRAF2 and TRAF2 DN (aa 241-501) by Dr. SY Lee^[15].

HBV production and infection

We transfected HepG2 cells with pHBV1.2 \times constructs for generation of HBV using Fugene 6 transfection reagent (Roche) as instructed by the manufacturer. After transfection, the cells were cultured for 5 d and harvested. HBV particles in the harvested media were cleared and concentrated through ultracentrifugation using PST55Ti rotor (Hitachi) for 1 h at 220 000 g with 3 mL cushion buffer containing 20 g/L sucrose, 50 mmol/L Tris-HCl pH 7.5, and 30 mmol/L NaCl. After ultracentrifugation, the pellet was resuspended with 1 \times PBS. The resuspended viral solution was filtered with a 0.2 μ m pore filter (Millipore). The titer of HBV solution was adjusted to 10⁹ virus genome equivalent (v.g.e.) per mL. PNHHs were infected with the above virus solution at about 100 v.g.e. per cell. Using this method, the efficiency of HBV infection to PNHHs was generally 50%^[16].

Isolation and culture of PNHHs

Healthy parts of a liver from a patient who underwent hepatic resection for an intrahepatic stone at the Inje University Paik Hospital, Pusan, Korea was obtained and used as the source of hepatocytes. The removed tissue was immediately placed in Hank's balanced salt solution (HBSS) and processed for cell culture. Isolation of hepatocytes was performed using a two-step collagenase perfusion technique^[17,18]. The isolated hepatocytes were resuspended in a nutrient medium containing 90 mL/L Williams' E and 10 mL/L Medium 199, supplemented with 10 μ g/mL insulin, 5 μ g/mL transferrin, 10⁻⁷ mol/L sodium selenite, and 50 mL/L FBS.

Confirmation of PNHH infection with HBV

A test was performed with the isolated DNA to determine whether the HBV-infected PNHHs formed cccDNA. Amplification with primers specific for both outside regions was performed with the isolated DNA because the region was specific for cccDNA rather than partially double-stranded DNA found in viral particles. The primers

used are (5'-CTATGCTGGGTCTTCCAAATT-3') which anneals to near the codon for amino acid 80 in human HBc open reading frame (ORF) and (5'-TTTCTGTGTA-AACAATATCTG-3') which anneals to near the codon for amino acid 680 in HBV Pol ORF. Therefore, if cccDNA was present in the isolated DNA, an amplified 1 kb product could be obtained. In this test, DNA isolated from mock-infected PNHHs was used as the negative control. A PCR test was performed with RNA to confirm whether HBV transcripts were produced. Reverse transcription amplification was performed with primers specific for the epsilon regions: (5'-CAACTTTTTCACCTCTGCC-TA-3') which anneals to DR1 and the reverse primer (5'-GATCTCGTACTGAAAGGAAAGA-3'). In addition, to detect HBV genome, real-time PCR was also performed as previously described^[12].

cDNA array analysis

RNA was isolated using TRIzol reagent (Life Technologies) according to the manufacturer's instructions. With the total isolated RNA, reverse transcription was performed with Cy5-labeled dUTP in the experimental sample and Cy3-labeled dUTP in the control. Fifty micrograms of RNA, 1.5 ng oligo dT primer, and 1 ng control RNA containing lambda DNA sequences with a poly A sequence at the 3' ends for reverse transcription, were mixed and volume of the mixture was adjusted to 20 μ L. The mixture was incubated at 70°C for 5 min. After incubation, the mixture was quickly cooled on ice. With this whole reaction mixture, the labeling reaction was performed under the following conditions: 1 \times reverse transcription buffer, 0.6 mmol/L Cy3- or Cy5-dUTP, 40 U of RNase inhibitor (Roche), 50 U of AMV-RT (Roche) and a dNTP mix containing 1 mmol/L dATP, 1 mmol/L dGTP, 1 mmol/L dCTP, and 0.4 mmol/L dTTP at 42°C for 1 h. After 1 h, 50 U of AMV-RT was added to the reaction mixture and the mixture was further incubated for 1 h for complete reverse transcription. Reverse transcription was stopped by the addition of 5 μ L 0.5 mol/L EDTA. The synthesized cDNA was purified using a chromaspin column (Clontech) as instructed by the manufacturer and precipitated with ethanol. Both Cy3- and Cy5-labeled cDNAs were resuspended with 100 μ L hybridization buffer, containing 6 \times standard saline citrate (SSC), 2 g/L sodium dodecyl sulfate (SDS), 5 \times Denhardt solution, and 1 mg/mL salmon sperm DNA. The labeled cDNA was used for hybridization to the cDNA microarray chip at 62°C. The chip was arrayed using a GMS417 arrayer (Genetic Microsystems Inc., Woburn, MA) with 4224 cDNAs and internal standards such as tubulin and actin and external standards such as lambda DNA. After 16-18 h of hybridization, the hybridized array was washed twice at 58°C for 30 min with washing buffer I containing 2 \times SSC and 2 g/L SDS and washed once with washing buffer II containing 0.05 \times SSC at room temperature for 5 min.

Analysis of chips

For quantification of the signals, the chips were scanned using an array scanner generation III (Molecular Dynamics) followed by image analysis using ImaGene ver. 3.0 software (BioDiscovery Ltd., Swansea, UK). The signal intensity

of each spot was adjusted to obtain more accurate data by subtracting the background signals from the immediate surroundings. In this analysis, a difference in the ratio of more than two folds was considered significant.

Cells and transfection

HepG2, Huh7, and Chang liver cells were maintained in minimum essential media (Sigma) supplemented with 100 mL/L fetal bovine serum. For reverse transcription-polymerase chain reaction and luciferase reporter assay, cells were seeded in 12-well plates at a density of 0.2×10^6 cells per well and transfected on the following day with the appropriate DNA and fugene 6 (Roche) as described by the manufacturer. To normalize the total DNA, pUC119 and backbone DNA of pHBV1.2 \times were used. The transfection efficiency for HepG2 with fugene 6 was usually 10%-20%.

RT-PCR analysis

Cells were transfected with pUC119 and pHBV1.2 \times . After 48 h of transfection, total RNA was extracted with TRIzol reagent (Life Technologies) as described by the manufacturer. cDNA was produced by reverse transcription using the same procedure as cDNA microarray analysis. Following reverse transcription, the synthesized cDNA was amplified with 2.5 U Hot start Taq polymerase (Takara), GAPDH specific primer set, and appropriate primer set. The sequences of the primer set are as follows: TRAF2 specific forward(5'-AGGGGACCCT-GAAAGAATAC-3'), TRAF2 specific reverse(5'-CAGGGCTTCAATCTTGTCTT-3'), NIK specific forward(5'-TACCTCCACTCACGAAGGAT-3'), NIK specific reverse(5'-CAAGGGAGGAGACTTGTTTG-3'), LT- α specific forward(5'-AGCTATCCACCCACACAGAT-3'), LT- α specific reverse(5'-GTTTATTGGGCTTCATC-GAG-3'), GAPDH specific forward(5'-ATCATCCCT-GCCTCTACTGG-3'), and GAPDH specific reverse (5'-TGGGTGTCGCTGTTGAAGTC-3'). PCR amplification was performed using Gene mp PCR system 2400 (Perkin-Elmer) with 5 min initial denaturation at 95°C and 35 cycles of 50 s at 95°C, 50 s at 60°C, and 50 s at 72°C, followed by 7 min of extension at 72°C. To separate the PCR fragments, 15% agarose gel was used.

Immunoblot analysis

To confirm NIK and TRAF2 protein expression, we performed immunoblot analysis with anti-NIK rabbit polyclonal antibody (Santa Cruz) and anti-TRAF2 mouse monoclonal antibody (Santa Cruz). HepG2 cells were seeded in 6-well plates at a density of 0.4×10^6 cells per well. Cells were lysed with RIPA buffer containing 25 mmol/L Tris-HCl (pH 7.4), 150 mmol/L KCl, 5 mmol/L EDTA, 10 mL/L Nonidet P-40 (NP-40), 5 g/L sodium deoxycholate, and 1 g/L SDS and centrifuged at 12000 g for 10 min. The supernatants were separated by 12% SDS-PAGE protein gel for immunoblot analysis.

Luciferase reporter assay

After seeded on 12-well plates, HepG2 cells were co-transfected with appropriate DNA (Figure 5), 0.1 μ g pNF- κ B-

Figure 1 Confirmation of HBV infection for PNHHs using PCR for cccDNA formation and RT-PCR for production of transcripts. From PNHHs infected with HBV, RNA and DNA were extracted using TRIzol reagent as described in Materials and Methods. As a negative control, mock-infected PNHHs were used. **A:** With the extracted DNA, cccDNA was confirmed by a PCR analysis as described in Materials and Methods; **B:** With the extracted RNA, a transcript of HBV was confirmed by RT-PCR analysis as described in Materials and Methods; **C:** With the extracted RNA, a transcript of HBV was confirmed by real-time PCR as previously described^[19].

luciferase and 0.1 μ g pCMV- β -galactosidase. After 48 h of transfection, cell extracts were prepared and luciferase reporter assay was performed using a luciferase assay system (Promega) as described by the manufacturer. The transfection efficiency was normalized by its galactosidase activity. The assay was triplicated and repeated at least twice.

RESULTS

Confirmation of PNHH infection with HBV

To confirm HBV infection to PNHHs, DNA was isolated during the RNA purification step with TRIzol reagent as instructed by the manufacturer. Infection was confirmed through PCR-based amplification specific only for cccDNA in nuclei of the infected cells. Figure 1 shows that the amplified product appeared in HBV-infected cells, indicating that HBV did infect PNHHs and that the nucleocapsid was transported into nuclei of the infected hepatocytes (Figure 1A). RT-PCR analysis of the HBV transcripts amplified with primers specific for epsilon and polymerase regions as described in Materials and Methods confirmed the presence of HBV RNA transcripts in the infected cells (Figure 1B). Real time PCR showed that HBV was not detected until 6 d after infection (Figure 1C).

Figure 2 Scatter plot analysis. For normalization of the Cy3 (3D) and Cy5 channel signal (5D) channels, data obtained from the raw image scanning were plotted in a scatter plot using Excel software (Microsoft). **A:** The X-axis represents Log_2 (3D/5D) and the Y-axis Log_2 (3D/5D); **B:** The X-axis represents Log (5D) and the Y-axis Log (3D/5D); **C:** The X-axis represents Log (5D) and the Y-axis Log (3D/5D) F, in which "F" is the function for normalization. The bottom panel shows data with signals fitted to an exponential decay curve.

Figure 3 Correlation between three sets of PNHHs infected for eight days. **A:** With the reliable signals in obtained signals, the correlation efficient was calculated between each experiment; **B:** In addition, another correlation efficient was also calculated with only the selected genes, which were differentially expressed more than 2 folds.

Raw data analysis

The experiments were carried out in triplicate at the infection step for more certain identification of genes differentially expressed by HBV infection. From each of the HBV infected cells for over 8 d, RNA was isolated and analyzed by microarray. As a result, three sets of cDNA array images were obtained. We analyzed the intensity of the raw image through scatterplot analyses. Figure 2A shows scatterplot analyses of \log (Cy3 signal \times Cy5 signal) *vs* \log_2 (Cy3 signal/Cy5 signal). This showed that each plot tended to divert from the general small curve (Figure 2A). But, each scatterplot analysis of Log (Cy3 signal/Cy5 signal) *vs* Log (Cy5 signal) showed a curve closer to the exponential decay (Figure 2B). Therefore, the data were fitted to an exponential decay curve for Cy3 per Cy5 channel correction (Figure 2C). Through these steps, we obtained a higher confidence ratio of the Cy3 signal compared to the Cy5 signal for each chip. With the ratios obtained, we analyzed the correlation coefficient between the data of the three chips. The correlation coefficient turned out to be more than 0.7 (Figure 3A), suggesting that the relationship between each chip was significant. The correlation coefficient for genes that were differentially expressed more than two folds was more than 0.95 (Figure 3B). Selected genes that were differentially expressed more than two folds, showed a high reproducibility among the triplicate microarray

analyses.

Analysis of differentially regulated genes

Through a microarray analysis of PNHHs infected with HBV, we obtained the profile of 45 genes that were down regulated more than two folds compared to the control. The 45 down-regulated genes were analyzed classified by function (Table 1). Table 1 shows that many transcription factors related to RNA polymerase II, were down-regulated by HBV infection. In contrast, transcription factors such as C/EBP, which is used for transcription of HBV genes^[19,20], were not differentially expressed. That is, the C/EBP expression level was changed less than two folds.

From the analysis by cDNA microarray, 53 up-regulated genes were identified by an increase of more than two folds in their differential expression. Table 2 shows that growth- and tumor-related molecules comprised a proportion of the up-regulated genes. The positive effector genes for tumor and proliferation have found to be GDF11^[21] and NOL1^[22] and the negative effector genes EXTL3^[23] and RAD50. The most interesting genes have found to be the TNF signaling pathway- related genes. LT- α is an inflammatory cytokine and induces the TNF signaling pathway as a ligand for TNF receptor (TNFR). LT- α binds to TNFR and recruits TRAF2. MAP3K14 (NF- κ B inducing kinase, NIK) binds to TRAF2 and activates NF- κ B^[24].

Table 1 Forty-five differentially down-regulated genes obtained and categorized by their function

Category	UniGene	Gene name	Symbol	Locus	Function	Control/ HBV infection	P-value

LT- α , TRAF2, and NIK were also up-regulated in the experiment (Table 2). This means that HBV activates NF- κ B through up-regulation of LT- α , TRAF2, and NIK.

RT-PCR analysis and immunoblot assay of selected genes

According to the cDNA microarray data, three genes related to the TNF signaling pathway, LT- α , TRAF2, and NIK, were up-regulated. Upregulation of these genes was confirmed by RT-PCR. For RT-PCR analysis, primer sets

specific to LT- α , TRAF2, and NIK, were used and experiments were performed in hepatoma-derived cell lines, including HepG2, Huh7, and Chang liver cells. As a result, the mRNA levels of these three genes in each cell line were increased by pHBV1.2 \times transfection (Figure 4). In addition to RT-PCR, the expression of NIK and TRAF2 was confirmed at the protein level (Figure 5). The expression of LT- α , was confirmed by immunofluorescence staining analysis (data not shown).

Figure 4 RT-PCR analysis of selected genes. Mock means untransfected cells. pUC119 is backbone of pHBV1.2x, so pUC119 transfected cells are the negative control for pHBV1.2x transfected cell. In the hepatoma-derived cell lines, HepG2, Huh7, and Chang liver cells, TRAF2, NIK, and LT- α mRNA level in pHBV1.2x transfected cells were up-regulated rather than mock and pUC119 transfected cells.

Figure 5 Immunoblot assay of TRAF2 and NIK. pUC119 is a backbone DNA about pHBV1.2x. In the HepG2 cells transfected with pHBV1.2x, the protein levels of NIK (A) and TRAF2 (B) were increased. β -actin was used to normalize total protein level.

NF- κ B activation through TRAF2, NIK mRNA up regulation

According to cDNA microarray and RT-PCR analysis, mRNA expression of LT- α , TRAF2, and NIK was up-regulated by HBV. Since their expression was related to NF- κ B activation. HBV-mediated NF- κ B activation might be involved in the up regulation of these genes. To determine whether these genes actually are involved in HBV-mediated NF- κ B activation, we performed a luciferase assay with a pNF- κ B-luciferase vector as a reporter plasmid. To elucidate whether HBV-mediated NF- κ B activation is dependent on TRAF2 and NIK of three genes, we cotransfected pTRAF2 DN or pNIK DN, the dominant negative form of pTRAF2 or pNIK, with pNF- κ B-luciferase, pCMV β -galactosidase, and pHBV1.2x (Figure 6). The experiment for LT- α was performed with anti-LT- α , to neutralize LT- α . The pHBV1.2x produced about a 4.2 folds greater increase in NF- κ B luciferase activity than pUC119. However, pHBV1.2x cotransfection with TRAF2 DN or NIK DN produced about a 3.5 or 1.2 fold relative increase (Figure 6) and treatment with anti-LT- α decreased the ratio to less than 4.2 folds (data not shown). These findings led us to think that HBV could activate NF- κ B and that this HBV-mediated NF- κ B activation might require LT- α , TRAF2, and NIK. DC.

DISCUSSION

In this report, we focused on the interaction between HBV and hepatocytes during the initial stage of infection. To mimic hepatocyte infection with HBV under *in vivo* conditions, we isolated PNHHs and infected them with HBV. We chose this method because cultured cell lines

Figure 6 HBV-mediated NF- κ B activation through TRAF2 and NIK. In pHBV1.2x transfected HepG2 cells, NF- κ B activity was increased more than pUC119 transfected cells. But in cotransfected cells with pHBV1.2x and TRAF2 DN or NIK DN, NF- κ B activity was decreased less than pHBV1.2x transfected cells.

such as HepG2 are seldom infected with HBV^[25,26], and transformed cultured cells have many physiological properties that are altered in the original state of hepatocytes^[27,28]. In this experiment, the same hepatocytes were used as a control. Since they are produced under identical conditions, a pair of samples of the same genetic background could be obtained. With these samples, we were able to analyze differentially expressed genes. As a result, we obtained gene expression profiles and 98 consistently differentially expressed genes were identified by gene expression profiles. Of these genes, 53 were up-regulated and 45 down-regulated. It was reported that there are no genes uniformly correlated with HBV DNA profile during the initial host response to HBV infection^[29]. However, because this study was performed on chimpanzees, there are some considerations in making a comparison between this study with our report. Our report analyzed the effect of HBV on PNHHs at cellular level without any other cell types, including immunocytes. So the influence of immunocytes was not included in this analysis. In addition, the difference in human beings and chimpanzees needs to be taken into consideration.

The results of our study showed that a proportion of the down-regulated genes was transcription factor-related genes and a proportion of the up-regulated genes was TNF signaling pathway-related genes. Down regulation of transcription factors may be helpful for the transcription of the HBV gene because the transcripts of the host cell can be repressed and the transcriptional machinery can be efficiently used for viral transcription. C/EBP, which is involved in viral genome transcription^[19,20], had no substantial differential expression in this experiment. In addition to down regulation of transcription factor for virus transcription, up regulation of cell proliferation-related genes may help viral replication. Of the up-regulated genes,

LT- α , TRAF2, and NIK may induce cell proliferation *via* NF- κ B activation.

In fact, LT- α is mainly related to the signal cascade for apoptosis and generally involves the host defense system^[30]. However LT- α is also related to cell proliferation. Usually, TNF signaling including LT- α , can induce apoptosis and proliferation^[31]. TNF signaling by LT- α has a signal cascade from TNFR to TRADD. In the case of apoptosis, TRADD-FADD interaction is needed to activate caspase 8^[31]. In the case of proliferation, TRADD-TRAF2 interaction induces activation of NF- κ B, a proliferation-inducing transcription factor^[31]. After TRAF2 binds to TRADD, NIK binds to TRAF2 and activates NF- κ B through IKK activation and I κ B- α degradation^[24,32-34]. In cDNA microarray data, among genes related to the two opposite effects initiated by LT- α , proliferation-related genes are up-regulated. FADD is not differentially altered by more than two folds. Therefore, HBV infection may strengthen the TNF signaling pathway to cell proliferation through the induction of gene expression.

In conclusion, HBV induces NF- κ B activation by up-regulating LT- α , TRAF2, and NIK, and cell proliferation by activating NF- κ B.

Abstract

AIM: To pharmacologically modulate Th polarization in the ileum exposed to ionizing radiation by using the immuno-modulatory/apoptotic properties of Caffeic Acid Phenethyl Ester (CAPE).

METHODS: Rats received CAPE (30 mg/kg) treatment ip 15 min prior to intestinal 10 Gy γ -irradiation and once a day for a 6 d period after irradiation. Expression of genes implicated in Th differentiation in ileal mucosa (IL-23/IL-12R β 2), Th cytokine responses (IFN- γ , IL-2, IL-4, IL-13), Th migratory behaviour (CXCR3, CCR5, CCR4), Th signalling suppressors (SOCS1, SOCS3), transcription factor (T-Bet, GATA-3) and apoptosis (FasL/Fas, TNF/TNFR, XIAP, Bax, caspase-3) was analyzed by RT-PCR 6 h and 7 d post-irradiation. CD4⁺ and TUNEL positive cells were visualized by immunostaining.

RESULTS: The expression of Th1-related cytokine/chemokine receptors (IFN- γ , IL-2, CXCR3, CCR5) was repressed at 7 d post-irradiation while Th2 cell cytokine/chemokines (IL-4, IL-13, CCR4) were not repressed or even upregulated. The irradiation-induced Th2 profile was confirmed by the upregulation of both Th2-specific transcription factor GATA-3 and SOCS3. Although an apoptosis event occurred 6 h after 10 Gy of intestinal γ -irradiation, apoptotic mediator analysis showed a tendency to apoptotic resistance 7 d post-irradiation. CAPE amplified apoptotic events at 6h and normalized Bax/FasL expressions at 7 d.

CONCLUSION: CAPE prevented the ileal Th2 immune response by modulating the irradiation-influenced cytokine environment and apoptosis.

INTRODUCTION

Radiation-induced acute enteritis is the major dose-limiting complication in the radiotherapy for cancers in the abdominal region^[1]. Irradiation injuries involve cytokine pathways^[2] that trigger an inflammatory process causing clinical symptoms (diarrhea, dysmotility). The immune-mediated pathologic development is the consequence of sustained local cytokine production. In particular, the modification of the CD4⁺ helper T (Th) cell polarization induced by abdominal irradiation has not been investigated and these cells may play a primary role in irradiation injury. Crohn's disease and TNBS-induced colitis are both Th1-like forms of gut inflammation^[3] whereas infection with *Schistosoma* is associated with a Th2 immune response^[4].

Activated CD4⁺ Th cells have been divided into at least two major exclusive T cell subsets according to their cytokine profile. The cytokine environment has been proposed as the major variable influencing Th development^[5]. In the presence of IL-12, activated Th cells differentiate into Th1 cells, secreting predominantly IFN- γ and IL-2 which promote delayed-type hypersensitivity responses and pro-inflammatory responses. In contrast, the Th cells that are activated in the presence of IL-4 differentiate into Th2 cells, producing mainly IL-4 and IL-13 and promote humoral and allergic responses^[6]. In addition, IL-4 inhibits the expression of the β 2 subunit of the IL-12 receptor, thereby preventing a Th1-type response, whereas IFN- γ stimulates it^[7]. Thus, IL-12R β 2 expression is preferentially found in Th1 cells and maintains responsiveness to IL-12, whereas Th2 cell development is accompanied by a loss of this receptor subunit. Th1 and Th2 cells were originally distinguished from each other by their partially specific profile of cytokine expression. Analysis of such *in vivo* polarized Th cells has revealed differential sets of gene expression, including specific chemokine/chemokine recep-

tors. Typically, Th1 cells migrate to inflammatory sites in response to CXCR3 and CCR5 ligands^[8]. Likewise, CCR4 is preferentially expressed on Th2 cells. The restricted expression of cytokines by polarized Th cells arises from a differential expression of transcription factors. T-Bet, expressed specifically in Th1, mediates IFN- γ production and GATA-binding protein 3 (GATA-3) plays a pivotal role in Th2 phenotype development and in Th1 phenotype inhibition^[9]. However, recent studies have shown that cytokine signalling is under a negative feedback regulation by proteins called suppressors of cytokine signalling (SOCS). Thus, the differentiation toward the Th1 or Th2 pathway may be mediated in part by the selective repression of IL-12 or IL-4 signalling pathways^[10].

Inhibition of pro-inflammatory molecules provides a logical therapeutic option for patients with abnormal immune cell activation^[11]. This concept should be re-evaluated in light of evidence that immune activation is also regulated by apoptosis. Because programmed cell death controls the life span of cells, an apoptosis defect could result in an inappropriately long cell survival and a state of uncontrolled inflammation leading to chronic and autoimmune diseases^[12]. This may be the case in Crohn disease, where abnormal mucosal T cell reactivity is well documented^[11]. Medical or accidental exposure to radiation could lead to an impairment of specific immune responsiveness by apoptotic death of resting lymphocytes. The transcription factor NF- κ B is a key regulator of genes implicated in the immune/inflammatory response^[13]. Recently, we have shown that abdominal irradiation induced an inflammatory process involving NF- κ B activation^[3]. NF- κ B also regulates the expression of many genes involved in the control of cell proliferation and cell death *via* extrinsic factors [TNF- α , Fas Ligand (FasL), IL-2], specific receptors [TNF and Fas receptors (TNFR, Fas)] and intrinsic mediators (XIAP, Bax)^[14]. Targeting of inducible extrinsic factors has been proposed as a method for constraining immune responses by selectively killing activated T cells or inhibiting differentiation^[15].

The modulation of NF- κ B action by specific drugs is primarily based on cytokine synthesis. However, little is known about the effects of these drugs on Th1 or Th2-derived cytokine production patterns, on their specific transcription factors (T-Bet, GATA-3) and on chemokine receptors CXCR3/CCR5 (on Th1 cells) or CCR4 (on Th2 cells). Here, using abdominal γ -irradiation where both type-1 and type-2 cells can be activated, the pattern of gene expression was analysed in the ileum mucosa. To test the hypothesis that defective apoptosis is involved in inflammation process^[16] and orients the immune response following irradiation, we used the apoptotic and immune regulation properties of Caffeic Acid Phenethyl Ester (CAPE), an active phenolic compound inhibitor of NF- κ B^[17] to modulate the irradiation-influenced cytokine environment and the Th polarization at the dose previously used^[18]. This study was performed at 6 h post-irradiation where apoptotic events occurred, and at one week (d 7) corresponding to the restoration of the intestinal morphological structure.

MATERIALS AND METHODS

Animals and treatment

Male Wistar rats (Elevage Janvier, France), weighing 200–250 g, were housed with *ad libitum* food and water. All experiments were conducted in accordance with the French regulations for animal experimentation (Ministry of Agriculture Order No. 87-848, October 19, 1987). Anesthetized rats received a single abdominal dose of 10 Gy γ -irradiation (⁶⁰Co source). Control rats were sham-irradiated. Rats were divided into four groups ($n = 6$): controls, controls treated with CAPE, irradiated untreated, and irradiated CAPE treated. Rats were injected intraperitoneally with CAPE (30 mg/kg in saline containing 200 g/L Tween 80) 10 min before irradiation and once a day for 6 d^[18]. The animals were sacrificed and the ileal tissues were dissected at 6 h and 7 d after exposure. Entire ileum specimens were taken for immunostaining and only mucosa layers, separated from the muscularis by scraping, were kept at -80°C for protein extraction and RT-PCR.

Immunostaining

Ileal tissue samples were washed in PBS and then fixed in 40 g/L buffered formaldehyde solution. After dehydration, specimens were embedded in paraffin and sectioned (5 μ m).

CD4⁺ detection: Immunohistochemistry was performed to assess the presence of CD4 phenotype cells. Briefly, deparaffinized and rehydrated tissue sections were treated with 3 mL/L hydrogen peroxide in methanol to inhibit the endogenous peroxidase activity. Sections were incubated in protein blocking serum (Dako, USA) before treatment for 90 min at room temperature with the monoclonal anti-CD4 antibody (ab6413; 1/100 dilution, Abcam). Slides were then rinsed in 50 mmol/L Tris/HCl, 3 g/L NaCl and 1g/L Tween-20. The secondary reagent was the Vector Elite ABC kit (Dako).

Apoptotic cell detection: Apoptotic cells were visualized by the terminal deoxynucleotidyltransferase (TdT)-mediated dUTP-biotin nick-end labelling assay (TUNEL) using the *In Situ* Cell Death Detection kit (Roche Molecular Biochemicals, France) according to the manufacturer's instructions. Briefly, deparaffinized and rehydrated ileum tissue sections were incubated in proteinase K (20 mg/L in 10 mmol/L Tris-HCl, pH 7.6) for 10 min at 37°C. Endogenous peroxidase activity was quenched with blocking solution (3 g/L H₂O₂ in methanol). Sections were exposed to the TUNEL reaction mixture at 37°C for 1 h. After washing in PBS buffer, POD (peroxidase) was added and allowed to react for 30 min at 37°C. For both staining methods, the slides were treated with a NovaRED™ kit (Vector Laboratories Inc, Burlingame, CA) for colour development and counterstained with Meyer's hemalum.

Caspase-3 activity assay

Mucosal protein extracts were prepared by a Dounce homogenization protocol from 50 mg of tissue in a hypotonic buffer (25 mmol/L HEPES, pH 7.5, 5 mmol/L MgCl₂, 1 mmol/L EGTA, 1 mmol/L PMSF, 5 mg/L aprotinin and leupeptin). After centrifugation of the homogenates, the supernatants were collected. Five

hundred μ g of extracted protein was incubated with 100 μ mol/L of the synthetic substrate Ac-DEVD-pNA in 500 μ l of 25 mmol/L HEPES (pH 7.5) containing 200 ml/L glycerol and protease inhibitors. After 20 min of reaction at 37°C, the caspase-3-like activity was assayed by measuring the absorbance at 405 nm.

Quantitative real-time RT-PCR

Real-time quantitative RT-PCR was used to measure the expression of Th1 (IL-23, IL-12R β 2, IFN- γ , IL-2, CXCR3, CCR5, T-Bet and SOCS1) or Th2-derived genes (IL-4, IL-13, CCR4, GATA-3, SOCS3), the cytokine TNF- α and its specific receptors (TNFR1, TNFR2), cytotoxic mediators (Fas/FasLigand, CTLA-4) and apoptotic genes (Bax, XIAP, caspase-3). Total RNA was prepared with the RNeasy total RNA isolation kit (Qiagen, France) according to the manufacturer's instructions. RNA integrity was confirmed by electrophoresis on a denaturing agarose gel and ethidium bromide staining. One μ g of total RNA was reverse transcribed with SuperScript II reverse transcriptase (Invitrogen, France) using random hexamers. IL-4 and IL-13 primers from the manufacturer were used to amplify first-strand cDNA with TaqMan technology (Applied Biosystems). PCR amplification of the other genes used SYBR PCR master Mix. The primer sequences (Table 1) have been designed by Primer Express software (Applied Biosystems). Optimized PCR used the ABI Prism 7000 Sequence detection system (Applied Biosystems). PCR fluorescent signals were normalized to the signal obtained from the housekeeping gene HPRT for each sample.

Immunoblot analysis

Total proteins were obtained by homogenization of ileal samples in a cold RIPA buffer containing classical protease-inhibitor cocktail. Total proteins (40 μ g) were boiled in SDS and mercaptoethanol buffer; then separated on a 120 g/L polyacrylamide gel (NuPAGE gels; Invitrogen, France) and electroblotted. Polyvinylidene difluoride membranes were incubated with a blocking solution (50 g/L skim milk in TPBS containing 1 mL/L Tween 20), washed with TPBS and incubated with rabbit polyclonal primary antibody directed against T-Bet for 1h at RT (dilution 1/200; Santa Cruz) or goat polyclonal GATA-3 overnight (dilution 1/100; Santa Cruz). After washing, immunodetection was performed with the respective horseradish-linked secondary antibody (1/2000; Amersham). Chemiluminescence was detected according to manufacturer's protocol (ECL, Amersham Biosciences).

Result expression and statistical analysis

We used the comparative $\Delta\Delta C_T$ -method^[19] for relative mRNA quantification of target genes, normalized to an endogenous reference (HPRT) and a relevant non-irradiated control, equal to $2^{-\Delta\Delta C_T}$. $\Delta\Delta C_T$ is the difference between the mean ΔC_T (irradiated sample) and mean ΔC_T (non-irradiated sample), where ΔC_T is the difference between the mean $C_{T(\text{genes})}$ and the mean $C_{T(\text{HPRT})}$. Each sample was monitored for fluorescent dyes, and signals were regarded as significant if the fluorescence intensity significantly exceeded (10-fold) the standard deviation of the baseline fluorescence, defined as threshold cycles (C_T).

All data are expressed as the mean \pm SD error of the

RESULTS

Effect of CAPE on the irradiation-modified mucosal cytokine environment

Activation and polarization of CD4⁺ Th cells was dependent on local dominant factors that control differentiation. IL-12 is a critical cytokine for polarizing naïve CD4⁺ T cells towards a Th1 dominance^[7]. Moreover, the T-cell responsiveness to this mediator depends on expression of the inducible IL-12Rβ2 subunit of the IL-12 receptor^[20]. IL-12Rβ2 is preferentially expressed by Th1 cells and is lost with Th2 cell development. From the analysis of IL-23 expression, the IL-12p40 form appears to be a key step in Th1 pathogenesis^[21], since irradiation repressed it ($P < 0.01$) and it fell to below the levels of IL-12Rβ2 at d 7 ($P < 0.01$) (Figure 1). Significant evidence exists for a relationship between IFN- γ expression and IL-23/IL-12R signalling since Th1 commitment is enhanced by IFN- γ ^[22]. Accordingly, the irradiation-induced down-regulation of IL-23/IL-12Rβ2 (-50% and -80%) was correlated with a drastically low level of IFN- γ expression (95% decrease, $P < 0.01$) at 7 d. These results suggest that irradiation did not induce the expression of a Th1 pattern of cytokines. In addition, the low IL-2 expression, the other Th1 cytokine representing one of the major growth factors for the expansion of activated T cells, observed 7 d after irradiation supports this hypothesis. Although CAPE did not significantly restore the radiation-induced decrease in IL-12Rβ2 expression, IFN- γ and IL-23 expression tended to return to normality and the IL-2 mRNA level was 1.5-fold increased as compared to controls.

To address the induction mechanism of Th2 dominance by irradiation, we examined the IL-4 and IL-13 mRNA

levels. As shown in Figure 1, irradiation only repressed IL-4 expression (-75%) soon after irradiation (6 h) but had no significant effect at 7 d on either IL-4 or IL-13 expression. CAPE did not influence IL-4 and IL-13 mRNA levels.

The presence of CD4⁺ T cells in the *lamina propria* was confirmed by immunostaining. The CD4⁺ T cell numbers were not modified at 6 h and 7 d post-irradiation compared to the control (Figure 1). CAPE did not influence the cell frequency.

Polarization of CD4⁺ T lymphocytes in ileal tissue following irradiation

To characterize the Th cell polarization, we exploited the fact that activated Th cells acquire and maintain at high levels a specific pattern of chemokine receptors: CXCR3/CCR5 present on Th1 or CCR4 on Th2. Irradiation modified the chemokine receptor profile. There was a 70% fall ($P < 0.01$) in CXCR3 levels at 6 h post-irradiation and a tendency for decline in CCR5, whereas CCR4 mRNA was about 2.5-fold ($P < 0.05$) up-regulated at both time-points after irradiation (Figure 2). CAPE significantly counter-balanced the CXCR3 mRNA repression ($P < 0.05$) and the CCR4 mRNA induction ($P < 0.01$) at d 7.

The transcription factor T-Bet is selectively expressed in Th1 cells whereas GATA-3 is selectively expressed in Th2 cells. Expression of these genes is rapidly induced in primary T cells triggering the Th1 or Th2 pathway^[23]. Our data showed that irradiation induced an early (6 h) significant decrease of T-Bet expression, followed by an accentuation of decline down to 20% of the control level at d 7 ($P < 0.005$). In contrast, GATA-3 was significantly up-regulated at 7 d ($P < 0.01$, Figure 3). Because T-Bet is reported to represent Th1 immune responses and GATA-3 those of Th2, it has been suggested that the ratio of expression of these transcription factor could

Figure 2 Expression of the chemokine receptors CXCR3/CCR5 and CCR4 post-irradiation in rats. (■): CAPE-untreated; (□): CAPE-treated (mean \pm SEM, $n = 6$); ^a $P < 0.05$, ^b $P < 0.01$ vs control; ^c $P < 0.05$, ^d $P < 0.01$ vs untreated rats.

be used to reflect the Th1 or Th2 status in mixed cell populations^[24]. The increase in GATA-3 expression was greater than for T-Bet, which was reflected by the T-Bet/GATA-3 ratio with a 2-fold decrease at d 7 ($P < 0.01$). These data confirm that irradiation causes a shift toward Th2 polarization. CAPE significantly reduced ($P < 0.05$) the radiation-induced T-Bet repression and GATA-3 was totally down-regulated at d 7 normalizing the T-bet/GATA-3 ratio. Western blot analysis confirmed the increased T-Bet/GATA-3 ratio where the T-Bet protein level reduction detected 7 d post-irradiation was removed after CAPE treatment (Figure 3).

Polarization of CD4⁺ regulated by SOCS proteins

Endogenous feedback regulators of cytokine activities such as SOCS proteins regulate the amplitude and duration of the polarization influenced by T-Bet or GATA-3^[10]. Since Th1 cells predominantly express SOCS1 while Th2 express high levels of SOCS3, we have hypothesized that SOCS genes might contribute to the establishment of a stable Th1 or Th2 phenotype. The analysis of the SOCS expression revealed a drastic reduction of SOCS1 mRNAs at d 7, whereas SOCS3 mRNAs were significantly up-regulated at 6 h with a high level maintained (2-fold, $P < 0.05$) for one week (Figure 4). The functional consequences of a high level of SOCS3 expression and a relatively low abundance of SOCS1 may drive the majority of CD4⁺ toward a Th2 pattern of cytokine expression. CAPE limited the irradiation effect on SOCS1, with a restoration to half the level of that of the controls at 7 d ($P < 0.05$), but had no effect on SOCS3 expression.

Early administration of CAPE modified apoptotic events in irradiated rats

Since the decision as to whether T cells survive or undergo apoptosis is of particular importance for adaptive immune responses^[14], we examined the expression of genes associated with the regulation of apoptosis, in the mucosa after irradiation. Real-time PCR was used to quantify mRNA levels of extrinsic factors (TNF- α , FasL, CTLA-4), specific receptors (TNFRs, Fas) and intrinsic mediators (XIAP, Bax, caspase-3). Irradiation led to an over-expression of TNF- α (20-fold at 6 h, $P < 0.001$), which correlated with a significant increase in TNF receptor (R1, R2) mRNAs (Figure 5). These over-expressions remained significant at d 7. It has been demonstrated that CAPE has anti-inflammatory and apoptotic properties^[3,17]. Accordingly, CAPE significantly reduced TNF- α up-regulation at 7 d post-irradiation and led to a dual effect on TNFR2 expression with an early (6 h) amplification of expression and, in contrast, a reduction of the irradiation effect at 7 d.

The engagement of the death receptor Fas by FasL plays an important role in apoptotic events. Our data have shown that irradiation has a biphasic effect with a significant increase of Fas and FasL mRNA levels at 6 h and a significant FasL repression at d 7 ($P < 0.05$). CAPE over-expressed Fas/FasL at 6 h with a persistent effect

Figure 4 Expression of the regulator cytokine gene SOCS1 and SOCS3 after irradiation in rats. (■): CAPE-untreated; (□): CAPE-treated (mean \pm SEM, $n = 6$); ^a $P < 0.05$, ^b $P < 0.01$ vs control; ^c $P < 0.05$, ^d $P < 0.01$ vs untreated.

on FasL mRNA level at d 7 (Figure 5). In association with Fas/FasL, CTLA-4 engagement could potentiate the elimination of pathogenic T cells^[24]. Irradiation significantly down-regulated CTLA-4 at d 7 (90% decrease compared to controls, $P < 0.01$), which was not modified by CAPE (Figure 5). These results suggest that an absence of cytotoxic mediators occurs at 7 d post-irradiation that is minimized by CAPE-induced FasL normalization.

The modulation of the members of the IAP (apoptosis inhibitors) family, such as the anti-apoptotic protein XIAP or the pro-apoptotic protein Bax, regulates apoptosis. No significant change in XIAP mRNA was observed at 6 h whereas Bax expression rose at 6 h then progressively decreased at 7 d leading to a 70% reduction ($P < 0.01$) (Figure 6). The apoptotic event was confirmed at 6 h by an increase in caspase-3 activity that contrasted with the normal activity found at 7 d; caspase-3 expression remained invariant. CAPE reduced the XIAP expression and over-expressed Bax as compared to irradiated rats at 7 d ($P < 0.01$), resulting in a significant caspase-3 activity increase ($P < 0.01$).

The irradiation-induced apoptosis events at 6 h were confirmed by TUNEL assay (Figure 6A-E). TUNEL⁺ cells were sparse in the lamina propria of controls, and were only located at the top of the villi. Six hours post-irradiation, the number of apoptotic cells was considerably increased and localized in the crypts and the bottom of the villi compared to controls. Some apoptotic cells appeared in the lamina propria. The irradiation-induced apoptotic effect was amplified in the crypts and the bottom by CAPE at 6 h but not at d 7, as compared to controls.

DISCUSSION

In this study, we investigated whether targeting defective mucosal cell death underlies the sustained therapeutic benefit of CAPE by orienting the immune response induced by irradiation. The results show firstly that irradiation led to an earlier apoptotic process, which progressively resulted in an apoptotic resistance and secondly, that irradiation oriented the immune response to a predominance of Th2 type polarization. Overall, the emerging picture is that, in the non-inflamed gut, the T cells manifest increased spontaneous apoptosis mediated by the Fas pathway that

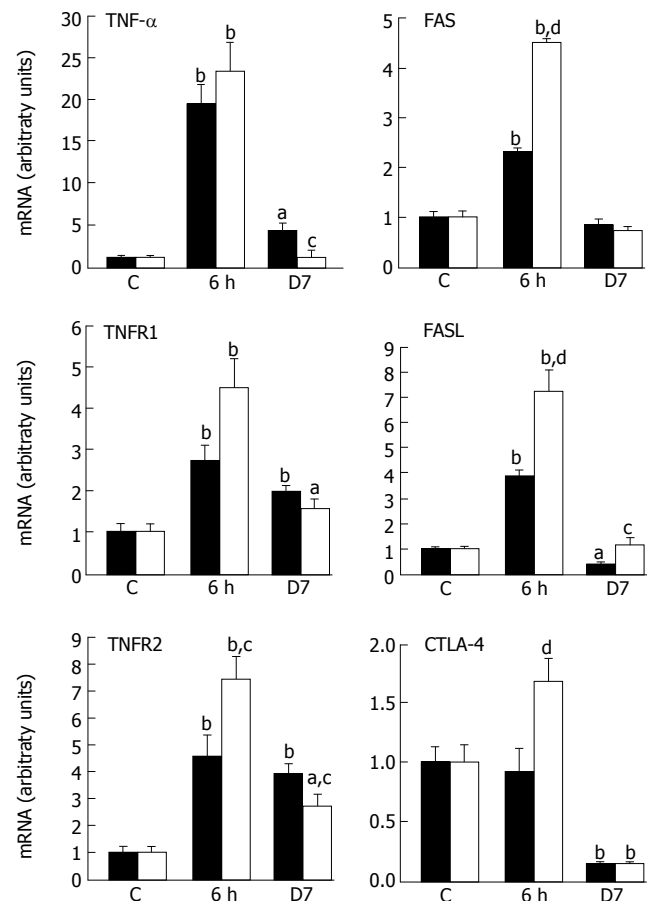

Figure 5 Irradiation effect on extrinsic apoptotic factors TNF- α , FasL and related-receptors expression post-irradiation in rats. (■): CAPE-untreated; (□): CAPE-treated (mean \pm SEM, $n = 6$); ^a $P < 0.05$, ^b $P < 0.01$ vs control; ^c $P < 0.05$, ^d $P < 0.01$ vs untreated rats.

limited expansion of T cells. By contrast, in the inflamed tissue, resident T cells are relatively resistant to apoptosis. Thus, they exhibit an enhanced cytokine production because of prolonged survival, which significantly aggravates the inflammation. The functional importance of T cell apoptosis resistance has been emphasized by recent studies in animal models of IBD showing that IL-12 and TNF- α antibodies appear to suppress chronic intestinal inflammation by the induction of T cell apoptosis^[25]. The regulation of T cell activation by immunosuppressive drugs is known to be relevant in the treatment of inflammatory disorders. Medical or accidental exposure to radiation leads to an inflammatory process^[2]. Currently, the purpose of using NF- κ B inhibitors as an adjuvant for cancer treatment is to increase the therapeutic index of radiotherapy and chemotherapy^[26,27]. The success of this approach relies both on its ability to promote cancerous cell killing by irradiation and to spare normal cells from enhanced damage. By analysing the immunomodulatory and apoptotic properties^[17], we have shown that CAPE shifts from the radiation-induced Th2-like pattern of gene expression toward Th1 gene expression by an apoptotic sensitization.

Irradiation led to the repression of genes involved in 4 key features of Th1 cell differentiation: genes involved in Th1 differentiation (IL-12, IL-12R β 2), genes associated with Th1 cytokine responses (IFN- γ , IL-2), genes

regulating cell death and apoptosis (Fas/FasL, CTLA-4) and genes controlling Th1 migratory behaviour (CXCR3, CCR5). Simultaneous to the down-regulation of Th1-associated chemokine receptors, the transcription factor T-Bet was moderately expressed while GATA-3 was up-regulated. Transcription factors such as T-Bet and GATA-3 play a critical role in the initiation of primary immune responses and skewing the response toward the Th1 or Th2 pathway^[23]. The duration of the response depends on the coordination of lymphocyte responses. These aspects of the adaptive immune response are regulated by endogenous feedback regulators of cytokine activities^[10]. Thus, SOCS proteins are differentially expressed: Th1 cells predominantly express SOCS1 whereas Th2 cells express very high levels of SOCS3. The restricted pattern of expression in Th1 and Th2 cells underscores the importance of SOCS members in Th cell subtypes. A preferential up-regulation of SOCS1 expression in Th1 but not Th2 after IL-12 stimulation argues for a role of cytokine signalling in SOCS regulation^[10,22]. In our study, we found a differential expression of SOCS at 7 d post-irradiation with a repression of SOCS1 and an overexpression of SOCS3. The functional consequence of SOCS3 expression may be to drive the majority of CD4⁺ toward a Th2 pattern of cytokine expression at this time. However, cytokines can override the effects of SOCS3 during Th differentiation. In fact, a major effect of IL-12 signalling in non-polarized Th cells is to down-regulate SOCS3 expression in cells committed to the Th1 lineage. In this way, Th1 differentiation requires IL-12/IL-12R β 2 signalling^[28] and SOCS1^[24], and the drastic repression of IL-23, closely related to IL-12, that occurred at 7 d post-irradiation reduces the possibility of a Th1 lineage. In addition, IL-12/IL-12R β 2 signalling supports high IFN- γ production and IFN signalling to down-regulate IL-4 and prevent Th2 dominance^[29]. In this way, although IL-4 expression induced by irradiation was not elevated, the protection of Th1 dominance after irradiation could not be maintained by the mere fact of the IFN- γ repression at d 7. Szabo *et al*^[7] have shown that when IFN- γ production is limited, a low IL-4 production in early responses may critically inhibit IL-12R β 2 expres-

sion with a significant effect on the development of a Th1/Th2 shift. In fact, only low IL-4 level is required in the complete absence of extrinsic Th1 signals (e.g. IL-12) to generate Th2 CD4⁺. These results showed the same prevalence of an irradiation-induced Th2 response in the lung. In fact, enhanced lymphocyte reactivity, dominated by Th2 cells, has been shown in radiation-induced pneumonitis and subsequent pulmonary fibrosis, suggesting a critical role for Th2 CD4⁺^[30].

TUNEL staining has revealed an increase of apoptotic cells observed at the top of the villi and in the crypts. Some apoptotic cells appeared after irradiation in the lamina propria which is formed from a majority of immune cells. In fact, a differential sensitivity of lymphocyte subpopulations to irradiation-induced apoptosis has been reported; in particular, CD4⁺ T cells are relatively radioresistant^[31]. In this work, CD4⁺ immunostaining confirmed their presence after irradiation. TUNEL positive cells increased at 6 h confirming the radiosensitization effect of CAPE but without real modification of the number of CD4⁺ cells. In this study and in accordance with other findings^[27], the earliest intestinal response to radiation injury reflects a complex series of apoptotic events involving extrinsic factors (TNF- α , FasL, IL-2), specific receptors (TNFR, Fas) and intrinsic mediators (XIAP, Bax and caspase-3). All these apoptotic events occurred rapidly after irradiation (6 h) but were amply repressed one week post-irradiation.

The extrinsic factors such as Fas and FasL are particularly important in T cell apoptotic events. The observed decrease in Fas/FasL expression may mediate T cells apoptosis and becomes especially important in the irradiation-inflammatory process at d 7, because failures of this mortality pathway can impair both autocrine and paracrine mechanisms for eliminating activated T cells. In fact, Fas is expressed by the both Th cell subsets whereas only Th1 cells express detectable amounts of FasL^[29]. The differential expression of FasL by Th1 and Th2 cells is correlated with the ability of these cells to undergo to apoptosis: Th1 clones are highly sensitive to apoptosis, whereas Th2 clones are relatively resistant. In this way, the genesis of Th2 orientation may occur early (6 h) post-

irradiation. In view of the ability of CAPE to induce an apoptotic event *via* Fas activation^[32], the restoration of FasL expression by CAPE may suggest a modification of the apoptosis resistance and of the Th1/Th2 balance at 7 d post-irradiation. This hypothesis must be confirmed by *in vitro* experiments. Interestingly in respect to asthma, it has been shown that intratracheal delivery of adenovirus encoding FasL could significantly suppress pulmonary Th2 immune response^[33].

Fas, a member of the TNF receptor family, is inducible by TNF- α itself^[34], a good correlation was observed concerning the radiation-induced expression variation between Fas/FasL and TNF- α . CAPE did not alter this high mRNA level at 6 h, but this correlation disappeared at 7 d with a repression of TNF- α and a normalization of FasL levels. The cell death signal induced by TNF- α is mediated by TNFR1. In contrast, the engagement of TNFR2 promotes cell survival by the induction of anti-apoptotic molecules^[35]. Although TNF- α was repressed at 7 d, the TNFR1 up-regulation induced by irradiation was not altered by CAPE in contrast to TNFR2 which was down-regulated. This observation, associated with FasL normalization, may be an indication of a limitation of apoptosis resistance induced by CAPE at 7 d. Intrinsic gene product analysis confirmed this argument at this time when CAPE also normalized Bax expression, contributing to increased caspase-3 activity.

Cell death is a complex series of events regulated by the intrinsic propensity of individual cells, the environment and cell surface. The regulation of T-cell activation/apoptosis depends on critical cell surface molecules, in particular CTLA-4 which down-regulates T cell activation. The immune importance of CTLA-4 has been reported *in vivo* where CTLA-4 blockade exacerbates some autoimmune diseases^[36] and CTLA-4-deficient mice exhibit a massive polyclonal increase in T cells. On the basis of these properties and in view of our data which showed that CTLA-4 was totally repressed at 7 d, it seems possible that an irradiation-induced T-cell activation effect may have occurred. CAPE had no effect on CTLA-4 expression, so that it seems probable that the T cell expansion/activation was maintained, but an orientation of the immune response cannot be excluded.

These results suggest that CAPE, by modulating the cytokine pattern, changed the orientation of immune responses after irradiation and favoured a Th1 response notably by the total or partial suppression of IL-12 and IFN- γ repression. Interestingly, CAPE could inhibit T-cell activation by targeting both NF- κ B and the nuclear factor of activated T cells (NFAT)^[37]. Diehl *et al.*^[38] showed that NFAT activation in CD4⁺ is required for the development of Th2 differentiation and its inhibition in T cells prevents the Th2 immune response in a model of allergic pulmonary inflammation. The activation of NFAT by irradiation still has not been demonstrated but we cannot exclude its potential involvement in the irradiation-induced Th2-like profile.

Abstract

AIM: To investigate the role of intercellular adhesion molecule-1 (ICAM-1) and its counter receptors LFA-1 and Mac-1 in acute pancreatitis (AP).

METHODS: SD rats were allocated to AP group and control group randomly (25 rats each). AP was induced by infusion of 5% chenodeoxycholic acid into the pancreatic duct, followed by ligation of pancreatic duct. The rats were sacrificed at 1, 3, 6, 12 and 24 h after induction of pancreatitis. Five rats were sacrificed at one time point in the two groups before the blood and specimens from pancreas and lung were obtained. Serum amylase and ascitic fluid were measured at each time point. Expression of ICAM-1 at different time points was assessed by immunohistochemistry in pancreas and lung, and the expression of LFA-1 and Mac-1 on neutrophils at different time points was detected by flow cytometer.

RESULTS: Induction of AP was confirmed by the serum levels of amylase and histological studies. The expression of ICAM-1 in pancreas increased significantly than that in the control group at all time points ($P < 0.05$ or $P < 0.01$), as well as the expression in lung except at 1 h. The expression of LFA-1 and Mac-1 on neutrophil in blood increased significantly in AP group than that in control group at several time points ($P < 0.05$ or $P < 0.01$). The amount of ascitic fluid and serum amylase level of AP group increased significantly than that of control group at all time points ($P < 0.05$ or $P < 0.01$). Parallel to these results, a significant neutrophil infiltration was found in pancreas and lung tissues of AP group rats.

CONCLUSION: Our findings suggest the important role for ICAM-1, LFA-1 and Mac-1 in mediating the

INTRODUCTION

Acute pancreatitis (AP) is a disease of variable severity. Approximately 80% of patients have a relatively mild attack that resolves with few or no complications. The mortality rate is low. However, 20% of patients in whom pancreatic necrosis develops may incur systemic complications with a mortality rate as high as 40%^[1]. Recent investigations have established that one of the earliest pathophysiologic events in pancreatitis is the colocalization of acinar cell organelles containing digestive and lysosomal enzymes, resulting in premature intracellular activation of proteases^[2,3]. The individual pancreatic cell injury becomes magnified and propagated by inducing impaired microcirculation, leukocyte adhesion, and leukocyte infiltration. These become central events in the pathogenesis of pancreatic necrosis and extrapancreatic complications^[4,5]. Organ dysfunction occurs in one of four patients with acute pancreatitis, and 60% of them die from pulmonary damage^[6].

Intercellular adhesion molecule-1 (ICAM-1) is expressed on endothelial cells and is responsive to numerous inflammatory mediators^[7]. It mediates both leukocyte adhesion and migration through the endothelium into tissues^[8]. Lymphocyte function-associated antigen 1 (LFA-1) and Mac-1 are the counter receptors of ICAM-1, both of which are expressed on leukocytes and are related with the above mediating activities of ICAM-1^[9].

The aim of the present study was to analyze the mechanism of upregulation and levels of expression of

ICAM-1 in the pancreas and lung tissues of AP, to detect the expression of LFA-1 and Mac-1 on neutrophils, and to explore the role of these adhesion molecules in the development of AP from a local disease to a systemic illness.

MATERIALS AND METHODS

Animals, anesthesia and surgical procedures

Sprague-Dawley rats (250 to 300 g) were fasted 12 h before the experiment but were allowed free access to water. Fluothane, oxygen and nitrous oxide were used in surgical anesthesia (2 L/min). All rats underwent a 2-cm-long midline laparotomy, and the pancreatic duct was visualized entering the duodenum. The duct was cannulated and AP was induced by retrograde intraductal injection of 5% chenodeoxycholic bile acid (0.1 mL/kg, Wako Pure Chemical Industries, Ltd., Osaka, Japan) for 2 min. After injection, the pancreatic duct was ligated and the abdomen was closed.

Experimental design

A total of 50 rats were allocated to control group and AP group (25 rats in each). The rats of control group only received laparotomy without retrograde intraductal injection of 5% chenodeoxycholic bile acid of pancreas and the pancreatic duct ligation. Blood samples (2 mL) were drawn through inferior vena cava. Pancreatic and lung tissues were removed and processed as indicated below before the rats were killed at 1, 3, 6, 12 and 24 h after induction of pancreatitis ($n = 5$ per group). Ascitic fluid was quantified by estimation of weight of towels after absorption of the ascitic fluid from the abdominal cavity (assuming 1 g = 1 mL).

Amylase in serum

One milliliter blood was sampled to measure amylase in plasma using the RaBA-SUPER (Kyoto First Science Ltd., Kyoto, Japan) kit.

Tissue immunohistochemical staining

For immunohistochemical staining, pancreatic and lung tissues were immediately snap-frozen in Freon precooled in liquid nitrogen and embedded in OCT embedding medium (Tissue-Tek, Miles Inc, Elkhart, USA). Cryostat sections (5 μ m) were fixed in acetone for 10 min, and endogenous peroxidase activity was quenched by incubation of methanol with 0.3% H₂O₂ for 5 min. After rinsing with 0.02 mol PBS, the sections were incubated with primary anti-ICAM-1 antibody (Santa Cruz Biotechnology, Inc., California, USA) diluted at 1:400 in antibody dilution (Dako Corporation, Carpinteria, CA, USA) for 10 min in moist chamber at room temperature. Unbound antibodies were washed from the tissue three times in PBS for 3 min, incubated for 10 min with the secondary biotinylated anti-mouse IgG antibody (LSAB II kit, Dako Corporation, Carpinteria, CA, USA), and then washed three times for 3 min. The sections were incubated with the LSAB reagent (LSAB[®] 2 System, HRP KIT, DAKO Corporation, Carpinteria, CA, USA) for 10 min, washed and developed

in DAB solution. Finally, the slides were fixed in alcohol, counter-stained 3 times with hematoxylin for 10 min, and covered with DAKO Glycergel. NIH Image 1.61/ppc software was used to detect the density of positive area of slides.

Flow cytometry analyses

Blood (1 mL) was anticoagulated with 2% EDTA (0.2 mL). Leukocyte-rich plasma was obtained by centrifugation for 10 min at 1500 r/min. The erythrocytes were then lysed 15 min with 4 mL of hemolysin twice. The leukocyte pellet was washed once with PBS and resuspended with 1 mL of PBS. Leukocytes suspensions (100 μ L) were mixed with 20 μ L of FITC-labeled monoclonal antibody anti-LFA-1 (CD11a/CD18) (BD Pharmingen, San Diego, CA, USA), FITC-labeled anti-Mac-1 (CD11b/CD18) (BD Pharmingen, San Diego, CA, USA), and FITC-labeled IgG (Sigama, Saint Louis, Missouri, USA) that acted as a nonspecific control antibody. It was then incubated at 4°C for 30 min, washed twice in ice-cold PBS, resuspended in 1 mL of PBS and kept on ice until analyzed. Flow cytometry was performed on an FACScan (Coulter Epics XL, USA). Data were collected for forward scatter, side scatter, and fluorescence on the FL1 channel (530 nm) with Coulter Elite software. Cells were analyzed with a gate setting for neutrophils and twenty thousand cell counts were accumulated for analysis. Green fluorescence (FL1) was determined and mean fluorescence intensity (MFI) was calculated. The nonspecific binding (IgG) in control group and AP group was measured at MFI values of 2.81 (0.57) and 3.74 (0.97) units, respectively.

Statistical analysis

Results are expressed as means and standard errors of the mean. Differences between AP and control groups were judged by using the Student's *t* test for parametric data. *P* values of less than 0.05 were considered significant.

RESULTS

Serum amylase

In AP group rats, there was a marked increase in serum amylase from 1 to 24 h with a peak value after 6 h (Figure 1).

Ascitic fluid

The amount of ascitic fluid in AP group increased significantly than that in control group at the same time point (Figure 2).

Histological findings

A low level of ICAM-1 expression was observed in the pancreas and lung tissues in control rats. ICAM-1 expression in the pancreas of AP rats was significantly increased above control levels at 1 h, and continued to increase until 12 h and remained elevated at that level for the whole observation period (24 h) (Figure 3).

ICAM-1 expression in the lung of AP rats was significantly increased above control levels at 3 h, and continued to increase until 24 h (Figure 4). Immunohistochemical analysis showed that overexpression of ICAM-1 was localized in small venules and capillaries.

Figure 1 The time course of serum amylase. ^a $P < 0.05$ vs control at the same point, ^b $P < 0.01$ vs control at the same point.

Figure 2 The time course of ascitic fluid output. ^b $P < 0.01$ vs control at the same time point.

Figure 3 ICAM-1 expression in pancreas. ^b $P < 0.01$ vs control at the same time point.

Expression of LFA-1 and Mac-1 on leukocytes

The expression of LFA-1 and Mac-1 on leukocytes in AP group increased significantly than that in the control group (Figure 5).

DISCUSSION

Intra-acinar cell activation of digestive enzyme zymogens is generally believed to be an early event in pancreatitis. Most researchers, however, believe that subsequent nonacinar cell phenomena, including the activation and recruitment of inflammatory cells, play a critical role in determining the ultimate severity of the disease. Nonacinar cell phenomena including the local generation and release of proinflammatory factors and activation of circulating inflammatory cells are also believed to couple pancreatic

injury to distant organ complications, such as lung injury.

Leukocyte sequestration within areas of injury and inflammation is a multistep process that begins with leukocyte activation. It involves the adhesion of circulating activated inflammatory cells to microvascular endothelial surfaces, and culminates in the transmigration of those cells across the endothelial barrier and into the involved tissue. Currently available evidence indicates that the adhesion of activated leukocytes, including neutrophils, to endothelial surfaces results from the interaction of leukocyte surface proteins, such as CD11/CD18, with endothelial cell surface adhesion molecules such as ICAM-1.

Surprisingly, little attention has been paid to probing the relationship between the ICAM-1 and its counter receptors (LFA-1, Mac-1). Furthermore, the time course of LFA-1

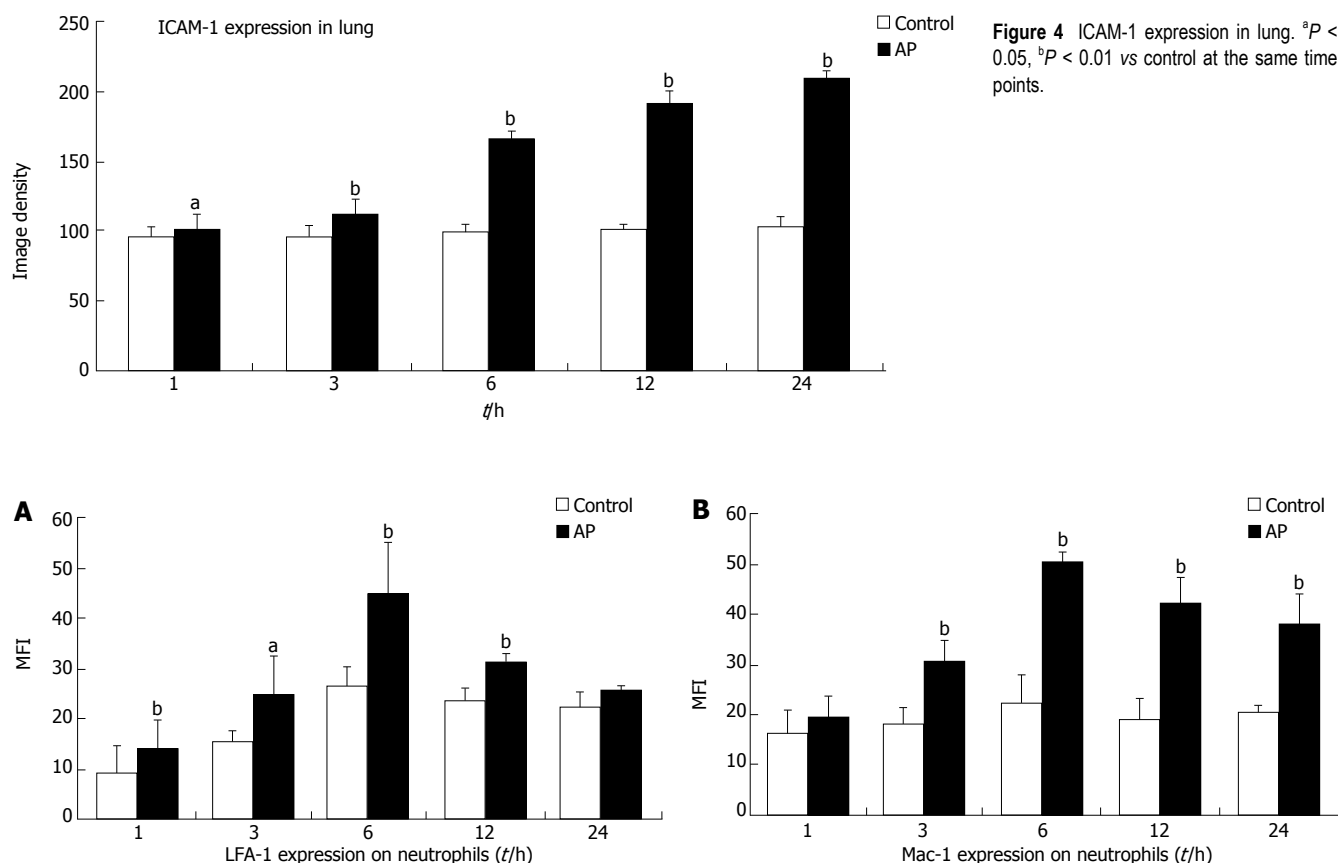

Figure 5 LFA-1 (A), Mac-1 (B) expression on neutrophils. ^a*P* < 0.05, ^b*P* < 0.01 vs control at the same time point.

and Mac-1 expression in severe acute pancreatitis has not been studied. We serially investigated LFA-1 and Mac-1 expression on circulatory neutrophils and ICAM-1 expression in pancreas and lung tissues of AP rats in the current study.

ICAM-1 is an adhesion molecule expressed on endothelial cells that mediates both firm adhesion of leukocytes to the endothelium and transmigration and infiltration of marginated leukocytes into the organs^[7]. Endothelial ICAM-1 is enhanced by hypoxia^[10] and cytokines, including, among others, interleukin-6, interleukin-8 and tumor necrosis factor- α ^[2,7]. These inflammatory mediators, oxygen free radicals, and cytokines respond early in the pathogenesis process of acute pancreatitis^[2,11,12].

ICAM-1 is a counter receptor for LFA-1 (CD11a/CD18) and Mac-1 (CD11b/CD18). The interaction between ICAM-1 and CD11/CD18 is a major determinant of leukocyte adhesion to endothelial cells^[13], a phenomenon that is itself a prelude to leukocyte transmigration across the endothelial barrier and into areas of inflammation.

The multistep model of leukocyte emigration provides a conceptual framework describing the molecular recognition mechanism that leads from cell capture to adhesion strengthening and transmigration. Neutrophils use selectins to tether to inflamed endothelium and subsequently arrest at septic sites in the vasculature through binding of the β_2 -integrins^[14,15]. The β_2 -integrins family members LFA-1 and Mac-1 are involved in firm adhesion of neutrophils to endothelial cells^[16]. Intravital

microscopy in mice and rats has shown that CD11a and CD11b each contribute significantly to firm adhesion, and concurrent blocking of both β_2 -integrins family is required for complete inhibition of human and canine neutrophil transmigration^[17-19]. Furthermore, the adhesion complex CD11b/CD18, induced by inflammatory cytokines, has been demonstrated to play a crucial role in neutrophil-induced tissue damage by enhancing neutrophil migration and adhesiveness^[20].

We probed the expression of adhesion molecules such as ICAM-1 and its counter receptors, LFA-1 and Mac-1 in AP. We found expression of ICAM-1 was markedly upregulated in AP, as well as the expression of LFA-1 and Mac-1 on neutrophils. ICAM-1 is also upregulated in organs beyond the pancreas in severe pancreatitis. Our experiments showed an increased expression of ICAM-1 in the endothelium of venules and capillaries within the lungs at 6 h in AP, followed by massive leukocyte infiltration. The results of this study imply the important roles for ICAM-1 and its counter receptors LFA-1 and Mac-1 in the pathogenesis of pancreatic and systemic injury in acute necrotizing pancreatitis. The current studies are consistent with the concept that expression of ICAM-1, LFA-1 and Mac-1 in the pancreas during AP is a critical link in the development of tissue injury and organ dysfunction. Although overexpression of inflammatory mediators do play an important role in pathogenesis but the molecular mechanisms of the whole cascade, i.e. cell surface molecules, signaling into the cell and resulting response of the cell has still not been worked out. It

may be possible to prevent tissue injury and necrosis and thereby to minimize the possibility for subsequent secondary infection by administering antibodies or other drugs in AP. Further studies are in progress to define the window of opportunity.

<http://www.wjgnet.com/1007-9327/12/5010.asp>

Abstract

AIM: To investigate the optimal strategy to treat dyspeptic patients in primary care.

METHODS: Dyspeptic patients presenting to primary care outpatient clinics were randomly assigned to: (1) empirical endoscopy, (2) *H pylori* test-and-treat, and (3) empirical prokinetic treatment with cisapride. Early endoscopy was arranged if patients remained symptomatic after 2 wk. Symptom severity, quality-of-life (SF-36) as well as patient preference and satisfaction were assessed. All patients underwent endoscopy by wk 6. Patients were followed up for one year.

RESULTS: Two hundred and thirty four patients were recruited (163 female, mean age 49). 46% were *H pylori* positive. 26% of *H pylori* tested and 25% of empirical prokinetic patients showed no improvement at wk 2 follow-up and needed early endoscopy. 15% of patients receiving empirical cisapride responded well to treatment but peptic ulcer was the final diagnosis. Symptom resolution and quality-of-life were similar among the groups. Costs for the three strategies were HK\$4343, \$1771 and \$1750 per patient. 66% of the patients preferred to have early endoscopy.

CONCLUSION: The three strategies are equally effective. Empirical prokinetic treatment was the least expensive but peptic ulcers may be missed with this treatment. The *H pylori* test-and-treat was the most

INTRODUCTION

Dyspepsia, defined as pain or discomfort centered in the upper abdomen, is a common complaint, affecting 18.5% of the population in our locality^[1]. Underlying pathology ranges from functional dyspepsia, peptic ulcer to gastrointestinal cancer. Among the various aetiologies, functional dyspepsia is the most common diagnosis in community-based patients^[2]. Up to 79% of dyspeptic patients referred from primary care for open-access endoscopy have normal endoscopic findings^[3].

Primary care medicine is the first point of presentation for dyspeptic patients. Studies have suggested that dyspepsia alone accounts for 20%-70% of all gastrointestinal consultations with general practitioners; up to one-third of these patients may eventually be referred to a gastroenterologist^[4]. The financial burden for diagnosis and treatment of this common condition is therefore great.

It is unclear how dyspepsia should be investigated and treated in primary care settings, but there are several common approaches. Empirical endoscopy would theoretically be the gold standard in diagnostic accuracy, but it is expensive and invasive. Empirical H₂ receptor antagonist therapy has been extensively studied, but has not been shown to have superior cost-benefit over empirical endoscopy^[5]. In addition, there may be concerns that antisecretory treatment may mask symptoms of

gastric cancer and lead to a delay in diagnosis.

Another possible approach is to test for *H pylori*. The close association between *H pylori* and chronic gastritis that accompanies peptic ulcer disease and gastric cancer offers an opportunity to screen for organic disease based on the presence of the bacterium.

An alternate approach is empirical prokinetic treatment. Studies have demonstrated that cisapride and domperidone are beneficial in the treatment of functional dyspepsia over placebo^[6-8]. By adopting this approach, the majority of patients with functional dyspepsia could be treated appropriately whereas the smaller number of patients with organic dyspepsia may not benefit from this treatment. Persistence of dyspepsia in this group would then lead to endoscopy and diagnosis. The small delay in diagnosis is not unreasonable since, in real life, many primary care doctors would give antacids to dyspeptic patients without alarm features and monitor symptoms on follow-up. Cisapride has been withdrawn from most markets since this study was carried out though related drugs such as mosapride are still in use in some countries.

In this study, we investigated empirical endoscopy, *H pylori* test-and-treat, and empirical prokinetic therapy as possible diagnostic and treatment strategies in primary-care patients presenting with dyspepsia.

MATERIALS AND METHODS

Patients aged 18 or older presenting with a primary complaint of previously uninvestigated dyspepsia in four government-run primary-care clinics in Hong Kong were recruited for the study. Dyspepsia was defined as pain or discomfort centered in the upper abdomen^[9]. History and physical examination were carried out by the primary care physician.

Exclusion criteria for this study were current intake of drugs other than antacids for dyspepsia, previous peptic ulcer disease, history of gastric surgery, presence of malignancy within the previous five years, history of intake of aspirin or non-steroidal anti-inflammatory drugs in the previous four weeks, presence of alarm symptoms, such as weight loss and gastrointestinal haemorrhage, and clinical suspicion of an organic cause of dyspepsia. In addition, those with a family history of sudden death, history of palpitations, co-existing intake of drugs that may interact with cisapride and those with an abnormal electrocardiogram were excluded.

After obtaining written consent for the trial, a locally-validated 13-C urea breath test was administered in the primary care clinic. The details of the breath test have been described elsewhere, and had a sensitivity and specificity of 96.5% and 97.7% respectively^[10]. The results were not disclosed to the patients until after the trial unless the patients were randomised into the *H pylori* test-and-treat group.

The patients were subsequently reassessed by one of the investigators in the gastroenterological unit of Queen Mary Hospital within 24 h of initial presentation. Inclusion and exclusion criteria were checked and a complete physical examination was performed. Electrocardiography was also performed on all recruited patients. A previously

validated Chinese (Hong Kong) version of the SF-36 health survey^[11], as well as a validated twelve-item dyspepsia symptom severity score^[12] were administered. Patients were then randomised using a computer-generated sequence into one of three investigation and treatment groups as detailed below.

This study was approved by the research and ethics committee, faculty of medicine, the University of Hong Kong.

Empirical endoscopy

Patients in this group received endoscopy on the initial day attending the gastrointestinal unit. Oesophagogastroduodenoscopy was performed by one of the investigators and an endoscopic diagnosis was made. A rapid urease test was performed if the patient had peptic ulcer disease and biopsies for histology were taken for gastric ulcers and suspicious lesions.

Patients with organic diagnoses were treated accordingly. *H pylori* eradication therapy was given to those with peptic ulcers or erosive gastritis with a positive test for the bacterium.

Dyspeptic patients with normal endoscopy or non-erosive gastritis were considered to have functional dyspepsia and were treated with cisapride 5 mg three times daily for six weeks.

Helicobacter test-and-treat

Patients who tested positive for *H pylori* in the 13C urease breath test received omeprazole 20 mg twice daily, amoxycillin 1 g twice daily, and clarithromycin 500 mg twice daily. The local eradication rate for this regimen is 87.8%^[13]. Patients who tested negative for *H pylori* were treated as functional dyspepsia and given cisapride 5 mg three times daily for six weeks.

Empirical prokinetics

All patients in this group were given cisapride 5 mg three times daily for six weeks regardless of *H pylori* positivity (Figure 1).

Follow-up

Patients were followed-up at two weeks, six weeks and one year after the initial treatment. At follow-up the dyspepsia symptom score and SF-36 survey were administered by an assessor blinded to the purpose of the study. Satisfaction of patients in regard to treatment was assessed at wk 6 using a 4-point Likert scale ranging from dissatisfied to very satisfied. Patients were asked whether they preferred endoscopy or a trial of drug treatment as the initial approach to their dyspepsia.

If the symptoms had not improved after two weeks of treatment, endoscopy was performed on group 2 and 3 patients. Organic pathology discovered at endoscopy was treated appropriately. For patients who had empirical endoscopy, no further investigation was offered unless there was a change in symptoms that raised suspicion of organic disease. At the end of the study, all patients who had not previously received endoscopy received an oesophago-duodenogastroscopy for a definitive diagnosis.

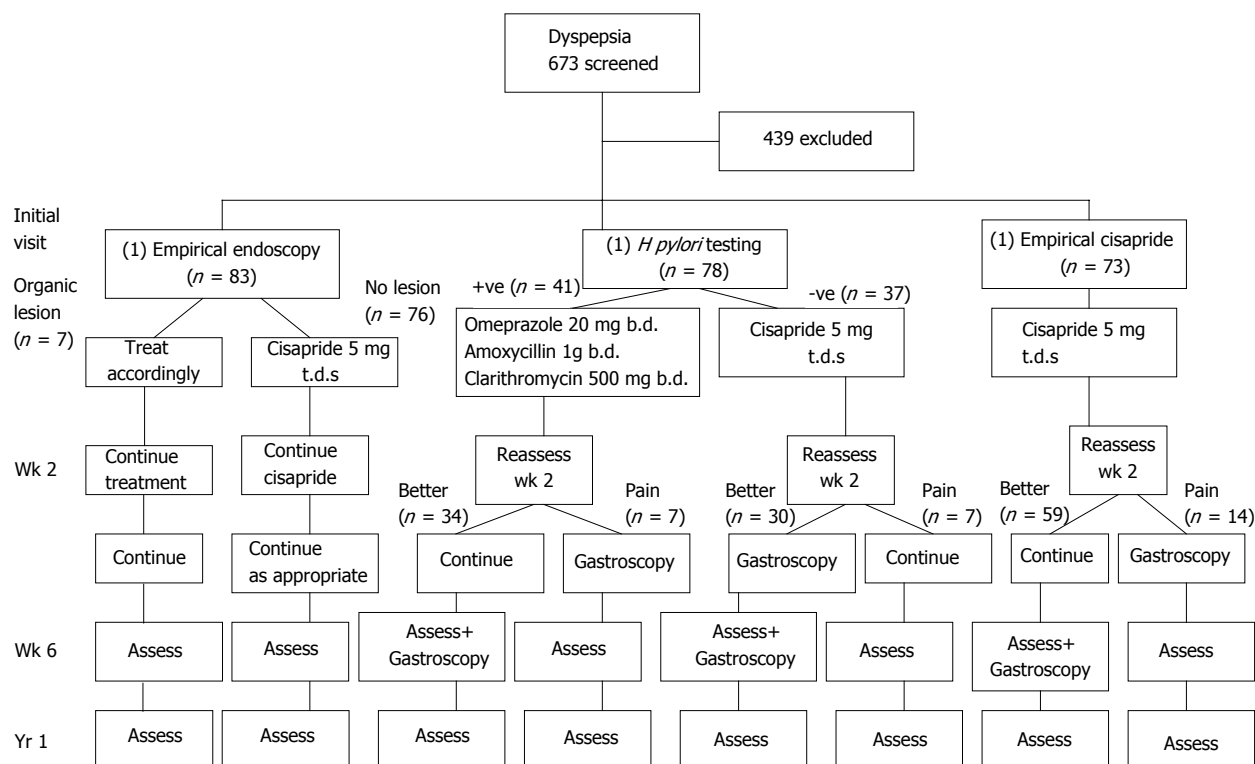

Figure 1 Flow chart for the three diagnostic and treatment arms.

Sample size

Sample size was determined using NCSS PASS 2002 (NCSS statistical software, Kaysville, Utah, USA). A previous study designed to develop dyspepsia severity scores found a mean of 20.7 and standard deviation of 3.8 in a local population of dyspeptic patients. The difference in mean symptom score between patients who felt better and those who did not was 1.2^[12]. Based on this result we estimated that 70 patients in each of the three groups would report a two-point difference in the mean symptom score between one group and the other two with a power of 0.9 and significance level of 0.05.

Cost analysis

Cost analysis was performed to examine the economic implications of the three strategies studied. The analysis was carried out from the provider's perspective, given all three treatment regimens were ambulatory procedures and therefore, assumed to incur similar direct personal, indirect and intangible costs to the patients and society generally. Costs were calculated according to the gazetted list of fees and charges of the Hong Kong Hospital Authority and hospital formulary costs.

Statistical analysis

The study was analysed according to intention-to-treat. Comparison of baseline dyspepsia scores and quality-of-life domains was made using one-way ANOVA and the Kruskal-Wallis test. Correlation between baseline dyspepsia scores and quality-of-life domains was calculated using Kendall's tau. Quality-of-life and dyspepsia symptom scores after treatment were compared among the three groups using a repeated measures procedure. The null

hypotheses regarding the main effects of time points and three treatment groups, and the interaction between treatment groups and different time points were tested using multivariate analysis. Age and sex were also included as covariables. Statistical analyses were performed using SPSS version 11.0 for windows (SPSS inc., Chicago, Illinois, USA).

RESULTS

Patients and demographic characteristics

Six hundred and seventy three patients were screened for inclusion in the study, of which 234 were recruited (mean age 49, range 18-79, 163 female). Reasons for exclusion included dyspepsia under treatment (257), refusal to participate (49), previous investigations for dyspepsia (51), non-steroidal antiinflammatory agent intake^[25], previous gastric surgery or peptic ulcer history^[34], alarm symptoms^[12], abnormal electrocardiogram^[6] and other malignancy^[3]. Baseline characteristics of the three groups of patients are as tabulated in Table 1. All patients completed the six-week treatment assessment period. One hundred and eighty one (77.4% overall; 77.1%, 69.2% and 86.3% in the three respective groups) attended one-year follow-up.

Diagnoses

Group one patients had endoscopy before commencing treatment and provided the most accurate data of the underlying diagnoses of dyspepsia. Among the 83 patients receiving empirical endoscopy 76 (91.5%) had normal findings or non-erosive gastritis, two (2.4%) had gastric erosions, four (4.8%) had peptic ulcer and one (1.2%) had

Table 1 Baseline characteristics

Group	Mean age	Sex (M/F)	<i>H pylori</i> positive (%)	Mean baseline dyspepsia score
Empirical endoscopy (n = 83)	52.5 ± 13.2	25/58	37 (44.6%)	20.4 ± 4.0
<i>H pylori</i> test-and-treat (n = 78)	46.5 ± 14.2	24/54	41 (52.6%)	20.8 ± 3.8
Empirical prokinetics (n = 73)	48.6 ± 13.0	22/51	30 (41.1%)	19.6 ± 3.8

^aP < 0.05.

oesophagitis. Endoscopic findings for the three groups are summarised in Table 2. Overall, 46% of patients were *H pylori* positive.

Fourteen patients (18%) randomised to the *H pylori* test-and-treat group had persistent dyspepsia after two weeks of treatment and needed early endoscopy. None of these patients had organic dyspepsia; two had non-erosive gastritis and 12 had normal endoscopy. At six weeks, three patients with symptom resolution after treatment were found to have duodenal ulcers and three had gastroduodenal erosions. All of these patients were originally tested to be positive for *H pylori* and had received appropriate eradication therapy, but the ulcer had not completely healed by the time of endoscopy.

Fourteen patients (19%) randomised to empirical prokinetic therapy had persistent dyspepsia at two weeks follow-up and received early endoscopy. Eleven of these patients had normal endoscopy results or non-erosive gastritis, two had gastroduodenal erosions and one had a gastric ulcer. More importantly, at the final diagnostic endoscopy, two patients were found to have erosions, duodenal ulcer and gastric ulcer among those who reported symptomatic improvement after treatment. If endoscopy was not performed, these organic lesions would have likely been missed.

All gastric ulcers detected in this study were benign.

Symptom severity

The mean baseline dyspepsia severity score was 20.3 ± 3.9 and was not significantly different among the three groups studied (Table 1). After six weeks of treatment, there was a decrease in mean symptom score to 15.0 ± 2.9 (5.6, 5.6 and 4.4 for empirical endoscopy, *H pylori* testing and empirical cisapride, respectively). On one year follow-up, the mean dyspepsia score increased to 19.7 ± 7.2. Repeated measures analysis showed no significant effect of treatment group on dyspepsia severity. However, patients with organic causes of dyspepsia were less symptomatic than those with non-ulcer dyspepsia after one year (Table 3).

Quality-of-life

The SF-36 health-related quality-of-life scores for the various domains are tabulated in Table 4. At baseline,

Table 2 Endoscopic findings in the three groups n (%)

	Normal	Gastritis/duodenitis	Gastric erosions	Gastric ulcer	Duodenal ulcer	Oesophagitis
Empirical endoscopy (n = 83)	49 (59)	27 (32.5)	2 (2.4)	3 (3.6)	1 (1.2)	1 (1.2)
<i>H pylori</i> test-and-treat (n = 78)	61 (78.2)	10 (12.8)	4 (5.1)	0	3 (3.9)	0
Empirical prokinetics (n = 73)	46 (63.0)	17 (23.3)	4 (5.5)	3 (4.1)	3 (4.1)	0

Table 3 Mean dyspepsia symptom score by initial diagnosis

	Baseline	Wk 6	Yr 1
Non-ulcer dyspepsia (n = 210) ¹	20.3	15.0	20.1
Duodenal Ulcer (n = 7)	19.1	13.0	13.7
Gastric ulcer (n = 6)	23.3	18.7	14.4
Oesophagitis (n = 1)	17.0	12.0	17.0
Gastric erosion (n = 10)	29.0	15.0	12.0
All causes organic dyspepsia (n = 24) ¹	20.5	15.1	16.3

¹P = 0.045 between the two groups with age and sex as covariables.

there was no difference in quality-of-life between the three groups of patients. There was a significant correlation between the severity of dyspepsia and the BP, GH, MH, RE, RP, SF and VT domains, but not the PF domain at baseline. At one-year follow-up, there was a general decline in quality-of-life when compared to 6 wk follow-up. Repeated measures analysis again showed no significant effect of treatment group on quality of life.

Cost analysis

The calculated six-week investigation and treatment costs for empirical endoscopy, *H pylori* test-and-treat and empirical prokinetic therapies are HK\$4343, \$1771 and \$1750 per patient, respectively.

Patient satisfaction and preference

Overall, 81% of patients were either satisfied or very satisfied with treatment. There was no significant difference in satisfaction among the three diagnostic paradigms that were tested (Table 5). 66% of patients preferred to have endoscopy before taking medication; the differences in scores were again not significant among groups (Table 5).

Side effects of cisapride

No patient given cisapride reported significant palpitations or other side effects. All patients were able to complete the six-week course of treatment.

DISCUSSION

Underlying diagnoses of dyspepsia range from peptic ulcer, gastric cancer to functional dyspepsia, and it may

be difficult to determine cause without investigation. Age, symptom assessment and even the presence of alarm symptoms appear to be poor predictors of underlying pathology^[14]. However, despite the prevalence and potential high economic cost of this condition, the optimal strategy to manage dyspepsia in primary care practice remains unclear^[15].

Community-based studies have generally indicated that peptic ulcer and cancer are uncommon causes of dyspepsia^[2], accounting for only 20% of patients referred to open-access endoscopy^[3]. Therefore, it is reasonable that any investigative and treatment strategy should be effective in functional dyspepsia, representing the bulk of patients. The optimal approach to investigation and treatment would aim to: (1) provide the most efficacious and cost-effective treatment for functional dyspepsia, (2) allow for prompt treatment of patients with peptic ulcer, with *H pylori* eradication, if appropriate, (3) correctly diagnose malignant lesions so that definitive treatment can be given and (4) to avoid unnecessary treatment for patients with functional dyspepsia.

Several treatments have generally been shown to be better than placebo in the treatment of functional dyspepsia. Meta-analysis studies have estimated a 20% gain of H2 antagonist treatment against placebo^[16], but there may not be global improvement in symptoms^[17]. Proton pump inhibitors may benefit dyspeptic patients with co-existing reflux^[18]; a study reported 10% therapeutic gain over placebo treatment but efficacy seems to be limited to patients with ulcer-like symptoms^[19]. Cisapride has also been extensively evaluated in studies, though many studies had methodological deficiencies^[20]. Meta-analyses have generally found a therapeutic gain of 36%-39% when compared to placebo^[16,21] but publication bias may have contributed to these results. *H pylori* eradication is likewise controversial, with some studies showing a long-term benefit^[22], and others showing no benefit^[23].

Various options have been suggested in the investigation and treatment of patients presenting with dyspepsia. The American Gastroenterological Association has suggested that patients over the age of 45 years or those with alarm features should have empirical endoscopy^[24]. For younger patients without alarm symptoms, there may be several options: (1) empirical medical therapy (antisecretory drugs or prokinetics) with investigation for therapeutic failures, (2) immediate diagnosis with endoscopy, (3) testing for *H pylori* and studying positive subjects, and (4) testing for *H pylori* and

Table 5 Patient satisfaction and preference among the three diagnostic and treatment groups *n* (%)

	Very satisfied	Satisfied	Neutral	Dissatisfied	Prefer initial endoscopy

treating positive cases with eradication^[24]. An Asian Pacific guideline also suggested a trial of antisecretory drugs or prokinetics for 2-4 wk^[25]. Among the alternatives, empirical prokinetic treatment has not been evaluated in previous studies.

Bytzer randomised 414 patients into groups receiving empirical endoscopy or ranitidine^[5]. Empirical treatment was associated with higher costs of ulcer drug use and a greater number of sick days. It was also notable that 33% of patients had organic causes of dyspepsia, compared to 8% in the present study. Another study comparing *H pylori* test-and-treat with endoscopy found greater patient satisfaction with endoscopy but comparable symptoms and sick leave days between the two groups^[26]. Comparative costs depend on individual centres. An American study reported similar costs between *H pylori* testing and empirical endoscopy^[27] whereas another claimed lower costs for *H pylori* eradication^[28]. A decision analysis supported a trial of proton pump inhibitor before endoscopy or test-and-treat^[29]. Test and endoscopy in primary care has been shown to increase endoscopy rates without benefit in symptom relief or quality of life^[30]. It is of note, however, that proton pump inhibitors may not be as efficacious in Asian populations; a paper using the same outcome instruments as the present study failed to show any benefit of four-week lansoprazole treatment over placebo in patients with functional dyspepsia^[31].

Most of the studies comparing different diagnostic strategies concentrated on cost. Less data is available concerning symptom resolution and quality of life. Many dyspeptic patients presenting for medical care have a fear of serious disease and malignancy^[32]. In addition

they are more anxious than non-presenters with similar complaints^[1]. It is possible that a completely normal endoscopy may relieve some of the anxiety. Indeed a study on barium meal in dyspeptic patients who were referred from general practice showed that the examination increased management confidence and allayed patients' anxiety^[33]. In this study, however, we failed to show any significant difference in symptom relief among the three groups, indicating that the comforting effect of a negative endoscopy may not be an important factor in the cure of functional dyspepsia.

We have calculated the cost of treatment and empirical endoscopy is most costly, followed by *H pylori* test-and-treat and the lowest cost was for empirical prokinetics. The high cost for empirical endoscopy in the present study is related to the relatively low rates of endoscopy for patients randomised to the other groups. In the *H pylori* test-and-treat and empirical cisapride groups, 18% and 19% of patients respectively had persistent dyspepsia after two weeks of treatment and needed early endoscopy. In Bytzer's study, 136 out of 206 patients randomised to empirical H₂ blocker therapy had therapeutic failure and required endoscopy^[5]. The difference may be due to differences in length of follow-up and also the lower rate of organic pathology in our study. In our population with dyspepsia, 8.5% had organic causes (empirical endoscopy group), compared with 33% prevalence of organic dyspepsia reported by Bytzer. The overall rate of organic dyspepsia is also lower than the rate in our previous study on open-access endoscopy, where 21% had organic pathology^[5]. The difference probably reflects differences in referral patterns, with family physicians referring more severe cases of dyspepsia for immediate endoscopy in the previous study.

We observed a high relapse rate of dyspepsia generally, with the mean dyspepsia severity score returning to the initial level on one-year follow-up. This is due to non-ulcer/functional dyspepsia being the predominant diagnosis in 92% of patients. Functional dyspepsia is a chronic disease that persists in patients; a study reported that 74% of dyspeptic patients are still symptomatic two years after the initial diagnosis^[34]. In contrast, the few patients with peptic ulcer in this study tended to remain asymptomatic after the ulcer has healed and these patients in fact have a better prognosis as far as symptom relapse is concerned.

Both empirical endoscopy and *H pylori* testing appeared to be safe options with similar patient satisfaction. All patients with organic dyspepsia were tested to be positive for *H pylori* and had appropriate eradication therapy. However, the main drawback in the study was the absence of malignancy; it was not possible to predict whether gastric cancers would have been missed by any approach. Although rare in younger patients, gastric cancers may present without sinister symptoms. A Canadian study reported a prevalence of 1.05 per thousand patients under 45 years presenting with dyspepsia without alarm symptoms^[35]. We may expect higher numbers in Asia, with a higher population prevalence of gastric cancer. The possibility of missing or delay in diagnosis of gastric malignancies needs to be considered in empirical treatment

approaches.

Since all patients with duodenal or gastric ulcer were positive for *H pylori*, another approach may be performing endoscopy only on those with a positive ¹³C urea breath test. Such an approach may prevent 54% of endoscopies. However, 60% of the patients with gastric erosions were negative for *H pylori*; inappropriate treatment of these patients may potentially lead to progression into ulcer disease.

There is limited data on empirical prokinetic treatment. Because of association with cardiac arrhythmia, the drug has been withdrawn in most markets. However, related drugs, such as mosapride, are still used in some countries and this study may throw light on the effectiveness of other prokinetic agents. In the present study we found this strategy to be associated with the lowest cost but with similar outcome regarding symptomatic improvement. However, interestingly, although prokinetic treatment was not targeted for the treatment of peptic ulcers, six patients (2 gastric ulcer, 2 duodenal ulcer, 2 gastric erosions) reported symptomatic improvement after cisapride alone and would not have received definitive therapy. Because of the dangers of misdiagnosing patients with peptic ulcers, empirical cisapride therapy could not be recommended. Despite concerns over potential QT interval prolongation and ventricular arrhythmia, a relatively low dose of 5 mg three times daily was not associated with any adverse event in our sample of patients.

In conclusion, most patients presenting to primary care physicians with dyspepsia appear to have non-ulcer dyspepsia, which is associated with a high one-year relapse rate. Empirical endoscopy, *H pylori* test-and-treat and empirical prokinetic treatments appear to have similar efficacy in improvement of dyspepsia and quality-of-life. Empirical prokinetics may result in organic lesions being missed in diagnosis. Most patients preferred having endoscopy first, if given the choice, but this is the most expensive option. *H pylori* test-and-treat is the most cost-effective safe treatment.

ACKNOWLEDGMENTS

We are indebted to the doctors and nurses of the Violet Peel, Sai Ying Pun, Aberdeen and Ap Lei Chau government outpatient clinics for recruitment of patients and Ms. Monique Chong, Ms. Vera Tang, Ms. Wong Ka-Wah, Ms. Diana Chang, Ms. Wing-Ping Yung for their assistance in the endoscopy room.

Abstract

AIM: To evaluate the gastric permeability after both acute and chronic use of non-steroidal anti-inflammatory drugs (NSAIDs) and to assess the clinical usefulness of sucrose test in detecting and following NSAIDs- induced gastric damage mainly in asymptomatic patients and the efficacy of a single pantoprazole dose in chronic users.

METHODS: Seventy-one consecutive patients on chronic therapy with NSAIDs were enrolled in the study and divided into groups A and B (group A receiving 40 mg pantoprazole daily, group B only receiving NSAIDs). Sucrose test was performed at baseline and after 2, 4 and 12 wk, respectively. The symptoms in the upper gastrointestinal tract were recorded.

RESULTS: The patients treated with pantoprazole had sucrose excretion under the limit during the entire follow-up period. The patients without gastroprotection had sucrose excretion above the limit after 2 wk, with an increasing trend in the following weeks ($P = 0.000$). A number of patients in this group revealed a significantly altered gastric permeability although they were asymptomatic during the follow-up period.

CONCLUSION: Sucrose test can be proposed as a valid tool for the clinical evaluation of NSAIDs- induced gastric damage in both acute and chronic therapy. This technique helps to identify patients with clinically silent gastric damages. Pantoprazole (40 mg daily) is effective and

INTRODUCTION

Non-steroidal anti-inflammatory drugs (NSAIDs) are largely consumed among the general populations worldwide, representing one of the most prescribed drugs^[1-6]. The main factor limiting their use is a high rate of adverse events, especially gastrointestinal toxicity^[7]. Although only a small number of patients develop serious gastrointestinal complications, they represent a large number of patients due to the widespread use of NSAIDs^[7-9].

Gastrointestinal toxicity is often clinically silent even in high risk groups due to the intrinsic analgesic activity of NSAIDs^[10]. Therefore aspecific symptoms such as dyspepsia, heartburn, nausea, vomiting or abdominal pain are frequently ignored by patients suffering, for example, from a chronic pain due to the underlying osteoarticular diseases.

A recent meta-analysis indicates that the association between use of NSAIDs and dyspepsia is unclear because of the variability of the terminology used in literature to report GI symptoms^[11]. Taking the "strict" definition of dyspepsia into account, based solely on epigastric pain-related symptoms, NSAIDs increase the risk of dyspepsia of 36%, which is useful for creating standard definitions. Endoscopy for diagnosis of NSAIDs- induced upper gastrointestinal damage is precise, sensitive and easy to perform, but it cannot be proposed as a screening test,

Figure 1 Sucrose test in patients of the study. Group A = pantoprazole 40 mg and Group B = no therapy.

especially in asymptomatic patients. Gastrointestinal permeability is usually tested to assess the small bowel function in many diseases such as coeliac disease and inflammatory bowel disease^[12,13]. Sucrose test is a simple, economic and non-invasive test for the assessment of gastric permeability and correlates with alterations detected with histology as previously demonstrated^[14]. Some authors have proposed sucrose test as an index for monitoring hypertensive gastropathy, confirming its clinical usefulness. Which is the best strategy in preventing NSAIDs-related adverse events in the gastrointestinal tract is still controversial^[16].

Many clinical trials have analyzed the efficacy and safety of concurrent administration of NSAIDs and misoprostol, H₂ blockers or proton pump inhibitors (PPIs) in reducing the occurrence of serious gastrointestinal events.

Available data show that PPIs are well tolerated and effective in preventing and treating non steroidal antiinflammatory drug-related mucosal lesions of the gastrointestinal tract^[17-20].

The aim of this study was to establish the clinical usefulness of sucrose test in early identification of both acute and chronic gastric mucosal damage irrespective of the presence of any symptoms and to define the efficacy of a single daily PPI administration in protecting gastric mucosa in patients requiring long term treatment with NSAIDs.

MATERIALS AND METHODS

Patients

Seventy-one consecutive outpatients (38 females, 33 males, mean age 53 years, range 26-78 years) with chronic use of NSAIDs (ASA, diclofenac, celecoxib) for rheumatic diseases (rheumatoid arthritis, osteoarthritis) were enrolled in the study. None of them consumed gastroprotective agents (PPIs, H₂-blockers, misoprostol).

All patients were asymptomatic at baseline and had no previous history of peptic ulcer, gastroesophageal surgery or malignancies.

Sucrose permeability test (40 mg of sucrose in 100 mL of water) was performed at baseline. The patients were divided in group A (31 patients receiving 40 mg pantoprazole daily) and group B (40 patients not receiving PPI therapy). Sucrose test was repeated 2, 4, and 12 wk after follow-up (Figure 1).

The patients gave their informed consent according to the principles of the Helsinki Declaration. Symptoms were recorded according to the presence of mild dyspepsia as previously defined (score 0 = absence; score 1 = mild dyspepsia)^[11].

Sucrose test

To evaluate gastric permeability, the subjects were requested to ingest 40 g sucrose in 100 mL of water after fasted for 8 h. Urine samples were collected in the following 6 h into a container with the addition of 2 mL of 20% chlorhexidine to prevent bacterial degradation. No food or liquid intake (except a glass of water) was allowed during urine collection. Urine samples were refrigerated and taken to the laboratory within 24 h. An aliquot was stored at -20°C for subsequent analysis.

Sucrose assay was based on its hydrolysis by β -fructosidase to glucose and fructose. Glucose was measured by the hexokinase method. The concentration of the reduced nicotinamide adenine dinucleotide phosphate (NADP) was measured at 340 nm. Results were expressed as the percentage of excretion of the ingested dose of sucrose and the normal range was < 0.15% sucrose.

Statistical analysis

Data were reported as mean \pm SD. Values of sucrose test at baseline and after 2 and 4 wk in group B were evaluated with Wilcoxon signed-rank test. Comparison between sucrose test values in groups A and B was made with Mann-Whitney test. Statistical Program for Social Sciences (SPSS Inc., Chicago, Illinois 60606) was used for calculations. $P < 0.05$ was considered statistically significant.

RESULTS

At baseline all the patients showed a mean sucrose value of $0.10\% \pm 0.08\%$. Two weeks later, all the patients underwent an additional sucrose test which showed a mean value of $0.13\% \pm 0.08\%$ in group A and $0.19\% \pm 0.06\%$ in group B. At wk 4 sucrose test showed $0.12\% \pm 0.07\%$ in the pantoprazole group and $0.24\% \pm 0.07\%$ in the other group ($P = 0.000$). Sucrose test was then repeated after 12 wk, showing the mean values of $0.13\% \pm 0.10\%$ in group A and $0.25\% \pm 0.07\%$ in group B respectively ($P = 0.000$) (Figure 1). At wk 4 the mean value of sucrose

Figure 2 Sucrose test in Group B patients accordingly to their symptoms.

test decreased in 7 patients of group A and in 15 patients of group B. At wk 12 the mean value of sucrose test decreased in 3 and additional 3 patients of group A and none of group B. Forty-six patients (21 in group A and 25 in group B) completed the follow-up (wk 12).

Regarding the consumption of NSAIDs, the patients on ASA therapy and without gastroprotection showed the mean sucrose values of $0.10\% \pm 0.05\%$ at baseline and $0.17\% \pm 0.06\%$, $0.24\% \pm 0.07\%$, $0.28\% \pm 0.06\%$ at 2, 4 and 12 wk respectively.

In the patients consuming diclofenac and without gastroprotection, the mean sucrose values were $0.08\% \pm 0.03\%$ at baseline and $0.24\% \pm 0.05\%$, $0.31\% \pm 0.06\%$ and $0.30 \pm 0.04\%$ at 2, 4 and 12 wk respectively.

In the patients consuming celecoxib, the mean sucrose values were $0.08\% \pm 0.04\%$ at baseline and $0.04\% \pm 0.05\%$, $0.17\% \pm 0.04\%$ and $0.15\% \pm 0.06\%$ at 2, 4 and 12 wk respectively. The patients with no symptoms accounted for 47.4%, 31.6% and 32.6% after 2, 4 and 12 wk respectively.

In group B, 37.5%, 32% and 28% of the patients remained asymptomatic after 2, 4 and 12 wk respectively. However, their mean sucrose values were $0.13\% \pm 0.08\%$, $0.20\% \pm 0.06\%$ and $0.21\% \pm 0.05\%$ during the follow-up period.

The mean sucrose values in patients complaining of mild dyspepsia in group B were $0.23\% \pm 0.04\%$, $0.25\% \pm 0.08\%$ and $0.25\% \pm 0.07\%$ after 2, 4 and 12 wk (Figure 2).

DISCUSSION

Sucrose test is considered as a useful tool for predicting the presence of clinically significant gastric disease after repetitive exposure to NSAIDs. Furthermore, sucrose test has been shown to be able to detect the differences in both formulation and dose of NSAIDs^[13].

NSAIDs reduce secretion of both bicarbonate and mucus, which are two of the most important gastric mucosal defensive mechanisms. In fact, bicarbonates stimulate cell renewal and repair, while mucus that coats over the mucosal lining provides a substrate for rapid restitution processes^[21,22]. NSAIDs-induced damage allows permeation of macromolecules such as sucrose through the gastric mucosa.

We have previously proposed sucrose test together with serum pepsinogens as useful non-invasive methods to as-

sess histological damages as they show a good relationship with histological findings^[14].

In our study, the patients without PPI therapy showed increasing mean values of sucrose test during the acute period (0.19% after 2 wk and 0.24% after 4 wk) compared to the 0.10% at baseline with a statistically significant difference ($P = 0.000$), suggesting that sucrose test is able to detect gastric mucosal damages in acute ingestion of NSAIDs.

The subjects on chronic therapy showed a stable mean value of 0.25% after 12 wk, without any statistically significant difference ($P = 0.39$). This can be explained with the underlying mechanisms of NSAIDs-induced gastric damage involving both direct irritant action and systemic effect due to the inhibition of cyclooxygenase (COX) activity, which represents their main pharmacological effect. However, some authors suggest that COX-independent effects may be important in inducing mucosal cell apoptosis and microvascular perturbation with subsequent acute lesions^[23].

Several studies have indicated that acute damage is much more widespread than damage observed after several days or weeks, indicating that the gastric mucosa has adaptive mechanisms that compensate for NSAIDs-induced injury^[24]. Although the mechanisms involved in adaptation have not been defined yet, they reflect the capacity of a rapid epithelial repair, which in turn depends on restitution and cell replication^[25].

In our study, the symptomatic patients showed a urinary sucrose excretion above the normal limit, suggesting a gastric damage. However, an alteration in gastric permeability was also undetectable by endoscopy, suggesting that sucrose test represents the only available method to detect "mild to moderate" gastric damages.

In our study, a proportion of patients without gastroprotection revealed higher mean sucrose excretion than normal although they remained completely asymptomatic. These patients had a normal sucrose test at baseline and after 4 wk, but the excretion increased significantly in the following weeks, suggesting that they had mucosal damage. These results indicate an important clinical role of sucrose test which can be used to identify gastric mucosal damages irrespective of the presence of a clinical picture, which is often absent in NSAIDs-induced damage.

Sucrose test could be performed sequentially in high risk patients such as chronic users and rheumatic patients, and could identify early gastric mucosal damages.

The best strategy in preventing NSAIDs-induced damage is still controversial^[13-19]. First, gastrointestinal complications may be avoided by the use of NSAID analgesics when possible. Second, using NSAIDs at their lowest effective dose decreases the risk of complications. Third, medical cotherapy could be used in patients with increased risk of complications. Finally, less injurious NSAIDs such as COX-2-specific inhibitors should be developed to decrease the risk of gastrointestinal events.

Many studies have demonstrated that PPIs give a good protection against both duodenal and gastric ulcers in patients taking NSAIDs^[27,28]. In addition, these drugs are safe and better tolerated as co-therapies than H₂-antagonists or prostaglandin.

Some studies have demonstrated a significant benefit of pantoprazole in preventing NSAIDs-induced peptic ulcers. There are also data regarding the efficacy of pantoprazole in preventing gastric lesions in rheumatic patients receiving long term treatment with NSAIDs. It has been reported that pantoprazole (40 mg daily) is well tolerated and more effective than placebo in preventing peptic ulcer in patients with rheumatic diseases on prolonged therapy with NSAIDs^[28-30].

In our study, the patients on pantoprazole therapy showed lower mean values of sucrose test both in acute and chronic treatment compared with those without gastroprotection, confirming the efficacy of this drug in protecting gastric mucosa. The presence of upper gastrointestinal symptoms was lower in patients receiving pantoprazole during the period of observation.

In conclusion, sucrose test can be used in the follow-up of patients on chronic therapy with NSAIDs. In fact, this method is non-invasive, well tolerated and inexpensive, and can be easily performed sequentially in chronic users of NSAIDs. This approach helps identify high risk patients that should undergo an upper gastrointestinal endoscopy if economic consideration is taken into account.

Abstract

AIM: Recently it has been reported that granulocyte colony stimulating factor (G-CSF) can induce hypercoagulability in healthy bone marrow donors. It is conceivable that the induction of a prothrombotic state in a recipient of an organ graft with already impaired perfusion might cause further deterioration in the transplanted organ. This study evaluated whether G-CSF treatment worsens liver perfusion following liver transplantation in the rat model.

METHODS: A non-arterialized rat liver transplantation model was employed to evaluate the effect of G-CSF treatment on the liver in a syngeneic and allogeneic strain combination. Study outcomes included survival time and liver damage as investigated by liver enzymes and liver histology. Observation times were 1 d, 1 wk and 12 wk.

RESULTS: Rats treated with G-CSF had increased incidence and severity of biliary damage following liver transplantation. In these animals, hepatocellular necrosis was accentuated in the centrilobular region. These lesions are indicative of impaired perfusion in G-CSF treated animals.

CONCLUSION: G-CSF should be used with caution in recipients of liver transplantation, as treatment might enhance preexisting, undetected perfusion problems and ultimately lead to ischemia induced biliary complications.

INTRODUCTION

In 1975 granulocyte colony stimulating factor (G-CSF) was purified from urine^[1] and serum^[2]. Nowadays G-CSF is in clinical use and is applied routinely for donor conditioning before stem cell transplantation due to its stem cell mobilizing property. It is also used to treat patients who suffer from infections and neutropenia^[3,4] and has been used successfully in endotoxin induced septic conditions^[5]. Recently G-CSF has been used in immunosuppressed patients, particularly transplant-recipients, suffering from CMV infection and severe neutropenia^[6].

Several clinical studies have evaluated the safety of G-CSF for transplant patients with a special focus on acute cellular rejection^[6,7]. Acute cellular rejection, however, is only one potential threat to the transplanted organ. Decreased organ perfusion can lead to impaired function and even graft failure^[8]. Impaired perfusion can result from ischemia-reperfusion damage or arterial insufficiency secondary to thrombosis at the site of anastomosis.

Recently it was shown that G-CSF can induce hypercoagulability in healthy bone marrow donors^[9,10]. A prothrombotic state when a grafted organ is already compromised by impaired perfusion might exacerbate ischemia and further jeopardize the function of the transplanted organ. This study was designed to establish whether G-CSF treatment aggravates impaired liver perfusion following liver transplantation in the rat model.

MATERIALS AND METHODS

Experimental design

A non-arterialized rat liver transplantation model was used

to evaluate the effect of G-CSF treatment on the liver in a syngeneic and allogeneic strain combination. Outcomes included survival time and liver damage as investigated by liver enzymes in combination with liver histology. Observation time was set to 1 d, 1 wk and 12 wk.

Animals

Female Lew and ACI rats were used as donors and male Lewis (LEW, RT¹) rats (Charles River Wiga GmbH, Germany), as recipients. The body weight of male rats was within 250-350 g (10-14 wk old), that of female rats were within 200-300 g (11-14 wk old). The animals were housed under standard animal care conditions and fed with rat chow *ad libitum* before and after operation. All procedures and housing were carried out according to the German Animal Welfare Legislation.

Administration of G-CSF

Animals in the treatment group received G-CSF (Neupogen 48TM, AMGEN GmbH, Germany) at a dose of 100 µg/kg daily by subcutaneous injection starting 5 d prior to the operation until postoperative d 21.

Surgical procedures of orthotopic liver transplantation

Orthotopic liver transplantation was performed according to the technique described by Kamada^[11]. Inhalation anesthesia with Isoflurane was used during the operation.

First step of the surgical procedure was a transverse abdominal incision. The liver of the donor was freed from its ligaments. The small-for-size liver graft was generated by 70% liver resection that included removing the left lateral lobe, the left medial lobe and the middle lobe. The weight of the resected liver lobes as well as the graft itself were recorded. The liver graft was perfused through the portal vein with chilled Ringer's solution. The organ was preserved at 4°C for a maximum of one hour until placed orthotopically in the recipient's abdomen. The donor suprahepatic vena cava was anastomosed end-to-end with the recipient suprahepatic vena cava using a continuous 7-0 polypropylene suture. The portal vein anastomosis as well as the infrahepatic vena cava anastomosis were performed by pulling the recipient's vein over a cuff which was secured with a circumferential 6-0 silk suture. Biliary continuity was restored by tying the bile duct over a stent (Klinika Medical GmbH, Germany).

Postoperative management

After transplantation animals were placed into clean cages, and were given free access to tap water and rat chow *ad libitum*. Animals were observed daily. Body weight loss and general condition including activity, jaundice and bleeding from eyes or nose were recorded. Animals with deteriorating general condition indicated by a weight loss of more than 30% were sacrificed and were classified as dying during the observation period.

Sampling procedures

After sacrifice a full autopsy was performed. Gross findings were documented using a digital camera (Nikon Coolpix 995). Blood was obtained from the infrahepatic

Table 1 Histologic damage score of the liver after liver transplantation

Single cell necrosis	0: No necrotic hepatocyte in 5 HPF (40 X) 1: 1-10 in 5 HPF 2: > 10
Confluent necrosis	0 1: Small in size and number 2: Large size and /or large number
Hepatic mitosis	0: No mitotic hepatocyte in 5 HPF (40 X) 1: 1-10 in 5 HPF 2: > 10 (extensive)
Bile duct inflammation damage	0: No inflammation; 1: A minority of the ducts are cuffed and infiltrated by inflammatory cells 2: More than an occasional duct showing degenerative changes or focal degenerative changes; Most of the ducts infiltrated by inflammatory cells 3: Most of the ducts showing luminal disruption, most of the ducts infiltrated by inflammatory cells
Ductular proliferation	0: None 1: Minimal (small proliferation in a minority of portal tracts) 2: Mild (most portal tracts but not involving the lobular parenchyma) 3: Moderate (all portal tracts and extending along the fibrous septa) 4: Severe (extending along the portal tracts and also slightly involving the lobular parenchyma) 5: Very severe (diffuse proliferation in the lobular parenchyma)
Fibrosis	0: None 1: Fibrosis slightly extending portal tracts 2: Fibrosis extending portal tracts with incomplete septa 3: Fibrosis with complete septa bridging portal to portal tracts 4: Incomplete (focal) or complete cirrhosis
Activated Kupffer cells	0: No activated Kupffer cells 1: Activated Kupffer cells
Eosinophilic globuli	0: No eosinophilic globuli 1: 1%-5% of all hepatocytes 2: > 5%
Small vacuolar transformation of the cytoplasm	0: No small vacuolar transformation of the cytoplasm 1: 1%-30% of all the hepatocytes 2: > 30%

vena cava. Tissue samples (liver, bile duct) were fixed in 4% buffered formalin. Paraffin embedding was performed using standard techniques (Tissue Processor TPC15, Medite Inc.). Paraffin sections (4 µm) were stained with Hematoxylin-Eosin (HE) and Elastic von Gieson (EvG).

Alanine aminotransferase (ALT), Aspartate aminotransferase (AST), Alkaline phosphatase (AP) and Bilirubin were measured with an Automated Chemical Analyzer (ADVIA 1650, Bayer AG, Germany).

Histological evaluation of grafts

Damage to the liver was assessed histologically using a semiquantitative scoring system (Table 1). The scoring

Figure 1 Histology of rat liver after 24 h (A, B), one week (C, D) and 12 wk (E, F) with and without G-CSF treatment showing varying degrees of inflammation and bile duct proliferation. HE; A, D, F 200 x; B 300 x; C, E 100 x.

system included assessment of the portal and lobular inflammatory infiltrate, the extent of hepatocellular necrosis and signs of unspecific hepatocellular damage like a fine vacuolar transformation of the cytoplasm of hepatocytes. The number of mitotic figures and of eosinophilic globular structures in the cytoplasm of hepatocytes were counted. The extent of bile duct inflammation, regenerative changes of biliary epithelial cells and the number of ductules was reported.

The liver damage score was calculated as sum of the scores of all parameters, and the bile duct damage score was calculated as sum of bile duct inflammation and ductular proliferation score.

Data analysis and statistics

Data analysis and statistical procedures were performed using SPSS 10.0 (SPSS Inc. USA). All graphs were generated using *Sigmaplot* 7.0 (SPSS Inc. USA).

The survival rate was depicted as Kaplan-Meier curve. Survival rates in different groups were tested using the *log rank* test. Biochemistry results and damage scores among different groups were tested using the *Mann Whitney Rank Sum* test.

RESULTS

Normal rats

Normal rats treated with G-CSF ($n = 6$) for 5 d showed a mean leucocyte count of 22 neutrophilic cells per nl compared to 15 per nL without G-CSF treatment, indicating the biologic activity of human G-CSF in rats. An isolated increase in the blood level of alkaline phosphatase was detected in 1 out of 6 animals. ALT, AST

Figure 2 Kaplan-Meier chart of rats after liver transplantation with and without G-CSF treatment.

Table 2 Blood levels of ALT, AST and AP in rats after liver transplantation with and without G-CSF treatment

Group	24 h		1 wk		12 wk	
	Untreated	G-CSF	Untreated	G-CSF	Untreated	G-CSF
ALT (u/L)	616 ± 194 ¹	418 ± 73 ¹	192 ± 49	148 ± 81	92 ± 84	49 ± 24
AST (u/L)	344 ± 204	204 ± 48	96 ± 81	59 ± 28	35 ± 15	24 ± 13
AP (u/L)	141 ± 22 ²	455 ± 99 ²	453 ± 147	449 ± 418	473 ± 543	221 ± 68

¹ Significant difference between two groups ($P < 0.05$, *t*-test); ² Significant difference between two groups ($P < 0.001$, *t*-test).

and bilirubin were within their normal range.

Histological evaluation revealed no pathologic changes; especially no alteration of the bile ducts or hepatocellular necrosis.

Rats after syngeneic liver transplantation

In both the G-CSF treated and untreated groups at 24 h, the liver macroscopically showed slight edema in the hilar region. Histologically a granulocytic infiltrate was found surrounding large hilar intrahepatic bile ducts in 50% of all G-CSF treated rats whereas in untreated rats hardly any inflammatory infiltrates in the large hilar intrahepatic bile ducts was detected (Figure 1).

Alkaline phosphatase was significantly higher in the G-CSF group compared to the untreated group (Table 2) indicating a more pronounced damage to the biliary system in the G-CSF treated animals.

Blood levels of liver enzymes were significantly lower in the G-CSF treated group compared to the untreated group (ALT: G-CSF treated group: 418.67 ± 73.08 μ /L *vs* untreated group: 634 ± 195.86 μ /L, $P = 0.041$), indicating a reduced number of damaged liver cells in G-CSF treated animals.

In both animal groups morphologic signs of minor hepatocellular damage like small vacuoles in the cytoplasm and a low number of single cell necrosis were visible.

In the treated group hepatocellular damage was mainly located in the centrilobular region. In contrast this distribution of hepatocytic injury was only observed in 2/6 animals of the untreated group. The other animals presented with single cell necrosis throughout the liver

lobule.

In the one week group with G-CSF treatment all animals survived. Survival rate without G-CSF treatment was 90% (Figure 2).

Upon gross examination, signs of limited inflammation around the common bile duct was found in all animals.

AST and ALT levels in both groups were elevated. Compared to the levels reached 24 h postoperatively, a decrease was observed, indicating recovery (Table 2). Two animals in the treatment group showed a massive increase in the AP-levels indicating severe damage to the bile ducts, whereas the other animals were within the normal range. In the untreated group, three out of six animals showed a slight increase in the AP-levels.

Histologically signs of damage to the biliary epithelial cells were visible in animals with and without G-CSF treatment. After G-CSF treatment rats showed a more pronounced proliferation of small biliary ducts suggesting a bile outflow problem.

Biliary epithelial cells showed signs of regenerative activation indicating repair of cellular damage rats with and without G-CSF treatment. Besides mitotic figures the biliary epithelial cells showed an increased nuclear polymorphism and nuclear enlargement leading to a shift of the nuclear to cytoplasmic ratio. Crowding of the biliary epithelial cells was visible. Nuclei did not show basal orientation. Furthermore signs of ongoing damage to the biliary duct were visible. In the cytoplasm of biliary epithelial cells vacuoles were discernible. A very low number of necrotic biliary epithelial cells could be detected. In the vicinity of bile ducts inflammatory cellular infiltrates were visible.

Biliary outflow obstruction is known to induce proliferation of biliary ducts leading to an increase in the number of bile ducts in the portal tracts. Proliferation of bile ducts was more pronounced in animals that underwent G-CSF treatment (Figure 1D). In one rat, the proliferated bile ducts extended into the parenchyma of the liver. In another animal a massive "biliary transformation" of the liver was observed. The biliary duct damage score was slightly higher in G-CSF treated animals at week one, but at this time point the difference did not reach statistical significance ($P = 0.074$, Mann-Whitney test).

Survival rate at 12 wk post operation was 88% in the untreated group compared to the treated group that showed a survival rate of only 64% (Figure 2).

Macroscopically concrements and sludge in large bile ducts was found slightly more frequent in G-CSF treated rats (3/6 compared to 2/6).

In the untreated group, black sludge in the bile duct was found in one rat. In another rat, a small yellow particle in the common bile duct was found, which was associated with a cystic dilatation of the bile duct.

In G-CSF treated animals a small amount of black sludge was found in 2 out of 6 rats. A 0.4 cm × 0.4 cm black stone-like particle in a dilated bile duct was found in another rat. Totally, macroscopically visible lesions of the large extrahepatic bile duct were found in 3 out of 6 rats.

Blood levels of liver enzymes and AP were increased but comparison of both groups did not show a statistically significant difference at this time point.

Figure 3 Median bile duct damage score at one and twelve weeks.

Microscopically the number of proliferating small biliary ducts was higher in G-CSF treated animals. The degree of liver cell damage was also higher in G-CSF treated animals. Median bile duct damage score in G-CSF treated animals reached statistical significance compared to rats without G-CSF treatment (Figure 3).

Rats after allogeneic liver transplantation

After full size liver transplantation in the ACI to Lewis strain combination animals died within 9 to 14 d. No difference in survival time was observed between animals with and without G-CSF treatment.

Animals dying spontaneously presented with morphological signs of severe rejection, as expected in this strain combination. Scoring of the histopathology according to the Banff-classification showed no difference in severity between the two groups. Portal tracts were wide and filled with activated lymphocytes and other inflammatory cells. Inflammatory cells extended into the parenchyma of the liver and hepatocellular single cell necrosis was obvious.

In addition inflammatory cells infiltrated small bile ducts that showed signs of damage and destruction. Single necrotic biliary cells and vacuolar transformation of biliary epithelium was the characteristic feature. Regenerative activation of biliary epithelial cells was detected. The number of mitotic figures in biliary epithelial cells was increased and nuclei were not evenly arranged in the vicinity of the basal membrane. In addition nuclear enlargement leading to a shift of the nuclear to cytoplasmic ratio was recorded. In addition to ductitis, there was also an inflammatory infiltrate in the luminal parts of the wall of blood vessels both in the portal tract and in the central regions of the lobules. This endothelitis was accompanied by a regenerative activation and proliferation of endothelial cells and in some vessels, minute fibrin deposits were discernible on the luminal surface.

In the G-CSF treated animals the number of granulocytes seemed to be slightly higher near the bile ducts, whilst hepatocellular single cell necrosis seemed to be slightly more prominent in centrilobular areas compared to rats receiving no G-CSF treatment. Differences were subtle and did not allow for clear discrimination between

the two groups. When slides were observed in a blinded fashion animals could not be clearly attributed to either group.

DISCUSSION

G-CSF is used routinely in conditioning of donors before stem cell transplantations. In donors and healthy volunteers it has been shown that G-CSF induces a prothrombotic state (Table 3). In addition to the increase in prothrombotic factors, enhanced platelet aggregation was also observed, potentially mediated by the G-CSF receptor on platelets^[12]. Therefore, it was suspected that G-CSF might lead to thrombotic complications in patients already at risk for thrombosis. Thus, careful monitoring was recommended for patients with additional risk factors for thrombosis^[13].

Furthermore other pathophysiological alterations induced by G-CSF may impair microcirculation. Microcirculation was disturbed in G-CSF treated rats using a free-flap model to investigate behavior of granulocytes after chemotherapy and G-CSF stimulation^[14]. Leukocyte rolling and sticking was enhanced to a degree that impaired microcirculation. However, this problem became only visible in this free-flap model with its inherent impairment to microcirculation.

Ischemia-reperfusion injury causing an impairment of microcirculation is unavoidable in transplantations^[15-17]. In clinical liver transplantation, impaired arterial perfusion, mostly due to arterial thrombosis in the hepatic artery, is an important cause of graft dysfunction and even failure^[18-20]. In the rat, rearterialization is not essential for the survival of the recipient, but is considered by some authors to enhance liver perfusion and especially perfusion of the biliary tract, resulting in a lower rate of biliary

complications^[21,22]. For this study, a model with a high risk of perfusion related problems was warranted. Therefore, the non-arterialized rat liver transplantation model, as developed by Kamada^[20] was employed.

In rats, subjected to liver transplantations and additional perioperative G-CSF treatment, in the early postoperative period we observed a centrilobular accentuation of necrotic hepatocytes. At the same time we also observed an increased blood level of alkaline phosphatase at 24 h. Alkaline phosphatase can be an indicator of damage to the biliary epithelial cells but an increase in the blood levels of alkaline phosphatase after G-CSF treatment is also described in some patients due to the induction of bone metabolism^[23]. Especially the pronounced increase after syngeneic liver transplantations in rats treated with G-CSF compared to non-operated G-CSF treated animals suggests damage to the biliary tract leading to cholangitis as the underlying reason.

In the animals observed for 12 wk, an increase in the number and severity of biliary complications and accompanying histomorphological damage was found. In particular, the number of proliferating small biliary ducts, which is indicative of a biliary outflow problem, was more prevalent in G-CSF treated rats.

Impaired arterial perfusion of the liver parenchyma leads to variable centrilobular necrosis^[24]. Impaired arterial perfusion of the bile duct leads to damage of the biliary epithelial cells indicated by the release of alkaline phosphatase. Aggressive bile seeping into the surrounding tissue can perpetuate the damage and attract inflammatory cells, causing cholangitis. Especially when larger bile ducts are affected, there can be a functional impairment of smooth muscle cells with loss of motility, which can impair bile outflow. Reduced biliary flow promotes the development of biliary sludge and concretions eventually leading to outflow obstruction. Biliary obstruction induces proliferation of small bile ducts as demonstrated experimentally in a rat liver ischemia model^[25] and after bile duct ligation^[26].

If this combination of morphological alterations, centrilobular hepatocellular necrosis and cholangitis with or without proliferation of small bile duct is present, as it is in our experiment, an underlying perfusion problem must be assumed. However, it might be difficult to achieve a diagnosis based on histomorphology alone since severe additional confounding alterations like rejection can be superimposed. In the allogeneic strain combination rejection was partially masking perfusion related morphologic alterations. Thus, a perfusion associated problem could only be suspected upon a detailed analysis.

Clinical studies performed to document the safety of G-CSF in transplant patients did not reveal relevant side effects in most studies. G-CSF is known to restore the compromised immune system in neutropenic patients by increasing the number of circulating granulocytes, thus it was suspected that the rejection rate might increase. In the published clinical trials^[6,7,27] an influence on rejection rate or severity was not reported, which was also confirmed in our study. Other problems seem to be out of focus in these studies. In a large clinical trial analyzing potential adverse effects of G-CSF in liver transplanted

patients^[7] not a single case of biliary complications was reported. Biliary problems are rather common after liver transplantations. The complete absence of any biliary problem in such a large cohort of 286 patients is rather surprising.

G-CSF-related histomorphological alterations of the liver were reported in studies, where patients were exposed to high levels of circulating cytokines. Suzuki^[28] reported on a small number of patients with endocrine tumors producing G-CSF as well as IL-1 and IL-8, who presented with liver dysfunction and fever in addition to marked leukocytosis. Biochemical examinations revealed high serum enzyme levels of the biliary system in contrast to normal or slight increases in transaminase levels in all patients studied. Three common pathologic changes of the liver were found: focal necrosis associated with neutrophil infiltration in the centrilobular zones^[1], fibrous change and enlargement of the portal area associated with neutrophil infiltration^[2], and intrahepatic cholestasis^[3]. The same pathologic changes, except for cholestasis, were observed in the liver of mice transplanted with G-CSF-producing cell lines (KHC287 or CHU-2)^[29]. Thus the pattern of liver lesions consisting of an impairment of bile ducts and centrilobular necrosis of hepatocytes was similar to morphologic changes observed in our experiment.

But on the other hand a beneficial effect of G-CSF on the liver after extended liver resection and toxic liver damage has been described^[30,31]. Yannaki observed an accelerated recovery and improved survival after liver injury and attributed this effect to the promotion of endogenous repair programs^[9], and not to stem cell transdifferentiation, as discussed recently. In the experiment presented here, the lower serum levels of AST and ALT 24 h after liver transplantation could be attributed to this beneficial G-CSF effect. In treated rats, hepatocyte necrosis was only observed in the vicinity of central veins, whereas single cell necrosis was distributed throughout the liver lobule in the untreated group, accompanied by a significantly higher release of liver enzymes. This distribution pattern of single cell necrosis gives rise to the speculation, that G-CSF had a beneficial affect on hepatocytes undergoing ischemia reperfusion injury, but had a detrimental effect on perfusion leading to centrilobular necrosis of hepatocytes and necrosis and vacuolization of biliary epithelial cells.

This contradictory effect contributes to the blurring clinical picture, which hinders one from reaching definitive conclusions from these studies. Perfusion related changes are rather subtle, thus it is necessary to give special attention to this problem, which does not always happen, neither in daily clinical routine nor in clinical studies as mentioned before^[7].

CONCLUSION

G-CSF should be used with caution in liver transplanted patients, as treatment might enhance preexisting, undetected perfusion problems and ultimately lead to ischemia induced biliary complications.

Abstract

AIM: To describe the trend in duodenal biopsy performance during routine upper gastrointestinal endoscopy in an adult Spanish population, and to analyze its value for the diagnosis of celiac disease in clinical practice.

METHODS: A 15 year-trend (1990 to 2004) in duodenal biopsy performed when undertaking upper gastrointestinal endoscopy was studied. We analysed the prevalence of celiac disease in the overall group, and in the subgroups with anaemia and/or chronic diarrhoea.

RESULTS: Duodenal biopsy was performed in 1033 of 13 678 upper gastrointestinal endoscopies (7.6%); an increase in the use of such was observed over the study period (1.9% in 1990-1994, 5% in 1995-1999 and 12.8% in 2000-2004). Celiac disease was diagnosed in 22 patients (2.2%), this being more frequent in women than in men (3% and 1% respectively). Fourteen out of 514 (2.7%) patients with anaemia, 12 out of 141 (8.5%) with chronic diarrhoea and 8 out of 42 (19%) with anaemia plus chronic diarrhoea had celiac disease. A classical clinical presentation was observed in 55% of the cases, 23% of the patients had associated dermatitis herpetiformis and 64% presented anaemia; 9% were diagnosed by familial screening and 5% by cryptogenetic hypertransaminasaemia.

CONCLUSION: Duodenal biopsy undertaken during routine upper gastrointestinal endoscopy in adults, has been gradually incorporated into clinical practice, and is a useful tool for the diagnosis of celiac disease in high risk groups such as those with anaemia and/or chronic diarrhoea.

INTRODUCTION

Celiac disease (CD) is a frequent immune-mediated enteropathy of worldwide distribution. It affects both children and adults and has a heterogeneous clinical presentation^[1]. Even though we currently possess sensitive and specific serological methods, the duodenal biopsy continues to be the gold standard for the diagnosis of CD^[2]. Knowledge of the diverse forms of presentation of CD, together with a high index of clinical suspicion and an improvement in the accessibility to endoscopy units have made it possible, in some geographical areas, that the number of diagnosed celiac patients approximates the number of patients estimated from population screening studies^[3].

Endoscopic duodenal biopsy is a diagnostic tool in the management of patients with chronic diarrhoea and ferropenic anemia^[4,5], these being frequent manifestations of CD^[1]. Several studies have been designed in order to know the prevalence of CD among those with anemia or diarrhoea^[6-13]. However, the usefulness of duodenal biopsy during upper gastrointestinal (GI) endoscopy for diagnosis of CD is less well known in daily clinical practice^[14].

In Spain, the prevalence of CD in the general population is similar to other European countries (1/118 to 1/389)^[15-17], we do not however possess data on the performance of duodenal biopsy in adults in clinical practice. The aims of the present study were to obtain information on the evolution of the practice of duodenal biopsy in adults over a 15-year period in a Spanish Digestive Endoscopy Unit and also to study the efficacy of such for the diagnosis of CD in high risk groups

of patients, such as those with anemia and/or chronic diarrhoea. The clinical characteristics of celiac patients diagnosed throughout the study are also described.

MATERIALS AND METHODS

Patients

The Gastroenterology Unit of Hospital Valle del Nalón (Asturias, Northern Spain) is the reference for an adult population of 75 212 people (27% > 60 years). All upper GI endoscopies were performed by three gastroenterologists (RS, F-RE and NR) and duodenal biopsies (3-5 samples per patient) were evaluated by the same pathologist (DF). A special interest in CD began in 1997, when an epidemiological study was undertaken on the prevalence of the disease in the general population of this area^[15]. In clinical practice, the access to Digestive Endoscopy Unit is not open to primary care and serological testing for CD has always been available (antigliadine, antiendomysium and/or antitransglutaminase, according to the period analysed). From 1998, the genetic study of HLA-DQ2/DQ8 has also been available.

Study design

Using the computerized register of all upper GI endoscopies performed between 1990 and 2004 (13 678), we created a database of all patients who had undergone a duodenal biopsy (1033). After excluding 12 explorations in which it was not possible to reach a histological diagnosis due to technical problems and another 12 which were performed in already known celiacs, the total sample analysed was 1009 explorations. The variables included for study are as follows: year when duodenal biopsy was undertaken, age and gender of patient, indication for upper GI endoscopy and the final histological diagnosis.

We studied the evolution over time of the performance of duodenal biopsy during the upper GI endoscopies; in some cases the endoscopic exploration was made exclusively in order to perform duodenal biopsies, since a high index of suspicion of CD previously existed (for example, positive serology or malabsorption syndrome). However, in the majority of the cases, it was the endoscopist who decided, at the time of exploration, whether or not to take duodenal biopsies, when faced with the finding of anomalies in the intestinal mucosa or the presence of certain symptoms or analytical changes (diarrhoea, anemia, iron deficiency, *etc*).

We analysed those cases diagnosed as celiacs; the enteropathy was described according to the Marsh' classification (modified by Oberhuer)^[18] and a response to a gluten-free diet, was used as the diagnostic criteria for CD. We studied the frequency of CD, according to the main indication for performing the duodenal biopsy. The subgroup of patients with anemia ($n = 514$) included those in which the indication for endoscopic study was the presence of ferropenic anemia, microcytic anemia or iron and/or folic acid deficiency; patients with anemia due to vitamin B12 deficiency or those in whom the anemia was associated with signs or symptoms of upper GI bleeding, were excluded from the analysis. The subgroup of patients

Figure 1 Fifteen-year evolution of the performance of duodenal biopsy during routine upper gastrointestinal endoscopy in an adult Spanish population.

with diarrhoea ($n = 141$) included those with a picture of chronic diarrhoea (> 4 wk) in whom a possible origin was suspected in the small intestine.

The clinical, serological and genetic characteristics of patients diagnosed with CD over the study period are presented in this paper.

Statistical analysis

Data are expressed as percentages or absolute number for categorical variables and medians and ranges for continuous variables. The Chi-square test was used to test for differences between groups of patients with regard to their clinical and demographic features. Multivariate logistic regression analysis was performed to describe the independent association of variables, and the output was converted into adjusted likelihood ratios. A stepwise (forward) selection procedure was employed in order to prevent exclusion of important variables from the model, as a result of mutual correlations. The covariables introduced in the model were age, gender, anemia, diarrhoea, and year of performance of duodenal biopsy (stratified into three periods). The relationship between CD and the above variables was quantified as odds ratios (OR) and 95% confidence intervals are provided. All statistical analyses were performed using MedCalc[®], Ver. 7.4.4.1 (MedCalc Software). A two-tailed $P < 0.05$ was considered to be statistically significant.

RESULTS

Temporal evolution of duodenal biopsy during the study period

From 1990 to 2004, duodenal biopsy was performed in 1033 out of a total of 13 678 upper GI endoscopies (7.4%). Figure 1 represents the 15-year evolution of the performance of duodenal biopsy in the final sample evaluated (1009); when a division was made into three consecutive periods of five years: 1990-1994, 1995-1999 and 2000-2004, we found a significant increase in the percentage of endoscopic explorations in which duodenal biopsy was performed: 58 out of 3121 (1.9%) in the first period, 258 out of 5128 (5%) in the second period, and 693 out of 5405 (12.8%) in the third (1.9% *vs* 5%, $P < 0.0001$; 5% *vs* 12.8%, $P < 0.001$).

Table 1 Prevalence of celiac disease in 1009 duodenal biopsies performed during upper gastrointestinal endoscopy

	Number	CD <i>n</i> (%)	95% CI
Study population	1009	22 (2.2)	1.4-3.3
Period:			
1990-1994	58	2 (3.4)	0.6-13.0
1995-1999	258	8 (3.1)	1.5-6.3
2000-2004	693	12 (1.7)	0.9-3.1
Gender:			
Female	600	18 (3)	1.8-4.8
Male	409	4 (1)	0.3-2.7
Age (yr):			
14-34	136	3 (2.2)	0.6-6.8
35-54	309	11 (3.6) ^b	1.9-6.5
55-74	365	7 (1.9)	0.8-4.1
≥ 75	199	1 (0.5)	0.03-3.2
Patient subgroups:			
Anemia	514	14 (2.7)	1.6-4.6
Diarrhoea	141	12 (8.5) ^d	4.7-14.7
Anemia plus diarrhoea	42	8 (19) ^f	9.1-34.6

^b*P* < 0.01 (35-54 yr *vs* ≥ 75 yr); ^d*P* < 0.01 (diarrhea *vs* anemia); ^f*P* < 0.0001 (anemia plus diarrhoea *vs* anemia).

Up to 1997 a duodenal biopsy was not indicated by positive serology for CD and up to 1999, this was not made in first-degree relatives of celiac patients. Duodenal biopsy was performed in 7.7% of the patients with anemia as the main indication for upper GI endoscopy during the first period, in 21% during the second, and in 73% during the third period.

Prevalence of celiac disease

The total group included 600 females and 409 males with a median age of 60 years (range 14-93 years), without significant differences in gender. Twenty two patients were diagnosed with CD, which accounted for 2.2% of the duodenal biopsies performed; in 6 subjects (27%) the duodenal biopsy was indicated after knowing the presence of positive serology for CD, while in the 16 remaining patients (73%), this was performed according to the clinical suspicion of CD (based on the presence of chronic diarrhoea, non-specific digestive symptoms, *etc*) or by the finding of persistent analytical changes (anemia and/or iron deficiency). The prevalence of CD in the overall group and also in the subgroups of anemia and/or chronic diarrhoea is shown in Table 1.

In the logistic regression analysis, only the presence of anemia (OR 2.82; 95% CI 1.11-7.14) and diarrhoea (OR 10.38; 95% CI 4.22-25.50) were risk factors for CD. The clinical and immune-histological characteristics of the celiac patients diagnosed in the study are shown in Table 2. No differences were observed in the frequency of classical presentation between patients diagnosed before or after 1999 (50% versus 58%, respectively). A gluten-free diet was strictly followed-up in 20 of the 22 adult celiac patients diagnosed.

Table 2 Clinical and immune-histological characteristics of celiac patients

Gender	
Female	18 (81.8%)
Male	4 (18.2%)
Age (yr)	50 (19-77)
Clinical characteristics	
Malabsorption syndrome	12 (54.5%)
Anemia	14 (63.6%)
Dermatitis herpetiformis	5 (22.7%)
Abnormal liver function test	7 (31.8%)
Celiac relatives	2 (9.1%)
Histology (Marsh type):	
I	3 (13.6%)
II	1 (4.5%)
III	18 (81.8%)
Serology ¹	
AGA	13 (86.7%)
EMA	17 (89.5%)
TTG	8 (88.9%)
HLA-DQ2 ²	18 (100%)
Autoimmune associated diseases ³	2 (9.1%)
Mortality ⁴	2 (9.1%)

n (%) are shown for categorical variables, while the median (range) is shown for age. ¹Serological analysis was performed using antigliadin (AGA) in 15, anti-endomysium (EMA) in 19 and tissue-trans-glutaminase antibodies (TTG) in 9 patients; ²Genetic study was performed in 18 patients; ³Addison disease (1) and juvenile arthritis (1); ⁴Stroke (1) and non-Hodgkin lymphoma (1).

DISCUSSION

This study shows the changes observed over a period of 15 years (1990-2004) in the performance of duodenal biopsy in an endoscopy unit for adults in Spain. At present, the practice of duodenal biopsy during upper GI endoscopies is common. During the period 1990-1994 duodenal biopsy was made in 1.9% of the endoscopic explorations, while during the period 2000-2004 this was 12.8%.

Advancement in the knowledge of CD has led to an increase in the indications for performing duodenal biopsy. It is currently known that mild digestive symptoms (dyspepsia, abdominal discomfort, *etc*), or analytical alterations (anemia, iron deficiency or hypertransaminasaemia), could be some forms of presentation of CD^[1]. We observed that during the first 5-year period, duodenal biopsy was usually made in persons with a classical or malabsorption syndrome, while in the later periods this was mainly performed in subjects with anemia (data not shown). Certain risk groups have been well characterised^[19,20], which has meant that during the upper GI endoscopies practised for whatever reason in persons belonging to these risk groups, duodenal biopsy is made even in the absence of symptoms of enteropathy or without previous serological studies.

CD was diagnosed more frequently in females than in males (3% *vs* 1%), although gender was not a significant

risk factor for CD, as has been observed in other similar studies^[14]. Only anemia and diarrhoea were found to be risk factors for CD. The prevalence of CD found in patients with anemia (2.7%) is included in the wide range communicated in previous studies (1.8% to 13.7%)^[6-11]; the differences are due mainly to the diverse selection criteria of patients with anemia, since if ferropenic refractory patients are included^[6,7] or subjects in which other causes of anemia have been ruled out^[7], the frequency of CD has been higher; on the other hand, the diagnostic strategy used also influences the results, as some studies have performed serological screening prior to duodenal biopsy^[6,8], while in others a duodenal biopsy has been performed in all cases^[7,11] or only in those in which another cause to justify the anemia was not found during the endoscopic exploration^[10].

We wish to emphasize that our study is based on clinical practice over a long period of time, for which reason various factors could have influenced the results. Thus, the percentage of patients with anemia in whom duodenal biopsy was performed has increased over the periods of time analysed as a consequence of a greater knowledge of the manifestations of the disease; although in the management guides of ferropenic anemia duodenal biopsy is recommended during the endoscopic procedure indicated in order to rule out causes of such in the upper GI tract^[4], this was only undertaken at the end of the period analysed in a percentage of 73% of the cases; the degree of fulfilment of this recommendation in countries such as the USA or the UK is low (10% and 46%, respectively)^[21,22], in spite of the fact that it has been shown that duodenal biopsy for CD in a patient with anemia is a cost-effective approach^[23]. We also observed that there were differences in the degree of implication of the endoscopist in the diagnosis of the disease (data not shown); in this sense, differences in the performance of duodenal biopsy among digestive endoscopic services, in the same country, have been reported^[21].

The generalization of serological testing in the later periods of the study, above all in the primary care level, allowed the selection for duodenal biopsy of celiac patients with anemia as the only manifestation of the disease; on the other hand, 13 out of 14 celiacs with anemia presented specific antibodies for CD (the only negative case had a mild intestinal lesion - Marsh type 1). These data support the strategies of serological screening in subjects with anemia at primary care level^[24,25], in blood donors^[26] or in biochemistry laboratories^[27] as an effective method of increasing the number of patients diagnosed with silent CD.

We found that adults diagnosed with CD had a mainly classical clinical presentation (55% with diarrhoea) and ferropenic anemia (64%), for which reason we believe that there must still be a large part of the celiac iceberg (silent or atypical forms) remaining undiagnosed. The prevalence of CD in the adult general population in our area, has been estimated to be 1/389^[15], which means that only one in nine celiacs could be diagnosed, this being similar to that reported for other geographical areas^[1].

We conclude that duodenal biopsy performed during routine upper GI endoscopy, has been incorporated into

the daily clinical practice in digestive endoscopic services. This has permitted a significant increase in the number of patients diagnosed with CD, although these are probably only a small percentage of the true number of celiacs in the general population. In our area, the existence of anemia and diarrhoea are the most common risk factors associated with the presence of CD. Clinicians should consider CD as a possible cause of unexplained anemia, and gastroenterologists should biopsy the duodenum when exploring patients with iron-deficiency anemia and/or chronic diarrhoea, even if biopsies are not specifically required.

Abstract

AIM: To study the role of an insertion/deletion polymorphism in the *pepsinogen C* (*PGC*) gene, an effective marker for terminal differentiation of the stomach mucosa, in the susceptibility to the development of gastric lesions.

METHODS: The study was performed with 99 samples of known gastric lesions and 127 samples without evidence of neoplastic disease. PCR was employed and the 6 polymorphic alleles were amplified: Allele 1 (510 bp), Allele 2 (480 bp), Allele 3/4 (450/460 bp), Allele 5 (400 bp) and Allele 6 (310 bp).

RESULTS: Our results revealed that Allele 6 carriers seemed to have protection against the development of any gastric lesion (OR = 0.34; $P < 0.001$), non-dysplastic lesions associated with gastric adenocarcinoma such as atrophy or intestinal metaplasia (OR = 0.28; $P < 0.001$) or invasive GC (OR = 0.39; $P = 0.004$).

CONCLUSION: Our study reveals that the Allele 6 carrier status has a protective role in the development of gastric lesions, probably due to its association with higher expression of PGC. Moreover, the frequency of Allele 6 carriers in the control group is far higher than that obtained in Asian populations, which might represent a genetic gap between Caucasian and Asian populations.

INTRODUCTION

Gastric adenocarcinoma (GC) is a major public health problem worldwide and the third cause of cancer-related mortality in Europe^[1-3]. In Portugal, gastric cancer represents a sixth of all cancer related deaths, with twice the average mortality of European Union and the highest among Western European countries 25/100 000 and 12/100 000 persons \times year in men and women, respectively^[4,5]. Portuguese inhabitants show a life-time risk for gastric cancer of approximately 2% (95% CI 1.9-2.1), with half the decline observed at other European countries during the last decade^[6].

Lauren's classification is most commonly used for gastric adenocarcinoma because of its epidemiologic importance^[2,7]. It defines two main morphological types: 'diffuse type' and 'intestinal type'. The latter is characterized by a stepwise transformation from normal mucosa through atrophic gastritis, atrophy, intestinal metaplasia and dysplasia to invasive gastric adenocarcinoma^[2,8]. This type shows a male:female ratio of 2:1 and it has been related mostly to environmental factors such as *H pylori* infection and diet^[2,6].

However, recently several host genetic variations have been regarded as potential risk markers^[9-18]. Pepsinogen is an effective marker of terminal differentiation of the stomach mucosa^[19,20]. Pepsinogen C (PGC) is mainly secreted by chief cells of gastric gland, while also by cardiac, pyloric and Brunner glands. Its serum levels have been related with atrophic changes in gastric mucosa and extension of intestinal metaplasia^[21,22]. The *pepsinogen C* (*PGC*) gene, localized on chromosome 6 between regions 6p11-6p21.3, encodes the PGC, also known as progastricsin, which is the precursor of pepsin C or gastricsin++^[20]. Taggart *et al* have described an insertion/deletion polymorphism of about 100 bp located between exons 7 and

8^[23-25], which was regarded as a susceptibility marker for the development of gastric adenocarcinoma^[26]. However, the role of this polymorphism has not been completely established and it has never been measured in Caucasian populations.

The aim of this control study was to evaluate the role of the *PGC* polymorphism in the development of GC within a southern European population from the north region of Portugal.

MATERIALS AND METHODS

Patients

A cross-sectional study was performed among healthy individuals without clinical evidence of cancer ($n = 127$ as control group) and consecutive patients with known gastric lesions ($n = 99$), both from the northern region of Portugal attending at the Portuguese Institute of Oncology of Porto (Portugal).

Patients were further divided according to the type of lesions presented upon histopathological diagnosis after endoscopic multiple biopsies. It included patients who displayed lesions as severe as high-grade dysplasia and intestinal type invasive gastric adenocarcinoma ($n = 52$) and patients with non-dysplastic but associated lesions with gastric adenocarcinoma such as atrophy or intestinal metaplasia ($n = 47$), who belonged to a standardized follow-up since 2001.

All individuals included in this study gave their informed consent before their inclusion in the study, according to the Declaration of Helsinki.

Sample collection and DNA extraction

Blood samples were obtained with a standard venipuncture technique using EDTA containing tubes, and the genomic DNA was extracted from the white blood cell fraction of each sample, using a standard salting out protocol^[27].

PGC polymorphism analysis

The analysis of *PGC* polymorphism (insertion/deletion of approximately 100 bp) located between exons 7 and 8 was carried out by polymerase chain reaction (PCR), as described by Yamagata *et al.*^[15]. The PCR reaction was performed with the antisense (*PGCa*: 5'-AGCCCTAA GCCTCTTTTGG-3') and sense primers (*PGCb*: 5'-GGCCAGATCTGCGTGTTTTA-3') in a 50 μ L PCR reaction mixture containing: 1 \times Taq buffer, 1.5 mmol/L of $MgCl_2$, 0.2 mmol/L of dNTPs, 0.25 μ mol/L of each primer and 1 U Taq DNA polymerase (Amersham Bioscience, USA). Cycling parameters are: 95°C for 5 min for Taq DNA polymerase activation, followed by 35 cycles of denaturation for 60 s at 94°C, annealing for 60 s at 55°C, extension for 60 s at 72°C and a final extension step at 72°C for 7 min.

PCR amplification identified the following products: 510 bp (Allele 1), 480 bp (Allele 2), 460 bp (Allele 3), 450 bp (Allele 4), 400 bp (Allele 5) and 310 bp (Allele 6); which were analyzed by electrophoresis in a 3% MetaP[®] Agarose gel (Cambrex Bio Science Rockland Inc, USA) stained with 5% ethidium bromide (Figure 1).

Figure 1 Analysis of *PGC* polymorphism by PCR. M1: 50 bp DNA ladder; M2: pUC DNA ladder; Allele 1 (510 bp); Allele 2 (480 bp); Allele 3/4 (450/460 bp); Allele 5 (400 bp) and Allele 6 (310 bp).

Table 1 Allelic distribution of *PGC* polymorphism according to the type of gastric lesion or its absence n (%)

	Allele 1 carrier	Allele 2 carrier	Allele 3/4 carrier	Allele 5 carrier	Allele 6 carrier
Controls ($n = 127$)	2 (1.6)	31 (24.4)	39 (30.7)	37 (19.1)	92 (72.4)
All cases ($n = 99$)	1 (1.0)	30 (30.3)	33 (33.3)	39 (39.4)	47 (47.5)
AIM ($n = 42$)	-	16 (38.1)	14 (33.3)	16 (38.1)	18 (42.9)
GC ($n = 57$)	1 (1.8)	14 (24.6)	19 (33.3)	23 (40.4)	29 (50.9)

AIM: Atrophy or intestinal metaplasia; GC: Gastric adenocarcinoma.

Variables

The study variables included gastric type of lesion: gastric adenocarcinoma or atrophy or intestinal metaplasia or its absence and *PGC* alleles (1-6).

Statistical analysis

Data analysis was performed using the computer software Statistical Package for Social Sciences - SPSS for Windows (version 11.5). Chi-square analysis was used to compare categorical variables, using a 5% level of significance. Logistic regression was used to estimate odds ratio (OR) and its 95% CI as a measure of the association between *PGC* Allele 6 carrier and risk for the development of gastric lesions.

RESULTS

Allelic distribution of *PGC* polymorphism

The allelic distribution of the *PGC* polymorphism is shown in Table 1. No significant differences between controls and patients with known gastric lesions were observed as far as Alleles 1 to 6 were concerned.

Risk estimates for associated lesions and invasive gastric adenocarcinoma

Table 2 describes the risk estimation for the development of different gastric lesions considering Allele 6 carrier status. Significant differences were found in controls and patients with known gastric lesions concerning Allele 6

Table 2 Association of *PGC* Allele 6 carriers and risk for development of associated lesions and invasive gastric adenocarcinoma

	Allele 6 carrier <i>n</i> (%)	<i>P</i>	OR	95% CI
Controls (<i>n</i> = 127)	92 (72.4)		1.00	Reference
All cases (<i>n</i> = 99)	47 (47.5)	< 0.001	0.34	0.20-0.60
AIM (<i>n</i> = 42)	18 (42.9)	< 0.001	0.28	0.14-0.59
GC (<i>n</i> = 57)	29 (50.9)	0.004	0.39	0.21-0.75

AIM: Atrophy or intestinal metaplasia; GC: Gastric adenocarcinoma; *P*: Pearson Chi-Square; OR: Odds ratio; CI: Confidence interval.

carrier status ($P \leq 0.001$). Moreover, significant differences were also found for Allele 6 carriers when comparing the different types of gastric lesions with healthy individuals ($P \leq 0.001$ and $P = 0.004$).

In addition, the results showed that Allele 6 carrier status had protection against the development of gastric lesions (OR = 0.34; 95% CI 0.20-0.60). This was also true when stratifying the analysis based upon the type of gastric lesions, such as atrophy or intestinal metaplasia (OR = 0.28; 95% CI 0.14-0.59) or invasive GC (OR = 0.39; 95% CI 0.21-0.75).

DISCUSSION

Gastric adenocarcinoma (GC) has distinct geographical distribution with the highest incidence rates in Asian countries, and it remains as the third cause of cancer-related mortality in Europe^[1-3]. Portugal has the highest incidence and mortality rates of Western Europe^[6]. On the other hand, it is well accepted that cancer is a multifactorial disease and that genetic polymorphism may influence the genetic susceptibility to the development of several cancers^[9-18].

Pepsinogen, an effective marker of terminal differentiation of the stomach mucosa, has been used as a serological test for more than 20 years^[21]. An insertion/deletion polymorphism in the *PGC* gene has been described as a susceptibility marker for the development of gastric adenocarcinoma. However, only a few studies have been published on pepsinogen C^[24-26,28,29]. Up to our knowledge, this is the first study within a southern European population, from the north region of Portugal.

Our results suggest that Allele 6 carriers have protection against the development of gastric lesions such as atrophy, intestinal metaplasia or invasive carcinoma. These results are not in concordance with the results in Asian populations (Table 3). By comparison with the results from Asian populations we observed that carriers of this allele were more frequent in our control group, which might represent a genetic gap between Caucasian and Asian populations. However, when we compared the Allele 6 distribution in the Chinese control population, no homogeneous frequencies were reported. Furthermore, the Allele 6 distribution we found within the Portuguese population is not significantly different from one of the Chinese reports^[26].

Table 3 Frequencies of *PGC* Allele 6 carriers within populations

	Population	<i>n</i>	Allele 6 Carriers <i>n</i> (%)
Our Study	Caucasian (Porto, Portugal)	127	92 (72.4)
Ohtaki et al, 1997	Asian (Fukui, Japan)	177	82 (46.3)
Liu et al, 2003	Asian (Shenyang, China)	42	24 (57.1)
	Asian (Zhuanghe, China)	113	69 (61.0)

Even though our study included a small sample of cases, both allelic distribution and risk estimate seemed to exclude a type I error. A cohort study would seem ideal to estimate accurately risks, however, only a few if any cohort studies in this field are published. The recruitment of controls and the follow-up of patients with atrophy and intestinal metaplasia and with the absence of Allele 6 will probably give us more information in the near future.

The role of the *PGC* polymorphism in the carcinogenesis of GC is not clear. It was reported that *PGC* was not only a digestive enzyme, but also a growth factor under strict conditions, whereby the levels of serum expression of *PGC* might play important roles. This *PGC* polymorphism is located between exons 7 and 8, and by the analysis of the genomic sequence (Genome USCS NM_002630; Ref. NM_002630.1) with the Discovery Studio Gene v1.5 (Accelrys Inc), it is possible to identify, within the polymorphic region, an extensive number of TATA-box sequences. TATA-box sequences are extremely important in the activation of gene expression.

We hypothesize that this insertion/deletion polymorphism interferes directly with the number of TATA-box accessible for the activation of *PGC* expression. Usually as many TATA-boxes are available, as many expressions we could achieve. Although, in the presence of a great number of TATA-boxes, altogether in sequence, they might function as a confounder for the transcriptional activation factors. Thus, if a deletion occurs in a site like this, it would stabilize the activation of gene expression, increasing its levels. Evidences of higher levels of *PGC* associated with pre-neoplastic lesions could be correlated with this gene expression stabilization^[22,30].

Although further studies are required to establish the role of this polymorphism in the development of GC, our study reveals that *PGC* Allele 6 (shorter allele) is associated with protection against development of gastric lesions in a Caucasian population.

Abstract

AIM: To investigate the association between common single nucleotide polymorphisms (SNPs) in inflammatory response-related genes such as interleukin (IL)-6, IL-8, tumor necrosis factor α (TNF α), peroxisome proliferators-activated receptor γ (PPAR γ), intercellular adhesion molecule-1 (ICAM-1) and the risk of colorectal cancer (CRC) in a group of Greek patients.

METHODS: The study group consisted of 222 CRC patients and 200 healthy controls. Genotyping was performed using allele-specific PCR of PRC-RFLP and the results were confirmed by sequencing. We studied the association of SNPs in the IL-6 (-174G > C), IL-8 (-251T > A), TNF α (-308G > A), ICAM-1 (R241G and K469E), and PPAR γ (Pro12Ala) genes and the risk of CRC.

RESULTS: The IL-6 -174G, R241 and K469 alleles of ICAM-1 were associated with increased risk of CRC (OR = 1.77, 95% CI: 1.34-2.34; OR = 1.83, 95% CI: 1.23-2.72; and OR = 1.35, 95% CI: 1.03-1.77 respectively). The IL-8 and TNF α polymorphisms had no effect. Whereas the PPAR γ Pro12 genotype was associated with increased risk of disease (OR = 1.78, 95% CI: 1.25-2.49).

CONCLUSION: The association between common SNPs in immunologic response-related genes and CRC is reported in the present study. Apart from shedding light on the mechanisms of malignancy initiation and

INTRODUCTION

Colorectal cancer (CRC), whether sporadic or hereditary, is caused by a defined set of molecular events^[1]. A wealth of knowledge has been acquired about the precise molecular events driving CRC formation. Germline mutations in tumor-suppressor adenomatous polyposis coli (APC) genes and DNA mismatch repair (MMR) genes lead to the recognized familial adenomatous polyposis (FAP)-related CRC and the hereditary non-polyposis colorectal cancer (HNPCC), respectively^[1]. These inherited cases account for about 5%-10% of CRC^[1]. Hereditary factors may then contribute to an estimated further 20% of CRC, especially in patients with a strong family history of CRC^[2]. So, up to a quarter of all CRC may occur due to some form of inherited susceptibility to CRC, either in the context of the recognized clinical syndrome or due to germline variants which may carry an increased risk of CRC^[2]. Even without a family history of CRC, 1 in 21 of the population develops the disease, usually later in life^[2]. Sporadic cases of CRC result from somatic hits to the aforementioned genes^[1]. Germline mutation detection is not capable of predicting and screening for sporadic CRC. In other words, excluding inherited types of CRC, the susceptibility of a certain individual to development of sporadic CRC remains largely undetermined.

Since most CRCs arise sporadically, environmental and host immunological factors could significantly

contribute to the initiation and even the progression of this malignancy^[3]. Indeed, colonic cells respond to various malignancies-contributing environmental factors based on the genotype of DNA loci associated with metabolic pathways that relate to various dietary constituents^[3]. Genetic polymorphisms are thought to play a role in determining how individuals respond at the cellular level to various environmental factors^[3].

Immune response undoubtedly has a significant impact on the potential for malignancy, which is highlighted by the clear association between chronic inflammatory conditions and subsequent malignant transformation in the inflamed tissue^[4]. Inflammation favors tumorigenesis by stimulating angiogenesis, damaging DNA and chronically stimulating cell proliferation^[4,5]. The mixture of cytokines that is produced in the tumor microenvironment plays an important role in cancer pathogenesis^[6]. Cancer cells can also respond to host-derived cytokines that promote growth, attenuate apoptosis and facilitate invasion and metastasis^[6]. Importantly, cytokine genetic polymorphisms have recently emerged as determinants of gastrointestinal malignant disease susceptibility and severity^[4]. Although rather limited, evidence already exists linking common polymorphisms in immunologic parameters to CRC tumorigenesis^[5-7].

Bacterial flora keeps the normal colon mucosa in a continuous state of low-grade inflammation, stimulating release of various pro-inflammatory cytokines by the immune cells^[8]. Cytokines activate the NF- κ B transcription factor signal pathway in epithelial and immune cells, leading to up-regulation of interleukin-6 (IL-6) and IL-8^[8]. IL-6 and IL-8 have pro-inflammatory activity in the intestine via the STAT3 intracellular signal pathway^[9]. IL-6 also acts as a potent stimulator of metastasis by up-regulating the expression of adhesion receptors on endothelial cells, such as the intercellular adhesion molecule-1 (ICAM-1)^[10]. The status of a common functional single G > C base exchange in the human IL-6 gene promoter (chromosome 7p21) increases IL-6 levels^[11,12]. It has been found that the A-allele of the -251 T > A SNP in the IL-8 gene is related to higher *in vitro* IL-8 levels after stimulation with lipopolysaccharide and respiratory syncytial bronchiolitis in children^[13].

Tumor necrosis factor α (TNF α) is a pro-inflammatory cytokine whose role has been established in the pathogenesis of rheumatoid arthritis and inflammatory bowel disease (IBD)^[14]. Its binding to two specific receptors sets up signal transduction mechanisms leading to cell apoptosis and gene regulation, via the MAPKinase and NF κ B pathways^[14]. The TNF α pro-cancerous effect has recently been established^[14]. A SNP within the TNF α locus (-308) has been identified in lymphoma patients^[15]. The presence of TNF α -308A allele involved in gene transcription is associated with higher levels of TNF α related to chemotherapy failure and worse overall prognosis^[15].

ICAM-1 is expressed on vascular endothelium and plays a key role in the transendothelial migration of neutrophils and T-cell activation^[16,17]. It functions as a ligand for β 2 integrin molecules present on leukocytes (LFA-1)^[17]. The human ICAM-1 gene is a single-copy gene and contains two polymorphic sites in codons 241 (G/R241; Gly/Arg; exon 4) and 469 (K/E469; Lys/Glu; exon 6)^[18].

Several immunologic disorders, including inflammatory bowel disease are associated with distinct polymorphisms of ICAM-1^[19].

Peroxisome proliferators-activated receptor γ (PPAR γ) is a ligand-activated nuclear transcription factor, which plays a central role in orchestrating gene expression in response to exogenous ligands like other PPARs, such as non-steroidal anti-inflammatory agents (NSAIDs)^[20-22]. Its implication in immunologic mechanisms and carcinogenesis has been strongly speculated. Natural ligands and drug agonists of PPAR γ reduce intestinal inflammation in IBD patients via inhibition of the NF- κ B and STAT3 pathways^[23], while inactivating PPAR γ mutations have been found in sporadic CRC^[24]. PPAR γ has a polymorphism in the coding region 34C > G that results in the aminoacid change of Pro12Ala^[25].

This study focused on the investigation of the aforementioned SNPs as host risk factors for sporadic CRC, using a Greek population cohort.

MATERIALS AND METHODS

Subjects

Two hundred and twenty-two consecutive Greek patients with CRC without previous diagnosis of IBD or any of the known hereditary cancer syndromes (128 males, mean age at diagnosis 66.21 \pm 10.67 years and 94 females, mean age at diagnosis 63.12 \pm 11.52 years) and 200 healthy sex and age matched controls (120 males, mean age 64.73 \pm 15.32 years and 80 females, mean age 60.58 \pm 12.35 years) were genotyped. The vast majority of the studied group consisted of truly sporadic cases (198 patients, 89.2%), while 24 patients (10.8%) reported CRC occurrence in at least one first degree relative. Overall, 35.1% of CRC patients had a family history of malignancy.

Genotypic analysis

DNA was extracted from peripheral blood using the QIAamp blood kit (Qiagen, Germany). To confirm the integrity of DNA, a 430-bp sequence in the human glyceraldehyde-3-phosphatate dehydrogenase (GAPDH) gene was amplified.

The IL-6 polymorphism at position 174 was analyzed by allele specific PCR as previously described^[26]. Briefly, we used primers framing a 347-bp region surrounding the G-174C allele to amplify the genomic DNA isolated from patients and controls by PCR (sense, 5'-TTGTCAAGACATGCCAAGTGC-3'; anti-sense, 5'-CAGAATGAGCCTCAGAGACATCTCC-3'). In addition, each PCR reaction contained two additional primers designed to detect the G-174G allele (anti-sense, 5'-GCAATGACGTCTTTAGCATCG-3') and another primer designed to detect the G-174C allele (sense, 5'-CCCCCTAGTTGTGTCTTGCCA-3'). We performed multiplex PCR with all the four primers in one tube. PCR products were isolated on 3% agarose gels and visualized with ethidium bromide staining. Individuals with the IL-6-174 C/C genotype were considered low producers and those with the IL-6 -174 G/C or G/G genotype were considered high producers^[27]. Single nucleotide polymorphism-251 T > A in the IL-8 gene was determined using allele specific PCR^[13]. The

allele specific primers were 5'-CCACAATT^TTGGTGAA TTATCAAT-3' (-251A) or 5'-CCACAATT^TTGGTGAA TTATCAAA-3' (-251T). The consensus primer was 5'-TGCCCCTTCACTCTGTAAAC-3', giving a PCR product of 336 bp. PCR products were isolated on 2% agarose gels and visualized with ethidium bromide staining.

The A-allele of a single nucleotide polymorphism in the promoter region of the TNF α gene (-308G > A) was determined by PCR-RFLP. The primer sequences used were: forward 5'-AGGCAATAGGT^TTTGAGGGCCA T-3' and reverse 5'-TCCTCCCTGCTCCGATTCCG-3', which could amplify a 107 bp sequence. PCR products with a G at position -308 were digested by *Nco* I to give two fragments of 87 bp and 20 bp. Those with an A-allele at position -308 were not digested by *Nco* I as previously described^[28].

Single base polymorphism at codon 241 (R241G) in exon 4 was determined using allele specific PCR as previously described^[29]. We used the primers (5'-GTGG TCTGTTCCCTGGACG-3' and 5'-GTGGTCTGTTCC CTGGACA-3') with the last nucleotide complementary to the allelic variant substitution base on the point mutation in question of the gene ICAM-1, and a common primer (5'-GCGGTCACACTGACTGAGGCCT-3'). The amplified PCR products of 137 bp were analyzed by 2% agarose gel electrophoresis followed by ethidium bromide staining and ultraviolet visualization. The second amino acid polymorphism at codon 469 (K469E) in exon 6 was detected as described by Matsuzawa *et al.*^[30]. The K469E polymorphism was amplified using primers 5'-CCARCGGGGAATCAGTG-3' and 5'-ACA GAGCACATTACGGTC-3'. The PCR products were identified by enzyme digestion with *Bst* UI which cuts the E469 allele but not the K469 allele.

Exon 2 of PPAR γ was amplified using PCR and the primers G2F (5'-CTGATGTCTTGACTCATGGG-3') and G2R (5'-GGAAGACAACTACAAGAGC-3') as previously described^[31]. The 295 bp PCR product was digested overnight with *Hga* I, which cleaves the Ala allele to generate DNA fragments 178 and 117 bp in size. The DNA fragments were separated on 3% agarose gel.

In all cases, the mutations were confirmed by sequencing analysis using a dye terminator cycle sequencing ready reaction kit (Applied Biosystems), and an ABI 377 automated sequencer. As negative control of the PCR amplifications, we used distilled water instead of genomic DNA and confirmed the fidelity of the reactions.

Statistical analysis

Frequency and susceptibilities of mutations among CRC patients and controls were compared with the chi-square (χ^2) distribution test. Odds ratios (OR) for association were estimated using logistical regression accounting for possible covariates: age, sex and for influence by the remaining genotype loci. Hardy-Weinberg equilibrium for the genotypes was tested using the χ^2 distribution test for the difference in the observed and expected frequencies. All tests were 2-tailed and $P < 0.05$ was considered statistically significant. Inference was aided by SPSS (version 11.0.1, SPSS Inc., Chicago, IL).

RESULTS

Tumor characteristics are depicted in Table 1. Among the CRC patients, the distribution of the IL-6 genotypes was as follows: GG in 111 patients (50%), CG in 76 patients (34.23%) and CC in 35 patients (15.76%). The distribution of genotypes differed significantly from that in the healthy individuals (Table 2). Additionally, the allele IL-6 -174G was associated with increased risk of CRC, since it was found to be overrepresented among CRC patients (67.1% *vs* 53.5%, $P < 0.0001$, $\chi^2 = 16.35$, OR = 1.77, 95% CI: 1.34-2.34).

Concerning the A allele and AA genotype frequencies of IL-8 at position -251, no significant differences were observed between CRC patients and healthy controls (Table 2). Similarly, no effect of the TNF α (-308G > A) polymorphism was found (Table 2).

Table 2 also summarizes the allelic frequencies and genotypes of the ICAM-1 gene in CRC patient group and controls. No significant differences were observed in the RR (for the R241G) or in the KK (for the K469E) genotype frequencies between CRC patients and controls. Nevertheless, the allelic frequency of both R241 and K469 was significantly higher in CRC patients than in controls ($P = 0.002$, $\chi^2 = 9.24$, OR = 1.83, 95% CI: 1.23-2.72; and $P = 0.031$, $\chi^2 = 4.62$, OR = 1.35, 95% CI: 1.03-1.77, respectively).

As also indicated in Table 2, the C allele (Pro12) of PPAR γ was significantly associated with an increased risk of CRC since it was found to be overrepresented among CRC patients compared to controls (84.7% *vs* 76.5% respectively; $P = 0.001$, $\chi^2 = 9.08$, OR = 1.78, 95% CI: 1.25-2.49). Consequently, the CC genotype appeared as the major risk genotype for CRC ($P < 0.001$, $\chi^2 = 16.43$, OR = 2.01, 95% CI: 1.32-3.09).

When co-carriage rates of the offending alleles (IL-6 -174G, ICAM-1 R241, ICAM-1 K469) were compared

between CRC patients and controls, no statistical differences were found. The distribution of genotypes was consistent with Hardy-Weinberg equilibrium only in IL-8 and ICAM-1 cases ($P > 0.05$). Deviation was observed in IL-6, TNF α , and PPAR γ cases ($P < 0.05$).

No allele frequency difference was observed when sex and age of either patients or controls were taken into account in the statistical analysis. In addition, stratification of cases by site, tumor stage and the rest of the examined histopathological parameters did not reveal any significant association with the studied polymorphisms.

DISCUSSION

The most compelling evidence for the role of inflammation in gastrointestinal (GI) malignancy comes from studies showing that pro-inflammatory cytokine gene SNPs increase the risk of cancer and its precursors. A number of pro-inflammatory genotypes related to known cytokines (IL-1B, TNF α , IL-10) increase the risk of *H. pylori*-induced gastric atrophy and gastric cancer^[32,33]. At present, relatively limited information exists on the relationship between colorectal malignancies and cytokine polymorphisms^[5,7,34]. Polymorphisms in the IL-6 gene promoter and the R241 and K469 ICAM-1 polymorphic sites were associated with a significantly increased risk of CRC, whereas the PPAR γ CC genotype and C allele were both related to reduced risk in the present study.

Our results contrast with the findings of Landi *et al*^[5] in terms of the influence of IL-6 SNPs on CRC predisposition, but parallel their results as far as the potential protective role of the PPAR γ Ala12 variant. The researchers con-

cluded that the IL-6-174 C genotype confers an increased risk of CRC^[5], but in our study, a similar outcome was related to the presence of the G allele in the respective gene. The biological role of the substitution 174G > C has not been fully elucidated by functional studies. Although the C-174 allele is associated with both lower and higher levels of IL-6 expression in various conditions^[35-37], one study^[7] has been conducted to evaluate the effect of -174G > C SNP on IL-6 serum levels in CRC patients, and found that the GG genotype and absence of the C allele are related to significantly increased levels of IL-6, particularly in the presence of hepatic metastasis. Accordingly, *in vitro*, macrophages from C-negative subjects produce higher IL-6 levels than those from C-positive subjects^[38]. Moreover, the fact that high levels of circulating IL-6 are observed in patients with different tumor types and the finding of different levels of IL-6 expression in relation to genetic variants suggest that this cytokine is mainly produced by host cells rather than by cancer cells^[7]. We could speculate that the IL-6 G allelic variant might influence the increased cytokine production by immune cells, which in turn induces its stimulatory effect in tumorigenesis. Interestingly as well, Landi *et al*^[5] reported that the C genotype is associated with an increased risk of CRC only in those subjects who do not habitually take NSAIDs^[5]. A possible cause for the conflicts and mismatches, like those observed here and the earlier study in allele and genotype distributions, may be the differences in ethnic backgrounds. The IL-8 A-251 allele's protective role against CRC, as having been demonstrated by Landi *et al*^[5] could not be replicated in our study. It is true that the function of this polymorphism and the role of IL-8 in intestinal inflammation have not yet been

adequately studied^[5].

Previous reports support that there is no significant association between the TNF α -308A allele and CRC development like in our study^[5,39]. The latter possibly precludes any hypothetical involvement of TNF α -308A in CRC tumorigenesis. In contrast to the aforementioned lack of relevance, the examined TNF α SNP has been found to participate in a genetic profile associated with a high risk for gastric cancer^[32,40]. The pro-inflammatory and acid inhibiting properties of TNF α seem to enhance *H. pylori* oncogenic or other effects on gastric mucosa^[32,40]. Although a similar extrapolation regarding certain large bowel-colonizing bacteria could be made, such a hypothesis would not be supported based at least on our results. Recent studies on SNPs at the TNF α -308 locus have not found any difference between prostate and breast cancer patients or controls^[41,42]. In contrast and at least for breast cancer, assays for germline SNPs in TNF β instead of TNF α may prove useful, since at least for breast cancer, the TNF β G/G genotype increases the risk of tumorigenesis, while the A allele inhibits that risk^[42].

The present study is the first study investigating ICAM-1 SNPs in CRC and reporting the increased allelic frequency of R241 and K469 polymorphisms in this cancer. Previous studies also reported that both R and K allelic variants are associated with IBD^[16,19,30], which adds to the mounting molecular evidence about the similarities between IBD-associated cancer and sporadic cancer^[8]. Based on ample data concerning the molecular mechanisms involved in colonic mucosal inflammation effects, it is reasonable to speculate that even sporadic cancer might be largely secondary to inflammation^[8]. The normal colon could be viewed as being in a perpetual state of inflammation, where cytokine profiles, glycosylation changes, other inflammatory molecule (i.e. prostaglandins) regulation and mucosa-associated bacteria play a central role^[8]. Adhesion molecule activity may also have a serious impact on immunologic response. R241 and K469 amino acid changes in the ICAM-1 gene may influence its functional role, as both are located on the Mac-1 binding domain and in the immunoglobulin-like domain 5, respectively. The relevance of these specific SNPs could be explained by the functional alteration of the gene product^[19]. Some of the inhibitors of HMG-CoA reductase (statins) have also been shown to bind to the ICAM-1 binding domain of LFA-1^[43]. The regulation of interaction mediated by adhesion molecules may provide a new target for controlling inflammatory and immune responses.

In keeping with Landi *et al.*^[5], the PPAR γ Ala12 variant is associated with reduced CRC risk. In our study, the PPAR γ CC genotype (Pro12) had the strongest relative risk for CRC among the examined genes. The protective effect of the Ala12 variant of PPAR γ gene has been recently confirmed by Gong *et al.*^[44] in sporadic colorectal adenomas. Similarly the polymorphic allele Ala12 is significantly over-represented in glioblastoma multiform patients, but such an association could not be verified in prostate cancer^[25,45]. The PPAR γ Ala12 is associated with increased tissue sensitivity to insulin, a decrease in insulin plasma level and reduced release of free fatty acids by adipocytes, which in turn are associated with reduced CRC risk^[46,47]. Other plau-

sible mechanisms accounting for this protective effect may lie in PPAR γ involvement in regulation and interactions with other colonic cell functions. Activation of PPAR γ by ligands inhibits the NF- κ B and STAT3 pathways attenuating IBD and related conditions, induces differentiation and apoptosis of CRC cells and decreases DNA synthesis in CRC cell lines^[23,48-50]. The recently investigated transcriptional regulation of the tumor suppressor PTEN gene via PPAR γ may provide a mechanism for phosphatidylinositol 3-kinase (PI-3kinase)-mediated signaling cascades^[51]. Disruption of PPAR γ expression seems to prevent the up-regulation of PTEN leading to resistance of tumor cells (i.e. pancreatic cancer cells) and macrophages to apoptosis^[52]. The latter may open a new dimension in fully understanding the complex mechanisms involved in the interaction of PPAR γ and various tumorigenesis elements.

PPAR γ activation can lead to altered expression of COX-2, while NSAIDs have been reported to be capable of activating PPAR γ ^[21]. NSAIDs can also alter synthesis of eicosanoids that may bind to and act as ligands for PPAR γ through their effects on COX activity^[21,22]. Acetylsalicylic acid causes an approximate halving of risk for sporadic CRC^[53]. In an era of ongoing attempts to identify suitable target population groups for chemoprevention with anti-inflammatory agents, such SNP analysis and mapping of suitable loci may prove invaluable.

It is noteworthy that other immunology-unrelated genes may also carry an increased risk of developing CRC. It was reported that the Harvey ras-1 variable number tandem repeat (HRAS1-VNTR) polymorphism, the methylenetetrahydrofolate reductase (MTHFR) valine/valine polymorphism and missense mutations in CDH1 (E-cadherin) gene all are associated with an increased risk of CRC tumorigenesis^[2]. Apart from shedding light on the mechanisms of sporadic malignancy initiation and progression, SNPs may provide appropriate screening recommendations in intermediate-risk patients, such as those with family history. Only a limited subset of our cohort consisted of such patients and no significant differences were derived in our analysis. Although rather difficult and possibly imprecise during the process of similar studies, taking relevant dietary and lifestyle habits into account is of paramount importance. Simultaneous genotyping and combined analysis of different SNPs in large numbers of patients and controls, stratified by ethnicity, gender and tumor location may make it possible to describe the exact relations between polymorphisms and CRC susceptibility with higher power and may open the way for population-wide genetic screening in the future.

Abstract

AIM: To investigate the relationships between polymorphisms of interleukin-1R receptor antagonist genes and susceptibility to chronic hepatitis B in Iran population.

METHODS: Genomic DNA was extracted from the peripheral blood of 80 patients with chronic hepatitis B (57 males, 23 females) aged 12-77 years (mean 36.1 ± 13.8 years) and 147 normal controls (96 males, 51 females) aged 6-75 years (mean 41 ± 18.7 years) who referred to a liver clinic of Tehran and then subjected to polymerase chain reaction (PCR) amplification. PCR products were resolved on a 3% agarose gel and stained with ethidium bromide.

RESULTS: Only three of the five kinds of polymorphism (2/2, 2/4, and 4/4) were found in this study. The frequencies of 2/2, 2/4, and 4/4 were 12.5%, 17.5%, 70% respectively in chronic hepatitis B patients and 6.8%, 24.5%, and 68.7% respectively in controls. IL-1 R allele 2 was detected in 30% of chronic hepatitis B patients and in 31.3% of controls, while IL-1 R allele 4 was detected in 87.5% of chronic hepatitis B patients and in 93.2% of controls. The frequency of IL-1R alleles 2 and 4 was detected in 21.25% and 78.75% of the patients and 19.04% and 80.96% of the controls, respectively.

CONCLUSION: Our results suggest that the carriage of IL-1R receptor antagonist alleles 2, 4, 6 may not play any role in the development of HBV infection. Large population-based studies are needed to investigate the role of IL-1 polymorphisms in the pathogenesis of developing chronic hepatitis B.

INTRODUCTION

Hepatitis B virus (HBV) infection is one of the most important chronic viral diseases in the world. An estimated 400 million people worldwide are carriers of HBV, and approximately 250 000 deaths occur each year as a consequence of fulminant hepatic failure, cirrhosis, and hepatocellular carcinoma^[1]. According to the last health and disease survey held in Iran in 1999^[2], the prevalence of HBV carriers is 1.7%. Therefore over one million people in Iran are HBV carriers. When HBV is acquired in adulthood, the majority of infections are cleared, with chronic infection occurring in 5%-10% of cases. However, the dynamic interaction of the host inflammatory response to HBV and the subsequent impact of this interaction on the clinical outcome of HBV infection, are not yet fully understood, nor are the underlying mechanisms for persistence of the virus.

Cytokines play an important role in defense against viral infection, indirectly through determination of the predominant pattern of the host response and directly through inhibition of viral replication^[3]. Interleukin (IL)-1 is one of the most pro-inflammatory agents and has a central role in inflammation and destruction^[4]. The most important members of the IL-1 family are the IL-1 α , IL-1 β , and IL-1 receptor antagonists (ra). IL-1ra is an IL-1 natural competitive inhibitor, acting by occupancy of cell surface receptor without triggering signal transduction^[5]. IL-1ra plays a role as an important regulator of inflammation and is currently evaluated in clinical trials. Genes encoding IL-1 are located on the 430 kb region of chromosome 2q13-21, consisting of three homologous genes: IL-1A, IL1B and IL-1ra (IL-1RN)^[6]. Biallelic polymorphisms at positions IL-1A -889, IL-1B -511, and

+ 3953 have been described, all representing a C/T single nucleotide polymorphism (SNP). IL-1RN contains an 86 bp variable number tandem repeat (VNTR) polymorphism in intron 2^[7]. These polymorphisms are located within the regulatory regions of the genes and have a potentially functional importance by modulating IL-1 protein production, and are related with the development of some diseases^[8].

This study was to discuss the relationship between polymorphisms of IL-1R gene and susceptibility to HBV in the Iranian population, and to reveal the correlation between the genotype and phenotype distributions, in order to provide a certain scientific basis for prevention and treatment of chronic hepatitis B.

MATERIALS AND METHODS

Subjects

A total of 80 patients with chronic hepatitis B (57 males, 23 females) aged 12-77 years (mean 36.1 ± 13.8 years) were recruited in a liver clinic of Tehran. The diagnosis of all the patients was confirmed according to the criteria for chronic hepatitis B, and the patients did not have other viral hepatitis. One hundred and forty-seven control subjects (96 males, 51 females) aged 6-75 years (mean 41 ± 18.7 years) were selected in a liver clinic of Tehran (HBsAg negative, anti-HBe negative, and anti-HBc negative). Liver, renal, endocrine and cardiovascular disorders were excluded. There was no statistical difference in sex between case and control groups, and we also saw a statistically significant difference in age between two groups ($P = 0.026$) but it was not clinically important. AST was over 40 U/L in 24.1% of cases and none of controls, and over 40 U/L in 31.6% of cases and none of controls, respectively.

PCR preparation

Two microliter peripheral venous blood was collected in an EDTA tube. Genomic DNA was extracted from peripheral blood leukocytes as previously described^[9]. Each PCR was carried out in 25 μ L reaction mixture containing 100-200 ng genomic DNA, 100 μ mol/L dNTP, 25 mmol/L $MgCl_2$, 20 pmol/L primers and 1U TaqDNA polymerase (DNA Technology)^[10].

The sequence of the forward primer is 5'-CTCAGCAACACTCCTAT-3'. The reverse primer sequence is 5'-TCCTGGTCTGCAGGTAA-3'. PCR conditions included an initial denaturing step at 94°C for 5 min, followed by 30 cycles at 94°C for 1 min, at 60°C for 1 min, at 70°C for 2 min, and a final extension at 70°C for 4 min. Using this PCR strategy, the common allele (allele 1) generated a 410-bp band (including four copies of an

86-bp repeat). The uncommon alleles generated a 240-bp band (two copies of the same repeat, allele 2), a 500-bp band (five copies of the same repeat, allele 3), and a 325-bp band (allele 4). The PCR products were resolved on a 3% agarose gel and stained with ethidium bromide.

HBV-DNA measurement

Serum HBV-DNA levels in patients with chronic hepatitis B were detected with the real-time fluorescent quantitative PCR method (reagents supplied by Sinagen Co. Ltd.). Results were considered abnormal when HBV-DNA > 200 copies/mL.

Statistical analysis

IL-1R (2-6) allele and genotype frequencies were calculated in patients with chronic hepatitis B and control subjects. Comparison of allele and genotype frequencies between groups, and association of IL-1R polymorphisms with HBV-DNA replication and other variables were examined for statistical significance with chi-square test. Analysis was completed with SPSS11.5. $P < 0.05$ was considered statistically significant.

RESULTS

IL-1R (2-6) allele frequencies were measured. IL-1R 3, 5, 6 were negative in all cases and controls. Therefore we deleted them in our results.

IL-1R genotypes

The intron 2 of IL-1RN polymorphism contained VNTR of 86 bp. There were five alleles in humans, including allele 1 (four repeats, 410 bp), allele 2 (two repeats, 240 bp), allele 3 (five repeats, 500 bp), and allele 4 (four repeats, 325 bp). Only three of the five kinds of polymorphism of IL-1R (2/2, 2/4, and 4/4) were found in this study.

Frequencies of IL-1R genotypes in both groups

The genotype and allele frequencies of IL-1RN in patients with chronic hepatitis B and control subjects were determined, and explored with 2×2 chi-square test (Table 1).

Only three of the five kinds of polymorphism of IL-1R (2/2, 2/4, and 4/4) were found in this study. The frequencies of 2/2, 2/4, and 4/4 were 12.5%, 17.5%, 70% respectively in chronic hepatitis B patients, and 6.8%, 24.5%, and 68.7% respectively in controls. IL-1R allele 2 was detected in 30% of chronic hepatitis B patients and 31.3% of controls, while IL-1R allele 4 was detected in 87.5% of chronic hepatitis B patients and 93.2% of controls. Allele frequency of IL-1R alleles 2 and

4 was detected in 21.25% and 78.75% of the patients and 19.04% and 80.96% of controls respectively.

There were no significant differences between patients and controls in these regards. However, the 2, 2 and 2, 4 and 4, 4 genotypes were not significantly different between patients and controls, which were 6.8% versus 12.5% ($P = 0.148$), 24.5% vs 17.5% ($P = 0.225$), and 68.7% vs 70% ($P = 0.840$) respectively. The genotype distribution in controls was also consistent with the Hardy-Weinberg equilibrium ($P = 0.215$).

DISCUSSION

HBV infection is a major global health problem with an estimated 300 million people chronically infected worldwide^[11,12]. Individuals with an inadequate primary immune response to HBV are at increased risk of developing chronic hepatitis B. Age is the strongest host feature associated with chronic infection with 90% infants and 5%-10% of adults developing chronic hepatitis B after exposure to HBV. In addition, people with the same age, sex and ethnical group are exposed to the same HBV strain, which could cause a broad spectrum ranging from no infection to different clinical outcomes^[13]. These data suggest that host genetic factors are responsible for the clinical outcomes of HBV infection. Clearance of HBV requires a coordinated innate and adaptive humor- and cell-mediated immune response. Cytokines are soluble polypeptide molecules that mediate cell-to-cell communication and regulate the intensity and duration of the immune response. Previous studies have shown that the maximal capacity of cytokine production varies among individuals and correlates with SNP in the promoter region of various cytokine genes^[14,15]. Furthermore, cytokine gene polymorphisms are associated with liver disease severity in patients with viral hepatitis^[16]. In the present study, we compared the distributions of interleukin-1R receptor antagonist gene polymorphisms between patients with chronic B and control subjects.

Interleukin-1R receptor antagonist gene is one of the IL-1 gene family members, and located in the proximal region of chromosome 2q13-21. Different polymorphisms have been described in interleukin-1R receptor antagonist genes, and at least two of them could influence the protein production. The IL-1ra gene is also polymorphic due to a variable number (2-6) of tandem repeats of 86 bp (VNTR) within its second intron^[17]. This polymorphism has been shown to be unambiguously functional at the level of secreted protein, as monocytes from individuals homo- or heterozygous for allele 2 (IL-1Ra A2 1, IL-1RN * 2, 2 repeats) produce significantly more IL-1ra in response to GM-CSF^[18].

Pociot *et al*^[19] reported that IL-1B polymorphisms are correlated with IL-1 β expression. IL-1B allele T carrier has higher productions of IL-1 β than IL-1B allele C carrier. In the present study, genotype distributions and allele frequencies for IL-1B (-511) promoter polymorphisms in patients with chronic hepatitis B and control subjects were not statistically different. Further analysis of the relationship between IL-1B polymorphism and HBV-DNA

replication in patients with chronic hepatitis B showed that IL-1B (-511) genotype CC was associated with HBV-DNA replication.

IL-1Ra is a naturally occurring anti-inflammatory protein, competitively blocks the binding of IL-1 α and IL-1 β type I and type II IL-1 receptors, but exerts no agonist activity, despite sharing 30% amino acid sequence homology with IL-1 β , and 19% with IL-1 α . IL-1ra has been shown to inhibit the effects of IL-1 both *in vitro* and *in vivo*^[20]. There is increasing evidence that IL-1RN polymorphisms are related with susceptibility to individual diseases, including psoriasis, systemic lupus erythematosus, and inflammatory bowel disease^[4]. By the study of interleukin-1R receptor antagonist gene intron 2 polymorphisms, our results suggested that the distributions of interleukin-1R receptor antagonist gene 2/2, 2/4, 4/4 genotype in patients with chronic hepatitis B were not significantly different from those in control subjects. A possible explanation of this result could be provided by the fact that carriage of IL-1R allele of each of these polymorphisms may be related with other production of IL-1 β ^[21], which may augment the production of other cytokines, such as IL-2, IL-6 and TNF- α , and trigger the complex immunological processes to eliminate the virus and its complex. It may be also due to the low sample size of our study (The power of study was 68%).

In summary, our results suggest that the carriage of IL-1R receptor antagonist alleles 2, 4, 6 may not play any role in the development of HBV infection. Large population-based studies are needed to investigate the role of IL-1 polymorphisms in the pathogenesis of developing chronic hepatitis B.

Abstract

AIM: To assess the possible role of occult HBV infection in the pathogenesis of chronic hepatitis in Iranian patients.

METHODS: After exclusion of autoimmune, metabolic and viral etiologies, 104 consecutive adult patients with histologic and biochemical features of chronic hepatitis and negative HBsAg were enrolled in the study. Qualitative PCR with a sensitivity of 150×10^3 copies/L, using two primers for Pre-S and core regions was applied to measure presence of HBV DNA in serum of the patients.

RESULTS: All 104 patients completed the study. Qualitative HBV DNA was positive in two patients (1.9%).

CONCLUSION: Occult HBV infection has negligible role in the pathogenesis of cryptogenic chronic hepatitis in Iranian patients.

INTRODUCTION

Several lines of evidence suggest that hepatitis B virus (HBV) may persist in the serum many years after clearance of hepatitis B surface antigen (HBsAg). These evidences include HBV transmission from liver donors even when HBsAg had been negative and the only positive serologic test was hepatitis B core antibody (HBcAb)^[1-3] and appearance of HBsAg and even overt hepatitis in previously HBsAg-negative patients after cancer chemotherapy or immunosuppression^[4,5]. It appears that low-level HBV infection may be the source of viral reactivation that is unmasked by immunosuppression. It is speculated that these occult infections may cause chronic hepatitis^[6,7], increase the rate of cirrhosis^[8,9] and eventually hepatocellular carcinoma^[10] and may transmit *via* blood transfusion.

The causes of undetectability of HBsAg in serum (in the presence of persistent HBV infection) may include mutations in the pre-S or S regions (mostly in "a" determinant region) of the virus genome^[11-14], decrease in viral load^[15] or insufficient sensitivity of the tests used to detect the HBsAg^[15]. In some regions with high endemicity (such as China), about 1/3 or more of cirrhotic patients with negative HBsAg may harbor HBV infection^[15].

The rate of HBV infection in Iran is unknown but it is the most frequent cause of chronic hepatitis, cirrhosis and hepatocellular carcinoma. It appears that Iran is in a region with intermediate or even low endemicity and the rate of positivity of HBsAg and HBcAb in the general population is 1.8%-5% and over 35% respectively^[16].

The goal of the present study was to determine whether a negative test for HBsAg in the serum is sufficient to rule out the possibility of chronic HBV hepatitis in Iranian patients with chronic liver disease and to assess the possible role of "a" determinant mutations in Iranian patients with chronic HBV hepatitis. We conducted a prospective study to determine the presence of HBV-DNA in serum of patients with chronic hepatitis and negative HBsAg.

MATERIALS AND METHODS

Patients

After completion of a questionnaire and physical examination, serum samples were collected from 104 adult (> 16 years old) patients (69 males and 35 females) with

chronic (6 mo or more) high alanine amino-transferase (ALT) and negative HBsAg who were referred for liver biopsy to endoscopy wards of Faghihi and Nemzee Hospitals, Shiraz University of Medical Sciences, Shiraz, Fars province, south of Iran, between February 1997 to December 2001.

Diagnosis of chronic hepatitis was based on a minimum of 6 mo or more persistent elevation of ALT (more than 60 or 1.5 times of upper limit of normal value) and grade of necro-inflammation of more than 3/18 of Ishak (modified Knodell) classification in liver histology. All active alcohol users (drinking of more than 20 g alcohol per day), patients with biliary obstruction, cardiac failure, active cancer or chronic infection (such as tuberculosis) and cirrhosis (shrunken liver in ultrasonography and regenerative nodules in histology and one of these features: history compatible with grade 2 of hepatic encephalopathy, endoscopically confirmed esophageal or fundal varices, ascites, hypersplenism), positive HBsAg, positive anti-smooth muscle antibody, positive anti-nuclear antibody, positive anti-mitochondrial antibody, low titers of alpha-one-anti-trypsin or ceruloplasmin, abnormal iron or copper levels, predominant steatohepatitis, biliary duct injury or congestion (Budd-Chiari syndrome) in liver histology were excluded from the study.

Demographic, biochemical and serological data, histological findings and results of PCR of our patients are shown in Table 1.

Serological assays and PCR

All serological tests including HBsAg, IgG-anti HBcAb, second generation of anti-hepatitis C virus antibody (HCVAb), hepatitis B e antigen (HBeAg) and IgG-antibody to hepatitis B e antigen (HBeAb) were performed using ELISA based on manufacturers' instructions.

PCR-assay

In order to prevent any contamination, we strictly adhered to the standard guideline of PCR procedure. Fifty microliters of serum were diluted 1:5 with 250 μ L NaOH (50 mmol/L) for DNA denaturation and RNA inactivation. Samples were then heated at 95°C for 20 min to denature proteins. Forty microliters of Tris 1 mmol/L (pH = 7.3) was then added and centrifuged at 14000 r/min for 7 min. Forty microliters of phenols-chloroform (1:1) were added and centrifuged at 14000 r/min for 7 min. Ten microliters of sodium acetate (3 mol/L) and 300 μ L absolute ethanol were added to each tube. After incubation at -70°C for 40-60 min, tubes were centrifuged at 14000 r/min for 10 min. Supernatant was removed and 50-100 μ L of TE buffer (pH = 7.8) was added to the pellets. PCR-amplification was performed using published oligonucleotide primers^[17] selected from highly conserved HBV surface gene, whereby primer 1 and primer 2 flank 597 base-pair fragment.

Five microliters of sample were added to 45 μ L of reaction mixture (2.5 U Tag polymerase, 22.5 μ mol/L of each primer, 200 μ mol/L of each deoxynucleotide triphosphate, 5 μ L of reaction buffer [50 mmol/L KCl, 10 mmol/L Tris-HCl pH = 8.3 and 1.5 mmol/L MgCl₂]). Samples were denatured for 5 min at 94°C and then subjected to 40 cycles of 1 min at 58°C, 1 min at 72°C and 1 min at 94°C

in an Eppendorf thermal cycler (Master cycler 5330).

Ten microliters of reaction product was electrophoresed in a 18 g/L agarose gel made in Tris-acetate-EDTA (TAE) buffer (pH = 8-8.5) and visualized by ultra-violet illumination after ethidium bromide (10 mg/L) staining. Positive and negative controls were also treated as samples.

PCR amplification was also performed using HBV-PCR detection kit (Cinna Gen Inc., Teheran, Iran). According to manufacturer's instruction, 5 μ L of extracted DNA was added to 20 μ L of a PCR mixture, which contained primers amplifying 353 bp of the region of the core gene. Samples were denatured for 2 min at 94°C and then subjected to 40 cycles of 93°C for 40 min, 62°C for 40 min, 72°C for 40 min and finally 72°C for 10 min. The sensitivity of PCR assay was 150×10^3 copies/mL.

RESULTS

Only two patients had HBV DNA in their sera. Demographic, biochemical data, serological data, and histological findings of these patients are shown in Table 2. Both patients had major thalassemia and were on regular blood transfusion for many years.

DISCUSSION

There is much controversy and suspicion about the possible role of hepatitis B infection in pathogenesis of cryptogenic chronic parenchymal liver diseases especially in areas with intermediate or high infection rates of hepatitis B. Although the exact mechanism for active viral infection with undetectable HBsAg in the serum is not clear, both mutations in S region of the viral genome as well as low-titer infections (including possible burned-out infections) are proposed as possible explanations. It is however obvious with either of these two mechanisms being true, there should be detectable viral genome in serum of a majority of such patients using sensitive amplification techniques.

In this study, only less than 2% of our patients had HBV-DNA in their sera and it appears that HBV infection had a minimal role in causing chronic hepatitis in HBsAg negative Iranian patients with chronic hepatitis. Because of lack of a control group of normal individuals to which

the incidence of positive HBV DNA in serum can be compared, the possible role of occult HBV infection in etiology of cryptogenic liver disease in this country cannot be totally excluded, nevertheless, it can be certainly stated that this role if, exist at all will be of minimal, negligible impact.

This data is the same as that found by western researchers but in contradiction with findings in high incidence areas of the world^[15]. The possible explanation for these different results may lie in the different incidences as well as different genotypes of hepatitis B prevalence in these areas.

It should be further emphasized that two patients with positive HBV DNA in this study were both known cases of major thalassemia with a history of multiple transfusions and also had concomitant HCV infection. It is therefore can be concluded that the incidence of occult HBV infection in those with no history of high risk conditions for blood borne infections will be much lower.

Based on the findings of this study, we conclude that there is no need for HBV DNA PCR in routine work up for the chronic liver disease patients with negative HBsAg in Iran.

Abstract

AIM: To investigate the differentiation of rat bone marrow stem cells in liver after partial hepatectomy.

METHODS: Bone marrow cells were collected from the tibia of rat with partial hepatectomy, the medial and left hepatic lobes were excised. The bone marrow stem cells (Thy⁺CD3⁺CD45RA⁻ cells) were enriched from the bone marrow cells by depleting red cells and fluorescence-activated cell sorting. The sorted bone marrow stem cells were labeled by PKH26-GL *in vitro* and autotransplanted by portal vein injection. After 2 wk, the transplanted bone marrow stem cells in liver were examined by the immunohistochemistry of albumin (hepatocyte-specific marker).

RESULTS: The bone marrow stem cells (Thy⁺CD3⁺CD45RA⁻ cells) accounted for 2.8% of bone marrow cells without red cells. The labeling rate of 10 μ M PKH26-GL on sorted bone marrow stem cells was about 95%. There were sporadic PKH26-GL-labeled cells among hepatocytes in liver tissue section, and some of the cells expressed albumin.

CONCLUSION: Rat bone marrow stem cells can differentiate into hepatocytes in regenerative environment and may participate in liver regeneration after partial hepatectomy.

Key words: Bone marrow stem cells; Liver regeneration; Differentiation

INTRODUCTION

Recent studies indicate that mice and human bone marrow cells can differentiate into hepatocytes in normal liver and rat bone marrow cells can turn into hepatocytes in severely damaged liver with the suppression of hepatocyte proliferation^[1-6]. However, whether rat bone marrow stem cells can differentiate into hepatocytes in liver after partial hepatectomy remains unclear. The aim of this study was to investigate the differentiation of rat bone marrow cells in regenerative environment after partial hepatectomy.

MATERIALS AND METHODS

Animals

Male Sprague-Dawley rats weight 170-190 g were obtained from the Animal Center of Peking University People's Hospital. They were allowed to have free access to standard laboratory chow and kept in a 12 h light/dark cycle.

Materials

Erythrolysin, phycoerythrin-conjugated mouse anti-rat CD45RA and phycoerythrin-conjugated mouse anti-rat CD3 were purchased from Becton Dickinson Inc. Fluorescein isothiocyanate-conjugated mouse anti-rat Thy-1.1 was obtained from Pharmingen Inc. PKH26-GL was purchased from Sigma Inc. Mouse anti-albumin antibody was obtained from Dako Inc. FITC-labeled anti-mouse IgG was supplied by Zhongshan Inc. RPMI 1640 was from Gibco Inc.

Partial hepatectomy rat model

The rats were anesthetized with intraperitoneal injection of sodium pentobarbital (35 mg/kg body weight). Local skin was sterilized by routine method. Partial hepatectomy rat model was established by resecting medial and left liver lobes.

Bone marrow stem cell enrichment

Under general anesthesia, bone marrow was aspirated

Figure 1 Bone marrow stem cells sorted by flow-cytometry. **A:** Control; **B:** Percentage of Thy⁺CD3⁺CD45RA⁻ cells in bone marrow cells without erythrocytes (about 2.8%).

from tibia with a syringe containing 1 mL heparin with an 18-gauge needle. The marrow cells were transferred to a sterile tube and mixed with 10 mL culture medium (RPM1640 supplemented with 10% fetal bovine serum, 100 μ /mL penicillin G and 100 μ g/mL streptomycin). Red blood cells in bone marrow were depleted by erythrolysin. After washed three times with phosphate-buffered saline (PBS), the cells were incubated at 4°C for 30 min with fluorescein isothiocyanate-conjugated anti-Thy, phycoerythrin-conjugated anti-CD3 and phycoerythrin-conjugated anti-CD45RA. The cells were washed three times and resuspended in medium. Labeled cells were analyzed and separated with FACS-vantage (Becton Dickinson, San Jose, CA). Gating was based on Thy-positive, CD3-negative and CD45RA-negative.

Bone marrow stem cell staining with PKH26-GL

The sorted Thy⁺CD3⁺CD45RA⁻ cells were labeled by 10 μ M PKH26-GL. Labeling conditions employed were essentially as described by the manufacturer. Briefly, cells were suspended in Diluent C at a density of 2×10^6 cells/mL and mixed with an equal volume of the PKH26-GL dye in Diluent C to give a final dye concentration of 10 μ mol/L. Labeling was carried out at room temperature for 3 min. The labeling reaction was terminated by the addition of an equal volume of fetal bovine serum. Labeled cells were diluted with culture medium containing serum and washed three times.

Bone marrow stem Cell transplantation

The PKH26-GL-labeled bone marrow stem cells were suspended in 300 μ L of RPM1640 without serum at a concentration of 1×10^6 cells and autotransplanted by portal vein injection.

Immunocytochemistry

The liver tissue was obtained at two weeks after partial hepatectomy. Frozen sections were made and incubated overnight at 4°C in 50 μ L anti-albumin antibody (1:50), then washed three times in PBS and incubated for 1 h at 37°C in 50 μ L FITC-labeled second antibody. After washed three times with PBS, the slides were occluded by glycerin buffer and observed under confocal laser scanning

Figure 2 PKH26-GL labeling of Thy⁺CD3⁺CD45RA⁻ cells. **A:** Control; **B:** Percentage of PKH26-GL-labeled cells in Thy⁺CD3⁺CD45RA⁻ cells. (M1: unlabeled cells; M2: labeled cells).

Figure 3 Red Thy⁺CD3⁺CD45RA⁻ cells with PKH26-GL under fluorescence microscope.

microscope.

RESULTS

Bone marrow stem cell enrichment

After erythrocytes were depleted in tibia bone marrow cells from rats after partial hepatectomy. Bone marrow stem cells were enriched by sorting the Thy⁺CD3⁺CD45RA⁻ cells. The sorted cells accounted for about 2.8 % (Figure 1).

Enriched bone marrow stem cell staining with PKH26-GL

The Thy⁺CD3⁺CD45RA⁻ cells were labeled with 10 μ M PKH26-GL. The percentage of labeled cells was about 95% (Figure 2). The labeled Thy⁺CD3⁺CD45RA⁻ cells were red under fluorescence microscope (Figure 3). PKH26-GL had no obvious effect on bone marrow cell viability. Trypan blue staining assay showed that the cell viability of PKH26-GL-labeled bone marrow cells was higher than 85%.

Immunohistochemistry staining for albumin

PKH26-GL could emit red fluorescence at the wavelength of 567 nm, while FITC could emit green fluorescence at the wavelength of 494 nm. We tested liver tissue sections under confocal laser scanning microscope at the two wavelengths respectively. There were sporadic cells with red fluorescence among hepatocytes in liver sections (Figure 4A), suggesting that PKH26-GL-labeled bone marrow

Figure 4 Red sporadic PKH26-GL-labeled cells (A), green hepatocytes (B), and yellow PKH26-GL-labeled cells expressing albumin (C).

stem cells could migrate into liver. Hepatocytes showing green fluorescence suggested that hepatocytes expressed albumin (Figure 4B). Yellow was mixed with red and green. Yellow cells derived from PKH26-GL labeled *in vitro* bone marrow stem cells expressed albumin (Figure 4C). The findings indicated that bone marrow stem cells could differentiate into hepatocytes in regenerative hepatic environment after partial hepatectomy.

DISCUSSION

Seventy percent hepatectomy rat model is a classical animal model to study liver regeneration. The remaining hepatic lobes of the model rat can restore the liver mass at 2 wk after partial hepatectomy. It has been considered that the regeneration process is due to the proliferation of residual mature hepatocytes. Recently, important developments have been achieved in the field of stem cell study. Petersen *et al.*^[3] used 3 separate approaches to follow transplanted bone marrow cells and found an extrahepatic source for the liver cells. In a careful histological analysis of irradiated female mice that received male donor cells, the Y chromosome could be detected in some hepatocytes 2 to 6 mo after transplantation in the absence of any intentional liver injury^[7]. In human female recipients of male bone marrow, some hepatocytes contain the Y chromosome^[8]. These findings suggest that there is a linkage between bone marrow cells and liver. It is hypothesized that, similar to other organ systems, the liver has 3 levels of cells: “mature” hepatocyte, original tissue-determined stem cells represented in the adult organ by cells in the terminal bile ductules (canals of Hering), and a multipotent stem cells in the liver derived from circulating bone marrow stem cells^[9]. However, whether circulating bone marrow stem cells can differentiate into hepatocytes in regenerative liver after partial hepatectomy remains unclear.

PKH26-GL shows little or no toxicity except for some

phototoxicity following prolonged exposure of PKH26-GL labeled cells to excitation light and can be used to track lymphocyte migration for weeks to months^[10,11]. It is the dye of choice for cell migration and proliferation studies. PKH26-GL has been used to *in situ* label mouse spleen cells and peripheral blood neutrophils, and is particularly effective in monitoring the *in vivo* homing and proliferation of haemopoietic stem cells^[12-14]. Our study showed that 10 $\mu\text{mol/L}$ PKH26-GL could effectively label rat bone marrow cells and has no obvious effect on cell viability. PKH26-GL-labeled bone marrow cells were autotransplanted in rats during partial hepatectomy. After 2 wk, there were PKH26-GL-labeled cells in liver, and the cells expressed hepatocyte-specific marker albumin. The result showed that bone marrow cells could differentiate into hepatocytes in regenerative hepatic environment. Bone marrow cells consist of white cells, erythrocyte, a few stem cells, *etc.* Only stem cells could differentiate into other type cells. As a result, the experiment indicated that circulating bone marrow stem cells could differentiate into hepatocytes in liver after partial hepatectomy and bone marrow stem cells might participate in hepatic regeneration. Fujii^[15] examined the differentiation of mice bone marrow cells in liver regeneration after partial hepatectomy and found that bone marrow cells participate in liver sinusoid. They believe the bone marrow cells participation in liver regeneration after hepatectomy, where the majorities were committed to sinusoidal endothelial cells probably through endothelial progenitor cell mobilization.

It has been accepted that the hepatocyte regeneration process after partial hepatectomy is associated with the proliferation of remaining hepatocytes. We hold that the mechanism of hepatocyte regeneration after partial hepatectomy includes at least two ways. That is, the remaining mature hepatocytes proliferate and circulating bone marrow stem cells migrate into residual liver and differentiate into hepatocytes. With the development and application of stem cell technique, it is possible to obtain stem cells from bone marrow or blood and to make the stem cells proliferate in a great deal. Stem cell autotransplantation may become a new method to promote liver regeneration.

Abstract

AIM: To assess the value of pre-transplant artificial liver support in reducing the pre-operative risk factors relating to early mortality after orthotopic liver transplantation (OLT).

METHODS: Fifty adult patients with various stages and various etiologies undergoing OLT procedures were treated with molecular adsorbent recycling system (MARS) as preoperative liver support therapy. The study included two parts, the first one is to evaluate the medical effectiveness of single MARS treatment with some clinical and laboratory parameters, which were supposed to be the therapeutical pre-transplant risk factors, the second part is to study the patients undergoing OLT using the regression analysis on preoperative risk factors relating to early mortality (30 d) after OLT.

RESULTS: In the 50 patients, the statistically significant improvement in the biochemical parameters was observed (pre-treatment and post-treatment). Eight patients avoided the scheduled Ltx due to significant relief of clinical condition or recovery of failing liver function, 8 patients died, 34 patients were successfully bridged to Ltx, the immediate outcome of this 34 patients within 30d observation was: 28 kept alive and 6 patients died.

CONCLUSION: Pre-operative SOFA, level of creatinine, INR, TNF- α , IL-10 are the main preoperative risk factors that cause early death after operation, MARS treatment before transplantation can relieve these factors significantly.

INTRODUCTION

Orthotopic liver transplantation (OLT) is an accepted mode of therapy for selected patients with advanced liver diseases, however, the early mortality after OLT remains relatively high due to the poor selection of candidates with serious conditions. The immediate outcome of OLT is dependent on many factors including pre-transplantation conditions such as renal function and some other organ functions, which indicate that the better preparation for stability or improvement of the previous OLT support, the better immediate outcome for the OLT. It is now widely accepted that the artificial liver support can be of the optional therapy to stabilize patients with liver failure and to gain time for recovery or re-compensation of the liver or to get a suitable donor available^[1]. Although the hybrid biologic method seems theoretically rational, criticism of and arguments against the concept in fear of rejection, transmission of porcine viruses and inducing release of cytokines such as TNF- α and IL-10 probably hinder these methods from gaining a prominent role in future liver support strategies^[2]. A new innovated blood purification system based on hemodialysis named molecular adsorbent recycling system (MARS) has been applied to a wide variety of hepatic failure patients and represents positive effects, the method was shown to be efficient in removing both hydrosoluble substances and strongly albumin-bound substances. The remarkable removal of strongly albumin-bound substances and kinds of metabolic toxins during MARS could therefore reduce the toxic effects and higher concentrations of these compounds exert on liver and kidney, thus could contribute to improvement in encephalopathy, renal and hepatic function and probably survival^[3,4].

The aim of this study is to assess the value of pre-transplant artificial liver support in reducing the preoperative risk factors relating to early mortality after OLT.

MATERIALS AND METHODS

Patients and design

Fifty adult patients undergoing OLT procedures with MARS preoperative liver support therapy in our transplantation institute from September 2002 to June 2003 were studied. The study population consisted of 28 men and 22 women with a mean age of 52.24 years (range 46-68). The indications for liver transplantation were post-hepatic cirrhosis ($n = 11$), fulminant hepatic failure ($n = 6$), alcoholic cirrhosis ($n = 5$), primary liver cancer ($n = 7$), primary biliary cirrhosis ($n = 12$), Wilsons disease ($n = 6$) and post-operative rejection ($n = 3$).

The study contains two parts, the first one is to evaluate the medical effectiveness of single MARS therapy with some clinical and laboratory parameters which were supposed to be the therapeutical pre-transplantation risk factors, the second part is to study the patients undergoing OLT using the regression analysis in preoperative risk factors relating to early mortality (30 d) after OLT.

Our trial was approved by the Ethical Committee of Human Experimentation in China, and was in accordance with the Helsinki Declaration of 1975. All procedures were performed after informed and written consent had been obtained from the patients or their kins.

Treatment and monitoring of clinical and laboratory parameters

Initially, patients were given conventional medical therapy and intensive monitoring or supportive treatment. They were evaluated biochemically and clinically with the prognostic scoring systems including Sequential Organ Failure Assessment (SOFA) score, Glasgow coma score and Hepatic encephalopathy (HE) grade before and after the treatment, no sedatives were administered during treatment, the laboratory variables as Tumor Necrosis Factor α (TNF- α), and Interleukin-10 (IL-10) levels were detected with the flow cytometer (FACSCalibur, Becton, Dickinson and Company, USA).

Those patients who were bridged to OLT were divided into two groups: survival group (survival time ≥ 30 d) and death group (survival time ≤ 30 d). There were different possible risk factors relating to early mortality after liver transplant including pre-operative, inter-operative and post-operative ones. Pre-operative information consisted of age, SOFA, mean artery pressure (MAP), serum Aspartate Transaminase (AST), serum albumin, International Normalized Ratio (INR), serum creatinine level (Cr), serum total bilirubin level, bile acid, serum ammonia, TNF- α , and IL-10.

The extracorporeal liver support system (MARS)

The MARS system (MARS monitor, Teraklin AG, Rostock, Germany) was used with a continuous veno-venous hemofiltration (CVVH) machine (GAMBRO AK 200), The MARS treatment was performed according to the recently published guidelines^[3], a vascular access via a double-lumen jugular central vein line was created, low molecular weight heparine (LMWH) was used for blood anticoagulation for the maintenance of the extracorporeal circuit. The blood

Table 1 Comparison of clinical and biochemical data pre-and post MARS treatment

Parameter	Pre-treatment	Post-treatment	P value
Prognostic scores			
SOFA score (points)	9.72 \pm 1.89	6.98 \pm 2.34	< 0.01

flow from the dialysis machine and the albumin dialysate circuit flow were equal at a rate of 80-120 mL/min, while the dialysate flow was set accordingly. The time length of each therapeutic session was 6-8 h.

Statistical analysis

Experiment data were presented as mean \pm SD, independent 2-tailed t tests were used to determine whether there were significant differences between the survival and dead group of OLT patients. Pearson's Chi-square statistics were used to test differences in all frequencies. Data with significant difference were entered into a stepwise logistic regression analysis.

RESULTS

In the 50 patients, 80 MARS treatments were performed. Patients who underwent the intended MARS treatment were all remarkably stable without any adverse events or complications except slight chill. All patients showed positive response to the therapy, with respect to remarkable release of severe meteorism, active diet, and significant improvement of liver and kidney functions. SOFA, GSH, MAP, TNF- α and IL-10 were improved significantly, the total bilirubin (TBIL), total bile acid (TBA), ammonia and creatinine (Cr) were shown decreased markedly, however, no difference was found in the markers of alanine-aminotransferase (ALT), albumin and INR before and after the MARS treatments (Table 1). Eight patients avoided the scheduled Ltx due to significant relief of clinical condition or recovery of failing liver function, 8 patients died, 34 patients were successfully bridged to Ltx, the immediate outcome of these 34 patients within 30d observation was: 28 kept alive and 6 patients died.

Comparison between the survival group and the death group showed significant differences in terms of age, SOFA, GSH, MAP, TNF- α , IL-10, INR and serum creatinine level ($P < 0.05$, Table 2). The stepwise logistic regression was used to create the best statistical model

Table 2 Risk factors relating to early mortality after liver transplantation

relating to early mortality after transplantation. The factors that had significant independent associations with early mortality after the stepwise procedure were serum creatinine level, INR, SOFA, TNF- α and IL-10, with regression coefficients of 0.315, 0.309, 0.224, 0.192 and 0.188, respectively (Table 3).

DISCUSSION

OLT is a treatment for end-stage liver disease. Early post-operative mortality was below 10% in the world. The mortality remains high in our country. The serious preoperative condition of recipient and the late timing for operation may account for this result. The serious preoperative conditions are due to the poor detoxification ability of the liver, the accumulation of large amounts of toxic substances including hydro-soluble and lipid soluble and various metabolic products, which causing further damage to the heart, brain, kidney and vessels leading to MODS. The accumulation will increase the mortality of OLT^[5]. So, in order to increase the successful rate of OLT, the toxic substances shall be removed as much as possible before operation. The removal of the toxins will help block the vicious cycle and benefit the organ function.

The albumin dialysis MARS is currently the novel cell-free liver support system which enables the selective removal of water-soluble and albumin-bound substances, in which human serum albumin serves as a shuttle based on facilitated diffusion between a blood-sided dialysis membrane on one side and a remove set of sorbent columns and a conventional dialysis unit on the other^[2,3]. MARS has avoided the drawbacks of conventional and bio-artificial liver. It combines the functions of molecular adsorption, hemo-filtration and hemo-dialysis, and can remove the albumin combined toxins quickly and selectively. The hemo-filtration can do nothing to the albumin combined toxins. The hemo-perfusion, whose adsorbents such as carbon or resin will contact with blood directly, cause fibrolysis or activation of complements and systemic

inflammation due to the bio-incompatibility, and also, cause the loss of hepatic cytokines and a large amount of hormones such as T3, T4 and insulin. The plasma exchange has very weak ability to remove toxins and causes loss of useful substances. Attempts to develop an artificial liver were started in the 1950s, today both mechanical devices and hybrid biologic-mechanical devices such as cell-free detoxification methods, whole organ perfusion, hepatocytes transplantation and bioreactor approaches using hepatocytes, however, are with inherent defectiveness and limitations respectively. Although the hybrid biologic methods seem theoretically rational, criticism of and arguments against the concept in fear of rejection, transmission of porcine viruses and inducing release of cytokines as TNF- α and IL-6 probably hinder these methods from gaining a prominent role in future liver support strategies. Many randomized, controlled trials were performed, all reported with statistically significant increases in survival in the MARS group compared with standard care, indications for treatment were hepato-renal syndrome, decompensated chronic disease with intrahepatic cholestasis, post-operative liver failure after heart surgery and cirrhosis with superimposed acute liver injury. The laboratory data of pre- and post-treatment in the 80 sessions on the 50 patients has proved the conclusion of some other researchers. The conclusion is that MARS can remove various toxins and cytokines caused by liver failure, decrease SOFA score and improve multi-organ function.

In this study, we are trying to explore the effects of MARS treatment in post-operative early survival rate. Aiming at this purpose, we analyzed multiple factors which may be related to the post-operative mortality rate. It is different with the bygoners. We only analyzed some pre-operative factors which are operable, measurable and curable although the factors are related to the post-operative mortality comprise of not only post-operative factors, but also intra- and post-operative ones such as ischemia time, ahepatic time, bleeding volume and rejection or various complications. Some factors, though very important, can't be controlled or cured, which are not drawn into our study, such as the pathology, former related operation or former transplantation history, ABO blood group, *etc.* The early mortality rate is 17% in the 34 patients in this study. We adopts Logistic regression analysis. The results show that preoperative SOFA, levels of creatinine, INR, TNF- α and IL-10 are the main preoperative risk factors causing early death after operation.

Renal dysfunction is a common dangerous complication in patients with end-stage liver disease. It results from acute tubular necrosis and caused by

hepatorenal syndrome. Literature shows a significant decrease of 43% in glomerular filtration rate (GFR) during transplantation in patients with normal renal function. Both high pre-operative serum creatinine level and inter-operative veno-venous bypass can lead to renal hemodynamic instability during operation. The post-operative nephrotoxic immuno-suppressants can also contribute to the irreversible renal insufficiency, leading to renal failure after liver transplantation. In our study, 2 of 10 patients died of renal failure, who were all along with high preoperative serum creatinine level and hepatorenal syndrome before transplantation. A significant difference found between the survival group and the death group was shown in serum creatinine level ($P < 0.001$), with a mean of 45.45 ± 12.12 and 110 ± 23.65 , respectively. The stepwise logistic regression analysis also showed a statistical independent association with early mortality after liver transplantation, with a regression co-efficient of 0.315. It is also a main risk factor which predicts early mortality after OLT. It is very important to improve renal malfunction before transplantation. If there are indications for hemodialysis, it should be performed without delay, trying to relieve the renal function before operation^[6]. The MARS is a recommended strategy for this kind of case. Because, not only can MARS lower the level of blood creatinine, but also raise mean artery pressure (MAP) and systemic vascular resistance (SVR), for it can lower the blood level of NO which is a vessel dilator to the liver failure patients^[7].

SOFA is currently a popular system applied in ICU for the assessment of multi organ function. SOFA covers the function of multi-system completely including respiratory, hemostatics, hepatic, circulatory, and of brain and kidney. Comparing with the widely used Acute Physiology and Chronic Health Evaluation (APACHE), SOFA has the advantage of daily sequential assessment, and is better than APACHE which is not specific enough to liver function and also better than Child-Turcotte-Pugh (CTP) system which is too specific to liver function^[8]. In this study, the SOFA score is 9.88 ± 1.09 , which is significantly higher than 8.18 ± 1.23 in the survival group ($P < 0.001$). Logistic regression analysis showed that SOFA is related to early mortality in certain extent, its regression coefficient is 0.224. SOFA is one of the main risk factors. It can be regarded as a reference index in choosing operation time.

Though the association between pre- and post-operative level of TNF- α and IL-10 is not so significant as the other risk factors, it still deserves much consideration. A lot of studies show that the systemic inflammatory responses syndrome (SIRS) caused by TNF- α and IL-10 is an important factor to the aggravation of liver failure leading to MODS. Not only does SIRS play an important role in the development of liver failure, but also makes a hormone-like effect, causing hypotension, lung injury, brain edema *etc.* So SIRS may be the common body fluid causing multi-organ injury. If we can remove these factors, theoretically, the MODS caused by the strike of the operation can be relieved, which is beneficial to increasing the success rate of operation. In this study, three patients died of MOF (multi-organ failure). The study showed that

the values of preoperative parameters were lower in the survival group, which may be due to being removed of the cytokine and being blocked of injury to organs by SIRS. The relief of oxygenation of the body will also do benefit to preventing MODS^[9]. Recent studies show that the TNF- α and IL-10 play important roles in mediating the inflammation and immune response caused by rejection. The variability of the cytokine initiator is a risk factor which is related to rejection. Whether the removal of preoperative TNF- α and IL-10 will be of benefit to relieve post-operative rejection is awaits further studies^[10].

In this study, we find that MARS can improve multi-organ function both before and after operation. The improvement is presented as the decreased SOFA score. This is in agreement with some reports in the world. The mechanism may be that MARS has selectively removed a large amount of albumin bound toxins and hydrosoluble toxins including cytokines such as TNF- α , IL-10 and endo-toxin, and repressed or relieved the pathological progress, and also improved the body blood circulation, organ blood dynamics and tissue oxygenation, benefiting the intervention on MODS. Regarding the risk factors, this preoperative MARS treatment will ensure a low post-operative MODS rate and increase the success rate of operation.

Furthermore, INR is an important risk factor related to post-operative early mortality. High preoperative INR is related to disfunction of blood clotting, leading to interoperative bleeding. Large amounts of blood transfusion may develop hemodynamic unsteadiness or even DIC. The long-term hypotension will aggravate the renal failure which has already existed before operation. INR acts as the medium of blood clotting mechanism. Abnormal INR accompanied with previous upper abdominal surgery, or extensive abdominal adhesions, portal hypertension and hypersplenism may develop severe bleeding. It is reported that intra-operative bleeding quantity is related to early mortality after liver transplantation^[11,12]. In this study, INR is not significantly improved by single MARS treatment, possibly because single MARS treatment is not enough to significantly improve of the synthesizing ability of the liver. But it will be improved after sequential treatment. Unlike the other artificial liver treatment, MARS is featured by high bio-compatibility and stable hemo-dynamics. It will not do harm to or initiate the disorder of blood clotting. MARS is very useful in stabilizing INR which is related to the prognosis.

Some other factors such as Glasgow Score (GSH) and mean artery pressure (MAP) showed associations with early mortality after liver transplantation, but the significance is not as high as SOFA and creatinine.

CONCLUSION

After studying the laboratory data of pre- and post-treatment in the 80 sessions on the 50 patients, we think that MARS can be used in transition to OLT. Preoperative SOFA, level of creatinine, INR, TNF- α and IL-10 are the main preoperative risk factors that cause early death after

operation. MARS treatment before transplant operation can relieve these factors significantly.

Abstract

AIM: To verify the effect of combined interventional therapy for hepatocellular carcinoma (HCC).

METHODS: The clinical data of 1126 HCC patients who received combined interventional therapy for transcatheter arterial chemoembolization (TACE) before or after hepatectomy, TACE and radio-frequency ablation (RFA), Chinese medicine treatment and biotherapy after TACE or transcatheter arterial infusion (TAI), were reviewed according to the results of their liver function, alpha-fetoprotein, image data, color-ultrasonography finding and survival rate.

RESULTS: A total of 874 patients were followed up for a period of 2 to 63 mo. The overall 1-, 3- and 5-year survival rates were 67.8%, 28.7% and 18.8% respectively. The 1- 3- and 5- year survival rates of patients who received TACE were 74.7%, 41.4%, 36.9% before hepatectomy and 78.9%, 40.4%, 37.5% after hepatectomy. The effective rate (PR + NC) after TACE and RFA was 93.4%, the 1- and 3- year survival rates were 74.5% and 36.8% after TACE and RFA. The effective rate of PR + NC after TACE was 83.2%. The 1-, 3- and 5- year survival rates were 69.3%, 21.7%, 8.4% after TACE. The effective rate of PR + NC after TAI was 27.5%, the 1- and 2- year survival rates were 11.6% and 0% after TAI. The liver function, color-ultrasonography finding and alpha-fetoprotein after TACE + RFA, TACE and TAI were compared. There was no significant difference in each index between TACE and RFA or TACE as well as in liver function between TACE and RFA or between TACE and TAI.

CONCLUSION: The therapeutic effectiveness of TACE before or after hepatectomy is most significant, while the

effect of TACE and RFA is better than that of TACE, and the effect of TAI is minimal.

INTRODUCTION

Transcatheter arterial interventional therapy is extensively used in treating hepatocellular carcinoma (HCC). To reduce the intra-hepatic recurrence and improve the protective efficacy after treatment for HCC, some scholars have proposed combined interventional therapy as a choice of treatment for HCC^[1]. We analyzed the therapeutic effectiveness of different combined interventional therapies for HCC according to the survival rate, liver function, image data and indications of tumor.

MATERIALS AND METHODS

Patients

A total of 1126 patients were retrospectively studied from January 1994 to October 2003. Of them, 873 were males and 253 were females (aged 32-76 years, mean 56.2 years). The patients were treated following the HCC Clinical Diagnosis and Staging Standard stipulated at the 8th National Academic Conference of Liver Cancer in September 2001. Among these patients, 78 had a family history of liver cancer, 985 had a medical history of serum hepatitis, 48 had a medical history of hepatitis C, 342 had cardinal symptoms of right upper quadrant pain, 336 felt epigastric distention after dinner or suffered from anorexia, 162 had low fever accompanied with progressing wasting, 286 exhibited no overt symptoms. Prior to the treatment, AFP was greater than 20 ng/mL in 735 cases, greater than 400 ng/mL in 521, negative in 227, unknown in 164. A total of 874 patients were followed up for 2

to 63 mo (averaged 26.3 mo). Combined interventional therapy was given, including transcatheter arteria hepatica chemoembolization (TACE) before or after hepatectomy, radio-frequency ablation (RFA) after TACE, Chinese medicine treatment and biotherapy after TACE or transcatheter arteria hepatica infusion (TAI). The clinical data of various kinds of combined interventional therapy for HCC are shown in Tables 1 and 2.

TACE

Twelve mg mitomycin (MMC) and 1.0 g 5-FU were diluted in 60 mL sodium chloride solution respectively and infused through a catheter. Then 50 mg epirubicin (EPI) and iodinated oil were compounded into a mixed emulsifier and infused into the blood-supply artery of the tumor through a catheter. Then, the artery was embolized with granules of spongia gelatinosa.

TAI

Fifty mg EPI, 12 mg MMC, and 1.0 g 5-FU were diluted in 60 mL sodium chloride solution respectively and infused through a catheter into the blood-supply artery of tumor. HCC patients treated 3-4 times with TACE at 1-2 mo intervals after hepatectomy, if pathological report showed remnant cancer cells on the cutting edge or AFP > 20 ng/mL or the image showed remnant tumor. Those who lost the chance of one-stage operation were treated with TACE and underwent re-examination of CT after 1-2 mo. If iodinated oil deposited in the tumor was reported to be coarctate, the volume of tumor was decreased or the normal liver had compensatory hyperplasia, the patients underwent hepatectomy after their recuperation. Those who did not recuperate or rejected hepatectomy were treated with RFA 3-4 wk after TACE. On the first day after TACE or TAI, the patients were treated with the following Chi-

Table 3 Accumulated survival rate for 874 HCC patients after various kinds of interventional therapy

Group	Cases (n)	1 yr		3 yr		5 yr	
		Cases (n)	Survival rate (%)	Cases (n)	Survival rate (%)	Cases (n)	Survival rate (%)
Preop. TACE	198	148/198	74.7	82/198	41.4	58/157	36.9
Postop. TACE	114	90/114	78.9	46/114	40.4	33/88	37.5

nese herbal medicines: 30 g Milkvetch Root, 20 g Dangshen, 15 g Largehead Atractylodes Rhizome, 15 g Indian Bread, 30 g Huaishan, 15 g Finger Citron, 15 g Bupleurum chinense, 15 g Danshen Root, 3 g Radix Notoginseng, 15 g Virgate Wormwood Herb, 20 g Tianjihuang, 20 g Canton Love-Pea Vine, 5 g Radix Glycyrrhizae. The herbal medicines were decocted in water for oral dose once daily for 3-4 wk as a course of treatment. After 3-5 d, the patients received intramuscular injection of 1000 U interferon once a day for 20 d as a course of treatment.

Follow-up

The liver and renal function, AFP, blood RT, KPS scores were re-examined, and sonography, CT, chest X-Ray were performed once a month, and then every 3 mo during the follow-up period. The date on which the patients lost their follow-up was regarded as the date of death. According to the WHO evaluation standard of therapeutic effect of solid tumor (1981), the patients who were treated with TACE + RFA, TACE and TAI were categorized into 4 degrees: complete remission (CR), partial remission (PR), no change (NC) and progression (PD). The first 3 degrees were considered efficient and the last degree was considered inefficient.

Statistical analysis

SPSS12.0 was used for statistical analysis. The survival rate was evaluated by adopting probability ratio multiplication theorem, and chi-square test was used for comparison between the 2 groups. $P < 0.05$ was considered statistically significant.

RESULTS

A total of 874 cases were followed up for 1-7 years. Comparison of the accumulated survival rate after various kinds of combined interventional therapy is shown in Table 3. The therapeutic effect of interventional therapy in 562 patients is shown in Table 4. Changes of liver function, tumor blood-supply and AFP in 562 cases after interventional therapy were compared. Fifteen days after combined interventional therapy, color Doppler was used to detect the blood flow around and inside the tumor. The change in recovery rate of AFP before and after TACE + RFA, TACE and TAI was compared. The results are shown in Table 5.

Table 4 Therapeutic effect of TACE+RAF, TACE and TAI in 562 patients

Group	Cases (n)	PR	NC	PD	Effective rate (%)

DISCUSSION

At present, hepatectomy remains the preferred method to treat primary liver cancer. Second-stage hepatectomy after TACE is a great breakthrough in the field of liver cancer treatment after hepatectomy of macro-hepatoma in the 1950-1960s and micro-hepatoma in the 1970s^[3]. TACE after radical excision of hepatoma can efficiently kill remnant cancer cells, decrease recurrence and increase survival rate remarkably^[4,5]. However, it was reported that TACE can damage hepatic and immunologic function, thus decreasing the survival rate^[6]. Zheng *et al*^[4] retrospectively analyzed the therapeutic results of 420 HCC patients after combined therapy, and found that the 1- and 3-year survival rates of non-angioencroached HCC patients after treated with TACE are 100% and 60% before radical excision, 77.8% and 22.2% before palliative excision, respectively, higher than those of the patients not treated with TACE before hepatectomy, and there is no significant difference between TACE before and after hepatectomy. Wang *et al*^[7] reported that the 1-, 3-, 5- year survival rates of 20 HCC patients after treated with combined therapy are 95.0%, 63.5%, 32.9% after second-stage hepatectomy, suggesting that the 1-, 3-, 5- year survival rates after TACE before or after hepatectomy are the highest. The reasons may be as follows: some of the 1126 cases treated with TACE before or after hepatectomy had hepatic AVF and embolus of hepatic portal vein, only interventional therapy was given before hepatectomy, and TACE treatment did not continue with double-chemoembolization or internal radiation. All these indicate that cancer cells can extend to distal ramulus along homonymous portal vein during operation procedures. Though macroscopic circumscription of hepatectomy is satisfactory, there are remnant cancer cells on the cutting edge, and liver cancer

complicating hepatic cirrhosis limits circumscription of hepatectomy. The above-mentioned factors are the major reasons for recurrence which is an important reason for the low survival rate after hepatectomy. For this reason, it is necessary to treat HCC patients with TACE combined with Chinese medicine and biotherapy to increase their immunologic function after hepatectomy. To effectively increase the survival rate, HCC patients should be treated with double-chemoembolization or internal radiation before hepatectomy.

Combined interventional therapy including TACE, TAI, RAF, percutaneous intra-tumor absolute alcohol injection (PEI), percutaneous intra-tumor acetic acid injection (PAAI), percutaneous intra-tumor hot saline water injection (PSI), percutaneous cryotherapy (PCT), is dominantly used in non-surgical treatment of HCC. Except for TACE and TAI, extra-hemal and circumscriptus "interstitial substance therapy"^[8] can treat HCC through different mechanisms. It was reported that chemoembolization can reduce the number of newly generated tumor vessels and the remnant tumor may generate new vessels through various ways^[9]. To increase the life span, we believe that HCC patients should be treated with RFA, PEI, PAAI, PSI, and PCT on the basis of TACE to kill remnant cancer cells. Liu *et al*^[10] reported that the 1-, 2-, 3- year survival rates of HCC patients after treated with TACE are 59.52%, 22.06% and 14.34% , while the 1- and 3- year survival rates of HCC patients after treated with TAI are 27.94% and 0%. In our study, the 1-, 2-, 3- year survival rates of 387 patients after treated with TACE were 69.3%, 21.7% and 8.4% respectively, and the 1- and 3- year survival rates of 69 after treated with TAI were 11.6% and 0%, suggesting that combined interventional therapy for HCC is influenced by many factors.

Abstract

AIM: To heighten recognition of primary pancreatic lymphoma (PPL) in clinical practice.

METHODS: A retrospective review of the clinical presentation, imaging characteristics and pathological features of PPL patients were presented, as well as their diagnosis and treatment, in combination with literature review.

RESULTS: Histological diagnosis was made in four patients by surgery and in two patients by EUS-FNA. The six PPL patients (5 males and 1 female; age range, 16-65 years; mean age, 46 years) had the duration of symptoms for two weeks to three months. The primary presenting symptoms, though not characteristic, were abdominal pain, abdominal masses, weight loss, jaundice, nausea and vomiting. One of the patients developed acute pancreatitis. In one patient, the level of serum CA19-9 was 76.3 $\mu\text{g/L}$. Abdominal CT scan showed that three of the six tumors were located in the head of pancreas, two in the body and tail, and one throughout the pancreas. Diameter of the tumors in the pancreas in four cases was more than 6 cm, with homogeneous density and unclear borders. Enhanced CT scan showed that only the tumor edges were slightly enhanced. The pancreatic duct was irregularly narrowed in two cases whose tumors were located in the pancreatic head and body, in which endoscopic retrograde cholangiopancreatography (ERCP) showed that the proximal segment was slightly dilated. Two patients underwent Whipple operation, one patient underwent pancreatectomy, and another patient underwent operative biliary decompression. PPL was in stage I E in 2 patients and in stage II E in 4 patients according to the Ann Arbor classification system. The diagnosis of B-cell non-Hodgkin's lymphoma was made in all patients histopathologically. All six patients underwent systemic chemotherapy, one of whom was also treated

with gamma radiometry. One patient died two weeks after diagnosis, two patients lost follow-up, two patients who received chemotherapy survived 49 and 37 mo, and the remaining patient is still alive 21 mo, after diagnosis and treatment.

CONCLUSION: PPL is a rare form of extranodal lymphoma originating from the pancreatic parenchyma. Clinical and imaging findings are otherwise not specific in the differentiation of pancreatic lymphoma and pancreatic cancer, which deserves attention. EUS-guided fine-needle aspiration (EUS-FNA) of the pancreas requires experienced cytopathologists as well as advanced immunohistochemical assays to obtain a final diagnosis on a small amount of tissue. Surgery and adjuvant chemotherapy or radiotherapy can produce fairly good outcomes.

INTRODUCTION

Lymphoma includes Hodgkin's and non-Hodgkin's forms. Hodgkin's lymphomas rarely disseminate to extra-lymphatic organs, while non-Hodgkin's lymphomas often invade extra-lymphatic organs. Most primary pancreatic lymphomas (PPL) are non-Hodgkin's Lymphomas. More than 25 percent of non-Hodgkin's lymphomas originate from extra-lymphatic organs, about 30 percent of which may involve the pancreas^[1]. Isolated PPL is quite rare, less than 1 percent^[2]. In a review of 207 cases of malignant pancreatic tumors, there were only three cases (1.5%) of pancreatic lymphoma^[3]. In fine-needle aspiration (FNA) of 1050 cases of pancreatic lesions, Volmar *et al*^[4] only found 14 cases (1.3%) of PPL. Clinically, PPL is most likely to be misdiagnosed as pancreatic cancer. The present article is a retrospective review of six cases of PPL, based on which the clinical presentation, imageologic characteristics and pathologic features of PPL are discussed in the context of the world literature in an attempt to heighten clinicians' awareness of the condition.

MATERIALS AND METHODS

Patients

Six cases of PPL were identified and treated in Department of Gastroenterology, Changhai Hospital, Second Military Medical University, Shanghai, China, during a 15-year period from January 1990 to June 2005. The clinical characteristics of all the patients were consistent with the criteria for the diagnosis of PPL defined by Behrns *et al*^[1]. On physical examination, no enlarged superficial lymph nodes were found; no enlarged diaphragmatic lymph nodes on chest X-ray films were found either. There was no change of WBC classification on hemograms; there were no significant hepatic and splenic focuses. However, there was evidence of a pancreatic mass on laparotomy, and the lymph nodes involved were confined to areas around the pancreas.

Methods

A retrospective review of the clinical data revealed that malignant lymphoma was unanimously the initial diagnosis of all the six cases. Immunohistochemical analysis by EnVision-methods included leukocyte common antigen (LCA), CD20, CD34, CD68, Chr, CD45RO and Ki-67, of which LCA indicates that tumor cells come from lymphocytes, CD20 is the marker of B-cell, and CD45RO is the marker of T-cell.

All patients were staged according to the Ann Arbor staging system for non-Hodgkin's lymphomas, stage I: invasion of lymphoma is confined to the pancreas; stage II: apart from pancreatic invasion, there is also invasion of local lymph nodes; stage III: apart from pancreatic invasion, the focus also infiltrates the upper diaphragm; and stage IV: apart from pancreatic invasion, there is generalized infiltration^[5].

RESULTS

Clinical presentation

The six PPL patients included five males and one female who ranged in age from 16 to 65 years with a mean of 46 years, and whose duration of symptoms ranged from two weeks to three months. The primary presenting symptoms were abdominal pain, an abdominal mass, weight loss, jaundice, nausea and vomiting, which were similar to what were reported in the overseas literatures^[6-9], except that there were no lower back pain, fever and chill, ascites and hemorrhage of the upper digestive tract (Table 1).

Laboratory and imaging findings

WBC count was within the normal range in all six cases. In four patients aspartate aminotransferase (ALT) was 80-265 U/L and alkaline phosphatase (AKP) was 120-216 U/L; in three patients, the level of serum bilirubin was 42-216 μ mol/L and CA19-9 was 76.3 μ g/L. Liver function was otherwise normal. Abdominal CT scan demonstrated that the tumor was located in the head of pancreas in three cases, in the body and tail in two cases, and in the whole pancreas in the remaining case. The tumors were larger than 6 cm in four cases, with almost homogeneous density and unclear edges. Enhanced CT scan only enhanced

Figure 1 Cytologically, lymphoma cells are round, oval, with prominent and large nucleus, arranged diffusely with obvious heterogeneity (Hematoxylin-eosin stain; original magnification $\times 200$).

the edges slightly. ERCP in two cases revealed that the pancreatic duct at the body of the head was irregularly narrowed, the proximal segment of which was slightly dilated.

Histopathologic study

The specimens were obtained from pancreatic resection in four cases, and from EUS-guided fine-needle aspiration (EUS-FNA) in the remaining two cases. Microscopic examination showed that the lymphoma cells were round or elliptic, and arranged diffusely, with little plasma, thick karyotheca, thick chromatin and clear nuclei. Immunohistochemical analysis showed LCA (+), CD20 (+), CD34 (-) and CD68 (-). Histopathological examination confirmed the diagnosis of the six cases as B cell pancreatic lymphoma (Figures 1-3).

Diagnosis, treatment and prognosis

Of the six patients, diagnosis was confirmed by pathological study of the pancreatic tissue resected by EUS-FNA in two patients, by my cytological study in one patient, and by general skeleton ECT scan in another patient. One patient underwent biliary-intestinal anastomosis. According to Ann Arbor classification, two cases belonged to I E stage, and the remaining four cases to II E stage. All six patients underwent chemotherapy, one of whom also underwent linear accelerator radio-

Figure 3 Immunohistochemical analysis showing Ki-67 (+) (EnVision's stain; original magnification × 200).

therapy, and another underwent stereotaxic γ -knife radiotherapy. One patient died two weeks after the diagnosis was confirmed; two patients were lost to follow-up; two patients survived for 49 and 37 mo, and the remaining one patient is still being followed up.

DISCUSSION

Primary pancreatic lymphoma (PPL) is an extremely rare disease which occurs in pancreatic situ, with or without involvement of peripancreatic lymph nodes. The clinical manifestation and imaging result of PPL resemble other pancreatic occupying lesions like pancreatic carcinoma. However, unlike carcinomas, PPLs are potentially treatable even if not found at early stage. PPL only accounts for fewer than 2% of extra-nodal malignant lymphomas and 0.5% of cases of pancreatic masses^[10,11]. To date, only fewer than 150 and 20 cases of PPL have been reported in English literature^[12] and Chinese medical literature, respectively. In China, from 1995 to 2003 there were totally 16 cases of PPL reported^[13]. The data show a strong male predominance (male to female ratio of 13:3) and increased trend with age (median age of 57.5 years), which is similar to the present study. However whether the mean age of PPL is older than that of pancreatic carcinoma remains controversial.

Although the clinical presentation of PPL is varied, some findings may support PPL rather than pancreatic

cancer. Bellyache and abdominal mass are two major symptoms which present in 83% and 58% of PPL cases, respectively^[12]. Two of six of our patients (33%) presented abdominal mass while Yu *et al* reported that only 1.3% of patients with adenocarcinoma presented abdominal mass^[14]. The other symptoms are jaundice, reflux, weight loss, bowel obstruction and diarrhea^[6,15]. Interestingly there are almost 12% of PPL mimicking acute pancreatitis. It is noticeable that one in six of our patients presented acute pancreatitis. Obstructive jaundice was found to be less frequent than in pancreatic cancer^[16]. While the common symptoms in non-Hodgkin's lymphoma like fever, chills and night sweats were rare in PPL, making it hard to diagnose only depending on the signs^[17]. The majority PPLs occur in the head of pancreas, though tumor could also be found in the body and tail regions^[7]. It was reported that over half of PPL patients presented with an epigastric mass and the diameter was bigger than 6 cm in 70% of patients of PPL^[18]. The laboratory test is non-specific for diagnosis of PPL. Our data reveal that serum carbohydrate antigen 19-9 (CA19-9) level in PPL patients was normal or slightly elevated. This is different from pancreatic adenocarcinoma, in which almost eighty percent of patients get a higher CA19-9 level. The abnormality of serum ALT, AKP, and bilirubin was secondary to the bile duct obstruction.

Imaging results play a key role in diagnosis of PPL. Percutaneous ultrasound (US), endoscopic ultrasonography (EUS), computed tomography (CT) and MRI are well-established procedures to evaluate pancreatic masses^[19,20]. Previously 16 Chinese PPL cases could all be found pancreatic masses by CT or US before therapy, with or without signs of peripancreatic lymph node invasion. CT is by far the most common imaging technique used in the detection and characterization of pancreatic tumors. The picture of PPL on CT resembled that of pancreatic carcinoma, including enlargement of pancreatic head and density changes. However, there are fewer signs of invaded large vessel and metastasis of the liver and spleen. There are fewer chances to find pancreatic duct dilation in PPL when compared with pancreatic cancer. Merkle *et al*^[9] reported the combination of a bulky localized tumor in the pancreas without significant dilation of the main pancreatic duct strengthens a diagnosis of pancreatic lymphoma over adenocarcinoma. Furthermore, if enlarged lymph nodes are encountered below the level of the renal veins, virtual exclusion of adenocarcinoma is possible. While Arcari *et al*^[17] insisted that imaging techniques could suggest the suspicion of PPL but are unable to distinguish PPL from pancreatic adenocarcinoma. Therefore, the final diagnosis of PPL should depend on histopathologic examination. In four of six PPL patients in current study the tissue was obtained during operation and in the other two cases the tissue was obtained by EUS-FNA. Most reported Chinese PPL cases were finally diagnosed by surgeons while there will be more studies using FNA in the future. However, when compared with surgery, it is difficult to obtain enough specimen by FNA to perform immuno-histochemical analysis and may lead to false-negative result^[7]. Di Stasi *et al*^[21] reported that CT or US guided FNA is a safe and rapid technique to make

histological diagnosis by which we could get more tissues than by EUS. However during CT scan it is difficult for operators to supervise the needle path. EUS-guided tissue sampling of pancreatic masses is the superior method because it is dynamic and real-time. EUS can clearly reveal the boundary of tumor and color doppler flow imaging(CDFI) can show the vein path, sequentially guide the needle aspiration and avoid the vessel damage^[22,23]. O'Toole *et al*^[24] reported the complication rate of EUS-FNA was as low as 1.6%, indicating it is a safe method. Most importantly, FNA depending methods should be further applied because it is helpful to avoid unnecessary surgery.

Totally four in six of our patients underwent operation. Among them two cases were treated with Whipple surgery, one by distal pancreatectomy and another by operative biliary decompression. The reason for operation is that the definitive diagnosis was not made before surgery. If these patients had been detected using FNA, the exploration could have been skipped. Thus the treatment strategy could have been direct chemotherapy or radiotherapy. Unfortunately, all published 16 Chinese PPL cases were treated with surgery, which made the final diagnosis. It can be predicted that the more frequent usage of FNA, including either CT or EUS guided-FNA may minimize the number of operations for PPL. Bouvet *et al*^[8] reported ten in eleven PPL patients, have been performed explorative surgery, only in three of them the tumor could be fully resected. Among eight unresected cases, seven cases were treated with combined CHOP chemotherapy and radiotherapy with dosage of 30 to 45 Gy. The median survival time was 67 mo (11-191 mo). Behrns *et al*^[1] reported that the median survival time for single chemotherapy and radiotherapy-treated PPL patients was 13 and 22 mo, respectively. While the survival time could be improved to 26 mo if combining medication with radiotherapy. Therefore, the first choice for PPL treatment should be combination of chemotherapy and radiotherapy, rather than surgery. With the advancement of techniques, surgery seems to be only effective when FNA is not available or diagnosis can not be made on histology. It has already been proved that single pancreas resection could not improve the survival rate of PPL but cause more complications. However, the PPL patient with biliary tract or gastrointestinal obstruction should be performed biliary or gastric bypass to relieve the symptoms.

In conclusion, PPL is a rare disease with non-specific symptoms, laboratory tests and imaging examination results. Cytology or tissue histology is fundamental for diagnosis and chemo- or radiotherapy is preferred for treatment. FNA technique is recommended as a routine examination, while total pancreatectomy is considered to have no impact on survival and with its associated morbidities, is not generally recommended for diagnosis and treatment of PPL. As a result, PPL will not be such a disease with poor prognosis in the future.

Abstract

AIM: To study the effect of combined indwelling catheter, hemofiltration, respiration support and traditional Chinese medicine (e.g. Dahuang) in treating abdominal compartment syndrome of fulminant acute pancreatitis.

METHODS: Patients with fulminant acute pancreatitis were divided randomly into 2 groups of combined indwelling catheter celiac drainage and intra-abdominal pressure monitoring and routine conservative measures group (group 1) and control group (group 2). Routine non-operative conservative treatments including hemofiltration, respiration support, gastrointestinal TCM ablation were also applied in control group patients. Effectiveness of the two groups was observed, and APACHE II scores were applied for analysis.

RESULTS: On the second and fifth days after treatment, APACHE II scores of group 1 and 2 patients were significantly different. Comparison of effectiveness (abdominalgia and burbulence relief time, hospitalization time) between groups 1 and 2 showed significant difference, as well as incidence rates of cysts formation. Mortality rates of groups 1 and 2 were 10.0% and 20.7%, respectively. For patients in group 1, celiac drainage quantity and intra-abdominal pressure, and hospitalization time were positively correlated ($r = 0.552, 0.748, 0.923, P < 0.01$) with APACHE II scores.

CONCLUSION: Combined indwelling catheter celiac drainage and intra-abdominal pressure monitoring, short veno-venous hemofiltration (SVVH), gastrointestinal TCM ablation, respiration support have preventive and treatment effects on abdominal compartment syndrome of fulminant acute pancreatitis.

INTRODUCTION

There are certain guidelines for treatment of severe acute pancreatitis (SAP). However, about 11% of SAP patients suffer from the complication of abdominal compartment syndrome (ACS), and about 25% of SAP patients are fulminant acute pancreatitis (FAP). Incidence rate of ACS is higher in FAP, and its mortality rate is as high as 60%. Up till now, there have been no standard treatments for ACS^[1,2]. In the present study, we used combination of celiac indwelling catheter drainage and intra-abdominal pressure monitoring, several short veno-venous hemofiltration (SVVH), respiration support and gastrointestinal TCM ablation for treatment and predicting patient's conditions of ACS in FAP. Through comparison with the control group, we demonstrate that the combined therapy is effective for treatment of ACS.

MATERIALS AND METHODS

Patients

A total of 110 FAP patients were received and treated in First Aid Center and Hepato-biliary Surgery Department of Affiliated Hospital of Guiyang Medical College^[3,4]. When they were hospitalized, the cumulative scorings of CT serious index (CTSI), APACHE II and SAP were 7.85 ± 1.10 , 17.51 ± 4.51 and grade II respectively.

Methods

Patients were divided randomly into groups of indwell-

Figure 1 Indwelling catheter. (✓) Celiac drainage; (✗) Intra-abdominal pressure detection.

ing catheter celiac drainage and intra-abdominal pressure monitoring and routine non-operative conservative treatment measures (Figure 1) group (group 1, 45 cases) and control group (group 2, 65 cases). There was no significant difference ($P > 0.05$) in gender, age, cumulative scorings of CTSI and APACHE II between the two groups. Routine non-operative conservative treatment measures, including SVVH, gastrointestinal TCM ablation, respiration support and drug therapy, were conducted in group 2 patients. For group 1 patients centesis in right side or two sides of abdominal cavity, installation of indwelling catheter for continuous drainage (drain quantity was recorded daily) were conducted on the first day of hospitalization, and intra-abdominal pressure was monitored and recorded on the first, second and fifth days since installation of indwelling catheter. The decision of time for hemofiltration was based on the indications of systemic inflammatory response syndrome (SIRS). On the day of hospitalization Dahuang or Qingyitang was infused by gastric canal or anus drip (3 times daily).

Observation of clinical effectiveness: Abdominalgia, burbulence time, hospitalization time for groups 1 and 2 were observed. Celiac drainage and intra-abdominal pressure were monitored for group 1; APACHE II cumulative scores before treatment, on the second and fifth days after treatment in groups 1 and 2 were recorded.

Statistical analysis

Data are expressed as mean \pm SD. SPSS 12.0 was used for statistical analysis. $P < 0.05$ means significant.

RESULTS

Patients' conditions

During hospitalization and treatment period, there was no significant difference in the two groups for cumulative scorings of CTSI and APACHE II. On the second and fifth days after treatment with combined indwelling catheter drainage, gastrointestinal TCM ablation, SVVH, respiration support and drugs, the cumulative scorings of APACHE II in group 1 were significantly lower than in group 2 ($P < 0.01$); cumulative scorings of APACHE II were significantly decreased compared with before treatment ($P < 0.01$, Table 1).

Table 1 Patient's conditions of severity transformation (mean \pm SD)

Group	State of illness when hospitalized		Change of APACHE II during treatment	
	CTSI scoring	APACHE II scoring	2 d after treatment	5 d after treatment
1	7.61 \pm 0.67	16.44 \pm 2.28	9.66 \pm 1.88 ^b	4.63 \pm 1.46 ^b

Celiac drainage and intra-abdominal pressure

Drains of 45 cases in group 1 were all dematiaceous bloody liquid. Drainage period was 3.5 ± 0.85 d; drain quantity was positively correlated ($r = 0.552$, $P < 0.01$) with intra-abdominal pressure (IAP) ($r = 0.552$, $P < 0.01$). While IAP was positively correlated with cumulative scorings of APACHE II ($r = 0.748$, $P < 0.01$, Table 2).

Relief time for abdominalgia and burbulence, and hospitalization time

The relief time of abdominalgia, burbulence, and hospitalization time in group 1 were significantly shorter than those in group 2 ($P < 0.01$). Mortality rates in group 1 were decreased compared to group 2, with no significant difference. Incidence rates of cysts in group 1 were significantly decreased compared to group 2 ($P < 0.01$, Table 3).

DISCUSSION

FAP is characterized by rapid deterioration of patient's conditions. Multi-organ (specially pancreas and gastrointestinal tract) dysfunction appeared in early stage.

ACS in FAP is divided into four grades according to IAP: first grade is 10-14 cm H₂O, second grade is 15-24 cm H₂O, third grade is 25-35 cm H₂O, and fourth grade is > 35 cm H₂O. In group 1 of our experiment, celiac intra-abdominal pressure of 45 cases was 29.29 ± 5.53 cm H₂O, diagnosed as ACS clinically^[4-6]. Currently, ACS is detected mainly by bladder manometry method, which is an indirect

method. However, there are certain influencing factors. Therefore we used indwelling catheter celiac laying canal to directly detect intra-abdominal pressure, and performed canal drainage. It could prevent celiac dropsy ACS, avoid disturbance of celiac function when operating, and the effect of anesthesia on laparotomy and celiac operation, and consequently prevent ACS^[7-12]. In our study, the combined approach of indwelling catheter drainage, SVVH and gastrointestinal TCM ablation, respiration support and use of other drugs was employed to treat ACS in FAP. We found that drain quantity was positively correlated with intra-abdominal pressure ($r = 0.55$), and intra-abdominal pressure was correlated with hospitalization time and APACHE II cumulative scorings ($r = 0.75, 0.92$). In comparison of effectiveness, that of the group 1 was significantly better than that of group 2 regarding abdominalgia disappearing time, burbulence relief time, and hospitalization time ($P = 0.000$); mortality rates were 10% and 20.7% in group 1 and 2, respectively; incidence rates of cysts between the two groups were significantly different ($P = 0.001$). The reasons for the better effect of group 1 might be that: (1) indwelling catheter drainage eliminated ACS caused by celiac dropsy; (2) hemofiltration or drainage improved paralysis of gastrointestinal tract caused by a variety of inflammatory cytokines, inflammation mediators, all kinds of enzymes and necrosis materials (including large, moderate and small molecular weight materials). As a consequence, damage of tissues and organs in dropsy (mesentery, epiploon, gastrointestinal and parietal peritoneal membrane) type of ACS was greatly reduced; (3) It was eliminated that the celiac disturbance and the effect on systemic multi-organs (especially gastrointestinal tract) caused by laparoscopic operation or laparotomy and anesthesia; (4) TCM, eg. Da-huang could effectively reduce intestinal tract endotoxin and bacterial shift, alleviate intestinal mucosal membrane damage, and facilitate gastrointestinal movement and emptying^[9,13-16]. As far as we know, such study has not been reported.

In summary, combined indwelling catheter celiac drainage, intra-abdominal pressure monitoring, multi-SVVH, gastrointestinal TCM ablation, respiration support and use of drugs can prevent and treat ACS in FAP effectively. However, the problem of slow speed of indwelling catheter celiac drainage has still to be resolved^[13].

Abstract

A 66-year-old woman underwent partial splenic embolization (PSE) for hypersplenism with idiopathic portal hypertension (IPH). One week later, contrast-enhanced CT revealed extensive portal vein thrombosis (PVT) and dilated portosystemic shunts. The PVT was not dissolved by the intravenous administration of urokinase. The right portal vein was cannulated *via* the percutaneous transhepatic route under ultrasonic guidance and a 4 Fr. straight catheter was advanced into the portal vein through the thrombus. Transhepatic catheter-directed thrombolysis was performed to dissolve the PVT and a splenorenal shunt was concurrently occluded to increase portal blood flow, using balloon-occluded retrograde transvenous obliteration (BRTO) technique. Subsequent contrast-enhanced CT showed good patency of the portal vein and thrombosed splenorenal shunt.

Transhepatic catheter-directed thrombolysis combined with BRTO is feasible and effective for PVT with portosystemic shunts.

INTRODUCTION

Acute portal vein thrombosis (PVT) after partial splenic embolization (PSE) in portal hypertension is a rare event^[1-3]. Stagnant splenic blood flow after PSE appears to result in PVT^[4,5]. Surgical treatment is generally ineffective and yields poor results. Consequently, direct percutaneous intervention is increasing in popularity as a therapeutic alternative. Portal systemic shunts (PSS) are frequently formed due to portal hypertension in patients with chronic liver diseases such as liver cirrhosis or idiopathic portal hypertension (IPH). Balloon-occluded retrograde transvenous obliteration (BRTO) is an effective treatment for gastric varices and encephalopathy with PSS^[6-8].

We report a patient with portal vein thrombosis after PSE in IPH with extensive portal systemic shunts treated with transhepatic catheter-directed thrombolysis combined with BRTO restoring portal blood flow.

CASE REPORT

A 66-year-old woman with a medical history of IPH was hospitalized with continuously bloody stool (melena). The HBV and HCV markers were all negative. IPH was diagnosed by liver biopsy and CT scan. Upper endoscopy was performed after admission and small esophageal varices without bleeding were pointed out. Telangiectasia was found in the transverse colon by colonoscopy and hemostasis was accomplished by endoscopic high-frequency coagulation. Despite repeated transfusion of red blood cells and platelets, laboratory examination revealed significant pancytopenia, with a white blood cell count of $1.1 \times 10^9/L$, red blood cell count of $2.71 \times 10^{12}/L$, and platelet count of $2.5 \times 10^{10}/L$. US and CT revealed splenomegaly.

The patient underwent PSE to reduce hypersplenism and portal hypertension. The splenic artery was catheter-

Figure 1 Abdominal CT one week after PSE. **A:** Plain CT showing high density lesions in the main portal vein and the 1st right branch (narrow arrow); **B:** Contrast-enhanced CT revealing no enhancement of portal vein indicating portal thrombosis (thick arrow) and portosystemic shunts (arrow head). Splenic infarction after PSE was also visualized.

Figure 2 No visualization of main portal vein due to extensive thrombosis (narrow arrow) and visualization of portosystemic shunts such as dilated left gastric vein and splenorenal shunt draining into left renal vein (thick arrow) on percutaneous transhepatic portography.

Figure 3 Percutaneous transhepatic portography after catheter-directed thrombolysis. **A:** Dissolution of the thrombus in portal vein (narrow arrow); **B:** Hepatofugal flow into dilated portosystemic shunts (thick arrow: left renal vein).

ized selectively *via* the femoral route, and the tip of micro-catheter was inserted in a peripheral branch of the splenic artery. Small particles (1 mm × 1 mm × 1 mm) of gelatin sponge soaked in antibiotics were injected to achieve PSE. The platelet count rose to $14 \times 10^{10}/L$ on the 7th d after PSE. Plain CT revealed a low-density area in the spleen and high-density thrombus in the main portal vein and the 1st right and left branches (Figure 1A), and contrast-enhanced CT revealed no enhancement of the portal vein indicating extensive portal thrombosis (Figure 1B). Porto-systemic shunts including a dilated left gastric vein to the paraesophageal vein and splenorenal shunt draining into the left renal vein were also visualized. Thrombolytics and anticoagulants were initiated, urokinase (240 000 U/d) and heparin (10 000 U/d) were given intravenously for 3 d. However, CT after systemic thrombolysis revealed that the thrombosis did not resolve.

It was therefore decided to attempt catheter-directed thrombolysis. With the patient under local anesthesia, a branch of the right portal vein was punctured with an 18-gauge needle under ultrasonic guidance. A 0.035-inch guidewire was advanced into the portal vein through the thrombus. A 4 Fr. straight catheter (Cook, Bloomington, IN) was advanced into the splenic vein and portography was performed. Percutaneous transhepatic portography (PTP) yielded no visualization of the main portal vein but did show large collaterals of the dilated gastric vein and splenorenal shunt (Figure 2). Urokinase at a dosage of 320 000 U was initially infused directly into the thrombus for 30 min. However, because immediate resolution of the thrombus was not observed, an hourly dose of 20 000 U of urokinase and a daily dose of 10 000 U of heparin

Figure 4 PTP after BROTO. BROTO was attempted to occlude splenorenal shunt in order to increase portal blood flow. A 7Fr balloon catheter (arrow) was advanced into the outflow pathway of the splenorenal shunt. A total of 10 mL of 5% ethanolamine oleate iopamidol (EOI) was injected and remained stagnant for a day during balloon occlusion.

were continuously infused into the thrombus. Two days later, PTP revealed total resolution of the thrombus in the portal vein and recirculation of portal blood flow to liver parenchyma (Figure 3A). However, there was still marked hepatofugal flow into the dilated PSS, inducing stagnation of portal blood flow (Figure 3B). BROTO was then attempted to occlude the splenorenal shunt in order to increase portal blood flow. An 8 Fr. J-type sheath (J Sheath; Medikid, Tokyo, Japan) was inserted into the left renal vein *via* the right femoral vein. A 7 Fr. balloon catheter (Selecon Cobra-shape MP catheter with 13 mm diameter balloon; Clinical Supply, Gifu, Japan) was advanced through the sheath into the outflow pathway of the splenorenal shunt (Figure 4). Balloon-occluded retrograde venography was carried out to identify the splenorenal shunt and the other outflowing vessels. The amount of sclerosing solution was

Figure 5 Contrast-enhanced CT 1 wk after catheter-directed thrombolysis and BROTO. **A:** Good patency of the portal vein (narrow arrow); **B:** Thrombosed splenorenal shunt (thick arrow).

determined from the volume of contrast material needed to fill these vessels. Preoperatively, 4000 U of haptoglobin (Mitsubishi Pharma, Osaka, Japan) was administered intravenously by drip infusion for the purpose of preventing a renal damage by hemolysis. A total of 10 mL of 5% (50 g/L) ethanolamine oleate iopamidol (EOI) was injected and remained stagnant in these vessels for a day during balloon occlusion. The following day, the balloon catheter was withdrawn after thrombosis of the splenorenal shunt was confirmed on contrast-enhanced CT (Figures 5A and B). The transhepatic catheter was subsequently removed using hemostatic microcoils for the transparenchymal tract without hemorrhagic complications. Six-month follow-up CT revealed good patency in the main portal vein.

DISCUSSION

Maddison^[9] first reported splenic embolization for hypersplenism in 1973. Spigos *et al*^[10] advocated partial splenic embolization (PSE) as an alternative method for the treatment of portal hypertension in 1979. PSE has been widely used for the treatment of portal hypertension and hypersplenism caused by IPH and liver cirrhosis since then^[1-3,9-11]. The aim of PSE is to decrease splenic blood flow and prevent platelet destruction in the spleen. An optimal increase in platelet count could be observed if a single procedure induces an infarct size of at least 60%-80% of the total spleen volume^[2,11]. Complications of PSE listed in the literature include local pain, ascites, pleural effusion, splenic abscess and also portal vein thrombosis (PVT) secondary to reduced blood flow in the splenic vein^[1-3]. Romano *et al*^[2] reported that no cases of PVT have been observed after PSE in patients with IPH. N'Kontchou *et al*^[3] reported that the incidence of PVT after PSE is 6.3% in patients with cirrhosis. Eguchi *et al*^[4] reported that the incidence of PVT after splenectomy is 25.0% in patients with IPH. PVT can occur with a higher incidence after splenectomy than after PSE.

PVT can occur due to other conditions including liver cirrhosis, IPH, direct invasion of neoplasm, hypercoagulable states, and inflammatory diseases such as pancreatitis and ulcerative colitis^[5,12,13]. PVT can result in intestinal ischemia and venous infarction in the acute stage. In the chronic stage, signs of portal hypertension such as esophageal varices, ascites, intestinal bleeding, liver atrophy, and liver failure become prominent^[12,13]. Management of acute

portal vein thrombosis is thus important. In our case, reduction of splenic blood flow due to PSE and outflow of the superior mesenteric vein (SMV) into the dilated PSS caused portal vein thrombosis.

The standard treatment for PVT is systemic thrombolysis with anticoagulants and local thrombolysis using interventional radiology (IVR) procedures^[13]. Urokinase (UK) has been used as a thrombolytic agent for PVT, but an enormous amount of UK is required for systemic use^[14], and often has no effect, as in our case. There are two IVR procedures to treat PVT: trans-arterial thrombolysis *via* the superior mesenteric artery (SMA) and catheter-directed thrombolysis^[15]. The angiographic method of trans-arterial thrombolysis is easy and involves only placement of a catheter into the SMA *via* the femoral artery^[16-18]. However, in our patient with remarkable portosystemic collaterals, UK would drain into hepatofugal collaterals and would not reach PVT easily. Local thrombolysis should be more effective for patients with PSS, since high concentrations of UK are directly infused into the PVT through a catheter. Access to catheter-directed thrombolysis is divided into two routes: the transhepatic route^[19-21] and the transjugular route^[22-24]. Uflacker^[24] emphasizes the advantages such as reduction of the possibility of intraabdominal bleeding and creation of adequate portal vein outflow by transjugular intrahepatic portosystemic shunt (TIPS) procedure. However, in our patient with complete portal vein occlusion and large PSS, additional and new creation of a portosystemic shunt can cause complications such as hepatic encephalopathy and hepatic failure^[25,26]. We therefore decided to use a transhepatic approach to treat PVT. The transhepatic approach is technically simpler than transjugular approach. This approach allows direct guidewire recanalization of the occluded portion and instillation of high concentrations of UK directly into the thrombus, and reduces the risks of systemic fibrinolysis. In this transhepatic approach there is a risk of uncontrollable bleeding through the transparenchymal tract after removal of the catheter especially in patients with coagulopathy^[27]. Avoiding such complications, complete transparenchymal tract embolization with microcoils or gelatin sponge after removal of the catheter is necessary to overcome intraabdominal bleeding. In our case, the transparenchymal tract was embolized with microcoils, and PVT was dissolved completely by transhepatic catheter-directed thrombolysis without hemorrhagic complications. We believe that local

thrombolytic therapy *via* transhepatic route should be considered as a feasible, efficacious and safe treatment.

In the present case, even after recanalization of the portal vein, the patient had stagnancy of portal blood flow with outflow of the SMV into the large PSS. Unless the blood flow to PSS is decreased to increase the portal blood flow, PVT may recur after dissolution. Concurrent BRTO was therefore performed to occlude the splenorenal shunt in our patient, and achieved long-term patency of the portal vein. There is no previous report describing the necessity for concurrent occlusion of portosystemic shunt after recanalization of PVT.

In conclusion, catheter-directed thrombolysis combined with BRTO is feasible and useful for recanalizing PVT and maintaining stable patency of the portal vein in patients with PVT.

INTRODUCTION

Lipomas are the most common nonepithelial benign tumors of the gastrointestinal tract. Nevertheless symptoms of a colonic lipoma are rare generally with a silent clinical course. When colonic lipomas achieve a proper size, they have manifestations such as change in bowel habits, rectal bleeding, abdominal pain or more disastrous consequences

like obstruction and intussusception requiring urgent interventions. Herein, we report four patients suffering from various sizes of colonic lipoma who were treated with different therapeutic modalities.

CASE REPORT

The first patient was a 77-year old female who presented with recurrent episodes of right upper quadrant abdominal cramping. Her physical examination and previous medical history were unremarkable except for a cholecystectomy. Standard laboratory values were within normal ranges. Abdominal computed tomography (CT) revealed a regular contoured 4 cm × 3 cm mass lesion with fatty density localized in the midportion of ascending colon causing a luminal narrowing defect (Figure 1A). In double contrast enema, a filling defect of the protruded polypoid lesion was detected at the same location (Figure 1B). Colonoscopy demonstrated a mass lesion with a broad base and normal overlying mucosa (about 4 cm in diameter) adjacent to the hepatic flexura. The patient was diagnosed having a symptomatic colonic lipoma during surgery. Following colotomy, mucosa overlying the mass lesion was dissected and a tumor with a macroscopic appearance similar to lipoma was enucleated (Figure 1C). Histopathologic examination verified the diagnosis of lipoma localized in the submucosal layer and the patient remained asymptomatic through a 2-year follow-up period.

The second patient was a 41-year old male admitted to our clinic with similar complaints of the first patient. Physical and laboratory examinations were natural only with a positive fecal occult blood test. He denied any significant medical or surgical history. Abdominal CT demonstrated a regular contoured 3 cm × 2 cm mass lesion with fatty density localized in the hepatic flexura causing a filling defect which was confirmed by double contrast enema (Figure 2A). A segmental resection was performed with the diagnosis of lipoma, pathological evaluation of the specimen showed that it was a benign submucosal lipoma (Figure 2B).

The third patient was a 77-year old female presented with recurrent abdominal pain in the left lower quadrant for a year, bloody defecation for 6 mo and constipation for 4 wk. Physical examination revealed no pathological change except for left lower quadrant distention. Blood biochemical analysis, sedimentation rate and complete blood count were normal. Colonoscopy revealed a broad-

Figure 1 Computed tomography (CT) scan showing a regular contoured 4 cm x 3 cm lesion with fatty density localised in midportion of ascending colon causing a luminal narrowing defect (A), double contrast barium enema showing a filling defect of the protruded polypoid lesion at the hepatic flexura of colon (B), and appearance of the colonic submucosal lipoma during the operation (C).

Figure 2 A mass lesion located in the hepatic flexura causing filling defect shown by double contrast enema (A), resected biopsy specimen showing a submucosal benign lipoma composed of mature lipocytes by hematoxylin and eosin staining (B) (x 400).

Figure 3 Colonoscopic appearance of a broad-based giant mass acquiring spontaneous hemorrhagic areas and obstructing more than 75% of the lumen of sigmoid colon (A); abdominal computed tomography scans showing the diffuse thickening of sigmoid colon wall, invagination and a distal intraluminal giant mass with fat density with a size of approximately 6 cm x 7 cm (B); macroscopic appearance of the giant sigmoid colon lipoma (C).

based giant mass acquiring spontaneous hemorrhagic areas and obstructing more than 75% of the colonic lumen (Figure 3A). Punch biopsy exhibited benign colonic mucosa showing inflammatory granulation. Abdominal CT showed diffuse thickening of the sigmoid colon wall, invagination and an intraluminal mass with a size of approximately 6 cm x 7 cm having density values equal to fat (Figure 3B). An evident sigmoid redundancy and a mass lesion nearly obliterating colonic lumen were detected during surgery. A segmenter resection of the sigmoid colon was the operative procedure of choice (Figure 3C). Microscopic examination confirmed that the lesion was a submucosal lipoma with a size of 6 cm x 7 cm.

The fourth patient was a 44-year old male presented with tenesmus. Physical examination revealed nothing significant. A pedunculated polypoid mass lesion projecting into the lumen with an approximate diameter of 2.5 cm was discovered at the 15th cm of the rectum by colonoscopy. An endoscopic snare polypectomy and rectal biopsy were performed during the same intervention. The histopathologic examination revealed normal rectal mucosa and underlocated lipoma.

DISCUSSION

Lipoma of the gastrointestinal tract was first described by

Bauer *et al*^[1] in 1757. Lipoma is the second most common benign colonic tumor following adenomatous polyps and the incidence has been reported to range between 0.2% and 4.4%^[2,3]. Colonic lipoma is more common in elderly women and tends to derive from right hemicolon with a decreasing frequency from cecum to sigmoid colon^[2-5]. Approximately in 90% of cases, lipoma is defined to arise from the submucosal layer and the subserosal or intermucosal layer accounting for the remaining 10%^[1,6]. They are usually solitary with varying sizes and may be sessile or pedunculated. Although the majority of these lesions are asymptomatic and detected incidentally during the examination of symptoms like abdominal pain, change in bowel habits, and rectal bleeding or in surgical specimen removed for various other reasons, on rare occasions colonic lipoma may present with massive hemorrhage, obstruction, perforation, intussusception, or prolapse^[7-11]. Severity of the signs and symptoms is attributed to the size of the lesions. Lipomas larger than 2 cm in diameter may cause symptoms such as constipation, diarrhea, abdominal pain, or rectal bleeding^[1,3,5]. Colicky pain may be due to intermittent intussusception whereas rectal bleeding can occur as a result of ulceration of the overlying mucosa. One of the greatest clinical significances of lipoma is its potential to be confused with colonic malignancies according to the similarity in both symptomatology, fortunately sarcomatous changes in colonic lipomas have not been reported yet^[1]. Colonoscopy, CT and barium enema are considered to be the diagnostic tools, but physicians should be aware that colonoscopic biopsies usually possess no histopathologic value as the lesion is beneath the normal mucosa and biopsy often can not promote diagnosis^[12]. The radiographic appearance of colonic lipomas may resemble that of carcinomas. The “squeeze sign” is told to be pathognomonic for colonic lipomas, and is characterized by the elongation of a spherical filling defect during peristalsis on barium enema examination^[1,13]. Despite recent diagnostic innovations in radiology, histopathologic evaluation is the gold standard in precise diagnosis. However, most colonic lipomas are asymptomatic incidental entities, the decision of removal is based on the criteria including those with suspicion of malignancy, and symptomatic lipomas. A wide range of treatment modalities have been suggested. The way of removal depends on the presentation of the case as an elective or an emergency. Surgical intervention is mandatory in surgical emergencies such as obstruction, intussusception, perforation, or very rarely massive hemorrhage. Elective endoscopic removal of submucosal lipoma up to 2 cm in diameter is reported to be safe and appropriate, however in larger lesions the risk of associated complications like uncontrolled hemorrhage and perforation makes the procedure controversial^[1,14-16]. Conventional laparotomy including enucleation, colotomy and excision, and segmental colonic resection has been described as a choice of treatment as well as minilaparotomy or transanal resection of lesions mimicking rectal prolapse^[1,7,16]. Minimally invasive surgeries such as laparoscopy-assisted re-

section under colonoscopic guidance has also been defined for selected cases^[15,17].

In the literature, the general consensus on colonic lipomas is that local enucleation is an appropriate and effective procedure of choice for the management of these lesions possessing no malignant potential. Colonoscopic removal can be safely performed for submucosal lipomas smaller than 2.5 cm in diameter, however larger or subserosal tumors associated with complication risks of obstruction, intussusception, hemorrhage and even perforation deserve extended interventions. Surgical approach should be established through the features of each case on individual basis.

Abstract

Disulfiram and calcium carbimide are two alcohol deterrents widely used in alcoholism treatment, however, there exist great concerns over their safety. Reports on hepatotoxicity, mainly related to disulfiram therapy, have been published. The hepatotoxic potential of calcium carbimide is less well characterized. Here, we describe four cases of liver damage related to this therapeutic group that were submitted to a Registry of hepatotoxicity and point out the limitations that we face when prescribing these compounds. A reassessment of the role of these compounds in the management of alcohol dependence is clearly needed.

INTRODUCTION

Disulfiram (tetraethylthiuram disulphide), an alcohol deterrent, is widely used in alcoholism treatment. Another

drug, calcium carbimide is less frequently prescribed and not on the market in many European countries, being commercialized in Australia, Canada, South Africa, Austria, Netherlands, Sweden and Spain, among others. These drugs produce physiological changes after ethanol consumption, which are sufficiently unpleasant to dissuade most alcoholics from further drinking. However, there exist great concerns over their safety. Both agents share a similar profile of adverse effects including dermatological and haematological reactions^[1]. Reports on hepatotoxicity, mainly related to disulfiram therapy and leading in some cases to fulminant liver failure, have been described^[2,3]. Indeed, in a recently published study by Björnsson & Ollson (2005) aimed to analyse the outcome of patients with severe drug-induced liver injury, disulfiram stood out as the second most commonly reported drug associated with mortality^[4]. Conversely, the hepatotoxic potential of the less prescribed calcium carbimide is not well recognized. We describe four cases of liver damage related to this therapeutic group that were submitted to a Registry of hepatotoxicity in work since 1994. The operational structure of the Registry, data recording and case ascertainment have been summarily reported elsewhere^[5]. Only cases considered drug-related by experts' clinical judgment were assessed by the Council for International Organizations of Medical Sciences scale (CIOMS scale)^[6], that provides a standardized scoring system according to the type of liver injury and based on six axes of decision-taking.

CASE REPORT

A 23-year-old man (patient 1) was prescribed calcium carbimide (120 mg/d) in July 1997. He was admitted to the hospital in August 1997 because of a week's history of fatigue, dark urine, and pruritus. Physical examination showed a pruriginous exanthema, marked jaundice, without any signs of chronic liver disease although he admitted an alcohol consumption of 80-100 g/d, and laboratory findings at presentation are shown in Table 1. Serology ruled out viral causes, screening for autoantibodies was negative and findings of an abdominal ultrasonographic examination were normal. A liver biopsy showed perivenular cholestasis and mild hepatobiliary damage. Liver tests were normal on 49 d after drug withdrawal. This case yielded 11 points when applying the CIOMS scale which fell into the category of highly probable.

A 39-year-old man (patient 2) on chronic alcohol con-

Table 1 Serum concentrations at time of presentation with calcium carbimide or disulfiram induced liver damage

Patient	Bilirubin (mg/L)		ALT (U/L)	AP (\times ULN)	Type of liver injury
	Total	Direct			
1	22.4	14.4	553	$\times 3.4$	Cholestatic hepatitis ¹
2	0.9	0.2	59	$\times 0.56$	PAS-positive ground glass hepatitis ¹
3	11.8	8.43	713	$\times 1.4$	Hepatocellular
4	27.1	16.72	1288	$\times 1.49$	Septal fibrosis and active Chronic hepatitis ¹

¹ Liver biopsy findings. Abbreviations: ALT, alanine aminotransferase ($n < 40$ U/L); AP, alkaline phosphatase; ULN, upper limit of normality; total bilirubin ($n < 1.2$ mg/dL). The ALT and AP values are these at presentation where as bilirubin values are the highest recorded.

sumption (110 g/d) was prescribed calcium carbimide (75 mg/d) for aversion therapy in February 1995. After 25 wk of treatment he was admitted to hospital because of an increase in serum transaminases, with a ratio of alanine aspartate and alanine aminotransferase of 1.05 (62/59, UL) (Table 1). The patient admitted alcohol abstinence for the previous 6 mo and during the course of the medical treatment. Physical examination disclosed hepatomegaly without any signs of chronic liver disease. Serology tests ruled out viral causes. Screening for autoantibodies produced negative results, and the results of an abdominal ultrasonographic examination were normal. A liver biopsy elicited ground-glass inclusion bodies in the hepatocytes associated with portal inflammation and fibrosis. The patient did not attend any further appointments.

A 42-year-old woman (patient 3) was prescribed venlafaxine (75 mg/d) and alprazolam (1.5 mg/d) for depression, and calcium carbimide (75 mg/d) since December 2002. Mean daily alcohol ingestion was 120 g/d that was stopped 45 d prior to admission. The results of prior liver function tests were normal. After 75 d of treatment she was admitted to hospital because of asthenia and fever, and a diagnosis of spontaneous bacterial peritonitis was made. Physical examination showed a jaundiced patient without stigmata of chronic liver disease. Serum chemistry indicated hepatocellular injury (Table 1) without evidence of viral causes. Over the next days she developed fulminant hepatic failure unresponsive to molecular adsorbent recirculating system (MARS) therapy which was unsuccessfully instituted three times and died on d 31 after hospitalization. This case yielded 6 points when applying the CIOMS scales which fell into the category of probable.

A 48-year-old man (patient 4) was admitted to hospital in August 2003 because of a five-day history of fatigue and dark urine one month after automedication with disulfiram (1000 mg/d). He had been taking phenytoin 200 mg/d for epilepsy for 5 years. He was a heavy alcohol drinker (> 80 g/d) and although he denied alcohol intake in the previous month he was actually an active consumer. Physical examination showed marked jaundice with signs of chronic liver disease. Serum chemistry indicated hepatocellular injury (Table 1). Screening for viral disease was negative and abdominal ultrasonographic examination

showed normal biliary ducts and moderate ascites. Liver biopsy revealed a chronic active hepatitis and septal fibrosis. Laboratory findings returned to previous baseline values 9 mo after drug withdrawal.

We described four cases of adverse liver reactions related to the use of calcium carbimide (3 cases) and disulfiram (1 case) because there was a temporal relationship between the administration of the drugs and the onset of hepatic abnormalities as well as between withdrawal of the drugs and improvement in liver dysfunction, the only exception being patient 3 who developed fulminant liver failure. In patient 2 de-challenge could not be ascertained because the patient was lost to follow up. Indeed, in this patient the increase in alanine aminotransferase was less than two times the upper limit of normal and since the biochemical expression of liver injury according to the International consensus criteria^[7] was a biological damage, causality assessment with the CIOMS scale was not performed. However, he presented in the liver specimen the hepatocyte inclusions seen only with calcium carbimide therapy along with fibrosis and lymphocyte portal inflammation characteristic of a chronic form of liver damage^[2,8].

On the other hand, causes of liver damage (viral, immunologic and metabolic) were ruled out. In patient 4, liver biopsy ruled out a diagnosis of alcoholic hepatitis. Patient 3 was prescribed venlafaxine which has been associated with non fatal cases of hepatotoxicity^[9].

The mechanism of aversion therapy-induced hepatotoxicity is presumed to be idiosyncratic. The absence of clinical features of hypersensitivity in these cases suggests that a toxic metabolite may be responsible, although an immune mechanism has been implicated in some cases^[3]. Both compounds are extensively metabolized in the liver and block the oxidation of alcohol at acetaldehyde stage increasing acetaldehyde blood levels. Therefore, their administration requires the agreement of the patient to stop drinking. In our series patient 4 self administered disulfiram while continuing drinking which could have rendered him at risk of severe medical complications. Furthermore, another concern related to the use of alcohol deterrents is the possibility of drug interactions. Actually, they may inhibit the metabolism of drugs such as phenytoin (CYP 2C19) and an interaction with the antidepressant venlafaxine cannot be discarded. Coadministration of aversive therapy with other drugs (antibiotics, amitriptyline, *etc.*) could aggravate/precipitate the disulfiram-alcohol reaction. It is not yet known whether associate medications might contribute to the hepatotoxic effect of these drugs^[1]. It is also important to highlight that since these compounds may be prescribed to patients with underlying alcoholic liver disease such as liver cirrhosis and alcoholic hepatitis (although they should be cautiously prescribed if at all in this population), the diagnosis of hepatotoxicity may go unrecognised.

In summary, these cases exemplify the main limitations of use that these two principal alcohol-sensitizing drugs present. Furthermore, since the efficacy of aversive therapy remains to be proved^[10], a reassessment of the role of these compounds in the management of alcohol dependence is clearly needed.

Abstract

Tailgut cyst is a rare congenital cystic lesion arising from the remnants of the embryonic postanal gut. It occurs exclusively within the retrorectal space and rarely in the perirenal area or in the subcutaneous tissue. A prerectal and retrovesical location of tailgut cyst is extremely rare. To the best of our knowledge, only three cases have been reported in the English literature. We experienced an unusual case of tailgut cyst developed in the prerectal and retrovesical space in a 14-year-old boy. Abdominal computed tomography demonstrated a prerectal cyst which was located at the anterolateral portion to the rectum. The cyst contained yellowish inspissated mucoid material. Microscopically, the cyst was lined by squamous, columnar, cuboidal and transitional epithelia and the wall was fibrotic with dispersed smooth muscle cells. Although tailgut cyst arising in prerectal area is extremely rare, its possibility should be considered in differential diagnosis of a prerectal and retrovesical cystic mass.

INTRODUCTION

Tailgut cyst, known as a retrorectal cystic hamartoma, is a rare congenital multicystic lesion arising from the remnants

of the embryonic postanal gut^[1-3]. It almost exclusively occurs within the retrorectal or presacral space^[4] and rarely in the perirenal area^[2,3,5], the subcutaneous tissue in the anorectal region^[6-9] and anterior to the rectum^[4,10]. The prerectal location of a tailgut cyst is extremely rare. To the best of our knowledge, only three cases have been reported in the English literature. Here we report an additional case of tailgut cyst arising in the prerectal and retrovesical space and review the relevant literature.

CASE REPORT

A 14-year-old boy presented with abdominal pain and dysuria for 2 d. Physical examination revealed suprapubic pain and tenderness. Routine laboratory tests including a complete blood count, electrolytes, and routine urine analysis were within normal limits. Abdominal computerized tomography demonstrated a well-demarcated oval-shaped cystic mass which was located at the prerectal and retrovesical space (Figure 1). He underwent explorative laparotomy for the definite diagnosis and treatment. Intra-operative finding showed that the cyst did not communicate with the prostate, bladder or rectum. Complete mass excision was performed. Macroscopic examination revealed an unilocular cyst measured 5 cm × 3 cm in cross diameter. The cyst showed a thickened fibrous wall and focal adhesion to the adjacent fibroadipose tissue. The cyst contained yellowish inspissated mucoid material. Microscopically, the cyst showed a variety of the lining epithelia including glandular, cuboidal, transitional and squamous epithelia (Figure 2). The cyst wall contained disorganized bundles of smooth muscle cells. The underlying stroma showed mild infiltration of chronic inflammatory cells. On immunohistochemical staining, prostate specific antigen (PSA) and neuroendocrine markers including chromogranin A were negative in the lining of the epithelial cells. The patient's recovery remained uneventful for 10 mo postoperation.

DISCUSSION

Tailgut cyst or retrorectal hamartoma, is a rare congenital multicystic lesion and is believed to originate from the remnant of the tailgut which is a primitive gut temporarily present at the caudal portion of the embryo^[2,3,8]. During its development the embryo possesses a true tail, reaching its largest diameter on the 35th d of gestation. The anus develops above the tail on the 56th d of gestation, by which time the latter has completely regressed. Remnants of the tailgut or neuroenteric cord may be the origin of tailgut

Figure 1 Abdominal computed tomography revealing an oval-shaped cyst with a thickened wall in anterolateral to the rectum.

Figure 2 Microscopically, the cyst wall showing a variety of lining epithelia including tall columnar or cuboidal (A), squamous (B), and transitional (C) epithelium (HE, x 200), the underlying stroma showing a mild infiltrate of chronic inflammatory cells, immunohistochemical staining showing negative prostate specific antigen in the lining of epithelial cells (D) (PAP, x 200).

cysts^[3,11].

Tailgut cyst can affect at any age but predominantly middle aged women. The female to male ratio is about 3:1. Half of them are asymptomatic and are frequently found on routine physical examination^[1,4]. Symptomatic patients present with abdominal pain, rectal bleeding, and rectal fullness^[2]. Complete surgical excision is necessary for accurate diagnosis and treatment, and prevents complications of the tailgut cyst, including infection, recurrence, and malignant transformation^[1]. Tailgut cyst is usually a well-circumscribed, soft, and multicystic or multilocated mass with adherent surrounding fibroadipose tissue. The varying-sized cysts contain clear serous or translucent mucoid fluids. Microscopically, the cysts are lined by a wide variety of epithelia varying from cyst to cyst, or even within the same cyst. Epithelia can be divided into the following types, such as the stratified squamous type, transitional and cuboidal type, stratified columnar type, ciliated pseudostratified columnar and gastric type. In most cases the cyst wall contains well-formed disorganized focal bundles of bland smooth muscle cells^[2,3].

Tailgut cyst occurs almost exclusively in the retrorectal

or presacral space. Infrequently, the cysts extend from the presacral space to involve the rectal wall and rarely extend laterally from the mid-line or into the postsacral space or lateral and anterior to the rectum^[4], but occur rarely in the perirenal area, the subcutaneous tissue in the anorectal region and anterior to the rectum^[2-10]. The prerectal location of tailgut cyst was noted in our patient. To the best of our knowledge, only three cases have been reported in the English literature^[4,10].

The main differential diagnoses of the prerectal tailgut cyst include the utricle cyst in the prostate, the rectal duplication and the simple cyst in the seminal vesicle. The prostatic utricle cyst, known as mullerian duct remnant, is a midline cyst of the prostate and also occurs in the prerectal or retrovesical area. Histologically, the cyst is lined with stratified columnar or cuboidal epithelium and continuous with the utricular wall. Immunohistochemically, the cyst lining epithelial cells show immunoreactivity for PSA and the neuroendocrine cells show immunoreactivity for chromogranin A^[12]. Duplication cyst is lined by epithelium similar to that of the gastrointestinal and respiratory tracts. The epithelium simulates normal mucosa of the gut. The main distinctive feature is a well-formed muscular wall overlying two layers of muscular bundles containing a nerve plexus^[2,3]. The simple cyst in the seminal vesicle is an unilocular cystic lesion located at lateral to the midline in the retrovesical area. The cyst is lined with a cuboidal or flattened epithelium with a fibrous wall of variable thickness. Characteristically, the fluid within the cyst contains sperm or sperm fragments^[13].

In conclusion, we report an unusual case of tailgut cyst arising in prerectal and retrovesical area in a 14-year-old boy. Although tailgut cyst arising in prerectal area is extremely rare, its possibility should be considered in differential diagnosis of a prerectal and retrovesical cystic mass.

Abstract

Cytomegalovirus enteritis is most usually associated with patients positive for human immunodeficiency virus or immunosuppressed transplant patients. The gastrointestinal tract may be affected anywhere from the esophagus to the colon, but the small bowel involvement is rare. We report a case of cytomegalovirus ileitis in an immunocompetent adult, which was confirmed by histopathologic findings through colonoscopic biopsy.

INTRODUCTION

Cytomegalovirus (CMV) is a β -group herpes virus and produces latent infection like other herpes viruses. Clinically significant CMV infection usually occurs in patients with immunosuppression, transplantations and acquired immune deficiency syndrome^[1]. In immunocompetent subjects, active infection is apparently rare, and the virus exhibits relatively low pathogenicity^[2]. We here describe a case of CMV ileitis without colon involvement in an immunocompetent subject.

CASE REPORT

A 63-year-old woman, with a one-day history of epigastric pain, was hospitalized at Ewha Womans University Hospital on Feb 16, 2006. She is a non-smoker and denied any medication or drug abuse.

On physical examination, the patient appeared to be acutely ill, with a blood pressure of 130/80 mmHg, heart

rate of 70 beats/min, respiratory rate of 20 breaths/min, and temperature of 37°C. The abdominal examination was notable for the presence of pain on the epigastric and the right lower quadrant areas with mild guarding but bowel sounds were normal. Laboratory values on admission were in normal range except elevated C-reactive protein.

The chest X-ray was normal. Abdominal computed tomography showed layering appearance of bowel wall and luminal dilatation from the distal jejunum to the pelvic ileal loop (Figure 1). The colonoscopy revealed scattered regions of geographic deep ulcerations and hyperemic edematous mucosa upon a background of normal mucosa in terminal ileum (Figure 2). We made differential diagnosis including nonspecific ileitis, Crohn's disease, tuberculosis induced ileitis and ischemic ileitis. Histological examination showed mild inflammation with lymphocytic infiltration without specific feature.

After the initial clinical and laboratory evaluation, the patient began therapy with intravenous antibiotics and fluids for the most probable diagnosis of nonspecific ileitis. During the admission, her clinical condition improved, and abdominal pain disappeared. Two weeks later, the follow up colonoscopy was performed. The ulcerations and hyperemic edematous lesions, which were previously noted on the terminal ileum, were much improved (Figure 3). The histological findings showed intranuclear and intracytoplasmic inclusions. Immunohistochemical stain for CMV showed scattered positive cells at the ulcer base (Figure 4). She was discharged without medication on March 7, 2006.

DISCUSSION

CMV is a member of the herpes virus family and is a prevalent pathogen, with 40 to 90 percent of the general population showing prior exposure by serology^[3]. Human CMV infection can be seen at all stages of life but most often affects those who are immunosuppressed and can commonly cause retinitis, pneumonitis or enteritis^[4]. Most primary CMV infections in immunologically healthy adults do not cause symptoms or are associated with a mild mononucleosis like syndrome^[5].

Gastrointestinal involvement in CMV infection is well known among immunocompromised patients. It is usually seen in advanced acquired immune deficiency syndrome with CD4 lymphocyte count less than 50 cells/mm³ and among transplant recipients as a reactivation of latent infection or rarely during primary infection^[6]. CMV colitis in immunocompetent individuals has been reported mainly in older patients, particularly those with other

Figure 1 Abdominal computed tomography on admission revealed layering appearance of bowel wall and luminal dilatation from the distal jejunum to the pelvic ileal loop.

Figure 3 Follow up colonoscopy was performed. The previously noted ulcers and hyperemic edematous lesion were improved.

Figure 2 Colonoscopy, performed on admission, revealed scattered regions of geographic ulcers and hyperemic edematous mucosa on the terminal ileum.

comorbidities, and is mostly community-acquired. This is likely a reflection of a weakened immune system, as a consequence of aging. Age-related dysfunctions of B and T cell lymphocytes, impaired cytokine, and perturbation of mucosal immunity are thought to contribute to a relative immunodeficiency in the elderly, predisposing them to various infectious and inflammatory diseases^[7].

Gastrointestinal tract may be affected anywhere from the mouth to the anus with the esophagus and colon being most common and small bowel relatively rare. The clinical manifestations of gastrointestinal CMV infection include gastrointestinal bleeding, abdominal pain, vomiting and diarrhea^[1,8]. Endoscopic findings of gastrointestinal CMV disease include erosions, ulceration and mucosal hemorrhage. The prototypical ulceration has a well-defined punched out appearance. The pathogenesis of CMV-induced ulceration is thought to involve ischemic mucosal injury secondary to infection of the vascular endothelial cells^[8,9].

CMV enteritis is remarkable for its ability to mimic many diseases, such as colitis caused by *C. difficile*, ischemia, malignant diseases of the colon and inflammatory bowel diseases. The diagnosis is made by the demonstration of the presence of CMV by routine histologic examination, culture or staining for CMV antigen or DNA^[10,11].

The primary therapy for clinically significant CMV

Figure 4 Pathologic findings. **A:** Enlargement of infected cells and intranuclear inclusions were noted (HE stain, $\times 100$); **B:** Immunohistochemical stain for CMV showed scattered positive cells.

infection is use of the antiviral drugs such as ganciclovir and foscarnet^[6,12]. Galiatsatos *et al*^[7] reported that spontaneous resolution occurred mainly in patients younger than 55 years of age, with no other comorbidities. They suggested that young, otherwise healthy, well-selected patients can improve without the need for antiviral therapy but immunocompromised patients and patients older than 55 years of age with comorbidities need antiviral therapy. Sakamoto *et al*^[13] thought that the administration of the antiviral agents is not always necessary for immunocompetent individuals.

In conclusion, we report a case of CMV ileitis not involving colon in an immunocompetent elderly adult who recovered without antiviral therapy.

INTRODUCTION

Pseudoachalasia is a disease entity usually associated with tumors causing obstruction at the gastroesophageal junction and producing abnormal esophageal motility mimicking an idiopathic achalasia^[1]. Idiopathic achalasia is a motility disorder of the esophagus characterized by aperistalsis and failure of the lower esophageal relaxation, resulting in symptoms such as dysphagia, regurgitation, chest pain and weight loss. The pathogenesis of idiopathic achalasia is due to the selective loss of inhibitory neuron of the myenteric plexus which produces vasoactive intestinal polypeptide (VIP), nitric oxide and inflammatory infiltration and is responsible for the unopposed excitation of lower esophageal sphincter (LES)^[2-4], thereby causing dysfunction or failure of the LES relaxation in response to each swallow^[4,5]. The pathogenesis of pseudoachalasia is different from idiopathic achalasia. In pseudoachalasia, the proposed pathogenesis is considered as a mechanical obstruction of the distal esophagus or an infiltration of the malignancy that affects the inhibitory neurons of the myenteric plexus. Endoscopy and radiologic tests are often important in distinguishing between them, although the eventual diagnosis is made only by surgical explorations in the most cases. These both types of achalasia share the same manometric phenomenon of aperistalsis of the esophageal body and incomplete LES relaxation. However, one report suggested that patients with achalasia have autonomic nerve dysfunction in the vagal nerve outside the esophagus^[6]. Trauma to the gastroesophageal junction may potentially damage the vagus nerve, thereby leading to secondary achalasia. Most case reports on pseudoachalasia were tumor related, but implicated vagal nerve injury following surgery as a cause of achalasia^[8-10] still occurred. We report herein a reversible pseudoachalasia following the truncal vagotomy for pyloric obstruction, which was successfully treated by pneumatic dilations.

Abstract

Pseudoachalasia is a difficult condition for the clinician to differentiate from idiopathic achalasia even by manometry, radiological studies or endoscopy. Its etiology is usually associated with tumors. In most cases, the diagnosis is made after surgical explorations. The proposed pathogenesis of the disease is considered as mechanical obstruction of the distal esophagus or infiltration of the malignancy that affects the inhibitory neurons of the myenteric plexus in the majority of cases. Surgery has been reported as a cause of pseudoachalasia. We report a 70-year-old man who suffered from deglutination disorder caused by pseudo-achalasia after truncal vagotomy. The patient was symptom-free after a nine-year follow-up and complete recovery of esophageal motility status from pseudoachalasia after pneumatic dilations. We also reviewed the literature of pseudoachalasia.

CASE REPORT

A 70-year-old male, suffered from repeated peptic ulcer bleeding for at least 10 years, developed progressive symptoms of post-prandial vomiting in October 1996.

Figure 1 A: Barium esophagography and upper gastrointestinal series showing an intact gastroesophageal junction; B: dilated distal esophageal lumen with food retention and narrowing of gastroesophageal junction after truncal vagotomy; C: barium esophagography showing a non-dilated esophageal lumen with smooth passage of contrast medium through gastroesophageal junction after pneumodilations.

Figure 2 Confirmation of achalasia by manometric findings of esophageal aperistalsis and incomplete relaxation of the lower esophageal sphincter during wet swallowing.

Figure 3 Manometric studies showing restoration of esophageal motility with normal peristalsis as a healthy subject after dilations.

A barium esophagogram and upper gastrointestinal series demonstrated an intact gastroesophageal junction (Figure 1A) and good esophageal peristalsis, but deformed gastric antrum and a deep ulceration. Malignancy was excluded by endoscopy biopsy. Under the condition of pyloric obstruction, he received a truncal vagotomy and pyloroplasty surgery. The month following surgery, the patient developed dysphagia, regurgitation of food. Endoscopy revealed food retention in the esophageal lumen and a tight gastroesophageal junction, thereby suggesting an achalasia. Barium esophagography showed a dilated distal esophageal lumen with food retention and narrowing of gastroesophageal junction (Figure 1B). Achalasia was confirmed using manometric findings of esophageal aperistalsis and incomplete relaxation of the lower esophageal sphincter during wet swallowing (Figure 2). Although the residual pressure was about 12 mmHg but the basal LES pressure was only about 25 mmHg. Achalasia caused by tumors was excluded by

computed tomography and endoscopic ultrasonography. The patient received two episodes of pneumatic dilatation. The symptoms gradually resolved within 4 mo after dilatation and the manometric studies showed restoration of esophageal peristalsis and normal swallowing relaxation (Figure 3). Barium esophagography showed a non-dilated esophageal lumen with smooth passage of contrast medium through gastroesophageal junction (Figure 1C). After nine years, the patient still remains symptom-free with a normal esophageal motility studies.

DISCUSSION

Pseudoachalasia or secondary achalasia is a motility disorder of the esophagus, and usually cannot be distinguished from primary achalasia^[1]. Approximately 2-4% of achalasia patients who fulfill the manometric criteria may develop in a malignant disease^[11]. The clinical spectrum of pseudoachalasia is almost the same

as idiopathic achalasia; both have progressive dysphagia, retrosternal pain, food regurgitation and weight loss. While the radiological findings show a dilated esophagus with "beak-like" distal end, there is aperistalsis of the esophageal body with an incomplete or non-relaxing lower esophageal sphincter on manometry studies in both groups of patients. Therefore, it is difficult for the clinician to distinguish pseudoachalasia from idiopathic achalasia. Pseudoachalasia has many etiologies, including tumor. Most of the patients with pseudoachalasia reported in the literature suffered from a primary or metastatic malignancy around the esophagogastric junction. Some are from benign diseases, such as pancreatic pseudocysts, mesenchymal tumors of the esophagus and mediastinal fibrosis^[11-15]. In rare instances, pseudoachalasia may be a complication of various surgeries, the majority being anti-reflux procedures, gastric banding and gastrectomy^[9,16,17]. Our case resulted as a complication from truncal vagotomy for pyloric obstruction.

The mechanisms of esophageal motor dysfunction in pseudoachalasia have been proposed as follows^[17]: (1) circumferential obstruction of the lower esophagus and/or LES; (2) infiltration of inhibitory neurons of the esophageal myenteric plexus by tumor cells; (3) neuronal degeneration distant from the primary tumor site with reduction in ganglion cells in the dorsal nucleus of the vagal nerve or in the vagal nerve itself; and (4) an interaction of tumor factors with the esophageal neuronal plexus without a direct infiltration of the esophagogastric junction (paraneoplastic).

Achalasia has been described following fundoplication and was attributed to vagal nerve damage during surgery^[18]. In patients who are found to have an achalasia-type motor dysfunction following anti-reflux surgery, Poulin *et al*^[7] suggested three additional explanations. In type 1, primary achalasia had been misdiagnosed, and dysphagia became obvious only after surgery. An alternative explanation for this type of achalasia may be the assumption of Spechler *et al*^[19] that achalasia may occasionally develop from underlying gastroesophageal reflux disease. Type 2 may be due to extensive development of scar tissue and/or an overly tight fundic wrap. In most instances, the motor abnormality disappears following dilation therapy or reconstruction of the fundoplication, as in our patient. Finally, in type 3, achalasia follows anti-reflux surgery after a more prolonged interval. In contrast to type 2, there is no stenosis or fibrosis of the esophagus or the periesophageal tissue, and myotomy is always an effective therapeutic strategy.

Shah *et al*^[20] reported that 25% of patients diagnosed with achalasia had a history of operative or non-operative trauma to the chest and/or upper gastrointestinal tract, compared with 9.5% of patients with dysphagia and normal manometry, thereby suggesting that, in some cases, operative and non-operative trauma may result in vagal disruption and lead to neuropathic dysfunction with the resultant development of achalasia^[20]. The mechanism of damage may not be the same as vagal transection. Vagal efferent fibers, with their cell bodies in the dorsal motor nucleus of the vagus nerve, have a crucial role in initiating and modulating esophageal peristalsis and lower

esophageal sphincter relaxation. Pathological analyses of operative and postmortem specimens from patients with achalasia have demonstrated abnormalities of both extrinsic and intrinsic innervations of the esophagus and LES. The majority of studies revealed a loss of ganglion cells from the dorsal motor nucleus of the vagus and demyelination of the vagal afferent fibers suggesting denervation^[21,22].

Neural control of the LES includes cholinergic and noncholinergic (or nonadrenergic) inhibitory pathways involving the presentation of nitric oxide, acetylcholine, and VIP. Nitric oxide plays an important role in mediating LES relaxation. Nitrergic neurons are present in the dorsal motor nucleus of the vagus, as the source of preganglionic motor neurons to the LES^[23]. Experimental inhibition of nitric oxide may produce a picture mimicking achalasia on manometry. An alternative explanation for post-traumatic achalasia may involve nitrergic pathways. By some mechanisms, trauma may impair the generation of nitric oxide, resulting in decreased inhibition of the lower esophageal sphincter and an abnormality in sequential relaxation of the body of the esophagus^[24].

Pneumatic dilation provides a safe, effective and relatively inexpensive option for achalasia treatment^[25,26]. The major adverse event caused by pneumatic dilations is esophageal perforation, with a 2%-6% cumulative rate^[25-27]. Less common complications are intramural hematoma, diverticula at gastric cardia, mucosal tears, reflux esophagitis, prolonged post-procedure chest pain, hematemesis without change in hematocrit, fever and angina^[25,26,28]. Pneumatic dilation for a malignancy-induced pseudoachalasia stenosis not only provides an ineffective treatment, but also delays adequate therapy of the underlying disorder. Surgery is the best treatment modality but the use of metallic stents is another therapeutic option for the unresectable ones^[29]. However, pneumatic dilation may improve the pseudoachalasia caused by benign etiology and may provide a complete recovery from stenosis as in our patient.

In summary, implicated vagal nerve injury following surgery can cause pseudoachalasia. The motor normality usually resolved following a therapeutic procedure, such as pneumatic dilation on the gastroesophageal junction. Further studies on comparing esophageal manometry and vagal integrity before and after surgery are required.

Abstract

Hepatic infarction rarely occurs due to the double supply of arterial and portal inflow. A 53-year-old man with diabetes mellitus developed multiple hepatic infarctions after an episode of fever and diarrhea. The infarction was documented by pathology after partial liver resection. Several causes of hepatic infarction may present in this patient: dehydration and hypotension caused by fever and diarrhea, type 2 diabetes and administration of glibenclamide, diabetic ketoacidosis and widespread atherosclerosis. We suggest that diabetic patient with elevated liver enzyme should be considered the possibility of hepatic infarction.

INTRODUCTION

Hepatic infarction is a rare event because of the dual blood supply of the portal vein and hepatic artery, and extensive hepatic arterial collateral system. It is characterized by parenchymal necrosis involving at least two entire lobules, accompanied by a local circulation insufficiency^[1].

Case reports of hepatic infarction in diabetes mellitus (DM) involved ketoacidosis^[2] and nephrotic syndrome^[3], in which upper abdominal pain was developed. We report a case of multiple hepatic infarction in diabetic patient, who

was misdiagnosed with hepatic carcinoma.

CASE REPORT

A 53-year-old man was admitted to the hospital because of fever complicated with diarrhea for 4 d. There was a 4-year history of diabetes mellitus without proper control, although he was treated with glibenclamide 2.5 mg bid. His past medical history included hypertension for 2 years with the highest blood pressure of 150/100 mmHg. The patient did not complain of upper abdominal pain.

At first, he was admitted to the emergency ward. Blood routine examinations showed: hemoglobin 142 g/L, red blood count $4.58 \times 10^{12}/L$, white blood count $11.7 \times 10^9/L$ with neutrophils 93.1%, platelet count $71 \times 10^9/L$, mean corpuscular hemoglobin concentration 402 g/L; urine tests: ketone (+), protein (\pm), glucose (+++); stool routine examination: white blood cell 2-4/HP. He was treated with antibiotics because of suspicion of intestinal infection. After his condition became relative stable, he was transferred to the general ward.

On admission, physical examination revealed no abnormalities except for a slight fever (37.3°C). A second blood routine examination revealed: hemoglobin 144 g/L, white blood count $8.4 \times 10^9/L$, platelet count $77 \times 10^9/L$; urine routine examination: ketone and protein were negative, glucose (+++); stool routine examination: white blood cell 2-4/HP; liver and renal function tests and blood lipid were normal; blood glucose 13.9 mmol/L; blood potassium 3.1 mmol/L, blood sodium 127.8 mmol/L, blood chlorine 98.9 mmol/L, CO₂ 19.7 mmol/L; coagulation function was normal. The chest X-ray and electrocardiogram showed normal.

Treatment was instituted with insulin, antibiotics, and other drugs to correct microcirculation and electrolyte disturbance. After admission into the general ward for 3 d, the patient had a normal temperature and stool. But abnormalities of liver function tests were found: aspartate aminotransferase 50 U/L (normal value, < 40 U/L) and alanine aminotransferase 65 U/L (normal value, < 40 U/L). Doppler ultrasound disclosed an enhanced echo in the liver, suggesting angioma or carcinoma. Liver computerized tomography showed an abnormal signal in the right lobe (Figure 1). On the ninth day, right hepatic wedge resection was performed and the pathologic diagnosis was multiple hepatic infarction with infection (Figure 2). One month after the operation, the patient had a good recovery.

Figure 1 A: Between the V and VIII segments, the right hepatic lobe near the surface has an abnormal signal which seems ellipse. In T₁WI, its center shows long T₁ and slight long T₁ intensity in row; B: In T₂WI, its center shows long T₂ and slightly long T₂ intensity in a row. It shows slight mass effect.

Figure 2 Pathologic section shows hepatic cell necrosis. Vasodilatation and infiltration of inflammatory cells are seen at the junction of necrosis and normal tissues (HE × 100).

DISCUSSION

The hepatic artery supplies about 35% of hepatic blood flow and 50% of the oxygen required by the liver, while the portal vein supplies the remainder^[3]. In addition, an extensive collateral system with 26 possible collateral arteries, and the hepatic arteries do not appear to be end arteries. These factors may explain why hepatic infarction is rare and usually requires impairment of both hepatic arterial and portal venous systems.

Hepatic infarction usually occurs when the hepatic artery or its branches are occluded or when the portal vein is thrombosed. Common cause of hepatic infarction is portal venous thrombosis, and hepatic infarction induced by isolated hepatic artery thrombosis is rare. Apart from vascular occlusion, other factors such as shock, sepsis, anaesthesia, biliary disease and diabetic ketoacidosis may result in hepatic infarction. Surgical factors, including abdominal surgery, laparoscopic surgery, liver transplantation, intra-arterial invasive procedures, transjugular intrahepatic portosystemic shunt, may be common causes of hepatic infarction in clinic^[3,4].

The mechanism of hepatic infarction in this case is unclear. The following factors may contribute to infarction: (1) An episode of fever and diarrhea should be considered to induce dehydration and hypotension, which further decreased both portal and hepatic arterial inflows. (2) Elevated level of catecholamine in diabetic ketoacidosis

might induce vasoconstriction causing ischemia and infarction^[2]. (3) Oral antidiabetic agent glibenclamide taken by the patient exerted splanchnic vasoconstricting effects, which might reduce portal venous inflow or impair hepatic arterial buffer response^[1]. (4) Widespread atherosclerosis is commonly seen in diabetic and hypertensive patients, and it may cause the thickening of blood vessels and arteriosclerosis. Abnormalities of hemodynamics, endothelial dysfunction and hypercoagulable state possibly leading to increased thrombosis and decreased fibrinolysis have been found in diabetic patients with angiopathy. These factors could contribute to the hepatic infarction in diabetes.

Hepatic infarction is usually accompanied by the outbreak of sudden upper abdominal pain, fever, elevated white blood cell count, and markedly elevated liver enzymes^[5]. Hyperglycemia may result in visceral autonomic nerve lesion and contribute to the insensitiveness to ischemic pain. This may explain why the patient did not feel abdominal pain.

Computerized tomography scan of upper abdomen in patients with hepatic infarction usually show a well-marginated peripheral zone without any contrast capture in the corresponding hepatic lobe, wedge-shaped and extending to the liver capsule^[4]. But in this case, liver computerized tomography scan exhibited untypical presentations, which led to the misdiagnosis of hepatic carcinoma and surgical operation and the diagnosis of hepatic infarction was finally established by liver pathology. MRI is the perfect method for the diagnosis of hepatic infarction because of its high resolution. In the early stage, the lesion shows slight long T₁ and slight long T₂ intensity. In the middle and late stages, it shows long T₁ and long T₂ intensity. The intensity is heterogeneous due to various degrees of ischemia and infarction in the lesion. Generally speaking, the center of lesion is more apparent than the rim and shows prominent abnormal intensity as in the present case. The lesion shows no apparent enhancement and slight mass effect, which is the primary differentiation feature from hepatic mass.

In summary, we suggest that the diabetic patient with elevated liver enzymes should be suspected much of hepatic infarction and further liver computerized tomography scan should be considered to exclude the diagnosis.

Abstract

Oxidized low density lipoprotein (ox-LDL) molecule is one of the most important modified lipoproteins produced during the oxidative stress. Modified lipoproteins have been defined as being part of the immune inflammatory mechanisms in association with oxidant stress. We have reported the accumulation of ox-LDL in Balb/c mice liver after bile duct ligation previously. Here, we investigated this finding in human beings with obstructive jaundice. Our study demonstrates that obstructive jaundice results in tremendous accumulation of ox-LDL in the liver tissue of patients.

TO THE EDITOR

Oxidized low density lipoprotein (ox-LDL) molecule is one of the most important modified lipoproteins. Its popularity has arisen after our understanding about its

key role in the pathogenesis of atherosclerosis^[1]. These molecules have been defined as being part of the immune inflammatory mechanisms in association with oxidant stress^[2]. Hepatocyte injury during obstructive jaundice is involved in such pathways associated with oxidant stress. This association has been testified also by us in Balb/c mice. Moreover, our study demonstrated that tremendous ox-LDL is accumulated in the liver after bile duct ligation in mice^[3]. Furthermore, we have investigated this finding in human beings with obstructive jaundice.

The study was composed of two groups. One group enrolled 11 patients with various causes of obstructive jaundice, 5 percutaneous and 6 intraoperative wedge-resection liver biopsies were taken from these patients. The other group included 7 patients undergoing elective abdominal operations without primary hepatobiliary pathologies. Wedge-resection type liver biopsies were taken from all these patients. Routine liver biochemical parameters including cholestatic liver enzymes were studied. In liver biopsies stained with hematoxylin and eosin, we investigated cholestatic findings. Moreover, a special immunofluorescent staining was done for investigation of ox-LDL in the liver tissue by fluorescent microscopy. All patients in group 1 demonstrated various degrees of cholestasis. The patients in group 2 showed neither cholestasis nor any histopathologic abnormality in the liver biopsy samples. First anti-ox-LDL antibody and fluorescence - stained anti-anti ox-LDL antibody were applied on liver tissue samples as previously described^[3]. The patients in group 1 were found to have enormous accumulation of ox-LDL in the liver (Figure 1A). No patient in group 2 demonstrated ox-LDL deposition (Figure 1B).

In this investigation, we clearly demonstrated retention of ox-LDL molecules in the liver tissue of human beings with obstructive jaundice, which was also found in our mice study. As demonstrated in our mice study, enhanced lipid peroxidation in the liver due to oxidative stress in association with obstructive jaundice has been clearly notified by many authors^[4,5]. A major and early lipid peroxidation product is ox-LDL which is mainly filtered by liver macrophages and Kupffer cells^[6]. During the jaundice period after biliary obstruction, ox-LDL accumulates in the liver either because of its decreased secretion into the bile or because of enhanced production due to lipid peroxidation as the filtration capacity of Kupffer cells becomes insufficient. It is well known that ox-LDL molecules have specific receptors on hepatocytes, Kupffer

Figure 1 Enormous accumulation of oxidized low-density lipoprotein in patients of group 1 (A) and no oxidized low-density lipoprotein deposition in patients of group 2 (B) (x 100).

and stellate cells^[2,7]. The interaction of ox-LDL with these cells can lead to apoptosis of hepatocytes, enhancement of tumor necrosis factor- α and secretion of transforming growth factor- β by Kupffer cells, as well as transformation of stellate cells into collagen secreting myofibroblasts^[2,7,8]. Thus, it seems theoretically possible that the main lipid peroxidation byproduct, ox-LDL, may have important roles in liver consequences of biliary jaundice. Our study results indicate a concrete fact that ox-LDL accumulates in human liver tissue during obstructive jaundice. Nevertheless, further investigation should be done for more detailed analysis of such accumulation and its role in liver outcomes of obstructive jaundice.

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (WJG, *World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly journal of more than 48 000 circulation, published on the 7th, 14th, 21st and 28th of every month.

Original Research, Clinical Trials, Reviews, Comments, and Case Reports in esophageal cancer, gastric cancer, colon cancer, liver cancer, viral liver diseases, etc., from all over the world are welcome on the condition that they have not been published previously and have not been submitted simultaneously elsewhere.

Indexed and abstracted in

Current Contents/Clinical Medicine and Science Citation Index-Expanded, *Index Medicus*, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, Nature Clinical Practice Gastroenterology and Hepatology, CAB Abstracts and Global Health.ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

Published by

The WJG Press

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297 mm × 210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, acknowledgements, References, Tables, Figures and Figure Legends. Neither the editors nor the Publisher is responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part without the written permission of both the authors and the Publisher. We reserve the right to put onto our website and copy-edit accepted manuscripts. Authors should also follow the guidelines for the care and use of laboratory animals of their institution or national animal welfare committee.

Authors should retain one copy of the text, tables, photographs and illustrations, as rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for the loss or damage to photographs and illustrations in mailing process.

Online submission

Online submission is strongly advised. Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/index.jsp>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. Authors encountering problems with the Online Submission System may send an email you describing the problem to wjg@wjgnet.com for assistance. If you submit your manuscript online, do not make a postal contribution. A repeated online submission for the same manuscript is strictly prohibited.

Postal submission

Send 3 duplicate hard copies of the full-text manuscript typed double-spaced on A4 (297 mm × 210 mm) white paper together with any original photographs or illustrations and a 3.5 inch computer diskette or CD-ROM containing an electronic copy of the manuscript including all the figures, graphs and tables in native Microsoft Word format or *.rtf format to:

Editorial Office

World Journal of Gastroenterology

Editorial Department: Apartment 1066, Yishou Garden,
58 North Langxinzhuan Road,
PO Box 2345, Beijing 100023, China
E-mail: wjg@wjgnet.com
<http://www.wjgnet.com>
Telephone: +86-10-85381901
Fax: +86-10-85381893

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using a word-processing software. All submissions must be typed in 1.5 line spacing and in word size 12 with ample margins. The letter font is

Tahoma. For authors from China, one copy of the Chinese translation of the manuscript is also required (excluding references). Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was accomplished, disclosure of any financial support for the research, and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (removing all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s) and full family name.

Abstract

An informative, structured abstract of no more than 250 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipments, and the experimental procedures should be included. RESULTS: The observatory and experimental results, including data, effects, outcome, etc. should be included. Authors should present *P* value where necessary, and the significant data should accompany. CONCLUSION: Accurate view and the value of the results should be included.

The format of structured abstracts is at: <http://www.wjgnet.com/wjg/help/11.doc>

Key words

Please list 6-10 key words that could reflect content of the study mainly from *Index Medicus*.

Text

For most article types, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include in appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both.

Illustrations

Figures should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. No detailed legend should be involved under the figures. This part should be added into the text where the figures are applicable. Digital images: black and white photographs should be scanned and saved in TIFF format at a resolution of 300 dpi; color images should be saved as CMYK (print files) but not as RGB (screen-viewing files). Place each photograph in a separate file. Print images: supply images of size no smaller than 126 mm × 76 mm printed on smooth surface paper; label the image by writing the Figure number and orientation using an arrow. Photomicrographs: indicate the original magnification and stain in the legend. Digital Drawings: supply files in EPS if created by freehand and illustrator, or TIFF from photoshops. EPS files must be accompanied by a version in native file format for editing purposes. Existing line drawings should be scanned at a resolution of 1200 dpi and as close as possible to the size where they will appear when printed. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes of atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...

Tables

Three-line tables should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each table. No detailed legend should be included under the tables. This part should be added into the text where the tables are applicable. The information should complement but not duplicate that contained in the text. Use one horizontal line under the title, a second under the column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. ^a*P*<0.05, ^b*P*<0.01 should be noted (*P*>0.05 should not be noted). If there are other series of *P* values, ^c*P*<0.05 and ^d*P*<0.01 are used. Third series of *P* values can be expressed as ^e*P*<0.05 and ^f*P*<0.01. Other notes in tables or under illustrations should be expressed as ¹*F*, ²*F*, ³*F*; or some other symbols with

a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, etc. in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions are included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should code the references according the citation order in text in Arabic numerals, put references codes in square brackets, superscript it at the end of citation content or the author name of the citation. For those citation content as the narrate part, the coding number and square brackets should be typeset normally. For example, Crohn's disease (CD) is associated with increased intestinal permeability^[1,2]. If references are directly cited in the text, they would be put together with the text, for example, from references [19,22-24], we know that...

When the authors code the references, please ensure that the order in text is the same as in reference part and also insure the spelling accuracy of the first author's name. Do not code the same citation twice.

PMID requirement

PMID roots in the abstract serial number indexed by PubMed (<http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed>). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information of the journal citations is very important. Through reference testing system (<http://www.wjgnet.com/cgi-bin/index.pl>), the authors and editor could check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in ASP file so that the readers can read the abstract of the citations online immediately.

Style for journal references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). Title of the cited article and italicized journal title (Journal title should be in its abbreviation form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634]

Note: The author should test the references through reference testing system (<http://www.aushome.cn/cgi-bin/index.pl>)

Style for book references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Morse SS. Factors in the emergence of infectious diseases. Emerg Infect Dis serial online, 1995-01-03, cited 1996-06-05; 1(1): 24 screens. Available from: URL: <http://www.cdc.gov/ncidod/EID/eid.htm>

Patent (list all authors)

- 16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those that are linked with a hyphen and the difference between the two numbers at two sides of the hyphen is more than 5. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered as inappropriate references. Authors should not cite their own unrelated published articles.

Statistical data

Present as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as γ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p*(B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5 µg/L; CO₂ volume fraction, 50 mL/L CO₂ not 5% CO₂; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format about how to accurately write common units and quantum is at: <http://www.wjgnet.com/wjg/help/15.doc>

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further mention.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kbo I*, *Kpn I*, etc.

Biology: *H pylori*, *E coli*, etc.

SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. Author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, the final check list for authors, and responses to reviewers by a courier (such as EMS) (submission of revised manuscript by e-mail or on the *WJG* Editorial Office Online System is NOT available at present).

Language evaluation

The language of a manuscript will be graded before sending for revision.

(1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing; (4) Grade D: rejected. The revised articles should be in grade B or grade A.

Copyright assignment form

Please download CAF from <http://www.wjgnet.com/wjg/help/9.doc>.

We certify that the material contained in this manuscript:

Ms:

Title:

is original, except when appropriately referenced to other sources, and that written permission has been granted by any existing copyright holders. We agree to transfer to *WJG* all rights of our manuscript, including: (1) all copyright ownership in all print and electronic formats; (2) the right to grant permission to republish or reprint the stated material in whole or in part, with or without a fee; (3) the right to print copies for free distribution or sale; (4) the right to republish the stated material in a collection of articles or in any other format. We also agree that our article be put on the Internet.

Criteria for authorship: The *WJG* requests and publishes information about contributions of each author named to the submitted study. Authorship credit should be based on (1) direct participation in the study, including substantial contributions to conception and design of study, or acquisition of data, or analysis and interpretation of data; (2) manuscript writing, including drafting the article, or revising it critically for important intellectual content; (3) supportive work, including statistical analysis of data, or acquisition of funding, or administration, technology and materials support, or supervision, or supportive contributions. Authors should meet at least one of the three conditions. The *WJG* does not publish co-first authors and co-corresponding authors.

We hereby assign copyright transfer to *WJG* if this paper is accepted.

Author Name in full (Full names should be provided, with first name first, followed by middle names and family name at the last, eg, Eamonn MM Quigley). Handwritten names are not accepted.

Author Name in abbreviation (Family name is put first in full, followed by middle names and first name in abbreviation with first letter in capital, eg, Quigley EMM). Handwritten names are not accepted.

Final check list for authors

The format is at: <http://www.wjgnet.com/wjg/help/13.doc>

Responses to reviewers

Please revise your article according to the comments/suggestions of reviewers. The format for responses to the reviewers' comments is at: <http://www.wjgnet.com/wjg/help/10.doc>

Abstract

Infection with *H pylori* is the most important known etiological factor associated with gastric cancer. While colonization of the gastric mucosa with *H pylori* results in active and chronic gastritis in virtually all individuals infected, the likelihood of developing gastric cancer depends on environmental, bacterial virulence and host specific factors. The majority of all gastric cancer cases are attributable to *H pylori* infection and therefore theoretically preventable. There is evidence from animal models that eradication of *H pylori* at an early time point can prevent gastric cancer development. However, randomized clinical trials exploring the prophylactic effect of *H pylori* eradication on the incidence of gastric cancer in humans remain sparse and have yielded conflicting results. Better markers for the identification of patients at risk for *H pylori* induced gastric malignancy are needed to allow the development of a more efficient public eradication strategy. Meanwhile, screening and treatment of *H pylori* in first-degree relatives of gastric cancer patients as well as certain high-risk populations might be beneficial.

INTRODUCTION

Despite decreasing incidence and mortality rates, gastric cancer remains the second most frequent malignancy worldwide, with the majority of cases diagnosed at an advanced stage^[1]. A number of environmental factors, e.g.

diets high in salt and N-nitrosamines and low in fruits and vegetables have been shown to contribute to gastric cancer development^[2]. Furthermore, it is now well recognized that chronic infection with *H pylori* is tightly associated with the development of gastric cancer, primarily noncardiac gastric cancer. The clinical course of *H pylori* infection is highly variable and the likelihood of developing gastric cancer is determined by both microbial and host factors (Figure 1). Based on the large number of experimental and epidemiological studies, it seems reasonable to conclude that the eradication of *H pylori* should prevent gastric cancer. However, convincing results from clinical trials are not yet available. Hence, current clinical decision-making has to be based on indirect evidence: data from animal models and studies supporting the beneficial effect of eradication on the development of gastric cancer precursor lesions^[3]. This article reviews the existing evidence that *H pylori* eradication prevents gastric cancer with a highlight on recent publications relevant for the clinician.

PATHOGENESIS AND EPIDEMIOLOGY

Pathogenesis

According to Correa's model, gastric cancer development is a multistep process where the gastric mucosa is slowly transformed from normal epithelium to chronic gastritis, to multifocal atrophy, to intestinal metaplasia of various degrees, to dysplasia and finally to invasive cancer^[4]. However, this sequence of events does not precede diffuse type gastric cancer and has even been debated for the intestinal type^[5] since less than 10% of patients with these lesions ultimately develop gastric cancer^[6]. Most *H pylori* infected individuals show antral predominant gastritis, which predisposes them to duodenal ulcers, but rarely causes gastric cancer. On the contrary, patients with corpus-predominant gastritis are likely to develop gastric ulcers, gastric atrophy, intestinal metaplasia and eventually gastric cancer. Our group, among others, has found that the pattern and the morphological distribution of gastritis correlate strongly with the gastric cancer risk^[7,8]. We showed that the expression of *H pylori* associated gastritis in patients with gastric cancer is high in the corpus and is frequently associated with intestinal metaplasia and atrophy^[9]. Based on these findings we developed a gastric carcinoma risk index, which evaluates grade and activity of corpus-dominant *H pylori* gastritis as well as the occurrence of intestinal metaplasia in the antrum or corpus to determine a patient's risk for developing gastric carcinoma^[10]. In a subsequent case control study, the gastric carcinoma risk index had a sensitivity of 93% and a specificity of 85% for diagnosing individuals with gastric carcinoma^[11].

Epidemiology

Infection with *H. pylori* occurs worldwide, but the prevalence varies greatly among countries and among different populations within the same country^[12]. The overall prevalence of *H. pylori* infection is closely linked to current socioeconomic conditions^[13]. Although the incidence of the infection in industrialized countries has decreased substantially over recent decades, it will remain endemic for at least another century, unless intervention occurs^[14]. In the early 1990s a series of prospective case control studies^[15-18] demonstrated a close link between *H. pylori* infection and gastric cancer, which prompted the World Health Organization to announce the bacterium a class I (definite) carcinogen in 1994. Since then data from various studies have accumulated that further strengthen the association between *H. pylori* infection and gastric cancer. One of the most compelling studies was conducted in Japan, where Uemura *et al*^[19] prospectively followed 1526 patients over a period of 7.8 years. A total of 2.9 percent of *H. pylori* infected individuals developed gastric cancer compared to none in the *H. pylori* negative control group. Among individuals with *H. pylori* infection, those with severe gastric atrophy (odds ratio: 4.9), corpus-predominant gastritis (odds ratio: 34.5) and intestinal metaplasia were at significantly higher risk for gastric cancer.

According to most retrospective, cohort and case control studies, the overall odds ratio for *H. pylori* infection and gastric cancer is around two to six^[19-23]. However, these numbers are likely to represent a gross underestimation of the real risk. Among the confounding factors that make risk appear lower in most studies are the long latency between the initiation of the carcinogenetic process and the clinical occurrence of cancer as well as the inclusion of individuals with antral predominant/duodenal ulcer phenotype^[24]. If selection of patients and methodology is optimized, the odds ratio for *H. pylori* infected individuals may increase to a factor of around 20^[25-27].

RISK FACTORS

Bacterial virulence factors

H. pylori displays a considerable amount of genetic variation. Even strains within an individual host commonly change over the course of the infection^[28,29]. A number of bacterial virulence factors have been discovered that influence disease outcome in infected individuals. The majority of *H. pylori* strains express and secrete VacA, a vacuolating cytotoxin, which is inserted into the gastric epithelial-cell and mitochondrial membranes, possibly providing the bacterium with nutrients and inducing apoptosis of the host cell^[12,30]. VacA has also been found to modulate the host immune system *via* T-cell inhibition^[31,32]. Studies indicate that expression of VacA increases bacterial fitness and in some western countries VacA *s1* and VacA *m1* genotypes are associated with more severe forms of gastritis, atrophy, intestinal metaplasia and perhaps gastric cancer^[33-36]. Another major focus of research is the analysis of the *cag* pathogenicity island (*cag PAI*), a genomic fragment comprising 31 genes that support the translocation of the 120-kD CagA protein

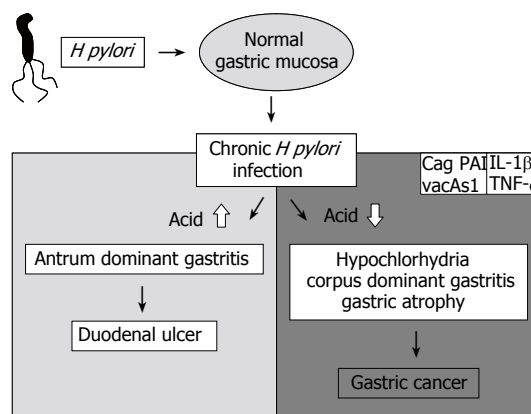

Figure 1 Variable course of *H. pylori* infection.

into the gastric epithelial cell^[37,38]. CagA has been shown to induce cytokine production along with a growth factor-like response in the host cell and to disrupt the junction-mediated gastric epithelial cell barrier function^[39,40]. In western countries, patients carrying CagA+ *H. pylori* strains are more likely to develop adenocarcinomas of the distal stomach than patients infected with CagA- strains^[41]. In particular, one recent meta-analysis of case-control studies concluded that infection with CagA+ strains increases the risk over *H. pylori* infection alone^[42]. However, similar findings are not reported from Asia, where about 95% of all infected individuals carry CagA+ strains^[3,43,44].

Host genetic factors

H. pylori leads to inflammation of the gastric mucosa in virtually all infected individuals. However, most *H. pylori* infected humans do not develop gastric cancer even if they are infected with so-called more virulent strains, indicating that host factors play a crucial role. The fact that first-degree relatives of gastric cancer patients have a significantly increased risk for developing gastric cancer compared to patients without a family history further emphasizes the importance of genetic factors. For example, our group found some important gastric cancer related genes to be more prevalent in the gastric mucosa of first-degree relatives^[45-49].

The infection with *H. pylori* triggers an extensive systemic and local inflammatory response. Gastric epithelial cells respond by producing enhanced levels of interleukin-1β, interleukin-2, interleukin-6, interleukin-8 and tumor-necrosis-factor-α^[50-52]. El-Omar and co-workers were the first to show that patients with certain Interleukin-1 gene cluster polymorphisms, which lead to enhanced production of the proinflammatory cytokine IL-1β are at increased risk for *H. pylori* induced hypochlorhydria and gastric cancer^[53]. Further studies found that proinflammatory polymorphisms of the IL-1 receptor antagonist, tumor necrosis factor-α and IL-10 are also associated with an increased risk for the development of noncardia gastric adenocarcinoma^[54,55]. Interestingly, the combination of pro-inflammatory polymorphisms in the interleukin-1β gene and infection with more virulent *H. pylori* strains seems to increase the gastric cancer risk even more^[56]. Most of the important studies exploring host

Table 1 Gastric cancer prevention studies

Study	Design	Follow-up	Patients	Treatment	Outcome
Uemura <i>et al</i> 1997	Nonrandomized intervention trial	2 yr	132 Japanese patients with endoscopically removed early stage gastric cancer and <i>H. pylori</i> infection	<i>H. pylori</i> eradication therapy or no treatment	Reduced rate of gastric cancer development after eradication of <i>H. pylori</i>
Saito <i>et al</i> 2000	Nonrandomized intervention trial	2 yr	64 Japanese patients with gastric adenoma and <i>H. pylori</i> infection	<i>H. pylori</i> eradication therapy or no treatment	Reduced rate of metachronous gastric cancer development after eradication of <i>H. pylori</i>
Correa <i>et al</i> 2000	Prospective, randomized, placebo controlled trial	6 yr	852 individuals from a high risk region in Colombia with <i>H. pylori</i> infection and precancerous lesions	<i>H. pylori</i> eradication therapy and/or ascorbic acid/beta-carotene or placebo	Significant increase in the rate of regression of precursor conditions after cure of <i>H. pylori</i> and/or treatment with dietary supplements
Wong <i>et al</i> 2004	Prospective, randomized, placebo controlled trial	8 yr	1630 individuals from a high risk region in China with <i>H. pylori</i> infection; with or without precancerous lesions	<i>H. pylori</i> eradication therapy or placebo	Significant reduction in gastric cancer risk after cure of <i>H. pylori</i> only for patients without precancerous conditions
Take <i>et al</i> 2005	Nonrandomized intervention trial	3.4 yr	1342 Japanese patients with peptic ulcer disease	<i>H. pylori</i> eradication therapy	Significant increase in gastric cancer risk for patients with persistent <i>H. pylori</i> infection

genetics were performed in Caucasian populations and still need to be confirmed in other ethnic groups^[3]. However, there is emerging evidence that similar associations can be found in Asian populations. For example, one study from Japan showed that proinflammatory IL-1 β polymorphisms in *H. pylori* infected Japanese individuals are significantly associated with hypochlorhydria and atrophic gastritis^[57]. Recent data by Goto *et al*^[58] also indicate that a common polymorphism in the coding gene for SHP-2 that interacts with the CagA protein can increase the risk for gastric atrophy in Japanese patients infected with CagA+ *H. pylori* strains. The authors speculate that this might explain why only a proportion of CagA+ individuals develop gastric atrophy even though this strain is almost universal in Asian countries.

IN VIVO STUDIES

Animal models

A number of animal models have been developed to study the mechanisms by which *H. pylori* induces gastric carcinogenesis. Using the Mongolian gerbil model, several studies provided evidence that *H. pylori* infection is in fact a potent carcinogen and able to induce gastric cancer by itself^[59-62]. The studies by Watanabe *et al*^[59] and Honda *et al*^[60] found that 37% and 40% of infected animals developed well-differentiated intestinal adenocarcinomas 62 and 72 wk after inoculation of the bacterium. Both studies used *cagA* and *vacA* positive *H. pylori* strains for infection of the animals. The risk of gastric carcinogenesis in Mongolian gerbils increases significantly through combination of *H. pylori* infection with other known carcinogens such as N-methyl-N-nitrosourea (NMU) and N-methyl-N-nitro-N-nitrosoguanidine (MNNG)^[63-65]. Studies using *H. pylori* or *H. felis* infected mice found that the gastric cancer development is strongly determined by host specific factors, for example specific patterns of immune response. Some mouse strains develop a vigorous

Th-1 response to the infection while others have a predominant Th-2 immune response and seem to be more resistant to mucosal damage. Those with the strong TH-1 response continue to develop atrophy, metaplasia and eventually invasive cancer in a gender specific manner^[66].

There is evidence from animal models, that eradication of *H. pylori* is able to prevent gastric carcinogenesis. The incidence of gastric adenocarcinoma in nitrosamine administered Mongolian gerbils with *H. pylori* infection was significantly lower in animals receiving *H. pylori* eradication^[67,68]. Mouse models have also provided important evidence of beneficial effects from the administration of anti-inflammatory drugs, where atrophy and metaplasia have been reversed, in some cases completely^[69].

Clinical studies

Cure of *H. pylori* infection results in several physiologic effects that are likely to reduce gastric cancer risk. These include reduction in cell turnover, elimination of DNA damage by a reduction of reactive oxygen species, increased gastric acid secretory capacity and restoration of ascorbic acid secretion into the gastric juice^[1,70,71]. However, evidence from well-designed clinical studies supporting the cancer protective effect of *H. pylori* eradication remains sparse (Table 1). Among the first clinical data to support the hypothesis that *H. pylori* eradication is able to prevent gastric cancer development were case-control studies from Sweden on patients undergoing hip replacement procedures. Akre *et al*^[72] showed that significantly reduced rates of gastric cancer occurred in such patients who frequently receive high doses of prophylactic antibiotics, incidentally eradicating *H. pylori* infection. As discussed earlier in this review, the study by Uemura *et al*^[19] provides some of the strongest evidence for the causative role of *H. pylori* infection in gastric cancer development. Here, gastric cancer developed in 2.9% of all *H. pylori* infected patients compared with 0% of those without infection. Notably,

no case of cancer developed in a subgroup of 253 *H pylori* infected patients who received eradication therapy at an early time point after enrollment in the study. The same group of investigators found that eradication of *H pylori* was able to prevent relapse after endoscopic resection of early stage gastric cancer^[73]. Another study by Saito *et al*^[74] showed that *H pylori* eradication had a favorable impact on gastric cancer development in patients with gastric adenoma. More recently, Take *et al*^[75] published the results from a large prospective Japanese intervention trial. The authors endoscopically followed 1342 patients with peptic ulcer disease for a mean period of 3.4 years. All patients initially received *H pylori* eradication therapy. The risk of developing gastric cancer was significantly higher in the group of patients who failed eradication therapy compared to those who were cured for the infection.

The first prospective randomized controlled study to examine the effect of *H pylori* eradication on gastric cancer development was published by Wong *et al*^[76] in 2004. The authors randomized 1630 individuals from a high-risk region in China with confirmed *H pylori* infection to eradication therapy or placebo. After a follow-up period of 7.5 years, they found no difference in gastric cancer incidence between those receiving *H pylori* eradication therapy and those who were not given treatment (7 *vs* 11 cases, *P* = 0.33). However, further subgroup analysis of the data demonstrated a significant benefit (*P* = 0.02) from eradication therapy in patients without baseline intestinal metaplasia at the time of study enrollment.

Unfortunately, several international prospective randomized controlled trials, designed to evaluate the long-term effect of *H pylori* eradication on gastric cancer development had to be abandoned. For example, the PRISMA study^[77], initiated in 1998 by our group to test the effect of *H pylori* eradication therapy in a high-risk population in Germany and Austria was discontinued due to insufficient recruiting. As might be expected, most eligible patients for those studies are not willing to enter the placebo arm after the nature of such a trial has been explained to them. Apart from ethical issues, the required follow-up time of 10 to 20 years for these trials remains an additional problem. A growing number of studies are therefore using surrogate markers for gastric cancer development, namely gastric atrophy and intestinal metaplasia as primary study endpoints.

There is consistent evidence that *H pylori* eradication cures gastritis and numerous studies have shown that atrophy and metaplasia do not progress in patients after *H pylori* eradication compared to control groups who remain *H pylori* positive^[78-86]. However, many of the available studies addressing the reversibility of gastric atrophy and intestinal metaplasia have yielded conflicting and inconsistent results, possibly because most of them are nonrandomized, not controlled, have short follow-up periods and only include small numbers of patients^[1,3]. One of the few randomized controlled trials for the prevention of gastric dysplasia was conducted by Correa *et al*^[87] in 2000. The authors found significant regression of gastric atrophy and intestinal metaplasia after *H pylori* eradication alone and in combination with β -carotene and ascorbic acid. Sung *et al*^[88] prospectively followed a total

of 587 *H pylori* infected patients, randomized to receive either eradication therapy or placebo, endoscopically for one year. Decrease in acute and chronic gastritis was significantly more frequent after *H pylori* eradication, but after the relatively short follow-up period, changes in intestinal metaplasia were similar between the two groups. The majority of available studies suggest, however, that regression of atrophic gastritis and, to a lesser extent, intestinal metaplasia can occur at least in a subset of patients with sufficient follow-up^[3,89].

In conclusion, there is little randomized controlled trial evidence to suggest that *H pylori* eradication decreases the risk of gastric cancer development. However, regression of gastric cancer precursor lesions may occur in some patients. At present, there are no markers that help to predict such a response in the individual patient. Therefore, eradication at the earliest possible time point in the disease process seems favorable. The optimal age for testing of *H pylori* infection still needs to be determined but available data suggest that eradication at a younger age might be a more favorable approach. Future research has to focus on identification of host and bacterial specific markers that will help to predict the development of gastric cancer in the *H pylori* infected individuals. Better identification of individuals at high risk for gastric cancer will allow for more effective prevention and eradication strategies. Meanwhile, screening and treatment of *H pylori* in first-degree relatives of gastric cancer patients as well as certain high-risk populations might be beneficial.

Abstract

Recent advances in techniques of therapeutic endoscopy for stomach neoplasms are rapidly achieved. One of the major topics in this field is endoscopic submucosal dissection (ESD). ESD is a new endoscopic technique using cutting devices to remove the tumor by the following three steps: injecting fluid into the submucosa to elevate the tumor from the muscle layer, pre-cutting the surrounding mucosa of the tumor, and dissecting the connective tissue of the submucosa beneath the tumor. So the tumors are resectable in an *en bloc* fashion, regardless of the size, shape, coexisting ulcer, and location. Indication for ESD is strictly confined by two aspects: the possibility of nodal metastases and technical difficulty, which depends on the operators. Although long-term outcome data are still lacking, short-term outcomes of ESD are extremely favourable and laparotomy with gastrectomy is replaced with ESD in some parts of therapeutic strategy for early gastric cancer.

INTRODUCTION

Endoscopic resection of stomach neoplasms has been originated from the development of a polypectomy technique using the high-frequency current to gastric polyps in 1968^[1,2], and it has become popular as endoscopic mucosal

resection (EMR) since the birth of a strip biopsy method in 1984^[3] and a cap technique in 1993^[4]. Endoscopic submucosal dissection (ESD) technique is a new endoscopic treatment using cutting devices, which has developed from one of the EMR techniques, namely endoscopic resection after local injection of a solution of hypertonic saline-epinephrine (ERHSE)^[5]. ESD consists of the following three steps: injecting fluid into the submucosa to elevate the tumor, pre-cutting the surrounding mucosa of the tumor, and dissecting the connective tissue of the submucosa beneath the tumor^[6-10]. Major advantages of this technique in comparison with conventional EMR are as follows. The resected size and shape can be controlled, *en bloc* resection is possible even in a large tumor, and tumors with ulcerative findings are also resectable. So this technique can be applied to the resection of complex tumors such as large tumors, ulcerative non-lifting tumors, and recurrent tumors. The disadvantages of this technique are requirement of 2 or more assistants, time-consuming, much more bleeding and a little higher perforation rate than conventional EMR^[11]. It is still controversial whether the esophageal or colorectal neoplasms in an early stage should be resected in an *en bloc* fashion by using ESD, considering the technical difficulty, associated risks, and favorable outcomes by conventional EMR^[12-16]. However, in case of the stomach neoplasms, especially when large or ulcerative tumors are targeted as the subjects of endoscopic resection, necessity of *en bloc* resection is emphasized, because multi-fragmental resection causes insufficient histological evaluation and local recurrence of multi-fragmental resection becomes significantly higher than that of *en bloc* resection^[17]. So in Japan, ESD is now gaining acceptance as the standard endoscopic resection techniques for stomach neoplasms in an early stage, especially for large or ulcerative tumors.

INDICATION FOR ENDOSCOPIC SUBMUCOSAL DISSECTION

Although institutional differences in indications for endoscopic resection have existed for a long time, empirical indication for conventional EMR is differentiated-type of mucosal cancers without ulcerative findings, with ≤ 2 cm in size if elevated or ≤ 1 cm in size if depressed or flat^[18]. The Japanese Gastric Cancer Association issued their gastric cancer treatment guidelines in 2001, showing that differentiated-type of mucosal cancers without ulcerative findings, with ≤ 2 cm in size, regardless of the tumor morphology are practically indicated for endoscopic resection^[19]. These criteria are determined by considering two aspects: the conditions free of lymph node metastasis and

Table 1 Frequency of lymph node metastases in early gastric cancer^[20]

Criteria	Frequency (No. with metastasis/total number)	95% CI
Intramucosal cancer	0/1230	0-0.3%
differentiated adenocarcinoma, no lymphatic vascular invasion, irrespective of ulcer findings, tumor \leq 3 cm		
Intramucosal cancer	0/929	0-0.4%
differentiated adenocarcinoma, no lymphatic vascular invasion, without ulcer findings, irrespective of tumor size		
Intramucosal cancer	0/141	0-2.6%
undifferentiated adenocarcinoma, no lymphatic vascular invasion, without ulcer findings, tumor \leq 2 cm

differentiated adenocarcinoma, no lymphatic vascular invasion, irrespective of ulcer findings, tumor \leq 3 cm		

the probability of successful *en bloc* resection. If the technical problems are overcome, indication could be expanded for all tumors which have been elucidated as node-negative tumors in clinical trials (Table 1)^[20].

TECHNIQUES OF ENDOSCOPIC SUBMUCOSAL DISSECTION

ESD requires special cutting knives, such as a needle knife^[5], an insulation-tipped electrosurgical (IT) knife^[6,21-24], a hook knife^[25,26], a flex knife^[8-10], and a triangle-tip (TT) knife^[27,28], or special devices such as a small-caliber tip transparent (ST) hood^[29] (Figure 1). As another approach to successful ESD, investigations of submucosal injection solutions have been actively done. It was reported that a hyaluronic acid solution makes a better long-lasting submucosal cushion without tissue damage than other available solutions^[29-33]. As a further improvement of hyaluronic acid solution, usefulness of a mixture of high-molecular-weight hyaluronic acid, glycerin, and sugar has also been reported^[34,35]. A representative case of ESD procedure using a flex-knife and a mixture of high-molecular-weight hyaluronic acid, glycerin, and sugar is shown in Figure 2^[36].

Marking around the tumor

After chromoendoscopy using 0.25% indigo carmine to clarify the border of the tumor, circumferential markings are made by using a flex-knife, which is set to about 1 mm in length of the knife, at about 5 mm outside of the tumor with 2-mm intervals between each marking.

Submucosal injection

Solutions prepared for submucosal injection are a 10% glycerine with 0.9% NaCl plus 5% fructose solution (glyceol, Chugai Pharmaceutical co., Tokyo Japan) alone for small distal gastric tumors without ulcer findings and a mixture of glyceol and 1% 1900 ku hyaluronic acid preparation (suvenyl, Chugai Pharmaceutical co. Tokyo Japan) for complex or proximal gastric tumors. The mixing ratio of glyceol and suvenyl is 7:1 for complex or proximal gastric tumors. A small amount of epinephrine to make a concentration of 0.0005% is added to obtain vasoconstriction for hemostasis and indigo carmine is also added to find out the seeping area of the submucosal injection solution as operators' preference. Injection of these solutions is performed into the submucosal layer just outside the markings where mucosal incision intends to be made

Figure 1 Devices for ESD. **A:** Needle knife (KD-1L-1, Olympus, Tokyo, Japan); **B:** IT (KD-610L, Olympus, Tokyo, Japan); **C:** Hook knife (KD-620LR, Olympus, Tokyo, Japan); **D:** Flex knife (KD-630L, Olympus, Tokyo, Japan); **E:** TT knife (KD-640L, Olympus, Tokyo, Japan); **F:** ST hood (DH-15GR, 15CR, Fujinon Toshiba ES Systems, Tokyo, Japan).

at first. The volume of injection is about 2 mL once, and injection is repeated several times before starting mucosal incision until the targeted area is lifted enough. After exposure of the submucosal layer, injection is applicable from the exposed submucosal layer to lift up the submucosal layer intended to be cut.

Mucosal incision

After the tumor is lifted, mucosa outside the markings is incised circumferentially by using the same flex-knife, which is set to about 2 mm in length of the knife. The starting point for cutting is principally a distal part from the mouth. Retroflex position of the endoscope is usually used if applicable when the distal part of the tumor is cut.

Submucosal dissection

Small tumors can be resected by an electrosurgical snare only after mucosal incision around the markings without submucosal dissection. However, large tumors and tumors with ulcer findings or located in a tortuous area cannot be resected by an electrosurgical snare, dissecting the submucosa completely is thus needed. A flex-knife, which is set to about only 1 or 2 mm in length of the knife is also

Table 2 Outcomes of ESD

Techniques	En bloc resection rate %		Local recurrent rate %	Complication rate %

used for dissecting the submucosa. If the target to be dissected cannot be seen directly by any way, a transparent attachment on the tip of the endoscope is useful to stretch the connective tissue and improve the field of viewing in the submucosa. Because the submucosal cushion flattens down as time is passed, it is also important to start dissecting the submucosa immediately from the incising part of the mucosa before further marginal mucosal cutting and to inject the prepared solution into the submucosa repeatedly if a security cushion is necessary to be kept.

Effective control of bleeding during the procedure, especially in the step of submucosal dissection is important for safer, faster, and more reliable ESD. It is more desirable to prevent bleeding than to stop it after its occurrence. For vessels, which are smaller than the tip of the knife, non-contact electrocoagulation of the vessels with a flex-knife is usually enough to prevent or stop bleeding without changing to another device. Bleeding from large vessels also can be prevented or stopped by using a hemostatic forceps.

Management of post ESD ulcer

After total removal of the tumor, all visible vessels located in the post-ESD ulcer base are treated using hemostatic forceps. Finally, 20 mL of sucralfate liquid is sprayed using the outer sheath of a rotational endoscopic clip device to confirm the achievement of correct hemostasis and to coat the post-procedure ulcer base^[37].

Management after ESD

After ESD, patients are prohibited from eating and drinking until the next day of ESD. If laboratory findings and chest and abdominal X-ray remain unremarkable, the patients are permitted oral soft foods. Follow-up endoscopy is performed within 1 wk to check up post ESD ulcer healing before the patient is discharged from the ward. Proton pump inhibitor and sucralfate are administered until confirmation of healing of the post ESD ulcers. All patients with ESD also undergo a follow-up endoscopy 2 mo after ESD to confirm the healing and exclude recurrence^[38-40]. In case of curative ESD *en-bloc* resection, annual endoscopies are performed to detect new metachronous tumors rather than recurrent tumors, since the local recurrence rate is very low^[17]. For tumors with non-curative or

non-evaluable resection margins, but fulfilling the criteria of node-negative tumors, endoscopy is performed every 6 mo to detect local recurrent tumors, at least for the first three years of follow-up.

Outcomes of endoscopic submucosal dissection

In comparison with outcomes of conventional EMR (approximately 75% of the *en bloc* resection rate, a high risk of local recurrence ranging from 2% to 35%^[41], those of ESD are extremely good. As shown in Table 2, the *en bloc* resection rate is more than 90% regardless of the size while the local recurrence rate is almost zero^[8,28,35,42-45].

Complications of endoscopic resection include pain, bleeding, perforation, stricture formation, *etc.* Bleeding is the most common complication, which is typically minor and treatable with endoscopy. The risks vary according to the definition of bleeding (Table 2). Most bleeding occurs during the procedure or within 24 h and predominantly in tumors located in the upper third during the procedure or the lower third of the stomach after the procedure^[42]. Our preliminary data show that 13 of 382 resections (3.4%) are complicated by post-ESD bleeding. Eight bleedings (62%) occur from the post-ESD ulcers located in the lower third, 4 from the middle third and 1 from the upper third of the stomach. Eight bleedings (62%) also occur within 24 h after ESD, 2 d after ESD, 3 between 6 d and 10 d after ESD. These findings indicate that post-ESD bleeding should be especially checked for within a day after ESD when the tumors are located in the lower third of the stomach.

Perforation is another major complication related to ESD. As a result of the techniques, the perforation rate of ESD has decreased to 0%-8%^[7,22,25,28,35,42,43] (Table 2). Furthermore, recent case series suggest that immediately recognized perforation can be successfully sealed with endoclips as conservatively observed without emergency laparotomy by endoscopic clipping, nasogastric suction, decompression of pneumoperitoneum, and antibiotics^[46].

CONCLUSION

Endoscopic resection has become a reasonable and convenient diagnostic and treatment modality, because

Figure 2 Endoscopic submucosal dissection (ESD). **A:** Ordinal endoscopy showing a whitish slight elevation with a blurred margin in the lesser curvature of the middle gastric body; **B:** Chromoendoscopy revealing margins of the lesion clearly; **C:** Marking dots on the circumference of the lesion; **D:** The incised mucosa around the marking dots of the distal margins; **E:** Before completion of circumferential mucosal incision, submucosal dissection from the distal edges; **F:** After mucosal incision with slight submucosal dissection circumferentially, submucosal dissection from the edge of the posterior wall to the anterior wall; **G:** Complete detachment of the lesion from the muscle layer and spraying sucralfate for confirmation of hemostasis; **H:** The resected specimen including the whole marking dots showing *en bloc* resection of the lesion.

histological information about the whole tumor can be obtained and furthermore, a curative treatment is achieved in case of localized tumors without lymph node metastasis, preserving the whole stomach. From this point of view, ESD enables us to resect not only small tumors, but also large or ulcerative tumors endoscopically. ESD has also brought us the concept of diagnostic endoscopic resection for some tumors clinically diagnosed as submucosal invasive cancers, because histopathological diagnosis of submucosal invasive cancers lacks consistency with clinical diagnosis in 66% of cases^[47]. If we can perform thorough and precise histopathological investigations using the resected specimens in an *en bloc* fashion, there is no way to deny the application of

endoscopic resection as the first step before gastrectomy, which would consequently avoid unnecessary gastrectomy. However, some complications related to ESD are still a matter of concern. Further refinements of the technique will ultimately help to achieve the goal of eradication of stomach neoplasms.

Abstract

Many epidemiological studies demonstrate that treatment with non-steroidal anti-inflammatory drugs (NSAIDs) reduce the incidence and mortality of certain malignancies, especially gastrointestinal cancer. The cyclooxygenase (COX) enzymes are well-known targets of NSAIDs. However, conventional NSAIDs non-selectively inhibit both the constitutive form COX-1, and the inducible form COX-2. Recent evidence indicates that COX-2 is an important molecular target for anticancer therapies. Its expression is undetectable in most normal tissues, and is highly induced by pro-inflammatory cytokines, mitogens, tumor promoters and growth factors. It is now well-established that COX-2 is chronically overexpressed in many premalignant, malignant, and metastatic cancers, including hepatocellular carcinoma (HCC). Overexpression of COX-2 in patients with HCC is generally higher in well-differentiated HCCs compared with less-differentiated HCCs or histologically normal liver, suggesting that COX-2 may be involved in the early stages of hepatocarcinogenesis, and increased expression of COX-2 in noncancerous liver tissue has been significantly associated with shorter disease-free survival in patients with HCC.

In tumors, overexpression of COX-2 leads to an increase in prostaglandin (PG) levels, which affect many mechanisms involved in carcinogenesis, such as angiogenesis, inhibition of apoptosis, stimulation of cell growth as well as the invasiveness and metastatic potential of tumor cells.

The availability of novel agents that selectively inhibit COX-2 (COXIB), has contributed to shedding light on the role of this molecule. Experimental studies on animal models of liver cancer have shown that NSAIDs, including both selective and non-selective COX-2 inhibitors, exert

chemopreventive as well as therapeutic effects. However, the key mechanism by which COX-2 inhibitors affect HCC cell growth is as yet not fully understood.

Increasing evidence suggests the involvement of molecular targets other than COX-2 in the anti-proliferative effects of COX-2 selective inhibitors. Therefore, COX-inhibitors may use both COX-2-dependent and COX-2-independent mechanisms to mediate their antitumor properties, although their relative contributions toward the *in vivo* effects remain less clear.

Here we review the features of COX enzymes, the role of the expression of COX isoforms in hepatocarcinogenesis and the mechanisms by which they may contribute to HCC growth, the pharmacological properties of COX-2 selective inhibitors, the antitumor effects of COX inhibitors, and the rationale and feasibility of COX-2 inhibitors for the treatment of HCC.

INTRODUCTION

Hepatocellular carcinoma is one of the most common malignancies worldwide, accounting for approximately 6% of all human cancers and 1 million deaths annually, with an estimated number of new cases of over 500 000 per year^[1,2]. Although the clinical diagnosis and management of early-stage hepatocellular carcinoma (HCC) has improved significantly, HCC prognosis is still extremely poor and the cellular mechanisms contributing to hepatic carcinogenesis are relatively unknown. Therefore, investigating HCC pathogenesis and finding new diagnostic and treatment strategies is important.

Various risk factors have been associated with HCC, such as hepatitis B (HBV) and hepatitis C (HCV) viral infections, alcohol consumption and aflatoxin B1 (AFB1) intake. HBV and HCV infections are the most frequent underlying causes of HCC. However, although a number of experimental observations underline the

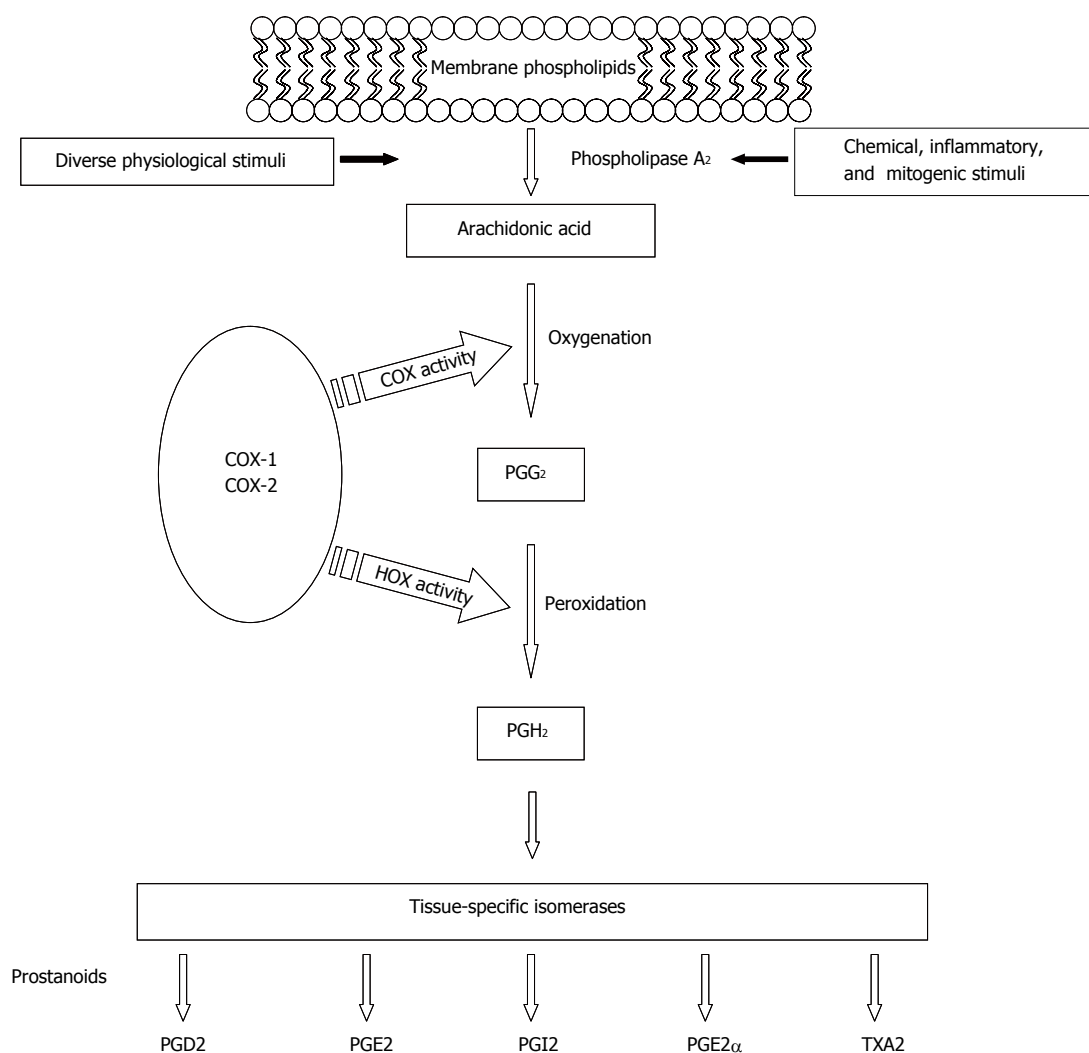

Figure 1 Prostanoids biosynthetic pathway.

potential for viral products in contributing to hepatocyte transformation, only in a minority of patients among the many suffering from chronic viral hepatitis and cirrhosis is there a neoplastic transformation in a given time lapse, suggesting that other co-oncogenic events are probably involved in the multistep process of hepatocyte transformation *in vivo*. HCC development is in fact a complex process associated with an accumulation of genetic and epigenetic changes that pass through the steps of initiation, promotion and progression.

Chronic inflammation is a recognized risk factor for carcinogenesis. Indeed it is thought to play a role in the pathogenesis of several types of cancers, such as cervical cancer, ovarian cancer, oesophageal adenocarcinoma, mesothelioma, colorectal cancer, lung cancer and also HCC^[3]. The ability of inflammation alone to cause malignancy is supported by the fact that other non-viral, inflammatory diseases of the liver such as alcoholic hepatitis, hemochromatosis, and primary biliary cirrhosis can also predispose to the development of hepatocellular carcinoma. Therefore, hepatic inflammation, due to viral and also non-viral chronic liver diseases, may represent an early step in the development of malignancy with genetic changes occurring as a later manifestation of a prolonged

(chronic) inflammatory process. Inflammatory-mediated events, such as the production of cytokines, reactive oxygen species (ROS), and mediators of the inflammatory pathway, such as cyclooxygenase-2 (COX-2), may therefore contribute to tumor formation. Recent evidence indicates that COX-2 is an important molecular target for anticancer therapies, and COX-2 inhibitors appear to have anticancer effects in different types of malignancies.

FUNCTIONS AND STRUCTURE OF THE CYCLOOXYGENASES

At least two distinct cyclooxygenases are present in humans, COX-1 and COX-2. COX enzymes, also referred to as prostaglandin H synthases, or prostaglandin endoperoxide synthases, are the rate-limiting enzymes that catalyze prostaglandin (PG) and thromboxane (TX) synthesis from 20 carbon polyunsaturated fatty acids, most commonly arachidonic acid (AA), which are released from membrane-bound phospholipids, usually by the action of phospholipase enzyme A₂ (Figure 1). Next, oxygenation of AA by COX produces an unstable intermediate, prostaglandin G₂ (PGG₂), which is converted to prostaglandin H₂ (PGH₂) by the peroxidase activity

of COX. PGH₂ is subsequently converted to other PGs (PGD₂, PGE₂, PGF₂α, PGI₂) or thromboxanes (TXA₂). The array of PGs produced varies according to the downstream enzymatic machinery present in a particular cell type (Figure 1).

COX enzymes are proteins with a molecular weight of about 68 kilodaltons (kDa) in an unmodified condition, which increases to 72-74 kDa after post-translation glycosylation^[4]. The structure of COX enzymes consists of three distinct domains: an N-terminal domain with a conformation that is highly similar to that of epidermal growth factor, a domain containing a series of amphipathic helices, which comprise the membrane attachment site, and a C-terminal catalytic domain, which contains the cyclooxygenase and peroxidase active sites.

Although the two enzymes are highly similar in structure and enzymatic activity they have different genomic structures and different gene regulations and expressions. COX-1 was first purified and characterized in the 1970s and the gene was isolated in 1988^[5-7], whereas the COX-2 gene was cloned in 1993^[8]. COX-1 and COX-2 are encoded by separate genes located on different human chromosomes. The gene encoding for COX-1 enzyme is located on chromosome 9 (9q32-9q33.3) and is approximately 40 kilobase (kb) pairs, contains 11 exons and its mRNA is 2.8 kb^[9]. The gene encoding for COX-2 is located on chromosome 1 (1q25.2-25.3), contains 10 exons and is approximately 8.3 kb with a 4.5 kb transcript^[10].

The COX-1 gene exhibits the features of a housekeeping gene, it lacks a TATA box^[11], and is generally not subject to transcriptional induction, but it is constitutively expressed with near-constant levels and activity in most tissues and cell types.

COX-2 is an inducible or early-response gene, whose expression is undetectable in most normal tissues. COX-2 is highly induced in response to a broad spectrum of stimuli such as bacterial lipopolysaccharide (LPS)^[12], cytokines^[13], and growth factors^[14,15]. The inducibility of COX-2 can be explained by the presence, in the 5'-flanking region of its gene promoter, of several potential transcription regulatory sequences, including a TATA box and multiple transcription factor binding sites (C/EBP, AP-2, SP1, NF-κB, CRE, Ets-1, PEA-3 and GATA-1)^[16,17]. Transcriptional control of the COX-2 gene is cell-specific, and it is evident that more than one pathway may co-operate to regulate COX-2 expression. As reported by Araki^[18], in human hepatocellular carcinoma cells, increased COX-2 mRNA and protein expression may result from the combined de-regulation of Wnt and Ras pathways. In addition, in the adult liver, hepatocytes show a behavior pattern unique among cells that respond to inflammatory stresses. In contrast to fetal hepatocytes, which express COX-2 in response to proinflammatory stimuli^[19], such as LPS and proinflammatory cytokines, adult hepatocytes fail to express COX-2 regardless of the type of challenge^[20]. The presence of high levels of C/EBP-α seems to be involved in the impairment of COX-2 expression in these cells when challenged with proinflammatory stimuli^[20]. Therefore, the expression of COX-2 associated with liver diseases, such as cirrhosis and HCC, could be considered a marker of dedifferentiation in adult hepatocytes.

COX-2 gene expression is also subject to negative regulation. Indeed, COX-2 expression can be inhibited by glucocorticoids, IL-4, IL-13 and the anti-inflammatory cytokine IL-10^[21-23].

COX-2 expression can also be regulated at post-transcriptional levels in tumors. In the 3' untranslated region (3'-UTR) of the COX-2 mRNA there are multiple copies of the AUUUA motif, which are known to be involved in the control of both mRNA stability and protein translation. Such motifs represent potential targets by which various agents can stabilize or destabilize the COX-2 mRNA, and this may ultimately lead to an increase or decrease in enzyme activity levels. It has been shown that some proteins, such as tristetraprolin^[24] and AUF1^[25], which also bind to the 3'-UTR, can decrease levels of the COX-2 mRNA. In contrast, other proteins such as HuR, a RNA binding protein prolong the half-life of COX-2 mRNA in colon cancer by binding to the COX-2 AU rich element^[26,27]. High levels of HuR protein have also been reported in HCC cell lines and therefore could be responsible for COX-2 overexpression in this tumor^[28].

As mentioned before, hepatitis C and hepatitis B virus infections are the major etiological agents of chronic liver diseases, which can lead to the development of liver cirrhosis and HCC. However, it is not well known how HBV and HCV are individually involved in human hepatocarcinogenesis. Recent studies have shown that both viruses are able to promote COX-2 expression. After integration of the HBV DNA into the host genome, the expression of the viral protein HBx upregulates COX-2 expression by transactivation of the COX-2 gene promoter through the NF-AT transcription factor^[29,30]. This study therefore demonstrated that COX-2 might be an important cellular effector of HBx protein, which is often the only viral protein expressed by transformed hepatocytes in HCC caused by HBV infection. In addition, the endoplasmic reticulum stress response, due to the expression of the HBV surface protein, may also lead to COX-2 expression through the activation of NF-κB and p38 MAPK^[31]. Similarly, a recent study showed that infection with HCV induces the production of ROS and subsequent activation of NF-κB, which in turn mediates COX-2 expression and subsequent PGE₂ production^[32]. These studies, therefore, provide new insights into the mechanisms by which hepatitis viral infection, through increasing COX-2 expression and PGs production, might be relevant to the development of liver diseases and hepatocarcinogenesis.

It has been suggested that there is another COX enzyme formed as a splice variant of COX-1^[33], referred to as COX-3. COX-3 is made from the COX-1 gene but retains intron 1 in its mRNA. Its expression was initially reported in the canine cerebral cortex and in lesser amounts in other analyzed tissues^[33]. Recent molecular biology studies revealed that indeed three distinct COX-1 splicing variants exist in human tissues^[34]. The most prevalent of these variants, called COX-1b1, arises via retention of the entire intron 1, leading to a shift in the reading frame and premature termination. This would make the expression of a full-length protein impossible, therefore a catalytically active form of the enzyme might

not exist in humans. However, the other two variant types, called COX-1b2 and COX-1b3, although retaining the entire intron 1, lack a nucleotide in one of two different positions, thereby encoding predicted full-length and probably COX-active proteins, as suggested by functional studies, which revealed that COX-1b2 is able to catalyse the synthesis of PGF₂ α from AA^[34].

COX INHIBITORS

NSAIDs have long been known as drugs that have the three favorable analgesic, anti-pyretic and anti-inflammatory effects. However, NSAIDs differ in their therapeutic potency, gastrointestinal side effects and COX inhibition ratios. NSAIDs cover a wide range in their ratios of inhibitory potencies (i.e. selectivity) towards COX-1 and COX-2. Some NSAIDs have moderate selectivity for COX-1 (e.g., ketorolac, flurbiprofen, ketoprofen, piroxicam), others inhibit both COX isoforms (dual inhibitors; e.g. indomethacin, aspirin, naproxen, ibuprofen), other NSAIDs favor COX-2 inhibition (e.g. sulindac, nimesulide etodolac, meloxicam), and finally the newest ones are highly selective for COX-2 (COXIB; e.g. celecoxib, rofecoxib, lumiracoxib, valdecoxib, etoricoxib) (Figure 2). Although the mechanism of action of the different COXIB is similar, their chemical structures differ. In addition, the pharmacokinetics and metabolism of each individual COXIB are unique (Figure 2)^[35,36].

COX IN HEPATOCELLULAR CARCINOMA

Strong support for a connection between COX-2 expression and carcinogenesis has come from genetic studies. The number and size of intestinal polyps in APC^{Δ716} mice, a murine model of human familial adenomatous polyposis coli (FAP), were reduced in animals that were engineered to be also COX-2 deficient^[37]. In a separate study, homozygous deficiency of COX-2 reduced skin tumorigenesis in a multistage mouse skin model^[38]. On the contrary, overexpression of COX-2 was sufficient to induce tumorigenesis in transgenic mice^[39-41].

The evidence that COX-2 may be a logical therapeutic target in HCC comes from studies that showed overexpression of COX-2 in patients with HCC^[42-46]. COX-2 expression is generally higher in well-differentiated HCCs compared with less-differentiated HCCs or histologically normal liver, suggesting that COX-2 may be involved in the early stages of hepatocarcinogenesis^[42,44,46]. In addition, a significant correlation between COX-2 expression and active inflammation in the adjacent noncancerous liver has been reported^[43,47], and increased expression of COX-2 in noncancerous liver tissue was significantly associated with shorter disease-free survival in patients with HCC^[43]. This result is of great importance from a clinical point of view, as it suggests that COX-2 expression may play an important role in the relapse of HCC after surgery.

Furthermore, we recently reported that COX-2 expression in the tumor tissue was significantly correlated to the presence of inflammatory cells, macrophages and mast cells^[46]. However, COX-2 expressing cells and the number of both types of inflammatory cells decreased with progression of the disease, suggesting their possible involvement in the early stages of hepatocarcinogenesis.

The decrease in COX-2 expression during tumor progression as observed in HCC is unusual. A possible explanation for this different behavior pattern is that, in some cell types, COX-2 overexpression may cause a growth disadvantage, as suggested by Trifan^[48], who reported that COX-2 overexpression may induce cell cycle arrest in a variety of cell types.

Although less attention has been drawn to the potential role of the constitutive COX-1 enzyme in carcinogenesis, recent evidence supports its implication in skin and intestinal tumorigenesis^[38,49-52]. COX-1 is up-regulated in human breast^[53], prostate^[54], cervical^[55] and ovarian cancers^[56,57]. On the other hand, loss of the COX-1 gene results in reduced intestinal tumorigenesis in Min mice^[49].

We recently analyzed COX-1 expression in HCC and the surrounding non-tumor tissues^[58]. On the whole, we found a higher COX-1 expression in the cirrhotic liver

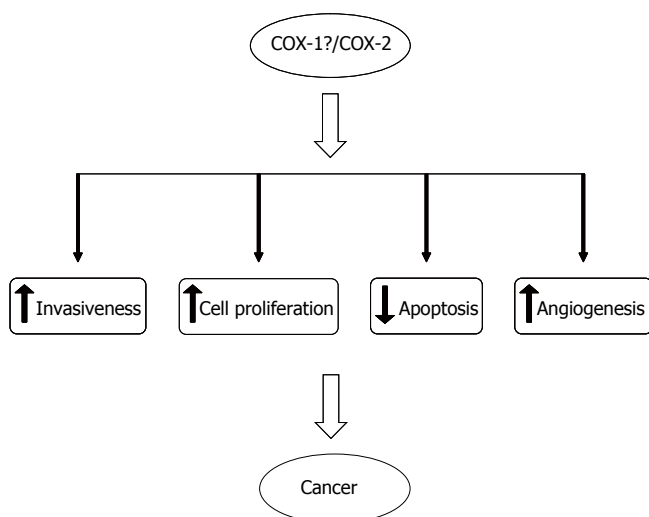

Figure 3 Effects of COX enzymes on different cellular dynamics.

tissues surrounding HCC than in the tumors. However, in some cases COX-1 was up-regulated in the tumor tissues compared to the adjacent non-tumoral cirrhotic tissues. In well-differentiated HCC, COX-1 expression was significantly higher than in the poorly-differentiated tissues, suggesting that the presence of COX-1 might be also involved in the early stages of tumor growth.

COX INHIBITORS IN HEPATOCELLULAR CARCINOMA

Evidence from animal models

Experimental studies on animal models of liver cancer have shown that NSAIDs, including both selective and non-selective COX-2 inhibitors, exert chemopreventive as well as therapeutic effects^[59-64]. In the rat model of choline-deficient, L-amino acid-defined diet (CDAA)-induced hepatocarcinogenesis the administration of aspirin or nimesulide with the diet decreased the number of preneoplastic and neoplastic nodules^[60,63]. In a recent study by Marquez-Rosado^[64] treatment with celecoxib was highly effective in inhibiting the multiplicity and size of liver preneoplastic lesions induced by DEN, 2-AAF and partial hepatectomy.

The therapeutical potential of the specific COX-2 inhibitors, such as celecoxib and meloxicam, in HCC generated in nude mice has also been shown^[65,66]. The treatment significantly reduced the growth of HCC *in vivo* by enhancing tumor cell apoptosis and reducing proliferation.

Overall, these results suggest that NSAIDs and other selective COX-2 inhibitors may be of value in the chemopreventive as well as therapeutic activities against liver cancer.

Evidence from "in vitro" experiments

The involvement of COX-2 in carcinogenesis is believed to be primarily mediated through its influence on cell proliferation, apoptosis, angiogenesis and cell invasiveness^[67] (Figure 3).

Figure 4 Molecular targets of NSAIDs in HCC.

The role of COX-2 in the stimulation of cell proliferation can be attributed to its involvement in the production of prostaglandins. Indeed, evidence indicates that PGs promote cell proliferation, and conversely the growth-inhibitory effects of COX inhibitors can be reversed by exogenous addition of PGs. It has been demonstrated that prostaglandins increase DNA synthesis and cell proliferation of rat hepatocytes^[68,69], and of human HCC cells^[45].

On the other hand, it has been demonstrated that COX-2 inhibitors are able to suppress HCC cell growth^[44,45,58,70-74]. Several mechanisms have been proposed for the antitumor effects of NSAIDs in HCC. However, the key mechanism by which COX-2 inhibitors affect HCC cell growth remains unclear. Some studies have shown that NSAIDs are able to inhibit HCC cell growth by cell cycle arrest^[72,73,75], induction of apoptosis^[44,73,74] or necrosis^[72].

Recent evidence indicates that pharmacological inhibition of COX-1 activity by selective COX-1 inhibitors also blocks cell growth, promotes apoptosis and inhibits the cell cycle in ovarian^[57], breast^[76], bladder and prostate^[77] cancer cells. In addition, a combination of COX-1 and COX-2 selective inhibitors was found to suppress polyp formation more effectively in the intestinal tumorigenesis of the *Apc* knockout mouse model^[52]. Interestingly, we recently showed that the selective COX-1 inhibitor SC-560 inhibits cell growth and induces apoptosis in HCC cells^[58]. Moreover, the combination of the COX-1 inhibitor with selective COX-2 inhibitors, resulted in additive effects on cell growth inhibition. These results suggest that both COX-1 and COX-2 inhibitors may have potential therapeutic implications in HCC patients.

However, it is still controversial whether the antitumor effects of COX-2 inhibitors in HCC are due predominantly to the inhibition of COX-2 activity^[45,58]. Indeed, the antineoplastic effect of NSAIDs might not be mediated only by COX-2 inhibition, but NSAIDs might act on different molecular targets as well^[78].

Increasing evidence suggests the involvement of molecular targets other than COX in the antitumor effects of selective inhibitors also in HCC, including the mitogen-activated protein kinase (MAPK)^[79] and the PI3K/Akt pathway^[45,70] (Figure 4). The existence of COX-independent mechanisms of NSAIDs action is further supported by the evidence that their antineoplastic effects are observed with concentrations that are greater than

those necessary to fully inhibit the synthesis of PGs, and by the observation that they inhibit HCC cell proliferation in COX-2 negative cells^[79]. Interestingly, COX-2-independent effects of celecoxib have also been observed during hepatocarcinogenesis *in vivo*. In the study by Marquez-Rosado^[64] neither COX-2 expression nor PGE₂ production were altered by celecoxib treatment, suggesting that celecoxib effects are mediated by COX-2/PGE₂-independent mechanisms.

COX-2 AND HCC ANGIOGENESIS

A substantial body of evidence supports a role for COX-2 in angiogenesis, the “sprouting” of capillaries from pre-existing vasculature, in a variety of human malignancies^[80-83]. COX-2 promotes angiogenesis, mainly through the synthesis of prostanoids, which can induce tumor angiogenesis in an autocrine and/or paracrine fashion by stimulating the expression of pro-angiogenic factors^[84,85]. However, the precise role of each individual prostanoid remains largely unknown.

COX-2 expression has been reported to correlate with tumor angiogenesis in patients with HCV- or HBV-associated HCC^[86,87]. Moreover, in a recent study we showed a positive correlation between COX-2 expression in tumor tissues of HCC patients and the presence of microvessels inside the tumor mass, assessed by staining endothelial cells with anti-CD34 antibody^[46]. In addition, we reported that COX-2 was the only independent variable that showed a positive correlation with CD34 in a multivariate analysis, confirming the possible role of COX-2 in HCC angiogenesis. These findings suggest the hypothesis that selective inhibition of COX-2 by treatment with COXIB may contribute to inhibit HCC-associated angiogenesis, and thus provide an additional rational approach for treatment of this malignancy.

COX-2 AND INVASIVENESS OF HCC CELLS

A link between COX-2 expression and invasiveness has been observed in several human malignancies^[88,89]. Colon cancer cells that constitutively expressed COX-2 acquired increased metastatic potential that could be reversed by treatment with COX inhibitors^[90]. This phenotypic change was associated with increased expression and activation of metalloproteinase-2 (MMP-2)^[90]. Similarly, PGE₂ induces MMP-2 expression and activation in HCC cells^[91], and treatment with aspirin and with the selective COX-2 inhibitor NS-398 inhibits the HGF-induced invasiveness of HCC cells^[92], suggesting the key role of the COX-2/PGE₂ pathway in tumor invasiveness of liver cancer.

COX-2 AND MULTIDRUG RESISTANCE

Growing evidence indicates that COX-2 overexpression can up-regulate the expression of the Multidrug Resistance 1 (MDR1) gene and the levels of its product, the multidrug efflux pump P-glycoprotein (P-gp)^[93,94]. COX-2 could therefore contribute to the development of resistance

to pharmacological treatment by the tumor cells^[93,94]. Recently, the MDR phenotype was associated with COX-2 overexpression in liver cancer cells^[95].

It could be speculated that a selective inhibition of COX-2 activity could reinforce the antitumor action of conventional chemotherapy by acting on the expression of P-gp. The rationale behind the possible combination of traditional chemotherapy and selective COX-2 inhibitors is further supported by the fact that chemotherapy itself induces COX-2 expression^[96].

CONCLUSION

There is compelling evidence that COX-2, and also COX-1, have a role in hepatocarcinogenesis, but many questions need to be answered. A number of studies have shown that several different mechanisms may account for the anticancer effects of NSAIDs, although the main mechanism remains unclear. The effects of NSAIDs on tumor growth are most likely to be multifactorial, and COX-inhibitors may use both COX-2 and non-COX-2 targets to mediate their anti-HCC activities. Consequently, a better understanding of the COX-2-dependent and COX-2-independent pathways may help to optimize the use of COX-2 inhibitors in the prevention and treatment of HCC.

Recently, concern was raised about the cardiovascular safety of the selective COX-2 inhibitor Rofecoxib^[97,98], and as a consequence it was withdrawn from the USA market by Merck and Co. Further investigation is required to define the safety profile of selective COX-2 inhibitors, especially when they are used at high doses and for long periods of time.

An exciting, novel concept in cancer chemoprevention and treatment is the use of a combination therapy. A combination therapy (which may allow dose reduction, and hence decreased systemic bioavailability) of NSAIDs or COXIBs with agents that specifically modulate relevant biochemical targets of COX-2 inhibitors may take advantage of synergistic growth inhibitory effects against cancer cells and could reduce the toxicity associated with the intake of COX-2 inhibitors. In addition, the use of COX-2 inhibitors, by their action on the MDR phenotype, may enhance the accumulation of chemotherapy agents and decrease the resistance of tumors to chemotherapeutic drugs. Indeed, several clinical trials are under way based on combinations of COXIBs with conventional anticancer treatments (chemotherapy or radiotherapy)^[99] and with novel molecular targeting compounds^[100].

On the other hand, since experimental studies have provided evidence that PGs are the molecules that mediate the effects of COX overexpression, other molecules involved in PG biosynthesis and signaling might represent potential targets. Recently, pharmacological inhibitors of PGE₂-EP receptors, which have anti-neoplastic activity, have been generated^[101]. Therefore, PG receptors and/or PG synthases may represent novel targets for the prevention and treatment of cancer.

Abstract

The present review gives an updated overview of transfusion transmitted virus (TTV), a novel agent, in relation to its molecular characteristics, epidemiological features, modes of transmission, tissue tropism, pathogenesis, role in various diseases and its eradication from the body. TTV, a DNA virus, is a single stranded, non-enveloped, 3.8 kb long DNA virus with a small and covalently closed circular genome comprising 3852 bases. It was tentatively designated *Circinoviridae* virus. TTV genome sequence is heterogeneous and reveals the existence of six different genotypes and several subtypes. TTV has been reported to transmit not only *via* parenteral routes, but also *via* alternate routes. This virus has been detected in different non-human primates as well. At present, TTV is detected by polymerase chain reaction (PCR) with no other available diagnostic assays. It shows its presence globally and was detected in high percent populations of healthy persons as well as in various disease groups. Initially it was supposed to have strong association with liver disease; however, there is little evidence to show its liver tropism and contribution in causing liver diseases. It shows high prevalence in hemodialysis patients, pointing towards its significance in renal diseases. In addition, TTV is associated with several infectious and non-infectious diseases. Although its exact pathogenesis is not yet clear, TTV virus possibly resides and multiplies in bone marrow cells and peripheral blood mononuclear cells (PBMCs). Recently, attempts have been made to eradicate this virus with interferon treatment. More information is still needed to extricate various mysteries related to TTV.

INTRODUCTION

Transfusion transmitted virus (TTV) is a recently discovered virus which was suspected to be a causative agent of non-A to non-E hepatitis. TTV was first identified in the serum of a patient who was hospitalized with post transfusion hepatitis of unknown etiology in 1997^[1]. Initially, TTV was described as a non-enveloped, 3739 bases long and single stranded DNA virus. Based on its genomic characteristics, it was reported to be a parvovirus-like pathogen. Later, studies on the molecular and biophysical characteristics of TTV demonstrated this novel agent as a non-enveloped virus with a small, covalently closed circular genome of single stranded DNA comprising 3852 bases^[2-4]. Its buoyant density is significantly different from that of parvoviruses. Also there was a significant sequence difference between TTV and members of the *Circoviridae*^[5]. It was proposed that TTV belongs to a new virus family that was tentatively designated *Circinoviridae*^[2] *paracircoviridae*^[6] or the TTV family^[7] by different research groups. TTV isolates have an extremely wide range of sequence divergence^[8-10] and were tentatively classified into 23 genotypes with sequence divergence of > 30% from one another^[11] or into four major phylogenetic groups^[7,11]. TTV like mini virus (TLMV) with 2.8-3.0 kb genomic length was also identified in humans and chimpanzees^[12-14].

Since the discovery of TTV, studies have been published describing the prevalence of TTV infection in people with acute or chronic hepatitis as well as in blood donors and drug users and also in healthy persons^[15-17]. It is apparent that currently it is not possible to ascribe TTV to any specific diseases. TTV can be transmitted parenterally and has been found in plasma and peripheral blood mononuclear cells. However, non-parenteral transmission is also possible as TTV can be excreted in feces^[10]. Molecular and phylogenetic analysis of polymerase

chain reaction (PCR) fragments revealed that TTV could be divided into several genotypes that are found worldwide without any direct correlation with geographical distribution of diseases^[2, 18-20]. This is an interesting area to investigate different aspects of TTV and several groups are working to extricate many mysteries related to this agent world over. Until now, an abundance of information has been published on TTV in relation to its molecular form and infectious status.

To have a compilation of information and also have a better understanding of TTV, the present article provides a holistic view on various characteristics of this novel agent with particular emphasis on its molecular characteristics, epidemiological features, endemic behavior and pathogenesis as well as prospects of its eradication on the basis of published information.

MOLECULAR BIOLOGY

TTV, a common virus in humans with high prevalence in the general population^[21,22] is a single stranded DNA virus. Its the genome was sequenced by Okamoto *et al*^[3] almost entirely on the prototype isolate TA278 encompassing 3739 nucleotides and was temporarily believed to be a linear DNA. However, later studies^[2] with the GHI isolate and TA 278 isolate^[4] have identified a GC-rich missing link of about 100 nucleotides that complete the TTV genome as a closed circular DNA with a length of 3852 nucleotides (nt) and a particle size of 30-50 nm. Thus, TTV is an unenveloped virus whose genome consists of a circular and single stranded DNA molecule of negative polarity and about 3.8 kb length^[2]. TTV has an isopycnic density of 1.31-1.34 g/mL in CsCl^[2,4]. The TTV genome has two or three possible open reading frames (ORFs) capable of encoding 770 aa (ORF1), 202 aa (ORF2) and 105 aa (ORF3) polypeptides^[4]. Analysis of the TTV transcription pattern in COS-1^[23] and bone marrow cells^[24] has revealed the existence of at least three species of spliced mRNA molecules of 2.9-3, 1.2, and 1.0 kb in length, with common 5' and 3' termini, leading to the creation of new reading frames (ORF3 and ORF4) in addition to the previously described ORF1 and ORF2^[25].

Many studies have indicated a high degree of genetic diversity of TTV. The entire genome was sequenced for SANBAN and TA 278 isolates^[26]. The genetic organization of the genome was similar in two isolates: two open reading frames (ORF1 and ORF2) were sandwiched by the motifs of TATA box and polyadenylation signal, and a GC-rich short stretch resided at the midst of the untranslated region. No other ORFs longer than 300 nt and common to SANBAN and TA278 were found. The overall nucleotide sequence identity between the two isolates was 56.7%, significantly lower than that (93%) between TA278 and GH1^[2]. Interestingly, the nucleotide sequence identity was relatively higher in the untranslated region (73.0%) than in the translated region (52.2%). A great degree of genetic diversity for a group of viruses represented by TTV most likely had a long history of evaluation and adaptation to humans. Despite the extensive sequence divergence of TTV and TLMV in coding regions of the genome, three areas of remarkable conservation

have been identified in the part of UTR that contains promoters and splice sites^[24]. Sequence conservation is found among all known human isolates of TTV and TLMV as well as those recovered from a range of non-human primates.

Based on its physico-chemical and genomic characteristics^[2-4], TTV was proposed as a member of new viral family tentatively named the *Circoviridae*^[3]. Although TTV shares some features, such as a negative-stranded circular DNA genome, with members of the *Circoviridae*^[1], the genetic organization of its genome is distinctly different from that of viruses that belong to this family. Therefore, TTV was tentatively classified into the virus family, *Circoviridae*^[3].

GENOTYPES

The TTV genome sequence is extremely heterogeneous. Phylogenetic analysis performed on TTV isolates recovered from several parts of the world revealed the existence of 6 different genotypes^[3,27]. The sequence heterogeneity of the TTV genome, however, is more complex. One report described the identification of 16 TTV genotypes^[28]. Another study identified 5 additional TTV genetic groups^[10]. One of these was found to represent an additional TTV genotype, whereas the other 4 additional genetic groups were significantly distinct from TTV and from one another compared to the original TTV genotypes. This observation suggested that these 4 new genetic groups represent closely related, yet different, TTV-like viral species. The existence of genetic divergence between different TTV isolates beyond genotypes was noted by another group of researchers^[8]. It has been hypothesized that a whole "swarm" of numerous TTV-like species circulates in the human population worldwide^[29]. Despite this extensive sequence diversity, all variants of TTV share a common genomic organization with three predicted encoded proteins of similar length and likely function.

TTV was originally found in humans; however, recent studies showed that TTV can also be identified in serum specimens obtained from domesticated farm animals^[29] and from non-human primates^[29, 30]. Phylogenetic analysis using the TTV sequence obtained from animals demonstrated that these sequences belong to already known human TTV genotypes^[29,30], although some sequences recovered from nonhuman primates remain unclassified^[30]. The results of these experiments demonstrated that chimpanzees may be infected with some TTV-related species that have not been found in humans. An additional phylogenetic analysis using all known TTV sequences, some of which were not classified^[26,30] or were classified previously as new TTV genotypes^[10], suggested the existence of 16 genotypes or 13 different TTV-like species. The prototype TTV-I^[8] sequences were classified into eight genotypes found in humans as well as in non-human primates and farm animals. Moreover, genetically distant variants, namely PMV, SANBAN and SEN viruses have been identified. Frequent homologous recombination, which can occur when a subject is co-infected with two or more isolates, is an important multiplier of the TTV genetic diversity. This

phylogenetic tree contains 13 major groups. Each major group represents sequences that are more distant from the other major group sequences. This observation is strongly supported by the analysis of frequency distribution of evolutionary distances. Comparison of sequences from one major group of branches to all other branches demonstrates that each of the 13 major groups of branches may represent different viral species. All of these viruses are closely related to the prototype TTV strains tentatively designated TTV-I. The other viral species identified with each major branch were also designated TTV with the addition of Roman numerals (e.g. TTV-II, TTV-III) as proposed previously^[8].

All 13 major groups of branches or viral species may be arranged into four groups. Group A contains viral species I and IX; group B contains II, III, X, XI, XII, and XIII; group C contains IV and V; and group D contains VI, VII, and VIII. The TT viruses found in humans belong to groups A, B, and C. Group C is composed exclusively of viruses found in humans and group D of viruses found only in non-human primates. The primate TT viruses can be also found in groups A and B. Group A includes two viral species. One of these viruses is the prototype TTV-I, which was originally identified in a Japanese patient with parenterally transmitted hepatitis of unknown etiology^[1]. Previously, seven TTV-I genotypes were identified^[27,28]. However, based on phylogenetic analysis, TTV-I genotypes 2 and 3 were suggested to be combined as genotype 2/3^[8]. This suggestion reduces the number of TTV-I genotypes to 6. Earlier, several new TTV variants were found in non-human primates^[29,30]. The phylogenetic analysis performed in this study confirmed that sequences Bo-Ho and Bo-De identified by Vergchoor *et al* belonged to genotype 2/3. However, sequences Ch-Pe and Ch-Br2 constituted two new TTV-1 genotypes^[29] whose sequences constituted a new major branch in the phylogenetic tree representing TTV-IX, which is different from, but closely related to the prototype TTV-I. TTV-IX detected in chimpanzees is most closely related to the TTV-I genotype 8 found only in non-human primates^[30]. Recently, several new TTV variants were identified in serum specimens from healthy Japanese individuals^[31]. Group B contains TTV-II, TTV-III, TTV-X, TTV-XI, TTV-XII and TTV-XIII, which can be found in non-human primates as well as in human specimens. TTV-II, TTV-III, TTV-X and TTV-XIII were found only in humans. Group C is composed of two human viruses, TTV-IV and TTV-V. Group D consists of three new chimpanzee viruses, namely TTV-VI, TTV-VII and TTV-VIII.

HUMAN TRANSMISSION

TTV was first characterized as a blood-borne virus and was thus referred to as a transfusion-transmitted virus (TTV)^[3,32]. However, later studies suggested the existence of other routes of transmission also. In fact the mechanism of TTV transmission has not yet been elucidated. The higher prevalence of TTV in persons treated with blood^[3] or blood products^[32] has suggested parenteral transmission as a frequent route of TTV infection. TTV is common in patients who have an increased risk of infection with blood-borne viruses, such as hemophiliacs (68%), patients

on maintenance hemodialysis (46%), and abusers of intravenous drugs (40%)^[3]. There is a high prevalence of TTV in blood products. TTV contamination was found in 10 of 18 batches (56%) of factor VIII and IX concentrates manufactured from non-remunerated donors, and in 7 (44%) of 16 batches of commercially available products^[32]. These observations suggest that TTV is transmitted by blood and blood products. However, infrequent detection of TTV-DNA in serum samples from prostitutes and homosexual men^[17] and the findings of fecal^[33] and bile^[34] excretion of TTV indicate that TTV may have characteristics different from other blood-borne viruses. The prevalence of TTV in blood donors in different countries varies between 1.9% to 62%^[3,22,27,32,35]: 1.9% in England^[32], 9.1%-12.8% in United States^[27], 12% in Japan^[3], 36% in Thailand^[35] and 62% in Brazil^[22]. Moreover, the majority of TTV infected people had no history of blood and/or blood products transfusion. The relatively high prevalence of TTV in blood donors and the large proportion of TTV infected patients with no history of transfusion of blood and blood products also suggest that alternative routes of transmission of TTV infection may exist^[36]. TTV DNA has also been detected in saliva^[36], throat swabs^[37], breast milk^[38], semen^[39] and vaginal fluid^[40] thus, supporting routes of transmission other than blood and blood products^[33,37].

Excretion of TTV in feces of infected individuals suggests of possible fecal-oral transmission^[33]. Some studies have reported placental transmission of TTV^[41-43], whereas others have not detected TTV in cord blood and amniotic fluid^[44-45]. These studies show the absence of transuterine transmission of TTV. Since children of TTV-infected mothers apparently tend to get infected more often and earlier after birth than children of TTV negative mothers, the role of postnatal transmission of TTV is being considered. Postnatal route of transmission from mother to child and infection *via* frequent social contacts seem to be very important modes of transmission in children^[46-48]. Furthermore, variation in the TTV prevalence in children from 5.1% in Japan^[49] to 54% in the Democratic Republic of Congo^[50] is also suggestive of the possible involvement of some specific environmental factors in the acquisition of TTV infection. The sexual mode of transmission is likely of low effectiveness^[51].

ANIMAL TRANSMISSION

Infection with both TTV and TLMV has been detected in various non-human primates^[2,52,53]. At the same time, there are reports showing cross-species transmission of TTV genotypes. Human TTV variants can infect chimpanzees and macaques^[13,54]. Beyond primates, host range of TTV and TLMV is uncertain. One study has demonstrated frequent TTV infection of domestic animals such as cows, pigs, sheep and chickens^[47]. However, it is not known how these species acquire TTV infection. Recently, highly divergent TTV like viruses were detected in pigs, cats and dogs, distinct from those found using the N22 primers^[55] suggesting that this virus family may indeed be widely distributed in the mammalian order. There are reports showing high prevalence of TTV infection in captured

chimpanzees and crab eating macaques^[56]. These findings suggest that TTV is widespread among wild Chimpanzees living in West Africa. However, this TTV infection was found non pathogenic. Based on analysis of full-length sequence data, this TTV may represent a new TTV-like viral species or genus, although it is closely related to human TTV^[56].

TARGET ORGANS

Regarding target organs for TTV infection, TTV-DNA has been detected by both PCR and in situ hybridization in liver and peripheral blood mononuclear cells (PBMC)^[57,58]. However, these studies have shown that TTV replicates in liver, but not in PBMC. Simultaneously, TTV was detected and found with replicative intermediates in bone marrow cells from TTV infected patients^[24]. This finding and few other studies^[59] indicate that TTV-DNA in PBMC corresponds to viral particles passively attached to cell membrane and TTV infects hematopoietic cells but only replicate when these cells are activated. Since the percentage of circulating activated cells is very low, this may be the cause for the lack of detection of TTV replicative intermediates in freshly isolated PBMC from TTV infected patients.

DIAGNOSTIC ASSAYS

The development of sensitive and reliable polymerase chain reaction (PCR) protocols allowed the detection of TTV DNA at a very high prevalence in sera of healthy populations around the world^[21,22,29]. Currently, the heteroduplex mobility assay to detect multiple infections with isolates of TTV belonging to different genotypes or subtypes has also been developed. In the simplest application of heteroduplex mobility assay, heteroduplexes are formed by denaturing and reannealing mixtures of PCR amplified DNA fragments from divergent isolates of the same virus. When these products are separated on polyacrylamide gels a homoduplex band plus two slow moving heteroduplex bands are observed. The mobility of heteroduplexes is related to the genetic distance between two strands. This technique was applied earlier to HIV isolates, measles virus, CMV and hepatitis C virus. While detecting TTV DNA by PCR, it was found that repeated freezing and thawing of serum did not have much effect on stability of TTV DNA. Specimens are not required to be aliquoted for repeated testing and retrospective studies^[60].

Both TTV and TLMV have sequence heterogeneity. Some TTV subtypes have less than 50% sequence identity. However, there are certain conserved regions. Primers were designed in such a way that most of the subtypes could be detected^[61]. Recently, real time PCR based methods with either SYBR Green or TaqMan Probe, designed to quantitate selectively TTV and TLMV, have also been used^[61].

EPIDEMIOLOGY

Epidemiological studies have shown that TTV is described

worldwide in various populations. The prevalence of TTV viremia in healthy adults of developed countries is in the range of 1%-34%. Prevalence reported from third world countries was found to be higher, typically 40%-70%. In people who have received multiple blood transfusions the virus is almost universally present with more than one subtype in each individual. Table 1 demonstrates the countrywide prevalence of TTV infection in different categories of populations including both healthy persons and patients with various types of diseases^[62-75].

TTV INFECTION IN LIVER DISEASES

From preliminary reports two characteristics of TTV infection have emerged rendering it as a potential cause of liver disease. First, Okamoto *et al*^[3] demonstrated that TTV-DNA levels in liver tissue were equal to or 10-100 times higher than those in serum, suggesting that this virus replicated in the liver. Second, Nishizawa *et al*^[11] reported the appearance of TTV-DNA in the sera of patients with post transfusion hepatitis of unknown etiology to display close correlation with ALT levels. Neither one of these characteristics, hepatotropism or correlation of viral titres with serum ALT, had previously been demonstrated for HGV. However, most subsequent investigations could not confirm their significance in the development of fulminant hepatitis, cryptogenic chronic liver disease and HCC. In addition, the implications of coinfection with TTV in the natural history of chronic HBV or HCV infection are also far from clear. Although TTV can be transmitted by parenteral route, its role in causing posttransfusion hepatitis has not been established^[76-79]. The majority of individuals who become TTV-DNA-positive after blood transfusion usually have normal ALT and do not develop chronic hepatitis, although TTV viremia frequently persists for several years. Patients who develop chronic hepatitis are invariably coinfecting with HBV or HCV and chronic hepatitis is closely correlated with HBV or HCV infection. This raises the possibility that TTV is merely an innocent bystander rather than a primary hepatitis virus.

In one of the studies^[79], the rate of TTV infections was found to be significantly higher among transfused than among non-transfused patients (26.4% and 4.7%, respectively) and the risk of infection increased with the number of units transfused. The rate of TTV infections with non A-E hepatitis (23.2%) was almost identical to the rate among patients who had been transfused, but did not develop hepatitis (21.8%). Of those patients with acute hepatitis C, 40.0% were simultaneously infected with TTV and TTV did not worsen either biochemical severity or persistence of hepatitis C. In non-A-E cases, the mean ALT was comparable among those positive for TTV and those negative. Neither was there a consistent relationship between ALT and TTV-DNA level among these patients^[80].

The role of TTV in acute hepatitis is another unresolved issue. In two Japanese studies^[81,82] TTV-DNA was identified in 13.6%-43% of cases of non-A-E community-acquired acute hepatitis. However, these positive rates of TTV do not differ statistically from either those obtained among patients with other types of viral

HCC: Hepatocellular carcinoma; IVDUs: Intravenous drug use.

hepatitis or among healthy volunteers. In addition, the ALT levels do not show any difference between TTV-positive and TTV-negative patients. Furthermore, the presence of TTV infection had no apparent effect on the clinical course of patients with hepatitis A, B or C. Thus, according to these studies no correlation appears to exist between TTV infection and the clinical features of sporadic hepatitis. Contrasting another Japanese study^[83], TTV-DNA was detected in 2 out of 7 (29%) patients with acute hepatitis of unknown etiology, but in none of the 4 patients with acute HCV-associated hepatitis. At least half of all cases of fulminant hepatitis are seronegative for hepatitis A-E viruses. TTV has been found in 27%-50% of patients with fulminant hepatitis^[3,16,84], but such patients probably received multiple transfusion before testing and recent TTV infection has not always been established. Therefore, it is unclear whether TTV infection is secondary to transfusion or plays an etiologic role in fulminant hepatitis.

Current data suggest that TTV is not the causative agent of chronic liver disease of unknown etiology and neither does it affect the degree of liver damage when present as a coinfection with HBV or HCV^[16,77,84-86]. According to our previous study^[86], for example, TTV-DNA was detected in 20% of the HBV-positive and 19.5% of the HCV-positive chronic liver disease patients, in 8.3% of seronegative chronic liver disease patients, in 8.3% of seronegative chronic hepatitis/cirrhosis patients and 7% blood donors. Yet, no significant differences between TTV infected and non-infected patients were found as to demographic data, assumed source of infection, biochemical abnormalities, or severity of liver histology. Thus, regarding etiology and progression towards serious chronic liver disease, its contribution seems to be minor if not altogether non-existent. Concerning antiviral therapy, there are no data or treatment of patients who are infected with TTV alone since the role of TTV as a cause of chronic hepatitis has yet to be determined. Studies of patients infected with both HCV and TTV who were treated with interferon showed that the responsiveness to therapy was correlated with HCV alone. In addition, certain genotypes of TTV were quite resistant to interferon although interferon effectively reduced HCV in

the same patients^[87].

Because the prevalence of TTV is high among patients with chronic viral hepatitis and cryptogenic liver disease, a similar situation has been anticipated to persist among patients with HCC. However, the prevalence of TTV in Thai patients with HCC has shown a wide range of divergence, for example, 6%-60% and 5%-50% in cases with HBV and HCV markers respectively, and 1%-67% in cases without HBV and HCV markers^[27,88]. Our study demonstrated the majority of TTV infected HCC to harbor double or triple infections with HBV and/or HCV and the prevalence of TTV infection was comparable to that of healthy volunteers^[89]. Contrasting that, another group reported TTV-DNA to occur more frequently in patients with liver cirrhosis and HCC than in those with chronic hepatitis^[27]. Using a case-control study to compare the prevalence of 174 Italian patients and matched controls, it was demonstrated that individuals infected with TTV did not exhibit an increased relative risk for developing HCC^[90]. Furthermore, it has been demonstrated that the TTV genome is not found integrated into host hepatocyte DNA^[91], the one process that might represent a potential risk factor in the development of HCC.

TTV INFECTION IN RENAL DISEASES

Using the polymerase chain reaction (PCR), epidemiological studies have indicated a worldwide distribution of this virus, with prevalence surveys in the general population reporting values of 12% to 19% in Japan^[3,92], 36% in Thailand^[27], 2% to 10% in European countries^[32,85] and 1% in the USA^[16]. In patients on maintenance hemodialysis (HD), who are at an increased risk of parenterally transmitted hepatitis virus infection, a high prevalence (32%-53%) of TTV infection has been reported^[93,94]. However, the transmission route of the virus is still unknown and the question of any association between duration of HD or previous transfusion and TTV infection is still a matter of controversy^[77,95]. There is also little information about the occupational risk of TTV infection in HD unit workers. By using logistic regression analysis, it was shown that a prior blood transfusion and time on HD were not predictors of the presence of TTV-

DNA, so that TTV may have a transmission route not shared by HBV, HCV or HGV. The possibility of TTV transmission, *via* a nosocomial route in HD units, must be considered^[77]. One of the possible routes of transmission in an HD unit is direct from person to person. For this reason, the healthcare staff in the HD unit was suspected as being at high risk for TTV infection. Although a low risk of TTV infection was suggested in hospital staff, there is little information on HD unit workers^[96]. TTV infection rate was not influenced by age, sex, or mean duration of dialysis^[77,79,97]. Nosocomial transmission may account for TTV infection in some patients on hemodialysis^[98].

TTV-DNA genotype 1 (G1) was found to be the main TTV DNA genotype in hemodialysis patients. The fact that hemodialysis patients are polytransfused makes it likely that they are at risk of multiple exposures. Therefore, it was interesting that a significant number of patients were apparently coinfecting with different strains of TTV. Sequence analysis of clones from two patients with apparent mixed infections showed that TTV strains belonging to two different major genotypes could coexist in a single patient. It was suggested that infection with one TTV type does not protect against infection with another TTV type^[99]. The preliminary data suggested that TTV is transmitted mainly *via* a parenteral route^[3,85]. When TTV infection was studied in hemodialysis patients who were monitored for HCV infection, co-infection was found in 48% at enrollment. The follow-up of the renal transplant patients revealed, that the persistence of single TTV variants over a long period after organ transplant was common. Considering the heterogeneity of TTV isolates, this finding is against frequent infection with different nucleotide sequences and so horizontal spread of certain variants could have been expected. Nevertheless, in the examined patient group, permanent infections, with only single nucleotide changes in the consecutive samples of the same patient could be observed and the TTV variant detected in one patient was usually remotely related to the TTV variants infecting the others with 58%-97% nucleotide sequence identity between the variants. As a highly variable region of the TTV genome, the N22 region is a candidate to carry humoral epitopes on the surface of the virions. Mutations in this region were, however, infrequently detected. The host's immunity is a plausible evolutionary driving force of the development of TTV genotypes and variants, which process affects most probably the hypervariable genomic regions. If so, the iatrogenic immunosuppression of the transplant recipients can contribute to the long persistence of one variant, while novel infections are infrequent^[100].

TTV COINFECTION

Accumulating molecular and clinical evidence indicated that the effects of HIV infection can be modified by coinfection with other viruses^[101-104]. However, limited information is available about the prevalence and possible pathogenic role of TTV in HIV infected patients with or without AIDS in relation to specific risk factors, and about the viral titres of TTV. Puig-Basagoiti *et al*^[105] reported no influence of TTV infection on CD4 T cell counts

and clinical or immune status in HIV-infected patients. In a recent study by Martinez *et al*^[106], no relationship was found between TTV DNA detection and HIV category, CD4 count, HBV and HCV infection or demography features. By contrast, Christensen *et al*^[101] reported correlation between a low CD4 T cell count and high TTV titre in Danish patients with HIV infection as well as a possible prognostic significance of TTV viral load in immunocompromised patients. High TTV viremia levels were found to be associated with decreased survival rates. A significantly higher rate of TTV positivity was noted in HIV-infected patients than in HIV-negative healthy individuals by two distinct PCR methods. Although the detectability of TTV by either of the two PCR features was as in previous studies^[105,106], the relative rate of TTV DNA in the patients studied was found to be associated with the HIV viral load and CD4 cell level as well as the development of AIDS.

A series of recent reports has indicated that viral infections can influence the pattern of autoantibody expression in patients with autoimmune diseases. Neidhart and coworkers^[107] demonstrated differences in the autoantibody pattern of patients with SSc with antibodies to cytomegalovirus. Other investigations showed a significantly lower prevalence of rheumatoid factors in RA patients infected with TTV, in comparison with non-infected patients. Hajeer *et al*^[108] reported a negative correlation between anti-parvovirus B19 antibodies and rheumatoid factors in patients with RA. In several studies, the autoantibody pattern found in patients with SSc was found to be similar^[109-111]. Comparison of the autoantibody patterns in virus infected and non-infected patients with SSc showed that continuing GBV-C or TTV infection or both, have no evident effect on the manifestation of autoantibodies. In conclusion, various reports showed neither a higher prevalence of GBV-C RNA and/or TTV DNA, nor changes in the pattern of expression of autoantibodies in patients with SSc. Therefore, these data provided no evidence for an association between GBV-C and/or TTV infections and SSc.

Not only the clinical significance and the pathogenesis of TTV infection but also the association between TTV infection and raised ALT values have been controversial^[1,3,113]. It was found that the raised ALT values were independently related to TTV viraemia among Taiwanese who were not infected with HBV and HCV. TTV infection seemed to be responsible for raised ALT values and to hint positive hepatopathic effects. Tuveri *et al* suggested that TTV might be implicated in a few cases of acute and chronic non A-non G hepatitis^[113]. However, Nakano *et al* reported that TTV was not the main causative agent of cryptogenic liver disease^[114]. Further efforts at confirming the pathogenicity of hepatocyte damage by TTV are necessary. As for direct correlations between TTV and *H pylori* infection, TTV DNA was detected at a similar rate in patients with and without *H pylori* infection, and *H pylori* infection was detected at a similar rate in patients with and without TTV infection. Similarities of prevalence of TTV between patients with and without infection by *H pylori*, and prevalence of *H pylori* between patients with and without infection by TTV, as well as the discrepancy in

age distributions between prevalence of TTV and *H. pylori* in our patients with peptic ulcer disease indicate that no correlation exists between TTV and *H. pylori* infection, even though the two agents have similar age distributions in the general population and similar routes of transmission have been suggested for the two agents^[115]. According to one report, the high prevalence of genogroup 1 TT virus infection in patients with laryngeal cancer and its striking co-prevalence with human papilloma virus infection is biologically important in the progression of squamous cell carcinoma of the larynx^[116].

TTV might replicate in the respiratory tract^[117]. Also, although we found no evidence that TTV might be the direct cause of ARD, TTV loads in both nasal swabs and plasma samples were substantially higher in subjects with bronchopneumonia (BP) than in the subjects with milder ARD (laryngitis, bronchitis, and bronchiolitis), suggesting among other possibilities that TTV could be locally or systemically immunosuppressive and aggravate disease induced by other agents^[117]. However, there is no information on this matter except for recent report showing an inverse relationship between TTV burdens and CD4 cell counts in patients with human immunodeficiency virus type^[101,118,119].

PATHOGENESIS

Although liver tropism has been suggested, TTV also has been found in other organs including kidneys, prostate, mammary glands, brain, bone marrow cells (BMCs) and peripheral blood mononuclear cells (PBMCs)^[3,59,120,121]. Although it is not known precisely in which cell(s) TTV replicates, TTV DNA has been detected frequently in the PBMCs^[58,120] and it has also been suggested to infect and replicate in hematopoietic cells in the bone marrow^[122,123]. Earlier reports had revealed that there was a higher TTV genome load in the PBMCs of cancer patients than in healthy controls (blood donors)^[124]. This could have been related to immune abnormality in cancer patients when compared with the controls, thereby allowing increased TTV replication in the former.

It was demonstrated that TTV is present in the nucleus and cytoplasm of some of the PBMCs. It is possible that infection of immune cells could facilitate escape of the virus from the immune response. Concealed as a "Trojan horse", TTV in PBMCs might serve as a reservoir of TTV for chronicity of the infection and transmission in some clinical and epidemiological settings. The observation that TTV-negative PBMCs bound considerable virus *in vitro* suggests that at least some TTV found associated with *ex vivo* derived PBMCs might be of plasma origin rather than produced by the cells themselves. We have, however, obtained evidence indicating that PHA-stimulated PBMCs support TTV replication *in vitro* and release substantial titres of virus into the culture fluid. TTV-related single-stranded DNA viruses such as circoviruses and parvoviruses require actively multiplying cells for productive replication^[125,126]. That proliferating hematopoietic cells might be an important source for the TTV that circulates in infected individuals is suggested by findings showing that baseline TTV viremia decreased

markedly in virus-positive prospective bone marrow transplant recipients after myelosuppression with cyclophosphamide and total body irradiation^[122]. Whether TTV is also dependent on cell cycling for active replication remains to be formally established.

It is well known that some viruses can be activated by immune stimulation, most notably HIV, which requires lymphocyte activation for optimum replication^[127,128]. In this regard, it has been shown recently that an animal circovirus related to TTV, porcine circovirus type 2 (PCV-2), can replicate to higher levels in piglets as a result of immunization with a bacterial porcine vaccine^[129]. One major distinction between PCV-2 stimulated in this study and TTV is that the porcine virus is capable of causing a wasting syndrome and may do so more effectively following immune stimulation. In addition, immune suppression due to drugs or induced stress resulted in a transient increase in TTV titers in humans^[130,131]. This indicated that resting PBMCs could not produce TTV, but that mitogen activated cells could be stimulated *in vitro* to replicate TTV. Thus, there is a suggestion that TTV levels may be related to the state of activation of the host immune system as postulated in an earlier publication^[132].

Recently, replicative circular double-stranded intermediates of TTV DNA have been reported in liver and BMC^[24,133]. TTV DNA has been detected by *in situ* hybridization in nuclei of hepatocytes from experimentally infected rhesus monkeys, indicating that TTV truly infects hepatocytes^[134]. However, TTV DNA titers in sera of TTV-infected patients decreased to undetectable levels during immunosuppression following bone marrow transplantation^[122]. Moreover, liver cells have been found to contain only TTV DNA and not mRNA^[123], suggesting that TTV replicates in hematopoietic cells rather than liver. Southern blot analysis argues against integration of the TTV genome into the genomes of human hematopoietic tumor cells, obtained from bone marrow aspirates, lymph nodes, or human hepatocellular carcinoma^[91,135]. Although, TTV DNA is frequently detected in PBMC of infected individuals^[58,120], double-stranded replicative intermediates have not been detected in PBMC.

TTV, a new member of the *Circoviridae* family, has not been cultured *in vitro* and its pathogenic potential is still not clear. A cell line for isolating and cultivating TTV will significantly accelerate the research on TTV. Human lymphoblastoid cells, particularly B cells, transformed with oncovirus such as Epstein-Barr virus, may be useful for culturing TTV. Because DNA viruses are often found integrated into host genomic DNA as has been reported for hepatitis B virus^[136-139], the possible integration of TTV DNA into the genome of hepatic cells was investigated. When a 2.2 kb TTV probe was used in a Southern blot analysis of liver genomic DNA, no signal was obtained. Thus, TTV DNA was not found to be integrated into hepatocyte chromosomes, and the liver apparently was not the site of TTV replication for this particular case. Similarly, Yamamoto *et al.*^[91] have reported the absence of viral replication in hepatocytes of TTV infected cases of hepatocellular carcinoma. These data, taken together, suggest that the site of TTV replication occurs in the bone marrow rather than in the hepatocytes, and that TTV

infection was the cause of the aplastic anemia. Similar findings suggesting TTV replication in bone marrow have been obtained by other researchers^[88].

ANTI VIRAL THERAPY

After IFN-alpha administration with a regimen of 6 MU thrice a week for 24 wk followed by 3 MU thrice a week for 12 wk, 24 of 50 (48%) concurrent TTV-infected patients achieved complete clearance of TTV DNA 6 mo after the cessation of therapy, with 7%-8% TTV spontaneous clearance rate reported annually in previous reports^[77]. Other studies indicated that IFN-alpha has a potential antiviral effect on TTV. In previous studies, IFN therapy was effective against TTV with an eradication rate of 45%-55%^[140,141]. Transient disappearance of TTV viremia during IFN-alpha therapy was observed in some reports, demonstrating the direct antiviral effects of IFN-alpha on the suppression of TTV. Nevertheless, delayed TTV clearance (TTV DNA positive at E/T and negative after cessation of therapy) that had not been reported previously occurred in few patients. Delayed complete virological response was observed in chronic hepatitis B patients after the end of therapy with Thymosin alpha 1^[142] or IFN^[143] that revealed immune modulation effects. Since TTV is a DNA virus as HBV, delayed clearance of TTV after IFN therapy may indicate that immune modulation plays an important role. The findings in the present study implied that both antiviral effects and immunomodulatory actions of IFN-alpha are important on the eradication of TTV. Further studies are needed to investigate and clarify the actual mechanism of responsiveness of TTV to IFN-alpha.

In evaluating the clinical characteristics and virological features related to clearance of TTV after IFN-alpha therapy, the viral clearance at the E/T was the only important factor associated with clearance of TTV viremia. Neither the pretreatment ALT levels nor the histopathology were predictors for TTV clearance. Besides, there was no correlation between response of HCV and TTV. All the results may indicate the difference in virologic kinetics and mechanism of IFN effects between TTV and HCV that influence the response and resistance to IFN-alpha. The ALT levels at E/T or 6 mo after cessation of treatment were not related to TTV but HCV viremia also denied the hepatopathic effects of TTV infection.

OUTLOOK ON TTV

From the compilation of published reports on this newly characterized virus and its global status, it is evident that TTV is prevalent in several countries of the world. As such, it is not involved in causation of a serious problem in the body and simply acts as a bystander without much impact of its single or co-infection with other viruses. Of course, attempts are still going on to find out exact clinical implications of TTV infection. Much is already known about the molecular biology of the virus, yet there still remains a need to develop simple techniques based on molecular and immunodiagnosics to diagnose TTV infection in all categories of laboratories. This will facilitate

studies on TTV in more detail and at several places to unravel mysteries related to this infection.

INTRODUCTION

Primary gastric carcinoma is one of the most common malignant tumors in China. The mortality rate is as high as 25.53/100 000, accounting for 23.93% of all the deaths caused by malignant tumors^[1]. Invasion and metastasis are the main cause for the death of cancer patients. On the other hand, invasion and metastasis of malignant tumors are closely related with angiogenesis of tumor tissue. Angiogenin (ANG) was originally isolated from serum-free supernatants of a cultured human colon adenocarcinoma cell line (HT-29) by Fett etcetera in 1985^[2]. ANG possesses a ribonuclease activity^[3]. Data have shown that in human colorectal cancer^[4], pancreatic cancer^[5], and other tumors, the expression of ANG is upregulated. However, the function of ANG in tumor angiogenesis is still unknown^[6]. We used RT-PCR and immunohistochemistry to detect the expression of ANG, CD34 and vascular endothelial growth factor (VEGF) in 68 primary gastric carcinomas and the surrounding nontumorous tissues, analyzed their correlation with each other, and explored the functional role of ANG in angiogenesis and growth of gastric carcinoma.

MATERIALS AND METHODS

Materials

The study enrolled 68 human gastric carcinoma (HGC) patients (56 men and 12 women; Ages, mean \pm SD, 60 \pm 11 years) who underwent gastric surgical resection at The First Affiliated Hospital of Fujian Medical University between March and July of 2002. The specimens for RT-PCR included both cancer tissues and the surrounding nontumorous tissues. The specimens for immunohistochemistry were taken simultaneously. All specimens were 40 g/L formaldehyde-fixed, paraffin-embedded and sliced into 4 μ m sections consecutively. None of these patients had preoperative radiative therapy or chemotherapy. All the diagnoses were confirmed by pathology reported by two pathologists. Clinical data of all the patients were reviewed. Histology type, lymph node metastasis stage and TNM stage of each case were determined according to WHO tumor classification standards (stomach cancer)^[7]. Twenty-seven patients had

Abstract

AIM: To investigate the implication of angiogenin (ANG) in the neovascularization and growth of human gastric carcinoma (HGC).

METHODS: ANG mRNA expression in HGC specimens obtained by surgical resection from patients with HGC were examined by RT-PCR. ANG, Ki-67, VEGF protein expression and microvessel density (MVD) in HGC specimens were detected by immunohistochemistry.

RESULTS: RT-PCR showed significantly higher ANG mRNA expression (0.482 ± 0.094) in HGC tissues than in the surrounding nontumorous tissues (0.276 ± 0.019 , $P = 0.03$). MVD within tumorous tissues increased significantly with ANG mRNA expression ($r = 0.380$, $P = 0.001$) and ANG protein expression ($P < 0.01$). The ANG expression levels of cancer tissues were positively correlated with VEGF ($P < 0.01$) and the proliferation index of cancer cells ($P < 0.01$).

CONCLUSION: ANG is one of the neovascularization factors of HGC. ANG may work in coordination with VEGF, and promote the proliferation of HGC cells.

Chen Y, Zhang S, Chen YP, Lin JY. Increased expression of angiogenin in gastric carcinoma in correlation

well-moderately differentiated adenocarcinoma, and 41 patients had poorly-undifferentiated adenocarcinoma. Fourteen patients were node-negative; 46 had first station lymph node metastasis, and 8 had second or distant lymph node metastasis. Twelve tumors were TNM I, 25 tumors were TNM II, 20 tumors were TNM III, and 11 tumors were TNM IV.

Methods

RNA extraction: Specimens were taken within 30 min after resection, and were stored at -80°C . RNA was extracted from HGC tissue and corresponding nontumorous gastric tissue using Trizol extraction reagent kit (Gibco BRL, USA), according to the instructions of the manual. Concentration and purity of RNA were determined by spectrophotometric method. Integrity of RNA was determined by electrophoresis.

RT-PCR and analysis of the products: ANG primers were synthesized by the Bioasia Biotechnology Company using the method as described previously^[10]. Each tube contained $5 \times$ buffer $5 \mu\text{L}$, 10 mmol/L dNTP $0.5 \mu\text{L}$, DTT $1.25 \mu\text{L}$, primers (sense, antisense) $4 \mu\text{L}$, RNA template $1 \mu\text{g}$, mix-enzyme $0.5 \mu\text{L}$, DEPC solution, with a total volume of $25 \mu\text{L}$ (Titan One Tube RT-PCR system, Roche, Germany). RT-PCR reaction condition is as follows: at 58°C for reverse transcription for 30 min, 94°C incubation for 2 min to terminate reverse transcription, followed by 30 cycles at 94°C for 30 s, at 52°C for 30 s, and at 72°C for 60 s; With a final extension at 72°C for 7 min. RT-PCRs were run in a Bio-rad thermocycler. The results were analysed in a Bio-rad GelDoc-1000 system, relative to the levels of β actin as the control.

Immunohistochemistry: ANG multiclonal antibody 1:25 was purchased from American Santa Cruz Co. VEGF-C multiclonal antibody (ready to use) was provided by American Zymed Co. Monoclonal antibody of CD34 (QEnd/10, ready to use) and monoclonal antibody of Ki-67 (MIB-1, 1:50) were supplied by American NeoMarkers Co. All operations were done according to the instructions of the manufacturers. Positive specimens were used as positive controls and PBS in substitution of the first antibody was used as a negative control at the same time.

ANG protein expression^[8]: Cytoplasm of gastric carcinoma cells was stained brown. According to the staining intensity of the tumor cells, the staining was graded as (-), when staining was weaker than negative control; (+), for light staining; (++), for moderate staining; and (+++), for strong staining.

MVD of HGC tissues^[9]: Gastric carcinoma vascular endothelial cells were stained brown. The isolated brown and yellow blood vessel endothelial cells or cell clusters in gastric carcinoma tissues were regarded as a single microvessel (Figure 1A). Areas with the highest microvessel densities were selected under $10 \times$ microscopic magnification. Then the numbers of microvessels stained by CD34 antibody in 10 vision fields were counted under $400 \times$ magnification (0.916 mm^2 per visual field), respectively. The average of 3 highest values was taken as MVD. Indistinguishable or indistinct cells were excluded.

VEGF protein expression: Membrane and cytoplasm

Figure 1 Expression of CD34, Ki-67, ANG and VEGF in gastric carcinoma tissue. A: CD34 (S-P $\times 200$); B: Ki-67 (S-P $\times 400$); C: ANG (EnVision $\times 400$); D: VEGF (S-P $\times 200$).

of gastric carcinoma cells were stained rose. The staining intensity of the tumor cells was classified as: light staining (+), moderate staining (++), deep staining (+++).

Proliferation index of tumor cells: The nuclei of the positive cells were stained deep brown (Figure 1B). The number of positive cells among 1000 tumor cells was counted per slide and taken as the tumor cell proliferation index.

Table 1 ANG and ANG mRNA expression and clinicopathological characteristics of gastric carcinoma

Characteristics	n	ANG mRNA (mean \pm SE)	ANG			
			+	++	+++	++++

Statistical analysis

Statistics software package was used for analysis. *t* test, analysis of variance, chi-square test and correlation analysis were used. $P < 0.05$ was taken as significance.

RESULTS

ANG mRNA expression in HGC tissues

ANG mRNA and its inner control β -actin were detected both in gastric carcinoma tissues and in corresponding nontumorous gastric tissues of all 68 cases. The RT-PCR products of ANG and β -actin were seen at 402 bp and 234 bp by gel electrophoresis (Figure 2). The expression of ANG mRNA was higher in 68 gastric carcinoma tissues (0.4822 ± 0.0943) than in corresponding nontumorous gastric tissues (0.2758 ± 0.0187 , $P < 0.05$). Although ANG mRNA expression was higher in poorly differentiated carcinomas, in carcinomas invading visceral peritoneum, carcinomas with lymph node metastasis and TNM stage III-IV than in well-moderately differentiated adenocarcinoma, in carcinomas invading lamina and muscularis propria, carcinomas without lymph node metastasis and TNM stage I-II, no statistical difference was found (Table 1).

ANG expression in HGC tissues

Immunohistochemistry staining showed that ANG located at the cytoplasm of gastric carcinoma cells as brown particles (Figure 1C). Over 90% of the gastric carcinoma cells were stained positive. The ANG expression level had no correlation with the age of patients, location, histological type, lymph node metastasis, and clinical stage of the tumor (Table 1).

ANG expression and the MVD of tumor tissues

ANG mRNA expression ratio of HGC tissues and the corresponding nontumorous gastric tissues (T/N) was

Figure 2 RT-PCR product electrophoresis. 1: β -actin of gastric carcinoma tissue, 234 bp; 2: ANG of gastric carcinoma tissue, 402 bp; 3: molecular weight marker; 4: β -actin of paired adjacent gastric mucosas, 234 bp; 5: ANG of paired adjacent gastric mucosas, 402 bp.

significantly correlated with the MVD of gastric carcinoma tissue. With the increase of ANG mRNA expression, MVD elevated also. A significant positive correlation was found between them ($r = 0.380$, $P < 0.01$). Also, with increase of ANG expression of gastric carcinoma tissues, MVD rose as well. The MVD of the ANG strong staining group (308.37 ± 25.57) was significantly higher than that of the negative group (196.00 ± 31.34) ($P < 0.01$).

Correlation between VEGF and ANG expression in HGC

The ANG expression in gastric carcinoma tissues was positively correlated with the expression of VEGF (Figure 1D) (Pearson correlation coefficient = 0.3490, $P < 0.01$).

Correlation between tumor proliferation index and ANG expression in HGC

The ANG expression levels of cancer tissues were positively correlated with the proliferation index of cancer cells ($P < 0.01$). The proliferation index of cancer cells of the group with strong ANG expression (579.58 ± 31.38) was much higher than that of the group with weak ANG expression (341.33 ± 84.01).

DISCUSSION

The up-regulation of expression of angiogenic factors in tumor tissue plays the role of switch-on in neoplastic angiogenesis. Research showed that hypoxia could induce up-regulation of ANG expression in human malignant melanoma, whereas it could induce down-regulation of ANG expression in normal melanocytes^[10]. It has been shown that ANG mRNA expression is significantly higher in human colorectal cancer^[4], pancreatic cancer^[5], malignant melanoma^[10], bladder carcinoma^[11] and other tumors than in normal tissues. Our results are similar to these. The ANG expression levels of gastric

carcinoma tissues were significantly higher than that in the surrounding nontumorous gastric mucosas. Both ANG mRNA and protein expression levels had no significant correlation with the patients' age, location, histological type, lymph node metastasis, and clinical stage of the tumor^[12]. Studies on pancreatic cancer^[5], invasive breast carcinoma^[13] and invasive cervical cancer^[14] have obtained similar results. In malignant melanoma, ANG expression is upregulated around necrotic areas and invasive borders of tumors, while necrotic tissues do not express ANG. This suggests that hypoxia is the reason for the upregulation of ANG in gastric carcinoma tissues.

Tumor angiogenesis is the precondition of tumor development. Tumor MVD is recognized as an important index for judging tumor angiogenesis, which is a multi-step process. Under the effect of angiogenic factors, endothelial cells proliferate and migrate to form new vessels, and new blood vessel networks. This study showed a positive correlation between ANG expression levels and tumor vascularity evaluated by MVD, suggesting ANG contributes to the angiogenesis of HGC. In addition, previous studies have shown ANG contributes to the neovascularization of hepatocellular carcinoma^[15], human colorectal cancer, and malignant melanoma^[10]. ANG is one of the efficient angiogenic factors, and the only angiogenic factor with RNase activity^[16]. There are two kinds of ANG-binding proteins on endothelial cells. One is actin, the other is a 170-kDa ANG-binding protein. Binding of ANG to cell surface actin causes activation of a cell-associated protease system and cell invasion. After the cells are activated, they migrate and invade the basement membrane, resulting in a decrease in the local cell density in the vicinity of the migrating cells, which may trigger the putative 170-kDa receptor gene expression in the remaining cells. These cells become ANG-responsive and divide to fill the space left by the migrating cells. The expression of the receptor gene is turned off when the gap is filled and cells become more dense. It may well be possible that the ANG-induced formation of a new capillary network is largely regulated by such cell density-dependent expression of the ANG receptor gene^[3].

ANG is required for cell proliferation induced by various other angiogenic proteins including acidic and basic fibroblast growth factors (aFGF and bFGF), epidermal growth factor (EGF), and vascular endothelial growth factor (VEGF). Angiogenin-stimulated rRNA transcription in endothelial cells may thus serve as a crossroad in the process of angiogenesis induced by various angiogenic factors^[17].

We found a positive correlation between ANG protein expression and VEGF expression in HGC tissues, suggesting ANG and VEGF may work in coordination in HGC angiogenesis. Asthmatic children have significantly higher levels of VEGF and angiogenin than healthy control children. A significant positive correlation exists between both angiogenic factors^[18]. Moreover, a correlation has been found between VEGF and ANG levels during fetal development and in maternal diabetes^[19]. Gonadotropin can not only stimulate the secretion of ANG by granulosa cells, but can also stimulate the secretion of VEGF by ovarian follicles. ANG and VEGF may also

work together in the angiogenesis of corpus luteum^[20]. Meanwhile, it was also found that hypoxia could induce the expression of VEGF^[16]. Hypoxic induced factor-1 (HIF-1) binds VEGF oxygen sensitive enhancer under hypoxic conditions. Through the activation of c-Src, it promotes the transcription and expression of VEGF. Expression of ANG may be up-regulated in response to hypoxia within the tumor. A significant increase in the secretion and mRNA expression of ANG from both term placental explants and trophoblast cultures subjected to hypoxia *in vitro* was observed^[21]. One study showed that ANG expression in invasive carcinomas is significantly positively correlated with HIF-1 alpha and the HIF-1 alpha target gene DEC-1^[22]. Hypoxia can also induce upregulated expression of ANG in corpus luteum granulosa cells. This is related to two HIF binding sites on the ANG promoter^[20]. Moreover, under hypoxic conditions, the ANG and VEGF secreted by renal proximal tubular epithelial cells may modulate angiogenesis and vascular remodeling in the renal *interstitium* via an increase in the production of HIF-1^[23]. Accordingly, hypoxia in HGC tissues may stimulate ANG and VEGF expression through the HIF-1 pathway. ANG and VEGF may work coordinately in the angiogenesis of HGC.

We found that ANG expression levels were closely correlated with rapid growth and metastasis of malignant tumors. Pancreatic cancers with high serum ANG (sANG) levels had larger volumes than those to low sANG levels^[5]. ANG expression in the gastric carcinoma tissues was significantly and positively correlated with the proliferation index of cancer cells. This suggests ANG could promote the growth of tumor cells. Studies have found that ANG can specifically combine with the leukemia cell line TF-1 and dose dependently promotes the growth of the leukemia cells^[24]. ANG is constitutively translocated into the nucleus of HeLa cells where it stimulates rRNA transcription, ribosome biogenesis, proliferation and tumorigenesis^[25].

In summary, ANG contributes to gastric carcinoma angiogenesis, and promotes the growth of tumor cells. Inhibition or blockage of the expression of ANG does not only reduce tumor angiogenesis, but also inhibits the growth of tumors directly. These have potential implications in tumor treatment.

Abstract

AIM: To analyze the biological effects of prolonged *in vitro* exposure of HT-29 and LoVo colon cancer cell lines to gefitinib (Iressa™), an inhibitor of epidermal growth factor receptor (EGFR) activity, and ZD6474, an inhibitor of both KDR and EGFR activities.

METHODS: Cells were treated with each drug for up to 2 wk using either a continuous or an intermittent (4 d of drug exposure followed by 3 d of washout each week) schedule.

RESULTS: In both cell types, prolonged exposure (up to 14 d) to gefitinib or ZD6474 produced a similar inhibition of cell growth that was persistent and independent of the treatment schedule. The effects on cell growth were associated with a pronounced inhibition of p-EGFR and/or p-KDR expression. Treatment with gefitinib or ZD6474 also inhibited the expression of EGFR downstream signal molecules, p-Erk1/2 and p-Akt, although the magnitude of these effects varied between treatments and cell lines. Furthermore, expression of the drug resistance-related protein ABCG2 was shown to significantly increase after 14 d of continuous exposure to the two drugs.

CONCLUSION: We conclude that long-term exposure of colon cancer cells to gefitinib and ZD6474 does not modify their cytotoxic effects but it might have an effect on sensitivity to classical cytotoxic drugs.

INTRODUCTION

Recently, a greater understanding of the molecular basis of cancer has fostered the development of rationally designed molecular-targeted therapies with agents that have been shown to prevent cell proliferation, differentiation and survival through the inhibition of receptor tyrosine kinases (TKs), such as epidermal growth factor receptor-1 (EGFR) and vascular endothelial growth factor receptors (VEGFRs)^[1,2].

Drugs that specifically target these receptors act *via* inactivation of the tyrosine kinase function of EGFR receptors resulting in lack of recruitment and phosphorylation of several intracellular substrates. A major downstream signalling route involved in this process is the Ras-Raf-MAPK pathway finally leading to ERK1 and 2 inactivation^[3,4]. Another important target in EGFR signalling is PI3K and the downstream AKT protein transducing signals to the cascade of survival and motility^[5,6]. Recently, the relevant role of the oncosuppressor gene PTEN in uncoupling some of these signalling pathways and thus generating gefitinib resistance has also been stressed^[7].

Gefitinib (Iressa) is a well-known oral EGFR inhibitor that is able to reduce tumour growth and the formation of metastases in a range of human cancer cell lines and human tumour xenografts^[8,9]. In the clinical setting, gefitinib monotherapy has demonstrated antitumour activity in patients with recurrent or refractory non-small-cell lung cancer^[10,11] and it has been approved for clinical cancer treatment in several countries. ZD6474 is a novel, orally available antiangiogenic agent that selectively targets two

key tumour growth pathways by inhibiting VEGFR and EGFR tyrosine kinase activities. Preclinical studies have shown ZD6474 to be a potent inhibitor of VEGF-induced endothelial cell proliferation, tumour-induced angiogenesis and tumour growth^[12].

Combining gefitinib or ZD6474 with other biological or cytotoxic agents has resulted in enhanced antitumour effects *in vitro* and *in vivo*^[13-17]. Several ongoing clinical trials are therefore investigating the clinical efficacy of these targeting molecules when administered (1-21 or 1-28 d) in combination with agents such as taxols, gemcitabine, cisplatin, oxaliplatin, 5-FU and irinotecan [www.clinical-trials.gov]. However, we have recently demonstrated that the effect of gefitinib used in combination with some cytotoxic drugs, can be schedule-dependent and have concluded that only extensive analysis of their main pathways of action could help in the design of an optimal multi-drug therapy^[13,15,16]. The great influence that schedules can have in combination treatments with TK-inhibitors and other cytotoxic drugs is also evinced by the fact that EGFR inhibitors can variously interact with proteins involved in resistance to some conventional cytotoxic drugs^[18,19]. In particular, ABCG2 and mdr-P glycoprotein (P-gp), belonging to ATP-binding cassette (ABC) transporters, are involved in sensitivity to topoisomerase I inhibitors^[20] and anthracyclines^[21].

In vitro data analyzing the activity of TK inhibitors on cell growth, apoptosis induction or cell cycle and target modulation are mainly limited to very short term cell exposures to drugs, generally lasting no longer than 5 d^[22-24]. Although such exposure times are useful to clarify the molecular mechanisms of action of this class of drugs, they do not account for some major cell mechanisms controlling the expression and function of EGFR receptors^[25]. Some such mechanisms that are known to produce EGFR down-regulation are endocytosis, pH-sensitive dissociation, dephosphorylation by PTP1B, trafficking to the lysosome, *etc.*^[26-29].

Data from *in vivo* studies on the effects of prolonged exposure to TK inhibitors are scant. An *in vivo* study on long-term exposure confirmed that TK inhibitors are able to reduce tumour growth when utilized alone or in association with other drugs^[9,30] but at least one other study has demonstrated that tumour cell lines can develop resistance to gefitinib^[31]. The only *in vitro* report analyzing the pharmacological and biological effects of prolonged exposure to an EGFR inhibitor supports the hypothesis that duration of cell exposure to such a drug is important in modulating its antitumour effect and synergism with other drugs^[32].

The aim of this study was to investigate the cytotoxic and biomolecular effects of different gefitinib and ZD6474 long-term exposure modalities on colon cancer cell lines and, whether phosphorylation of their specific targets (EGFR and/or KDR), activity of downstream signalling molecules and multidrug resistance proteins were modified in an exposure time-dependent manner.

MATERIALS AND METHODS

Drugs and chemicals

Gefitinib and ZD6474 were provided by AstraZeneca Phar-

maceuticals (Macclesfield, UK). Stock solutions were prepared at 20 $\mu\text{mol/L}$ in dimethyl sulphoxide (DMSO) and stored in aliquots at -20°C . Further dilutions were made in F-12/HAM or McCoy's medium supplemented with 10% fetal bovine serum, 2 mmol/L glutamine, 50 000 U/L penicillin, and 80 $\mu\text{mol/L}$ streptomycin.

Cell lines

Two colon cancer cell lines of human origin were used, LoVo and HT-29. Cells were routinely cultured in F-12/HAM (LoVo) or McCoy's (HT-29) medium, supplemented as above, in a humidified incubator at 37°C with a 50 mL/L CO_2 atmosphere. Cells were trypsinized once a week with trypsin 0.25% ethylenediaminetetraacetic acid 0.02%, and the medium was changed twice a week. Doubling times were 20 ± 1 h for HT-29 cells and 24 ± 1 h for LoVo cells.

HPLC drug analysis

Gefitinib or ZD6474 (1-100 $\mu\text{mol/L}$) were incubated in F-12/HAM or McCoy's medium, supplemented as above, in a humidified incubator at 37°C with a 50 mL/L CO_2 atmosphere for 1, 5 and 7 d, after which HPLC analysis was performed. The stock solutions of each drug in DMSO were used as controls. The HPLC consisted of an LC9010 system coupled with a UV detector (Varian Inc, Palo Alto, CA, USA). Purified drug was eluted from an Aspec Bond Elut-C2 column (Varian Inc) using a solution of triethylamine and acetonitrile (76:24 [v/v]) adjusted to pH 3.0 with 0.2 mol/L phosphoric acid.

Evaluation of cytotoxicity

Determination of the IC_{50} of gefitinib or ZD6474 was performed using the 3-[4, 5-dimethylthiazol-2-yl]-2, 5-diphenyltetrazoliumbromide (MTT) assay. On d 1, 10 000 cells/well in a volume of 200 μL were added to 96-well plates. In each plate, one column contained cells not exposed to the drug (control), and five columns contained cells exposed to increasing concentrations of the drug. Each drug concentration was repeated in six identical wells. On d 2, gefitinib or ZD6474 (0.01, 0.1, 1, 10 and 100 $\mu\text{mol/L}$) was added allowing for different times of drug exposure (18 h to 3 d). Results were expressed as dose-effect curves with a plot of the fraction of unaffected (surviving) cells *versus* drug concentration. The IC_{50} was defined as the drug concentration yielding a fraction = 0.5 of affected (not surviving) cells, compared with untreated controls.

Cell growth inhibition following prolonged drug exposure

LoVo and HT-29 cells were exposed to gefitinib (0.12 $\mu\text{mol/L}$ and 1.2 $\mu\text{mol/L}$, respectively) and ZD6474 (0.6 $\mu\text{mol/L}$ and 5 $\mu\text{mol/L}$, respectively). These sub-toxic concentrations induced 30% cell growth inhibition after 3 d of continuous drug exposure. Cell survival was determined by cell counts after 7 and 14 d of drug exposure, using either a continuous or intermittent (4 d with drug followed by a 3-d washout) schedule. Controls were untreated cells which, at a quite complete confluence, were counted, divided, and plated again at 70% of confluence. Results were expressed as percentage of cell survival compared with untreated controls.

Table 1 AUC and retention time of gefitinib or ZD6474 following incubation for 7 d at 37 °C, by HPLC analysis

Drug	Medium	Concentration (μmol/L)	Retention time (min)	AUC
Gefitinib	DMSO	100	2.47 ± 0.03	1.30 ± 0.20
	Complete medium	100	2.52 ± 0.05	1.27 ± 0.16
ZD6474	DMSO	100	1.75 ± 0.02	0.88 ± 0.08
	Complete medium	100	1.71 ± 0.04	0.86 ± 0.10

Cell-cycle perturbation and apoptosis

LoVo and HT-29 cells were exposed to gefitinib (0.12 μmol/L and 1.2 μmol/L, respectively) and ZD6474 (0.6 μmol/L and 5 μmol/L, respectively) for 7 and 14 d, using either a continuous or intermittent (4 d with drug followed by a 3-d washout) schedule. Cells were then harvested, washed twice in ice-cold PBS (pH 7.4), fixed in 4.5 mL of 70% ethanol at -20 °C and washed once again in ice-cold PBS. After resuspension of the pellet in PBS containing 1 mg/mL RNase and 0.01% NP-40, cellular DNA was stained with 50 μg/mL propidium iodide (Sigma-Aldrich, St Louis, MO, USA). Cells were stored in ice for 60 minutes before analysis. Cell cycle and apoptosis determinations were performed using a FACScan flow cytometer (Becton Dickinson, Franklin Lakes, NJ, USA), and data were interpreted using the ModFit software provided by the manufacturer.

Immunoprecipitation and Western blot analysis of targets after prolonged drug exposure

Expressions of EGFR, KDR, Akt, p-Akt, Erk1/2, p-Erk1/2, PTEN, ABCG2 and PgP were determined by Western blot analysis using β-actin as the standard protein. Expressions of p-EGFR and p-KDR were determined by immunoprecipitation and Western blot. Protein bands were quantified by densitometric analysis followed by analysis with Quantity One software (BioRad, Hercules, CA, USA). The primary antibodies used were anti-EGFR (clone 13) and anti-KDR (clone A-3) from BD Transduction Laboratories (San Diego, CA, USA); Anti-Akt, anti-p-Akt, anti-Erk1/2 and anti-p-Erk1/2 (clone E10) from Cell Signaling Technology (Beverly, MA, USA); Anti-ABCG2 (clone BXP-21) from Alexis Corporation (Lausen, Switzerland); Anti-PgP (clone F4) and anti-β-actin from Sigma-Aldrich; And anti-phosphotyrosine polyclonal antibody PY99 and anti-PTEN (A2B1) from Santa Cruz Biotechnology (Santa Cruz, CA, USA). The secondary antibodies used were horseradish-peroxidase-conjugated anti-mouse and anti-rabbit from Amersham Pharmacia Biotech (Uppsala, Sweden).

Statistical analysis

All the *in vitro* experiments were performed in triplicate, and results are expressed as the mean ± SD unless otherwise indicated.

RESULTS**Time-dependent drug stability**

To verify gefitinib and ZD6474 stability in our

Table 2 IC₅₀ of gefitinib and ZD6474 in HT-29 and LoVo cells at various times of incubation

Exposure time	Gefitinib (μmol/L)		ZD6474 (μmol/L)	
	LoVo cells	HT-29 cells	LoVo cells	HT-29 cells
18 h	48.5 ± 2.5	> 100	16 ± 5.1	80 ± 4.8
1 d	29 ± 3.1	> 100	13 ± 2.6	59 ± 3.6

Table 3 Cell cycle and apoptosis modulation after prolonged exposure to gefitinib or ZD6474 in HT-29 and LoVo cells

Drug exposure	LoVo cells		HT-29 cells	
	Apoptosis (%)	G0/G1 (%)	Apoptosis (%)	G0/G1 (%)
Control	0	74.3 ± 1.3	0	69.5 ± 1.4
Gefitinib	1 wk continuous	10.1 ± 0.5	80.4 ± 1.5	7 ± 0.4
	2 wk continuous	23.2 ± 0.9	87.9 ± 1.3	20 ± 1.2
	1 wk intermittent	13.8 ± 0.6	75.4 ± 1.4	6.5 ± 0.3
	2 wk intermittent	29.7 ± 0.8	78.0 ± 2.1	18.3 ± 1.8
Control	0	74.3 ± 2.1	0	69.5 ± 1.8
ZD6474	1 wk continuous	15.4 ± 0.6	77.6 ± 1.9	7 ± 0.9
	2 wk continuous	30.3 ± 0.9	81.8 ± 2.3	15 ± 0.8
	1 wk intermittent	18.3 ± 1.3	74.6 ± 2.1	7.3 ± 1.1
	2 wk intermittent	29.6 ± 1.5	76.5 ± 1.5	16.4 ± 2.2

Each experiment was conducted in triplicate.

experimental conditions, each drug was incubated in complete medium for 1, 5 and 7 d. The HPLC retention time and the area under the curve (AUC) for the peak of each drug were measured and compared to those of the same drugs in DMSO (standard). The HPLC retention times for the internal standards were 2.47 min for gefitinib and 1.75 min for ZD6474. Each drug showed the same retention time as its standard, irrespective of concentration, exposure time and the absence or presence of complete medium; the AUC of each peak was proportional to the drug concentration. These results confirmed the stability of gefitinib and ZD6474 in our experimental conditions. Table 1 shows the AUC and retention times of gefitinib and ZD6474 peaks obtained by HPLC after 7 d of drug exposure.

Drug-dependent cell growth inhibition and apoptosis

The IC₅₀ values for gefitinib and ZD6474 in HT-29 and LoVo cells are shown in Table 2. A time-dependent reduction in IC₅₀ was observed for both drugs, with the IC₅₀ after 3 d of exposure being 4-8 times lower than after 18 h of exposure.

Treatment with gefitinib for 1 wk, according to a continuous or intermittent schedule, did not significantly affect LoVo cell growth, and 2 wk of treatment was necessary to show an inhibitory effect (Figure 1A). By contrast, HT-29 cell growth was inhibited by gefitinib at 1 wk and to an even greater extent at 2 wk. ZD6474 induced a progressive, exposure-dependent inhibition of cell growth in both cell lines, but HT-29 cells appeared to be more sensitive than LoVo cells (Figure 1B).

As expected, prolonged exposure of the cells to gefit-

Figure 1 Drug-dependent cell growth inhibition. LoVo and HT-29 cells were incubated with gefitinib (0.12 and 1.2 $\mu\text{mol/L}$, respectively) or ZD6474 (0.6 and 5 $\mu\text{mol/L}$, respectively) for 7 and 14 d with continuous and intermittent exposure. Cell survival was determined by cell counts.

inib or ZD6474 produced an exposure-dependent increase in apoptosis (Table 3). This effect was observed with both the continuous and the intermittent treatment schedules. There was also a moderate accumulation of cells in the G0/G1 phase and this effect became more evident at 2 wk with continuous exposure (Table 3).

Modulation of TK receptor signal transduction pathways

The ability of gefitinib and ZD6474 to modulate their specific targets and downstream effectors was analyzed by measuring the expression levels of total and phosphorylated proteins.

TK receptor modulation: Prolonged exposure to gefitinib and ZD6474 of both cell lines, using either a continuous or intermittent treatment schedule, did not change the total amount of EGFR or KDR protein. HT-29 cells exposed to gefitinib for 7 and 14 d showed almost no detectable p-EGFR (Figure 2). In LoVo cells, gefitinib produced partial inhibition of p-EGFR that was appreciable only after 14 d of treatment. In both cell lines, ZD6474 almost completely inhibited p-KDR (approximately 98% inhibition compared with the control; Figure 2). ZD6474 also inhibited p-EGFR, with a greater effect in HT-29 cells than in LoVo cells.

EGFR signal transduction pathway modulation: Prolonged exposure to gefitinib and ZD6474 did not change the expression of Akt and Erk1/2 in HT-29 or LoVo cells. Gefitinib produced only modest effects on p-Akt but markedly decreased p-Erk1/2, the downstream effector of the proliferation pathway (Figure 3). Compared with the 7 d exposure, the magnitude of gefitinib-mediated

Figure 2 p-EGFR and p-KDR modulation after prolonged exposure to gefitinib or ZD6474. Cells were incubated with gefitinib or ZD6474 for 7 and 14 d with continuous and intermittent exposure. Drug-dependent modulation of p-EGFR (180 kDa) and p-KDR (195 kDa) was determined by immunoprecipitation followed by Western blotting. All data are shown relative to the baseline level (control = 0), which was similar after 7 and 14 d.

inhibition of p-Erk1/2 at 14 d was similar in the HT-29 cells, but had decreased in the LoVo cells.

Continuous or intermittent treatment with ZD6474 was associated with only a slight inhibition of p-Akt (Figure 3). ZD6474 induced a progressive and almost complete inhibition of p-Erk1/2 in HT-29 cells, but not in LoVo cells.

PTEN modulation: With a progressive increase in exposure time from 1 to 14 d, neither gefitinib nor ZD6474 modulated the total amount of PTEN in either cell line (data not shown).

Drug resistance induction

Preliminary analysis of the baseline expression levels of

Figure 3 p-Akt and p-Erk1/2 modulation after prolonged exposure to gefitinib or ZD6474. Cells were incubated with gefitinib or ZD6474 for 7 and 14 d with continuous and intermittent exposure. Drug-dependent p-Akt and p-Erk1/2 modulation was determined by Western blotting. All data are shown relative to the baseline level (control = 0), which was similar after 7 and 14 d.

Figure 4 Increased ABCG2 expression after prolonged exposure to gefitinib or ZD6474. Cells were incubated with gefitinib or ZD6474 for 7 and 14 d with continuous and intermittent exposure. Drug-dependent increases in ABCG2 expression were determined by Western blotting. All data are shown relative to the baseline level (control = 0), which was similar after 7 and 14 d.

proteins related to drug resistance showed that ABCG2 was detectable in HT-29 and LoVo cells while P-gP was undetectable. LoVo cells also showed a higher level of ABCG2 than HT-29 cells. Interestingly, both gefitinib and ZD6474 exhibited time exposure-dependent increase in ABCG2 expression only in HT-29 cells; this effect became

evident after 5 d of drug exposure (data not shown) and was progressive until 14 d (Figure 4). Stimulation of ABCG2 expression was more evident after continuous exposure to gefitinib or ZD6474 (150% and 90% increase in ABCG2 expression, respectively) than after intermittent exposure (80% and 50% increase compared with controls, respectively).

DISCUSSION

Analysis of the biomolecular effects that the TK inhibitors, gefitinib and ZD6474, can have on tumour cells after prolonged drug exposure is instrumental in leading to optimization of their use in monotherapies and in combination with other biological or conventional cytotoxic drugs^[10,11,33,34]. Several cell effects have been demonstrated to depend directly on the modality and duration of cell exposure to these drugs; these effects include receptor expression, function of signal transduction, modulation of drug resistance proteins, etc. Nonetheless, and in spite of the clinical modalities of administration of these drugs, *in vitro* studies describing the inhibitory effect of gefitinib or ZD6474 on cell growth have considered only short drug exposures of 1-5 d^[22-24].

In our study, we assessed the effects of prolonged exposure to the TK inhibitors, gefitinib and ZD6474, on cell viability and on their specific molecular targets by directly monitoring the modulation of the phosphorylated form of EGFR and of the two effectors, Akt and Erk1/2, that are important in the cell survival and proliferation pathways, respectively.

Two weeks exposure to gefitinib resulted in up to 70% cell growth inhibition and no apparent differences between the continuous and the intermittent treatment schedules. Moreover, as already reported for erbitux^[32], gefitinib inhibited the phosphorylated forms of the receptor p-EGFR and of the downstream effector p-Erk1/2 involved in the proliferation pathway. The effects of gefitinib on p-Akt were less dramatic and appeared to be cell line-specific.

Comparison of these results with those obtained after short-term drug exposure^[13] highlighted differences in the molecular effects produced by different drug schedules. Although a high rate of cells died after 2 wk of drug exposure in our investigation, cells tried to escape the attack by an exogenous agent by further modulating the survival and proliferation pathways. These findings suggest that a combination of Gefitinib and other PI3K/Akt pathway inhibitors, such as mTor inhibitor, may produce a more powerful synergistic effect.

ZD6474 proved to be able to inhibit the growth of our two colon cancer cell lines, thus confirming similar effects previously observed in GEO cells^[23]. In both cell lines, the ZD6474-mediated inhibition of growth was associated with almost complete inhibition of p-KDR and p-EGFR, as well as a slight inhibition of p-Akt. In contrast, the modulation of p-Erk1/2 by ZD6474 was evident in HT-29 cells only.

Another aspect we considered was the effect on the expression of the tumour suppressor PTEN. Unlike Nagata, who reported PTEN modulation after 1 hour of exposure to the anti-ErbB2 antibody, trastuzumab^[35], no appreciable modulation of this protein was observed in our study after short or long, continuous or alternate drug exposures. Our conclusion was that 14 d of drug exposure may be long enough for recovery of the possibly transient and short-term modulation of this gene potentially occurring in the first few hours after treatment with TK inhibitors.

Tyrosine kinase inhibitors have shown the potential to modulate cytotoxic drug resistance, through an interaction

with ABCG2 and PgP^[18,19]. In our study, ABCG2, which is involved in camptothecin resistance^[20], was detectable in both HT-29 and LoVo cells while PgP, which is involved in anthracycline resistance, was not detectable in either cell line. The increased ABCG2 expression, following exposure to gefitinib or ZD6474, was cell line-specific. The HT-29 cells showed a progressive exposure-related increase of 100%-150%, while expression in the LoVo cells was unaffected. The increased expression of ABCG2 in HT-29 cells was schedule-dependent, and it was higher with continuous than with intermittent incubation. Our results seem to be in contrast with those obtained by Nakamura^[19] but the experimental conditions used were completely different. Nakamura used a short time (15 min) to show a gefitinib-dependent increase in topotecan accumulation in transfectant cells, overexpressing ABCG2, and 4 d of gefitinib plus cytotoxic drugs exposure to led to reversal of drug resistance. In our experiments the ability of gefitinib to enhance ABCG2 expression proved to be a late effect of the drug and may account for the antagonism between Topoisomerase-I inhibitors and TK-inhibitors in HT-29 cells induced by a pre-exposure to gefitinib for 5 d^[13]. Moreover, the cell-line-specific effects of gefitinib and ZD6474 on drug-related proteins may provide an explanation for the different results. Wakeling and Ciardiello obtained^[30,31] when analyzing the onset of drug resistance *in vivo* after long-term drug intake.

In conclusion, our investigation studied, in an *in vitro* model of colon cancer, some crucial points related to the clinical use of these TK inhibitor drugs. Evidence has emerged that long term use (maximum 14 d) of these drugs does not lead to a loss of cell activity and intermittent or continuous exposures to these drugs do not produce significantly different toxic effects. The main signal transduction steps for TK receptor pathways were also studied and the findings demonstrated that the effects of these drugs may be highly cell-line-specific (HT-29 *vs* Lovo), drug-dependent (gefitinib *vs* ZD6474) and schedule-related (continuous *vs* intermittent), thus indicating that a predictive factor for these drugs cannot be easily identified or broadly applicable. The data concerning the modulation of drug resistance related proteins in tumour cells treated with long-term drug exposure are even more interesting. ABCG2 expression was shown to be induced by these drugs in a cell-line- specific and schedule-dependent manner. This evidence should suggest caution in choosing exposure times when combining these drugs with Topoisomerase-I inhibitors in particular. The findings of this study can be instrumental in the implementation of future *in vitro* and clinical studies on these drugs.

Abstract

AIM: To assess the feasibility of using BRAF, K-ras and BAT26 genes as stool-based molecular markers for detection of colorectal adenomas and hyperplastic polyps (HPs).

METHODS: We applied PCR-SSCP and direct sequencing to detect BRAF mutations of polyps and paired stool samples. Primer-mediated restriction fragment length polymorphism (RFLP) analysis and mutant-enriched PCR were used in detection of K-ras mutations of polyp tissues and paired stool samples respectively. BAT26, a microsatellite instability marker was examined by detection of small unstable alleles in a poly (A) repeat.

RESULTS: No genetic alterations were detected in the 36 colonoscopically normal patients in either tissues or stools. BRAF, K-ras and BAT26 mutations were found in 4 (16%), 10 (40%) and 3 (12%) of 25 adenoma tissues and among them, 75%, 80% and 100% of patients were observed to contain the same mutations in their corresponding stool samples. In HPs, mutations of BRAF and K-ras were detected in the tumor DNA of 2 (11.1%) and 8 (33.3%) of 18 patients respectively, all of whom had identical alterations in their stools. Taken together, the three genetic markers detected 15 (60%) of 25 adenomas and 8 (44.4%) of 18 HPs. The sensitivity of stool detection was 80% for adenomas and 100% for HPs with an overall specificity of 92% for adenomas and 100% for HPs.

CONCLUSION: BRAF, K-ras and BAT26 genes have the potential to be molecular markers for colorectal adenomas and HPs, and can be used as non-invasive screening markers for colorectal polyps.

INTRODUCTION

Colorectal cancer (CRC) is one of the most common malignancies in the world and it is a disease that can be easily cured either by surgery or by endoscopic excision when diagnosed at an early stage^[1]. It has been generally accepted that a majority of CRC develop through a well-defined adenoma-carcinoma sequence in which multiple genetic changes are involved in this pathway that is known as chromosomal instability pathway. K-ras gene is known to play an important role along this pathway in transitioning from early to intermediate adenomas^[2]. However, increasing evidence accumulates that a subset of CRC arises *via* the hyperplastic polyp (HP)-serrated adenoma (SA)-carcinoma sequence that is associated closely with microsatellite instability (MSI) positive colorectal carcinomas^[3-5]. These polyps are usually large and/or multiple and/or located in the proximal colon^[6,7]. APC mutation is not involved in this pathway whereas K-ras and BRAF mutations are frequently observed in these polyps with MSI^[8,9]. Both BRAF and K-ras are proto-oncogenes that interact in tandem in the RAS-RAF-MEK-ERK-MAP kinase signaling pathway, which plays an important role in the control of cell differentiation, proliferation, survival, and apoptosis^[10].

HPs have long been regarded as safe lesions without neoplastic potential^[11]. However, this view has been changed due to the discovery of the HP-SA-carcinoma sequence. Now it is believed that adenomas as well as some types of HPs are precursors of sporadic CRCs that may eventually develop into adenocarcinomas^[2,5]. So detection and surveillance of these premalignant polyps may be of great importance in reducing the incidence of colorectal cancer. BRAF and K-ras mutations have been frequently observed in both adenomas and HPs^[8-10]. This prompted us to detect colon polyps through analysis of these genes in stool DNA. In this study, we detected mutational activation of the K-ras and BRAF genes and along with an MSI marker, BAT26 in patients with adenomas or HPs, and

performed a pair comparison between tumor tissue and stool sample in individual patients to assess the feasibility of using these genes as molecular markers for colon polyps.

MATERIALS AND METHODS

Patients and samples

We recruited 79 patients who underwent colonoscopy for various reasons at the 2nd Affiliated Hospital of Harbin Medical University from June 2004 to March 2005. These included 36 control patients without neoplasms, 18 patients with hyperplastic polyps and 25 patients with adenomas. Diagnosis was histologically confirmed. The mean age of control patients was 49.6 years compared with 51.6 years for patients with HPs and 56.5 years for patients with adenomas. Of the 43 polyps, 34 were from males and 9 were from females. Twenty-seven were from the left colon and 16 were from the right colon. The size of these polyps ranged from 3 to 50 mm in maximal dimension (mean = 5.28 mm for HPs and 18.7 mm for adenomas). Patients who had familial adenomatous polyposis or hereditary nonpolyposis colon cancer, and inflammatory bowel diseases were excluded.

Fresh stool specimens were collected from patients prior to colonoscopy. All the patients were given detailed oral and written instructions for stool collection. Stool samples were frozen immediately at -20°C after collection and transferred to -80°C for permanent storage within 24 h.

With the informed consent of all patients and approval of the ethics committee, paired bioptic polyp tissues were obtained during polypectomy. One part of the tumor was snap frozen in liquid nitrogen and stored at -80°C until the extraction of nucleic acids. Another part was fixed in formalin and paraffin-embedded for diagnosis.

DNA extraction

DNA was isolated from stool samples by means of the QIAamp DNA stool mini kit (QIAGEN, USA) and from snap frozen tissues using Trizol reagent (Invitrogen, Life Technologies, USA) according to the manufacturer's instructions.

Mutational analysis and sequencing of the BRAF gene

To detect possible sequence alterations in BRAF, we performed nonisotopic single-strand conformational polymorphism (SSCP) analysis. The complete sequence of exon 15 of the BRAF gene was amplified from 50 ng of genomic DNA using the primers described previously^[9]. PCR was carried out for 40 cycles with initial denaturation at 95°C for 5 min, followed by 95°C for 40 s, 55°C for 40 s, and 72°C for 40 s in a reaction volume of 25 µL. The PCR products were then separated on 8% nondenaturing polyacrylamide gels (29:1) with or without 5% glycerol, and electrophoresis of the gels was carried out at 4°C-8°C. The gels were then fixed in 10% acetic acid, silver stained in a freshly prepared silver nitrate (0.1%) and developed in 3% sodium carbonate with 0.05% formaldehyde and 0.2% sodium thiosulphate.

All PCR products showing mobility shifts on SSCP were reamplified and purified, and evaluated by direct

sequencing with an ABI 3700 DNA sequencer (Applied Biosystems).

Primer-mediated RFLP analysis

The mutations at codons 12 and 13 of K-ras gene in tumor samples were screened by primer-mediated restriction fragment length polymorphism (RFLP) analysis as described^[12]. Human placental DNA (Sigma, USA) was used as a wild type control. Colorectal carcinoma DNA with known mutations at K-ras codon 12 (GGT to GTT) and at codon 13 (GGC to GAC) was used as mutant controls.

Mutant-enriched PCR

Mutant-enriched PCR was used to analyze the mutational status of the K-ras gene in stool samples. The procedure was the same as described^[12] with the only exception that 5 U of BstNI or Bgl I (NEB, Beijing) was used for the digestion, and the reaction was completed overnight. Final products were separated on 4% agarose gel and visualized by ethidium bromide staining. The same positive and negative controls were used as in PCR-RFLP analysis.

MSI analysis

The MSI marker used was BAT-26, a mononucleotide repeat that by itself is a very good measure of generalized instability. PCR reactions were performed with the specific primers reported previously^[13]. PCR products were loaded on 8% polyacrylamide/ 7 mol/L urea DNA-denaturing sequencing gels and silver stained as described above.

Statistical analysis

Differences between groups were assessed by χ^2 test and Fisher's exact test. All P values were two sided. Factors with $P < 0.05$ were considered statistically significant. The 95% confidence intervals (CI) were determined based on the exact binomial distribution.

RESULTS

Twenty-five sporadic adenomas and 18 hyperplastic polyps were collected and analyzed for the alterations of K-ras, BRAF and BAT26 genes. The median age of the patients with HPs was 56 years (range: 28-70) compared with 61.8 years for patients with adenomas (range: 40-74). Thirty-six stool samples from control patients were also detected.

Adenomas

Mutations of exon 15 of BRAF and codons 12, 13 of K-ras genes were analyzed, as these cover most of the mutation hot spots known of the two genes. The alterations of BRAF, K-ras and BAT26 genes in adenomas and their relationship with clinico-pathological characteristics are shown in Table 1.

Of 25 tumor samples detected, 15 [60%, 95% CI: 39%-79%] were found to have at least one alteration in BRAF, K-ras or BAT26 genes. BRAF mutations were identified in 4 (16%, 95% CI: 5%-36%) cases, all at nucleotide position 1799 with T-A transversions (V599E) as confirmed by direct sequencing (Table 1, Figure 1). No significant correlation was found between BRAF mutations with

Group HPs included the individuals with only hyperplastic polyps. If an individual had multiple polyps and if any one of the polyps exceeded 10 mm in diameter, it was regarded as ≥ 10 mm in size. SP: Single polyp; MP: Multiple polyps. Proximal tumors were defined as cecum through transverse colon; tumors in the splenic flexure, descending, and sigmoid colon were defined as distal. ¹Fisher's exact test, *P* = 0.01.

Table 2 BRAF mutations in colorectal adenomas and HPs with BAT26 status

	No of samples	No of BRAF mutation (%)

patient's gender, age, location of tumor and tumor size (Table 1). The identical V599E mutations of the BRAF gene were also observed in 3/25 (12%, 95% CI: 3%-31%) of fecal samples with a 75% agreement between tumor and stool.

In total, 3/25 (12%, CI: 3%-31%) of tumor DNAs showed BAT26 alterations (Table 1) and the same mutations were also observed in all the 3 paired stool samples. Two of the 3 samples with a BAT26 alteration also harbored a BRAF mutation that showed a close

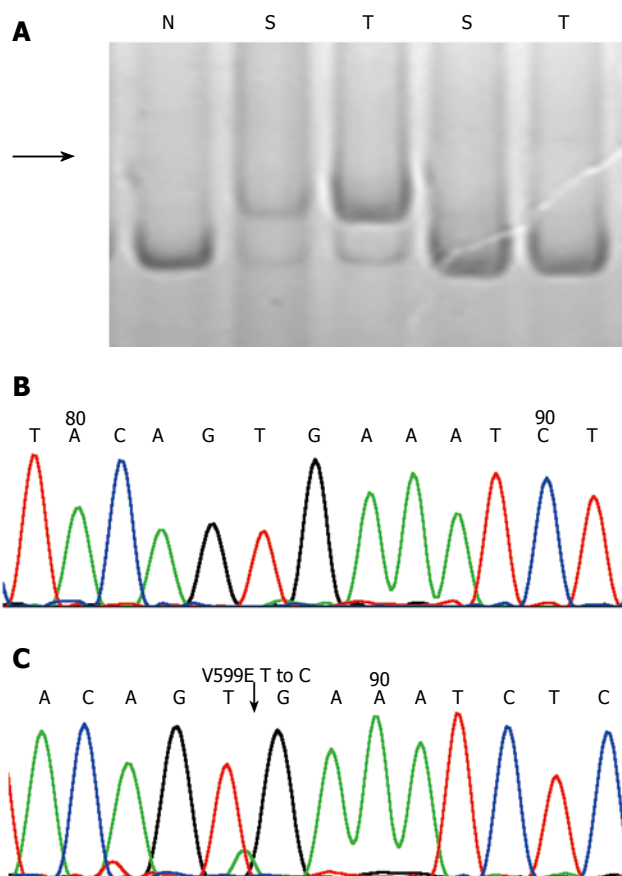

Figure 1 Example of BRAF mutation analysis in adenoma tissues (T) and paired stool (S) samples. **A**: SSCP analysis; **B**: Direct sequencing showing the wild type BRAF; **C**: BRAF V599E mutation; N: normal. Arrows indicate the new band (**A**) and the mutation site (**C**).

Figure 2 Analysis of K-ras mutations at codon 12 (**A**) and codon 13 (**B**) in adenoma tissues (T) and paired stool (S) samples. Fragments of 157 bp indicate mutations, and fragments of 128 bp (**A**) or 125 bp (**B**) respectively represent wild-type alleles. M: 100 bp ladder marker; P: Positive control; **B** shows the result that a mutation at codon 13 of K-ras in stool DNA was not observed in tumor counterpart.

relationship between BRAF mutation and MSI (66.7% vs 4.5%, *P* < 0.05, Table 2). All 3 BAT26 positive samples were found in patients younger than 60 year and in adenomas larger than 10 mm in size but of no statistical significance. Also no significant relationship was found with respect to patient's gender and tumor site.

Among 25 tumor samples analyzed for K-ras mutations at codons 12 and 13, 10 (40%; 95% CI: 21%-61%) samples were found to carry a mutation, 8 of which were at codon 12 and 2 at codon 13 (Table 1, Figure 2). Mutations of the K-ras gene in corresponding stool samples were detected by mutant-enriched PCR^[12]. Of 25 stool samples

analyzed, K-ras alterations were observed in 9 (36%, 95% CI: 18%-58%) patients, 7 at codon 12 and 2 at codon 13. Eight of 10 stool DNAs had a mutation that matched exactly with the results of the corresponding tumor analysis (sensitivity: 80%, 95% CI: 44%-97%) whereas there was one case in which a K-ras mutation at codon 13 was observed in stool DNA but could not be detected in the corresponding tumor (specificity: 94%, 95% CI: 71%-100%, Figure 2). None of the tumor or stool samples with V599E carried a K-ras mutation.

To sum up, the three genetic markers detected 13/25 (52%) of stool samples of adenoma patients. The overall sensitivity of stool analysis using these three genes was 80% (12/15, 95% CI: 52%-96%) with a specificity of 92% (12/13, 95% CI: 64%-100%).

Hyperplastic polyps and normal controls

Eight (44.4%, 95% CI: 22%-69%) of the 18 HPs were found positive in either the BRAF or K-ras gene while no alterations were found in the BAT26 gene (Table 1). In corresponding stool samples, the same mutations were identified in all the 8 samples whose tumors contained the alterations with a 100% agreement between tumors and stools. No alterations were found in the other 10 samples. The specificity was also 100%. BRAF mutations were more common in polyps larger than 10 mm in size ($P < 0.05$, Table 1). BRAF and K-ras mutations were also mutually exclusive. No alterations were found in any of the three markers tested in 36 control DNAs of fecal origin.

DISCUSSION

In this study, we assessed the use of genetic alterations of BRAF, K-ras and BAT26 genes as stool-based molecular markers for colon adenomas. To our knowledge, this is the first time to show the results of stool-based gene detection of colorectal hyperplastic polyps.

We identified 16% of BRAF mutations and 40% of K-ras mutations in adenoma tissues. The results are similar to those reported previously^[10]. However, in HPs, we observed a relatively lower incidence of BRAF mutations and a higher incidence of K-ras mutations than other studies^[8,9]. Chan^[8] reported a 36% BRAF mutation rate in HPs and Yang^[9] reported an even higher mutation rate of 69.6%, but our result was only 11.1%. The incidence of K-ras mutations was 18% and 20% respectively by Chan^[8] and Yang^[9] but ours was 33.3%. This difference may be due to the small sample numbers in our study. The only form of BRAF mutation observed in our study was V599E. It is the most common mutation identified to date^[8-10]. This missense mutation has been proven to maximally activate kinase activity of the BRAF protein and mutated forms of BRAF can transform NIH3T3 cells^[14]. It is obvious that this variant has a strong functional selection for growth advantage. The high incidence of mutually exclusive mutations of BRAF and K-ras in both adenomas and HPs supports the previous hypothesis that activations of both genes are an early event in tumorigenesis of CRC^[8-10].

BAT26 alteration was observed in 3/25 (12%) of adenomas, two of which also harbored a BRAF mutation. This close relationship between BRAF and MSI status

agrees well with the findings in sporadic CRC^[10]. By contrast, no BAT26 alteration was found in HPs. High level MSI was more often found in tumors located in the right colon, and most of our HPs were located in the left colon. However, several other studies have also reported a low MSI in HPs and serrated adenomas^[15].

It is interesting to note that although not significant, in our study, patients with > 60 years of age had a tendency towards a lower prevalence of any mutation in both the adenoma and HPs groups. This may be due to the small sample numbers detected in our study, and larger sample analysis is needed to prove this phenomenon.

Based on our findings in the adenomas and HPs, we tried to use these three genes as stool based molecular markers for colon adenomas and HPs. Of the 15 adenomas that showed positive results, 12 (80%) samples have been detected to be positive in corresponding stool DNA, with a specificity of 92%. This result is quite comparable with the findings reported previously^[16-20], in which DNA panel targeted mutations at K-ras, APC and p53 genes as well as BAT26 and long DNAs were used. But our detection seemed to be more convenient. First, mutation at the BRAF V599E hotspot is relatively simple to detect using SSCP and the sequencing method used in the present work (Figure 1). Second, the entire sequence of BRAF exon 15 is rather short, about 250 bp long, which can be amplified effortlessly, even in the stool DNA (data not shown).

In our study, we have detected a K-ras mutation in one stool DNA that could not be observed in corresponding adenoma tissue DNA. This is not caused by the different detection method we used in stools and tissues, because we analyzed this tissue DNA again using mutant-enriched PCR as in stool DNA, but still no mutation was found. This disparity might be due to other polyps present in the colon of this patient which we failed to detect through colonoscopy or because other neoplasms outside the colon were present in this patient that we did not know, since K-ras mutations have been detected in patients with pancreatic diseases^[21].

In addition to adenomas, we also analyzed the DNA panel in patients with HPs. Our results showed that 44.4% of stool samples carried a mutation of either the BRAF or K-ras gene. All the mutations found in HPs could also be detected in corresponding stool DNA with a specificity of 100%. The results indicate that the mutations in HPs, even if they come from a very small tumor, can be detected in the stool DNA. It also proves that the technique of stool-based DNA detection for colorectal tumors is very sensitive.

Considering the small sample numbers and selected populations of symptomatic patients in our study, large investigations of fecal DNA analysis using these genes in asymptomatic populations are needed. In addition, recent investigations have shown that methylation of the hMLH1 is very common in HPs with MSI^[5]. Thus, the combinations of genetic markers with epigenetic methylated genes will probably increase the sensitivity of the colorectal polyps detection rate.

In summary, our data indicate that mutations of BRAF, K-ras and BAT26 genes in adenomas and HPs are frequent and can be detected in corresponding stool samples. They

can be used as stool based genetic markers for detection of colon polyps.

Abstract

AIM: To study the effect of oxymatrine-baicalin combination (OB) against HBV replication in 2.2.15 cells and α smooth muscle actin (α SMA) expression, type I, collagen synthesis in HSC-T6 cells.

METHODS: The 2.2.15 cells and HSC-T6 cells were cultured and treated respectively. HBsAg and HBeAg in the culture supernatants were detected by ELISA and HBV DNA levels were determined by fluorescence quantitative PCR. Total RNA was extracted from HSC-T6 cells and reverse transcribed into cDNA. The cDNAs were amplified by PCR and the quantities were expressed in proportion to β actin. The total cellular proteins extracted from HSC-T6 cells were separated by electrophoresis. Resolved proteins were electrophoretically transferred to nitrocellulose membrane. Protein bands were revealed and the quantities were corrected by β actin.

RESULTS: In the 2.2.15 cell culture system, the inhibitory rate against secretion of HBsAg and HBeAg in the OB group was significantly stronger than that in the oxymatrine group (HBsAg, $P = 0.043$; HBeAg, $P = 0.026$; respectively); HBV DNA level in the OB group was significantly lower than that in the oxymatrine group ($P = 0.041$). In HSC-T6 cells the mRNA and protein expression levels of α SMA in the OB group were significantly lower as compared with those in the oxymatrine group (mRNA, $P = 0.013$; protein, $P = 0.042$; respectively); The mRNA and protein expression levels of type I collagen in the OB group were significantly lower as compared with those in the oxymatrine group (mRNA, $P < 0.01$; protein, $P < 0.01$; respectively).

CONCLUSION: OB combination has a better effect

against HBV replication in 2.2.15 cells and is more effective against α SMA expression and type I collagen synthesis in HSC-T6 cells than oxymatrine *in vitro*.

INTRODUCTION

The human hepatitis B virus (HBV) belongs to the family of small DNA hepadnaviruses. HBV infection is a major cause of chronic hepatitis, hepatic fibrosis, liver cirrhosis, and hepatocellular carcinoma and results in one million deaths annually^[1]. In China there are about thirty million patients suffering from chronic hepatitis B. Hepatic fibrosis is a kind of compensating and healing response to liver injuries. And hepatic fibrogenesis has been known to be a gradual and dynamic process associated with the continuous deposition and resorption of connective tissues and collagens^[2,3]. During the hepatic fibrogenesis process, hepatic stellate cells (HSC, formerly termed as lipocytes, Ito cells or fat-storing cells) play a central role based on their ability to undergo activation following liver injury of any cause. HSC has been recognized to be responsible for most of the excess extracellular matrix (ECM) observed in chronic hepatic fibrosis^[4].

For a few decades, interferon α (IFN α) has been the only approved therapy for chronic HBV infection around the world. But its efficacy is not satisfactory and associated with some adverse reactions such as influenza-like syndrome, leukocyte and platelet decrease^[5]. Recently, lamivudine has been the first nucleotide analog approved for treating chronic HBV infection in many regions of the world; but its efficacy is just similar to IFN α and prolonged administration is associated with drug

resistance and virus variation, which could lead to severe consequences including liver failure^[6] and even death^[7]. Up to now, the treatment of HBV is still a difficult problem. Therefore, it is necessary to develop novel drugs and treatment methods.

Oxymatrine is a kind of alkaloid extraction derived from a Chinese herb *Sophora flavescens* Ait^[2,3]. It has been widely used for treating viral hepatitis B and C and hepatic fibrosis in recent years in China^[8,9]. But just like other anti-HBV drugs, how to improve its efficacy against HBV and hepatic fibrosis is still an urgent challenge in clinical practice. On the basis of our previous findings^[10], in the present study, the 2.2.15 cells^[11], the hepatoblastoma cell line HepG2 transfected with cloned hepatitis B virus DNA, and the rat HSC-T6 cells^[12], an immortalized rat hepatic stellate cell line, were cultured respectively, and the effects of a novel oxymatrine-baicalin combination^[10] (OB) against HBV replication and α smooth muscle actin (α SMA) expression, type I collagen synthesis *in vitro* were evaluated.

MATERIALS AND METHODS

Drugs, reagents and instruments

Oxymatrine, and OB combination were prepared and provided by Shanghai Kairuisi Biotech Co. Ltd. according to our applied China National Invention Patent^[13]. Dulbecco's modified Eagle's medium (DMEM) and modified Eagle's medium (MEM) culture media were the products of Gibco BRL. Fetal bovine sera (FBS) were purchased from Hyclone (Logan, Utah, USA). G418 was purchased from Shanghai Jiebeisi Gene-Tech Co. Ltd. L-glutamine and EDTA were supplied by Shanghai Shisheng Biotech Co. Ltd. The ELISA kits for HBsAg (hepatitis B surface antigen) and HBeAg (hepatitis B e antigen) kits were ordered from Huamei Biotech Co. Ltd. The penicillin and streptomycin were the products of Shanghai Xianfeng Pharmacological Co.

The HBV DNA (deoxyribonucleic acid) PCR (polymerase chain reaction)-fluorescence quantitative diagnostic kit was purchased from Shanghai Kehua Bio-engineering Co. Ltd. Trizol reagent was the product of Invitrogen. DNA marker was purchased from Tiangen Co. The cDNA synthesis kit and PCR master mix kit were purchased from Fermentas Co. The specific primers were synthesized by Shanghai Shenggong Co. The rabbit anti-rat type I collagen polyclonal antibody was the product of Merck. The mouse anti-rat α SMA mAb and anti-rat β actin mAb were purchased from Sigma (St. Louis, MO). The DC protein quantification kit was the product of Bio-Rad (Bio-Rad Laboratories, Hercules, CA, USA). Enhanced chemiluminescence reagents were purchased from Pierce. The other reagents routinely used in our laboratory were all of analytical grade.

Cell culture flasks and plates were the products of Corning Inc (Corning, NY, USA). CO₂ culture hood and Healforce hood were the products of Heraeus Co. Labsystems Multiskan MS Microplate Reader was made in Finland. XDS-1B invert phase-contrast microscope was purchased from Chongqin Guangdian Co. The LightCycler fluorescence PCR system was the product of Roche Co.

The Rotor-Gene RG-3000 PCR machine was the product of Gene Co. The Furi FR-980 image analysis system was provided by Shanghai Furi Co. Western blot instrument was produced by Bio-Rad.

Cell culture and treatment

The 2.2.15 cell line was purchased from the Department of Microbiology, Tianjin Medical University, China. The 2.2.15 cells were cultured in complete MEM culture media (supplemented with 100 mL/L FBS, 3.8 g/L L-glutamine, 0.38 g/L G418, 50 ku/L penicillin and streptomycin, pH 7.0) at 37°C in 50 mL/L CO₂, 950 mL/L air. When cells were in the logarithmic growth phase, they were trypsinized and seeded. Experiments were performed when cells reached 80% confluence. The cells were supplemented with oxymatrine or OB combination and incubated for an additional 4 d. The working concentration of oxymatrine was 1 g/L and the OB combination contained 1 g/L oxymatrine^[10] and a specific concentration of baicalin^[13] according to our previous findings. At the above concentrations these drugs have no cytotoxic effect to cells by MTT colorimetric assay^[10]. Then the cell culture medium was collected according to the experimental protocol. All experiments were performed in duplicate or triplicate samples.

HSC-T6 cells were kindly provided by Professor Scott Friedman (Liver Center Laboratory, San Francisco General Hospital, USA) and has been stored and passaged routinely in our institute. HSC-T6 cells were seeded in DMEM with 100 mL/L FBS at 37°C, in 50 mL/L CO₂, 950 mL/L air. When cells were in the logarithmic growth phase, they were trypsinized and seeded into 60 mm culture plates. Experiments were performed when cells reached 80% confluence. Each plate was supplemented with 2 mL culture media with oxymatrine or OB combination and incubated for an additional 24 h. Then the cells were harvested according to the experimental protocol. All experiments were performed in duplicate or triplicate samples.

Measurement of HBV antigens secretion in supernatants of 2.2.15 cells by ELISA

The 2.2.15 cells were incubated at a density of 1×10^9 /L in 1 L MEM medium containing 100 mL/L FBS. After 24 h incubation, the 2.2.15 cells were treated with oxymatrine or OB combination respectively. Cells were cultured in the presence of drugs for 4 d. Then the supernatants were collected and stored at -20°C until measurement. The HBsAg and HBeAg were detected simultaneously by ELISA kits according to the manufacturer's instruction, and the inhibitory rates for HBsAg and HBeAg were calculated respectively.

Measurement of HBV DNA replication in supernatants of 2.2.15 cells by fluorescence quantitative PCR

The HBV DNA level in the supernatants post-drug treatment was determined by the HBV DNA PCR-quantitative diagnostic kit using the Roche LightCycler system according to the manufacturer's protocol. One hundred microliter culture medium was added to 100 μ L sample reagent A, and then centrifuged at 13000 r/min

for 10 min. The supernatants were discarded and 25 μ L sample reagent B was added. After centrifugation for a few seconds, the mixture was heated at 100°C for 10 min. Then 2 μ L of the supernatants after centrifugation at 13 000 r/min for 10 min was mixed with 18 μ L PCR reaction reagent, and analyzed at Channel F1 by the LightCycler system.

Determination of α SMA and type I collagen mRNA levels by semi-quantitative RT-PCR

Total RNA was extracted from HSC-T6 cells by Trizol reagent following the protocols provided by the manufacturer. The integrity of total RNA was confirmed by the denaturing formaldehyde agarose gel electrophoresis. The quantity and purity of RNA were detected by determining absorbance at 260/280 nm using a spectrophotometer. Total RNA was reverse transcribed into complementary DNA (cDNA) using the cDNA synthesis kit. The reverse-transcription (RT) reaction mixtures were amplified by semi-quantitative PCR using specific primers for the target genes and β actin. The primers used are as follows: Type I collagen, forward: 5'-TAC AGC ACG CTT GTG GAT G-3', reverse: 5'-TTG AGT TTG GGT TGT TGG TC-3', target fragment length 259 bp; α SMA, forward: 5'-CCG ACC GAA TGC AGA AGG-3', reverse: 5'-ACA GAG TAT TTG CGC TCC GGA-3', target fragment length 88 bp; β actin, forward: 5'-TGA CGA GGC CCA GAG CAA GA-3', reverse: 5'-ATG GGC ACA GTG TGG GTG AC-3', target fragment length 330 bp. The 20 μ L reaction mixture consisted of the corresponding primers, 1 U of Taq polymerase, 50 μ mol/L of each of the four dNTP, 1 \times PCR buffer supplemented with 2.5 mmol/L MgCl₂. After an initial melting time of 5 min at 94°C, the mixtures were subjected to 35 PCR cycles, consisting of denaturation for 1 min at 94°C, primer annealing for 1 min at 55°C, and primer extension for 1 min at 72°C, with a final extension time of 10 min at 72°C. Quantification of the final products was performed by electrophoresis in 30 g/L agarose gel using the Furi FR-980 image analysis system. The number of mRNA molecules was expressed in proportion to the number of internal control β actin in the same sample as described before^[14].

Determination of α SMA and type I collagen protein levels by Western blot

HSC-T6 cell lysates were prepared from 1×10^7 cells by dissolving cell pellets in 100–200 μ L lysis buffer (150 mmol/L NaCl, 10 g/L tergitol NP-40, 5 g/L sodium deoxycholate, 0.1 g/L sodium dodecyl sulfate, 50 mmol/L Tris, and a protease inhibitor cocktail, pH7.5). Lysates were centrifuged at 4°C, 12 000 r/min for 15 min, then the supernatants were collected and stored at -70°C until detection. Protein content was analyzed by DC protein assay and at 690 nm wavelength. Sodium dodecylsulfate polyacrylamide gel electrophoresis (SDS-PAGE) sample buffer (0.31 mL 2 mol/L Tris buffer (pH6.8), 20 g/L SDS, 100 mL/L glycerol, 2.4 g/L DTT, 50 g/L β -mercaptoethanol, 0.02 g/L bromophenol blue) was added to the lysates. After mixing the lysates were heated to 100°C for 5 min, and 50 μ g sample protein was loaded into

Figure 1 The inhibition rate of OB on HBsAg and HBeAg secretion in the 2.2.15 cell culture system. $n = 3$, mean \pm SD. ^a $P < 0.05$ vs oxymatrine.

each well of 100 g/L SDS-PAGE gel. Resolved proteins were electrophoretically transferred to nitrocellulose membrane and blocked with 50 mL/L non-fatty milk. Then the primary antibodies (mouse anti-rat β actin antibody, 1:5000 dilution; mouse anti-rat α SMA antibody, 1:5000 dilution, rabbit anti-rat type I collagen antibody, 1:200 dilutions) in 50 mL/L non-fatty TTBS solution (1.21 g/L Tris, 9 g/L NaCl, 1 g/L Tween-20, pH7.5) were added respectively. After incubation at 4°C overnight the blots were washed, then membranes were incubated with corresponding horseradish peroxidase-conjugated secondary antibodies for 1 h. Protein bands were revealed by the ECL kit according to the manufacturer's protocol and the Furi FR-980 image analysis system was used for quantitative analysis of the blots. β actin protein was used as the internal control as described before^[15].

Statistical analysis

All results were expressed as mean \pm SD. Comparisons were analyzed by one-way ANOVA using the SPSS 10.0 statistical package. Differences were considered statistically significant if the $P < 0.05$.

RESULTS

Effect of OB on HBV antigen secretion in 2.2.15 cells

After incubation for 4 d, HBsAg and HBeAg secretion in the culture medium was determined by ELISA. As shown in Figure 1, both OB and oxymatrine had remarkable inhibitory effects on secretion of HBsAg and HBeAg in the 2.2.15 cells, the inhibitory rate in the OB group was significantly stronger than that in oxymatrine group (HBsAg, $P = 0.043$; HBeAg, $P = 0.026$; respectively). And the inhibitory rate on HBeAg in both groups exceeded that of HBsAg.

Effect of OB on HBV DNA replication in 2.2.15 cells

After incubation for four days, the levels of HBV DNA in the culture medium were determined by fluorescence quantitative PCR. As shown in Figure 2, both OB and oxymatrine reduced the HBV DNA level in the supernatant of the 2.2.15 cells, and the HBV DNA level in the OB group was significantly lower than that of the oxymatrine group ($P = 0.041$), indicating that OB inhibited

Figure 2 The effect of OB on the HBV DNA level in the 2.2.15 culture system. $n = 3$, mean \pm SD. ^a $P < 0.05$, ^b $P < 0.01$ vs control, ^c $P < 0.05$ vs oxymatrine.

Figure 3 Effect of OB treatment on the α SMA mRNA level in HSC-T6 cells. The α SMA mRNA level was determined by semi quantitative RT-PCR analysis and corrected by β actin mRNA level. $n = 3$, mean \pm SD. ^a $P < 0.05$, ^b $P < 0.01$ vs control, ^c $P < 0.05$ vs oxymatrine.

Figure 4 Effect of OB treatment on the α SMA protein level in HSC-T6 cells. The α SMA protein level was determined by Western blot analysis and corrected by β actin protein level. $n = 3$, mean \pm SD. ^a $P < 0.01$ vs control, ^b $P < 0.05$ vs oxymatrine.

HBV DNA replication more effectively than oxymatrine did.

Effect of OB on α SMA expression in HSC-T6 cells

The α SMA mRNA and protein expression levels in HSC-T6 cells were determined by semi-quantitative PCR and Western blot analysis respectively. The β actin mRNA and protein were chosen as internal controls. The results

Figure 5 Effect of OB treatment on the Collagen I mRNA level in HSC-T6 cells. The collagen mRNA level was determined by semi quantitative RT-PCR analysis and corrected by the β actin mRNA level. mean \pm SD. ^b $P < 0.01$ vs control, ^d $P < 0.01$ vs oxymatrine.

Figure 6 Effect of OB treatment on the collagen I protein level in HSC-T6 cells. The collagen protein level was determined by Western blot analysis and corrected by the β actin protein level. $n = 3$, mean \pm SD. ^b $P < 0.01$ vs control, ^d $P < 0.01$ vs oxymatrine.

showed that the mRNA and protein expression levels of α SMA in both the oxymatrine and OB groups were significantly reduced compared with the control group (mRNA, $P = 0.033$ and $P = 0.001$ vs the control; protein, $P < 0.01$ and $P < 0.01$ vs the control; respectively). As shown in Figures 3 and 4, the mRNA and protein expression levels of α SMA in the OB group were significantly lower as compared with those in the oxymatrine group, suggesting that OB reduced the HSC-T6 activation more effectively than oxymatrine (mRNA, $P = 0.013$; protein $P = 0.042$; respectively).

Effect of OB on type I collagen synthesis in HSC-T6 cells

The type I collagen mRNA and protein expression levels were also determined. As shown in Figures 5 and 6, the mRNA and protein expression levels in both the oxymatrine and OB groups were significantly reduced compared with the control group (mRNA, $P < 0.01$ and P

< 0.01 ; protein, $P < 0.01$ and $P < 0.01$; respectively). The results showed that the mRNA and protein expression levels in the OB group were significantly lower as compared with those in the oxymatrine group, suggesting that the OB combination reduced the synthesis of type I collagen in HSC-T6 cells more effectively than oxymatrine not only at mRNA level but also at the protein level (mRNA, $P < 0.01$; protein, $P < 0.01$; respectively).

DISCUSSION

The World Health Organization places HBV infection among the top 10 causes of death worldwide. It is estimated that there are over 400 million carriers of HBV. At least 20% to 30% of HBsAg carriers will die of complications of chronic liver disease, including cirrhosis and liver cancer. The serious consequences of end-stage liver disease and liver cancer occur in 30% of chronic carriers^[1,5,16]. Investigation of the expression and replication of the HBV genome has been hampered by the lack of an *in vitro* tissue culture system until the 2.2.15 cell line was established^[11]. The medium of these cells contains not only all of the particles present in the serum of infected individuals but also a number of replicative intermediates that probably represent recircularized, ccc, and single-stranded HBV DNA. Various parameters of the replicative cycle can be quantitated in the 2.2.15 culture system, for example, the secretion of HBsAg or HBeAg and the amount of episomal HBV DNA. At present, the 2.2.15 cell line is still the main *in vitro* model used for evaluating the anti-HBV effect of drugs^[10].

Because HBV infection plays a key role in the development of decompensated cirrhosis and hepatocellular carcinoma, HBV patients with serum aminotransferase twice the upper limit of reference value and HBV DNA positive in the blood were advised to receive antiviral agents treatment^[5,8]. Oxymatrine has been used widely in the treatment of chronic liver disease including hepatitis B, hepatitis C and hepatic fibrosis^[2,3,7,8]. As for etiological treatment, oxymatrine could effectively treat chronic viral hepatitis and promote the serum markers of HBV in chronic hepatitis B patients to convert to negative and reduce serum level of ALT^[8,9]. But its efficacy is similar to IFN α , therefore, it is urgent to improve the treatment efficacy of oxymatrine. The present study showed that the inhibitory rate of OB combination against HBV antigens secretion in the supernatant of the 2.2.15 culture system was significantly stronger than that of oxymatrine. In order to elucidate the influence of OB combination on HBV replication, HBV DNA was determined in the supernatants also and the results indicated that OB combination could suppress virus replication and the effect was superior to oxymatrine treatment alone. The pattern of OB combination against HBV is consistent with those reports on oxymatrine elsewhere^[16,17].

The objective of anti-HBV therapy is not only to eradicate the virus but also to prevent the development of hepatic fibrosis. Hepatic fibrosis, a precursor of cirrhosis, is a consequence of severe liver damage that occurs in many patients with chronic liver disease, and involves the abnormal accumulation of ECM^[2,3,9,14]. Liver fibrosis

represents a major healthcare burden worldwide. During hepatic injury, HSCs become active and undergo profound phenotypic changes^[4,18]. HSCs are non-parenchyma cells, located perisinusoidally in the space of Disse. The expression of α SMA is the most important feature of HSC activation. HSC is the primary source of excessive production of ECM. The collagens are the major ECM component of normal and fibrotic livers. In the normal liver the amount of type III collagen is greater than type I collagen, but type I collagen is particularly produced predominantly during fibrogenesis. While the primary HSC cultures are a useful tool for studying hepatic fibrogenesis, their isolation is extremely time-consuming, the yields are modest, and there is considerable preparation-to-preparation variability. The rat HSC-T6 cell line^[12] is constructed through transfecting SV40 into rat HSC and its phenotype is activated HSC. HSC-T6 has the stable phenotype and biochemical characters of activated HSC, expressing myogenic and neural crest cytoskeletal filaments, and the cell line has been a useful tool for studying hepatic fibrogenesis and it is also a reliable cell model for investigating antifibrotic drugs^[19].

In this study the RT-PCR and Western blot analysis results showed that OB combination had a stronger inhibitory effect against the activation of HSC, and this was proven by the significantly lower levels of α SMA mRNA and protein in the OB group than those in the oxymatrine group. Type I collagen is produced predominantly during hepatic fibrogenesis^[4,18]. Inhibiting the secretion of type I collagen not only reduced the ECM component, but also decreased further activation of HSC^[19]. Our results showed that the OB combination could not only inhibited the synthesis of type I collagen at the transcription level but also at the translation level, and these inhibitory effects of the OB combination were superior to those of oxymatrine.

In addition to the anti-HBV effect^[8,16], it was reported that oxymatrine has an effect against liver fibrosis *in vitro*^[15] and *in vivo*^[2,3,17,21], protects animals from fulminant hepatitis^[22] or inflammation^[23]. Baicalin, a flavonoid isolated from the root of *Scutellaria baicalensis* Georgi^[10], has been demonstrated to have multiple biological functions, such as anti-HBV^[9,24], inhibiting HIV infection^[25], inhibiting SARS coronavirus^[26]. Romero^[24] confirmed that baicalin has a moderate ability to reduce HBV production and has no toxic effect on host cells, and this effect against HBV was confirmed by our findings^[10] also. Moreover, it was reported that baicalin^[25] at the noncytotoxic concentrations inhibited both T cell tropic (X4) and monocyte tropic (R5) HIV-1 Env protein mediated fusion with cells expressing CD4/CXCR4 or CD4/CCR5, and the presence of baicalin at the initial stage of HIV-1 viral adsorption blocked the replication of HIV-1, resulting in an early definitive DNA replication cessation. Chen^[27] found that baicalin had antiviral activity against 10 clinical isolates of SARS coronavirus by neutralization tests, which was confirmed by plaque reduction assays. Jang^[28] reported that baicalin had a protective effect against acetaminophen-induced hepatotoxicity in mice and showed that the effects might be due to a block of the bioactivity of acetaminophen by inhibiting the cytochrome P450 2E1 expression. As an antioxidant flavonoid *in vitro*

baicalin has a strong antioxidant activity toward reactive oxygen species (ROS), including hydroxyl radical ($\text{OH}\cdot$), superoxide anions ($\text{O}_2\cdot^-$) and peroxynitrite (ONOO_2), and inhibits lipid peroxidation, promoting the repair of DNA single strand breakage caused by H_2O_2 in cultured NIH3T3 fibroblasts^[29]. It has long been accepted that Sho-saiko-to functions as a potent anti-hepatic fibrosis agent, and Japanese investigators confirmed that the active components of Sho-saiko-to are baicalin and baicalein of flavonoids, and the chemical structures of baicalin and baicalein are very similar to silybinin, which shows anti-fibrogenic activities^[30,31].

The mechanism of hepatic fibrosis is too complicated for a single drug to resolve. A drug or drug compounds with multi-effect-pathways and multi-effect-targets may have better efficacy than a single drug alone, and could change the current predicament in the therapy of hepatic fibrosis^[19]. Continued progress is essential in order to identify the determinants and dynamics of fibrosis reversibility, to discover additional targets for anti-fibrotic therapy, and to develop customized multi-drug regimens^[32]. Taken together, the results from 2.2.15 cells show that the inhibitory effect of OB combination on HBV antigen secretion and HBV DNA replication is better than that of oxymatrine alone; furthermore, the results from HSC-T6 also show that the suppressing effect of OB combination on α SMA and type I collagen expression is more effective than that of oxymatrine. This study indicates that the addition of baicalin to oxymatrine can strengthen the treatment effect of oxymatrine *in vitro*. However, this finding needs to be verified in *in vivo* studies.

Abstract

AIM: To examine the underlying mechanisms of erlotinib-induced growth inhibition in hepatocellular carcinoma (HCC).

METHODS: Erlotinib-induced alterations in gene expression were evaluated using cDNA array technology; changes in protein expression and/or protein activation due to erlotinib treatment as well as IGF-1-induced EGFR transactivation were investigated using Western blotting.

RESULTS: Erlotinib treatment inhibited the mitogen activated protein (MAP)-kinase pathway and signal transducer of activation and transcription (STAT)-mediated signaling which led to an altered expression of apoptosis and cell cycle regulating genes as demonstrated by cDNA array technology. Overexpression of proapoptotic factors like caspases and gadd45 associated with a down-regulation of antiapoptotic factors like Bcl-2, Bcl-X_L or jun D accounted for erlotinib's potency to induce apoptosis. Downregulation of cell cycle regulators promoting the G₁/S-transition and overexpression of cyclin-dependent kinase inhibitors and gadd45 contributed to the induction of a G₁/G₀-arrest in response to erlotinib. Furthermore, we displayed the transactivation of EGFR-mediated signaling by the IGF-1-receptor and showed erlotinib's inhibitory effects on the receptor-receptor cross talk.

CONCLUSION: Our study sheds light on the understanding of the mechanisms of action of EGFR-TK-inhibition in HCC-cells and thus might facilitate the design of combination therapies that act additively or synergistically. Moreover, our data on the pathways

INTRODUCTION

Hepatocellular carcinoma (HCC) is the fifth most common malignancy in the world and is estimated to cause half a million deaths annually. The incidence of HCC is dramatically increasing in the USA, Europe and Asia, due to high prevalence of chronic hepatitis B and hepatitis C virus infections, alcohol disease, diabetes and obesity^[1]. Unfortunately, the majority of patients suffer from advanced disease at presentation. Therefore curative local ablation, surgical resection of HCC, or liver transplantation can be achieved only in a minority of patients. Local tumor destruction, chemoembolization or systemic chemotherapy are the treatment options of advanced HCC. However, overall survival is poor. Apart from chemoembolization, which improves survival in well-selected patients with unresectable HCC, palliative treatment options do not appear to greatly improve overall survival^[2]. Therefore, innovative treatment approaches are urgently needed. Recently, evidence has been accumulated that the epidermal growth factor receptor (EGFR) is a promising target for cancer therapy. A great variety of tumors show abnormal, enhanced and/or constitutive expression of EGFR. Several reports indicate that EGFRs are expressed frequently in human HCC, most likely contributing to the aggressive growth characteristics of these tumors^[3,4]. Especially in poorly differentiated HCCs, EGFR overexpression has been demonstrated to be a negative prognostic factor, since it positively correlated with early

tumor recurrence and the occurrence of extrahepatic metastasis^[3,5]. Hence, the EGFR is a promising target for innovative treatment strategies in HCC.

The EGFR is a member of a family of four closely related receptors: EGFR (ErbB-1), HER-2/*neu* (ErbB-2), HER-3 (ErbB-3), and HER-4 (ErbB-4). Upon ligand binding the EGFR becomes activated by dimerization which leads to subsequent activation of EGFR tyrosine kinase (TK) activity, initiating receptor-mediated signal transduction, cell mitogenesis and cell transformation^[6]. The EGFR downstream intracellular signal transduction pathways include components of Ras/mitogen-activated protein kinase (MAPK), phosphatidyl inositol 3-kinase, signal transducer and activator of transcription (STAT), downstream protein kinase C and phospholipase D pathways^[7]. The Ras/MAPK cascade is supposed to be one of the major signaling routes of the EGFR system^[8].

Erlotinib [N-(3-ethynylphenyl)-6,7-bis(2-methoxyethoxy)-4-quinazolinamine] is a novel orally available low-molecular-weight quinazolinamine that acts as a potent and reversible inhibitor of EGFR-TK activity. The mechanism of action of erlotinib is competitive inhibition of the binding of ATP to the TK domain of the receptor, resulting in inhibition of EGFR autophosphorylation^[9]. Single agent activity was observed in pretreated patients with non-small-cell lung cancer (NSCLC), head and neck carcinoma and ovarian cancer^[10]. Recently, the results of the BR.21 phase III trial showed a significant 42.5% improvement in median survival compared to placebo in patients with advanced NSCLC^[11] and the US Food and Drug Administration (FDA) has approved erlotinib for this indication in November 2004.

In a previous study we have shown that EGFR-TK-inhibition by erlotinib potently suppresses the growth of human EGFR-expressing HCC cells by inducing both apoptosis and cell cycle arrest at the G₁/S-transition^[12].

The objective of the current study was to examine the underlying mechanisms of erlotinib-induced growth inhibition in HCC cells. For this purpose we studied the effects of erlotinib on downstream signaling molecules of the EGFR. We used cDNA array technology to investigate the EGFR-TKI-induced modulation of apoptosis- and cell cycle-related genes and Western blot analysis to evaluate changes in the activation of the mitogenic MAP-kinase- and Jak-STAT-pathways as well as changes in the expression of cell-cycle regulating and antiapoptotic proteins. Additionally, we investigated the influence of IGF-1R-activation on EGFR-mediated signaling and erlotinib's effects on the IGF-1R/EGFR-network.

MATERIALS AND METHODS

Materials

The highly differentiated human hepatocellular carcinoma cell line Huh-7 and the well differentiated hepatoblastoma cell line HepG2 were cultured in RPMI 1640 medium containing 100 mL/L fetal bovine serum and 100 kU/L penicillin and 100 mg/mL streptomycin. Erlotinib hydrochloride was a kind gift from Roche (Penzberg, Germany), cell culture material was from Biochrom (Berlin, Germany); all other chemicals were from Sigma (München,

Germany), if not stated otherwise. Stock solutions were prepared in DMSO and stored at -20°C and were diluted to the final concentration in fresh media before each experiment. In all experiments, the final DMSO concentration did not exceed 5 g/L, thus not affecting cell growth. To evaluate the effects of erlotinib, cells were incubated with either control medium or medium containing rising concentrations of erlotinib.

Drug combination studies

To check for possible additive or synergistic effects, combination treatment of erlotinib plus AG1024 (Calbiochem, Bad Soden, Germany) was studied. The 5 µmol/L or 10 µmol/L of the tyrphostine AG1024 was combined with 10 µmol/L erlotinib (e.g. approximately its IC₅₀ value). The antineoplastic activities of the combinations were compared to those of each drug alone. For all experiments cell number was evaluated by crystal violet staining as described^[12]. In brief, cells in 96-well plates were fixed with 10 g/L glutaraldehyde, then cells were stained with 1 g/L crystal violet in PBS. The unbound dye was removed by washing with water. Bound crystal violet was solubilized with 2 g/L Triton-X-100 in PBS. Light extinction which increases linearly with the cell number was analyzed at 570 nm using an ELISA-reader.

Western blot analysis

Western blotting was performed as described^[13]. Blots were blocked in 2.5% BSA and then incubated at 4°C overnight with the following antibodies: ERK1/2 (1:500), p-ERK1/2 (1:500), cyclin D1 (1:100), Bcl-X_L (1:200), STAT1 (1:1000), STAT3 (1:1000), STAT5 (1:1000), β-IGF-1R (1:1000), p21^{Waf1/CIP1} (1:200; all from Santa Cruz Biotechnology, CA), p27^{KIP1} (1:2500; Becton-Dickinson, Heidelberg, Germany), p-EGFR, p-STAT1(TYR701), p-STAT3(TYR705), p-STAT5 (TYR694) (all 1:500 and all from Cell Signaling, MA) and p-IGF-1R (1:1500; Biomol, Hamburg, Germany). β-actin (1:5000; Sigma, Deisenhofen, Germany) served as loading control. One representative out of three independent experiments was shown for each Western blot.

RNA extraction and poly(A)⁺ mRNA preparation

Total RNA was extracted from cultured HepG2 cells with RNAClean according to the manufacturer's recommendations (Hybaid, London, UK). Polyadenylated (poly(a)⁺) mRNAs were enriched using magnetic Dynabeads according to the instructions of the supplier (Dyna, Oslo, N). The quality of poly(A)⁺ and total RNA was assessed by agarose gel electrophoresis.

cDNA array

HepG2 cells were treated with 10 µmol/L erlotinib for 48 h to determine erlotinib-induced differential gene expression. Untreated cells served as controls. We used the Atlas Human Apoptosis cDNA array with 205 human cDNAs spotted in duplicate on a nylon membrane (Clontech, Palo Alto, CA) as previously described^[14]. A complete list of the cDNAs and controls as well as their accession numbers is available on the web (http://www.clontech.com/clontech/atlas/genelists/7743-1_HuApop.pdf). The hybridization signals were

Figure 1 EGF-induced EGFR- and ERK1/2-activation in HCC cells.

photometrically evaluated using TINA software (Raytest Isotopenmessgeräte, Straubenhardt, D). Altered expression of a respective gene is given as a fold increase or decrease compared to the signal of the control. Data analysis was performed as described^[14].

Statistical analysis

The means of three independent experiments of the cDNA expression arrays and the drug combination studies \pm SD are shown. Significance between AG1024 treated samples and AG1024 plus erlotinib treated samples was calculated by Student's two sided *t*-test. $P < 0.05$ was regarded as significant.

RESULTS

EGF-induced EGFR- and ERK1/2-activation

To shed light on the signaling pathways modulated by EGFR-TK inhibition in HCC cells, we investigated the phosphorylation of ERK1/2 known to be involved in EGFR-mediated mitogenic and antiapoptotic signaling. In order to demonstrate the influence of the epidermal growth factor (EGF) on the activation of the EGFR and ERK1/2, serum-starved HepG2 cells were incubated for 15 min with increasing concentrations of EGF (1-50 μ g/L). Serum-starved cells were chosen to exclude the influence of growth factors contained in the fetal calf serum (FCS) of the cell medium. Western blotting of whole cell lysates revealed a dose-dependent increase of activated EGFR and ERK1/2 in response to EGF incubation (Figure 1).

Inhibitory action of erlotinib on EGF-induced EGFR- and ERK1/2 activation

EGF-induced activation of the EGFR and the mitogenic ERK1/2 was blocked by pretreating the cells with erlotinib. HepG2 cells were incubated for 30 min with escalating concentrations of erlotinib (0.1, 1, 10 μ mol/L) and subsequently stimulated with EGF (10 μ g/L). Again, activation of EGFR and ERK1/2 was determined by Western blotting. Erlotinib-untreated cells (control) displayed a pronounced activation of EGFR and ERK1/2 due to EGF-stimulation. Low concentrations of erlotinib (0.1 μ mol/L) completely blocked EGFR-phosphorylation and ERK1/2-activation decreased dose-dependently (Figure 2A).

To mimic *in vivo* conditions, we finally examined the influence of erlotinib (10 μ mol/L) on the activation of ERK1/2 in HepG2 cells stimulated by growth factors contained in the medium's FCS. We revealed a time-dependent decrease in phosphorylation of ERK1/2 (Figure 2B) in HCC cells due to erlotinib treatment (up to 72 h).

Figure 2 Erlotinib inhibited EGFR (A) and ERK1/2 (B) activation in HCC cells.

STAT expression and EGF-induced activation

EGFR activation is supposed to result in autophosphorylation of Janus-kinases (Jaks) with subsequent activation of mitogenic STATs but has not been investigated in HCC so far. Western blot analyses revealed the expression of STATs 1, 3 and 5 in Huh-7 cells (Figures 3A-C). Moreover, EGF induced STAT activation could be shown for STATs 1 and 3 (Figures 3A and B) but not in the case of STAT5 (Figure 3C). Serum-starved Huh-7 cells were stimulated with EGF (10 or 50 μ g/L, 15 min) and whole cell lysates were used for determinations.

Inhibitory effect of erlotinib on STAT-activation

EGF-induced STAT activation was blocked by pretreating Huh-7 cells with erlotinib. Erlotinib-untreated cells (control) displayed a pronounced activation of STATs 1 and 3 in response to EGF-incubation (10 μ g/L, 15 min). Erlotinib pretreatment (0.1, 1, 10 μ mol/L; 30 min) dose-dependently inhibited the phosphorylation of STATs 1 and 3, whereas the total quantity of STAT 1 and 3 remained unchanged (Figure 4; +: addition of the respective substance, -: absence of the respective substance).

Differential gene expression induced by erlotinib

To further characterize the underlying molecular mechanisms of erlotinib-induced apoptosis and cell cycle arrest, the differential expression of genes related to cell cycle and apoptosis control was investigated using cDNA array technology. HepG2 cells were incubated for 48 h with 10 μ mol/L erlotinib, as a significant arrest of both the cell cycle and apoptosis-induction had been observed under these conditions^[12]. Erlotinib modulated the expression of 25 genes (Table 1). We found an overexpression of genes encoding apoptosis-related cysteine proteases (caspases) 3 and 7, both known to be important enzymes of the apoptotic process. Moreover, growth arrest and DNA-damage inducible (gadd-) genes encoding gadd45 and 153 both associated with induction of apoptosis and growth arrest^[15,16] as well as the insulin-like growth factor

Figure 3 STAT-expression and EGF-induced activation in HCC cells. EGF induced STAT activation could be shown for STATs 1 and 3 (A and B) but not in the case of STAT5 (C).

Figure 4 Erlotinib inhibited STAT-activation in HCC cells.

binding protein 6 (IGFBP-6) and cyclin B1, an important molecular regulator of the G₁/S and G₂/M cell cycle transitions^[17] were markedly overexpressed. Genes encoding cell-cycle progression promoting proteins were found to be suppressed (particularly those proteins promoting the transition from the G₁ to the S-phase, e.g. CDK4 or cyclin A2). Additionally, a suppression of anti-apoptotic genes like Bcl-2 or the jun D proto-oncogene was detected as well as of the DNA-replication promoting proliferating cell nuclear antigen (PCNA).

Modulatory effect of erlotinib on expression of cell cycle regulators and antiapoptotic members of the Bcl-2 family

Changes in the expression of important cell cycle and apoptosis regulating proteins due to EGFR-inhibition were assessed by Western blotting. Treating HepG2 cells for up to 48 h with erlotinib (10 μmol/L) resulted in an increase of the cyclin-dependent kinase inhibitors (CDKIs) p21^{Waf1/CIP1} and p27^{Kip1}. The expression of cyclin D1, a protein regulating the transition from the G₁ to the S-phase remained unchanged. Alterations in protein expression of the respective cell cycle regulators occurred within 24 h (Figure 5A). Additionally, a 48-h-treatment of HepG2 cells with 10 μmol/L erlotinib led to a significant suppression of the antiapoptotic Bcl-2 family members Bcl-XL (Figure 5B) and Bcl-2 (Figure 5C).

Modulation of the MAP-kinase pathway and transactivation of EGFR induced by IGF-1

Comparable to the EGFR, the IGF-1-receptor is associated with carcinogenesis and tumor growth. Thus, we evaluated the mitogenic effects of IGF-1 on Huh-7 and HepG2 cells, both cell lines strongly expressing the IGF-1R^[18]. Besides, we focused on a possible transactivation

of the EGFR in response to IGF-1 treatment. Serum-starved HepG2 cells were treated for 15 min with IGF-1 (50-250 μg/L) followed by the determination of changes in EGFR- and ERK1/2-activation by Western blot. IGF-1 dose-dependently activated the mitogenic MAP-kinase pathway, moreover we could show that IGF-1 treatment in the absence of EGF or other growth factors resulted in an activation of the EGF-receptor, indicating a possible IGF-1R/EGFR cross talk in hepatocellular carcinoma cells (Figure 6).

Inhibitory action of erlotinib on mitogenic effects of EGF and/or IGF-1 and EGFR/IGF-1R receptor cross-talk

Erlotinib-pretreated (30 min, 10 μmol/L) serum-starved

Figure 5 Erlotinib modulated the expression of cell cycle regulators (A) and antiapoptotic members of the Bcl-2 family (B and C).

Figure 6 IGF-1-induced activation of ERK1/2 and transactivation of the EGFR.

HepG2 cells were incubated with EGF (10 μg/L) and/or IGF-1 (100 μg/L) for 15 min. Growth factor untreated cells served as control. Comparable to the experiments described above, EGF and/or IGF-1-treatment resulted in the activation of both EGFR and ERK1/2. Erlotinib pretreatment completely inhibited growth factor-induced EGFR activation and reduced p-ERK1/2 levels below control values. Thus, in addition to the blockade of EGF and IGF-1-induced mitogenic signaling, erlotinib potently suppressed IGF-1 induced IGF-1R/EGF-receptor transactivation (Figure 7). In order to exclude unspecific effects of erlotinib on the activation of the IGF-1R by its ligands, we additionally investigated the effects of the EGFR-blocker on the expression and activation of IGF-1R. HepG2 cells were cultured up to 48 h in medium containing 100 mL/L FCS and 10 μmol/L erlotinib. Western blot analysis showed neither changes in the expression of the β-chain of IGF-1R or the IGF-1R

Figure 7 Erlotinib inhibited EGF and/or IGF-1-induced ERK1/2-activation and EGFR/IGF-1R cross talk.

Figure 8 Erlotinib did not influence IGF-1R expression or activation.

Figure 9 Antiproliferative effects of erlotinib plus AG1024. A: HepG2; B: Huh-7.

precursor nor in the phosphorylation of the receptor as compared to control (Figure 8).

Growth inhibitory effects of simultaneous blockade of EGFR and IGF-1R

On the basis of the results obtained in our investigations on EGFR/IGF-1R receptor signaling, we evaluated the growth inhibitory effects of a simultaneous blockade of the EGFR by erlotinib and the IGF-1R by AG1024. The typhostine AG1024 is a specific inhibitor of the IGF-1R-tyrosine kinase activity. Cells were treated with 5 or 10 μmol/L AG1024 and 10 μmol/L erlotinib for

72 h. Upon treatment with the IGF-1R-TKI alone both HepG2 (Figure 9A) and Huh-7 cells (Figure 9B) displayed a pronounced reduction of cell numbers (Figure 9, black bars). When combining AG1024 with erlotinib, synergistic antineoplastic effects were observed in both cell lines (Figure 9, hatched bars).

DISCUSSION

Treatment options of advanced hepatocellular cancer (HCC) are unsatisfactory, and the prognosis of patients suffering from advanced HCC is poor. New, effective and well-tolerated therapy strategies are urgently needed. The EGF/EGFR system is known to have strong stimulatory effects on the growth of hepatoma cells. Several studies have demonstrated EGFR expression to be a common feature of HCCs^[4,5], underlining the role of the EGFR-TK as a rational target for future hepatocellular cancer treatment. We recently demonstrated that the EGFR-TK-inhibitor erlotinib potently inhibited the growth of EGFR-expressing human hepatocellular cancer cells by a time- and dose-dependent induction of apoptosis and an arrest at the G₁-to-S-transition of the cell cycle^[12]. In accordance, preliminary results of a phase II trial of erlotinib in patients with HCC suggest a clinical benefit by erlotinib^[19]. However, the underlying mechanisms and corresponding molecular events by which erlotinib mediates apoptosis and cell cycle arrest are not yet understood. In this study, we identified signaling molecules involved in erlotinib-mediated apoptosis and cell cycle modulations and showed the functional involvement of the identified pathways.

We demonstrate that EGFR is activated upon EGF binding in HCC cells with a subsequent activation of ERK1/2, a key protein of the mitogen-activated protein kinase (MAPK)-pathway and that erlotinib potently inhibits EGFR activation associated with an inhibition of the mitogenic downstream signaling. MAPKs are important regulators of apoptosis, proliferation and differentiation^[20]. Once activated, ERK1/2 translocates to the nucleus where it acts as a regulator of gene expression of various proteins, e.g. activated ERK1/2 inhibits the expression of the cell cycle inhibitors p21^{Waf1/CIP1}^[21,22] and p27^{Kip1}^[23]. Using Western blotting we could demonstrate an increase of expression of both proteins in response to erlotinib treatment within 24 h. Moreover, ERK1/2-inhibition is known to up-regulate the expression of gadd45^[24] which could be confirmed in this work by cDNA expression arrays. The expression of the gadd45 gene has been correlated with the presence of a strong growth arrest as it interacts with p21^{Waf1/CIP1} to induce cell cycle arrest^[25]. Overexpression of gadd genes causes growth inhibition and/or apoptosis, and combined overexpression of gadd genes leads to synergistic suppression of cell growth^[26]. Furthermore, activated ERK1/2 has been reported to inhibit the apoptotic process by inhibiting caspase activation^[27] and the expression of several antiapoptotic proteins^[20]. In accordance, our previous investigations demonstrated the increase of caspase-3 activity due to EGFR-blockade^[12,28]. In this work cDNA expression arrays revealed that gene expression of caspases 3 and 7 is up-regulated due to erlotinib treatment. In addition to the activation of the proapoptotic caspase

network a decrease of gene and protein expression of antiapoptotic members of the Bcl-2 family as demonstrated by cDNA expression arrays and Western blotting may account for erlotinib's apoptosis inducing capabilities.

Comparable to the MAPK-pathway, Jak-STAT-signaling is involved in cell proliferation and cell cycle progression^[29]. STATs are latent in the cytoplasm and become activated through tyrosine phosphorylation which typically occurs through JAKs or growth factor receptor-TKs. Phosphorylated STATs form homo- or hetero-dimers, enter the nucleus and function as transcription factors. Transcriptional changes concerning apoptosis and cell cycle related genes are similar to those described for ERK1/2^[30]. In normal cells, ligand dependent activation of STATs is a transient process but in tumors the STAT proteins (in particular STATs 1, 3 and 5) are often constitutively activated^[29]. STATs 3 and 5 are noted for the proliferative effects and inhibition of apoptosis whereas the role of STAT1 in oncogenesis and tumor progression is controversial^[31]. Effects of EGFR-TK-inhibition on Jak-STAT-signaling has not been investigated so far. We demonstrated the expression of STATs 1, 3 and 5 in HepG2 cells and the activation of STATs 1 and 3 but not STAT5 due to EGF-stimulation. Erlotinib-treatment inhibited STAT-activation thus contributing to cell cycle arrest and apoptosis-induction.

To shed light on transcriptional changes in response to EGFR-TK-inhibition by erlotinib we performed cDNA expression arrays. As described above, erlotinib increased the expression of genes encoding proapoptotic factors like caspases and gadd whereas the expression of genes encoding antiapoptotic proteins like Bcl-2 or the jun D proto-oncogene was found to be decreased. At the same time we found a different expression of a variety of genes encoding cell cycle regulators: Cell-cycle promoters like CDK4 or cyclin A2 were suppressed, the important molecular regulator of the G₂/M cell cycle transition cyclin B1^[17] was markedly overexpressed probably accounting for a partial G₂/M-block we observed in response to EGFR-blockade in previous investigations^[12,28]. Interestingly, the insulin-like growth factor binding protein 6 (IGFBP-6) was found to be the gene with the strongest overexpression. IGFBPs are a family of six homologous proteins with high binding affinity for IGF-1 and IGF-2. In addition to functioning as simple carrier proteins, IGFBPs in serum regulate the endocrine actions of IGFs by changing the amount of IGF available to activate IGFs, and locally produced IGFBPs act as autocrine/paracrine regulators of IGF action^[32]. Furthermore, recent *in vitro* and *in vivo* findings show that IGFBPs may function independently of the IGFs as growth modulators^[32]. IGFBP-6 differs from the other IGFBPs because it has a markedly higher affinity for IGF-2 than for IGF-1, whereas the other IGFBPs bind the two IGFs with similar affinities^[33]. IGF-2 overexpression is described in several tumor-xenograft models and in human HCCs^[34]. Additionally, a correlation of IGF-2 overexpression with HepG2 and Huh-7 cell growth has been shown^[35] as well as a modulation of IGFBP-expression through the EGFR signaling pathway^[36]. It may be speculated that reduced amounts of bioavailable IGF-2 as a result of EGFR-blockade-induced IGFBP-overexpression contribute to the growth inhibition of hepatocellular can-

cer cells by a further reduction of mitogenic stimuli. However, additional investigations on the complex network of IGF-2R, IGF-2 and IGFBPs have to be undertaken in order to explain our observations and their relevance with anti-EGFR based therapy strategies.

Some of the molecular targets investigated in this study may be used as surrogate biomarkers for anti-EGFR-based therapeutic strategies. The rational selection of cancer patients for EGFR inhibition therapies remains a major challenge because there is no clear correlation between EGFR overexpression and response to EGFR inhibitors^[10]. Thus, the finding of new biomarkers is mandatory. Interestingly, using gadd153 induction as a predictor of clinical response has already been evaluated for paclitaxel treatment of cancer patients^[37].

Like the EGFR, the insulin-like growth factor receptor 1 (IGF-1R) contributes to the growth, survival, adhesion and motility of cancer cells. The IGF-1R is a tetrameric tyrosine kinase receptor which can be activated by either IGF-1 or IGF-2. IGF-1R signaling is mediated through MAPK, phosphatidylinositol-3-kinase (PI3K) and stress-activated protein kinase (SAPK)^[38]. In the present study we showed that the MAPK-pathway was activated by IGF-1 in HCC cells. Moreover, our results revealed an IGF-1R mediated transactivation of the EGFR in HCC cells. Several modes of indirect EGFR activation have been described so far^[39]. As compelling evidence demonstrates the significance of EGFR signal transactivation in human disorders, the components of this signaling mechanism represent promising targets for therapeutic intervention. EGFR transactivation induced by activation of G-protein-coupled receptors, cytokine receptors and voltage-dependent Ca^{2+} -channels has been described. Though the exact mechanisms of the receptor-receptor cross talk are not known yet, RTKs are supposed to be important mediators of the transactivation process^[40]. In accordance, our results exhibited erlotinib's potency to inhibit IGF-1 induced transactivation without affecting the activation of the IGF-1R by its ligands. This finding may explain results of previous *in-vitro* studies showing greater antineoplastic activity for EGFR-TK-inhibition in HepG2 and Huh-7 cells^[12,18] than for inhibition of endogenous ligand binding by cetuximab^[28].

In addition to the induction of EGFR-transactivation, IGF-1R is known to be involved in resistance towards anti-EGFR-based therapeutic approaches. This arises from the fact that alternative signaling pathways of the IGF-1R can compensate for a blocked primary EGFR pathway. As IGF-1R is strongly expressed in HCC cells^[34], co-targeting of IGF-1R and EGFR in HCC cells may be a way to avoid or overcome resistance towards EGFR blockade. Combining erlotinib with the IGF-1R-TKI AG1024 resulted in synergistic effects in HepG2 and Huh-7 cells. These results suggest that combination regimens targeting both EGFR and other growth factor receptors such as IGF-1R may simultaneously yield greater anticancer activity than approaches that address only a single receptor and should be investigated more extensively in future studies.

In summary, our data suggest that EGFR-TK-blockade by erlotinib leads to an inhibition of the mitogenic MAP-kinase pathway as well as to an interruption of STAT-

mediated signaling, resulting in a different expression of apoptosis and cell cycle regulating genes in HCC cells. Overexpression of proapoptotic factors like caspases and gadd5 associated with a down-regulation of antiapoptotic factors like Bcl-2, Bcl-X_L or jun D may account for erlotinib's action to induce apoptosis. Downregulation of cell cycle regulators promoting the G₁-to-S-transition and overexpression of cyclin-dependent kinase inhibitors and gadd5 contribute to the induction of a G₁/G₀-arrest in response to EGFR-TK-inhibition by erlotinib. Moreover, our results point at the transactivation of EGFR-mediated signaling by the IGF-1R and show erlotinib's inhibitory effects on the receptor-receptor cross talk mechanisms. Finally we demonstrate that synchronous targeting of EGFR and IGF-1R yields greater antineoplastic effects than approaches that address only a single receptor. To conclude, our study sheds light on the understanding of the mechanisms of action of EGFR-TK-inhibition in HCC-cells and thus might facilitate the finding of combination therapies that act additively or synergistically. Moreover, our data on the pathways activated by erlotinib could be helpful in predicting the responsiveness of tumors to EGFR-TKIs in the future.

ACKNOWLEDGMENTS

We thank Roche (Penzberg, Germany) for providing us with erlotinib and the Institute of Physiology, Charité - Universitätsmedizin Berlin, Campus Benjamin Franklin, for laboratory facilities.

Abstract

AIM: To evaluate the mechanism underlying the effects of 5-Fluorouracil (5-FU) on adenoviral infection.

METHODS: Low and high Coxsackievirus-Adenovirus Receptor (CAR) expressing human colon carcinoma cell lines were treated with 5-FU and two E1-deleted adenoviral constructs, one transferring GFP (Ad/CMV-GFP) the other bax (Ad/CEA-bax). The number of infected cells were monitored by GFP expression. To evaluate the effects of 5-FU in a receptor free system, Ad/GFP were encapsulated in liposomes and treated with 5-FU. Ad/GFP release was estimated with PCR and infection of 293 cells with the supernatant. Electron microscopy of the Ad5-GFP-liposome complex was made to investigate morphological changes of the liposomes after 5-FU.

RESULTS: Infection rates of all cell lines increased from 50% to 98% with emerging 5-FU concentrations. The enhanced viral uptake was independent of the CAR expression. Additionally, 5-FU treated liposomes released 2-2.5 times more adenoviruses. Furthermore, 5-FU-treated liposomes appeared irregular and porous-like.

CONCLUSION: adenoviral uptake is enhanced in the presence of 5-FU irrespective of CAR and is associated with morphological changes in membranes making the combination of both a promising option in gene therapy.

Key words: 5-Fluorouracil; Coxsackievirus-adenovirus receptor; Adenoviral infection; Gene therapy

INTRODUCTION

It is widely accepted that cancer is the endpoint of an accumulation of genetic mutations that result in a cellular phenotype characterized by uncontrolled growth and reduced apoptosis. Consequently, therapeutic strategies, which address the genetic lesions and thus kill cancer cells, are reasonable. This concept has made virus-mediated gene therapy an ideal candidate for therapeutic approaches either alternative or complementary to chemotherapy or radiotherapy. Human adenoviruses are widely used as delivery systems but adenovirus (Ad)³ uptake is dependent on expression of Coxsackievirus-adenovirus receptor (CAR). Unfortunately, tumor cells are usually characterized by a reduced expression of CAR that binds the fiber knob domain of the Ad serotypes 2 and 5^[1]. Cells lacking this receptor are more resistant to adenoviral infection and, consequently, they are poor targets for Ad-associated tumor therapies^[2-5]. Further, it has been shown that the treatment of colorectal cancer with the replication-selective Ad d/1520 in combination with 5-Fluorouracil (5-FU) was more efficient in inducing apoptosis than the administration of the two agents separately^[6-9]. Therefore we evaluated the mechanism underlying the effects of 5-FU in the context of adenoviral infection in this study. To better understand the role of 5-FU in adenoviral infection of tumor cells, we used two E1- and replication-deficient adenoviral mutants expressing GFP (Ad-GFP) to infect colorectal cancer cell lines that show different CAR expression. A significantly higher number of GFP-expressing cells were observed after treatment with 5-FU and Ad-GFP compared to Ad-GFP alone. The effect of 5-FU was even more striking in a cell line with low CAR expression (SW480) indicating that a CAR-independent mechanism may be responsible for the transport of Ad through the cell membrane. This enhancement

of infection was dose-dependent and maximal with simultaneous application of 5-FU and Ad-GFP. To assess this effect in a CAR-independent pathway, Ad-GFP was encapsulated in liposomes, which were treated with 5-FU. Supernatants of these liposomes contained 2.4 times more Ad-GFP after 5-FU treatment compared to controls. In addition, morphological changes in the lipid membranes were seen by electron microscopy. In conclusion, we could demonstrate that simultaneous treatment with 5-FU enhances adenoviral uptake into tumor cells. More importantly, this effect could be observed irrespective of CAR expression and 5-FU favors the crossing of the viral protein capsid through the lipid membranes. Regardless of the underlying mechanism, the combination of adenoviral and 5-FU treatment might be of significant importance in the context of gene transfer.

MATERIALS AND METHODS

Cell lines and culture conditions

All cell lines used in this study were purchased from the German Collection of Microorganisms and Cell Cultures (Braunschweig, Germany) and were grown in the appropriate media containing 100 mL/L FCS, 10 g/L Pen/Strep (PS) and 10 g/L glutamine. The human embryonic kidney 293 cells were grown in DMEM, the human colon adenocarcinoma cells DLD-1, LOVO, SW480 and SW620 in RPMI 1640, and the RKO cells in McCoy.

Recombinant virus construction and purification

The adenoviral vectors for gene expression were constructed with the AdEasy system^[10]. Briefly, Ad-CEA_{Abax} was constructed with the pAdTrack vector containing the CEA promoter in front of the bax gene and the gene for GFP under the control of the CMV promoter, whereas Ad-GFP was constructed with the pAdTrack vector containing GFP under the control of the CMV promoter. The resulting plasmids were then transformed into *Escherichia coli* cells with pAdEasy-1. The recombinant adenoviruses were generated in the 293 cells (E1-transformed) and purified by CsCl gradient ultracentrifugation^[11]. The titer was determined by counting the green cells after 48 h.

Cell culture and infection

For Ad infection of SW480 the cells were seeded onto 96-well plates at 1500 cells/well and grown for 2 d. For the 5-FU pretreatment, the cells were first incubated at 37°C in RPMI/FCS/PS containing 5-FU at concentrations of 2, 10, 30 and 50 µmol/L. After 2 h the medium was removed, the cells were washed and infected with Ad-GFP at 300 pfu/well in 200 µL medium without the drug. For the co-treatment, the cells were infected with Ad-GFP diluted in 200 µL medium containing 5-FU at the concentrations reported above. Controls were incubated with medium without 5-FU. The number of green cells was counted after 24, 48 and 72 h with a fluorescence microscope for GFP expression. For the infection of the Lovo and SW480 cells with Ad-CEA_{Abax}, the cells were plated onto 60 mm dishes at a density of 2×10^5 cells/

dish. After 1 d, the cells were infected with the virus (1 MOI) in 1 mL medium without FCS and PS. After 30 min incubation at 37°C, the cells were treated with the medium containing FCS, PS and 5-FU at the final concentrations of 2 µmol/L for Lovo and 20 µmol/L for SW480. For the treatment of the colon cancer cells with Ad-GFP and 5-FU, 5-BrU, 5-FC, DOC, or taxol, the cells were seeded onto 6-well plates at 2×10^5 cells/well. After 1 d, Ad-GFP was added at 3×10^4 pfu/well in 1 mL medium without FCS and PS. After 30 min incubation at 37°C, 2 mL growth medium were added containing FCS, PS and the drug at the following final concentration: 4 µmol/L for 5-FU, 5-BrU, 5-FC and DOC, and 5 µg/L for taxol. The number of green cells was counted 48 h after infection.

Liposome preparation

To assess the effects of 5-FU of lipid membranes and the ability of Ad to penetrate the membranes, we encapsulated Ad in liposomes with and without 5-FU. The release of Ad was measured by PCR for E4orf6. In addition, the number of infective particles was evaluated by infection of 293 cells with the supernatant. The liposomal formulation of Ad was prepared as follows: Ad-GFP (3×10^4 pfu) was mixed with lipofectamine (Invitrogen) that was brought to a final concentration of 0.4 g/L with PBS. After 2 h incubation at room temperature, 5-FU was added to the final concentration of 20 µmol/L. The mixture was incubated overnight at room temperature and then centrifuged at 2060 g for 50 min at 20°C. The supernatant (100 µL/well) was diluted to 1 mL with DMEM without FCS and PS and added to the cells that were then incubated for 30 min at 37°C. Afterwards, 2.5 mL DMEM containing FCS and PS were added and the cells were further incubated. For the experiment with the liposome-encapsulated Ad-GFP, the 293 cells were plated into 6-well plates at 2×10^5 cells/well and were grown overnight.

PCR analysis

The following adenoviral DNA samples (each 2 µg) were prepared for PCR: DNA alone, DNA in the presence of 9.6 µmol/L 5-FU, DNA/lipofectamine (0.2 g/L), DNA/lipofectamine (0.2 g/L) in the presence of 9.6 µmol/L 5-FU. The samples were incubated overnight at room temperature, then centrifuged at 2060 g for 35 min at 18°C. For control, an additional sample of DNA/lipofectamine (0.2 g/L) was prepared and treated with a lysis buffer for 1 h at 4°C prior to centrifugation. The DNA was precipitated from the supernatants upon addition of NaOAc and isopropanol, isolated by centrifugation, washed with 750 mL/L ethanol and dried. The PCR was performed by using the Taq PCR Master Mix (Qiagen). The resultant PCR products were then resolved on a 1.5% agarose gel containing 0.25 mg/L of ethidium bromide.

Flow cytometric analysis

Single cell suspensions were fixed in 700 mL/L ethanol and incubated with 50 g/L PI and 20 g/L RNase for 15 min. at 37°C. Flow analysis was done at 488 nm excitation and > 525 nm Em range collected for GFP fluorescence. Elite Software 4.0 (Coulter Corp, Miami, FL) and Multi

Cycle DNA Analysis program software (Phoenix Flow Systems, San Diego, CA).

Western blot analyses

Protein concentration was determined by using the BC assay (Interchim, Montluçon, France). The protein samples [(40 µg for the CAR detection, 60 µg for the bax detection and 50 µg for the fiber detection (samples were not cooked)] were separated on SDS-polyacrylamide gels (100 g/L for the CAR detection, 150 g/L for the bax detection and 75 g/L for the fiber detection), and transferred to nitrocellulose membranes (Bio-Rad, Hercules, CA). The blots were blocked with 50 mL/L nonfat dry milk in 1 g/L Tween 20 PBS (TPBS-MLK) for 1 h at room temperature, then incubated overnight at 4°C with the appropriated antibodies: CAR (goat polyclonal antibody, Santa Cruz) at the dilution of 1:285, bax (polyclonal rabbit anti-human, PharMingen) at the dilution of 1:1000, fiber (polyclonal mouse, NeoMarkers, Fremont, CA) at the dilution of 1:1000 and actin (goat polyclonal antibody, Santa Cruz) at the dilution of 1:1000. After washing with TPBS, the following secondary antibodies were added at the dilution of 1:500 and incubated for 1 h at room temperature: HRP-conjugated IgG from donkey anti-goat for CAR and actin detection, and from goat anti-rabbit for bax detection. The proteins were finally visualized by enhanced chemiluminescence (ECL, Amersham Pharmacia Biotech).

CAR blockade

SW480 cells were plated into 6 well plates at 2×10^5 cells/well and incubated with CAR antibody (goat polyclonal antibody, Santa Cruz) at the dilution of 1:1000, 1:750, 1:500, 1:250, 1:100 and 1:50 for 24 h. The cells were incubated with Ad-GFP and the number of green cells was counted 48 h after infection.

Transmission electron microscopy

The following solutions were analyzed by electron microscopy (EM): (A) lipofectamine at 0.5 g/L, (B) lipofectamine at 0.5 g/L treated overnight with 20 µmol/L 5-FU, (C) Ad-GFP (4×10^8 pfu/L) complexed with lipofectamine at 0.5 g/L, (D) Ad-GFP (4×10^5 pfu/mL) complexed with lipofectamine at 0.5 g/L and incubated for 1 h at room temperature prior to treatment overnight with 20 µmol/L 5-FU. The EM samples were prepared by using the negative stain procedure. Briefly, a drop of each sample was deposited on a copper grid and coated by a formvar/carbon film. The film was then stained with 20 g/L tungsten phosphoric acid and dried on air. The EM images were recorded on a Zeiss instrument operating at 80 kV.

RESULTS

5-FU augments the viral infection rate of both high and low CAR-expressing cell lines

Several cell lines (DLD-1, Lovo, SW480 and SW620) were treated with Ad-GFP or Ad-CEAbax at a MOI that infected 50% of the cells. The infection of all cell lines was surprisingly efficient (up to 98%) when the adenoviral constructs were used in combination with 5-FU, as

Figure 1 Effect of 5-FU on the adenoviral infection of colon carcinoma cell lines differing in CAR expression. The drug was used at the dose of 2 µmol/L for the Lovo cells and of 20 µmol/L for the SW480 cells. The virus (Ad-CEAbax) was used at 1 MOI. The cells were treated with 5-FU alone, or infected with the virus in the absence and in the presence of 5-FU (A). The expression of bax with 5-FU and/or the virus was controlled by western blot after 24 h, 36 h and 48 h incubation (B). The expression level of CAR on the colon carcinoma cells line was confirmed by western blot analysis (the expression of actin is reported as a control for loading) (C).

indicated by the high population of green cells in Lovo and SW480 cell examples (Figure 1A and 2A). In accordance with GFP expression, an increased expression of bax was detected (Figure 1B) after Ad-CEAbax infection and 5-FU. The RKO cells died after simultaneous treatment and thus the number of green cells decreased after 24 h (Figure 4). As control 293 cells were transfected with the CMV Promoter/GFP DNA and treated with 10 µmol/L 5-FU. No difference in the amount of green cells was seen after 5-FU indicating that 5-FU does not interfere with the transcription of the reporter gene (data not shown). In addition, SW480 cell lysates of 5-FU treated (10 µmol/L) and control cells were blotted for adenoviral fiber protein after treatment with two different adenoviral MOI (200 and 50). In both cases more fiber protein could be detected in 5-FU treated cells (Figure 2B) indicating a higher amount of intracellular adenovirus. 5-FU enhanced the uptake of Ad not only in cell systems expressing CAR at high levels, such as the Lovo cells, but even more in cells with a low-level CAR expression (Figure 1C), indicating that the effect might not be dependent on CAR expression. To block the function of CAR SW480 cells were incubated with

Figure 2 The number of GFP expression cells was measured by flow cytometry in SW480 and LoVo cells (A). Treatment with 5-FU resulted in increased number of GFP expression cells and increased intensity of GFP expression in both cell lines. Intracellular adenoviral fiber protein was assessed by western blot analysis of SW480 cell lysates (B) after Ad-GFP treatment. In control cells and 5-FU treated cells no fiber protein could be detected. Low amounts of fiber protein could be seen in Ad-GFP treated cells dependent on Ad-GFP concentrations (MOI of 200 and 50). Additional 5-FU treatment increased fiber protein in whole cell lysates indicating enhanced adenoviral uptake. Function of CAR was blocked by anti CAR antibody at a concentration of 1:500 but 5-FU enhanced the number of GFP expressing cells even at anti CAR antibody concentrations of 1:50 (C).

antibody against CAR (Santa Cruz, N-17) in increasing concentrations from 1:1000 to 1:50 for 24 h and incubated with Ad (MOI 400). Viral uptake was blocked at higher concentrations than 1:500 but treatment with 5-FU still enhanced viral uptake (Figure 2C) accounting for a CAR independent mechanism of 5-FU.

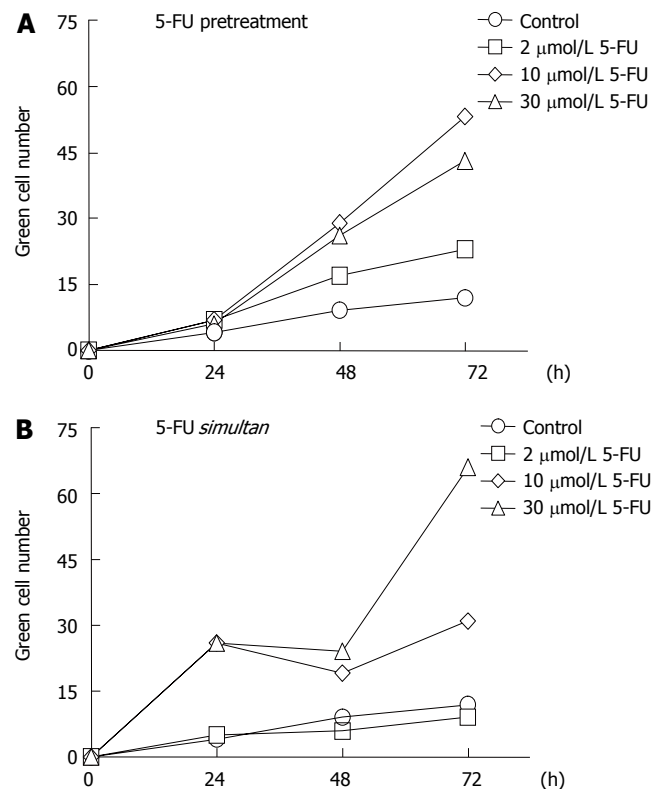

Figure 3 Dependence of adenoviral efficacy on the sequencing of 5-FU and virus administration to the SW480 cells. Two h postincubation with the drug at the indicated concentrations, the drug was removed and the cells were infected with the adenoviral construct Ad-GFP (A). Alternatively, the cells were infected with the virus in combination with 5-FU (B). The number of green cells was counted after 24, 48 and 72 h infection. The reported data points are the average of three experiments and the standard deviation values were in the range of 10%-15% (the error bars were not reported for clarity).

Efficacy of 5-FU on Ad uptake is dependent on drug concentration

The GFP expression in 5-FU-pretreated SW480 cells was significantly higher than in untreated cells, and the number of cells producing the fluorescent protein increased with increasing concentrations of the anticancer agent up to 10 μ mol/L. Indeed, after 48 and 72 h the rate of Ad infection in cell pretreated with 10 μ mol/L 5-FU was more than twice the infection rate obtained with 2 μ mol/L 5-FU (Figure 3A). At the higher concentrations of 30 μ mol/L, however, the drug was shown to be moderately less effective, a phenomenon that could be due to an inhibitory effect of 5-FU on the viral DNA replication (data not shown). All experiments were done in triplicate and the standard deviation was less than 15%. A superior efficacy of 5-FU was observed by its simultaneous application with Ad, which led to an improvement not only in the yield but also in the rate of the infection, especially when the drug was used at 30 μ mol/L. Under these conditions the number of green cells counted after 24 h was three times higher than in the case of the drug pretreatment and there was an increment of more than 50% in the density of green cells after 72 h (Figure 3B).

The increase in cellular Ad uptake is a specific response to 5-FU

The positive effect of 5-FU on Ad infection could be

Figure 4 Other pyrimidine-based drugs do not show the positive effect of 5-FU on adenoviral infection. The colon carcinoma cell lines were treated concurrently with the virus Ad-GFP and 5-FU, 5-BrU, 5-FC, DOC or taxol, each at the indicated concentration. The number of the infected green cells was counted after 40 h infection. The reported data are the average of three experiments and the error bars indicate the standard deviation values.

related to its function as a chemotherapeutic agent or to its structural and chemical characteristics. To assess which structural and chemical features of 5-FU might play a role in the entry of Ad into the cells, the two compounds 5-BrU and 5-FC, which are pyrimidine derivatives as 5-FU, were used in combination with Ad. In 5-BrU the halogen is bigger and less electronegative than in 5-FU. In 5-FC an amino group is present at position 4 instead of a carbonyl group as in 5-FU, thus conferring a higher hydrophilicity to the molecule. In both cases, the level of the infection did not change with respect to Ad alone, indicating that the ability of 5-FU to favor Ad infection is specific and not common to other molecules structurally-related to 5-FU. Additionally to other chemotherapy drugs, such as taxol^[12], the cell membrane-destabilizing bile salt sodium deoxycholate^[13] was used in combination with Ad. In the case of the DLD-1 and SW480 cells only 5-FU positively influenced the cellular entry of Ad, whereas taxol did not show any effect. In contrast, the infection of the Lovo cells was improved by both anticancer drugs, with taxol being twice more effective than 5-FU (Figure 4). The effect of these drugs was only moderate in the RKO cells, which do express high levels of CAR.

5-FU increases the release of Ad from liposomal formulations

Based on the observation that 5-FU positively affected the Ad uptake independently of CAR, we postulated a 5-FU-mediated transfer of Ad through lipid membranes. To investigate whether 5-FU exerts any effect on ordered lipid structures, a liposome mixture of DOSPA/DOPE at a 3:1 ratio was used to encapsulate the Ad, and the resulting complex was then treated with 5-FU overnight. After centrifugation, the number of infective particles in the supernatant was tested on 293 cells, which provide a system for the replication of E1B deleted Ad mutants. As shown in Figure 5A, the green cell number obtained from the infection with the supernatant of the 5-FU-treated Ad-liposome preparation was at least 2.4 times higher than that obtained from the infection with the supernatant of

the same preparation but without 5-FU. This is indicative of an augmented viral concentration in the supernatant as the result of the incubation of the liposome-entrapped Ad with 5-FU. In order to control whether the treatment with 5-FU could induce the release of adenoviral DNA from the liposomes, samples of DNA-liposome solutions with and without 5-FU were subjected to PCR and then analyzed by agarose gel electrophoresis. No adenoviral DNA was visualized by ethidium bromide staining, indicating that there was no release of the DNA component from the liposome complex in the presence of 5-FU. As a control, the DNA-liposome complex was subjected to liposome disruption prior to PCR and the resultant PCR product was visualized on the agarose gel, as it was expected (Figure 5B).

5-FU induces a morphological change of the lipid layers

The EM images of the liposomal formulations upon 5-FU treatment showed a multilayer motif that was characterized by an irregular thickness of the liposome as a result of the disappearance of an ordered layer structure in some regions (Figure 5C). Similarly, in the case of the Ad-liposome complex treated with 5-FU, the lipid surface was not uniform, but showed some bright spots that are probably indicative of perturbations in the packing and ordering of the multilayers.

DISCUSSION

In this study we could demonstrate that 5-FU increases the effectiveness of adenoviral uptake into colorectal cancer cells, thus overcoming the resistance of several colorectal cancer cells to adenoviral treatment. This effect is independent of CAR expression on the cell surface and could be confirmed in a receptor free system. In addition this effect is associated with changes in lipid membranes. Thus, the combination of the anti-tumor drug 5-FU with adenovirus enhances gene transfer capabilities of the virus in colon cancer cells. The synergistic effect of oncolytic Ad (*dl1520*) and chemotherapeutic agents, such as 5-FU and cisplatin^[6-9], is already known, but the reason for such behavior is not completely elucidated. One proposed explanation is the enhancement of cell chemosensitivity induced by viral replication, probably through the expression of the E1A gene that occurs after Ad infection and increases tumor cell killing^[14]. Nevertheless, this mechanism does not apply to all cell systems, because it can occur only in those cells that are not resistant to the Ad entry and, more strikingly, our data demonstrate that even E1-deleted constructs, which are replication-deficient, are more effective in the context of 5-FU treatment.

As stated before, a replication defect of human Ad was used to transfer CMV promoter/GFP DNA but 5-FU could probably increase transcription of the CMV promoter similar to FDXR induction by p53 in cells treated with 5-FU^[15]. Therefore we transfected cells with CMV promoter/GFP plasmid and could not see any enhancement of GFP expression with 5-FU. In addition, higher amounts of adenoviral fiber protein were detected in cell lysates after Ad and 5-FU treatment indicating more Ad particles within the cells

Figure 5 Increased release of viral particles from liposome-encapsulated adenoviral formulations. 293 cells were infected with the supernatant from centrifuged liposome-entrapped Ad-GFP solutions with and without 5-FU incubation. The number of the infected green cells was counted after 48 h and 72 h infection. The reported data are the average of three experiments and the error bars indicate the standard deviation values (**A**). On the other hand, the 5-FU treatment of liposome-encapsulated viral DNA did not lead to any DNA release, as confirmed by PCR analysis. Following samples (each loaded in duplicate) were separated by agarose gel electrophoresis: DNA alone (lanes 1 and 2), DNA and 9.6 $\mu\text{mol/L}$ 5-FU (lanes 3 and 4), DNA and lipofectamine (lanes 5 and 6), DNA with lipofectamine and lysis buffer (lanes 7 and 8), DNA with lipofectamine and 5-FU 9.6 $\mu\text{mol/L}$ (lanes 9 and 10) (**B**). EM images of liposomal preparations. (1) lipofectamine, (2) lipofectamine after treatment overnight with 5-FU, (3) Ad-GFP complexed with lipofectamine, (4) Ad-GFP complexed with lipofectamine after treatment overnight with 5-FU (**C**).

and suggesting that the higher amount of green cells is a result of higher Ad uptake into cells. Furthermore, it was proposed that the loss of sensitivity of cancer cells to Ad treatment is generally a consequence of loss of CAR

representing a severe limitation of the application of gene therapeutic strategies with Ad as a gene delivery system^[11]. Interestingly, although the binding of Ad to its receptor is suggested to be the first step for infection, our results indicated that the presence of CAR does not provide a guarantee for efficient viral infection. Indeed, not only cells expressing low levels of CAR, such as the SW480 cells, but also cells expressing normal levels of CAR, such as the DLD-1, Lovo and SW620 cells, were found to be Ad-resistant. However, simultaneous treatment with 5-FU and Ad could enhance the sensitivity to adenoviral infection in all tested cell systems but the effects of 5-FU treatment was more impressing in cell lines which are difficult to infect with Ad. To assess the effect of 5-FU we blocked CAR and could still see enhanced viral uptake. Interestingly, the positive effect of 5-FU was superior when both Ad and 5-FU were added simultaneously in comparison to the pre-incubation of the cells with the drug before the addition of Ad. This suggests that the entry of Ad into cells may occur independently of the production or degradation of effectors caused by 5-FU treatment. Therefore we assessed the capability of Ad to pass through liposomal membranes in the presence of 5-FU and, in accordance with this hypothesis, we observed an increased adenoviral release from liposomes treated with 5-FU.

In light of our experiments on cells differing in CAR expression, we postulate that Ad uptake could be based on a mechanism alternative to that requiring the binding to the Ad receptor. In the presence of CAR, Ad is delivered into the cell via an internalization process involving receptor-mediated endocytosis^[16]. Alternatively, in the absence of CAR, the adenoviral protein capsid is likely to interact directly with the phospholipid layers of the cell membrane; however, such interaction results in an effective intracellular transfer only in the presence of 5-FU. The intra- and extra-cellular drug diffusion across the membrane could be coupled to temporary changes in the packing and ordering of the lipid bilayers building the cell membrane, which, in turn, could become more accessible to external agents. Nevertheless, the potential effects of 5-FU on the membrane must be different from those of other amphiphilic molecules that are known to exert a lytic action on membranes, such as DOC^[17], as suggested by the observation that this bile salt did not increase the Ad uptake. Previous studies have reported on morphological changes of cells after treatment with adenoviruses^[18] or with detergents^[17]. Moreover, the interactions between biological or model membranes and hydrophobic drugs, such as 1, 4-dihydropyridines^[19] and benzocaine^[20], have been investigated in detail, but the exact mechanism of 5-FU with cell membranes remains elusive. The human colon cancer cells tested in this work generally became bigger and adopted a spindle shape upon incubation with 5-FU. This supports our hypothesis that, beside its well-known anti-cancer action, 5-FU may exert a potential disturbing effect at the cell membrane. Interestingly, 5-FU changes intestinal absorption in rat of dextran^[21]. However, the exact mechanism of adenoviral passage through lipid membrane in the presence of 5-FU remains unclear.

In conclusion, we suggest that 5-FU might play a role

in increasing the sensitivity of cells for environmental influences by changes in the phospholipid bilayers of cell membranes in addition to its chemotherapeutic property. This would be especially useful for the transport of therapeutic compounds independently of the presence or absence of specific cell surface receptors, as in the case of the transfer of Ad into CAR-negative cells. On the other hand, side effects of adenoviral infections during high-dose chemotherapy might not only be based on a suppressed immune system, but, if 5-FU enhances viral uptake, flue-like side effects of the 5-FU chemotherapy might be caused by a higher adenoviral uptake into cells.

Abstract

AIM: Thioacetamide (TAA) has been used in studying liver fibrosis and cirrhosis, however, the mechanisms of TAA-induced apoptosis in liver are still unclear. The hepatic epithelial cell line clone 9 was cultured and treated with TAA to investigate the causes of cell death.

METHODS: The cell viability of TAA-induced clone 9 cells was determined using MTT assay. Total cellular GSH in TAA-induced clone 9 cells was measured using a slight modification of the Tietze assay. The activity of caspase 3 in TAA-induced clone 9 cells was monitored by the cleavage of DEVD-p-nitroaniline. TUNEL assay and flow cytometry were applied for the determination of DNA fragmentation and the proportion of apoptosis in TAA-induced clone 9 cells, respectively. The alterations of caspase 3, Bad, Bax and Phospho-P53 contents in TAA-induced clone 9 cells were measured by Western blot.

RESULTS: The experimental data indicated that TAA caused rat hepatic epithelial cell line clone 9 cell death in a dose- and time-dependent manner; 60% of the cells died (MTT assay) within 24 h after 100 mg/L TAA was applied. Apoptotic cell percentage (TUNEL assay) and caspase 3 activities were highest after 100 mg/L TAA was added for 8 h. The release of GSH and the elevation in caspase content after TAA treatment resulted in clone 9 cell apoptosis *via* oxidative stress and a caspase-dependent mechanism. The phospho-p53, Bax and Bad protein expressions in clone 9 cells were increased after TAA treatment.

CONCLUSION: These results reveal that TAA activates p53, increases caspase 3, Bax and Bad protein contents, perhaps causing the release of cytochrome c from mitochondria and the disintegration of membranes, leading to apoptosis of cells.

INTRODUCTION

Thioacetamide (TAA) is employed as a curing ingredient, a chemical reagent, a raw medicine, a pesticide, a textile dye and a finishing auxiliary. TAA^[1-4] is a typical hepatotoxin that causes centrilobular necrosis similar to carbon tetrachloride^[5-8] and D-galactosamine^[9]. TAA-induced hepatotoxicity *via* its S-oxide metabolite (thioacetamide-S-dioxide), that interferes with the motion of RNA from the nucleus to the cytoplasm, resulting in structural and functional cellular deformation and leading to membrane injury. TAA induces hepatocyte damage following its metabolism to thioacetamide sulphene and sulphone, *via* a critical pathway that involves CYP450E1-mediated biotransformation^[10,11]. TAA is a well-known hepatotoxicant whose administration to rodents *in vivo* causes cell death *via* both apoptosis and necrosis^[2,12,13]. The observed liver enzyme activities of aspartate and alanine aminotransferases (AST, ALT), glutamate dehydrogenase and threonine deaminase were low in the TAA-treated group. The declines were significant for both transaminases and threonine deaminase^[14]. TAA (200 µg/mL)-incubated hepatocyte cells exhibited a 40%-62% reduction in the marker enzymes (AST, ALT, and alkaline phosphatase (AP)) and a 50%-61% reduction in both viability and O₂ uptake^[15]. It may reduce the amount of antioxidant reagents, including vitamin C, vitamin E and glutathione contents^[16].

Elevated levels of reactive oxygen species (ROS) are believed to mediate damage by their interaction with proteins, nucleic acids, carbohydrates and lipids^[17-19], changing the enzymatic function and forming oxidation products. ROS is maintained at physiologically optimal levels under normal conditions by antioxidant defense systems that contain nonenzymatic antioxidants-glutathione and enzymes such as superoxide dismutases

(SOD), catalase and glutathione peroxidase (GPX)^[20]. The reduction in the antioxidant defenses and the reduced scavenging capacity reported herein may contribute to oxidative stress in rats with hemorrhagic shock and can be explained by various factors. The observations of apoptosis in liver are based on histochemical changes^[2], the participation of ROS^[21] and lipid peroxidation^[22-24], and cysteine-aspartate proteases3 (caspase 3) activation^[16,25] following the administration of TAA. However, the mechanisms of TAA-induced liver injury are not yet completely understood. The rat liver cell line, clone 9, is an epithelial cell line isolated from a young male rat in 1968 and has primarily been used for studies of *in vitro* carcinogenesis and toxicology. This study was to investigate whether TAA-induced oxidative stresses caused cell death and to seek the pathway that is involved in TAA-induced apoptosis using the rat hepatic epithelial cell line clone 9 as a model and to understand the regulatory mechanisms of TAA-induced liver injury.

MATERIALS AND METHODS

The rat hepatic epithelial cell line clone 9 (CRL-1439, ATCC, USA) was cultured with DMEM/F-12 medium to which 10% fetal bovine serum was added in 50 ml/L CO₂ at 37°C.

Experimental treatments

In Expt1, 5×10^5 clone 9 cells were cultured for 12-16 h in 6 wells and the medium was changed. Afterward, 25, 100 or 200 mg/L TAA was added to the wells and incubated for various times to determine the cell viability (MTT assay). In order to get a large enough cell pellet for chemical assay, the density of cultured cells was changed to 2×10^6 and cells were cultured in 25 cm² flasks. In Expt2, 2×10^6 clone 9 cells were cultured for 12-16 h in 25 cm² flask and the medium was changed. Then, 100 mg/L TAA was added to the flask and incubated for various periods to measure caspase 3, Bad, Bax and Phospho-P53 contents (Western blot), as well as total GSH and caspase 3 activity. In Expt3, 2×10^6 clone 9 cells were cultured for 12-16 h in a 25 cm² flask and the medium was changed. Thereafter, 100 mg/L TAA was added to the flask and incubated for various times to examine DNA fragmentation (TUNEL assay) and measure the proportion of apoptosis (flow cytometry).

MTT assay

750 µL of MTT (5 mg/mL, Sigma-Aldrich Chemie GmbH, Deisenhofen, Germany) solution was added to each well and incubated for 4 h. 1 mL of a DMSO working solution (180 mL DMSO with 20 mL 1 N HCl) was added to each well, and the OD of the yellow reaction product was evaluated in an ELISA reader at a wavelength of 570 nm with a reference wavelength of 630 nm after 15 min.

TUNEL assay

DNA strand breaks were identified using the Boehringer TUNEL assay (Boehringer Mannheim, Marburg, Germany). Briefly, cells in each experiment were washed

with phosphate-buffered saline (PBS). The cells were fixed and permeabilized using the Starfix IQP-200 reagents (Immuno Quality Products, Groningen, The Netherlands) according to the manufacturer's instructions. Subsequently, the TUNEL reaction mixture (60 min, 37°C) was added and the samples were washed and analyzed using FACSsort flow cytometry (Becton Dickinson, New Jersey, USA). The cells that expressed FITC fluorescence were considered to be TUNEL positive. This experiment was performed separately: the observed numbers of apoptotic cells could not be compared directly with those counted in the other experiments. Additionally, this experiment was conducted after a culturing period of 48 h.

Caspase 3 activity assay

The caspase 3 assay was performed according to the method of Hampton *et al*, 2002^[26]. Briefly, cells were treated with lysis buffer (100 mmol/L Hepes, 10% sucrose, 5 mmol/L dithiothreitol and 0.1% Chaps at pH 7.25). The extracted lysates were incubated with DEVD-p-nitroaniline for 3 h at 37°C. Caspase 3-dependent cleavage of p-nitroaniline (pNA) was monitored at 405 nm by spectrophotometry. Caspase 3 activity is expressed in pmol/min per µg protein.

Glutathione assay

Total cellular GSH was measured using a slight modification^[27,28] of the Tietze assay^[5]. The Tietze assay is a sensitive and specific method for determining the amounts of both reduced (GSH) and oxidized (GSSG) forms of glutathione in unknown samples^[28]. A stock buffer solution of 0.1 mmol/L sodium phosphate, pH 7.5, with 1 mmol/L EDTA was prepared in distilled water and utilized to make separate solutions of 12 mmol/L NADPH, 0.1 mmol/L DTNB and 50 U/mL GSH reductase. The assay was carried out directly in 96-well plates. 100 µL DTNB, 20 µL GSH reductase and 20 µL NADPH were added to each well. Absorbance at 405 nm with a reference wavelength of 595 nm was measured for 30 min at room temperature, using an automatic multiwell microplate spectrophotometer (Beckman, Opsys, MR, USA), and final values were calculated as a mean of three readings. The automatic mix function on the microplate reader was utilized to shake the plate before each reading. Standards of known GSSH content were prepared by serial dilution in 1x MES buffer and used to construct a standard curve. The rate of increase in absorbance at each concentration of GSSH standard was linear throughout the 1.5 min assay. The total protein concentration of each sample was determined using a Bio-Rad kit^[29] with bovine serum albumin as standard, such that GSH levels could be expressed as µmol per µg protein. All determinations were carried out in multiples of 12 wells.

Western blotting

After treatment, the cells were washed in D-PBS and lysed with protein lysis buffer (137 mmol/L NaCl, 20 mmol/L Tris-HCl, pH 7.4, 1 mmol/L CaCl₂, 1 mmol/L MgCl₂ and 0.1 mmol/L sodium orthovanadate, containing 1% Nonidet P-40 and 1 mmol/L phenylmercuric sulfonfyl chloride). The lysate was centrifuged at 12000 r/min for 10 min at 4°C and the supernatant was collected. The protein

Figure 1 Cell viability of clone 9 after treatment with 100 mg/L TAA for various periods. The results were obtained using MTT assay. Data are presented as mean \pm SE. Individual experiment was repeated three times and each time point of treatment was triplicate.

content was determined using Bradford assay (BioRad) with BSA as a standard. The supernatant (total protein 20 μ g) was mixed with 6x electrophoresis sample buffer that contained 1, 4-dithiothreitol (DTT). The proteins were separated by electrophoresis on a 10% gradient polyacrylamide slab gel and were electrophoretically transferred to a PVDF membrane (Amersham Life Science, Buckinghamshire, UK). The blots were incubated overnight in 3% BSA/TBS-T buffer (50 mmol/L Tris-HCl, 2.7 mmol/L KCl, 0.01 mol/L phosphate, 0.09% NaCl, pH 7.5 and 0.05% Tween-20) for 2 h. Membranes were incubated for 12–16 h with rabbit anti-caspase 3 polyclonal antibody (in a 1:1000 dilution, MWt 35 kDa, Cat. #9665, Cell Signaling, MA, USA), rabbit anti-Bad polyclonal antibody (in a 1:2000 dilution, MWt 21.5 kDa, Cat. #9292, Cell Signaling), rabbit anti-Bax polyclonal antibody (in a 1:1000 dilution, MWt 20.5 kDa, Cat. #2772, Cell Signaling) or mouse anti-Phospho-P53 monoclonal antibody (in a 1:2000 dilution, MWt 53 kDa, Cat. #9286S, Cell Signaling). After three washes with PBST, the blot was incubated with AP-conjugated secondary antibody for at least 2 h and immunoreactive proteins were visualized using BCIP/NBT (ZYMED, 00-2209). The band intensities of the control and the TAA treatment were determined using PHORETIX (Feng Jin Biomedical & Instruments Co Ltd, 61397/28052 Memo-HASP1) and the TAA treatment was compared with the control following-actin normalization.

Statistical analysis

All data are presented as mean \pm SE. For each measurement, data obtained at different times were compared statistically ($P < 0.05$) by one-way analysis of variance (ANOVA) with a Duncan multiple range test from SAS/STAT for multiple comparisons. A P value of less than 0.05 was considered to indicate a significant difference.

RESULTS

Cell viability

To determine the effective concentration of TAA, various concentrations of TAA were added to the clone 9 cell line, respectively. The cell survival rate fell to 67% and

Figure 2 Total glutathione (GSH and GSSG) of clone 9 after treatment with 100 mg/L TAA for various times. Data are presented as mean \pm SE. ^b $P < 0.001$ vs the control (0 h). Individual experiments were repeated three times and each time point of treatment was triplicated.

40% at 12 and 24 h after 100 mg/L TAA-treated clone 9 was applied, respectively (Figure 1). Treatment with a low concentration (25 mg/L) of TAA did not cause significant cell death at 48 h (data not shown). Nevertheless, 200 mg/L TAA was too toxic for clone 9 cells and most cell death occurred within 2 h of treatment. Thus, 100 mg/L TAA was chosen for the subsequent experiments.

Total GSH content

The clone 9 cells were treated with 100 mg/L TAA for various times (4, 8, 12, 16, 20, and 24 h). The total glutathione (GSH plus GSSG) of cell homogenate was measured. The total GSH content of the 100 mg/L TAA-treated clone 9 cells was elevated at 4 h and reached a peak level at 8 h ($P < 0.05$). Afterward total GSH content of the 100 mg/L TAA-treated clone 9 cells declined from 12 h to 24 h compared to that of the TAA-treated 4 h (Figure 2).

Caspase 3

The clone 9 cells were treated with 100 mg/L TAA for various times (4, 8, 12, 16, 20, and 24 h). The caspase 3 activity and protein content (Western blot) of cell homogenate were determined. The caspase 3 activity of the 100 mg/L TAA-treated clone 9 cells reached a peak between 8 and 12 h (Figure 3A). The caspase 3 protein content of the 100 mg/L TAA-treated clone 9 cells was gradually elevated from 4 h and reached a peak between 8 and 16 h (Figure 3B).

DNA fragmentation

The cell morphology was changed and irregularly shaped DNA was distributed close to the interior of the cell membrane, appearing like an apoptotic body (Figure 4A). Hoechst 33342 and TUNEL assay were applied to elucidate the type of cell death after TAA-treated clone 9 cells. The occurrence of apoptosis increased by 23% at 8 h after 100 mg/L TAA-treated clone 9 cells (Figure 4B).

Phospho-P53 expression

The clone 9 cells were treated with 100 mg/L TAA for various times (4, 8, 12, 16, 20, and 24 h). The phospho-P53

Figure 3 A: Caspase 3 activity; B: Caspase protein level (Western blot); C: Alterations of caspase protein compared to H0 (zero hour) after β -actin normalization (Western blot) in clone 9 after treatment with 100 mg/L TAA for various times. Data are presented as mean \pm SE. ^a $P < 0.05$ vs the control (0 h); ^b $P < 0.01$ vs the control (0 h). Individual experiments were repeated three times and each time point of treatment was triplicate.

Figure 4 A: Morphology of clone 9 cell; (a) untreated (Hoechst 33342 staining); (b) after treatment with 100 mg/L TAA treatment for 16 h (light field); (c) after treatment with 100 mg/L mmol/L TAA for 16 h (Hoechst 33342, 5 mg/mL in PBS). The arrow indicates the apoptotic cells; B: Flow cytometry of apoptosis in clone 9 cells (TUNEL assay) after treatment with 100 mg/L TAA for various times (a) 0 (b) 4 and (c) 8 h. R1 presents the area of cell apoptosis. Individual experiments were repeated three times and each time point of treatment was triplicate.

protein (Western blot) of cell homogenate was determined. The phospho-P53 expression of 100 mg/L TAA-treated clone 9 cells was increased at 4 h and maintained to 8 and 12 h ($P < 0.05$) (Figure 5).

Bax and Bad expressions

The clone 9 cells were treated with 100 mg/L TAA for various times (4, 8, 12, 16, 20, and 24 h). The Bax and Bad protein (Western blot) of the cell homogenate were determined. The Bax and Bad expressions of 100 mg/L TAA-treated clone 9 cells were elevated at 4 h ($P < 0.05$) and maintained to 8 and 12 h ($P < 0.05$) (Figures 6 and 7). These results were consistent with the phospho-P53 expression.

DISCUSSION

In the present study, rat hepatic epithelial cell line clone 9 was found apoptotic following TAA-induction.

Total GSH

The binding of the reactive compound thioacetamide-S dioxide to tissue macromolecules may be responsible for hepatic necrosis, apoptosis^[16], perturbations of mitochondrial activity^[30,31] and the elevation of serum cytokine levels. Several studies of rats and cultured cells

Figure 5 A: Phospho-p53 protein level (typical data, Western blot); B: Alterations of phospho-p53 protein as compared to H0 following β -actin normalization of clone 9 after treatment with 100 mg/L TAA for various times. have shown the involvement of oxidative stress in the etiology of TAA-induced liver damage. In these works, TAA caused lipid peroxidation^[29,32-35], increased the susceptibility of hepatocytes to *in vitro* lipid peroxidation^[23], reduced the GSH/GSSG ratio^[23,34,36,37], increased GSH

Figure 6 A: Bax protein level (typical data, Western blot); B: Alterations of Bax protein as compared to H0 following β -actin normalization of clone 9 after treatment for various times with 100 mg/L TAA. Data are presented as mean \pm SE. ^a $P < 0.05$ vs the control (0 h). Individual experiment was repeated three times and each time point of treatment was triplicate.

synthesis^[33], alterations in low molecular weight^[16] and the formation of enzymatic antioxidants^[36-38]. The data herein revealed that the total GSH content of 100 mg/L TAA-treated clone 9 cells was elevated at 4 h, reached the highest level at 8 h and decreased from 12 to 24 h (Figure 2). The method in this work detects the total level of GSH. It addresses not only the origin of intracellular GSH and GSSG but also that of the new generation of GSH. Accordingly, total GSH represents the level of cell to anti-oxidative stress. TAA induces oxidative stress, causing the hepatocytes to have a high total GSH content.

Dependence of apoptosis on caspase 3

The discovery of a family of cysteine-aspartate proteases (caspases) and their participation in signaling and apoptosis indicates the critical importance of these enzymes in this form of cell death^[39]. When cells are caused to undergo apoptosis, caspases—in particular caspase 3—cleave ICAD to dissociate the CAD: ICAD complex, allowing CAD to cleave chromosomal DNA^[40]. This study tested caspase 3 protein expressions by western blotting and detected caspase 3 enzyme activity to determine the time point of hepatic apoptosis with TAA treatment. The data herein demonstrate that enzyme activity and western blotting both indicated that caspase 3 activity and the protein of caspase 3 in the 100 mg/L TAA-treated clone 9 cells peaked between 8 and 12 h. The apoptosis caused by TAA involved the activation of caspase 3.

Phospho-p53 and Bax/Bad

In the signaling process associated with apoptosis, the membrane integrity of mitochondria plays an important role and is regulated by the Bcl-2 protein. On the basis of structural and functional attributes, Bcl-2 proteins can be divided into three subgroups; (1) anti-apoptotic channel-forming Bcl-2 proteins with four BH domains (BH1 to -4) and a transmembrane anchor sequence, (2) proapoptotic channel-forming proteins with all but the BH4 domain (Bax, Bak and Bok) and (3) proapoptotic

ligands (BAD, BOD/Bim and BID) that contain only the BH3 domain^[41-43]. The first two subgroups of proteins are believed to be anchored on the mitochondrial membrane, while the third subgroup of proteins act as ligands that dimerize with the membrane-anchored, channel-forming Bcl-2 “receptors”^[44,45]. The BH3 domains in the third subgroup are critical for the binding activity of these ligands. Proapoptotic BOK and BAX with a channel-forming domain regulate apoptosis by releasing APAF-1 because of suppression by anti-apoptotic proteins and by promoting the release of cytochrome c^[46]. Most studies that compare Bax and cytochrome c proteins in cytosolic and mitochondria demonstrate the results of Bax translocation^[47]. In this work, after TAA treatment, the total protein levels of Bax and Bad are elevated perhaps because the regulation of Bax genes increases the amount of Bax protein and the translocation into mitochondria, disintegrating the membrane and causing cell death. The increment of cytosolic Bad protein may be caused by phospho-Bad dephosphorylation; the dephosphorylated Bad and Bcl-XL then generates a dimer that influences the release of cytochrome c and, consequently, apoptosis^[48]. DNA damage activates latent tetramers of p53 to bind in a loosely defined DNA recognition sequence within target gene regulatory elements; p53 then typically activates gene transcription^[49,50]. The activation of DNA binding and subsequent transactivation activities of p53 occur *via* a phosphorylation-acetylation cascade^[51]. The carboxyl-terminus of p53 is phosphorylated in response to DNA damage, as is the amino-terminus; the effects of the amino- and carboxyl-terminal modifications on p53 determine its downstream specificity. Overall, the combination of different phosphorylation and acetylation events that affect p53 tetramers probably determine binding preferences of the downstream target gene-response elements, causing DNA damage-induced signaling *via* p53 phosphorylation. In this work, the expression levels of phospho-p53 and Bax are increased 4 h after treatment with TAA. The apoptotic rate reached 23% at 8 h after treatment with

TAA. This difference may be caused by the activation by ROS of p53. The formation of free radicals and the increase in ROS by H₂O₂ constitute the mechanism of apoptosis^[52-57]. The H₂O₂-induced apoptosis penetrates the cell membrane^[58] and alters Ox-red and free OH-damaged DNA^[59].

Abstract

AIM: To investigate the role of wireless capsule endoscopy (WCE) in detection of small bowel (SB) pathology in patients with chronic renal failure (CRF) and obscure bleeding.

METHODS: Consecutive CRF patients with obscure bleeding were prospectively studied. Patients with normal renal function and obscure bleeding, investigated during the same period with WCE, were used for the interpretation of results.

RESULTS: Seventeen CRF patients (11 overt, 6 occult bleeding) and 51 patients (33 overt, 18 occult bleeding) with normal renal function were enrolled in this study. Positive SB findings were detected in 70.6% of CRF patients and in 41.2% of non-CRF patients ($P < 0.05$). SB angiodysplasia was identified in 47% of CRF patients and in 17.6% of non-CRF patients. Univariate logistic regression revealed CRF as a significant predictive factor for angiodysplasia ($P < 0.05$). Therapeutic measures were undertaken in 66% of the patients with the positive findings.

CONCLUSION: According to our preliminary results, SB angiodysplasia was found in an increased prevalence among CRF patients with obscure bleeding. WCE is useful in diagnosis of gastrointestinal pathologies and in planning appropriate therapeutic intervention and, therefore, should be included in the work-up of this

INTRODUCTION

Unexplained gastrointestinal bleeding (overt or occult) and anemia are common complications of advanced chronic renal failure (CRF)^[1,2]. Furthermore, 19% of patients with advanced CRF prior to dialysis and 6% of those on maintenance hemodialysis have hemoccult positive stool^[3]. In some cases, upper and lower gastrointestinal tract endoscopic and imaging studies cannot explain these symptoms and findings and bleeding remains a real diagnostic and therapeutic challenge.

Until recently, small bowel (SB) investigation with the available endoscopic and imaging studies was incomplete. Consequently, there are no studies giving information on the pathology of the entire SB in CRF patients, except for two autopsy studies^[4,5]. In view of the scarcity of information, we conducted this study and used wireless capsule endoscopy (WCE) to evaluate SB pathology in patients with advanced CRF and obscure bleeding. This novel method is well tolerated and allows complete visual investigation of the SB^[6,7]. Moreover, the diagnostic yield of WCE, especially in obscure gastrointestinal bleeding, is significantly higher to that of any other methods, including push enteroscopy, small bowel radiography, computed tomography, magnetic resonance imaging and angiography^[8]. To the best of our knowledge, this is the first endoscopic study to explore the entire SB in CRF patients with obscure gastrointestinal bleeding.

MATERIALS AND METHODS

This prospective ongoing study included consecutive patients referred to our institution with advanced CRF needing SB investigation for obscure bleeding. Advanced CRF was defined as creatinine clearance of less than 30 mL/min. Renal transplant recipients with stable renal function and serum creatinine concentration ≥ 2 mg/dL for at least a 6-mo period were eligible to enter the study as well.

Age- and sex-matched patients with normal renal function and obscure gastrointestinal bleeding, investigated with WCE during the same period, were used for the interpretation of CRF patients' findings.

Obscure gastrointestinal bleeding was defined according to the American Gastroenterological Association position statement^[9]. Patients with obscure bleeding had been initially investigated with esophagogastroduodenoscopy and colonoscopy in other institutions and, if negative, were subsequently referred for WCE.

Generally accepted contraindications for the WCE procedure are described elsewhere^[10]. Written informed consent was obtained from all patients. Patients' clinical characteristics, including sex, age, total duration of CRF (pre-treatment plus post treatment period), NSAID or aspirin use, comorbid diseases (practically any serious diseases, e.g. cardiovascular, collagen diseases, endocrinopathies, portal hypertension), need for previous transfusions as well as the etiology of renal failure were recorded. Biochemical tests of renal function (serum creatinine and urea) and hemoglobin level were obtained as well.

WCE procedure

M2A capsule (Given Imaging, Yoqneam, Israel) was used in this study. Patients' preparation and WCE procedure were carried out following the generally recommended guidelines^[11]. Hemodialysis patients were not given the two-liter solution of polyethylene glycol as preparation, due to restriction of fluid intake; instead, they were advised to abstain from solid food, on the day before the procedure.

Interpretation of WCE results

A single gastroenterologist (experienced in gastrointestinal endoscopy and WCE) initially screened all videos and selected images of potential abnormalities. Then, two gastroenterologists (also experienced in interpreting WCE findings) independently reviewed the selected images to confirm the accuracy of diagnosis. All videos were extensively discussed and findings identified by both reviewers were considered as definitive and included in the report. The procedure was defined as incomplete if the capsule failed to pass into the cecum during an eight and a half-hour period of the examination. The diagnostic yield of WCE was calculated for both CRF and non-CRF patients. Only lesions with a high potential for bleeding, as defined by Saurin *et al.*^[12], were considered.

Statistical analysis

The Statistical Package for Social Sciences (SPSS) program

Table 1 CRF patients' characteristics

No. of patients	17
Etiology of renal failure, <i>n</i> (%)	
Nephrosclerosis	4 (23.5)
Glomerulonephritis	3 (17.6)
Chronic pyelonephritis	1 (5.9)
Diabetic nephropathy	1 (5.9)
Other etiologies	3 (17.6)
Unknown	5 (29.4)
Duration of CRF (mean \pm SE), mo	139.9 \pm 13.0
Median serum creatinine (range), mg/dL	3.2 (2.0 - 9.4)
Serum urea (mean \pm SE), mg/dL	133.9 \pm 11.0

version 10.0 (Chicago, Illinois) was used for statistical analysis. Continuous data with normal distribution were expressed as mean \pm SE, while those without as median (range). Differences between groups were evaluated using χ^2 test for qualitative variables and Student's *t* test for quantitative variables following a normal distribution or the Mann-Whitney *U*-test for those who failed the normality test. A *P* value of less than 0.05 was considered statistically significant. Logistic regression analysis was used to find predictive variables of findings, which were identified in terms of odds ratio (OR) with 95% confidence intervals (95% CI).

RESULTS

A total of 17 CRF patients fulfilled the inclusion criteria (7 predialysis patients, 4 on maintenance hemodialysis and 6 renal transplant recipients). CRF etiology and duration as well as biochemical parameters are shown in Table 1. Duration of dialysis ranged between 20 to 60 mo (mean \pm SE: 38.7 \pm 3.8) and the treatment schedule consisted of 4 h hemodialysis procedures three times weekly. Post-transplantation period ranged between 16 to 93 mo (mean \pm SE: 53.2 \pm 12.5). Immunosuppressive treatment in transplant recipients consisted of a combination of mycophenolate mofetil (MMF), cyclosporine and prednisone (3/6 patients), MMF, tacrolimus and prednisone (2/6) and MMF, sirolimus and prednisone (1/6). Two out of 17 CRF patients were taking low-dose aspirin and 1 non-steroidal anti-inflammatory drug (NSAID).

The group of non-CRF patients consisted of 51 patients with obscure bleeding. Table 2 shows the demographic and clinical characteristics of CRF and non-CRF patients. The two groups were found comparable regarding indications for WCE (overt, occult bleeding), NSAID or aspirin use, comorbid diseases, hemoglobin level and need for previous transfusions.

CRF patients completed the procedure uneventfully. One case of capsule retention was observed in a non-CRF patient with an adenocarcinoma of the mid ileum. In 3 (17.6%) CRF and 10 (19.6%) non-CRF patients, the capsule did not reach the colon, and, therefore, the entire SB was not imaged. Causes of failure of the capsule to reach the colon within the recording time in CRF patients were: slow gastric passage (1 case), presence of food

Table 2 Demographic and clinical characteristics of CRF and non-CRF patients

	CRF patients	Non-CRF patients	P
No. of patients	17	51	
Male/female	12/5	36/15	NS
Age (mean \pm SE), yr	57.1 \pm 2.5	57.2 \pm 2.1	NS
Indication of WCE (overt/occult bleeding)	11/6	33/18	NS
NSAIDs or aspirin use, n (%)	3/17 (17.6%)	14/51 (27.5%)	NS
Comorbid diseases, n (%)	10/17 (58.8%)	23/51 (45.1%)	NS
Hb (mean \pm SE), g/L	84.3 \pm 2.0	87.7 \pm 1.3	NS
Need for previous transfusions, n (%)	6/17 (35.3%)	28/51 (54.9%)	NS

NS: Non-significant.

Table 3 Small bowel findings revealed by wireless capsule endoscopy

SB findings	CRF patients n = 17 (%)	Non-CRF patients n = 51 (%)
Angiodysplasia	8 (47.0)	9 (17.6)
Single ulcer	2 (11.8)	3 (5.9)
Ulceration with cobblestoning and stricture	1 (5.9)	3 (5.9)
Non-specific ulcers, erosions, submucosal bleeding, erythema and edema	1 (5.9)	-
Fresh blood without an obvious explanation	-	2 (3.9)
Tumor	-	2 (3.9)
Multiple erosions	-	2 (3.9)
No findings	5 (29.4)	30 (58.8)

impairing the capsule progression (1 case), and no clear reason (1 case). Gastric emptying time in CRF patients ranged from 5 to 288 min (median: 20) and SB transit time from 99 to 393 min (median: 275).

WCE findings of SB in both CRF and non-CRF patients are listed in Table 3. In CRF patients, the most frequent type of SB lesion identified was angiodysplasia (8/17, 47%; two actively bleeding) (Figure 1). Patchy mucosal redness and a big jejunal ulcer (Figure 2) were revealed in 2 patients, 1 of which had a recent history of NSAIDs use. Ulceration, cobblestoning, stricture and a pattern of discontinuous involvement of the mid ileum, suggestive of Crohn's disease, were found in 1 patient. Finally, in 1 patient with erythema, edema, submucosal bleeding, erosions and non-specific ulcers of the distal ileum, caecum and ascending colon (Figure 3), tissue diagnosis of CMV enterocolitis was subsequently made by means of ileocolonoscopy and biopsies. Preceded colonoscopy in another institution, ten days earlier, had missed the lesions. Consequently, the diagnostic yield of WCE in CRF patients with obscure bleeding was significantly higher (70.6%, 12/17) compared with the non-CRF patients (41.2%, 21/51) ($\chi^2 = 4.42$, $P < 0.05$).

Angiodysplasia was the most frequent finding in the SB of CRF patients. A single lesion was found in 5 patients, 2 lesions in 2 and 3 in 1. Angiodysplasias were located

**Figure 1** Single ileal angiodysplasia revealed by WCE.**Figure 2** Patchy mucosal redness and a big jejunal ulcer detected by WCE.**Figure 3** Wireless capsule endoscopy showing erythema, edema, submucosal bleeding and ulcer of the distal ileum in a renal transplant recipient.

in jejunum (5 patients), ileum (2 patients) and both (1 patient).

We assessed presence of CRF, age, sex, comorbid diseases, hemoglobin level at the time of the procedure and need for previous transfusions as potentially relevant independent variables for angiodysplasia in both CRF and non-CRF patients. Univariate logistic regression revealed only CRF as a significant predictive factor for angiodysplasia (OR = 4.1, 95% CI = 1.3-13.7, $P < 0.05$). Moreover, we evaluated sex, age, duration of CRF and comorbid diseases as potentially relevant independent variables for SB angiodysplasias in CRF patients. SB angiodysplasias seem to be associated only with the duration of CRF (OR = 1.03, 95% CI = 0.99-1.06, $P < 0.1$).

In view of the WCE findings, 4/8 patients with angiodysplastic lesions within the reach of push enteroscopy were referred for endoscopic treatment with argon plasma coagulation and 1 patient with 3 angiodysplasias received estrogen therapy. Pharmacotherapy was provided in the patient with Crohn's disease as well as in the patient with CMV enterocolitis, and discontinuation of NSAIDs in the patient with the big jejunal ulcer was undertaken. Iron supplementation was decided to be the only measure in the remaining 3 cases with angiodysplasias and in the patient with the jejunal ulcer.

DISCUSSION

Gastrointestinal bleeding is a common complication of advanced CRF^[1,2]. Although there have been many studies concerning implication of upper gastrointestinal tract and colon, data concerning SB are limited. WCE is a new method for the investigation of SB pathology, but already has an established role in cases of obscure gastrointestinal

bleeding^[8]. We conducted this study in order to investigate SB pathology in CRF patients with obscure gastrointestinal bleeding and assess the diagnostic and therapeutic yield of the method in this group of patients. To our knowledge, there is only one case report on this issue^[13].

According to the preliminary results of our ongoing study, angiodysplasia was recognized as a sole causative lesion of obscure bleeding in a markedly higher percentage, 47% in CRF patients *vs* 17.6% in non-CRF patients. A high prevalence (66.7%) of SB angiodysplasia among 6 CRF patients has also been reported in a recent study on the impact of WCE in obscure gastrointestinal bleeding^[14]. In our study, logistic regression analysis showed that CRF was a significant predictive factor for SB angiodysplasia (OR = 4.1, 95% CI = 1.3-13.7, $P < 0.05$). Furthermore, our data suggested that the prevalence of angiodysplasia seemed to be inversely related with the duration of CRF, although this finding was statistically insignificant (OR = 1.03, 95% CI = 0.99-1.06, $P < 0.1$). Previous reports on the prevalence of angiodysplasia in CRF patients, as well as its association with patient's age and duration of the disease are conflicting^[15-18]. However, all those studies used data obtained by conventional upper gastrointestinal endoscopy.

The diagnostic yield of WCE in CRF patients with obscure bleeding was significantly higher (70.6%) than that in non-CRF patients ($\chi^2 = 4.42$, $P < 0.05$), which is in agreement with previous data^[19-21]. Given that WCE has already become the method of choice in the investigation of patients with obscure bleeding^[8], its value in the subgroup of CRF patients is even more crucial.

WCE findings led to plan a specific intervention in 8/12 patients with positive findings. Therapeutic measures included push enteroscopy with coagulation of angiodysplasias in 4 patients, pharmacotherapy in 3 and discontinuation of medication in another 1.

In conclusion, according to the preliminary results of our ongoing study, SB angiodysplasia has an increased prevalence among CRF patients with obscure bleeding. WCE is useful in diagnosis of gastrointestinal pathologies and in planning appropriate therapeutic intervention and, therefore, should be included in the work-up of this group of patients.

Biagini MR, Tozzi A, Grippo A, Galli A, Milani S, Amantini A. Muscle fatigue in women with primary biliary cirrhosis: Spectral analysis of surface electromyography. *World J Gastroenterol* 2006; 12(32): 5186-5190

Abstract

AIM: To evaluate the myoelectric manifestations of peripheral fatigability in patients with primary biliary cirrhosis in comparison to healthy subjects.

METHODS: Sixteen women with primary biliary cirrhosis without comorbidity and 13 healthy women matched for age and body mass index (BMI) completed the self-reported questionnaire fatigue impact scale. All subjects underwent surface electromyography assessment of peripheral fatigability. Anterior tibial muscle isometric voluntary contraction was executed for 20 s at 80% of maximal voluntary isometric contraction. During the exercise electromyographic signal series were recorded and root mean square (expression of central drive) as well as mean and median of electromyographic signal frequency spectrum (estimates of muscle fatigability) were computed. Each subject executed the trial two times. EMG parameters were normalized, then linear regression was applied and slopes were calculated.

RESULTS: Seven patients were fatigued (median fatigue impact scale score: 38, range: 26-66) and 9 were not fatigued (median fatigue impact scale score: 7, range: 0-17). The maximal voluntary isometric contraction was similar in patients (82, 54-115 N) and controls (87, 74-101 N), and in patients with high (81, 54-115 N) and low fatigue impact scale scores (86, 65-106 N). Root mean square as well as mean and median of frequency spectrum slopes were compared with the Mann-Whitney U test, and no significant difference was found between fatigued and non-fatigued patients and controls.

CONCLUSION: No instrumental evidence of peripheral fatigability can be found in women with primary biliary cirrhosis but no comorbidity, suggesting that fatigue in

INTRODUCTION

Fatigue affects 60%-80% of patients with primary biliary cirrhosis (PBC), and is considered to be specifically associated with PBC^[1-3]. However, current understanding of fatigue pathophysiology in PBC is limited and comorbidity may play a significant role in fatigue pathophysiology^[4].

The comprehension of this symptom has been hampered by the complexity of its nature and relationships with somatic illnesses, psychological disturbances, and stress reactions. Moreover, fatigue is subjective and difficult to measure^[5]. The most used instruments for measuring fatigue in PBC are self-reported questionnaires such as the fatigue impact scale (FIS)^[3,6-10].

Several studies support the hypothesis that fatigue has a central origin^[10-13]. In contrast, Goldblatt and colleagues^[7] assessed muscle fatigability in PBC patients with a grip strength protocol, and found that patients with high FIS scores are characterized by an accelerated decrease in muscle function compared with both healthy controls and non-fatigued patients.

However grip strength cannot distinguish if muscle fatigability is due to a central or a peripheral dysfunction, and it is not able to detect volitional components. Moreover, Stanca *et al*^[14] have not found any difference in grip strength between patients with high FIS scores and controls. No study has completely excluded a peripheral component of fatigue in PBC patients.

A validated surface electromyographic technique which provides objective measures of peripheral fatigability

has been developed^[15-17]. This method is able to monitor central drive and has been applied in both physiological and pathological conditions, but never in chronic liver diseases^[18-20].

The aim of this study was to investigate if myoelectric manifestations of peripheral fatigability during voluntary isometric contractions in women with PBC, but no comorbidity, are significantly different from those in healthy subjects matched for their age, sex and body mass index (BMI).

MATERIALS AND METHODS

Patients

Fifty-seven patients with PBC were screened for several common diseases (renal failure, anaemia, electrolyte imbalance, thyroid-associated disease, rheumatic fibromyalgia, polyneuropathy and diabetes) for assumption of drugs that could cause fatigue (b-blockers, *etc.*).

A subgroup of 16 women without nonhepatic causes of fatigue underwent EMG assessment of peripheral fatigability. The other patients did not participate in the study because of nonhepatic causes of fatigue or because they denied their consent. All patients were stable with no history of bleeding, ascites or encephalopathy. Laboratory investigations included blood cell count, liver function tests, detection of creatinine, thyroid hormones, HbA1c, iron, serum electrolytes, and anti-mitochondrial antibodies. All patients were treated with ursodeoxycholic acid (UDCA) at the time of the study.

Controls

Thirteen healthy women comparable for age and BMI who declared that they did not assume drugs or suffer from any disease served as controls.

Ethics

The study protocol conformed to the ethical guidelines of the 1996 Helsinki Declaration and all subjects gave their informed written consent to participating in the experimental study.

Questionnaires

All subjects completed two self-reported questionnaires in a proper setting: fatigue impact scale and Rand MOS depression screening. FIS is a multidimensional scale composed of 40 items providing a global score (maximum 160), containing the intermixed physical, cognitive (maximum score 40 each) and psycho-social (maximum score 80) domains of fatigue^[21]. FIS has been recently validated in PBC patients^[22].

Rand MOS depression screening is composed of 8 items to screen the depressive disorders (major depression and dysthymia) and has been used in general and chronic disease populations, and in PBC patients^[23]. It does not consider physical depressive symptoms that can be found also in abdominal diseases.

Experimental protocol

EMG analysis of isometric contractions of the dominant anterior tibial muscle was conducted in this study. This

muscle was chosen because of its simple anatomy and because it has been analyzed by other investigators for fatigue studies^[15].

Subjects laying on a bed were asked to put on a specially designed boot. The ankle joint was fixed with Velcro straps. A force transducer (Digitalanzeiger mod. 9180) was displayed to measure the force produced by the dorsal extension of the feet, and a display located at bed side showed the instantaneous force values expressed in Newton.

Before EMG signal acquisition, the subjects were requested to perform a short (5 s) maximal voluntary isometric contraction three times with a 2 min rest between each contraction. The mean maximal voluntary isometric contraction (MVC) of the three recorded maximal force values was used as the reference value.

Fatigue test for anterior tibial muscle isometric contraction was performed for 20 s at 80% of MVC. This target force was reached and held by means of the visual feedback display located at bed side showing the instantaneous force values. Standardised verbal encouragement was given throughout this force-failure point. Fatigue test was performed two times with 5 min rest between the two sessions.

The following clinical force parameters were considered: MVC and fatigue threshold (FT) which is time necessary to reduce target force more than 10%. The first one could be considered as an estimation of the muscle force, while the second parameter could be considered as the clinical evidence of fatigability.

The skin was cleaned and two pregelled disposable surface electrodes (Bionen Firenze) were placed 20 mm apart on the longitudinal midline of the dominant anterior tibial muscle between the motor point and the tendon. A ground electrode was attached to the knee. EMG signals were recorded during each session of the fatigue test.

Neurophysiologists were blinded to FIS scores of the subjects.

Analysis of data

Twenty series of 500 ms windows were taken from the 20 s data of the EMG signal of the fatigue test. For each window, root mean square (RMS) amplitude of the EMG signal and spectral analysis (512 points, Hanning window processing, fast Fourier transform) were applied. The mean MNF and median MDF values of EMG signal frequency spectrum were computed. EMG parameters were normalized to the values generated at the beginning of each session. Then, linear regression was applied to the time-series of RMS, MNF and MDF to estimate their rate of change (slope of their respective linear regression).

MNF and MDF slopes are an estimate of muscle fatigability^[15]. MNF and MDF tended to decrease during the trial in normal subjects, thus the slope values of their respective linear regression were negative. Subjects with a higher fatigability have greater absolute values of MNF and MDF slopes. RMS is an expression of the central drive and its value tended to increase during the trial, thus the slope value of its linear regression was positive. The analysis of peripheral fatigability was possible only when RMS slope was positive. The finding of a low central drive

Figure 1 Normalized values of EMG variables during voluntary isometric contractions at 80% MVC from a patient with low central drive. In this case the trial was not included in the analysis of peripheral fatigue.

could be used as an index of the central pathology or it could be due to a volitional component.

Statistical analysis

The Mann-Whitney *U* test (non-parametric test for independent samples) was used to identify whether significant differences in MVC existed between subject groups. Statistical comparison was made between controls and patients, between controls and subgroups of fatigued and non-fatigued patients.

EMG parameters were analyzed during each recording session by repeated measurements (ANOVA). The univariate solution was obtained after correction for the Greenhouse-Geisser factor when appropriate, to protect against type I errors associated with nonsphericity of data. In each case, the approximate *F* value associated with the univariate test was reported. Variables showing significant effects or interactions ($P < 0.05$) were subjected to *post hoc* testing (Scheffé) using an alpha level of less than 0.05. Sample regression of EMG parameters was used to evaluate the inter-observation variation between the first and second session.

All statistical analyses were performed using StatView for Windows.

RESULTS

Clinical features of the 16 selected patients (median age: 54 years, range: 37-73 years; median BMI: 23 kg/m², range: 17.9-28.5 kg/m²) and the controls (median age: 51 years, range: 45-64 years; median BMI: 23.2 kg/m², range: 18.2-28.4 kg/m²) were comparable. Our PBC population was composed of 2 patients in stage I, 6 in stage II, 7 in stage III and 1 in stage IV. Liver biopsies were taken no more than 5 years of post-muscle testing, during which time clinical and laboratory features were not substantially modified.

We divided the patients into two groups according to their FIS scores: seven fatigued (median total FIS: 38, range: 26-66) and nine non-fatigued (low or very low total FIS; median total FIS: 7, range: 0-17). Depression assessed by Rand MOS Depressions Screening was present in two patients.

The MVC force was not statistically different between patients (median: 82 N; range: 54-115 N) and controls (median: 87 N; range: 74-101 N). No difference was found also between patients with high (median: 81 N; range:

Figure 2 Mean normalized values of EMG variables during voluntary isometric contractions at 80% MVC from patients and controls. The time course of MNF, MDF, RMS and force were combined to produce a "fatigue plot". Plots were obtained by normalizing each variable with respect to the initial value of its own regression line.

54-115 N) and low FIS scores (median: 86 N; range: 65-106 N). Fatigue threshold was reached only in two patients.

RMS did not increase during the trial in two patients (Figure 1), so EMG analysis of peripheral fatigability was performed on the remaining 14 patients. These two patients reached the fatigue threshold. Fatigue testing was performed twice in each patient, consequently 28 slope values of each parameter for patients and 26 for controls were obtained.

The mean normalized values of all variables (MNF, MDF, RMS) during voluntary isometric contractions at 80% MVC from patients and controls are shown in Figure 2. RMS ($P = 0.84$), MNF ($P = 0.66$) and MDF ($P = 0.4$) slopes were not significantly different between fatigued

and non-fatigued patients and controls, as well as between the two groups of patients. Inter-observation variation between the first and second sessions was as follows: $r = 0.88$, $P < 0.01$ for MDF; $r = 0.93$, $P < 0.01$ for MNF; $r = 0.80$, $P < 0.05$ for RMS.

DISCUSSION

Fatigue is an overwhelming sense of tiredness, lack of energy or feeling of exhaustion. It is frequently present even at rest. Fatigue is a multidimensional symptom caused by the interaction of physical, psychosocial and cognitive factors. It cannot be confused with weakness or fatigability. The last one in particular is a generalised sense of exhaustion, not present at rest, affecting the patient after a few minutes of physical activity and disappears after a short rest^[24].

Fatigue muscle arises only when muscle fibres are sufficiently activated and consequently develop an effective contraction. Stimulation can be obtained artificially with electrodes or through the physiologic voluntary nervous pathways. The first method gives a more constant elicitation, however it is not physiologic and it is quite an irritation for patients. The second one employs the will of the subjects in keeping the contraction of the analyzed muscle. In our study, isometric contraction of the dominant anterior tibial muscle was voluntary.

Fatigue can be evaluated using a particular EMG analysis. In fact, when muscle fibres contract, they generate electric activities which are recordable with EMG electrodes. EMG signals have different amplitudes and frequencies. The sum of all signals generated by all muscle fibres during the contraction provides a frequency spectrum. As the contraction carries on and the fatigue arises, the frequency spectrum changes. In particular, the mean and median frequency spectrum values (MNF and MDF) decrease proportionally with the duration of contraction and the fatigue of muscle.

As fatigue increases, the subjects effort in keeping a target force increases as well. This effort corresponds to an increase of the stimulation of muscle fibres, in other words we have a higher central drive. The increment of central drive determines the increase of amplitude of the frequency spectrum. Thus EMG analysis of the frequency spectrum can evaluate also the central drive of the subjects during the isometric contraction. Root mean square is an estimate of the amplitude of frequency spectrum, and its value tends to increase during exercise. In our study, as in others, this parameter was used as an estimate of central drive^[15].

When a subject develops fatigue and is not able to keep a target force, it can be due to an inadequate force generation by muscle fibres or by a lack of central drive (peripheral and central fatigue)^[25]. If muscle fibres are not sufficiently stimulated because of a lack of central drive, they do not contract enough to develop fatigue, thus in this condition peripheral fatigue cannot be evaluated.

Central drive is not sufficient for two main reasons: the subject is not motivated and does not make enough effort to execute an adequate muscle contraction and the subject is affected by a pathologic neurological central condition that does not allow activation of the muscle. Hence

peripheral fatigue can be analyzed only in the presence of an adequate central drive, and central drive can be low for a lack of motivation or for a neurological pathology.

To the best of our knowledge, this is the first study in patients affected by PBC in which it has been used as an EMG technique able to quantify fatigability and analyse the presence of peripheral dysfunction.

In our population MVC values were similar in patients and controls. These findings agree with those of Goldblatt *et al*^[7] and we can suppose that PBC patients are not weaker than the general population. In addition, fatigue testing showed that fatigability in women affected by PBC without comorbidity was not significantly different from that in healthy controls matched for age, sex and BMI. Moreover, we did not find any significant difference in peripheral fatigability between fatigued and non-fatigued patients as assessed by FIS.

Two patients had a defective central drive as shown by a flat RMS slope and both of them had high FIS scores and were not able to maintain the 80% MVC target (Figure 1). We do not know if this lack of central activation was due to a volitional component or to a central dysfunction. In fact, our EMG technique was not able to analyze central dysfunction. These two patients had a normal MVC and standard EMG did not show any pathological neuromuscular abnormality. Interestingly, both women were positive for Rand MOS Depression Screening. So, according to the previous studies showing a positive correlation between depression and fatigue, we may suppose a lack of motivation in these two patients^[2,3,6]. If they would have been analysed only with force recording, as done in previous studies, they would be classified as subjects with high muscle fatigability^[7].

In conclusion, no evidence of peripheral fatigability in PBC patients without comorbidity is demonstrable. If these data will be confirmed, fatigue pathogenesis in PBC patients may be related to a central mechanism. This central alteration may be due to a common genesis with the liver disease, or in alternative to one or more causes not related to the hepatic damage (specific or not specific symptom of PBC). Some data support the last hypothesis, in fact two recent reports have failed to demonstrate a significant difference in FIS scores between patients and controls and no correlation has never been found between fatigue and parameters of disease severity and activity^[2,4,6,9,14]. Future research should be addressed on the investigation of central fatigue and the role of depression, which is the only parameter significantly associated with fatigue in several studies^[2,3,6].

Abstract

AIM: To estimate the serum α_1 -antichymotrypsin (ACT), α_1 -acid glycoprotein (AGP) and transferrin (Tf) concentrations and to evaluate the microheterogeneity of these acute phase proteins in patients with ulcerative colitis.

METHODS: Twenty-seven patients with ulcerative colitis (UC) and 17 healthy control subjects were studied. The patients were categorised as severe ($n = 9$), moderate ($n = 10$) and mild groups ($n = 8$) using Truelove and Witts' classification of ulcerative colitis. Microheterogeneity of ACT, AGP and Tf was analysed by crossed immunoaffinity electrophoresis (CIAE) with concanavalin A. In all serum samples standard electrophoresis of serum proteins was performed, iron (Fe) concentration, total iron binding capacity (TIBC) and C-reactive protein (CRP) were also measured.

RESULTS: Our patients suffering from ulcerative colitis had significantly higher serum ACT and AGP concentrations and lower serum transferrin concentration in comparison to healthy subjects. Changes in concentrations of acute phase proteins were dependent on the activity of the inflammatory process. The glycosylation patterns of transferrin were related to the inflammation status. We also observed the correlation between ACT and AGP concentrations, patterns of transferrin glycosylation and changes in standard protein electrophoresis or blood cell count.

CONCLUSION: The glycosylation patterns of transferrin obtained from patients suffering from ulcerative colitis are highly branched and sialylated compared with those obtained from healthy subjects. In contrast, the glycosylation patterns of transferrin do not differ according to the activity index of ulcerative colitis. The microhetero-

INTRODUCTION

In ulcerative colitis, a chronic inflammatory disease of unknown etiology, proinflammatory cytokines, such as tumor necrosis factor (TNF), interleukin-1 (IL-1), IL-6 and IL-2, play a major pathophysiological role^[1-5]. Acute phase response is a systemic answer to mechanical injuries, infections as well as an unspecific inflammation. Acute phase proteins (APP) play an important role in this non-specific immune reaction. These proteins are produced by the liver in answer to cytokine mediation. The concentrations of many APP have been studied in ulcerative colitis patients^[6-8]. Measurement of APP serum concentrations offers a valuable means of assessing the intensity of inflammatory bowel disease. Unsurprisingly, various studies have shown the correlation between these inflammatory mediators and acute phase proteins, such as C-reactive protein (CRP), α_1 -acid glycoprotein (AGP), α_1 -antichymotrypsin (ACT) and serum amyloid A (SAA)^[9-11]. A acute phase proteins and clinical signs are also of a high value for the treatment and remission of ulcerative colitis. However, the etiological and clinical importance of these proteins is still not completely revealed.

Except for CRP, albumin and SAA, all acute phase proteins are glycoproteins. Glycosylation is the primary cause of microheterogeneity in proteins. It is an enzyme-directed and site-specific process. Protein sugar prints are conserved, not random and determined independently from the synthetic rate of protein. There is O-linked glycosylation to the hydroxy oxygen of serine and threonine side chains and N-linked glycosylation to the amide nitrogen of asparagine side chains. The N-glycan chains of α_1 -AGP, α_1 -ACT and Tf differ in their branching, showing

Table 1 Clinical characteristics of patients with UC (mean \pm SD)

Trulove and Witts' classification	UC (n = 27)	Severe (n = 9)	Moderate (n = 10)	Mild (n = 8)	P
Female (n)	16	4	6	6	
Male (n)	11	5	4	2	
Age (yr)	41.80 \pm 18.00	40.20 \pm 20.20	38.00 \pm 16.00	48.40 \pm 18.30	NS
Hemoglobin (g/dL)	12.01 \pm 2.21	11.17 \pm 1.92	11.88 \pm 2.14	13.11 \pm 2.38	< 0.05

Albumin (g/dL)	3.22 \pm 0.82	2.70 \pm 0.78	3.63 \pm 0.59	3.40 \pm 0.89	< 0.05

bi-, tri-, and tetra-antennary structures^[12-14]. These serum N-glycoproteins physiologically occur in few variants, called microheterogeneity. During acute phase response both concentrations and percentage of individual variants are changed.

Glycosylation may play a role in cell-cell adhesion. The highly branched and sialylated form of AGP which is the ligand for cell adhesion molecules such as E-selectin and P-selectin, inhibits migration of neutrophils, monocytes and T-cells, and ameliorates complement activity^[15]. The asialylated carbohydrate-deficient variant of AGP appears mainly in sera of patients after acute inflammation, infection, burn or other severe tissue damage or necrosis^[16]. The immunomodulatory properties of AGP have been shown to depend on its glycosylation. The inhibition of lymphocyte proliferation depends on the branching degree of the glycans of AGP^[17]. The sialylated acute phase proteins protect against immune complex-induced injury^[18]. An increase of sialyl-variants of APP seems to be a mechanism responsible for feedback inhibition of leucocyte migration to inflamed tissues. The heterogeneity of the glycosylation pattern of AGP that has been found in patients with ulcerative colitis reflects changes in response to inflammation^[19].

The changes in patterns of glycosylation of transferrin have been observed in iron deficiency anaemia, rheumatoid arthritis, liver cirrhosis or in physiological status such as pregnancy^[20]. The microheterogeneity pattern of Tf shifts under inflammatory conditions towards highly branched glycans. Differences in glycosylation of Tf seem to alter the iron metabolism.

The aim of this study was to estimate the changes in microheterogeneity in glycosylation patterns of α_1 -AGP, α_1 -ACT and Tf in sera of patients suffering from ulcerative colitis.

MATERIALS AND METHODS

Twenty-seven patients suffering from biopsy-proven ulcerative colitis and 17 healthy control subjects were studied.

The sera were separated by centrifugation after clotting and stored at -70°C. Rocket immunoelectrophoresis was used to determine the total serum concentrations of AGP, ACT, Tf, and CRP.

Microheterogeneity of ACT, AGP and Tf was analysed by crossed immunoaffinity electrophoresis (CIAE) with lectin-concanavalin A. The lectin-concanavalin A was

included in the first-dimension gel as the diantennary-specific affino-component. Separation of different glycoforms of proteins in sera was done *via* electrophoresis of these fluids with a concanavalin A-containing (Con A) polyacrylamide slab gel. Proteins lacking glycans of the diantennary type are not retarded by Con A, whereas proteins containing one or more diantennary glycans bind to Con A, and are electrophoretically retarded in the gel. Detection of the separated glycoforms was achieved through electrophoresis in the second dimension, using the polyclonal protein-specific anti-IgG antibody. The resulting precipitation lines were stained, and the relative occurrences of lectin-retarded and lectin-nonretarded glycoforms were calculated from the areas under the curves.

AGP, ACT and Tf in sera were separated into four variants: W 0-3 for AGP, A 1-4 for ACT, T 1-4 for Tf. Furthermore, the following parameters were measured: standard electrophoresis of serum proteins, iron (Fe) concentration, total iron binding capacity (TIBC), CRP, haemoglobin concentration and blood cell count.

RESULTS

Clinical characteristics and laboratory data

Twenty-seven patients suffering from ulcerative colitis were studied (16 females, 11 males). The patients were categorised according to the clinical activity index for ulcerative colitis using Trulove and Witts' classification of ulcerative colitis (severe $n = 9$, moderate $n = 10$ and mild $n = 8$). There were no significant differences in age, gender or body mass index (BMI) among the three studied groups (mean age 41.8 \pm 18 years, mean BIM 21.858 \pm 3.58 kg/m²). The nutritional status evaluated by physical characteristics was also comparable in the three groups (Table 1).

The haemoglobin concentration and platelet count were significantly lower in the severe group than in the mild group (11.17 \pm 1.92 g/dL and 13.11 \pm 2.38 g/dL, respectively, $P < 0.05$; and 428.78 \pm 116.65 thsd/mm³ and 257 \pm 173.18 thsd/mm³, respectively, $P < 0.05$). The serum iron concentration was significantly lower in the severe group than in the moderate (52.3 \pm 19.2 μ g/dL and 73.3 \pm 26.7 μ g/dL, respectively, $P < 0.05$) and mild groups (52.3 \pm 19.2 μ g/dL and 99 \pm 45.2 μ g/dL, respectively, $P < 0.05$). The white blood cell count was higher in the severe group than in the mild group (10.2 \pm 5.61 thsd/mm³ and 6.48 \pm 1.6 thsd/mm³, respectively, $P < 0.05$).

Figure 1 Microheterogeneity of AGP in sera of UC patients and healthy controls. ^b $P < 0.001$ vs severe UC patients; ^c $P < 0.001$ vs healthy subjects.

Figure 2 Microheterogeneity of ACP in sera of UC patients and healthy controls. ^b $P < 0.001$ vs severe UC patients; ^d $P < 0.001$ vs healthy subjects.

There were also significant differences in total protein concentration and albumin concentration between severe and moderate groups (5.72 ± 1.2 g/dL and 6.52 ± 0.71 g/dL, respectively, $P < 0.05$; 2.7 ± 0.78 g/dL and 3.63 ± 0.59 g/dL, respectively, $P < 0.05$).

Acute phase proteins

The CRP concentration was significantly higher in the severe group than in the moderate and mild groups (49 ± 34 mg/L and 5 ± 8.4 mg/L, respectively, $P < 0.001$; 49 ± 34 mg/L and 15 ± 24.42 mg/L, respectively, $P < 0.05$).

The serum concentration of AGP was significantly higher in all UC patients than in healthy subjects (151.3 ± 65.5 mg/dL and 80 ± 11 mg/dL, respectively, $P < 0.001$). However, there were also significant differences between the three groups. The highest concentration of AGP was found in the severe group (severe to moderate group: 191.1 ± 77.6 mg/dL and 130.3 ± 40.7 mg/dL, respectively, $P = 0.02$; severe to mild group: 191.1 ± 77.6 mg/dL and 132.9 ± 62.4 mg/dL, respectively, $P = 0.053$) (Figure 1).

The serum concentration of ACT was also elevated in all studied patients compared to that of the control group (72.8 ± 29.5 mg/dL and 40 ± 5.2 mg/dL, respectively, $P < 0.001$). Similar to AGP, the ACT concentration was significantly higher in the severe group than in the moderate and mild groups (severe to moderate group: 94.3 ± 36.7 mg/dL and 61.8 ± 18 mg/dL, respectively, $P = 0.01$; severe to mild group: 94.3 ± 36.7 mg/dL and 62.2 ± 19.2 mg/dL, respectively, $P = 0.02$) (Figure 2). There were no statistically significant differences in AGP and ACT serum concentrations between the moderate and mild groups.

As a negative acute phase protein, serum transferrin concentration was decreased in patients with ulcerative colitis compared to that in the healthy volunteers (237.0 ± 82.3 mg/dL and 352.0 ± 59.1 mg/dL, respectively, $P < 0.001$). There was no difference in the serum transferrin concentration between the three groups (Figure 3).

Microheterogeneity of acute phase proteins

The increased concentrations of AGP and ACT were not associated with a large shift in the microheterogeneity patterns.

Interestingly, we noticed a strong positive correlation

Figure 3 Microheterogeneity of Tf in sera of UC patients and healthy controls. ^b $P < 0.001$ vs healthy subjects.

between the serum AGP concentration, particularly W1 glycoform of AGP and platelet count ($r = 0.578$, $P = 0.0016$). The negative correlation was found between the albumin and serum AGP concentrations ($r = -0.448$, $P < 0.05$) as well as ACT concentration ($r = 0.429$, $P < 0.05$). A particular strong negative relationship occurred between W1 serum fraction of AGP ($r = 0.444$, $P = 0.0296$) as well as A2 serum fraction of ACT and albumin concentration ($r = 0.578$, $P = 0.003$). There was also a positive correlation between the platelet count and the serum concentration of A2 glycoform of ACT ($r = 0.39$, $P < 0.05$).

Decreased serum transferrin concentration in ulcerative colitis patients was accompanied with redirection of glycan synthesis to the highly branched and sialylated glycan. We noticed that the percentage of T2 (bi-, tri- and tetra-antennary) and T1 (tetra- and more antennary) fractions of transferrin were significantly higher in the investigated groups than in healthy subjects, while the percentage of T3 (biantennary) and T4 (asialylated, carbohydrate-deficient) fractions were lower.

We noticed that the correlation between T2 variant of transferrin and platelet count, as well as $\alpha 2$ protein electrophoretic fraction was positive ($r = 0.432$, $P < 0.05$ and $r = 0.407$, $P < 0.05$). The negative correlation was found between this particular T2 variant and albumin

concentration ($r = 0.407$, $P < 0.05$).

The positive correlation between the serum concentration of T4 glycoform of transferrin and haemoglobin concentration was observed ($r = 0.405$, $P < 0.05$). We also found a negative correlation between T3 glycoform and AGP concentrations, as well as the α_1 electrophoretic fraction of proteins ($r = 0.48$, $P < 0.05$ and $r = 0.475$, $P < 0.05$).

DISCUSSION

Measurement of acute phase proteins may bring new insights into the mechanisms of inflammatory reactions occurring in ulcerative colitis. In our study, both during remission and exacerbation of ulcerative colitis the glycosylation profiles of AGP and ACT were altered. AGP variant W3 was not present in sera of both healthy individuals and ulcerative colitis patients during remission. However, it appeared in sera of the same patients during exacerbation. This variant is always present in the sera of patients after inflammation, infection, burn or other severe tissue damage. Its presence in the sera of our studied patients was probably caused by the active necrotizing and inflammatory processes in the gut. The high concentration of ACT demonstrated in our patients, is also characteristic for disorders where tissue necrosis occurs (e.g. in burns).

Though the clinical image can confirm ulcerative colitis (UC) is a chronic inflammatory disease, alternations in APP concentrations and microheterogeneity depict rather a domination of "acute inflammatory image" that is probably caused by IL-6. Even in remission of UC the glycosylation profile of the best described AGP does not return to normal but remains altered, with a relative increase of Con A reactive (thus: biantennary) glycoforms. This constant inflammatory stimulation probably contributes to altered Tf glycosylation and, as a consequence to deteriorated iron metabolism and anaemia. In our study, the concentration of transferrin, a negative acute phase protein, was markedly decreased in the acute phase of ulcerative colitis, suggesting that low concentration and especially changes of the glycosylation profile of Tf may be responsible for the impaired iron metabolism in patients suffering from ulcerative colitis.

In sera of healthy individuals, transferrin separates into four variants: T1 weakly reacting with Con A (with mainly triantennary glycans), T2 (with one biantennary glycan and one triantennary glycan), T3 (with two biantennary glycans) and T4 (with probably defective sugars). The variant T3 covers about 80% of the total protein and is the main fraction able to bind to iron, consisting mainly of apo-transferrin. Our study showed the alterations of Tf glycosylation in sera of patients suffering from ulcerative colitis. It is well known that existing anaemia in UC patients is not only to the blood loss with a stool, but also due to the chronic inflammatory process. It is possible that the different glycoforms of Tf have a different iron affinity that may affect the iron balance in the organism.

A correlation was shown between the concentration of transferrin T2 variant, bearing partially triantennary glycans and platelet count as well as α_2 protein electrophoretic fraction, whereas a negative correlation was shown

between T2 variant and albumin concentration. We are thus able to show that inflammation influences the microheterogeneity of transferrin. The higher intensity of the inflammatory process is combined with deteriorated iron transport ability to transferrin, which may intensify anaemia.

The present study revealed a strong negative correlation between variant T1 of transferrin, α_1 -acid glycoprotein and α_1 -antichymotrypsin concentration. A negative correlation was observed between the patient status and iron concentration. Disturbances in the iron balance (low TIBC and iron concentration) reflected a higher amount of variant T1 of transferrin in the sera of UC patients.

In conclusion, glycosylation patterns of transferrin in ulcerative colitis patients shift to the highly branched and sialylated glycans compared with those in healthy subjects. However, the glycosylation patterns of transferrin do not differ according to the activity index of ulcerative colitis. The microheterogeneity patterns of AGP and ACT are similar in ulcerative colitis patients and healthy subjects, though the total concentrations of these acute phase proteins are increased due to the disease.

Abstract

AIM: To analyze the relationship between smoking and nonalcoholic fatty liver disease (NAFLD).

METHODS: This is a cross-sectional study of a healthy population, carried out in a check-up unit of a university hospital in Mexico City. We enrolled 933 subjects, 368 current smokers (cases) and 565 persons who had never smoked (controls). Demographic, metabolic and biochemical variables were measured in the two groups. NAFLD was determined by ultrasound and metabolic syndrome according to ATPIII.

RESULTS: A total of 548 men (205 cases and 343 controls) and 337 women (114 cases and 223 controls) were included in the analysis. Statistical differences between cases and controls were observed only in high blood pressure prevalence (6.6% vs 11.3%, $P < 0.05$; cases and controls respectively), high-density lipoproteins (1.00 ± 0.26 vs 1.06 ± 0.28 mmol/L, $P < 0.005$), triglycerides (2.18 ± 1.49 vs 1.84 ± 1.1 mmol/L, $P < 0.001$), and erythrocyte sedimentation rate (11.3 ± 9.3 vs 13.5 ± 11.9 mm/h, $P < 0.001$). No differences were observed in the prevalence of NAFLD (22.27% vs 29.68%, $P = \text{NS}$) and metabolic syndrome (41.69% vs 36.74%, $P = \text{NS}$). Univariate analysis showed that smoking was not a risk factor for NAFLD (OR = 0.89, 95% CI 0.65-1.21).

CONCLUSION: No differences in NAFLD prevalence were observed between current smokers and nonsmokers, and furthermore, no differences were observed in heavy smokers (more than 20 packs/year), indicating that there is no relationship between smoking and NAFLD.

INTRODUCTION

Nonalcoholic fatty liver disease (NAFLD) is an increasingly recognized condition that may progress to end-stage liver disease^[1]. The clinical implications of NAFLD are derived mainly from its common occurrence among the general population (from 2.8% to 25%) and its potential to progress to fibrosis, cirrhosis and liver failure^[2].

Obesity or a high body mass index (BMI) is a major risk factor for development of liver disease, and the prevalence of NAFLD is elevated 4.6-fold among obese people. In obese subjects, metabolic syndrome that links type 2 diabetes mellitus, dyslipidemia and hypertension to a visceral or male pattern of adipose tissue distribution is a more important risk factor for most comorbidities of obesity than obesity *per se*^[3]. Other risk factors associated with NAFLD are waist circumference (> 102 cm for males and > 88 cm for females)^[4], hyperinsulinemia, hypertriglyceridemia and impaired glucose tolerance or type 2 diabetes^[5,6]. In fact, hepatic steatosis (HS) is now considered to be the hepatic manifestation of insulin resistance (IR)^[7].

Smoking is a well-studied risk factor for many malignant neoplasms, cardiovascular diseases, chronic obstructive pulmonary diseases and other important diseases^[8]. However, it was recently shown that smoking is associated with many of the risk factors for NAFLD, particularly obesity^[9], IR, diabetes and dyslipidemia^[10].

Basic and clinical research demonstrates that smoking alters enzymatic and inflammatory pathways in liver physiology^[11,12], and is considered to be a risk factor for liver neoplasm, and affects the prognosis of chronic liver diseases^[13,14].

Currently, there is no information available about the epidemiologic importance of smoking in NAFLD. The aim of this study was thus to investigate the relationship between smoking and NAFLD.

MATERIALS AND METHODS

Study population

We conducted a cross-sectional study in the Check-up

Unit of the Diagnostic Clinic at the Medica Sur Clinic and Foundation (a university hospital with subspecialty care) in Mexico City, Mexico. This hospital provides private care for mainly middle- and high-income individuals from Mexico City and the surrounding metropolitan areas. Our sample population was formed from a series of consecutive asymptomatic subjects who were referred to the Check-up Unit by their companies as an annual requirement. The study was approved by the Human Subjects Committee of The Medica Sur Clinic and Foundation as conforming to the ethical guidelines of the 1975 Declaration of Helsinki, and written informed consent was obtained from all participants before entry. After informed consent was obtained, all patients were asked to complete a questionnaire that included demographic and medical variables. Cases were defined as current tobacco smokers (and were classified according to the number of packets smoked per year), while controls were defined as patients who had never smoked.

Questionnaire

Subjects were asked to complete a questionnaire that asked for information on demographic data, age, gender, alcohol consumption, smoking habits, diabetes mellitus, hypertension, chronic liver disease, hyperlipidemia, and the use of drugs that predispose to NAFLD.

Physical examination

Body weight was measured, in light clothing and without shoes, to the nearest 0.10 kg. Height was measured to the nearest 0.5 cm. BMI was calculated as weight (kg) divided by height (m) squared. Waist circumference (to the nearest 0.1 cm) was measured at the midpoint between the lower border of the rib cage and the iliac crest, and hip circumference was similarly obtained at the widest point between hip and buttock.

Three blood pressure readings were obtained at 1 min intervals, and the second and third systolic and diastolic pressure readings were averaged and used in the analyses.

Smoking exposure

In a detailed questionnaire, all participants were asked about smoking frequency, duration and type of cigarette. Secondhand smoking was not evaluated. Subjects exposed to chemical or industrial gases were excluded, as were those regularly exposed to other environmental smoke (i.e., open fires using firewood and crop residues as fuel). Based on the number of cigarettes and years of smoking, we calculated pack/year (each pack was considered consisting of 200 cigarettes).

Metabolic syndrome

Participants having three or more of the following criteria were defined as having the metabolic syndrome. The criteria were defined according to the Executive Summary of the Third Report of the National Cholesterol Education Program^[15]. (1) Abdominal obesity: Waist circumference > 102 cm in men and > 88 cm in women; (2) Hypertriglyceridemia: Triglycerides \geq 1500 mg/L (1.69 mmol/L); (3) Low high-density lipoprotein (HDL)

cholesterol: HDL < 400 mg/L (1.04 mmol/L) in men and < 500 mg/L (1.29 mmol/L) in women; (4) High blood pressure: \geq 130/85 mmHg (17.33/11.33 kPa); (5) High fasting glucose: \geq 1100 mg/L (\geq 6.1 mmol/L).

Hepatic steatosis

The diagnosis of NAFLD was first suspected in those subjects with a record of at least six months of abnormal serum aminotransferase levels that were not related to other causes of liver disease, including hepatitis B and C virus infections, autoimmune disorders, alcohol consumption or hemochromatosis, and who had ultrasonographic findings compatible with HS. Real-time ultrasonographic studies were performed while the subjects were fasting. A 3.5 MHz transducer (Elegra; Siemens Medical Systems, Mountain Grove, CA, USA) was used to obtain the following images: sagittal view of the right lobe of the liver and right kidney; transverse view of the left lateral segment of the liver and spleen; transverse view of the liver and pancreas, and any focal areas of altered echotexture. The protocol used to evaluate the pattern of HS by ultrasound was graded according to the method of Saadeh *et al.*^[16]. In the second evaluation, all studies for each subject were viewed side-by-side in a masked fashion ($\kappa = 0.92$).

Analytical procedures

Plasma glucose of subjects in the fasting state was measured in duplicate using an automated analyzer. The coefficient of variation for a single determination was 1.5%. Cholesterol, HDL-cholesterol and triglyceride concentrations were measured by enzymatic colorimetric methods, using CHOL, HDL-C plus (second generation) and triglyceride assays (Roche Diagnostics Co., Indianapolis, IN, USA), respectively. Low-density lipoprotein (LDL) cholesterol concentrations were calculated using the Friedewald formula^[17].

Statistical analyses

Means and standard deviations were used to describe the distributions of continuous variables in comparisons between smokers and controls. The nonparametric Mann-Whitney *U* test was applied because of the nonnormal distribution of some of these variables. By means of cross-tabulations, the risks associated with the probability of having HS were estimated. Odds ratios (ORs) were calculated with the independent variables coded in a binary form. Statistical significance was determined by Fisher's exact test (two-tailed) and 95% confidence intervals. To derive adjusted OR (by confounders) associated with the probability of HS, multivariate unconditional logistic regression analyses were conducted. Multicollinearity in the adjusted models was tested by deriving the covariance matrix. All statistical analyses were conducted using the statistics program SPSS/PC version 12.0 (Chicago, IL, USA).

RESULTS

We enrolled 885 consecutive subjects: 319 current smokers

Table 1 Comparative characteristics between smokers and nonsmokers

Variable	Smokers (<i>n</i> = 319) (mean ± SD)	Non-smokers (<i>n</i> = 566) (mean ± SD)	<i>P</i>
Age (yr)	46.9 ± 11.19	46.8 ± 12.05	NS
Weight (kg)	75.5 ± 15.99	73.84 ± 14.14	NS
Gender <i>n</i> (%)			
Male	205 (64.26)	343 (60.60)	NS
Female	114 (35.74)	223 (38.40)	
Height (m)	1.68 ± 0.09	1.66 ± 0.09	NS
BMI (kg/m ²)	26.8 ± 4.49	26.6 ± 4.02	NS
Overweight and obesity <i>n</i> (%)			
BMI ≥ 25 kg/m ²	205 (64.26)	369 (65.19)	NS
BMI ≥ 30 kg/m ²	54 (16.93)	105 (18.55)	NS
Waist circumference (cm)	84.3 (11.2)	83.4(11.5)	NS
Glucose (mmol/L)	5.42 ± 1.53	5.42 ± 1.52	NS
Type 2 diabetes mellitus <i>n</i> (%)	12 (3.7)	13 (2.3)	NS
High blood pressure (> 17.33/11.33 kPa) <i>n</i> (%)	21 (6.6)	64 (11.3)	< 0.05
Cholesterol (mmol/L)	5.4 ± 1.14	5.33 ± 0.95	NS
C-LDL (mmol/L)	3.48 ± 0.97	3.46 ± 0.85	NS
C-HDL (mmol/L)	1.0 ± 0.26	1.06 ± 0.28	< 0.005
Triglycerides (mmol/L)	2.18 ± 1.49	1.84 ± 1.10	< 0.001
C-reactive protein (mg/L)	3.5 ± 6.03	3.4 ± 5.10	NS
Erythrocyte sedimentation rate (mm/h)	11.3 ± 9.38	13.5 ± 11.90	< 0.001
Albumin (g/L)	4.0 ± 0.28	4.0 ± 0.31	NS

ALT (UI/L)	31.4 ± 20.33	33.3 ± 26.8	NS
AST (UI/L)	26.9 ± 10.25	28.9 ± 16.28	< 0.05
Metabolic syndrome <i>n</i> (%)	133 (41.69)	208 (36.74)	NS
ALT 2 times upper normal limit value <i>n</i> (%)	4 (1.25)	8 (1.41)	NS
Hepatic steatosis <i>n</i> (%)	87 (27.27)	168 (29.68)	NS

(205 men and 114 women) and 566 controls (343 men and 223 women). The general characteristics between groups are described in Table 1. We observed that both groups were very similar, although there were significantly more hypertensive subjects in the nonsmoker group (11.3% *vs* 6.6%, *P* < 0.05). In the current smokers group, serum levels of triglycerides were higher (2.18 ± 1.49 *vs* 1.84 ± 1.1 mmol/L, *P* < 0.005); While in contrast, they showed lower levels of HDL cholesterol (10.0 ± 206 *vs* 10.6 ± 2.8 mg/L, *P* < 0.001). Other differences between the groups were observed in erythrocyte sedimentation rate and AST values. We did not observe any differences in the prevalence of metabolic syndrome and HS. When only subjects with HS were analyzed according to smoking status, only differences in globulin values were significant (Table 2).

Univariate unconditional logistic regression analysis revealed no increased risk for HS in smoking subjects. Several models were tested, with smokers divided into subgroups depending on their smoking amount: > 10 packs/year but ≤ 20 packs/year, and > 20 packs/year, and then compared with all other subjects and with nonsmoking subjects only (Table 3). Although there appeared to be a dose-dependent effect, this could not be confirmed. Similar analyses were made using ALT values (twice the upper normal limit value) comparing

Table 2 Comparative characteristics in liver function tests between smokers and nonsmokers (including only subjects with hepatic steatosis)

Variable	Smokers (<i>n</i> = 87) (mean ± SD)	Non-smokers (<i>n</i> = 168) (mean ± SD)	<i>P</i>
Albumin (g/L)	4.07 ± 0.23	4.10 ± (0.37)	NS
Total bilirubin (mg/L)	0.94 ± 0.31	0.93 ± 0.37	NS

smoking and smoking intensity, which found no statistical associations (Table 4).

DISCUSSION

The liver is a complex organ that has numerous enzymatic pathways involved in its physiology; Many drugs can alter these delicate processes. In particular, substances derived from smoking could impair antioxidant mechanisms^[11], induce cytochrome P450^[18], other enzymatic pathways^[19,20] and inflammatory cytokines^[12]. Although the clinical importance of smoking in hepatology has been described, specifically in hepatocellular carcinoma^[13], chronic infection due to hepatitis C virus^[13,21] and alcoholic cirrhosis^[22], less is known about NAFLD. In the present study, we found that smoking was not associated with NAFLD or elevated liver enzymes in subjects without

chronic liver disease. Recently, a prospective study by Suzuki *et al.*^[23] demonstrated the importance of smoking in increased levels of ALT (only in subjects who started smoking in the study); This finding supported a putative relationship between NAFLD and smoking, although in our study, the effect of chronic smoking did not appear to be significant. Indeed, such an association is implicated by data other than an epidemiological study. Currently, smoking is known to be associated with several metabolic disturbances that are considered risk factors for NAFLD. In large study cohorts, smoking increases the prevalence of diabetes mellitus, and subjects who smoke have greater IR^[24], which are considered to be the hallmarks of NAFLD^[2,25].

In this study, we did not find associations between smoking and smoking intensity (number of packs/year), and the prevalence of HS and ALT at twice the upper normal limit value. As the data showed both samples were very similar. It suggests that smoking does not affect directly the prevalence of NAFLD, despite our inability to evaluate insulin values and the IR index.

Another important risk factor for NAFLD is obesity, and especially the distribution of adipose tissue. The study of den Tonkelaar *et al.*^[9] clearly showed that smoking could influence the distribution of adipose tissue, with an increased waist/hip ratio that is considered metabolically important^[26], in other nonrelated liver diseases^[27-29] and NAFLD^[30]. In this study, we did not observe statistical differences related to obesity, fasting serum glucose levels or prevalence of metabolic syndrome; We found minimal (but significant) differences between current smokers and nonsmokers in levels of serum triglycerides and HDLs. This indicates that the samples are very similar, and the primary variable of the study (smoking) does not influence the prevalence of NAFLD. We observed that smoking subjects had a lower prevalence of high blood pressure, where this unexpected result did not change the results in the multivariate analysis (data not shown). Similar findings are reported in samples that analyze metabolic syndrome in non-diabetic subjects^[31,32]. This phenomena could be due to a long term exposure to nicotine that alters stress response resulting in a reduction in the number or affinity of receptors mediating effects of nicotine in different central nervous system structures that integrate the neuroendocrine stress response and may also lead to lower responses of other stress hormones (ACTH, prolactin, growth hormone) to a variety of stimuli^[33].

However, limitations of the study should be mentioned, which could explain the lack of association between smoking and NAFLD. First, we did not evaluate IR; the information derived from this variable could partially explain our results and clarify whether smoking impairs insulin sensitivity in our population (particularly considering a potential bias because our sample includes only a selected group of subjects). The other factor that helps to explain this result is that we did not evaluate physical activity, which is another factor related to IR and possibly affected by smoking^[34]. Ultrasound is non-invasive but highly unspecific in the diagnosis of NAFLD, but in large populations it does not confer ethical conflicts.

Finally the low number of subjects with ALT values twice the upper normal limit value, could underpower statistical models.

In conclusion, this is the first study that has analyzed specifically the importance of smoking in NAFLD. Although some evidence suggests a role in this disease, we could not observe differences between current smokers and nonsmokers; Furthermore, no differences are found in heavy smokers (> 20 packs/year), indicating that there is no relationship between smoking and NAFLD.

Abstract

AIM: To find out whether there are differences in attitudes about colorectal cancer (CRC) screening among gastrointestinal (GI) specialists and general practitioners (GPs) and which method is preferred in a national screening program

METHODS: Four hundred and twenty Dutch GI specialists in the Netherlands and 400 GPs in Amsterdam were questioned in 2004. Questions included demographics, affiliation, attitude towards screening both for the general population and themselves, methods of screening, family history and individual risk.

RESULTS: Eighty-four percent of the GI specialists returned the questionnaire in comparison to 32% of the GPs ($P < 0.001$). Among the GI specialists, 92% favoured population screening whereas 51% of GPs supported population screening ($P < 0.001$). Of the GI specialists 95% planned to be screened themselves, while 30% of GPs intended to do so ($P < 0.001$). Regarding the general population, 72% of the GI specialists preferred colonoscopy as the screening method compared to 27% of the GPs ($P < 0.001$). The method preferred for personal screening was colonoscopy in 97% of the GI specialists, while 29% of the GPs favoured colonoscopy ($P < 0.001$).

CONCLUSION: Screening for CRC is strongly supported by Dutch GI specialists and less by GPs. The major health issue is possibly misjudged by GPs. Since GPs play a crucial role in a successful national screening program, CRC awareness should be realized by increasing knowledge about the incidence and mortality, thus increasing awareness of the need for screening among GPs.

INTRODUCTION

Colorectal cancer (CRC) is the second leading cause of cancer-related death in the Western world, with over 4400 deaths per year in The Netherlands and 500 000 deaths per year worldwide^[1]. Due to the aging population and population growth, the expected number of CRC patients will increase in the forthcoming years^[2]. CRC is suitable for screening. Pre-malignant lesions can be identified and removed, and in case of detection in an early stage, its five year survival rate exceeds 90%^[3].

The call for a national screening program in the Netherlands is increasing and implementation of the faecal occult blood test (FOBT) as a method of screening is planned within 2-3 years^[4]. A meta-analysis of results from four randomised controlled trials showed that screening reduces mortality of colorectal cancer patients by 23% of those who have been actually screened^[5]. However, a recent study has shown a moderate sensitivity (12%) in detecting CRC with FOBT and patient compliance of only 40%-60%^[6]. Mortality reduction by means of endoscopic screening is expected to be 15%-20% higher, but evidence from prospective randomized trials is lacking^[7].

The Netherlands rank the lowest public awareness regarding CRC among countries in Europe^[8]. In some countries feasibility and implementation studies of nationwide screening programs, together with capacity inventories, are ongoing, while Dutch reports are still awaited^[9-11].

A high participation level of the general population is essential for a national screening program to succeed. The key to achieving adequate compliance is informing the community through an educational campaign about the nature and extent of the disease, as well as education re-

Table 1 Population and personal screening

	GI specialists (%)	GPs (%)	Fisher exact test
In favour of population screening	92	51	$P < 0.001$
In favour of personal screening	95	30	$P < 0.001$

Table 2 Favoured method of population screening

	GI specialists (%)	GPs (%)	Fisher exact test
FOBT	0	26	$P < 0.001$
Sigmoidoscopy	0	18	$P < 0.001$
Combination FOBT + sigmoidoscopy	12	0	$P < 0.001$
Colonoscopy	72	27	$P < 0.001$
Fecal DNA test/CT-colonoscopy	16	19	NS ($P = 0.49$)
Indifferent/Unknown	0	10	$P < 0.001$

garding the method of screening to be used. Involvement of the general practitioners (GPs) is crucial in increasing the yield of a CRC screening program with FOBT^[12-14].

There is ongoing debate among physicians and politicians on the necessity of CRC screening and which screening modality is to be used. This study was to inquire into the attitudes regarding screening among Dutch gastroenterologists, gastrointestinal (GI) surgeons and GPs.

MATERIALS AND METHODS

During a biannual meeting in 2004 in the Netherlands, addressing all general topics in gastroenterology, all the attending Dutch gastroenterologists and gastrointestinal surgeons were questioned ($n = 420$). The same 17-item questionnaire was sent to all GPs in Amsterdam ($n = 400$) in fall, 2004. In an attempt to achieve a comparable sample size between GI specialists and GPs, only GPs from Amsterdam were asked to return the questionnaire. Questions included demographics, affiliation, attitude towards screening both for the general population and themselves, methods of screening, family history and individual risk.

Statistical analysis

SPSS for Windows version 11.0 was used for the descriptive statistical analysis. The Fisher exact test was used for the comparison of proportions. $P < 0.05$ was considered statistically significant.

RESULTS

Responses were obtained from 354 of the 420 GI specialists (84%) who were questioned. Among the GI specialists 82% were gastroenterologists and 18% gastrointestinal surgeons. Eleven percent of the GI specialists worked in an academic setting and 89% in a community hospital. The mean age of GI specialists was 48

Table 3 Age at initiation of screening

	GI specialists (%)	GPs (%)	Fisher exact test
50 yr	37	29	NS ($P = 0.39$)
55 yr	42	18	$P = 0.005$
60 yr	21	13	NS ($P = 0.29$)
Unknown	0	40	$P < 0.001$

Table 4 Familial predisposition to CRC and personal judgment of increased risk of developing CRC

	GI specialist (%)	GPs (%)	Fisher exact test
Familial predisposition for CRC ¹	4	25	$P < 0.001$
Personal judgment of increased risk for CRC	2	8	$P = 0.006$

¹ Defined as one or more first degree relatives diagnosed with CRC.

years (range 28-71 years). The response rate among the 400 potentially eligible GPs was 32% (126). All GPs worked in Amsterdam. The mean age of the GPs was 49 years (range 32-69 years).

A highly significant difference in appreciation of population and personal screening was found between GI specialists and GPs ($P < 0.001$, Table 1). Moreover, significant differences were found in the preferred screening method. Colonoscopy was considered the primary population screening tool by the majority of GI specialists, while FOBT, sigmoidoscopy and colonoscopy were almost equally supported by GPs (Table 2). Personal screening with colonoscopy was favoured by 97% and 27% of GI specialists and GPs, respectively ($P < 0.001$). Forty-two percent of GI specialists considered 55 years as the proper age to start personal screening, whereas the age of 50 years was chosen by GPs (Table 3). Four percent of GI specialists and 25% of GPs reported a familial predisposition to CRC. Nevertheless, within the latter two groups only 50% and 33% regarded themselves at a higher risk of developing CRC (Table 4). Finally, a subgroup analysis was performed on the GPs with familial predisposition to CRC, regarding their opinion on population screening. In this group 61% preferred population screening, compared to 51% in the total group of GPs ($P = 0.32$).

DISCUSSION

Population screening for CRC is strongly supported by Dutch GI specialists. In their opinion benefits definitely outweigh the drawbacks and their discussion focuses on how to implement a national CRC screening program and which method should be used. Unfortunately, the above-mentioned results suggest that GPs are more reluctant to speak out in favour of a CRC population-based screening program than GI specialists. Only 51% of responding GPs are in favour of population screening. A challenging task is reserved for the GI specialists to convince GPs of the need for screening. It has been shown that by increasing

knowledge about the incidence and mortality of CRC, as well as the possibility for early detection, the attitudes of GPs will change^[15].

There is a remarkable difference in returned questionnaires between GI specialists and GPs. It can be hypothesized that completing a short questionnaire on a meeting is less of a burden than during daily routines, where other priorities may prevail. However, the response rates differ significantly, suggesting that GPs are ignorant of the CRC screening issue or are in a low state of awareness of the problem's magnitude. These findings correspond to the previous reports stating a lack of interest and knowledge in the definition of the high risk population among GPs^[16,17].

Another argument may be that only half of all GPs favour population screening and only 30% intend to be screened themselves. In the present study, no significant difference was observed in preference of population screening (61% *vs* 51%; $P = 0.32$) even between a subgroup of GPs with a familial predisposition to CRC which results in an increased risk of developing CRC and the total group of GPs. In contrast, 92% of all the GI specialists supported such a nation-wide CRC screening program and 95% planned to undergo personal screening. In this context, it can be put forward that knowledge of the natural course of CRC, its pre-malignant precursor lesions and therapeutic options in case of early detection, might explain the large differences in opinion. Since GPs play a crucial role in achieving a successful national screening program, the latter suggestion should be a concern to GI specialists and central government. On the other hand, GPs are subjected to a continuous barrage about the different types of screening (lung, breast, prostate, CRC, cervix) and they might have a wider view on priorities and cost-efficiency in the health sector.

Regarding the screening modalities for both personal and population screening, a clear preference to colonoscopy was observed among GI specialists.

Colonoscopy is the method of screening preferred by GI specialists. In the present study, 97% of the GI specialists preferred this method for their personal screening, and 72% for population screening. The higher preference to alternative methods for population screening presumably reflects concerns regarding the capacity and logistics (Table 2).

Among GPs, population screening with FOBT or colonoscopy was equally supported (respectively 26% and 27%). A rather surprising finding is that none of the GI specialists preferred FOBT as a screening method, since there is evidence in terms of cost-effectiveness and mortality reduction^[18-20]. Nevertheless, the fact that GI specialists agree with and encourage the implementation of FOBT for nationwide screening can be explained by the fact that FOBT is the only screening method accepted by the central government at this moment. Furthermore, there is a convincing mortality reduction using FOBT as a method of screening and in this perspective screening with FOBT is better in any case than no screening^[15,18]. In addition, an ongoing screening program allows future alternatives to be implemented more easily, when they are proven superior to FOBT.

Finally, a large proportion of GI specialists plan to start

personal screening at the age of 50-55 years, even though only 4% are found at a high risk of developing CRC. In 40% of responding GPs in favour of personal screening, the age at which screening should be initiated is unknown (Tables 3 and 4). This emphasises the importance of education about this disease since one out of 20 people will develop CRC during a lifetime, with advancing years of age as the foremost risk factor for CRC development. The highest mortality rate for CRC appears to be around the age of 60 years, the time interval in which a precursor lesion develops into an invasive cancer is 10-15 years^[21].

In conclusion, the findings of our study are relevant to GPs in Amsterdam. However it is unknown whether GPs in other parts of the Netherlands have similar attitudes. Nonetheless, this inquiry clearly indicates the urgent need for GI specialists and GPs to solve the ongoing debate on CRC screening. Education of all parties involved should lead to an increased knowledge about the magnitude of the CRC problem. An unambiguous policy stressing the crucial role of GPs in a CRC screening program, may improve patient compliance, thereby reducing the mortality of CRC. More studies are mandatory to draw firm conclusions.

Abstract

AIM: To find out if a functional promoter polymorphism in the IL-8 gene along with *cagA* status and polymorphisms in *vacA* gene influence the type of diseases in Iranian patients infected by *H pylori*.

METHODS: IL-8 -251 A/T polymorphism was genotyped by oligonucleotide allele specific PCR (ASO-PCR) in a sample of 233 patients with *H pylori* infection undergoing upper gastrointestinal endoscopy. The presence of *cagA* gene and polymorphisms in *vacA* gene was also determined by PCR. Association of these genetic polymorphisms with the development of gastritis, peptic ulcers as well as gastric cancer was tested.

RESULTS: When the patients with different clinical manifestations were compared according to the presence of *cagA* gene or various *vacA* genotypes, only the *vacA* genotypes were significantly different among gastritis, peptic ulcer and gastric cancer patients ($\chi^2 = 17.8$; $P = 0.001$). Furthermore, there was a significant difference in the frequency of IL-8 -251 A/T genotypes between patients with gastric cancer and benign diseases ($\chi^2 =$

INTRODUCTION

Infection with *H pylori* has plausible associations with a variety of clinical outcomes, including chronic gastritis, peptic ulcer and gastric cancer^[1-4]. Variation in the clinical outcome of *H pylori* induced pathology is multifactorial, involving a complex interplay between the host immune responses, pathogen virulence factors, and niche characteristics. Many putative virulence factors have been identified in *H pylori* that contribute to its pathogenesis. The 128-kDa cytotoxin-associated gene encoded antigen A (*cagA*)^[5] and vacuolating cytotoxin antigen gene (*vacA*)^[6] are known as the most important ones. *cagA* gene was identified as a strain-specific *H pylori* gene and has been recognized as a marker for strains that confer increased risk for peptic ulcer disease^[7-8] and gastric cancer^[9]. The *cagA* gene is present downstream of a 40-kb cluster of virulence genes known as the *cag* pathogenicity island (*cag*-PAI). These genes encode a type IV secretion system that forms a syringe-like structure to translocate the immunodominant *cagA* protein into the gastric epithelial cells. *cag*-PAI has also been implicated in the induction of IL-8 in cultured gastric cells^[10]. This property contributes to the proinflammatory power of the strains and thus

to their virulence capability. The difference between *H pylori* strains in virulence capability is also dependent on the expression of *vacA* (87 kDa), which is toxic to epithelial cells *in vitro*^[11-13]. Moreover, mice which were administered *vacA* orally developed gastric ulcers^[14]. Unlike the *cagA*, *vacA* gene is conserved among all *H pylori* strains, although significant polymorphism exists in its gene^[15]. *vacA* alleles possess one of two types of signal regions, s1 or s2, and one of two mid-regions, m1 or m2, occurring in all possible combinations. The *vacA* signal region encodes the signal peptide and the N-terminus of the processed *vacA* toxin: type s1 *vacA* is fully active, but type 2 has a short N-terminus extension that blocks vacuole formation^[16]. *vacA* s2 strains are rarely isolated from patients with peptic ulcers or gastric adenocarcinoma^[15]. The *vacA* mid-region encodes part of the toxin cell binding domain. Vacuolating activity is higher in s1/m1 genotypes than in s1/m2 genotypes, and is absent in s2/m2 genotypes^[16]. Consequently, *vacA* s1/m1 genotypes are more frequently associated with peptic ulceration and gastric carcinoma^[17,18]. The genetic heterogeneity in immune responses among individuals is another important factor which determines the clinical outcome of *H pylori* infection. Support for this consideration is provided by the low frequency of gastric cancer in some developing countries in spite of the paradoxically high prevalence of *H pylori* infection in those countries^[19,20]. Up to now, there are several reports indicating the association of IL-1 β , tumor necrosis factor α (TNF- α), and IL-10 gene polymorphisms with an increased risk of developing gastric atrophy, hypochlorhydria, and non-cardia gastric cancer^[21-23]. Due to the roles which are played by IL-8 in the pathogenesis of *H pylori* infection, the IL-8 gene is one of the most important candidate host genes in determination of the outcome of *H pylori* infection. This cytokine is produced by gastric epithelial cells as an early response to *H pylori* virulence factors, such as *cagA*^[10]. IL-8 is also a major host mediator involved in neutrophil and phagocyte chemotaxis and activation^[24,25], thereby causing mucosal damage by releasing reactive oxygen radicals^[25]. It is therefore tempting to speculate that mucosal IL-8 production due to *H pylori* infection may be an important factor in the immunopathogenesis of peptic ulcer diseases and may also be relevant in gastric carcinogenesis^[26]. Interestingly, previous studies have suggested that the production of IL-8 is genetically determined and neutrophils from individuals who are homozygous for the AA genotype at the -251 position demonstrated a trend toward higher levels of IL-8 production in response to lipopolysaccharides than those without the allele^[27]. More recently, Ohyauchi *et al* reported that IL-8 -251 A/T polymorphism influences the susceptibility of *H pylori* related gastric diseases in the Japanese population^[28]. Furthermore, in an *H pylori* infected Chinese population the risk of gastric cancer was also significantly elevated in patients with the IL-8-251 AA genotype^[29]. Considering the above information, the aim of this study was to look for an association between IL-8 -251 A/T polymorphism, *vacA* genotypes, the presence of *cagA* gene and clinical outcome of *H pylori* infection in Iranian patients.

MATERIALS AND METHODS

Patients and Bacterial strains

In the present study 298 patients were classified at the time of endoscopy into those having gastritis ($n = 199$), gastric ulcer ($n = 12$), duodenal ulcer or duodenitis ($n = 67$) and non-cardia gastric carcinoma ($n = 20$). This classification was also confirmed by histological examinations. These patients have been referred for upper gastrointestinal endoscopy to the Gastroenterology Section of the University Hospitals (Namazi and Shahid Faghihi) of Shiraz University of Medical Sciences between 2002 and 2005. Patients who had received non-steroidal anti-inflammatory drugs were excluded. *H pylori* strains were successfully isolated from the gastric biopsies of 286 patients (150 males, 136 females; median age 45.3 ± 16.6 years). The present study was approved by the local ethics committee.

Bacterial culture and histological examination

Biopsy specimens were taken from the antrum and corpus of the stomach. These specimens were used for the rapid urease test, bacterial culture, and histological assessment. After 5 d of culture on selective agar plates, the organisms were identified as *H pylori* by Gram staining, colony morphology, and positive oxidase, catalase and urease reactions.

Preparation of patients and H pylori genomic DNA

After 3-5 d of culture, *H pylori* colonies were pooled from the plates and washed using phosphate-buffered saline. *H pylori* genomic DNA was prepared after bacterial cell lysis using SDS and proteinase K solution and phenol-chloroform extraction. Patients genomic DNA was extracted from EDTA anticoagulated peripheral blood leucocytes using a salting out method. The DNA samples were maintained at -70°C until use in polymerase chain reaction (PCR).

Analysis of IL-8 and bacterial vacA and cagA genotypes

All primer sets used were selected from the published literature and are shown in Table 1. An allele-specific oligonucleotide polymerase chain reaction (ASO-PCR) was used to detect the polymorphism at position -251 of the IL-8 gene^[30]. As an internal control, the β -globin specific primers were included in the ASO-PCR (Table 1). For IL-8 genotyping, 10 μL of PCR reaction mixture consisting of 250 ng of genomic DNA, 200 $\mu\text{mol/L}$ dNTPs, 2.25 mmol/L MgCl_2 , 1 \times Taq DNA polymerase buffer, 2 units of Taq DNA polymerase (Boehringer Mannheim, Germany), 10 pmol of each test primer and 5 pmol of internal control primers were employed. Then, a touch-down procedure was followed that consisted of 25 s at 95°C , annealing for 45 s at temperatures decreasing from 68°C (four cycles) to 61°C (20 cycles), and an extension step at 72°C for 40 s. The annealing temperature for the remaining 5 cycles was 58°C for 40 s. For *cagA* and *vacA* genes the PCR was performed using a thermal cycler (Master Cycler; Eppendorf, Germany) under the following conditions: an initial denaturation for 5 min at 94°C , 35 cycles of 60 s at 94°C , 60 s at 57°C and 60 s at

Table 1 Primer sequences used for detection of *cagA* gene status and IL-8 or *vacA* gene polymorphisms

Locus	Primers	Size (bp)

72°C, with a final extension step at 72°C for 5 min. The PCR system for *cagA* contained 10 × PCR buffer, 2.5 μ L; MgCl₂, 1.2 mmol/L; dNTP, 200 μ mol/L; *cagA* specific primers, 10 pmol; Taq DNA polymerase, 1.0 U; and the DNA template, 50 ng. To confirm the identification of the bacteria as *H. pylori*, 10 pmol of *glmM* specific primers were included in each PCR reaction for *cagA* gene (*glmM* is a conserved gene formerly known as *ureC*). For detection of *vacA* polymorphisms a multiplex PCR was performed using the specific primers for amplification of s and m genes (Table 1). The PCR system for *vacA* genotyping was similar to *cagA* genotyping, PCR products were examined by 2% agarose gel electrophoresis and photographed using an ultraviolet reflection analyzer.

Statistical analysis

Fisher's exact test and the χ^2 test were used to analyze the data from different disease groups. All tests were performed two tailed with a confidence interval (CI) of 95%. A *P*-value of less than 0.05 was accepted as statistically significant. The Statistical Package for the Social Sciences (SPSS) version 11.5 was used for statistical analysis.

RESULTS

Prevalence of the *cagA* and *vacA* gene in different disease groups

Table 2 shows the distribution of the 286 strains according to their *cagA* and *vacA* types in different patient groups. To detect the *cagA* subtype of *H. pylori*, *cagA* specific PCR was performed on extracted bacterial DNA from patients with gastric diseases. Amplified *cagA* DNA fragments were detected in 219/286 (76.6%) of our *H. pylori*. Sixty seven patients (23.4%) were *cagA*-, although they were *glmM*+ or *vacA*+. When the patients with different clinical manifestations were compared according to the presence of the *cagA* gene (Table 2), insignificant differences in *cagA* status were found among patients with peptic ulcer, gastritis and gastric cancer ($\chi^2 = 1.9$; *P* = 0.38). Also, when the frequency of *cagA*+ and *cagA*- subtypes were compared among patients with gastritis and gastric ulcer

Table 2 IL-8 -251 A/T polymorphism, *cagA* status and *vacA* gene polymorphism in patients with gastric diseases

Locus	Genotype	Patients Gastritis n (%)	Peptic Ulcer n (%)	Gastric Cancer n (%)	<i>P</i> value
IL-8 -251	AA	22 (14.4)	14 (23.0)	9.0 (47.4)	0.013
	AT	74 (48.4)	28 (45.9)	6.0 (31.6)	
	TT	57 (37.3)	19 (31.1)	4.0 (21.1)	
<i>cagA</i>	+	148 (74.4)	54 (80.6)	17 (85.0)	0.39
	-	51 (25.6)	13 (19.4)	3.0 (15.0)	
<i>vacA</i>	s1m1	48 (26.5)	21 (32.3)	12.0 (66.7)	0.001
	s1m2	74 (40.9)	33 (50.8)	3.0 (16.7)	
	s2m2	59 (32.6)	11 (16.9)	3.0 (16.7)	

($\chi^2 = 1$; *P* = 0.3), gastritis and peptic ulcer ($\chi^2 = 0.75$; *P* = 0.38), gastritis and cancer ($\chi^2 = 0.61$; *P* = 0.42) or between peptic ulcer and gastric cancer ($\chi^2 = 0.01$; *P* = 0.75), the difference always remained insignificant. In the case of *vacA* gene, three of the four possible combinations of signal sequence and middle-region types were identified. The s1/m1 type was found in 81/264 (30.7%) of the isolates, the s1/m2 type in 110/264 (41.7%) of the isolates, and the s2/m2 type in 73/264 (27.7%) of the isolates. The distribution of *vacA* genotypes (s1/m1, s1/m2 or s2/m2) were significantly different among peptic ulcer, gastritis and gastric cancer patients ($\chi^2 = 17.8$; *P* = 0.001). Interestingly, the difference in distribution of three different *vacA* genotypes between patients with gastric cancer and gastritis ($\chi^2 = 12.57$; *P* = 0.0018) was more significant than the difference in distribution of *vacA* genotypes between patients with gastric cancer and peptic ulcer ($\chi^2 = 7.97$; *P* = 0.018). In fact, the frequency of s1m1 genotype was notably higher in gastric cancer patients (66.7%) compared to those with gastritis or peptic ulcer (26.5% and 32.3%, respectively). Furthermore, similar to previous reports^[15], there is a strong statistical linkage between the s1 genotype of *vacA* and the presence of the *cag* island ($\chi^2 = 27.95$; *P* = 0.0000001; OR = 4.99, 95% CI = 2.61-9.58). Similarly, the s2 genotype is associated with the lack of the *cag* island. In fact, strains that are *cag*+ are more likely to possess the *vacA* s1 allele than *cag*- strains.

Prevalence of the IL-8 -251 A/T polymorphism in different disease groups

The allelic frequencies of IL-8 -251 A/T polymorphism and genotype distributions are given in table 2. The IL-8 -251 A/T polymorphism showed no evidence of deviation from the Hardy-Weinberg equilibrium, with a non-significant χ^2 value ($\chi^2 = 0.05$, *P* = 0.4). Interestingly, there was a significant difference in the frequency of IL-8 -251 A/T genotypes between patients with gastric cancer and those with benign diseases ($\chi^2 = 10.47$; *P* = 0.005). Moreover, when the patients were categorized to high producer (AA) and intermediate + low producer (AT + TT) genotypes, a more meaningful difference in the frequency of IL-8 -251 A/T genotypes between patients with gastric cancer and benign diseases was noticeable (OR = 4.45, 95% CI = 1.53-12.94; $\chi^2 = 8.58$, *P* = 0.003). In fact, the prevalence of AA genotype in gastric cancer

patients was 47.4% compared to 16.8% in benign diseases. While comparing different patient groups, no significant differences were demonstrated in frequencies of IL-8 -251 A/T genotypes between patients with peptic ulcer and gastritis ($\chi^2 = 2.4$; $P = 0.25$) or gastric cancer ($\chi^2 = 4.22$; $P = 0.12$). However, IL-8 -251 A/T polymorphism showed a significant difference between patients with gastric cancer and gastritis ($\chi^2 = 12.5$; $P = 0.001$).

DISCUSSION

After exposure to *H pylori*, the clinical manifestations are variable and depend on host and pathogen factors. There is no information on the prevalence and role of *H pylori* genotypes and/or the role of IL-8 -251 A/T genotypes in the disease outcome of Iranian patients. Therefore, in the present study, we determined the presence of the *cagA* gene (as a marker of *cag* pathogenicity island) and the genotypes of *vacA* gene in the infecting strains along with the distribution of host IL-8 genotypes in relation to the occurrence of different clinical manifestations in Iranian patients with *H pylori* infection. It has been shown that exposure of gastric epithelial cells to *cag+* *H pylori* strains can activate the proto-oncogenes *c-fos* and *c-jun*, a crucial step in the development of *H pylori*-related neoplasia^[31]. The presence of *cagA* has been statistically associated with duodenal ulceration, gastric mucosal atrophy, and gastric cancer^[7-9], although some studies deny this association^[32-34]. Audibert and her colleagues reported that *cagA* status is not sufficient to predict the IL-8 induction ability of *H pylori* and is not correlated with the presence or absence of ulcer^[35]. In a series of patients from Taiwan, the presence of *cagA* gene in the PAI also showed no relationship to the type of disease and/or the histological features of the patients^[36]. The results of the present study also shows that the prevalence of *cagA* is not significantly different among different disease groups ($P > 0.05$), which is in accordance with the results of other Asian countries. Therefore, the *cag*-PAI may not be the principal virulence factor, as suggested by the absence or sporadic distribution of the *cag*-PAI genes among strains from varied clinical outcomes. However, considering the high prevalence of *cag+* strains in Iranian patients (76.6%), the relationship of *cag* status with disease type is more difficult to establish in our population. Therefore, larger sample sizes are recommended for such studies.

Furthermore, the lack of association may be due to the fact that the development of cancer or ulcer disease is a complex process that also involves factors other than the *cag*-PAI, such as *vacA*. Certain *vacA* genotypes causing a high vacuolating activity are correlated with increased disease severity in humans^[15]. Several studies have also shown that the presence of *vacA* is associated with peptic ulcer diseases^[14,17-18]. The *vacA* gene displays a considerable polymorphism, especially in the signal region (genotypes s1 and s2) and in a mid region (genotypes m1 and m2). Vacuolating activity is higher in s1/m1 genotypes than in s1/m2 genotypes, and is absent in s2/m2 genotypes^[15]. Consequently, *vacA* s1/m1 strains cause more direct epithelial damage and are more frequently associated with

peptic ulceration and gastric carcinoma^[9,17,18]. The results of the present study also show a significant difference in *vacA* genotype distribution between gastric cancer and gastritis ($P = 0.0018$) or peptic ulcer ($P = 0.018$) patients. The marked increase of s1m1 genotype in gastric cancer patients (66.7%) compared to those in patients with gastritis (26.5%) or peptic ulcer (32.3%) confirms the pathogenic role of this virulence determinant in Iranian patients. However, different disease outcomes were encountered in subjects infected with *H pylori* strains sharing the same virulent *vacA* genotype, s1m1. The different outcomes of *H pylori* infection may depend not only on other bacterial factors but also on the different genetic background of the host. Concerning host genetic factors, Thye *et al* performed a genome wide screen analysis to identify the genetic factor(s), which define susceptibility to *H pylori* infection^[37] and suggested the presence of a possible linkage with chromosomes^[4]. Considering the location of the human IL-8 gene on chromosome 4 (4q13-q21), the results of their study may support the hypothesis that the IL-8 gene polymorphism is probably associated with *H pylori* induced gastrointestinal diseases. Interestingly, the inheritance of the IL-8 -251A allele was associated with progression of gastric atrophy in patients with *H pylori* infection and increased the risk of gastric cancer in Japanese and Chinese people^[28,29,38]. Our results also indicate that gastric cancer is significantly associated with the functional polymorphism in the promoter region of the IL-8 gene. Specifically, individuals genetically predisposed to produce more IL-8 are at a higher risk of developing gastric cancer. The finding that there was an increased risk of gastric cancer in high IL-8 producers was in agreement with the concept that IL-8 may influence the risk of developing gastric cancer by altering the quality and vigor of inflammatory responses produced by the host after exposure to *H pylori*. In addition, IL-8 stimulated neutrophils to synthesize active radicals such as nitric oxide^[25]. These radicals by their mutagenic potential^[39] could cause mutations in gastric epithelial cells. In addition, IL-8 by inducing angiogenesis would be one of the important factors in gastric carcinogenesis. In support of this hypothesis, the expression of IL-8 has been associated with increased vascularization and poor prognosis in gastric carcinoma^[40,41]. Thus, inheritance of the high producer allele of IL-8 (carriers of -251 A allele) may induce chronic gastritis, which may then be followed by the development of gastric cancer.

In conclusion, similar to studies performed in China and Japan, the association between *cagA* positivity and virulence of *H pylori* strains was equally frequent among Iranian patients with different disease types. Moreover, the present study provides further evidence that in addition to genetic polymorphism of the *vacA* gene in the pathogen, genetically determined differences in IL-8 production via promoter polymorphisms could contribute to individual susceptibility to gastric cancer development after *H pylori* infection in Iranian patients.

INTRODUCTION

Human hepatitis B virus (HBV), which is the prototype member of the family Hepadnaviridae, is a circular, partially double-stranded DNA virus of approximately 3200 nt^[1]. This highly compact genome contains the four major open reading frames encoding the envelope (preS1, preS2 and surface antigen HBsAg), polymerase (HBPol) and X (HBX) proteins, respectively^[2]. HBV is an etiologic agent of acute and chronic liver disease, including fatal fulminant hepatitis, liver cirrhosis and hepatocellular carcinoma^[3-6]. Over 2 billion people worldwide have been exposed to HBV and 350 million are chronic carriers of HBV^[7-9].

In 1988, HBV was classified into four genotypes by a sequence divergence in the entire genome exceeding 8%, and designated by capital letters of the alphabet from A to D^[10,11]. In 1994, Norder *et al*^[12] found an additional two HBV genotypes by the same criteria, and named them E and F, respectively. Genotype G was reported recently in 2000^[2] and genotype H, which is phylogenetically closely related to genotype F, was proposed in 2002^[11]. HBV genotypes have distinct geographical distribution^[2,7,13,14].

In general, genotype A is pandemic, but most prevalent in North West Europe, North America, Central Africa^[2,13] and India^[7]. Genotypes B and C are prevalent in Asia^[7,8,13,15], especially in populations of Eastern Asia and the far East origin^[3,16]. Genotype D is also more or less pandemic, but is predominant in the Mediterranean area and the Middle East^[2,3,16]. Genotype E is restricted to Africa and genotype F is found in Central and South America^[7,8,13,16]. Genotype G has been recently identified in France and North America^[7,8]. It has been reported that there are remarkable differences in the clinical and virologic characteristics between the patients with different genotypes^[17,18,19]. According to Iranian studies^[20], over 35% of Iranians have been exposed to HBV, approximately 2% are chronic carriers. Compared to the United States where HBV infection is responsible for 25% of chronic hepatitis, HBV accounts for up to 70%-80% of chronic hepatitis cases in Iran, indicating that HBV alone is the leading

Abstract

AIM: To determine the prevalence of hepatitis B virus (HBV) genotypes in Iranian hepatitis B surface antigen (HBsAg) carriers, chronic hepatitis B and cirrhotic patients.

METHODS: A total of 109 HBsAg-positive patients were included in this study. HBV genotypes were determined by using INNO-LiPA methodology which is based on the reverse hybridization principle.

RESULTS: The distribution of patients with different stages of liver disease was as follows: 95 (86.4%) chronic hepatitis, 11 (10%) liver cirrhosis, and 3 (2.7%) inactive carrier. Of the chronic hepatitis and liver cirrhosis patients, 26.4% were HBeAg-positive while 70% were HBeAg-negative. Genotype D was the only detected type found in all patients.

CONCLUSION: Classifying HBV into genotypes has to be cost-effective and clinically relevant. Our study indicates that HBV genotype D prevails in the Mediterranean area, Near and Middle East, and South Asia. Continued efforts for understanding HBV genotype through international co-operation will reveal further virological differences of the genotypes and their clinical relevance.

Key words: Hepatitis B virus; Genotype; Chronic Hepatitis B; Cirrhosis

cause of chronic liver disease in Iran^[21]. Until now, to our knowledge, no data regarding HBV genotype is available, and also the genotypes distribution of HBV and genotype-related differences with the liver disease are still unclear in Iran. In this study, we therefore determined the prevalence of HBV genotypes in Iranian hepatitis B surface antigen (HBsAg) carriers, chronic hepatitis B and cirrhotic patients.

MATERIALS AND METHODS

This cross-sectional study was performed in Tehran Hepatitis Center in 2004. A total of 109 patients with hepatitis B surface antigen (HBsAg) positive for at least 6 mo were enrolled in this study. Of the 109 patients, 95 were classified as chronic hepatitis, defined as HBsAg positive with or without the presence of HBeAg, high level of HBV-DNA ($> 100\,000$ copies/mL) detected by Amplicor HBV monitor, persistent or intermittent elevation in ALT levels and compatible liver biopsy. Three were inactive carriers characterized by persistent HBV infection of liver without significant, ongoing necro-inflammatory disease. Eleven had liver cirrhosis characterized by clinical evidence (splenomegaly, ascitis) and paraclinical results, including low platelet count, prolongation of prothrombin time and esophageal varices on upper gastrointestinal endoscopy. Liver cirrhosis was confirmed by liver biopsy. Patients were excluded if they were co-infected with hepatitis C virus (HCV), hepatitis D virus (HDV) or human immunodeficiency virus (HIV).

The following parameters were recorded for each patient from patient's document in Tehran Hepatitis Center: sex, age, stage of liver disease, alanine aminotransferase (ALT) level, aspartate transaminase (AST) and presence of hepatitis B virus E antigen and anti-hepatitis B virus E antibodies.

HBV genotypes were determined by using INNO-LiPA methodology (LiPA, INNO-LiPA HBV genotyping assay, Innogenetics N.V., Ghent, Belgium). The INNO-LiPA HBV genotyping assay is a line probe assay designated to identify hepatitis B virus genotypes A to G by detection of type-specific sequences in the HBV-pol gene domain B to C. This method is based on the reverse hybridization principle. Biotinylated DNA material generated from the HBsAg open reading frame was hybridized with specific oligonucleotide probes immobilized as parallel lines on membrane-based strips. After hybridization, unhybridized DNA was washed from the strip, alkaline phosphatase-labeled streptavidin was added and bounded to any biotinylated hybrid previously formed. Incubation with BCIP/NBT chromogen resulted in a purple/brown precipitate. Amplification of appropriate the HBV genomic region was performed using the INNO-LiPA HBV DR amplification kit. The INNO-LiPA HBV genotyping strip contains 1 red marker line, 2 control lines, and 14 parallel probe lines. The conjugate control line is a control for the color development reaction and the amplification control line contains universal HBV probes to check for the presence of amplified the HBV genomic material.

Statistical analysis

Data were analyzed with SPSS 11.5 software (SPSS Inc. Chicago, Illions, USA) using Student's *t* test, χ^2 test and Fisher's exact test.

RESULTS

A total of 109 patients with a mean age of 37.17 ± 11.75 years, including 13% females and 87% males, were enrolled in this HBV genotype study. The distribution of patients in different stages of liver disease was as follows: 95 (86.4%) chronic hepatitis, 11 (10%) liver cirrhosis, and 3 (2.7%) inactive carrier. Of the chronic hepatitis and liver cirrhosis patients, 26.4% were HBeAg-positive and 70% were HBeAg-negative. The mean serum ALT, AST, and ALP levels were 126.08 IU/L (88.46-163.71), 86.46 IU/L (49.54-123.39), 173.34 IU/L (152.74-193.94), respectively.

Genotype D was the only detected type found in all patients. Mean age of patients was significantly higher in the anti-HBe-positive group as compared with the HBeAg-positive group ($P = 0.000$). Also, the number of the patients in the anti-HBe-positive group was significantly higher than the HBeAg-positive group ($P = 0.019$; Fisher's exact test). Moreover, significant difference was found between the mean age of patients with different stages of liver disease. None of the patients in the HBeAg-positive group had a normal ALT level. Most of the patients in the chronic hepatitis stage had an abnormal ALT level in comparison with the liver cirrhosis stage ($P = 0.024$; Fisher's exact test).

DISCUSSION

Classifying HBV into genotypes has to be cost-effective and clinically relevant. It is imperative to collect more information on HBV genotypes from all over the world to reach a decision on their clinical utility^[11].

Data on the relation among the HBV genotypes, their pathogenicity in chronic liver disease including hepatocellular carcinoma and their effect on therapy are awaited with great interest, especially in Asia which is an endemic region of blood-borne hepatitis viruses^[15].

Presently, based on an intergroup divergence of 8% or more in the complete nucleotide sequence, HBV can be classified into eight genotypes A-H, and different HBV genotypes are dominant in various parts of the world^[14,16]. The most important finding of our study was that the only HBV genotype D was detected in all patients. The pattern of distribution of genotypes seemed to be simpler and was predominantly centralized into genotype D in all forms of the chronic HBV infection. The results of this study concur with previous studies, indicating that HBV genotype D prevails in the Mediterranean area, Near and Middle East, and South Asia^[3,4,16]. For example, the result of a similar study performed in Turkey showed all 44 patients studied had genotype D^[16]. Another study in Yemen demonstrated that genotype D was the dominant genotype in a settled population, while genotype A was

found only in communities with continuing African links^[22]. In addition, one study in Egypt revealed genotype D was the most prevalent HBV genotype^[23]. On the contrary, genotypes A, B and C were found to be predominant in Pakistan^[24]. According to recent studies, genotype D in Asia is associated with more severe disease and may predict occurrence of hepatocellular carcinoma in younger patients^[9].

After all, only less than 1 000 of the 350 million persistent HBV infections have yet been genotyped. Continued efforts for understanding HBV genotypes through international co-operation will reveal further virological differences of the genotypes and their clinical relevance.

Abstract

AIM: To observe the effect of Fructus Psoraleae on motility of isolated gallbladder muscle strips of guinea pigs and its mechanism.

METHODS: Guinea pigs were hit to lose consciousness and the whole gallbladder was removed quickly. Two or three smooth muscle strips (8 mm × 3 mm) were cut along a longitudinal direction. The mucosa was gently removed. Every longitudinal muscle strip was suspended in a tissue chamber which was continuously perfused with 5 mL Krebs solution (37°C), pH 7.4, and aerated with 950 mL/L O₂ and 50 mL/L CO₂. The isometric response was recorded with an ink-writing recorder. After 2 h equilibration under 1 g-load, 50 µL Fructus Psoraleae (10, 20, 70, 200, 700, 1000 g/L) was added cumulatively into the tissue chamber in turn every 2 min to observe their effects on gallbladder muscle strips (cumulating final concentration of Fructus Psoraleae was 0.1, 0.3, 1.0, 3.0, 10.0, 20.0 g/L). The antagonists, including 4-DAMP, benzhydramine, hexamethonium, phentolamine, verapamil and idomethine were given 2 min before Fructus Psoraleae respectively to investigate the mechanisms involved.

RESULTS: Fructus Psoraleae dose-dependently increased the resting tension ($r = 0.992$, $P < 0.001$), decreased the mean contractile amplitude ($r = 0.970$, $P < 0.001$) and meanwhile increased the contractile frequency of the gallbladder muscle strip *in vitro* ($r = 0.965$, $P < 0.001$). The exciting action of Fructus Psoraleae on the resting tension could be partially blocked by 4-DAMP (the resting tension decreased from 1.37 ± 0.41 to 0.70

± 0.35 , $P < 0.001$), benzhydramine (from 1.37 ± 0.41 to 0.45 ± 0.38 , $P < 0.001$), hexamethonium (from 1.37 ± 0.41 to 0.94 ± 0.23 , $P < 0.05$), phentolamine (from 1.37 ± 0.41 to 0.89 ± 0.22 , $P < 0.01$) and verapamil (from 1.37 ± 0.41 to 0.94 ± 0.26 , $P < 0.05$). But the above antagonists had no significant effect on the action of Fructus Psoraleae-induced mean contractile amplitude ($P > 0.05$). Moreover, the increase of the contractile frequency due to Fructus Psoraleae was inhibited by 4-DAMP (decreased from 8.3 ± 1.2 to 6.8 ± 0.5 , $P < 0.01$) and hexamethonium (from 8.3 ± 1.2 to 7.0 ± 0.9 , $P < 0.05$). Idomethine had no significant effect on the Fructus Psoraleae-induced responses ($P > 0.05$).

CONCLUSION: Fructus Psoraleae enhances the motility of isolated gallbladder muscle strips from guinea pigs, in a dose-dependent manner. The effect of Fructus Psoraleae is partly related to M₃, N receptor, α receptor, H₁ receptor, Ca²⁺ channel, but not related to prostaglandin.

INTRODUCTION

Fructus Psoraleae is the dry fruit of the leguminous plant *Psoralea corylifolia* L. In recent years, researchers from home and abroad have made extensive studies on its chemical composition and extraction^[1-4]. Studies on the pharmacological action of Fructus Psoraleae have been focused on its therapeutic effect on leucopenia, uterine bleeding, chronic bronchitis and psoriasis^[5-8]. However, reports of the effect and mechanism of Fructus Psoraleae on the gallbladder smooth muscle strips *in vitro* are rare. In this experiment, we observed the effects of Fructus Psoraleae on the gallbladder muscle strips from guinea pigs and studied the possible mechanisms involved.

Pso: Fructus Psoraleae; Ben: Benzhydramine; Phe: Phentolamine; Hex: Hexamethonium; Ido: Idomethine; Iso: Verapamil.

MATERIALS AND METHODS

Materials

Fructus Psoraleae was ground into coarse powder, boiled, filtered and made into (1000 g/L) extract (the drug was prepared and tested by Gansu Institute for Drug Control), and then diluted to 10, 20, 70, 200, 700, 1000 g/L solutions respectively. The antagonists are as follows: 4-DAMP (1 μ mol/L) (Sigma Chemicals Company), hexamethonium (10 μ mol/L) (Sigma Chemicals Company), phentolamine (1 μ mol/L) (Beijing No 13 Pharmaceutical Factory), verapamil (0.05 μ mol/L) (Lanzhou Pharmaceutical Factory), idomethine (1 μ mol/L) (Beijing Two-bridge Pharmaceutical Factory), and benzhydramine (1 μ mol/L) (Jiangsu Taicang Pharmaceutical Factory). Guinea pigs of either sex, weighing between 350 and 450 g [purchased from Animal Center of Lanzhou Veterinary Institute, laboratory animal certificate FCXK (Gan2004-0005)]. The following equipments were used: JZ-BK external isometric force transducer (BK Company), LMS-ZB two channels recorder (Chengdu Equipment Factory, China).

Methods

Guinea pigs were fasted with free access to water for 24 h. They were hit on the head to become unconscious. The whole gallbladder was removed, quickly transferred to Krebs solution and rinsed. The wall of the gallbladder was incised from the end of the cystic duct to the base to make two or three longitudinal smooth muscle strips (8 mm \times 3 mm). The mucosa was gently removed with forceps. Every longitudinal muscle strip was suspended in a tissue chamber which was continuously perfused with 5 mL Krebs solution (37°C), pH 7.4, and aerated with 950 mL/L O₂ and 50 mL /L CO₂. One end of the strip was fixed to a hook on the bottom of the chamber. The other end was connected to an external isometric force transducer (JZ-BK, BK). The strip was subjected to 1 g load tension and washed with 5 mL Krebs solution every 20 min. Motility of gallbladder strips in tissue chambers was simultaneously recorded by electrophysiograph (LMS_ZB, Chengdu), including the resting tension, the mean contractile amplitude, and the contractile frequency^[9]. After 2 h equilibration, 10, 20, 70, 200, 700, 1000 g/L Fructus Psoraleae was added

cumulatively in turn every 2 min to observe their effects on contractility of gallbladder. The 4-DAMP (1 μ mol/L), benzhydramine (1 μ mol/L), hexamethonium (10 mol/L), phentolamine (1 μ mol/L), verapamil (0.05 μ mol/L) and idomethine (1 μ mol/L) were added 2 min before Fructus Psoraleae was added to investigate whether the actions of Fructus Psoraleae were mediated *via* M₃, N receptor, α receptor, H₁ receptor, Ca²⁺ channel and prostaglandin(PG).

Statistical analysis

The data were presented as mean \pm SD and analyzed with one-way ANOVA and correlation. $P < 0.05$ was considered statistically significant.

RESULTS

Effect of Fructus Psoraleae and antagonists plus Fructus Psoraleae on the resting tension of gallbladder muscle strips

Fructus Psoraleae dose-dependently increased the resting tension of gallbladder muscle strips *in vitro* ($r = 0.992$, $P < 0.001$). The 4-DAMP (1 μ mol/L), benzhydramine (1 μ mol/L), hexamethonium (10 μ mol/L), phentolamine (1 μ mol/L), verapamil (0.05 μ mol/L) and idomethine (1 μ mol/L) had no significant effects on the resting tension of gallbladder muscle strips. But when given 2 min before the administration of Fructus Psoraleae (0.1, 0.3, 1.0, 3.0, 10.0, 20.0 g/L), 4-DAMP, benzhydramine, hexamethonium, phentolamine and verapamil partly blocked the enhancing action of Fructus Psoraleae on the resting tension of gallbladder muscle strips. However, idomethine had no significant action on the increasing effect of Fructus Psoraleae on resting tension (Table 1).

Effect of Fructus Psoraleae and antagonists plus Fructus Psoraleae on the mean contractile amplitude of gallbladder muscle strips

Fructus Psoraleae dose-dependently decreased the mean contractile amplitude of gallbladder isolated smooth muscle strips ($r = 0.970$, $P < 0.001$). The 4-DAMP (1 μ mol/L), benzhydramine (1 μ mol/L), hexamethonium (10 μ mol/L), phentolamine (1 μ mol/L), verapamil (0.05 μ mol/L) and idomethine (1 μ mol/L) had no significant effects on the mean contractile amplitude of gallbladder muscle strips. When

^a $P < 0.05$, ^b $P < 0.01$, ^d $P < 0.001$ vs control (under 1-g initial load the gallbladder spontaneous contraction frequency when Fructus Psoraleae was 0 g/L) ($n = 8$). ^c $P < 0.05$, ^f $P < 0.01$, ^h $P < 0.001$ vs Fructus Psoraleae (contraction frequency of adding each concentration of Fructus Psoraleae) ($n = 8$).

added 2 min before administration of Fructus Psoraleae (0.1, 0.3, 1.0, 3.0, 10.0, 20.0 g/L), none of the above antagonists showed significant action on the decreasing effect of Fructus Psoraleae on the mean contractile amplitude (Table 2).

Effect of Fructus Psoraleae and antagonists plus Fructus Psoraleae on the contractile frequency of gallbladder muscle strips

Fructus Psoraleae dose-dependently increased the contractile frequency of gallbladder muscle strips from guinea pigs *in vitro* ($r = 0.965$, $P < 0.001$). The 4-DAMP (1 μ mol/L), benzhydramine (1 μ mol/L), hexamethonium (10 μ mol/L), phentolamine (1 μ mol/L), verapamil (0.05 μ mol/L) and idomethine (1 μ mol/L) had no significant effects on the contractile frequency of gallbladder muscle strips. When given 2 min before the administration of Fructus Psoraleae (0.1, 0.3, 1.0, 3.0, 10.0, 20.0 g/L), 4-DAMP and hexamethonium partly inhibited the action of Fructus Psoraleae on contractile frequency of gallbladder muscle strips; nevertheless, the other antagonists had no significant effects on the action of Fructus Psoraleae on the contractile frequency (Table 3).

DISCUSSION

Cholelithiasis is a common disease worldwide and many epidemiological studies have shown that the incidence of

cholelithiasis has been on a rapid increase in some regions of the world since the last decade. Motor dysfunction of the gallbladder plays an important role in cholelithiasis and cholecystitis^[10-12]. According to the literature, traditional Chinese medicine, western medicine and surgical management have been employed to treat cholelithiasis at home and abroad^[13-16]. Herbal medicine is characterized by having few side effects and good curative effects, which is gradually accepted by people over the world. Zhou^[17] reported that Fructus Psoraleae extract excited the intestinal canal *in vivo* and *in vitro*, and relaxed the uterus of guinea pigs. In the present study, we observed that Fructus Psoraleae significantly increased the resting tension and contractile frequency; meanwhile decreased the mean contractile amplitude of isolated gallbladder muscle strips of guinea pigs.

All smooth muscles in the gallbladder are involuntary and the nerves are controlled by both extrinsic and intrinsic nervous systems. Von Schrenck *et al*^[18] reported that gallbladder smooth muscle cells possess muscarinic receptors of the M₃ type, which mediate contraction. Chen *et al*^[19] reported the M₃ receptors are preferentially associated with the activation of phospholipase C, intracellular Ca²⁺ release and the calmodulin-dependent pathway. It has been identified that cholinergic N-receptor exists on the membrane of nerve ganglion cells of gallbladder smooth muscle. Our results showed that M₃

antagonist (4-DAMP) and hexamethonium(nicotinic cholinergic antagonist) partly blocked the enhancing action of Fructus Psoraleae on the resting tension and contractile frequency of gallbladder muscle strips, but not that of the contractile amplitude of the strips. These results suggested that Fructus Psoraleae excited gallbladder muscle strip *via* M₃ and ganglion N receptors.

Moreover, there were some relevant reports about histamine and histamine receptors. Jennings *et al.*^[20] proposed that histamine is distributed in the guinea-pig gallbladder and it could regulate contractile activity *via* activation of H₁ and H₂ but not H₃ receptor. Gallbladder muscle possesses stimulatory H₁ receptors and inhibitory H₂ receptors^[21]. The depolarization and associated contraction of gallbladder smooth muscle represent the net effect of activation of both H (1) (excitatory) and H (2) (inhibitory) receptors, with the H (2) receptor-mediated response involving the activation of K (ATP) channels^[22]. In this experiment, we observed that H₁ antagonist-benzhydramine partly inhibited the enhancing action of Fructus Psoraleae on the resting tension, but had no effect on the mean contractile amplitude and contractile frequency of gallbladder muscle strip. The results showed the excitatory action of Fructus Psoraleae on gallbladder muscle strip was possibly mediated *via* H₁ receptor. Yanaura *et al.*^[23] reported that contractions and relaxations produced by sympathomimetic amines are mediated by alpha-excitatory and beta-inhibitory adrenoceptors in the biliary system (gallbladder, common bile duct and sphincter of Oddi) of guinea-pigs. We also observed that adnephren antagonist-phenolamine partly inhibited the enhancing action of Fructus Psoraleae on the resting tension, but had no effect on the mean contractile amplitude and contractile frequency of gallbladder muscle strip, and the results revealed that the excitatory action of Fructus Psoraleae on gallbladder muscle strip was possibly mediated *via* α receptor. Ca²⁺, which participates in excitation contraction coupling plays an important role in the contraction process of smooth muscle. The action potential in gallbladder smooth muscle (GBSM) is caused by Ca²⁺ entry through voltage-dependent Ca²⁺ channels (VDCC), which contributes to the GBSM contraction^[24]. Shimada^[25] believed the L-type Ca²⁺ current is dominant in gallbladder smooth muscle cells and may contribute to excitation-contraction coupling. In addition, our data showed that verapamil partly inhibited the exciting action of Fructus Psoraleae on the resting tension, suggesting that Fructus Psoraleae-induced gallbladder contraction was related to the Ca²⁺ channel. Verapamil is an L-type calcium channel blocker which inhibited the exciting effect induced by Fructus Psoraleae; whereas idomethine (prostaglandin enzyme suppressor) had no significant effects on the action of Fructus Psoraleae, indicating that the exciting action of Fructus Psoraleae on gallbladder smooth muscle strips was not related to prostaglandin (PG).

In summary, results from this study provide us new insights into the mechanisms underlying gallbladder motility and will be useful for further understanding of

biliary dyskinesia diseases and the treatment.

Abstract

AIM: To investigate the value and prospect of RT-PCR in detecting micrometastasis in regional lymph nodes of gastric cancer.

METHODS: Histopathology was used and K19 mRNA expression was detected by RT-PCR in tumor tissues and lymph nodes from gastric cancer patients undergoing radical resection of gastric carcinoma.

RESULTS: K19 mRNA was expressed in all tumor specimens of 30 cases; of the 126 lymph nodes, 26 were histopathologically positive (20.6%), and 42 positive (33.3%) by RT-PCR. Amplification fragments of 460 and 540 bp were shown in all the tumor tissues and metastatic lymph nodes after K19 and β -actin RT-PCR, while only a 540 bp fragment appeared in the lymph nodes of non-tumor patients.

CONCLUSION: K19 mRNA RT-PCR is sensitive and specific in testing micrometastasis in regional lymph nodes of gastric cancer, and it is superior to routine histopathology.

INTRODUCTION

Gastrointestinal cancer is the most common malignant tumor of the digestive tract. For histologically node-negative gastrointestinal cancer, even after curative resection of an early cancer, some patients die of metastasis and recurrence^[1]. Metastasis and recurrence result from dissemination of cancer cells. Micrometastasis has been proposed by many investigators. Usually it is through blood and lymphatic vessels and no more than 2 mm in diameter^[2]. Detection of occult metastatic cells is useful for prognosis, prediction of recurrence, and adjustment of therapies.

Among many prognostic factors, lymph node metastasis is one of the most useful indicators for patients with gastric and colorectal carcinoma^[3-7]. Metastasis is usually detected by conventional histological examination, but many negative lymph nodes have micrometastasis on re-examination by serial sectioning and immunohistochemical assay^[8-11]. Serial sectioning and immunohistochemical staining certainly increase the yield of occult metastasis, however, it seems to be time-consuming and labor intensive. These methods have not been performed routinely in most hospitals. To overcome this drawback, diagnostic procedures for the detection of micrometastasis at the genetic level have developed rapidly, such as RT-PCR^[12-14]. RT-PCR can detect genes that are exclusively expressed in carcinoma cells but not in normal lymph nodes or bone marrow. It is a highly sensitive and specific method. It was reported that by RT-PCR it was possible to detect one cancer cell from among 10^4 to 10^6 normal appearing lymph node cells. Lymph node occult metastasis of gastrointestinal cancer indicated by K19 mRNA expression can be considered as confirmation of the presence of metastasis. The current study was designed to investigate the value and prospect of RT-PCR in detecting micrometastasis in regional lymph nodes of gastric cancer by examination of K19 mRNA expression.

MATERIALS AND METHODS

Tissue samples

The 30 tumor specimens and 126 lymph nodes were obtained through radical resection of gastric carcinoma of patients from the Department of General Surgery, First Hospital, Jilin city from 2001 to 2002, and tumor specimens were confirmed by pathology. The specimens

were processed immediately after the resection: tumor tissues were obtained; lymph nodes were peeled off carefully. Fat tissue and blood were wiped off, lymph nodes were cut into two halves by clean bistouries, and sterilized physiological saline was used for rinsing to prevent the contamination of tumor cells. One half of a lymph node was fixed by formaldehyde; the other half was immersed into liquid nitrogen, and then preserved in a -70°C freezer till the next day for RNA extraction. Meanwhile, lymph nodes from 8 non-tumor patients were used as negative control.

Reagents

The reagents included TRI reagent (GIBCO), AMV, Taq enzyme, DNTPs and Rnasin (Promega), Marker and Olig (dt) (TaKaRa); the rest of the reagents were all homemade provided by local suppliers.

Methods

Primer design and synthesis: Primer design of CK19 and β -actin was based on previous methods^[15] with some modifications. CK19 primer is: 5'-AGGTGGATTCCTGCTCCGGGGCA-3', 5'-ATCTTCCTGTCCCTCGAGCA-3'. The amplification fragment of the primer (Wubo Gene Corp., Beijing) was 460 bp. β -actin primer is: 5'-GTGGGGCCCCAGGCACCA-3', 5'-CTTCCTTAATGTCACGCACGATTTC-3'; the amplification fragment of the primer (Dinguo Bio Corp., Beijing) was 540 bp. It was used as an internal control to determine that the RNA did not decompose.

RNA extraction: TRIzol was used to extract total RNA. The absorbency (A) was tested. Then gel electrophoresis was performed to identify its components.

Reverse transcription (cRNA synthesis): Reverse transcription system was 50 μ L, containing RNA 4 μ L, Oligo(dt) 2 μ L, 5 \times Buffer 10 μ L, dNTPs 4 μ L, Rnasin 1 μ L, AMV 4 μ L and DEPC-H₂O₂ 5 μ L incubated for 60 min at 42°C, to acquire cRNA.

PCR reaction: The reaction system was 100 μ L, containing cDNA 25 μ L, 10 \times Buffer 10 μ L, dNTPs 8 μ L, K19 primer 2 μ L, β -actin primer 0.5 μ L, Taq enzyme 1 μ L, MgCl₂ 6 μ L, DEPC-H₂O₂ 47.5 μ L. The cycle parameters of the reaction system were 94°C for 45 s, 55°C for 45 s, 72°C for 1 min, 35 cycles and extension for 10 min at 72°C.

PCR product analysis: PCR products were electrophoresed on 2% agarose gel, EB stained, and observed with ultraviolet light and photographed. The results were compared with pathological result.

Statistical analysis

We used t-test to compare between the histopathological results and RT-PCR results. $P < 0.05$ was taken as significant.

RESULTS

Comparison between histopathological result and K19 mRNA RT-PCR in detecting micrometastasis in regional lymph nodes

In 126 lymph nodes, 26 were positive in both routine

Figure 1 Representative results of RT-PCR. Lane 1: Marker; Lane 2: Tumor tissue sample; Lane 3: Negative lymph node by routine histopathology (K19 positive); Lane 4: Negative lymph node by routine histopathology (K19 negative); Lane 5: Normal lymph node of the non-tumor cases; Lanes 6, 7: Positive lymph node by routine histopathology.

histopathological testing and RT-PCR, K19 mRNA was expressed in 42 lymph nodes by RT-PCR amplification. It showed that there was metastasis in 16 lymph nodes which could not be found by histology examination. Of the regional lymph nodes, 20.6% were positive in histology, while 33.3% were positive in K19 mRNA by RT-PCR; and there were none that were positive for histology and negative by RT-PCR. In 30 cases of gastric tumor, 3 were positive in regional lymph nodes by RT-PCR while pathology showed no metastasis.

Specificity of RT-PCR amplification

All the tumor tissues and metastatic lymph nodes showed amplification fragments of 460 bp and 540 bp after RT-PCR amplification of K19 mRNA and β -actin, while in the lymph nodes of 8 non-tumor cases it showed only specific amplification fragments of 540 bp, indicating no K19 mRNA amplification product was expressed. Thus this system had superior amplification specificity (Figure 1).

DISCUSSION

There has been no uniform criterion for micrometastasis. In general, a focus not larger than 2 mm is called micrometastasis, which can not be easily found by routine method, whereas RT-PCR could increase the detection rate greatly. Zheng *et al*^[16] suggest selecting an ideal marker gene of the tumor as a histology specific marker. Keratin 19 is one of the histology markers, which is highly specific and only expressed in tumor tissue and tumor-originating normal tissue, but not expressed in normal mesenchymal tissues like lymph nodes^[17-20].

In this study, K19 mRNA was expressed in both tumor tissue and metastatic lymph nodes, but not in non-tumor cases. It indicates that K19 mRNA is applicable to detect the micrometastasis in regional lymph nodes by RT-PCR amplification. Moreover, the results of our study suggest that RT-PCR is more sensitive than routine histopathology in detecting micrometastasis and K19 can be a sensitive index for detecting metastasis in regional lymph nodes,

which accords with Liu's report^[21].

Because RT-PCR is the method that is sensitive and has great capability to amplify, sometimes there can be a pseudopositive, and the main reason could be that the lymph nodes are contaminated by tumor cells and normal epithelial cells and there is cross-contamination of byproduct during RT-PCR amplification. In the experiment, as the internal control, β -actin ensured reliability and the result showed that no K19 mRNA was expressed in any of the non-tumor cases under the same amplification condition, indicating that there was no pseudopositive in the RT-PCR amplification system. K19 mRNA RT-PCR has a high sensitivity and specificity in detecting micrometastasis in regional lymph nodes of gastric cancer and can detect the subtle metastasis which cannot be found by routine histology. This is of great clinical significance. According to the present staging criterion for gastroenteric cancer, the positive result will lead to change in the staging of tumor and alteration in therapy and prognosis judgment. Ye^[22] and Yan^[23] concluded that compared with lymph node-negative cases, K19 mRNA RT-PCR has obvious prognostic value on recurrence and survival time for the patients after the operation, even if there is a single metastasised tumor cell in the lymph node. Thus, the resection for early and intermediately staged patients should be as radical as possible^[24-25], so as not to miss the micrometastasis in lymph nodes and to reduce the recurrence; and the adjuvant therapy and follow-up should be enhanced as well.

The development of the subtle tumor cells in the lymph nodes depends on the immunity of the human body and other factors, which is possible but does not develop into an obvious metastasis. At present, there are still some questions left unanswered about detecting the micrometastasis in regional lymph nodes: one is that pseudopositives are possible because of its great capability of amplification; the other is how to choose a more specific tumor marker. Before the advent of serial analysis of micrometastasis of tumor cells, tumor cells were separated by an immunomagnetic method and extracted, which was thought to be the most attractive technique^[26]. Okadda^[27] put forward that a multiple-marked RT-PCR has a better effect on detecting micrometastasis in lymph nodes, and researchers are trying to find more sensitive and specific tumor markers including combinations of multiple-markers.

Abstract

In the developed and developing countries, corrosive injury to the gastrointestinal system as a consequence of either accidental ingestion or as a result of self-harm has become a less common phenomenon compared to decades ago. This could partly be attributed to the tighter legislation imposed by the government in these countries on detergents and other corrosive products and general public awareness. Most busy upper gastrointestinal surgical units in these countries, especially in the developed countries will only encounter a small number of cases per year. Up to date knowledge on the best management approach is lacking. In this article, we present our experience of two contrasting cases of corrosive injury to the upper gastrointestinal tract in our thoracic unit in the last 2 years and an up-to-date Medline literature search has been carried out to highlight the areas of controversies in the management of corrosive injuries of the upper gastrointestinal tract. We concluded that the main principle in managing such patients requires a good understanding of the pathophysiology of corrosive injury in order to plan both acute and future management. Each patient must be evaluated individually as the clinical picture varies widely. Signs and symptoms alone are an unreliable guide to injury.

INTRODUCTION

In the developed and developing countries, corrosive injury to the gastrointestinal system as a consequence of either accidental ingestion or as a result of self-harm has become less of a common phenomenon. This could partly be attributed to the tighter legislation imposed by the government on detergents and other corrosive products and general public awareness^[1,2]. Most busy upper gastrointestinal (GIT) surgical units, especially in the developed countries will only encounter a small number of cases per year. Up to date knowledge on the best management approach may therefore be lacking.

We present two contrasting cases of corrosive injury to the upper GIT, which presented to our thoracic unit in the last 2 years to highlight the contrasting aspects of chemical burn injury to the upper GIT. A Medline search has been carried out to extract relevant articles to enable us to perform a literature review to discuss the areas of controversies in the management of corrosive injuries of the upper GIT.

CASE REPORTS

Case 1

A 22-year-old male with learning disability attended the Casualty Department following accidental ingestion of a cupful of 30% caustic soda and had vomited immediately after it. On presentation, his voice was hoarse. He was also short of breath and drooling his saliva. On examination, he had a red, swollen tongue and his oropharynx was oedematous and inflamed. He was intubated to secure his airway and transferred to the intensive care unit. Other supportive treatments received included intravenous proton pump inhibitor (PPI) and total parental nutrition (TPN). He was extubated 2 d later. Early oesophagogastrosocopy (Figure 1) revealed generally inflamed oropharynx and Savary grade 3 oesophagitis from 20 cm. Examination beyond this point was not attempted. Barium meal (Figure 2) carried out two weeks later showed a long stricture segment from just distal to the hypopharynx to the oesophago-gastric junction. The patient did not receive steroid therapy during any stage of his treatment. He was successfully managed with repeated progressively time spaced dilatation using a guide wire under fluoroscopy. He currently attends Day Procedure Unit every 6-12 wk for oesophageal dilatation.

Figure 1 Endoscopic picture showing gross laryngeal edema with inflamed adjacent structures (case 1).

Figure 3 Oesophagogastric dissociation (OGD) of the patient after ingestion of battery acid showing circumferential burn to the lower oesophagus (case 2).

Figure 2 Barium meal showing a long stricture segment from just distal to the hypopharynx to the oesophago-gastric junction (case 1).

Figure 4 Barium study of patient showing partial gastric outlet obstruction with marked gastric dilatation with an irregular stricture of the pylorus and proximal duodenum (case 2).

Case 2

A 33-year-old male with a history of overdose and assaults presented to the Casualty Department with hoarseness and stridor following ingestion of about 40 mL of battery acid (hydrochloric acid) secondary to deliberate self-harm. He was intubated to secure his airway and transferred to ITU. A CT scan of his chest and abdomen showed thickened distal oesophagus and stomach, small bilateral pleural effusion and no obvious sign of perforation. Early endoscopy showed inflammation and ulceration of the pharynx and oesophagus with contact bleeding and circumferential ulceration of the oesophageal mucosa at 25 cm (Figure 3). His stomach was filled with blood. The immediate supportive treatments included intravenous PPI, TPN for nutrition, steroids and broad-spectrum antibiotics because of gross laryngeal oedema and positive blood culture. He improved on conservative management and following extubation was allowed oral feeding. Endoscopy was repeated 10 d later and it showed small ulcers at the level of the vocal cords. Upper oesophagus was relatively spared. A tight cricopharyngeus was noted and his lower oesophagus showed a circumferential burn with slough. Similar findings were noted on the mid-body of the stomach and the antrum but the duodenum was spared.

He was discharged home three weeks later only to be readmitted a week and a half post-discharge with symptoms and signs of gastric outlet obstruction. Endoscopy at this stage showed a normal oesophagus with an ulcerated and scarred gastric pylorus. The endoscope failed to advance beyond this point. These findings were confirmed on a dilute barium swallow (Figure 4). Roux-en-Y gastrojejunostomy was performed subsequently

in order to bypass the stricture. He remained well post-operatively.

DISCUSSION

There are a vast variety of chemicals commonly available in a modern western household that can be ingested either inadvertently or intentionally. Failure to recognize the seriousness of the accident and to provide adequate therapy could result in serious morbidity and mortality. Children account for more than 80% of accidental corrosive ingestion but ingestion in adult is more often of suicidal intent, and, therefore, tend to be more serious^[3]. The mortality rate is between 10% to 20% and rises to 78% in cases of attempted suicide^[4]. The extent of the injury depends on the type of agent, its concentration, quantity and physical state, the duration of exposure and the presence of food particles in the stomach^[5-7].

Pathophysiology

The dichotomy of oesophageal versus gastric injury in cases of acid and alkali ingestion has long been recognized by surgeons and gastroenterologists^[8]. Whilst acid is said to “lick the oesophagus and bite the pyloric antrum”, alkaline tends to cause a more uniformly severe mucosal injury to the oesophagus^[3,6,9]. Although acid injury is usually limited to the stomach, 6%-20% of patients have other associated oesophageal and small intestinal injuries^[6]. Our two cases clearly illustrated this with the caustic injury in case 1 causing extensive oesophageal injury whilst the acid resulting in gastric injury and sparing the oesophagus.

Acid injuries cause “coagulation necrosis” on tissue contact; the coagulum formed hinders any further tissue

penetration^[3,4,9,10]. On the other hand, caustic injuries induce “liquefaction necrosis”, a process that leads to the dissolution of protein and collagen, saponification of fats, dehydration of tissues and thrombosis of blood vessels, resulting in deeper tissue injury^[3,4,9,10]. Zargar *et al* noted that acute gastric injury was present in 85.4% of their patients who had ingested acid, involving mainly the distal half of the stomach with 44.4% having late complications in the form of pyloric or antral stenosis and linitis plastica-like deformity^[11]. The relative sparing of the duodenum is thought to be due to pyloric spasm induced by the irritant acid in the antrum and the alkaline pH of the duodenum^[11]. Our patient who ingested battery acid developed partial gastric outlet obstruction. Contrast study performed documented duodenal rigidity and lack of normal mucosal pattern. However, the distinction between the expected sites of gastrointestinal injury following acid versus alkali ingestion is not always clear.

Burn classification

Injuries secondary to chemical burns of the upper gastrointestinal tract are classified in similar fashion to thermal burn of the skin. They are classified into three degrees based only on the extent and severity of the superficial lesions^[12]. An appreciation of the depth of the involvement may improve our treatment, but at present, no definite measurements of the depth can be made, and the grading at best is subjective. Endoscopic ultrasound may provide an answer. A third-degree burn can easily be mistaken for a second-degree burn^[9].

Oropharyngeal burns and clinical symptoms have a low predictive value for severity of oesophageal injury^[13,14]. Haller *et al* observed that 70% of their patients with oropharyngeal burns did not have significant damage to the oesophagus^[15]. Both our patients had severe oropharyngeal burns requiring immediate intubation in order to protect their airway but only one developed severe oesophageal injury.

Early versus late endoscopy

Early endoscopy is regarded as the most appropriate measure based on which clinical decisions are made in people who have ingested corrosive substances^[3,8,12,16-18]. The majority of physicians and surgeons now favour early endoscopy. Nevertheless, early endoscopy in the hands of a less-experienced endoscopist could be hazardous^[2,10]. It is important to minimize force and air insufflation when passing the endoscope in this group of patients^[10]. The risk of oesophageal perforation is low if the procedure is performed under general anaesthesia and the endoscope is passed to the first burned area but not beyond it^[16]. Hawkins *et al* recommend diagnostic oesophagoscopy under general anaesthesia within the first 36 h of corrosive ingestion. In severe oropharyngeal burns, endoscopy may be deferred up to seven days to allow the acute oedema to subside, thereby reducing the risk of airway complication^[8]. Zargar *et al* performed endoscopies on 88 patients within 96 h following corrosive ingestion and found no complications related to the procedure^[19]. Others have also documented the safety of early endoscopy^[3]. Both our

patients had endoscopy carried out within 72 h following corrosive ingestion. Early endoscopy is essential in the continuing management of patients with corrosive injury as it affords an opportunity to verify directly the healing state of the mucosa and may be of value in predicting which patients require further early intervention^[1,2,8,19,20].

Endoscopy is not without its limitations^[1]. It is difficult to assess the depth of any burn with absolute certainty by observing superficial epithelial necrosis^[2]. If a severe burn is encountered in the upper third of the oesophagus, the scope is not passed beyond this point. In this case, it will be difficult to ascertain the degree of injury to the rest of the oesophagus^[3]. The area of burn may not be visualised, thus delaying the diagnosis^[2]. Others have attempted the use of endoscopic ultrasound to improve the accuracy of diagnosis. However, Chiu *et al* did not find concomitant use of endoscopic ultrasound (EUS) useful in improving the accuracy of predicting early or late complication of stricture^[21].

Manometric study

Genc and Mutaf investigated the use of manometric studies and suggested that it could give important data about the severity of the initial oesophageal injury^[22]. Dantas *et al* showed that a majority of their patients with caustic oesophageal injury exhibit alterations in oesophageal motility, ranging from low amplitude non-peristaltic contractions to some degree of alteration of lower oesophageal sphincter pressure^[5]. Thus, it could play a role in determining the prognosis. PPI is generally prescribed on the basis of associated reflux. This data provide supporting evidence for its use.

Complications of corrosive ingestion

Severe complications, often life threatening are common following corrosive injury to the upper gastrointestinal tract. These include tracheobronchial fistula in 3%, severe haemorrhage secondary to gastric involvement, aortoenteric fistula or gastrocolic fistula, strictures and perforation in 10% of cases^[3,5,13,20]. Stricture formation, by far, remains the main long-term complication of this injury. Over 90% of patients with third-degree burns go on to develop stricture and 15%-30% if they have second-degree burns^[3]. Mamede *et al* observed an 89.3% incidence of oesophagitis in their 37-year historical series; 72.6% of the cases involved progression to stenosis and 1% died during acute phase^[7]. A lumen >10 mm in diameter is thought not to impede normal life and should be left alone^[13].

Early use of steroids and antibiotic: Prevention of stricture formation

Corticosteroids inhibit the transcription of certain matrix protein genes, procollagen, fibronectin, TGF- β and many cytokines. They also reduce the synthesis of α 2-macroglobulin, an inhibitor of collagenase activity^[23]. Animal experiments have shown that if antibiotics and steroids are given early following ingestion of a corrosive substance, the likelihood of stricture formation is reduced^[2,24]. Bautista *et al* found dexamethasone more

effective than prednisolone in preventing stricture formation following experimental oesophageal burns^[24]. Mamade *et al* concluded from their clinical experience of 239 cases over 38 years that lower doses of steroid have little effect on the prophylaxis of stricture^[25]. Higher doses only seem to contribute to the onset of complications such as increased vulnerability to infection and gastrointestinal bleeding^[16,25]. Several authors have found corticosteroids ineffective in preventing oesophageal stricture^[10,12,14,16,18]. This has also been shown in a more recent randomised controlled clinical trial in children.

Intra-lesional corticosteroid therapy has shown beneficial effects for refractory oesophageal strictures caused by corrosive burns. A report by Kochhar *et al* concluded that patients treated in this way experience a longer dilatation-free interval, thus requiring fewer dilations^[26]. However, the number of patients involved in the study is small.

In our two contrasting cases, steroid was given to the patient with acid burns for the first 24 h in view of the severity of laryngeal oedema at presentation to avoid casualty. In another patient who suffered from caustic burns, steroid was not given because the literature suggests that the complication risk outweighs the efficacy in preventing stricture formation.

To date, there is no convincing evidence supporting the use of antibiotics in reducing stricture formation^[18]. An animal study has shown that it could decrease infection in steroid treated burns^[3]. Kirsh *et al* recommended the use of antibiotics for 7 d to 2 wk as a means to both decrease the risk of pulmonary infection and bacterial invasion through the injured oesophagus into the mediastinum^[2]. Our general consensus when treating a patient with such injury is that antibiotic treatment should only be commenced when the patient is treated with steroids or there are signs of infection with source of infection and infecting organism identified. Prophylactic use of antibiotics without steroid treatment is unjustified^[18].

Routine use of nasogastric (NG) tube

Mamede *et al* reported a significant lower incidence of stricture formation with routine use of NG tube for 15 d following the injury^[25]. However the NG tube could not act as an oesophageal 'mould' because one could expect the stenosing effect to continue longer than 15 d. Wijburg *et al* also reported a decline in stricture formation in a patient with long-term nasogastric tube placement^[27].

However, contrasting results were obtained from other literatures stating that long-term indwelling nasogastric insertion is known to cause long strictures of the oesophagus even in patients without oesophageal burns^[3,18]. We do not advocate the use of a NG tube as we have experienced a number of patients who developed complex stricture following nasogastric insertion. Furthermore, the presence of a NG tube will aggravate reflux by making the lower oesophageal sphincter incompetent. We used TPN in both patients and would have proceeded to feeding jejunostomy if oral feeding was not soon established.

Experimental studies to prevent stenosis

In a recent experimental study, cytokines have been used

successfully in preventing stricture formation by Berthet and colleagues^[20]. The theory was based on the rationale of the inflammatory process and cascade of events. Epidermal growth factor (EGF) was used because of its properties of fibroblast stimulation and improvement of local vascular conditions. Interferon- γ (IFN- γ) was also used to reduce fibrosis as it inhibits collagen I and III formation and fibronectin synthesis^[20]. Hydroxyproline was used as an indirect measurement of collagen production as it is the ultimate product of collagen degradation^[20]. Stenosis was not observed in treated animals^[20]. There was a lower level of hydroxyproline in combined treatment compared to EGF alone^[20].

Kaygusuz *et al* investigated the effect of interferon- α -2b and octreotide in the treatment of corrosive burns of the oesophagus^[28]. A histopathological examination of the exposed oesophagus demonstrated that octreotide and interferon- α -2b distinctively depressed the fibrotic activity in the second phase of wound healing that occurred in the oesophageal wall after a corrosive burn^[28]. Gunel *et al* showed in their animal experiment that treatment with an antioxidant, such as vitamin E and methylprednisolone decreased tissue hydroxyproline and thus, inhibiting new collagen synthesis and stricture formation following corrosive injury^[29]. However, all these studies are only carried out on animals and these treatments have not been tested on humans.

Management

The acute management is based on the acute trauma life support (ATLS) guidelines for burn injury. This includes securing the airway, pain relief and attending to adequate intravenous fluid replacement. Tracheostomy may be necessary in cases of severe laryngeal oedema, whereby tracheal intubation fails and there is a danger of completely closing over of the airway due to the edema^[2,30]. The aim of treatment at this stage is to stabilize vital parameters. The patient is kept strictly nil by mouth in acute phase. A plain chest radiograph is advisable and might reveal signs of perforation, i.e. pneumomediastinum and free air under the diaphragm^[3,19,28,30]. However the sensitivity is low and if perforation is suspected, diluted barium swallow should be carried out. It is crucial that the attending medical officers are aware of the severity of such injury and able to identify life-threatening complications associated with the injury. The use of antidote such as water or milk does not seem to prevent stenosis^[25]. Endoscopy is the diagnostic procedure of choice in the absence of known perforation^[3]. Patients with perforation require immediate surgery^[3]. Gastric acid suppression with PPIs and H₂-antagonists are often used in corrosive burn injury as oesophagitis and gastritis are common and patients have been kept fasting^[18]. This treatment has been employed in both our patients in order to suppress gastric acid production and to prevent stress ulcers in the stomach.

Our first patient with the alkaline burns of the gastrointestinal tract who later developed oesophageal strictures was managed with frequently repeated dilatation. Hawkins *et al* reported a relatively high success rate with dilatation^[16]. Dilatation could be antegrade or retrograde or a combination of

both^[1]. Early dilatation is not recommended due to associated high incidence of perforation and associated morbidity^[3]. Most authors advised waiting 3 to 6 wk after the initial injury before attempting oesophageal dilatation^[3,30]. Overall, oesophageal dilatation has proved to give good results in short strictures but might be dangerous for long and narrow oesophageal strictures^[14,20]. Complex strictures are refractory to dilation therapy and fluoroscopic guidance has a valuable role in managing these types of strictures^[23]. Repeat dilation sessions are needed in most cases with a goal of achieving a luminal diameter of 12 mm or larger in order to alleviate symptoms of solid dysphagia^[23]. We suspect that the strategy of intense PPI therapy and repeated dilatation will reduce the number of impassable stricture that otherwise would have required oesophageal resection and reconstructive surgery.

The second patient with acid burns of the gastrointestinal tract developed gastric outlet obstruction within 3 wk of injury. The use of a steroid is of questionable value, and overall evidence from the literatures is not in favour of routine use. This is because it could mask the clinical signs of free perforation and infection^[12,13,16]. Therefore, its use is limited mainly to patients with severe laryngeal oedema. Antibiotics have been used in this case for the treatment of an obvious chest infection. Gastric outlet obstruction has been found in association with oesophageal stricture in the region in 20% of cases^[17]. In some cases gastric outlet obstruction can yield balloon dilatation but our patient required surgical bypass because of the complex nature of his stenosis. Alternative surgical reconstruction would be hemigastrectomy and resection of the first part of the duodenum with Bilroth I reconstruction. At the time of presentation, our patient was unfit for such a major operation.

Understanding the pathophysiology of corrosive injury is important in planning both acute and on-going management. Scar retraction begins as early as the end of the second week and lasts for 6 mo. Six to twelve months is considered the average time before full fibrosis is achieved after the injury^[31]. Oesophagectomy carried out too early prior to the scar tissue maturation might increase the risk of anastomotic stenosis^[32]. Han *et al* advocate delaying major reconstructive surgery in patients with caustic burns for at least 6 mo from time of injury provided that emergency surgery is not indicated^[32]. Emergency oesophagectomy plus exteriorisation or immediate reconstruction is however indicated in cases of perforation and contamination of the mediastinum^[9].

Risk of carcinoma

The association of lye stricture and carcinoma of the oesophagus has been known since 1896^[2]. Kiviranta believed that the incidence of oesophageal cancer among victims of lye stricture is at least 1000 times greater than that in the normal population^[33]. The interval between lye ingestion and the development of carcinoma ranges between 25 to 40 years. However, this risk may be overestimated. Marchand did not encounter a single case in 135 patients with caustic strictures of the oesophagus over a period of 6 years^[34]. Carver and colleague had 2 patients out of 233 patients with lye strictures over a period of 25

years^[35]. Mamede and colleague found 4 (1.6%) out of the 239 patients from their 37-year historical series developed oesophageal cancer after caustic soda ingestion^[7]. In these cases, operative risk may exceed the potential risk of cancer.

The risk of gastric cancer is less known^[8]. Gray and Holmes first reported in 1948 findings of squamous metaplasia in the stomach of a patient who had ingested acid^[36]. Similar findings were subsequently reported by O'Donnell and colleagues^[37] and later by Eaton and Tennekoon^[38]. Some surgeons are more aggressive in resection of the involved stomach because of the danger of subsequent gastric metaplasia^[6,9]. The predisposition to cancer justifies regular follow-up and surveillance endoscopy. However, the patient should be warned of the cumulative dangers of other risk factors for oesophageal cancer, such as alcohol abuse and smoking^[30].

CONCLUSION

The literature on treatment of patients with corrosive injuries to the upper gastrointestinal tract is both controversial and inconclusive. The main principle in managing such patients is that each patient must be evaluated individually as the clinical picture varies widely. Signs and symptoms alone are an unreliable guide to injury. Both the acute and the chronic phases of the clinical presentation require different management. Psychiatric support is sometimes needed during both the acute and chronic phases. The general consensus is that the initial treatment is supportive; ensuring the airway is patent and to establish haemodynamic stability. Early endoscopy has a crucial role in both diagnosing the severity of the injury, as well as, in managing the patient. Total parenteral nutrition is a useful adjunct. Operation is generally reserved for patients who have ingested large amounts of corrosive substance and in whom tissue necrosis is highly likely. Extensive necrosis noted on endoscopy and patients with evidence of perforation are indications for immediate surgical intervention. As for intractable oesophageal strictures when dilatation is dangerous or impossible, surgical intervention may be unavoidable. However, this must be balanced against the mortality and sometimes considerable morbidity following surgery^[2,30]. Follow up endoscopy should be carried out within 6 wk following discharge from the hospital^[30]. Diligent follow-up is advised to ensure patient has satisfactory gastrointestinal function restored and to correct late onset complications.

One year after the latest surgery the patient tolerated oral feeding and did well, suggesting that congenital (partial) mechanical obstruction of the small bowel in humans can evoke progressive adaptive changes of the ENS which are similar to those found in animal models of intestinal mechanical occlusion. Such ENS changes mimic neuronal abnormalities observed in intestinal pseudo-obstruction.

Abstract

Experimental evidence indicates that chronic mechanical sub-occlusion of the intestine may damage the enteric nervous system (ENS), although data in humans are lacking. We here describe the first case of enteric degenerative neuropathy related to a congenital obstruction of the gut. A 3-year and 9-mo old girl began to complain of vomiting, abdominal distension, constipation with air-fluid levels at plane abdominal radiology.

Her subsequent medical history was characterized by 3 operations: the first showed dilated duodeno-jejunal loops in the absence of occlusive lesions; the second (2 years later) was performed to obtain full-thickness biopsies of the dilated intestinal loops and revealed hyperganglionosis at histopathology; the third (9 years after the hyperganglionosis was identified) disclosed a Ladd's band which was removed and the associated gut malrotation was corrected. Repeated intraoperative full-thickness biopsies showed enteric degenerative neuropathy along with reduced interstitial cells of Cajal network in dilated loops above the obstruction and a normal neuromuscular layer below the Ladd's band.

INTRODUCTION

The enteric nervous system (ENS), the third component of the autonomic nervous system, plays a crucial role in the control of gastrointestinal functions, including motility, secretion, absorption, blood flow, mucosal growth and aspects of the local immune system^[1]. Hence, any condition altering the integrity of the ENS is responsible for a wide spectrum of disorders affecting the gastrointestinal tract. Abnormalities of the ENS (also referred to as enteric neuropathies) may be secondary to a variety of inflammatory, infectious, metabolic and neurological diseases, or they can be labelled idiopathic when no causes can be found^[2-6]. The most common clinical manifestation related to an underlying enteric neuropathy (either idiopathic or secondary) is a severe functional impairment of gastrointestinal motility as that identifiable in patients with chronic intestinal pseudo-obstruction (CIPO)^[4,7,8]. The diagnosis of CIPO is based on the exclusion of any mechanical lesion occluding the

gut lumen^[4,7,8]. On the other hand, in animals chronic incomplete mechanical occlusion of the intestine may induce ENS damage^[5]. The effects of chronic obstruction on the human ENS are still unknown.

Herein we describe the case of a girl in whom an initial diagnostic work-up suggested a diagnosis of CIPO with an underlying neuropathy characterized by hyperganglionosis of the ENS, whereas a laparotomy about 10 years later showed a chronic congenital obstruction of the small bowel due to a Ladd's band. Full-thickness gut biopsies, taken during this last laparotomy, showed an enteric degenerative neuropathy in the bowel loops located above the obstruction. Because the correct pathology remained undiagnosed for a long time, this case can be considered a human model of mechanical partial obstruction of the gut. Specifically the case indicates that a long-standing ("chronic") intestinal sub-occlusion can evoke progressive changes of the ENS similar to those found in animal models, and that the observed ENS changes mimic abnormalities often found in CIPO related to idiopathic neuropathies.

CASE REPORT

G. S. was a full term baby girl weighing 2040 g at delivery whose clinical history was unremarkable until 3 years and 9 mo of age when she began to complain of post-prandial vomiting (often bilious) and constipation. Clinical examination revealed abdominal distension, dehydration and decreased bowel sounds. Systemic and neurologic diseases, as well as infections and malabsorption syndromes were excluded by physical examination and blood tests. X-ray of the small bowel showed mild gaseous distension of the proximal small bowel loops with air-fluid levels although a CT scan failed to reveal any mechanical obstruction. Due to the severity of the clinical picture and the marked small bowel distension, the patient underwent laparoscopy showing duodeno-jejunal dilatation with no obvious mechanical cause. The patient was discharged with a diagnosis of intestinal pseudo-obstruction and treated with prokinetics and a low-fiber diet.

Subsequently, she had recurrent episodes of vomiting, abdominal pain, early satiety and fullness. Because of the persistence of severe dyspeptic symptoms, at 5 years and 7 mo of age the patient was referred to a tertiary center for pediatric gastroenterology where, based on the clinical history and previous examinations, a decision to undertake an explorative laparotomy was reached. The intra-operative evaluation showed a marked degree of duodeno-jejunal dilatation but no mechanical obstruction.

Analysis of full-thickness biopsies taken from the dilated jejunal loop revealed enlarged myenteric and submucosal neurons whose number was increased as compared to sex-age-matched normal controls^[9]. A further important feature was the increased density of the nerve fibers in the lamina propria and submucosa. Based on the histopathology suggesting a case of hyperganglionosis, the diagnosis of CIPO was confirmed and the patient received several courses of prokinetics, metronidazole and high-caloric liquid diet supplementation.

Figure 1 Representative pictures showing clinical (A and B) and laparoscopic views (C and D) observed in this case. Note (A) the hugely distended abdomen and (C and D) abnormally dilated loops located proximally to the removed Ladd's band (not visible in these examples) at laparotomy. B illustrates the considerable deflation of the abdomen following surgery.

During a subsequent recovery the patient underwent an upper gastro-intestinal manometry which showed a pattern indicative of neurogenic-type CIPO. Due to the progressive worsening of her clinical status, at 14 years and 2 mo of age, the patient was referred to our center in Bologna. Physical examination showed a highly distended (Figure 1A) and painful abdomen, with absence of peristaltic sounds. An X-ray examination showed multiple air-fluid levels in the upper abdomen with a striking elevation of the diaphragm. In order to achieve bowel decompression, she underwent surgery. At laparotomy a Ladd's band was detected and removed with correction of the associated malrotation. Bowel loops with marked dilatation (Figures 1C and 1D) were resected and a protective ileostomy was created. Full-thickness biopsies were taken from the loops located proximally (dilated segments) and distally (macroscopically normal) to the Ladd's band.

Following surgery, the clinical course was uneventful with immediate deflation of the abdomen. One year after the last laparotomy the patient was healthy and tolerated oral feeding, her height and weight were markedly increased, and her quality of life was good (Figure 1B).

Immunohistochemical analysis

Full-thickness tissue specimens were processed for immunohistochemistry according to standard protocols commonly applied in our laboratory. Compared to controls (jejunal specimens collected from patients operated on for intestinal bleeding due to angiodysplasia; $n = 4$, 2 females, age range: 6-16 years) (Figure 2A) and the non-dilated segment (Figure 2B), the immunohistochemical evaluation of biopsies taken from the dilated loop showed evidence of intrinsic neuropathy of the gastrointestinal tract characterized by severe myenteric and submucosal neuron depletion (Figure 2C), as identified by the reduced number of neural elements labeled by the general marker neuron specific enolase (NSE) (purchased from DakoCytomation, Milan, Italy). Furthermore, analysis of several transmitters/neuromodulators of the ENS demonstrated a marked decrease of substance P, vasoactive intestinal polypeptide, calcitonin gene-related peptide (all these antibodies were kindly donated by Dr. C. Sternini and H. E. Wong, Center for Ulcer Research and Education/Digestive Diseases Center, UCLA School of Medicine, Los Angeles, CA) and nitric oxide synthase (purchased from BD Biosciences, San Jose, CA) in the myenteric and submucosal neurons and related processes of the dilated segment compared to

the non-dilated segment and controls. In order to explore the possible abnormalities of neuronal cell survival, we used a specific antibody against the product of B-cell lymphoma-2 (*BCL-2*) (DakoCytomation, Milan, Italy), a gene encoding a protein involved in cellular pathways of neuronal apoptosis^[10,11]. Compared to the controls (Figure 2D) and the non-dilated segment (Figure 2E), *BCL-2* immunoreactivity of the dilated segment was markedly reduced in myenteric (Figure 2F) and submucosal neurons and nerve processes. The interstitial cells of Cajal (ICC), visualized by an antibody against c-Kit (DakoCytomation, Milan, Italy), were markedly decreased in the dilated segment compared to the non-dilated segment and controls. Compared to the controls, the anti- α -smooth muscle actin antibody (DakoCytomation, Milan, Italy) showed an apparently normal muscular layer both in dilated and in non-dilated segments.

Transmission electron microscopy study

Full-thickness tissue specimens were also processed for electron microscopy according to standard protocols commonly applied in our laboratory.

Compared to the controls (Figure 2G) and the non-dilated segment (Figure 2H), electron microscopy analysis of myenteric (Figure 2I) and submucosal neurons of the dilated loop showed degenerative features characterized by nuclear chromatin clumping, shrinkage of the cell body and cytoplasmic vacuoles mostly deriving from the enlargement and matrix clearing of mitochondria.

DISCUSSION

The present case illustrates the occurrence of gut failure as a result of longstanding mechanical small bowel obstruction due to a Ladd's band, which has been unrecognized for more than 10 years despite extensive radiological investigation and 3 explorative laparotomies. A Ladd's band, which arises from the posterior abdominal peritoneum and extends from the liver to the colon (passing anteriorly to the duodenum), is responsible for gut malrotation^[12]. Symptomatic patients usually present either acutely with bowel obstruction and intestinal ischemia, or chronically with vague abdominal pain. Chronic symptoms can often make diagnosis difficult, as was the case in our patient. Although Ladd's band and associated gut malrotation are more common in the first 2 wk of life^[13,14], our case provides evidence that patients having this developmental abnormality may be found in childhood.

The clinical and laboratory features of this case have expanded our knowledge on the ENS neuropathology. First, chronic intestinal partial obstruction occurring as a result of a long-standing mechanical cause (Ladd's band) evokes changes similar to those found in animal models; second, enteric neuropathologic changes observed in the advanced stage of this case could not be differentiated from the neurodegenerative findings often detected in cases of CIPO.

In the current case, early tissue analysis of dilated bowel segments (i.e., from the region which was subsequently identified as proximal to the Ladd's band) showed hyperganglionosis of the ENS. These neuronal changes,

Figure 2 Representative examples illustrating the general neuronal marker NSE (A, B, C) and *BCL-2* (D, E, F) immunoreactivities in the neuromuscular layer of a control subject (A, D), in the non dilated loop distal to the congenital obstruction of the patient (B, E) and in the dilated loop proximal to the congenital obstruction of the patient (C, F). Note the marked reduction of NSE and *BCL-2* immunoreactivities in myenteric ganglion cells and nerve fibers targeting the muscular layer observed only in the dilated loop. Streptavidin biotin immunoperoxidase technique. Calibration bar (A-F): 20 µm. Compared to controls (G) and the non-dilated segment (H), myenteric neurons of the present case (representative example in I) showed chromatin clumping, cell body shrinkage and cytoplasmic vacuolization. Uranyl acetate and lead citrate staining, transmission electron microscopy. Calibration bar (G, H, I): 2 µm.

which were reported when the patient was 5 years old, may be considered the result of adaptive phenomena to a long-standing mechanical stimulus, such as obstruction limiting bowel propulsion. Several experimental models have been instrumental in supporting the concept that adaptive changes to the ENS occur proximal to a partially obstructed gut^[5,15-21]. These studies showed increased density and size in both myenteric^[16,18,19,21] and submucosal neurons^[19-21], along with neurochemical^[18,20] and cytoskeletal abnormalities of myenteric neurons^[21]. Recently, Galvez *et al.*^[20] induced surgical stenosis (about 20% of the lumen) of rat sigmoid colon and reported changes in ENS structure after 6-12 wk. The molecular mechanisms involved in enteric neuroplasticity secondary to a partially obstructed bowel remain to be elucidated. Further, enteric neuronal changes, ICC (the pace-maker cells of the gut, which act in concert with neurons in governing gut motility) have been found to be reduced in experimental mechanical sub-occlusion of the small bowel as indicated by a decrease in c-Kit immunoreactivity and loss of functions attributed to ICC^[17,18]. In contrast, other data do not support the existence of ICC abnormalities (according to c-Kit immunostaining) in dilated gut segments of patients with Crohn's disease, a well-known cause of intestinal mechanical sub-occlusion^[22]. The possible explanations for the discrepancy between this and other studies remain to be defined.

About nine years after the initial observation of hyperganglionosis, the evaluation of new full-thickness biopsies from the dilated bowel above the stenosis showed evidence of a significant loss of both enteric neurons and ICC, which may explain the marked deterioration of the digestive function observed in our patient. Enteric neuron depletion is supported by the evidence of neurodegenerative changes detected by electron microscopy along with the reduced expression of the protein encoded by *BCL-2*,

a gene related to one of the intracellular pathways involved in the inhibition of programmed cell death^[2,3,10,11]. These findings indicate that neuronal cell loss may be due to apoptosis triggered by the persistent mechanical sub-occlusion of the gut. The neurodegenerative abnormalities observed in this phase of the clinical history of the patient may resemble ENS changes described both in humans^[23] and in an experimental model of small bowel atresia^[24]. In human intestinal atresia, Masumoto *et al*^[23] have shown hypoplasia of myenteric ganglia and marked reduction of both intramuscular nerve fibers and ICC in the dilated bowel segments above atresia. Similarly, in a chick embryo model of intestinal atresia, Schoenberg and Kluth^[24] have found an almost complete loss of both ganglionated plexuses in proximal dilated loops.

Taken together, enteric hyperganglionosis followed by degenerative changes can be considered the result of a bi-phasic adaptive process of the ENS in response to a persistent mechanical obstruction of the gut.

A further consideration which can be drawn from the present case concerns the accuracy of ENS pathology in patients with intestinal sub-occlusion. This case report clearly indicates that the enteric neuropathologic changes observed in different stages of a mechanical obstruction could not be distinguished from the neurodegenerative findings often detected in cases of CIPO. Neuropathology of CIPO includes a wide spectrum of ENS changes ranging from hyperganglionosis up to marked reduction of intramural (especially myenteric) neurons associated with swollen cell bodies, variable neurochemical abnormalities and fragmentation and loss of axons sometimes accompanied with proliferation of glial cells^[2-5]. If the mechanical obstruction remains unrecognized, as it did in our case, the ENS abnormalities mimic those identifiable in CIPO associated with an underlying neuropathy. Therefore, our case should be considered as a reminder that ENS changes observed in patients with suspected CIPO may be secondary in nature and should not necessarily be interpreted as definitive evidence for a primary neuropathy.

In conclusion, congenital (partial) mechanical obstruction of the upper small bowel leads to progressive adaptive/neuroplastic changes of the ENS similar to those described in experimental models of intestinal occlusion. Interestingly, such ENS abnormalities mimic those often observed in cases of CIPO.

Abstract

Renal cell carcinoma (RCC) is the most common renal tumor, accounting for 2%-3% of all malignancies. Though RCC is known to spread hematogenously, isolated RCC metastasis to the stomach is a rare event. In this article, we describe the clinical course of a patient who developed a pancreatic recurrence of RCC and 1 year later a gastric recurrence of RCC treated 10 years ago with a resection and interleukin-2 (IL-2).

Accumulating evidence indicates that metastatic involvement of the pancreas and stomach should be suspected in any patient with a history of RCC who presents with gastrointestinal symptoms even 10 years after RCC resection and immunotherapy.

INTRODUCTION

Renal cell carcinoma (RCC) is the most common renal tumor, accounting for 2%-3% of all malignancies^[1]. It has

the highest incidence in the 6th decade and occurs twice as often in men compared to women^[2]. Several risk factors are associated with a high risk for RCC such as tobacco smoking, obesity, exposure to asbestos or chemicals, thiazide drug intake and urinary tract infections^[3]. RCC causes only few early warning signs. The symptoms are often non-specific and the triad of Virchow consisting of an abdominal mass together with flank pain, and macroscopic hematuria is nowadays rare^[4]. RCC spreads hematogenously and is known for its ubiquitous metastatic patterns. While pancreatic localization of recurrence is quite common^[4,5], the gastric localization of recurrences of this type of tumor is quite rare. Some authors have described a recurrence of RCC in the stomach but among them only a few are well documented^[6-14].

In this article, we describe a patient who developed a pancreatic recurrence of HCC and 1 year later a gastric recurrence of RCC treated 10 years ago before with a resection and IL-2.

To our knowledge, this is the first report that describes the recurrence of metastatic RCC 10 years after a complete response to high-dose IL-2 therapy showing as a pancreatic metastasis and a year later again as a gastric metastasis.

CASE REPORT

This paper reports the history of a 68-year-old male patient. He underwent a right radical nephrectomy for RCC in 1990 followed by a high-dose IL-2 treatment. No other relevant disease was present in his past clinical history.

Ten years after the above-mentioned intervention he developed a disease recurrence involving the spleen and tail of the pancreas. He underwent a standard diagnostic work-up that included hematochemical determinations, then a splenectomy and distal pancreatectomy followed by a high-dose IL-2 therapy. No evidence of involvement of other abdominal organs was present.

One month after the last intervention, he visited the emergency room with a 10-d lasting history of polyuria and polydipsia. His physical examination was negative and hematochemical assays revealed the presence of hyperglycemia (494 mg/dL) and an increase of serum amylase (329 IU/L), while the hematocrit and differential blood counts were normal. The diagnosis was diabetes related to the recent distal pancreatectomy. He was treated with fast-acting insulin and discharged with a

Figure 1 Metastases of 1 and 3.5 cm in diameter as shown by chest X-ray.

Figure 2 An irregular mass (5 cm in diameter) corresponding to gastric metastasis, several para-aortic lymphadenopathies and liver metastatic nodules as shown by CT scan of the abdomen.

prescription of insulin. Eleven months later, he again visited the emergency room with a 3-d history of postural dizziness and weakness. He also reported melena the day before admission. The only other gastrointestinal symptom that could be elicited was early increasing satiety after meal during the pervious year. No weight loss was present. Hematochemical determinations revealed anemia (hematocrit 17.7%, hemoglobin 56 g/L) with a rise in the count of platelets (579 000/ μ L). The level of glycemia at fasting was 453 mg/dL though the patient was following his therapy. No abnormal finding was present on physical examination. A nasogastric tube was placed and fresh blood in the stomach was revealed at aspiration. The patient immediately received intravenous fluids and 3 units of blood. His hyperglycemia was treated with fast-acting insulin. The patient underwent upper gastrointestinal endoscopy showing a multilobulated, polypoid, friable, and bleeding mass (5 cm in diameter) in the gastric fundus with a central bleeding ulcer. Epinephrine was injected into the lesion and the bleeding stopped. The patient underwent a further endoscopy 3 d later and a sample of the mass was taken for biopsy. Histopathologic examination revealed a metastatic RCC which was a poorly differentiated clear cell variant lesion, being consistent with a metastasis of RCC resected 11 years ago. Chest X-ray showed two metastases with a maximum size of 1 and 3.5 cm respectively (Figure 1). Computed tomography (CT) scans of the abdomen displayed a gastric mass (5 cm in diameter), several para-aortic lymphadenopathies and liver metastases (Figure 2).

Chemotherapy was proposed to reduce the tumor size as well as the hepatic and pulmonary metastases, but the patient refused to undergo any treatment and was

1	13-years	2-year survival

RCC: Renal cell carcinoma; DFS: Disease-free survival.

discharged.

After one month, he presented again to the emergency room with postural dizziness, melena, and weakness. The patient eventually underwent surgery. The large mass described above was found in the posterior wall of the fundus and body of the stomach. It was penetrating the surrounding tissues. Many lymphadenopathies along the common hepatic artery, left gastric artery and celiac trunk were also present. Therefore, total gastrectomy was performed with lymphadenectomy and omentectomy, and esophago-jejunostomy according to the Roux technique. Histopathological examination confirmed the presence of metastatic clear RCC. Both proximal and distal resection margins appeared to be tumor free. The patient had an uneventful postoperative course.

One month after the intervention, he was started on chemotherapy with gemcitabine and IL-2. The therapy lasted for 20 mo. The patient during this period had a good quality of life. Because of the presence of abdominal pain, a treatment with morphine was started. He also received erythropoietin and iron to treat anemia. Then he received blood transfusions in the following 3 mo. The patient finally died due to the worsening of anemia and cachexia.

DISCUSSION

This paper describes for the first time an uncommon biological and clinical behavior of RCC. RCC is known to cause metastatic recurrences many years after its resection and even after immunotherapy^[14]. However, while recurrence at the pancreatic site is quite common, gastric recurrence is atypical^[15]. Metastatic involvement of the stomach is usually considered as an extraordinary event and accounts for only 0.2%-0.7% of gastric neoplastic diseases. In a large series consisting of 23 019 autopsies, Davis and Zollinger^[16] found 67 metastases to the stomach from primary tumors outside the gastrointestinal tract. None was from the kidney. Higgins^[17] reported 64 metastases in the stomach out of 31 541 examined autopsies. In this series, none was from the kidney.

An isolated gastric metastasis from RCC is extremely rare and only 15 cases including the present one have been described^[6-14]. The characteristics of all the reported cases

including our one are summarized in Table 1. From Table 1, we could see that RCC metastasizes to the stomach several years after nephrectomy.

Gastric RCC metastasis often starts as a submucosal lesion, which encroaches onto the mucosa and becomes ulcerated. The lesion may be single or multiple and is grossly polypoid or plaque-like. Metastatic tumors can be distinguished from gastric carcinoma based on the absence of cellular atypia in the gastric glandular structures which may appear compressed by the metastatic tumor. The most common presenting symptom is abdominal pain but nausea, vomiting, and gastrointestinal bleeding can also be present. Gastrointestinal bleeding is mainly related to acid erosion of the metastatic lesion. Diagnosis is confirmed by upper gastrointestinal endoscopy and histopathological examination of a biopsy sample of the lesion.

Surgical excision of gastric metastasis is mandatory as these lesions may bleed again after endoscopic coagulation treatment. A unique metastasis should be treated as a new tumor with prompt surgical excision. This often results in a significant survival prolongation with a good quality of life. In the present case, though multiple pulmonary and hepatic metastases were present, surgery had to be performed because of the high risk of rebleeding.

Compared to previously reported cases, our patient had the longest disease-free interval from the resection of RCC to the stomach metastasis as he developed recurrence at the pancreatic site 10 years after the resection of RCC and gastric metastasis 1 year later.

The prolonged disease-free time could be at least in part due to the IL-2 immunotherapy that apparently yielded a complete response. Immunotherapy with IL-2 is in fact considered as the mainstay of treatment for RCC as cytotoxic chemotherapy fails^[18]. This treatment can achieve certain effects in patients with a metastatic disease^[19]. The mechanism of action of IL-2 at the cellular level is not perfectly known. It is hypothesized that IL-2 stimulates a cellular immune response to tumor involving mainly the natural killer cells and T lymphocytes^[20]. The response rate fluctuates from 15% to 20% and complete responders account for one-third of this group^[19]. The survival time of complete responders is significantly prolonged and exceeds 60% at 5 years, while non-responders with metastatic RCC have a median survival time of less than 1 year^[19].

The present case draws attention to an important aspect of the biological behavior of RCC. This tumor is often a slow-growing lesion and may be associated with a late onset of solitary metastases that may occur even 11 years later than the primary tumor. Usually metastases grow slowly. In our patient, the first pancreatic recurrence was 1 year earlier than the gastric one. Gastric localization was undetectable when the patient underwent surgery for the first recurrence. Therefore, a careful follow-up should be made in patients who develop

a first recurrence of RCC since they may develop multiple recurrences at different sites even after several years. IL-2 therapy seems to be able to treat the disease once it spreads out but has no effect on its prevention.

Abstract

We report for the first time the possibility of weekly paclitaxel chemotherapy for a patient with advanced, nonresectable gastric cancer undergoing hemodialysis. A 50-year-old man with chronic renal failure due to bilateral polycystic kidneys, who had undergone hemodialysis three times a week for 5 years, presented with hematemesis in December 2004. Based on the diagnosis of gastric cancer with lymph node metastases, surgery was performed. On the 15th postoperative day, the patient was treated with chemotherapy using paclitaxel. Paclitaxel was administered at a dose of 60 mg/m² as a 1 h iv infusion in 250 mL of saline. Hemodialysis was started 1 h after the completion of the paclitaxel infusion and was performed for 3 h. Paclitaxel was administered weekly on d 1, 8, and 15 on a 28-d cycle. The maximum plasma concentration of paclitaxel was 1390 µg/L. The area under the curve of paclitaxel was 4398.6 µg h/L. Grade 2 leukopenia was encountered during the first cycle. The plasma concentrations of paclitaxel from 6 to over 24 h after the infusion were 0.01 to 0.1 µmol/L in our patient, and these concentrations have been shown to be effective on inhibiting the growth of gastric cancer cells without producing adverse side effects in the patient. The plasma concentration of paclitaxel was not influenced by hemodialysis. We conclude that the pharmacokinetics of paclitaxel is not altered in a patient with renal failure, and that weekly paclitaxel is a suitable treatment regimen for hemodialysis patients with advanced gastric cancer.

Kawate S, Takeyoshi I, Morishita Y. Pharmacokinetics of paclitaxel in a hemodialysis patient with advanced gastric cancer: A case report. *World J Gastroenterol* 2006; 12(32): 5237-5239

INTRODUCTION

The necessity of chemotherapy for hemodialysis patients with malignancies has increased as the life span of hemodialysis patients has grown longer because of improvements in hemodialysis. The median survival time of patients receiving the best supportive care for advanced, nonresectable gastric cancer (AGC) is only 3 to 4 mo. Some randomized studies have demonstrated the superiority of chemotherapy over best supportive care for improving patient prognosis, and the significance of performing chemotherapy for patients with AGC is now recognized^[1,2]. Although TS-1 has frequently been used for patients with AGC as a first line chemotherapy in Japan, this drug is prohibited for use in patients with renal failure because adverse reactions, such as bone marrow depression, may be enhanced. In this case report, we describe for the first time the possibility of weekly paclitaxel chemotherapy for a hemodialysis patient with AGC.

CASE REPORT

A 50-year-old man with chronic renal failure due to bilateral polycystic kidneys, who had undergone hemodialysis 3 times a wk for 5 years, presented with hematemesis in December 2004. Endoscopic examination demonstrated a large tumor on the lesser curvature of the antrum. Biopsy specimens of the tumor revealed poorly differentiated adenocarcinoma. Computed tomography of the abdomen showed enlarged lymph nodes surrounding the stomach and displayed bilateral polycystic kidneys. Based on the diagnosis of gastric cancer with lymph node metastases, surgery was performed. On entering the peritoneal cavity, peritoneal disseminations were encountered. Although a curative intervention was not possible, distal gastrectomy was performed to prevent bleeding from the cancerous lesion. On the 15th postoperative d, the patient was treated with chemotherapy using paclitaxel.

Paclitaxel was administered at a dose of 60 mg/m² as a 1 h iv infusion in 250 mL of saline. The following premedication was administered as a 60 min pretreatment prior to paclitaxel: dexamethasone, 10 mg iv; chlorphenamine, 10 mg iv; and ranitidine, 50 mg iv. Hemodialysis was started 1 h after the completion of the paclitaxel infusion and was performed for 3 h. Paclitaxel was administered weekly on

Figure 1 The plasma concentrations of paclitaxel following iv infusion. PTX: Paclitaxel; HD: Hemodialysis.

d 1, 8, and 15 on a 28-d cycle.

The plasma concentrations of paclitaxel following iv infusion are shown in Figure 1. The maximum plasma concentration (C_{max}) of paclitaxel was 1390 µg/L. The area under the curve (AUC) of paclitaxel was 4398.6 µg·h/L. Grade 2 leukopenia occurred during the first cycle. Chemotherapy had to be stopped because bleeding from the jejunum near the anastomosis occurred, in spite of the fact that the platelet count was normal during the first cycle. Unfortunately, peritonitis carcinomatosa occurred, and the patient died in April 2005.

DISCUSSION

Anticancer drugs such as 5-FU, cisplatin, and irinotecan hydrochloride are effective for gastric cancer, but in a patient with hemodialysis-dependent renal failure, the dosages of these drugs must be carefully chosen because of potential side effects arising from the increased blood concentration of these drugs. Paclitaxel is the first drug from a group of drugs that inhibit microtubule disaggregation and is extensively metabolized by the liver and secreted in bile, with less than 10% extracted by the kidneys^[3,4]. As a single agent, phase II study results on gastric cancer have demonstrated an overall response rate of approximately 15% to 20%^[5,6]. Paclitaxel has a cytotoxic effect on human gastric cancer cell lines in a dose- and time-dependent manner. Chang *et al*^[7] reported that exposure of gastric cancer cells to 0.01 µmol/L of paclitaxel for 24 h appeared to be cytotoxic. On the other hand, some investigators have reported that a paclitaxel threshold of 0.1 µmol/L was informative with respect to neutropenia, and that the total dose and AUC did not correspond with the incidence or severity of neutropenia^[8,9]. In our phase I study of weekly paclitaxel and doxifluridine in AGC patients, the recommended dose of paclitaxel was 80 mg/m² plus doxifluridine at 533 mg/m². However, the effective rate was 33.3% with no adverse events at a paclitaxel dose of 60 mg/m²^[10,11]. Therefore, we decided to use a dose of 60 mg/m² of paclitaxel for the first cycle to ensure the safety of our patient. To our knowledge, there are a small number of reports in the

literature on the treatment of advanced ovarian cancer with paclitaxel in patients with renal failure, but there are no reports of chemotherapy with paclitaxel in an AGC patient with renal failure^[12,13]. The plasma concentrations of paclitaxel at 6 to over 24 h after the infusion were 0.01 to 0.1 µmol/L in our patient, and these concentrations have been shown to be effective on inhibiting the growth of gastric cancer cells without producing adverse effects for patients. Kim *et al*^[14] reported the pharmacokinetic analysis in the treatment of relapsed breast cancer by weekly paclitaxel. In that report, the peak concentrations at 0 min (C_{max}), 30 min, and 24 h in patients treated with a dose of 60 mg/m² of paclitaxel were 2.18 ± 0.68 , 0.65 ± 0.20 , and 0.017 ± 0.012 µmol/L, respectively. These findings are similar to our results and suggest that the plasma concentration of paclitaxel is not influenced by hemodialysis.

Chemotherapy has to be stopped because of bleeding from the postoperative peptic ulcer. Neither thrombocytopenia nor coagulopathy occurs as a result of chemotherapy. We conclude that the pharmacokinetics of paclitaxel is not altered in a patient with renal failure and that weekly paclitaxel is a suitable treatment regimen for patients with AGC on hemodialysis.

Abstract

A 56-year-old woman with a 29-year history of rheumatoid arthritis (RA) was admitted to the hospital, complaining of high fever, abdominal pain and severe bloody diarrhea. Colonoscopy revealed friable and edematous mucosa with spontaneous bleeding, diffuse erosions and ulcers extending from the rectum to the distal transverse colon. Histopathological findings of rectal biopsies were compatible with ulcerative colitis (UC). Being diagnosed as having severe active left-side UC, she was successfully treated with intravenous methylprednisolone followed by prednisolone and leukocytapheresis. Laboratory tests revealed low serum and saliva IgA levels, which might play a role in the development of UC. To our knowledge, this is the first case of UC occurring during the course of RA, accompanied by selective IgA deficiency.

INTRODUCTION

Recent case reports described the development of ulcerative colitis (UC) in patients with rheumatoid arthritis (RA)^[1,2]. Although UC is commonly associated with arthritic manifestations such as ankylosing spondylitis and sacroiliitis^[3], RA complicated by UC is uncommon^[4], hence the underlying mechanisms of the association between UC and RA remain unclear. Differentiation between UC and colitis, primarily or secondarily related to RA or drug-induced colitis associated with medications for RA, can be difficult sometimes^[5].

Selective deficiency of immunoglobulin A (IgA) is the most frequent hypogammaglobulinemia^[6]. It is associated with increased risk of autoimmune diseases including RA^[6,7]. One might speculate that IgA deficiency plays a role in the mucosal immune and inflammatory responses of UC^[6]. Herein, we describe the development of UC in a patient with longstanding RA and selective IgA deficiency. To the best of our knowledge, this is the first case report on the association of RA with UC and IgA deficiency.

CASE REPORT

A 56-year-old woman who had been diagnosed with UC at a local clinic 5 mo earlier, was admitted to our hospital, complaining of high fever, exacerbated lower abdominal pain and a 4-wk duration of bloody diarrhea, despite treatment with 30 mg/d of oral prednisolone. She had suffered from RA for 29 years and the current stage and class of RA, based on Steinbrocker's classification, was IV and II, respectively. RA had been stable for the last 5 years under continuous treatment consisting of bucillamine (100 mg/d), prednisolone (5 mg/d) and D-penicillamine (600 mg/d). She had a history of adverse events of proteinuria and skin eruption with itching against bucillamine and mesalazine, respectively. She had not taken any other medications such as antibiotics, non-steroid anti-inflammatory drugs (NSAIDs) or gold salts, prior to the development of UC. She was a non-smoker, did not drink alcohol and had not undergone previous gastrointestinal surgery.

On admission, physical examination revealed body weight of 32 kg, height of 146 cm, body temperature of 37.9°C, regular pulse rate of 96/min and blood pressure of 148/76 mmHg. Conjunctiva palpebra and bulbus were

Figure 1 Barium enema shows loss of mucosal pattern with speculation, absent haustration, narrowing and shortening of the bowel, extending from the rectum to the distal transverse colon.

Figure 3 Histopathological examination of biopsied rectal mucosa showed severe neutrophil infiltration, goblet cell depletion and mild crypt abscess (hematoxylin and eosin staining).

Figure 2 (A) Sigmoidoscopy revealed friable, edematous mucosa with granularity, mucous exudates and bleeding throughout the rectum and sigmoid colon. Multiple erosions and punctate ulcers were observed without normal-appearing intervening mucosa. (B) Repeated colonoscopy before discharge revealed almost normal mucosa from the distal transverse colon to the rectum.

normal without pallor or jaundice. Heart sounds were clear with regular sinus rhythm and no rales were audible in the lung fields. The abdomen was tender on palpation in the lower quadrant with weak bowel sounds, but neither muscular guarding nor Blumberg's sign was noted. Digital rectal examination revealed dark red blood. There was no edema on the face or extremities and there were no signs of motor or sensory disturbances. Typical joint deformities and morning stiffness of RA were noted in both hands.

Laboratory investigations showed leukocyte count, $10\,900/\text{mm}^3$ (normal, $3500\text{--}9100$); platelet, $30.6 \times 10^4/\text{mm}^3$ (normal, $13.0\text{--}36.9 \times 10^4$); hemoglobin (Hb), 132 g/L (normal, 113–152); C-reactive protein (CRP), 6.6 g/L (normal, < 0.3); serum total protein, 53 g/L (normal, 65–82); albumin, 23 g/L (normal, 37–52); IgG, 16.58 g/L (normal, 8.7–17); IgA, 0.2 g/L (normal, 1.1–4.1); IgM, 0.63 g/L (normal, 0.46–2.6); rheumatoid factor, 48 000 IU/L (normal, 0–20 000); passive agglutination (RAPA), 1:80 (normal, $< 1:40$); antinuclear antibodies < 40 (normal, < 40); CH50, 23.2 g/L, (normal, 25–48); and C3, 0.63 g/L (normal, 0.86–1.6). Saliva IgA level was low at 37.6 mg/L (normal, 51.6–931). Urinalysis was normal and no infectious agents were identified in stool specimens. *Clostridium difficile* toxin was negative in feces.

Chest X-ray revealed no abnormalities such as pneumonia and interstitial pneumonitis. Abdominal plain X-ray revealed a small amount of bowel gas without formation of air-fluid level or free air and no toxic dilation of the colon was seen. Hand X-rays revealed bilateral involvement of most metacarpal phalangeal joints with destruction and deviation, whereas systemic skeletal X-ray

study showed no abnormalities in cervical and lumbar spine and hip joints. Barium enema showed disappearance of haustra coli, narrowing and shortening of the affected colon, and uneven surface with spiculation, extending from the rectum to the distal transverse colon (Figure 1). The terminal ileum and the ascending and proximal transverse colon were intact. Barium study of the small intestine and upper gastrointestinal endoscopy were normal. Contrast computed tomography of the abdomen and pelvis showed diffuse mural thickening of the affected colon. Initial sigmoidoscopy performed on the next hospitalization day revealed friable, edematous mucosa with granularity, mucous exudates and spontaneous bleeding throughout the rectum and sigmoid colon. Diffuse erosions and punctate ulcers were noted with lack of normal-appearing intervening mucosa (Figure 2A). Histopathology of colorectal biopsies showed diffuse mucosal infiltration of inflammatory cells, deformed atrophic crypts, goblet cell depletion and crypt abscess (Figure 3). No granulomas, inclusion bodies, vasculitic lesions or amyloid deposits were detected under microscopic examination of hematoxylin-eosin and Congo-red stained sections (data not shown). Based on the clinical, radiological, endoscopic, and histopathological findings, the patient was diagnosed as having severe active, left-sided UC.

Under total parenteral nutrition, she received a course of intravenous methylprednisolone pulse therapy (1 g/d for 3 consecutive days), followed by large doses of intravenous prednisolone, starting with 50 mg/d. Since cytomegalovirus antigenemia was detected 7 d after admission, she also received a 14-d course of intravenous gancyclovir injection at 400 mg/d.

She also received leukocytapheresis (LCAP) therapy, employing a commercially available leukocyte removal column (Cellsorba, Asahi Medical, Tokyo) once a week for 10 successive weeks. Such intensive treatment led to dramatic improvement of clinical symptoms and signs without any adverse reaction and to normalization of laboratory tests. Follow-up colonoscopy 3 wk later revealed marked improvement, and normal colonic mucosa at discharge from the hospital three months after admission (Figure 2B). The RA disease status was unchanged during hospitalization and thereafter. At the last visit to the outpatient clinic, 6 mo after discharge, the patient was still

in complete remission of colitis under 10 mg/d of oral prednisolone.

DISCUSSION

When colitis appears in RA patients, drug-induced colitis, ischemic colitis due to vasculitis associated with RA and secondary amyloidosis must be ruled out first^[8-12]. It is known that therapeutic agents for RA such as NSAIDs, gold salts and D-penicillamine give rise to various types of gastrointestinal complications, evidences indicate that colitic lesions are associated with these anti-RA drugs^[8-10]. Although Langer *et al*^[9] reported a case of gold salts-induced colitis resembling UC, our patient was not treated with gold salts or NSAIDs. There are also reports on D-penicillamine-induced colitis^[10], with rapid recovery after cessation of the agent. Although the patient had used penicillamine for 6 years, colitis had never appeared. Moreover, her colitis improved despite continuous use of this drug. Thus, anti-RA medications are unlikely to be the underlying cause of colitis in our patient.

Rheumatoid vasculitis (also known as malignant RA) affects a variety of organs including kidneys, lungs and gastrointestinal tract^[13]. Previous studies indicate that clinically apparent rheumatoid vasculitis occurs in less than 1% of RA patients and intestinal involvement is noted in about 20% of such cases^[11]. The gastrointestinal lesions associated with rheumatoid vasculitis are characterized by multiple sharply-defined ulcers, typically spared by normal-appearing mucosa, with a predilection for the small intestine, the sigmoid colon and cecum^[8,11]. Burt *et al*^[11] described a patient with RA who had colonic vasculitis presenting as pancolitis similar to UC. In that patient, however, repeated colonoscopy following treatment with prednisolone showed that the intervening mucosa among superficial ulcers was normal, allowing differentiation of colitis due to RA-related vasculitis from idiopathic UC. Histopathological examination of multiple biopsies taken from colorectal mucosa identified no vasculitic lesions in our patient, who showed no other vasculitic diseases such as scleritis and interstitial pneumonitis^[13,14].

Recent clinical studies have indicated that the incidence of amyloidosis confirmed by biopsies in RA patients is about 10%^[12]. Kato *et al*^[15] reported a suggestive case of gastrointestinal amyloidosis secondary to RA manifested as pancolitis resembling UC. In our patient, however, rectal biopsy specimens showed diffuse infiltration of mono- and poly-nuclear leukocytes and crypt abscess, which were compatible with UC, but no intramucosal amyloid deposits. In addition, neither microbiological nor histopathological examinations showed any pathognomonic findings in this case, thus allowing differentiation between UC and other possible inflammatory bowel conditions.

Being diagnosed as having severe active UC extending to the left-side colon, the patient was treated with intravenous methylprednisolone and subsequently with prednisolone. Given that the patient had already received oral prednisolone even at 30 mg/d with exacerbation of UC, she was also treated with LCAP. In previous studies, LCAP frequently led to significant improvement of UC that had been intractable to steroids^[16,17]. A recent open-

label multicenter study demonstrated that LCAP can be more effective than high-dose steroid treatment with fewer adverse effects^[17]. Currently, LCAP is used as a treatment modality for active UC. Although histopathological examination of colorectal biopsies showed no inclusion bodies, cytomegalovirus antigenemia was detected, allowing our patient to undergo additional treatment with intravenous gancyclovir. We believe that the intensive combination therapies led to complete clinical and endoscopic remission of severe and steroid-refractory colitis.

Arthritic manifestations represent the most common extraintestinal manifestations of inflammatory bowel diseases, affecting 31% and 36% of patients with UC and Crohn's disease, respectively^[5]. Coexistence of RA and UC is, however, rare and no more than 0.14% to 0.8% of UC patients suffer from RA^[4,18]. Larger population-based studies are warranted to unravel the mechanisms underlying the association between UC and RA. In this regard, accumulation of HLA data may provide a potential clue for this relationship^[19].

In the present case, serum concentrations of IgA, but not IgG or IgM, were constantly low ranging from 1 to 20 mg/dL and reduction of secretory IgA in saliva was also noted during hospitalization. Systemic and local reduction of IgA might result in weakening of the mucous barrier against intestinal flora and enhance exposure of the mucosal immune system to intestinal bacteria or the toxic components, eventually leading to sustained inflammation within the colorectal mucosa^[4]. However, the precritical serum IgA level had not been estimated in our patient, and the etiology of selective IgA deficiency remains elusive as to whether it occurred primarily or not. In fact, secondary IgA deficiency may be caused by such anti-RA drugs as D-penicillamine, steroids, both of which had been prescribed for her RA, sulfasalazine and gold salts^[7,20].

Liblau *et al*^[6] reported that the frequency of autoimmune diseases in IgA deficient patients ranged from 7 to 36%, supporting the notion that selective IgA deficiency may be a risk factor of organ-specific and systemic autoimmune diseases. A recent study showed that the prevalence of IgA deficiency in RA patients was quite low (0.3%)^[6], whereas Badcock *et al*^[7] reported that IgA deficient patients were more likely to have a history of RA in the first-degree relatives, suggesting inheritance of predisposing factor(s). Of note, Snook *et al*^[4] reported that 6.6% of UC patients had at least one autoimmune disorder and the prevalence of a specified group of autoimmune disorders was three times greater than expected in patients with UC.

In conclusion, we described the first case of RA, complicated with UC and selective IgA deficiency. Underlying immune dysfunction, possibly in addition to genetic predisposition, might play a role in these associations.

Abstract

Assigning causality in drug-induced liver injury is challenging particularly when more than one drug could be responsible. We report a woman on long-term therapy with raloxifene who developed acute cholestasis shortly after starting fenofibrate. The picture evolved into chronic cholestasis. We hypothesized that an interaction at the metabolic level could have triggered the presentation of hepatotoxicity after a very short time of exposure to fenofibrate in this patient. The findings of an overexpression of vascular endothelial growth factor in the liver biopsy suggest that angiogenesis might play a role in the persistence of toxic cholestasis.

INTRODUCTION

Fibrates are extensively prescribed for patients with pri-

mary hypertriglyceridemia. Raloxifene, a selective estrogen receptor modulator that prevents bone resorption without causing endometrial or breast cancer, is effective in the treatment of osteoporosis in postmenopausal women. Both agents are widely used in clinical practice, thus posing an increased likelihood of their concomitant prescription. Although hepatotoxicity is a rare phenomenon associated with their use^[1-3], we report a patient on long term therapy with raloxifene who developed prolonged cholestatic hepatitis shortly after the introduction of fenofibrate.

CASE REPORT

A 60-year-old woman was started on raloxifene hydrochloride (60 mg/d) in 2000 for the prevention of osteoporosis. On December 1st 2003 she was prescribed fenofibrate (250 mg/d) for hypertriglyceridemia (triglyceride level 423 mg/dL). Her liver function was normal and she had no toxic habits, no drug allergies and was not taking other drugs. There was no family history of cholestatic and non-cholestatic diseases of the liver and biliary tract. She did not suffer from diabetes mellitus or pancreatitis and was moderately obese (BMI 26.7). On December 14th she noticed dark urine and both drugs were discontinued, no attempt of drug reintroduction was recorded. On admission (December 16), she was afebrile and jaundiced. Aspartate aminotransferase (AST) was 153 U/L (normal < 30), alanine aminotransferase (ALT) 241 U/L (normal < 36), alkaline phosphatase (AP) 174 U/L (normal < 104), gamma-glutamyltransferase (GGT) 271 U/L (normal < 32), and total bilirubin 11.07 mg/dL with direct bilirubin 9.6 mg/dL. The leucocyte count was $3.3 \times 10^9/L$ with 17.7% lymphocytes. Serology ruled out viral causes and screening for autoantibodies was negative. Imaging testing including a magnetic resonance cholangiography showed cholelithiasis with no other pathological findings (i.e. gallstones, tumour). A liver biopsy showed a moderate inflammatory infiltrate of lymphocytes with hepatocellular cholestasis and focal necrosis. Immunohistochemistry showed that expression of vascular endothelial growth factor (VEGF) (clone C-1, Santa Cruz Biotechnology, IC, USA) resulted in mild to moderate granular staining in hepatocytes of zone 3 (Figure 1A). Immunohistochemical staining was performed as previously described^[4]. Ten days later a morbiliform and very pruriginous rash appeared in the lower extremities that progressively generalized to the trunk, upper extremities and face.

Liver enzymes decreased initially but on January 20, 2004, the total bilirubin peaked at 21.84 mg/dL (direct

Treatment was stopped on 14 December 2003. Total bilirubin ($n < 1.8$ mg/dL); AST: Aspartate aminotransferase ($n < 30$ U/L); ALT: Alanine aminotransferase ($n < 36$ U/L); GGT: Gamma-glutamyl transpeptidase ($n < 32$ U/L); Alkaline phosphatase ($n < 104$ U/L); lymphocytes ($n = 20\%-40\%$); VEGF: Plasma vascular endothelial growth factor.

Figure 1 A: The first liver biopsy in December 2003 showing mild to moderate granular stain in hepatocytes of zone 3; B: The second liver biopsy in February 2004 showing diffuse VEGF stain with predominance of zone 3 (original magnification 200 x).

bilirubin 19.7 mg/dL), with increases in ALT, GGT and AP values (Table 1). Lymphocytes were 0.077×10^9 /L (5.9%). The multifomed erythema worsened at this time with subsequent resolution. In February, a second liver biopsy was performed (Figure 1B). The liver specimen showed intense hepatocellular and canalicular cholestasis, mainly in zone 3, with mild to moderate lymphocytic infiltrate in portal tracts (one of them with focal interface hepatitis). Biliary ducts were absent in three out of the 7 portal tracts present in the biopsy. In this biopsy VEGF showed diffuse positivity which was more intense in zone 3, and Kupffer cells were also reactive. At this time, EDTA plasma VEGF levels (determined using a commercially available ELISA kit, R&D Systems, MN, USA) were 144 pg/mL (healthy subjects levels < 80 pg/mL)^[5]. On July 1, 2004, ALT was 91 U/L, AP 1195 U/L, GGT 1279 U/L, and total bilirubin 0.72 mg/dL. Plasma VEGF values increased to 244 pg/mL. ALT, GGT and AP levels still remained high 21 mo after the initial episode (Table 1).

DISCUSSION

Assigning a causal relationship to a drug associated with hepatic injury remains a major challenge, especially when it is the first report of a particular reaction and when more than one drug could be the culprit. If treatments are not started simultaneously, common sense and causality assessment methods tend to incriminate the last drug introduced, as the fenofibrate in our patient. Actually,

fenofibrate scored higher than raloxifene when the CIOMS scale was applied to yield 9 and 6 points which fell in the category of highly probable and probable, respectively.

However, this issue may not always be so straightforward and other considerations should be born in mind. Acute hepatitis is rarely related to fenofibrate and the reported cases do not reflect the type of injury that is presented here. Most cases present with hypergammaglobulinemia and high titers of anti-nuclear antibodies, and on liver biopsies a lympho-plasmocytic infiltrate, resembling type I auto-immune hepatitis, is evident^[1]. The chronic forms of liver damage are more exceptional, usually appearing after long periods of exposure. They show different histopathological findings such as chronic active hepatitis with bridging necrosis or a reduction in the number of interlobular bile ducts in a clinically asymptomatic patient^[2]. On the contrary, the only published case of raloxifene-associated hepatitis did exhibit a late peak of bilirubin one month after drug withdrawal^[3], similarly to our patient.

To our understanding, this patient suffered from hepatic toxicity due to an interaction between raloxifene and fenofibrate that could result in liver toxicity by altering the threshold for exposure to toxic metabolites. Both compounds are highly protein bound to albumin with the potential of competitive drug displacement^[7], and an irreversible inhibition of CYP3A4 by raloxifene has been described which is more frequently associated with unfavorable drug-drug interactions^[8,9].

The prolonged course of the abnormalities in liver biochemistry deserves further consideration. Indeed, an immune mechanism is suggested in the patient by the presence of a severe toxic cutaneous reaction and cytopenia. In these circumstances, a self propagating immune response may persist, which might explain the outcome^[6].

An interesting finding in this case was the over-expression of VEGF (the most potent proangiogenic growth factor) in the liver and increased plasma VEGF levels, when the clinical and biological picture was in remission and the hepatic lesion evolved into a chronic

cholestatic phase. This suggests that angiogenesis may be an important mechanism involved in the persistence of toxic cholestasis which is up-regulated in response to tissue damage and release of pro-inflammatory cytokines. This has been recently shown in primary biliary cirrhosis^[10]. Indeed, angiogenesis is a novel mechanism involved in chronic liver damage and its role in drug-induced liver injury also deserves to be defined.

In summary, an interaction between raloxifene and fenofibrate may occur in a postmenopausal woman with resulting hepatotoxicity. Clinicians should be aware of this adverse reaction and patients should be followed up closely. Clinical judgment of the attribution of causality must be made, especially in particularly troublesome cases in which major drug metabolism mechanisms and the potential for pharmacokinetic drug interactions should always be kept in mind.

Abstract

Bone metastases are rare in primary hepatocellular carcinoma (HCC). Spinal cord compression (SCC) due to bone metastases occur commonly in patients with lung and breast carcinomas, and metastatic HCC is an unusual cause of SCC. Spinal cord compression is an oncologic emergency and treatment delays can lead to irreversible consequences. Thus, the awareness that SCC could be a potential complication of bone metastases due to HCC is of significance in initiation of early treatment that can improve the quality of life and survival of the patients, if diagnosed earlier. This paper describes four cases of primary HCC with varied manifestations of SCC due to bone metastases. The first patient presented primarily with the symptoms of bone pains corresponding to the bone metastases sites rather than symptoms of associated hepatic pathology and eventually developed SCC. The second patient, diagnosed as having HCC, developed extradural SCC leading to paraplegia during the course of illness, for which he underwent emergency laminectomy with posterior fixation. The third patient developed SCC soon after the primary diagnosis and had to undergo emergency laminectomy. Post laminectomy he had good neurological recovery. The Fourth patient presented primarily with radicular pains rather than frank paraplegia as the first manifestation of SCC.

INTRODUCTION

Hepatocellular carcinoma (HCC) is the most common primary tumor of the liver and has a mean survival of less than one year after primary diagnosis, if left untreated^[1]. Extra-hepatic spread of HCC occurs commonly to the lungs (37%-70%) and regional lymph nodes (23%-45%)^[1]. The reported incidence of bone metastases is comparatively low (2%-20%)^[2-5]. However, an incidence of 28% of bone metastases from HCC has been reported by Katyal *et al*^[1]. The most frequent sites of bone metastases reported by Kuhlman *et al* were ribs, spine, femur, pelvis and humerus^[2]. Spinal cord compression (SCC) is a rare event in the natural course of metastatic HCC as evidenced by Bharat Kantharia *et al* in their study on HCC^[6]. Review of literature shows only a few patients with HCC who developed radiculopathy or SCC secondary to bone metastases. SCC is an oncologic emergency and awareness that SCC could be a potential complication of bone metastases, can improve the survival and quality of life of these patients, if treated promptly. We herein report four cases of pathologically confirmed primary HCC with spinal metastases who developed extradural SCC.

CASE REPORTS

Case 1

A 55-year-old normotensive, nondiabetic, non-alcoholic man with no history of chronic liver disease, presented with the complaints of low backache and generalized weakness for 20 d. Clinically, he had tenderness in the presacral region. Further investigations revealed normal hematology and biochemical parameters. Magnetic resonance imaging (MRI) of the whole spine showed a tumor deposit in the presacral area. Whole body 99 mTc bone scan revealed increased radiotracer uptake in right ilium, sacrum including both sacroiliac joints and D3 vertebra. Computerised Tomography (CT) guided biopsy and fine needle aspiration cytology (FNAC) from the presacral tumor were consistent with the metastatic

Figure 1 Tru cut biopsy of liver lesion showing increased trabecular thickness, cellular pleomorphism with vesicular nuclei. Sinusoids are lined by flat endothelial cells, Kupffer cells are absent.

Figure 3 FNAC of vertebral metastasis showing cellular monomorphism, moderate pleomorphism with occasional intranuclear inclusion.

Figure 2 A: Sagittal MR image of cervicodorsal spine showing vertebral lesions with most prominent D3 vertebral lesion (arrow); B: Post contrast sagittal T1W SE MR image of the same patient showing lesion involving S2, S3 vertebrae (arrow) with associated large soft tissue component; C: T1W SE axial post contrast MR image showing right lateral epidural soft issue enhancing component (arrow) causing cord compression.

poorly differentiated neoplasm. Serum alpha feto protein (AFP) level was more than 500 IU/mL (normal AFP level < 10 IU/mL). Ultrasound of testis, upper GI endoscopy, CT chest scan were unremarkable but CT scan of the abdomen revealed a large well defined hypodense lesion, 7.5 cm × 5.8 cm in dimensions with areas of necrosis, in the right liver lobe, in segment V, with no involvement of the portal vein. Additionally there was a destructive lesion in the right ala of the sacrum associated with a bulging soft tissue component, 5.3 cm × 3.9 cm in dimensions, which corroborated with MRI spine and bone scan findings. The patient underwent CT guided FNAC and Tru-cut biopsy of the right liver lobe lesion. Histopathological examination (HPE) was suggestive of poorly differentiated primary HCC, showing increased trabecular thickness and cellular pleomorphism with vesicular nuclei (Figure 1). Viral marker profile was positive for Hepatitis B surface antigen (HbsAg) and was non-reactive to hepatitis C virus. He was diagnosed as having primary HCC with bone metastases. The option of palliative chemotherapy was declined by the patient and he was started on palliative external beam radiotherapy (EBRT) to the right pelvis in view of pain. He developed acute onset paraplegia along with urinary retention shortly after initiation of EBRT. Immediate intravenous Solumedrol and other supportive measures were taken. Whole spine MRI was done and revealed multiple vertebral metastases at D2-D3, L1, L5, S1, S3

vertebral levels (Figure 2A and 2B) and epidural deposits with extradural cord compression at D2 and D3 vertebrae (Figure 2C). FNAC from vertebral metastases (Figure 3) revealed metastatic carcinoma consistent with primary HCC. Decompression and fixation surgery was suggested, but the family did not opt for any surgical intervention. He continued to receive EBRT for SCC. Although, there was symptomatic improvement in the pain intensity, there was no significant improvement in the neurological status. After further discussion with the family, oral chemotherapy was performed with Capecitabine and Thalidomide with no response after two cycles. Despite prompt treatment of SCC with steroids and EBRT, the patient succumbed to the disease five months after primary diagnosis.

Case 2

A 52-year-old non-alcoholic man presented with complaints of heaviness and discomfort in the right upper abdomen of two months duration. Whole abdomen ultrasound done elsewhere was suggestive of liver mass. Clinical examination revealed presence of mild hepatomegaly. Laboratory investigations showed a normal hematological profile and mild derangement of liver function tests (LFTs). Viral marker profile was positive for HbsAg and non-reactive to HCV. Whole abdomen CT scan revealed mild hepatic enlargement with an ill-defined hypodense lesion of 3.8 cm in diameter, in segment V and VI of the liver with no involvement of portal vein. His AFP levels were 3540 IU/mL. Magnetic resonance cholangio pancreatography (MRCP) revealed a nodular outline and texture of liver consistent with cirrhosis, with a focal lesion in segment V and VI, measuring 3.5 cm × 4.0 cm × 4.1 cm. He underwent CT guided FNAC from right liver lobe mass which was suggestive of primary HCC. Whole body 99 m Tc bone scan revealed no evidence of bone metastases. He was diagnosed as having primary HCC with no evidence of extra-hepatic spread. He underwent hepatic segmentectomy. HPE of the resected specimen of liver segment revealed poorly differentiated HCC with cirrhosis and regenerative nodules. CT scan of the abdomen after surgery as a part of reevaluation revealed a new focal hypodense lesion measuring 2.4 cm × 2.5 cm, in the caudate lobe of the liver and another

ill defined hypodense lesion in the right lobe of the liver with an expansile lesion with soft tissue component in the right seventh rib. Whole body 99 mTc bone scan showed irregular radiotracer uptake in the right seventh rib anterolaterally. He underwent FNAC from right seventh rib, which revealed metastatic deposit of HCC. There was a rise in serum AFP level from 3540 IU/mL at the time of diagnosis to 7920 IU/mL, suggestive of relapse. He received palliative chemotherapy with Gemcitabine and Cisplatin. CT scans after three cycles of chemotherapy revealed complete regression of caudate lobe, right liver lobe and right seventh rib lesion with a new development of a well defined lytic lesion in L2 vertebra. He also had pain in the right hip joint. Chemotherapy was continued with the same protocol for three more cycles. Subsequent CT chest scan revealed development of a new lesion in the left third rib with destruction of the left transverse process of D3 vertebra along with erosion of D5 vertebra. CT guided FNAC from the third left rib lesion was positive for malignant cells, consistent with primary in liver. He received palliative EBRT to the symptomatic areas like right hip joint, C7 to D7 vertebrae and L1 to L4 Vertebrae. One month later, he developed paraplegia with complete loss of bladder and bowel control. MRI of Dorso-lumber spine was suggestive of metastatic lesion at dorsal and lumbosacral spine with cord compression at the D6 vertebral level. The patient underwent D5 to D6 laminectomy with posterior fixation. HPE of laminectomied specimen was reported as metastatic carcinoma consistent with primary HCC. Postoperatively there was no significant improvement in the paraplegia and he did not regain bladder and bowel control. He was supported with intravenous steroids, bisphosphonates and physiotherapy. After laminectomy, although palliative EBRT was planned to the dorsal spine, (D4 to D7) vertebrae and to the lower dorsal spine, his general condition deteriorated and he succumbed to his illness 11 mo after the primary diagnosis.

Case 3

A 70-year-old man who was alcoholic, diabetic and a smoker, presented with complaints of pain in the right side of the chest. Clinical examination revealed mild hepatomegaly and pallor. Whole abdomen CT scan revealed left liver lobe mass suggestive of primary HCC with portal vein thrombosis and abdominal lymphadenopathy. He underwent MRCP and MR angiography, which revealed a soft tissue lesion in the left lobe of the liver with portal vein thrombosis and abdominal lymphadenopathy, with no signs of cirrhosis of liver. His hematological and biochemical profile were within normal range. HbsAg and HCV were not reactive in viral marker profile. His serum AFP level was 250 IU/mL. Tru-cut biopsy of left liver lobe lesion was consistent with the diagnosis of HCC. Whole body 99 mTc bone scan revealed no evidence of bone metastases at the time of diagnosis. Chemotherapy was given with Gemcitabine and Capecitabine. After the second cycle, he had sudden onset of weakness of bilateral lower limbs. Neurological examination revealed paraplegia with sensory loss below D5 level with moderate sphincteric involvement. Whole spine MRI showed extradural cord compression at D4 and

D5. Whole body 99 mTc bone scan revealed abnormal areas of radiotracer uptake in D4 and D5 vertebrae, consistent with bone metastases. Emergency D1 to D4 vertebral laminectomy was performed with posterior fixation from C7 to D5 vertebrae. HPE of laminectomied specimen showed metastasis from HCC. He received EBRT to the spine along with aggressive physiotherapy and with other supportive measures after surgery. He achieved good neurological and symptomatic recovery, and was discharged in the hemodynamically stable condition. As the patient was not willing to receive further treatment, he was followed up on palliative supportive care. However, he succumbed to the disease four months after the diagnosis.

Case 4

A 62-year-old normotensive, non diabetic, nonalcoholic man presented with complaints of pain in neck and lower back of one month duration. Pain radiated from neck to fingers bilaterally. He also had difficulty in walking due to radicular pain. Clinical examination revealed painful neck movement and mild hepatomegaly. Hematological profile was normal mild derangement of liver enzymes. Both HbsAg and HCV were non-reactive. Whole abdomen ultrasound revealed a well defined solid mass, measuring 8.4 cm × 4.9 cm, in the right lobe of the liver, with heterogeneous echotexture. Upper abdomen CT scan also revealed enlarged liver with a large hypodense lesion, measuring 10.5 cm × 10.1 cm, in the right lobe of the liver. Whole spine MRI was suggestive of multiple bone metastases in C5-C6, D9, D11-D12 and L4 vertebrae and the bodies of D9 and L4 vertebrae revealed wedge compression fracture. A small anterior epidural space soft tissue collection was also present, causing compression of the thecal sac at L4 vertebral level. Whole body 99 mTc bone scan revealed increased radiotracer uptake in D7, D9, D11-D12 and the L4 vertebrae, sacrum and bilateral sacroiliac joints, suggestive of bone metastases. He underwent CT guided FNAC from right liver lobe mass which revealed primary HCC. FNAC from vertebra was consistent with metastasis from primary HCC. Serum AFP level was elevated to 121 IU/mL at the time of diagnosis. He was diagnosed as having primary HCC with multiple bone metastases with SCC, manifesting primarily as radiculopathy. The patient and the family were given the options of surgical decompression as well as chemotherapeutic management, which they were not inclined for in view of disseminated disease. Hence, he was started on palliative EBRT to L2-L5 vertebrae and to C4-C7 vertebrae. EBRT to the thoracic spine was performed later. After completion of radiotherapy (RT) there was symptomatic improvement in the pain intensity. However, after EBRT, there was progression of SCC leading to development of paraparesis with urine incontinence. He was managed conservatively in view of deteriorating general condition. He died from his illness three months after the primary diagnosis.

DISCUSSION

HCC is the most common solid organ tumor with a high mortality^[2]. Most patients with HCC present with right upper quadrant pain or an abdominal mass due to the

presence of hepatomegaly^[7,8,9]. Rarely though, the patients may have initial symptoms related exclusively to the extra-hepatic metastases^[6]. Serum AFP level is the most useful serum tumor marker for primary HCC. Serum AFP level is elevated in most of the patients, which is highly specific for a tumor larger than three cm in diameter, and also is of prognostic value as rise after initial effective chemotherapy or surgery suggests a relapse^[3]. This was evident from the fact that AFP level was elevated in all our cases and relapse occurred after hepatic segmentectomy in the second patient corresponded to the elevation of AFP levels.

Extra-hepatic spread from HCC is not uncommon and reported to be 30%-78% at autopsy examination. Bone metastases are rare with an incidence of only about 2%-20%^[2-5,10,11]. Although incidence of metastasis of HCC to the bones is low, recent reports have shown an increasing incidence and is estimated to be about 28%^[1].

The most frequent sites of the bone metastases are ribs, spine, femur, pelvis and humerus according to Khulman *et al*^[2]. Patients with bone metastases most often present with pain as the principal symptom^[3,7]. Two of our patients presented with the chief complaints of backache. Very rarely patient may present with bone pains without any symptom of underlying hepatic pathology, as seen in our first case.

In the majority of cases, vertebral body metastases result from hematogenous dissemination of tumor which is evident by the vertebral column bone marrow involvement^[6,10]. Radiologically, bone metastases from HCC appear osteolytic on plain films. All the four patients in our series had osteolytic lesions. They are destructive, expansive and often associated with large soft tissue masses^[2-6,10]. Conventional radiography is however, not a very sensitive modality for the diagnosis of early bone metastases as the cancellous part of the bone is usually the first site of bone metastases and cortical part of the bone is responsible for most of the bone density depicted on plain X-Ray films^[6]. For the same reason the bone scan is also less sensitive. MRI is most helpful for early diagnosis as well as delineation of the extent of metastases^[2,6].

The histological appearance of the bone metastases from primary HCC is similar to that of the primary tumor, with positive bile staining^[2,4]. Recent insight into the causation of bone metastases of HCC has been correlated with angiogenesis^[8]. Significant hemorrhage from metastatic lesions is reported to occur either spontaneously or after biopsy of the lesion^[2].

The level of vascular endothelial growth factor (VEGF) has been reported to be elevated in HCC with bone metastases^[8]. VEGF, the most important angiogenic factor, has been shown to stimulate bone resorption through its effects on osteoclasts^[8,12]. Thus in the era of targeted therapy, VEGF could be an important target for the treatment of these tumors. In their study on metastatic HCC, S. Kummar *et al* have evaluated TNP-470, a derivative of fumagillin and a potent angiogenetic inhibitor, as a treatment for experimentally induced HCC in animal models^[8]. Similarly, the serum levels of C-terminal telopeptide of type 1 collagen are also significantly elevated in patients with bone metastases^[13].

The overall frequency of the malignant SCC has been

reported to be approximately 5% in cancer patients. In approximately 95% of cases, SCC is caused by extradural metastases from tumors involving the vertebral column. Thoracic spine (70%) is most commonly involved as compared to the lumbosacral (20%) and the cervical spine (10%)^[12,14]. Three cases reported by us had SCC at thoracic vertebrae level and all of them had extradural compression. Although SCC is rare with HCC, the symptoms and involvement are similar to other primary tumors, commonly leading to SCC, such as lung, breast and prostate cancer.

Omura *et al* in 1989 described a case of a 57-year-old male with primary HCC diagnosed when he developed paraplegia secondary to a SCC due to vertebral tumor. After laminectomy, the tumor histology was reported to be metastatic HCC^[15]. Kantharia *et al* in 1993, also described a case of radiculopathy and rapidly developing SCC, due to bone metastases and diagnosed as HCC at autopsy^[6]. Pinazo Seron *et al* in 1999 reported a case of a 55-year-old man, who had alcoholic cirrhosis and HCC. This patient developed SCC due to soft tissue epidural metastases, seated at the paravertebral zone. Plain radiography and bone scan were normal and diagnosis was achieved by MRI and FNAC^[16]. Cho *et al* in 2002 reported a case of pathologically confirmed HCC who developed lower leg weakness, which was found to be due to spinal metastases as evidenced by MRI spine. This patient received emergency radiotherapy (RT) and recovered from SCC^[17]. Melicher *et al* in 2002 also described a case of asymptomatic liver mass of uncertain histology of one year duration. He presented with back pain and developed signs of SCC, and he underwent laminectomy, which established the diagnosis of metastatic HCC^[18].

Cord compression occurs due to invasion of epidural space, most often as a direct extension of vertebral body metastases. There are various routes of the epidural invasion by tumor cells, hematogenous being the most common mode of spread. Hematogenous spread occurs directly or *via* the involvement of Batsons venous plexuses^[19].

In metastatic SCC, back pain is not only the most common symptom but also the earliest manifestation of SCC, as seen in two of our patients. First sign after development of pain is weakness due to myelopathy. Once lost, neurological functions cannot be regained in most of the patients^[12,20,21].

Though various modalities such as plain radiography, CT scan, CT-myelography and MRI can be used to evaluate SCC, whole spine MRI is the best method of evaluating epidural SCC. Apart from being most sensitive, cost-effective and noninvasive, MRI is also helpful in distinguishing between benign and malignant causes of SCC^[20,21]. In all our patients, SCC was diagnosed with the help of MRI spine, which revealed the site of extradural cord compression with precision. Presently CT-myelography is used only for patients in whom MRI is contraindicated^[21].

The pre-treatment degree of neurologic dysfunction is the strongest predictor of therapeutic outcome. However, the most important weapon against the prevention of devastating complications of SCC is the high index

of suspicion and the awareness that SCC is a potential oncologic emergency^[20]. Thus the development of any new pain or any change in the character of the pain mandates complete neurological examination along with MRI whole spine as a screening modality to rule out early signs of SCC^[21].

The treatment modalities available for SCC are individualized with a definite role of corticosteroids, RT, chemotherapy and surgery. Corticosteroids act by relieving edema and help preserve neurological function. They may also improve overall outcome after specific therapy^[19,22,23].

RT is an important part of the management of SCC and it helps in pain relief, cytoreduction of tumor, prevention of progressive neurologic dysfunction and structural damage to the cord. RT reduces pain in approximately 70%, improves motor function in 45% to 60%, and reverses paraplegia in 11% to 21% of the patients. The outcome of RT is related to the neurological status prior to the treatment and the radiosensitivity of the tumor. RT should also be given following surgery in patients who have not previously received radiation^[24-27]. Our third patient was given EBRT to the affected region after emergency posterior laminectomy was performed.

Surgical interventions are usually indicated in situations where the diagnosis is unknown, in cases of spinal instability or compression by the bone requiring prompt relief of pressure related symptoms^[12,20,27]. These four cases suggest that surgery should be the integral part of SCC management in HCC. Our first patient immediately received RT after developing SCC, with no improvement in neurological status, and in the second patient, SCC developed at the vertebra which was earlier irradiated. RT did not help prevent paraparesis in the fourth patient. Whereas, the third patient who underwent emergency laminectomy followed by EBRT had best palliation. Surgery should also be considered in the patients who fail to respond to RT or deteriorate further while on RT and the patients who have received maximal allowable radiation dose to the spinal cord^[12,20]. The surgical approach should be determined based on the location of vertebral involvement and the direction of compression^[20]. The two main surgical approaches used for decompression are laminectomy with posterior fixation and anterior decompression of the spine with reconstruction. Anterior decompression of the spine with mechanical stabilization has been accepted as the surgical intervention of choice for anterior vertebral body involvement^[21,28]. Our second and third patient underwent posterior laminectomy for emergency decompression without any immediate morbidities. But the aim is to diagnose SCC in the early stage so that emergency decompressive surgery will not be needed.

CONCLUSION

Extra-hepatic spread of HCC is usually to the lungs and regional lymph nodes, but rarely to the bones. SCC due to vertebral bone metastases is a rarer phenomenon. SCC is an oncologic emergency and treatment delay can lead to irreversible consequences. These four cases highlight unusual metastatic presentation of HCC, in the form of

bone metastases resulting in SCC. High index of suspicion is required to achieve good outcome in patients who are at risk to develop SCC secondary to bone metastases. Thus, any change in the character of already existing bone pain or new development of pain mandates a complete neurological examination along with MRI of the whole spine to rule out cord compression. Although, radiation, steroids and surgery can be used as treatment modalities, surgery followed by EBRT can result in better palliation. But the aim is to diagnose SCC at an early stage so as to prevent the devastating consequences of this complication.

Abstract

We report a case of fulminant hepatic failure associated with *Salmonella paratyphi A* infection, in a 29-year-old patient who was admitted to the intensive care unit (ICU) with fever of two days, headache and vomiting followed by behavioural changes and disorientation. On examination, the patient appeared acutely ill, agitated, confused, and deeply jaundiced. Temperature 38.5°C, pulse 92/min, blood pressure 130/89 mmHg. Both samples of blood grew *S. paratyphi A*, which was sensitive to ceftriaxone and ciprofloxacin. Ceftriaxon was administered with high-dose dexamethasone. Two weeks after treatment with ceftriaxon, the patient was discharged in satisfactory condition.

INTRODUCTION

Fulminant hepatic failure is a dramatic clinical syndrome characterized by massive necrosis of liver cells^[1]. It is caused by acute viral hepatitis A, B, C, D, E (40%), other viruses, drugs, Weil's disease, Wilson's disease, acute fatty liver in pregnancy, ischemic hepatitis, acute Budd-Chiari, malignant infiltration or bacterial infection including *salmonella*.

Although salmonella hepatitis is a rare presentation of typhoid fever, fulminant hepatic failure is extremely uncommon, few cases were reported with such presentation.

To our knowledge, this is the first reported case of fulminant hepatic failure in the state of Qatar, associated with *Salmonella paratyphi A* infection.

CASE REPORT

A 29-year-old Nepali male patient admitted to the intensive care unit (ICU) through accident and emergency (A&E) department with fever for two days, headache and vomiting followed by behavioral changes and disorientation. The patient returned back from his country two months ago. No other history of possible relevance was found. On examination, the patient appeared acutely ill, agitated, confused, and deeply jaundiced. Temperature was 38.5°C, pulse 92/min, and blood pressure 130/89 mmHg. Examination of the nervous system showed a disoriented patient, moving all his limbs, with incoherent speech and negative meningeal signs. Examination of the abdomen revealed mild splenomegaly. Chest and heart were unremarkable. Hemoglobin level was 150 g/L, total leucocyte count 5000/ μ L (60% neutrophils, 31% lymphocytes) and adequate number of platelets. Blood chemistry showed aspartate aminotransferase (AST) level of 966 IU/L, alanine amino-transferase (ALT) 176 IU/L, alkaline phosphatase 267 IU/L, total bilirubin 180 μ mol/L, direct bilirubin 109 μ mol/L, total proteins 74 g/L, albumin 38 g/L, urea nitrogen 3 mmol/L, creatinine 44 μ mol/L, sodium 135 mEq/L and potassium 3.6 mEq/L, bicarbonate 22 mmol/L, Ca 2.2 mmol/L, ammonia level 100 μ mol/L (normal up to 50 μ mol/L), prothrombin time 30.8 s and an international normalized ratio (INR) of 3.1. Macroscopic and microscopic examination of urine and stool were normal. Viral markers for hepatitis A, B, C, Monospot test and cytomegalovirus serology were negative. Antismooth muscle antibody and antimithochondrial antibody were negative. Peripheral smear for malaria was negative on several occasions. Lumbar puncture was done, and CSF study was normal.

Computerized tomography (CT) scan of the head with intravenous contrast was normal. Electroencephalography showed findings suggestive of metabolic encephalopathy. Chest X ray was normal. Ultrasonography of abdomen revealed enlarged spleen. Rest of abdomen including liver, gall bladder, and kidney were all within normal limits.

A CT scan of the abdomen, with intravenous contrast showed moderate spleen enlargement and liver enlargement with homogeneous parenchyma. There was no evidence of abscess or tumor. No evidence of mass or fluid collection was seen in the abdomen or pelvis. Kidneys and

Table 1 Laboratory data on admission and discharge

	Alanine amino- transferase (ALT)	Aspartate aminotrans- ferase (AST)	Alkaline phosphatase (ALP)	Total bilirubin
On admission day	176 IU/L	966 IU/L	267 IU/L	180 μ mol/L
On discharge day	65 IU/L	105 IU/L	110 IU/L	33 μ mol/L

pancreas were within normal limits. Echocardiography was normal. Magnetic resonance image (MRI) of the abdomen with MR cholangiography showed peri-portal edema within the liver and collapsed gall bladder, suggesting the possibility of hepatitis.

The patient was admitted to the ICU as a case of fulminant hepatic failure evidenced by marked elevation of hepatocellular enzymes, prolonged prothrombin time, hyperbilirubinemia and hyperammonaemia. The patient was given vitamin K and fresh frozen plasma to correct the prolonged INR, and Lactulose (enema and oral). Broad-spectrum antibiotic and high dose dexamethasone (3 mg/kg loading dose over 30 min, followed by 1 mg/kg every six hours for two days) were initiated. Cultures of urine were sterile and no pathogen was isolated from stool culture.

However, both samples of blood grew *S. paratyphi A*, which was sensitive to ciprofloxacin and ceftriaxone. Once the culture report was available the treatment was changed to ceftriaxone 2 gm twice daily. After one week of therapy, the patient was afebrile and oriented, and the dose of ceftriaxone was reduced to 2 gm daily for one more week. Two weeks after treatment with ceftriaxone, the liver enzymes dropped obviously (Table 1). Consequently, the patient was discharged in satisfactory condition.

DISCUSSION

Typhoid fever may be an important cause of illness and death for centuries, although historical accounts do not clearly distinguish it from other febrile illnesses. It has been implicated in the death of Alexander the Great, in 323 B.C.^[2]

The causative organism widely spreads in all parts of the world, although the disease is more prevalent in developing countries than in developed ones. The most common cause of typhoid fever is *Salmonella enterica* serotype typhi, although salmonella of other serotypes, particularly *Salmonella enterica* serotype paratyphi A, can cause a similar enteric fever. *Salmonella enterica* serotype typhi has no animal reservoir.

In typhoid, involvement of liver is a consistent feature^[3,4]. Typhoid hepatitis is a rare presentation of typhoid fever, clinically suspected in patients with persistent fever, hepatomegaly and jaundice and especially in cases whose liver function tests show predominantly conjugated hyperbilirubinemia, modest elevation of liver enzymes and negative serology for viral hepatitis^[5,6].

The differential diagnosis of fever in the icteric phase of hepatitis, include: viral hepatitis, malaria hepatitis, Weil's disease, typhoid hepatitis, autoimmune hepatitis and drug

induced hepatitis.

In this patient, viral markers for hepatitis A, B, C, Monospot test and cytomegalovirus serology were negative. Peripheral smear for malaria was negative on several occasions. Antismooth muscle antibodies (Ab) and antimitochondrial Ab were negative and whether the patient had taken any hepatotoxic drugs was unknown.

The common complications of typhoid fever include relapse, perforation and hemorrhage from bowel ulcerations^[3]. Extreme hepatic dysfunction with hepatic encephalopathy is a rare coexisting complication in salmonella hepatitis.

The pathogenesis of severe hepatic involvement in salmonella infection may be multifactorial, involving endotoxin, local inflammatory and/or host immune reactions.

In typhoid hepatitis, liver biopsy would have shown pathognomonic lobular aggregates of Kupffer's cells-so-called typhoid nodules, but liver biopsy was not performed in this case^[2].

Although, viral markers for hepatitis E and leptospiral test were not made in this case, the diagnosis of fulminant hepatic failure due to *S. paratyphi A* was based mainly on three facts: first, positive blood culture for *S. paratyphi A*; second, elevated alkaline phosphatase level, aspartate aminotransferase (AST) level higher than alanine aminotransferase (ALT), and only mild prolongation of the prothrombin time^[7]; and third, excellent response to ceftriaxone and dexamethasone^[7].

The most important aspect of treatment for typhoid fulminant hepatic failure is to provide good intensive care support, recognize the condition promptly and initiate early dexamethasone and proper antibiotics. Monitoring the complications and instituting appropriate therapy are also critical.

The current drug of choice for adults is ciprofloxacin, which combines little documented resistance with excellent penetration into macrophages and the biliary system. This may lower the rate of relapse and chronic carrier states. Alternative antibiotics can be used if sensitivities are known or suspected resistance is low^[8]. The current drug of choice for children and pregnant women is parenteral ceftriaxone^[9].

Thus, in patients from endemic areas, typhoid hepatitis should be considered in the differential diagnosis of fulminant hepatic failure since early institution of specific therapy in these cases yields a good prognosis.

Abstract

Necrotizing fasciitis is a devastating soft tissue infection affecting fascias and subcutaneous soft tissues. Literature reviews have identified several related risk factors, including malignancy, alcoholism, malnutrition, diabetes, male gender and old age. There are only scanty case reports in the literature describing its rare association with colorectal malignancy. All published cases are attributed to bowel perforation resulting in necrotizing fasciitis over the perineal region. Isolated upper or lower limb diseases are rarely identified. Simultaneous upper and lower limb infection in colorectal cancer patients has never been described in the literature. We report an unusual case of multi-limb necrotizing fasciitis in a patient with underlying non-perforated rectal carcinoma.

INTRODUCTION

Necrotizing fasciitis is a devastating soft tissue infection affecting fascias and subcutaneous soft tissues^[1]. Two distinctive clinical entities are recognized: hyperacute and subacute variants^[2]. Hyperacute necrotizing fasciitis usually manifests as a rapidly progressing infection with resultant multi-organ failure due to group A streptococcus or clostridium species^[3]. Contrarily, polymicrobial infection is implicated in subacute necrotizing fasciitis that represents a slowly evolving disease with less fulminant systemic complications^[4]. Regarding its etiology, necrotizing soft tissue infection can be secondary to trauma, wound

infections, perianal or urogenital abscesses, decubitus ulcers or idiopathic in origin^[5]. Malignancy, alcoholism, malnutrition, diabetes, male gender and old age are general risk factors associated with necrotizing fasciitis^[6,7]. There are only scanty case reports in the literature describing its rare association with colorectal malignancy^[8-13]. All these cases are attributed to bowel perforation resulting in necrotizing fasciitis over the perineal or abdominal region. Isolated upper or lower limb diseases are exceedingly uncommon. Multi-limb necrotizing fasciitis is even rarer. We report here the first case of multi-limb involvement of necrotizing fasciitis in a patient with underlying rectal carcinoma.

CASE REPORT

A 56-year-old male patient, who had a medical history of alcoholic cirrhosis, poorly-controlled diabetes mellitus and mild renal impairment, presented with an one-month history of per rectal bleeding. Digital rectal examination revealed a non-obstructing rectal tumour situated at 8 cm above the anal verge. Tumour biopsy was taken through proctoscope and the histology confirmed it to be an adenocarcinoma. No abdominal discomfort or increase in per rectal bleeding was reported after the procedure. However, one day after the tumour biopsy, he complained of bilateral lower limb pain over the pre-existing ankle edema. He denied any previous history of trauma. No wound or skin abrasions could be identified over both lower limbs. In addition to the swollen lower limbs, he was noticed to have unexplained sinus tachycardia (pulse rate 100 per min) despite normal haemodynamic status and oxygen saturation. Examination of other organ systems was unremarkable. The arterial blood gas, white cell counts, chest radiograph and electrocardiogram were normal. Though Doppler ultrasound did not show any evidence of deep vein thrombosis in both lower limbs, low molecular weight heparin was commenced as pulmonary embolism was not excluded.

His clinical condition rapidly deteriorated over the next 24 h when he developed acute on chronic renal impairment, hypotension and worsening metabolic acidosis that necessitated inotropes and hemodialysis support in the intensive care unit. Urgent ultrasound of the abdomen did not reveal any evidence of obstructive uropathy. He became hypothermic (core temperature 32°C), drowsy and mentally confused. Blood parameters revealed marked leukocytosis and disseminated intravascular coagulation. Empirical intravenous antibiotics including augmentin (amoxycillin and clavulanate), clindamycin and metronidazole were commenced in view of the clinical

features of sepsis. Shortly after his stay in the intensive care unit, blisters (Figure 1) were discovered on both swollen lower limbs. Necrotizing fasciitis was suspected and ultimately confirmed with surgical exploration 12 h after the appearance of blisters. Initially, fasciotomy and excisional debridement were endeavored in an attempt to preserve the lower limbs. Meanwhile, high dose penicillin was introduced to replace augmentin. Nevertheless, the worsening clinical sepsis and migratory soft tissue necrosis inevitably resulted in bilateral above knee amputation. Microbiological cultures of blood and necrotic tissues invariably grew group G streptococcus only. Histological examination of the excised tissue also confirmed the diagnosis of necrotizing fasciitis. One day afterwards, similar features of skin changes developed over both upper limbs (Figure 2) that required repeated excisional debridements. In spite of limb amputation, surgical debridement and parenteral antibiotics, he developed fulminant group G streptococcal septicaemia and deteriorated rapidly until he succumbed to multi-organ failure six days after the onset of sepsis. Throughout his disease course, the perineum, groin and abdominal wall remained uninvolved.

DISCUSSION

In the English literature, there are only six reported cases of necrotizing fasciitis associated with colorectal malignancy (Table 1). In these cases, necrotizing fasciitis was all preceded by perforation of colorectal tumours. All except two cases^[8,10-12] presented as Fournier's gangrene.

One case manifested as psoas abscess with spreading infection to the thigh after retroperitoneal perforation of a sigmoid tumour^[9]. The other one involved the anterior abdominal wall as a result of direct tumour invasion and perforation from the transverse colon^[13]. In essence, perforated colorectal tumours represent an entry focus for bacterial translocation that might penetrate the subcutaneous soft tissues, leading to necrotizing infection^[14]. To our knowledge, our patient is the first reported case of disseminated necrotizing fasciitis affecting all limbs in a non-perforated rectal tumour.

With regard to its etiology, we postulate three causes for such a fulminating disease in our patient. First, chronic subcutaneous tissue edema due to cirrhotic hypoalbuminaemia predispose him to subcutaneous tissue infection^[6]. In addition, systemic immunosuppression could well be secondary to the cumulative effects of malignancy, diabetes mellitus and cirrhosis^[7]. Lastly, transient bacteraemia might have arisen as a consequence of bacterial translocation emanated from occult necrosis of his rectal tumor^[14]. Interestingly, there was a close temporal association between tumour biopsy and the onset of necrotizing sepsis in our patient. Transient bacteraemia following endoscopic tissue biopsy has been reported^[15]. However, Gram negative organisms were the main bacteria retrieved and it was elusive to verify the causative association between rectal biopsy and necrotizing soft tissue infection in our patient.

So far as the bacteriological origin was concerned, group G streptococcus was the only culprit in our patient. In 1935, Lancefield, an American microbiologist, first

described a Gram positive facultative anaerobic coccus as group G streptococcus that constitutes parts of the normal flora of human skin, respiratory tract and gastrointestinal tract^[16-18]. Although it has been rarely implicated in necrotizing fasciitis^[19], its associated mortality could be comparable to those induced by streptococcus pyogenes^[20], suggesting that group G streptococcus, being a normal flora of the gastrointestinal tract, could represent a potentially life-threatening pathogen for all patients^[20].

Regardless of the disparity in pathological and microbiological etiologies, the mortality rate of necrotizing fasciitis remains high. High index of suspicion and prompt surgical intervention are the cornerstone of treatment for improving the disease outcome^[7]. We believe that delay in diagnosis and surgical treatment contributes to the demise of our patient.

Key words: Columnar lined esophagus; Barrett esophagus; Gastroesophageal reflux disease

Lenglinger J, Ringhofer C, Riegler FM. Cardiac mucosa indicates risk for Barrett esophagus. *World J Gastroenterol* 2006; 12(32): 5259

<http://www.wjgnet.com/1007-9327/12/5259.asp>

TO THE EDITOR

With interest we read the article by Bani-Hani *et al*^[1] entitled "Pathogenesis of columnar-lined esophagus", which has been published in the recent issue of *World Journal of Gastroenterology*. The review profoundly adds to our understanding of columnar-lined esophagus (CLE) and clearly indicates that CLE represents an acquired condition and develops as a consequence of gastroesophageal reflux disease (GERD)^[1]. However, it should be pointed out that inclusion of CLE-histopathology helps to define those at risk for dysplastic and malignant transformation. Histopathology characterizes *nondysplastic* and *dysplastic* (low-, high grade dysplasia) CLE^[2-4]. Going in line with the *Paull-Chandrasoma* classification^[2], *nondysplastic* CLE includes oxyntocardiac mucosa, cardiac mucosa, multilayered epithelium (a mixture of basal layer of squamous epithelium and cardiac mucosa) and cardiac mucosa with goblet cells (i.e.

intestinal metaplasia; *Barrett* esophagus, BE). In contrast to cardiac mucosa, goblet cells have never been detected within oxyntocardiac mucosa^[2,3]. Consequently, following a 4-quadrant biopsy protocol of the esophagogastric junction (including squamous and gastric type mucosa, irrespective of the presence or absence of endoscopic CLE) presence of oxyntocardiac mucosa in all biopsies indicates absence of risk to progress towards intestinal metaplasia and dysplasia^[2,3]. In contrast to that, presence of cardiac mucosa indicates risk to undergo intestinal metaplasia and progress towards dysplasia and adenocarcinoma of the esophagus (annual incidence for BE 0.2%-2.0%). Controversy still exists if CLE is esophageal or gastric. Normally the esophagus is lined by squamous epithelium and the stomach is covered by oxyntic mucosa. Recently Chandrasoma *et al*^[4] showed that CLE, but not oxyntic mucosa, is present above submucosal glands and adjacent to submucosal gland ducts. Since submucosal glands are absent in the stomach, CLE is considered to be esophageal, irrespective of endoscopic appearance^[2-4]. Taken together, CLE represents the morphologic consequence of GERD. GERD should be included into histopathologic routine. Hopefully, future studies will evaluate the incidence and prevalence of CLE subtypes in the normal population for identification of those at risk for intestinal metaplasia and adenocarcinoma of the esophagus.

ACKNOWLEDGMENTS

Acknowledgments to Reviewers of *World Journal of Gastroenterology*

Many reviewers have contributed their expertise and time to the peer review, a critical process to ensure the quality of *World Journal of Gastroenterology*. The editors and authors of the articles submitted to the journal are grateful to the following reviewers for evaluating the articles (including those were published and those were rejected in this issue) during the last editing period of time.

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (WJG, *World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly journal of more than 48 000 circulation, published on the 7th, 14th, 21st and 28th of every month.

Original Research, Clinical Trials, Reviews, Comments, and Case Reports in esophageal cancer, gastric cancer, colon cancer, liver cancer, viral liver diseases, etc., from all over the world are welcome on the condition that they have not been published previously and have not been submitted simultaneously elsewhere.

Indexed and abstracted in

Current Contents/Clinical Medicine and Science Citation Index-Expanded, *Index Medicus*, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, Nature Clinical Practice Gastroenterology and Hepatology, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

Published by

The WJG Press

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297 mm × 210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures and Figure Legends. Neither the editors nor the Publisher is responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part without the written permission of both the authors and the Publisher. We reserve the right to put onto our website and copy-edit accepted manuscripts. Authors should also follow the guidelines for the care and use of laboratory animals of their institution or national animal welfare committee.

Authors should retain one copy of the text, tables, photographs and illustrations, as rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for the loss or damage to photographs and illustrations in mailing process.

Online submission

Online submission is strongly advised. Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/index.jsp>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. Authors encountering problems with the Online Submission System may send an email, describing the problem to wjg@wjgnet.com for assistance. If you submit your manuscript online, do not make a postal contribution. A repeated online submission for the same manuscript is strictly prohibited.

Postal submission

Send 3 duplicate hard copies of the full-text manuscript typed double-spaced on A4 (297 mm × 210 mm) white paper together with any original photographs or illustrations and a 3.5 inch computer diskette or CD-ROM containing an electronic copy of the manuscript including all the figures, graphs and tables in native Microsoft Word format or *.rtf format to:

Editorial Office

World Journal of Gastroenterology

Editorial Department: Apartment 1066, Yishou Garden,
58 North Langxinzhuan Road,
PO Box 2345, Beijing 100023, China
E-mail: wjg@wjgnet.com
<http://www.wjgnet.com>
Telephone: +86-10-85381901
Fax: +86-10-85381893

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using a word-processing software. All submissions must be typed in 1.5 line spacing and in word size 12 with ample margins. The letter font is

Tahoma. For authors from China, one copy of the Chinese translation of the manuscript is also required (excluding references). Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was accomplished, disclosure of any financial support for the research, and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (removing all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s) and full family name.

Abstract

An informative, structured abstract of no more than 250 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipments, and the experimental procedures should be included. RESULTS: The observatory and experimental results, including data, effects, outcome, etc. should be included. Authors should present *P* value where necessary, and the significant data should accompany. CONCLUSION: Accurate view and the value of the results should be included.

The format of structured abstracts is at: <http://www.wjgnet.com/wjg/help/11.doc>

Key words

Please list 6-10 key words that could reflect content of the study mainly from *Index Medicus*.

Text

For most article types, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both.

Illustrations

Figures should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. No detailed legend should be involved under the figures. This part should be added into the text where the figures are applicable. Digital images: black and white photographs should be scanned and saved in TIFF format at a resolution of 300 dpi; color images should be saved as CMYK (print files) but not as RGB (screen-viewing files). Place each photograph in a separate file. Print images: supply images of size no smaller than 126 mm × 76 mm printed on smooth surface paper; label the image by writing the Figure number and orientation using an arrow. Photomicrographs: indicate the original magnification and stain in the legend. Digital Drawings: supply files in EPS if created by freehand and illustrator, or TIFF from photoshops. EPS files must be accompanied by a version in native file format for editing purposes. Existing line drawings should be scanned at a resolution of 1200 dpi and as close as possible to the size where they will appear when printed. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes of atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...

Tables

Three-line tables should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each table. No detailed legend should be included under the tables. This part should be added into the text where the tables are applicable. The information should complement but not duplicate that contained in the text. Use one horizontal line under the title, a second under the column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. ^a*P*<0.05, ^b*P*<0.01 should be noted (*P*>0.05 should not be noted). If there are other series of *P* values, ^c*P*<0.05 and ^d*P*<0.01 are used. Third series of *P* values can be expressed as ^e*P*<0.05 and ^f*P*<0.01. Other notes in tables or under illustrations should be expressed as ¹*F*, ²*F*, ³*F*; or some other symbols with

a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, etc. in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions are included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should code the references according to the citation order in the text in Arabic numerals, put references codes in square brackets, superscript it at the end of citation content or the author name of the citation. For those citation content as the narrate part, the coding number and square brackets should be typeset normally. For example, Crohn's disease (CD) is associated with increased intestinal permeability^[1,2]. If references are directly cited in the text, they would be put together with the text, for example, from references [19,22-24], we know that...

When the authors code the references, please ensure that the order in text is the same as in reference part and also insure the spelling accuracy of the first author's name. Do not code the same citation twice.

PMID requirement

PMID roots in the abstract serial number indexed by PubMed (<http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed>). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information of the journal citations is very important. Through reference testing system (<http://www.wjgnet.com/cgi-bin/index.pl>), the authors and editor could check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in ASP file so that the readers can read the abstract of the citations online immediately.

Style for journal references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). Title of the cited article and italicized journal title (Journal title should be in its abbreviation form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634]

Note: The author should test the references through reference testing system (<http://www.aushome.cn/cgi-bin/index.pl>)

Style for book references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Patent (list all authors)

- 16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those that are linked with a hyphen and the difference between the two numbers at two sides of the hyphen is more than 5. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered as inappropriate references. Authors should not cite their own unrelated published articles.

Statistical data

Present as mean \pm SD or mean \pm SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as γ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p*(B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4 \pm 2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5 μ g/L; CO₂ volume fraction, 50 mL/L CO₂ not 5% CO₂; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format about how to accurately write common units and quantum is at: <http://www.wjgnet.com/wjg/help/15.doc>

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further mention.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kbo I*, *Kpn I*, etc.

Biology: *H pylori*, *E coli*, etc.

SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. Author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, the final check list for authors, and responses to reviewers by a courier (such as EMS) (submission of revised manuscript by e-mail or on the *WJG* Editorial Office Online System is NOT available at present).

Language evaluation

The language of a manuscript will be graded before sending for revision.

(1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing; (4) Grade D: rejected. The revised articles should be in grade B or grade A.

Copyright assignment form

Please download CAF from <http://www.wjgnet.com/wjg/help/9.doc>.

We certify that the material contained in this manuscript:

Ms:

Title:

is original, except when appropriately referenced to other sources, and that written permission has been granted by any existing copyright holders. We agree to transfer to *WJG* all rights of our manuscript, including: (1) all copyright ownership in all print and electronic formats; (2) the right to grant permission to republish or reprint the stated material in whole or in part, with or without a fee; (3) the right to print copies for free distribution or sale; (4) the right to republish the stated material in a collection of articles or in any other format. We also agree that our article be put on the Internet.

Criteria for authorship: The *WJG* requests and publishes information about contributions of each author named to the submitted study. Authorship credit should be based on (1) direct participation in the study, including substantial contributions to conception and design of study, or acquisition of data, or analysis and interpretation of data; (2) manuscript writing, including drafting the article, or revising it critically for important intellectual content; (3) supportive work, including statistical analysis of data, or acquisition of funding, or administration, technology and materials support, or supervision, or supportive contributions. Authors should meet at least one of the three conditions. The *WJG* does not publish co-first authors and co-corresponding authors.

We hereby assign copyright transfer to *WJG* if this paper is accepted.

Author Name in full (Full names should be provided, with first name first, followed by middle names and family name at the last, eg, Eamonn MM Quigley). Handwritten names are not accepted.

Author Name in abbreviation (Family name is put first in full, followed by middle names and first name in abbreviation with first letter in capital, eg, Quigley EMM). Handwritten names are not accepted.

Final check list for authors

The format is at: <http://www.wjgnet.com/wjg/help/13.doc>

Responses to reviewers

Please revise your article according to the comments/suggestions of reviewers. The format for responses to the reviewers' comments is at: <http://www.wjgnet.com/wjg/help/10.doc>

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Publication fee

Authors of accepted articles must pay publication fee.

EDITORIAL and LETTERS TO THE EDITOR are free of charge.
