Contents

World Journal of Gastroenterology (*World J Gastroenterol , WJG*), a leading international journal in gastroenterology and hepatology, has an established reputation for publishing first class research on esophageal cancer, gastric cancer, liver cancer, viral hepatitis, colorectal cancer, and *Helicobacter pylori* infection, providing a forum for both clinicians and scientists, and has been indexed and abstracted in *Index Medicus*, MEDLINE, PubMed, Chemical Abstracts, EMBASE, Abstracts Journals, Nature Clinical Practice Gastroenterology and Hepatology, CAB Abstracts and Global Health. *WJG* is a weekly journal published by The *WJG* Press. The publication date is on 7th, 14th, 21st, and 28th every month. The *WJG* is supported by The National Natural Science Foundation of China, No. 30224801 and No.30424812, which was founded with a name of *China National Journal of New Gastroenterology* on October 1,1995, and renamed as *WJG* on January 25, 1998.

Abstract

Symptoms of functional dyspepsia are characterized by upper abdominal discomfort or pain, early satiety, postprandial fullness, bloating, nausea and vomiting. It is a chronic disorder, with symptoms more than 3 mo per year, and no evidence of organic diseases. Dysfunctional motility, altered visceral sensation, and psychosocial factors have all been identified as major pathophysiological mechanisms. It is believed that these pathophysiological mechanisms interact to produce the observed symptoms. Dyspepsia has been categorized into three subgroups based on dominant symptoms. Dysmotility-like dyspepsia describes a subgroup of patients whose symptom complex is usually related to a gastric sensorimotor dysfunction. The brain-gut peptide cholecystokinin (CCK) and serotonin (5-HT) share certain physiological effects. Both have been shown to decrease gastric emptying and affect satiety. Furthermore the CCK induced anorexia depended on serotonergic functions probably acting via central pathways. We believe that abnormalities of central serotonergic receptors functioning together with a hyper responsiveness to CCK or their interactions may be responsible for the genesis of symptoms in functional dyspepsia (FD).

Key words: Functional dyspepsia; Cholecystokinin; Serotonin; Gastric emptying

INTRODUCTION

The term dyspepsia defies definition, although it is widely used in clinical practice. It comes from the Greek word, dys meaning bad and peptein meaning digestion. It causes much confusion among both patients and clinicians. Dyspepsia itself is not a diagnosis but stands for a constellation of symptoms referable to the upper gastrointestinal tract. A recent working party has recommended that dyspepsia refers to pain or discomfort centered in the upper abdomen (ROME II) [1]. Pain is the unpleasant sensation mainly in or around the midline. Discomfort may be characterized by early satiety, fullness, abdominal bloating, belching, nausea, retching and vomiting. When dyspeptic patients have no underlying identifiable disease process to account for their symptoms, then they are considered to be suffering from functional dyspepsia (FD). FD runs a chronic course and the Rome II criteria states that symptoms have to be present for at least 12 wk, which need not be consecutive, in the preceding 12 mo. The symptoms are persistent or recurrent and not associated with a change in bowel pattern or stool form.

FD is a heterogeneous condition and not all patients present with the same symptoms. The patients may be divided into subgroups based on their symptoms cluster. 3 major subgroups are recognized: Ulcer-like dyspepsia, dysmotility-like dyspepsia and nonspecific dyspepsia. Dysmotility-like dyspepsia describes a subgroup of FD patients whose symptom complex seems to suggest a relation to feeding and involvement of an underlying gastric sensory or motor disorder. The pathogenesis of this common disorder remains unclear but probably involves multiple pathophysiological mechanisms with complex interactions involving the enteric nervous system, the afferent sensory pathways and the brain, the so called brain-gut axis. There appears to be disturbed motor functions with altered visceral sensations and a strong association to psychosocial factors. Present opinion is that FD is a biopsychosocial disorder where dyspeptic symptoms may arise from these interactions[2].

The brain-gut peptide CCK and brain-gut indolamine 5-HT share some physiological effects. 5-HT is involved in gut motility, visceral sensation and other aspects of gut function while CCK is involved in mediation of pain in the gut and nociception in the central nervous system (CNS). CCK and fenfluramine (increases neuronal release of 5-HT) both slow gastric emptying and block stress induced hyperphagia[3-7]. Both neurotransmitters have been

independently implicated as factors affecting food intake [8,9]. Peripheral and central administration of CCK and fenfluramine produces anorexia in both humans and animals. The CCK induced anorexia depended on serotonergic function, probably at central sites[10]. Furthermore intravenous CCK administration stimulates the release of 5-HT and noradrenaline in the paraventricular and supraoptic nuclei, both important in central modulation of feeding and gastrointestinal motility [11].

Stressful events in life are known to alter ingestive behaviors and associated physiological events such as gastric acid secretion and gastrointestinal motility. Evidence also implicated corticotrophin releasing factor (CRF) in the mediation of stress-induced inhibition of upper gastrointestinal (GI) tract and stimulation of lower GI motor function. Endogenous 5-HT, peripherally released in response to stress, seems to be involved in the central CRF-induced effect on the GI tract[12,13]. Acute psychological stress, if produces significant emotional change may lead to an increase in sensitivity to experimental visceral stimuli. Whether chronic stress has the same effects remain to be seen.

The symptom complex described in dysmotility-like FD is usually related to feeding and also suggests an underlying abnormal GI sensory and motor function. There is an indirect correlation between severity of early satiety and gastric emptying rate, as well as an association between bloating and delayed gastric emptying[58]. Severe postprandial fullness and vomiting are independently associated with delayed gastric emptying of solids[19]. Since the neurotransmitter 5-HT and the neuropeptide CCK have been implicated in the regulation of feeding and the control of GI function, they may play an important role in the pathophysiology of functional dyspepsia.

ROLE OF SEROTONIN IN FUNCTIONAL DYSPEPSIA

Serotonin is a monoamine that acts as both a peripheral transmitter in the gut and a neurotransmitter in the brain[14,15]. Within the enteric nervous system (ENS), 5-HT is stored in myenteric neurons and acts as a neurotransmitter[16,17]. It plays an important role in regulating peristalsis and intestinal tone and thought to be one of the most important gut neurotransmitters. Sumatriptan, a 5-HT1 receptor agonist, inhibits antral motor activity, delays gastric emptying and relaxes the gastric fundus[18]. Intravenous injection of 5-HT in dogs have been observed to modulate gastric emptying, and furthermore gastric emptying can be inhibited by injecting fenfluramine into the cerebral ventricles of rats[20,21]. The primary neuronal effect of fenfluramine includes release of 5-HT from nerve terminals and inhibition of reuptake. Some serotonergic drugs induce anorexia through central pathways[22]. Warner suggested that some cases of functional abdominal pain are due to hyperserotoninemia[23]. Furthermore the hyperserotoninaemia of the carcinoid syndrome causes nausea, vomiting, colicky abdominal pain and diarrhea[24]. The majority of patients with FD are however not hyperserotoninemic. Nonetheless, altered sensitivity of 5-HT receptors might have similar consequences as high levels of serotonin. Interestingly, the functional activity of central serotonergic receptors can be studied using a neuroendocrine challenge test.

Neuroendocrine challenge test

The neuroendocrine axis provides an acceptable means of assessing brain 5-HT receptor function. The development of neuroendocrine challenge tests rest on the demonstration that the release of certain anterior pituitary hormones is controlled by brain monoamine pathways. Thus , monoamine function can be assessed by measurement of the hormonal response in plasma which follows stimulation of a particular brain monoamine pathway by a specific drug [25]. The size of the hormonal response is taken as an index of the functional activity of the monoamine synapses with which the drug interacts. It is apparent that for a neuroendocrine challenge test to provide a valid measure of brain 5-HT function, it must demonstrate that the hormone measured is indeed under the control of brain 5-HT pathways and that the drug employed to produce the hormonal response is acting specifically through 5-HT synapses. The release of prolactin (PRL) from the anterior pituitary is under the inhibitory control of dopamine and stimulatory control of 5-HT[25]. When hypothalamic receptors are stimulated by an appropriate 5-HT agonist, an increase in serum PRL takes place, via stimulation of a PRL releasing factor by 5-HT neurons originating in the medial and dorsal raphe nuclei.

Buspirone, an azaspirodecanedione, stimulates central 5-HT1A receptors at the hypothalamic level and brings about PRL release in a dose dependent manner[26,27]. Its effects can be blocked by the antagonist methysergide and pindolol, a specific 5-HT1A receptor blocker. It crosses the blood brain barrier easily and has a rapid onset of action. The extent of prolactin release can thus be used reliably as a measure of central 5-HT1A receptor sensitivity.

The response to the buspirone challenge test in FD patients was compared to normal healthy subjects and patients with peptic ulcer disease[63,64]. Considerable greater prolactin responses were found in FD patients than in healthy controls or PUD patients (Figure 1A). The mean (+/- SEM) increase in plasma PRL after buspirone in male FD patients was 672.2 +/- 65.0 Mu/L, in contrast to male healthy controls with 222.9 +/- 59.9 Mu/L. The corresponding results for female FD and controls are 1428.8 +/- 232.5 Mu/L and 352.5 +/- 33.8 Mu/L respectively. The mean PRL response for the PUD group was 325+/- 91.1 Mu/L. A highly significant difference was obtained when the FD patients was compared to the healthy controls (males; $P<0.05$, females; $P<0.001$). Differences between the responses became apparent around 60 minutes (Figure 1B). There is a significant difference in the prolactin response to Buspirone challenge, between males and females. Why is there such a difference is still not very clear. There is also evidence to suggest that, the prolactin response in females, varies at different times in the female menstrual cycle. All the neuroendocrine challenges were carried out at the same period of the cycle. Interestingly, gastric emptying rates have also being observed to be influenced by the menstrual cycle[74]. This may explain the fact

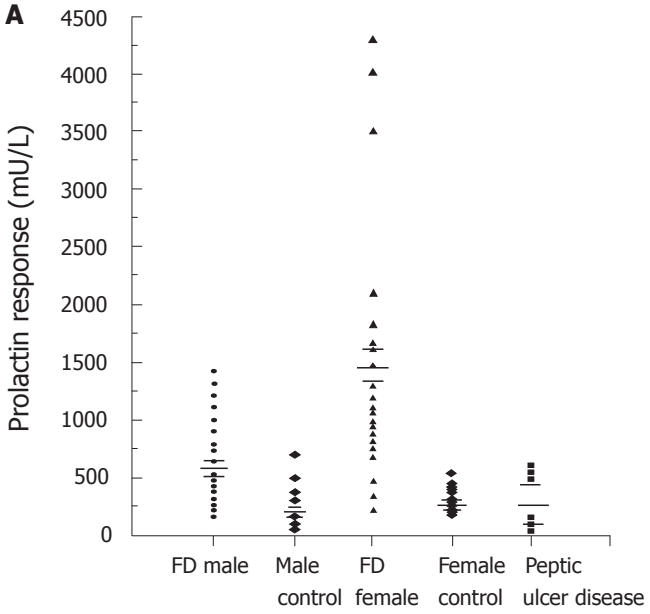

Figure 1A Prolactin response to buspirone challenge in healthy controls and patients with functional dyspepsia and peptic ulcer disease

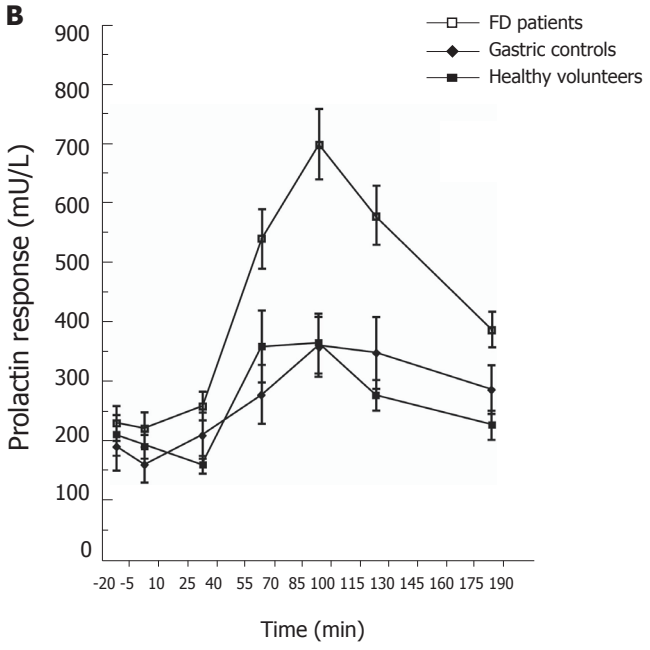

Figure 1B Prolactin response to buspirone 60 mg in male functional dyspeptics, peptic ulcer disease patients and healthy controls.

why FD, is more common in women and generally their symptoms are more severe compared to man. Our results indicated that central serotonergic receptors are considerably more sensitive in FD patients and provide evidence that FD is a disorder characterized by a neurochemical dysfunction in the brain.

Serotonin neuronal system of the brain have been postulated to modulate many basic physiological tasks, including gating of pain perception, control of eating and GI sensorimotor functions. An abnormal central 5-HT receptor function may interfere with any one or all of the above functions. Interference with the pain gating system may affect patients perception to pain or give rise to an abnormal response to nociception from visceral receptors. Fenfluramine, a 5-HT releasing agent and reuptake inhibitor, reduces hunger ratings, delays onset of feeding and provokes termination of a bout of eating. The presence of hypersensitive central serotonergic receptors would function in the same manner as an increase release of 5-HT. Interestingly, FD patients are known to have abnormal feeding behavior with symptoms that are related to meals. Furthermore, gastric motility has been shown to be affected by injection of 5-HT into the cerebral ventricles of animals[4]. Thus a hypersensitive central 5-HT receptor function could easily affect gastric motility.

ROLE OF CHOLECYSTOKININ (CCK) IN FUNCTIONAL DYSPEPSIA

CCK is an established brain-gut peptide that plays an important regulatory role in gastrointestinal function[28]. CCK is involved in the control of food intake and satiety in both man and animals[29-31]. It inhibits gastric motility and emptying via capsaicin-sensitive vagal pathways[32,33]. In humans, CCK regulates gastric emptying under physiological conditions[34,72]. An altered response to CCK may be responsible for the dyspeptic symptoms in FD and may be accountable for the frequently observed abnormal gastric motility. The sensitivity of FD patients to CCK has been tested using a CCK challenge test.

CCK challenge test

Subjects for the provocation test undergo an overnight fast. The test was performed using a synthetic CCK-octapeptide (CCK-8), sincalide. Response to CCK was assessed by an intravenous CCK-8 infusion (6 nanograms/kg/min) over 10 min in a double-blind, cross-over design using normal saline as placebo. A break of 15 min was given between infusion. The CCK test was deemed positive when the infusion reproduced the patients' symptoms (epigastric pain or discomfort, nausea, abdominal distension, bloating, belching and vomiting). Patients' response to the infusion was assessed by a third independent observer and patients scored their response (reproduction of the symptoms) on a visual analogue scale.

When FD patients were subjected to the CCK-8 challenge test, majority (90%) of them responded positively to the challenge test[75]. Commonly reported symptoms included abdominal pain, abdominal bloating and fullness, belching, nausea and occasional vomiting (dysmotility type symptoms). Most of the healthy subjects complained only of very minor symptoms including mild nausea and minor abdominal discomfort (Figure 2A). No subject reported any symptoms on saline (placebo) infusion. Interestingly it was also shown that, intravenous atropine was able to abolish the response to the CCK-8 provocation test in a dose-dependent fashion (Figure 2B). Similarly, oral loxiglumide (CCK-A antagonist) 800 mg, consumed 1 h before the CCK challenge, was successful in controlling the symptoms (Figure 2C). Solid phase gastric emptying were also measured in the FD patients using scintigraphic assessment of a standard breakfast with Tc-99M tin colloid and compared with healthy controls. Solid-phase gastric emptying (analyzed in terms of half-emptying times) dif-

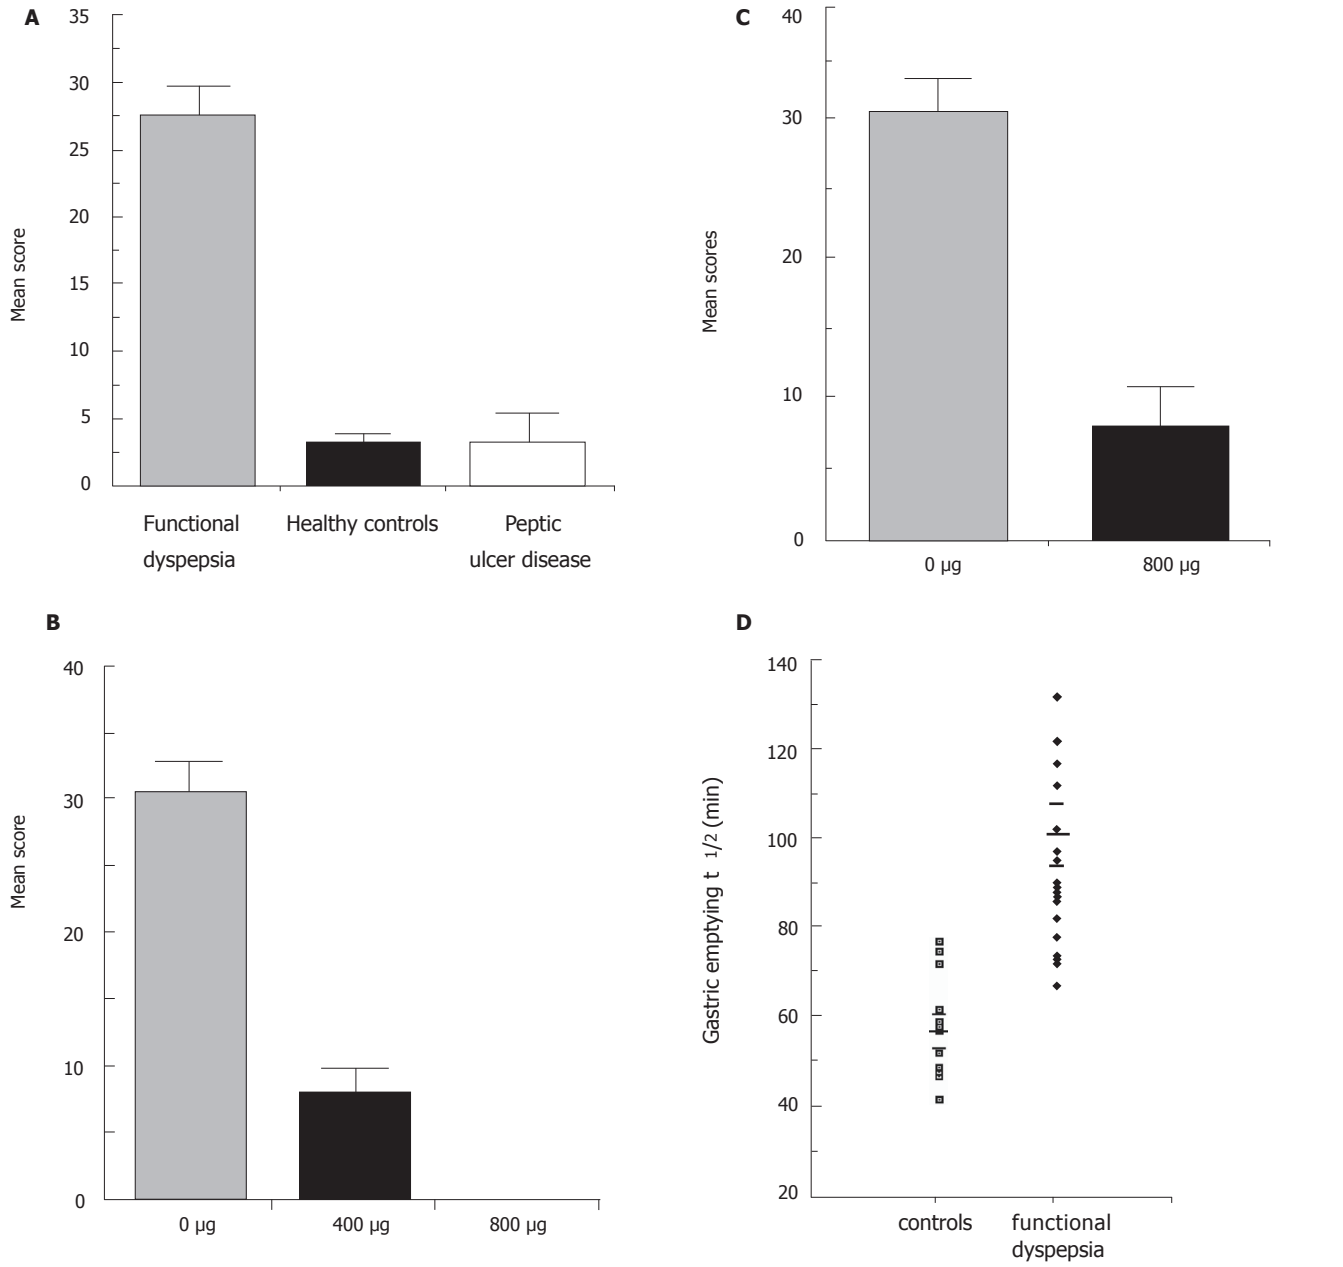

Figure 2 **A**: Response to CCK-8 challenge in healthy controls, patients with functional dyspcpsia and peptic ulcer disease; **B**: Effects of atropine on CCK-8 infusion in functional dyspeptic patients. **C**: Effects of loxiglumide 800mg on CCK-8 infusion in functional dyspeptic patients; **D**: Solid phase emptying rates in functional dyspeptic patients and healthy controls.

fered significantly between the two groups (Figure 2D).

These results indicated that a high proportion of the patients with dysmotility-type FD have an abnormal response to CCK-8 infusion. This abnormal hyperresponsiveness to CCK may account for the genesis of dyspeptic symptoms in FD. It is interesting to note that gastric emptying is also delayed in the FD group. CCK-8 contribution to the slowing of gastric emptying may be due to the stimulation of pyloric contractions and suppression of antral and proximal duodenal motility[34]. The response to CCK-8 challenge may be mediated via a vagovagal reflex arc, resulting in the perturbation of gastric motility. It is possible that CCK-A receptors are involved with the sensory afferent limb, while the cholinergic receptors are responsible for the motor efferent limb of this reflex arc. Ingestion of a meal (especially a fatty meal) leads to the release of CCK that acts locally in a paracrine fashion, and the information generated conveyed to the CNS *via* vagal afferent fibers. This pathway is also responsible for the feedback inhibition of gastric tone and motility. The gastric motor changes can lead to dyspeptic symptoms in FD patients.

CHOLECYCSTOKININ AND SEROTONIN INTERACTIONS IN FUNCTIONAL DYSPEPSIA

Stallone first provided evidence for the interactions between 5-HT and CCK in the control of feeding behavior[10]. It was demonstrated that while the 5-HT receptor antagonist, metergoline, acted to attenuate the CCK-induced anorexia, the peripheral 5-HT antagonist xylamidine, had no

effect. Therefore the inhibitory effect of CCK-8 on food intake depended upon central serotonergic activity[10,35,37]. Studies have shown that dl-fenfluramine can reduce the rate of gastric emptying[21,36]. The reduction in gastric emptying produced by dl-fenfluramine could be blocked by the CCK-A receptor antagonist, devazepide[38]. This suggested that the serotonergic effects on gastric emptying depended upon CCK mechanism. It has also been shown that administration of CCK-8 can excite 5-HT neurons[39], and result in 5-HT being released in the hypothalamic paraventricular nuclei (PVN) and supraoptic nuclei[11,41] both important in central modulation of feeding and gastrointestinal motility. It is likely that endogenous CCK, released post prandially, activates the central 5-HT system, leading to increased release in the PVN. There is evidence that 5-HT acts within the PVN to suppress carbohydrate intake[42]. Activation of central 5-HT mechanisms by CCK-8 may then be involved in the control of satiety. Likewise efferent fibers descending from the CNS to the ENS are important in the control of gastrointestinal functions. Abnormalities involving either the CCK or the 5-HT pathways can result in perturbation of feeding and disruption of gastrointestinal motility. Thus the symptoms encountered in FD may result from a dysfunction of either of the above pathways or interaction between the two.

We examined a group of FD patients (early satiety, upper abdominal pain or discomfort, post-prandial bloating, fullness, nausea and vomiting) who has an abnormal response to the CCK challenge test, a delayed solid-phase gastric emptying and determined their central 5-HT receptor activity using the buspirone stimulation test. Solid phase gastric emptying (half emptying time) were significantly prolonged in the dyspeptic group compared to the controls (mean +/- SE; 90.3 +/- 3.9 min *vs* 54.6 +/- 5.9 min). Dyspeptic patients (mean +/- SE; Females: 1450+/- 132.5 Mu/L, Males: 672.5 +/- 84.9 Mu/L) were found to have a significantly higher ($P < 0.001$) PRL response when compared to the healthy volunteers (mean +/- SE ; Females: 352 +/- 33.5 Mu/L, Males: 187 +/- 44.3 Mu/L).

These results indicated that FD patients with an abnormal response to CCK-8 challenge also have hypersensitive central 5-HT receptor functioning. However, no correlation can be obtained between PRL response and severity of response to CCK challenge (R= 0.24, NS). Patient's response was rated on a Visual Analogue Scale, which is very subjective and patient dependent. A weighted scoring system may be better in assessing patient's response and may thus show a significant correlation then.

DISCUSSION

Dysfunctional motility[19,43,44], visceral hypersensitivity[45,46], impaired accommodation[47,48] and disordered feeding behaviour are pathophysiological abnormalities that have been described in FD. Each of these disorders may result from primary pathologies arising from the ENS, aberrant signal transmission in the afferent and efferent nerves and abnormal integration within the CNS, which can lead to disruption in peripheral GI sensorimotor functions. Psychological factors, either acute or chronic[12,49,50-54] (stress, negative life events, personality traits or illness seeking behaviors) and presence of certain nutrients in the intestine[55-57] (abnormal exaggerated response) can influence pathways of the brain-gut axis resulting in the observed pathophysiological abnormalities and the resultant symptoms.

It has been reported that agents that modulate 5-HT function may be useful in the treatment of visceral hypersensitivity, either directly on perception or through alteration in visceral tone or motility[59-61]. Visceral sensation can be modified at various levels of the brain-gut axis. It is believed that FD patients perceive visceral stimuli in an abnormal manner[62]. It is still uncertain at what level the dysfunction originates. Altered threshold of visceral mechanoreceptor sensitivity, abnormalities in sensory input transmission and a decrease pain threshold at the CNS may all be responsible. Evidence for central dysfunction exists in that central serotonergic receptors have been shown to be hypersensitive in FD patients[63,64]. This was demonstrated by an exaggerated prolactin response to the buspirone challenge test. Furthermore gastric emptying was also delayed in this group of patients. More importantly the gastric emptying rates and the prolactin response were very highly correlated[63]. This observation suggests that in FD, hypersensitive central 5-HT receptors may be involved in mechanisms giving rise to abnormalities of gastric emptying.

Central 5-HT pathways are also implicated in the mechanisms of nociception. Descending 5-HT systems in the supraspinal and spinal pathways are involved in the control of nociception and thus can modify visceral perception and awareness of pain. Pathways arising from the brainstem and projecting to the dorsal horn of the spinal cord can alter the sensitivity of the dorsal horn neurons and thus centrally control the intensity of perception of pain [65,66]. Similar mechanisms have been implicated in the increase perception to visceral sensation[67].

The neuropeptide CCK act on vagal gastric afferents to inhibit gastric emptying and decrease food intake[29,34,70]. CCK receptors have been demonstrated on gastric afferent nerves[71]. Studies have compared various gastrointestinal responses to exogenous and endogenous CCK at plasma levels measured after a meal or intestinal nutrients. Similar plasma CCK levels after endogenous release and exogenous administration, appear to cause equal degrees of gallbladder contraction[73] and inhibition of gastric emptying in man[72,74]. Animal studies suggest that CCK acts via a vagal afferent pathway to decrease gastric motility and this pathway is important in mediating CCK induced delay in gastric emptying[32]. By acting on the vagal afferents, CCK is seen as part of the mechanism by which information from the peripheral GI tract is conveyed centrally to the CNS to modulate feeding behaviour and the autonomic control of the digestive tract. The abnormal response to CCK octapeptide infusion observed in FD patients may be due to sensitized gastric mechanoreceptors or modification in the transmission of sensory impulse. The satiety effect of CCK depends on intact central 5-HT function[10]. It may be possible that hypersensitive central 5-HT receptors may up-regulate the sensory receptors in the gut wall that then respond abnormally to the CCK infusion. Interestingly postprandial CCK levels in a normal healthy person are not significantly different from FD patients. It is conceiv-

able that the gut in a sensitized subject may react more vigorously to external stimuli (stress or presence of nutrients).

SUMMARY

An interaction between the CCK and serotonergic pathways may explain the constellation of symptoms observed in FD. An altered central 5-HT receptors functioning can reset the threshold for sensitivity to CCK (more sensitive to stimuli) in the gut receptors. Consequently, a normal peripheral stimulus (presence of nutrients in the small intestine or food in stomach) will result in an abnormal afferent input that leads to a distortion of GI perception and function[68,69], either through intrinsic ENS reflexes or through the autonomic or central nervous systems. This will also help to explain how stress and psychological factors may precipitate dyspeptic symptoms in FD patients. Depending on the presence and degree of the stressor at the time, different dyspeptic symptoms will predominate.

Abstract

Selective cyclooxygenase (COX)-2 inhibitors (coxibs) were developed as one of the anti-inflammatory drugs to avoid the various side effects of non-steroidal anti-inflammatory drugs (NSAIDs). However, coxibs also have an ability to inhibit tumor development of various kinds the same way that NSAIDs do. Many experimental studies using cell lines and animal models demonstrated an ability to prevent tumor proliferation of COX-2 inhibitors. After performing a randomized study for polyp chemoprevention study in patients with familial adenomatous polyposis (FAP), which showed that the treatment with celecoxib, one of the coxibs, significantly reduced the number of colorectal polyps in 2000, the U.S. Food and Drug Administration (FDA) immediately approved the clinical use of celecoxib for FAP patients. However, some coxibs were recently reported to increase the risk of serious cardiovascular events including heart attack and stroke. In this article we review a role of COX-2 in carcinogenesis of gastrointestinal tract, such as the esophagus, stomach and colorectum, and also analyze the prospect of coxibs for chemoprevention of gastrointestinal tract tumors.

Key words: Cyclooxygenase-2 (COX-2); Selective COX-2 inhibitors; Esophageal cancer; Gastric cancer; Colorectal cancer

DEVELOPMENT OF SELECTIVE COX-2 INHIBITORS

The administration of non-steroidal anti-inflammatory drugs (NSAIDs), one of the most prevalent antipyretics and analgesics, is also known to reduce the risk of cancer development in the gastrointestinal tract organs including the esophagus, stomach and colorectum[1, 2]. Vane[3] indicated in 1971 that NSAIDs act upon cyclooxygenase (COX), a rate-limiting enzyme in the arachidonate metabolism. The enzyme catalyzes the biosynthesis of prostaglandin H_2, the precursor of derivatives such as prostaglandins, prostacyclin, and thromboxanes. Up to now there have been at least two isoenzymes of COX reported, COX-1 and COX-2. COX-1 is constitutively expressed in many tissues and it controls homeostasis by maintaining physiological levels of prostaglandins, while COX-2, induced by cytokines, mitogens, and growth factors, is responsible for inflammatory reactions and tumor development. Recently, COX-3, was reported to be related with pain and fever, and identified as an alternative splice of COX-1[4].

COX-2 and PGE2 play an important role in tumorigenesis from the development to invasion and metastasis of carcinoma through various mechanisms. COX-2 expression promotes cell proliferation by the activation of EGFR[5] and inhibit apoptosis by up-regulation of bcl-2[6], and suppresses host immune response[7]. Furthermore, COX-2 induces angiogenesis with VEGF and bFGF expression[8], and facilitates a metastatic potential by up-regulation of uPA and MMP-2[9, 10]. Theoretically, NSAIDs may be a candidate for chemopreventive agents against tumorigenesis by inhibiting COX-2. In fact, two large-scale randomized, double-blind trials demonstrated that aspirin, a representative of NSAIDs, could prevent colorectal adenoma[11, 12].

But the regular use of NSAIDs causes severe adverse effects including gastrointestinal bleeding, a reduction of the renal blood flow, and dysfunction of platelets because they inhibit both COX-1 and COX-2. To avoid these side effects of NSAIDs the development of selective COX-2 inhibitors was gradually aroused after the discovery of

COX-2 in the early 1990s[13]. Some drugs were discovered as a result of a search for selective COX-2 inhibitors, others were revealed as being COX-2 selective after the discovery of COX-2. There are three classes of selective COX-2 inhibitors (Table 1), the first one being 1,2-diarylcyclopentenes (so-called tricyclic compounds), such as celecoxib and rofecoxib; the second one being methanesulphonamide compounds, such as NS-398 and nimesulide; and the third one being NSAIDS-derivates, such as meloxicam and etodolac. Some selective COX-2 inhibitors, which demonstrate chemopreventive effects on gastrointestinal cancers in experiments and human studies, are already commercialized as anti-inflammatory drugs, but no drug except for celecoxib is presently allowed for use in chemoprevention. In this paper we review the role of COX-2 in the carcinogenesis of gastrointestinal tract cancers and also discuss the prospect of selective COX-2 inhibitors for chemoprevention of gastrointestinal tract cancers.

COX-2 IN CARCINOGENESIS OF GASTROINTESTINAL TRACT CANCER

Esophageal cancer

Recently, the incidence of Barrett's esophagus (BE) and esophageal adenocarcinoma (EAC) has been rapidly increasing in individuals of Western countries, particularly, among white males. The sequence of events leading from gastroesophageal reflux disease (GERD) to EAC is thought to involve the development of inflammation-stimulated hyperplasia and metaplasia, followed by multifocal dysplasia and adenocarcinoma. The up-regulation of COX-2 expression in human tissue of esophagitis, BE and EAC has been demonstrated. The incidence of COX-2 protein expression gradually increases with the development of esophageal lesions, from 75% in metaplasia, to 83% in low-grade dysplasia and up to 100% in high-grade dysplasia and EAC[14]. Combined reflux of the duodenal contents with gastric juice contributes to the development of these diseases[15] and BE patients have higher bile acid levels in the stomach than healthy controls and GERD patients without BE[16]. These observations strongly indicate that duodenal juice including bile is associated with the inflammation-metaplasia-adenocarcinoma sequence. In particular, bile acid is likely to play a pivotal role. Zhang *et al*[17] reported that COX-2 was expressed in the esophageal mucosa using a duodenogastroesophageal reflux model and bile acids, not only unconjugated but also conjugated ones, induced COX-2 mRNA, followed by COX-2 protein and PGE2 production.

The suppressive effects of a COX-2 inhibitor, NS398, on the epithelium of BE have been demonstrated in two independent *in vitro* studies[18, 19]. An increase in apoptosis and a suppression of cell proliferation are supposed to be responsible for the inhibition of cancer cells in these articles. Furthermore, some selective COX-2 inhibitors have been reported to prevent the development of esophageal cancer using *in vivo* animal models. N-nitrosomethylbenzylamine-induced esophageal tumorigenesis in rats was prevented by the administration of another selective COX-2 inhibitor, JTE-522[20]. The study was carried out using a carcinogen-induced rodent model, whereas two studies have been reported using an esophageal reflux model. Buttar *et al*[21] showed the preventive effect on EAC of MF-tricyclic in a rat model of BE and EAC induced by duodenogastroesophageal reflux. In their report, MF-tricyclic prevented the development of EAC, but did not suppress the prevalence of BE. On the other hand, celecoxib suppressed not only the development of EAC, but also that of BE in our study.

We have investigated the effect of celecoxib on esophageal adenocarcinogenesis by using duodenoesophageal reflux model, established by Miwa and his colleagues [22, 23]. Male Fisher 344 rats underwent a duodenoesophageal reflux procedure and were divided into two groups. One

group was given commercial chow (control group), while the other group was given experimental chow containing celecoxib (celecoxib group). The animals were sacrificed sequentially, at 10th, 20th, 30th and finally 40th wk after surgery. In the control group, esophagitis, BE and EAC were first observed at 10th wk, 20th wk and 30th wk, respectively. Their incidences sequentially increased and at the 40th wk reached 100%, 89% and 47%, respectively. In the celecoxib group, the esophagitis was mild and the incidence of BE was significantly lower at each week ($P<0.001$), in comparison with the control group, and EAC was not identified throughout the experiment ($P<0.05$) (Table 2). COX-2 expression was up-regulated at the 10th and 20th wk ($P<0.05$, respectively) (Figure 1). PGE_2 level and proliferative activity were also up-regulated in both groups, but they were lower in the celecoxib group than in the control group ($P<0.05$) (Figures 1 and 2). Apoptosis increased after the celecoxib treatment ($P<0.05$) (Figure 2). Celecoxib thus proved to be effective for preventing reflux esophagitis, BE and EAC by suppressing PGE_2 production in a rodent model.

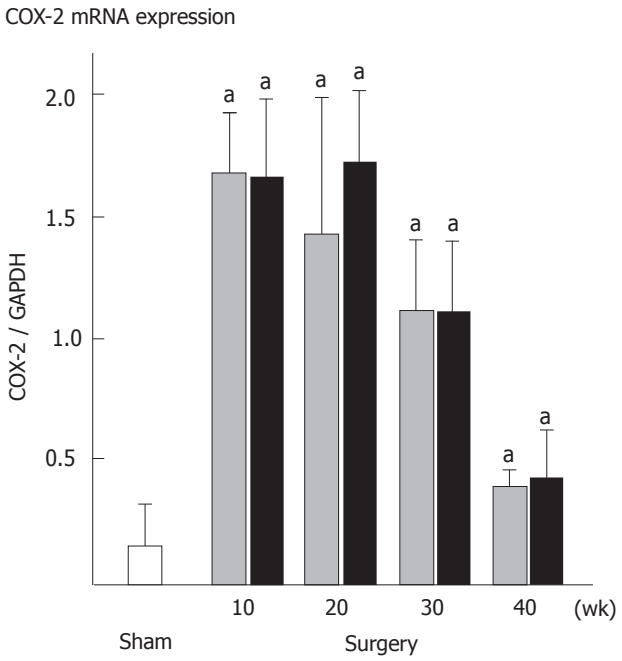
Our results showed surges of COX-2 and PGE_2 between the beginning and the 20th wk in the control group, thus suggesting that the COX-2 expression played an important role in the early phase of the esophageal carcinogenesis in the inflammation-metaplasia-adenocarcinoma sequence. The fact that the suppression of PGE_2 continued throughout the experiment in the celecoxib group may explain that celecoxib suppressed not only the development of EAC, but also that of BE. These data led to perform a clinical chemoprevention study for the patients with BE. Kaur *et al*[24] administered 25-mg/day rofecoxib to twelve patients with BE for 10 days and reported that COX-2 expression, PGE_2 contents and PCNA of epithelium of BE were 3-fold, 2-fold, and 2-fold higher than those of epithelium of normal esophagus, respectively, and all biomarkers decreased after treatment by 77%, 59%, and 62.5%, respectively. Furthermore, a Chemoprevention for Barrett's Esophagus Trial (CBET) was started in 2003 as a phase IIb, multicenter, randomized, double-masked, placebo-controlled study of celecoxib in patients with Barrett's dysplasia[25].

Gastric cancer

Though the incidence of gastric cancer has recently decreased in the United State of America and Western European countries, it is still a major cause of cancer death in many countries, such as Eastern Asia, Eastern Europe, and Latin America. Gastric cancer develops in a multistep process from normal gastric mucosa to chronic active gastritis, to gastric atrophy and intestinal metaplasia, and finally to dysplasia and cancer[26]. According to recent epidemiologic evidence, it is very likely that *Helicobactor pylori* (*H pylori*) plays an important role in this carcinogenic sequence. It is shown that *H pylori* induces COX-2 mRNA/protein levels with the production of PGE_2 in premalignant and malignant lesions[27, 28]. A chronic infection of *H pylori* causes gastritis due to COX-2, iNOS, and other cytokines, but the precise mechanism of *H. pylori* involvement in gastric carcinogenesis remains to be elucidated. Normal gastric mucosa scarcely expresses COX-2, but the expression of COX-2 increases through the multistep process of gastric carcinogenesis. Sun *et al*[29] reported the positive rates of COX-2 by immunohistochemistry in superficial gastritis, gastric atrophy, intestinal metaplasia, dysplasia, and cancer to be 10.0%, 35.7%, 37.8%, 41.7%, and 69.5%, respectively. In addition to these findings several studies have strongly suggested COX-2 expression to be a relatively early event in the sequence of gastric carcinogenesis[30, 31].

Since Ristimaki *et al*[32] first described an elevated expression of COX-2 in gastric carcinoma in 1997, numerous studies have reported the relationship between COX-2 expression and gastric cancer. According to a review article, COX-2 mRNA is up-regulated in 51% to 76% (median 73%) of the tumors by Northern blot or RT-PCR, while COX-2 protein is overexpressed in 67% to 83% (median 73%) by immunoblotting and 43% to 100% (median 62%) by immunohistochemistry[33]. The COX-2 expression is more frequent in intestinal-type than in diffuse-type gastric cancer[34-36], and it also correlates with noncardia cancer[37], tumor size[38], depth of invasion[36, 38, 39], lymph node metastasis[38-42], lymphatic invasion[41, 42], clinical stage[41-42], and angiogenesis[39, 43].

Sawaoka *et al*[44, 45] demonstrated the inhibitory effects of a COX-2 inhibitor, NS-398, on the gastric cell line expressing COX-2 (MKN45) and on its xenograft in nude mice *in vivo*. Hu *et al*[46] examined the chemopreventive effect of indomethacin and celecoxib, using a rat model. They induced gastric cancer by the administration of 100 μg/ml MNNG to Wistar rats for 40 wk and reported the incidence and the tumor multiplicity of gastric cancer of 10 mg celecoxib group to be 18.8% and 0.19, which was significantly lower than 75.0% and 1.0 of the control group, but indomethacin did not show any such preventive effect. Curiously, indomethacin strongly inhibited PGE_2 production in comparison with celecoxib. They supposed that chemopreventive effects of the celecoxib may not be mediated by the inhibition of the COX-2 activity or prostaglandins production alone and thus carried out another experiment to elucidate the cell kinetics[47]. They indicated that both drugs suppressed cell proliferation, but celecoxib



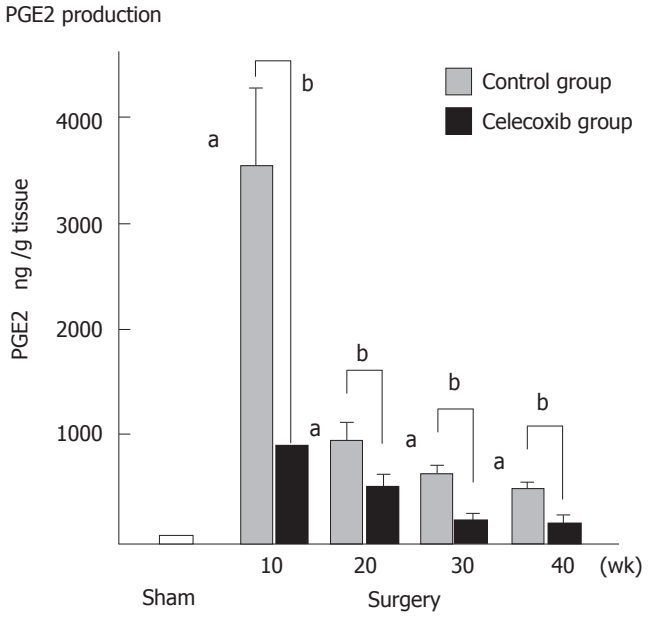


Figure 1 COX-2 mRNA expression and PGE2 production of esophageal mucosa. [a]$P < 0.005$ *vs* sham; [b]$P < 0.01$ between the two groups , Mann-Whitney U test

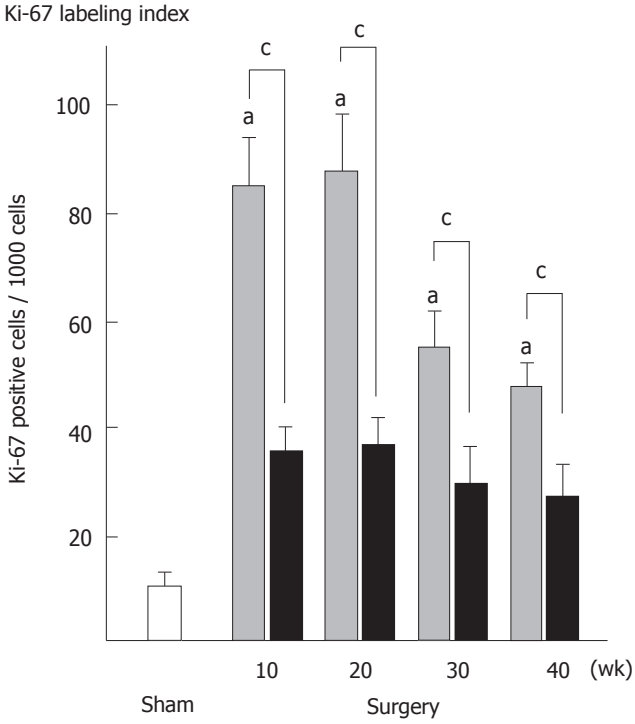

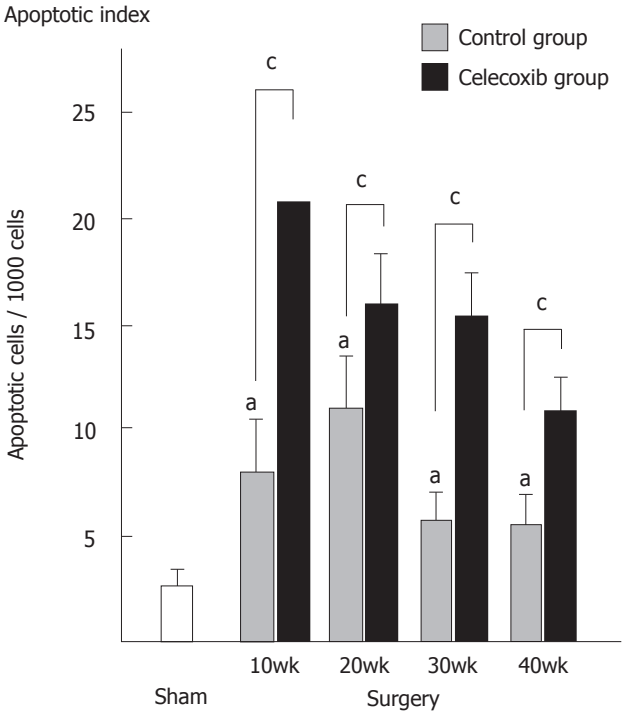

Figure 2 Cell kinetics of esophageal mucosa in a duodenoesophageal reflux model. [a]$P < 0.05$ *vs* sham; [c]$P < 0.05$ between the two groups , Mann-Whitney U test

increased the apoptosis of gastric cell in a dose-dependent manner, whereas indomethacin did not effect apoptosis, thus suggesting that celecoxib inhibits gastric carcinogenesis by the COX-2 independent pathway, such as by the inhibition of the NF-1-κB signaling pathway. Furthermore, Nam *et al*[48] examined the effect of nimesulide on gastric carcinogenesis using an N-methyl-N-nitrosourea (NMU)-induced and an *H pylori*-infected mouse model, demonstrating that gastric tumors developed in 68.8% of mice given both MNU and *H pylori*, whereas the tumor incidence in the mice receiving nimesulide in addition to MNU and *H pylori* was 27.8%.

More recently COX-2 was proven to have a strong relationship with gastric tumorigenesis in a study using transgenic mice[49]. In the transgenic model expressing both COX-2 and microsomal prostaglandin E synthase (mPGES)-1, the animals developed inflammation-associated hyperplastic gastric tumors in the proximal glandular stomach. In addition, NS-398 treatment for four weeks completely suppressed the gastric hypertrophy, thereby reducing the mucosal thickness in the same model. We previously established a rodent duodenogastric reflux model, in which gastric cancer developed for 50 to 60 wk without any chemical carcinogens[50]. We have now started an experiment to prove the chemopreventive effects of

meloxicam on gastric tumors including gastric adenoma and adenocarcinoma using this model and have preliminarily confirmed a suppressive effect on gastric lesions (data not shown).

Colorectal cancer

Colorectal cancer is one of the most popular cancers and its incidence is increasing with high mortality rates in westernized countries. The relationship between the carcinogenesis and COX-2 is most intensively elucidated in both basic and clinical research about colorectal polyps, adenoma, and cancer. Before the discovery of COX-2, numerous studies about inhibitory effects of NSAIDs on intestinal tumorigenesis were performed using chemical carcinogen-induced animal models and *Apc* gene mutant mouse models[51, 52]. The *Apc* gene plays an important role in colon cancer development. An epoch-making paper was published by Oshima *et al*[53] in 1996 about the contribution of COX-2 to carcinogenic sequence in Wnt/Apc/Tcf pathway. They induced COX-2 mutations in $Apc^{\Delta 1716}$ knockout mice, which led to the development of numerous polyps in the intestine. In COX-2-/- $Apc^{\Delta 1716}$ and COX-2+/- $Apc^{\Delta 1716}$ mice, the number of polyps dramatically decreased by 86% and 66%, respectively, in comparison to that in the littermate COX-2+/+ $Apc^{\Delta 1716}$ mice. They also reported in the same paper that MF-tricyclic suppressed number of polyps in $Apc^{\Delta 1716}$ mice. This is the first report that COX-2 inhibitor reduced the number of intestinal polyps. Following this finding several COX-2 inhibitors have been reported to succeed in polyp reduction in knockout *Apc*

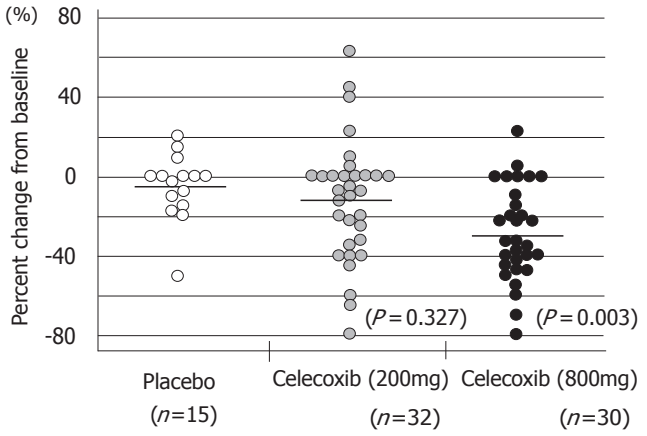

Figure 3 Percentage change from the baseline in the number of colorectal polyps in FAP patients

mice (Table 3).

Both celecoxib and refecoxib, two popular drugs as the first generation of selective COX-2 inhibitors, are now commercially available for orthopedic diseases. Both drugs have been shown to have chemopreventive effects on intestinal polyps in *Apc* mutant mouse models. Jacoby *et al*[54] performed two experiments of adenoma prevention (early phase) and regression (late phase) by celecoxib using the *Min* mice model. They showed that celecoxib decreased not only tumor size and multiplicity in the prevention study, but also caused a decrease in the size of established polyps in the regression study. In the rofecoxib study using $Apc^{\Delta 716}$ mice model, the drug successfully decreased the number and size of polyps in a dose-dependent manner[55].

The *Apc* gene mutation is also responsible for familial adenomatous polyposis (FAP). Some articles have demonstrated the chemopreventive effects of NSAIDs on colorectal polyps of FAP patients[51]. The successful outcomes of selective COX-2 inhibitors in animal models enabled us to start a clinical study of chemoprevention of FAP. Steinbach *et al*[56] of the University of Texas, Anderson Cancer Center, in Houston, reported that treatment with celecoxib significantly reduced the number of colorectal polyps in patients with FAP in 2000. I also joined this trial, which was performed as a double-blind, placebo-controlled study and was supported by a contract with the U.S. National Cancer Institute, and Searle Pharmaceuticals. All patients underwent total colonoscopy at the beginning and end of the study. All polyps observed by endoscopy were photographed and videotaped. Several members in the study group assessed the number and size of the polyps using these records in a completely blind manner. A statistical analysis was independently carried out by a biomathematician. Seventy-seven FAP patients were randomly assigned to treatment with celecoxib (100 or 400 mg twice daily) or a placebo for six months. Twice daily treatment with 400 mg celecoxib brought a 28% reduction in the number of polyps, a 100-mg dose led to an 11.9% reduction. In contrast, the polyp counts in patients who received placebo fell by only 4.5%. (Figure 3). At least a 25% reduction in polyps was experienced by 53% of the patients in the 400-mg treatment group, compared with 31% of the 100-mg group and 7% of the placebo group (Figure 4). The incidence of adverse events was similar among the groups.

Corresponding to these results, the U.S. Food and Drug Administration (FDA) immediately approved the clinical use of celecoxib for FAP patients, since it was considered to be a potentially useful adjunct to current management by suppressing polyp formation in patients with a residual rectum after colectomy and in patients with an intact colon who are awaiting a colectomy. Several years later the preventive effects on duodenal polyps in FAP patients were established by the same group[57]. Thereafter, three large trials of the chemopreventive effect on the recurrence of neoplastic polyps of the large bowel in patients with a history of colorectal adenoma have been initiated. The APPROVe (Adenomatous Polyp Prevention On Vioxx) was designed to examine the effects of treatment with rofecoxib in April 2000. The APC （Adenoma Prevention with Celebrex）cancer trial and the PreSAP（Prevention of Spontaneous Adenomatopus Polyps) cancer trial started using celecoxib in December 1999 and March 2001, respectively. Unexpectedly, all the trials now have been stopped because of an observed increased risk in cardiovascular (CV) events.

HEAD WIND AGAINST COX-2 INHIBITORS

In spite of the advances and successes of COX-2 inhibitors, recently some pharmaceutical companies have abandoned the development or marketing of such inhibitors. The Vioxx Gastrointestinal Outcomes Research Study (VIGOR study) foreshadowed a current tough situation of COX-2 inhibitors. The VIGOR study was originally designed to assess whether rofecoxib is associated with a lower incidence of clinically important upper gastrointestinal (GI) events (gastroduodenal perforation or obstruction, upper GI bleeding, and symptomatic gastroduodenal ulcers) than is naproxen, a nonselective NSAID, among 8 076 patients with rheumatoid arthritis[58]. As expected, 2.1 confirmed the incidence of GI events per 100 patient-years occurred with rofecoxib, in comparison to 4.5 per 100 patient-year with naproxen (relative risk, 0.5; $P<0.001$). However, the VIGOR study also showed the relative risk of developing a confirmed adjudicated thrombotic CV event (myocardial infarction, unstable angina, cardiac thrombus, resuscitated cardiac arrest, sudden or unexplained death, ischemic stroke, and transient ischemic attacks) with rofecoxib treatment in comparison to that with naproxen to be 2.38 ($P=0.002$). On the other hand, another similar study, the Celecoxib Long-term Arthritis Safety Study (CLASS) yielded different results[59]. The CLASS was conducted to determine whether celecoxib is associated with a lower incidence of significant upper GI toxic effects and other adverse effects in comparison with conventional NSAID, ibuprofen or diclofenac. For all 8 059 patients enrolled in the CLASS, the annualized incidence rates of upper GI ulcer complications alone and combined with symptomatic ulcers of celecoxib vs NSAIDs were 0.76% *vs* 1.45% ($P=0.09$) and 2.08% *vs* 3.54% ($P=0.02$), respectively, whereas there was no significant difference in the CV event (myocardial infarction, stroke, and death) rates between celecoxib and NSAIDs. It was later reported

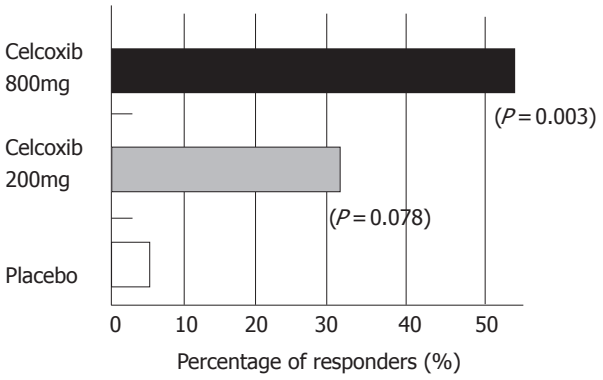

Figure 4 Percentage of responders who showed a 25% or more decrease in the mean number of colorectal polyps

that the adjusted odds ratio for myocardial infarction (MI) among celecoxib users, relative to persons who did not use NSAIDs, was 0.43 in comparison with 1.16 among rofecoxib users, and the use of rofecoxib was associated with a significantly higher odds of MI in comparison wtih the use of celecoxib (adjusted odds ratio for rofecoxib *vs* celecoxib, 2.72, $P = 0.01$) in a study comparing rofecoxib with celecoxib regarding the risk of MI incidence[60].

Merck withdrew rofecoxib from the market in September, 2004 because of an increased risk of serious CV events, including heart attack and stroke, among study patients taking rofecoxib compared to patients receiving placebo (the APPROVe). Japan Tobacco Incorporation has already declined to develop JT-522 for clinical use after phase II study in September, 2003. Regarding celecoxib, in an APC cancer trial, Pfizer demonstrated an increased CV risk over placebo, while the PreSAP cancer trial revealed no greater cardiovascular risk than the placebo. The outcomes of two trials were completely different, but Pfizer nevertheless decided to stop them. The US FDA issued a Public Health Advisory, which stated that the long-term use of NSAIDs and selective COX-2 inhibitors might increase the risk of severe CV events (myocardial infarction, strokes, *etc*) at the beginning of 2005. According to the conclusions of an advisory panel, Pfizer decided to withdraw valdecoxib from the market in April, 2005. Recently, Shaya *et al*[61] performed an observational cohort study to examine the CV risk of COX-2 inhibitors compared with nonspecific NSAIDs except naproxen in Maryland Medicaid enrollees, a high-risk population. But they did not find that COX-2 inhibitors increased CV risk over nonnaproxen NSAIDs. Whether or not selective COX-2 inhibitors really increase the risk of CV events compared with other NSAIDs remains unknown and still controversial.

COX-1 is constitutively expressed in most tissues and cells, such as the kidney, stomach, platelets, and vascular endothelium, while COX-2 expression is induced in fibroblasts, endothelial cells, monocytes, and ovarian follicles[62, 63]. Accordingly, COX-1 alone is expressed in platelets. Ironically, because the selective COX-2 inhibitors hardly suppress COX-1 inducing thromboxane A2, which activates aggregation of platelets, CV risk might be increased among the users of COX-2 inhibitors[64]. In this sense, drugs belonging to the intermediate class of COX-1/COX-2 inhibitors (moderately selective COX-2 inhibitors), such as meloxicam and etodolac, might be reassessed in the near future. But it is very beneficial for most patients that selective COX-2 inhibitors undoubtedly reduce GI disorders about in half compared with NSAIDs[58, 59]. Physicians should select COX-2 inhibitors or NSAIDs, after carefully considering which events are most important for each patient, namely GI or CV events. Recently, COX-2 inhibitors have been found to have new pharmacological advantages. Pyo *et al*[65] reported that NS-398 enhanced the effect of radiation on the COX-2 expressing cells. It was also shown that COX-2 inhibitors had a synergistic antitumor effect in combination with several chemotherapeutic agents, including gemcitabine or 5FU in pancreatic cancer[66], and paclitaxel and carboplatin in non-small-cell lung cancer[67]. Furthermore, the combination of celecoxib and an angiotensin-converting enzyme inhibitor enhanced the antitumor effect through insulin-like growth factor I receptor pathway[68] and low doses of celecoxib was useful for chemoprevention of intestinal polyps in omega-3 polyunsaturated fatty acid-rich diet [69]. These facts are very encouraging to both researchers and clinicians regarding COX-2 inhibitors, thus offering hope for their eventual use in the future.

Abstract

Helicobacter pylori (H pylori) has been etiologically linked to gastric cancer. *H pylori* infection is more frequent in less developed Asian countries like India, Bangladesh, Pakistan, and Thailand and is acquired at early age than in more developed Asian countries like Japan and China. Frequency of gastric cancer, however, is very low in India, Bangladesh, Pakistan and Thailand compared to that in Japan and China. Similar enigma has been reported from Africa as compared to the West. Seroprevalence of *H pylori* infection in adult populations of India, Bangladesh, Pakistan and Thailand varies from 55% to 92%. In contrast, seroprevalence of *H pylori* in Chinese and Japanese adults is 44% and 55%, respectively. Annual incidence rate of gastric cancer in India, Bangladesh, and Thailand is 10.6, 1.3, 7.1 per 100 000 populations, respectively; in contrast, that in China and Japan is 32-59 and 80-115 per 100 000 populations, respectively. Several studies from India failed to show higher frequency of *H pylori* infection in patients with gastric cancer than controls. Available evidences did not support difference in *H pylori* strains as an explanation for this enigma. Despite established etiological role of *H pylori*, situation is somewhat enigmatic in Asian countries because in countries with higher frequency of infection, there is lower rate of gastric cancer. Host's genetic make-up and dietary and environmental factors might explain this enigma. Studies are urgently needed to solve this issue.

Key words: Stomach cancer; *Helicobacter pylori;* Tropical countries; Carcinogenesis; Infectious diseases

INTRODUCTION

Helicobacter pylori (*H pylori*) is a major cause of gastroduodenal diseases like peptic ulcer and an important risk factor for gastric carcinoma (GC) and primary gastric lymphoma (PGL). Evidences supporting the etiological role of *H pylori* in GC and PGL include higher frequency of isolation of *H pylori* in patients with GC and PGL[1,2], regression or lower rate of occurrence or recurrence of the tumor in patients in whom the infection is eradicated[3-6], occasional reports of recurrence following re-infection[7,8] and development of tumor in patients[5,9] or animals[10,11] infected with the organism. Several meta-analyses also revealed a strong relationship between *H pylori* and GC and PGL[12,13]. Though the evidences available in literature support causal relationship between *H pylori* and GC and PGL, some interesting observations from the Asian countries make such causal relationship somewhat enigmatic[14-15]. Similar enigmatic situation has also been reported from Africa[16]. Here we have reviewed the available evidences on this issue and attempted to explain possible reasons for such an enigma.

FREQUENCY OF *H PYLORI* INFECTION IN DIFFERENT ASIAN COUNTRIES

Figure 1 shows seroprevalence of *H pylori* infection in different Asian countries[4,15,17-29]. Frequency of *H pylori* infection differs markedly in different countries. In the developing countries like India, Bangladesh, Pakistan and Thailand, infection with *H pylori* is more frequent among general population and is acquired at an early age. There are several studies from India that showed that *H pylori* is acquired by most people in early childhood[30]. Gill *et al*[31] from India showed that the prevalence of IgG and IgA antibodies to *H pylori* was 22%, 56% and 87% in 0-4, 5-9 and 10-19 years age groups, respectively. In contrast, in more industrialized and developed regions of Asia like Japan, China and Singapore, frequency of *H pylori* infection has been reported to be somewhat lower[14]. The prevalence of *H pylori* in the United States has decreased to approximately 10% in the white middle and upper class population of 50 years of age or younger[32]. As *H pylori* is transmitted by feco-oral route, overcrowding, poor sanitation, lower socioeconomic status and poor water

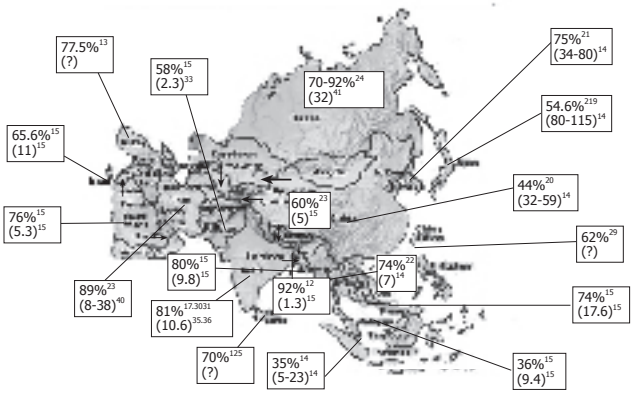

Figure 1 Map of Asia showing frequency of *Helicobacter pylori* infection in each country, crude annual incidence of gastric cancer per 100 000 populations (shown within parenthesis, where data are available). The reference from where data are obtained is shown in superscript. **A:** frequency in the year 1984; **B:** lower annual incidence of gastric cancer for Indians and higher values for Chinese living in Singapore; **C:** studies using PCR among patients with dyspepsia; #: annual-age standardized incidence rates; $: annual age-standardized death certification rate estimated from the graph that appeared in the report (year 1998-99).

supply are some of the major factors that result in higher frequency and lower age of acquisition of *H pylori* in less developed Asian countries[30,33] . Though frequency of *H pylori* as shown in the Figure 1 is not age-standardized, all these data are in adults. As *H pylori* is acquired in early childhood in most developing countries and later in life in most developed countries and as average life expectancy is higher in developed countries as compared to developing countries, age standardization of frequency of infection is unlikely to alter our conclusions.

FREQUENCY OF GASTRIC CANCER IN DIFFERENT ASIAN COUNTRIES

Gastric cancer is the world's second commonest malignancy, having been overtaken only by lung cancer in 1980's[34]. There is a marked international variation in gastric cancer incidence with highest rates reported from Japan. Figure 1 shows annual incidence of gastric cancer per 100 000 populations from Asian countries[14,15,35-41]. It is interesting to note that despite Japan being a developed country with a lower frequency of *H pylori* infection, it has highest frequency of gastric cancer. Similarly, frequency of gastric cancer is quite high in China despite a lower frequency of *H pylori* infection. In contrast, people living in less developed countries of Asia with high frequency of *H pylori* infection[17,18,22,30,31,42-44] that is acquired at an earlier age have the lowest risk of developing gastric cancer[14]. It has also been observed that frequency of gastric cancer differs in different parts within many countries; for example, in Japan[45], variation in gastric cancer risk has been well-documented in different regions and has been presumed to be related to variation in nutrient consumption. In China[46], gastric cancer mortality in Changle county is about 10-fold higher than that in Hong Kong and has been attributed to variation in frequency of *H pylori* infection in the two regions. In India, southern[35] and eastern parts (personal observation) of the country experience somewhat higher frequency of gastric cancer than the northern parts of the country. Interestingly, similar epidemiological observations were made long ago in India in respect of another *H pylori*-related gastroduodenal ailment, i.e., peptic ulcer disease[47].

STUDIES ON ASSOCIATION BETWEEN *H PYLORI* INFECTION AND GASTRIC CANCER IN ASIA

Studies from India failed to show an association between *H pylori* infection and gastric cancer[48-51]. In a study on 50 patients with gastric cancer and 50 controls with non-ulcer dyspepsia, *H pylori* infection was detected less frequently in gastric cancer (38%, 19/50) than those with non-ulcer dyspepsia (68%, 34/50)[48]. An another study demonstrated that 64.7% (33/51) patients with gastric carcinoma and 74.4% (32/43) with non-ulcer dyspepsia had infection with *H pylori* [49]. These studies can be criticized due to small sample size with a consequent type II statistical error. Also, in most of these studies, endoscopy-based tests were used to diagnose *H pylori* infection. Endoscopy-based tests can be false negative in patients with gastric cancer due to gastric atrophy and intestinal metaplasia[52]. However, a recently completed large study from our center in which 279 patients with gastric neoplasms (263 gastric cancer and 16 primary gastric lymphoma) failed to show a higher frequency of *H pylori* infection in patients with gastric neoplasms as compared with the controls (101 non-ulcer dyspepsia and 355 healthy subjects)[53]. In contrast, studies from China and Japan showed association between *H pylori* infection and gastric cancer[54,55].

WHAT IS ASIAN ENIGMA?

Oxford dictionary describes the term "enigma" as a mysterious or puzzling thing. What is puzzling about gastric cancer and *H pylori* infection in Asia? The countries with highest frequency of *H pylori* infection have the lowest risk of gastric cancer in contrast to the countries like Japan and China where gastric cancer risk is highest in the world despite a lower occurrence of *H pylori* infection. This casts major objection to some of the simplified model of gastric carcinogenesis resulting from *H pylori* infection that stated that if the infection is acquired at an early age particularly in presence of malnutrition, it may reduce gastric acid secretion, pangastritis and gastric cancer may be the likely outcome. In contrast, infection acquired later in life and in person with good nutritional status and normal gastric acid secretion would result in hyperchlorhydria and duodenal ulcer disease[56]. It is well documented in the literature that patients with duodenal ulcer infrequently or never develop gastric cancer[5,57]. If this simplified model of gastric carcinogenesis would have been true, India, Bangladesh, Pakistan would have higher frequency of gastric cancer than Japan and China.

WHAT ARE THE POSSIBLE EXPLANATIONS FOR THE ASIAN ENIGMA?

Agent factors

All strains of *H pylori* are not pathogenic. Is it possible

that people living in countries with lower frequency of gastric cancer are infected with non-pathogenic strains of *H pylori* than people living in China or Japan? However, available evidences do not support this hypothesis. Peptic ulcer disease, which is associated with infection by pathogenic strains of *H pylori,* has been reported a common problem in India and Bangladesh[47]. Genotypic analysis of *H pylori* strains from India showed pathogenic strains to be present in more than 80% of adults and children with gastroduodenal diseases as well as in control population[58-59]. Studies that used CagA antibody in patients with non-ulcer dyspepsia have shown that CagA antibody is detected in sera of most patients[60]. From our center, a recently completed large study on 279 patients with gastric neoplasms (263 gastric cancer and 16 primary gastric lymphoma) and controls (101 non-ulcer dyspepsia and 355 healthy subjects) showed that frequency of CagA IgG antibody was similar among the patients with gastric carcinoma and the controls, suggesting that difference in virulence factor of *H pylori*, at least CagA, is unlikely to explain the variation in outcome of *H pylori* infection[53]. In a study from US, Korea and Colombia[61] in which the first-degree relatives of patients with gastric cancer were evaluated to know whether similar strains of *H pylori* or similar environmental factors are responsible for pattern of gastritis. However, this study failed to show any relationship between specific virulence factors or *H pylori* strains and specific histologic pattern or outcome even among those sharing the same environment in childhood[61]. However, several studies from Japan and China[62,63] showed that virulence factors of *H pylori* are strongly associated with gastric carcinoma. Based on the available evidences, one can not conclude that in Asian countries, despite high frequency of *H pylori* infection, low frequency of gastric cancer is related to infection with non-pathogenic strains. Though a study from Africa showed that virulence-associated genes of *H pylori* may partially explain the African enigma[64], the same corollary may not hold well to explain the Asian enigma.

Host's genetic factors

Host's genetic make-up determines in a major way response to any infection, including that to *H pylori*. This is evidenced by the fact that relatives of patients with gastric cancer infected with *H pylori* developed precancerous abnormalities like gastric atrophy and hypochlorhydria more often than those with non-ulcer dyspepsia[65]. Patients with duodenal ulcer, which is also caused by *H pylori,* do not develop gastric cancer in contrast to other conditions associated with *H pylori* infection, such as gastric ulcer, non-ulcer dyspepsia and hyperplastic gastric polyp[5]. These also depict variations in host's response despite infection with the same organism. Japanese immigrants to the United States have higher gastric cancer risk than native-born Americans, though lesser than Japanese living in Japan[66]; this suggests importance of the genetic factors with additive effects of environmental factors.

Difference in carcinogenic risk in people living in different geographical areas might be related to variation in genetic make-up among different races. Specific allelic variation of different genes (polymorphism) present in a proportion of general population may determine variation in carcinogenic potential in different populations in response to environmental carcinogenic exposure, including that to *H pylori* infection[67]. Genetic susceptibility of a person may be important in a number of carcinogenic processes that include: (1) mucosal protection against *H pylori* infection and injury by other carcinogens; (2) mucosal inflammatory response to infection with *H pylori*; (3) degree of apoptotic cell death[68]; (4) carcinogen activation and detoxification by various enzyme systems of the hosts; (5) variability in the repair of mutated DNA; and (6) ability of the cell to proliferate in a controlled manner to repair the damage.

Several studies have been carried out on single nucleotide polymorphism in relation to gastric carcinogenesis[67]. However, many of these studies did not take into account the role of *H pylori* infection and dietary factors in addition to the genetic factors. Therefore, there is need of more data on genetic polymorphism in relation to *H pylori* infection and dietary factors. In fact, genetic studies comparing Asian population with high gastric cancer risk like Japan and China and low cancer risk despite a very high prevalence of *H pylori* infection like India are needed to understand the explanation for the Asian enigma at a molecular level.

Dietary and environmental factors

Diet may play a major role in gastric carcinogenesis. In India, southern[35] and eastern parts (personal observation) of the country experience somewhat higher frequency of gastric cancer than the northern parts of the country. Rice is the staple cereal in eastern India. Non-vegetarian foods, particularly fish, are very common in eastern Indian diet, which is also spicy with more salts. Diet in southern India is somewhat similar to that in eastern India with rice, fish, excess spice and salt being commonly eaten. In contrast, northern Indian diet is mainly wheat-based and a greater proportion of people are vegetarian. Tobacco smoking, high-temperature food intake, spicy food and rice eating have been shown to be risk factors for gastric cancer in India[69,70]. In another study, consumption of dry fish has been shown to be a risk factor for gastric cancer in India[71]. Diet has been considered to be a major factor for increased frequency of gastric and esophageal cancer in Kashmir province of India[72]. Similar observations have also been made in several countries, including Japan where northern districts have reported a higher frequency of gastric cancer than southern district and this has been related to increased dietary intake of salts in northern districts[14]. Tobacco use and alcohol consumption are the other factors that may influence the international variation in frequency of gastric cancer[15]. Possible explanation of Asian enigma might be related, at least in part, to difference in diet between different countries.

CONCLUSIONS AND FUTURE DIRECTIONS

The available evidences clearly show that *H pylori* alone is not the only independent factor in gastric carcinogenesis. Host's genetic make-up and dietary factors play a major role in determining whether or not a person infected with *H pylori* will develop gastric atrophy, intestinal

metaplasia and gastric cancer. This has major importance in preventive strategies of gastric cancer. Despite *H pylori* being an important agent for causing gastric cancer, a recent randomized controlled trial from high risk region of gastric cancer in China failed to show benefit of eradicating *H pylori* in preventing gastric cancer[73]. This might be related to the fact that only 1-2% people infected with *H pylori* develop atrophic gastritis per year, which is a precancerous lesion[74]. Racial and genetic factors are also important as evidenced by difference in gastric cancer risk in different populations, and a recent study, though not from Asia, showed differences in IgG subclass responses between subjects from Gambia and United Kingdom[75]. Unless randomized controlled trials of eradication of *H pylori* among people who are not only infected with *H pylori* but also carry multiple genetic factors which increase their predisposition to developing gastric cancer are undertaken, it is difficult to obtain meaningful conclusions about how useful *H pylori* eradication would be to prevent gastric carcinoma. In fact, in foreseeable future, a day may come when an individual infected with *H pylori* may be able to know, using mathematical modeling and his genetic make-up, as to what would be his risk of developing gastric cancer, and based on that his physician may advise him whether he should undergo *H pylori* eradication treatment and/or modification of his diet to reduce risk of gastric cancer. Since gastric cancer is likely to be a multifactorial disease, which include genetic, dietary and environmental factors and not *H pylori* alone, all these factors need to be considered while constructing the model.

Abstract

AIM: To look for the evidence of human papilloma virus (HPV) infection in esophageal squamous cell carcinomas (ESCC) and to investigate the potential role and epidemiology of HPV infection in the pathogenesis of esophageal carcinomas in Henan emigrants.

METHODS: Papilloma virus（PV）and HPV were determined by Ultrasensive™ S-P immunohistochemistry (IHC) and *in situ* hybridization (ISH) in esophageal carcinoma tissues (82 cases) and the normal mucosa (40 cases).

RESULTS: IHC revealed that the positive rate of PV was 75.0%, 68.18% and 72.5% respectively while the HPV (16/18-E6) positive rate was 45.0%, 36.36%, 37.5%, respectively in esophageal carcinoma tissue specimens from Henan emigrants,the local citizens and patients in Hubei Cancer Hospital. The PV and HPV (16/18-E6) were negative in all normal esophageal mucosa specimens. No correlation was found between HPV in esophageal squamous cell carcinoma tissues and in grade 1-3 esophageal squamous cell carcinoma cells. *In situ* hybridization showed that the HPV (16/18) DNA positive rate was 30.0%, 31.8%, 25.0%, respectively in the 3 groups of samples. No positive hybridization signal was found in 40 normal esophageal mucosa specimens. The positive rate of HPV (16/18) DNA in the esophageal carcinoma specimens was significantly higher than that in normal mucosa specimens ($P < 0.05$). The positive rate was not different among the 3 groups of esophageal carcinoma tissue specimens ($P > 0.05$).

CONCLUSION: HPV infection is high in esophageal carcinoma of Henan emigrants, local residents and patients in Hubei Cancer Hospital. HPV is closely related with esophageal squamous cell carcinoma. HPV infection may play an important role in esophageal squamous cell carcinoma.

Key words: Human papillomavirus; Esophageal squamous cell carcinoma; Immunohistochemistry; *in situ* hybridization

INTRODUCTION

Chaihu area in Hubei Province, China is a high incidence area of esophageal carcinoma because almost 40 000 residents were emigrated from Henan, the highest incidence province of esophageal carcinoma incidence area. The incidence and mortality of esophageal cancer in Hubei have been increased since 1970s ($\geqslant 131/10^5$)[1]. Studies have shown that HPV plays a key role in the development of squamous cell carcinoma at various body sites, including cervix, anogenital region and oral cavity[2-4]. Esophageal squamous epithelium is one of the susceptible sites to HPV. So far, there is no report on the correlation of HPV infection and high incidence of esophageal carcinomas in Henan emigrants and its epidemiology has not been fully studied. In this study, we determined the incidence of the high-risk HPV types 16 and 18 in patients with esophageal cancer using ultrasensitive™ S-P immunohistochemistry (IHC) and in situ hybridization (ISH) and investigated the potential role and epidemiology of HPV infection in the pathogenesis of esophageal carcinoma.

MATERIALS AND METHODS

Tissue collection

Twenty specimens of esophageal carcinoma were collected from Zhongxiang Chaihu Hospital in the high-

incidence area. The average age of the patients was 58 years (range 41-58 years). Twenty patients were all Henan emigrants. Twenty-two specimens were collected from Macheng district. The mean age of patients was 55.7 years (range 33-67 years). Forty specimens were collected from Department of Pathology, Hubei Cancer Hospital. The mean age of patients was 56.9 years (range 37-75 years). The patients were all natives. All the patients were histologically diagnosed as esophageal squamous cell carcinoma.

All the samples were cut into 5-μm thick sections using Leica RM2135 microtome. H-E staining was performed before IHC and ISH. At the same time, all the samples were confirmed by pathologists and 40 normal esophageal mucosa tissue specimens were used as controls. PV and HPV (16/18-E6) antibody and Ultrasensive™ S-P immunohistochemistry kit were purchased from Maixin Biotechnology Company (Fuzhou, China). Biotinylated HPV (16/18) DNA probes and *in situ* hybridization detection systems were purchased from DAKO Company.

Immunohistochemistry

Immunohistochemistry (Ultrasensive™ S-P method) for detection of PV and HPV (16/18-E6) was performed following the manufacturer's instructions. Briefly, paraffin-embedded sections were dewaxed, antigen retrieval was performed by heating the sections in 10mM of citrate buffer (pH 6.0) for 90 s. The tissue sections were treated with 3% hydrogen peroxide in PBS containing 0.01 mol/L sodium phosphate (pH 7.2), then with 0.15 mol/L NaCl to block endogenous peroxidase and normal rabbit serum to block non-specific binding sites. Mouse monoclonal anti- HPV (16/18-E6) antibody was used as the primary antibody at a dilution of 1:100. Rabbit polyclonal anti-PV antibody was used as the primary antibody at dilution of 1:50 and 1:100, respectively. Peroxidase activity was measured with 3, 3'-diaminobenzidine. The primary antibody was absent in negative controls. Sections were counterstained with hematoxylin. The positive control sections were supplied by Maixin Bio Company.

In situ hybridization

All in situ hybridizations were performed using in situ hybridization detection systems and biotinylated HPV (16/18) DNA probes from DAKO Company. Briefly, paraffin-embedded sections were dewaxed and then digested by immersion in 0.8% pepsin solution in 0.2N HCl at 37℃ for 10 min. Following digestion, the sections were rinsed 4 times in deionized water, then immersed in 0.3% H_2O_2 for 20 min, and rinsed 5 times in deionized water. The slides were dried in air for 15 min, one drop (approximately 20 μL) of probe was applied to the sections, and covered with coverslips. The probe and HPV target DNA were denatured by placing the slides on a PCR cycler at 90℃ for 5 min. Following denaturation, slides were transferred to a pre-warmed humid chamber for hybridization at 37℃ for 60 min. Following hybridization, coverslips were removed by immersing the slides in 1×TBST at room temperature. The slides were transferred to fresh TBST bath before strigent washing at 58℃ for 30 min followed by rinsing the slides 3 times in 1×TBST, one min each. The slides were placed on a level surface and enough streptavidin-AP reagent was applied to each section to cover the tissue, incubated for 20 min at room temperature and then enough BCIP/NBT substrate solution was applied to each section to cover the tissue. The slides were incubated at room temperature for 60 min, counterstained in nuclear fast red and cover slips were mounted. Purple-blue ISH signals were observed under microscope and photos were taken for analysis. Slides with PV and HPV positive esophageal cancer tissues were used as positive controls. The hybridization solution without probe or streptavidin-AP reagent was used as a negative control.

Evaluated standard of results and statistical analysis

Without any knowledge of any patient's clinical and pathological data, all slides were evaluated independently by two pathologists. An evaluated standard of results was established corresponding to the staining intensity of positive cells: - , negative; +, 5-25% positive cells; ++, 26-50% positive cells; +++～+++++, positive cells > 50%. Statistical analyses were performed with SPSS 10.0 software and Fisher's exact probability test was used to analyze the correlation between HPV expression and clinicopathologic features of ESCC. $P<0.05$ was considered statistically significant.

RESULTS

Immunohistochemical data of PV and HPV (16/18-E6)

IHC revealed that the positive rate of PV was 75.0% (15/20), 68.18% (15/22) and 72.5% (29/40) respectively and the HPV positive rate was 45.0% (9/20), 36.36% (8/22), 37.5% (15/40) respectively in esophageal carcinoma tissues from Henan emigrants, the local citizens, and patients in Hubei Cancer Hospital. No PV and HPV were detectable in all normal esophageal mucosa tissues. Only few samples showed weak staining. No correlation was found between HPV infection in esophageal carcinoma tissues and grades of esophageal carcinoma cells. The positive rate of HPV in three groups of esophageal cancer samples was significantly higher than that in normal mucosa samples ($P < 0.01$). The positive rate was not obviously different among the three groups of esophageal carcinoma tissue samples. PV concentration at 1:50 and 1:100 showed the same positive rate (Table 1, Figures 1 A-1C).

In situ hybridization data of HPV (16/18) DNA

In situ hybridization showed that the HPV (16/18) DNA positive rate was 30.0% (6/20), 31.8% (7/22), 25.0% (10/40) respectively in esophageal carcinoma tissues from Henan emigrants, the local citizens, and patients in Hubei Cancer Hospital. Forty normal mucosa tissue specimens showed negative results (Table 2). Among the three kinds of esophageal carcinoma tissue samples, no statistically significant difference was found ($P>0.05$), while significant difference was found between normal mucosa tissues and the three kinds of esophageal carcinoma tissue samples ($P<0.05$). Positive signals of HPV (16/18) DNA were located in nuclei. Positive cells located in the center of carcinoma were in the shape of small shuttle (Figure 2A). The negative control is shown in Figure 2B.

Table 1 Expression of PV and HPV (16/18-E6) in esophageal carcinoma and normal mucosa

Origin of ESCC samples	Patients (*n*)	Positive rates of PV (%)	Positive rates of HPV (%)
Henan emigrants	20	(15/20) 75.00	(9/20) 45.00
Local residents	22	(15/22) 68.18	(8/22) 36.36
Hubei Cancer Hospital	40	(29/40) 72.50	(15/40) 37.50
Normal mucosa	40	(0/40) 0.00	(0/40) 0.00

Table 2 Expression of HPV (16/18) DNA in esophageal squamous cell carcinoma and normal mucosa tissues

Origin of ESCC samples	Patients (*n*)	-	+	+ + ~ + + + +	Positive rate (%)
Henan emigrants	20	14	3	3	30.0
Local residents	22	15	5	2	31.8
Hubei Cancer Hospital	40	30	6	4	25.0
Normal mucosa	40	40	0	0	0.00

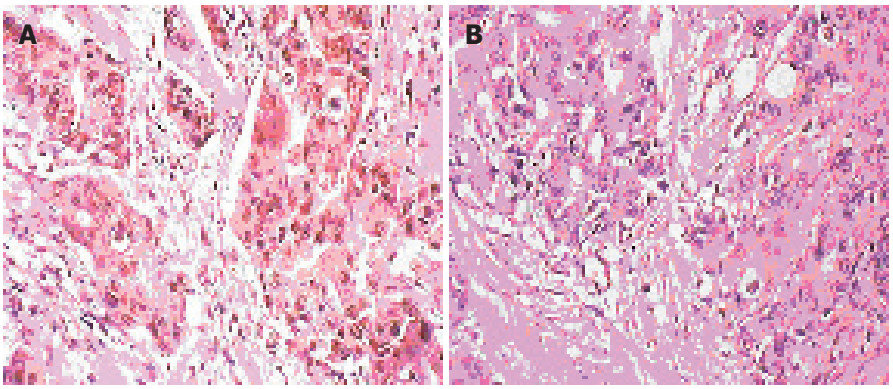

Figure 2 Positive (**A**) and negative (**B**) expression of HPV(16/18) DNA in esophageal squamous cell carcinomas (ISH×100)

DISCUSSION

Esophageal carcinoma is one of the major cancers in China. It may be closely related with heredity, environment, diet and infection with some microorganisms. One of the characteristic features of esophageal carcinoma is its variation in both geographic location and way of life. At present, it is generally believed that esophageal carcinoma is a kind of disease involving many factors. Esophageal carcinoma usually shows a typical course of carcinogenesis. Progression to malignancy during HPV-associated carcinogenesis is related to gene amplification and activation as well as high expression of many cancer genes because of mutation and deletion of cancer suppressor genes[7]. However, its mechanism has not been fully elucidated.

In 2004, approximate 1 000 questionnaires of epidemiology to Henan emigrants showed that the high incidence and mortality of esophageal carcinoma in Henan emigrants are related with environment, diet and genetic susceptibility.

Why HPV infection is related with etiology of esophageal cancer remains unclear[8]. HPV infection is first suggested as a contributory factor for the development of

esophageal cancer in 1982 by Syrjanen *et al*[9]. The presence of HPV antigen has been demonstrated by immunohistochenmical techniques[10]. Subsequently, many studies on HPV infection in esophageal cancer have been reported[11-13, 21]. However, the involvement of HPV remains controversial. Up to now, no report is available on esophageal carcinoma of Henan emigrants. In our study, the PV and HPV positive expression in esophageal carcinoma tissues was determined by Ultrasensive^{TM} S-P immunohistochemistry and *in situ* hybridization. The results showed that the positive rate in three groups of samples was high. HPV positive cells were found in the central region of tissue sections, suggesting that the positive signals (i.e. HPV DNA in the section area) are free of contamination which might come from the experiment. In immunohistochemistry, the PV and HPV positive rates were 75%, 68.18%, 72.5% and 45%, 36.36%, 37.5% respectively, while the expression rate of HPV was 30.0%, 31.8%, 25.0% respectively *in situ* hybridization in the 3 groups of samples, suggesting that HPV infection may be an integral part of a multistep process leading to esophageal cancer in high risk area. The results are consistent with other reports[14,15,20]. The positive rate of HPV detected by immunohistochemistry was higher than that by *in situ* hybridization in our study. These differences probably result from variations in the specificity and sensitivity of the analytical techniques used. *In situ* hybridization is more sensitive and specific than immunohistochemical method. Studies have generated contradictory data possibly due to the geographical location with respect to either low or high incidence areas[16,17]. In addition, variations in infection rate of HPV from the same geographical areas have been confirmed[18,19].

In conclusion, HPV infection is high in esophageal carcinoma of Henan emigrants. HPV is closely related with esophageal squamous cell carcinoma.

Abstract

AIM: To study the apoptosis induced by preoperative oral 5′-DFUR administration in gastric adenocarcinoma and its mechanism of action.

METHODS: Sixty gastric cancer patients were divided randomly into three groups (20 each group) before operation: group one: 5′-DFUR oral administration at the dose of 800-1200mg/d for 3 - 5 d, group two: 500mg 5-FU + 200 mg/d CF by venous drip for 3 - 5 d, group three (control group). One or two days after chemotherapy, the patients were operated. Fas/FasL, PD-ECGF and PCNA were examined by immunohistochemistry and apoptotic tumor cells were detected by *in situ* TUNEL method. Fifty-four patients received gastrectomy, including 12 palliative resections and 42 radical resections. Six patients were excluded. Finally 18 cases in 5′-DFUR group, 16 cases in CF + 5-FU group, and 20 cases in control group were analyzed.

RESULTS: There was no significant difference in patient mean age, gender, white blood cell count, haematoglobin (HB), thromboplastin, perioperative complication incidence, radical or palliation resection, invasion depth (T), lymphonode involvement (N), metastasis (M) and TNM staging among the three groups. However, the PCNA index (PI) in 5′-DFUR group (40.51 ± 12.62) and 5-FU + CF group (41.12 ± 15.26) was significantly lower than that in control group (58.33 ± 15.69) ($F = 9.083$, $P = 0.000$). The apoptotic index (AI) in 5′-DFUR group (14.39 ± 9.49) and 5-FU + CF group (14.11±9.68) was significantly higher than that in control group (6.88 ± 7.37) ($F = 4.409$, $P = 0.017$). The expression rates of Fas and FasL in group one and group three were 66.7% (12/18) and 50% (9/18), 43.8% (7/16) and 81.3% (13/16), 45.0% (9/20) and 85% (17/20), respectively. The expression rate of FasL in 5′-DFUR group was significantly lower than that in the other two groups (χ^2=6.708, $P = 0.035$). Meanwhile, the expression rate of PD-ECGF was significantly lower in 5′-DFUR group (4/18，28.6%) than in CF + 5-FU group（9/16，56.3%）and control group (13/20，65.0%) ($\chi^2 = 7.542$, $P = 0.023$). The frequency of Fas expression was significantly correlated with palliative or radical resection ($\chi^2 = 7.651$, $P = 0.006$), invasion depth ($\chi^2 = 8.927$, $P = 0.003$), lymphatic spread ($\chi^2 = 4.488$, $P = 0.034$) and UICC stages ($\chi^2 = 8.063$, $P = 0.045$) respectively. By the end of March 2005, 45 patients were followed up. The 0.5-, 1-, 2-, 3-year survival rates were 96%，73%，60%，48%, respectively, which were related with T, N, M and Fas expression, but not with PD-ECGF and FasL expression.

CONCLUSION: Preoperative oral 5′-DFUR administration may induce apoptosis of gastric carcinoma cells and decrease tumor cell proliferation index, but cannot improve the prognosis of patients with gastric cancer. Down-regulation of FasL and PD-ECGF expression mediated by 5′-DFUR may be one of its anti-cancer mechanisms. Fas expression correlates with the progression of gastric carcinoma and may be an effective prognostic factor.

Key words: Apoptosis; Preoperative chemotherapy; 5′-DFUR; Gastric carcinoma

INTRODUCTION

Cell apoptosis and proliferation regulate homeostasis.

Disordered balance results in tumorigenesis. Cell apoptosis can hinder tumor growth[1-3]. Therefore, induction of tumor apoptosis is a good anti-cancer therapy. At present, the relationship between chemotherapy and cancer cell apoptosis has drawn more and more attention. However, studies on induction of apoptosis in gastric carcinoma are performed *in vitro*. Inducers reported include γ-ray, beta-ionone, biological response modifiers, chemotherapeutics, *etc*[4-8]. Chemotherapeutics-induced apoptosis is one of its anti-cancer mechanisms. Arsenic trioxide[9], hydroxycamptothecin[10], cisplatin[11] , paclitaxel[12], fluorouracil and its derivant [13,14] , oxaliplatin[15] can induce apoptosis in human gastric carcinoma cells. 5'-deoxy-5-flurouridine (doxifluridine or 5'-DFUR (known as Furtulon) is a selective anticancer medicine, which can be converted into 5-FU by thymidine phosphorylase (the same substance as traversing platelet-derived endothelial cell growth factor, PD-ECGF)[14,19,20]. Accordingly, the concentration of 5-FU is high in tumor tissue[19, 21]. The therapeutic index of doxifluridine is ten times that of 5-FU[19]. Doxifluridine has been widely used in treatment of breast cancer, colorectal carcinoma, ovarian adenocarcinoma, bladder cancer and gastric carcinoma[22-26].

In this study, we used doxifluridine as an apoptosis inducer to study the change of apoptosis and expression of proliferative cell nuclear antigen (PCNA), Fas and Fas ligand (FasL), and PD-ECGF in gastric adenocarcinoma and its mechanism of action.

MATERIALS AND METHODS

Patients

Patients who were diagnosed as malignant gastric neoplasm (age ⩽ 70 years, Karnofsky's scale >90) and could endure chemotherapy and operation, were enrolled in this study. The patients were divided into three groups (20 each): group 1: 800 mg - 1 200 mg/d 5'-DFUR for 3-5 days, group 2: 500 mg 5-FU + 200 mg/d CF by venous drip for 3-5 d and group 3 (control group). One or two days after chemotherapy, the patients underwent surgery. From Oct. 2001 to Oct. 2003, 60 gastric cancer patients (20 in each group) were enrolled (37 males and 17 female, mean age 57.5 years, range 32-70 years) .

Groups

Of the 60 patients, 54 underwent gastrectomy (including 12 palliative resections and 42 radical resections, and 6 were excluded. No perioperative mortality occurred during the first 30 days after surgery. Complications were recorded in four of 54 patients resected, one gastric perforation on the fourth day after 5'-DFUR oral chemotherapy, one preoperative gastrorrhagia and one postoperative cerebral infarction in CF+5-FU group, one venous thrombosis of lower extremities in control group complicated by cerebral hemorrhage during thrombolysis treatment. The patients with gastric perforation and gastrorrhagia required emergency laparotomy.

Immunohistochemistry

PCNA, Fas/FasL and PD-ECGF expression was determined by En Vision immunohistochemistry[27] .The kit was purchased from DAKO Co., USA. Apoptotic cells were detected by terminal deoxynucleotidyl transferase (TdT)-mediated dUTP nick end labeling (TUNEL) method. The kit was purchased from Bochringer Mannheim Co., Germany. The proliferation index (PI) and apoptotic index (AI) of gastric carcinoma cells were evaluated by PCNA immunohistochemical staining and *in situ* TUNEL.

Result assessment

The stained cells had Fas/FasL or PD-ECGF positive expression. Brown-stained nuclei were considered as positive cells of PCNA and apoptosis, brown cellular membrane and cytoplasm were considered as Fas or FasL positive cells (Figures 1A and 1B), brown or yellow staining in cytoplasm and/or cell nuclei was considered as PD-ECGF positive cells (Figure 1C). PCNA index (PI) and apoptotic index (AI) of positive cells in 1000 tumor cells were calculated under high power field (*400) of microscope.

AI = TUNEL mark cells/tumor cells (more than one thousand)*100%

PI = PCNA mark cells/tumor cells (more than one thousand)*100%

Statistical analysis

All data were analyzed by ANOVA and chi square test. $P < 0.05$ was considered statistically significant.

RESULTS

Patients and groups

Fifty-four patients underwent surgical resection, including 18 cases in 5'-DFUR group, 16 cases in CF+5-FU group, and 20 cases in control group. There was no significant differences in patient mean age, gender, white blood cell count, haematoglobin (HB), thromboplastin, perioperative complication incidence, radical or palliation resection, invasion depth (T) , lymphonode involvement (N) , metastasis (M) and TNM staging among the three groups.

AI and expression of PCNA, Fas/ FasS-L, PD-ECGF in gastric carcinoma

The expression of PI, AI, FasL and PD-ECGF was not statistically significant as compared to the operation procedure (radical or palliation resection), early or advanced tumor, T, N, M and UICC stages. In contrast, positive staining of Fas was closely related to radical resection but not with serosal invasion, lymphnode metastasis and early UICC stages (Table 1, Figure 1).

Influence of preoperative chemotherapy on expression of AI, PI, Fas/FasL and PD-ECGF

Either 5'-DFUR or CF+5-FU preoperative chemotherapy could significantly inhibit cell proliferation and induce apoptosis as compared to control group. The frequency of Fas expression had no significant difference among three groups. However, the frequency of FasL expression was significantly lower in 5'-DFUR group (50%) than those in CF+5-FU group (81.3%) and control group (85%) . There was no significant difference between groups two and

three. The PD-ECGF expression was detected in 28.6% of 5'-DFUR group, 56.3% of CF+5-FU group and 65.0% of control group (Table 2).

Prognosis

By the end of March 2005, 45 patients were followed up. During the follow-up, 22 cases died, 23 remained alive (including one patient with cerebral hemorrhage after operation). The 0.5-, 1-, 2-, 3-year survival rates were 96%, 73%, 60%, 48% respectively, which were related with T (χ^2=30.32, *P*=0.0000), N (χ^2=22.10, *P*=0.0000), M (χ^2=17.04, *P*=0.0000) and Fas expression (χ^2=12.24, *P*=0.0005, Figure 2), but not with PD-ECGF (χ^2=0.78, *P*=0.3775) and FasL expression (χ^2=0.7, *P*=0.7967).

DISCUSSION

Gastric carcinoma is one of the most common malignant tumors and remains a leading cause of cancer-related death worldwide [15, 16, 28-30]. In China, it still ranks the first[31, 32]. Operative resection is the most effective treatment nowadays. However, the 5-year survival rate was 25%~60% even after radical resection[33-36], micrometastasis is the major reason for recurrence[29,37,38]. Preoperation chemotherapy can inhibit micrometastasis, but strong chemotherapy may potentially increase operation complications in resectable patients[30,35,36]. It was reported that surgical resection may serve as a stimulus for the growth of residual tumor[30]. Inada *et al*[3] have reported the effectiveness of preoperative 5-Fu venous chemotherapy, which can induce cancer cell apoptosis *in vivo*. Our study showed that preoperative venous CF+5-Fu chemotherapy and 5'-DFUR oral administration could induce gastric carcinoma cell apoptosis and inhibit cancer cell proliferation. Wang *et al*[22] reported that preoperative 5'-DFUR chemotherapy is able to partially inhibit the expression of extracellular signal-regulated kinase (ERK) which is closely related with cell proliferation in breast cancer. PCNA index decrease in our studies might be related with inhibition of ERK-1 and ERK-2 expression. Liang *et al*[39] studied apoptosis in ovarian cancer and found that apoptosis induced by che-

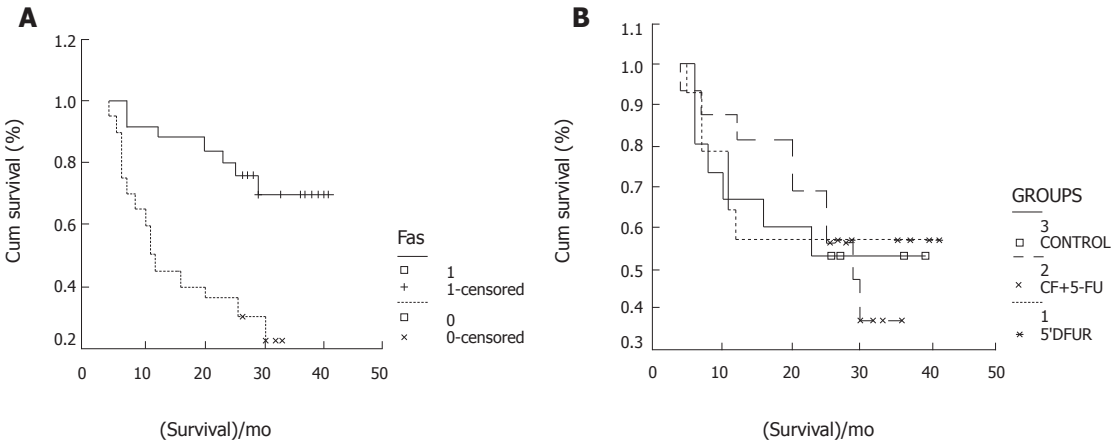

Figure 2 Fas expression (**A**) and survival rate (**B**) in three groups.

motherapy is decreased, suggesting that apoptosis induced by chemotherapy has a time limit. Therefore, preoperative chemotherapy-induced tumor cell apoptosis can inhibit malignant behavior in some degree.

Fas(CD95/APO-1)/Fas ligand (FasL) system is one of the major apoptotic pathways and plays an important role in maintenance of cell colony, elimination of malignant transformation cells and regulation of immune system[1-3, 40]. In general, Fas/FasL system plays an important role in prognosis and immune escape. Fas of activated T lymphocytes and tumor-infiltrating lymphocytes(TIL) can increase apoptosis[1-3,40-45]. Tumor cells combined with activated T lymphocytes and TIL can kill surrounding normal infiltrating lymphocytes, escape immune system[1,2,22,23,43,44]. Our investigation showed that preoperative 5'-DFUR oral administration chemotherapy could down regulate FasL expression, which may be one of its mechanisms underlying tumor cell apoptosis. But CF+5-FU venous chemotherapy had no influence on Fas/FasL expression, suggesting that 5'-DFUR and 5-FU have a different mechanism of action. Induction of 5-FU is relevant with activation of apoptosis gene bax[45], and expression of bcl-2 oncogene[13].

PD-ECGF, one of the angiogenesis factors, extracted from fresh thrombocytolysis matters is the same substance as thymidine phosphorylase(TP), PyNPase[20,46-49]. It can promote angiogenesis, cell proliferation and inhibit apoptosis[46-49]. Konno *et al*[47] reported that expression of PD-ECGF in gastric carcinoma has a positive correlation with PCNA, and PD-ECGF can also promote tumor growth. Osaki *et al*[20] found that increased PD-ECGF expression is closely related with decreased apoptosis in gastric carcimoma. The mean apoptotic index in early and advanced gastric cancer is significantly lower in positive PD-ECGF than in negative PD-ECGF. Koizumi *et al*[21] determined PD-ECGF expression in gastric carcinoma and found that the responsive rate to chemotherapy is 56.8% in positive PD-ECGF group and 0% in negative group, and 82.4% in PD-ECGF over expression group, indicating that chemosensitivity is closely related with PD-ECGF expression. PD-ECGF can increase the activity of 5-FU and other anti-cancer medicines[50]. Cytokine such as interferon, can up-regulate PD-ECGF and cytokine levels, thus detecting PD-ECGF level in tumor tissue can predict chemotherapy sensitivity and its efficacy[18,26,51]. PD-ECGF inhibitors can decrease tumor angiogenesis, prevent infiltration and metastasis[52]. PD-ECGF is the key enzyme for the metabolism of Fortulon. Satoh B *et al*[14] reported that by oral administration of 5'-DFUR, 1 200 mg per day for seven days significantly decreases PD-ECGF activity and acidic protein. Our results showed that preoperative oral administration of Fortulon for 3 - 5 d can down-regulate PD-ECGF expression and induce cancer cell apoptosis in gastric carcinoma. Over expression of PD-ECGF is an important factor of tumor metastasis [53]. Our results also showed that patients with PD-ECGF overexpression had a higher tendency toward liver metastasis. For this reason, down regulation of PD-ECGF expression by preoperative 5'-DFUR chemotherapy plays a certain role in preventing postoperative recurrence and metastasis of gastric carcinoma. It was reported that PD-ECGF level is closely related with tumor metastasis[24,25].

Kabayashi and kimur[8] performed a multicenter clinical trial of preoperative chemotherapy for gastric cancer and

found that oral administration of 5'-DFUR may induce apoptosis of gastric carcinoma and decrease proliferation index in old patients with advanced gastric cancer, but cannot improve their prognosis. However, Fas expression is often presented in early stage of tumors and shows a better prognosis. Thus, Fas expression in gastric carcinoma may be an effective prognostic factor for survival.

In conclusion, 5'-DFUR or CF+5-FU chemotherapy can induce apoptosis and inhibit proliferation of tumor cells. Down regulation of FasL and PD-ECGF induced by 5'-DFUR may be one of its anti-cancer mechanisms. Fas expression is correlated with progression of gastric carcinoma and may be an effective prognostic factor.

Abstract

AIM: Prednisone and azathioprine represent the standard treatment for autoimmune hepatitis (AIH). However, only 65% of the patients enter complete histological remission. Recently, budesonide (BUD) was reported to be a promising alternative. In this study we assessed the efficacy and safety of BUD in AIH.

METHODS: Eighteen patients (12 women, 6 men; mean age 45.4 ± 21 years) with AIH were treated with BUD (Budenofalk®) 3 mg thrice daily and followed up for at least 24 wk. Seven patients also had features of primary biliary cirrhosis ($n = 5$) or primary sclerosing cholangitis ($n = 2$). Advanced liver fibrosis or cirrhosis was present in 6 patients.

RESULTS: Fifteen (83%) patients had a complete clinical and biochemical remission. Ten patients, including five with acute hepatitis, were given BUD as first-line therapy, of which seven enter remission. Three patients, two with liver cirrhosis, did not improve. All patients with second-line therapy experienced long-term remission. A histological remission was also seen in three patients. Clinically relevant BUD-induced side effects were recorded only in patients with liver cirrhosis ($n = 4$).

CONCLUSION: BUD is effective in remission induction in the majority of our patients with AIH. Side effects and treatment failure was mainly observed in patients with liver cirrhosis.

Key words: Budesonide; Autoimmune hepatitis; Complete remission; Adverse events

INTRODUCTION

Autoimmune hepatitis (AIH) is a chronic inflammatory liver disease characterized by a female preponderance, hypergammaglobulinemia and circulating non-tissue specific autoantibodies. AIH usually responds to immunosuppressive therapy; and prednisone (PRD) with or without azathioprine (AZA) is the treatment of choice. This results in histological remission in approximately 65% of the cases. Several patients become intolerant to this regimen and in some it is even contraindicated[1]. Thus, new first-line and salvage therapies are needed, and several drugs are currently under investigation[2].

Budesonide (BUD), a nonhalogenated glucocorticoid, is of particular interest for the treatment of autoimmune liver diseases: it has a 15-fold greater receptor binding capacity than PRD, and a high hepatic first-pass clearance, exceeding 90% of the orally administered dose. Hence it was reported to be free of systemic effect in patients without advanced liver fibrosis[3,4]. However, as yet, data of BUD for the treatment of AIH are very limited and controversial.

In our present study we evaluated the efficacy and safety of BUD as first- and second-line therapy for AIH.

Patients

Eighteen patients (12 women and 6 men; mean age 45.4 ± 21 years, range 21 and 68 years) were selected from a collective of fifty patients with the initial diagnosis of AIH and treated with BUD between January 2002 and July 2004. Selection was based on the following criteria:

Criteria for AIH were: (1) serum alanine aminotransferase (ALT) level at least three times of the upper limit of normal (ULN); (2) serum immunoglobulin G (IgG) level at least 1.5 times of ULN; (3) positive test result(s) for non-tissue or organ-specific autoantibodies (titer ⩾ 80); (4) liver histology consistent with the diagnosis of AIH. Definite diagnosis of AIH required the presence of at least three of the four criteria or 16 points or more on aggregate score proposed by the International Autoimmune Hepatitis Group[5]. An "overlap" syndrome of primary biliary cirrhosis (PBC) and AIH was defined by the simultaneous

CR = complete response; NR = no response; ANA = antinuclear antibodies; SMA = antibodies to smooth muscle; AMA = antimitochondrial antibodies; ANCA = antineutrophil cytoplasmic antibodies; 3 = anti-Sp100 positive; PSC = primary sclerosing cholangitis; PBC = primary biliary cirrhosis; ALT = alanine aminotransferase; ALP = alkaline phosphatase; AE=adverse event; HAI = Hepatitis Activity Index; 1 = the therapy was continued with azathioprine; 2=discontinuation of the therapy because of no response;

association of these disorders.

Diagnostic criteria of *PBC* used in this study were: (1) a positive test for antimitochondrial antibodies (AMA) in serum (titer≥ 80); (2) serum alkaline phosphatase (ALP) level at least 2 times of ULN or gamma glutamyl transferase (GGT) activity at least 5 times of ULN; (3) a diagnostic or compatible liver histology. Two of these criteria were required for the diagnosis of PBC.

Eleven of our patients were categorized as AIH alone, and seven satisfied the revised international criteria for definite diagnosis of AIH (≥ 16 points) and five the probable diagnosis of AIH [5]. The median score of patients with AIH was 16 points (range, 11 to 22 points). Five patients presented also with features of PBC. Primary sclerosing cholangitis (PSC) was diagnosed in two patients who had elevated cholestatic and aminotransferase enzyme activities, concentric periductal sclerosis and interface hepatitis on liver biopsy, serum antinuclear antibodies and elevated IgG level (Table 1). The median score of patients with overlap syndrome was 13.6 points (range, 6 to 17 points).

Absence of biliary obstruction was assessed by ultrasound. None of the patients had a history of excessive alcohol consumption (>30 g/d), and there was no evidence of exposure to hepato- or cholangio-toxic drugs. Serological tests for hepatitis B and C virus infection were negative. Metabolic liver disease including hereditary hemochromatosis, Wilson`s disease and α1-antitrypsin deficiency was excluded by appropriate biochemical tests and histologically.

Of the eleven patients with AIH alone, ten patients were designated as type 1 AIH. Antinuclear antibodies (ANA) alone were found in four patients, ANA and anti-smooth muscle antibodies (SMA) in six. Antibodies against anti-neutrophil granulocyte were present in a single patient. One patient remained autoantibody-negative. One patient with AIH had high-titer AMA without any clinical or histological evidence of PBC. Whereas all patients with AIH-PSC overlap syndrome were ANA-positive, of the patients diagnosed as having an overlap of AIH and PBC two presented AMA in serum, and a further one had PBC-specific ANA recognizing Sp100 protein (Table 1).

Clinical presentation of our patients included acute hepatitis ($n=10$), with jaundice in two cases, and chronically elevated serum liver function test(s) ($n=8$). Advanced liver fibrosis which was defined according to Ishak *et al*[6] as stages ranging from stage 4 to stage 6 was diagnosed in four patients with AIH and in two cases with overlap syndrome. The diagnosis of liver cirrhosis was made in seven patients, three with AIH and four with an overlap syndrome - [clinical stage Child A ($n=5$) and Child B ($n=2$)]. Four patients had concurrent immunologic diseases, including one patient each with Sharp`s syndrome, multiple sclerosis, Sjögren`s syndrome, and panniculitis.

Ten patients received BUD as first-line therapy (Table 1). Five of them had presented with acute hepatitis mimicking viral hepatitis. The median of ALT activities was 13.61 μmol/s.L (range, 10.73-38.89 μmol/s.L; reference interval 0.17-0.85 μmol/s.L). Eight patients were treated with BUD as second-line therapy (Table 1). Four of them experienced an acute exacerbation of autoimmune liver disease in spite of an immunosuppressive therapy. Exacerbation of the disease was defined as > 2x elevation of ALT activity above the ULN. Five patients treated in the second-line group were intolerant to PRD or AZA or proved to be resistant to PRD (Table 2).

Liver biopsy

Liver biopsies were obtained from all patients to assess

Table 2 Patients receiving budesonide as second-line therapy

inflammatory activity and stage of fibrosis before the initiation of therapy. All biopsy specimens were fixed immediately in 10% neutralized formalin and subsequently embedded in paraffin. Deparaffinized serial sections were stained using a hematoxylin and eosin stain (H&E), periodic-acid Schiff reagent with and without diastase pretreatment, Masson`s trichrome stain, reticulin stain, and iron stain. At least eight sections (three sections stained with H&E and one section for each special stain) were evaluated per biopsy specimen. Grading and staging of hepatitis was performed according to the modified Histological Activity Index[6]. Follow-up tissue examinations were done only in patients who had a complete clinical and laboratory resolution and consented for a follow-up liver biopsy. Our protocol was approved by the local Ethics Committee of the Otto-von-Guericke University of Magdeburg. Informed consent was obtained from all patients.

Treatment

BUD (Budenofalk®), 3 mg thrice daily, was administered to each participant with an intention to treat for at least six months. Patients who met the criteria for a complete biochemical response and were free of BUD-related side effects were treated for an indefinite period of time. Drug intolerance, exacerbation of disease or treatment failure justified discontinuation of the medication any time. Therapy was discontinued beyond 6 mo in three patients (wk 4, wk 12 and wk 24) because of treatment failure or deterioration of disease. Patients who experienced a complete biochemical response and had also side effects of BUD or were suspected to be at risk for drug-induced side effects were given AZA in a dose of 1-1.5 mg/kg body weight. Significant cholestasis or pruritus was treated with Ursodeoxycholic Acid (Ursofalk®) in a dose of 10-15 mg/kg body weight in three divided doses.

Patients were monitored at 1-mo intervals in the first three mo of therapy and at 3-mo intervals afterwards by determining serum ALT, ALP, bilirubin, and IgG levels. Treatment outcomes included clinical and biochemical remission, treatment failure, and drug toxicity or side effects. Remission was defined as absence of clinical symptoms, normal serum ALT, ALP, and IgG levels. In patients with an overlap syndrome, remission included also the near normalisation of GGT ($\leqslant$2x ULN). Treatment failure connoted clinical and biochemical deterioration. The development of intolerable cosmetic, biochemical, and/or somatic changes during treatment indicated drug toxicity (= intolerable side effects).

Statistical analysis

Descriptive analyses were used to characterize the study population.

RESULTS

The serum ALT level improved significantly, and completely normalised in fifteen patients (overall response rate 83%). Before initiation of the therapy the median ALT level was 12.44 μmol/s.L (range; 1.48-28.65 μmol/s.L, reference interval 0.17-0.85). At the end of our evaluation, the median of ALT activity was 0.77 μmol/s.L (range 0.18-5.79 μmol/s.L). The median time to complete normalisation of transaminase or cholestatic liver enzyme activities was about three months. The deterioration of ALT activity was noted in a woman (TH) with advanced liver fibrosis and acute hepatitis who did not respond to BUD and had a corticosteroid-dependent AIH. Under PRD (40 mg/d) she entered a complete biochemical remission, but after reducing the doses of PRD under 20 mg she experienced again an acute exacerbation of the disease. She is now in remission receiving 150 mg AZA and 5 mg PRD. BUD therapy was ineffective in two women with liver cirrhosis after 12 and 24 wk. One of them (KM) did respond to PRD and was put on AZA after six months therapy. The other one (DC) did not respond to corticosteroid and is awaiting liver transplantation. A young man (ST) with a history of pathological elevated ALT activities, fatigue and malaise lasting for five years whose liver biopsy revealed no hepatitic changes responded rapidly to BUD leading to complete normalisation of serum liver tests and disappearance of clinical symptoms.

Levels of serum bilirubin with 5.95 mg/dL (reference interval 0.1-1.1 mg/dL), ALP with 6.62 μmol/s.L (reference interval 0.8-2.15 μmol/s.L) and IgG with 2068 mg/dL (reference interval 900-1600 mg/dL) also improved in all patients with initially pathological serum levels. The median of all these parameters (serum total bilirubin: 0.81 mg/dL, range 0.33 to 2.47; ALP: 1.41 μmol/s.L, range 0.63-2.40; IgG: 1385 mg/dL, range 928-3140) was normal at the end

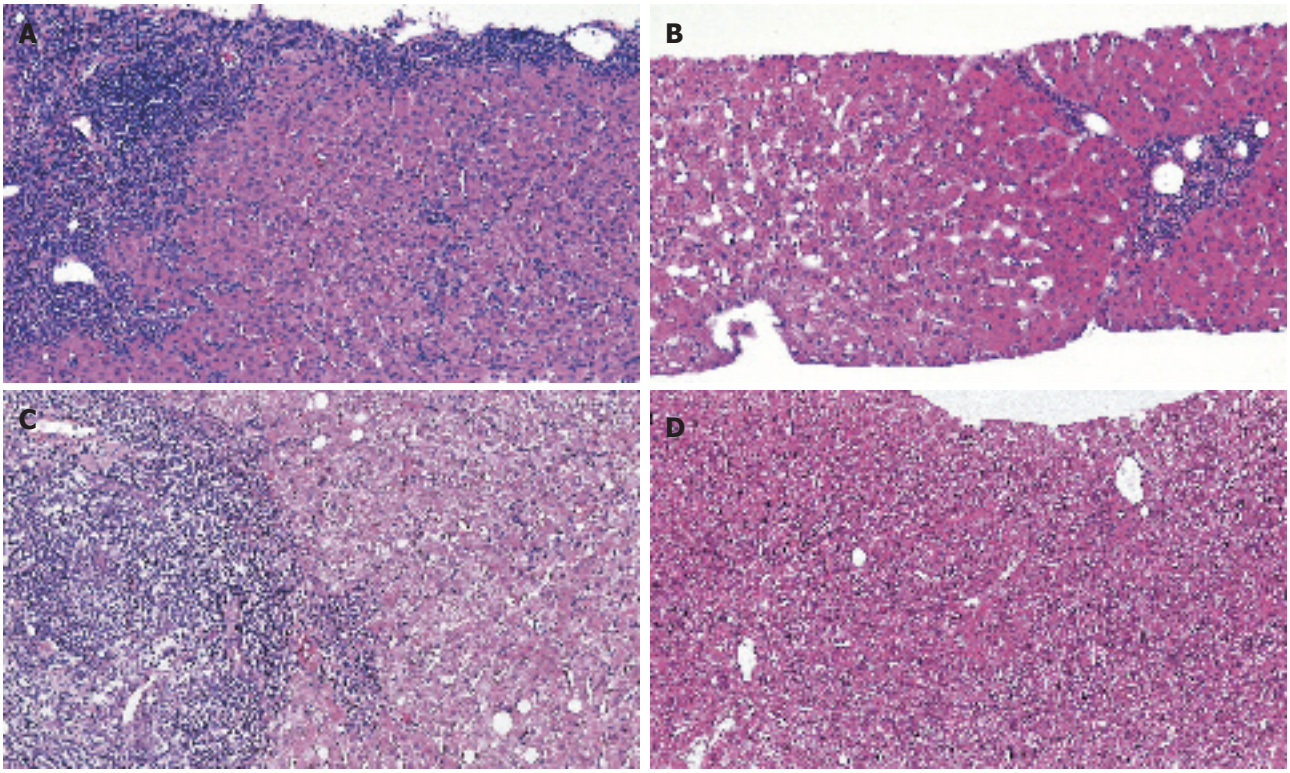

Figure 1 Histology of biopsy specimens obtained from a patient with AIH (**A**, **B**) and from a patient with AIH and PBC (overlap; **C**, **D**). Before treatment was started (**A**, **C**), liver biopsies showed a severe hepatitis with interface and lobular activity. Following administration of budesonide, follow-up biopsies were obtained 10 mo later from each patient and showed a significant improvement of disease activity (**B**, **D**).

of our evaluation.

Side effects of BUD therapy were noted in six patients (33%). However, clinically relevant side effects including abdominal pain ($n = 1$), weight gain of > 3 kg ($n = 3$), acne ($n = 2$) and hair lost ($n = 1$) and cushingoid appearance ($n = 3$) were reported only in patients with liver cirrhosis. Discontinuation of the therapy was warranted only in one woman (DC) who did not respond to BUD and developed intolerable gastrointestinal symptoms. No one of the patients developed impaired glucose tolerance or overt diabetes mellitus. A man with insulin-dependent diabetes mellitus showed no deterioration of his diabetes under BUD therapy. Changes in bone mineral density were not determined during the follow-up.

Histology

Twenty-six liver biopsies were obtained from 18 patients, of which eight were follow-up biopsies from seven patients. Histopathological changes compatible with AIH were found in eleven patients (Figure 1). Biopsy specimens from five patients showed histological signs of an overlap with either PBC or PSC (Figure 1). In a single biopsy from one patient the histological changes were very mild, with few portal tracts showing only a scattered inflammatory infiltrate, which were then categorized as unspecific changes, inconclusive for AIH. Follow-up biopsies obtained from seven patients showed a remarkable improvement of disease activity in all patients. Using the modified Ishak`s scoring system[6], disease activity was assessed with regard to periportal or periseptal interface hepatitis (maximum possible score 4), confluent necrosis (maximum possible score 6), lobular inflammation (maximum possible score 4), and portal inflammation (maximum possible score 4). By adding up the individual categories, a mean total score of 5.17 (range, 1-11) was found in the pretreatment biopsies and of 2.33 (range, 1-5) in the post-treatment biopsies (Figure 1). Staging of AIH (maximum possible score 6 - cirrhosis, probable or definite) ranged between 0 and 5. The absence of portal fibrosis (stage 0) was found in three patients, and advanced fibrosis (stage 5) was found in two. The mean values for staging showed no difference between specimens obtained before (mean value 2.39; range, 0 - 5) or after (mean value 2.10; range, 0 - 4) treatment. A mild steatosis of 20% or less was found only in four biopsy specimens of four patients. Steatosis was not found in any follow-up biopsy specimen.

DISCUSSION

BUD induced clinical and biochemical remission in the majority of our study patients with AIH including those with an overlapping PBC or PSC. Complete remission or significant improvement of liver histology was confirmed in the majority of our patients with a follow-up liver biopsy. In contrast, only three patients, two with liver cirrhosis and one with severe, corticosteroid-dependent disease, did not benefit from the therapy with BUD. 33% of patients experienced side effect(s), but only patients with advanced liver fibrosis or cirrhosis had severe adverse events as reported previously in patients with PBC because of the reduced hepatic metabolism of the drug[7]. Discontinuation of the drug was warranted only in one

patient with liver cirrhosis because of drug intolerance and non-response. These findings support the value of BUD in the management of treatment-naive patients with AIH and also as salvage therapy in individuals who are intolerant to PRD or AZA or experience an acute exacerbation of the disease in spite of an immunosuppressive therapy (Table 2).

Published data with BUD in patients with AIH are limited and controversial. Currently, two papers presenting a total of 23 patients with AIH have been published in the English literature[8,9]. The first report on BUD in AIH came from Sweden. This study included 13 patients with AIH who were treated with BUD as second-line therapy, initially with a daily dose of 6 to 8 mg, after they had experienced a relapse after discontinuation of the first-line therapy with PRD and AZA. Two patients were shown to have liver cirrhosis at presentation. Using BUD, ALT level normalized within 12 wk of treatment in the majority of the study patients[8]. Further small studies including a total of 36 patients with treatment-naive AIH published as abstract from Europe suggested that BUD may induce complete biochemical remission in about two-thirds of patients after one year of therapy who received the drug as first-line therapy. The frequency of the reported drug-related side effects ranged from 29% to 55%.

In contrast, in the second published report, experiences on 10 patients receiving BUD in AIH from a single center in the U.S., suggested that BUD as second-line therapy is able to induce remission only in a minority of patients with severe steroid-dependent AIH and is inferior to PRD[9]. In this report, all patients receiving BUD experienced at least one side effect. These results may be influenced by patient selection, as the presence of fibrosis increases the risk of side effects and advanced fibrosis and steroid-dependent disease are frequently associated with treatment failure and adverse events to drugs used in AIH.

Our data indicate that BUD is able to induce not only biochemical but also histological remission in patients with treatment-naive AIH. Furthermore, BUD can also be used as salvage therapy in those cases where PRD and AZA fail or patients become intolerant to these drugs. Patients presenting with severe acute hepatitis or having an overlap syndrome with PBC or PSC experience the same frequency of remission. As advanced liver fibrosis or cirrhosis is frequently associated with side effects and treatment failure, initiation of this therapy in histologically proven liver cirrhosis may deserve further considerations.

Abstract

AIM: To study the blood-brain barrier integrity in prehepatic portal hypertensive rats induced by partial portal vein ligation, at 14 and 40 d after ligation when portal pressure is spontaneously normalized.

METHODS: Adult male Wistar rats were divided into four groups: Group I: $Sham_{14d}$, sham operated; Group II: PH_{14d}, portal vein stenosis; (both groups were used 14 days after surgery); Group III: $Sham_{40d}$, Sham operated and Group IV: PH_{40d} Portal vein stenosis (Groups II and IV used 40 d after surgery). Plasma ammonia, plasma and cerebrospinal fluid protein and liver enzymes concentrations were determined. Trypan and Evans blue dyes, systemically injected, were investigated in hippocampus to study blood-brain barrier integrity. Portal pressure was periodically recorded.

RESULTS: Forty days after stricture, portal pressure was normalized, plasma ammonia was moderately high, and both dyes were absent in central nervous system parenchyma. All other parameters were reestablished. When portal pressure was normalized and ammonia level was lowered, but not normal, the altered integrity of blood-brain barrier becomes reestablished.

CONCLUSION: The impairment of blood-brain barrier and subsequent normalization could be a mechanism involved in hepatic encephalopathy reversibility. Hemodynamic changes and ammonia could trigger blood-brain barrier alterations and its reestablishment.

Key words: Blood-brain barrier; Rats; Prehepatic portal hypertension

INTRODUCTION

Portal hypertension (PH) and hepatic encephalopathy are major complications in human cirrhosis or portal vein thrombosis. Hyperdynamic splanchnic circulation and hyperaemia associated to systemic circulatory alterations are usually present[1,2].

Our laboratory found in the last years, the presence of derangement in the CNS in a prehepatic portal hypertensive rat model. Increases in the uptake and release of norepinephrine in diencephalic and telencephalic discrete brain regions and significant increments in tyrosine hydroxylase activity in these nuclei were described in previous publications[3-5].

Finally, morphologic alterations in astrocytes (AS) and endothelial cells (EC) located in the hippocampal region (CA1 and CA4) were also found in this experimental model[6].

The morphological cell components of BBB are basically AS, EC and pericytes. Two of this, AS processes and EC, were found altered in this model and in acute acetaminophen intoxication fourteen days after portal vein ligation[7,16,17].

Beside this, forty days after portal vein stricture, portal pressure spontaneously turns to normality. The aim of the present experiment was to investigate if normalization of PP was accompanied by the reestablishment of BBB properties and relate these findings with plasma ammonia concentration.

MATERIALS AND METHODS

Animals and surgical procedures

Male Wistar rats, with an average weight of 240 g were utilized and animal welfare was in accordance with the guidelines of the Faculty of Pharmacy and Biochemistry and approved by the Ethical Committee of the Faculty accordingly with Helsinki's Declaration. The animals were placed in individual cages, with free access to food (standard laboratory rat chow) and water, and 12 h light cycle: 8 a.m. - 8 P.M. Special care for perfect air renewal was taken.

Four groups of rats were used: $Sham_{14d}$- sham operated rats; PH_{14d} - Portal vein stenosis; both groups were used 14 d post-surgery. $Sham_{40d}$- sham operated; PH_{40d}- Portal vein stenosis; used 40 d after surgery.

Each group had separated subgroups for portal pressure determination, serum and CSF fluid determinations, Trypan blue and Evans blue injection respectively.

Portal hypertension was obtained by calibrated stenosis of the portal vein (PH) according to Chojkier *et al*[1]. Rats were lightly anesthetized with ether and then a midline abdominal incision was made. The portal vein was located and isolated from the surrounding tissues. A ligature of 3.0 silk sutures was placed around the vein, and snugly tied to a 20-gauge blunt-end needle placed along side the portal vein. The needle was subsequently removed to yield a calibrated stenosis of the portal vein. Operations were performed at 2 PM to obey circadian rhythm. Fourteen days after portal vein ligation, animals exhibit an increase in portal pressure. After 20 d portal pressure begins to fall down to normal values approximately after 30 d.

Sham operated rats underwent the same experimental procedure except that the portal vein was isolated but not stenosed. Animals were placed in individual cages and allowed to recover from surgery. Portal pressure was measured the 14^{th} d and the 40^{th} d after surgery in the corresponding group, by puncture of the splenic pulp. Animals were sacrificed by decapitation between 2 and 4 PM to avoid circadian variations.

Experimental procedures

Portal pressure measurement Fourteen and forty days after the corresponding operation, the rats were anaesthetized with sodium pentobarbital (40 mg/kg), intraperitoneally (ip). Portal pressure was measured through a needle placed in the splenic pulp, and maintained in place by cyanoacrylate gel. The needle was cannulated to a polyethylene catheter (50) filled with a heparinized saline solution (25 U/mL) and connected to a Statham Gould P23ID pressure transducer (Statham, Hato Rey, Puerto Rico) coupled to a Grass 79D polygraph (Grass Instruments, Quincy, MA).

Biochemical determinations Plasma was obtained from blood drained from aorta artery puncture. Under anesthesia, samples of cerebrospinal fluid (CSF) were obtained by cisternal puncture for pro-tein determination according to Bradford[8]. Plasma ammonia concentrations were determined using Ammoniac Enzyimatic UV Kits (Biomerieux, France). Aspartate aminotransferase (AST) and alanine aminotransferase (ALT) were determined in plasma using a commercial standardized and optimized Boehringer-Mannheim (Germany) kits.

Brain water content Cortical brain zones were utilized for the determination of water content in order to quantify possible brain edema. Gravimetric method was employed according to Marmorou *et al*[9].

Trypan blue transcardial perfusion Rats were perfused with Trypan blue (TB, Sigma Chemical Co. St. Louis MO. USA.) solution and then fixed with paraformaldehyde. TB solution (0.5%) was prepared by dissolving 1 g of TB in 200 mL of PBS, with gentle heat. The solution was allowed to cool at room temperature, added to the filtrate and placed on ice for immediate use. The temperature of TB solution was 10-12 ° C at the time of perfusion. Rats were anaesthetized with ethyl urethane (1mg/kg) and perfused transcardially with 200 ml of TB solution; followed by 300 mL of ice-cooled paraformaldehyde (2% in PBS). The flow rate of perfusate was maintained at 25 mL/min. Brains were dissected and post-fixed overnight in 30% sucrose for 2 d. Subsequently, the brains were placed in powdered dry ice and stored at -80 °C until processed for microscopic studies. Slices of brain tissue were obtained with cryostat in section of 300 microns according to Paxinos and Watson[10]. Hippocampal slices were evaluated under light microscope and expressed as positive (+) or negative (-) for TB staining. Medial eminence and choroids plexus staining were used as control of TB adequate perfusion. This method was adapted from Ikeda *et al*[11].

Evans blue test Evans blue (EB, Sigma Chemical Co. St. Louis MO. USA.) dye (25% in 0.9% NaCl solution) was intravenously injected at dose of 25 mg/kg in rats under ether anesthesia. One hour after the injection, animals were sacrificed by decapitation. Brains were weighed, clipped and individually placed within formamide p.a. (2mL/brain). These tubes were kept at 37°C for 48 h. The content of dye extracted from each brain was determined by spectrophotometer (Photometer 4010, Boehringer) at 620 nm and compared to standard graph created through the recording of optical densities from serial dilutions of EB in 0.9% NaCl solution[11, 12].

Statistical analysis

Results were expressed as mean ± SE. For multiple comparisons ANOVA, followed by Newman-Keuls or Student Newman Keuls tests were used. A $P<0.05$ was considered significant.

RESULTS

Portal pressure

The portal pressure (Figure 1) in Group Sh_{14d} was 7.6 ± 1.90 ($n=6$), in Group PH_{14d} 14±1.80 ($n=6$), in Group PH_{40d} was 2.52 ± 1.35 ($n=3$), Sh_{40d} 7.7 ± 1.98 ($n=5$). Differences between the following groups were significant: Sh_{14d} *vs* PH_{14d} ($P<0.001$); PH_{14d} vs. PH_{40d}, ($P<0.001$); Sh14d vs PH_{40d} ($P<0.01$). When sham groups (Sh_{14d} *vs* Sh_{40d}) were compared differences were not significant.

Plasma protein concentration.

Group PH_{14d} presented 87.40 ± 8.00 *mg/mL* ($n=4$); Group PH_{40d}, 107.60 ± 2.10 *mg/mL* ($n=5$); Group Sh_{14d}, 108.80±7.60

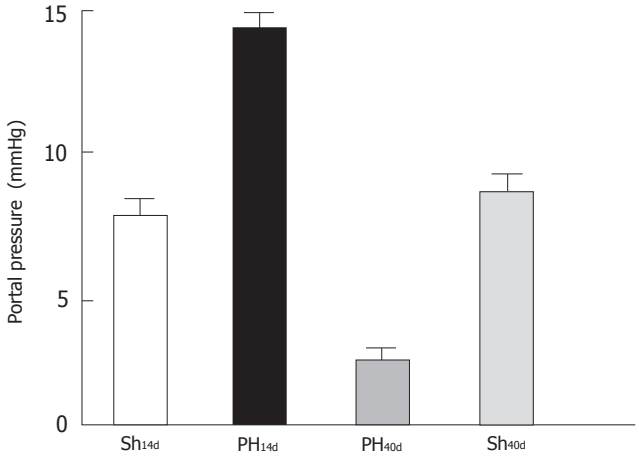

Figure 1 Portal pressure (mmHg). Group Sh14d *vs* Group PH_{14d} ($P<0.001$). Group PH14d *vs* Group PH_{40d} ($P<0.001$). Group Sh14d vs PH40d $P<0.01$. Sh14d *vs* Sh40d (n.s).

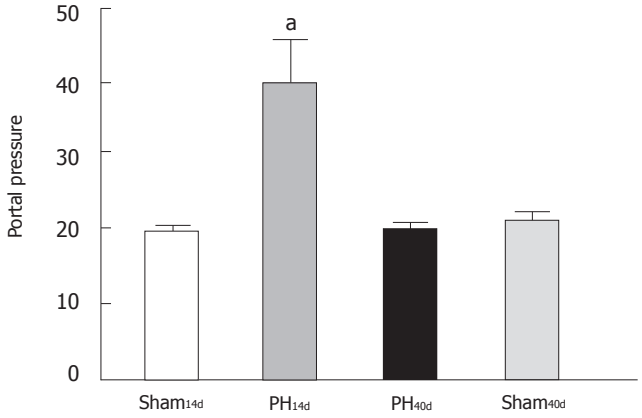

Figure 2 Protein content in cerebrospinal fluid. Hatched column corresponds to PH_{14d} ham shows an increased protein filtration through the BBB. This increment is not present, in black column,corresponding to PH_{40d} Results are expressed as mean ± SE.

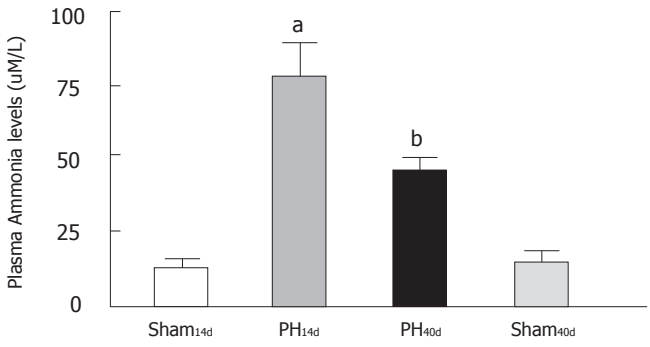

Figure 3 Plasma ammonia levels.significant elevation of plasma ammonia content in PH14d rats correspond to hatchet column. After 40 days of portal vein ligation, the portal pressure normalized, but plasma ammonia is still high (black column). $^{b}P<0.001$ and $^{a}P<0.05$, compared to Sham column.

mg/mL ($n=4$) and Group Sh_{40d}, 113.00 ± 2.10 *mg/mL* ($n=4$) (PH_{14d} *vs.* $Sham_{40d}$, $P<0.05$). Results showed a plasma protein concentration decrease tendency in portal hypertensive animals of day 14, which was only significant when compared with sham operated group after 40 d. This tendency was opposite to that observed in CSF.

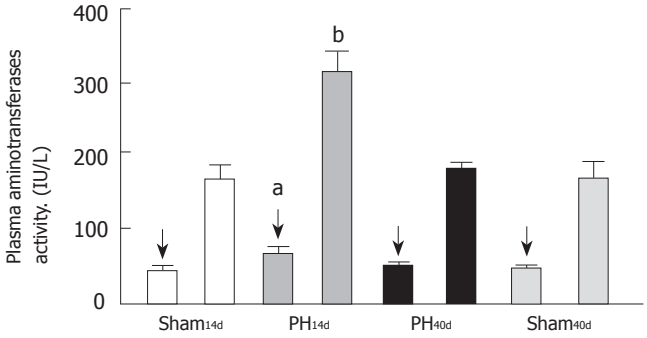

Figure 4 Plasma aminotransferases. The first column of each group corresponds to ALT activity (arrows) and the 2nd to AST activity. Both enzymes activities appear elevated in PH_{14d} (hatched columns) when compared to $Sham_{14d}$ ($^{b}P<0.001$; $^{a}P<0.05$).

Protein content in cerebrospinal fluid

Protein content in cerebrospinal fluid was 40.60±6.80 *μg/mL* in Group PH_{14d} ($n=4$), 20.62±0.69 *μg/mL* ($n=5$) in Group PH_{40d}, 19.52±0.80 *μg/mL* ($n=4$) in Group Sh_{14d}, and 21.70 ±2.27 *μg/mL* ($n=4$) in Group Sh_{40d}. Statistical analysis indicated that there were significant differences between $Sham_{14d}$ and Group PH_{14d} ($P<0.05$) and between Group PH_{14d} and Group Sh_{40d} ($P<0.01$) (Figure 1). According to these results PH_{14d} rats had increased protein permeability through the BBB. This increment was reverted when CSF protein was measured 40 days after portal vein stricture (Figure 2). These changes were not related to the above-cited variations in plasma protein values.

Ammonia plasma levels (Figure 3)

Portal hypertensive rats showed that ammonia plasma level was 79.00 ± 15.00 *μm/L* in Group PH_{14d}, ($n=8$), 44.76± 4.51*μm/L* in Group PH_{40d} ($n=5$), 12.99 ± 3.94 *μm/L* in Group Sh_{14d} ($n=11$) and 11.00 ± 4.20*μm/L* in Group Sh_{40d} ($n=9$) (Figure 2). This graphic shows a clear increase of plasma ammonia in PH_{14}, and a decrease in plasma ammonia levels when portal pressure is normalized. Levels in Group PH_{40d} are still higher than in Group Sh_{14d}, with statistical significance between groups: Sh_{14} vs. PH_{14} ($P<0.001$); Sh_{40} *vs* PH_{40} ($P<0.01$) and Sh_{14} *vs* Sh_{40} (NS). Group I_{14d} and Group IV_{40d} showed a very similar and low plasma concentration. When comparing groups PH_{14} with PH_{40}, P value is <0.01, thus indicating a better ammonia metabolism.

Plasma transferases activity (Figure 4)

Plasma ALT activity was 63.00 ± 9.00 *IU/L* in Group PH_{14d} ($n=6$), 44.00±4.50 *IU/L* in Group PH_{40d} ($n=7$), 39.00±4.00 *IU/L* in Group Sh_{14d} ($n=6$) and 39.00±3.50 *IU/L* in Group Sh_{40d} ($n=6$). Statistical analysis shows an increase of PH_{14d} levels when compared to groups Sh_{14d} and Sh_{40d} ($P<0.05$).

The activity of plasma AST was 316.0 ± 23.0 *IU/L* in Group PH_{14d} ($n=6$), 167.0±14.0 *IU/L* in Group PH_{40d} ($n=7$), 155.0 ± 25.0 *IU/L* in Group Sh_{14d} ($n=6$) and 155.0 ± 32.0 *IU/L* in Group Sh_{40d} ($n=6$). Statistical calculations outline

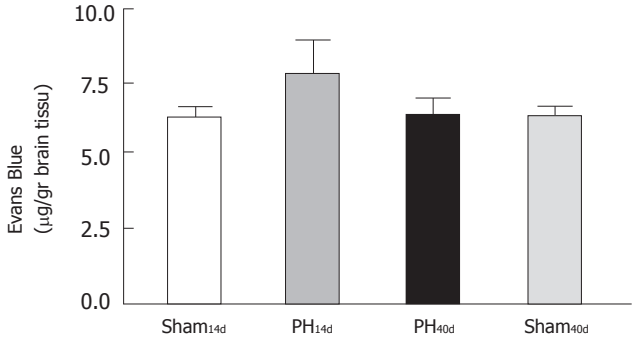

Figure 5 Evans blue test.The systemic injection of Evans blue showed a statistically significant increase of the dye presence in the hippocampal region in PH_{14d} presence in the indicate $p < 0.01$ when compared with the other 3 groups.

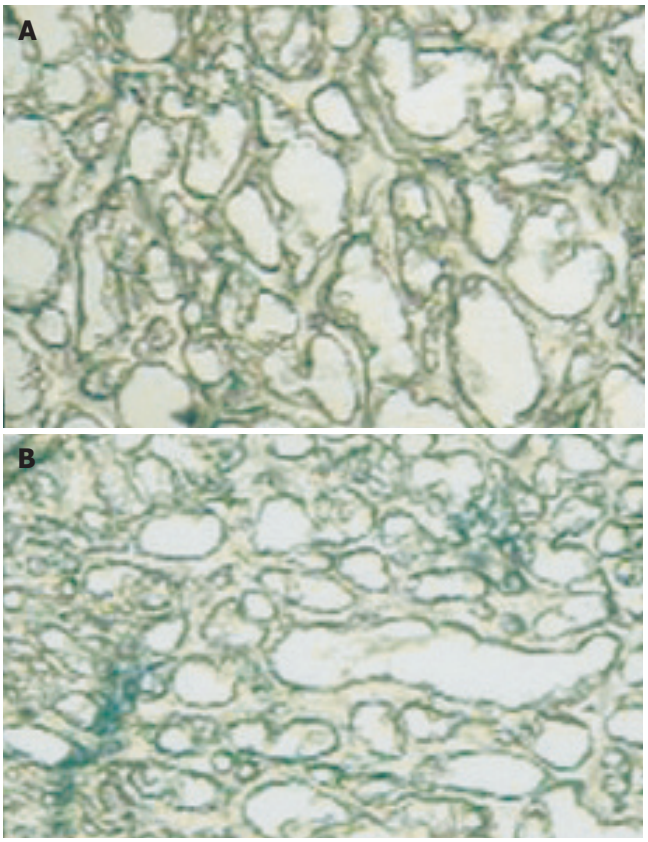

Figure 6 **A:** In the rest of the groups, including that were portal pressure normalized 40 days after portal vein stricture and Sham groups, the image is negative for Trypan blue dye (100 x); **B**: Light microscopy showed a marked Trypan blue dye diffusion in brain hippocampal of PH rats of 14 d (100 x).

an increment of the enzyme in PH_{14d} group, when compared with groups of Sh_{14d} ($P < 0.001$), PH_{40d} ($P < 0.01$), and Sh_{40d} ($P < 0.001$). The elevation of their activity usually indicates some level of rat liver alteration, which is observed in this model of prehepatic portal hypertension.

Water content in cortical brain areas

Water content in cortical brain areas (H_2O/gr %) was 79.21 ±0.17 in Group PH_{14d} ($n = 6$), 79.21 ± 0.17 in Group PH_{40d} ($n = 7$), 78.95 ± 0.18 in Group Sh_{14d} ($n = 6$) and 77.26 ± 0.29 in Group Sh_{40d} ($n = 6$). No significant differences were found between the groups.

Trypan blue and Evans blue tests

Trypan blue test showed the presence of the dye limited to the vascular area, not involving other areas in Groups Sh_{14d} and Sh_{40d}. Meanwhile, EB appeared positively in vascular area and diffusely in perivascular area in Group PH_{14d}. In Group PH_{40d} both were detected in vascular area and very slightly in perivascular areas. These findings demonstrate the existence of an increased BBB permeability to the dye in PH_{14d} rats, which turns to normal when pressure levels are normalized 40 d later (Figures 6 A and B).

The systemic injection of EB confirmed quantitatively the results found with TB. The results, expressed in μg/g of brain tissue, were 6.170±0.380 in Group Sh_{14d} ($n = 12$), 8.680 ±0.700 in Group PH_{14d} ($n = 9$), 6.300 ± 0.590 in Group PH_{40d} ($n = 6$) and 6.250 ± 0.450 in Group Sh_{40d} ($n = 6$). Statistical comparison showed that there was significant difference between Group PH_{14d} and Group PH_{40d} ($P < 0.01$) and between Group Sh_{14d} and Group PH_{14d} ($P < 0.01$). There was no significant difference between Group Sh_{14d} and Group PH_{40d}; Group Sh_{40d} and Group Sh_{14d} shared almost identical values (Figure 5).

DISCUSSION

The BBB is formed by complex tight junctions of the brain capillary endothelial cells in close relation with the astrocyte processes. These morphological and functional structures make possible a selective transport across BBB and a non-selective brain distribution of drugs[13]. Three cellular components characterize BBB: Endothelial cells, astrocyte end feet and pericyte[14]. Tight junctions present between cerebral endothelial cells form a diffusion barrier that restricts the influx of most blood-borne substances from entering the central nervous system (CNS). Dysfunction of BBB complicates a number of neurological diseases[15].

Alterations in astrocytes architecture as well as changes in its metabolism due to ammonia detoxification, osmotic balance and cell homeostasis are a well-known feature of hepatic or porto-systemic encephalopathy[16,17].

In previous publications, we described the alteration of BBB in this model of prehepatic portal hypertension, with or without acute acetaminophen intoxication[18,19]. In this paper, the addition of Evans blue technique confirms previous results and adds a quantitative measurement to morphologic findings.

No difference in brain water content was found in this model of partial portal vein ligation, opposed to changes in brain water content found in rats with acetaminophen intoxication as previously described[19]. The presence, however, of EEG modifications[18] and rota rod test modifications[19], led us to classify it as a probable sub-clinic encephalopathy. The lack of a rise in brain water content observed in this model is probably due to the fact that the chronic nature of the portal pressure rise and porto-systemic circulation probably allows some kind of compensation mechanism[16].

Alterations of BBB permeability have been studied in different models of cirrhosis and porto-caval shunting, observing different kind of BBB changes like for some aminoacids but not others[20-22], Evans blue[23] , but not for 14C mannitol or 3H-glutamate[22].

Our results show an altered BBB permeability, qualitative and quantitative, in portal vein ligated rats 14 d after surgery (PH_{14d}) and posterior normalization after 40 d of portal vein stricture (PH_{40d}). This alteration is shown by significant differences observed in protein concentration in CSF and concentration of Evans blue dye in CNS and confirmed by microscopic observation of Trypan blue diffusion. It is interesting to stress out that in PH_{14d} group, protein concentration in CSF is elevated despite a tendency to fall in plasma protein when compared to control (Sh_{14d}). There were no differences in plasma or CSF protein content between Sh_{14d} and PH_{40d} or Sh_{40d}, nor in the same groups when comparing Evans Blue concentration.

In this study, a decrease in portal pressure accompanies normalization of BBB permeability expressed as CSF protein content and diffusion of Evans blue and Trypan blue dyes. Despite these results, ammonia remains moderately elevated after 40 d, indicating the presence of some amount of portal systemic shunting and that some levels of increased ammonia may not interfere with BBB normal function. This presence of portal systemic shunting could also explain the fact that portal pressure is lower in PH_{40d}, when compared to the sham operated group. In spleen-portographies done in the past, we observed in rats of more than 30 d of portal ligation, some cases of porto-portal collateral circulation shunted the silk ligature (personal observation, unpublished).

The fact that BBB altered permeability is resolved but plasma ammonia concentration is not completely normal remains unexplained. Further studies should be conducted to clarify the responsibility of vasoactive substances released in portal hypertension in BBB alterations in this rat model.

The elevated AST and ALT may indicate some kind of liver alteration present in this model with an otherwise almost normal liver function. Astrocyte changes and ammonia detoxification in the brain are probably some of the mechanisms implicated in BBB alteration and posterior normalization. Other factors have been implicated like cytokines and carbon monoxide[23-25].

The normalization of BBB permeability could be a necessary part of hepatic encephalopathy reversibility. This could be a simple model for further studies in BBB function and reversibility of permeability mechanisms useful for a faster recovery of hepatic encephalopathy in patients.

We confirm the spontaneous tendency of this model to normalize portal pressure. No changes in cortical brain water content were found. Following the spontaneous decrease of portal pressure at 40 d, the BBB altered permeability reestablished its properties. Despite BBB permeability normalization, ammonia concentration remained moderately high, but significantly lower than the portal hypertension group 14 d after surgery. This could be a useful model to study BBB alterations and posterior normalization in portal hypertension with a low grade of encephalopathy.

ACKNOWLEDGEMENTS

We thank Dr. C. Taira and Dr. C. Ghanem for their kind advise.

Abstract

AIM: To investigate the protective effect and mechanism of alanyl-glutamine dipeptide (Ala-Gln) against hepatic ischemia-reperfusion injury in rats.

METHODS: Rats were divided into group C as normal control Group (n=16) and group G as alanyl-glutamine pretreatment (n=16). Rats were intravenously infused with 0.9% saline solution in group C and Ala-Gln -enriched (2% glutamine) 0.9% saline solution in group G via central venous catheter for three days. Then all rats underwent hepatic warm ischemia for 30 min followed by different periods of reperfusion. Changes in biochemical parameters, the content of glutathione (GSH) and the activity of superoxide dismutase (SOD) in liver tissue, Bcl-2 and Bax protein expression and morphological changes of liver tissue were compared between both groups.

RESULTS: One hour after reperfusion, the levels of liver enzymes in group G were significantly lower than those in group C (P<0.05). Twenty-four hours after reperfusion, the levels of liver enzymes in both groups were markedly recovered and the levels of liver enzyme in group G were also significantly lower than those in group C (P<0.01). One and 24 h after reperfusion, GSH content in group G was significantly higher than that in group C (P <0.05). There was no statistical difference in activities of SOD between the two groups. One and 24 h after reperfusion, the positive expression rate of Bcl-2 protein was higher in group G than in group C (P<0.05) and the positive expression rate of Bax protein was lower in group G than in group C (P < 0.05). Histological and ultrastructural changes of liver tissue were inhibited in group C compared to group G.

CONCLUSION: Our results suggest that Ala-Gln pretreatment provides the rat liver with significant tolerance to warm ischemia-reperfusion injury, which may be mediated partially by enhancing GSH content and regulating the expression of Bcl-2 and Bax proteins in the liver tissue.

Key words: Alanyl-glutamine dipeptide; Hepatic ischemia-reperfusion injury; Glutathione; Bcl-2; Bax

INTRODUCTION

Temporary clamping of the portal triad, ie, inflow occlusion by the Pringle's maneuver, is a common strategy to minimize bleeding during hepatic resection. Unfortunately, this method resulted in hepatic ischemia-reperfusion (I/R) injury and may cause postoperative functional disorder of the liver. Development of new pharmaceutical strategies to attenuate hepatic I/R injury is important for achieving a better clinical outcome. Hepatic I/R injury factors usually include oxygen radical species, intracellular calcium overloading, inflammatory cytokines and infiltration of neutrophils[1]. However, its mechanism has not been fully elucidated.

Glutamine (Gln) is a conditionally essential nutrient during serious injury or illness, and plays a vital role in the metabolism of tissue[2-4]. Recently, Gln has been demonstrated to protect against I/R injury of gut, heart and skeletal muscle and its possible mechanism is partially related to preservation of the content of glutathione (GSH)[5-7].

Recently, apoptosis has been indicated as an important mode of cell death during hepatic I/R injury[8]. Apoptosis is governed by a number of regulating genes, such as *bcl-2* and *bax* and the ratio of *bcl-2* to *bax* determines survival

or death following an apoptotic stimulus[9]. Animal studies demonstrate that GSH depletion is associated with decreased *bcl-2* gene expression and increased apoptosis in cholangiocytes[10]. Overexpression of *bcl-2* gene by transferring this gene into hepatocytes with adenovirus is resistant to hepatic I/R injury[11].

However, there are few studies dealing with the effect of Gln on hepatic I/R injury. Consequently, we designed this experiment to study the effect of Gln on hepatic I/R injury in rats and its possible mechanisms. Dipeptide L-alanyl-L-glutamine is soluble in water and remains stable after heat sterilization[12]. Peptidase activity in all body compartments shows rapid hydrolysis and release of appropriate amino acids after intravenous infusion. Therefore, alanyl-glutamine dipeptide (Ala-Gln) was used in this experiment.

MATERIALS AND METHODS

Experimental animals

Male Wistar rats weighing 250-300 g (supplied by the Experimental Animal Center of Shengjing Hospital) were housed in a standard animal laboratory with free activity and access to water and chow. They were kept under constant environment conditions in a 12 h light-dark cycle. All operations were performed under clean conditions.

Intravenous drugs and other relevant chemicals

Dipeptiven (Ala-Gln solution) was from Sino-Sweden and Fresenius Pharmaceutical Corp. LTD. GSH and superoxide dismutase (SOD) detection kits were purchased from Nanjing Jiancheng Bioengineering Institute, China. Mouse anti-rat Bcl-2 and Bax monoclonal antibodies were provided by Beijing Zhongshan Biotechnology Co.Ltd, China.

Animal model and grouping

Under urethane anesthesia (intraperitoneal injection, 10 mg/kg), a silastic catheter was inserted through the right external jugular vein into the superior vena cava, tunneled subcutaneously and brought out through the skin of mid-scapular region. A flexible spring guarded the catheter, and then hooked up to an infusion pump. All rats were maintained in individual metabolic cages. After catheterization, all rats received intravenously 0.9% saline solution at a constant rate by a pump (2 mL/h) with free activity and access to water and chow for 3 d. Then, all rats were randomly divided into Group C infused with 0.9% saline solution (n=16) and group G infused with Ala-Gln-enriched (2% glutamine) 0.9% saline solution (n=16). After 3 d, under urethane anesthesia (intraperitoneal injection, 10 mg/kg) a midline laparotomy was performed and all structures in the portal triad to the liver were clamped for 30 min followed by different periods of reperfusion. Liver tissues and blood were sampled at 1 and 24 h after reperfusion for liver function tests, antioxidant enzyme measurement, Bcl-2 and Bax protein expression and morphological examination.

Liver function tests

Blood samples collected at 1 and 24 h after reperfusion were used to measure the alanine aminotransferase (ALT) and lactic dehydrogenase (LDH) levels with a standard biochemistry automatic analyzer.

Antioxidant enzyme measurement

The content of GSH and activity of SOD in rat liver tissue were measured following instructions of the commercial kit.

Immunohistochemistry

S-P immunohistochemistry was performed to detect Bcl-2 and Bax proteins following instructions of the commercial kit. Only cytoplasmic staining was evaluated and nuclear reaction was interpreted to be nonspecific staining. No positive cells was negative expression. The positive cells were considered weak positive expression when their percentage was lower and scored as (+), moderate positive expression when their percentage was between 1/3 and 2/3 and scored as (++), and strong positive expression when their percentage was higher than 2/3 and scored as (+++).

Histological and electron microscopic analysis

Liver specimens were taken at 1 and 24 h after reperfusion for hematoxylin-eosin staining and light microscopy. The specimens were immediately cut for electron microscopy. The sections were examined under a Philips CM10 electron microscope.

Statistical analysis

The data were presented as mean ± SD. Student's t test was performed for the biochemical parameters and antioxidant enzyme levels. $P < 0.05$ was considered statistically significant. Software SPSS11.0 was used in all statistical analyses.

RESULTS

Hepatic serum enzyme concentration

One hour after reperfusion, the serum ALT and LDH concentrations in group G were significantly lower than those in group C ($P<0.05$). Twenty-four hours after reperfusion, liver enzyme levels in both groups were markedly recovered, the serum ALT and LDH concentrations in group G were also significantly lower than those in group C ($P<0.01$, Figures 1 A and 1 B)

Antioxidant enzyme level

One and 24 hours after reperfusion, the GSH content in the liver tissue of group G was significantly higher than that in group C ($P<0.05$). There was no statistical difference in the activity of SOD between the two groups ($P>0.05$, Figures 2 A and 2 B)

Bcl-2 and Bax expression

One and 24 h after reperfusion, the positive expression rate of Bcl-2 was higher in group G than in group C ($P<0.05$) and the positive expression rate of Bax was lower in group G than in group C ($P<0.05$) (Table 1, Figures 3 A-3D).

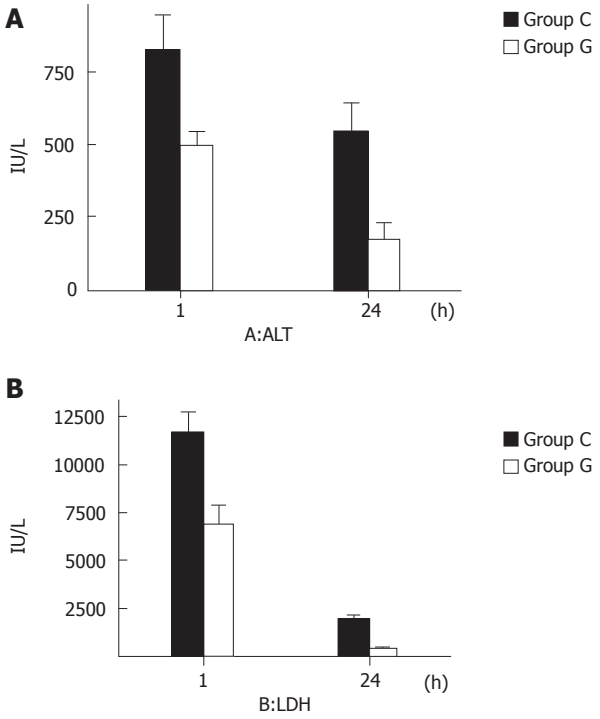

Figure 1 Liver function 1 and 24 h after reperfusion of ALT (**A**) and LDH (**B**) in groups C and G.

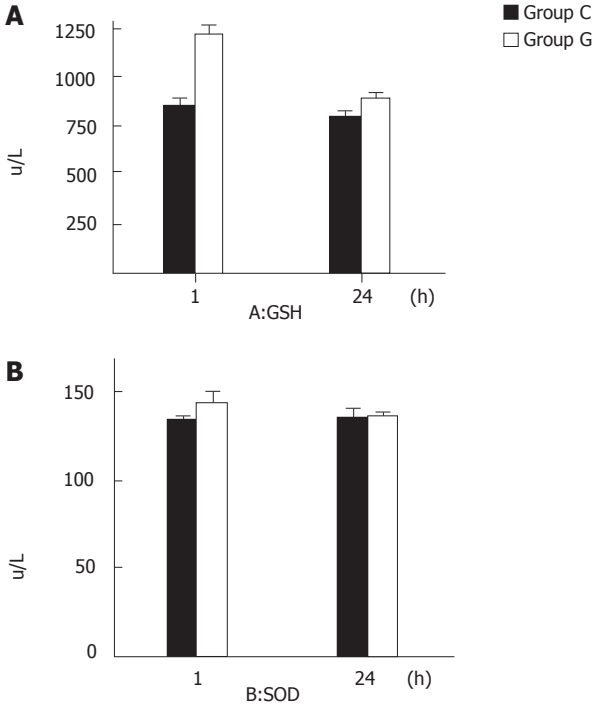

Figure 2 GSH content (**A**) and SOD activity (**B**) 1 and 24 h after reperfusion in groups C and G.

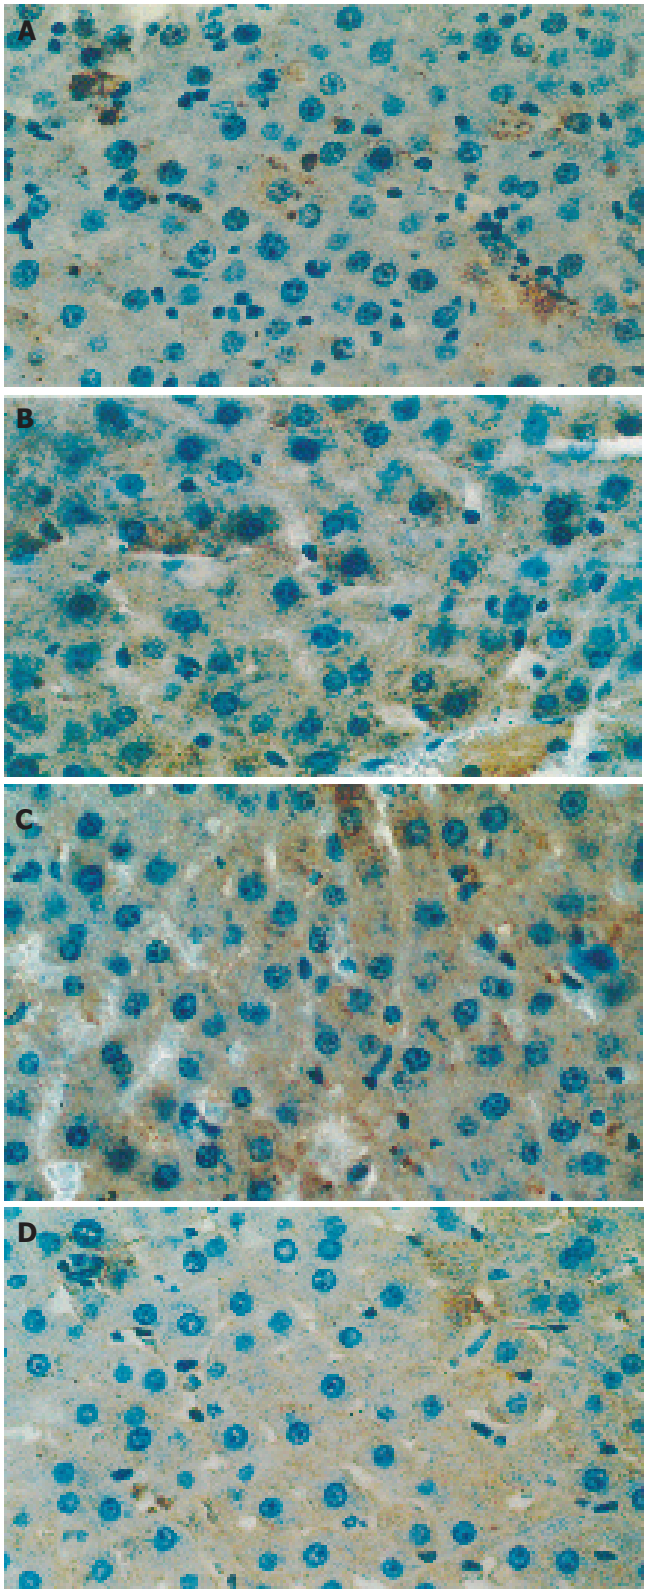

Figure 3 Bcl-2 expression in group C (**A**) and group G (**B**) (post-reperfusion 1 h) (× 400), and Bax expression in group C (**C**) and group G (**D**).

Histological changes

One hour after reperfusion, only slight swelling and less fatty and vacuolation degeneration were found in hepatocytes of group G. However, severe swelling was observed in group C along with more fatty and vacuolization degeneration in hepatocytes. Compartment of hepatic sinus became narrow or disappeared. Infiltration of neutrophils and hemorrhage were also observed. Twenty-four h after reperfusion, the swelling and vacuolization degeneration in group G became worse, but the hepatic cellular structure was still clear and only single-cell necroses were observed. However, derangement of constitution was observed in group C along with a few necroses of hepatocytes.

Table 1 Positive expression of Bcl-2 and Bax proteins in liver tissue

Group	Bcl-2 protein						Bax protein					
	positive expression				total positive expression		positive expression				total positive expression	
	-	+	++	+++	number	percentage(%)	-	+	++	+++	number	percentage(%)
group C (1 h)	5	0	0	3	3	37.5[a]	0	1	3	4	7	87.5[c]
group G (1 h)	0	0	0	8	8	100.0	4	2	1	1	2	25.0
group C (24 h)	5	1	1	1	2	25.0[e]	0	1	4	3	7	87.5[g]
group G (24 h)	1	0	0	7	7	87.5	5	1	1	1	2	25.0

[a]$P<0.05$, [c]$P<0.05$, [e]$P<0.05$, [g]$P<0.05$ *vs* group G.

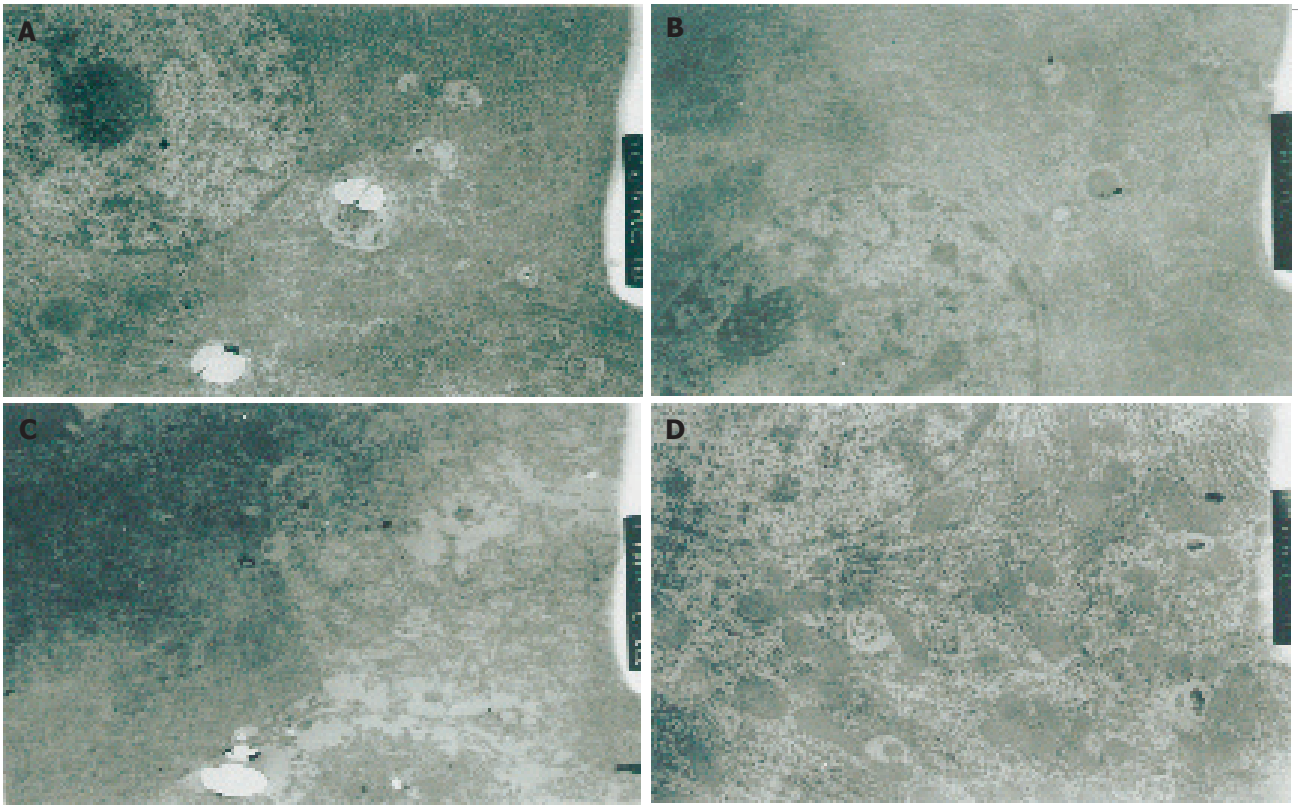

Figure 4 Hepatic ultrastructure 1 h after reperfusion (×1500) in group C (**A**) and group G (**B**), 24 h after reperfusion in group C (**C**) and group G (**D**).

Ultrastructural changes

One h after reperfusion, mitochondria and glycogen granules were observed in hepatic cytoplasm of group G. Rough endoplasmic reticulum was arrayed as lamellar. Mitochondria and rough endoplasmic reticulum were slightly swollen. More primary lysosomes were found. In group C, mitochondria were severe swollen and had a reduction in the number of cristae. Rough endoplasmic reticulum was dilated and ruptured in different degrees. Smooth endoplasmic reticulum increased and glycogen granules decreased. More secondary lysosomes were observed. Twenty-four h after reperfusion, more mitochondria, endoplasmic reticulum and a few of glycogen granules and secondary lysosomes were observed in cytoplasm of group G, along with slightly focal swelling. In group C, hepatocytes only were observed with cellular contour. Severe edema, deformation and necrosis were also observed. The structure of organelles in cytoplasm was not clear. (Figures 4A-4D)

DISCUSSION

Gln is one of the most abundant amino acid in plasma and plays an important role in the metabolism of body. The circulating and tissue concentrations of Gln diminish precipitously after stress. When Gln is exhausted to a certain extent, a large amount of Gln released from skeletal muscle and a small amount from lung are transported to liver and gut. Recently, Gln has been demonstrated to protect against ischemia-reperfusion injury of gut, heart and skeletal muscle[5-7].

The results of our study indicated that after 30 min

ischemia, liver function and morphology were impaired and Gln pretreatment could protect against liver damage.

The exact mechanisms of the protective effect of Gln against ischemia and reperfusion injury of organs and tissues are still incompletely understood. Gln protects against ischemia-reperfusion injury of gut, heart and skeletal muscle by preserving the GSH content in the tissues[5-7]. GSH is an important endogenous antioxidant that protects against oxygen free radical injuries and intravenous GSH administration during reperfusion of ischemic liver can prevent reperfusion injury in rats[13]. The content of GSH is useful for determination of the degree of tissue damage[14]. In this study, Gln pretreatment could obviously increase the GSH content in rat liver tissue, indicating that Gln can protect against hepatic I/R injury by maintaining the relatively high content of GSH in tissue and relieving the cellular oxidant injuries[15].

In addition, Gln pretreatment can also protect against hepatic I/R injury by participating in energy metabolism, increasing the cellular energy metabolism, protecting the structure and function of mitochondria and decreasing the production of oxygen free radicals, leading to less consumption of GSH in liver tissue. A complete inhibition of α-ketoglutarate dehydrogenase activity in the TCA cycle has been observed in hyperoxia-exposed glutamine-deprived cells and Gln could protect α-ketoglutarate dehydrogenase from inactivation under oxidative stress as well as mitochondria from oxidative stress and increase cellular ATP levels[16]. Gln could stimulate the synthesis of glycogen and increase the glycogen store in hepatocytes, reinforcing the ability of liver against cellular oxidant injuries[17]. In this study, mitochondria and glycogen granules were observed in hepatic cytoplasm, mitochondria and rough endoplasmic reticulum were protected.

Gln increases the activity of SOD in liver tissue after stress[18], which was not confirmed in our study due to the model of rat, the number of samples and the dosage of Gln in this experiment.

It was reported that portal triad clamping produces not only ischemic injury of the liver but also portal venous congestion[19]. Acute portal venous congestion for a long period may impair the intestinal mucosal barrier and increase intestinal permeability, causing endotoxemia, bacterial translocation, activation of reactive oxygen radicals and inflammatory cytokines, such as tumor necrosis factor-α (TNF-α)[20-23]. Reperfusion of stagnant portal venous blood with deleterious chemical mediators into the ischemic liver aggravates the liver injury, leading to intra-abdominal sepsis and abscess formation, which is the major cause of postoperative septic complications induced by hepatic I/R injury[24-26]. However, attempts to protect against hepatic I/R injury by alleviating the possible detrimental effects of portal venous congestion have not achieved satisfactory results.

Gln is a precursor for synthesis of nucleic acids and glutathione. It is the main fuel for rapid proliferating and dividing cells such as enterocytes and lymphocytes. It can maintain the metabolism of intestinal mucosal cells directly or indirectly, promote hyperplasia of epithelial cells of ileum and colon, maintain the structure and function of small intestinal mucosal and reduce the increment of intestina permeability[27-30].

Gln can enhance the function of gut-associated lymphoid tissue (GALT) and gut[31]. Gln administration can prevent the depletion of GSH in Peyer's patches of endotoxaemic mice[32] and promote secretion of mucosal secretory immunoglobulin A (S-IgA), a major effector of the gut-associated lymphoid tissue in the intestine, which can bind to bacteria and prevent their adherence to the epithelium and bacterial translocation[33, 34].

Hepatic injury caused by ischemia can be described as necrosis. It was reported that apoptosis of hepatocytes and sinusoidal endothelial cells is a critical mechanism contributing to hepatic I/R injury[8]. The mechanism of apoptosis in ischemia and reperfusion injury usually includes prodtion of oxygen radical species and intracellular calcium overloading[35]. Translocation of bacteria and endotoxin from gut, well documented in hepatic I/R injury, also contribute to the induction of hepatocyte apoptosis. TNF-α induced by endotoxin also can induce hepatocyte apoptosis[36]. A number of genes regulate the apoptotic process. The family of *bcl-2*-related proteins plays a key role in the regulation of apoptosis.

Bcl-2, a member of the *bcl-2*-related protein family, can promote cell survival through protein-protein interactions with other *bcl-2*-related protein family members. Recent studies indicate that overexpression of Bcl-2 protein could reduce hepatocellular apoptosis after reperfusion and protect against hepatic I/R injury[8, 11]. Bax, another member of the *bcl-2*-related protein family, has extensive amino acid homology with Bcl-2 and may form homodimers to accelerate cell death or form heterodimers with Bcl-2 to inhibit cell death. Therefore, changes in the ratio of Bcl-2 and Bax expression may determine survival or death following apoptotic stimuli and attenuate the anti-apoptotic effect of Bcl-2 protein by reducing post-ischemic apoptosis[9, 37].

In this study, up-regulation of Bcl-2 protein expression and down-regulation of Bax protein expression in rat liver were found 1 and 24 h after reperfusion, indicating that Gln can protect against hepatic I/R injury by regulating the expression of Bcl-2 and Bax proteins. Our findings suggest that Gln pretreatment could enhance GSH content and protect against oxidative stress in hepatic I/R injury. It has been proved that reduction in the cellular level of GSH increases degradation of Bcl-2 protein and apoptosis[10]. Gln pretreatment can significantly increase cellular ATP levels and synthesis of glycogen and glycogen store in hepatocytes[16, 17]. Gln can decrease the diminution of liver tissue ATP content and intracellular calcium overloading maintain the activity of Na^+-K^+ and Ca^+-ATPase, and prevent hepatocellular apoptosis. On the other hand, Gln pretreatment can protect gut barrier and decrease the release of enteric endotoxin and inflammatory cytokines (such as TNF-α), thus reducing the direct pro-apoptotic effect of endotoxin and TNF-α.

In conclusion, glutamine pretreatment can protect against hepatic I/R injury by enhancing GSH content and regulating the expression of Bcl-2 and Bax proteins in liver tissue.

Abstract

AIM: To investigate the possible mechanism of the protective effects of a bioactive fraction, *Ganoderma lucidum* proteoglycan (GLPG) isolated from *Ganoderma lucidum* mycelia, against carbon tetrachloride-induced liver injury.

METHODS: A liver injury model was induced by carbon tetrachloride. Cytotoxicity was measured by MTT assay. The activities of alanine aminotransferase (ALT) and aspartate aminotransferase (AST) were determined with an automatic multifunction-biochemical analyzer and the levels of superoxide dismutase (SOD) and TNF-α were determined following the instructions of SOD kit and TNF radioimmunoassay kit. Liver sections were stained with hematoxylin and eosin (H&E) for histological evaluation and examined under light microscope.

RESULTS: We found that GLPG can alleviate the L-02 liver cells injury induced by carbon tetrachloride (CCl_4) through the measurements of ALT and AST activities and the administration of GLPG to L-02 cells did not display any toxicity. Furthermore, histological analysis of mice liver injury induced by CCl_4 with or without GLPG pretreatment indicated that GLPG can significantly suppress the toxicity induced by CCl_4 in mice liver. We also found that GLPG reduced TNF-α level induced by CCl_4 in the plasma of mice, whereas increased SOD activity in the rat serum.

CONCLUSION: GLPG has hepatic protective activity against CCl_4-induced injury both *in vitro* and *in vivo*. The possible anti-hepatotoxic mechanisms may be related to the suppression of TNF-α level and the free radical scavenging activity.

Key words: *Ganoderma lucidum proteoglycan* (GLPG); Carbon tetrachloride (CCl_4); Liver injury; Hepatic protective activity

INTRODUCTION

The mainstream pharmaceutical industry makes use of many plant products[1]. In traditional Chinese medicine (TCM) many products from plants are used in the treatment of a wide range of disorders including cancer[2]. Moreover, the researches on the bioactive ingredients and the investigation of the functional mechanism of natural products used in TCM are becoming increasingly important. Several substances which are successful in tumor therapy, such as betulinic acid and indirubin, have been elucidated by molecular biological and cell biological methods[3, 4].

Fungi are an important source of materials in TCM. Extracts from about 200 species of fungi have been shown to stimulate immunoactivity and inhibit the growth of different kinds of tumors[5-8]. *Ganoderma lucidum* (Leyss. ex Fr.) *Karst* is a medicinal mushroom belonging to the polyporaceae of aphyllophorales. Its fruiting body is called "Lingzhi" in China and "Reishi" in Japan. For hundreds of years, this mushroom has been regarded as a TCM or a folk medicine used in the prevention and treatment of various human diseases, such as chronic bronchitis, hepatitis, hypertension, hypercholesterolemia, tumorigenic disease and immunological disorders in China and other Asian countries[9].

Carbon tetrachloride (CCl_4) is a xenobiotic producing hepatotoxicity in human beings and animals[10-11]. In fact

it has been shown that the trichloromethyl radical formed in the metabolism of CCl_4 via the liver microsomal cytochrome P450 system, reacts rapidly with molecular oxygen to produce trichloromethyl peroxy radicals. These radicals react with unsaturated fatty acids of phospholipids present in cell membranes, initiating lipid peroxidation in liver cells[12]. Hydrogen atoms are removed from unsaturated fatty acids by such radical-created carbon-centered lipid radicals[13]. These lipid radicals quickly add molecular oxygen to form lipid peroxyl radicals which in turn abstract hydrogen atoms from other lipid molecules, thereby propagating the process of lipid peroxidation[14]. Transition metals such as copper and iron can catalyze oxygen free radical reactions that lead to peroxidation of membrane lipids or inactivation of antioxidant defense[15]. Previous studies have also reported involvement of iron as a mediator of CCl_4-hepatotoxicity[16]. When the amount of reactive oxygen species (ROS) production exceeds the capacity of the endogenous cellular antioxidant system, significant cellular injury can occur[17, 18]. Treatment of animals with different antioxidants such as vitamin E[19], vitamin E-like compounds[20], 5-methylthioadenosine[21], colchicines[22] and desferrioxamine[23] can significantly improve hepatic conditions by reducing CCl_4-induced damage.

Ganoderma lucidum contains many biologically active components[24, 25]. Previous studies suggested that *Ganoderma lucidum* polysaccharide (Gl-PS), one of the main efficacious ingredients of *Ganoderma lucidum Karst,* has been under modern pharmacological research in recent 30 years and is effective in modulating immune functions, inhibiting tumor growth, resisting invasion of various viruses[9, 26, 27]. Miyazaki and Nishijima[28] have separated a heteroglycan from the fruit body of Ganoderma lucidum. Moreover, Some researchers have isolated several hypoglycemic glycans from another fraction of the same crude polysaccharide[29].

Though the fruit body and the spores of *Ganoderma lucidum* have been used as medicines for a long time, no data is available about the protective activity of extracts from mycelium on CCl_4-induced liver injury. The main aim of this study was to investigate the effects of GLPG isolated from mycelium of *Ganoderma lucidum* on CCl_4-induced liver injury *in vivo* and *in vitro*, and the possible mechanism of the hepatic protective activity of GLPG.

MATERIALS AND METHODS

Materials and reagents

Ganoderma lucidum (*FR.*) *Karst* (Ganodermataceae) was preserved in our laboratory. RPMI-1640, trypsin, penicillin and streptomycin were purchased from Gibco BRL (Grand Island, NY, USA). SOD kit was purchased from Jiancheng Bioengineering Institute of Nanjing. TNF radioimmunoassay kit was purchased from Jiuding Corporation (Tianjin, China). 3-(4, 5-dimethylthiazol-2-yl)-2, 5-diphenyltetrazolium bromide (MTT), crystal violet and trypan blue were from Sigma (St. Louis, MO). L-02 cells were obtained from China Center for Type Culture Collection (CCTCC, Wuhan, Hubei). All the other commercially available chemicals used were of the highest grade.

Extraction and purification of GLPG

Ganoderma lucidum (Fr.) Karst was extracted as previously described[30]. In brief, fungal mycelia were collected by filtration, dried and disrupted, and then the residue was extracted with 30-40 fold boiling water for 30 min. After centrifugation, the supernatant solution was concentrated under reduced pressure and intensively dialyzed. The retentate was added to three volumes of ice cold EtOH to precipitate the crude extracts. Then the sample was allowed to stand overnight at 4 ℃ and then centrifuged. The precipitate obtained was lyophilized. The lyophilized products were a dark brownish powder of water-soluble substance.

To purify the crude products, a portion of crude polysaccharide fraction was dissolved in double-distilled water and centrifuged to remove the insoluble materials. The supernatant was applied onto the DEAE-cellulose column and eluted with 0.1 N NaCl. Each perk eluent was separately pooled, concentrated, dialyzed, and three volumes of ice cold EtOH was added to precipitate the polysaccharides. The polysaccharide content in each fraction was determined by phenol-sulfuric acid method [31]. The GLPG fraction was lyophilized and further dissolved to indicate the concentrations for subsequent experiments.

Animal treatment and CCl_4-induced hepatotoxicity

Male BALB/c mice weighing 18-22 g (6-8 wk old), were provided by Experimental Animal Center, Wuhan University, and fed with standard diet and tap water. The animals were housed in cages (4-5 each cage) and maintained at 24±2 ℃, under 50-60% relative humidity in a 12 h light/ dark cycle throughout the experiment.

GLPG was diluted with saline and given orally by gavage for 20 d, at daily doses of 300, 600 and 900 mg/kg as aqueous extract. The saline control group received equal amounts of saline given orally for 20 d. During this treatment, carbon tetrachloride was introduced to the mice orally (1600 mg/kg CCl_4, mixed with corn oil) for the last 3 d. The same volume of corn oil was given to vehicle control mice orally for the last 3 d. After 3 d, the mice were euthanized under ether anaesthesia, blood and liver samples were collected.

Cell culture and liver cells injury induction

L-02 cells were cultured in RPMI-1640 medium supplemented with 10 % heat inactived fetal bovine serum (FBS), 100 IU /mL penicillin, 100 μg/mL streptomycin and 250 U/L insulin. The cells were maintained at 37 ℃ in a humidified atmosphere containing 5 mL/L CO_2 and subcultured 2-3 times a week.

Semi-confluent L-02 cells in 24-well culture plate (Falcon, NJ, USA) were divided into control group, dimethyl sulfoxide (DMSO) vehicle group, GLPG group, and CCl_4-induced hepatotoxicity group (20 mmol/L final concentration) with or without GLPG at various concentrations. After 4 h the culture supernatant was collected and stored at -20 ℃.

Cytotoxicity assay

Cytotoxicity was measured by MTT assay. The cells were

seeded in 96-well culture plate (Falcon, NJ, USA) at the concentration of 4×10^3 cells per well in 100 μL medium. After incubation of the cells for 12 h at 37 ℃, various concentrations of GLPG were added and the incubation was continued for 48 h, or at a given concentration of GLPG (200 μg/mL final concentration) the incubation time was prolonged for 72 h. Then the viable cells were determined by MTT reduction assay. In brief, MTT was dissolved in phosphate-buffered saline (PBS) at 5 mg/mL and sterilized by filtration to remove insoluble reside present in some batches of MTT. At the indicated time, the MTT solution (20 μL) was added to each well. After incubation for 5 h, cell culture medium was removed carefully, and 150 μL dimethyl sulfoxide (DMSO) was added to each well and mixed thoroughly to dissolve the dark purple crystals. The plate was incubated for 10 min at room temperature, to ensure that all formazane were dissolved. The plate was thenread on a Perkin-Elmer ELISA reader (HTS7000 plus) at a wavelength of 570 nm.

The effects of GLPG on cell proliferation and viability were compared according to the commonly accepted method of staining cells with trypan blue. L-02 cells were seeded in 96-well plate at the concentration of 2×10^3 cells per well in 100 μL of RPMI-1640 medium. The cells were incubated with or without various concentrations of GLPG for 48 h. Then the cells were trypsinized and collected. The number of cells was determined in a Neubauer hemacytometer using the trypan blue exclusion method, and the mean values were calculated.

Assay of ALT and AST activities in vivo and in vitro

As a marker of hepatocyte necrosis, the activities of ALT and AST were determined with an automatic multifunction-biochemical analyzer (Beckman, USA) in serum and cell culture medium.

Superoxide dismutase (SOD) determination

Wistar rats weighing 80-120 g (7 wk old) were divided into 3 groups, 22 rats each group. GLPG was diluted with saline and given orally for 10 wk at daily doses of 1 000 and 3 000 mg/kg as an aqueous extract. The saline control group received equal amount of saline given orally for 10 wk. After 10 wk the rats were sacrificed by decapitation and the serum was collected to determine the activity of SOD, according to the instructions of the kit used.

SOD measurement method was based on the principle in which xanthine reacts with xanthine oxidase to generate superoxide radicals reacting with 2-(4-iodophenyl)-3-(4-nitrophenol)-5-phenyltetrazolium chloride (INT) to form a red formazan dye. The SOD activity was then measured as previously described [32].

Histopathological examination

Liver was removed, fixed overnight in 10% buffered formalin and paraffin-embedded. The sections were stained with hematoxylin and eosin (H&E) for histological evaluation and examined under light microscope. In brief, 4-μm thick sections of paraffin-embedded mice liver were dewaxed in xylene, rehydrated in graded alcohol series, and washed with distilled water for 2 min. Subsequently, the sections were stained with hematoxylin for 5 min at room temperature. After 15 min, the sections were counterstained with eosin for 2 min, dehydrated in graded alcohol series, washed with xylene, and blocked by rosin. H&E- stained slides were observed under microscope at × 40 magnifications.

Measurement of plasma TNF-α level

Plasma TNF-α level was determined by TNF radioimmunoassay kit. All the mice were introduced orally with CCl_4 with or without GLPG, and the mice in control group were euthanized, then the blood was collected in the tubes with previous addition of 25 μL of heparin solution (4 000 IU). The plasma samples obtained after centrifugation at 3 000 r/min for 10 min at 4 ℃ were stored at -70 ℃ until assay.

The TNF-α levels of plasma samples were measured by sequential-saturation-type assay as previously described [33]. In brief, 200 μL of standard sample, the plasma samples, and the control were added to each tube, then 100 μL anti-TNF-α antibody was added to each tube and mixed thoroughly. After 18 h of incubation at 4 ℃, 100 μL of solution containing radioactive label was added to each tube and mixed. After a further incubation for 3 h at 37 ℃, 1 000 μL of the secondary antibody was added for 15 min. the tubes were centrifuged at 3 600 r/min for 20 min, the supernatant was discarded carefully. The gamma cpm of deposition was measured with a gamma counter, and the plasma TNF-α levels were measured by standard sample curve diagram. TNF-α values were expressed as ng/mL.

Statistical analysis

Data were expressed as mean ± SD. The difference between the means of two groups was evaluated by ANOVA. $P<0.05$ was considered statistically significant.

RESULTS

Effects of GLPG on cytotoxicity

Compared with the L-02 cells administrated with GLPG and the control cells, there was no obvious change occurred in cell growth and morphology (Figures 1A and 1B). Trypan blue exclusion method showed that the total cell number of L-02 cells treated with GLPG was approximately 96 % as compared to that of the control cells Even at the GLPG concentration was 1 024 μg/mL. And we also found that no toxic response and death was occurred *in vivo* experiment (data not shown). And we also found that no toxic response and death was occurred *in vivo* experiment (data not shown).

Detection of liver weight and assay of ALT and AST activities in vivo and in vitro

Compared to the control and GLPG groups, GLPG (300, 600 and 900 mg/kg) markedly ameliorated hepatic injury induced by CCl_4. The liver weight (Table 1) and serum ALT and AST activities (Table 2) were observed in mice 24 and 72 h after CCl_4 administration. The liver weight did not increase compared to CCl_4-treated group. Furthermore, the serum ALT and AST activities in GLPG pretreatment groups induced by CCl_4 were lower than those in CCl_4-treated group. Simultaneously, GLPG treatment reduced

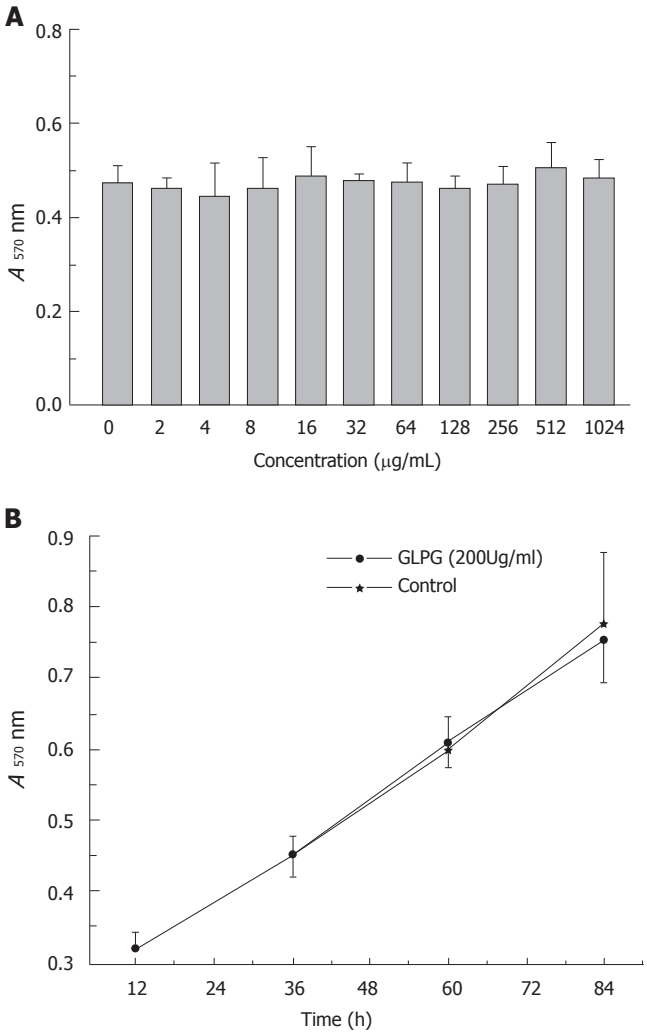

Figure 1 Effects of GLPG on proliferation of L-02 cells treated with GLPG at the concentration of 2-1024 μg/mL for 2 d (A) and at the concentration of 200 μg/mL for 3 d (B). Viable cells were detected every 24 h. The cells untreated with GLPG were used as controls in experiment. Results shown represent the mean ± SD for at least three separate experiments.

Table 1 Effect of GLPG on liver weight in mice with CCl_4-induced hepatic injury after 72 h (mean ± SD)

Group	Liver weight (g)
Control	1.77 ± 0.26
GLPG (500 mg/kg)	1.74 ± 0.21
CCl_4 (1600 mg/kg)	2.22 ± 0.34
CCl_4 (1600 mg/kg) + GLPG(300 mg/kg)	1.67 ± 0.17
CCl_4 (1600 mg/kg) + GLPG(600 mg/kg)	1.57 ± 0.18
CCl_4 (1600 mg/kg) + GLPG(900 mg/kg)	1.52 ± 0.14

activities of ALT and AST in a dose-dependent manner (Figure 2).

Superoxide dismutase (SOD) assay

According to the results of SOD assay, the activity of SOD in the serum of rats pretreated with GLPG increased significantly compared with that of control group. As shown in Figure 3, compared to the control group, the activities of SOD in the group administered orally with GLPG at the concentrations of 1 000 mg/kg and 3 000mg/kg increased by 57.2 % and 70.6 %, respectively.

Histological analysis

We examined the effects of GLPG at various doses (300, 600 and 900 mg/kg) on histopathological changes of CCl_4-induced liver injury in mice *in vivo*. GLPG showed strong

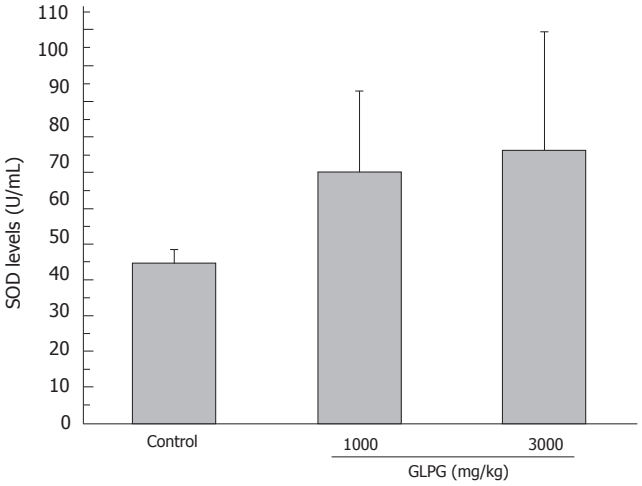

Figure 3 Effect of GLPG on SOD activity in serum of rats. The rats were administered orally with or without GLPG at 1000 mg/kg and 3000 mg/kg. The increment of SOD activities was 57.2 % and 70.6 %, respectively.

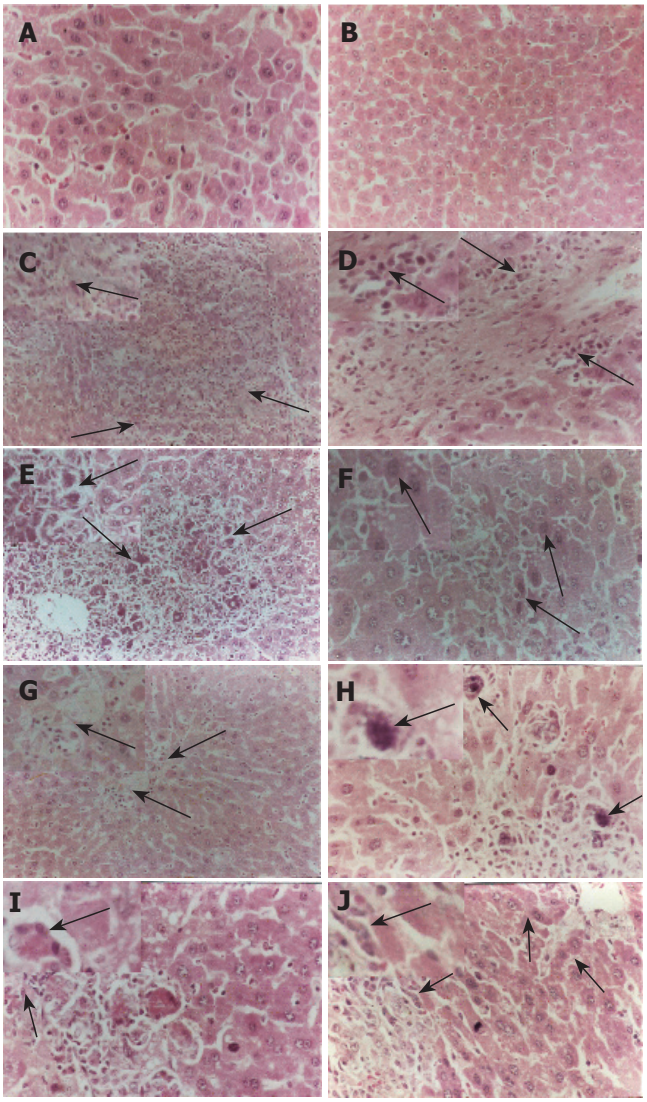

Figure 4 Histological changes (marked by arrows) of CCl_4-induced hepatic injury in the presence or absence of GLPG in mice by hematoxylin-eosin (**H&E**) staining in control group (**A**), GLPG group (**B**), and CCl_4-induced liver injury group (**C-J**) 24 and 72 h after GLPG pretreatment at different doses(0, 300, 600 and 900 mg/kg).

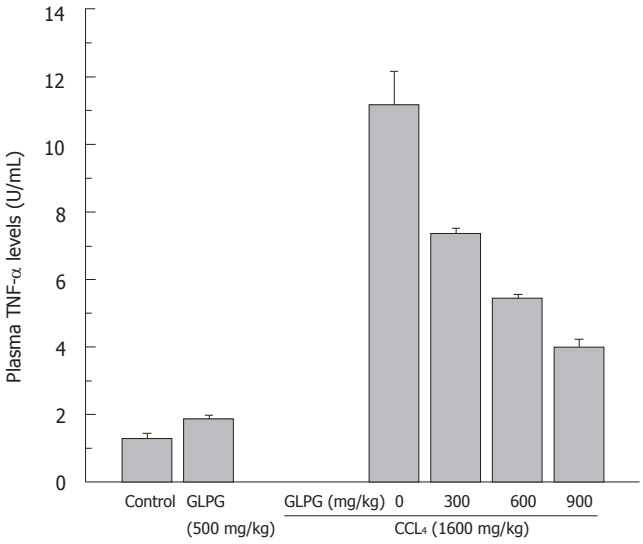

Figure 5 Effect of GLPG on the levels of TNF-α in the plasma of mice, as determined by TNF-α radioimmunoassay kit. Compared with control group, administration of GLPG at various doses could significantly suppress the level of TNF-α in a dose-dependent manner after 48 h. Data are the mean ± SD from 4 determinations.

hepatic protective activity. Significant changes of liver tissue were observed in carbon tetrachloride-induced group after 24 h and 72 h (Figures 4C and 4D) as compared to the control group (Figure 4A) and the GLPG pretreated group (Figure 4B). No obvious histopathological change was observed in control and GLPG groups. and Both the control group and the GLPG group had no infiltrations and hemorrhagic signs. Figure 4C shows the histological changes after 24 h of CCl_4 post-administration with a marked liver injury. After 72 h of CCl_4 post-administration, liver lobule structures disappeared and necrotic hepatic tissues induced by CCl_4 with pretreatment GLPG (300 mg/kg) after 24 h (Figure 4E) and 72 h (Figure 4F) were had no evident recovery. liver injury and necrotic hepatic tissue recovered markedly. As shown in Figure 4G-J, basophilic granules and many double-nuclear regenerative liver cells appeared 24 and 72 h after GLPG pretreatment at different doses (600 mg/kg and 900 mg/kg). These results showed that GLPG could alleviate CCl_4-induced liver injury *in vivo* in mice.

Measurement of plasma TNF-α level

Figure 5 showed that the changes of TNF-α levels in the plasma of experimental groups 48 h after CCl_4 treatment with or without GLPG at different doses. Low TNF-α levels were detected in the plasma of the control group and GPLG group. In contrast, a marked rise of TNF-α level was found in the plasma of CCl_4-pretreatment group. Simultaneously, GLPG (500 mg/kg) can decrease the level of TNF-α in the plasma of mice treated with CCl_4 (data not shown). Administration of GLPG at 300, 600 and 900 mg/kg significantly suppressed the levels of TNF-α in dose-dependent manner after 48 h. The mean values of TNF-α levels at 48 h were 34 %, 51.3 % and 64.2 % at 300, 600 and 900 mg/kg respectively.

DISCUSSION

Rapid lipid peroxidation of the membrane structural lipids has been proposed as the basis of CCl_4 liver toxicity[34-35]. In fact the first step in liver injury induced by CCl_4 is the formation of reactive oxygen species (ROS) that may further lead to membrane peroxidation or cell injury. There is evidence that Kupffer cells as well as hepatocytes have inducible cytochrome P-450 and are capable of metabolizing CCl_4 or other toxic species[36]. Moreover, it was reported that Kupffer cell activation is a crucial step in hepatocyte injury induced by CCl_4 or other toxic agents[37-38]. Transition metal ions like Cu^{+2} and Fe^{+3} play an important role as components of proteins essential for biological functions. However, these metals can also initiate Haber-Weis and Fenton reactions where superoxide anions are transformed into detrimental hydroxyl radicals which are in turn responsible for attack of the membrane polyunsaturated fatty acids[15]. The use of metal chelating agents may have therapeutic effect by reducing the oxidative burst and the consequent membrane lipid peroxidation[39-40]. Previous findings have shown that transition metals can mediate free radical production after CCl_4 administration in rats[16, 41-42]. Treatment of these animals with agents capable of chelating these metal ions can protect hepatocytes against damage by reducing oxidative burst and lipid peroxidation[16, 41-42].

In this study, a water soluble substance, *Ganoderma lucidum* proteoglycan was isolated from mycelia of *Ganoderma lucidum* by EtOH precipitation and DEAD-cellulose column chromatography. GLPG is a proteoglycan consisting of about 86.4 % carbohydrates and has antioxidant activity against CCl_4-induced liver injury. Treatment with GLPG could ameliorate hepatic injury induced by CCl_4. Administration of GLPG significantly decreased ALT and AST activities in CCl_4-induced liver injury *in vivo* and *in vitro* (Table 2 and Figure 2). Histological changes observed in GLPG-pretreatment groups were less than in CCl_4-induced group. Some histological changes, such as hemorrhage, inflammatory infiltration and necrosis in hepatic tissue, were simultaneously improved after pretreatment with GLPG. These results suggested that the hepatic protective activity of GLPG against CCl_4-induced liver injury was in a dose-dependent manner.

Though the scavenging effect of *Ganoderma lucidum* polysaccharide (Gl-PS) has been reported [25, 43-46], no report is availabe about the hepatic protective activity of GLPG. In our study, the activity of SOD after pretreatment with GLPG increased significantly in the serum of rats, while SOD could eliminate peroxide *in vivo*, suggesting that GLPG might scavenge the free radicals induced by CCl_4.

Although it is generally believed that the hepatic protective activity of GLPG is mainly due to its ability to scavenge free radicals induced by CCl_4. However, there may be other mechanisms. A large amount of this cytokine may be interpreted as a progression of hepatic damage[47]. TNF-α induced by CCl_4 may contribute to cellular damage in liver injury. The antioxidant activity of GLPG can reduce TNF-α level in the plasma of mice, thus inhibit inflammation occurrence. Though the mechanism of GLPG down-regulates CCl_4-induced TNF-α level *in vivo* in mice remains unknown, the suppression of GLPG on TNF-α level might play an important role in its hepatic protective activity against CCl4-induced liver injury.

In conclusion, GLPG exhibits strong hepatic protective activity against CCl_4-induced liver injury both *in vivo* and *in vitro*. And the possible anti-hepatotoxic mechanisms may be related to the suppression of TNF-α level and the free radical scavenging activity.

Abstract

AIM: To study the therapeutic effect of exogenous interleukin-10 on CCl_4-induced hepatic fibrosis in rats and its possible mechanisms.

METHODS: Fourty-seven SD rats were randomly divided into control group (group N) and CCl_4-induced hepatic fibrosis model group (group C). After CCl_4 was given for 9 wk, the model group was divided into three groups. Rats in group M were put to death immediately, rats in group T were treated with IL-10 for another three wk and then put to death, rats in group R recovered after three weeks and were then killed. The degree of hepatic fibrosis was measured by HE staining and histological activity index (HAI). Histological activity index (HAI), change of collagen types I and III were measured by Picrosirius staining. The expression of TNF-α, MMP-2 and TIMP-1 in liver tissue was measured by S-P immunohistochemistry.

RESULTS: CCl_4- induced experimental rat hepatic fibrosis model was established successfully. The degree of hepatic fibrosis was markedly lower in group T than in groups M and R, and there was no difference between the two groups. The expression of collagen types I and III was significantly suppressed in group T and was slightly suppressed in groups M and R. The positive levels of TNF-α, MMP-2 and TIMP-1 in group M increased significantly compared to those in group N ($P < 0.01$). The positive signals decreased significantly in groups T and R ($P < 0.01$), but positive score was significantly lower in group T than in group R ($P < 0.01$).

CONCLUSION: Exogenous IL-10 can reverse CCl_4-induced hepatic fibrosis in rats. IL-10 may exert its reversible effects on hepatic fibrosis by blocking CCl_4-induced inflammation, inhibiting expression of MMP-2 and TIMP-1 and promoting resolution of collagen types I and III.

Key words: Rat; Hepatic fibrosis; Interleukin-10; Tumor necrosis factor; Matrix metalloproteinase; Collagen

INTRODUCTION

Hepatic fibrosis represents the final common pathological outcome for the majority of chronic liver insults. Its final stage is cirrhosis. Liver cirrhosis, the irreversible terminal stage of chronic liver disease, characterized by widespread fibrous scaring, is a major cause of morbility and mortality worldwide, with no effective therapy. Regardless of causes, hepatic fibrosis involves abnormal accumulation of extracellular matix (ECM) components, particularly collagens. Present data indicate that a specific potentially safe orally bioavailable and inexpensive antifibrotic agent is not yet available[1]. Interleukin-10 (IL-10) has anti-inflammatory and immunomodulatory effects and can down-regurate production of proinflammation cytokines, such as interleukin-1, interferon-gama and interleukin-2 from T cells. Previous reports indicate that IL-10 might have antifibrogenic properties by downregulating profibrogenic cytokines, such as TGF-β_1. Many studies indicate that IL-10 may become a new therapeutic target[2]. Therefore, the aim of this study was to evaluate its therapeutic effect on reversing well-established hepatic fibrosis after 9 wk of CCL_4 administration through different markers.

MATERIALS AND METHODS

Materials

Forty-seven clean male Sprague-Dawley rats weighing 180-280 g were provided by Shanghai Experimental Animal Center. All the rats were bred under routine condition (room temperature of 22±2℃, humidity of 55±5%) in a 12 h light/dark cycle with free access to water and food. The food was provided by BK Company (Shanghai,

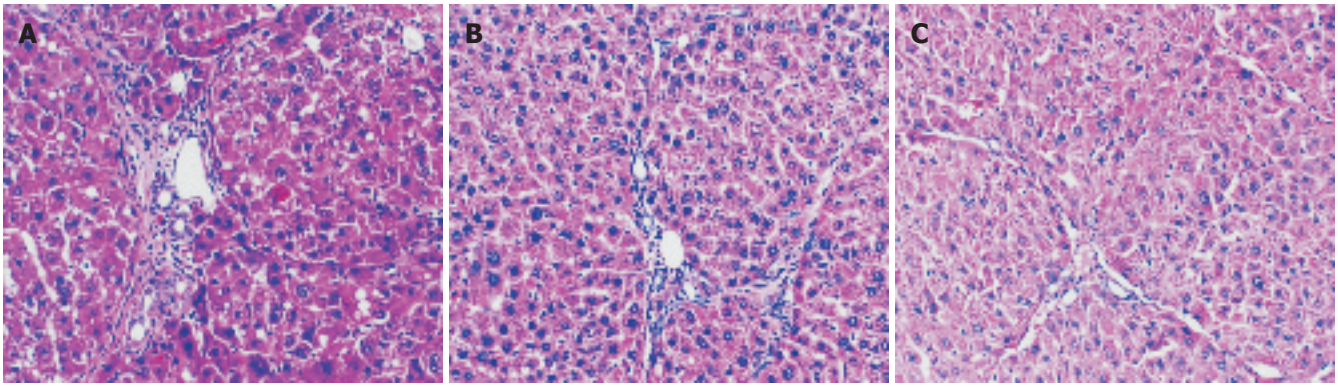

Figure 1 Effects of IL-10 on histology of CC4-induced fibrotic rat liver after treated with CCL4 for 9 wk (**A**), IL-10 for 3 wk (**B**) and spontaneous recovery for 3 wk (**C**).

China). IL-10 was purchased from Jingmei Biotechnology Company of Shenzhen. MMP-2 monoclonal antibody was purchased from NeoMarkers Company. TNF-α, TIMP-1 polyclonal antibodies and S-P immunohistochemical kit were obtained from Zhongshan Company of Beijing.

Preparation of rats

Forty-seven clean SD rats were randomly divided into control group (group N, $n=6$) and CCl_4-induced hepatic fibrosis model group (group C, $n=41$). The rats of group N were injected intraperitoneally with saline (2 mL/kg) twice a week. After 9 and 12 wk, 3 rats of groups N were sacrificed and their livers were taken out. The rats of group C were injected intraperitoneally with 50 % CCl_4 dissolved in castor oil (2 mL/kg) twice a week for nine weeks. After injection group C was divided into three groups. Rats in group M were put to death immediately by the end of week 9, rats in group T were treated with IL-10 (4 ug/kg) three times a week for three weeks and then put to death, rats in group R recovered after three weeks and were then killed.

Histopathological examination

Rats of groups N, M, T and R were sacrificed and their livers were taken out. The specimens were fixed in 10% formalin and embedded with paraffin. The sections stained with hematoxylin and eosin were evaluated by two pathologists. Histological activity index (HAI) was evaluated using a numerical system proposed by Knodell *et al*[3].

Picrosirius staining and collagen measurement

The sections were deparaffinized with xylene and rehydrated with graded ethanol. After rinsing, the sections were washed 3 times with distilled water, stained in 0.1% Sirius red in saturated picric acid solution for 30 min, and put into ethanol for differentiation for 2 min. The sections were then rinsed once in phosphate-buffered saline and twice in water for 30 s each to remove any unbound dye. After drying for two hours, slides were mounted. Quantitative analysis of collagen types I and III was made with the Olympus-BX41 image analyzing system in 5 microscopic fields (40x magnification) of per section. The average of the 5 fields was calculated for assessment of the degree of fibrosis in each case. All sections were examined by the same person. The liver tissue was distinguished from the background according to a difference in light density, which allowed the measurement of the total liver tissue area. Then the amount of connective tissue stained red was measured. Finally, the percentage of collagen on the section was calculated.

Immunohistochemistry

Rat liver tissues were sectioned at the thickness of 4 μm. After deparaffinization with xylene and rehydration in graded ethanol, the sections were incubated in PBS containing 30 mL/L H_2O_2 to remove endogenous peroxidase and in PBS containing 0.1 mol/L citrate to retrieve microwave antigens and then with normal goat serums to block the nonspecific binding sites. After incubation with rabbit anti-rat MMP-2(monoclonal antibody) as well as TNF-α and TIMP-1 polyclonal antibodies respectively, the sections were treated with instant S-P immunohistochemical reagents and then incubated in a buffer solution containing 3, 3-diaminobenzidine tetrahydrochloride (DAB) and H_2O_2 to produce a brown reaction product, dehydrated and coverslipped. Microscopic examination of the sections was then performed as previously described[4].

Statistical analysis

All data were expressed as mean ± SE. The difference between groups was studied with SPSS11.0 by one-way ANOVA. $P<0.05$ was considered statistically significant.

RESULTS

Histological examination

CCl_4-induced experimental rat hepatic fibrosis model was established successfully. After treatment with CCl_4 for 9 wk (group M), the liver had severe pathological damages, such as hepatocyte degeneration and necrosis, mononuclear cells and neutrophil infiltration and collagen deposition. The collagen fibers began to extend with hepatic plate and formed intact fibrous septum and distorted tissue architecture, abnormal hepatic lobules could be observed occasionally (Figure 1A). The liver tissue in group N showed normal lobular architecture with central veins and radiating hepatic cords. The liver of group T showed that

Table 1 Grading and staging of rat liver histopathology

Group	Number	Grading of inflammation					Staging of fibrosis				
		0	1	2	3	4	0	1	2	3	4
N	6	6	0	0	0	0	6	0	0	0	0

I [bdhfi]	9	0	7	2	0	0	0	0	3	6	0

Grading of inflammation: $^{b}P<0.01$ *vs* group N ; $^{d}P<0.01$ *vs* group M; staging of fibrosis: $^{f}P<0.01$ *vs* group N; $^{h}P<0.01$ *vs* group M; $^{i}P<0.01$ *vs* group R.

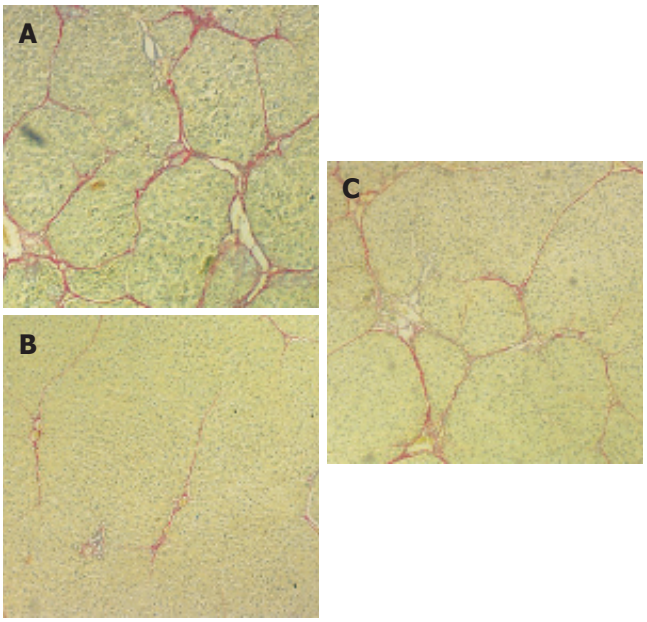

Figure 2 Photomicrographs of liver tissue from rats after treatment with with CCL_4 (**A**), IL-10 for 3 wk (**B**) and spontaneous recovery for 3 wk(**C**) by Picrosirius staining (40x).

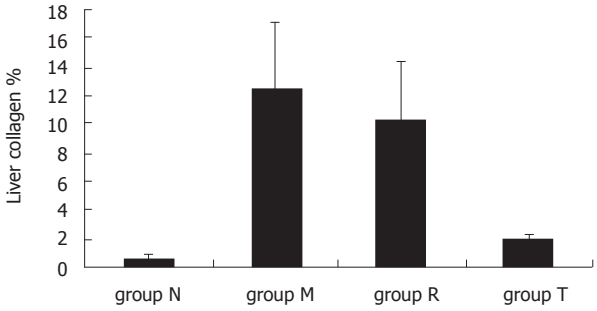

Figure 3 Percentage of collagen types I and III in fibrotic rats.

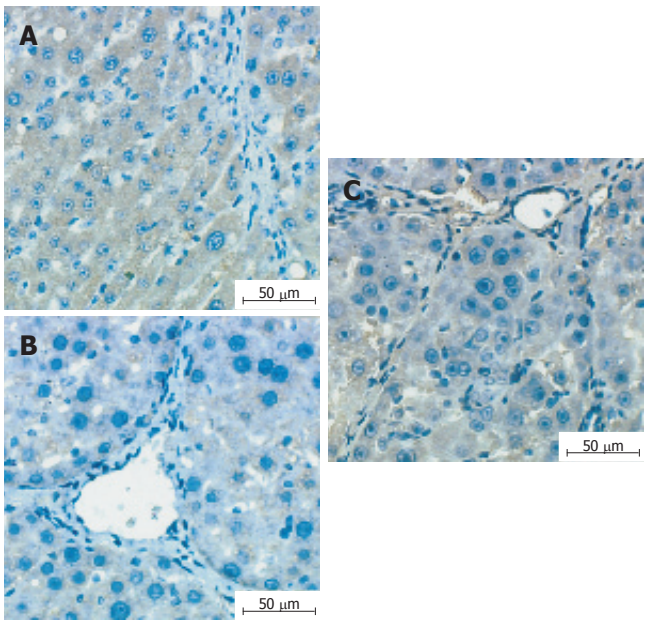

Figure 4 Expression of MMP-2 protein in liver tissue of rats treated with CCL_4 for 9 wk (**A**), IL-10 for 3 wk (**B**) and spontaneous recovery for 3 wk (**C**).

the degree of hepatocyte necrosis and degeneration was decreased markedly, and there were a few inflammatory cell infiltrates around central lobular veins, deposition of collagen fibers was relieved (Figure 1B). In addition, collagen fibers were changed slightly in group R (Figure 1C). According to HAI score, the degree of inflammation of liver decreased markedly in groups T and R compared to group M. The degree of hepatic fibrosis decreased markedly in group T compared to group M ($P<0.01$), but there was no difference between groups R and M ($P>0.05$, Table 1).

Change of collagen types I and III in liver

Collagen types I and III were stained intensely red with the Picrosirius procedure, while the non-collagen tissue was stained yellow. CCL_4 treatment for 9 wk induced a significant deposition of collagen types I and III, leading to severe fibrosis (Figure 2A). Little collagen was deposited around central vain in group N. After IL-10 treatment for 3 wk, the degree of hepatic fibrosis was markedly reduced, the area of collagen types I and III was significantly decreased (Figure 2B). After spontaneous recovery for 3 wk, obvious deposition of collagen types I and III was observed (Figure 2C).

The area of collagen types I and III increased from $0.64\pm0.11\%$ of field area in group N to $12.41\pm4.62\%$ of field area in group M ($P<0.01$), while the areas of collagen dramatically decreased to $2.00\pm0.31\%$ in group T ($P<0.01$, Figure 3). Although there was a trend toward lower values of collagen types I and III in group R ($10.24\pm4.12\%$.) compared to group M, the difference failed to reach any statistical significance ($P>0.05$).

Relative quantities of MMP-2 and TIMP-1 in the liver

Positive expression of MMP-2 was localized in endothelial and hepatic cells. Positive expression of TIMP-1 was localized in cytoplasm of hepatocytes and biliary epithelial cells, but not in nuclei. After treatment with IL-10, the distribution area of MMP-2 and TIMP-1 was smaller and the color was lighter (Figures 4 and 5).

The expression of MMP-2 and TIMP-1 was markedly higher in group M than in group N ($P<0.05$). The expression of these two cytokines in group T and R was significantly reduced compared to those in group M ($P<0.05$). However, the levels of MMP-2 and TIMP-1 decreased markedly in group T compared to those in group R ($P<0.05$). Tissue concentrations of MMP-2 and

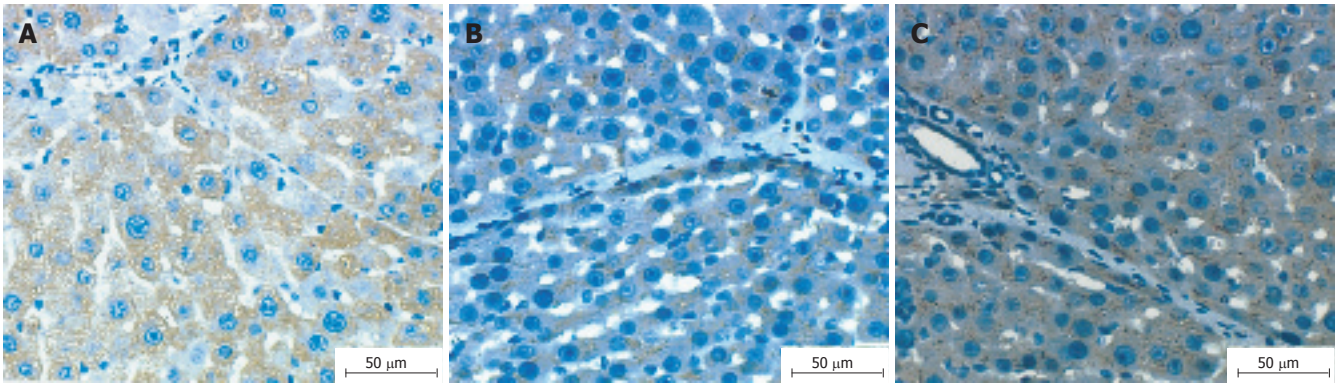

Figure 5 Expression of TIMP-1 protein in liver tissue of rats treated with CCL_4 for 9 wk (**A**), IL-10 for 3 wk (**B**) and spontaneous recovery for 3 wk (**C**).

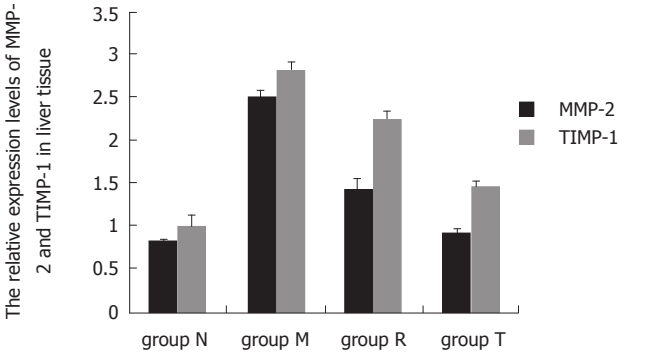

Figure 6 Relative expression levels of MMP-2 and TIMP-1 in liver of different groups.

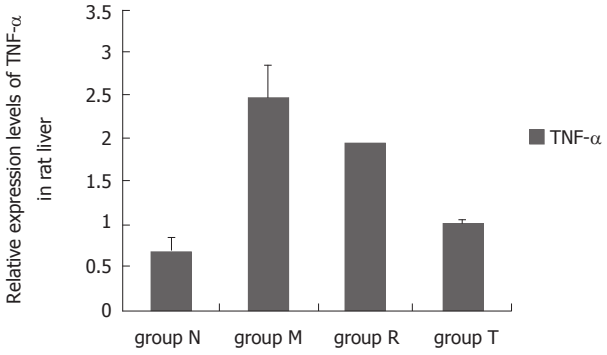

Figure 8 Relative expression of TNF-α in rat liver of different groups.

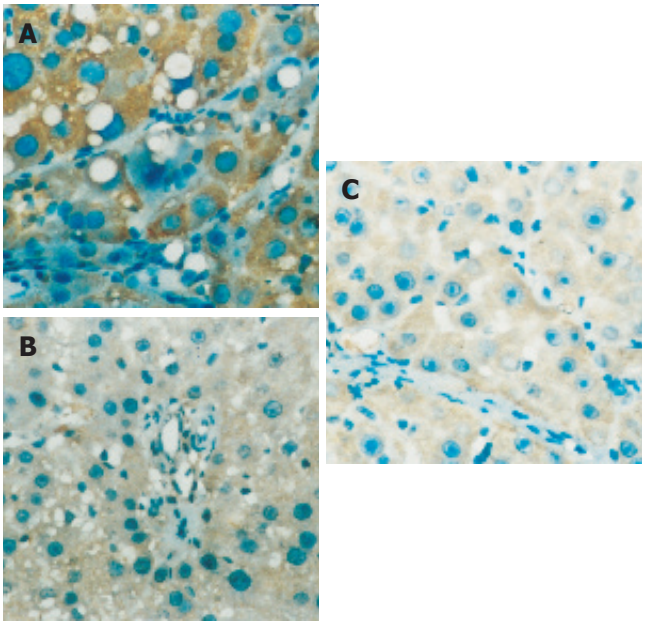

Figure 7 Expression of TNF-a protein in liver tissue of rats treated with CCL4 for 9 wk (**A**), IL-10 for 3 wk (**B**) and spontaneous recovery for 3 wk (**C**).

TIMP-1 were decreased after IL-10 treatment for 3 wk (Figure 6).

Relative quantity of TNF-α in liver

Positive expression of TNF-α was localized in most hepatic cells. After treatment with IL-10, the distribution area was smaller and the color was lighter (Figure 7).

The expression of TNF-α was markedly higher in group M than in group N ($P<0.05$). The expression of this cytokine in group T was significantly reduced compared to group M ($P<0.01$), but the level of TNF-α in group R was lower than that in group M but higher than that in group T ($P<0.01$, Figure 8).

DISCUSSION

Hepatic fibrosisis is a progressive pathological process involving multi-cellular and molecular events that ultimately lead to deposition of excess matrix proteins in the extracellular space. It is generally accepted that hepatic stellate cells (HSCs) are central to the process of fibrosis as the major source of ECM components[5-10]. Advanced fibrosis and cirrhosis are generally considered to be irreversible conditions even after removal of the injurious agent. However, data from the histological assessment of biopsy tissue from patients with liver fibrosis complicating chronic viral infection after successful treatment and from animal models of fibrosis indicate that recovery with remodeling of the excess collagens is possible[11-15], but current therapies targeting at arresting or reversing hepatic fibrosis are largely ineffective and have unacceptable side effects in long-term therapy.

IL-10, initially discovered in 1989, is a cytokine synthesis inhibitory factor for T lymphocytes[16]. IL-10 is produced by other cells of the immune system including

the liver. Within the liver, production of IL-10 has been documented within hepatocytes, sinusoidal cells, kupffer cells, stellate cells and liver-associated lymphocytes[17]. It was reported that endogenous IL-10 can decrease intrahepatic inflammatory response and fibrosis in several models of liver injury[18, 19]. It is well known that HSCs are the principal cells involved in hepatic fibrosis. Our previous studies indicate that exogenous IL-10 down regulates collagen type I in cultured HSCs and up regulates metalloproteinase gene expression *in vitro*[20, 21]. IL-10 may promote apoptosis of HSCs by up-regulating the expression of FasL and Bax and down-regulating the expression of Bcl-2 *in vitro*[22]. It also exerts antifibrogenic effect by down regulating profibrogenic cytokines such as TGF-b1 and TNF-a[23,24]. All these studies indicate that IL-10 might become a new therapeutic target. In this study, exogenous IL-10 was used to treat well-established hepatic fibrosis after 9 wk administration of CCL_4. Liver biopsy, the gold-standard method for detecting changes in liver fibrosis, showed that advanced fibrosis or cirrhosis was established after 9 wk administration of CCL_4, most of the fibrotic septa were resolved, and only small fibrotic fragments could be found after 3 wk of IL-10 treatment. The results indicated that exogenous IL-10 had therapeutic effect on advanced fibrosis. Predominant collagens in fibrotic liver were collagen types I and III. There were massive depositions of collagen types I and III in the peak of fibrosis, while the areas of collagen types I and III were significantly decreased 3 wk after IL-10 treatment. Matrix degradation may occur predominantly as a consequence of the action of a family of enzymes called matrix metalloproteinases (MMPs), and the expression of these enzymes is inhibited by a family of TIMPs[25-27]. To explore the reason why IL-10 results in a significant reduction of hepatic fibrosis, we investigated the effect of IL-10 on expression of MMP-2 and TIMP-1 by immunohistochemistry. The data showed that in the peak of fibrosis, the expression levels of MMP-2 and TIMP-1 were significantly increased. After 3 wk IL-10 treatment, the expression levels of MMP-2 and TIMP-1 were significantly decreased, indicating that collagen types I and III are be associated with the decrease of MMP-2 and TIMP-1 levels.

IL-10 is a pleiotropic cytokine, which has anti-inflammatory inhibitory action on the immune response under various stimuli. TNF-α is a pro-inflammation cytokine and a major endogenous mediator of hepatotoxicity[28]. TNF-α is expressed in chronic liver injuries by both infiltrating inflammatory cells and hepatocytes and plays an important role in tissue damage[29]. In this study, the results of HE staining showed that IL-10 could suppress inflammation induced by CCL4. TNF-α was significantly increased 9 wk after initial CCL_4 treatment, but 3 wk treatment with exogenous IL-10 markedly suppressed the expression of TNF-α in liver, suggesting that IL-10 exerts its inhibitory effect on hepatic fibrosis by blocking the release of inflammatory mediators such as TNF-α, which may consequently suppress HSC activation leading to hepatic fibrosis. A similar result has been reported by Nakamuta *et al*[30].

Issa *et al*[31] studied a model of cirrhosis to determine the mechanisms mediating and limiting spontaneous recovery, and found that micronodular cirrhosis undergoes remodeling to macronodular cirrhosis. Lee *et al*[32] reported that hepatic fibrosis can reverse gradually[32]. In this study, livers were harvested from rats for spontaneous recovery from hepatic fibrosis induced by CCl_4. Histology of liver sections indicated that advanced septal fibrosis observed at peak fibrosis was not remodeled. On the other hand, the degree of inflammation of liver decreased markedly after spontaneous recovery and the expression levels of TNF-α, MMP-2 and TIMP-1 decreased, suggesting that inflammation is decreased, but fibrosis is not significantly changed after removal of CCL_4. The mechanisms need to be elucidated.

In conclusion, the therapeutic effect of IL-10 on hepatic fibrosis is not only related with removal of deposited collagen and expression levels of MMP-2 and TIMP-1, but also related with the degree of inflammation.

Abstract

AIM: To study the relationship between interleukin-1beta (IL-1β) up-regulating tissue inhibitor of matrix metalloproteinase-1 (TIMMP-1) mRNA expression and phosphorylation of both c-jun N-terminal kinase (JNK) and p38 in rat hepatic stellate cells (HSC).

METHODS: RT-PCR was performed to measure the expression of TIMMP-1 mRNA in rat HSC. Western blot was performed to measure IL-1β-induced JNK and p38 activities in rat HSC.

RESULTS: TIMMP-1 mRNA expression (1.191 ± 0.079) was much higher after treatment with IL-1β (10 ng/mL) for 24 h than in control group (0.545 ± 0.091) (P<0.01). IL-1β activated JNK and p38 in a time-dependent manner. After stimulation with IL-1β for 0, 5, 15, 30, 60 and 120 min, the JNK activity was 0.982 ± 0.299, 1.501 ± 0.720, 2.133 ± 0.882, 3.360 ± 0.452, 2.181 ± 0.789, and 1.385 ± 0.368, respectively. There was a significant difference in JNK activity at 15 min (P < 0.01), 30 min (P < 0.01) and 60 min (P < 0.01) in comparison to that at 0 min. The p38 activity was 1.061 ± 0.310, 2.050 ± 0.863, 2.380 ± 0.573, 2.973 ± 0.953, 2.421 ± 0.793, and 1.755 ± 0.433 at the 6 time points (0, 5, 15, 30, 60 and 120 min) respectively. There was a significant difference in p38 activity at 5 min (P < 0.05), 15 min (P < 0.01), 30 min (P < 0.01) and 60 min (P < 0.01) compared to that at 0 min. TIMMP-1 mRNA expression trended to decrease in 3 groups pretreated with different concentrations of SP600125 (10 μmol/L, 1.022 ± 0.113; 20 μmol/L, 0.869 ± 0.070; 40 μmol/L, 0.666 ± 0.123). Their decreases were all significant (P < 0.05, P < 0.01, P < 0.01) in comparison to control group (without SP600125 treatment, 1.163 ± 0.107). In the other 3 groups pretreated with different concentrations of SB203580 (10 μmol/L, 1.507 ± 0.099; 20 μmol/L, 1.698 ± 0.107; 40 μmol/L, 1.857 ± 0.054), the expression of TIMMP-1 mRNA increased. Their levels were higher than those in the control group (without SB203580 treatment, 1.027 ± 0.061) with a significant statistical significance (P < 0.01).

CONCLUSION: IL-1β has a direct action on hepatic fibrosis by up-regulating TIMMP-1 mRNA expression in rat HSC. JNK and p38 mitogen-activated protein kinases (MAPKs) are involved in IL-1β-induced TIMMP-1 gene expression, and play a distinct role in this process, indicating that p38 and JNK pathways cooperatively mediate TIMP-1 mRNA expression in rat HSC.

INTRODUCTION

Hepatic fibrosis is a common consequence of chronic liver disease and results from the activation of hepatic stellate cells (HSC). After liver tissue damage, HSC undergo a transition from quiescent to activated phenotypes and increase proliferation and synthesis of extracellular matrix (ECM)[1-4]. Activated HSC express matrix metalloproteinases (MMPs), the key enzyme in the degradation of ECM, but also expresses the tissue inhibitors of matrix metalloproteinases (TIMMPs). Many cytokines may affect the activation of HSCs and regulate the secretion of MMPs and TIMMPs[5,6].

Mitogen-activated protein kinase (MAPK) plays an important role in the transduction of extracellular signals to the nuclei[7,8]. Four groups of mammalian MAPK-family have been characterized, namely extracellular signal-regulated kinases (ERK), c-jun N-terminal kinase (JNK),

p38 and ERK5. Studies indicate that JNK and p38 are essential members of MAPK supper family and play a role in the responses of HSC to hepatic injury and inflammation[9,10]. JNK and p38 are activated by lipopolysaccharide endotoxin (LPS), tumour necrosis factor-α (TNF-α) and interleukin-1 (IL-1). Activated JNK translocates to the nuclei, activates transcription factors and involves a wide range of cellular events, including cell proliferation, differentiation and apoptosis[11,12].

IL-1 is a pro-inflammatory cytokine that has a key role both in the inflammatory response and in autoimmune diseases[13-17]. Although HSC activation is insufficiently documented, IL-1 is accepted as a potent cytokine for fibrosis of other organs such as the heart, gingival tissue, and kidney[15,18,19]. Recent findings suggest that activation of MAPKs participates in intracellular signaling events induced by IL-1. In this study, we demonstrated the relationship between effects of interleukin-1β up-regulating TIMMP-1 mRNA expression and MAPK signal transduction in rat HSC.

MATERIALS AND METHODS

Reagents

RPMI 1640 was purchased from GIBCO BRL. SP600125, SB203580 and HEPES were purchased from Sigma Chemicals International. IL-1β was obtained from PeproTech INC. Mouse anti-phospho-JNK antibody and mouse anti- phospho-p38 antibody were purchased from Santa Cruz Company. Rabbit anti-β-actin polyclonal antibody was obtained from Zhongshan Company. RNasin was purchased from Promega Company.

Cell culture of rat HSC

HSC cell line (CFSC) was established and presented by Professor Greenwell, Marion Bessin Liver Research Center, Albert Einstein College of Medicine. The phenotype of CFSC was activated HSC obtained from CCl_4-induced cirrhotic liver of rats after spontaneous immortalization in culture. Cells were seeded and grown at 37℃ in 50 mL/L CO_2 RPMI 1640 supplemented with 10% fetal calf serum (FCS), 4 mmol/L L-glutamine, 1 mmol/L HEPES and 100 U/mL penicillin/streptomycin. When the cells were 80%-90% confluent, HSC were serum-starved in medium containing 1% FCS for 12 h. HSC of IL-1β groups were treated with IL-1β (10 ng/mL) for 24 h, but HSC of control group were treated with nothing, then TIMMP-1 mRNA expression in rat HSC was examined. After stimulation with IL-1β (10 ng/mL) for 0, 5, 15, 30, 60, and 120 min, the activities of JNK and p38 were examined. To study the relationship between IL-1β up-regulating TIMMP-1 mRNA expression as well as JNK and p38 signal pathway, JNK inhibitor SP600125 and p38 inhibitor SB203580 were used to inhibit JNK and p38 activities. When HSC were pretreated for 30 min with 1% dimethyl sulfoxide (DMSO, a solvent of SP600125 and SB203580), SP600125 or SP203580 was then treated with IL-1 beta (10 ng/mL) for 24 h, and subsequently TIMMP-1 mRNA expression in rat HSC was examined. SP600125 and SB203580 were prepared as previously described[20, 21].

Reverse transcriptase polymerase chain reaction (RT-PCR)

RT-PCR was performed to measure the expression level of TIMMP-1 mRNA in rat HSC. The sequences of the primers used for TIMMP-1 sense and antisense are 5' -TCC CCA GAA ATC ATC GAG AC-3' (sense) and 5' -ATC GCT GAA CAG GGA AAC AC-3' (antisense), a 329 bp fragment was amplified. The sequences of the primers used for GAPDH sense and antisense are 5'-GGC CCC TCT GGA AAG CTG TG -3' (sense) and 5'-CCG CCT GCT TCA CCA CCT TCT-3' (antisense), a 239 bp fragment was amplified. Total RNA was extracted from cultured HSC using TRIzol reagent following the manufacturer's instructions. Then 2 μg RNA of each sample was reverse-transcribed using random primer and reverse transcriptase in 25 μL of volume. Subsequently PCR was carried out in 25 μL reaction mixture containing 5 μL cDNA template, 2.5 μL 10×PCR buffer, 1 μL 10 mmol/L dNTPs, 1.5 μL 15 pmol/L TIMMP-1 or GAPDH primers, 2.5 U Taq DNA polymerase. Thirty-five cycles of PCR amplification for TIMP-1 and 30 cycles of PCR amplification for GAPDH were carried out for 5 min at 94℃ for initial DNA denaturation, followed by individual cycles of denaturation (at 94℃ for 45 s), annealing (at 56 ℃ for 35 s), polymerization (at 72℃ for 45 s) and then a final extension at 72℃ for 5 min. PCR products were electrophoresed on 2% agarose gel, stained with ethidium bromide (EB) and quantitated using Gel-Pro Analyzer Version 3.0. The band intensity of TIMMP-1 was compared to that of GAPDH, and the amount of TIMMP-1mRNA was estimated.

Western blot analysis

Western blot was performed to measure IL-1β-induced JNK and p38 activation in rat HSC. The HSC were lysed on ice by lysis buffer containing 50 mol/L Tris-HCl (pH 7.5), 150 mol/L NaCl, 10% glycerol, 1% Nonidet P-40, 1% SDS, 0.5% deoxycholate, 1.0 mol/L PMSF, and 1 mol/L sodium orthovanadate for 30 min. The cell lysate was centrifuged at 10 000 r/min for 10 min and the supernatant was collected for Western blot analysis. Protein concentration was measured using Coomassie brilliant blue G-250 (CBB) kit following the manufacturer's instructions. Protein samples (50 μg) were subjected to 10% SDS-PAGE gel electrophoresis and then transferred onto a nitrocellulose membrane by electro-blotting. The membrane was incubated at 4 ℃ overnight in Tris-buffered saline/Tween 20 (20 mol/L Tris-HCl, pH 7.4, 150 mol/L NaCl, 0.05% Tween 20) with 5% nonfat milk. After blocking, the membrane was incubated for 5 h at room temperature in TBS buffer (50 mol/L Tris-HCl, 150 mol/L NaCl) containing an 1:100 dilution of mouse anti-phospho-JNK monoclonal antibody, anti-phospho-p38 monoclonal antibody or rabbit anti-β-actin polyclonal antibody. Then the membrane was incubated for 2 h at room temperature in TBS containing an 1:300 0 dilution of anti-mouse IgG (H+L) / HRP, 1:100 0 dilution of anti-mouse IgM (H+L) /HRP or 1:300 0 dilution of anti-rabbit IgG (H+L) /HRP antibody. Specific binding of the antibody was visualized by the enhanced chemiluminescence (ECL) detection system following the manufacturer's instructions. The intensity of

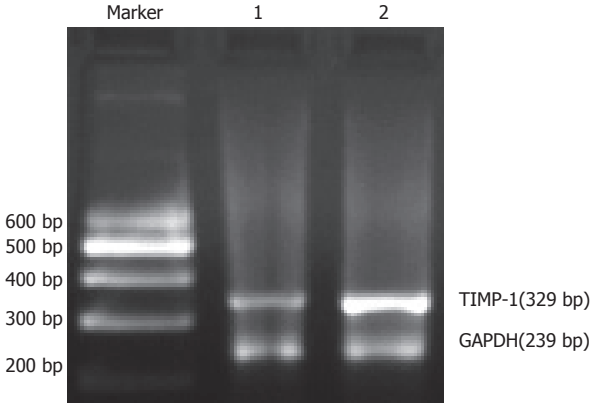

Figure 1 Expression of TIMMP-1 mRNA in HSC detected by RT-PCR. Marker: 200-600 DNA marker; lane 1: control group (without IL-1beta treatment); lane 2: IL-1β group (with IL-1β treatment)

the bands was determined by scanning video densitometry using Gel-Pro Analyzer Version 3.0. The levels of phospho-JNK protein and phospho-p38 protein were normalized to the level of β-actin protein.

Statistical analysis

The data were presented as mean ± SD. Statistical analysis was performed by the statistical software SPSS 11 using independent-sample *t* test and one-way ANOVA test. $P<0.05$ was considered statistically significant.

RESULTS

IL-1β up-regulated mRNA expression of TIMMP-1

We examined the mRNA expression of TIMMP-1 in rat HSC with RT-PCR. The ratio of TIMMP-1/GAPDH represented the expression of TIMMP-1 mRNA. The data showed that the TIMMP-1 mRNA expression (1.191 ± 0.079) in the group treated with IL-1β (10 ng/mL) for 24 h was much higher than that in the control group (0.545 ± 0.091). There was a statistical significance between the two groups ($P<0.01$, Figure 1).

IL-1β activated JNK and p38 in a time-dependent manner

After stimulation with IL-1β for 0, 5, 15, 30, 60 and 120 min, the activities of JNK, p38 and β-actin were measured. The intensity of the two bands at 46 KD and 55 KD of JNK and the band at 38 KD of p38 were compared to that of β-actin and the ratio represented JNK and p38 activity. At the 6 time points, the JNK activity was 0.982 ± 0.299, 1.501 ± 0.720, 2.133 ±0.882, 3.360 ± 0.452, 2.181 ± 0.789, and 1.385 ± 0.368 , respectively. There was a significant difference in JNK activity at 15 min ($P<0.01$), 30 min ($P<0.01$) and 60 min ($P<0.01$) compared to that at 0 h. The data showed that JNK activity increased slightly after stimulation with IL-1β for 5 min, but the difference was not significant when compared to that at 0 h (without IL-1β treatment). An apparently increased phosphorylation of JNK was first detected at 15 min in HSC and reached its peak at 30 min after IL-1β treatment. The values restored to the original levels at 120 min (Figure 2). On the other hand, the p38 activity was 1.061 ± 0.310, 2.050 ± 0.863, 2.380 ± 0.573, 2.973 ± 0.953, 2.421 ± 0.793, and 1.755 ± 0.433, respectively at the 6 time points. There was a significant difference in p38 activity compared to that at 0 h, 5 min ($P<0.05$), 15 min ($P<0.01$), 30 min ($P<0.01$) and 60 min ($P<0.01$). A significant increase was first observed at 5 min and peaked at 30 min. The values restored to the original levels at 120 min (Figure 2).

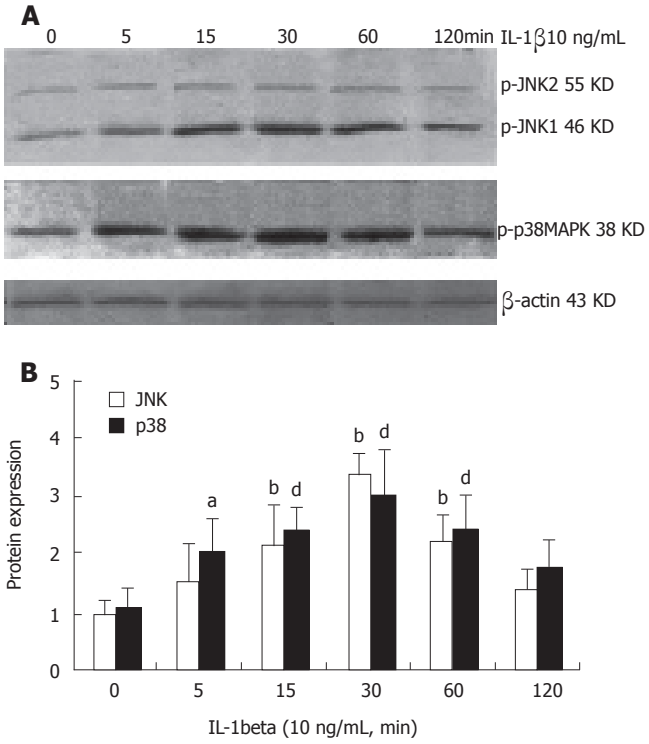

Figure 2 IL-1β activates JNK and p38 in a time-dependent manner in rat HSC. **A:** Representative Western blot results of JNK and p38; **B:** Densitometry of Western blot analyzed by Gel-Pro software. *n*=6. $^bP < 0.01$ *vs* 0 h of JNK, $^aP < 0.05$ *vs* 0 h of p38, $^dP < 0.01$ *vs* 0 h of p38.

Effect of SP600125 and SB203580 on IL-1β-induced expression of TIMMP-1 mRNA in rat HSC

TIMMP-1 mRNA expression induced by IL-1β trended to decrease in groups pretreated with different concentrations of SP600125 (10 μmol/L, 1.022 ± 0.113; 20 μmol/L, 0.869 ± 0.070; 40 μmol/L, 0.666 ± 0.123). When the concentration of SP600125 was increased, the expression of TIMMP-1 mRNA was gradually reduced. Compared to control group (without SP600125 treatment) (1.163 ± 0.107), there was a significant difference ($P<0.05$, $P<0.01$, $P<0.01$) (Figure 3). However, the expression of TIMMP-1 mRNA trended to increase in groups pretreated with different concentrations of SB203580 (10 μmol/L, 1.507 ± 0.099; 20 μmol/L, 1.698 ± 0.107; 40 μmol/L, 1.857 ± 0.054). When the concentration of SB203580 was increased, the expression of TIMMP-1 mRNA increased gradually. In comparison to control group (without SB203580 treatment) (1.027 ± 0.061), the difference was significant ($P<0.01$, Figure 3).

DISCUSSION

Hepatic fibrosis represents a repairable process of chronic hepatic damages including viral infection, toxic damage, alcohol, as well as autoimmune reactions. In response to

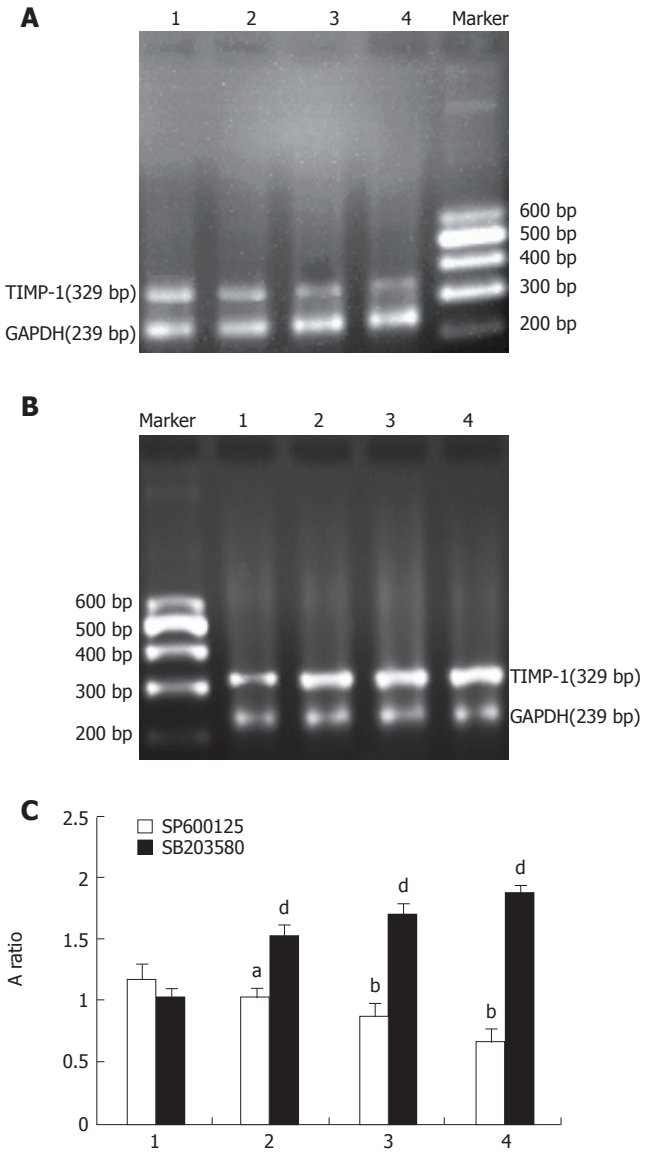

Figure 3 Effect of SP600125 and SB203580 on IL-1β-induced expression of TIMMP-1 mRNA in rat HSC. **A:** Representative photos of different concentrations of SP600125 of RT-PCR; **B:** Representative photos of different concentrations of SB203580 of RT-PCR. **C:** TIMMP-1 mRNA expression in **A** and **B**. 1: IL-1β + DMSO; 2: IL-1β + SP600125 or SB203580 (10 μmol/L); 3: IL-1β + SP600125 or SB203580 (20 μmol/L); 4: IL-1β + SP600125 or SB203580 (40 μmol/L).*n* = 6.^{a}P < 0.05 *vs* Il-1β+SP600125, ^{b}P < 0.01 *vs* IL-1β+SP600125, ^{d}P < 0.01 *vs* IL-1β + SB203580.

liver injury of any etiology, the normally quiescent HSC undergo a progressive process of trans-differentiation into α smooth muscle action (α-SMA) on positive myofibroblast-like cell-activated HSC. By increasing secretion of extracellular matrix proteins (TIMMP-1 and TIMMP-2), activated HSC is responsible for deposition and accumulation of the majority of excess ECM in the fibrotic liver. Furthermore, activated HSC can contribute to the fibrogenic process through their ability to secrete and respond to a wide range of cytokines and growth factors, such as IL-1, IL-6, transforming growth factor β(TGF-β) and platelet-derived growth factor (PDGF). MMPs are a family of zinc metalloendopeptidases and responsible for the turnover of all the ECM components. TIMMPs, specific inhibitors of MMPs, are the key regulators of MMP activity and ECM degradation. Some studies have shown that TIMMP is a very important promoting factor for hepatic fibrosis and inhibits MMPs to decompose ECM. In the liver, TIMMP-1 and TIMMP-2 have been identified and TIMMP-1 plays a more important role in the pathological process of hepatic fibrosis than TIMMP-2[22-26].

Inflammation is a key component of chronic liver disease. IL-1 is one of the major mediators regulating inflammatory response[27, 28]. There are two forms of IL-1, namely IL-1alph and IL-1beta with indistinguishable biological activities. IL-1 may be involved in hepatic fibrosis, causing hepatic tissue injury which induces the fibrotic response and participating in hepatic fibosis by promoting the deposition of ECM[5,7,29,30]. In the present study, TIMMP-1 mRNA expression after treatment with IL-1beta for 24 h was much higher than that in control group. Strong expression of TIMMP-1 inhibits the degradation of collagen by MMPs, thus promoting the deposition of ECM. The continuous deposition of ECM in the liver finally results in hepatic fibrosis, suggesting that IL-1beta has a direct action on hepatic fibrogenesis through stimulating TIMMP-1 production in activated HSC.

As we known, IL-1 could activate the MAPK cascades including ERK, p38 and JNK[31]. In 3 groups of the MAPK family, the role of ERK has been studied in HSC[9,10,30,32], but the role of p38 and JNK in regulating TIMMP-1 expression in HSC is poorly understood. The aim of our study was to evaluate the effect of p38 and JNK on TIMMP-1 mRNA expression induced by IL-1beta in HSC. Our data demonstrated that following stimulation with IL-1beta, the 2 MAPK pathways including p38 and JNK were all activated. In comparison to control group (without IL-1beta treatment), phosphorylation of JNK was first detected at 15 min in HSC and reached its peak at 30 min. The values restored to original levels at 120 min. In comparison to control group (without IL-1beta treatment), a significant increase of p38 activity was first observed at 5 min for p38 peaked at 30 min. The values returned to control levels at 120 min (Figure 2). The data showed that IL-1beta could activate JNK and p38 MAPKs in a time-dependent manner in rat HSC.

To study the relationship between IL-1beta up-regulating TIMMP-1 mRNA and phosphorylation of JNK and p38, JNK inhibitor SP600125 and p38 inhibitor SB203580 were used to inhibit JNK and p38 activities. Then TIMMP-1 mRNA expression in rat HSC induced by IL-1beta was observed. Our study clearly showed that blocking JNK could result in inhibition of TIMMP-1 mRNA expression in HSC, but inhibition of p38 in HSC increased TIMMP-1 mRNA expression. When the concentration of SP600125 was increased, the expression of TIMMP-1 mRNA was gradually reduced, but when the concentration of SB203580 was increased, TIMMP-1 mRNA expression increased gradually, indicating that the 2 MAPKs cooperatively modulate the TIMMP-1 mRNA expression in HSC when they are activated simultaneously by IL-1β. As a result, interaction between JNK and p38 pathways up-regulates TIMMP-1 mRNA expression in rat HSC induced by IL-1beta.The signal transduction in HSC induced by IL-1beta is very complex. Following the treatment with

IL-1beta, whether TIMP-1 has any other pathways such as JAK/STAT and PI3-K to promote hepatic fibrosis is still unknown. Further studies are needed to elucidate its mechanism.

In summary, differential signal transduction pathway triggered by IL-1β can lead to TIMMP-1 gene up-regulation in rat HSC. A better understanding of these pathways may contribute to the development of more rational therapies to counteract the devastating effects of hepatic fibrosis.

Abstract

AIM: To investigate the sonographic features at time of diagnosis and follow-up in patients with neutropenic enterocolitis.

METHODS: The sonographic findings in 14 patients with neutropenic enterocolitis were described and evaluated regarding symptoms and clinical outcome.

RESULTS: In all patients with neutropenic enterocolitis, the ileocoecal region was involved with wall thickening >10 mm. A transmural inflammatory pattern, hypervascularity of the thickened bowel wall and free abdominal fluid were the common findings. The sonographically revealed thickness of the bowel wall was associated with lethal outcome ($P < 0.03$). In the 11 surviving patients, the improvement of clinical symptoms was accompanied by progressive reduction of intestinal wall thickness.

CONCLUSION: High-end sonography of the bowel is a helpful tool for diagnosis, assessment of prognosis and follow-up of patients with neutropenic enterocolitis. The ultrasonographically revealed bowel thickness reflects the severity and the course of the disease, and seems to be predictive for the clinical outcome.

Key words: Neutropenia; Bowel wall thickness; Ultrasonography

INTRODUCTION

Neutropenic colitis, also termed necrotizing enterocolitis or neutropenic typhlitis (Greek: *typhlon* = cecum), was first described by Cooke in 1930[1,2]. It is a necrotizing inflammatory disease of the ileocoecal region. The pathogenesis is not entirely known, although bacterial infection of damaged mucosa, often with superinfection, e.g., *clostridia* (especially *Clostridium septicum*) and other bacteria, seems to play an important role[3-7].

Neutropenic colitis is a complication of severe neutropenia, often in patients after (high-dose) chemotherapy. Although most reported cases occurs in patients, who received chemotherapy for leukemia or solid tumors, it has been seen in a variety of other conditions, e.g. aplastic anemia, benign cyclic neutropenia, AIDS and allergic or toxic agranulocytosis as well[8,9].

Neutropenic colitis has a wide spectrum of severity, ranging from mild gastrointestinal symptoms to peritonism and sepsis with lethal outcome. As abdominal discomfort and diarrhea are common in patients receiving chemotherapy, the prevalence of this condition is not well known. The finding of thickened bowel wall, in association with a clinical syndrome characterized by fever, diarrhea, and abdominal pain, confirms the clinical diagnosis of neutropenic enterocolitis in neutropenic patients who have completed intensive chemotherapy.

A Recent report[10] has shown that sonographic findings might be helpful in this condition and can be easily repeated in these severely ill patients. Herein we report on 14 neutropenic patients with sonographic features of neutropenic colitis, evaluating the clinical findings, sonographic features and outcome of these patients and reviewing of the literature regarding this condition.

MATERIALS AND METHODS

Patients

We reviewed the clinical records of 14 neutropenic patients (absolute neutrophil count $< 500/mm^3$) with sonographic signs of neutropenic colitis who presented at the Department of Gastroenterology for sonography during a period of three years. The patients consisted of 8 men and 6 women [age = 48 (22-66) years; body mass index = 23.5 (17.8-28.2) kg/m^2; weight loss = 3.5 (0-14) kg]. Neutropenia occurred due to intensive chemotherapy in 13 patients (six patients with non-Hodgkin lymphoma, four patients with acute lymphatic leukemia, two patients with acute lymphoblastic leukemia, and one patient with chronic myeloid leukemia). One patient had allopurinol-in-

Table 1 Frequency of clinical symptoms, laboratory, and microbiological findings in 14 patients with neutropenic enterocolitis.

Clinical symptoms	Frequency
Abdominal pain	14 (100%)
Fever	14 (100%)
Diarrhea	10 (71.4%)
Hypotension	3 (21.4%)
Right lower quadrant pain	10 (71.4%)
Peritonism	6 (42.9%)
Abdominal distension	10 (71.4%)
Vomiting	9 (64.3%)
Bloody diarrhea	6 (42.9%)
Ileus	6 (42.9%)
Reduced clinical condition	12 (85.7%)
Palpable resistance	7 (50%)
Daily bowel movements	4 (1-7)
Laboratory findings	
C-reactive protein [mg/dL]	26.3 (6.6-64.0)
Haemoglobin [g/dL]	9.1 (6.9-11.4)
Haematocrit [%]	25.8 (21.1-33.9)
Platelets [/nL]	33 (19-43)
Microbiological findings	6 patients with negative cultures 3 patients with *Streptococcus epidermidis* in blood culture 2 patients with *Enterococcus* in blood culture 1 patient with *Pseudomonas aeroginosa* in blood culture 1 patient with *Streptococcus*, *Enterobacteriaceae*, Enterococcus, and *Escherichia coli* in blood culture 1 patient[1] with *Candida albicans* in bronchio¬alveolar lavage, *Candida glabrata* and *Entero¬coccus faecium* in blood culture, *Pseudomonas aeroginosa* and *Candida albicans* in urine culture

[1]Patients did not survive.

duced severe neutropenia. All patients were monitored by performing blood and feces cultures. In addition, sputum, nasopharynx, oropharynx, and external-genital cultures were performed when appropriate. Clinical symptoms, chemotherapeutic and antibiotic agents, and microbiological findings were documented and evaluated in relation to sonographic results and outcome.

Examination technique

Real-time ultrasound scanning of the bowel wall was performed using a 7 MHz linear transducer (Siemens Elegra, Erlangen, Germany or Acuson Sequoia, Siemens Erlangen, Germany). Bowel wall thickness (outer wall to luminal surface) was measured at terminal ileum, cecum, sigmoid colon, and small intestine by high resolution sonography with moderate pressure as previously described[11,12]. A thickness of less than 2 mm was considered normal, more than 2 mm and less than 5 mm was considered unspecific bowel wall thickening, and a thickness of more than 5 mm was considered abnormal confirming the diagnosis of neutropenic enterocolitis. The morphology and the five layers of ileum and colon were evaluated assessing a mucosal or transmural pattern of inflammation. Bowel wall vascularity was examined by color Doppler imaging and graded as ischemic (no flow pattern), normal or hypervascular[12,13] as recently shown for graft *versus* host disease (GvHD) as a prognostic factor.

Statistical analysis

Data were expressed as median and range. χ^2 test was used to evaluate differences in sonographic findings (ascites, bowel wall vascularity, extension of inflammation), symptom presentation and death rate. Differences in bowel thickness and laboratory data between surviving and non-surviving patients were analyzed using the nonparametric Wilcoxon rank sum two-tailed test. 95% confidence intervals were calculated. $P < 0.05$ was considered statistically significant.

RESULTS

The clinical symptoms and laboratory findings of the 14 neutropenic patients with sonographic signs of neutropenic enterocolitis are mentioned in Table 1.

In all 14 patients, treatment consisted of multiple antibiotic therapy. The antibiotic treatment usually started using beta-lactamic combined with aminoglycoside. Vancomycin was added if the fever persisted. In 9 cases, antimycotic agents were administered due to suspected invasive fungaemia.

G-CSF was given in 8 patients to shorten the time of neutropenia. Supportive treatment consisted of bowel wall rest and total parenteral nutrition. Packed RBC's, platelets, and albumin were infused when appropriate.

Intensive chemotherapies, according to the protocols for the underlying malignant diseases, preceded in 13 patients with the onset of symptoms. The chemotherapies were intended to induce (first) complete remission. In all protocols, drugs were administered in daily doses which are known to be toxic for the gastrointestinal mucosa (500 to 3 000 mg/m^2 high dose cytarabine instead of the standard dose of 100 to 200 mg/m^2, 100 to 200 mg/m^2 etoposide, 10 to 12 mg/m^2 idarubicin, 10 mg/m^2 mitoxantrone, 60 mg/m^2 daunorubicin, 50 mg/m^2 doxorubicin, or 500 to 3 000 mg/m^2 methotrexate).

Three patients died due to sepsis with multiorgan failure. High C-reactive protein ($P < 0.001$) and the sonographically revealed significantly thickened bowel wall ($P < 0.03$) were associated with the lethal outcome.

The surviving 11 patients recovered from neutropenic enterocolitis. The reduction of abdominal symptoms was accompanied by progressive decrease in intestinal mural thickening in follow-up ultrasound examinations. The sonographic findings in 14 patients with neutropenic colitis are summarized in Table 2. Nearly all patients with neutropenic enterocolitis (92.9%, 13/14) presented a transmural inflammatory pattern of the thickened bowel wall. In all patients, the ileocoecal region was involved. The thickness of the inflammated bowel section was at least 10 mm. Hypervascularity on color Doppler imaging and the detection of small amounts of free fluid in the abdomen were documented in the majority of patients with neutropenic enterocolitis. Free abdominal air, fistula or abscesses were not observed in our collective. Typical sonographic charac-

Table 2 Sonographic findings in 14 patients with neutropenic enterocolitis (frequency of findings or median and ranges are given)

Localisation of inflammation	13 in ileocoecal region 1 in ileocoecal region and colon transversum
Pattern of inflammation	10 transmural 4 mural
Longitudinal extension of inflammation	5-15 cm in all 14 patients
Bowel wall thickening (mm)	12 (10-20)
Ascites	11 of 14
Hypervascularisation	84.61% (13/14)
Fistula	None
Abscess	None

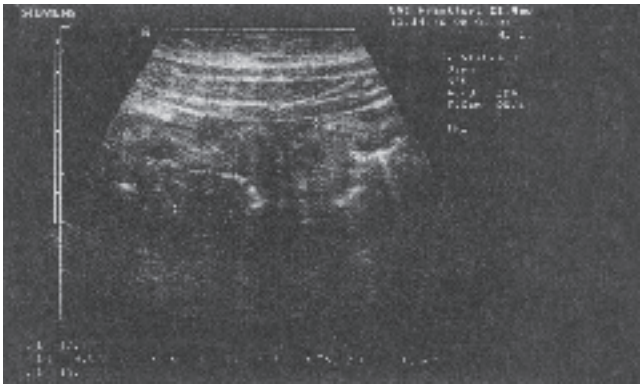

Figure 1 Characteristic sonographic findings in neutropenic enterocolitis showing asymmetric, echogenic (between markers) and inhomogenous bowel wall thickening with areas of hypoechogenity (between markers).

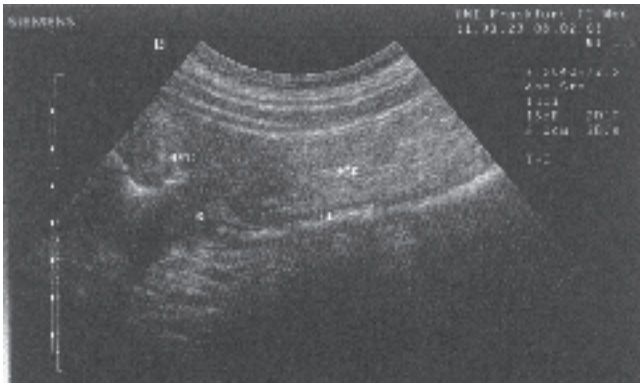

Figure 2 Asymmetric and inhomogenous wall thickening, transmural inflammatory reaction in a patient with neutropenic enterocolitis (NPC). The ileocoecal valve of Bauhin (**B**) and the terminal ileum (not affected, TI) are also indicated. Typically, the surrounding omentum shows echogenic reaction (UGR).

teristics in neutropenic enterocolitis are depicted in Figures 1 and 2.

DISCUSSION

Epidemiology

The incidence of neutropenic colitis in cytopenia patients ranges from 2.6[14] to 33%[15] with a pooled incidence rate from 21 studies of 5.3%[16]. With the use of more intensive chemotherapy regimens, especially after autologous and allogeneic stem-cell transplantations, a higher incidence of neutropenic colitis should be expected. The tendency to relapse has been reported to range from 27% to 83%[17].

Etiology and pathogenesis

Various factors are in discussion to play a role in the pathogenesis of neutropenic colitis. Apart from direct damage to the mucosa by leukemic of lymphatic infiltrates, toxic effects of chemotherapeutic agents contribute to the pathogenesis. The first step is the severe initial damage to the mucosa caused by release of pro-inflammatory cytokines from macrophages and monocytes, followed by a near complete arrest of the cell cycle, inhibition of mechanisms of repair and finally apoptosis. Several cytotoxic agents and combinations of chemotherapeutic agents, depending on their dose, have a high toxic potential[1,17-19].

According to the literature, neutropenic colitis is mainly localized in the ileocoecal region, although other parts of the bowel can be affected as well. The high concentration of lymphatic tissue in this area and the special anatomy of the terminal branches of the superior mesenteric artery with consecutive less vascular perfusion may contribute to ischemia. The cecum represents an area of relative stasis of bowel content and is easily distensible, causing a high intramural pressure and insufficient blood supply[7].

The role of bacteria and viruses in the pathogenesis of neutropenic colitis has been discussed controversially in the literature. Infection is thought to be largely secondary (e.g., Clostridial bacteria, especially *Clostridum septicum*). Abnormal bacterial colonisation in connection with the neurotoxic effects of vincristine is thought to contribute to the pathomechanism[20]. Although *Clostridium septicum* is found in stool cultures of healthy persons only in 2%, it is detectable in a higher percentage in the ileocoecal region, especially in the healthy appendix (63%)[2]. Clostridia produce a number of tissue degrading enzymes, which may play a significant role in the development of mucosal injury. In the absence of neutrophil granulocytes which produce toxin degrading proteases, an important defence mechanism is missing. Similar pathomechanisms have been described for other Clostridial species (e.g., *Clostridium perfringens*, *paraperfringens* and *Clostridium tertium*).

Symptoms

The initial symptoms are not specific and usually occur during the nadir with rapid improvement after neutrophil recovery. The symptoms very often consist of a combination of crampy abdominal pain (sub-ileus symptoms), a palpable mass and tenderness in the right lower quadrant with rebound tenderness (a sign of peritonism) and fever. Diarrhea, occasionally bloody diarrhea, may be present, but the leading symptom is abdominal pain in the right lower quadrant. Sepsis and signs of perforation with peritonism, as well as profuse bleeding are life-threatening complications.

A localized tenderness with rebound tenderness above the affected area is very often the only clinical sign in these severely ill patients. Recurrent abdominal pain, caused by mechanical obstruction of the ileocoecal area, indicates

symptoms of ileus with dilatation of the bowel loops of the small intestine. Other more unspecific symptoms like abdominal distension, nausea, vomiting and meterorism *etc.* have also been described in the literature. Table 3 summarizes the symptoms mentioned in 36 case reports (including 209 patients overall). Abdominal pain was described in nearly all patients (98%), followed by fever in 87%, diarrhea in 61%, and peritonism in 30% of the patients with neutropenic enterocolitis (Table 3).

Differential diagnosis

Appendicitis is very often the main differential diagnosis. Because of the high perioperative mortalitiy in these patients, the operative approach should be avoided. The perioperative mortality rate in the literature varies widely and ranges between 0%-100%, depending on the case reports or the studies[1]. Besides appendicitis, other acute or chronic inflammatory diseases of the ileocoecal area, e.g., bacterial ileocecitis, cytomegalovirus (CMV) infection, Crohn's disease, pseudomembranous and ischemic colitis, should be taken into account. In patients after allogeneic stem-cell transplantation, one has to think of graft *versus* host disease, although this usually occurs after engraftment.

A neoplastic (lymphocytic leukemia) infiltration of the ileocoecal region must be excluded especially in case of a palpable mass in this area. In pancytopenic patients, one has also to think of an acute hemorrhage into the mucosal wall.

Diagnosis

Besides the routine laboratory and microbiological tests for bacteria (e.g., *Clostridium difficile* and toxin) viruses and parasites, one should perform the CMV PCR- and CMV early (pp65) antigen-test. The endoscopic approach during pancytopenia is relatively contraindicated, although the definitive diagnosis of CMV-colitis, leukemic or neoplastic infiltrates can be definitively diagnosed only by histological examination.

High resolution sonography The characteristic sonographic features of neutropenic colitis are echogenic, asymmetric thickening of the mucosal wall[10,21,22] with transmural inflammatory reaction and areas of different echogenity caused by edema, necrosis and/or circumscript hemorrhages. Intramural air suggests an infection with anaerobic bacteria. Pericolic fluid is a sign of a (possible) perforation.

Sonography may demonstrate free abdominal air which is usually right sided, e.g. perihepatic. In advanced disease with catastrophic prognosis, air bubbles in the vena porta may be demonstrated, as seen after application of contrast enhancing agents. Another feature may be pneumatosis cystoides intestinalis, as seen in premature infants with

necrotizing enterocolitis. It is mentionable that in these patients, the hydrogen content of the expiration air is massively increased.

Computed tomography Although most authors favor the computed tomography as the most sensitive diagnostic tool to diagnose neutropenic colitis[23,24], high resolution sonography is of advantage. In contrast to CT, sonography can be easily performed and repeated (e.g., at the bedside) even in severely ill patients in intensive care or transplantation units.

Abdominal X-ray The findings on abdominal X-ray are often nonspecific and may show small bowel ileus, an ill-defined soft tissue density in the region of the cecum, thickened air-filled loops of bowel or signs of pneumatosis intestinalis.

Barium enema As barium enema should not be performed, when perforation is expected, and as it increases the pressure in the ileocoecal area and therefore may produce ischemia, this diagnostic tool is relatively contraindicated to diagnose neutropenic colitis.

Enteroclysis The oral application of radiopaque medium, such as the barium enema, is not without risk, as large amounts of contrast medium increase the pressure and the risk of perforation. This method is, therefore, also relatively contraindicated.

Other methods Other methods, such as gallium-scintigraphy, or indium-labeled granulocytes, are not routinely used in clinical practice. In certain circumstances, they might give additional informations[25].

Histopathology The macroscopic findings are dilated, edematous thickened bowel wall with areas of hemorrhage and necrosis. The characteristic histological lesions are mucosal ulceration without accompanying inflammatory response, which might progress to gangrene. Often thrombosis of intestinal veins and extensive macroscopic thrombosis of adjacent mesenterial veins in some cases are present, which are probably caused by endotoxins. The main histologic features of neutropenic colitis are edema, hemorrhage and necrosis. Inflammatory, fungal, leukemic or neoplastic infiltrates, as well as frank perforation are occasionally seen.

Therapy

The conservative approach, total parenteral nutrition, antibiotic and antifungal treatment should be placed in forefront. As neutropenia represents the "sine qua non" of neutropenic colitis, time of neutropenia should be shortened, e.g. with granulocyte-colony-stimulating factors or granulocyte transfusions[7, 25].

As the perioperative mortality in these patients is very high, surgical intervention should be placed into the background. On the other hand, the right time for surgery should not be missed, therefore, a close clinical evaluation of the patient by physicians and surgeons is mandatory. The indications for surgical intervention are the same as in immunocompetent patients: Persistant gastrointestinal bleeding after resolution of neutropenia and thrombocytopenia and correction of clotting abnormalities, evidence of intraperitoneal perforation, clinical deterioration requiring support with vasopressors, or large volumes of fluid, suggesting uncontrolled sepsis[7,26].

Selective or complete bowel decontamination as well as prophylactic granulocyte transfusions, especially in patients who had previous episodes of neutropenic colitis, are possible preventive measures.

Prognosis

The prognosis depends on the underlying disease and on the clinical conditions of the patient. The mortality rate in patients with signs of perforation, sepsis and multi-organ failure is higher than 50%[27]. The main prognostic factor is neutrophil recovery and overall time of neutropenia, as neutropenia allows continuous bacterial invasion of the bowel, perpetuating the lesion, with possible necrosis and perforation[28].

In our study, we observed an involvement of the ileocoecal region in all patients, only one patient showed an additional inflammatory reaction of the transverse colon. The sonographically revealed thickness of the bowel wall was associated with poor prognosis and also proved to be a useful tool for monitoring the clinical follow-up by showing the decreasing bowel wall thickening in responding patients. The results of our study agree with the findings of Cartoni *et al*[10] who described an increased mortality in patients with bowel thickness of more than 10 mm. However, all of our patients were classified into this group. We also could demonstrate an increased death rate in patients with thicker bowel walls in the sonographic examination. Although nearly all patients showed a transmural pattern of inflammation, fistulas or abscesses were not observed. This might be explained by the neutropenic condition with restricted defense mechanisms. In addition, sonography might indicate complications of the disease by detection of free abdominal air or intramural hemorrhage. These complications, however, did not occur in our patients.

In conclusion, the high-end sonography of the bowel proved to be a helpful tool in diagnosis, prognosis and follow-up of patients with neutropenic enterocolitis. The ultrasonographically revealed bowel thickness reflects the severity and course of the disease, and seems to be predictive for the clinical outcome.

Abstract

AIM: To investigate the effects of long-term albumin administration on survival, recurrence of ascites and onset of other complications.

METHODS: One hundred consecutive patients admitted for first-onset ascites were randomized to receive diuretics plus human albumin 25 g/wk in the first year and 25 g every two wk thereafter (group 1) or diuretics alone (group 2). The primary endpoint was survival without liver transplantation. Secondary endpoints were recurrence of ascites and occurrence of other complications.

RESULTS: Median follow-up was 84 (2-120) mo. Albumin-treated patients had significantly greater cumulative survival rate (Breslow test = 7.05, $P = 0.0078$) and lower probability of ascites recurrence (51% *versus* 94%, $P < 0.0001$). Chronic albumin infusion resulted in a mean increase in survival of 16 mo.

CONCLUSION: Long-term albumin administration after first-onset ascites significantly improves patients' survival and decreases the risk of ascites recurrence.

Key words: Cirrhosis; Ascites; Human albumin; Circulatory dysfunction; Plasma expansion; Effective plasma volume; Diuretics; Renin-aldosterone axis

INTRODUCTION

Ascites is one of the most frequent complications of cirrhosis, occurring in more than 50% of patients within 10 years of the diagnosis of cirrhosis[1-3]. The development of ascites in cirrhosis severely affects patient's prognosis and heralds more severe complications, such as spontaneous bacterial peritonitis and the hepatorenal syndrome[1,3]. Two factors are of major importance in the pathogenesis of ascites: sodium retention, leading to extracellular fluid volume expansion; and imbalance in Starling's equilibrium in liver sinusoids and splanchnic capillaries, which is responsible for translocation of fluid from the intravascular compartment to the abdominal cavity[4,5]. The pathogenesis of sodium retention in cirrhosis is still debated. However, there is no doubt that even if total plasma volume is normal or even increased in cirrhosis, patients with cirrhosis and ascites have a decreased effective arterial blood volume and activation of the renin-angiotensin-aldosterone and sympathetic nervous systems, which stimulate the kidney to retain sodium[4-7]. Starling's forces in the splanchnic compartment are altered because of the increased hydrostatic pressure due to portal hypertension and the low oncotic pressure due to hypoalbuminemia.

Treatment of grade 2 (moderate) ascites is based on sodium restriction and administration of an aldosterone antagonist, with addition of a loop diuretic in the non-responding patients[8]. The same regimen plus paracentesis is recommended in patients with grade 3 (tense) ascites[8]. At present, the main indications to intravenous albumin in cirrhosis are type I hepatorenal syndrome[8,9] and spontaneous bacterial peritonitis[8-10].

In a previously published, controlled study performed at our institution[11], administration of human albumin to a series of patients with ascites improved the response rate to low-sodium diet and diuretics and reduced the cumulative probability of developing ascites during a 20-mo follow-up, but did not affect survival after a mean follow-up of 20 mo.

We report herein the results of an another randomized study aimed at investigating the effects of long-term human albumin administration in a series of consecutive cirrhotic patients with first-onset ascites. The primary endpoint of this study was survival without liver transplantation. Secondary endpoints were recurrence of ascites and occurrence of other complications.

MATERIALS AND METHODS

Patients

The study was performed at the Liver Unit, Department of Internal Medicine, University of Florence, in accordance with the Declaration of Helsinki. It was approved by the University of Florence Ethics Committee in October, 1992 and revised periodically thereafter. One hundred consecutive cirrhotic patients admitted from January 1, 1993 to June 30, 2003 because of first-onset, clinically detectable ascites (i.e., grade 2-3 ascites, according to the more recent definition by Moore *et al*[8]) were included in this randomized, unblinded trial. Exclusion criteria were: age below 35 or over 70 years; active alcohol abuse; previous episode(s) of grade 2-3 ascites; cardiac, respiratory or renal impairment (serum creatinine $\geqslant$1.5 mg/dL); diabetes; refractory ascites; hepatocellular carcinoma or other malignancies; present or previous hepatic encephalopathy of any degree; gastrointestinal bleeding at admission (endoscopy); infections; intravascular coagulation; impossibility or unwillingness to return for follow-up; and refusal of informed, written consent. Diagnosis of cirrhosis was based on history, clinical and biochemical data, abdominal ultrasound, gastrointestinal endoscopy and liver biopsy, when not contraindicated.

At admission, eligible patients were randomly assigned to either group 1 (albumin) or group 2 using sealed envelopes containing the treatment assignments. Allocation schedule was generated using a computed random number generation system. Patients from both groups received low-sodium diet and diuretics in increasing dosage, as commonly used at our institution[12] and later recommended by the International Ascites Club[8]. Briefly, they received low (80 mEq/d) sodium diet, spironolactone (100 - 400 mg), frusemide (25-150 mg), as appropriate. Nineteen group 1 and 16 group 2 patients had tense ascites at admission and had 4 L therapeutic paracentesis without plasma volume expansion. After disappearance of ascites, all patients were given low-sodium diet, diuretics and other drugs (e.g. β-blockers), as appropriate, to prevent ascites accumulation and other complications. In addition, group 1 patients intravenously received 25 g albumin per wk in the first year and 25 g every two wk thereafter. Albumin was administered in the outpatient clinic at our institution. All patients were followed in the outpatient clinic every 1-3 mo by members of the clinical staff not involved in this investigation to monitor the development of ascites or other complications of cirrhosis and modify therapy, as needed. Development of grade 2 - 3 ascites during the follow-up was assessed by clinical examination and confirmed by ultrasound and diagnostic paracentesis. Patients with recurrent ascites or other complications received adequate treatment at our institution as inpatients or outpatients, as indicated. In particular, patients with refractory ascites received therapeutic paracenteses of less than 4 L with no intravenous fluid infusion. The following parameters were recorded and analyzed: liver transplant-free survival; causes of death; recurrence of ascites; and onset of other complications.

Statistical analysis

The data were analyzed using the SPSS 10 (SPSS Inc., Chicago, IL). Being the follow-up loss limited to the first month for withdrawing consent to experimental design, the per protocol analysis was performed as previously described[13]. Student's t test, Fisher's exact test and χ^2 test were employed for the analysis of data, as appropriate. Dependence of survival from other disease parameters besides albumin treatment was analyzed using univariate analysis. Survival time was analyzed by the Kaplan-Meier method and differences were tested by the Breslow test. Data were expressed as median (range). $P<0.05$ was considered statistically significant.

RESULTS

Of the 100 consecutive patients included in this study, 54 were assigned to group 1 (albumin), the remaining 46 patients to group 2 (no albumin). The clinical characteristics of patients at the time of inclusion are shown in Table 1. No significant differences were observed between the two groups with respect to any of the measured biochemical parameters. However, group 1 (albumin) patients had significantly greater Child-Pugh score; as a consequence, significantly more patients in this group were in Child-Pugh class C (Table 1). No patient died during hospital stay. Nine patients in group 1 and eight in group 2 withdrew their consent at discharge or were lost at follow-up immediately afterwards. Median follow-up was 84 (range 2-120) mo.

Transplant-free survival

Among the 100 patients recruited, 81 were still alive at 2 years and 57 at 5 years, survival rates being 81% at 2 years and 57% at 5 years. Univariate analysis showed that the most important factor affecting survival was albumin treatment (R-squared = 0.975) ($F=16.55$, $P=0.005$), followed by Child-Pugh score ($F=6.363$, $P=0.021$) and age ($F=2.783$, $P=0.082$). Albumin-treated (group 1) patients had a significantly greater cumulative survival rate than those in group 2 (group 1: median 108, range 99.55-116.45 mo; group 2: median 36, range 22-50 mo, Breslow test = 7.05, $P=0.0079$, Figure 1). In particular, 34 out of the 54 patients randomized to receive albumin (75%) were still alive at 24 mo, 31 (69%) at 48 mo, 28 (62%) at 60 and 2 (4%) at 120 mo, while the corresponding figures for group 2 patients were 26 (68%), 11 (29%), 10 (26%) and 3 (8%), respectively.

Causes of death

Fifty-four patients (29 in group 1 and 25 in group 2) died during the follow-up. The causes of death in group 1 and group 2 patients are indicated in Table 2. No significant differences were observed between the two groups with

Table 1 Clinical data of the 54 group 1 and 46 group 2 patients at recruitment

Parameters	Group 1 (diuretics plus albumin)	Group 2 (diuretics alone)	*P* value
Age (yr)	63 (44 - 70)	63 (47 - 70)	NS
Sex (M/F)	33/21	29/17	NS

Creatinine clearance (mL/min)	69 (64 - 85)	71 (65 - 75)	NS

Continuous data are given as median (range); MAP = mean arterial pressure; NS = not significant.

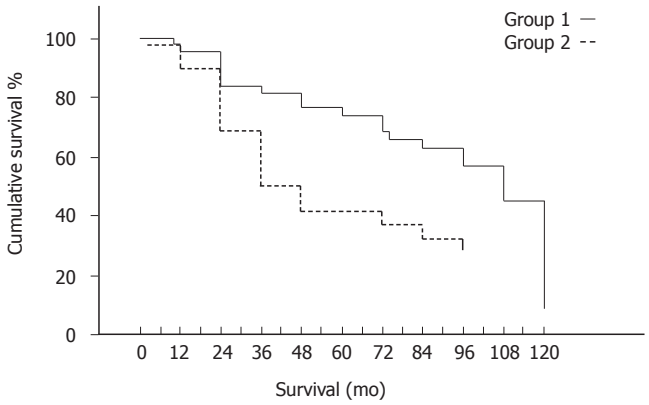

Figure 1 Cumulative survival rate in group 1 (albumin) and group 2 patients. Breslow test = 7.05; *P* = 0.0079.

Table 2 Causes of death in the 25 group 1 and 29 group 2 patients who died during the follow-up

Causes of death	Group 1	Group 2	*P* value
Hepatocellular carcinoma	9	14	NS
Other neoplasms	2	0	NS
Hepatorenal syndrome	1	0	NS
Variceal bleeding	5	4	NS
Liver Failure	10	6	NS
Heart Failure	0	1	NS
Sepsis	2	0	NS

NS = not significant.

respect to causes of death. Liver transplantation was performed in one patient in the albumin group because of hepatocellular carcinoma, and in three patients in group 2 because of progressive hepatic failure (2 patients) and chronic encephalopathy.

Recurrence of ascites

Recurrence of grade 2-3 ascites was markedly lower in group 1 patients (38.88%, 21/54) as compared with group 2 patients (84.78%, 39/46, $P<0.0001$). In group 1, 4 patients had 3 episodes and 2 patients 2 episodes of ascites, the total number of ascitic episodes being 31; whereas in group 2, ascites recurred 4 times in 1 patient, 3 times in 2 and 2 times in 8 patients, the total number of ascitic episodes being 54 ($P<0.001$). Five patients in each group developed refractory ascites ($P>0.05$), while 3 patients in group 1 and two in group 2 developed SBP ($P>0.05$).

Other complications

During the follow-up, there were 19 episodes of hepatic encephalopathy in 11 (20%) patients in group 1 and 15 episodes in 11 (24%) patients in group 2. Variceal bleeding occurred in 5 patients in group 1 and 10 patients in group 2 and hepatic failure in 5 patients in group 1 and seven patients in group 2 ($P>0.05$). One patient in the latter group received transjugular intrahepatic porto-systemic stent shunt (TIPSS) to stop intractable hemorrhage. Surgical porto-systemic shunt was performed in 1 patient in group 1 and 1 patient in group 2 to control severe chronic anemia due to portal hypertensive gastropathy.

Side effects of albumin

No side effects caused by administration of albumin were observed during the whole study period.

DISCUSSION

At the beginning of the 1940's, when salt-poor albumin became available, it was widely used in the management of cirrhotic patients with ascites in an attempt to correct the unbalanced Starling's forces in the splanchnic circulation, so reducing ascites formation, and to improve circulatory and renal function[13,14]. However, few studies investigated the role of albumin in the treatment of ascites and prevention of its recurrence, however, these investigations were uncontrolled and/or included a low number of patients. Albumin infusion usually produced a subjective feeling of "well-being", as also observed in our previous[11] and current studies, but had variable effects on ascites and

edema[14-17].

With the introduction of effective diuretics, the use of albumin for the treatment of ascites in cirrhosis was almost totally abandoned at least in the US. At present, the AASLD recommends albumin only in patients with SBP[18]. Albumin is superior to dextran 70 and polygeline in preventing circulatory dysfunction after paracentesis involving the removal of more than 5 liters of fluid[9] and is therefore widely used outside the US; however, randomized studies have shown no significant difference in survival between patients treated with albumin and those treated with other plasma expanders[19-22].

Despite no evidence from randomized studies support the long-term administration of albumin in patients with cirrhosis and ascites, this practice is widely used at least in Italy, as indicated by a recent study aimed at reaching a consensus among Italian hepatologists as to the use of albumin in patients with cirrhosis and ascites that involved 68 hepatology centers[23]. In the opinion of most experts, long-term use of albumin can help to improve the patient' s general conditions and well being. Seventy-seven percent of the experts involved in this survey agreed that albumin administration can shorten hospital stay or reduce the number of hospital admissions. As a matter of fact, 79% out of the 39 gastroenterological centers participating to a survey organized by the Italian Association of Hospital Gastroenterologists and Endoscopists (AIGO, available on the web site of this association) stated that they usually administer albumin to patients with cirrhosis and ascites.

In a previous randomized study from our department, which included 81 cirrhotic patients with ascites (38 treated with diuretics and 43 with diuretics plus human albumin), and had a follow-up of 20.0 ± 1.9 (range 6-36) mo, patients receiving human albumin had greater rate of ascites disappearance (90.5% *versus* 74.7%, $P < 0.05$) and lower cumulative probability of developing ascites, but no improvement in survival[11].

In the current investigation, we extended the follow-up period up to 62.7 ± 4.2 (mean $\pm$ SE) mo. The main result of our study was that human albumin administration to patients affected by liver cirrhosis (25 g/wk in the first year and 25 g every two wk thereafter) resulted in a significantly greater cumulative survival rate. In addition, as in the previous investigation, albumin administration markedly reduced ascites recurrence.

The patients in group 1 and group 2 were quite similar with respect to arterial pressure and the measured parameters of liver and renal function. However, despite our attempt to reduce variability by including only cirrhotics with first-onset ascites, patients randomized to receive albumin had a slightly greater Child-Pugh score (Table 1), with more patients in this group belonging to Child class C (39 *vs* 15). It is conceivable that the effects of any therapeutic intervention, as albumin infusion in the current investigation, will be quite different in patients with different baseline characteristics. This is confirmed by the results of univariate analysis, showing that transplant-free survival was related to treatment, but also to Child-Pugh score. Albumin administration resulted in a gain of 16 mo of mean survival time (88.63 *vs* 61.39 mo).

Other aspects of this investigation deserve consideration. First, group 2 patients did not receive placebo. This was made to avoid the expenses, discomfort and risks of coming to the outpatient clinic and receive an unnecessary intravenous infusion every 7 - 14 d. On the other hand, patients not receiving albumin are easily identified since they have lower plasma albumin levels. Second, we used the same protocol proved effective in reducing ascites recurrence in our previous investigation[11]. Whether different amounts of albumin would be equally or even more effective in all ascitic patients remains to be established.

The mechanisms determining a better survival in cirrhotic patients with ascites receiving long-term human albumin were not specifically investigated in this study. Albumin is responsible for about 70% of plasma oncotic pressure and therefore plays a major role in modulating the distribution of fluid between compartments. In a hemodynamic study by Brinch *et al*[24], acute administration of albumin (40 g) expanded plasma and blood volume in cirrhosis, although central blood volume only increased in Child class A patients. In addition, arterial compliance increased and plasma renin activity decreased in Child C patients, indicating that albumin is able to improve the low effective arterial blood volume of cirrhosis, so reducing baroreceptor-induced activation of the renin-aldosterone axis and probably of the other vasoconstriction and sodium-retaining factors. Albumin prevented circulatory dysfunction in patients submitted to large-volume paracentesis[19-21], and circulatory dysfunction was found to be related to a shorter survival[22]. It also proved valuable in the treatment of diuretic-induced hepatic encephalopathy[25] and hyponatremia[26], improved survival in patients with spontaneous bacterial peritonitis and was effective in reversing the hepatorenal syndrome when administered together with vasoconstrictors[8-10,18]. It is tempting to speculate that the favorable effect of human albumin on survival observed in this study could be related to its ability to improve the circulatory dysfunction of liver cirrhosis and ascites, so reducing the degree of activation of the main vasoactive systems and antinatriuretic factors that characterize this particular group of patients and are associated with a poor prognosis[8,27].

The use of albumin has been criticized due to its high costs. In Italy, one vial of albumin (10 g) costs € 43.5; so, expenses for albumin were € 4 524 per patient in the first year and € 2 262 thereafter. However, these charges are comparable or even lower than those of other treatments showed to improve survival, such as antiviral treatment of HBV-HCV-related hepatitis, or immunoprophylaxis of HBV reinfection of liver grafts. The advent of recombinant human serum albumin[28] will probably overcome these economic considerations.

Whether albumin should be administered to all patients with cirrhosis and ascites is a problem related to the overall allocation of available resources. In view of the net gain of 16 mo of adjusted survival time demonstrated in the present investigation, in our opinion albumin can be especially useful in patients on waiting list for liver transplantation.

In conclusion, long-term albumin administration to patients with cirrhosis after the first ascitic episode significantly improves patient survival and decreases the

risk of ascites recurrence.

Abstract

AIM: To establish a more sensitive method for detection of free cancer cells in peritoneal washes from gastric cancer patients during surgery and to evaluate its clinical significance.

METHODS: The carcinoembryonic antigen (CEA) mRNA levels in peritoneal washes from 65 cases of gastric cancer were detected by real-time RT-PCR. Peritoneal lavage cytology (PLC) was applied simultaneously to detection of free cancer cells. Negative controls included peritoneal washes from 5 cases of benign gastric disease and blood samples from 5 adult healthy volunteers.

RESULTS: There was no CEA mRNA in peritoneal washes from benign gastric disease patients and in blood of adult healthy volunteers. The positive percentage of free cancer cells detected by real-time RT-PCR was 47.7% and only 12.3% by PLC. The positive rate of CEA mRNA was significantly related with serosa invasion between peritoneal metastasis and stage of gastric cancer.

CONCLUSION: Real-time RT-PCR is a sensitive and rapid method for the detection of free cancer cells in peritoneal washes. The presence of free cancer cells in peritoneal washes is related to the pathologic stage of gastric cancer.

Key words: Real-time RT-PCR; Peritoneal washes; Gastric cancer; Carcinoembryonic antigen

INTRODUCTION

Gastric cancer is one of the most common causes of cancer death in China. The postoperative survival rate of patients with advanced gastric cancer remains very low[1-3]. About 50-60% of gastric cancer patients with serosal invasion after curative resection eventually develop peritoneal metastases[4, 5]. Free cancer cells in the abdominal cavity can predict the prognosis of gastric cancer patients[6-8]. Peritoneal lavage cytology (PLC) has been used to examine cancer cells in peritoneal washes for more than a decade. But it lacks sensitivity and is time consuming[9, 10]. Since CEA is a specific marker of gastric cancer cells, detecting CEA mRNA in peritoneal washings from gastric cancer patients may determine the treatment strategy[11]. To date, many methods to detect CEA mRNA of cancer cells are available, but their sensitivity remains to be improved[11-13]. Recently real-time reverse transcription polymerase chain reaction (RT-PCR) has been used to detect CEA mRNA of free cancer cells in peritoneal washes from gastric cancer patients and micro peritoneal metastasis in these patients[14-17]. In the present study, we used real-time RT-PCR to detect CEA mRNA in peritoneal washes during gastrectomy with its clinical significance evaluated.

MATERIALS AND METHODS

Patients and collection of samples

Sixty-five patients with gastric cancer (aged 35-76 years, mean age 60.6 ± 11.5 years, 50 men and 15 women) undergone curative surgery in our hospital were enrolled

[1] It is considered as positive If CEA mRNA is detected.

in the present study. No patients received preoperative radiation therapy or pre-chemotherapy prior to their enrollment. Five patients with benign gastric disease undergone gastrectomy and 5 blood samples from health volunteers were included as negative controls. During the operation, peritoneal metastasis was found in 6 patients. At the beginning of operation, 50 mL of saline was poured into the Douglas cavity and aspirated after gentle stirring. After centrifugation, a certain amount of washes was cytopathologically examined. The total RNA was extracted from the rest washes or from blood cells using phenol-chloroform kit according to the manufacturer's instructions(Fermentas Company, Hanover, USA). All experiments were approved by the local ethic committee.

Real-time RT PCR

CEA specific primers and probes were synthesized by the Shengyou Company (Shanghai, China). The donor probe was labeled with fluorescence at the 3' end, while the acceptor probe was labeled with LC Red 640 at 5' end (Table I). The standard CEA mRNA sample was taken from a liver metastasis in a colon cancer patient. All procedures were carried out according to the manufacturer's protocol. In brief, real-time RT-PCR of CEA mRNA was performed in two steps. For reverse transcription, it was carried out in a 40-μL reaction mixture containing 1 μg oligo(dT)18, 2 μg total RNA, 4 μL 10 mmol/L dNTP and 400 units RevertAid M-MuLV reverse transcriptase. For real-time PCR amplification, it was carried out in a 20 μL reaction mixture containing 2 μL cDNA, 22.5 pmol of both forward and reverse primers, 5 pmol probes, 2 μL 10 mmol/L dNTP and 1 unit Tag DNA polymerase. Thermal cycling conditions included at 95 °C for 1 min to activate Taq polymerase. After that, 45 cycles of PCR amplification were performed at 95 °C for 5 s, at 60 °C for 10 s and at 72 °C for 10 s. Samples were amplified in duplicate. All PCRs were performed on LightCycler (Roche Diagnostics).

Table 3 Comparison of CEA mRNA in gastric cancer patients with or without peritoneal metastasis (mean ± SD)

Peritoneal metastasis	CEA mRNA	*P*-value
Yes	16006.2±18242.	$P<0.001$
No	40.5±158.9	

Statistical analysis

The statistical significance of differences in clinical pathological factors and positive rates of CEA mRNA was analyzed with the chi-square test. Comparisons of CEA mRNA values between groups with or without peritoneal metastasis were analyzed by the Mann-Whitney test. $P<0.05$ was considered statistically significant.

RESULTS

Positive CEA mRNA was found in 31 (47.7%) out of the 65 patients by real-time RT-PCR, whereas free cancer cells were found only in 8 patients (12.3%) by cytological method. CEA mRNA in peritoneal washes was significantly correlated to the depth of tumor invasion, peritoneal metastasis and different pathologic classifications (Tables 2 and 3).

DISCUSSION

TNM classification[18, 19] or modified TNM classification[20, 21] has been used to evaluate the prognosis of patients with gastric carcinomas for many years. However, it cannot cover all clinical situations in these patients[21]. The prognosis of gastric cancer is poor mainly due to intraperitoneal relapse. Free cancer cells (FCC) may exfoliate from cancer-invaded serosa contributing to peritoneal dissemination, which is the most frequent pattern of recurrence in patients with gastric cancers[5]. The presence of FCC in the peritoneal cavity is significantly correlated with classical prognostic factors (TNM classification)[22]. Since 1998, Japanese Gastric Cancer Association (JGCA) has suggested that the presence of free cancer cells in the peritoneal cavity should be considered as an independent prognostic marker in patients with gastric cancers[23]. Detecting micro peritoneal metastasis in gastric cancer patients during gastrectomy may determine the prognosis of gastric cancer patients. Many methods can detect free cancer cells in peritoneal washes. Peritoneal lavage cytology (PLC) is an

established routine method for detecting free cancer cells in the peritoneal washes, but the positive rate of PLC for FCC is only 11%[24]. In our study, the positive rate of PLC for FCC was 12.3% (Table 2). More sensitive and specific methods are necessary for the improvement of detecting FCC in peritoneal washes. With the development of PCR technology[25], real-time RT-PCR can detect specific markers of free cancer cells in peritoneal washes. CEA mRNA is one of the most common specific markers of FCC, although Goeminne *et al*[26]reported that mesothelial cells and infiltrating leukocytes also express CEA. This cross-reaction could be avoided by combining different markers. Real-time RT-PCR allows rapid amplification and accurate quantification of CEA mRNA and online data analysis without a post-PCR procedure, making it an applicable method for routine diagnosis[27]. In the present study, no CEA mRNA expression was detected in the control samples collected from patients with benign gastric diseases or from volunteer's blood. Moreover, the positive rate of CEA mRNA was related with membrane invasion, peritoneal metastasis, and stage of gastric cancer, suggesting that free cancer cells in peritoneal washes are closely related to tumor stages. The mean value of CEA mRNA was much higher in patients with peritoneal metastasis than in those without peritoneal metastasis (Table 3), suggesting that CEA mRNA can be used in the evaluation of peritoneal metastasis. Marutsuka *et al*[28] reported that RT-PCR can be used in routine assays. With improvement of skill the sample handling could be shortened and becomes more practicable.

In conclusion, real-time PCR is a sensitive and rapid method for the detection of free cancer cells in peritoneal washes.

ACKNOWLEDGEMENTS

The authors thank Qing-Feng Mu for providing excellent technical assistance.

Abstract

AIM: To examine the paclitaxel concentrations in plasma and ascites after its intravenous administration in patients with ascites due to peritonitis carcinomatosa resulting from advanced gastric cancer.

METHODS: Two patients with ascites due to peritonitis carcinomatosa resulting from gastric cancer were included in this study. The paclitaxel concentrations in plasma and ascites were investigated for 72 h in case 1 and 168 h in case 2 after intravenous administration.

RESULTS: The paclitaxel concentration in plasma peaked immediately after administration, followed by rapid decrease below the threshold value of 0.1 μmol (85 ng/mL) within 24 h. In contrast, the paclitaxel concentration in ascites increased gradually for 24 h after administration to a level consistent with the level found in plasma. After 24 h the level of paclitaxel in ascites and plasma became similar, with the optimal level being maintained up to 72 h following administration.

CONCLUSION: The concentration of paclitaxel in ascites is maintained within the optimal level for the treatment of cancer cells for up to 72 h after intravenous administration. Paclitaxel is a promising drug for the treatment of malignant ascites of gastric cancer.

Key words: Paclitaxel; Chemotherapy; Gastric cancer; Peritoneal carcinomatosis; Pharmacokinetic study; Ascites

INTRODUCTION

Paclitaxel (PTX) is a potent inhibitor of cell replication and was originally isolated from the bark of the tree *Taxus brevifolia*. The anti-mitotic activity of PTX results from its effectively blocking the late G_2 and M phases of the cell cycle. PTX has significant antitumor activity in several human tumors, such as advanced ovarian, lung, and breast cancers[1]. Chang *et al*[2] demonstrated that PTX inhibited the proliferation of gastric carcinoma cell lines at clinically attainable concentrations. Several reports have shown that PTX in combination chemotherapy with 5-fluorouracil and cisplatin is effective in the treatment of advanced gastric cancer[3-8].

We have recently completed two phase I clinical studies of combination chemotherapy involving weekly administration of PXT with either 5-fluorouracil or cisplatin. The recommended dose of PTX was 80 mg/m^2 in both regimens. Some cases with peritoneal carcinomatosis showed a marked decrease in malignant ascites following combination chemotherapy. In the present study, we investigated changes in PTX concentration in plasma and ascites over time to determine the effectiveness of weekly administration of PTX in treating malignant ascites.

MATERIALS AND METHODS

We investigated 2 cases with gastric carcinoma and malignant ascites. Case 1 was recruited in our phase I study of combination chemotherapy involving 5-fluorouracil and weekly administration of 80 mg/m^2 PTX. Case 1 received 60 mg/m^2 of PTX intravenously. Case 2 was involved in our phase II study of combination chemotherapy involving cisplatin and weekly administration of 80 mg/m^2 PTX intravenously. The PTX concentrations in plasma and ascites were measured for both the cases.

PTX was administrated by drip infusion for 1.5 h

Table 1 Changes of paclitaxel concentrations over time in plasma and ascites (ng/mL).

	0	4	8	12	24	36	48	60	72	84 (h)
Case 1 (60 mg/m^2)										
Plasma	1240	-	112	-	55	40	26	20	-	
Ascites	19	30	50	54	62	40	25	20	20	
Case 2 (80 mg/m^2)										
Plasma	468	-	203	-	55	31	27	15	14	
Ascites	11	17	27	30	27	23	19	17	12	ND

ND: Paclitaxel in ascites was not detected after 84 h through to 168 h.

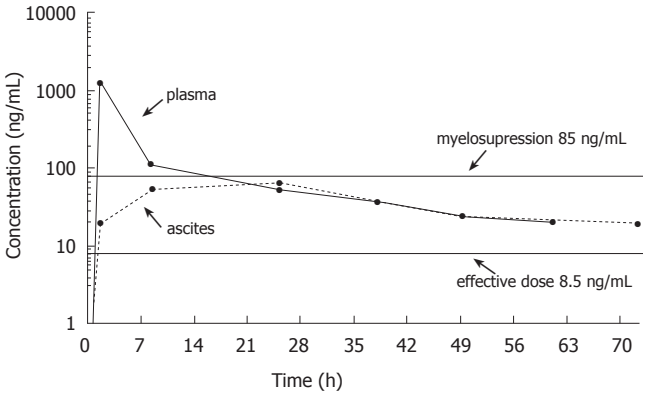

Figure 1 Concentrations of PTX in plasma and ascites in case 1 administrated with 60 mg/m2 PTX intravenously for 1.5 h.

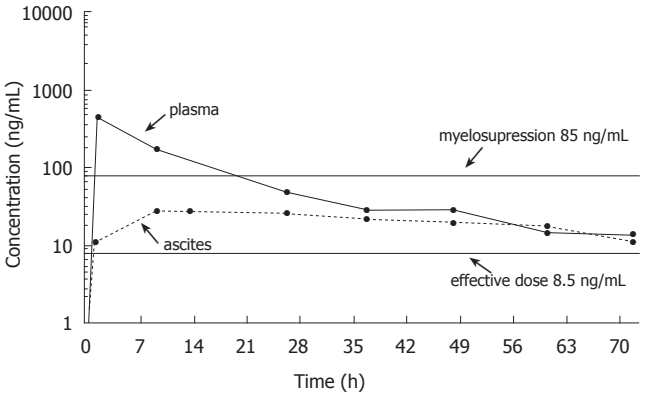

Figure 2 Concentrations of PTX in plasma and ascites in case 2 administrated with 80 mg/m2 PTX intravenously for 1.5 h.

following standard prophylaxis for taxol-associated hypersensitivity reactions with dexamethasone (20 mg iv), diphenhydramine (25 mg *po*), and ranitidine (50 mg iv). After taking informed consent from the patients, samples from blood and ascites were taken prior to PTX administration, immediately after PXT administration, then 4, 8, 12, 24, 36, 48, 60, and 72 h after PXT administration in case 1, and after a further 84, 96, 108, 120, 132, 144, 156, and 168 h in case 2. Ascitic fluid was not drained for the duration of the study and the volume taken for measurement of PTX concentration was limited to 5 mL. Ascites and blood samples were collected in heparinized tubes, centrifuged, and the supernatant was stored at -20℃ until assay. The PTX concentrations in plasma and ascites were analyzed by high-performance liquid chromatography as previously described[9].

RESULTS

The PTX concentrations in plasma and ascites are shown in Table 1. The concentration of PXT in plasma peaked immediately after administration, followed by rapid decrease below the threshold value of 0.1 μmol (85 ng/mL) within 24 h. On contrary, the concentration of PTX in ascites increased gradually to the peak level, as found in plasma, within 24 h of administration. From 24 h, the concentration of PXT in plasma and ascites became almost the same and remained above 0.01 μmol (8.5 ng/mL) up to 72 h after administration. The PTX concentration in ascites after 84 h was below 0.01 μmol in case 2. Figures 1 and 2 show the disappearance curve of PTX in the plasma and ascites in cases 1 and 2, respectively.

Both cases showed marked decrease of ascites after chemotherapy. The CT scan showed that the amount of ascites was markedly decreased after 2 courses of combination chemotherapy of 5-fluorouracil and PTX (Figure 3).

DISCUSSION

Gastric cancer is one of the most common cancers in Japan. Although advances in early diagnosis and surgical technique have improved the outcome of treatment for gastric cancer, optimal chemotherapy regimes have not been determined for advanced or recurrent gastric cancer. The most serious recurrence of gastric cancer is peritoneal carcinomatosis and is usually regarded as the terminal stage of advanced gastric cancer. At present, there are no effective therapeutic regimes for control of malignant ascites due to peritoneal carcinomatosis, which is essential for quality of life. Several reports have demonstrated that intraperitoneal infusion of anti-cancer agents is effective only to a limited shallow area beneath the peritoneum[10,11]. Inadequate exposure of the peritoneum to anti-cancer drugs presents a limitation to their effectiveness. Intraperitoneal administration of PTX has been used to treat ovarian cancer[12-14], but there is limited information on the levels of PTX in ascites following intravenous administration. O'Boyle *et al*[15] investigated the level of PTX in sera and in cerebrospinal, ascitic and pleural

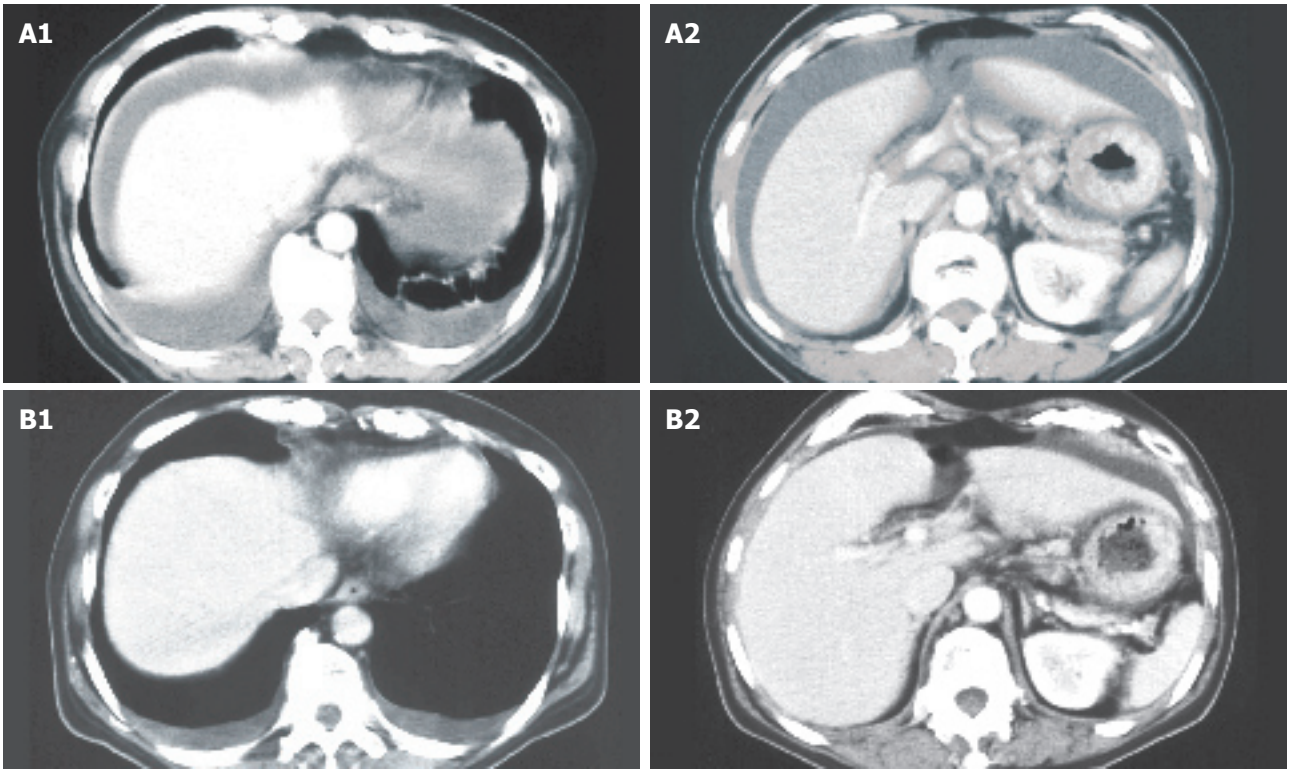

Figure 3 CT scanning of case 1 showing markedly decreased amount of ascites after 2 courses of the combined chemotherapy of 5-fluorouracil and PTX. **A1, A2:** before chemotherapy; **B1, B2:** after chemotherapy.

fluids by immunoradiometric assay and conventional radioimmunoassay and showed the maintenance of high levels of PTX in ascitic fluid in a patient with ovarian carcinoma treated with 135 mg/m^2 PTX.

Several reports have demonstrated that systemic administration of PTX is effective in the control of malignant ascites in gastric cancer patients[16,17]. In the present study, we showed a marked decrease in ascitic fluid volume after combination chemotherapy involving PTX and 5-fluorouracil (case 1), and PTX and cisplatin (case 2).

Chang *et al*[2] demonstrated that exposure of cells to 0.01 μmol/L of PTX for 24 h was cytotoxic. In another study, Gianni *et al*[18] revealed that exposure of plasma to PTX concentrations over 0.05 μmol/L led to myelosuppression and that a concentration of 0.1 μmol/L was clinically relevant. The clinical relevant threshold of 0.1 μmol/l is consistent with findings from other investigators[19-21]. Taken together, the above findings suggest that the clinically effective range for PXT is 0.01 to 0.1 μmol and this range was applied to the present study.

The pharmacokinetic data of the present study revealed that PTX remains within the effective dose range in malignant ascites for at least 72 h following systemic administration. The peak plasma level of PTX varies according to case and peaks immediately after administration. These results are consistent with our previous investigation of 36 cases recruited in two Phase 1 studies (submitted for publication). The observed variation in peak PXT levels according to case may be the result of slight time differences between administration and blood sampling during the period of rapid increase in PTX levels following administration.

PTX has a bulky molecular structure, high molecular weight, and an affinity for binding proteins found at high levels in the peritoneal cavity, especially in malignant effusions. For these reasons, the intraperitoneal clearance of PTX is extraordinarily low, probably the lowest of any known anti-neoplastic agent. As a result of the low clearance rate of PXT from the peritoneal cavity, biologically relevant concentrations can be sustained for long periods allowing maximal exposure to cancer cells. It is well established that the cytotoxic activity of PTX is related to duration of exposure[22-25]. In conclusion, the inherent properties of PXT allowing its sustained exposure to cancer cells in ascites make this drug an effective candidate in the control of malignant ascites. As administration of PXT is systemic, PXT may also be effective for the control of cancer cells in other regions of the body.

Abstract

AIM: To clarify whether mucosal crypt patterns observed with magnifying colonoscopy are feasible to distinguish non-neoplastic polyps from neoplastic polyps.

METHODS: From June 1999 through March 2000, 180 consecutive patients with 210 lesions diagnosed with a magnifying colonoscope (CF-200Z, Olympus Optical Co., Ltd., Tokyo, Japan) were enrolled. Magnification and chromoendoscopy with 0.2% indigo-carmine dye was applied to each lesion for mucosal crypt observation. Lesions showing types I and II crypt patterns were considered non-neoplastic and examined histologically by biopsy, whereas lesions showing types III to V crypt patterns were removed endoscopically or surgically. The correlation of endoscopic diagnosis and histologic diagnosis was then investigated.

RESULTS: At endoscopy, 24 lesions showed a type I or II pit pattern, and 186 lesions showed type III to V pit patterns. With histologic examination, 26 lesions were diagnosed as non-neoplastic polyps, and 184 lesions were diagnosed as neoplastic polyps. The overall diagnostic accuracy was 99.1% (208/210). The sensitivity and specificity were 92.3% (24/26) and 99.8% (184/186), respectively.

CONCLUSION: Magnifying colonoscopy could be used as a non-biopsy technique for differentiating neoplastic and non-neoplastic polyps.

Key words: Non-biopsy technique; Magnifying colonoscopy; Indigo-carmine dye spraying; Pit Pattern

INTRODUCTION

At colonoscopy, the most frequently encountered lesions are polyps, which are either non-neoplastic (hyperplastic, inflammatory, and hamartomatous) or neoplastic (adenoma and carcinoma). Most polyps detected during colonoscopy are hyperplastic or adenomatous. The adenoma-carcinoma sequence suggests that colorectal cancers develop from benign adenomas, and, thus, removal of adenomas but not hyperplastic polyps, could prevent colorectal cancers[1, 2]. Therefore, it is important to distinguish hyperplastic polyps from adenomatous polyps at colonoscopy, as removal or biopsy of hyperplastic polyps wastes time and resources and might increase the incidence of complications, such as bleeding and perforation. We routinely use magnifying colonoscopes, which offer both standard and magnifying views[3]. A magnifying view after chromoendoscopy enables us to observe the lesions' surface structures, the so-called pit patterns, which are reported to be closely related to the histology[4-6]. To investigate whether magnification with chromoendoscopy using indigo-carmine can be used to reliably differentiate non-neoplastic lesions from neoplastic lesions before histological evaluation, we conducted this prospective study.

MATERIALS AND METHODS

From June 1999 through March 2000, all of the patients with lesions detected on colonoscopy without the following exclusion criteria were enrolled in this study, at the National Cancer Center Hospital East. The study protocol was approved by the institutional review board of our hospital. Informed consent was obtained from all patients before examination. Patients with colorectal

Total	26	184	210	

lesions that had been previously evaluated by histologic examination or colonoscopy were excluded from this study. Patients, without informed consents, with inflammatory bowel disease, hereditary nonpolyposis colorectal cancer and familial adenomatous polyposis were also excluded.

A dose of two liters of preparatory solution of electrolytes and polyethylene glycol was administered orally to each patient for preparation before colonoscopy. If there was no contraindication to its use, an anticholinergic agent (buscopan 20 mg) was administered intramuscularly before each examination to prevent persistent colonic spasms. All colonoscopies were carried out using commercially available videocolonoscopes (CF-200Z; Olympus Optical Co., Ltd., Tokyo, Japan) that provide both conventional and magnifying images. All lesions detected at colonoscopy were diagnosed with magnification and chromoendoscopy using 0.2% indigo-carmine dye. The size of a lesion was estimated using open biopsy forceps or a method of removal (i.e., hot biopsy or snare polypectomy). The classification of mucosal crypt patterns was based on Kudo's classification (types I to V). The type I crypt pattern consists of regular round crypts, type II consists of stellar or papillary crypts, type III consists of tubular crypts or roundish crypts smaller than normal crypts, type IV consists of sulcus, branch, or gyrus-like crypts, and type V consists of irregular or severely distorted crypts[4-6]. On the basis of mucosal crypt patterns observed with magnification and chromoendoscopy, detected lesions were divided into a non-neoplastic group (types I and II mucosal crypt patterns) or a neoplastic group (types III to V mucosal crypt patterns). All diagnostic and treatment procedures were performed by a colonoscopist (SK) well trained in magnifying colonoscopy.

For histological evaluation, the lesions diagnosed as non-neoplastic were examined at biopsy and lesions diagnosed as neoplastic were removed endoscopically or surgically without exception. Histological diagnosis was made by a pathologist blinded to the colonoscopic diagnosis. The pathological definition of the lesions was established by the Japanese Research Society for Cancer of the Colon and Rectum[7]. Histologically, adenoma and carcinoma were defined as neoplastic lesions and other non-neoplastic lesions including hyperplastic polyps, were defined as non-neoplastic lesions. The correlation of magnifying colonoscopic diagnosis and final pathological findings was evaluated to calculate the accuracy rate of endoscopic diagnosis.

Chi-square analysis was performed for comparisons. Differences with a p-value less than 0.05 were considered significant. All analyses were performed using Stat View software (Version 5.0 for Windows, SAS Institute Inc., Cary, NC)

RESULTS

The characteristics of the patients and colorectal lesions are shown in Table 1. The 180 patients included 124 males and 56 females, with a mean age of 63.0 years (range, 37 to 76 years). The mean sizes of non-neoplastic lesions and neoplastic lesions were 7.8 mm and 9.2 mm, respectively. Although, neoplastic lesions seemed to be larger than non-neoplastic lesions, they did not differ significantly in size. Two hundred ten colorectal lesions, including 24 non-neoplastic lesions (hyperplastic polyp, 20; others, 4) and 186 neoplastic lesions were detected and evaluated at histologic examination without exception. Ninety-one lesions were located in the proximal colon, and 119 lesions were located in the distal colon. Total colonoscopy and histological evaluation were performed without complications in all cases.

At colonoscopy, 24 lesions showed a type I or II pit pattern, whereas 186 lesions showed types III to V pit patterns. At histologic examination, 26 lesions were diagnosed as non-neoplastic polyps, and 184 lesions were diagnosed as neoplastic polyps. The overall diagnostic accuracy was 99.1% (208/210). The diagnostic accuracy for non-neoplastic pit patterns (negative predictive value) was 100% (24/24). The accuracy of neoplastic pit patterns (positive predictive value) was 99.8% (184/186) (Table 2). The sensitivity and specificity of this endoscopic diagnosis

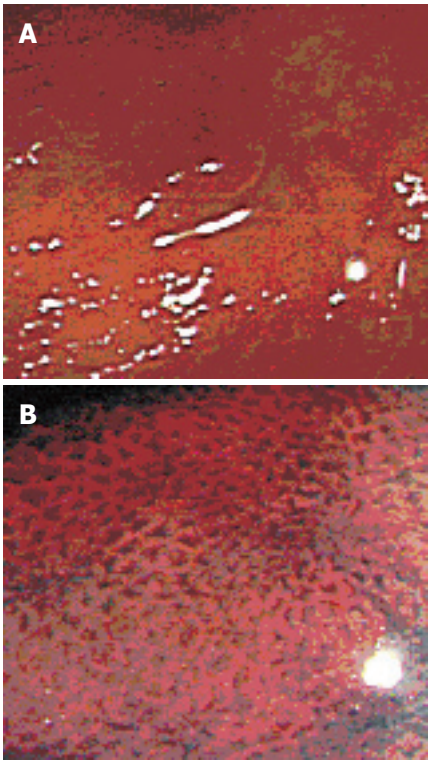

Figure 1 A: Colonoscopy revealed a small reddish polypoid lesion 3 mm in diameter. **B:** Chromoendoscopy with magnification disclosed a type II pit, and the lesion was diagnosed as non-neoplastic and examined at biopsy. The histologic diagnosis was hyperplastic polyp.

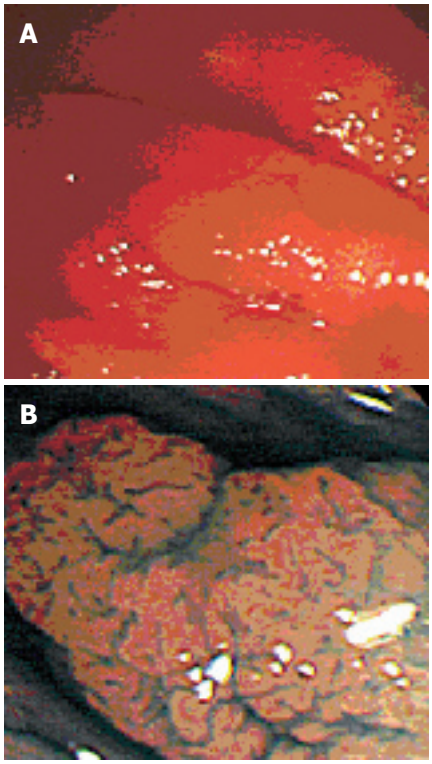

Figure 2 A: Colonoscopy revealed a small flat lesion 5 mm in diameter. **B:** Chromoendoscopy with magnification disclosed a type IIIL pit, and the lesion was diagnosed as neoplastic and resected by snare polypectomy. The histologic diagnosis was adenoma with moderate atypia.

are 92.3% (24/26) and 99.8% (184/186), respectively. (Figures 1 and 2).

DISCUSSION

Previous studies in patients undergoing colonoscopy for various reasons were found that small polyps are identified at more than 50% of examinations[8]. More than 50% of these small polyps are adenomas[8-12]. Therefore, a key clinical decision in patients with small polyps may depend on the determination of histology. According to the American Society for Gastrointestinal Endoscopy guidelines issued in 2005, during colonoscopy every effort should be made to obtain a tissue diagnosis when encountering polyps, mass, lesions, or colonic strictures[13]. However, if lesions could be accurately determined to be non-neoplastic or neoplastic at colonoscopy, biopsies or resections would be unnecessary. Various data on the diagnostic abilities of such differentiation by conventional colonoscopy, chromoendoscopy, and magnifying colonoscopy have been reported and are summarized in Table 3[14-24].

Among the methods described above, magnifying colonoscopy with chromoendoscopy seems to provide higher diagnostic accuracy than that by conventional colonoscopy or chromoendoscopy. The efficacy of magnifying colonoscopy is often determined in conjunction with intravital staining techniques, of which indigo-carmine staining is generally preferred. Surface analysis of colorectal lesions by magnifying colonoscopy

in addition to chromoendoscopy has been established by Kudo *et al*[4-6] . They compared the mucosal crypt patterns on stereomicroscopy and colonoscopy with histological sections taken on the horizontal axis and found strong correlations with the histologic features of the lesions. The mucosal crypt patterns were divided into six groups: types I, II, IIIL, IIIs, IV, and V[4-6]. Furthermore, with regard to treatment decision, we re-categorized these patterns into 3 groups as non-neoplastic (types I and II), no treatment or biopsy, non-invasive (types IIIL, IIIs, IV), endoscopic removal; and invasive (type V), surgical resection[25]. The present study was conducted prospectively to show the usefulness of pit patterns for distinguishing non-neoplastic lesions from neoplastic lesions with magnifying colonoscopy.

Our data indicate that magnifying colonoscopy with chromoendoscopy can be used to differentiate almost all lesions detected at colonoscopy before histological evaluation. This method requires a magnifying colonoscope and 0.2% indigo-carmine dye to render the pits clearly visible, but this technique may be slightly troublesome.[26] However, the poor diagnostic reliability of conventional colonoscopy would lead to a significant number of biopsies or resections of non-neoplastic polyps, which would also waste time and resources on unnecessary histopathological examinations. Matsuda *et al* have described the cost-effectiveness of conventional colonoscopy and magnifying colonoscopy[27]. They reported that the percentage of hyperplastic polyps resected after conventional colonoscopy was significantly higher than that after magnifying colonoscopy (8.6% vs 2.9%) and also concluded that routine use of magnifying colonoscopy would reduce unnecessary resections.

Undoubtedly, colonoscopists require training and experience to correctly judge lesions with magnifying colonoscopy. However, there has been little systematic investigation of this issue. Kobayashi *et al*, have investigated the case with which an inexperienced examiner could learn pit pattern diagnosis[28]. According to their results, five nurses, without any prior knowledge of mucosal crypt patterns, could achieve a diagnostic accuracy of up to 85.4% in distinguishing non-neoplastic polyps from neoplastic polyps after hearing short lectures on pit pattern diagnosis. Furthermore, a foreign doctor without prior knowledge of pit patterns required 3 mo of training at our hospital to reach a differential diagnostic ability more than 90%, similar to that of well-trained endoscopists at our hospital[29]. Togashi *et al* have suggested that experience with approximately 200 lesions is needed to learn to correctly diagnose polyps with magnifying colonoscopy[19]. Endoscopic diagnosis based on a conventional view or chromoendoscopy is subjective and unreliable, as it depends on estimations of the size, shape, overlying mucus, and color of the lesions. However, pit patterns are more objective[14-15]. A further well-designed prospective study to investigate the learning curve for endoscopic diagnosis with magnifying colonoscopy compared to that with conventional colonoscopy or with chromoendoscopy is necessary to clarify this issue.

In conclusion, magnification with chromoendoscopy is a reliable tool for predicting histology, especially for differentiation of non-neoplastic and neoplastic lesions. This method could be used as a non-biopsy technique at colonoscopy to limit the need for biopsy or resection, and thus reduce complications, time, and resources required. If possible, an international collaborative prospective study including colonoscopists of eastern and western countries would be desirable for further confirmation of its efficacy.

Abstract

AIM: In colorectal surgery, anastomotic failure is still a problem in ischemia. Here, we analyzed the effects of hyperbaric oxygen and beta-glucan on colon anastomoses in ischemic condition.

METHODS: Colonic resection and anastomosis in rectosigmoid region were done in forty Wistar-Albino rats of four groups of equal number. Colon mesentery was ligated to induce ischemia. The first group was the control group. The subjects of second group were treated with hyperbaric oxygen; the third group with glucan and the forth group were treated with both. At the forth day, rats were sacrificed, anastomotic segment was resected and burst pressures and hydroxyproline levels of anastomotic line were measured.

RESULTS: The burst pressure difference of second and third groups from the control group were meaningful ($P < 0.01$); the forth group differed significantly from the control ($P < 0.001$). There was no difference between the treated groups on burst pressure level ($P > 0.05$). The hydroxyproline levels in all treated groups were different from the control group significantly ($P < 0.001$). Hydroxyproline levels in the forth group were higher than those of the second and the third groups ($P < 0.001$). There were no significant differences between the second and the fourth groups in burst pressure and hydroxyproline levels ($P > 0.05$).

CONCLUSION: Hyperbaric oxygen and glucan improve healing in ischemic colon anastomoses by anti-microbic, immune stimulating properties and seem to act synergistically when combined together.

Key words: Anastomosis; Ischemic colon; Hyperbaric oxygen; PGG-Glucan

INTRODUCTION

Insufficient anastomosis healing and resulting anastomotic leakage is still a big problem in colorectal surgery[1,2]. Colon is very riskful to leak due to its rich bacterial flora and insufficient collateral circulation[3].

There are systemic and local factors affecting wound healing. Ischemia and local infection are the two most important factors that interrupt healing[4–7]. Hyperbaric oxygen (HBO) and β-1, 3-glucan are two new subjects of search to overcome these problems.

HBO therapy means the inhalation of 100% oxygen in a high pressure-environment. It is adjuvant to surgery. It causes an increase in plasma oxygen level by 20-25%, thus increasing tissue oxygenation. Its current use is in the treatment of air emboli, carbon monoxide intoxication and as an adjuvant to surgery in some diseases[8].

Its effects include an increase in tissue perfusion by both increasing oxygen level in blood and redistributing oxygen from normal tissues to the ischemic ones via vasoconstriction. It also increases angiogenesis and improves inflammatory cell functions, which are necessary for healing[8-10]. β-1, 3-Glucan is a glucose polymer obtained from cereals, yeasts, and fungi. It was found to have some immune-modulatory effects. It stimulates complement system and macrophages[11]. It has anti-bacterial, anti-tumoral, anti-fungal, and wound-healing properties.

In this study, we analyzed the effects of HBO and β-1, 3-glucan on ischemic colon-anastomosis model.

MATERIALS AND METHODS

[b]$P<0.01$ significant compared to the control group. [d]$P<0.001$ very significant compared to the control group.

This experimental study was held in Cerrahpasa Medical Faculty. Forty Wistar-albino female rats of 180-220 g were used. They were divided into four groups of equal number. All rats were kept in constant environmental conditions. Without making colonic preparation, all subjects were anesthetized with intramuscular ketamine (Ketala® 50 mg/kg) and ether inhalation. Weight of the rats were measured and recorded. Operations were done in a randomized fashion. Abdominal wall was shaved and Povidone–Iodine solution of 10% was used for cleaning. Median laparotomy was performed. Ischemia was formed in a 4 cm-colonic segment, 3 cm proximal to peritoneal reflection, by ligating marginal arteries and vasa recti with 4/0 silk. The ischemic segment was resected at mid-point and reanastomosed end to end with 6/0 polypropylene suture. Abdominal fascia and skin were closed. Oral feeding was started at the 24th h postoperatively. First group was the control group and no further treatment was given following anastomosis. The subjects of the second group were started HBO at the 3rd h after surgery. The rats in the third group were given 20 mg soluble β-1, 3-glucan intraperitoneally following anastomosis. The fourth group was treated with HBO and β-1, 3-Glucan together. All rats were killed on the 4th postoperative day under ether anesthesia. Healing of anastomosis was evaluated by measuring burst pressure and hydroxyproline level.

HBO treatment was started at the 3rd h of operation and continued for 4 d. Before HBO treatment, pressure cabin was washed out with 1 ATA oxygen for 10 min. HBO was given as oxygen of 100% at 2.5 ATA for 60 min. Total treatment time was 80 min, including pressure increase and decrease periods of 10 min for each. The number of HBO treatment was 14 in total, which were four times in a day for the first 2 d and three times in a day for the last 2 d.

At the end of the 4th post-operative day, relaparotomy was done. The colon was clamped at 2 cm distal to anastomosis and resected at 2 cm proximal to it. Burst pressure was measured by an insufflation pump that was sealed intraluminally in the proximal tip of the segment. Insufflation was at a constant value of 6 mL/min under the water and the pressure level where air bubbles were seen on anastomosis line that was accepted as burst pressure value.

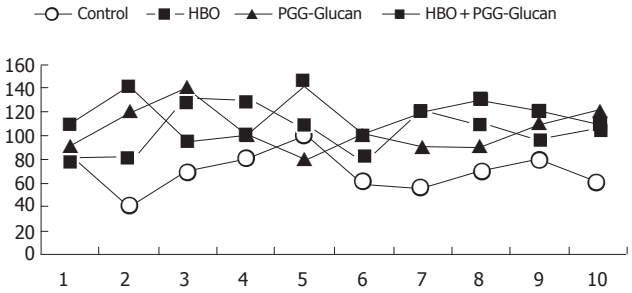

Figure 1 The burst pressure curves of rats for each group (mmHg).

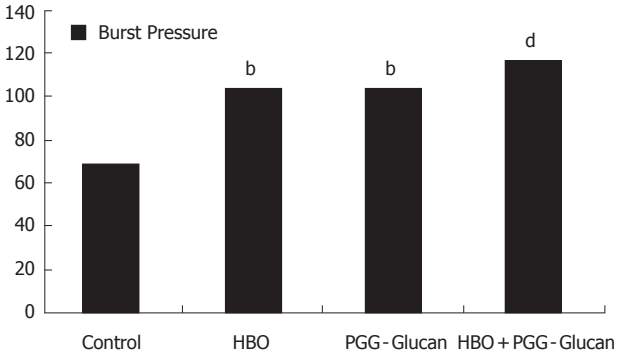

Figure 2 Burst pressure compartment between groups (mm/Hg). [b]$p<0.01$ significant compared to the control group. [d]$p<0.001$ very significant compared to the control group.

The colonic segment 0.5 cm proximal and 0.5 cm distal of anastomosis line was resected, weighed and homogenized in serum physiologic solution to 20% (20% g/mL) homogenisates by using a Potter type glass homogenisator (Heidolphy - RZR 2021, Germany). Homogenisates were centrifuged at 1 500 r/min for 15 min and obtained supernatants were hydrolyzed by adding hydrochloric acid of equal amounts for 16-18 h. Using the hydroxyproline kit (Hipronisticon, Organon, Holland) working on the principles of Stegeman and Stadler, hydroxyprolene amount was calculated in microgram per milligram of wet tissue by reading the absorbance of solution on spectrometry at 560 nm.

statistical analysis

The values were expressed as mean±SD. Differences between groups were evaluated with ANOVA method by using SSPS 10.0 program. Differences within the same group were evaluated with instat test. The values with $P<0.05$ were statistically significant.

RESULTS

There were no deaths during anesthesia or surgical procedure. In all subjects, the burst of the colon was on the anastomotic line. Burst pressure values and standard deviations of groups are shown in Table 1 and Figure 1.

On the comparison of the burst pressure values of the second, third and fourth group to those of control group, results of second and third group showed a significant difference ($P<0.01$); results of fourth group showed a

DISCUSSION

Though there is advancement in techniques, complications in colorectal anastomosis is still a big problem with high mortality and morbidity, especially in ischemic circumstances[12]. Leakage of anastomosis has been reported to be 0-30%. In a series of 1 446 patients, the leakage rate was reported as 13%[2]. Radiological studies revealed that the leakage rate might be up to 51%[13].

There are local factors like infection, perfusion, suture materials, surgical techniques and systemic factors like systemic diseases, septicemia, malnutrition that affect healing[14]. Insufficient oxygenation is one of the most important factor.

Hypoxia interrupts wound healing. If oxygenation of tissue is disrupted due to local damage and anaerobic infection present, HBO therapy may be useful[15]. In experimental studies it was found that oxygen and antibiotics had an additive effect and HBO was more effective under hypoxic conditions where antibiotics were less effective[16,17].

Oxygen is necessary for oxidative function of neutrophils, activation of leukocytes, fibroblast production, angiogenesis, and re-epithelialization, which are of great importance in wound healing[18-21]. Hypoxia also disrupts collagen synthesis and decreases stretching force of the healing wound[22].

Tissue oxygenation is provided by blood volume, tissue perfusion and intra-arterial oxygen saturation[22,23]. HBO increases intra-arterial oxygen saturation thus partial oxygen pressure in tissue, which accelerate wound healing[5,21,24]. HBO was reported to be useful in the treatment of different kinds of problematic wounds; it improved survival of skin grafts, decreased mortality and morbidity in clostridial myonecrosis, accelerated healing of burns, increased re-epithelialization of both normal and ischemic tissues, decreased size of wound and wound complications of diabetes mellitus[25,26].

In a study on the patients who underwent colorectal surgery, a direct relationship between subcutaneous partial oxygen pressure and postoperative wound infection was detected. In this study, although increasing the concentration of oxygen in inhalational air, subcutaneous oxygen concentration did not increase and, 45% of patients were infected postoperatively. On the contrary, when tissue was perfused with a partial oxygen pressure higher than 90 mmHg, there was no infection in any of the patients[27].

The mechanism that HBO improves healing is still uncertain. It is thought that HBO affects in the same way in both ischemic and non-ischemic wounds, because all wounds are ischemic in the first period of healing[18].

A perianastomotic oxygen pressure less than 20 mmHg was shown to result in a major leakage in 100% of subjects and increasing the pressure, rate, and quantity of leakage decreased[12]. On the contrary, Kirk and Irvin reported oxygen had no significant effect on anastomotic and dermal healing. But, these scientists used normobaric oxygen of 50%, and not hyperbaric[28].

Mechanism of HBO may be also on accelerating an-

giogenesis and re-epithelialization process, which are two main phases of wound healing[24,25]. Increase in oxygen was found to increase energy metabolism, thus ADP and ATP in wounds and to result increase in collagen synthesis[23]. In trauma patients, oxygen decreases in wounds, which interrupts healing and increases infection risk[7]. Infection of the mucosa was shown to decrease oxygenation of tissue fibroblasts, spoiling healing. Enteric flora makes colon very prone to postoperative infections.

HBO decreases postischemic edema formation by vasoconstriction in normal tissues, which disrupts wound healing[29]. Intermittent hyperoxygenation makes it more effective; hypoxic periods increases cytokines which increase healing and, cell response to them is also oxygen dependent[30]. This is called oxygen paradox. It has also antibacterial effect[17,27]. Thus, HBO has a double-effect. In our study, statistical significance of increase in burst pressure and hydroxyproline level in second group correlates to the findings that HBO increases healing of anastomosis in ischemic colon.

It has also some complications such as oxygen toxicity, air embolization, and pneumothorax. Its cost, need of frequent application and difficulty in providing medical support are its disadvantages. But, it decreases mortality and morbidity in surgical patients. Its benefits are more than disadvantages. If applied by a specialist, it can be a useful adjuvant in high-risk patients. Moreover, combination with glucan may be more effective.

Immunosuppression is a significant problem in surgical patients. Some causes such as decrease in circulating T-cell number, decrease in lymphoblast transformation, inhibition of leukocyte migration, decrease in cellular immunity and reticulo-endothelial system activity had been proposed. Immunosuppression makes wound more prone to infection, interrupts wound healing and results in failure of anastomosis[31,32].

β-1, 3-Glucans are glucose polymers in the cell walls of yeasts. They have immune-modulating, anti-bacterial, and anti-tumor effects[11,34,35].

β-Glucans activate both humoral and cellular immunity (Wooles and Di Luzio, 1962). They act in a dose-dependent way by binding the receptors on human neutrophils, monocytes, and macrophages. They activate macrophages and increase phagocytotic activity of neutrophils[36]. Macrophages are key cells in wound healing. These cells produce humoral factors, which controls fibroplasia, fibrogenesis, and angiogenesis[37,38]. They also control energy metabolism of wounds. Cytokines like IL-1 from activated macrophages are secreted. These products result in fibroblast activation and proliferation thus increase collagen production and cross-linking between collagen. Macrophages also increase angiogenesis[39]. Although studies analyzing the effects of macrophage activation on colonic anastomosis exist, there is no study that searched its effects in ischemic conditions. Glucans were shown to increase tensile strength of the wound[39].

Having some adverse effects like headache, tiredness, stomatitis, pharyngitis, glucans are nontoxic, nonimmunogenic and apyrogenic substances[40]. Glucans were reported to be safe and effective in decreasing morbidity and cost of a major surgery[41].

In our study, the burst pressure and hydroxyproline levels in glucan group were found to be significantly different from that of the control ($P<0.01$ and $P<0.001$), suggesting that glucan has an increasing effect on early collagen cross-linking, which improves healing. Our results correlate to the previous studies which showed that glucan improved healing.

On burst pressure levels, groups 2 and 3 differed from the control ($P<0.01$). Comparisons between groups 2 and 3 in each other, and between these 2 and 4 groups show no difference ($P>0.05$).

Hydroxyproline is present only in collagen (14%) and elastine (2%) in animals. Thus, it is a good marker in wound healing. In our study, hydroxyproline level of all groups differed from the control very significantly ($P<0.001$). Also, the levels in group 4 were significantly different from groups 2 and 3 ($P<0.001$). There were no differences between groups 2 and 3 ($P>0.05$).

The use of HBO and PGG-glucan together seems to act synergistically to increase wound tensile strength. We think that the reason for this synergistic effect not seen on burst pressure is due to ischemia related ileus, which affects measurements. Also, the finding burst pressures of group 4 differ very significantly from the control supports that HBO plus PGG-glucan is more effective on wound healing.

As a result, we think that this study showed benefical effects of HBO and PGG-glucan on healing of bowel anastomoses experimentally but, we need advanced clinical research in future.

Abstract

AIM: To evaluate the potential association between *p53* codon 72 polymorphism and sporadic colorectal adenocarcinoma development, and human papillomavirus (HPV) infection.

METHODS: One-hundred and nine controls and 53 patients with colon cancer from the city of La Plata, Argentina were analyzed. *p53* codon 72 genotypes and HPV infection were identified using allele-specific polymerase chain reaction and nested polymerase chain reaction, respectively.

RESULTS: The differences in the distribution of *p53* codon 72 polymorphism between the cases and controls were statistically significant. The arginine allele had a prevalence of 0.65 in controls and 0.77 in cases. The corresponding odds ratio for the homozygous arginine genotype was 2.08 (95% *CI*, 1.06-4.05; $P<0.05$). Lack of association was found between *p53* polymorphism and HPV infection in the set of adenocarcinomas.

CONCLUSION: The findings of the present study indicate that *p53* codon 72 arginine homozygous genotype may represent a genetic predisposing factor for colon cancer development. However, further studies are needed in order to elucidate the role of *p53* codon 72 polymorphism in colorectal cancer.

Key words: *p53* codon 72 polymorphism; Human papillomavirus; Colorectal cancer

INTRODUCTION

Sporadic carcinoma of the colon and rectum is a common cause of cancer deaths in the more developed countries, accounting for 44/100 000 new cases per year in males from the United States, and 33.1/100 000 in women. The incidence of colon cancer is lower in South America, ranging from 16.4/100 000 in males and 14.8/100 000 in females. By contrast, Argentina has increased rates of colon cancer compared with other South American countries, which represents the second and the third cause of cancer deaths in women and men, respectively[1].

Colorectal cancer development is a complex, gradual, multistep process, in which many factors are known to be implicated. The molecular and histological changes involved are also well described, though not well understood. Most of these cancers are adenocarcinomas (95%), showing a high frequency of *p53* mutations, mainly at advanced stages of colorectal cancer progression[2]. Regarding the etiology, epidemiological studies have associated several risk factors with colorectal cancer, including alcohol consumption, low-fiber or high-fat diet intake, hereditary conditions, familial history of colorectal cancer, personal history of colonic polyps and bowel inflammatory diseases. Subjects with the highest risk for colorectal cancer have either a hereditary condition or a bowel inflammatory disease. However, it is worth mentioning that this group comprises only 6% of the general population, while the remaining of colorectal cancer occurs in individuals with no known risk factors[3].

p53 is an important tumor suppressor gene involved in the regulation of cell growth, DNA maintenance and apoptosis. Also, experimental evidence suggests that the p53 protein is related to cell aggressiveness and tumor metastasis[4]. Recent studies have shown that a common polymorphism at codon 72 of the *p53* gene results in two alleles, the arginine (*Arg*) and proline (*Pro*) isoforms, which differ biologically and biochemically[5]. In this sense, it appears that this polymorphism may be associated with differential susceptibility to cancer. Several studies conducted in different countries reported significant associations

Table 1 Genotype frequencies of *p53* codon 72 polymorphism in colorectal controls and tumors according to Dukes staging

	Genotype frequencies			Odds ratio	95% *CI*
	Arg/*Arg* *n* (%)	*Arg*/*Pro* *n* (%)	*Pro*/*Pro* *n* (%)		
Controls	44 (40.3)	53 (48.6)	12 (11.1)	1 (reference)	
Carcinomas	31 (58.5)	20 (37.7)	2 (3.8)	2.08[a]	1.06-4.05
Dukes A-B	13 (52.0)	11 (44.0)	1 (4)	1.6	0.66-3.83
Dukes C-D	18 (64.3)	9 (32.1)	1 (3.6)	2.66[a]	1.12-6.29

[a] $P<0.05$.

between *p53* polymorphism and human cancer. However, the data available for most cancers remain inconclusive, including for colorectal cancer[6-10]. In addition, the *Arg* isoform of the p53 protein was shown to be more susceptible to degradation by the human papillomavirus (HPV) E6 protein than the proline one, and homozygosity for the arginine allele was found at higher frequency in the germlines of individuals affected by HPV-linked cancer[11]. Although the presence of HPV-DNA in colorectal tissues and adenocarcinomas was reported in populations from different regions[12-16], the association of *p53* codon 72 polymorphism with colorectal cancer taking into account HPV infection was investigated only once[17]. In order to elucidate the potential significance of *p53* polymorphism in sporadic colorectal cancer, in association with high-risk HPV infection, a sample of 53 cases and 109 controls from the city of La Plata, Argentina was characterized, using PCR-based methods.

MATERIALS AND METHODS

Fifty-three patients with sporadic colorectal carcinomas and 109 healthy individuals were screened for *p53* codon 72 polymorphism variants. The age range for cases was 51-80 years, and the age range for the controls was 18-67 years. Colorectal adenocarcinomas were obtained from patients during surgical procedures. Liquid cytologies and gastrointestinal biopsies were taken from controls, consisting of subjects with no evidence of neoplastic disorders. Specimens were classified according to the Dukes staging system, 7 as Dukes A, 18 as Dukes B, 19 as Dukes C and 9 as Dukes D.

Paraffin embedded tissues were washed twice with xylene and then with 100% ethanol, air-dried and suspended in 300 μL of digestion buffer (Tris-HCL pH 8, Triton X-100 and Tween 20) with proteinase K (100 μg/mL) for 2 h at 56℃ (Promega, Madison, Wisconsin, USA). Liquid cytologies were suspended and washed twice with 1 mL PBS, resuspended in 400 μL of digestion buffer and digested with proteinase K for 2 h at 56℃. DNA was extracted from the lysates using the salting-out (salt precipitation) procedure [18]. The samples were stored at –20℃ until used.

p53 codon 72 polymorphism analysis

The *p53* codon 72 polymorphism was studied using allele-specific PCR, as previously described[11], with minor modifications[19]. Detection of the amplicons was made by electrophoresis onto a 6% polyacrylamide minigel and ethidium bromide staining. Genotypes were finally determined under UV illumination.

Human papillomavirus detection and genotyping

HPV infection was investigated in colon tissues from 53 patients. HPV DNA was detected by nested PCR, according to the methods previously described[20]. The region L1 of the viral genome was amplified, using MY09/11 as outer primers, and GP05/06 as inner primers. HPV genotyping was performed using the low ionic strength-single strand conformational polymorphism (LIS-SSCP) procedure, as described elsewhere[21]. To determine DNA quality for PCR amplification, a fragment of the human thymidine kinase gene was amplified by PCR in all the samples[22].

Statistical analysis

Association between *p53* codon 72 genotypes, colorectal adenocarcinoma and HPV infection was assessed by the chi-square (χ^2) test. The basic significance level was fixed at $P < 0.05$. The statistical analysis was performed using the statistical package SPSS™.

RESULTS

Histological classification of adenocarcinomas showed that 41.5% of the cases presented high differentiation, meanwhile 30.2% and 24.5% presented moderate and low differentiation, respectively. The remaining cases were unidentified (3.8%). All DNA samples were successfully amplified by PCR for TK gene, demonstrating that the DNA recovered from the paraffin embedded tissues had quality enough to be analyzed for gene polymorphisms and HPV infection. In control samples, the genotype distribution for *p53* polymorphism showed 40.3%, 48.6% and 11.1% for the *Arg*/*Arg*, *Arg*/*Pro* and *Pro*/*Pro* genotypes, respectively. Allelic frequencies corresponded to 0.65 for the arginine allele and 0.35 for the proline allele. The obtained genotype frequencies fitted the Hardy-Weinberg equilibrium ($P > 0.05$). On the other hand, 58.5% of the cases were *Arg*/*Arg*, 37.7% were *Arg*/*Pro* and 3.8% were *Pro*/*Pro*. The corresponding frequencies were 0.77 for the arginine allele and 0.23 for the proline allele. A significant difference between cases and controls was found for the *Arg*/*Arg* genotype compared with (grouped) *Arg*/*Pro* and *Pro*/*Pro* genotypes. Table 1 shows the obtained risk estimation for

colorectal cancer with its corresponding confidence intervals.

HPV-DNA detection and genotyping was carried out using PCR-SSCP on a smaller set of adenocarcinomas (n = 53). HPV 16 was detected in 41.5% (22/53) of the tissues analyzed, HPV 18 in 24.5% (13/53) and HPV 33 in 7.5%. The distribution of the *p53* polymorphism in HPV negative samples was 53.8% (7/13) and 46.1% (6/13) for the *Arg/Arg* and *Arg/Pro* genotypes, respectively. None of the HPV negative samples tested positive for *Pro/Pro*. On the other hand, 60% (24/40) of the HPV positive samples were *Arg/Arg*, 35% (14/40) were *Arg/Pro* and 5% (2/40) were *Pro/Pro*. No significant differences were found between these two groups regarding *Arg* allele and HPV infection (OR, 1.28; 95% CI, 0.36-4.53; P>0.05).

DISCUSSION

In this study, a positive correlation of *p53* polymorphism and colorectal cancer was observed through analysis of a sample of 162 individuals from La Plata, Argentina. This observation is in agreement with the original study of Storey *et al.* (1998) on cervical cancer[11]. However, the distribution of *p53* genotypes according to type-specific HPV infections showed no significant association in this set of adenocarcinomas.

It is well known that the distribution of *p53* codon 72 polymorphism varies in different geographic regions and ethnicity. According to the literature, general populations from Latin America, United States and Europe exhibit high frequencies of the *Arg* allele compared to the *Pro* one, while lower prevalences of *Arg* are found in African and Asian populations [23-26]. In this study, the frequency for the arginine allele was estimated at 0.65. This result is concordant with that obtained for the control group in a previous case-control study on cervical cancer performed in the city of La Plata[19].

The present study provides additional evidence regarding the role of both HPV infection and *p53* codon 72 variants in colon tissues. In agreement with previous studies, HPV-DNA was detected in a high proportion of adenocarcinomas of the colon[12-16]. These findings may suggest a potential role for high-risk HPV in colorectal cancer. Although the present study did not examine HPV DNA in normal colon tissues, its prevalence was reported in a case-control study on colorectal cancer conducted in La Plata[16]. Using PCR-based techniques, the authors found that 33% (10/30) of the normal samples were positive for HPV DNA. Interestingly, eighty percent (8/10) of the positives were single infections of HPV 16.

With respect to the *p53* polymorphism, the frequency of the *Arg* allele in colorectal cancer lesions showed a two-fold increase compared with that in normal samples. The estimated risk (OR) of the *Arg/Arg* genotype for colorectal cancer was 2.08, and subjects with Dukes C and D reported the highest frequency of *Arg/Arg*. This finding suggests that the *Arg* allele may be associated with increased malignancy in colorectal cancer progression. When stratified by HPV infection, the frequency of *Arg/Arg* genotype in HPV positive adenocarcinomas was not statistically different from that in HPV negative samples. However, it should be considered that this finding may represent an artifact, possibly produced as a result of the small sample size.

Case and control studies conducted in Japan and Turkey failed to find an association between the prevalence of *p53* polymorphism and colorectal cancer[6,17]. In the study conducted by Murata *et al.* (1996), the allelic frequencies were concordant between the controls and two sets of colorectal and lung cancer cases, reaching a frequency of approximately 0.6 for the *Arg* allele. The authors only found a significant association between *p53* polymorphism and lung cancer in non-smoking patients[6]. Similar to our study, Sayhan *et al.* (2001) incorporated the analysis of HPV infection in a case-control study on colorectal cancer and *p53* codon 72 polymorphism. However, *p53* genotypes did not correlate with colon cancer, or with the prevalence of high-risk HPV infections[17]. On the other hand, a case-control study conducted in Spain showed a modest association between the *Pro* allele and colorectal cancer (OR, 1.34; P = 0.066). However, such an association was of borderline significance, and it was lost when the analysis was adjusted to another common polymorphism of *p53* examined in that study, *p53*PIN3[10].

The present study has several strengths, including the use of a representative group of controls from the city of La Plata and the careful examination of all stages of colon cancer. Regarding methodology, misclassification and allelic loss was avoided by the use of two separate allele-specific PCR reactions, so that low copies of one allele would not be affected by the presence of several copies of the other. On the other hand, the present study was not controlled for other potential predisposing factors, such as smoking or life-style habits. This is an important issue to be addressed in further studies in order to assess the role of *p53* polymorphism in this tissue.

The mechanisms which lead to the increase of the *Arg* allele in human cancers are not well-established. Another mechanism proposed to explain the epidemiological findings was postulated by Marin *et al.* (2000)[27]. In their study, the authors demonstrated that certain conformational p53 mutants bind and inactivate the p73 protein, a p53 homologue and transcription factor of some p53 target genes[28]. In experimental assays, the binding of the p53 *Arg* isoform to p73 equaled to or exceeded that promoted by the corresponding *Pro* isoform. Thus, it appears that the *p53* codon 72 polymorphism influences the interaction between p53 mutants and p73, and therefore its ability to activate some p53 target genes. In this sense, preferential mutation and retention of the *Arg* allele was found in a set of various cell cancers from *p53* codon 72 germline heterozygotes[27]. However, a recent study did not find that p53-p73 beta interactions were influenced by the *p53* polymorphism[29]. Moreover, no significant differences were found in *p53* mutation prevalence between *Arg/Arg* (40/97) and *Pro/Pro* (7/16) genotypes in a set of colorectal tumors[7]. These contradictory findings implicate that the involvement of *p53* polymorphism in human cancer demands further study. More recently, Schneider-Stock *et al.* (2004) found preferential mutation of the *Arg* allele in a group of colorectal adenocarcinomas. They also reported selective loss of the *Pro* allele in tumors with loss of het-

erozygosity (LOH), resulting in a positive association between *Arg* prevalence and Dukes progression. The authors discarded the possibility of HPV as a potential mechanism for the higher frequency of *Arg* alleles in colorectal tumors and hypothesized that carcinogenic exposure may selectively affect the *p53 Pro* allele in the development of colon cancer[8].

Overall, the findings of the present study indicate that the *p53* codon 72 polymorphism may act as a predisposing factor to colorectal cancer but it is not associated with high-risk HPV infections. Clearly, the data available are still inconsistent and it would be unwise to draw conclusions. Further studies of larger sample sizes, including the analysis of the premalignant lesions and the status of the *p53* gene, are awaited in order to elucidate the magnitude of genetic susceptibility in sporadic colorectal carcinogenesis.

ACKNOWLEDGEMENTS

We thank Dr. Echeverría and Dr. Galosi from the Virology Department, Faculty of Veterinary Sciences, National University of La Plata for their technical help.

Abstract

AIM: To investigate the prevalence of celiac disease (CD) as well as CD marker antibodies and susceptibility HLA-DQ haplotypes in 134 karyotyped Down's syndrome (DS) patients.

METHODS: Immunoglobulin A (IgA) and G (IgG) type anti-gliadin antibodies (AGA), IgA type anti-tissue transglutaminase (tTG) antibodies (anti-tTG) with antigen of guinea pig and human source were determined by enzyme-linked immunosorbent assay and endomysium antibodies (EMA) by indirect immunofluoresence test. HLA-DQA1*0501/DQB1*0201 (DQ2) was revealed by polymerase chain reaction. Celiac disease was diagnosed by revised ESPGHAN criteria.

RESULTS: 41% of DS patients had AGA, 6.0% IgA anti-tTG with guinea pig antigen, and 3.0 % IgA EMA (all positive for anti-tTG with human tTG). Subtotal villous atrophy was found in 5 out of 9 DS patients who had agreed to small bowel biopsy. One of them had DQA1*0501/DQB1*0201 and anti-tTG and EMA i.e. typical for CD markers (this case also fulfilled the ESPGHAN diagnostic criteria), but other four lacked these markers. Three non-biopsied DS patients had also most probably CD because DQA1*0501/DQB1*0201 and IgA anti-tTG (EMA) were detected. Thus, the prevalence of CD among our DS patients population is 3.0 % (95 % of confidence interval [CI]: 0.1-5.9 %).

CONCLUSION: We confirm the increased frequency of CD among DS patients. In addition, we have revealed a subgroup of patients with subtotal villous atrophy but without characteristic for CD immunological and genetic markers. Whether these cases represent CD (with atypical immunopathogenesis) or some other immune enteropathy, requires further investigations.

INTRODUCTION

Patients with Down's syndrome (DS), trisomy 21, have a variety of gastrointestinal disorders[1] and immunological disturbances that are related to the gastrointestinal tract[2]. However, the mechanisms underlying the complex phenotype of these associations have remained largely unknown.

Celiac disease (CD), characterized by villous atrophy of the small intestine induced by wheat, rye, and barley in the food [3], is the most common immune disease in patients with DS being detected in 1.6% to 16.9% of cases[4 - 12]. In general, susceptibility to CD is associated with the major histocompatibility complex (MHC) genes from extended HLA haplotypes DR3-DQ2 (*DRB1*03, DQA1*0501, DQB1*0201*) or DR5/DR7-DQ2 *(DRB1*11/DRB1*07 or DRB1*12/DRB1*07, DQA1*0501, DQB1*0201*) and about 95% of CD patients have these haplotypes[13, 14]. However, as many as 25-30 % of the general Caucasian population carry DQ2 molecules, showing that other non-HLA genes are also involved[14]. Systematic genome screenings in CD and affected siblings have revealed several other loci possibly involved in CD susceptibility. However, no CD associated

loci have been revealed in chromosome 21[15, 16]. The reason for the association of CD and DS, as well as variability of CD frequency in different populations of DS patients, is unknown. It seems that at least one cannot ascribe it to the increased number of polymorphic susceptibility genes on chromosome 21[17] and chromosome 21 located autoimmune regulator (*AIRE*) gene[18].

Typically, CD is characterized by chronic diarrhoea, weight loss, and failure to thrive. However, in most cases, the symptoms might be mild and non-specific or even absent, which makes it difficult to diagnose. Early diagnosis is needed because the long-term persistence of untreated CD leads to the development of various complications, including malignancy[3]. The gold standard for the diagnosis of CD is small bowel biopsy. According to the revised criteria of the European Society of Paediatric Gastroenterology, Hepatology and Nutrition (ESPGHAN), the diagnosis of CD is based on the results of histological investigations of small bowel mucosa and confirmed by the demonstration of gluten dependence on clinical symptoms[19, 20]. However, in some cases where the small bowel biopsy procedure is not applicable or the investigation results are unequivocal, CD might be exceptionally diagnosed by specific clinical, serological, or HLA data[21]. Patients with DS may be very difficult continent for biopsy due to their mental development retardation, particularly if the the peroral biopsy capsule is used[22].

During the last decades many efforts have been made to find serological markers for CD. Since the 1970s, antigliadin antibodies (AGA) of IgG and IgA types have been used for CD screening, but these antibodies tended to be present also in a number of patients without CD and even in healthy persons[23, 24]. On the other hand, endomysium antibodies (EMA) or antibodies to the EMA's specific target, tissue transglutaminase (tTG), are highly specific for CD[3, 22]. Also, other autoantibodies, including IgA-type anti-smooth muscle (SMA), antiactin and antidesmin antibodies, are frequently detected in patients with CD but revealed in other disease groups as well[25, 26].

The present study aimed to investigate the prevalence of CD, CD marker antibodies and HLA-DQ in DS patients and to compare the results with kariotype and clinical data in these patients.

MATERIALS AND METHODS

Patients

One hundred and thirty-four patients (73 males) with a mean age 11 years (ranging from six months to 45 years) with DS were enrolled in the study. The DS diagnosis was confirmed by chromosome analysis. Regular trisomy was found in 124 patients, translocation in 7 patients (four with 46,XX,der(14;21)(q10;q10),+21 karyotype, one with 46,XY,der(14;21)(q10;q10),+21, and two with 46,XX,der(21;21)(q10;q10),+21), and mosaicism in three cases. One child had translocation between 13;14 chromosomes (46;XY,der(13;14)(q10;q10),+21) with regular trisomy (Table 1). None of the patients had previously been diagnosed with CD and all patients had been on a gluten-containing diet for at least two months. All the studied persons were Caucasians living in Estonia, a country of 45 227 square kilometers and 1.4 million inhabitants. Patients were seen at the Children's Clinic of the Tartu University Clinics. After written informed consent from the patient and his/her parents or guardian, three blood samples were taken – one for antibody analyses, the second for DNA isolation for immunogenetic analysis, and the third for chromosome analysis.

Antibody analysis

In-house enzyme-linked immunosorbent assay (ELISA) was used to detect IgA and IgG AGA using 96-well microtitre plates (Biohit OY, Finland) as described elsewhere [24]. The results were reported in arbitrary units (AU) as a percentage of the optical density of a highly positive serum sample. Values of AU over 59 were considered as a sign for AGA presence. Antiendomysium antibodies of IgA-type were determined by the indirect immunofluorescence test on unfixed frozen sections of the human (blood group 0) umbilical cord using sera from patients and IgA EMA positive and negative controls diluted at 1:10. The serum of a patient was considered positive for IgA EMA if a typical staining pattern was observed around smooth muscle cells of the blood vessels[27]. Smooth muscle antibodies of IgA type were detected using the standard indirect immunofluorescence test with unfixed frozen sections of rat liver, kidney, and mouse stomach in the patients sera by the same procedure as described above. The intracellular staining of smooth muscle cells was designated as IgA SMA[26]. Immunoglobulin A anti-tTG were determined by two assays. The in-house ELISA test[26] was used to determine IgA against the guinea pig tTG (IgA anti-gptTG). The results were reported in arbitrary units (AU) as a percentage of the optical density of a positive serum sample. Test results over 25 AU were considered positive. In order to determine IgA against human tTG (IgA anti-htTG), the Celikey tTG ELISA kit (Pharmacia and Upjohn Diagnostics, Freiburg, Germany) with human recombinant tTG was used according to the manufacturer's instructions. Values of IgA anti-htTG higher than 8 U/ml were considered positive. Antibodies were determined under the external quality control of UK NEQAS (Sheffield, UK). In the disease control group of consecutive untreated CD patients 100.0% had IgA and/or IgG AGA, 89.0% IgA EMA and IgA anti-hutTG (data not shown).

Immunogenetic studies

The HLA-DQA1*0501 and DQB1*0201 alleles, encoding for DQ2 molecule, were determined by PCR-based methodology with allele-specific primers as published elsewhere[28].

Chromosomal analysis

Chromosome preparations were made from peripheral blood lymphocyte cultures. The cytogenetic analysis was performed using GTG banding technique[29].

Diagnosis of celiac disease

Communicating with DS patients and invasive diagnostic

Table 1 Comparative frequency of different karyotypes among 134 Down's syndrome patients and the incidence of EMA, anti-tTG, AGA, and celiac disease in these patients

Karyotype groups	No. of patients	No. with positive AGA	No. with positive anti-tTG (guinea pig antigen)	No. with positive anti-tTG (human antigen) and EMA	No. with celiac disease
Regular trisomy	124	54	8	4	4
Translocation	7	1	0	0	0
Mosaicism	3	0	0	0	0
Total	134	55 (41.0 %)	8 (6.0 %)	4 (3.0 %)	4 (3.0 %)

procedures like endoscopy and intestinal biopsy involves considerable difficulty. Therefore, we did not invite all DS patients with whatever CD marker antibodies for small intestinal biopsy procedure to confirm or deny CD, but only those who had most probably CD, that is, all AGA-positive patients with complaints compatible with CD, all patients with IgA EMA and/or anti-tTG, and all seronegative infants with typical CD symptoms (failure to thrive, chronic diarrhoea). Biopsy specimens were taken from the proximal part of the mucosa of the small intestine (at the level of ligamentum Treiz) under fluoroscopic control using the Watson capsule. The diagnosis of CD was established on the basis of revised ESPGHAN criteria[19].

Ethics

The study was approved by the Ethics Committee for Medical Investigations at the University of Tartu.

Statistical analysis

The SAS/STAT (version 6, 1990, SAS Institute Inc., Cary, NC, USA) statistical package was used for calculations. A *P*-value of less than 0.05 was taken to be significant.

RESULTS

Fifty-five (41.0 %) out of 134 DS patients had a positive test for IgG or/and IgA AGA test (Table 1). Eight (6.0 %) out of 134 DS patients had a positive IgA anti-gptTG test. When the positive sera were retested for IgA anti-htTG, only four that had also IgA EMA, remained positives. No additional anti-htTG positive cases were revealed among 2 DS patients with borderline anti-gptTG values (18-25 AU) and 24 randomly selected anti-gptTG negative DS patients (including 16 with the positive IgA AGA test).

Altogether, 11 DS patients with antibodies and gastrointestinal symptoms compatible with CD were invited to small bowel biopsy. In addition, there was a 11-months-old infant with typical CD symptoms (failure to thrive, chronic diarrhea) but without IgA AGA and IgA anti-htTG (EMA). In all patients cow milk protein allergy, as another possible reason for intestinal villous atrophy, was excluded. Among 9 patients who agreed to the procedure, subtotal villous atrophy (SVA) was revealed in 5 and normal small bowel mucosa in 4 (Table 2). Only one out of these 5 patients had characterisic for CD IgA anti-tTG/EMA (none of them had had total serum IgA below the normal value as evaluated by nephelometry - data not shown) and HLA-DQA1*0501/DQB1*0201, although a clear clinical effect from gluten-free diet-disappearance of chronic diarrhea, abdominal distension and discomfort, and/or failure to thrive with the disappearance of IgA AGA positivity was revealed in four. However, we revealed IgA SMA in 3 out of 5 DS cases with SVA but only in 8 out of 119 DS cases without SVA ($P < 0.001$; Chi-square with Yates correction).

In all 4 IgA anti-htTG positive cases HLA-DQA1*0501/DQB1*0201 haplotype was revealed. This group of DS patients includes aforementioned patient with biopsy verified CD and 3 patients who had not agreed with intestinal biopsy procedure (two had IgA SMA). All patients had positive clinical effect from gluten free diet and therefore CD was confirmed in all four patients. Thus, we had revealed the CD prevalence at least 3.0% (95% CI: 0.1-5.9) among our DS patients.

No significant differences were found in the karyotype characteristics between DS patients with and without antibodies or CD (Table 1).

DISCUSSION

Celiac disease deserves special attention as most common gastrointestinal autoimmune associate of DS[2, 3]. However, the mechanisms underlying the development of CD in DS have remained unknown. We have revealed SVA compatible for CD and/or CD by characeristic IgA anti-tTG and HLA-DQ2 data as well as clinical effect of gluten-free diet in 4 (3.0 %) of studied 134 (95 % confidence interval ([CI]: 0.1-5.9%) DS patients. This finding 3 or more times exceeds the prevalence of CD in general population[3].

Similar CD frequencies in DS patients have been revealed in countries of different regions of the world [4-12, 22]. The only exceptionally high prevalence of CD in DS (16.9%) was revealed in Sweden by Jansson and Johansson [5]. However, the selection of DS patients and screening methods, as well as frequency of CD cases in local background population could significantly affect the results. Aforementioned Swedish authors have screened DS patients by AGA test and diagnosed CD in 9 of 19 biopsied patients. In line of their results we have also detected a set of EMA-negative but igA AGA positive DS patients with SVA (Table 2).

In the present study we used in parallel all the commonly available serological CD screening assays-AGA, EMA and anti-tTG tests – and confirmed three opinions presented in the literature. First, we found a high prevalence (41%) of IgA and/or IgG AGA among DS patients[4-11]. Second, the IgA anti-tTG reactivity is best detected by human tTG[12, 30, 31]. Third, the IgA EMA and anti-htTG highly

Table 2 Profile of 12 Down's syndrome patients (all with regular trisomy) invited for small bowel biopsy

Patient No.	Age (yr) sex	Symptoms	Small bowel biopsy	IgA AGA	IgG AGA	IgA SMA	IgA EMA	IgA anti-gptTG	IgA anti-htTG	HLA-DQB1 *0201	HLA-DQA1 *0501
6	0.9 F	+ #	SVA	-	-	+	-	-	-	-	+
10	13 M	+ ##	SVA	+	+	-	-	-	-	-	-
18	10 M	-	Norm.	+	+	-	-	+	-	-	-
59	1 M	+ ##	SVA	+	+	+	-	-	-	-	-

98	7 F	-	Norm.	-	+	-	-	-	-	n. d.	n. d.
105	9 M	+ ####	n. d.	+	+	+	+	+	+	+	+
130	3 F	-	Norm.	-	+	-	-	-	-	n. d.	n. d.

Numbers in bold denote positive values in antibody tests; SVA – subtotal villous atrophy; Norm. – normal mucosa; n. d. – studies not done (biopsy procedure was denied). # - symptoms did not disappear during the four-year gluten-free diet – CD was not diagnosed. ## - symptoms disappeared after introduction of gluten-free diet – CD was not diagnosed due to lack of anti-htTG and HLA-DQ2. ### - symptoms disappeared after introduction of gluten-free diet – CD was diagnosed by morphology data (by ESPGHAN criteria). #### - symptoms disappeared after introduction of gluten-free diet – CD was confirmed without morphology data.

correlates with the presence of DQ2 haplotype[3, 14]. However, as a new observation, we revealed a portion of DS patients with SVA but without characteristic for CD serological and genetical markers. One might ask whether these patients have cow milk protein allergy or B-cell immunodeficiency representing other well-known associates of SVA. This was not a case as revealed by the additional clinical inves-tigations in these patients. However, these patients may have severe imbalances in immune regulation leading to the development of this type of enterpathy. As a support to this view we have detected a substantial decr-ease of peripheral blood regulatory T cells (including $CD4^{+}CD25^{high}$ cells) in one of these SVA patients compared to age-sex mached controls (data not shown). Regulatory T cells play a key role in the maintenance of self-tolerance, thus preventing autoimmune disease, as well as inhibiting harmful inflammatory diseases[32].

Noteworthy, in three of five DS patients with SVA IgA SMA were revealed. Smooth-muscle antibodies group may include different antibodies types, antibodies to actin, tubulin, desmin and others[33], among which antibodies against actin and desmin have been found in untreated CD patients[25, 26]. Also a number of autoimmune enteropathy cases have been described to be associated with SMA (reviewed by Russo and Alvarez[34]). Whether our patients with SVA but without typical immunologic and genetic characteristics of CD represent an entity of autoimmune enteropathy of DS or just a group of atypical CD cases, needs further invstigations. The latter possibility could be easily drawn from the recent studies[11, 12, 35] where immunologically and immunogenetically atypical CD cases were discovered among DS patients.

What is the actual cause of the rised prevalence of CD in DS patients? According to special analysis there is a number of immune response influencing genes in chromosome 21[36]. Thus, the abnormal function of these genes (whatever the mechanism) as the cause of general immune dysfunction, including impaired local immunity and high susceptibility to infections, might contribute to the impairment of the integrity of the small bowel and lead to food antigen leakage through the intestinal mucosa. However, some genes responsible for gut mucosa integrity could be involved as well. As indirect evidence for this suggestion, we have revealed AGA in as many as 41% of DS patients. This supports the earlier studies about the high frequency of AGA[5-8] and other food antibodies in DS[37].

To conclude, the results of our study confirm the earlier reports about an increased prevalence of CD in DS. However, according to our results there are also some DS patients with SVA not fulfilling the typical immunological an genetical criteria for CD. Whether these patients with SVA represent just a subgroup of CD (as judged by the clinical effect of gluten-free diet) but with a deviation in immunopathogenesis, or other types of immune enteropathies (as judged by immunological data), needed to be answered in future studies.

Abstract

AIM: To determine the demography and clinical presentation of CD and secondly to determine any differences in the prevalence between the different ethnic groups in a multiracial Asian population.

METHODS: Patients with CD who were seen in 2001–2003 in the University of Malaya Medical Centre (UMMC) were enrolled in this study. Prevalence of disease was calculated for the group as a whole and by race with hospital admissions per ethnic group as the denominator.

RESULTS: Thirty-four patients were diagnosed to have CD. Basic demographic data of patients; male:female 17:17; mean age 29.1 years (±13.5 years); ethnic group: Malays 5 (14.7%), Chinese 12 (35.3%) and Indians 17 (50%). Twenty-six (76.5%) were diagnosed under the age of 40 and 8 (23.5%) were diagnosed over the age of 40. Location of the disease was as follows: ileocolonic 13 (38.2%), terminal ileum only 9 (26.5%), colon only 8 (23.5%), and upper gastrointestinal 4 (11.8%). Sixteen (47.1%) had penetrating disease, 9 (26.5%) had stricturing disease and 9 (26.5%) had non-penetrating and non-stricturing disease. The hospital admission prevalence of CD was 26.0 overall, Indians 52.6, Chinese 6.9, and Malays 9.3 per 10^5 admissions per ethnic group. The difference between Indians and Malays: [OR 5.67 (1.97, 17.53) $P < 0.001$] was statistically significant but not between the Indians and the Chinese [OR 1.95 (0.89, 4.35) $P = 0.700$]. The difference between the Chinese and the Malays was also not statistically significant. [OR 2.90 (0.95, 9.42) $P = 0.063$].

CONCLUSION: The clinical presentation of CD is similar to the Western experience. Although the overall prevalence is low, there appears to be a clear racial predominance among the Indians.

INTRODUCTION

Crohn's disease (CD) and ulcerative colitis (UC) have long been recognized in the West, but is thought to be relatively uncommon in the Asia[1]. To illustrate this point, the prevalence rates of CD have been estimated to be 3.6 and 5.8 per 10^5 in Singapore[2] and Japan[3], respectively compared to 144.1 per 10^5 in Olmsted, Minnesota[4] and 147 per 10^5 in North East Scotland[5]. However, the incidence appears to be increasing in this part of the world and is likely to become clinically more important in future. For example, in another Japanese study, the prevalence and the annual incidence were estimated to be approximately 2.9 and 0.6 per 10^5 population, respectively in 1986, but this had increased to 13.5 and 1.2 per 10^5 population in 1998[6]. Leong *et al* found a similar increase in the annual incidence of CD among the Chinese population in Hong Kong[7] and a study by Law *et al* found an increase in the number of admissions for CD among the Chinese population in Singapore[8].

Another interesting observation is that there appears to be ethnic differences in the prevalence of idiopathic inflammatory bowel disease[1,2,9-15]. This is particularly relevant in Malaysia which has a multiracial society mainly made up of three major Asian races: Malay, Chinese, and Indian. In particular, studies in neighboring Singapore which although has a predominantly Chinese population has a similar racial mix; significantly higher prevalence rates among the Indians for UC but not CD compared to the Chinese and the Malays have been found[2,9,10] These racial differences for UC were also seen in our own study in UMMC[15] The aim of this study is to determine the demography and clinical presentation of CD in a hospital setting in Malaysia and to determine any racial differences in prevalence.

MATERIALS AND METHODS

Patients with CD in UMMC as identified by International

Table 1 Demographic characteristics of patients with CD in UMMC

Number	All patients 34
Total males	17 (50%)
Total females	17 (50%)
Age (range)	12-56 years
Mean age	29±13.5 years
Ethinc group	
Malay	5 (14.7%)
Chinese	12 (35.5%)
Indian	17 (50%)
Family history	0 (0%)
Appendicectomy	2 (5.9%)
Smoking history	
Non smoker	27 (79.4%)
Ex smoker	2 (5.9%)
Current smoker	5 (14.7)

Table 2 Prevalence of CD overall and according to ethnicity

	Malays	Chinese	Indians	Overall
CD (*n*)	5	12	17	34
Total admissions	53906	44592	32330	130828
Prevalence per 10^5 admissions	9.2	26.9	52.6	26.0

Classification Coding for Crohn's disease from 2001 to 2003 were retrospectively included into the study. Patients under the age of 12 were excluded. The diagnosis of Crohn's disease was made in accordance with previously accepted criteria based on a combination of clinical presentation as well as typical radiographic, endoscopic, histological, and laboratory findings[16]. Diagnosis was at least of 6 mo duration. Microscopic colitis, collagenous colitis, Behcet's disease and infective enterocolitis were excluded. Stool microscopy and culture, bacterial and amoebic serology, acid-fast staining of biopsies were performed to exclude infectious enterocolitis. Baseline patient characteristics in particular race, date of diagnosis, clinical features, method of diagnosis, location of disease, complications and surgical intervention were documented. Phenotype of the disease was classified according to the Vienna classification[17]. Family history, smoking history and whether or not the patient had a previous appendectomy was also recorded.

The denominator were hospital admissions in UMMC in 2001-2003 as a whole and according to each of the major ethnic groups; Malays, Chinese, and Indians.

Statistical analysis

Data was analyzed using the SPSS 11.5 for Windows. Prevalence of the disease was calculated for the group as a whole with total hospital admissions for the same period of time and by race with hospital admissions per 100 000 ethnic group as the denominator. Prevalence rates were expressed with 95% confidence intervals.

RESULTS

Demographic characteristics

The demographics of the patients with CD are summarized in Table 1. There was no gender difference, 17 males and 17 females with a ratio of 1:1. The mean age was 29.1 years (±13.5 years). Twenty-six (76.5%) were diagnosed under the age of 40 and 8 (23.5%) were diagnosed over the age of 40. The breakdown according to ethnic group was as follows: ethnic group: Malays 5 (14.7%), Chinese 12 (35.3%), and Indians 17 (50%). None of the patients had a family history of IBD and only 5 (14.7%) were smokers whereas 2 (5.9%) were ex-smokers and the majority 27 (79.4%) were lifelong non smokers. Two (5.9%) patients had previous appendectomy.

Clinical features and disease location

In terms of clinical features, the commonest presenting complaints were diarrhea 29 (85.3%), abdominal pain 25 (73.5%), rectal bleeding 17 (50%), and weight loss 15 (44.1%). Other features included fever 8 (23.5%), vomiting 8 (23.5%), and abdominal mass 6 (17.6%). Perianal disease was seen in 10 (26.5%), and extraintestinal manifestations in 7 (20.6%). Thirteen (38.2%) presented with an acute abdomen and diagnosis was made following laparotomy.

Location of the disease was as follows: ileocolonic 13 (38.2%), terminal ileum only (with or without cecal overflow), 9 (26.5%), colon only 8 (23.5%), and upper gastrointestinal 4 (11.8%). Of the patients who had upper gastrointestinal disease (upper GIT), two had coexisting disease in the ileocolon, one in the terminal ileum only and one in the colon only.

Disease behavior and surgical rate

The median duration of follow up from the time of diagnosis till the date of recruitment into this study was 8 years (5-18.25). In terms of disease behavior, 16 (47.1%) had penetrating disease, 9 (26.5%) had stricturing disease and 9 (26.5%) had non-penetrating and non-stricturing disease. Of the 34 patients with CD, 16 (47.1%) of patients had undergone at least one operation. Seven (20.6%) had more than one operation.

Racial prevalence

The ethnic distribution of patients with CD were; Malays 5, Chinese 12, and Indians 17. Over the same period of time as the study, hospital admissions per ethnic group were as follows: Malays 53 906 Chinese 44 592, and Indians 32 330. The hospital admission prevalence of CD was 26.0 overall, Indians 52.6, Chinese 26.9, and Malays 9.3 per 10^5 admissions per ethnic group (Table 2). The difference between Indians and Malays: OR 5.67 (1.97, 17.53) $P<0.001$ was statistically significant but not between the Indians and the Chinese OR 1.95 (0.89, 4.35) $P=0.700$. The difference between the Chinese and the Malays was also not statistically significant [OR 2.90 (0.95, 9.42) $P=0.063$].

DISCUSSION

In terms of gender and typical age of presentation, CD in Malaysia appears similar to other Western studies[12,13] in that there was generally no major gender differences and most patients presented under the age of 40, mainly

between the ages of 16 to 25. However, the majority of patients did not have any of the known risk factors identified from previous studies. For example, 79.4% of them were lifelong non smokers. As the number of patients with CD is less and there are no controls, this may not be a true finding although there have been other studies that have failed to identify smoking as a risk factor of CD[18,19]. None of our patients had a positive family history as with Leong *et al* study from Hong Kong[7]. This is in marked contrast to other published studies from the West , where a positive family history is found in 5-10% of patients with CD[20-22].

The commonest presenting complaints were also typical of CD. One interesting observation is that 38.3% of these patients presented with an acute abdomen requiring laparotomy and the diagnosis was subsequently made on histology. In terms of location of the disease, the distribution is also similar to the Western experience. For example, a study by Freeman looking at 877 patients in a single center in Vancouver, Canada found similar findings; CD was located in the ileocolon in 34.6% followed by colon alone in 27.2% and terminal ileum in 25.3% as divided according the Vienna Classification[21].

It is expected for most Crohn's patients to develop either stricturing or penetrating (fistula, abscess, perforation) complications with time[23] As the median duration of follow up in our patients was fairly long (8 years [5-18.3]), it is not surprising that most of our patients either had stricturing or penetrating disease. Also demonstrated in this study was a high rate of surgery. Almost half the patients had undergone at least one operation.

Therefore, it appears that overall; the clinical presentation of CD in our patient population is similar to that seen in Western countries. Cohort studies looking at the clinical course of the disease in Asian patients suggest that like in the West, most will have chronic, intermittent disease although they may have a more favorable prognosis[24-27].

In terms of prevalence, however, this appears to be low, with CD making up only about 26.0 per 10^5 admissions. The low frequency of diagnosis of CD had been previously reported in our center when only thirteen cases of CD were identified over an eight year period from 1982 to 1989[28]. Our present study was only able to look at the prevalence of hospital admission. The best epidemiological studies should be population based and in countries such as Japan, an IBD registry is available and incidence and prevalence rates are calculated based on the whole population. However, in most countries in Asia such registries are not established and studies are often made based on hospital statistics with the population of the "catchment area" as the denominator[2,7]. Our main limitation is identifying this catchment area to define the population served by our hospital.

Ethnic differences in IBD are intriguing as they point to either differences in host genetic susceptibility or exposure to environmental factors specific to an ethnic group. A recent study on UC carried out in our center showed the highest prevalence among the Indians followed by the Chinese and the Malays[15]. The hospital admission-based prevalence rates were significantly higher in the Indians compared to the Malays but not the Chinese. In Singapore however, there was a statistically significant difference showing a higher prevalence among the Indians compared to the Chinese[2] With respect to CD, the same Singaporean study showed an increased prevalence in CD among the Indians (4.9 per 10^5 compared to 4.0 per 10^5 in the Chinese and 2.9 per 10^5 in the Malays) although this was not statistically significant. In our present study, the highest prevalence of CD was again found in the Indians.

Therefore, in a multiracial Asian country such as Singapore and Malaysia, IBD appears to be more common among the Indians. It is pertinent to note that all the three races have lived together for more than three generations and are exposed to similar environmental factors indicating that perhaps host genetic susceptibility play a more important role in the pathogenesis of IBD in this region.

In conclusion, in our hospital setting, the clinical features of CD are similar to the Western experience. Although the overall prevalence is low, there appears to be ethnic differences in the prevalence of the disease with a probable racial predominance among the Indians. Racial differences in prevalence may provide vital clues to the pathogenesis of the disease, particularly in the Asian setting.

Abstract

AIM: To study the effect of retrorsine on mouse hepatocyte proliferation.

METHODS: Mice and rats were treated respectively with two injections of retrorsine (as retrosine-treated group) or saline (as non-treated group) at 2 wk intervals. They received a single injection of carbon tetrachloride (CCl_4) 4 wk later. On d 0, 1, 2, 3, 4, 6, 15 after CCl_4 administration, the animals were killed and their livers were excised. Hematoxylin and eosin (HE) staining and Ki-67 antibody immunohistochemical analysis of liver samples were used to evaluate the pathological changes and hepatocyte proliferation.

RESULTS: In rats treated with retrorsine and CCl_4, the liver displayed obvious megalocytosis, proliferation of mild bile duct, small hepatocyte-forming nodule, which were not found in liver samples from non-treated group. However, in mice treated with retrorsine combined with CCl_4, the liver displayed hepatocyte degeneration and necrosis in perivenous areas. There was no obvious difference between retrorsine-treated group and non-treated group. Ki-67 immunohistochemical analysis showed that in rats treated with retrorsine, the positive hepatocytes mainly found in small hepatocyte nodules, were obviously less than those in non-treated group. The mice treated with retrorsine showed that the number of Ki-67 positive hepatocytes was very high and more than that in non-treated group.

CONCLUSION: Retrorsine has no effect on mouse hepatocyte proliferation.

INTRODUCTION

Hepatocyte transplantation can not only treat liver degenerative disorders and other serious liver injuries, but also replace liver transplantation[1, 2]. Before clinical application, it is necessary to use an animal model to test whether exogenous liver cells can integrate and grow in the recipient liver. Observations in humans and other vertebrates demonstrated that native liver cells have a very high regenerative potential and outgrow the exogenous cells[3]. Therefore, in animal models for hepatocyte transplantation, it is very important to inhibit the proliferation of native hepatocytes. It has been reported that retrorsine, a member of the pyrrolizidine alkaloid (PAs) family can impair the proliferative capacity of mature hepatocytes. Retrorsine-induced blockade is in G1/S, late "S" and /or "G2/M" phase of cell cycle[4-6]. Laconi *et al*.[4] reported that syngeneic transplantation of hepatocytes in liver of dipeptidyl-peptidase type IV-deficient (DPPIV) rats treated with retrorsine could achieve 95% chimerism and restore its normal function. Although retrorsine has been used in rat model, there are very few reports on its use to create a mouse model for hepatocyte transplantation[7]. In this study, we investigated the effect of retrorsine on mouse mature hepatocytes. The results indicate that retrosine cannot inhibit mouse hepatocyte proliferation after liver injury.

MATERIALS AND METHODS

Animals

Male C57BL/6J mice (6 wk) and male F344 rats (5 wk) were purchased from National Rodent Laboratory Animal Resources, Shanghai Branch, China. They were maintained in a 12 h light/dark cycle and fed with standard food and water *ad libitum*. All animals received humane care and study protocols complied with guidelines of Shanghai Second Medical University.

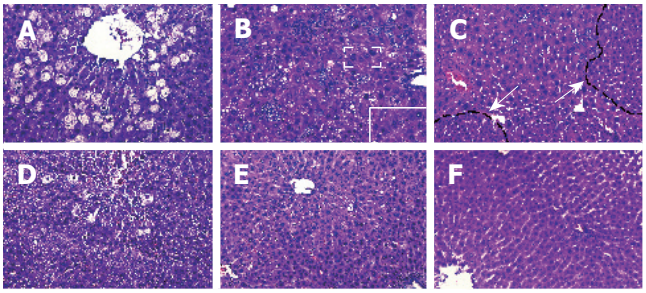

Figure 1 Pathological analysis of rat liver. **A**: Much more severe hepatocyte balloon degeneration and necrosis in perivenous areas of retrorsine-treated group compared with non-treated group (**D**). **B**: Mild bile duct proliferation and megalocytosis (the insert showed the area enclosed in the box at high magnification). **C**: Proliferation of small hepatocytes formed nodules. **E** and **F**: No obvious pathological change was found in non-treated group.

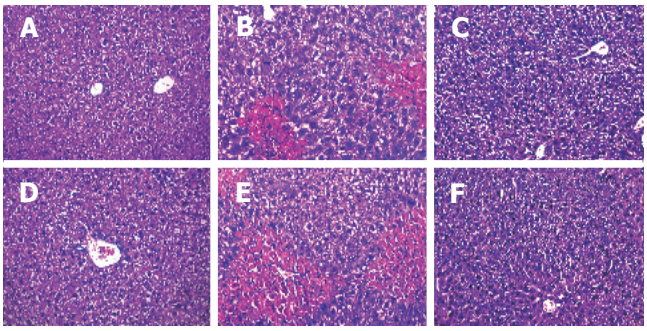

Figure 2 Pathological changes of mouse liver. **A** and **D**: No obvious morphological abnormity. **B** and **E**: Necrosis in perivenous areas, arrow indicates the mitotic figure of hepatocytes. **C** and **F**: Hepatic parenchyma in both groups became normal.

Reagents

Retrorsine (Sigma-Aldrich) was added to distilled water at 10 mg/mL and titrated to pH 2.5 with 1 mol/L HCl to dissolve it completely. The solution was neutralized using 1 mol/L NaOH. Subsequently NaCl was added. The final concentration was 5 mg/mL retrorsine and 0.15 mol/L NaCl, pH 7.0. The working solution was used immediately after preparation.

Carbon tetrachloride (CCl_4) was diluted 1:10 using sterile mineral oil and maintained in a rubber plug-sealed glass tube. Ki-67 (Clone SP6) rabbit monoclonal antibody, a cell proliferation marker[8] was purchased from Lab Vision.

Experimental groups

After one week of acclimatization, the mice and rats were randomly divided into two groups and received two intraperitoneal injections of retrorsine (70 mg/kg for mice[7] and 30 mg/kg for rats[4, 6] (as retrosine-treated group)) or saline (as non-treated group) at 2-week interval. Four weeks after the second injection, diluted CCl_4 was respectively injected into mice and rats, ip 5 mL/kg[7]. Day 0 was set just before CCl_4 injection. On days 1, 2, 3, 4, 6, and 15 after CCl_4 administration, 3-5 animals from each group were killed. The liver of animals was excised and fixed in 40 g/L formaldehyde for the following study.

Pathology and immunohistochemistry

Samples were dehydrated in alcohol and embedded in paraffin. Sections were cut at 5 μm thickness. For pathological analysis, the liver sections were stained with hematoxylin and eosin (HE) according to the standard procedures.

For Ki-67 immunohistochemical staining, antigen retrieval was carried out by incubating slides in antigen retrieval buffer (0.01 mol/L citrated buffer, pH 6.0) at 95 °C for 30 min. The slides were incubated with the primary antibody, Ki-67, at 4°C overnight. The secondary antibody used was anti-rabbit conjugated with horseradish peroxidase (Jackson Immunoresearch). 3,3-diaminobenzidine tetrahydro-chloride containing 0.1g/L hydrogen peroxide was used as a substrate. The proportion of Ki-67 positive hepatocytes was counted from at least 2000 cells from serial fields for each sample under microscope with 20× magnifications.

Statistics analysis

Data were expressed as mean±SE. Sigmaplot 2001 and SAS for windows 6.12 softwares were used for data analysis and plot. The significance of variances was found to be appropriate by Student's *t*- test or χ^2 test.

RESULTS

Pathological analysis

Before CCl_4 administration, liver morphology had no obvious change both in mice and in rats treated with retrorsine. After injecting CCl_4, much more severe hepatocyte balloon degeneration and necrosis in perivenous areas were found on day 1 in retrorsine-treated group than in non-treated group. Some megalocytosis, mild bile duct proliferation and small hepatocyte proliferation-formed nodules occurred in retrosine-treated group but not in non-treated group (Figure 1).

Livers of both retrorsine-treated and non-treated groups showed necrosis in perivenous areas on day 2 after CCl_4 injection. After then hepatocytes in periportal areas began to proliferate, mitotic figures of liver cells could be found. Such a pathological phenomenon might be due to destruction of CCl_4 in liver[9, 10]. There were no megalocytosis and other pathological changes in rats. On the 15th day, hepatic parenchyma in both groups became normal (Figure 2).

Ki-67 immunohistochemical analysis

Before CCl_4 injection, a small number of Ki-67 positive hepatocytes appeared in mice and rats treated with retrorsine. For the rats, the number of positive hepatocytes was increased slowly, reached the peak on day 6 in retrorsine-treated group and most of positive cells were small hepatocytes in nodules. In non-treated group, the maximum number of positive hepatocytes appeared on day 3 (Figures 3 and 5A).

The maximum number of positive hepatocytes was observed on day 4 in retrorsine-treated group of mice and almost all the positive cells were from mature hepatocytes. The maximum number of positive cells appeared on the 2nd day in non-treated group. Both groups showed a similar proliferation pattern (Figures 4 and 5B).

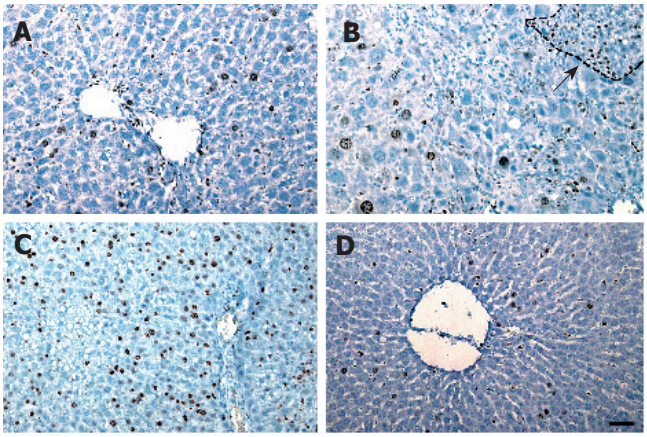

Figure 3 Ki-67 immunohistochemical analysis of rat liver. **A**: A few hepatocytes were Ki-67 positive. **B**: Ki-67 positive hepatocytes were mainly found in small hepatocyte nodules as the arrow indicated. **C**: Abundant Ki-67 positive cells. **D**: Only a few hepatocytes were Ki-67 positive in rat liver.

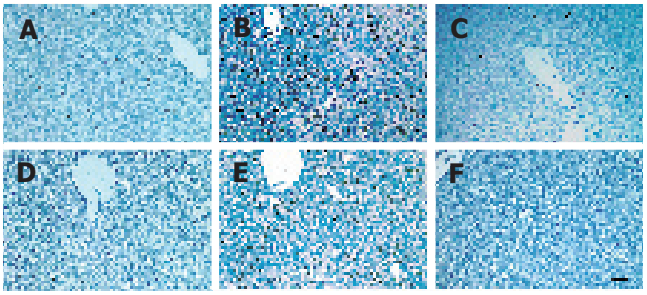

Figure 4 Ki-67 immunohistochemical analysis of mouse liver. **A** and **C**: Some Ki-67 positive cells appeared in retrorsine-treated mice on days 0 and 15. **B** and **D**: The maximum number of Ki-67 positive cells in retrorsine-treated mice on day 4. **E** and **F**: The maximum number of Ki-67 positive cells in non-treated group on day 2.

DISCUSSION

The present study described the comparative pathological changes and kinetic of hepatocyte proliferation in mice and rats treated with retrorsine and CCl_4. Guo *et al* [7] reported that two doses of retrorsine (70 mg/kg at 2 wk interval) could be tolerated by >90% of mice. If the dosage is over 70 mg/kg, the mortality rate of animals would increase. We used this dosage in our experiments and tested ethanol or water as a solvent for retrosine and treated mice with the same dosage (70 mg/kg). The survival rate was 85% (22/26) and 84% (27/32), respectively. No statistically significant difference was displayed between them ($\chi^2=0.001$, $P=0.980$), suggesting that only water can be used as a solvent for retrosine.

The rats treated with retrorsine and CCl_4 showed megalocytosis, mild bile duct proliferation and small hepatocyte proliferation-formed nodules. This phenomenon has been described by many authors[4, 6, 12-15]. But in mice treated with the same protocol, we did not find similar pathological changes. Guo *et al*[7] studied liver repopulation after cell transplantation in mice treated with retrorsine and CCl_4, and found that there are no liver pathological changes.

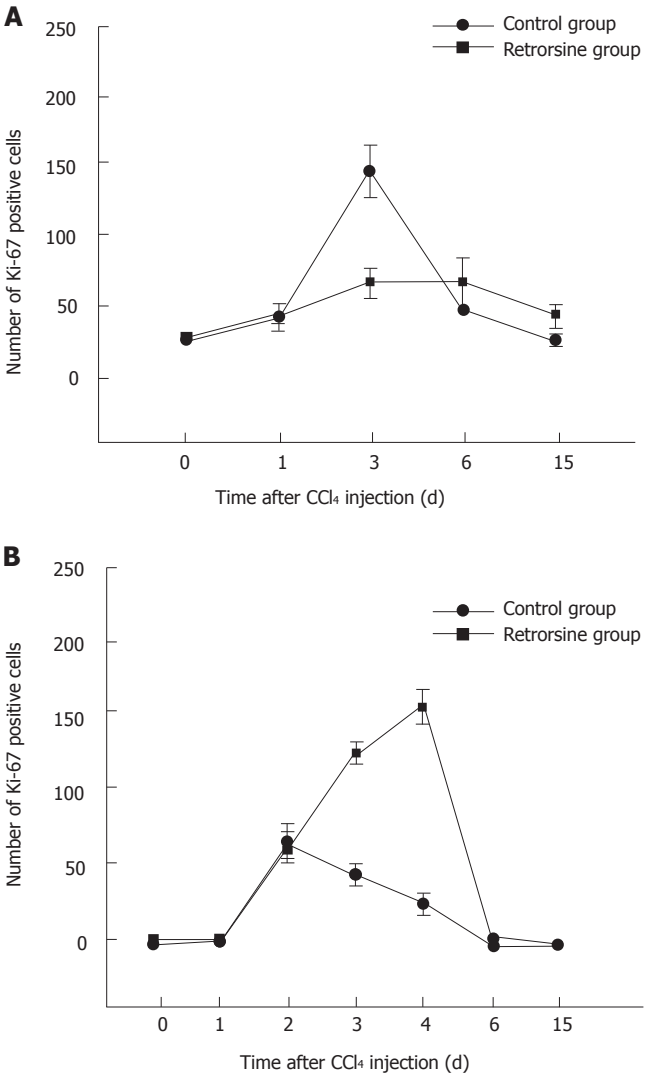

Figure 5 Kinetics of Ki-67 expression in rats (A) and mice (B) after CCl4 injection. **A**: The maximum number of Ki-67 positive hepatocytes on day 6 after injection of CCl4 in retrorsine-treated rats and on day 3 in non-treated group. **B**: The number of Ki-67 positive hepatocytes in retrorsine-treated mice was higher than that in non-treated group delayed. $^aP<0.05$, $^bP<0.01$, $^cP<0.001$ *vs* control group.

Ki-67 immunohistochemical analysis showed that proliferation of hepatocytes in rats treated with retrorsine was blocked. Avril *et al*[16] have reported similar results. Laconi *et al*[6] reported that BrdU labeling index of rats treated with retrorsine combined with partial hepatectomy is also significantly lower than that in non-treated group.

The number of Ki-67 positive hepatocytes in mice treated with the same protocol was higher than that in non-treated group. Guo *et al*[7] reported that the number of proliferating liver cells (detected by proliferating cell nuclear antigen, PCNA) in mice treated with CCl_4 alone is >60%. Our result is consistent with theirs. Since they did not show hepatocyte proliferation after retrorsine treatment combined with CCl_4, we considered that after liver injury mouse hepatocyte proliferation might not inhibited by retrorsine. Since Ki-67 positive hepatocytes in mice treated with retrorsine combined with CCl_4 was higher than that in non-treated group in our study, it is possible that retrorsine might increase the sensitivity of mouse liver to CCl_4 injury because the cell proliferation

response is always dependent on the extent of liver injury.

Retrorsine has long been known for its ability to block hepatocyte division[4-6]. Megalocytosis results from replicating hepatocytes which are blocked after DNA synthesis and prior to mitotic division, thus resulting in a large number of cells with enlarged nuclei (megalocytosis)[4, 6, 17]. Our results demonstrated megalocytosis was only present in livers of rats but not in livers of mice treated with retrorsine, indicating that the effect of retrorsine on mice is different from that on rats. Significant species difference in susceptibility to PAs intoxication has been reported, which is mainly due to the variations in balance between the formation of toxic metabolites and detoxification pathways[18-20]. Although both mice and rats belong to murine, they might have a different process of metabolism or detoxification of PAs in their livers, which may lead to resistance of mice to retrorsine. Moreover, rats receiving CCl_4 2 wk after the second injection of retrorsine displayed higher mortality rate than those receiving CCl_4 4 wk after the second injection of retrorsine (data not shown). There was no obvious difference in the mortality rate and other physiological indices in mice receiving CCl_4 2 wk or 4 wk after the second injection of retrorsine, which proved our hypothesis that retrorsine could seriously injure rat liver but not mouse liver.

As reported by Guo *et al*[7], when hepatocytes are transplanted into mice treated with retrorsine alone, the chimerism rate of exogenous liver cells is less than 1%. It was reported that the chimerism rate of rats treated with retrorsine alone could reach 95%[14]. It is possible that the effect of retrorsine on suppressing proliferation of mouse liver cells is limited in decreasing the chimerism rate. Therefore, retrorsine has no effect on mouse hepatocytes.

Abstract

AIM: To clarify the pathogenesis of ductular proliferation and its possible association with oval cell activation and hepatocyte regeneration.

METHODS: Immunohistochemical staining and image analysis of the ductular structures in the liver tissues from 11 patients with severe chronic hepatitis B and 2 healthy individuals were performed. The liver specimens were sectioned serially, and then cytokeratin 8 (CK8), CK19, OV6, proliferating cell nuclear antigens (PCNA), glutathione-S-transferase (GST), α-fetal protein (AFP) and albumin were stained immunohistochemically.

RESULTS: Typical and atypical types of ductular proliferation were observed in the portal tracts of the liver tissues in all 11 patients. The proliferating ductular cells were positive for CK8, CK19, OV6 and PCNA staining. Some atypical ductular cells displayed the morphological and immunohistochemical characteristics of hepatic oval cells. Some small hepatocyte-like cells were between hepatic oval cells and mature hepatocytes morphometrically and immunohistochemically.

CONCLUSION: The proliferating ductules in the liver of patients with severe chronic liver disease may have different origins. Some atypical ductular cells are actually activated hepatic oval cells. Atypical ductular proliferation is related to hepatocyte regeneration and small hepatocyte-like cells may be intermediate transient cells between hepatic oval cells and mature hepatocytes.

Key words: Ductular proliferation; Chronic hepatitis B; Hepatocyte regeneration

INTRODUCTION

Ductular proliferation is often used to describe the appearance of biliary epithelial cells in the portal tracts of diseased livers. The proliferating bile ductules are heterogeneous and are histologically classifiable into typical and atypical types[1]. Atypical and typical ductules have been reported in long-standing biliary diseases such as primary biliary cirrhosis, primary sclerosing cholangitis, extrahepatic biliary obstruction, etc[2-5]. Bile ductular proliferation is also the most commonly observed finding in patients with chronic hepatitis C[6,7]. According to our experience, however, such proliferating ductules are also frequently seen in patients with severe or end-stage chronic liver disease induced by hepatitis B virus (HBV). It is still not clear why these ductular structures are often increased in the liver tissue of such patients. One possibility is that the proliferating ductular cells are human counterparts of rat oval cells or these proliferating ductules may be engaged in hepatocyte regeneration[8-10].

To explore the pathogenesis of ductular proliferation and its possible association with hepatic oval cell activation in patients with severe chronic hepatitis B, we performed immunohistochemical staining and image analysis of the ductular structures in the liver tissues of such patients.

MATERIALS AND METHODS

Liver tissues

A total of 11 liver specimens were obtained from patients (9 male and 2 female) with severe chronic hepatitis B. The average age of the patients was 39.2 years, ranging from 22 to 54. The total serum bilirubin of all patients exceeded 171 μmol/L and the plasma thrombinogen activity of the patients decreased to 40% or less. Among the 11 patients, 10 were infected with HBV and 1 was superinfected with HBV and hepatitis D virus. All of the liver tissue specimens were obtained by needle puncture or by autopsy. For control purposes, archival normal liver tissue was obtained from 2 subjects who had no abnormal liver pathology and

Table 1 Average optical density of typical and atypical ductular cells for CK8, CK19 and OV6 staining

Cell Types	Fields	CK8	CK19	OV6
Typical	8	0.402 ± 0.083	0.902 ± 0.355	0.324 ± 0.121
Atypical	9	0.998 ± 0.238[b]	0.371 ± 0.105[b]	0.752 ± 0.210

[b]$P < 0.001$ *vs* typical

Table 2 Morphometric parameters of hepatic oval cells, hepatocyte-like cells and hepatocytes

Cell types	Cell numbers	At (μm^2)	D_{max} (μm)	D_{max}/D_{min} ratio
Hepatic oval cells	97	19.5 ± 5.9	12.4 ± 7.4	1.8 ± 0.5
Hepatocyte-like cells	42	32.1 ± 6.3[b]	18.9 ± 7.8[b]	1.2 ± 0.1
Hepatocytes	114	41.5 ± 2.3	24.7 ± 5.1	1.1 ± 0.1

[b]$P < 0.001$ *vs* hepatic oval cells and hepatocytes

no biochemical or serological evidence of liver disease. All 10 specimens were fixed in 10% neutral-buffer formalin and embedded in paraffin.

Histology and immunohistochemistry

Serial 4 μm thick sections were prepared and the sections were deparaffinized in xylene and rehydrated through graded alcohol. Part of the sections were stained with hematoxylin and eosin for histological diagnosis. The remaining sections were processed for immunohistochemical staining and a three-step indirect immunoperoxidase procedure was used. The sections were digested with protease (Sigma Chemical Co., St. Louis, MO) for 4 min at 37℃ or boiled in 10 mmol/L citrate buffer, pH6.0, in a microwave for two treatments of 2 min. Endogenous peroxidases were inactivated by immersing the sections in 3% hydrogen peroxide for 10 min. Sections to be used were incubated for 10 min with normal goat serum in Tris-buffered saline to block nonspecific binding. The sections were subsequently incubated overnight at 4℃ with the relevant antibodies. The following day, the sections were incubated with biotinylated anti-mouse IgG (Dako A/S, Glostrup, Denmark) for 45 min at 37℃. The sections were then incubated with peroxidase-conjugated streptavidin (Dako A/S, Glostrup, Denmark) for 45 min at 37℃. The chromogenic reaction was developed with diaminobenzidine and all of the sections were counterstained with hematoxylin. The monoclonal antibodies used were mouse-anti-human cytokeratin 8 (CK8) (Dako A/S, Glostrup, Denmark), CK19 (Serotec Ltd, UK), mouse-anti-human proliferating cell nuclear antigen (PCNA)(Zymed Laboratories, Inc., CA), mouse-anti-human α-fetal protein (AFP) (Zymed Laboratories, Inc., CA), mouse-anti-human glutathione-S-transferase (GST), mouse-anti-human albumin (Zymed Laboratories, Inc., CA) and mouse-anti-rat OV6 (a kind donation from Dr. D. Hixson, Brown University, USA).

Image analysis

Cell image analysis was performed on the liver tissue sections by Tiger® cell image analysis system (Center of Industrial Computer Tomography, Chongqing University, Chongqing, China) to determine total cell area (At), maximum diameter (D_{max}), minimum diameter (D_{min}), D_{max}/D_{min} ratio and average optical density of proliferating ductular structures.

Statistical analysis

Data were analyzed using the t test. $P<0.05$ was considered statistically significant.

RESULTS

Histopathological findings

Massive/submassive hepatocyte necrosis, lymphocyte infiltration, fibrous tissue hyperplasia and cholestasis were observed apparently in the liver tissues of all 11 patients. Hepatocyte proliferation foci and pseudolobules were seen in 6 and 4 patients respectively. In the portal tracts of all the liver specimens from the patients, obviously increased bile ductules were seen, some of which invaded into parenchyma. However, only 1 or 2 bile ductules were observed in the portal tracts of normal liver tissues. The proliferating ductules were also classifiable into typical and atypical types, but cell image analysis showed that the ductular cells from typical and atypical ductules had no significant difference in At, D_{max} and D_{max}/D_{min} ratio.

Immunohistochemical findings

Both types of proliferating ductular cells of patient group were positive for CK8, CK19, OV6 and PCNA staining. However, typical proliferating ductular cells showed strong staining for CK19 and weak staining for CK8 and OV6. In contrast, some atypical proliferating ductular cells showed strongly positive for CK8 and OV6 staining and weakly positive for CK19 staining. There was no significant difference between typical and atypical ductular cells for PCNA staining. In the normal liver tissue taken as control, ductular cells were positive only for CK19 staining. Image analysis demonstrated that typical and atypical ductular cells had significant difference in the intensity and extent of staining (Table 1).

Atypical ductular cells and hepatic oval cells

Morphometrically, the proliferating ductular cells were similar to hepatic oval cells, which were characterized by ovoid nuclei and scanty basophilic cytoplasm. Some atypical ductular cells expressed phenotypes of both ductular cells and fetal hepatocytes, including CK8, CK19, OV6, AFP and GST. These cells were consistent with hepatic oval cells morphologically and immunohistochemically.

Ductular proliferation and liver regeneration

The foci of hepatocyte proliferation were observed in the liver tissues of 6 patients. The regenerating hepatocytes were characterized by different size of cells, anisokaryosis and basophilic cytoplasm. Some hepatocyte-like cells surrounding the proliferative foci were between hepatic oval cells and mature hepatocytes in cell size and morphology (Table 2), and were positive for AFP, GST, OV6 and albumin, demonstrating the features of both hepatocytes and biliary epithelial cells.

DISCUSSION

Bile ductules connect bile canaliculi of periportal hepatocytes with interlobular bile ducts in portal tracts. The bile canaliculi, which form a complicated polyponal network with many anastomotic interconnections, drain into a relatively few bile ductules in periportal area. These bile ductules adjacent to bile canaliculi are the commencement of the biliary tree, and they are composed of ductular cells and hepatocytes. Some may show slight luminal dilatation where several bile canaliculi converge. In normal livers, only a few bile ductules are recognizable in a portal tract, while in various chronic hepatobiliary diseases these ductular structures are often increased. The pathogenesis and significance of this kind of ductular proliferation differ from disease to disease, but generally speaking, typical type of proliferating ductules originate from preexisting ductules and atypical type of proliferating ductules have more complicated origins and may be related to the activation of hepatic stem cells and the transformation of hepatocytes[11].

In ordinary circumstances, liver regeneration is usually achieved by the entry of normal, proliferatively quiescent, differentiated hepatocytes into the cell cycles, but, when hepatocyte regeneration is defective, bile ductular cells can migrate outwards from the portal tracts and then differentiate into hepatocytes. These biliary cells are called hepatic oval cells or oval cells, and their emergence when hepatocyte regeneration is impaired suggests they are the progeny of hepatic stem cells. End-stage chronic liver disease often develops from advanced chronic liver disease and is characterized by massive/submassive hepatocyte necrosis and severe liver failure. The mortality of severe chronic hepatitis B is very high. Our data showed that 72.5% (306/422) of such patients would die of the disease[12]. Theoretically, hepatic stem cells might be activated and proliferated in the liver of those patients. On one hand, massive/submassive necrosis of hepatocytes leads to a sharp decrease in the mass of hepatocytes, and thus the liver has a demand of regeneration. On the other hand, various toxins resulting from hepatocyte necrosis inhibit the proliferation and regeneration of residual hepatocytes. These conditions will activate hepatic stem cells and induce them to proliferate and differentiate toward hepatocytes. However, the above speculation has yet to be confirmed. Investigation of the nature of ductular proliferation will help to understand the mechanism of hepatocytes regeneration in the liver tissues of chronic hepatitis B patients.

Our results showed that two types of ductular proliferation, typical and atypical, existed in the liver of patients with severe chronic hepatitis B, and the phenotypes of the two types of ductular cells differed in some ways. The former were characterized by well-formed lumina and distinct cell borders and the latter characteristically had vague or no visible lumina and rather indistinct cell border. The typical ductular cells and ductules in normal liver were strongly positive for CK19 staining, suggesting that typical ductules originated from preexisting ductules. Some atypical ductular cells displayed the phenotypes of both biliary duct cells and hepatocytes and had the morphometric features of hepatic oval cells, suggesting that at least part of the atypical ductular cells originated from hepatic stem cells. It implied that some atypical ductular cells were actually activated hepatic oval cells. Our results also demonstrated that hepatocyte regeneration in the liver of patients with severe chronic liver disease was related to ductular proliferation. Firstly, some atypical ductular cells were actually activated hepatic oval cells, which could differentiate into hepatocytes ultimately. Secondly, there was histopathological and immunochemical evidence of hepatocyte regeneration in the liver of the patients. And thirdly, some regenerating small hepatocyte-like cells were between hepatic oval cells and mature hepatocytes morphometrically and immunohistochemically, suggesting that these cells were differentiated from hepatic oval cells and were the transient cell type from hepatic oval cells to mature hepatocytes. These findings are consistent with those of *Tan et al*[13]. It is believed that liver stem cells are a potential source of hepatocytes[14-16]. Although hepatic stem cells are activated and can differentiate into hepatic oval cells and transient hepatocyte-like cells ultimately, it is not clear why the diseased liver cannot be regenerated completely. We speculate that the toxins released from hepatocyte necrosis inhibit not only the proliferation and regeneration of residual hepatocytes but also the differentiation and evolution of hepatic oval cells toward hepatocytes.

In conclusion, the proliferating ductules in the liver of patients with severe chronic hepatitis B may have different origins. Some atypical ductular cells are actually activated hepatic oval cells. Atypical ductular proliferation is related to hepatocyte regeneration and small hepatocyte-like cells may be intermediate transient cells between hepatic oval cells and mature hepatocytes. However, why the diseased liver cannot be regenerated completely after hepatic stem cell activation remains to be investigated further.

Abstract

AIM: To explore the effects of interferon-α (IFN-α) application on peripheral circulating CD1α dendritic cells (DCs) in patients with chronic hepatitis B, and the expression of HLA-DR, CD80, and ICAM-1 on CD1α DCs in order to explore the mechanism of immune modulation of IFN-α.

METHODS: By flow cytometry technique, changes of CD1α DCs were monitored in 22 patients with chronic hepatitis B treated with IFN-α and in 16 such patients not treated with IFN-α within three months. Meanwhile, the expression of HLA-DR, CD80, and ICAM-1 on CD1α DCs was detected.

RESULTS: In the group of IFN-α treatment, the percentage of CD1α DCs in peripheral blood mononuclear cells was increased after three months of therapy. In patients who became negative for HBV-DNA after IFN-α treatment, the increase of DCs was more prominent, while in control, these changes were not observed. Increased expression of HLA-DR, CD80, and ICAM-1 on CD1α DCs was also observed.

CONCLUSION: CD1α DCs can be induced by IFN-α *in vivo*, and the immune related molecules such as HLA-DR, CD80, and ICAM-1 are up-regulated to some degree. This might be an important immune related mechanism of IFN-α treatment for chronic hepatitis B.

INTRODUCTION

Dendritic cells (DCs) play a key role in the process of immune response. They are involved in pathogenesis of tumor and virus infection, and show prospect in immunotherapy[1-3]. Recent studies suggest that DCs are involved in the development of chronic hepatitis B in some extent, and more attentions have been paid to the relation between DCs and hepatitis B[4,5]. Patients with chronic HBV infection have the defective function and immature phenotype of DCs, which may be associated with the inability of efficient presentation of HBV antigens to host immune system for the clearance of HBV[6]. How to increase the levels of DCs and improve their function is important in patients with chronic HBV infection. Patients in the immune active phase are candidates for antiviral therapy.

Interferon-α (IFN-α) is an important therapeutic agent in non-cirrhotic hepatitis patients with mild to moderate disease activity. The primary goal of therapy for chronic hepatitis B is suppression of viral replication, which has been shown to reduce hepatic necroinflammation and retard progression of hepatic fibrosis. Long-term suppression of serum HBV DNA is likely to reduce progression to cirrhosis and hepatic decompensation and may also decrease the risk of hepatocellular carcinoma, but the efficiency of IFN-α is not satisfactory, and further study on its mechanism in the treatment of chronic hepatitis B is necessary.

Many kinds of cytokines such as GM-CSF, IL-4 can induce DCs *in vitro*, and the expression of immune molecules can be up-regulated[7]. Some recent studies suggested that GM-CSF induce DCs *in vivo*[8]. It has been shown that IFN-α could exert the anti-tumour immune modulation action through inducing DCs *in vitro*[9], but the mechanisms of IFN-α to induce DCs *in vivo*, especially to affect immune molecules on the surface of DCs are unclear. CD1α is an important surface marker on DCs[7].

The aim of this study was to evaluate the immune modulation function of IFN-α on DCs besides the direct

Table 1 Effects of IFN-α on CD1 α DC in peripheral blood with chronic hepatitis B

Group	*n*	Percentage of CD1 α DC		*P*

anti-HBV action of IFN-α. The CD1 α DC and the expression of ICAM-1, HLA-DR, and CD80 on the cells were determined in the peripheral blood of patients with chronic hepatitis B. Whether DCs can be induced *in vivo* in patients with chronic hepatitis B treated with IFN-αwas investigated. Our study will shed new light on the mechanism of enhanced immune response by IFN-α.

MATERIALS AND METHODS

Subjects

Thirty-eight patients with chronic viral hepatitis B were randomly divided into IFN-α group ($n=22$, 16 males, 6 females, aged from 24-48 years, mean 34±6.67) and control group ($n=16$, 11 males, 5 females, aged from 25-45 years, mean 35±5.40). Patients were diagnosed with chronic hepatitis B according to the Programme of Prevention and Treatment for Viral Hepatitis revised by Chinese Society of Infectious Disease and Parasitology, Chinese Society of Hepatology, Chinese Medical Association in 2000. Those patients who were diagnosed with chronic hepatitis B were seropositive for HBV markers (HBsAg, HBeAg/anti-HBe, anti-HBc) for more than 6 months, characterized by an intermittent pattern of disease activity with elevations of alanine aminotransferase (ALT) values preceded, and in most instances, by an increase of HBV-DNA levels. The enrolled patients were diagnosed with chronic hepatitis B, in whom serum markers of HBV (HBsAg, HBeAg, HBcAb, HBV-DNA) were positive, ALT level between two and five times normal limit, total bilirubin below two times normal limit, who could bear treatment with IFN-α. Patients who were infected by other virus and diagnosed with autoimmune disease were excluded.

Treatment procedures and reagents

Patients in IFN-αgroup were treated with 5.0 million units IFN-α daily for 15 d and then every other day for an additional (85) d. The control group was not treated with IFN-α or any other anti-viral or immune modulation drug except routine therapy for protecting liver. Two milliliter blood each time was taken from the enrolled patients with informed consent pre- and post-therapy. The samples were sent for CD1 α DCs assay and the expression of the immune molecules on the cells. Fluorochrome-labeled antibodies were used for flow cytometric analysis such as anti-CD1α-PE, anti-CD80-FITC, anti-ICAM-1-FITC and anti-HLA-DR-FITC (Immunotech, Marseille, France).

Flow cytometric analysis of CD1αDC

CD1 α DCs of peripheral blood was analyzed by flow cytometry, and the expressions of ICAM-1, CD80, and HLA-DR was examined. The ratio of CD1 α DCs/peripheral blood mononuclear cells (PBMC) was counted. One hundred microliter peripheral blood with heparin was mixed with 10 μL homogenic antibody Ig-PE, then were hemolyzed by optilyse C, which served as negative control. One hundred microliter peripheral blood with heparin was mixed with 10 μL anti-CD1α-PE, then hemolyzed with optilyse C. After that, they were analyzed by flow cytometry. Lymphocyte or mononuclear cell subpopulations were distinguished by Forward Scatter (FSC) and Side Scatter (SSC). The percentage of CD1 α DCs in PBMC was investigated.

Analysis of ICAM-1, HLA-DR, and CD80 on surface of CD1αDC

The expression of immune associated molecules(ICAM-1, HLA-DR, CD80) on surface of CD1 α DC was evaluated by flow cytometry by analyzing the percentage in double-stained PBMCs. One hundred microliter peripheral blood with heparin was mixed with 10 ul homogenic antibody Ig-PE, then hemolyzed by formic acid, which served as negative control. One hundred microliter peripheral blood with heparin was hemolyzed by formic acid in each group, next mixed with 10 μL anti-CD1α-PE, and then blended respectively with anti-ICAM-1-FITC, anti-HLA-DR-FITC, and anti-CD80- FITC. Lymphocyte or mononuclear cell subpopulations were distinguished by FSC and SSC. The percentage of $CD1\alpha^+$ $ICAM\text{-}1^+$, $CD1\alpha^+$ $CD80^+$ or $CD1\alpha^+$ HLA-DR in PBMCs was investigated.

Statistical analysis

The results were expressed as mean ± SD and analyzed using the Student's *t* test. $P<0.05$ was taken as statistically significant.

RESULTS

CD1αDC in peripheral blood with chronic hepatitis B and effect of IFN-αon DCs

The results showed that CD1 α DCs existed in peripheral blood of patients with active chronic hepatitis B, and most of them was less than 1% of PBMCs. In IFN-αgroup, after treatment for three months, the percentage of CD1αDCs in PBMC in some patients was increased. There were significant differences between pre- and post-therapy with IFN-α ($P<0.05$). In control group, the percentage of CD1 α DCs pre-therapy was close to that post-therapy ($p>0.05$).In IFN-αgroup, the percentage of CD1 α DCs in the group with decreased HBV-DNA was more than that in the group with HBV-DNA not decreased ($p<0.05$) (Table 1).

Effects of IFN-α on the expression of ICAM-1,HLA-DR,and CD-80 on surface of CD1αDC

It showed that ICAM-1, HLA-DR, and CD-80 on surface of CD1 α DC in peripheral blood of patients with active chronic hepatitis B also existed to some extent. Among them, the expression of ICAM-1, HLA-DR was stronger than that of CD80. After treatment with IFN-α for three months, the expression of ICAM-1, HLA-DR, and CD80

on surface of CD1 α DC was increased to some extent. In IFN-α group, the percentage of ICAM-1, CD80, and HLA-DR on CD1αin peripheral blood after treatment with IFN-α for three months was more than that before treatment. There were significant differences between pre- and post-therapy with IFN-α ($P<0.05$). In control group, there were no significant differences between pre- and post-therapy ($P>0.05$) (Table 2).

DISCUSSION

Currently, IFN-α is frequently chosen in treatment of chronic hepatitis B[10], but only 30%-40% of treated patients show response to it. How to improve the efficacy of IFN-α is a challenge. IFN-α is involved in immune modulation besides direct anti-HBV effect. The defect in specific T cell immunity, especially HBV-specific cytotoxic T lymphocyte (CTL) dysfunction has long been assumed to be a central mechanism for hepatitis B virus persistent infection. The cause that effective specific T cell immunity is not induced in patients with chronic hepatitis B is not completely clear. DCs are the most potent antigen-presenting cells that initiate protective T-cell immunity. Recent studies in transgenic mice have suggested, however, that functional deficit of DCs is an underlying cause for T cell dysfunction. Studies showed that HBsAg presentation by cytokine-activated DCs can break tolerance and trigger an anti-viral CTL response in HBV transgenic mice[11-12].In chronic hepatitis B, DCs are present to some degree in peripheral blood and in the liver tissue and might be involved in the immunopathogenesis of chronic liver diseases[13-15]. The current results showed that CD1 α DCs existed in peripheral blood in patients with active chronic hepatitis B, and most of them was less than 1% of PBMC. Whether the immune function of these DCs is effective in patients with chronic hepatitis B needs to be studied.

In literature, the reports on whether IFN-α is involved in immune modulation through DCs in treatment of chronic hepatitis B are few. DCs are most powerful to induce immune response among antigen presenting cells *in vivo*[16]. In recent years, more attentions have been paid to the relation between DCs and hepatitis B. DCs sensitized with HBsAg *in vitro* enhanced the proliferation response of T cell from chronic hepatitis B patients, and successfully induced MHC-I restricted HBV-specific CTLs in mice[4]. These suggest that DCs have powerful ability to present HBsAg. HBV-specific CTLs could be induced in HBV transgenic mice treated with sensitized DCs, therefore,the immune tolerance state of HBV transgenic mice would be broken[11]. It was reported that degree of activation of DC following vaccination would possibly help to predict the outcome of vaccine therapy in HBV carriers[17,18]. All above suggest that DCs play a role in inducing effective immune response to HBV.

However, recent studies have suggested that functional deficit of DCs is an underlying cause for T cell dysfunction. In hepatitis B, not only the numbers of DC subsets were decreased, but also the function of these DCs was impaired in peripheral blood[19-24]. DCs in liver from murine hepatitis B carriers also showed impaired functional capacities[25]. Therefore, to increase the number of and improve the function of DCs is important in patients with chronic HBV infection. DCs could be induced by many kinds of cytokines such as GM-CSF, IL-4 *in vitro*, and the expression of immune costimulatory molecules can be also up-regulated[7,9]. Most of studies on DCs in hepatitis B were done through incubation of PBMCs *in vitro*. In the process, some cytokines were added in order that DCs were induced. So the results observed *in vitro* could not reflect truly the condition of DCs *in vivo*. Whether DCs can be induced *in vivo* in patients with chronic hepatitis B treated with IFN-α was investigated in the current study in an effort to explore the mechanism of enhanced immune response through DCs of IFN-α treatment. In order to observe the changes of peripheral circulating CD1α+DCs and the expression of ICAM-1, HLA-DR, and CD80 on CD1 α DCs *in vivo* by IFN-α application, flow cytometry technique was employed to detect directly CD1α+DCs.

In our study, the effects of IFN-α on CD1α+DCs were investigated. The results showed IFN-α could up-regulate the percentage of CD1α+ DCs in PBMCs besides its direct anti-HBV action. Our findings that the number of CD1α+DCs rose in peripheral blood of patients treated with IFN-α suggested that IFN-α can induce DCs *in vivo*. Previous studies argued that DCs were lack in patients with chronic hepatitis B, and that immune activity was weak. IFN-α could enhance specific immune response to HBV through inducing DCs *in vivo*, consequently, facilitating antigen presentation of HBV and specific T cell triggering.

Previous studies suggested that DCs from patients with chronic hepatitis B showed significantly lower expression of costimulatory molecules B7-1 (CD80), B7-2 (CD86) and impaired allostimulatory mixed lymphocyte reaction, as well as decreased number compared with normal group[3,18]. It indicates that the immune response to HBV is enhanced by up-regulating the immune associated molecules on DCs in patients with chronic hepatitis B. Recent studies showed that IFN-α had similar action *in vitro*. IFN-α is partially involved in immune modulation by inducing DCs *in vitro*[9]. In our study, the expression

of ICAM-1, HLA-DR, and CD80 on surface of $CD1\alpha^+$ DCs differently increased in IFN-α group, but there was no significant change in control group. It suggests that IFN-α played some role in up-regulating the expression of ICAM-1, HLA-DR, and CD80. Many immune molecules are involved in triggering T lymphocyte cells by DCs, especially MHC-II, B7-1 (CD80), B7-2 (CD86), ICAM-1, LFA-3, etc. MHC molecules combined with antigen peptides provide first signal for the activation of T lymphocyte cells. The costimulatory molecules (B7-1, B7-2) are important to trigger T lymphocyte cells. The lowered expression of those immune molecules impaires DCs to trigger T lymphocyte cells. During the treatment of IFN-α for patients with chronic hepatitis B, the ability of DCs presenting HBV antigen was differently improved. Our results suggest that IFN-α improves the presenting ability of DCs to some degree, and strengthens the interaction of DCs and T lymphocyte cells through up-regulating the expression of ICAM-1, HLA-DR, and CD80. IFN-α up-regulating the expression of immune molecules on DCs might be an important mechanism of immune modulation in anti-HBV treatment for patients with chronic hepatitis B.

However, the correlation between the efficacy of IFN-α and DCs is still unclear. Although in patients with chronic hepatitis B, peripheral circulating DCs and their expression of ICAM-1, HLA-DR, CD80 are increased by IFN-αapplication, only a minority of treated patients show response to IFN-α. It indicates that the effects of anti-HBV treatment of IFN-α are affected by many other factors[26,27], for example, CD80-B7 interaction promotes immune response, and CD80-CTLA4 interaction down-regulates the response. The function of DC might be affected by these factors, as well[28,29].

Abstract

AIM: To develop a highly efficacious method for preparation of soluble SARS S-protein using adenovirus vector to meet the requirement for S-protein investigation.

METHODS: The human adenovirus vector was used to express the soluble S-protein (corresponding to 1~1190 amino acids) fused with Myc/His tag using codon-optimized gene construct in HEK239 cells. The recombinant adenovirus bearing S-protein gene was generated by ligation method. The expressed S-protein with Myc/His tag was purified from culture medium with Ni-NTA agarose beads followed by dialysis. The S-protein was detected by Western blot and its biologic activity was analyzed by binding to Vero cells.

RESULTS: Under the conditions of infection dose (MOI of 50) and expression time (48 h), the high-level expression of S-protein was obtained. The expression level was determined to be approximately 75 μg/10^6 cells after purification. Purified soluble S-protein was readily detected by Western blot with anti-Myc antibody and showed the ability to bind to surface of Vero cells, demonstrating that the soluble S-protein could remain the biologic activity in the native molecule.

CONCLUSION: The high-level expression of S-protein in HEK293 cells mediated by adenovirus can be achieved under the optimized expression conditions. The proteins possess the biologic activity, which lays a foundation for further investigation of S-protein biological function.

INTRODUCTION

Severe acute respiratory syndrome (SARS) is a life-threatening disease. The etiological agent of SARS has been identified as a novel coronavirus, called SARS coronavirus (SARS-CoV)[1-3]. SARS-CoV is a positive-strand RNA virus encoding several structural proteins including spike (S) glycoprotein, nucleocapsid protein (N), membrane protein (M) and envelope protein (E)[4, 5]. S-protein, a 1255 amino-acid type I membrane glycoprotein, is the prominent protein present in viral membrane and consists of a signal peptide sequence (amino acids 1 to 13), an extracellular domain (amino acid 14 to 1190), a transmembrane domain (amino acids 1191 to 1227) and a short intracellular tail (amino acids 1228 to 1255). S-protein plays an important role in SARS coronavirus infection by interaction with cellular receptor, angiotensin-converting enzyme 2 (ACE2) on the host cells[6-8]. S-protein also has efficient antigenicity and could induce neutralization antibodies[9-12]. These characteristics make it a potential candidate for subunit vaccine and anti-SARS drug development and diagnostic application. Large-scale preparation of S protein is desirable for S protein investigation, such as protein-protein interaction, S protein-based vaccination and diagnostic approach. In order to obtain sufficient quantities of S-protein, we used human adenovirus vector to construct the recombinant adenovirus bearing SARS soluble S-protein gene and express it in human embryonic kidney 293 cells (HEK293 cells).

MATERIALS AND METHODS

Materials

HEK293, HEK293T and Vero African green monkey kidney cells were purchased from American Type Culture Collection (ATCC); Manassas VA. HEK293 cells were cultured in Dulbecco's modified Eagle's medium (DMEM) supplemented with 10% (v/v) fetal bovine serum, 100 u/mL penicillin, 100 μg/mL streptomycin, 2mM L-glutamine and 1×MEM non-essential amino acid solution (DMEM

complete medium) at 37℃ and 50 mL/L CO_2. Vero cells were cultured in medium 199 supplemented with the same components as above except for 1×MEM non-essential amino acid solution (medium-199 complete medium). Adenovirus vectors (pShuttle2 and Adeno-X DNA) based on human adenovirus type 5 (Ad5) were purchased from BD Sciences Clontech (Palo Alto, CA). QuikChange® XL site-directed mutagenesis kit was obtained from Stratagene (La Jolla, CA). Restriction enzymes and T4 DNA ligase were obtained from Promega (Madison, WI).

Plasmid constructions

The full-length codon-optimized SARS-CoV S-protein cDNA, cloned into *Xba*I/*Bam*HI sites in the pcDNA3.1 (-) expression vector, was kindly provided by Dr. Mecheal Farzan (Brigham and Women's Hospital, Harvard University, Boston, USA) [6]. The vector was modified to express soluble SARS S-protein fused with Myc/His tag at C-terminus. Briefly, a *Eco*RI site was introduced in S-protein DNA between extracellular and transmembrane domains (corresponding to residues K1193 and W1194) using QuikChange® XL site-directed mutagenesis kit and the following primers: 5'gtacgagcagtacatcgaattcccttggtatgtg tggctg3' and 5' cagccacacataccaagggaattcgatgtaatgctcgtac3'. The EcoRI-mutated expression vector was then digested with EcoRI and BamHI. The DNA fragment encoding Myc/His with additional EcoRI and BamHI sticky ends at 5' and 3' terminuses was generated by annealing the following primers: 5'aattcgaacaaaaactcatctcagaagaggatctg (myc)accggtcatcatcaccatcaccat(6His) tga(stop codon)g3' / 5'gatcctca(stop codon)atggtgacggtgatgatg(6His)accggtc agatcctc ttctgagatgagtttttgttc(myc)g3'. Then the Myc/His fragment was inserted into the *Eco*RI and *Bam*HI sites of *Eco*RI-mutated vector to generate pcDNA3.1-S/MH containing the soluble S-protein fused with Myc/His gene.

In order to conveniently subclone fused soluble S-protein gene into adenoviral shuttle vector, the multiple cloning sites (MCS) of pShuttle2 were modified with a new MCS sequence. Briefly, the new MCS sequence was amplified by PCR method with a pair of primers: 5'tttggctagcggtaccgcggccgcgggatccaagatatcgggc3' and 5'tttcccgggttcgaatctagagggcccgatatcttggatc3' under the conditions of 94 ℃ for 5 min, 50 ℃ for 1 min and 72 ℃ for 10 min. The amplified 65 bp PCR product (the new MCS sequence) was digested with *Sma*I (blunt end) and *Nhe*I, respectively. The digested products were purified with GFX™ PCR DNA and gel band purification kit (Amersham). The pShuttle2 plasmid was first digested with *Kpn*I, after filled using *Klenow* DNA polymerase to generate blunt end, the linearized plasmid was then digested with *Nhe*I. Finally, the new MCS was inserted into NheI and blunt sites of the pShuttle2 to generate pShuttle3 vector.

The fused soluble S-protein gene in pcDNA3.1-S/MH was cut out with *Xba*I and *Bam*HI and downstream cytomegalovirus immediate early (CMV) promoter of pShuttle3 was subcloned using *Nhe*I and *Bam*HI sites to produce pShuttle3-S/MH.

Construction of recombinant adenoviral plasmid

Recombinant adenovirus vector expressing fused soluble S-protein gene downstream of CMV promoter was constructed using the Adeno-X™ expression system (BD Sciences Clontech), following the manufacturer's instructions by the ligation method (Mizuguchi & Kay 1998)[13]. Briefly, the pShuttle3-S/MH was digested with PI-*Sce*I and I-*Ceu*I to release the expression cassette including the promoter, fused soluble S-protein gene and the SV40 polyadenylation signal (SV40 poly A). This DNA fragment was subsequently ligated to the pAdeno-X DNA (provided with kit) to generate pAdeno-S/MH. After ligation it was digested with *Swa*I restriction enzyme to eliminate non-recombinant plasmids and used to transform *E. coli* DH5α competent cells, clones bearing ampicillin resistance were selected. Positive recombinant plasmids were identified by screening plasmids with *Xho*I digestion.

Generation and identification of recombinant adenovirus

Approximately 1-2×10^6 HEK293 cells were plated in T25 flasks 24h before transfection when they reached 60-80% confluence. About 3 μg of pAdeno-S/MH, digested with *Pac*I, was transfected into HEK293 cells using Lipofectamine 2000 reagent (Invitrogen) according to the manufacturer's instructions. The transfected HEK293 cells were cultured in DMEM complete medium at 37 ℃ and 50mL/L CO_2. After two days the medium was changed to maintaining medium (containing 5% serum). After about two-week maintaining culture, the cytopathic effect (CPE) appeared in the monolayer of HEK293 cells. The cells was harvasted and viral DNA was prepared with Hirt method[14]. The recombinant adenovirus carrying S-protein gene (Ad-S/MH) was identified with PCR method using a pair of primers: 5'agcaacttccgcgtg3'/5'ggtgttgcggtcctg3' (corresponding to Ser_{301} to Thr_{760} residues) and the viral DNA as template. The viral titer was determined by plague assay in HEK 293 cells.

S-protein purification and identification

Eighty percent confluent HEK 293 cells in 4×T75 flasks were infected with 3 mL harvested medium from the initial recombinant adenovirus lysates (~10 MOI) in 20 mL culture medium. One day later, the medium was replaced with serum-free medium (Opti-MEM, 50μg/mL BSA, L-glutamine and antibiotics). After 48h, the medium containing S-protein was harvested and centrifuged at 8 000 r/min for 10 min. The supernatant was mixed with Ni-NTA-agrose beads and 1×binding buffer (20 mmol/L Tris, 150 mmol/L NaCl, 5 mmol/L imidazole, pH 8.0), incubated at 4 ℃ overnight with shaking, and then precipitated. The beads were washed with washing buffer (20 mmol/L Tris, 500 mmol/L NaCl, 10 mmol/L imidazole, pH 8.0). Bound S-protein was eluted with elutting buffer (20 mmol/L Tris, 500 mmol/L NaCl, 250 mmol/L imidazole, pH 8.0).

The eluted samples were subjected to sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) on 7.5% (w/v) gels. The separated proteins were either stained with silver staining method or electro-blotted and detected by Western-blotting using a mouse anti-His antibody followed by a goat anti-mouse IgG conjugated with alkaline phosphatase. The blots were developed using the Immun-Star™ substrate pack (Bio-Rad).

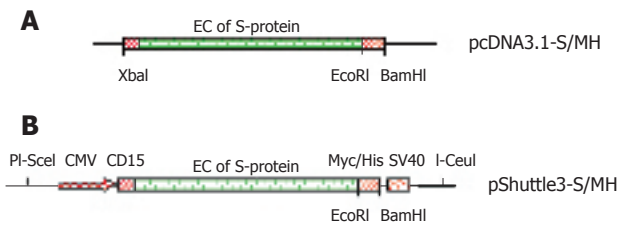

Figure 1 Construct of codon-optimized SARS S-protein genes. The full-length of SARS codon-optimized S-protein gene was modified by inserting Myc/His gene immediately downstream extracellular domain of S-protein gene to generate pcDNA3.1-S/MH (**A**) and the S-protein fused with Myc/His gene was transferred into pShuttle3 vector to produce pShuttle3-S/MH vector (**B**).

The eluted protein was dialysed against PBS (pH 8.0) to elimminate imidazole. The protein concentrations were determined using the Bio-Rad (CA, USA) protein assay kit developed based on the method of Bradford (Bradford, 1976) [15].

S-protein binding to the cell surface

The Vero and HEK293T cells were detached from flask walls with 0.5mM EDTA in PBS, washed and re-suspended in PBS containing 0.5% (w/v) BSA (PBS-BSA) at ~4×10^7 cells/mL. Each cell sample (50 μL) was incubated with 2 μg of S-protein for 3 h at 4℃ with rotation. The cells were washed with PBS-BSA and incubated in 20% (v/v) goat serum in PBS-BSA for 30 min on ice. After washing with cold PBS-BSA, the cells were incubated with a mouse anti-myc antibody (Roche, Indianapolis, OIN) at 10 μg/mL for 30 min on ice. As a control, the cells were not incubated with S-protein. After washing with PBS-BSA, the cells were incubated with goat anti-mouse IgG conjugated with PRE for 40 min on ice, were washed and fixed in 1% (w/v) paraformaldehyde and analyzed by a FACScalibur flow cytometer (BD Biosciences).

RESULTS

Construction of pAdeno--S/MH recombinant adenovirus plasmid

SARS-CoV S-protein, like other coronaviruses, is the prominent surface protein existed in viral lipid envelope, which mediates virus interaction with host cells leading to infection. To investigate the S-protein-mediated interaction between virus and host, soluble S-protein was needed for the investigations.

In order to express the codon-optimized soluble S-protein fused with Myc/His tag using adenovirus vector, the transmembrane and C-terminal domain of full-length S-protein gene were deleted by creating *Eco*RI site immediately downstream the extracellular domain and then the DNA fragment encoding Myc/His with stop codon was inserted into *Eco*RI and *Bam*HI sites of the *Eco*RI-mutated vector to generate pcDNA3.1-S/MH (Figure 1A). The pShuttle3-S/MH (Figure 1B) was constructed by transferring soluble S-protein gene fused with Myc/His tag from pcDNA3.1-S/MH into adenoviral pShuttle3 vector derived from pShuttle2 by modification on MCS. The fusion of Myc/His tag to S-protein could facilitate purification and detection of expressed S-protein.

The entire expression cassette of S-protein, which in pShuttle3-S/MH (Figure 1B) is flanked by unique PI-*Sce*I and I-*Ceu*I sites, was released using these enzymes and ligated into the pAdeno-X DNA vector. The new vector contained a different resistance marker (ampicillin) from pShuttle3-S/MH (kanamycin), preventing pShuttle3-S/MH recovery. The candidate clones were screened by digesting the recombinant plasmids using *Xho*I enzyme. Three positive pAdeno--S/MH plasmids were constructed.

Obtaining Ad-S/MH adenovirus in HEK293 cells

The plasmid pAdeno-S/MH containing two *Pac*I restriction sites, was located in both ends of the viral genome, 3' and 5' of the inverted terminal repeats (ITRs). Thus, to ensure efficient replication and packaging of recombinant adenovirus carrying S-protein gene (Ad-S/MH), the plasmid was digested with *Pac*I and used to transfect HEK293 cells. After 15 d plaques appeard and then a large number of cells were detached from the flask, indicating the presence of adenovirus. To confirm the presence of the S-protein gene in recombinant adenovirus, the viral DNA was extracted and identified by PCR using the viral DNA as template. The specific DNA fragment (1 370 bp) was amplified from recombinant adenoviral DNA .

Expression of soluble SARS-CoV S-protein

Using Ad-S/MH adenoviruses to infect HEK 293 cells cultured in serum-free medium, the medium was harvested. The S-protein was purified using Ni-NTA agarose columns binding to the C-terminal His tag at 4 ℃. Fractions of eluted proteins were analyzed by SDS-PAGE under reducing conditions and identified either by silver staining and assignment using a molecular marker (Figure 2A) or Western-blotting using anti-Myc antibody detection (Figure 2B). The analysis revealed that the size of the purified S-protein under reducing conditions was consistent with previous studies[6,16]. However, it was much larger than the calculated molecular weight of ~132ku (1199 residues: 1181 residues of extracellular domain and 18 residues of myc/His tag (EQKLISEEDLTGHHHHHH)). This difference was considered to be related to glycosylation[16] since the extracellular domain of S-protein was predicted to have 18 potential N-link glycosylation sites, contributing to the observed such bigger molecular weight of S-protein.

Tunicamycin, an inhibitor of N-linked glycosylation, was used to treat the cells (7μg/mL) when they were infected with Ad-S/MH adenoviruses. S-protein secretion from the cells into the media was effectively blocked in the presence of tunicamycin, S-protein could not be detected by Western blotting from the culture media. In contract, without tunicamycin, S-protein could be detected from the media. However, when the cell lysate was detected by Western blotting, S-protein was detected from tunicamycin-treated cells as a size of 130 ku, smaller than the size of ~200 ku detected from non-tunicamycin-treated cells (Figure 3). This indicated that the low molecular weight of S-protein in tunicamycin-treated cells was due to lack of N-liked glycosylation, interfering with S-protein maturation and secretion.

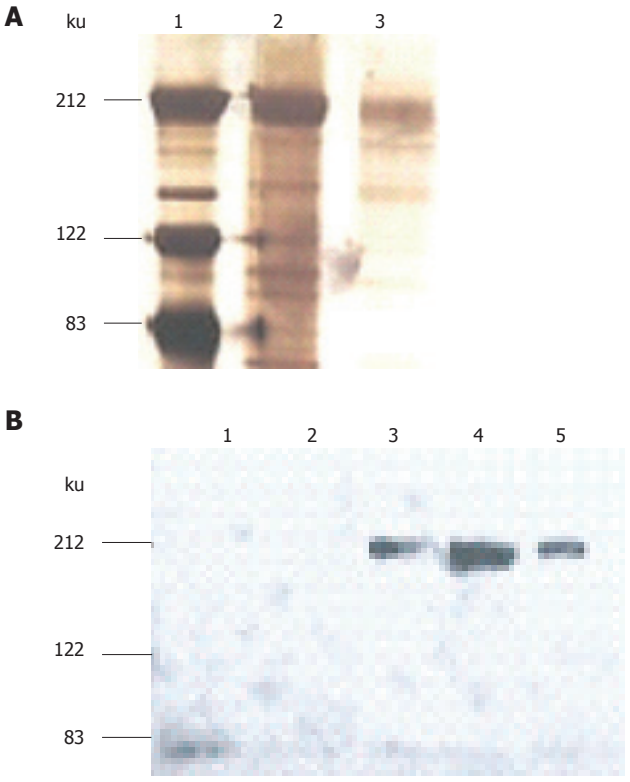

Figure 2 Expression and purification of fused S-protein soluble. S-protein fused with Myc/His was expressed in HEK293 cells mediated by adenovirus and purified on Ni-NTA-agarose column and eluted with imidazole at 6 fractions. The eluted proteins were separated by 7% SDS-PAGE gels and identified by both silver staining (**A**) for elutions 4, 5 and Western-blotting using anti-Myc antibody (**B**) for elutions 1-5.

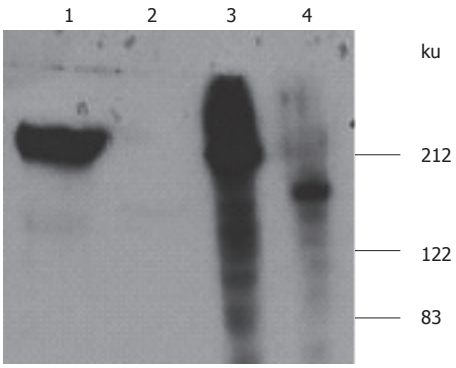

Figure 3 Effects of tunicamycin on expression of S-protein. HEK293 cells were infected with Ad-S/MS virus for 48h in the presence or absence of tunicamycin (7μg/mL). The media were mixed with Ni-NTA-agarose beads and bound protein was eluted with imidazole elution buffer. The pelleted cells were lysed. After centrifugation, the supernatant with eluted protein from the media was separated on SDS-PAGE gels (7%, v/v). Separated proteins were detected by Western blotting using anti-Myc antibody.

To determine the optimal dose (M.O.I.) of adenovirus for cell infection and optimal time for harvesting the culture media for S-protein purification, the HEK293 cells were prepared at the same confluence (about 70%) and infected with different doses of Ad-S/MH viruses and the culture media were harvested at different time points. The purified S-protein levels were evaluated with Bio-Rad protein assay kit. The high-level S-protein (above 75μg/10^6 cells) was obtained using an MOI of 10-100 at 72 h, or

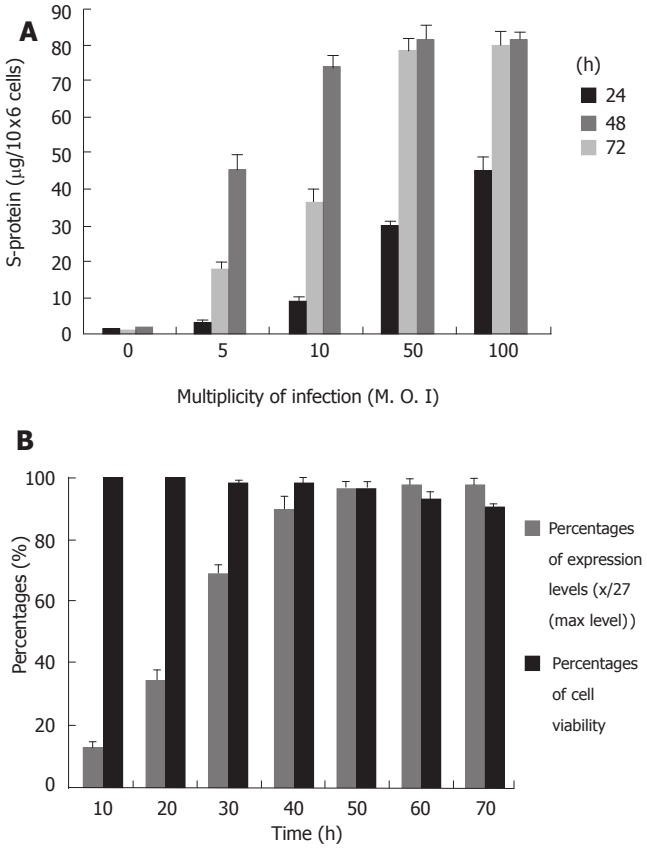

Figure 4 Analysis of expression conditions. **A:** HEK293 cells were infected with Ad-S/MH viruses at different MOI of 5-100. The culture media were harvested at 24, 48 and 72 h after infection. **B:** Cells were infected with same viruses at MOI of 50. The media were harvested at 10, 20, 30, 40, 50, 60 and 70h after infection. The expressed protein was purified with Ni-NTA-agarose and measured with protein assay kit. The dada of expression levels were the mean of three separate experiments.

50-100 at 48 h after infection (Figure 4A). On the basis of these results, we chose an MOI of 50 for viral infection and 48 h for expression time as the suitable conditions because these conditions led to high-level expression and low time-consuming. To confirm these conditions, time-course of expression and cell viabilities were carried out with MOI of 50 for infection. The high expression levels (above 75 μg/10^6 cells) and high cell viabilities (above 96%) were obtained using MOI of 50 between 40 h and 50 h periods (Figure 4B). We repeated three expressions and purifications under these conditions. The average yield of purified S-protein was approximately 75 μg/10^6 cells.

Biological analysis of S-protein

ACE2 of host cells was reported to be a functional receptor for SARS-CoV[6]. S-protein interaction with ACE2 was reported to be related to S-protein extracellular domain, in which amino acids 270 to 510 were identified to be essential for the interaction[17,18]. Vero cells, but not 293T cells could permit replication of SARS-CoV since the receptor ACE2 could be expressed on Vero but not 293T cells[6]. To determine whether the expressed S-protein had the biological activity to bind to Vero cells, Vero cells and 293T cells (as a negative control) were incubated with the purified S-protein and bound S-protein was detected by flow

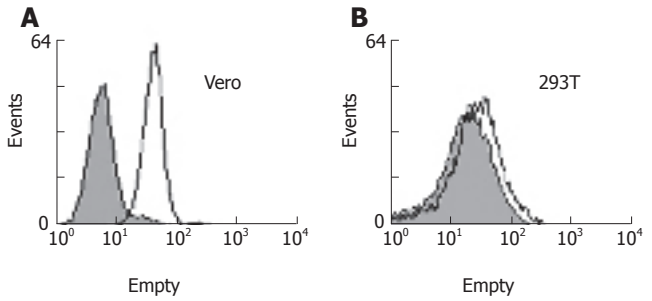

Figure 5 Binding of S-protein to Vero and 293T cells. Vero and 293T cells were detached from culture flask with 0.5 mmol/L EDTA/ PBS, washed and incubated with purified S-protein in 0.5% BSA/ PBS. Binding was measured by flow cytometry using anti-Myc antibody and goat anti-mouse IgG antibody conjugated with RPE (open profiles). As control (filled profiles), the cells were not incubated with S-protein but stained with the same antibodies.

cytometry using a mouse anti-Myc antibody. Binding assay showed that the purified S-protein could bind to Vero cells (Figure 5A) but not 293T cells (Figure 5B). These results demonstrated that the purified S-protein here had the biological activity.

DISCUSSION

Using codon-optimized gene constructs to express the corresponding protein in host cells is a common strategy for increasing expression levels. It was reported that codon-optimized construct can express S-protein in mammalian cells and a reasonably high-level expression is obtained[11,17]. In this paper, we used adenovirus vector to express S-protein with codon-optimized gene and very high-level expression was observed in HEK293 cells. However, we did not successfully express S-protein in 293T cells with wild-type gene construct at a detectable level since the majority of wild-type S-protein codons were deviated from main codons of humans or animals.

Another strategy to increase expression level of S-protein with wild-type S-protein gene in mammalian cells is co-infection of vaccine virus expressing T7 polymerase[16] which facilitates the corresponding mRNA synthesis in cells when the gene clones downstream T7 promoter of the eukaryotic expression vector.

Studies have been conducted to express full-length or truncated S-protein genes in prokaryotic cells[19] and eukaryotic cells[6,16]. Expression of S-protein in *E. coli* leads to the accumulation of recombinant protein in inclusion bodies which requires solubilization followed by *in vitro* refolding. Moreover, the expressed S-proteins tend to lose some biological activities because the proteins are not modified by glycosylation which involves protein-protein interactions and receptor binding. Mammalian cells are widely used to prepare S-protein for the investigation of S-protein interaction with receptors. Although the expressed S-protein is glycosylated and functionally active using mammalian expression system, the expression level of S-protein is relatively lower than expected and the procedure involved in the expression and purification is relatively time consuming and labor intensive. We report here an adenovirus-mediated expression system for SARS S-protein. Once the recombinant adenovirus is made, the high yields of S-protein expression can be obtained in a shorter time period, thus making the procedure more time- and cost-effective.

Many adenovirus expression systems are commercially available and can be used to exploit the different strategies to construct recombinant adenoviruses. The Adeno-X^{TM} expression system we used in this paper could exploit the ligation method to construct recombinant adenovirus, which makes the recombination more efficient. The new MCS sequence of pShuttle vector modified in this paper makes it more flexible for cloning.

Since the replication-deficient recombinant adenovirus grows and propagates extremely fast in HEK293 cells, the conditions for S-protein expression in these cells should be accurately controlled and optimized. In general, the high-titer virus used and the long expression time maintained result in a high level of expression. Nevertheless, exposure of the cells to the high-titer adenovirus for a long time lends to decrease cell viability, in which intracellular components of the dead cells are released into media, interfering with the following S-protein purification.

ACKNOWLEDGMENTS

The authors thank Dr. Lu Jinhua (National University of Singapore Medical School) for thoughtful scientific discussion and support pertaining to this work as well as Dr. Micheal Farzan (Brigham and Women's Hospital, Harvard University) for kindly providing the codon-optimized S-protein gene sequence.

Abstract

AIM: To investigate the prognostic factors of 96 young patients with colon cancer within a cancer center by univariate and multivariate analysis.

METHODS: A total of 723 patients with colon cancer were treated surgically during a period of 10 years. Ninty six of them were 40 years old or younger. R0, R1 and R2 operations were performed in 69 (71.9%), 4 (4.1%) and 23 patients (24%), respectively. Left hemicolectomy was performed in 43 patients, right hemicolectomy in 37 patients, transverse colon resection in 9 patients and low anterior resection in 7 patients. Cox multivariate regression analysis was performed to identify predictors of survival.

RESULTS: The operation mortality was 0%, 54 patients died within 111 mo after operation due to occurrence or metastases of the tumor. Liver, lung and bone metastases occurred in 3, 1 and 5 patients, respectively. The mean survival time for all patients was 77.9 ± 5.01 mo and the overall 3-, 5- and 10- year survival rates were 66.68%，58.14% and 46.54%, respectively. In the univariate survival analysis, patient age，type of operation, radical resection, blood transfusion, histological type, diameter of tumor, depth of tumor invasion, lymphatic invasion, distant metastases, liver metastases and TNM stage were found to be predictors of survival in young patients with colon cancer. In the Cox-regression analysis, blood transfusion and lymphatic invasion were determined as independent prognostic factors of survival.

CONCLUSIONS: Age, type of operation, radical resection, blood transfusion, histological type, diameter of tumor, depth of tumor invasion, lymphatic invasion, distant metastasis and TNM stage are the predictors of survival in young patients with colon cancer after surgery.

INTRODUCTION

Colorectal cancer is one of the most common malignancies and nearly 600 000 cases are diagnosed annually worldwide [1]. Advances in the management of colon cancer over the past decades have resulted in improvement of the prognosis of this disease. The proportion of early stage (stages I and II) patients has increased from 39.6% to 56.6%, with a corresponding decrease in the proportion of patients with advanced stages, leading to an improvement in five-year relative survival from 33.0% in 1970s to 55.3% in 1990s [2]. The 5-year survival rate is around 60% [3].

Most of the patients with colon cancer are middle-aged or older and the peak of morbidity is around 65 years of age [2]. However, young patients are not rare and the incidence of colon cancer in young patients has increased gradually in recent years. We therefore analyzed retrospectively the clinical and pathological characteristics of a large cohort of colon cancer patients (40 years old or younger) treated in a cancer center over a 10-year period to investigate the prognostic factors.

MATERIALS AND METHODS

Patients

A total of 723 patients with colon cancer were treated between January 1991 and January 2000. All the patients were surgically treated, diagnosed pathologically and included in follow-up procedure. Ninety-six (13.3%) were 40 years old or younger. The cancer was found in the ileocecal junction of 23 patients, in ascending colon of 19 patients, in hepatic flexure of 7 patients, in transverse colon of 11 patients, in splenic flexure of 4 patients, in descending colon

AST: average survival time; 3-YSR: 3-year survival rate; 5-YSR: 5-year survival rate; 10-YSR: 10-year survival rate; LHC: left hemicolectomy; RHC: right hemicolectomy; TCR: transverse colon resection; WDAC: well-differentiated adenocarcinoma; MDAC: moderately-differentiated adenocarcinoma; PDAC: poorly-differentiated adenocarcinoma; PAC: papillary adenocarcinoma; MAC: mucinous adenocarcinoma; SRCC: signet-ring cell carcinoma

of 6 patients and in sigmoid colon of 26 patients. Stage III or IV disease was found in 54.2% of the patients, lymph node metastasis occurred in 53% of the patients, poorly-differentiated mucinous adenocarcinoma and/or signet-ring cell carcinoma were found in 48 patients (Table 1).

Treatment methods

All patients received surgical treatment. Right hemicolectomy was performed in 37 patients, left hemicolectomy in 43 patients, transverse colon resection in 9 patients and low anterior resection in 7 patients. R0 (pathological radical resection of tumor) operation was performed in 69 patients (71.8%), R1 (positive microscopic margins) in 4 (4.2%) patients and R2 (gross tumor was seen at the resection margins) in 23 (24%) patients.

Follow-up

All the patients were followed up through telephone, letter or re-examination in outpatient department annually. The dead line of follow-up was up to January 2002. The longest follow-up time was 120 mo with an average period of 67.6 mo.

Statistical analysis

All data were analyzed by SPSS 10.0 statistical software. Analysis of variance was used to determine significant differences in prognosis of patients. Cox multivariate regression analysis was performed to identify predictors of survival. Quantitative data were expressed as mean ± SD. Survival was analyzed using the Kaplan-Meier survival method. $P<0.05$ was considered statistically significant.

RESULTS

Operative mortality

Operative procedure was carried out in all patients. No pa-

tient died within 30 d after operation, and 2 patients died within 3 mo after operation.

Metastasis

A total of 54 patients died of recurrence and/or metastasis within 111 months after operation. Liver, lung and bone metastases were found during follow-up in 3, 1 and 5 patients, respectively.

Survival

The average survival time of the 96 patients was 77.90 ± 5.01 months. The 3-, 5- and 10-year survival rates were 66.68%, 58.14% and 46.54%, respectively. The average survival time for male and female patients was 81.00 ± 6.41 months and 73.62 ± 7.92 months, respectively. The 3-, 5- and 10-year survival rates were 69.92%, 61.35%, 45.5% for male patients respectively and 62.48%, 53.69%, 48.32% for female patients respectively ($P = 0.499$, Table 1).

Results of univariate analysis

The prognostic factors of young patients with colon cancer are demonstrated in Table 1. Among them, age, operative procedures, perioperative blood transfusion, pathological staging, diameter of tumor, depth of tumor invasion, lymph node metastases, distant metastases and liver metastases had a significant impact on the prognosis of young patients with colon cancer.

Results of multivariate analysis

Perioperative blood transfusion and lymph node metastases were the only independent factors of postoperative survival in young patients with colon cancer (Table 2).

DISCUSSION

Colorectal cancer is a predominant disease of elderly. The risk of developing this disease increases with age, but is not unusual in young patients at the age of 40 years or under [1]. It was reported that the incidence of colon cancer remains stable while rectal cancer incidence is decreased 11% in old patients, while the incidence of colon cancer is increased 17% and rectal cancer incidence is increased 75% in young patients [4]. A total of 723 patients with colon cancer were treated in our hospital in a 10-year period. Among them, 96 patients were under 40 years of age (13.3%). The incidence of colon cancer in young patients is higher than that of gastric cancer (4.9%) [3]. Only 3-4% and 1.6% of colorectal cancer patients in Europe and United States are 40 years old or younger [5-7], but the proportion of young patients is 30% in a domestic report [5]. Hereditary colorectal tumors [hereditary nonpolyposis colorectal cancer (HNPCC), adenomatosis coli, and suspected HNPCC] occur in 38.4% of patients younger than 40 years old and in only 3.5% of individuals older than 55 [8]. Thus, hereditary colorectal tumors are detected more often in young individuals demonstrating hereditary factors rather than dietary and life-style [9].

It is generally believed that young patients with colorectal cancer have a worse survival rate. Reports from Europe demonstrate that the 5-year survival rate for patients (30 years old or younger) is only 25-30% [10, 11]. Young patients are more likely to present with late-stage disease. The young patients also have higher grade tumors [12]. About 60-67% of young patients with colorectal cancer have a later stage (III/IV) disease [11, 13], most of which are poorly-differentiated or mucinous tumors [11-15] indicating a very poor prognosis. Domestic reports demonstrate that the 5-year survival rate of patients 30 years old or younger is 40.1% [16]. The 5-year survival rate of patients at the age of 30-40 years in the present study was 63.12%. Poorly-differentiated and mucinous tumors were present in about 50% of them. On the other hand, patients at the age of 30 years or younger are more likely to present with late-stage disease, lymph node metastasis and distant metastasis compared to patients at the age of 30-40 years, but the difference is not significant. It was reported that patients younger than 40 years old with colorectal cancer display three biological indicators of aggressive and potentially

metastatic tumor biology, signet-ring cell carcinoma, infiltrating tumor edge, and aggressive histologic grade in primary adenocarcinoma[16].

The gender was not a prognostic factor for young patients in the present study. The 3- and 5-year survival rates were better for male patients than for females (69.92% *vs* 61.35% and 62.48% *vs* 53.69%). The prognosis of female colorectal cancer patients is better than that of male colorectal cancer patients, especially those with rectal cancer [17].

Location of tumors is one of the prognostic factors. Patients with colon cancer are considered having a better prognosis than those with rectal cancer [18]. Distal location and advanced stage of tumor are determined as independent prognostic factors for survival of young patients with colorectal cancer [19]. The present study indicated that there was no relationship between tumor location and prognosis. The prognosis of the patients undergone left hemicolectomy (splenic flexure of colon, descending colon and most part of sigma colon) was not different from that of the patients undergone right hemicolectomy (caecum, ascending colon and hepatic flexure of colon).

The diameter of tumors is also a prognostic factor. The prognosis of the patients in different groups with different tumor diameters (<4 cm, 4-8 cm, >8 cm) was significantly different ($P<0.001$).

The current data indicate a significant difference in the 5-year survival rate among patients who did not received blood transfusion but 400 mL and ⩾800 mL blood transfusion. Perioperative blood transfusion produces host immunosuppression and contagious diseases, increasing postoperative infectious complications [20]. Blood transfusion may be associated with the tumor staging. In our study, more advanced diseases (stages III and IV) were found in patients who received 400 mL or ⩾ 800 mL blood transfusion than in patients who did not receive blood transfusion (50%, 58.6% and 71.4%). The 10-year survival rate of patients who received blood transfusion was significantly lower than patients who did not received blood transfusion (38.93%, 59.17%). Therefore, blood transfusion is a prognosis factor for young patients with colon cancer.

Pathological classification is one of the prognostic factors for patients with colorectal cancer. Patients with different papillary adenocarcinoma have the best outcome, patients with moderately-differentiated and mucinous adenocarcinoma have a moderate outcome, patients with signet-ring cell poorly-differentiated adenocarcinoma have a poor prognosis. Carcinoma and data from a national registry including 164 628 colorectal cancer patients [21] indicate that the signet-ring cell subtype has worse outcomes, whereas survival rate for mucinous tumor patients is similar to that of adenocarcinoma patients.

Radical resection is one of the important prognostic factors. In our study, the average survival time for patients who received R2 procedure was 24 moths, the 3-year survival rate was 6.5%. Therefore, it is important to emphasize the radical resection.

Another important factor of prognosis is pathological stage. In our study, the 3-year survival rate for IV stage patients was 8.7%. When distant metastasis (including liver metastasis) occurred, the 3-year survival rate was only 4.76%. The 5-year survival rate decreased from 92% to 35% when lymph node metastasis occurred and was 19% when N2 was positive. Multivariate analysis showed that lymph node metastasis was an independent prognostic factor for young patients with colon cancer.

The prognosis of young patients with colon cancer depends mainly on the clinicopathological characteristics. A high proportion of advanced stage tumors is the main reason for the worse prognosis of patients under 30 years old. The prognostic factors for young patients with colon cancer are age, surgical procedure, radical resection, blood transfusion, pathological type, diameter of tumor, depth of tumor invasion, lymph node metastasis and distant metastasis. The independent prognostic factors are only blood transfusion and lymph node metastasis.

Abstract

AIM: To discuss the relationship between onset of peptic ulcer (PU) and meteorological factors (MFs).

METHODS: A total of 24 252 patients were found with active PU in 104 121 samples of gastroscoic examination from 17 hospitals in Nanning from 1992 to 1997. The detectable rate of PU (DRPU) was calculated every month, every ten days and every five days. An analysis of DRPU and MFs was made in the same period of the year. A forecast model based on MFs of the previous month was established. The real and forecast values were tested and verified.

RESULTS: During the 6 years, the DRPU from November to April was 24.4 -28.8%. The peak value (28.8%) was in January. The DRPU from May to October was 20.0 -22.6%, with its low peak (20.0%) in June. The DRPU decreased from winter and spring to summer and autumn ($P < 0.005$). The correlated coefficient between DRPU and average temperature value was -0.8704, -0.6624, -0.5384 for one month, ten days , five days respectively ($P < 0.01$). The correlated coefficient between DRPU and average highest temperature value was -0.8000, -0.6470,-0.5167 respectively ($P < 0.01$). The correlated coefficient between DRPU and average lowest temperature value was -0.8091, -0.6617, -0.5384 respectively ($P < 0.01$). The correlated coefficient between DRPU and average dew point temperature was -0.7812, -0.6246, -0.4936 respectively ($P < 0.01$). The correlated coefficient between DRPU and average air pressure value was 0.7320, 0.5777, 0.4579 respectively ($P < 0.01$). The average temperature, average highest and lowest temperature, average air pressure and average dew point temperature value of the previous month, ten days and five days could forecast the onset of PU, with its real and forecast values corresponding to 71.8%, 67.9% and 66.6% respectively.

CONCLUSION: DRPU is closely related with the average temperature, average highest and lowest temperature, average air pressure and average dew point temperature of each month, every ten days and every five days for the same period. When MFs are changed, the human body produces a series of stress actions. A long-term and median-term based medical meteorological forecast of the onset of PU can be made more accurately according to this.

Key words: Peptic ulcer; Meteorological factors; Temperature

Liu DY, Gao AN, Tang GD, Yang WY, Qin J, Wu XG, Zhu DC, Wang GN, Liu JJ, Liang ZH. Relationship between onset of peptic ulcer and meteorological factors. *World J Gastroenterol* 2006;12(9): 1463-1467

http://www.wjgnet.com/1007-9327/12/1463.asp

INTRODUCTION

The onset of peptic ulcer (PU) is characterized by seasons, with a high incidence in winter and spring and a low incidence in summer[1-8]. We made a correlated analysis of the relationship between detectable rate of PU (DRPU) from 1992 to 1997 in Nanning and a regressive analysis of the meteorological factors (MFs) in the same period. We found that DRPU was closely related to the seasons and MFs.

Table 1 The 7 meteorological factors

MF	Symbol	Unit
Average temperature of 1 month, ten days and five days	Tpj	^{0}C
Average highest temperature of 1 month, ten days and five days	Tmax	^{0}C
Average lowest temperature of 1 month, ten days and five days	Tmin	^{0}C
Average air pressure of 1 month, ten days and five days	P	hPa
Average relative humidity of 1 month, ten days and five days	FF	%
Average dew point temperature of 1 month, ten days and five days	Td	^{0}C
Average total amount of precipitation of 1 month, ten days and five days	RR	mm

MATERIALS AND METHODS

Materials

A total of 24 252 patients with active PU were found from 17 hospitals in Nanning from 1992–1997. We then calculated the detectable rate of peptic ulcer in every season, every month, every ten days and every five days. The average value of the 7 MFs was provided by Guangxi Meteorological Observation Station (Table 1).

Methods

We used detectable rate of peptic ulcer (DRPU) to represent the incidence. The detectable rate of a disease was higher than the incidence of its natural multitude, but the variation of both was similar as previous;y described[8]. (DRPU = number of persons of PU at the same period of time /total number of persons of gastroscopic examination at the same period of time × 100%).

Statistical analysis

We made a correlated analysis of the DRPU of 1 month, ten days and five days and the 7 MFs in the same period in Nanning. On the basis of it, we carefully chose the meteorological factors. A regressive effect F value test was made for all the independent variables and factors. A multiple linear regressive mathematical model was established for DRPU forecast equation[9].

RESULTS

Relationship between DRPU and seasons

From 1992 to 1997, the average DRPU in Nanning was 23.29%. The average DRPU from November to April was 24.2-28.8%, with its peak value being 28.8% in January. The average DRPU from May to October was 20.0-22.6%, with its low peak value being 20.0% in June. The DRPU in winter was 26.48%, 24.98% in spring, 21.10% in summer, and 20.91% in autumn. The seasonal DRPU was χ^2 = 343.3004 (P <0.005), indicating that the DRPU differed remarkably in seasons. When the DRPU in winter and spring was compared with that in summer and autumn, χ^2 = 327.4435 (P <0.005). When the DRPU in winter was compared with that in spring, summer and autumn, χ^2 = 194.0589 (P <0.005). When the DRPU in spring was compared with that in summer and autumn, χ^2 = 153.8931 (P <0.005). When the DRPU in summer was compared with that in autumn, χ^2 = 0.2744 (P >0.750). The above values showed that the onset of PU was as follows: winter and spring>summer and autumn, winter >spring >summer and autumn. The difference was significant.

Relationship between DRPU AND MFs

We made a further correlated analysis of the DRPU and the 7 MFs in the same period. The results showed that the DRPU was not evidently related to the relative air humidity, but had a negative relation with the average temperature, average highest and lowest temperature, average dew point temperature (P <0.01) and a positive relation with the AAP (P <0.01, Table 2). We found that when the monthly average temperature ≤21℃, the monthly average highest temperature ≤26℃, the monthly average lowest temperature ≤18℃, the monthly average air pressure ≥ 1007 hPa,the monthly average dew point temperature ≤ 15℃, the average ten-day temperature ≤19℃, the average ten-day highest temperature ≤24℃, the average ten-day lowest temperature ≤17℃, the average ten-day air pressure≥1008 hPa, the average ten-day dew point temperature ≤14℃, the average five-day temperature ≤17℃, the average five-day highest temperature ≤20℃, the average five-day lowest temperature ≤14℃, the average five-day air pressure≥1008hPa,the average five-day dew point temperature ≤12℃. The correlated analysis of the high onset of DRPU of 1 month, ten days, five days and the above single factors corresponded to 75%-78%. The statistical relation between the factors, can be described by the multivariate linear regression equation:

$$\hat{y} = b_0 + b_1 x_{i1} + b_2 x_{i2} + \Lambda\Lambda + b_p x_{ip} \quad \ldots\ldots \quad (i = 1,2,3\Lambda\Lambda n)$$

where b_0, b_1, b_2…bp stand for regression coefficients; n is sample size; x_{i1}, x_{i2}, …, x_{ip} are predictors; $\hat{y}$ is the predicted value. The multiple linear regressive equation was established as follows:

YmonthDRPU=127.89366 + 0.95687Tpj - 0.46658Tmax-0.97166Tmin - .0929P-0.07886Td,

average error = 2.0051, complex relative coefficient = 0.8129, F month test value = 25.7068, F0.01 = 3.60, F month > F_a, thus P<0.01.

Yten-dayDRPU=62.93681 = 0.34811Tpj + 0.06056Tmax-0.18958Tmin-0.02957P + 0.0004Td, average error = 2.981, complex relative coefficient = 0.664,Ften-day test value = 33.1117, F0.01 = 3.40, F ten- day > Fa, thus P <0.01.

Yfive-dayDRPU=63.49121-0.76259Tpj+0.27832Tmax-

Table 2 Correlated analysis of DRPU and 7 MFs

Related DRPU	Group	Related coefficient	*P* value

Ten-day precipitation	216	-0.0916	>0.05
Five-day precipitation	432	-0,0418	>0.05

The results of regressive effect analysis indicated that the 3 multiple regressive equations based on DRPU and variation of the 5 MFs had remarkable effects.

0.06448Tmin - 0.03043P + 0.0764Td, average error = 4.0499, complex relative coefficient = 0.5434, Ffive - day test value = 35.6956, F0.01 = 3.07, F five - day >Fa, thus *P* <0.01.

Establishment of DRPU forecast equation and test of its significance

The correlated analysis of DRPU of 1 month, ten days, five days and 7 MFs of the previous month, ten days and five days indicated that the average temperature, average highest and lowest temperature, average air pressure and average dew point temperature of the previous month were also closely related to the DRPU of the present month, ten days and five days (Table 3). Thus if we made the 5 MFs of the previous month, ten days and five days and the DRPU of the present month , ten days and five days, the factors of three DRPU forecast equations could be established as follows:

YmonthDRPU=-358.09409-4.75833Tpj+2.08101 Tmax+2.97619Tmin+0.37869P-0.29906Td, average error=2.1138, complex relative coefficient=0.7907, F month test value= 21.6887, F0.01 =3.60, F month >Fa, thus *P*<0.01.

Yten-dayDRPU=-45.84159-0.26677Tpj+0.05189Tmax-0.09075Tmin+0.07605P-0.04132Td, average error=3.0625, complex relative coefficient=0.6383, F ten-day test value= 28.7387, F0.01=3.40, F ten- day>Fa, thus *P*<0.01.

Yfive-dayDRPU=-0.826-0.13995Tpj-0.00568Tmax-0.24365Tmin+0.04104P+0.00342Td, average error=4.0629, complex relative coefficient=0.5362, Ffive-day test value=34.2292, F0.01=3.07, F five -day> Fa, thus *P*<0.01.

DISCUSSION

It is generally believed that the occurrence of PU is due to the effect of unbalance between the attacking factors such as hydrochloric acid in gastric juice and the defending factors of the mucosa. *Helicobacter pylori* (*H pylori*) infection is also an important cause of PU[10-25]. Treatment of hydrochloric acid in gastric juice and anti- pylorus bacteria can protect stomach duodenum mucosa, yet the occurrence of PU still has remarkable seasonal variations [8]. Therefore the influence of variations of meteorological factors on PU must be considered. Research has shown that the occurrence of PU in winter is related to the higher air pressure and temperature [8]. The high occurrence of PU

The above analysis showed that the 3 forecast equations had good regressive effect. The real test values of the three forecast equations were 71.8%, 67.9% and 66.6%, respectively.

in summer is likely to be related to the lower air pressure. Our study also confirmed the seasonal onset of PU. Analysis of MFs has shown that special attention should be paid to PU patients in winter and spring [26]. Since increased air pressure and dry air result from the cold air, temperature plays a more important role [27]. When these meteorological factors are changed violently, a series of stress action take place, causing endocrinopathy. It was reported that severe cold and changing temperature result in acute stress actions in human body, causing excitation of sympathetic nerve and adrenal gland marrow and rapid secretion of adrenaline and noradrenalin[28]. Animal tests also showed that mouse hypertensin II is much higher compared with acute stress action, sub-acute stress action and other chronic stress action [28]. When human body is stimulated by acute or slow stress action, hypertensin II in plasma increases remarkably. Cold stimulation and oxygen shortage stimulation may accelerate secretion of endothelin. Adrenaline, hypertensin II and endothelin may cause contraction of duodenal mucosa and blood vessel, leading to mucosa blood flow fall and mucosa damage [29-30]. Stomach blood insufficiency may also stimulate the rise of endothelin [31]. Kou and Li [32] reported that the stomach mucosa blood vessels contract immediately after injection of endothelin. It has also been verified that plasma endothelin density of PU patients is related to the degree of damaged stomach mucosa [33]. Stress action may lessen the stomach mucosa mucus, and lower the stomach mucosa's protective function [28]. Furthermore cold stress action may lessen the secretion of inhibitable growth factors [34, 35]. When the secretion of the inhibitable growth factors becomes less, secretion of hydrochloric acid increases in gastric juice. Meanwhile endothelin can accelerate the secretion of hydrochloric acid in gastric juice. It has been verified that when endothelin is injected, plasma progastrin increases progressively [32]. When blood supply is insufficient in the duodenal mucosa and the protection barrier is damaged due to insufficient oxygen, the increase of hydrochloric acid in gastric juice accelerates the occurrence is of PU. Moreover, cold weather decreases human body's immunity function [28]. Some Japanese experts pointed out that from December to March, the number of human body outer lymph cells and B lymph cells is small [36], indicating lower body cell immunity and body fluid immunity function. Therefore when the temperature stimulates human body, adrenocorticotropin increases its secretion and hypertensin II rises, restraining the body immunity function and causing immunity functional disorder, and making it easy for the duodenal mucosa to be attacked by *H pylori* [37], which destroys the stomach mucosa protection barrier, impairs the stomach mucosa and then restrains secretion of inhibitable growth factors and stimulates secretion of progastrin[12-25].

In conclusion, acute, sub-acute and slow stresses on the human body are likely the cause of PU in winter and spring.

Abstract

AIM: To detect the expression of pituitary adenylate cyclase-activating polypeptide receptor 1 (VPCAP$_1$-R) and VPCAP$_2$-R mRNA in gallbladder tissues of patients with gallstone or gallbladder polyps.

METHODS: The expression of VPCAP$_1$-R and VPCAP$_2$-R mRNA in gallbladder tissues was detected in 25 patients with gallstone, 8 patients with gallbladder polyps and 7 donors of liver transplantation by reverse transcription polymerase chain reaction (RT-PCR).

RESULTS: The VPCAP$_2$-R mRNA expression level in the control group (1.09±0.58) was lower than that in the gallbladder polyp group (1.64±0.56) and the gallstone group (1.55±0.45) ($P<0.05$) while the VPCAP$_1$-R mRNA expression level in the control group (1.15±0.23) was not apparently different from that in the gallbladder polyp group (1.28±0.56) and the gallstone group (1.27±0.38).

CONCLUSION: The abnormal expression of VPCAP$_2$-R mRNA in gallbladder tissue may play a role in the formation of gallbladder stone and gallbladder polyps.

Key words: VPCAP$_1$-R; VPCAP$_2$-R; RT-PCR; Gallbladder disease

INTRODUCTION

Gallbladder motility and bile delivery to the duodenum involve a complex interplay between neural and hormonal factors. Acetylcholine, cholecystokinin (CCK) and vasoactive intestinal polypeptide (VIP) in the nerve endings function as neurotransmitters, leading to contraction and relaxation of the gallbladder musculature [1-3].

VIP can relax the gallbladder, reduce gallbladder tone and inhibit CCK- stimulated contraction in a dose-dependent manner [4]. VIP exerts its action through receptors on the gallbladder wall and binds to two subtypes of VIP receptors, previously called VIP$_1$ and VIP$_2$ receptors. Because these receptors also have a high affinity for pituitary adenylate cyclase-activating polypeptide (PACAP), they have recently been named VPCAP$_1$ and VPCAP$_2$ receptors. The purpose of this study was to detect the expression of VPCAP$_1$-R and VPCAP$_2$-R mRNA in gallbladder tissue and to define their role in the formation of gallstone and gallbladder polyps.

MATERIALS AND METHODS

Patients

Gallbladder tissue from 25 patients with gallbladder cholesterol stone (12 men, 13 women, mean age 59.6 years, range 34-5 years) and 8 patients with gallbladder cholesterol polyps (2 men, 6 women, mean age 46.8 years, range 26-64 years) was obtained during surgery. Patients who had a history of acute cholecystitis were excluded. Gallbladder tissue from 7 donors of liver transplantation (all men, mean age 41.4 years, range 25-63 years) was used as control. The tissues were frozen in liquid nitrogen and stored at -80 ℃.

Extraction of RNA

Total RNA was extracted from 100 mg gallbladder tissue samples using TRIzol reagent according to the manufacturer's instructions. The concentration and purity of RNA were determined by a spectrophotometer at 260 and 280 nm. All RNA isolates had an OD$_{260}$:OD$_{280}$ value of 1.8:2.0, indicating clean RNA isolates.

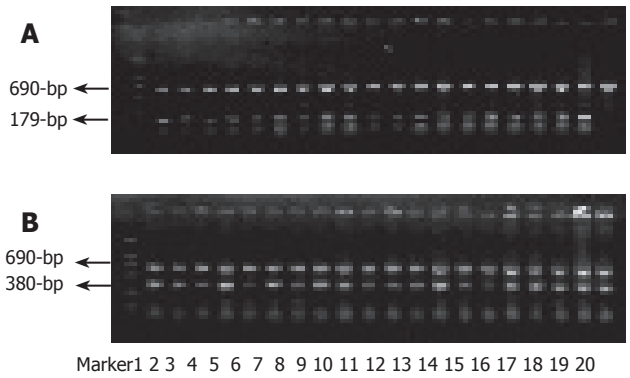

Figure 1 Expression of $VPCAP_1$-R (**A**) and $VPCAP_2$-R (**B**) in gallbladder tissues of patients with gallstones or gallbladder polyps. Lanes 1-15: gallbladder stone group; lanes 16-17: control group; lanes 18-20: gallbladder polyp group.

Reverse transcription-polymerase chain reaction (RT-PCR)

The primers for amplifying $VPCAP_1$-R and $VPCAP_2$-R cDNA were designed by the corresponding software based on the published Homo sapiens $VPCAP_1$-R mRNA (NM 004624) and $VPCAP_2$-R mRNA (NM 003382) sequences. The sequences of primers for $VPCAP_1$-R mRNA were: forward 5'- AGATGCAGCTCACTACCCTAT -3' and reverse 5'- TTCAGAGTCCCTCAGTCCTT-3', which generated a 179-bp amplification product. The sequences of primers for $VPCAP_2$-R mRNA were:forward 5'-TGCTGCAACAAGCTCATCCCT -3' and reverse 5'- GACCCAACACCTTCAGTTACCAC -3', which generated a 380-bp amplification product. The sequences of primers for internal reference gene *β-actin* used to monitor the quality of the RNA samples were:forward 5'- TCTGGATCACCTTCTGCTG G -3' and reverse 5'-GATTGCTCAGGACATTTCTG -3', which generated a 690-bp amplification product.

Two micrograms of total RNA was used as a template for subsequent RT-PCR. The total RNA was mixed with 1 μL oligo$(dT)_{15}$, 1 μL dNTPs and H_20 and preheated at 65 °C for 1 min to denature the secondary structure. The mixture was then cooled rapidly to 30 °C and then 10 μL 2 X RT buffer, 4 μL 25% $MgSO_4$, 1 μL 22 u/μLAMV, 0.5 μL40 u/uL RNase-inhibitor were added. Reverse transcriptase was added for a total volume of 20 μL. The RT mixture was incubated at 65 °C for 30 min and then stopped by heating at 98 °C for 5 min and cooling at 5 °C for 5 min.

RCR was performed on a PTC-200 PCR machine using 3 μL of cDNA, 0.1 μL of each oligonucleotide primer, 2 μL of each dNTP, 0.2 μL Taq polymerase and 10 X Taq polymerase buffer in a total volume of 25 μL. The PCR conditions were denaturation at 94 °C for 3 min, then a 94 °C for 45 s, followed by 35 cycles of annealing of $VPCAP_1$-R mRNA at 52.5 °C for 1 min and $VPCAP_2$-R mRNA at 57.3 °C for 1 min, extension at 72 °C for 1 min, a final extension at 72 °C for 7 min.

The PCR products were analyzed by electrophoresis on 2% agarose gels containing ethidium bromide. The gels were photographed on top of a 280 nm UV light box. The gel images were captured with a digital camera and analyzed with the ID Kodak Imager analysis program. RT-PCR values were presented as a ratio of the receptor mRNA signal divided by the β-actin signal.

Table 1 Expression of $VPCAP_1$-R and $VPCAP_2$-R mRNA in gallbladder tissues of patients with gallstones or gallbladder polyps (mean ± SD)

Group	$VPCAP_1$-R mRNA	$VPCAP_2$-RmRNA
Gallstone (n=25)	1.27±0.38	1.55±0.45[a]
Gallpolyp (n=8)	1.28±0.56	1.64 ±0.56[a]
Control (n=7)	1.15±0.23	1.09±0.58

[a]P <0.05 *vs* control group, n represents the number of patients involved in the study.

Statistical analysis

Data were expressed as mean ± SD. Statistical analyses were performed by the independent two-tailed t test. $P < 0.05$ was considered statistically significant. The SPSS11.5 software was used for statistical analysis.

RESULTS

Total RNA isolated from gallbladder tissues was subjected to reverse transcription-PCR analysis for the expression of $VPCAP_1$-R and $VPCAP_2$-R mRNA. A 179-bp band and a 380-bp band, specific for $VPCAP_1$-R and $VPCAP_2$-RmRNA were found in gallbladder tissue of all the three groups (Figures 1A and 1B). Furthermore, expression of $VPCAP_1$-R and VP C A P $_2$-R mRNA was detected by RT-PCR assay. The levels of PCR amplified $VPCAP_1$-R and RT-PCR amplified $VPCAP_2$-R mRNA and β-actin mRNA in three groups were compared.

Expression of $VPCAP_1$-R mRNA in gallbladder tissue

The $VPCAP_1$-R mRNA level in control group (1.15 ± 0.23) was not significanty different from that in gallbladder polyps group (1.2 8± 0.56) and gallstone group (1.27 ± 0.38) (Table 1).

Expression of $VPCAP_2$-R mRNA in gallbladder tissue

The $VPCAP_2$-R mRNA level in the control group (1.09 ± 0.58) was lower than that in gallbladder polyps group (1.64 ± 0.56) and gallstone group (1.55 ± 0.45) *(P* <0.05) while no difference in the expression of $VPCAP_2$-R mRNA was found between these two groups (Table 1).

DISCUSSION

Vasoactive intestinal peptide (VIP), a 28-amino acid peptide capable of inducing vasodilation, was first isolated from porcine intestine[5]. It has many other actions as a neuroendocrine hormone and neurotransmitter. It may play an important role in the central nervous system (CNS)[6]. VIP can stimulate prolactin secretion from the pituitary[7], regulate noncholinergic trans-synaptic functions of the adrenal medulla[8], and inhibits proliferation of T cells in the immune system[9]. Other functions of VIP include protection against oxidant injury[10], stimulation of

electrolyte secretion[11], relaxation of smooth muscle[12]. Intrinsic neurons modulate gallbladder function. Nitric oxide synthase (NOS) and VIP are present in gall bladder neurons and nitric oxide and VIP modulate its epithelial functions[13]. Intravenous infusion of VIP is associated with the secretion of bicarbonate from the gallbladder mucosa[14]. Relaxation of canine gallbladder depends on nerve stimulation by adrenergic and non-adrenergic as well as non-cholinergic (NANC) nerves. Nitric oxide and VIP contribute to relaxation of NANC nerves in canine gallbladder[15]. The effect of VIP on guinea pig gallbladder *in vitro* suggests that VIP has no effect on basal tone, but produces a $26.7 \pm 6.6\%$ relaxation of CCK-contracted strips[4].

The first recombinant receptor for VIP is isolated from rat lung by Ishihara *et al* [16]. This receptor is originally described as the VIP receptor and subsequently designated as the VIP_1 receptor[17]. Messenger RNA encoding the $VPCAP_1$ receptor is widely distributed in CNS[18], peripheral tissues of liver[19], lung[20] and intestine[20] as well as in T lymphocytes[21]. The second receptor that responds to VIP and PACAP with comparable affinity has been cloned from the rat olfactory bulb by Lutz *et al* [17]. The highest concentration of messenger RNA is found in CNS[18]. The receptor is also present in several peripheral tissues of pancreas, skeletal muscle, heart, kidney, adipose tissue, testis and stomach[22-25].

Researches about the distribution of VIP receptor in the gallbladder tissues are relatively few. Gao *et al* [26] studied VIP receptor expression in patients with gallstones using immunohistochemical technique and found that positive VIP receptor expression level is higher in patients with abnormal fasting gallbladder volume than in patients with normal fasting gallbladder volume. Fu *et al*[27] studied values of the max bind content (Bmax) of VIP receptor in gallbladder wall tissue of guinea pigs by radioligand binding assay and found that the values of Bmax are obviously increased during formation of gallstone. Dupont *et al* [28] found that there are specific binding sites for VIP in isolated epithelial cells of human gallbladder measured by radioimmunoassay. Their results indicate two functionally independent classes of receptor sites and VIP strongly stimulates adenosine 3':5' monophosphate (cyclic AMP) production.

In our study, the$VPCAP_1$ receptor mRNA level in gallstone group was not significantly different from that in control group; the$VPCAP_2$ receptor mRNA level in gallstone group was higher than that in control group; predominant $VPCAP_2$ receptor was found in smooth muscle (in blood vessels and smooth muscle layer of the gastrointestinal and reproductive systems). The main hormonal regulator of gallbladder contraction is CCK. Recent studies suggest that CCK receptor mRNA level is down-regulated in patients with gallstone and animals[29,30]. Previous studies have shown that human gallbladders with cholesterol stone reduce their contractions in response to agonists such as cholecystokinin, acetylcholine and muscle defects responsible for impaired gallbladder muscle contraction in plasma membranes of smooth muscle cells because of excessive incorporation of cholesterol[31,32]. The diffuse membrane defect caused by cholesterol may also affect other transmembrane proteins that mediate muscle relaxation. It was reported that gallbladder relaxation is significantly reduced in gallbladders with cholesterol stones[33]. Up-regulation of $VPCAP_2$ receptor mRNA may compensate for the abnormal receptor function of cholesterol. But the down-regulation of CCK receptor mRNA cannot compensate for the abnormal receptor function of membranes. There fore the contraction function of gallbladder is greatly affected rather than the relaxation function. Since up-regulation of $VPCAP_2$ receptor mRNA in epithelial cells can affect their secreting function, the abnormal expression of $VPCAP_2$ receptor mRNA may play a role in gallstone formation.

Excess cholesterol is the main cause of gallbladder polyps and may reduce the membrane fluidity, which in turn affects receptor function or receptor G-protein interaction. There are two specific binding sites for VIP in isolated epithelial cells of human gallbladder. In our study, $VPCAP_2$ receptor mRNA was over-expressed in patients with gallbladder polyps, which may be due to the abnormal receptor functions of cholesterol. Over-expression of $VPCAP_2$ receptor mRNA may occur in epithelial cells, leading to abnormal secretion and absorption of epithelial cells. This disorder may play a role in formation of gallbladder polyps.

A large number of factors, such as genetics, cholesterol saturation, sphincter of Oddi pressure, bacterial contamination of biliary tree, can induce formation of gallbladder stone and gallbladder polyps. The motility disturbances related to up-regulation of $VPCAP_2$ receptor mRNA may play a role in formation of gallbladder stones and gallbladder polyps. However, what cell membranes does the over-expression of $VPCAP_2$ receptor mRNA occur needs to be further studied.

Abstract

A 49-year-old Japanese woman was referred to our department because of high fever and a huge abdominal mass. Computed tomography (CT) and magnetic resonance (MR) imagings revealed a tumor, about 30 cm in diameter, occupied the right hepatic lobe and the peritoneal cavity. Abdominal angiography showed that the tumor was fed mainly by the cystic artery. We preoperatively diagnosed angiosarcoma of the gallbladder and performed tumor resection with cholecystectomy because the tumor was almost casplated, however the posterior wall of the gallbladder attached to the tumor firmly. Histologically, the tumor was composed of spindle cells including lipoblasts with cellular pleomorphism, which were also detected in the muscular layer of the gallbladder. We finally diagnosed pleomorphic liposarcoma of the gallbladder. At 10 mo and 29 mo after the first operation, she underwent two more operations because of recurrence. Now she has a good quality of life 3 years and 6 mo after the first operation.

Key words: Liposarcoma; Gallbladder; Liver; Pleomorphic type; Recurrence

INTRODUCTION

Liposarcoma is a mesenchymal malignant tumor that is usually detected in the extremities and the retroperitoneum[1]. Primary intra-abdominal liposarcomas are rare: most originate from the mesentery and peritoneum[1]. We experienced a case of liposarcoma originated from the gallbladder, which is extremely rare - only one case has been reported[2]. Our case is the longest surviving case treated by surgery in previously reported cases. Herein, we report the case of gallbladder liposarcoma and review the literature.

CASE REPORT

A 49-year-old woman was referred to our department for high fever and a huge abdominal mass in October 2001. At admission, she was emaciated (body height: 150cm, body weight: 42.5 kg, blood pressure: 100/60 mmHg, pulse rate: 78/min, body temperature: 38.4℃); the elastic huge mass, about 30 cm in diameter, was palpated at the right side of the abdomen. Laboratory data revealed severe anemia (hemoglobin: 76 g/L), leukocytosis (white blood cells count: 10 920/mm^3), hypoproteinemia (total protein: 5.8 g/dl, Albumin: 19 g/L) and elevation of serum alkaline phosphatase (ALP) and γ-glutamyl transpeptidase (GTP) levels (ALP: 841 IU/l, γ-GTP: 247 IU/l). Serum levels of tumor markers (carcinoembryonic antigen [CEA], carbohydrate antigen [CA] 19-9, and alpha-fetoprotein [AFP]) were within their normal ranges. By computed tomography (CT), the tumor, which was detected as a low-density area with irregular enhancement, occupied the right hepatic lobe and the peritoneal cavity (Figure 1). As shown by the magnetic resonance imaging (MRI) series, the tumor had homogeneous hypo-intensity on T1-weighted MRI (Figure 2A) and heterogeneous hyper-intensity on fat-suppressed T2-weighted MRI (Figure 2B). Furthermore, MR cholangiography showed that it apparently compressed the right lobe of the liver to the cranial side and the gallbladder to the medial-caudal side (Figure 2C,2D). Stronger enhancement of tumor was revealed by CT during selective cystic arteriography (Figure 3) than that during other arteriographies (i.e., right hepatic artery, middle hepatic artery, left hepatic artery, right subphrenic artery, and right renal artery). Based on those findings, on 23 October 2001, we performed an operation under the preoperative diagnosis of angiosarcoma originated from the liver or the gallbladder.

FIRST OPERATION AND PATHOLOGICAL FINDINGS

At laparotomy, a huge tumor occupied the right side of

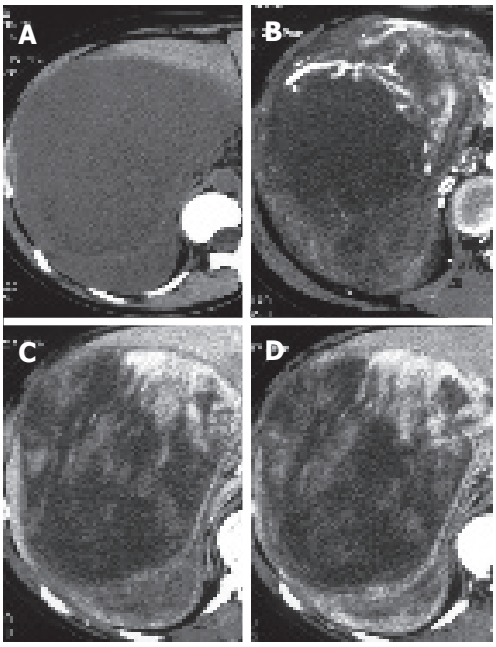

Figure 1 Preoperative dynamic CT images. **A**: plain; **B**: early phase; **C**: delayed phase; **D**: late phase. The tumor detected as a low demsity area and opputied the right hepatic lobe and the peritoneal cavity (**A**). Dynamic study revealed that the tumor enhanced irregularly at any phase (**B**-**D**).

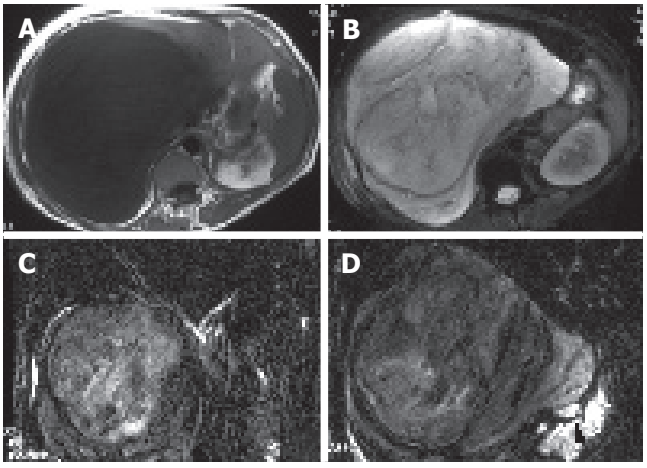

Figure 2 Preoperative MRI images. A: T1-weighted;B:fat-supressed T2-weighted;B and C: MR Cholangiography. The tumor appeared hypointense on T1-weighted images (**A**) and hyperintense on fat-suppressed T2-weighted images (**B**). MR cholangiography revealed that the tumor compressed the right lobe of the liver to the cranial side (**C**) and gallbladder to the medial-caudal side(arrow head: gallbladder) (**D**).

the abdomen; the liver was displaced to the cranial side. The tumor infiltrated tightly into the gallbladder, but not to the liver and the retroperitoneum, thus we performed a resection of the tumor with cholecystectomy. The cystic lymph node enlarged and atypical cells were detected in this node from frozen section. The resected specimen weighed 3 300 g and gross examination revealed a yellowish tumor measuring 25 cm × 23 cm, but the mucosa of the gallbladder was intact with the cholesterosis alone. The cutting section of the tumor appeared whitish solid and included hemorrhage and necrosis in parts (Figure 4A). Histological examination

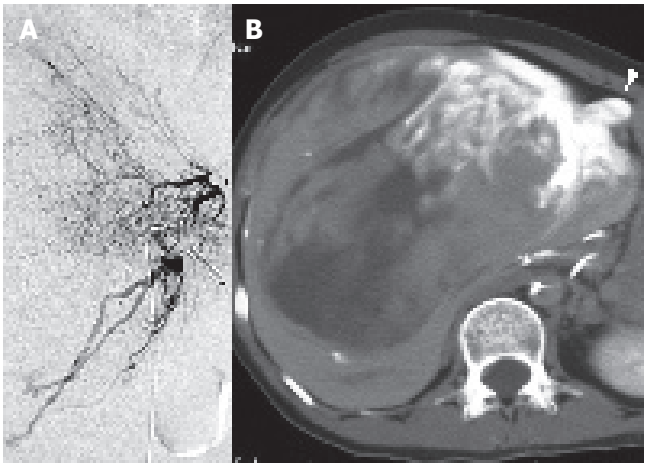

Figure 3 Preoperative angiography. **A**: Hepatic arteriography; **B**: CT during cystic arteriography. Many arteries (i.e., right, middle, left hepatic, and subphrenic arteries fed the tumor (**A**) (arrow head:the root of cystic artery). However, CT during the selective cystic arteriography revealed stronger enhancement of the tumor than during any other arteriographies (**B**)(arrow head:gallbladder).

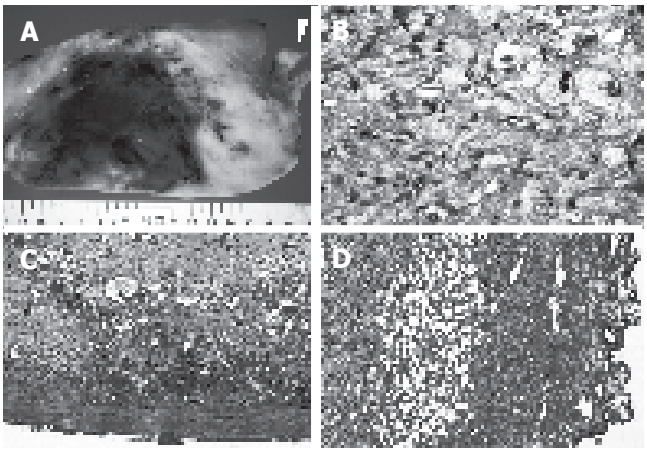

Figure 4 Resected specimen and histological findings. **A**: Cutting section of the tumor; **B**: The main tumor; **C**: The edge of the tumor(hepatic side); **D**: The posterior wall of the gallbladder. The cutting section of the tumor appeared whitish solid and included parts of hemorrhage and necrosis and attached to the gallbladder firmly (**A**) (arrowhead: gallbladder). On histological examination, the tumor was mainly composed of spindle cells with cellular pleomorphism, and included lipoblasts (**B**). The tumor had a capsule (**C**), but the capsule annihilated a border of the gallbladder, where these tumor cells were detected in the muscle layer of the gallbladder (**D**).

revealed that the tumor mainly comprised spindle cells with cellular pleomorphism, and included lipoblasts (Figure 4B). The tumor was almost capsulated (Figure 4C), however the capsule annihilated a border of the posterior wall of the gallbladder, in which these tumor cells were detected in the muscle layer but did not extended to the submucosal layer (Figure 4D). From these findings, we finally diagnosed pleomorphic type liposarcoma originated from the gallbladder with extramural growth (T4N1M0: stage IV).

SECOND AND THIRD OPERATIONS AND FINDINGS

The patient was discharged 24 d after the first operation.

Table 1 Characteristics of previously reported cases of primary liposarcoma of the liver and the gallbladder

Case Number	Source, (yr)	Age Sex	Location	Therapy	Prognosis
Liver					
1	Wolloch Y, et al[3] 1973	22 yr Female	Right lobe	Right hepatic lobectomy	Died on 46 postoperative day because of complications
2	Kim TW, et al[4] 1985	86 yr Male	Right lobe	No therapy	Died
3	Kim YI, et al[5] 1987	30 yr Female	Left lobe	Left lateral subsegmentectomy	Free of recurrence at 10 months after surgery With no further medical and surgical therapy
4	Soares FA, et al[6] 1989	2y 4mo. Male	Hepatic hilum	Chemotherapy	Died
5	Aribal E, et al[7] 1993	48 yr Female	Hepatic hilum	Unresectable Regional chemotherapy	Not described
6	Wright NB, et al[8] 1993	3 yr Male	Hepatic hilum	Surgery Radiation, chemotherapy	Died at 15 y.o. Because of fatal recurrence
7	Khan AN, et al[9] 2001	50 yr Male	Right lobe	Right hepatic lobectomy	Not described
8	Nelson V, et al[10] 2001	54 yr Female	Left and Right lobes	No therapy	Died
Gallbladder					
1	Bader H, et al[2] 1983	79 yr Male	Intramural	Cholecystectomy	Died 2 years after operation because of peritoneal dissemination
2	Our case	49 yr Femal	intramural	tumor resection with cholecystectomy	Alive

Computed tomography (CT) revealed the tumor size as 4.5 cm in Couinaud's segments 4 and 5 of the liver on August 2002. At 10 months after the first operation, she underwent extended right hepatectomy and pancreatoduodenectomy including partial resection of the portal vein according to the intraoperative findings of liposarcoma metastases that were recognized pathologically by frozen sections. Pathological examination of the specimen showed not only liposarcoma metastases in the right lobe of the liver, but also those extending to the surrounding fatty tissue of the hilus and left hepatic bile ducts, the hepatoduodenal ligament, and the pancreas head. She underwent CT scanning every 3 or 4 months at the outpatient clinic. On February 2004, CT revealed tumors of 7 cm and 5 cm in Couinaud's segments 4 and 2 of the liver, respectively, and the recurrent tumor of 1.5 cm in the upper lobe of the left lung. She underwent partial resections of Couinaud's segments 4 and 2 with a partial resection of intrahepatic left portal vein and partial resection of the left lung under a thoracic scope at 29 mo and 30 mo respectively, after the first operation. At more than 3 years 6 mo after the first operation, she is now continuing to enjoy a good quality of life.

DISCUSSION

Liposarcoma is the second-most common soft tissue sarcoma among adults. Its incidence was reported as 10-12% among soft tissue sarcomas. The two major sites of liposarcoma are the lower extremities and retroperitoneum: their respective incidences are 30.1% and 18.5%. Other less common sites have been reported: the inguinal and paratesticular regions, chest wall, breast, and mediastinum[1]. Notwithstanding, few cases of intra-abdominal liposarcoma have been reported. Furthermore, most of those are from the mesentery and peritoneum[1].

In our case, the original sites of liposarcoma were considered to be the posterior wall (hepatic-side surface) of gallbladder, according to operative and pathological findings. At the first operation, the tumor was dissected easily from the liver and the retroperitoneum. The tumor was almost capsulated histologically, except the hepatic surface of the gallbladder. Furthermore, the tumor cells originated from the muscular layer only at the hepatic side of gallbladder, where the capsule disappeared. Generally, liposarcoma takes its origin from primitive mesenchymal cells rather than mature adipose tissue; it often seems to arise from intermuscular fascial planes or richly vascular structures[1]. From these findings, we concluded that the tumor originated from the muscular layer of the gallbladder on the hepatic surface. Thereafter, it might grow rapidly and extramurally.

In this case, we also want to emphasize that we could preoperatively make an accurate diagnosis about the origin of the tumor. It is usually very difficult for many doctors to confirm the origin of such a huge abdominal sarcoma pre- and post-operatively, however, our case was detectable because we could comprehend the relation of the tumor to the surrounding organs (in our case; liver, gallbladder, and bile duct) from MR cholangiography and the main feeding artery of the tumor from selective arteriography with CT imaging (CT during cystic arteriography). These imaging studies might be useful to detect the origin of such a huge abdominal mass as our case.

Among the rare cases of intra-abdominal liposarcoma, the mesentery, omentum, and gastrointestinal organs are its common sites. However, liposarcoma of the liver and the biliary system are exceedingly rare and have been reported in only 10 cases, including our case (Table 1). Those patients were younger than patients with other malignant tumors: two of those cases were infants. No dif-

ferences of sex were apparent in these patients. Seven of the cases received medications, but three cases could not because of complications by the tumors. Only one case of seven medicated patients was unresectable and thus got regional chemotherapy and radiation therapy. Prognoses of liposarcoma of the liver and gallbladder seem to be poor. Previous reports about liposarcoma have described cases among which six of eight patients died, three cases were inoperable because of rapid tumor growth, two cases were recurrent, and one ended in death by complications engendered by a difficult operation. Generally, pleomorphic liposarcoma, as in our case, is defined as a high-grade pleomorphic sarcoma containing multivacuolated lipoblasts and rare form with a poor prognosis [11,12]. It occurs in about 10% of liposarcoma cases and has a 45% local recurrence rate and 42.5% metastatic rate. Five-year overall, metastasis-free, and local recurrence-free survival was shown respectively as 57%, 50%, and 48%[13]. From these reports, she had better postoperative course than many cases of liposarcoma in Table 1, and is now receiving a good quality of life, because the primary and recurrent tumors were located on curatively resectable area luckily and we could detect the recurrences soon by using CT frequently. In the future, it is also important to find recurring tumors using imaging studies and to resect them as soon as possible for her quality of life.

In conclusion, we experienced a case of liposarcoma of the gallbladder that has not yet been reported in detail and for which the patient has survived long after the primary operation because of two operations that were undertaken aggressively.

INTRODUCTION

Tracheoesophageal fistula (TEF) or bronchoesophageal fistula may be congenital, inflammatory, neoplastic, or secondary to trauma[1-3]. Congenital TEF or bronchoesophageal fistula is usually associated with esophageal atresia and is readily diagnosed in infancy. But if it is not associated with esophageal atresia, it may persist until adulthood. Some theories have been proposed to explain this delay in diagnosis. The long, silent interval until adulthood and the irregular character of the signs have been attributed to the presence of a membrane that subsequently ruptures, to the proximal fold of esophageal mucosa initially overlapping the orifice but subsequently becoming less mobile, and to the fact that the fistulous tract runs upward and may close during swallowing[1,2,4-6]. The oldest was an 83-year-old man with congenital bronchoesophageal fistula[7].

We present a case of a 70-year-old man with congenital TEF. The TEF was successfully diagnosed by multidetector-row computed tomography (CT) esophagography.

CASE REPORT

A 70-year-old man was admitted to our hospital with the complaint of severe cough and choking after swallowing liquid. The patient had done well until 7 mo prior to the admission. Then increased symptoms of cough and dysphagia were developed. Esophagoscopy showed a depressed lesion that looked as if it was punched without inflammation at a distance of 23 cm from the incisors in the middle intrathoracic esophagus, but the fistula opening was invisible (Figure 1). Histological examination of the esophageal biopsy specimens had only normal findings. A multidetector-row CT scan using Aquilion M8 (Toshiba, Tokyo, Japan) was performed with 3-dimensional reconstruction. A nasogastric tube was inserted into the esophagus during the examination, and the esophagus was inflated with oxygen flow (1L/min). The CT scanning parameters were 120 kVp, 200 mA, 8 × 0.5 mm collimation, a pitch of 10.0, and a 0.3-mm reconstruction interval. CT esophagography revealed the presence of a TEF (Figure 2). Conventional barium esophagography was not performed for the patient.

The patient underwent a right posterior lateral thoracostomy. The fistula was identified between the middle intrathoracic esophagus and the distal trachea. There was no evidence of inflammation or adherent lymph nodes around the fistula. The fistula was divided and closed using endostapler (EndoGIA Universal stapler®; US Surgical Corporation, Norwalk, Conn.), and covered with an intercostal muscle flap to avoid the recurrence of fistula. Intra-

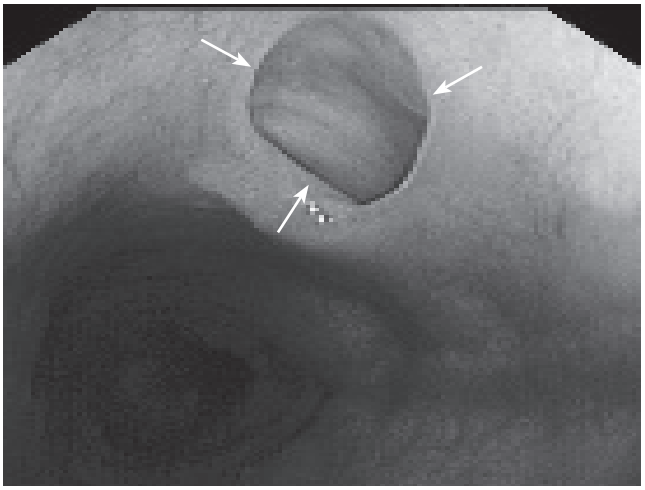

Figure 1 Esophagoscopy reveals a depressed lesion (arrows) that looked as if it was punched at a distance of 23 cm from the incisors in the middle intrathoracic esophagus (E).

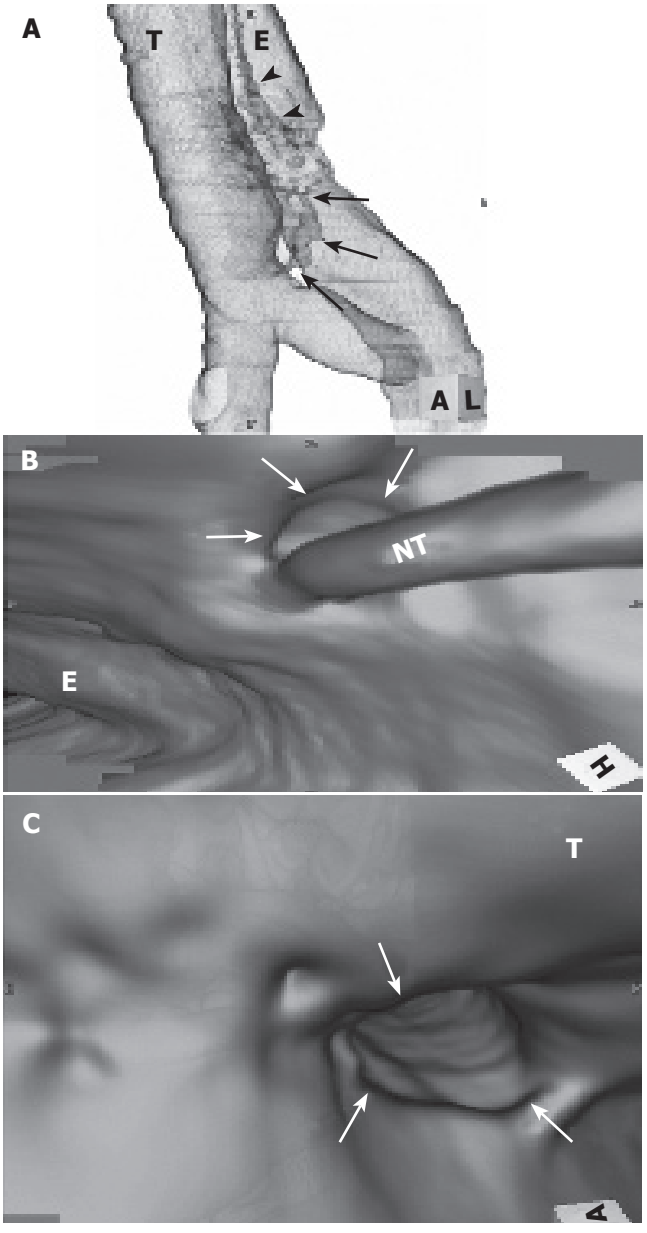

Figure 2 **A:** CT esophagography demonstrates communication between the middle intrathoracic esophagus and the distal trachea just proximal to the carina (arrows). Note a distortion caused by tube inserted into the esophagus (arrowheads). T, trachea; E, esophagus. **B:** Virtual esophagoscopy shows the orifice of the fistula (arrows) and it is similar to that of (conventional) esophagoscopy (Figure 1). NT, naso-gastric tube; E, esophagus. **C:** Virtual bronchoscopy also demonstrates the orifice of the fistula (arrows). T, trachea.

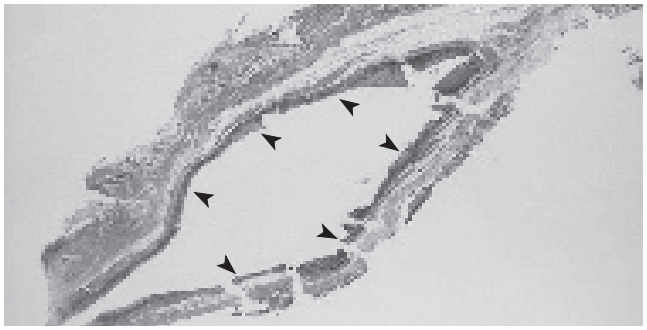

Figure 3 Pathological examination of the resected specimen revealed that the fistula was lined by benign squamous epithelium with the muscularis mucosa (arrowheads).

operative esophagoscopy was found to be useful for the definitive localization and complete excision of the fistula and the avoidance of stenosis of the esophagus. Pathological examination of the resected specimen revealed that the fistula was lined by benign squamous epithelium with the muscularis mucosa, and there was no evidence of malignancy, infection, or chronic inflammation (Figure 3). The postoperative course was uneventful. At 18 mo follow-up, there was no clinical or radiographic evidence of recurrence of the fistula.

DISCUSSION

Congenital TEF or bronchoesophageal fistulas were first reported by Negus in 1929 and Gibson in 1696[8]. These congenital fistulas are still controversial and rare clinical problem in adults. Generally, the criteria for the diagnosis of a congenital fistula in adults has the following features: absence of past or present surrounding inflammation or malignancy, complete recovery after resection, and the presence of normal mucosa and absence of adherent lymph nodes[1,2,7]. We could confirm our case as a congenital TEF by the above mentioned features, even though it was found in a 70-year-old man.

The anatomy of TEF should be shown before surgery because the surgical approach depends on a correct evaluation of TEF. Conventional barium esophagography is considered to be the most sensitive test for diagnosing tracheoesophageal or bronchoesophageal fistula[9,10]. Other examinations that have been used but are less successful include esophagoscopy, bronchoscopy, and bronchography[9,10]. Three-dimensional (3D) displays of many organs and structures using multidetector-row CT have recently become a popular clinical examination tool with significant improvement which was made on quality of image due to a rapid progress in computer technology[11-13]. Multidetector-row CT esophagography correctly showed TEF in our case. Images of TEF could be easily made and provide crucial information for planning surgery. Fitoz *et al* report-

ed that 3D CT imaging are used to assist in the diagnosis of TEF[14].

Fitoz's and our experience indicates CT esophagography might be clinically useful for the accurate diagnosis of tracheoesophageal fistula. CT esophagography without contrast medium is less invasive examination.

Abstract

We report a case of 28-year-old woman presenting with small bowel obstruction. She had neither prior surgery nor delivery. An upright abdominal radiograph revealed several air-fluid levels in the small bowel in the midabdomen and the pelvic cavity. Computed tomography demonstrated a dilated small bowel loop in the Douglas's fossa, but no definite diagnosis could be made. Supportive therapy with draining the intestinal fluid by a long intestinal tube did not result in improvement, which suggested the possibility of a strangulated hernia. Exploratory laparotomy revealed mobile cecum and a 20-cm length of the ileum herniated into a defect of the right broad ligament. As a gangrenous change was recognized in the incarcerated bowel, its resection was carried out, followed by end-to-end anastomosis and closure of the defects of the broad ligament. The postoperative course was uneventful. Intestinal obstruction is a very common cause for presentation to an emergency department, while internal hernia is a rare cause of obstruction. Among internal hernias, those through defects of the broad ligament are extremely rare. Defects of the broad ligament can be either congenital or secondary to surgery, pelvic inflammatory disease, and delivery trauma. In conclusion, we emphasize that hernia of the broad ligament should be added to the list of differential diagnosis for female patients presenting with an intestinal obstruction. Early diagnosis and surgical repair reduce morbidity and mortality from strangulation.

INTRODUCTION

Intestinal obstruction is a very common cause for presentation to an emergency department, while internal hernia is a rare cause of such obstruction. Even rare is the hernia through defects of the broad ligament. This report describes a rare case of intestinal obstruction from internal hernia through a defect of the right broad ligament. The diagnosis of this condition was not made preoperatively due to its rarity and nonspecific manifestation.

CASE REPORT

A 28-year-old woman, gravida 0 para 0, presented complaining of acute lower abdomen colicky pain, nausea, and vomiting. She had no prior relevant medical history. On physical examination, her right lower quadrant was tender with mild voluntary guarding and increasing bowel sounds. Rectal examination did not show any abnormalities. Laboratory studies showed no definite abnormalities except for an elevated leukocyte count of 13 800/mm^3 with a left shift. An upright abdominal radiograph revealed multiple air-fluid levels in the small bowel in the midabdomen and the pelvic cavity. Computed tomography demonstrated a dilated small bowel loop in the Douglas's fossa (Figure 1), but no definite diagnosis could be made.

Supportive therapy with draining the intestinal fluid by a long intestinal tube did not result in improvement, thereby suggesting the possibility of a strangulated hernia.

The patient underwent an exploratory laparotomy, which revealed two defects of the right broad ligament and mobile cecum. A 20-cm length of the ileum had been herniated into the outer defect. As a gangrenous change was recognized in the incarcerated bowel, it was resected and an end-to-end anastomosis was performed while the defects of the broad ligament were also closed. The postoperative course was uneventful.

DISCUSSION

Internal hernia is responsible for about 0.9% of intestinal obstruction. Hernia of the broad ligament is extremely rare and accounted for less than 7% of all internal hernias.

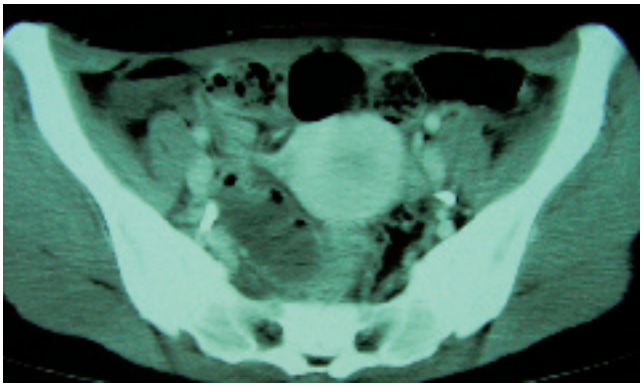

Figure 1 Contrast-enhanced computed tomography demonstrating a dilated small bowel loop in the Douglas's fossa.

The earliest reported case of an incarcerated hernia through a defect of the broad ligament of uterus was in 1861 by Quain, found at autopsy[1]. Two types of hernia of the broad ligament have been classified by Hunt[2]: the fenestra type that involves a complete fenestration through a defect in the broad ligament; and the pouch type that involves hernia into the pouch from an anterior or a posterior aperture. The defects in our case were of the fenestra type.

Preoperative diagnosis of hernia of the broad ligament is quite difficult. The usefulness of computed tomography has been reported[3], but the causal lesion of the intestinal obstruction could not be detected with computed tomography in our case. Although computed tomography suggests an internal hernia, it may be impossible to diagnose the hernia through a defect of the broad ligament[4].

Although the precise pathogenesis of a defect of the broad ligament remains unknown, its causes are considered to include surgery, pelvic inflammatory disease, delivery trauma and congenital anomaly[5]. Our case had neither any relevant medical history nor delivery, thereby suggesting a congenital anomaly in our case. In female embryos, fusion of the paramesonephric ducts forms the broad ligament. The present case showed both incomplete fusion of the broad ligament and incomplete fixation of the ascending colon leading to mobile cecum. These anomalies might have resulted from some abnormalities in a similar embryonic period.

In conclusion, we emphasize that intestinal hernia through a defect of the broad ligament should be added to the list of differential diagnosis for female patients presenting with an intestinal obstruction without any prior history of laparotomy. Early diagnosis and surgical repair reduce morbidity and mortality from strangulation.

Abstract

A 60-years old male was admitted to our department for investigation of constipation and hypogastric discomfort intensified during defecation of a few weeks duration. The cause proved to be a rectal carcinosarcoma that was treated by abdominoperineal resection and postoperative chemo-radiotherapy. The patient died 6 months later due to hepatic failure, showing evidence of disseminated disease. In general colonic carcinosarcomas constitute a rare category of malignant neoplasms whose nature is still incompletely understood. No specific treatment guidelines exist. Surgery is the mainstay of treatment and regardless of the addition of adjuvant therapy the prognosis is very poor. Systematic genetic analysis may be the clue for understanding the pathogenesis of these mysterious tumors.

Key words: Carcinosarcoma; Rectum

INTRODUCTION

The coexistence of carcinomatous and sarcomatous elements within the same tumor is a rare entity, variably labeled as "carcinosarcoma", "metaplastic carcinosarcoma", "sarcomatoid carcinoma", "pseudosarcomatous carcinoma", "carcinoma with mesenchymal stroma", "carcinoma with sarcomatoid change", "spindle cell carcinoma", "pleomorphic anaplastic carcinoma" and "small cell carcinoma"[1]. This confusing, non-standardized terminology reflects the rarity and uncertainty regarding the nature of these tumors.

The term carcinosarcoma implies a mixed malignant tumor that is composed of an epithelial element, typically the common form of carcinoma seen in the tissue harboring the neoplasm, close to or intermixed with a sarcomatous component. The mixed nature of these tumors is confirmed by a positive immunohistochemical staining for both cytokeratins and vimentin. The common denominator of all carcinosarcomas is the lack of staining of the sarcomatous component for epithelial markers. On the contrary in the cases where both the sarcomatous and carcinomatous components are stained positively for epithelial markers the term "sarcomatoid carcinoma" should be addressed[2,3]. For all practical purposes in our review we consider carcinosarcomas as only cases where the sarcomatous component was stained negative for epithelial markers, irrespective of the term an author decided to utilize for describing the mixed tumor encountered.

The earliest report of a possible, due to lack of immunohistochemistry, carcinosarcoma can be tracked back to 1864 by Virchow[4]. These neoplasms usually arise in the female reproductive tract, urinary tract, the head and neck areas, breast and respiratory tract. The gastrointestinal tract is an uncommon location of carcinosarcomas, the esophagus being the most common location within it[1-4]. To our knowledge, only 7 cases of colonic carcinosarcomas have been reported in the English literature, and this case is the 8th. We report this case of rectal carcinosarcoma and review the literature on this rare malignancy.

CASE REPORT

A 60-years old male was admitted to our department for investigation of constipation and hypogastric discomfort intensified during defecation of a few weeks duration. He had a history of acute myocardial infarction and benign prostatic hyperplasia under medical treatment.

Abdominal and chest clinical examinations were unrevealing. However on digital examination a rubbery, fixed polypoid mass could be palpated just proximal to the dentate line. The complete blood count revealed only a slight anemia. Blood biochemistry was unrevealing.

On colonoscopy the mass was confirmed and a smaller polyp of 0.4 cm in diameter was detected on the upper rectum. Biopsies were obtained, which resulted in the

diagnosis of adenocarcinoma. A CT scan of the abdomen and pelvis was subsequently performed revealing the lower rectal mass and distortion of adjacent perirectal fat. No metastatic foci to the liver or the abdominal cavity could be detected. The CXR was normal.

An abdominoperineal resection was performed. On intraoperative abdominal inspection and palpation, no abnormal findings could be detected asides from the pelvic mass. The patient had an uneventful postoperative course and was discharged on the 10th d.

The resected specimen, measuring 34 cm in length, consisted of anus, anal canal, rectum and sigmoid colon. The surgical margins were tumor free. The rectal tumor had a diameter of 7 cm, was elastic on palpation and had a whitish-yellow cut surface.

Histological examination revealed an invasive tumor infiltrating the full thickness of the rectal wall, as well as the perirectal fat and external sphincteric muscle fibers at the level of anal canal. The tumor consisted of poorly differentiated carcinomatous and spindle-shaped sarcomatous elements. Extensive areas of necrosis and hyaline degeneration of the stroma were evident. In a few locations the carcinomatous cells were organized into tubular and cribiform structures. 24 lymph nodes were recognized in the resected specimen. Five of them were positive for malignancy. The carcinomatous element was predominant, but sarcomatous cells could also be detected within the involved lymph nodes. The immunohistochemical profile is listed on Table 1. The final histologic diagnosis was rectal carcinosarcoma, TNM stage III.

Postoperatively the patient received 4 cycles of 5-fluorouracil/leucovorin chemotherapy. Follow-up radiological examination revealed a 16cm x 17cm hepatic metastatic focus as well as lung and peritoneal implants, local recurrence in the resection field and inguinal lymph node involvement, evident by the 4th postoperative month. Pelvic and inguinal radiotherapy was added. The patient finally succumbed to its disease at the 6th postoperative month. A postmortem examination was not performed.

DISCUSSION

Carcinosarcomas of the gastrointestinal tract are extremely rare. Most of them occur in the esophagus; about 40 cases have been reported in the gallbladder and less than 30 in the stomach. In a review of the English literature we found only seven immunohistochemicaly confirmed cases of carcinosarcoma of the large intestine, our case being the eighth[1-7]. Four further reports exist regarding colonic sarcomatoid carcinomas that should not be confused with carcinosarcomas, when purely immunohistochemical criteria are employed[8-11]. However the clinical relevance of this distinction is doubtful because the biological behavior of these neoplasms appears to be similar. In three other cases of colonic biphasic tumors the exact nature of the neoplasm is not clear.[12-14] The cases of colonic carcinosarcoma reported in the English literature are listed on Table 2.

Colonic carcinosarcomas present in the age group of 60 to 84 years, averaging 73 years of age at diagnosis. Males and females are equally affected. The tumor can be located anywhere in the large bowel, but a left-sided predominance is evident (six out of eight cases).

Histologically colonic carcinosarcomas are composed of two parts, an epithelial component and a mesenchymal component. The epithelial component appears indistinguishable from colonic adenocarcinoma. The malignant mesenchymal component of the tumor may be differentiated or undifferentiated. The differentiated is described as homologous or heterologous. Homologous elements resemble fibrosarcoma or leiomyosarcoma. If the sarcomatous part contains elements not normally found in the colon (e.g., cartilaginous, osseous, or rhabdomyoblastic), it is then described as heterologous. As stated in carcinosarcomas of other organs, the quality of the sarcomatous component does not appear to affect prognosis[1-3].

The possible histogenesis of colonic carcinosarcomas is a matter of debate. Several theories have been proposed to explain the histologic features of these tumors. These include the "collision tumor theory" suggesting that the two tumor components are derived from separate and distinct malignant cell clones. In favor of this opinion are investigators that observed sharply defined epithelial and sarcomatous components without demonstrable cells showing shared or transitional features on ultrastructural or immunohistochemical examination. Others propose a common origin of both components of carcinosarcomas, since common characteristics, epithelial in nature, between the different cellular populations as well as a transitional population could be observed. This could be either due to a malignant transformation of a pluripotential stem cell capable of both epithelial and mesenchymal differentiation (the combination theory) or due to a sarcomatoid/carcinomatous differentiation of a carcinoma/sarcoma (the conversion theory). Regarding the conversion theory it is believed that the carcinomatous element is the tumor' s "driving force", and the sarcomatous component derives from this as a result of dedifferentiation. Some postulate that this sarcomatoid transition of carcinomatous cells could be related to an infection by a retrovirus[2,10]. Another theory that has been proposed to explain the presence of sarcomatous elements in carcinosarcomas questions the neoplastic nature of this component. According to this theory the sarcomatous component is a benign reparative or granulomatous tissue mass representing a conspicuous

connective tissue response to the carcinoma, i.e. an epithelial-stromal interaction (the composition theory).

Evidence coming from studies on esophageal, breast, endometrial and uterine carcinosarcomas suggests that the combination or conversion theories, which are not mutually exclusive, are the prime nodes of histogenesis of these tumors, i.e. most carcinosarcomas are monoclonal and should be better considered as metaplastic carcinomas[1-4,15]. It is of interest to note that most lymph node metastases reflect the carcinomatous component. This adds to the hypothesis that the carcinomatous component is the driving force of these tumors, but this is not always the case. In our case one lymph node was infiltrated by both elements.

Over the recent years the increasing use of immunohistochemistry and electron microscopy has added to our understanding of these tumors. However the information gathered was proved to be insufficient. Systematic genetic analysis may be the clue for understanding the pathogenesis of these mysterious tumors. Recently great interest has been shown on p53 status of these tumors. It has been suggested that the transition of carcinoma to sarcoma is associated with progressive accumulation of p53 proteins in this component[10]. However in our case this could not be confirmed since only the carcinomatous element stained positive for p53. Others have demonstrated the same p53 mutations on both sarcomatous and carcinomatous elements. Furthermore reports indicating no p53 mutation detection have been published[16,17](Figures 1 and 2).

The same diagnostic and operative treatment options that apply for colonic adenocarcinoma are also employed in the case of colonic carcinosarcomas, since no carcinosarcoma-specific treatment guidelines exist. All the reported cases of colonic carcinosarcomas underwent resection of the primary tumor and draining lymph nodes in the course of typical colectomies. Adjuvant therapy was added in four cases, consisting of chemotherapy in three and irradiation in two, but the efficacy of this approach remains questionable. However it should be noted that none of the patients who did not receive adjuvant therapy survived more than 6 mo, while the 2 cases that survived more than 6 mo had received postoperative chemotherapy[1-7].

The prognosis of carcinosarcomas is very poor. These tumors are very aggressive neoplasms characterized by rapid growth and a high incidence of both local recurrence and distant spread. Six of the eight reported cases died of the disease within 5 years of diagnosis. Survival ranged from 0 to 49 mo averaging 12 mo. For the remaining two

cases there are no available data concerning their 5 year survival. These patients were reported to be alive at 3 and 14 mo postoperatively respectively, but only the patient that was alive at 14 mo was apparently "disease free". Due to the lack of sufficient amount of cases no safe conclusions regarding prognostic factors can be made. Interestingly the stage of the disease does not appear to provide accurate information about prognosis since all four patients with reportedly stage II disease died within five years. Three of them were dead by the sixth postoperative month[1-7].

In general colonic carcinosarcomas constitute a rare category of malignant neoplasms whose nature is still incompletely understood. No specific treatment guidelines exist. Surgery is the mainstay of treatment and regardless of the addition of adjuvant therapy the prognosis is very poor. However some state that these neoplasms may be commoner than reported. This is due to the fact that the sarcomatous and carcinomatous elements are arranged unevenly at separate areas of the tumor, resulting in common preoperative and possible postoperative misdiagnosis if the specimen is not thoroughly examined. Careful examination of the resected colonic specimens may be the cornerstone of preventing underdiagnosis of these tumors and allow accumulation of knowledge to guide proper therapeutic intervention.

Abstract

A 35-year-old female patient presented with the following symptoms of Holmes-Adie syndrome: photophobia, enlargement of the left pupil unresponsive to light, Achilles areflexia. The pilocarpine test was positive. No tumor or other neurological abnormality was found. She had a 19-year history of autoimmune hepatitis. Flares up were observed following each 3 deliveries. At age of 31 she presented with diarrhea and weight loss. Abdominal tumor was detected by ultrasound. The surgically removed tumor was histologically a benign mesenteric multicystic lymphangioma. Simultaneously, celiac disease was diagnosed. Gluten-free diet resulted in a significant improvement of celiac disease, but not of autoimmune hepatitis. Autonomic neuropathy was proven by standard cardiovascular tests. The patient was a homozygous carrier for HLA DQ2 antigen characteristic for celiac disease and heterozygous for HLA DR3 B8 frequent in autoimmune liver diseases. Our novel observation on association of Holmes-Adie syndrome with autoimmune hepatitis and celiac disease is suggestive for a common immunological background for all three entities present in a patient with mesenteric multicystic lymphangioma.

Key words: Holmes-Adie syndrome; Autoimmune hepatitis; Celiac disease; Mesenteric lymphangioma; Autonomic neuropathy

INTRODUCTION

Holmes-Adie syndrome (HAS) first described in 1931 is characterized by unilateral or bilateral dilatation of the pupil and lack of light reaction because of postganglionic injury of the parasympathetic oculomotor nerve. Ciliary muscle denervation causes accommodation impairment, while sphincter pupillae denervation produces mydriasis. It is often accompanied with peripheral nerve dysfunctions. Deep tendon reflexes (knee- and Achilles-reflex) are absent because of impaired spinal monosynaptic connections[1]. Most cases are caused by viral infection. Trauma, tumors, vascular lesion with ischemia, giant cell arteritis, diabetes mellitus or autonomic neuropathies can also damage the ciliary ganglion[2]. This is the first report on association of Holmes-Adie syndrome with autoimmune hepatitis (AIH) and celiac disease (CD) raising the probability of common autoimmune background in a patient with multicystic mesenterial lymphangioma.

CASE REPORT

A 35-year old female patient presented with symptoms of Holmes-Adie syndrome: photophobia and enlargement of the left pupil with absent reaction to light, accompanied with knee- and Achilles-areflexia (Figure 1). The positivity of pilocarpine test confirmed the diagnosis of HAS. Tumor, actual infection, ischemic disease, trauma and mechanical compression were excluded.

She had a 19-year history of AIH proven by liver biopsies, autoantibody positivity (antinuclear antibody/ANA and smooth muscle antibody/SMA) and exclusion of other causes. The liver disease initially responded well to prednisone and azathioprine treatment. Flares up were observed following each 3 deliveries.

At age of 31, after the third delivery, she presented with anorexia, severe diarrhea, rapid loss of weight (18 kg/6 mo), amenorrhea and sideropenic anemia. Abdominal tumor was found by ultrasound and CT. The surgically removed tumor was 10 cm in diameter, histologically proven as a benign mesenteric multicystic lymphangioma. Simultaneously, in the background of malabsorption syndrome, celiac disease (CD) was diagnosed. Biopsy proved villous atrophy, anti-endomysium and transglutaminase antibody test was positive. Gluten-free diet resulted in a significant improvement and disappearance of symptoms of celiac disease. The secondary lactose intolerance ceased and the severe calcium deficient osteopenia (osteodensitometric Z-score L2-L4: -4,4) improved. The family history

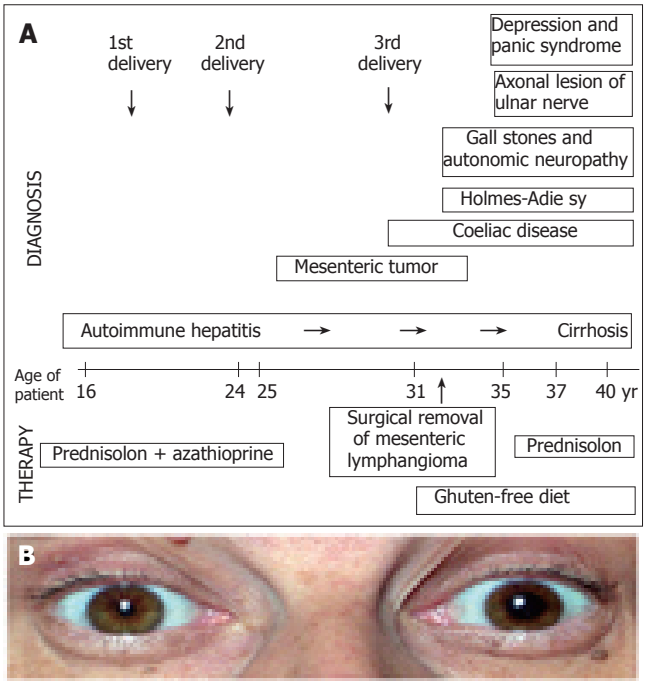

Figure 1 A: Sequence of events, appearance of symptoms and applied treatment. B: Dilated and light insensitive left pupil as symptom of Holmes-Adie syndrome.

was negative for any autoimmune disease.

Holmes-Adie syndrome developed 4 years later and still persisted at the time when she was admitted. The progression of AIH was observed after immunosuppressive treatment and the strict gluten free diet. Now, at her age of 40 the liver biopsy showed cirrhosis. Axonal lesion of ulnar nerve was detected by electroneurography-electromyography (ENG-EMG) and autonomic neuropathy was proven by standard cardiovascular tests. The patient had gallstones in the enlarged gall bladder with reduced motility. In the last few years panic syndrome and severe depression developed. Alprazolam and fluoxetin were applied. She had polyarthralgia with the involvement of lumbar spine, knee and proximal interphalangeal and metacarpophalangeal joints. She complained of morning stiffness of 1 h duration. However, the X-ray examination was not characteristic for rheumatoid arthritis and the rheuma factor was negative. The sequence of events, appearance of symptoms and applied treatment are summarized on Figure 1.

The patient was a homozygous carrier for HLA DQ2 antigen characteristic for celiac disease and heterozygous for HLA DR3 B8 frequent in autoimmune liver diseases.

DISCUSSION

Association of autoimmune hepatitis and celiac disease has been reported, but not with Holmes-Adie syndrome. Initial reports in the late 1970s revealed that hepatic aminotransferase enzymes are frequently elevated at the time of diagnosis of CD[3]. The scale of the liver dysfunction in CD is wide: from raised transaminases with mild hepatic steatosis to chronic hepatitis and cirrhosis caused mainly by primary biliary cirrhosis (PBC), autoimmune hepatitis (AIH) or primary sclerosing cholangitis (PSC). Prevalence of CD in patients with primary biliary cirrhosis (2-7%) and AIH (3-5%) is higher than that in the normal population[4]. Liver dysfunction should therefore be examined in patients with CD at the time of diagnosis. On the other hand, CD should be searched in the background of cryptogenic liver diseases. Two mechanisms must be considered in the pathogenesis of liver dysfunction associated with CD: impaired gut mucosal integrity, malabsorption and increased permeability; and a common inherited predisposition for AIH and CD[4]. The HLA pattern in our patient supports the latter theory. She was a homozygous carrier for HLA DQ2 antigen characteristic for celiac disease and heterozygous for HLA DR3 B8 frequent in autoimmune liver diseases. HLA DR3 B8 is in close linkage disequilibrium with HLA DQ[4, 5].

This is the first report on the association of Holmes-Adie syndrome with these two autoimmune diseases. The exclusion of other etiologies of Holmes-Adie syndrome suggests the possibility of common autoimmune background. Tumors, actual infection, ischaemic disease, diabetes mellitus, trauma or mechanical compression which can damage the ciliary ganglion[2], were excluded in our patient. Autonomic neuropathy is well known in Holmes-Adie syndrome. Evidence of autonomic dysfunction has been proven in 40% of the patients with Holmes-Adie syndrome[5]. In recent years it has been suspected that autonomic failure has an autoimmune pathogenesis and autoantibodies against ganglional nicotinic acetylcholine receptor can induce autonomic neuropathy similar to the pathophysiology of myasthenia gravis[7, 8]. However, there are only three case reports in the literature in which autoimmunity is hypothesized in the background of Holmes-Adie syndrome[9,10]. There are no data about the HLA pattern in Holmes-Adie syndrome. Since no other cause of HAS has been found, it is a logical hypothesis that the neurological abnormalities including damage of postganglionic parasympathetic nerves, are connected with autoimmune pathomechanism characteristic features in celiac disease and autoimmune hepatitis.

The presented case is a further example for manifestation of celiac disease in adulthood[5]. The immunosuppressive treatment for AIH might have delayed the manifestation of CD at age of 31. Several extrahepatic manifestations of CD could be the first presenting symptoms, making difficult the diagnosis. Known associated diseases of CD are autoimmune liver disease, thyroid gland disease, arthritis, Sjörgen syndrome, neurological and psychiatric symptoms, diabetes mellitus, cardiomyopathy, osteoporosis, tumors, infertility and dermatitis herpetiformis[5]. An increased occurrence of axonal neuropathy has been observed in well treated CD[11]. Usai *et al*[12] reported that autonomic nervous system (ANS) abnormalities are found in 45% of patients with CD. In a patient reported by Giorgetti *et al*[13]. ANS dysfunction does not improve after gluten-free diet. They speculated that ANS dysfunction may be a two step process: a gluten-related, reversible first phase and a gluten-independent, probably autoimmune-related second phase, which does not improve on gluten-free diet. Our case supports this hypothesis, because both the axonal lesion of ulnar nerve and the autonomic neuropathy proven by standard cardiovascular tests manifested during a strict gluten-free diet. Probably CD initiates cer-

tain autoimmune processes which enhance and perpetuate the subclinical neuropathy having existed since at least the manifestation of CD or perhaps of AIH.

Patients with CD have a 2.0-fold higher risk of death of gastrointestinal malignancies, mainly lymphomas[14]. However, there are no data on the coincidence of mesenteric multicystic lymphangioma and celiac disease. Mesenteric multicystic lymphangioma is often misdiagnosed as a malignant disease[15]. Retrospectively, rapid weight-loss is the consequence of CD but not of the tumor. Therefore, in the background of rapid loss of body weight, CD should be considered even in patients with large abdominal tumors.

Autonomic neuropathy common in chronic liver diseases might be a cofactor for gallstone formation via gall bladder hypomotility[16, 17]. Decreased gall bladder motility has been described in celiac disease as a risk factor for gallstone formation[18]. In our patient, autonomic neuropathy was proven by standard cardiovascular tests and gall bladder hypomotility by ultrasound as the contributing factors to the development of gallstones.

In conclusion, association of Holmes-Adie syndrome with autoimmune hepatitis and celiac disease is suggestive for a common immunological background for all three entities presented in a patient with mesenteric multicystic lymphangioma. One of the messages of this report is that by observing anisocoria, Holmes-Adie syndrome should be considered, and in case of Holmes-Adie syndrome of unknown etiology, autoimmune diseases as AIH or CD should be searched.

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*WJG, World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly journal of more than 48 000 circulation, published on the 7th, 14th, 21st and 28th of every month.

Original Research, Clinical Trials, Reviews, Comments, and Case Reports in esophageal cancer, gastric cancer, colon cancer, liver cancer, viral liver diseases, *etc.*, from all over the world are welcome on the condition that they have not been published previously and have not been submitted simultaneously elsewhere.

Published by
The WJG Press

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297mm×210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page , Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures and Figure Legends. Neither the editors nor the Publisher is responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part without the written permission of both the authors and the Publisher. We reserve the right to put onto our website and copy-edit accepted manuscripts. Authors should also follow the guidelines for the care and use of laboratory animals of their institution or national animal welfare committee.

Authors should retain one copy of the text, tables, photographs and illustrations, as rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for the loss or damage to photographs and illustrations in mailing process.

Online submission
Online submission is strongly advised. Manuscripts should be submitted through the Online Submission System at: http://www.wjgnet.com/index.jsp. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/wjg/help/instructions.jsp) before attempting to submit online. Authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com for assistance. If you submit your manuscript online, do not make a postal contribution. A repeated online submission for the same manuscript is strictly prohibited.

Postal submission
Send 3 duplicate hard copies of the full-text manuscript typed double-spaced on A4 (297 mm×210 mm) white paper together with any original photographs or illustrations and a 3.5 inch computer diskette or CD-ROM containing an electronic copy of the manuscript including all the figures, graphs and tables in native Microsoft Word format or *.rtf format to:

Editorial Office

World Journal of Gastroenterology
Editorial Department: Apartment 1066, Yishou Garden,
58 North Langxinzhuang Road,
PO Box 2345, Beijing 100023, China
E-mail: wjg@wjgnet.com
http: //www.wjgnet.com

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using a word-processing software. All submissions must be typed in 1.5 line spacing and in word size 12 with ample margins. The letter font is Tahoma. For authors from China, one copy of the Chinese translation of the manuscript is also required (excluding references). Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page
Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was accomplished, disclosure of any financial support for the research, and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (removing all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s) and full family name.

Abstract
An informative, structured abstract of no more than 250 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipments, and the experimental procedures should be included. RESULTS: The observatory and experimental results, including data, effects, outcome, *etc.* should be included. Authors should present *P* value where necessary, and the significant data should accompany. CONCLUSION: Accurate view and the value of the results should be included.

The format of structured abstracts is at: http://www.wjgnet.com/wjg/help/11.doc

Key words
Please list 3-10 key words that could reflect content of the study mainly from *Index Medicus*.

Text
For most article types, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include in appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both.

Illustrations
Figures should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. No detailed legend should be involved under the figures. This part should be added into the text where the figures are applicable. Digital images: black and white photographs should be scanned and saved in TIFF format at a resolution of 300 dpi; color images should be saved as CMYK (print files) but not as RGB (screen-viewing files). Place each photograph in a separate file. Print images: supply images of size no smaller than 126 mm × 76 mm printed on smooth surface paper; label the image by writing the Figure number and orientation using an arrow. Photomicrographs: indicate the original magnification and stain in the legend. Digital drawings: supply files in EPS if created by freehand and illustrator, or TIFF from photoshops. EPS files must be accompanied by a version in native file format for editing purposes. Existing line drawings should be scanned at a resolution of 1200 dpi and as close as possible to the size where they will appear when printed. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes of atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...

Tables
Three-line tables should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each table. No detailed legend should be included under the tables. This part should be added into the text where the tables are applicable. The information should complement but not duplicate that contained in the text. Use one horizontal line under the title, a second under the column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations
Data that are not statistically significant should not be noted. $^{a}P<0.05$, $^{b}P<0.01$ should be noted ($P>0.05$ should not be noted). If there are other series of *P* values, $^{c}P<0.05$ and $^{d}P<0.01$ are used. Third series of *P* values can be expressed as $^{e}P<0.05$ and $^{f}P<0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or some other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.* in a certain sequence.

Acknowledgments
Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions are included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should code the references according the citation order in text in Arabic numerals, put references codes in square brackets, superscript it at the end of citation content or the author name of the citation. For those citation content as the narrate part, the coding number and square brackets should be typeset normally. For example, Crohn's disease (CD) is associated with increased intestinal permeability[1,2]. If references are directly cited in the text, they would be put together with the text, for example, from references [19,22-24], we know that...

When the authors code the references, please ensure that the order in text is the same as in reference part and also insure the spelling accuracy of the first author's name. Do not code the same citation twice.

PMID requirement

PMID roots in the abstract serial number indexed by PubMed (http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information of the journal citations is very important. Through reference testing system (http://www.aushome.cn/cgi-bin/index.pl), the authors and editor could check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in ASP file so that the readers can read the abstract of the citations online immediately.

Style for journal references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). Title of the cited article and italicized journal title (Journal title should be in its abbreviation form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634]

Note: The author should test the references through reference testing system (http://www.aushome.cn/cgi-bin/index.pl)

Style for book references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Format

Standard jounal article (list all authors and include the PubMed ID [PMID] where applicable)

1 **Das KM,** Farag SA. Current medical therapy of inflammatory bowel disease. *World J Gastroenterol* 2000; 6: 483-489 [PMID: 11819634]

2 **Pan BR**, Hodgson HJF, Kalsi J. Hyperglobulinemia in chronic liver disease: Relationships between *in vitro* immunoglobulin synthesis, short lived suppressor cell activity and serum immunoglobulin levels. *Clin Exp Immunol* 1984; 55: 546-551 [PMID: 6231144]

3 **Lin GZ,** Wang XZ, Wang P, Lin J, Yang FD. Immunologic effect of Jianpi Yishen decoction in treatment of Pixu-diarrhoea. *Shijie Huaren Xiaohua Zazhi* 1999; 7: 285-287

Books and other monographs (list all authors)

4 **Sherlock S,** Dooley J. Diseases of the liver and billiary system. 9th ed. Oxford: Blackwell Sci Pub, 1993: 258-296

Chapter in a book (list all authors)

5 **Lam SK.** Academic investigator's perspectives of medical treatment for peptic ulcer. In: Swabb EA, Azabo S. Ulcer disease: investigation and basis for therapy. New York: Marcel Dekker, 1991: 431-450

Electronic journal (list all authors)

6 **Morse SS.** Factors in the emergence of infectious diseases. Emerg Infect Dis serial online, 1995-01-03, cited 1996-06-05; 1(1):24 screens. Available from: URL: http//www.cdc.gov/ncidod/EID/eid.htm

Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those that are linked with a hyphen and the difference between the two numbers at two sides of the hyphen is more than 5. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered as inappropriate references. Authors should not cite their own unrelated published articles.

Statistical data

Present as mean ± SD and mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as γ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, *p*(B)= 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2 not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format about how to accurately write common units and quantum is at: http://www.wjgnet.com/wjg/help/15.doc

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further mention.

Italicis

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyr*A, *arg* 1, *c myc*, *c fos*, *etc.*

Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*

Biology: *Helicobacter pylori, H pylori, E coli, etc.*

SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. Author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, the final check list for authors, and responses to reviewers by a courier (such as EMS) (submission of revised manuscript by e-mail or on the *WJG* Editorial Office Online System is NOT available at present).

Language evaluation

The language of a manuscript will be graded before sending for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing; (4) Grade D: rejected. The revised articles should be in grade B or grade A.

Copyright assignment form

It is the policy of *WJG* to acquire copyright in all contributions. Papers accepted for publication become the copyright of *WJG* and authors will be asked to sign a transfer of copyright form. All authors must read and agree to the conditions outlined in the Copyright Assignment Form (which can be downloaded from http://www.wjgnet.com/wjg/help/9.doc).

Final check list for authors

The format is at: http://www.wjgnet.com/wjg/help/13.doc

Responses to reviewers

Please revise your article according to the comments/suggestions of reviewers. The format for responses to the reviewers' comments is at: http://www.wjgnet.com/wjg/help/10.doc

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Publication fee

Authors of accepted articles must pay publication fee.

EDITORIAL and LETTERS TO THE EDITOR are free of change.

Abstract

Increasing evidence suggests that derangement of gut flora is of substantial clinical relevance to patients with cirrhosis. Intestinal bacterial overgrowth and increased bacterial translocation of gut flora from the intestinal lumen, in particular, predispose to an increased potential for bacterial infection in this group. Recent studies suggest that, in addition to their role in the pathogenesis of overt infective episodes and the clinical consequences of sepsis, gut flora contributes to the pro-inflammatory state of cirrhosis even in the absence of overt infection. Furthermore, manipulation of gut flora to augment the intestinal content of lactic acid-type bacteria at the expense of other gut flora species with more pathogenic potential may favourably influence liver function in cirrhotic patients. Here we review current concepts of the various inter-relationships between gut flora, bacterial translocation, bacterial infection, pro-inflammatory cytokine production and liver function in this group.

Key words: Gut flora; Bacterial translocation; Cirrhosis

Almeida J, Galhenage S, Yu J, Kurtovic J, Riordan SM. Gut flora and bacterial translocation in chronic liver disease. *World J Gastroenterol* 2006; 12(10): 1493-1502

http://www.wjgnet.com/1007-9327/12/1493.asp

INTRODUCTION

Disturbances of the microecology of the indigenous gut flora are prevalent in patients with chronic liver disease. Significantly increased viable counts of both Gram-positive and negative bacterial species have been recovered from faeces of cirrhotic patients[1]. A high prevalence of small intestinal bacterial overgrowth, in particular, has been demonstrated in this group[2-5]. This has been attributed, at least in part, to a decrease in small intestinal motility associated with increased adrenergic activity and portal hypertension[4-8]. Studies performed in experimental animals demonstrating important effects of gut flora on intestinal motility[9,10] suggest that the development of small intestinal bacterial overgrowth in the setting of intestinal stasis may further impair intestinal motility, thereby creating a self-perpetuating vicious cycle.

In addition to the range of symptoms and consequences of bacterial overgrowth *per se*[11], increasing evidences suggest that derangement of gut flora is of substantial clinical relevance to patients with cirrhosis. Intestinal bacterial overgrowth and increased bacterial translocation of gut flora from the intestinal lumen, in combination with failure of immune defence mechanisms to efficiently remove these translocating microorganisms, predispose to an increased potential for bacterial infection in this group[12]. Impaired immune defences include reduced opsonic activity due to low hepatic synthesis of complement, deranged function of macrophage Fc gamma receptors and reduced phagocytic and killing capacity of neutrophils[13-16]. Impairment of mucosal immunity may also be important. The high prevalence of associated malnutrition in cirrhotic patients[17] exacerbates the potential for infection to occur.

Recent studies suggest that, in addition to their role in the pathogenesis of overt infective episodes and the clinical consequences of sepsis, gut flora contributes to the pro-inflammatory state of cirrhosis even in the absence of overt infection[18]. Furthermore, manipulation of gut-flora using either a Gram-positive synbiotic (probiotic and fermentable fibre) regimen or fermentable fibre alone to augment the intestinal content of lactic acid-type bacteria at the expense of other gut flora species with more pathogenic potential may favourably influence liver function in cirrhotic patients[19]. Here we review current concepts of the various inter-relationships between gut flora, bacterial translocation, bacterial infection, pro-inflammatory cytokine production and liver function in this group.

BACTERIAL TRANSLOCATION IN CIRRHOSIS

Bacterial translocation is defined as the migration of bacteria from the intestinal lumen to mesenteric lymph nodes or other extra-intestinal sites[20]. Gram-negative

members of the Enterobactereaceae family (such as *Escherichia coli* and *Klebsiella spp*), enterococci and other streptococci species are the most effective at bacterial translocation to mesenteric lymph nodes[21]. These bacterial flora, the organisms most commonly implicated in community-acquired infective episodes in patients with cirrhosis[22], can translocate across even histologically normal intestinal mucosa[21,23]. Certain strains of *Escherichia coli* are especially efficient at translocation, possibly as a result of a greater ability to adhere to the intestinal mucosal surface[24]. While obligate anaerobic bacterial flora outnumber aerobic species by more than 100-fold, these flora only rarely translocate from the intestinal lumen[21]. Conversely, anaerobic strains limit the growth of other species with higher translocation potential and their selective elimination has been shown to promote translocation of such aerobic flora[25].

Most data in support of the occurrence of increased bacterial translocation in cirrhosis come from studies performed in experimental animals, in which bacterial translocation was defined by the presence of positive bacteriological cultures for gut flora in surgically-removed mesenteric lymph nodes[26]. These studies demonstrate that the prevalence of bacterial translocation to mesenteric lymph nodes is around 40% in cirrhotic rats with ascites and around 80% in such animals with spontaneous bacterial peritonitis (SBP)[27-31]. The concept of bacterial translocation predisposing to infection in experimental cirrhosis is further supported by data showing that bacteria isolated from mesenteric lymph nodes are genetically identical to strains causing SBP in the same animal[32].

Clinical studies of bacterial translocation in cirrhosis have been limited by the lack of non-invasive methods to detect its presence. Nonetheless, available evidence suggests that increased translocation of gut flora does occur in cirrhotic patients. A high rate of positive mesenteric lymph node cultures for enteric bacteria (30.8%) has been reported in patients with Child-Pugh class C cirrhosis undergoing liver transplantation or hepatic resection, with the incidence in the order of five times higher in this group than in Child-Pugh class A or B patients[33]. In another study, almost 20% of cirrhotic patients were found to have positive mesenteric lymph node cultures following partial hepatectomy, with bacteria responsible for instances of post-operative infection the same as those recovered from mesenteric lymph nodes in most cases[34].

The presence of bacterial DNA in serum and ascitic fluid has recently been proposed as a relatively non-invasive surrogate marker of bacterial translocation in the clinical setting[35]. Using such molecular techniques, bacterial translocation may be present in as many as one third of cirrhotic patients with portal hypertension and culture-negative ascites, with *Escherichia coli* the most frequently identified bacterial species[35]. The clinical relevance of the presence of bacterial DNA in culture-negative ascites has been suggested by the finding of increased local levels of pro-inflammatory cytokines[36], although the validity of this approach and the full clinical relevance of a positive result remain to be firmly established. Increased serum levels of lipopolysaccharide-binding protein, a phenomenon attributed to translocation of bacteria from the gut to the circulation, have been documented in a proportion of cirrhotic patients without overt infection and to predict the later development of severe bacterial infection in this group[37].

Pathogenesis of bacterial translocation in cirrhosis

Intestinal bacterial overgrowth Intestinal bacterial overgrowth is a major factor promoting bacterial translocation[38-41] and available evidence suggests that factors that promote intestinal bacterial overgrowth in particular, such as impaired intestinal motility, are important in facilitating bacterial translocation in cirrhosis. In experimental animals with cirrhosis, strategies to increase the intestinal transit rate, such as treatment with propranolol or cisapride, have been shown to reduce bacterial overgrowth and bacterial translocation[38,40,41]. In the clinical setting, cisapride has been shown to increase small intestinal motility and reduce bacterial overgrowth in patients with cirrhosis, with a trend towards a lower incidence of infection in treated patients[3,42].

Structural changes in intestinal mucosa Most clinical studies performed to investigate structural changes of intestinal mucosa in patients with cirrhosis have focussed on the small intestine. Shorter and thicker microvilli have been described. Morphologically intact tight junctions, which join together the apical poles of enterocytes and represent the first line of mucosal defence against paracellular absorption, have been reported in a small cohort of clinically stable cirrhotic patients with no prior history of infection with gut-derived bacteria[43]. Whether tight junctions are also intact in cirrhotic patients with a history of such infection and those with elevated nitric oxide levels may be more relevant, since nitric oxide, which is discussed in more detail below in relation to the clinical course of SBP, has been shown to reversibly dilate tight junctions in cultured intestinal epithelial cells[44]. Notably, dilatation of the intercellular space below tight junctions, the second line of defence against paracellular absorption, has been documented in patients with cirrhosis[43]. Mucosal alterations attributed to oxidative stress, including disturbed enterocyte mitochondrial function and increased lipid peroxidation of brush border membranes, have been reported in experimental animal models of cirrhosis[45], although the relevance of these changes to the pathogenesis of bacterial translocation is uncertain.

Thick-walled, dilated capillaries along with oedema of the lamina propria, fibromuscular proliferation, a reduced villus/crypt ratio and thickened muscularis mucosa in the small bowel have been found in cirrhotic patients with portal hypertension[46] and it has been proposed that an increased potential for bacterial translocation may exist in this setting[47]. However, in a study of cirrhotic patients with an elevated mean portal venous pressure in the order of 25 mm Hg undergoing liver transplantation, portal venous pressure was not significantly different in 8 cirrhotic patients with bacterial translocation and 71 with negative mesenteric lymph node culture results, implying that additional factors are required for bacterial translocation to occur in this group[33].

Luminal factors contributing to intestinal barrier function Other factors that contribute to the normal intestinal barrier against bacterial translocation (BT), including luminal factors, such as levels of bile acids, secretory immunoglobulin A, mucins, defensins, lysozyme and phopholipase A2, have been little studied in cirrhotic patients. Bile acids exert a trophic effect on intestinal mucosa[48] and inhibit intestinal bacterial overgrowth, especially of Gram-positive species[49]. An increased incidence of bacterial translocation in patients with obstructive jaundice has been reported[50]. However, whether the reduced intestinal luminal levels of bile acids that may be found in cirrhotic patients, as a consequence of reduced hepatic secretion and luminal deconjugation by overgrowth bacteria[12], contribute importantly to the potential for increased bacterial translocation in this group has not been established.

Intestinal immunity Little is known concerning the functional capacity of intestinal immunity in patients with cirrhosis and whether any disturbance of intestinal immune mechanisms contributes importantly to bacterial translocation, especially in the clinical setting. An increased number of intraepithelial lymphocytes with markedly impaired proliferative activity and capacity for production of interferon-γ have been reported in a murine model, with these changes correlating with increased bacterial translocation[51]. Whether this mechanism is important in the clinical situation is unknown. Notably, modest increases in small intestinal intraepithelial lymphocyte counts are found in patients with small intestinal bacterial overgrowth[52], raising the possibility that the increased levels found in cirrhotic animals may be explained on this basis. Whether the number or function of dendritic cells and other mononuclear cells in intestinal mucosa are deranged and contribute to the pathogenesis of bacterial translocation in patients with cirrhosis remains to be defined.

Anatomical site of bacterial translocation in cirrhosis

The anatomical site(s) from which bacterial translocation in cirrhosis occurs remains to be determined. Data in the non-cirrhotic setting suggest that the small intestine rather than the colon may be the major site of bacterial translocation. In particular, experimental studies involving inoculation of various regions of the gastrointestinal tract with equal quantities of *Escherichia coli* suggest that translocation occurs preferentially from the small bowel rather than the colon[53]. Similarly, in experimental animals with impaired intestinal motility, treatment with the prokinetic agent, cisapride, is associated with a reduced rate of bacterial translocation that parallels a reduction in jejunal but not caecal bacterial counts[3].

Intestinal permeability and its relation to bacterial translocation in cirrhosis

Functional studies have demonstrated that increased intestinal permeability, as reflected by dual sugar absorption tests or absorption of other test substances, occurs in patients with cirrhosis, especially in those with advanced liver disease[54-58]. Factors predisposing to this increased permeability in cirrhosis remain to be defined. In particular, any relationships with the structural changes of intestinal mucosa described above are uncertain. Enhanced intestinal permeability, likely via the paracellular route, has been reported in association with small intestinal bacterial overgrowth with Gram-negative gut flora in the non-cirrhotic setting[52], raising the possibility that this entity may at least contribute to the increased intestinal permeability in patients with cirrhosis. The relationship between intestinal permeability and the potential for bacterial translocation is uncertain, as increased permeability results have been found to correlate with a history of septic complications in some, but not all, reports.

GUT FLORA AND BACTERIAL INFECTION IN CIRRHOSIS

Bacterial infection, especially with intestinal-type flora, is a common complication in patients with cirrhosis[59-62]. Spontaneous bacterial peritonitis (SBP), urinary tract infection, respiratory tract sepsis (pneumonia and spontaneous bacterial empyema) and bacteraemia are the most frequent infective complications occurring in this group. The incidence of infection with Gram-positive cocci, in particular, has increased in recent years, with such flora now the most frequent isolates in hospitalised cirrhotic patients with nosocomial infection, especially those admitted to intensive care units, presumably due to the high rate of invasive procedures, including placement of indwelling vascular and bladder catheters, performed in this group[62]. Recent data suggest that between 15% and 35% of cirrhotic patients admitted to hospital develop nosocomial bacterial infection, substantially higher than the rate of hospital-acquired infection in the order of 5% to 7% in the general hospital setting[63].

Complicating infection may have severe adverse clinical consequences in cirrhotic patients. The associated pro-inflammatory response exacerbates hepatic dysfunction, encephalopathy and the haemodynamic disturbances that underlie the development of portal hypertension and hepatorenal syndrome[60,64,65]. Increasing evidence suggests that bacterial infection is a trigger for variceal haemorrhage in patients with cirrhosis[66,67], possibly as a consequence of both activation of hepatic stellate cells, leading to increased intrahepatic vascular resistance, and prostacyclin-related inhibition of platelet aggregation[66]. Conversely, variceal haemorrhage predisposes cirrhotic patients to bacterial infection with gut-derived flora[68-73], setting up a vicious cycle between gastrointestinal bleeding and infection in this group. This is a phenomenon of substantial clinical importance, as complicating infection is independently associated with early mortality in bleeding cirrhotic patients[69,70,72]. Worsening coagulopathy, due to the consumption of clotting factors by the extrinsic coagulation pathway[74] and the production of endogenous heparinoids[75], occurs in patients with cirrhosis and complicating bacterial infection. Sepsis is a common cause of death in cirrhotic patients[60,61,76-78]. The mortality rate associated with bacterial infection in this group is more than twenty times higher than in the general population[79].

SPONTANEOUS BACTERIAL PERITONITIS(SBP)

SBP, an infection of ascitic fluid typically with a single bacterial species in the absence of any other primary intra-abdominal source, is the most characteristic and serious infection occurring in patients with cirrhosis. Prospective studies suggest that SBP, including culture-negative and non-neutrocytic cases, is present in up to 23% of all cirrhotic patients with ascites admitted to hospital[80]. Gram-negative gut flora, especially *Escherichia coli* and *Klebsiella* species, are isolated in approximately 70% of culture-positive cases of community-acquired SBP. Aerobic Gram-positive bacteria belonging to *Streptococcus* and *Staphylococcus* spp constitute most of the remaining isolates. Pathogens belonging to *Aeromonas, Plesimonas, Listeria, Salmonella* and *Neisseria* spp are occasionally responsible. In keeping with their reduced potential for translocation from the intestine discussed above, obligate anaerobes are isolated in fewer than 5% of cases[81]. In hospitalised cirrhotic patients with nosocomial SBP, Gram-positive pathogens are predominant, accounting for over 70% of isolates, with methicillin-resistant *Staphylococcus aureus* accounting for nearly 25% of cases in one recent series[82].

The overall likelihood of a cirrhotic patient with ascites developing SBP at one year is in the order of 10%[80]. Clinical studies have identified several sub-groups of patients with cirrhotic ascites at particularly high risk for SBP. Over 70% of cases occur in those classified as Child-Pugh C[83]. An increased prevalence of SBP has been reported in patients with small intestinal bacterial overgrowth compared to their non-overgrowth counterparts, presumably due to the increased propensity for bacterial translocation[84]. Gastrointestinal haemorrhage is another important precipitant of SBP in this group. Bacteraemia and/or SBP, typically with Gram-negative enteric-type flora, develop within 48 hours of gastrointestinal haemorrhage in nearly 50% of Child-Pugh C patients with ascites[85]. The likelihood of SBP is related to the functional activity of Kupffer cells, which is impaired in patients with advanced liver disease[86]. However, the most powerful predictive factor identified in several series is an ascitic fluid total protein level $\leqslant$10 g/L, which reflects a low complement protein C3 concentration and, hence, opsonisation capacity. Patients with such low levels are at a six- to ten-fold increased risk of a first episode of SBP compared to cirrhotic counterparts with ascitic fluid total protein levels > 10 g/L[87,88].

CLINICAL COURSE

Despite a trend towards earlier diagnosis and commencement of antibiotic treatment, along with overall improvements in the general medical care of cirrhotic patients, the in-hospital mortality rate associated with SBP remains 30-50%[80]. This is largely related to underlying hepatic decompensation and a high prevalence of complicating hepatorenal syndrome. The latter occurs in approximately 30% of patients with SBP, predominantly in those with pre-existing renal impairment, and is progressive despite cure of infection in half of these cases[89]. Ascitic levels of nitric oxide, which are significantly increased in cirrhotic patients with SBP and persist for over two weeks despite appropriate antibiotic treatment[90,91], independently predict renal impairment in this setting[92]. Use of nephrotoxic antibiotics adds to the risk of renal failure in this setting[93]. The development of renal failure is the most important predictor of in-hospital mortality associated with SBP. This is in the order of 50% in those with complicating renal failure compared to only 6% in those without[89]. Albumin infusion improves systemic haemodynamics, prevents renal failure and improves survival compared to antibiotic treatment alone in patients with SBP. Beneficial effects are related to reduction in arterial vasodilatation and improved cardiac function[94]. Other correlates of poor outcome include increased ascitic levels of the pro-inflammatory cytokines, interleukin-6 and tumor necrosis factor-α (TNF-α)[95]. A recent report suggests a higher mortality rate in patients with nosocomial infection with staphylococcal species compared to that in patients with community-acquired SBP[82]. A trend towards a higher mortality rate when infection is with encapsulated strains of *Escherichia coli* associated with tissue invasiveness has also been reported[96].

The medium term prognosis for cirrhotic patients who have recovered from an episode of SBP is similarly poor, with a mortality rate at one year in the order of 30-80%[80]. Approximately 20% of patients who die within one year of an episode of SBP succumb to a further episode of spontaneous peritoneal infection, the remainder dying of causes, such as variceal haemorrhage, hepatorenal syndrome or hepatocellular carcinoma[97-99]. The risk of SBP recurrence within one year ranges from 40-70% and, as for an initial episode, is influenced mainly by the degree of underlying liver dysfunction and the ascitic fluid total protein level[83,98,99]. Survivors of an episode of SBP should be evaluated for liver transplantation in view of the high risk of recurrence and poor overall prognosis.

PROPHYLAXIS

Antibiotic prophylaxis against SBP may be beneficial in three high risk groups of cirrhotic patients, namely those who have survived a previous episode, those with low ascitic fluid total protein levels and those presenting with gastrointestinal haemorrhage[67-71,73,100-103]. Most prophylaxis studies have aimed to reduce or eradicate aerobic Gram-negative bacilli from the intestine using norfloxacin, a poorly absorbed quinolone with activity against these flora. The importance of antibiotic prophylaxis in patients with cirrhosis presenting with variceal haemorrhage is increasingly recognised. Treatment with norfloxacin, 400 mg twice daily either orally or via a nasogastric tube for seven days commencing immediately after emergency endoscopy, was associated with a significantly reduced in-hospital incidence of bacteraemia and/or SBP, especially with aerobic Gram-negative flora, compared to patients receiving no prophylactic antibiotics (3% *vs* 17%)[68]. Ciprofloxacin, 500 mg twice daily either orally or via nasogastric tube for 7 d immediately following endoscopy, has similarly been shown to significantly reduce the incidences of bacteraemia, SBP and urinary tract infection compared to placebo (0% *vs* 23%, 3% *vs*

13% and 5% *vs* 18%, respectively)[103]. Implementation of treatment protocols that incorporate antibiotic prophylaxis led to a fall in post-variceal bacterial infection rates from 38% to 14% over the past two decades in a large French centre[69]. Antibiotic prophylaxis has been shown to reduce the incidence of not only bacterial infection, but also early re-bleeding following variceal haemorrhage, especially in Child-Pugh class C patients, those requiring ventilatory support and those initially treated with balloon tamponade[67,70,71,73].

Several cost analysis studies have shown that prophylactic treatment with norfloxacin in each of these high risk groups is cost effective, as a consequence of the reduced incidence of SBP and its associated resource utilisation[67,104,105]. Short-term prophylaxis with trimethoprim-sulphamethoxazole is also cost-effective, especially in those at high risk for SBP[105]. Most studies report a reduction in overall mortality associated with prophylactic antibiotic treatment, although a statistically significant survival benefit has been more difficult to demonstrate. This is not surprising, as the likelihood of dying as a result of progressive liver failure, variceal haemorrhage, hepatocellular carcinoma or other causes is unaffected by the use of prophylactic antibiotics. More recently, a meta-analysis of 13 randomized controlled trials has suggested that antibiotic prophylaxis of hospitalized cirrhotic in-patients is efficacious in reducing the relative risk of in-hospital death (relative risk of dying 0.70), irrespective of underlying risk factors[107]. In addition, a meta-analysis of 534 cirrhotic patients with gastrointestinal bleeding has shown that short-term antibiotic prophylaxis significantly increases short-term survival rates by a mean 9% in this setting[107].

A particular concern, especially with long-term antibiotic prophylaxis, is the potential for the development of infection with antibiotic-resistant bacteria. Initial studies of norfloxacin prophylaxis against SBP reported a low incidence of infection with quinolone-resistant Gram-negative bacterial species. More recent studies, however, suggest an increased prevalence of infection with such microorganisms. Over 20% of cases of SBP due to *Escherichia coli* were with a norfloxacin-resistant strain in a recent series from Spain[108], while 50% of cases of culture-positive SBP in patients receiving long-term norfloxacin prophylaxis and 16% of instances in patients not treated with this drug were caused by norfloxacin-resistant Gram-negative bacteria in another Spanish report[62]. A high rate of SBP due to trimethoprim-sulphamethoxazole-resistant Gram-negative flora in excess of 40% was also documented in norfloxacin-treated patients. An increased proportion of infections with Gram-positive bacterial species has also been reported in this setting, including instances of severe hospital-acquired staphylococcal infections[109]. An increased incidence of carriage of methicillin-resistant *Staphylococcus aureus* has also been documented in cirrhotic patients treated with norfloxacin prophylaxis[110].

Such experiences highlight the need for non-antibiotic-based strategies to prevent intestinal bacterial overgrowth, bacterial translocation and SBP in patients with cirrhosis. As alluded to earlier, a six-month trial of the pro-motility agent, cisapride, was associated with improved small intestinal motility, reversal of bacterial overgrowth and a tendency towards a reduced incidence of infection with gut-derived flora in a cohort of cirrhotic patients[3,42]. Unfortunately, cisapride has been withdrawn from use in some countries because of potential for cardiac arrhythmia. Alternatively, treatment with either symbiotics (in the form of four species of lactic acid bacteria and fermentable fibre) or fermentable fibre alone has recently been shown to significantly reduce viable counts of potentially pathogenic Gram-positive and Gram-negative gut flora in patients with cirrhosis[19]. In another study, a lower rate of post-operative bacterial infection was documented in liver transplant recipients treated with an early enteral supply of a synbiotic regimen that included *Lactobacillus plantarum* and fermentable fibre than in patients receiving selective intestinal decontamination[111]. A follow-up randomised double-blind trial in liver transplant recipients showed that early enteral nutrition supplemented with a mixture of lactic acid bacteria and fermentable fibre significantly reduced the incidence of post-operative bacterial infection compared to supplementation with fermentable fibre alone[112]. Based on these reports, the possible use of synbiotics for prophylaxis against SBP in cirrhotic patients warrants investigation. Conversely, probiotic treatment with a lactobacillus strain without additional fermentable fibre was ineffective in preventing bacterial translocation and SBP in rats with experimental cirrhosis, despite successful intestinal colonisation[113].

GUT FLORA AND PRO-INFLAMMATORY STATE OF CIRRHOSIS IN ABSENCE OF OVERT INFECTION

Pro-inflammatory cytokines, such as TNF-α, have been shown to be critically involved in the development and/or exacerbation of liver injury in animal models[115,116]. Activation of macrophages by endotoxin, a cell wall component of Gram-negative bacteria, plays a key role in the over-production of TNF- α and liver injury in these settings[117,118]. Increased translocation from the gut lumen and reduced hepatic clearance have each been proposed to predispose to endotoxaemia in this situation[119,120]. In the clinical setting, increased circulating levels of both endotoxin and pro-inflammatory cytokines have been documented in patients with chronic liver disease, even in the absence of overt infection[120-125]. Based on experiences in experimental animals, it has, until recently, been assumed that endotoxaemia causes the raised pro-inflammatory cytokine levels in this group[121,126-128]. However, a significant correlation between circulating endotoxin and pro-inflammatory cytokine levels has generally not been show n[18,120,121,124,126], raising the possibility that, unlike in animal models, stimuli other than endotoxin may be important.

Recent analyses of the expression of Toll-like receptors (TLRs) in patients with cirrhosis have helped to clarify this issue. These receptors are the human homologues of the Drosophila Toll protein and comprise a family of at least ten transmembrane receptor proteins, the intracellular domains of which show distinct sequence homology with the interleukin-1 receptor. TLRs play a critical role in the

induction of innate immunity to microbial pathogens via recognition of conserved molecular patterns. In particular, it is known that TLR4, in association with CD14 and MD-2, is responsible for signal transduction leading to TNF-α production in response to endotoxin. In contrast, TLR2 is required for signaling in response to a number of Gram-positive microbial stimuli, including whole bacteria and cell wall components, such as peptidoglycan and lipoteichoic acid[129-131]. Indeed, significantly increased expression on peripheral blood mononuclear cells (PBMCs) of TLR2 but not of TLR4 has recently been demonstrated in patients with cirrhosis but no overt infection[18]. Furthermore, PBMC expression of TLR2 but not that of TLR4 was shown to correlate significantly with circulating levels of both TNF-α and anti-inflammatory soluble TNF receptors[18]. These novel findings suggest that signaling via TLR2 but not TLR4 contributes to the increased circulating levels of TNF-α levels found in cirrhosis and imply, contrary to previous assumptions, an important role for Gram-positive microbial stimuli rather than endotoxin in this process. This contention is supported by *in vitro* PBMC stimulation data consistent with presensitisation by Gram-positive microbial stimuli but not endotoxin *in vivo*. In addition, supplementation of cirrhotic patients with a synbiotic regimen including four Gram-positive gut flora and fermentable fibre led to further increases in PBMC expression of TLR2 and circulating TNF-α levels in most cases, suggesting that Gram-positive stimuli derived from the gut, in particular, may be important in promoting the increased circulating levels of both pro-inflammatory and anti-inflammatory TNF-related molecules found in patients with cirrhosis[18].

GUT FLORA AND HEPATIC FUNCTION IN CIRRHOSIS

Reversal of minimal hepatic encephalopathy has been reported in 50% of predominantly Child-Pugh class B or C cirrhotic patients treated with a lactic acid bacteria-based synbiotic regimen for 30 d, an efficacy comparable to that of treatment with lactulose[19]. In addition, the Child-Pugh class improves in nearly 50% of initially Child-Pugh class B or C synbiotic-treated patients, a proportion significantly higher than that in placebo-treated counterparts (8%). Treatment is associated with a significant increase in the faecal content of lactobacilli at the expense of potentially pathogenic Gram-positive and negative bacterial species. Bacterial overgrowth is also reversed and improvements in minimal hepatic encephalopathy and the Child-Pugh class occurs in 50% and 29%, respectively, of cirrhotic patients treated with fermentable fibre alone. Both in synbiotic- and fermentable fibre alone-treated patients, improvement in the Child-Pugh class occurs as a result of significant improvements in the serum bilirubin and albumin levels and in prothrombin activity. Significantly reduced hepatic necro-inflammatory activity, as reflected by serial ALT levels, is documented in both groups. Improvement in clearance of indocyanine green has also been reported in cirrhotic patients treated with synbiotics[132]. These findings are in keeping with reported experiences in experimental animals' suggesting that oral supplementation with Gram-positive probiotics can protect against hepatocellular damage. In particular, rats fed lactobacilli have been shown to be protected against alcohol-induced liver damage[133], while studies of probiotic use in a murine model of non-alcoholic fatty liver disease have found reductions in the intra-hepatic expression of various molecular markers of inflammation, including nuclear factor kappa-B and TNF-α[134,135].

Abstract

A variety of hepatic and biliary tract disorders may complicate the clinical course of celiac disease. Some of these have been hypothesized to share common genetic factors or have a common immunopathogenesis, such as primary biliary cirrhosis, primary sclerosing cholangitis and autoimmune forms of hepatitis or cholangitis. Other hepatic changes in celiac disease may be associated with malnutrition resulting from impaired nutrient absorption, including hepatic steatosis. In addition, celiac disease may be associated with rare hepatic complications, such as hepatic T-cell lymphoma. Finally, pancreatic exocrine function may be impaired in celiac disease and represent a cause of treatment failure.

Key words: Celiac disease; Liver disease; Cholangitis; Autoimmune hepatitis; Hepatic vein obstruction; Primary biliary cirrhosis

INTRODUCTION

A number of hepatobiliary and pancreatic disorders occur in celiac disease, a genetically-based small intestinal disorder that resolves with the complete restriction of dietary gluten[1]. Almost 3 decades ago, liver changes in celiac disease were first recognized by Hagander *et al*[2]. Later, Dickey *et al*[3] have confirmed these findings in a prospective evaluation of celiac disease patients and extended observations to results of gluten-free diet therapy. In some, these liver test changes are entirely reversible following administration of a gluten-free diet, while in others, clinically significant liver disease is not amenable to diet treatment alone[3]. Now, almost a decade after this report, recognition of celiac disease has been substantively improved, in part, a result of more modern serological assays for screening[4], the detection of tissue transglutaminase (tTG) as an autoantigen in celiac disease[5] and the increasingly widespread serological use of tTG ELISA to screen for celiac disease[6]. As a result of improved recognition of celiac disease, even more precise estimates of the overall disease burden related to hepatobiliary tract and pancreatic disorders will emerge.

In patients with unexplained elevations of liver enzymes, several studies using serological screening methods have estimated that almost 10% will prove to have celiac disease[7,8]. For example, Volta *et al*[7] examined endomysial and gliadin antibodies in 55 patients with elevations of liver chemistry tests in the absence of a known cause. Five patients had positive serological studies and small intestinal biopsies showed changes of celiac disease that responded to a gluten-free diet. Liver biopsies done in some patients showed a nonspecific inflammatory process and liver chemistry tests normalized with a gluten-free diet. Bardella *et al*[8] screened 140 patients with chronically elevated transaminase values for gliadin and endomysial antibodies; of these, 13 were seropositive. After 1 year on a gluten-free diet, 12 patients had normalization of liver enzyme tests.

In patients with known celiac disease, abnormal liver enzyme tests also occur[2,9-11]. Hagander *et al*[2] described elevated liver enzymes in 30 of 75 (40%) patients, while Bonamico *et al*[9] showed increased levels in 39 of 65 (60%) children, and Jacobsen *et al*[10] documented almost 50% with increased liver enzymes. In some, liver biopsy showed a nonspecific inflammatory process, although a more specific "chronic active hepatitis" was detected in 5 of 37 (13.5%) patients. Bardella *et al*[11] evaluated 158 consecutive adults with celiac disease and showed that 42% had abnormal liver enzyme levels. A gluten-free diet for 1 to 10 years resulted in complete normalization of liver chemistry tests in 95% patients.

In celiac disease, persistently abnormal liver chemistry tests may reflect the presence of a clinically occult hepatobiliary tract disorder with a possibly common immunopathogenesis. Specific examples of immune-mediated disorders include primary biliary cirrhosis, primary (lymphocytic, autoimmune) sclerosing cholangitis or autoimmune hepatitis. Alternatively, in some, a common genetically-based disorder, including altered control of small intestinal iron absorption resulting in a concomitant iron overload disorder, may be present, such as hemochromatosis. In addition, chronic changes

in liver chemistry tests may reflect a direct effect of the celiac disease. For example, impaired absorption and resultant malnutrition may lead to deposition of fat in the liver, related, in part, to reduced fat mobilization from hepatocytes. Indeed, massive hepatic steatosis has occasionally been reported in celiac disease. Finally, but very rarely, patients may develop a specific complication of celiac disease that involves the liver, such as a T-cell form of lymphoma.

HEPATOBILIARY TRACT DISEASES

Primary biliary cirrhosis

In 1978, Logan *et al*[12] described the first cases of primary biliary cirrhosis with celiac disease. Later, numerous additional cases have been reported[13-16]. In both disorders, other conditions having an immunological basis have been described, including diabetes and thyroiditis[16-19]. In addition, co-existence of primary biliary cirrhosis and celiac disease has not only been reported in Europe and the Americas, but also in migrants from South Asia[20] and the Coast Salish, an aboriginal population inhabiting the west coast of Canada thought to be of Asian descent[16]. To date, however, a definitive genetic predisposition or specific immunological alteration has not been clearly identified. Loss of weight, malabsorption, osteopenic bone disease, steatorrhea and elevated alkaline phosphatase activities are common features of both diseases, so that early in their coexistence, celiac disease or primary biliary cirrhosis may not be easily appreciated. In patients reported with both disorders, regardless of geographical origin or race, restriction of dietary gluten may have improved the diarrhea, but abnormal liver chemistry tests were usually not significantly altered with a gluten-free diet.

Some more recent studies have explored serological testing in primary biliary cirrhosis or celiac disease. Kingham and Parker[21] used a patient registry in the United Kingdom and defined the prevalence of primary biliary cirrhosis in 143 celiac patients as 3%, while the prevalence of celiac disease in 67 primary biliary cirrhosis patients was 6%. As a result, screening with antimitochrondrial antibodies in celiac disease was recommended, while in primary biliary cirrhosis, serological screening with gliadin antibodies or small intestinal biopsy was suggested. Dickey *et al*[22] found similar findings of 7% (4/57) primary biliary cirrhosis patients based on initial evaluation using endomysial antibodies (11% positive), followed by later duodenal biopsy confirmation. Despite 12 to 24 mo on gluten-free diets, however, improvement in liver chemistry tests was not detected even though endomysial antibodies disappeared. Using Danish and Swedish registry data based on over 8 000 patients with celiac disease, Sorensen *et al*[23] also suggested an increased risk of primary biliary cirrhosis. Using stored sera from 378 Canadian patients with primary biliary cirrhosis, Gillett *et al*[24] found that screening for IgA antibodies to endomysium and primary biliary cirrhosis were both positive in 10 (2.6%) patients and 5 patients had small intestinal biopsies confirming celiac disease. Intertestingly, however, another 44 primary biliary cirrhosis patients had raised IgA tissue transglutaminase antibodies but were negative for IgA endomysium antibody. In 255 patients with autoimmune cholestatic liver disorders, including 173 with primary biliary cirrhosis, Volta *et al*[25] found 9 with celiac disease (including 7 in those with primary biliary cirrhosis, 4%). In some recent studies, however, the importance of biopsy confirmation in patients with primary biliary cirrhosis has been demonstrated in sero-positive patients as false-positive IgA or IgG tTG antibodies may occur in primary biliary cirrhosis[26,27].

In a recent study using a general practice longitudinal database from the United Kingdom[28], an overall 3-fold risk of primary biliary cirrhosis was demonstrated in 4 732 patients diagnosed with celiac disease as compared with 23 620 age- and sex-matched controls.

Primary sclerosing cholangitis

Primary sclerosing cholangitis was first found to be associated with celiac disease in 1988 in 3 patients with diarrhea and steatorrhea[29]. Two also had concomitant "ulcerative colitis" (one with "inactive" quiescent disease and one with "mild" or "minimal change" colonic disease), a disorder known to be associated with primary sclerosing cholangitis. Although hepatobiliary tract changes were defined by cholangiography and liver biopsy, these did not respond to a gluten-free diet. Later, other cases were reported[10,25,30]. In one, the predominant lymphocytic nature of the portal inflammatory process was emphasized with increased intra-epithelial lymphocytes in biliary ductal epithelium[30], an observation also noted in gastric and colonic epithelium of celiac patients[31,33]. To date, despite some case report data[33], it has been difficult to show good evidence for a response of the hepatobiliary tract disease to a gluten-free diet. This may, in part, reflect sampling difficulties associated with liver biopsy as well as the response or lack of response of relatively non-specific liver chemistry test markers of cholestasis (e.g., serum alkaline phosphatase). Indeed, the origin of alkaline phosphatase activities measured in serum include the hepatobiliary tract and other tissues that may be substantially altered in celiac disease (i.e., bone and the intestine); conceivably all might be improved with a gluten-free diet.

Autoimmune hepatitis and cholangitis

This has been evaluated in only a limited numbers of case reports and survey studies. Unfortunately, many appeared before hepatitis C testing[13,35]. Jacobsen *et al*[10] performed liver biopsies in 37 of 171 celiac patients and found changes of "chronic active hepatitis" in 5 (2.3%) patients. Using antibodies to endomysium and gliadin, Volta *et al*[36] surveyed 157 patients with type 1 autoimmune hepatitis and 24 with type 2 autoimmune hepatitis for celiac disease. They found that 8 of these 181 (4%) patients were positive for endomysial antibodies, including 6 (4%) with type 1 disease and 2 (8%) with type 2 disease. Five of the 8 patients had a duodenal biopsy, most being asymptomatic, and all showed changes of subtotal villous atrophy, consistent with untreated celiac disease. The effects of steroid with or without azothioprine treatment on the underlying small intestinal histological changes were considered and also may have masked intestinal symptoms. Unfortunately, in this study, the effects of gluten-free

diet administration on the hepatic and intestinal changes were not reported. Recently, Villalta *et al*[37] evaluated 47 consecutive patients with autoimmune hepatitis, including 39 with type 1 disease and 8 with type 2 disease. Anti-IgA tissue transglutaminase and endomysial antibodies were positive in 3 (6.4%) patients and small intestinal biopsies confirmed the presence of the celiac disease histological changes[37].

Finally, celiac disease and other types of autoimmune liver and biliary tract disease may coexist. A case report of autoimmune cholangitis[38], a cholestatic liver disorder with biochemical evidence of cholestasis, histological evidence of inflammatory bile duct damage and an absence of anti-mitochondrial antibodies, was has been described in a patient with celiac disease. Interestingly, this patient's small intestinal biopsies were reported to be normal without a gluten-free diet while being treated with steroids and azathioprine. In an another case, Sedlack *et al*[39] reported an improvement in hepatic biochemistries without use of immunosuppressive agents.

HEMOCHROMATOSIS OR IRON OVERLOAD LIVER DISEASE

Celiac disease has been associated with hemochromatosis, which is not surprising, since both are relatively common disorders based on a common Celtic ancestry, so any association could be coincidental[40-42]. Iron absorption largely occurs in the proximal duodenum, the site most often histologically altered in celiac disease. Indeed, "isolated" iron deficiency with anemia may be the initial clinical manifestation of clinically occult celiac disease. In contrast, in iron overload liver disease, inappropriate iron absorption from the proximal small intestine occurs as body iron stores are markedly increased. In one of these early case reports, treatment of celiac disease and improvement in the pathological small intestinal changes led to worsening liver chemistry test values and recognition of occult iron overload liver disease (C282Y-negative), presumably related to improved intestinal uptake of dietary iron[41]. Another similar case of C282Y-positive hemochromatosis presented with diarrhea, positive anti-gliadin and endomysial antibodies. Subsequent small bowel biopsies showed villous atrophy[42]. Interestingly, in this latter case, phlebotomy therapy had to be terminated early because of an unexpectedly rapid fall in the serum ferritin measurement. A genetically-based linkage was also suggested since both diseases are associated with the HLA-region on chromosome 6. Later investigations have sought to resolve this possible relationship. Butterworth *et al*[43] observed that HFE (hemochromatosis susceptibility gene) locus mutations are common in celiac disease patients from the United Kingdom and may be important in protecting the celiac from iron deficiency, while others suggested that the significance of these observations may be controversial[44]. More recent studies in an Italian population with untreated celiac disease found that HFE mutations failed to protect against the development of iron deficiency[45]. Interestingly, in a recent case study of a patient with homozygous C282Y and celiac disease[46], reduced expression of the divalent metal transporter 1 (DMT1) was observed, but not ferroportin 1 (FP1) or transferrin receptor 1 (TfR1).

OTHER LIVER DISORDERS IN CELIAC DISEASE

Hepatic steatosis

Common causes of hepatic steatosis include alcohol-induced steatosis, diabetes mellitus, NASH syndromes and some forms of drug therapy, including corticosteroids. In some countries, dietary protein deficiency and kwashiorkor are important causes. Intestinal malabsorption is often associated with hepatic steatosis in patients with a prior jejunoileal bypass procedure for morbid obesity[47,48] and, sometimes, in those with inflammatory bowel disease, particularly after extensive intestinal resections[49]. Because celiac disease is now frequently recognized in a clinically occult form before manifestations of marked nutrient depletion are detected, hepatic steatosis is probably less common than in other intestinal diseases.

Several cases of fatty infiltration of the liver, often massive, have been described in adults with celiac disease[50-53]. Presumably, lesser degrees of hepatic fat deposition may occur. Most often if massive steatosis is evident, elevated transaminase and alkaline phosphatase activities have been documented along with alterations in coagulation. However, in most, clinical and biochemical changes attributed to the hepatic steatosis were improved with a gluten-free diet. In a patient with massive hepatic steatosis[52], a gluten-free diet for about 1 year also resulted in histological improvement in the fatty changes detected in the liver.

The mechanisms involved in fat deposition in the liver are not defined. Interestingly, after jejunoileal bypass, reduced serum levels of some essential and nonessential amino acids may be observed[47,48]. In addition, changes in serum amino acids have been recorded in patients with starvation-associated kwashiorkor[54,55]. Based on these nutritional disorders, it has been suggested that malabsorption in celiac disease might lead to chronic deficiency of a lipotropic factor (e.g., choline), with an associated pyridoxine deficiency, hepatic steatosis might occur[52]. Further studies are needed to define the precise pathogenetic mechanism or mechanisms for fatty liver in celiac disease.

Gallstone disease

Several studies have focused on gallbladder function in celiac patients. In some studies, slow emptying of the gallbladder has been documented[56,57], along with impaired contraction response to fat[56]. Studies of enteric endocrine cells showed significant quantitative changes in celiac patients, including complete absence of mucosal secretin cells[59]. In addition, studies with test meals have suggested impaired secretion of cholecystokinin in patients with celiac disease[59] or, possibly, impaired gallbladder responsiveness to cholecystokinin[56].

In spite of these physiological alterations, there does not appear to be a significant predisposition to gallstones in celiac disease. Only 9 of 350 patients had a cholecystectomy for gallstone disease[60]. However, in a

survey of elderly celiacs initially diagnosed after the age of 60 years, 6 of 30 (20%) had gallstone disease[61].

Hepatic vein obstruction

Although mesenteric vascular ischemia[62] and vasculitis[63-66] have been described in celiac disease, there are also reports of a unusual Budd-Chiari-like syndrome among celiac children from North Africa, particularly Tunisian and Algeria[67,68]. Hepatic vein obstruction has also been documented in 3 adults[69]. Deficiencies in protein C and antithrombin III are detected, and malabsorption of vitamin K in celiac disease has been proposed to cause transient protein C or protein S deficiencies. Further studies are needed to identify possible factors, either dietary or environmental agents, that may be important. More recently, a celiac patient with a Budd-Chiari syndrome associated with membranous obstruction of the inferior vena cava treated successfully with percutaneous balloon angioplasty has been reported[70].

Hepatic malignancies

While hepatocellular cancer has been reported in 1 patient, cirrhosis was also present[71]. Occasionally, the liver may be involved with lymphoma, the most frequently detected malignant disorder in celiac disease patients[72]. In some patients with celiac disease, lymphomatous deposits have been detected in the liver, presumably as metastatic lesions[71]. For example, lymphoma in the liver is apparently secondary to jejunal lymphoma, complicating celiac disease[71]. In general, involvement of the liver in celiac disease patients with lymphoma is limited and overshadowed by the clinical course of the intestinal disease. However, a fulminant cholestatic syndrome has been described in a celiac disease patient, resulting in hepatic failure[73]. Later investigations have shown widespread hepatic involvement with an unusual lymphoid neoplasm classified as a hepatosplenic lymphoma, a rare type of peripheral T-cell lymphoma with rearrangement of the gamma-delta T-cell receptor[74,75].

Liver failure

In patients with severe liver failure from a variety of causes in celiac disease, dietary treatment reverses hepatic dysfunction, even in patients with consideration for possible liver transplantation[76].

PANCREATIC DISEASE

While celiac disease is associated with insulin-dependent diabetes[77], pancreatic exocrine insufficiency and celiac disease have only occasionally been recorded[78-84]. Pancreatic calcification is most often associated with chronic or persisting pancreatic inflammation which is usually due to excessive consumption of alcoholic beverages. Atrophy, fibrosis and altered pancreatic function have been observed in experimental animals treated with diets deficient in protein, in adults with protein-energy malnutrition, in children with kwashiorkor and in some early autopsy studies of patients with celiac disease. In addition, pancreatic calcification has been reported with chronic protein malnutrition in the Indian subcontinent and in some African countries. Finally, a patient with celiac disease and pancreatitis with calcification has been described[83].

Although the frequency of pancreatic disease in celiac patients is not known, impaired pancreatic function occurs and may be a cause of persistently impaired nutrient assimilation and malnutrition. It has been estimated that over 20% of children with celiac disease have defective exocrine pancreatic function[85]. This may be related to several factors. Impaired secretion and/or release of pancreatic stimulating hormones from the diseased proximal small intestine may be important[60]. Immunohistochemical studies have demonstrated alterations in enteric endocrine cells, and in biopsies from patients with untreated celiac disease, an absence of secretin cells has been reported[59]. Studies with test meals in celiac patients have suggested impaired secretion of cholecystokinin-pancreozymin resulting in reduced pancreatic exocrine cell stimulation[81]. In addition, a deficiency of amino acids may result from impaired small intestinal amino acid uptake, leading to a reduction in precursors for pancreatic enzyme synthesis[55,80]. Also, protein malnutrition may lead to structural changes in the pancreas, including atrophy of acinar cells and pancreatic fibrosis[55], resulting in impaired pancreatic exocrine function. In a more recent study[86], pancreatic enzyme measurements were reduced with mucosal atrophy and could be inversely correlated with the degree of intestinal damage.

Abstract

The existence of a possible link between inflammatory bowel disease (IBD) and nonsteroidal anti-inflammatory drugs (NSAIDs) has been repeatedly suggested. Recently, a few studies have addressed the issue of a possible, similar effect by selective cyclooxygenase-2 inhibitors (COXIBs). The present article reviews the available scientific evidence for this controversial subject.

Key words: COX-2 inhibitor; Inflammatory bowel disease; Non-steroidal anti-inflammatory drugs

Guslandi M. Exacerbation of inflammatory bowel disease by nonsteroidal anti-inflammatory drugs and cyclooxygenase-2 inhibitors: Fact or fiction? *World J Gastroenterol* 2006; 12(10): 1509-1510

http://www.wjgnet.com/1007-9327/12/1509.asp

The use of nonsteroidal anti-inflammatory drugs (NSAIDs) has been associated with the onset of inflammatory bowel disease (IBD) or with a clinical flare-up of IBD in a number of case reports[1]. Both rectal and colonic frank ulcerations[2], small bowel ulcers[3] and intestinal, diaphragm-like strictures[1,3,4] have been reported after prolonged NSAID intake. On the other hand, no relationship is reported between NSAID treatment and exacerbation of underlying IBD[5,6].

The absence of controlled, prospective trials makes it difficult to draw definitive conclusions. Uncontrolled clinical experience suggests that anti-inflammatory agents can occasionally elicit relapse of IBD[7] and therefore should be employed with caution in patients with either ulcerative colitis or Crohn's disease. A recent systematic review of the available medical literature concluded that the epidemiological evidence for a positive link between NSAID exposure and relapse of IBD is weak, while admitting that "some patients with IBD do relapse when given NSAIDs[8].

Given the inconsistency of the conflicting data concerning the relationship between NSAIDs and IBD, the possible effect of selective cyclooxygenase-2 inhibitors (COXIBs) in this respect remains even more controversial. In order to better understand the relationship between anti-inflammatory treatment and IBD it is necessary to consider the possible pathogenetic mechanisms involved in the adverse effects on the bowel by non-selective NSAIDs. Several mechanisms have been postulated, such as enhanced intestinal permeability[9], enterohepatic recirculation of NSAIDS and formation of drug enterocyte adducts , the latter phenomena having been observed in animal studies[9] but never demonstrated in humans.

The major mechanism involved, however, is thought to be the inhibition of colonic prostaglandin synthesis[10], in particular of the COX-2 isoform. In the inflamed colon COX-2 expression is upregulated in an effort to repair mucosal damage[11] and its inhibition may result in exacerbation of colonic injury and in impairment of the mucosal repair processes elicited by the COX-2 enzyme[12]. In this respect both NSAIDs and COX-2 inhibitors could hamper the progression of the inflammatory state toward healing. On the other hand, if COX-2 is important in the reparative mechanisms in IBD, then patients with quiescent disease should have a lower risk of flare-up when taking NSAIDs[13].

The studies on the effect of COX-2 inhibitors on animal models of colitis have yielded conflicting results[9,14] even taking in account the differences in experimental conditions, type and dosages of the employed compounds. The only available study on human colonic mucosa, carried out on colonic biopsies taken in IBD patients, found that a highly selective COX-2 inhibitor, L-745337 inhibits local release of PGE2 and PGI2 to the same extent as indomethacin, a nonselective NSAID[15], an effect which would likely promote aggravation of mucosal damage..

In a clinical setting a perspective, open-label study in IBD patients with associated arthropathy rofecoxib, administered at a dose of up to 25 mg daily for 20 d, failed to elicit any flare-up of the intestinal disease[16]. Similarly, a retrospective analysis of IBD patients treated with

either celecoxib or rofecoxib for periods ranging from one week to 22 mo[17]. apparently confirmed the safety of COX-2 inhibitors in this respect. By contrast, a clinical exacerbation of the underlying IBD that subsided after the drug was discontinued, has been reported in 19% of patients taking rofecoxib[18]. In keeping with this finding a recent retrospective study in IBD patients taking either celecoxib or rofecoxib has found clinical relapse of the intestinal disease in 39% of cases, again with resolution of symptoms after COX-2 inhibitor withdrawal[19].

On the other hand, the first multicenter, random, double-blind, placebo-controlled study performed in USA ,taking into consideration of both clinical and endoscopic parameters, has shown that celecoxib 200 mg bid for 2 wk is as safe as placebo in patients with ulcerative colitis in remission[20].

Thus, as with nonselective NSAIDs, the available data remain conflicting and confusing. Summing up, on theoretical ground both NSAIDs and COX-2 inhibitors appear capable of triggering a flare-up of IBD by inhibiting the intestinal production of prostaglandins involved in the tissue reparative processes. In clinical practice, although clear-cut evidence is difficult to obtain due to the variable incidence of IBD reactivation and the paucity of prospective, controlled studies, both types of anti-inflammatory agents may precipitate recurrence of intestinal symptoms and therefore should be avoided, when possible, in patients with ulcerative colitis or Crohn's disease.

Abstract

Outcomes in patients with gastric cancer in the United States remain disappointing, with a five-year overall survival rate of approximately 23%. Given high rates of local-regional control following surgery, a strong rationale exists for the use of adjuvant radiation therapy. Randomized trials have shown superior local control with adjuvant radiotherapy and improved overall survival with adjuvant chemoradiation. The benefit of adjuvant chemoradiation in patients who have undergone D2 lymph node dissection by an experienced surgeon is not known, and the benefit of adjuvant radiation therapy in addition to adjuvant chemotherapy continues to be defined.

In unresectable disease, chemoradiation allows long-term survival in a small number of patients and provides effective palliation. Most trials show a benefit to combined modality therapy compared to chemotherapy or radiation therapy alone.

The use of pre-operative, intra-operative, 3D conformal, and intensity modulated radiation therapy in gastric cancer is promising but requires further study.

The current article reviews the role of radiation therapy in the treatment of resectable and unresectable gastric carcinoma, focusing on current recommendations in the United States.

EPIDEMIOLOGY

Worldwide, gastric cancer is the 5th the most common malignancy and the 2nd leading cause of cancer death. Significant geographic variation exists, with high risk areas including Japan, Central and South America, and Eastern Asia, and low risk areas including Kuwait, Israel, and the United States[1, 2]. Despite its relatively low incidence in the United States, gastric cancer is a significant cause of morbidity and mortality, with 22 000 cases per year, resulting in 13 000 deaths[3].

According to the Surveillance, Epidemiology, and End Results (SEER) database, 5-year survival rate for all gastric cancer patients treated in the United States from 1995 to 2001 was 23.2%. This represents an improvement from 15.3% in the time period from 1974-1976[4]. As expected, patients with localized disease have a higher 5-year survival rate (59%) compared to patients with regional (21.9%) or distant disease (3.1%)[4]. Unfortunately, only 25-40% of patients have localized disease at diagnosis.

Outcomes for patients in high risk countries such as Japan are generally better than outcomes in low incidence countries[2, 5]. This variation is likely due to earlier diagnosis (due to aggressive screening programs) and greater clinical experience in high risk countries, as well as differences in the etiology and biology of the tumors in high versus low risk countries[1,2]. The relative contributions of these factors to outcome and the implication for therapeutic decisions remains ill-defined.

Despite the poor prognosis for those patients with gastric cancer, progress has been made in their management. Improved surgical expertise, better systemic therapy, and the integration of radiation therapy have resulted in modest, but significant improvements in local control and survival. The current review article focuses on the role of radiation therapy in the management of gastric carcinoma in the United States.

PATTERNS OF FAILURE

Following surgical resection, both local and distant recurrences are common, indicating the importance of both local and systemic treatment. Patterns of failure have been reported in clinical series, re-operation series, and autopsy series. As expected, recurrences are greatest in autopsy series and least in clinical series, reflecting limitations in

Table 1 Patterns of relapse based on University of Minnesota re-operation series and autopsy series

	Univ. of Minnesota Re-operation series[10] (*n*=107)	Autopsy series[6-9]
Pattern of relapse	%	%
Gastric bed	55	52-68
Anastomosis	27	54-60
Abdominal wound	5	-
Peritoneal seeding	42	30-43
Lymph nodes	43[1]	52
Local-regional as any site	69	80-93
Local-regional only	23	-
Lymph Nodes only	7	-
Lymph nodes only in nodal dissection sites	3	-
Distant metastases	36	50

[1]Most common nodal sites of relapse were porta-hepatis, celiac, and para-aortic regions. Other sites were suprapancreatic, pancreaticoduodenal, and splenic hilar regions.

the ability to detect recurrences clinically. Patterns of recurrence based on re-operation and autopsy studies are summarized in Table 1.

In the University of Minnesota re-operation series gastrectomy patients underwent a "second look" procedure in the absence of known recurrence or a "symptomatic look" in the setting of known recurrence. Local-regional failure alone was detected in 23% of patients and local-regional failure as any component of failure was detected in 69% of patients. Autopsy series report even higher local-regional failure rates (80-93%)[6-9]. These findings suggest that improvements in local-regional control may be potentially curative and provide a strong rationale for adjuvant radiation therapy.

Distant metastases are reported in approximately 50% of patients by autopsy series[6, 7, 9]. The predominant site of distant organ failure is the liver, involved in 30% of patients at initial exploration[5]. Peritoneal seeding, considered distant metastatic disease, is also common, occurring in 42% of patients from the University of Minnesota re-operation series[10], and in 30-43% of patients based on autopsy series[6-9], Lung metastases are less common, observed in only 10% of cases in one autopsy series[5], These findings provide a strong rationale for adjuvant chemotherapy.

ADJUVANT THERAPY

Radiation alone

At least 2 randomized trials compared surgery alone to surgery plus radiation therapy in gastric carcinoma. These results are summarized in Table 2. The first trial, by the British Cancer Stomach Group, randomized patients to surgery alone, surgery followed by radiation therapy, or surgery followed by chemotherapy (mitomycin, adriamycin, and 5-FU). Of note, 40% of patients on this trial had gross or microscopic residual disease following surgery. No survival difference was detected, but the addition of radiation therapy to surgery resulted in a significant reduction in local recurrence (27% with surgery versus 10% with surgery plus radiation therapy)[11, 12]. Interestingly, 24% of patients on the radiation therapy arm did not receive any radiation, and 32% received a dose < 40.5 Gy (well below that required to control microscopic or gross disease). The benefit of adjuvant radiotherapy may be been greater if given to all patients and in adequate doses.

The second trial, by Zhang *et al* in Beijing, randomized 370 patients with gastric cardia carcinoma to neoadjuvant radiation therapy or surgery alone. Neoadjuvant radiotherapy resulted in improved survival (5-year overall survival was 30% *vs*. 20%, $P=0.009$), improved local control (61% *vs*. 48%, $P<0.025$), and improved regional nodal control (61% *vs*. 45%, $P<0.005$)[13]. Additionally, resection rates were higher in the neoadjuvant radiation arm (89.5%) compared to the surgery alone arm (79%, $P<0.01$). Operative mortality and morbidity did not differ between the two arms. While encouraging, this trial included only cardiac lesions, and it is unknown if these results can be generalized to include distal lesions.

While the British and Beijing trials yielded conflicting results regarding a survival advantage with radiation, both demonstrate significant improvement in local control. Local recurrence in gastric cancer has the potential for substantial morbidity, and thus local control alone is a valid endpoint in evaluating the value of neoadjuvant and adjuvant therapy, including radiation.

Chemoradiation

Three randomized trials have compared surgery alone to surgery plus adjuvant chemotherapy and radiation in gastric carcinoma. These trials are summarized in Table 2. The Mayo Clinic trial randomized 62 patients to surgery alone versus surgery plus adjuvant radiation therapy concurrent with 5-FU chemotherapy[14]. A significant improvement in overall survival and disease free survival was identified with the addition of chemoradiation when analyzed by intention to treat. The five-year survival rate for patients randomized to adjuvant chemotherapy and radiation was 23% compared to 4% for those randomized to no adjuvant therapy. When evaluated by actual treatment received, these benefits were no longer statistically significant. Local control was superior in the chemoradiation arm, although this difference did not reach statistical significance.

The trial by Walsh *et al* included primarily patients with adenocarcinoma of the esophagus, but 35% of patients had lesions involving the gastric cardia. Patients were randomized to surgery alone or neoadjuvant chemotherapy and radiotherapy followed by surgery. The addition of chemoradiation resulted in a statistically significant improvement in overall survival[15]. The median survival of patients assigned to preoperative chemoradiation therapy was 16 mo compared with 11 mo for those assigned to surgery alone ($P=0.01$). Three-year survival was 32% versus 6% favoring combined modality therapy ($P=0.01$).

The landmark trial in the combined modality treatment of gastric cancer in the U.S. is Intergroup 0116 study[16]. In this study, 556 patients with resected adenocarcinoma of the stomach or gastroesophageal junction (stage IB through IVM0 disease) were randomly assigned to surgery

Table 2 Randomized trials of adjuvant radiation therapy in gastric carcinoma

[1]Refers to local relapse. Regional relapse with 54% with surgery alone versus 39% with chemoradiation, $P < 0.05$.

plus postoperative chemoradiotherapy or surgery alone. The adjuvant treatment consisted of two cycles of 5-FU and leucovorin followed by two more cycles of chemotherapy concurrent with radiation therapy. Patients received 45 Gy of radiation in 25 fractions to the preoperative tumor volume, surgical bed, and regional lymph nodes. The majority of patients on this trial had advanced disease (66% were T3/4 and 85% were node positive) and surgical margins were required to be negative.

Three-year overall survival was improved from 41% to 50% with combined modality therapy ($P = 0.005$). The median survival was improved from 27 mo in the surgery only group to 36 mo in the chemoradiotherapy group ($P = 0.005$). Local regional relapse was decreased from 29% to 19% (*P* value not reported). Interestingly, distant metastases were higher in the chemoradiation arm (18% versus 33%), likely a result of patients living long enough to develop clinically detectable distant metastases.

Toxicity was significantly higher with chemoradiation, with nearly three-quarter of patients experiencing grade 3/4 toxicity, and 17% of patients were unable to complete radiation due to toxicity. However, treatment related mortality was low (1% on the chemoradiation arm versus 0% on the surgery alone arm) and overall chemoradiation appeared tolerable in light of its benefits. Postoperative chemoradiotherapy should be considered for all patients at high risk for recurrence of adenocarcinoma of the stomach who have undergone a potentially curative resection.

An important consideration in the interpretation of the Intergroup 0116 trial is the extent of surgery. At least 54% of patients received suboptimal lymph node dissection based on current National Comprehensive Care Network (NCCN) guidelines, raising the question of whether chemoradiation was simply compensating for inadequate surgery. The extent of lymph node dissection as it relates to outcome is discussed further below.

Extent of lymph node dissection and its impact on adjuvant therapy

A D1 lymph node dissection includes perigastric lymph nodes along the lesser and greater curvature. In addition to those nodes included in a D1 lymph node dissection, a D2 dissection includes lymph nodes along the left gastric artery, the common hepatic artery, the celiac trunk, the splenic hilum, and the splenic artery. A D3 lymph node dissection further includes lymph nodes along the hepatoduodenal ligament and the root of mesentery. A D4 lymph node dissection is a D3 dissection plus dissection of para-aortic and para-colic lymph nodes.

While D2 dissection (at a minimum) is considered standard in Japan, randomized Western trials have not shown a survival difference between D1 and D2 dissection, and have demonstrated a substantial increase in post-operative mortality (Table 3)[17, 18]. These trials have been criticized due to the unexpectedly high morbidity and mortality rates, which may be in part explained by the frequent use of pancreatectomy and splenectomy in patients undergoing D2 dissection (which is no longer considered necessary) and by surgeon inexperience[19-21].

In Japan, Maruyama *et al* reported an improvement in 5 year overall survival from 20.3% with D0 dissection to 41.2% with D1 dissection to 63.8% with D2 dissection[22]. Perhaps the greatest criticism of the Japanese data supporting extended lymph node dissection has been its retrospective and/or non-randomized nature. To address these criticisms, the Japanese recently completed a prospective, randomized trial comparing D2 versus D4 dissection. Although disease control data has not yet been reported, acute toxicity data show no difference.[21] Of note, D2 patients had in-hospital mortality rate of 0.8%, which is substantially lower than that reported in the MRC and Dutch trials.

The results of this trial will represent a tremendous contribution to the treatment of gastric cancer. Unfortuna-

Table 3 Randomized trials of D1 versus D2 lymph node dissection in gastric cancer

	MRC[18] (*n*=711)			Dutch[17] (*n*=400)		
Endpoint	D1	D2	*P* value	D1	D2	P value
5 year overall survival	45%	47%	NS	35%	33%	NS
Post-operative morbidity	25%	43%	<0.001	28%	46%	<0.001
Post-operative mortality	4%	10%	0.004	6.5%	13%	0.04

Abbreviations: NS = non-significant.

tely, it is unclear how and if the results of this trial can be applied to Western countries given significant differences in physician experience and patient populations compared to Japan. While surgeon training at tertiary centers in the United States may aid in addressing issues of surgeon experience, hospitals in the United States simply do not have the volume of gastric cancer patients seen in Japan, limiting the ability for surgeons to gain experience. Furthermore, patient related issues such as body mass index and age at diagnosis may differ by geographic location and may influence the risks and benefits of extensive nodal dissection[23].

Evaluation of the benefit of more extended nodal dissection is confounded by stage migration. Bunt *et al* reported that up to 75% of patients with stage IIB disease on D1 dissection are upstaged to IV on D2 dissection[24]. Therefore, when compared stage for stage, results with more extensive nodal dissection may appear superior.

Given these considerations, the optimal extent of lymph node dissection remains elusive. Per NCCN guidelines in the United States, at a minimum a D1 dissection is recommended. Furthermore, it is recommended that at least 15 lymph nodes be evaluated.

On the Intergroup 0116 trial, 10% of patients underwent D2 dissection, 36% underwent D1, and 54% underwent less than a D1 dissection[16]. Subset analysis did not detect differing effects of adjuvant treatment based on the type of lymph node dissection performed (adjuvant treatment appeared to be of benefit regardless of type of lymph node dissection)[25]. This observation is difficult to interpret based on the small number of patients actually treated with D2 dissection. The role of post-operative chemoradiation in patients who undergo D2 dissection by an experienced surgeon is, therefore, unknown.

Lim *et al* reported the outcome of 291 patients treated in Korea with D2 dissection and post-operative chemoradiation identical to that delivered on the Intergroup 0116 trial[26]. 5-year overall survival and local-regional failure were superior to that observed on the chemoradiation arm of the Intergroup 0116 trial, but it is unknown if these outcomes were related primarily to the use of D2 dissection, chemoradiation, or both. It is also unknown if the outcomes were related to surgeon experience and other confounding variables in Korea compared to the United States. The value of chemoradiation in patients who have undergone D2 dissection by an experienced surgeon can only be fully answered by a prospective, randomized trial.

Chemotherapy alone

While the randomized Intergroup 0116 trial showed a benefit in both local control and overall survival with adjuvant chemoradiation, the relative contributions of radiation versus chemotherapy to this benefits are unknown.

The aforementioned British Stomach Group trial, which randomized patients to surgery alone, surgery followed by radiation therapy, or surgery followed by chemotherapy, found no improvement in overall survival with chemotherapy compared to surgery alone or surgery and radiation[11, 12]. A randomized Southwest Oncology Group (SWOG) trial showed no benefit to adjuvant chemotherapy (5-FU, adriamycin, and mitomycin-c) following surgical resection[29]. To date, meta-analyses evaluating the role of adjuvant chemotherapy have demonstrated no or minimal benefit[27, 28].

More recently, however, a British MRC randomized trial (the MAGIC trial) showed an improvement in both overall survival and disease free survival with the addition of pre- and post-operative chemotherapy (epirubicin, cisplatin, and 5-FU) to surgery[30, 31]. Five-year overall survival was improved from 23% to 36% ($P=0.009$). This trial suggests a survival benefit with adjuvant chemotherapy in the absence of radiation therapy. Newer chemotherapeutic regimens may be superior and therefore provide a greater benefit compared to epirubicin, cisplatin, and 5-FU[30, 32-36].

While the results of the MAGIC trial demonstrate a survival advantage to adjuvant chemotherapy in the absence of radiation therapy, only an adequately powered, prospective randomized trial of chemotherapy with or without radiation therapy can fully evaluate the benefit of radiation treatment, and to date no such trial exists. A recent Korean trial treated 81 patients with resection (including D2 dissection) followed by chemotherapy alone (FU, cisplatin) versus chemotherapy (FU, cisplatin) before and after radiation concurrent with capecitabine. With short follow-up (15 mo) there is no difference in disease free or overall survival. Further follow-up is necessary to confirm these results, and radiation therapy should not be omitted on the basis of this trial alone[37].

Currently in the United States, NCCN guidelines recommend adjuvant chemoradiation following complete surgical resection in T3, T4, or node positive gastric cancer patients or in patients with microscopically positive margins. Adjuvant chemotherapy alone or adjuvant radiation therapy alone are considered investigational.

Pre-operative versus post-operative adjuvant radiation therapy

Based on the Intergroup 0116 trial, chemoradiation in the United States is most commonly delivered post-operatively. However, pre-operative radiation therapy offers a number

Table 4 Prospective trials of pre-operative chemoradiation in gastric cancer

Reference	Chemo	RT dose (Gy)	Overall survival % (2 yr)	Median survival time (mo)	Complete response (%)	Partial response (%)	R0 resection (%)	% Distant metastases during therapy	rate (%)
RTOG 99-04[46] (n=49)	5FU/LV/cis×2 prior to RT; 5FU with RT	45	NR	NR	27	NR	77	NR

Klautke[67] (n=21)	Cis/5FU or tax	50.4	42	18	14	62	53	-	

Abbreviations: Cis = cisplatin, 5FU = 5-fluorouracil, LV = leucovorin, tax = paclitaxol, RT = radiation therapy, R0 = resection with negative margins.
[1]Given 1.2 Gy b.i.d. in a phase I dose escalation trial; [2]At a median follow-up of 36 mo; [3]PR defined as <10% residual cells in resected specimen.

of theoretical advantages. First, target tissues are better oxygenated prior to surgery, and radiation therapy is more effective against oxygenated tissues[38]. Second, pre-operative therapy may enhance the ability to perform R0 resection (defined as removal of all tumor such that surgical margins are histologically negative). The MAGIC trial demonstrated an improvement in potentially curative resection rates from 60% with surgery alone to 70% with pre-operative chemotherapy[30], and the Beijing trial demonstrated an improvement in resection rates from 79% with surgery alone to 89.5% with pre-operative radiation therapy[13]. A phase II, multi-institutional trial by the Radiation Therapy Oncology Group (RTOG 99-04) of pre-operative chemoradiation demonstrated a pathologic complete response rate of 27% and an R0 resection rate of 77%, which compares well to historical controls[39, 40]. Table 4 summarizes trials evaluating pre-operative chemoradiation in the setting of gastric carcinoma.

Third, preoperative treatment is generally better tolerated than postoperative treatment and patients are more likely to receive the prescribed doses of chemotherapy and radiation. For example, 88% of patients treated on a phase II trial of pre-operative 5-FU and radiation therapy were able to complete full dose chemoradiation[41], compared to 65% on the Intergroup 0116 trial, which delivered radiation and chemotherapy post-operatively[42]. Furthermore, during pre-operative therapy, distant metastases may manifest clinically and therefore spare patients unwarranted surgery. Prospective trials have reported the development of distant metastatic disease in 12-17% of patients during pre-operative chemoradiation, despite the use of staging laparoscopy at diagnosis[41, 43].

Pre-operative radiation also has potential risks. Perhaps most notably, a significant proportion of patients are under-staged clinically, and based on clinical stage may undergo unnecessary irradiation. Bonenkemp *et al* report that 29% of eligible surgical patients were discovered at laparotomy to have peritoneal, hepatic, or distant lymph node metastases[17]. Careful evaluation including endoscopic ultrasound, CT scans, and laparoscopy is therefore indicated prior to initiation of radiation therapy.

While the potential exists for increased surgical morbidity and mortality with pre-operative treatment, trials of pre-operative chemoradiation have yielded conflicting results in this regard[41, 43-47]. The RTOG 99-04 reported a 21% grade 4 toxicity rate but no treatment-related deaths, demonstrating that pre-operative therapy can be delivered in a multi-institutional setting with acceptable toxicity[46].

The timing of chemoradiation can only be definitively answered through a prospective, randomized trial. An ongoing European trial (SWS-SAKK-43/99) is randomizing gastric cancer patients to pre- versus post-operative chemotherapy; however, this trial does not use radiation and will not address the optimal timing of radiation therapy.

THE ROLE OF RADIATION THERAPY IN UNRESECTABLE GASRTIC CARCINOMA

Only 25-40% of patients with gastric adenocarcinoma will be able to under go potentially curative surgical resection[48]. While the prognosis of these patients is poor, radiation therapy with or without chemotherapy occasionally results in long-term survival (5 year survivals of 5-15%). However, this is not a viable alternative to resection (and adjuvant therapy as indicated) in patients who have resectable disease (Table 5).

Gastric adenocarcinoma is a radioresponsive tumor.

Table 5 Treatment results: Unresectable or residual gastric cancer

Reference	*n*	Treatment	Radiation therapy	Chemotherapy	Results
Randomized					
Mayo Clinic[51]	48	EBRT±CT	35-37.5 Gy in 4-5 wk	5FU 1st wk of EBRT	Median survival 13 *vs* 6 mo and 5-year overall survival 12% *vs* 0% favoring EBRT+5FU
GITSG[53]	90	CT±EBRT	50 Gy split course in 8 wk	5FU during EBRT, maintenance 5FU/MeCCNU	4-year survival 18% *vs* 7%, favoring CT+EBRT
EORTC[52]	90	EBRT±CT	55.5 Gy in 6 wk	5FU	14% long-term survival (3 patients) with EBRT and 5FU
Retrospective					
MGH[55]	32	EBRT±CT	45-55 Gy in 5-6 wk	5FU during EBRT, maintenance 5FU/MeCCNU	EBRT+CT: Unresectable disease 14 mo median survival; unresectable and residual disease 10% 4-year survival

Abbreviations: EBRT=external beam radiation therapy; CT=chemotherapy; 5FU=5-fluorouracil; MeCCNU=semustine; GITSG=gastrointestinal study group; EORTC=European organization for research and treatment of cancer; MGH=Massachusetts General Hospital; Gy=gray.

Wieland and Hymmen used radiotherapy alone in patients with unresectable gastric cancer. The radiation dose was 60 Gy when feasible, in 1.5 to 2.0 Gy fractions. They noted an 11% (9 of 82) 3-year and 7% (5 of 72) 5-year survival[49]. Abe and Takahashi reported a 14.7% 5-year survival rate with intraoperative radiation therapy (28 to 35 Gy) in a group of 27 patients with stage IV disease. In the same study, there were no 5-year survivors in the 18 stage IV patients randomized to a surgery-alone control arm[50].

Most phase III trials for unresectable or residual gastric cancer show an advantage for combined-modality treatment over single-modality treatment. Two randomized trials compared radiation therapy alone to chemoradiation. The seminal trial in the treatment of unresectable gastric cancer is from the Mayo clinic[51]. All patients were randomized to radiotherapy (35 to 37.5 Gy in 4 to 5 wk) with or without 5-FU chemotherapy during the first 3 d of radiation. Mean and overall survival was improved in the combined-modality treatment group compared to radiotherapy alone (13 *vs* 6 mo median survival and 12% *vs* 0% 5-year survival, respectively). The EORTC performed a randomized trial of radiation therapy with or without 5-FU chemotherapy following attempted surgical resection[52]. Residual disease after resection was identified in 22 patients and the three long-term survivors (14%) received both irradiation and 5-FU.

Two randomized trials compared chemotherapy alone to chemoradiation. In a study by the GITSG, 90 patients were randomized to radiation therapy and 5-FU followed by maintenance 5-FU/MeCCNU or 5-FU/MeCCNU alone[53]. The radiotherapy dose was 50 Gy given in a split course. This trial included patients with unresectable, gross, microscopic, or no residual disease after resection, though only 7 patients had no residual disease. Radiation and chemotherapy resulted in a statistically significant improvement in 4-year survival compared with chemotherapy alone (18% *vs* 6%, respectively). A second trial performed by the GITSG comparing radiation and chemotherapy to chemotherapy alone did not demonstrate a survival advantage to combined modality therapy[54]. However, the results from this second trial are difficult to interpret as nearly 50% of patients on the combined modality arm either did not receive the prescribed dose of radiation or had a major deviation in radiation delivery.

Data from retrospective series also suggest an improvement in disease control and survival with the combination of radiation therapy and chemotherapy. In published series from the Mayo Clinic and Massachusetts General Hospital (MGH), long-term survival of 10% or more has been demonstrated in patients receiving external beam radiation and chemotherapy following subtotal surgical resection with residual disease (MGH) or unresectable disease[55,56]. In the MGH experience, patients with unresectable or gross residual disease treated with combined radiation and chemotherapy had median survivals of 14 mo and 15 mo, respectively, and the overall four-year survival rate was 10%.

In the University of Pennsylvania experience with unresected adenocarcinoma of the GE junction or esophagus, both local control and overall survival was superior with combined modality versus single modality therapy[57]. Local control was 52% with radiation and chemotherapy, compared to 4% with radiation alone and 0% with chemotherapy alone. Median survival with radiation and chemotherapy was 10 mo compared with 5 mo for radiation alone. Overall, considering the randomized and retrospective data, there appears to be improved survival with combined radiation and chemotherapy for unresectable gastric cancer. However, the use combined-modality therapy in unresectable gastric cancer is tempered by the fact that relatively few of these patients will be long-term survivors.

To the best of our knowledge, there are no randomized trials of neoadjuvant radiation and chemotherapy in unresectable gastric adenocarcinoma. Neoadjuvant chemotherapy alone has been used in unresectable and locally advanced disease in numerous phase II and in at least one phase III trial. Wilke *et al* treated 34 patients with unresectable gastric cancer confirmed at exploratory laparotomy with etoposide, adriamycin and cisplatin chemotherapy[58]. Following chemotherapy and second look operation, fifteen patients (44%) underwent potentially curative resection and five patients (15%) were pathologic complete respon-

ders. Median survival in this phase II trial was 18 mo for all patients. In an update, 79% of these patients had local-regional failure[58].

Taken as a whole, neoadjuvant chemotherapy for unresectable gastric cancer results in clinical response rates of 30% to 68%, potentially curative resections in as few as 8% or as many as 73% of patients, high rates of local relapse, and except for the Wilke study, pathologic complete response rates of <15%. In view of the high incidence of local recurrence and relatively low pathologic complete response rates, radiation therapy has been integrated into neoadjuvant studies of unresectable gastric cancer. A recent US Intergroup trial, to confirm the Walsh trial[15], of neoadjuvant combined-modality therapy in esophageal and GE junction carcinoma was closed due to inadequate accrual.

In the purely palliative setting for gastric cancer, total or subtotal gastric resection can successfully relieve symptoms of obstruction, hemorrhage, and ulceration. In advanced gastric cancer, total gastrectomy for bulky or proximal tumors has resulted in good quality of life, but was less helpful for relief of symptoms due to linitis plastica[59]. In the absence of surgery, radiation therapy is effective in 50% to 75% of patients in the palliation of gastric outlet or biliary obstruction, pain, and bleeding[48]. In select patients with good performance status, the administration of concurrent 5-FU chemotherapy may improve response.

RADIATION THERAPY TECHNIQUES

Intra-operative radiation therapy

Intraoperative radiation therapy (IORT) delivers a single high dose of radiation to areas at high risk relapse. A substantial advantage of intraoperative radiation therapy is that normal tissues can be largely excluded from the radiation field, such that larger doses of radiation can be delivered to the target tissues and toxicity minimized. Although appealing, the role of intraoperative radiation therapy in the setting of gastric cancer remains ill-defined. Several studies suggest an advantage to IORT in locally advanced gastric carcinoma, but these trials do not define the role of IORT in patients receiving EBRT.

A randomized trial by Sindelar *et al* compared gastrectomy with IORT to gastrectomy with or without EBRT (EBRT was not used in early stage lesions confined to the stomach) in forty-one patients[60]. Survival was equivalent between the 2 arms, but local-regional control was superior on the IORT arm versus the control arm (64% versus 8% respectively; $P < 0.001$). Skoropad *et al* randomized patients with gastric cancer to pre-operative EBRT (20 Gy in 5 d) followed by IORT (20 Gy) plus gastrectomy versus gastrectomy alone[61]. The addition of radiation therapy had a statistically significant survival advantage in more advanced stages (T3-4 and/or node positive). In a randomized trial of 211 patients from Kyoto, Japan, patients were randomized to 28-35 Gy of IORT or surgery alone[62]. This study also demonstrated improved survival in patients with disease penetrating the wall of the stomach or in patients with involved lymph nodes, but not in patients with disease limited to the wall of the stomach. While these trials suggest an advantage to radiation therapy in locally advanced disease, they do not answer the question of whether EBRT alone, IORT alone, or EBRT plus IORT should be used. To date, no randomized trials exist evaluating EBRT with or without IORT.

Notably, prospective and retrospective trials have not demonstrated increases in morbidity and mortality with IORT[63]. Given its potential benefits and limited morbidity, IORT in the setting of gastric cancer continues to be used in select centers in the United States.

3D conformal and intensity modulated radiation therapy (IMRT)

Radiation therapy technique is important in evaluating the benefits of radiation. In the Intergroup 0116 trial, 2D radiation therapy with an anterior-posterior (AP) and a posterior-anterior (PA) radiation beam was utilized. Radiation therapy portals were centrally reviewed prior to radiation, and 34% had major protocol violations prior to revision. These findings demonstrate that trials without central review may suffer from inadequate radiation therapy field design, and suggest that the skill and experience of the treating radiation oncologist is important.

Technology has evolved over time to allow increasingly conformal radiation therapy, potentially sparing normal tissues and decreasing toxicity and/or allowing dose escalation to the target volume. However, as technology allows progressively more conformal treatment, the radiation oncologist must be increasingly mindful of known patterns of recurrence.

Two such targeted techniques are 3D conformal radiation therapy and intensity modulated radiation therapy (IMRT). 3D conformal radiation therapy uses 3D reconstruction of the target volume and normal tissues from CT data to plan multiple radiotherapy beams conforming to the target and sparing, as much as possible, normal tissues. Leong *et al* compared a 6-field 3D conformal radiation therapy plan a 2D AP:PA radiation therapy plan in 15 patients and noted lower radiation doses to the kidneys and spinal cord, both important radiation dose-limiting normal tissues[64]. Dose was higher to the liver with the 3D plans, but still well below tolerance. Princess Margaret Hospital treated 50 patients per the chemoradiation arm of the INT 0116 protocol, but used a 5-field 3D conformal radiation technique. Grade 3 or 4 toxicity occurred in 52% of patients, similar to the INT 0116 trial, suggesting minimal impact on toxicity compared to 2D radiation therapy.

Intensity modulated therapy, like 3D conformal radiation therapy, uses multiple beams with the shape of each beam conforming to the target. Unlike 3D radiation therapy, the intensity of radiation within any given beam varies such that normal organs are spared compared to target tissues. Planning studies of IMRT in the use of gastric cancer demonstrate decreased dose to the kidneys compared to conventional plans[65-67]. In treating abdominal organs, however, IMRT must be used with caution as intra-abdominal motion can be significant and highly conformal treatments can miss targeted areas. The role of IMRT in gastric cancer is not yet defined and remains investigational.

To date, 3D conformal and IMRT techniques have not

demonstrated a convincing reduction in acute or late radiation toxicity. However, both techniques offer great potential to decrease radiation toxicity by avoiding normal tissues and to allow dose escalation to target tissues.

CONCLUSION

From the available clinical data in the treatment of gastric carcinoma, the following conclusions can be reached: (1) Patterns of failure following surgical resection demonstrate high local and distant failure rates, suggesting a need for both local and systemic adjuvant treatment. (2) Adjuvant radiation therapy improves local control based on randomized trials. (3) Adjuvant chemoradiation improves survival in the randomized Intergroup 0116 trial, and adjuvant chemoradiation following complete resection with negative margins is currently considered standard of care in the United States. (4) Chemoradiation allows long-term survival in a small number of patients with locally advanced, unresectable gastric carcinoma.

However, each advancement in the treatment of gastric cancer leads to further questions, which should serve as the basis for future clinical trials: (1) In the adjuvant or neoadjuvant setting, what is the benefit of adding radiation therapy to chemotherapy? (2) Does adjuvant chemotherapy and/or radiation therapy provide benefit in patients who have undergone a D2 lymph node dissection? (3) Is pre-operative radiation therapy superior to post-operative radiation therapy? (4) Will conformal radiation technologies including IORT, 3D conformal, and intensity modulated radiation therapy improve outcomes?

Despite its disappointing survival rates, the treatment of gastric carcinoma has improved modestly over time. Radiation therapy has a role in the adjuvant setting for improving local control and, in combination with chemotherapy, survival. Radiation therapy in unresectable disease provides effective palliation and, in combination with chemotherapy, long term survival in a small number of patients.

Abstract

Since its initial description, the pathogenesis of the columnar-lined esophagus (CLE) has been surrounded by many controversies. The first controversy is related to the existence of the condition itself. The second controversy centers on whether the CLE is a congenital or an acquired condition. In this article, we review the congenital and acquired theories of development of CLE and discuss the various factors in acquisition of CLE. The bulk of evidence in the literature suggests that CLE is an acquired condition.

Key words: Barrett's esophagus; Risk factors; Esophageal adenocarcinoma; Pathogenesis; Reflux esophagitis; Gastroesophageal reflux

INTRODUCTION

The lower esophagus lined by columnar epithelium is a condition poor in fact but rich in theory. It invites speculation but resists laboratory reproduction[1]. Columnar-lined esophagus (CLE) is commonly called "Barrett's esophagus". The same eponym is also used to describe the metaplastic epithelium and complications of this condition. Barrett's epithelium, Barrett's mucosa, Barrett's ulcer, Barrett's stricture and Barrett's carcinoma are used frequently in the literature. It is a pathological premalignant condition in which the lower segment of the esophagus becomes lined by a metaplastic columnar epithelium in the form of either circumferential extension of the gastric columnar epithelium or islands of columnar mucosa or both. The presence of specialized columnar epithelium anywhere in the esophagus represents a true metaplasia of the normal squamous epithelium and is highly suggestive for the diagnosis of CLE.

Since its initial description, the pathogenesis of CLE has been surrounded by many controversies. The first controversy is related to the existence of the condition itself. For more than six years, Norman Barrett[2,3] argued that the columnar-lined structure is an intrathoracic stomach due to a congenitally short esophagus. Earlier in 1943, Allison *et al*[4] described peptic ulceration in the 'short' esophagus. Allison[5] introduced the term reflux esophagitis and showed that peptic ulcer is in the esophagus. Our current concept of CLE is based on the demonstration by both Allison and Johnstone[6]. They have proven that the columnar-lined structure is esophagus on the basis of the following criteria: (1) The tubular structure grossly resembles the esophagus; (2) absence of peritoneal covering; (3) presence of squamous islands within the columnar mucosa; (4) presence of muscularis propria and submucosal glands of esophageal type; and (5) absence of the acid-producing oxyntic cells in the gastric mucous membrane, which line the lower esophagus.

The second controversy center on whether the CLE is a congenital or an acquired condition.

CONGENITAL THEORY OF COLUMNAR-LINED ESOPHAGUS

This theory is based upon the fact that the embryonic esophagus has a columnar epithelial lining, which may later be incompletely replaced with squamous epithelium leaving the lower esophagus lined by the fetal columnar epithelium. Many investigators showed that the embryonic columnar and glandular epithelium might persist in the esophagus after birth. Islets of ciliated columnar epithelium have been reported in post-mortem examination of esophagus from premature and newborn infants. There are four types of congenital columnar epithelium in the esophagus.

Embryonic ciliated columnar epithelium

Johns[7] showed that the fetal esophagus is lined by ciliated columnar epithelium until the 17th wk of development, and is later replaced by squamous epithelium. Initially, this replacement starts in the middle of the esophagus and then extends in both directions. Although, at birth, the esophagus is entirely lined by squamous epithelium, remnants of this embryonic ciliated columnar epithelium sometimes remain in the esophagus after birth. Rector and Connerley[8] found such columnar epithelium in the

esophagus of 7.8% of infants and children. It was more than 8 times commoner in the upper end than the lower end. A sheet of ciliated columnar epithelium has also been found lining the lower esophagus of one asymptomatic adult[9].

Heterotopic or ectopic gastric epithelium

Occasional foci of gastric epithelium were also reported to be present in the esophagus. Carrie[10] reported islands of ectopic gastric mucosa in 50% of his patients. Bosher and Taylor[11] reported the presence of heterotopic gastric mucosa associated with esophageal ulcer and stricture formation. Moreover, Abrams and Heath[12] also showed such epithelium.

Superficial cardiac glands

Normally superficial cardiac glands are present in the lamina propria, particularly in the lower end of the esophagus.

Congenital Barrett's epithelium

Although there is no similarity between the ciliated columnar epithelium and Barrett's epithelium, some investigators considered Barrett's epithelium to be a congenital remnant of the ciliated columnar epithelium.

Initially, Norman Barrett argued that since the early embryonic esophagus is lined by columnar epithelium, and that the metamorphosis to squamous epithelium only occurs after proliferation and recanalization of the original layer, the presence of columnar epithelium in the esophagus of an adult might be explained on the basis of a failure of this process to achieve completion[13]. Later on in 1962, Barrett changed his views and argued that the difficulty in accepting this explanation is that if it were true, one might expect the whole esophagus, and not simply the lower end to be abnormally lined more often than it is[14].

EVIDENCE SUPPORTING CONGENITAL ORIGIN OF COLUMNAR MUCOSA

Epidemiological evidence

Several studies have reported the cases of CLE in patients who had no GER[21-23]. Many authors reported the cases of CLE in children[24-26]. Two reports showed that a 9-year-old boy[24] and a 10-year old girl[24] had experienced dysphagia since infancy. The authors who favored the congenital theory assumed that the columnar mucosa is present since birth, but it becomes symptomatic later in life as a result of the development of a hiatal hernia and GER. Only a very small proportion of patients with CLE develop esophageal adenocarcinoma.

Morphological evidence

Postlethwait and Musser[27] in an autopsy study described a neonate with CLE. Haque and Merkel[28] reported a case of total CLE, where an adult patient had typical Barrett' s mucosa involving the esophagus. The authors argued that such a case support a congenital origin. However, a review of this case shows that this patient had long-standing, severe GER requiring antireflux surgery. Wolfe *et al*[29] and Mangla[22] described the presence of islands of heterotopic/ectopic gastric mucosa in the esophagus. Mangla[22] also described the cases with squamous epithelium interposed between Barrett's and gastric mucosa. Stadelmann *et al*[23] described patients with a linear, smooth squamo-columnar junction rather than the irregular junction commonly found in patients with CLE, and they argued that this observation support the congenital origin. Other several studies[22,30,31] argued that the presence of parietal and chief cells in Barrett's mucosa, which are highly differentiated cells, is unlikely to be an acquired condition.

Experimental evidence

Failure of experimental models has been reported by Van de Kerckhof and Gahagan by injuring the esophageal mucosa[32]. The absence of reversion of Barrett's mucosa to squamous epithelium after antireflux surgery has been cited as evidence supporting a congenital origin[22].

Details of evidence for production of CLE experimentally will be presented when discussing the acquired origin of columnar mucosa.

ACQUIRED THEORY OF COLUMNAR-LINED ESOPHAGUS

The arguments against the congenital theory include the fact that the embryonic studies have shown that the squamous replacement of the fetal columnar epithelium begins in the mid esophagus and progresses toward each end[7]. In addition, despite the fact that the islets of congenital ectopic gastric mucosa are more common in the cervical region of the esophagus which appears to be the last area to lose the embryonic columnar lining, the columnar epithelium is always found in the lower esophagus.

The association between CLE and gastroesophageal reflux (GER) was recognized early and led to the concept that CLE is an acquired condition. Tileston[15] suggested that the first requisite for the formation of peptic ulcer of the esophagus is an insufficiency of the cardia. He concluded that hyperacidity of the gastric juice plays a part in preventing healing of the esophagus ulcer seems probable. In the same article, he noticed with interest the close resemblance of the mucous membrane around the esophageal ulcer to that normally found in the stomach. In their historical paper, Allison and Johnstone[6] concluded that peptic esophagitis and peptic ulceration of the squamous epithelium of the esophagus are secondary to regurgitation of digestive juices, are most commonly found in those patients in whom the competence of the cardia has been lost through herniation of the stomach into the mediastinum. In the past, there has been some discussion about gastric heterotopia as a cause of peptic ulcer of the esophagus, but this point was very largely settled when the term reflux esophagitis was coined. It describes accurately in two words the pathology and etiology of a condition which are a common cause of digestive disorder. They reported seven patients in whom the lower esophagus

Table 1 Various evidences to support the congenital and acquired theories

Evidences	Congenital theory	Acquired theory
Epidemiological	1 Cases in children	1 Association with gastroesophageal reflux
	2 Cases without demonstrated reflux	2 Usual occurrence after middle age
Morphological	1 Neonate with columnar-lined esophagus	1 Absence of typical cases in fetuses
	2 Adult with involvement of entire esophagus	2 Presence of intestinal-type goblet cells and sulphomucins.
	3 Islands of heterotopic/ectopic gastric mucosa	3 Absence of gastrin-containing cells.
	4 Cases with squamous epithelium interposed between Barrett's and gastric mucosa	4 Endoscopic demonstration of upwards migration of Barrett's mucosa with ongoing gastroesophageal reflux
	5 Cases with linear, smooth squamo-columnar junction	
	6 Presence of parietal and chief cells in Barrett's mucosa	
Experimental	1 Failure of experimental models	1 Animal models.
	2 Absence of reversion to squamous epithelium after antireflux operation	2 Regression after successful antireflux surgery.
		3 Acquisition of Barrett's mucosa after onset of reflux following esophagogastrostomy, Heller myotomy and esophagojejunostomy.

Modified from Hamilton SR. Pathogenesis of columnar cell-lined (Barrett's) esophagus. In: Spechler S J, Goyal R K, (Eds.) Barrett's esophagus: Pathophysiology, diagnosis, and management. New York: Elsevier Science, 1985: 29-37.

was lined by gastric mucous membrane, and all these patients had reflux esophagitis. Four of these patients had progressed to stricture formations and one patient had ulceration in the esophageal part, which was lined by gastric epithelium. They termed such ulcers as Barrett's ulcer although they stressed that the use of this eponym does not imply agreement with Barrett's description of an esophagus lined with gastric mucous membrane as "stomach".

Although Allison and later on Barrett recognized the association between CLE and hiatal hernia and reflux esophagitis, nevertheless, they assumed that the condition is congenital in origin. Moersch *et al*[16] were the first to suggest that the columnar lining might be an acquired condition as a sequel of reflux esophagitis. Hayward[17] suggested that the CLE is an acquired condition due to reflux esophagitis that destroys the squamous epithelium. Moreover, he suggested that the denuded area is re-epithelialized from the columnar cells below, and that the lower 1 to 2 cm of the esophagus is lined by columnar epithelium which acts as a buffer zone of junctional epithelium, does not secrete acid or pepsin but is resistant to them.

The principal of the acquired theory is that the columnar epithelium is an adaptive change in response to the continued harmful environment present in the esophagus due to ongoing GER. Following repeated cycles of destruction and regeneration, in some individuals, a simple columnar epithelium more resistant to digestive action finally replaces the destroyed squamous epithelium[1].

Many earlier observations documented the ascent up the esophagus of a stricture at the squamo-columnar junction as squamous epithelium is replaced by columnar epithelium, supporting the concept of an acquired dynamic epithelium[18,19]. Adler[1] reported a series of 11 patients with CLE associated with strictures, in three of them, progression and ascent of the strictures were documented over 3 to 5 years. Moreover, he also suggested that the occurrence of islets of squamous epithelium within the sheet of columnar epithelium could be interpreted as the more resistant remnants of squamous epithelium that survived the erosive action of the digestive secretions. He stated that the findings of these squamous islets are less easily explained by the congenital theory.

Hamilton[20] summarized the epidemiological, morphological and experimental evidence cited in the literature to support the congenital and acquired theories (Table 1).

EVIDENCE SUPPORTING ACQUIRED ORIGIN OF COLUMNAR MUCOSA

Epidemiological evidence

(1) Many investigators reported the frequent association between CLE and GER[33]. Allison and Johnstone[6] suggested that if gastric reflux occurs, and causes ulceration of squamous epithelium without producing stenosis, is healing of the ulcer in an acid medium more likely to be by overgrowth of gastric rather than of esophageal epithelium? If this were so it might be that some examples of the gastric mucosa in the esophagus were acquired rather than congenital. (2) The usual occurrence of CLE in patients of middle and older ages. If the congenital columnar epithelium lining the esophagus produces acid and pepsin itself as some believe it is difficult to understand why complications do not occur early in life. (3) Dahms and Rothstein[34] reported that CLE in children is a consequence of chronic GER.

Morphological evidence

There is no typical cases of CLE in fetuses[33]. The histopathologic and histochemical characteristics of Barrett' s epithelium have also been quoted to support an acquired origin. The presence of intestinal-type goblet cells, and sulphomucins has suggested an acquired origin[35,36]. Dalton *et al*[37] and Dayal and Wolf[38] suggested that the absence of gastrin-containing cells from Barrett's mucosa as contrasted with congenital gastric heterotopia such as in a Meckel's diverticulum, support an acquired origin for CLE. However, Mangla *et al*[30] have demonstrated the presence of gastrin in Barrett's mucosa. The strongest morphological evidence for acquired origin has been

provided by cases with endoscopic demonstration of cephalic migration of the peptic esophagitis and stricture above an ascending boundary of CLE with continuing GER[19,26,39]. These cases provided strong evidence that the condition could be progressive and result from persistent severe GER and complicating esophagitis. The concept of erosive reflux esophagitis healing by upward migration of adjacent columnar epithelium was advanced by Hayward[17]. Adler[1] reported that out of five patients with CLE associated with strictures, three patients had progression and ascent of the strictures, which were documented over 3 to 5 years. He proposed the possibility of repair by extension from esophageal glands following reflux esophagitis.

Experimental evidence

Bremner *et al*[40] and Wong and Finckh[41] successfully produced columnar-lined mucosa in the esophagi of dogs and rats in the presence of GER, respectively. Li *et al*[42] showed that seven of the 10 dogs developed Barrett's mucosa after a reflux procedure was created, suggesting that a squamous injury in the esophagus is repaired by columnar epithelium in the presence of reflux. The columnar epithelium is acquired when the squamous epithelium is injured and during repair it undergoes columnar metaplasia. Although damage to squamous mucosa is a requisite factor for the development of columnar metaplasia, acute injury alone is not a sufficient stimulus for columnar metaplasia. The acquisition of the columnar epithelium requires a chronically abnormal esophageal environment during the period of mucosal repair. In an experimental study on dog esophagus, Gillen *et al*[43] found that a surgical injury in the esophageal squamous mucosa healed by the regeneration of squamous epithelium in normal dogs. However, if the surgical injury is preceded by alteration of the gastroesophageal junction to cause chronic GER, then the injured squamous mucosa is replaced by a columnar lining. Radigan *et al*[44] and Ransom *et al*[45] reported restoration of squamous mucosa after a successful antireflux operation. The acquisition of Barrett's mucosa after onset of GER following esophagogastrostomy, Heller myotomy, and esophagojejunostomy provide strong evidence for an acquired origin[46-49].

The arguments regarding the etiology of CLE have centered on an acquired *versus* congenital origin; the possibility remains that examples of both do occur[50]. However, the available evidence suggests that the vast majority of cases, if not all, are acquired due to chronic GER. The question remaining to be answered is why Barrett's mucosa develops in only 8-20% of patients with reflux, but not in other patients with reflux of similar severity[20].

FACTORS IN ACQUISITION OF CLE

Patients with CLE frequently have anatomical and physiological abnormalities which either predispose to or exaggerate the severe GER, which in turn leads to the acquisition of the columnar epithelium. Another group of these patients acquire the columnar epithelium secondary to esophagitis or mucositis due to irritant or cytotoxic agents. Given the combination of these anatomical and physiological abnormalities, it is not surprising that severe esophagitis commonly accompanies Barrett's epithelium.

The major risk factors that can lead to acquisition of the columnar epithelium are: (1) GER with acid and pepsin; (2) extreme lower esophageal sphincter incompetence; (3) alkaline reflux (duodeno-gastroesophageal reflux of bile and pancreatic juices); (4) gastric acid hypersecretion; (5) abnormal esophageal motility and delayed acid clearance; (6) diminished esophageal pain sensitivity; and (7) alcohol consumption.

The minor risk factors that can lead to acquisition of the columnar epithelium are: (1) Caustic injury by lye; (2) cytotoxic chemotherapy agent; and (3) acid and pepsin secretion by Barrett's epithelium.

GER with acid and pepsin

Much attention has been directed to reflux of the gastric juices containing acid and pepsin. Patients with CLE frequently have an extremely incompetent lower esophageal sphincter, and therefore, are exceptionally predisposed to GER. In most patients with CLE, GER is judged to be the principal factor that causes injury to the squamous epithelium and provides the abnormal esophageal environment necessary for columnar metaplasia. It is now widely accepted that a substantial proportion of patients with Barrett's esophagus do have severe GER. Schnell *et al*[51] conducted a study to test the hypothesis that since acid contact time is related to formation of Barrett' s epithelium, then a greater esophageal acid contact time might result in longer segments of Barrett's epithelium. They studied 116 patients with CLE and demonstrated a definite positive correlation between the length of Barrett' s esophagus and the duration of esophageal acid exposure. Recently some of the published Swedish studies linked adenocarcinoma of esophagus with duration, frequency and severity of GER symptoms[52,53].

Extreme lower esophageal sphincter incompetence

An important factor that contributes to mucosal injury in patients with CLE is lower esophageal sphincter (LES) hypotension. Stein *et al*[54] found that 11 of 12 patients with CLE had an incompetent LES. The abnormalities were defined as LES pressure of less than 6 mm Hg, overall LES length of less than 2 cm, or abdominal LES length of less than 1 cm. They concluded that this predisposes to GER. This study also confirmed earlier reports documenting extreme LES hypotension in patients with CLE. Attwood *et al*[55] reported that 90% of patients with CLE had a mechanically defective LES and 93% had increased esophageal exposure to gastric juice on esophageal pH monitoring.

Alkaline reflux (duodeno-gastro-esophageal reflux of bile and pancreatic juices)

Most of the earlier studies on CLE traditionally focused on the role of gastric acid and pepsin, but other reports suggested that other factors contributed to the esophageal damage in patients with CLE. Bile reflux into the esophagus was reported as an important causative

factor in acquisition of CLE by many investigators[39,47]. DeMeester *et al*[56] using 24-h esophageal pH monitoring found abnormal alkaline reflux (esophageal pH >7 for more than 10.5% of a 24-h period) in 34% (14/41) cases. Gastric secretions normally are not alkaline, suggesting that bile and other alkaline materials in the duodenum frequently reflux into the stomach and esophagus in patients with CLE and this alkaline reflux has a role in the esophageal injury. Waring *et al*[57] also documented the frequent occurrence of duodeno-gastric reflux in patients with CLE. In their study, radionuclide appeared within 95 min of an intravenous injection of ^{99m}Tc-diisopropyl iminodiacetic acid in the stomach of 46% (6/13) patients with CLE. In contrast, 11% (2/19) persons in the control group had radionuclide evidence of duodeno-gastric reflux. The role of alkaline reflux is particularly evident in those cases of CLE acquired after total gastrectomy in which gastric juices were eliminated[49]. Tada *et al*[58] also provided evidence that refluxed substances other than acid and pepsin play a pathogenic role in CLE. They reported a patient with severe GER disease who developed CLE at age 47, 22 years after a total gastrectomy. At age 64, an endoscopic examination revealed adenocarcinoma in Barrett's epithelium. This report confirms previous reports that acid and pepsin are not necessarily the only pathogenic factors for either Barrett's esophagus or esophageal adenocarcinoma, and further supports the important role of alkaline reflux in the development of CLE and adenocarcinoma. Stoker and Williams[59] suggested that a mixture of gastric and duodenal secretions causes esophageal mucosal disruption and intracellular damage through a toxic synergism between the two secretions. The clinical importance of the alkaline reflux is that the treatment of GER in patients with CLE should involve shifting or neutralizing the alkaline substances as well as the acid. As with duodeno-gastric reflux, the stomach contents available for reflux into the esophagus will include bile and pancreatic enzymes in addition to acid. Therefore, suppressing the acids alone may be ineffective in healing esophagitis for patients with CLE. Hetzel *et al*[60] showed that omeprazole, a drug that is dramatically effective in reducing gastric acid secretion and in healing mild esophagitis, was far less reliable for healing ulcerations in Barrett's epithelium. van der Veen *et al*[61] reported that previous gastric surgery represents an increased risk factor for the development of adenocarcinoma in patients with CLE. Attwood *et al*[62] conducted a study to determine the role of intra-esophageal alkalinization in the genesis of complications in Barrett's esophagus. They found that the esophageal acid exposure (% time pH<4) was similar in patients with or without complications (19.2% *vs* 19.3%). In contrast, the esophageal alkaline exposure (% time pH>7) was greater in patients with complications (24.2% *vs* 8.4%). In 81% of patients, there was a clear relationship between gastric and esophageal alkalinization. They concluded that complications in Barrett's esophagus develop in association with increased exposure of the esophagus to an alkaline environment, which appears to be secondary to duodeno-gastric reflux.

Gastric acid hypersecretion

Patients with CLE may have elevated gastric acid secretion. Collen *et al*[63] suggested that hypersecretion of gastric acid may contribute to the frequency of complications in Barrett's esophagus. In a prospective study, 75% (9/12) patients who had heartburn intractable to treatment with conventional doses of ranitidine (150 mg twice per day) were found to have gastric acid hypersecretion (basal acid output > 10 mEq/h). Among those 12 refractory patients, 10 had Barrett's esophagus, and increasing the conventional dose of ranitidine 2 to 6 times controlled their heartburn, which reduced the gastric acid output to less than 1 mEq/h. With gastric acid hypersecretion and duodeno-gastric reflux of bile and pancreatic enzymes, the gastric material available for reflux can be unusually caustic and harmful.

Abnormal esophageal motility and delayed acid clearance

Many patients with CLE have abnormal motility in the distal esophagus that can delay esophageal clearance, and so the refluxed material may have prolonged contact with the esophageal mucosa. Winter *et al*[64] reported on the importance of delayed acid clearance from the esophagus as a contributory factor in the causation of CLE. Stein *et al*[54] using 24-h esophageal motility monitoring reported that there was an increase in the frequency of abnormally weak contractions (<30 mm Hg) of the distal esophagus in patients with CLE compared with patients with uncomplicated reflux disease. These weak contractions may not empty the esophagus effectively, and could be responsible for the delayed esophageal acid clearance that has been observed in patients with Barrett's esophagus.

Diminished esophageal pain sensitivity

There are large proportions of patients with CLE who are asymptomatic. Cameron *et al*[65] estimated that for every case identified clinically, there are approximately 20 cases in the general population that go unrecognized. Patients with CLE usually seek medical advice when they develop complications, such as esophagitis, stricture, ulcer, bleeding or adenocarcinoma. Many patients with CLE have diminished esophageal pain sensitivity. Skinner *et al*[66] suggested that persistence of severe reflux after antireflux surgery in some patients with Barrett's esophagus who are asymptomatic is due to the Barrett's epithelium not being sensitive to acid after ulceration or strictures heal. Iascone *et al*[67] found that as compared to patients with reflux esophagitis without Barrett's epithelium, patients with Barrett's esophagus have less severe symptoms of heartburn and regurgitation in spite of significantly greater duration of acid reflux in the distal esophagus. Johnson *et al*[68] suggested that the CLE has diminished pain sensitivity and that acid reflux may not cause heartburn for many patients with CLE. Perhaps most patients with Barrett's esophagus escape medical attention because their reflux symptoms are minimal. Diminished pain sensitivity may play a role in the development of the complications that frequently accompany CLE. Patients whose reflux is not heralded by heartburn are unlikely to take antacid or seek medical advice. With no symptomatic warning that caustic material is damaging the esophagus, patients are unlikely to take medications that may prevent further injury[69]. The decrease in pain sensitivity may explain the

lack of reflux symptoms before the onset of dysphagia in some of the patients who develop adenocarcinoma.

Alcohol consumption

Martini and Wienbeck[70] noted the frequent history of chronic alcohol abuse in patients with CLE. Whether this association is related to a direct effect of alcohol on the mucosa or to promotion of GER by the effects of alcohol on the LES is uncertain. It is interesting to notice that alcohol abuse was quoted as early as 1906 as an important cause for peptic ulcer of the esophagus. Tileston[15] in 1906 suggested that the abuse of alcohol deserves a mention among the predisposing causes, occurring with considerable frequency. Alcohol probably acts in two ways: first, by irritation of the esophagus, and second, by the production of gastritis, with vomiting and insufficiency of the cardia.

Caustic injury by lye

Spechler *et al*[71] reported a case with fundic-type Barrett's epithelium in the mid esophagus with sparing of the distal esophagus complicating caustic injury by lye ingestion.

Cytotoxic chemotherapy agent

Cases of CLE have been reported in 63-75% of patients who received a prolonged course of chemotherapy for breast carcinoma. Sartori *et al*[72] reported that CLE could be acquired through an iatrogenic injury by prolonged chemotherapy with anti-neoplastic agents (cyclophosphamide, methotrexate and 5-fluorouracil). These agents injured the esophageal mucosa and caused columnar epithelium secondary to the drug-induced mucositis. In this regard, they published two reports suggesting that chronic chemotherapy with these agents frequently causes columnar metaplasia of the esophagus. In the first report, they described a woman who, because of duodenal ulcer disease, had an endoscopic examination before the beginning of prolonged chemotherapy for breast cancer. The esophagus was normal, but after 4 mo of chemotherapy, a second endoscopy revealed an esophageal ulcer with columnar epithelium. Endoscopic examinations in another eight women who had been treated with the same chemotherapy agents showed columnar epithelium in six of them. The length of the columnar epithelium was more than 3 cm in all six patients[72]. In the second paper, they reported a prospective endoscopic study carried out to document the development of CLE in women receiving the same chemotherapy drugs**.** Ten of sixteen women (63%) who had no endoscopic or histologic evidence of CLE before chemotherapy were found to develop a CLE after 6 mo of chemotherapy[73].

Acid and pepsin secretion by Barrett's epithelium

Secretion of acid and pepsin by the parietal and chief cells in the Barrett's mucosa has been considered as possible factors in development of CLE by some investigators like Mangla *et al*[30] and Ustach *et al*[74]. However, there are no recent data to support this.

SUMMARY

The incidence of CLE and adenocarcinoma is rising at an epidemic rate, and the cause for this rapid rise is unclear and the answer to this principle question remains to be determined. Due to the causal relationship between CLE and GER, risk factors which enhance reflux such as tobacco smoking, alcohol consumption, dietary changes including high fat diet, obesity, and the wide spread usage of the medications that affect the upper gastrointestinal tract could be partially responsible for this rise. Although other several factors can be offered as possible explanations for this rise in incidence such as increased awareness of the condition, widespread use of endoscopy, and improved diagnostic techniques, this rapid increase in the incidence of CLE and adenocarcinoma raises serious concern that the current management for GER is inadequate and deserves reassessment.

Abstract

AIM: To analyse the Chibby expression and its function in colon carcinoma cell lines and colorectal carcinoma (CRC).

METHODS: Chibby expression levels were investigated by quantitative RT-PCR in a panel of seven different colon carcinoma cell lines. By sequencing, we analysed mutational status of Chibby. To test whether Chibby exhibited effects on β-catenin signalling in colon carcinoma cells, we transfected SW480 cells with Chibby expression plasmid and, subsequently, analysed activity of β-catenin and tested for alterations in cellular phenotype. In addition, we examined Chibby mRNA levels in samples of colorectal carcinomas and adjacent normal tissues by using quantitative RT-PCR and hybridised gene chips with samples from CRC and normal tissues.

RESULTS: Chibby mRNA expression was strongly downregulated in colon carcinoma cell lines in comparison to normal colon epithelial cells and no mutation in any of the examined colon carcinoma cell lines was found. Further, we could show that Chibby inhibited β-catenin activity in TOPflash assays when over-expressed in SW480 cells. Proliferation and invasion assays with Chibby transfected SW480 cells did not reveal profound differences compared to control cells. In contrast to these *in vitro* data, quantitative RT-PCR analyses of Chibby mRNA levels in CRC tumor samples did not show significant differences to specimens in adjacent non-cancerous tissue. Consistent with these findings, gene chips analysing tissue samples of tumors and corresponding normal tissue did not show altered Chibby expression

CONCLUSION: Altered Chibby expression might be observed *in vitro* in different colon carcinoma cell lines. However, this finding could not be confirmed *in vitro* in CRC tumors, indicating that Chibby is not likely to promote CRC tumor development or progression. As Chibby is an important inhibitor of ß-catenin signalling, our data implicate that the usability of colon carcinoma cell lines for *in vitro* studies analysing the Wnt/β-catenin pathway in colorectal carcinoma needs extensive verification.

INTRODUCTION

The Wnt/Wingless pathway has been shown to exhibit important functions in embryonic and cancer development. In the absence of Wnt signalling, β-catenin is phosphorylated by glycogen synthase kinase-3 (GSK-3) and targeted for ubiquitin-mediated proteasomal degradation[1]. Upon Wnt binding to its cellular receptor Frizzled, the degradation complex is destabilised, and, as a result, unphosphorylated β-catenin accumulates and translocates into the nucleus. There, it functions as a co-factor of lymphoid enhancer factor/T-cell factor (LEF/TCF) transcription factors leading to upregulation of a variety of genes. It has been shown that mutations in different genes of the Wnt pathway are involved in development of various cancers. One of those tumor entities is colorectal carcinoma where approximately 90% of the tumors have been shown to harbour activating mutations within the canonical Wnt signalling pathway[2-4].

The most potent transcriptional activation domain of β-catenin is located within the C-terminal region of β-catenin and has been used as bait in a yeast screening to identify interacting proteins. In this screening, Chibby, a novel protein that is conserved from Drosophila to human, was isolated [5]. It is a nuclear protein of 126 amino

acids, and as it inhibited Wnt signalling by preventing the interaction between β-catenin and LEF/TCF factors, it was suggested as a potential tumor suppressor gene. Chibby is encoded by the human *C22orf2* gene located at chromosome 22q12-q13. This chromosomal region is known to be mutated frequently in colorectal cancer[6], and therefore, Chibby might be an interesting candidate as a tumor suppressor in CRC. Gad *et al*[7] performed loss of heterozygosity (LOH) analyses of tumors of 36 patients involving the *C22orf2* region in CRC and were not able to detect differences between normal and CRC tumor tissues, but did not analysed effects of Chibby on cellular functions.

In this study, we aimed to analyse whether Chibby is mutated in CRC, to evaluate Chibby mRNA expression levels in colon carcinoma cell lines and tumor samples, and to investigate whether Chibby over-expression in colon carcinoma cell lines has an effect on cell behaviour in functional assays.

MATERIALS AND METHODS

Isolation and cultivation of colon epithelial cells

Isolation and cultivation of colon epithelial cells (CEC) were performed as previously described[8,9].

Cell lines and culture conditions

The colon carcinoma cell lines SW48 (ATCC CCL-231), SW480 (ATCC CCL-228), CaCo-2 (ATCC HTB-37), LoVo (ATCC CCL-229), HCT116 (ATCC CCL-247), and HT29 (ATCC HTB-38) were used for *in vitro* experiments. The cell line HT29M3 was chosen as a highly differentiated colon carcinoma cell line[10-13].

For tissue culture, the cells were maintained in Dulbecco's modified Eagle medium (DMEM) supplemented with penicillin (400 U/mL), streptomycin (50 μg/mL), L-glutamine (300 μg/mL), and 100 mL/L fetal calf serum (FCS) (Sigma, Deisenhofen, Germany) and split 1 : 5 every three days.

For demethylation assays, the cells were treated with 5-azacytidine at a final concentration of 10 μmol/L for 48 h (Sigma)[8]. HT29 M3 cells were used as control cells in the demethylation experiments.

RNA isolation and reverse transcription

For RT-PCR, total cellular RNA was isolated from cultured cells or laser microdissected tissue samples using the RNeasy kit (Qiagen, Hilden, Germany). The integrity of the RNA was controlled on 10 g/L agarose/formaldehyde gel, and subsequently cDNAs were generated by reverse transcriptase reactions. The reverse transcription (RT) reaction was performed in 20 μL reaction volume containing 2 μg of total cellular RNA, 4 μL of 5x first strand buffer (Gibco), 2 μL of 0.1 mol/L DTT, 1 μL of dN_6 primer (10 mmol/L), 1 μL of dNTPs (10 mmol/L) and DEPC water. The reaction mix was incubated for 10 min at 70 ℃. Then 1 μL of Superscript II reverse transcriptase (Gibco) was added and RNAs were reverse transcribed for 1 h at 37 ℃. Subsequently, reverse transcriptase was inactivated at 70 ℃ for 10 min and RNA was degraded by digestion with 1 μL of RNase A (10 mg/mL) at 37 ℃ for 30 min. cDNAs were controlled by PCR amplification of ß-actin.

Chibby mRNA mutational analysis

The entire coding region of Chibby was amplified by RT-PCR from cDNA using16, ATGCCTTTCTTTGGGAATTACGTTC (forward) and chibby496, TCATTTTCTCTTCCGGCTGATC (reverse), which resulted in a 380-bp fragment. The PCR reaction was performed in 50 μL reaction volume containing 5 μL of 10x Taq buffer, 1 μL of cDNA, 0.5 μL of each primer (0.2 μmol/L), 0.5 μL of dNTPs (10 mmol/L), 0.5 μL of Taq polymerase (5 U/μL), and 41 μL of water. The amplification reactions were performed by 35 repetitive cycles of denaturation for 30 s at 94 ℃, annealing for 30 s at 64 ℃, extension for 30 s at 72 ℃, and a final extension step at 72 ℃ for 5 min. The PCR products were resolved on 15 g/L agarose gels. For sequencing, the products were purified by PEG precipitation to remove unincorporated primers and dNTPs. Both strands were sequenced for each PCR product from at least two independent PCR reactions. Sequences were compared with the gene data bank by means of BLAST search (National Center of Biotechnology Information).

Analysis of Chibby expression by quantitative PCR

Quantitative real-time PCR was performed on a LightCycler (Roche, Mannheim, Germany). Two microliters of cDNA template, 1.6 μL of 25 mmol/L $MgCl_2$, 0.2 μmol/L forward and reverse primers {chibby125, TTTGGGAATACGTTCAGTCCG (forward) and chibby395, TCAGCCGCAAGAGATTGTTC (reverse)} and 2 μL of SybrGreen LightCycler mix in 20 μL volume were PCR-amplified through 40 cycles, each cycle consisting of initial denaturation at 95 ℃ for 30 s, 20 ℃/s temperature transition rate up to 95 ℃ for 15 s, 64 ℃ for 3 s, 72 ℃ for 5s, 85 ℃ acquisition mode single. The PCR product was evaluated by melting curve analysis following the manufacturer's instructions and by checking the PCR products on 18 g/L agarose gels. All quantitative PCR experiments were repeated three times.

Transient transfection of SW480 cells

A total of 2×10^5 cells were seeded onto six-well plates one day before transfection. Transfections with pCMX PL2 or pCMX PL2 flag Chibby plasmid (0.5 μg per well) were performed using the LipofectAMINE plus method (Life Technologies) according to the manufacturer's instructions. Cells were harvested 48 h after transfection and the amount of Chibby expression was determined by RT-PCR and Western blot analysis.

Protein analysis in vitro (Western-blotting)

For protein isolation, 2×10^6 cells were washed in 1x PBS and lysed in 200 μL RIPA buffer (Roche). The protein concentration was determined using the BCA protein assay reagent (Pierce, USA). Equal amounts of cellular protein (40 μg total protein) were denatured at 94 ℃ for 10 min after addition of Rotiload buffer (Roth, Karlsruhe, Germany) and subsequently, separated on NuPage SDS gels (Invitrogen, Groningen, The Netherlands). After transferring the proteins onto PVDF membranes (BioRad, Richmond,

USA), the membranes were blocked in 50 g/L dry milk in TBS-T and incubated overnight with primary monoclonal anti flag antibody (1 : 4500 dilution, Sigma) at 4 ℃. A 1 : 4 000 dilution of anti IgG AP (Sigma) was used as secondary antibody. Staining was performed using 5-bromo-4-chloro-3-indolyl phosphate/ nitroblue tetrazolium tablets (Sigma). All Western blot experiments were repeated at least three times.

Immunofluorescence staining of flag-tagged Chibby

A total of 2×10^4 SW480 cells were seeded per chamber of four-well-Falcon chamber slides (Becton Dickinson, Le Pont de Plaix, France) and cultivated overnight before transfection with either control vector or Chibby flag pCMX PL2. After 48 h of transfection, cells were washed with PBS, fixed with 40 g/L paraformaldehyde, permeabelised with 1 ml/L Triton X-100, washed again, and blocked for 30 min in 10 g/L BSA in PBS. Anti flag antibody (dilution 1 : 1 000) was used as primary antibody, and anti mouse FITC-conjugated antibody (dilution 1 : 40) was used as secondary antibody. Incubations took place at room temperature for 1 h each. Staining of nuclei occurred with DAPI.

Reporter gene assays

For transient transfections, 2×10^5 cells per well were seeded into six-well plates and transfected with 0.5 μg of TOPflash or FOPflash reporter gene plasmids using the LipofectAMINE plus method (Gibco) according to the manufacturer's instructions. For cotransfection, 0.125 μg, 0.25 μg, 0.5 μg, and 1 μg of Chibby expression plasmid per well were used, respectively. At 48 h post-transfection, the cells were lysed and the luciferase activity in the lysate was measured. To normalise transfection efficiency, 0.2 μg of a pRL-TK plasmid (Promega, Mannheim, Germany) was cotransfected and renilla luciferase activity was measured by a luminometric assay (Promega). All transfection experiments were repeated at least three times.

Proliferation assay

Proliferation was measured as previously described[14]. Proliferation of Chibby transfected SW480 cells was compared to non or mock transfected SW480 cells in an XTT assay. Results were expressed as mean ± SD (range). All experiments were repeated three times.

Invasion assay

Invasion assays were performed as previouly described[14]. Briefly, the assays were performed in Boyden chambers containing polycarbonate filters with an 8-μm pore size. In brief, filters were coated with a commercially available reconstituted basement membrane (Matrigel; Becton Dickinson, Heidelberg, Germany), and the lower compartment was filled with fibroblast-conditioned medium as chemoattractant. SW480 cells and Chibby transfected SW480 cells were harvested by trypsinization, resuspended in DMEM without FCS at a density of 2×10^5 cells/mL, and placed in the upper compartment of the chambers. After incubation for 4 h at 37 ℃, the filters were removed. The cells adhering to the lower surface were fixed, stained, and counted.

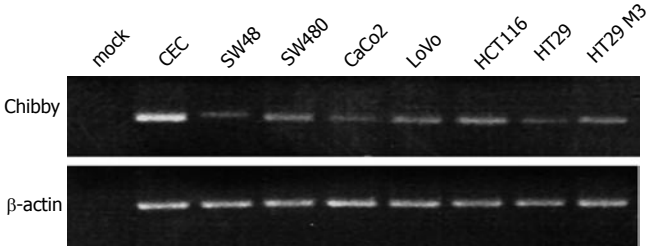

Figure 1 PCR amplification of the complete coding region of Chibby mRNA. The Chibby coding region was amplified using RT-PCR. All colon carcinoma cell lines were shown to express full-length Chibby mRNA. Expression levels cannot be estimated from this experiment as the PCR was carried out to saturation in order to illustrate full-length mRNA expression and to obtain enough PCR products for sequencing. β-actin amplification served as control to ascertain the integrity of the cDNA in all samples.

Fifteen random fields were counted at 200-fold magnification. Each sample was assayed in triplicate, and all experiments were repeated three times.

RESULTS

It is well known that the Wnt/β-catenin signalling pathway is constitutively active in a large number of colorectal cancers. The most commonly mutated proteins within the pathway are β-catenin and APC. Intriguingly, the activation of the cascade cannot in all cases of CRC be explained by mutations in these proteins. It remains unclear what other proteins of the pathway have to be altered in addition to the aforementioned mutations to lead to activation of the Wnt/β-catenin signalling pathway. Hence, we were interested in analysing other potential endogenous inhibitory factors that might accomplish regulatory functions within the Wnt/β-catenin signalling pathway and thus influence signal transduction. Due to these reasons, we analysed the role of the β-catenin-associated antagonist Chibby in colorectal carcinoma cell lines and compared our *in vitro* findings of Chibby expression with the *in vivo* situation by analysing colorectal tumor samples and the corresponding normal tissue.

Analysis of Chibby mutational status and expression level in colon carcinoma cells

We analysed a panel of seven colon carcinoma cell lines, such as SW48, SW480, CaCo2, LoVo, HCT116, HT29, and HT29 M3, that are frequently used as model systems to study effects in colorectal carcinoma. We evaluated the panel of colon carcinoma cell lines for alterations in the Chibby mRNA expression. The complete Chibby coding region was amplified by RT-PCR. All cell lines examined expressed Chibby mRNA at the expected length, indicating that no deletions or mutational insertions had occurred (Figure 1). As a control the Chibby coding sequence was amplified using CEC cDNA as template. The same cDNAs were used to amplify β-actin as a control for the integrity of the cDNA.

The cell lines were evaluated for levels of Chibby mRNA expression using quantitative RT-PCR in comparison to normal colon epithelial cells (CEC). Chibby

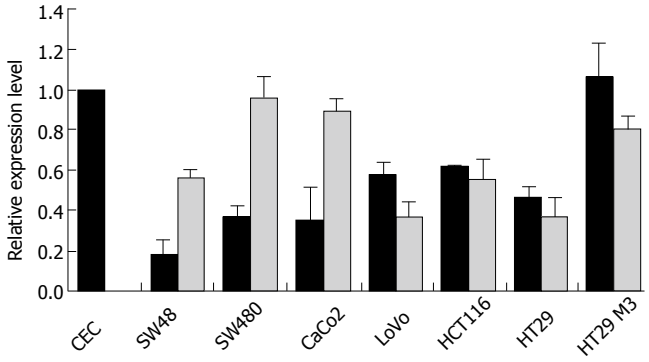

Figure 2 Quantification of Chibby expression in colon carcinoma cell lines. The amount of Chibby mRNA expression was carefully quantified by real-time PCR. All colon carcinoma cell lines showed down-regulation of Chibby mRNA expression in comparison to colon epithelial cells (CEC) and HT29 M3 cells, a cell line derived from HT29 cells that is considered to be a highly differentiated colon carcinoma cell line (black bars). Treatment of cells with the demethylating agent 5-azacytidine caused a modest increase in Chibby mRNA levels in SW48, SW480, and CaCo2 cells, but not in the other cell lines (grey bars). HT29 M3 cells were used as controls for the demethylation experiments as the experiment could not have been performed with primary CEC due to culture conditions.

mRNA was found to be down-regulated in all cell lines in comparison to CEC and HT29 M3 cells which are considered to be a highly differentiated colon carcinoma cells and express Chibby in amounts similar to those of CEC (Figure 2, black bars). Three of the analysed cell lines, SW48, SW480, and CaCo2 cells, showed residual expressions of Chibby mRNA of 18%, 37%, and 35%, respectively, in comparison to CEC or HT29 M3 (100% and 106%, respectively). LoVo, HCT116, and HT29 cells were also shown to have reduced Chibby mRNA levels, but down-regulation was not as explicit as in the other examined cell lines (57%, 62%, and 46%).

To investigate the reason for down-regulation of Chibby expression in colon carcinoma cell lines, we amplified and analysed the exons of the *chibby* gene. All PCR products were purified and subsequently sequenced using two different primers. The analysis of sequenced PCR products did not reveal any sequence variation within the coding region of the *chibby* gene locus (data not shown).

From these results, we concluded that Chibby does not harbour mutations within the coding sequence in all seven analysed colon carcinoma cell lines.

As this reduction in mRNA expression in colon carcinoma cell lines could not be explained by loss or mutation of the *chibby* gene, we hypothesised that promoter hypermethylation could have silenced gene expression. To test this hypothesis, all cell lines were exposed to the demethylating agent 5-azacytidine. Treated and untreated cells were tested for Chibby mRNA expression which was quantified by quantitative RT-PCR. HT29 M3 cells were used as controls in these experiments. HT29 M3 cells are highly differentiated cells that were used as an additional control as CEC could not be used in demethylation experiments as controls due to culturing issues.

Our results showed that 5-azacytidine treatment did not lead to induction of Chibby expression in LoVo, HCT116, HT29, or HT29 M3 cells, but to a moderately increased expression in SW48, SW480, and CaCo2 cells (Figure 2, grey bars). Therefore, we conclude that promoter hypermethylation might play a minor role for altered Chibby expression in some of the analysed cell lines, but we do not consider this silencing mechanism to be a general event in down-regulation of Chibby mRNA expression in the colon carcinoma cell lines.

Effect of Chibby expression on β-catenin transcriptional activity

As colon carcinoma cell lines display reduced levels of Chibby expression in comparison to normal CEC, we were interested in whether over-expression of Chibby in these cells influences functional processes. To test for the potential effects, we over-expressed Chibby in the colon carcinoma cell line SW480 by transfecting a flag-tagged Chibby expression construct. Successful over-expression was observed by quantitative RT-PCR (data not shown) and Western blotting (Figure 3A). Exogenous Chibby protein was not detected following mock or control transfection with pCMX PL2 flag plasmid which did not alter Chibby levels. Strong over-expression of Chibby was observed after transfection of SW480 cells with Chibby flag expression plasmid. Immunofluorescence staining revealed correct expression patterns of Chibby flag-tagged protein in the nucleus of SW480 cells (Figure 3B), also displaying high transfection efficiency.

As Chibby as endogenous antagonist of β-catenin is expected to exert negative functions on the Wnt/β-catenin signalling pathway, we performed LEF/TCF luciferase reporter gene assays using the TOPflash/FOPflash system. Analysing the activity of β-catenin in control and Chibby over-expressing cells, we observed reduced activation levels in the TOPflash system in accordance to the amount of transfected Chibby expression plasmid (Figure 3C). Transfection with 0.125 μg or 0.25 μg of Chibby plasmid per well did not affect the activity of TOPflash reporter, whereas activity dropped to 44% and 48%, respectively, when 0.5 μg and 1 μg expression plasmids were applied. FOPflash reporter construct activity was not affected by Chibby expression (Figure 3C). These results showed that transfection of SW480 cells with Chibby expression plasmid reveals functional Chibby protein.

Functional assays with Chibby over-expressing SW480 cells

To assay whether altered Chibby levels had an impact on proliferation and invasion potential of SW480 cells, we performed functional experiments utilizing mock and Chibby transfected cells. Boyden chamber assays were performed to examine the effect of Chibby on the invasiveness of SW480 cells. In this assay, the tumor cells have to invade through matrigel mimicking the basal lamina. Comparing mock treated cells, control transfected cells, and Chibby over-expressing cells, we did not observe any differences with regard to their invasiveness.

As the Wnt/β-catenin signalling pathway is known to influence cell proliferation, we next assayed for alterations of proliferation and performed *in vitro* proliferation assays with Chibby transfected SW480 cells and mock or control transfected cells. Modifying the Chibby protein level had

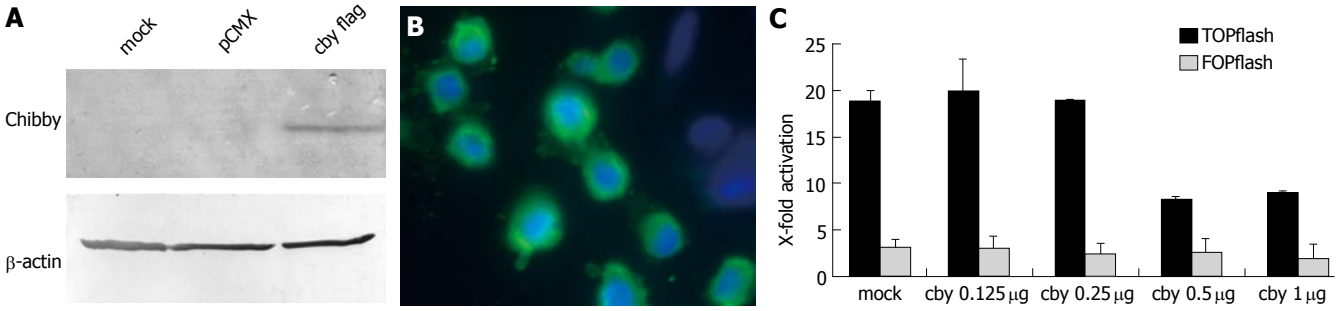

Figure 3 Expression of Chibby in transfected SW480 cells. A: Western blot analysis showing Chibby protein expression levels in untransfected (mock), control vector, or Chibby transfected SW480 cells. B: immunofluorescence staining of flag-tagged Chibby transfected SW480 cells. Nuclei were stained with DAPI in blue, flag-tagged Chibby was detected with FITC-labelled anti-flag antibody (green). C: TOPflash reporter gene assays showing inhibition of β-catenin signalling after transfection of SW480 cells with Chibby expression plasmid.

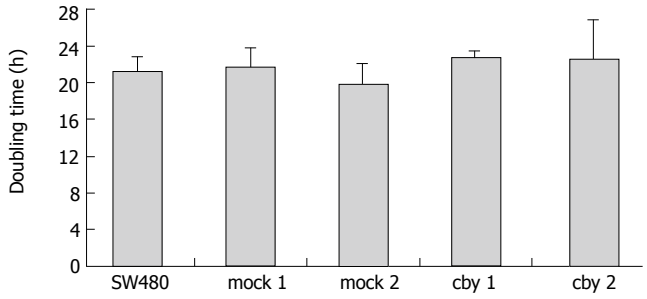

Figure 4 Proliferation Assay. Analysis of the cells over-expressing Chibby could not altered doubling time in comparison to mock or control transfected SW480 cells. Assays were performed in triplicates.

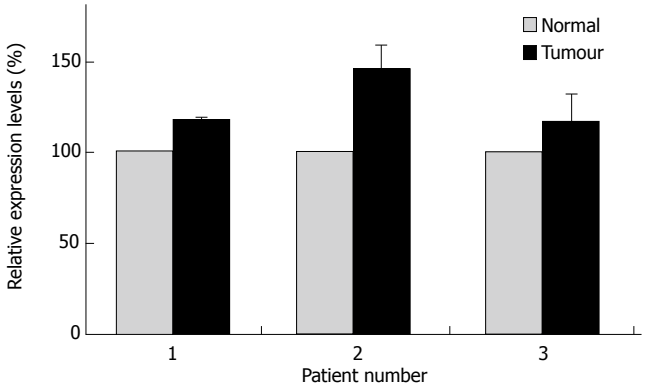

Figure 5 Chibby mRNA expression levels in colorectal tumor and corresponding normal tissue samples. Quantitative RT-PCR showing Chibby mRNA expression levels in matched pairs of tumor and normal colorectal tissue of 3 different patients.

no significant effect on cell proliferation (Figure 4). Doubling times were as follows: SW480: 21.2 h, mock 1: 21.7 h, mock 2: 19.7 h, cby 1: 22.6 h, and cby 2: 22.5 h, respectively. Thus, we did not consider proliferation to be affected by Chibby expression levels in SW480 cells.

Chibby mRNA expression in vivo

As our experiments in colon carcinoma cell lines had revealed sound down-regulation of Chibby expression, the absence of effects on cell functions of over-expressed functional Chibby protein in one of these cell lines (SW480) was rather unexpected. We next performed experiments with samples from patients with diagnosed colorectal carcinoma to assess the question whether Chibby expression was altered not only in colon carcinoma cell lines, but also in coloreactal tumors and might therefore contribute to or support development and progression of colorectal tumors.

We analysed Chibby transcript expression levels in tumor samples and corresponding normal colonical tissue from the same patients by hybridisation of an oligonucleotide-based array (Affymetrix HG-U133A) with 43 samples of colorectal cancer and 34 matched normal mucosa (unpublished data). The ratio of expression levels between tumors and normal tissues was 1.11, displaying no altered Chibby expression in CRC tumors in comparison to adjacent normal colon tissue. In addition, when tumor samples with microsatellite stability (MSS; $n = 24$) and microsatellite instability (MSI; $n = 19$) were separately assessed, again no difference in Chibby expression was observed.

To further validate this result, using quantitative RT-PCR, we tested whether expression levels of Chibby mRNA differed between normal colorectal tissue and adjacent cancerous tissue. We manually microdissected frozen material and analysed the extracted mRNAs. Figure 5 shows the results of 3 examined matched samples, displaying no profound alterations between tumor and adjacent normal tissue. Relative Chibby levels ranged from 100% in normal tissue to 117.4% (patient 1), 146.1% (patient 2), and 116.4% (patient 3), respectively.

DISCUSSION

The cellular antagonist and β-catenin interacting factor Chibby, a small nuclear protein, has been shown to be an endogenous inhibitor of the canonical Wnt signalling pathway. It binds to the LEF/TCF interaction domain at the C-terminus of β-catenin and thereby eliminates interaction of β-catenin with LEF/TCF transcription factors[5]. This leads to a block of transcriptional activation within the signalling cascade. It has been shown for colorectal carcinoma that more than 90% of all tumors harbour activating mutations within proteins of the canonical Wnt/β-catenin signalling cascade[2] and most mutations affect either the β-catenin or the APC

protein[14,15]. Interestingly, tumor development cannot in all cases be solely explained by these mutations, but there need to be further and additional disrupting cellular events. Hence, we were analysing other factors within the Wnt/β-catenin pathway and this study showed our results on the cellular antagonist of β-catenin, Chibby. Due to its function, Chibby has been suggested as a potential tumor suppressor[5]. The aim of our study was to analyse whether Chibby expression is altered in colon carcinoma cell lines and tumors, and if so, whether restoration of Chibby amounts in colon carcinoma cell lines affects cell functions and behaviour.

Examining six colon carcinoma cell lines and one highly differentiated cell line (HT29 M3) that was used as additional control with regard to the mutational status, we could not detect any alterations within Chibby coding sequence. Using quantitative RT-PCR methods, we detected down-regulation of Chibby mRNA expression levels in all six cell lines in comparison to normal colon cells (CEC) or HT29 M3. We demonstrated in another study that gene silencing via promoter hypermethylation might be responsible for down-regulated transcript expression if the coding region does not harbour any mutations[8]. We, therefore, speculated that promoter hypermethylation might be a mechanism for Chibby down-regulation in the examined cell lines, but treating cells with the demethylating agent 5-azacytidine did not lead to sound induction of Chibby mRNA expression in all cell lines. SW48, SW480, and CaCo2 cells showed the lowest default expression levels among all the cell lines tested and displayed a moderate increase in Chibby mRNA expression upon 5-azacytidine treatment. But we do not reckon epigenetic alterations as a common mechanism for Chibby down-regulation.

To assess the functional implication of reduction of chibby expression, we used the cell line SW480 to re-express Chibby via transfection of a Chibby expression plasmid. Tests for correct expression of Chibby were followed by functional assays for proliferation and invasion. We were not able to detect altered invasion potential of Chibby over-expressing cells in comparison to control cells or mock transfected cells. Also, proliferation rate of control and Chibby transfected cells was not different (Figure 4) by means of doubling times. These findings were unexpected as Chibby seemed to be a promising candidate as tumor suppressor in colorectal carcinoma. We speculate that the experimental over-expression of Chibby in SW480 cells does not lead to changes in cell behaviour as mutations in other molecules further downstream within the cascade could overcome Chibby effects. This hypothesis is based on the knowledge that the SW480 cell line is known to harbour several mutations, not only in the Wnt/β-catenin signalling pathway but also in a number of other proto-oncogenes[16,17].

In the very contrast to our findings concerning Chibby expression in a panel of colon carcinoma cell lines, the *in situ* and *in vivo* analyses of colorectal tumors did not support the *in vitro* conclusions. Neither quantitative RT-PCRs, nor hybridisation of an oligonucleotide-based array gave an indication of dysregulation of Chibby in colorectal tumors in comparison to normal colorectal tissue. Our results are supported by a recent study by Gad *et al*[17] who have reported neither somatic mutations in samples of colorectal tumors from 36 patients, nor have they been able to correlate Chibby expression levels to tumorigenicity. Gad *et al*[17] have reported very similar findings to our data that also display no differences in expression levels between normal colon tissue and tumor material.

Taking these data together, we conclude that in contrast to colon carcinoma cell lines where Chibby expression was down-regulated in comparison to normal colonical epithelial cells, *in vivo* Chibby expression is not altered in colorectal tumors and therefore neither a cause nor an indicator for tumor development in colorectal carcinoma.

Our data point out that the use of colon carcinoma cell lines to analyse events within the Wnt/β-catenin signalling pathway has to be considered very carefully. The status of protein expression in these cell lines, at least with regard to Chibby, varies compared to that of tumors and may end up in different phenotypical behaviour of the cells. Thus, direct conclusions on *in vivo* situations could be misleading. Therefore, these differences have to be taken into account when performing *in vitro* studies on cellular signalling pathways.

Abstract

AIM: To detect the new serum biomarkers for colorectal cancer (CRC) by serum protein profiling with surface-enhanced laser desorption ionisation - time of flight mass spectrometry (SELDI-TOF MS).

METHODS: Two independent serum sample sets were analysed separately with the ProteinChip technology (set A: 40 CRC + 49 healthy controls; set B: 37 CRC + 31 healthy controls), using chips with a weak cation exchange moiety and buffer pH 5. Discriminative power of differentially expressed proteins was assessed with a classification tree algorithm. Sensitivities and specificities of the generated classification trees were obtained by blindly applying data from set A to the generated trees from set B and vice versa. CRC serum protein profiles were also compared with those from breast, ovarian, prostate, and non-small cell lung cancer.

RESULTS: Mass-to-charge ratios (m/z) 3.1×10^3, 3.3×10^3, 4.5×10^3, 6.6×10^3 and 28×10^3 were used as classifiers in the best-performing classification trees. Tree sensitivities and specificities were between 65% and 90%. Most of these discriminative m/z values were also different in the other tumour types investigated. M/z 3.3×10^3, main classifier in most trees, was a doubly charged form of the 6.6×10^3-Da protein. The latter was identified as apolipoprotein C-I. M/z 3.1×10^3 was identified as an N-terminal fragment of albumin, and m/z 28×10^3 as apolipoprotein A-I.

CONCLUSION: SELDI-TOF MS followed by classification tree pattern analysis is a suitable technique for finding new serum markers for CRC. Biomarkers can be identified and reproducibly detected in independent sample sets with high sensitivities and specificities. Although not specific for CRC, these biomarkers have a potential role in disease and treatment monitoring.

INTRODUCTION

Colorectal cancer is the third most common cause of cancer-related death in both men and women, accounting for about 10% of all cancer deaths annually. When diagnosed and treated early, the overall 5-year survival rate is around 90%. However, most patients present with locally advanced or metastasised disease at the time of diagnosis, or develop metastasis during follow-up. Suitable tumour markers will facilitate colorectal cancer detection, determination of prognosis, and disease and therapy evaluation.

However, currently used non-invasive methods, such as measurement of serum carcinoembryonic antigen (CEA) levels, faecal occult blood testing and faecal DNA analysis,

have low sensitivities and/or specificities for colorectal cancer[1-4]. Although CEA is currently the best available marker for follow-up of resected colorectal cancer and monitoring of chemotherapy, its use to determine eligibility for adjuvant therapy or its routine use as a single parameter for treatment monitoring has significant clinical limitations[5,6].

Detection of so-called biomarker proteins in serum may lead to new and better tumour markers for colorectal cancer. The proteome, contrary to the genome, is not a static parameter: it reflects not only the presence of active or inactive (mutated) genes, but also their extent of expression at a specific time point. In addition, the proteome reflects all proteins and peptides that may rise from only one gene, i.e. different cleavage products and proteins with different post-translational modifications. Both characteristics allow a more detailed evaluation of a disease status using the human proteome.

Protein profiling in complex biological matrices has become more easily achievable with the Surface-Enhanced Laser Desorption Ionisation (SELDI) ProteinChip technology in combination with a time of flight (TOF) mass spectrometer. This is a relatively new technique, which lacks the disadvantages of 2D-gel-electrophoresis for proteomic research in that it has high sensitivity in the low molecular weight range and high throughput capability, and proteins with extreme characteristics (highly hydrophobic, acidic or basic) can be analysed more easily[7,8]. With this technique, whole serum is applied to protein chips with different chromatographic affinities in a suitable binding buffer. Selectively bound proteins are retained on the surface and non-selectively bound proteins are washed off. In the mass spectrometer, a laser desorbs the bound proteins from the chip surface, which are subsequently detected in the TOF analyser by their respective mass-to-charge ratios (m/z). Since a whole pattern of proteins is analysed, more than one biomarker can be detected. Combination of several of these biomarkers for the evaluation of a patient's status may result in enhanced sensitivities and specificities.

SELDI-TOF MS has already been applied to several forms of cancer, including breast, ovarian, prostate, and lung cancer[9-12]. In the obtained protein profiles, proteins with high sensitivity and specificity for disease have been detected. For colorectal cancer, a discriminative protein of $12*10^3$ Da has been found in tumour cell lines, the identity of which was prothymosin-alpha[13]. Comparing epithelial colorectal carcinoma cells with normal tissue, 3.48×10^3-, 3.55×10^3- and 3.6×10^3-Da proteins were found to be increased in cancer tissue[14]. In Asian patients with colorectal cancer and healthy controls, discriminating serum protein profiles have been recently reported, m/z 5911, 8922, 8944 and 8817 being the most important biomarkers[15-18]. These results were obtained in a single sample set and the reported sensitivities and specificities resulted from cross-validation within this single set. In addition, the identities of the reported biomarker proteins remain unknown.

The objective of this study was to detect biomarker proteins for colorectal cancer in serum using SELDI-TOF MS, and to validate these with an independent sample set. In addition, we aimed at identifying any found biomarkers so that further insight into the pathological processes involved in colorectal cancer can be obtained.

MATERIALS AND METHODS

Patient samples

Two independent serum sample sets were analysed for their protein profiles on different occasions. The first set consisted of samples from 40 patients with colorectal cancer (all Dukes' D) and 49 healthy controls. The second set consisted of samples from 37 patients with colorectal cancer (1 Dukes' A, 2 Dukes' B, 12 Dukes' C, 17 Dukes' D, 5 unknown) and 31 healthy controls. For comparison of colorectal cancer protein profiles with those from other tumour types, a third sample set consisting of serum samples from 8 non-small cell lung cancer (NSCLC) patients (stage III and IV), 10 breast cancer patients (stage II and III), 10 prostate cancer patients (stage I-IV), and 10 ovarian cancer patients (stage I-IV) was analysed. All serum samples were obtained from the serum bank at the Netherlands Cancer Institute, where they were stored at -30 ℃ until analysis. Sample collection was performed after taking individuals' informed consent under approval of the Institutional Review Board. Samples were drawn before surgery or chemotherapy was started, except for 9 patients with metastatic disease in sample set B who had already had surgery.

Protein profiling

Protein profiling was performed using SELDI-TOF MS (Ciphergen Biosystems Inc., Freemont, CA, USA). Several chromatographic chip surfaces and binding conditions were screened for discriminative m/z values between colorectal cancer patients and healthy controls. The most discriminating peaks were seen on CM10 chips, a weak cation exchange chip, which contains anionic carboxylate groups that bind positively charged proteins in serum. Best results were obtained using a sodium phosphate binding buffer (pH 5) and a 500 mL/L solution of sinapinic acid (SPA; Ciphergen Biosystems) in 500 mL/L acetonitrile (ACN) + 5 mL/L trifluoracetic acid (TFA) as energy absorbing molecule.

All serum samples were denatured by adding 180 μL of 9 mol/L urea, 20 g/L CHAPS, 10 g/L DTT (all from Sigma, St. Louis, MO, USA) to 20 μL of serum. CM10 chips were assembled in a 96-well format bioprocessor (Ciphergen Biosystems) which can hold twelve 8-spot protein chips. During all steps of the protocol, the bioprocessor was placed on a platform shaker at 350 r/m. Chips were equilibrated twice with 200 μL of binding buffer consisting of 20 mmol/L sodium phosphate (Sigma) buffer (pH 5) with 1 g/L TritonX-100 (Sigma) for 5 min. Subsequently, 180 μL of binding buffer and 20 μL of denatured sample were applied to the chip. Sample allocation was at random. Incubation was set to 30 min. After binding, the chips were washed twice for 5 min with binding buffer, followed by two 5-min washes with binding buffer without TritonX-100. Lastly, chips were rinsed with deionised water. After air-drying, two times 1 μL of the SPA was applied to the spots.

Protein chips were analysed using the PBS-IIC

ProteinChip Reader (Ciphergen Biosystems). Data were collected between 0 and 200 000 Da. Data collection was optimised for detection of discriminating peaks, resulting in an average of 65 laser shots per spectrum at laser intensity 150 and detector sensitivity 8, and laser focusing at 3000 Da. M/z values for the detected proteins were calibrated externally with a standard peptide mixture (Ciphergen Biosystems) containing [Arg8] vasopressin (1 084.3 Da), somatostatin (1 637.9 Da), dynorphine (2 147.5 Da), ACTH (2 933.5 Da), insulin β-chain (bovine) (3 495.9 Da), insulin (human recombinant) (5 807.7 Da), and hirudin (7 033.6 Da).

Statistics and bioinformatics

Data were analysed with ProteinChip Software package, version 3.1 (Ciphergen Biosystems). For each sample set, all acquired spectra were compiled and analysed as a whole. Spectra were baseline subtracted and normalised to the total ion current between 1 500 and 200 000 Da. For validation of either sample set, the normalisation factor from the training set was applied to the spectra of the validation set. The Biomarker Wizard (BMW) software application (Ciphergen Biosystems) was used to autodetect m/z peaks with a signal-to-noise ratio of at least 5. Peak clusters were completed with peaks with a signal-to-noise ratio of at least 2 in a 0.5% cluster mass window. For validation purposes, peak clusters of the training set were applied in the validation set. Group differences were calculated with the same application, comparing mean intensities of all detected peaks between groups with non-parametric statistical tests. *P* values less than 0.01 were considered statistically significant.

Next, Biomarker Patterns Software (BPS; Ciphergen Biosystems) was used to generate classification trees from the BMW files. A classification tree is built of nodes with an m/z value and a cut-off value for the peak intensity. An example of such a tree is shown in Figure 1. When an analysed spectrum has a peak intensity at the specified m/z below the cut-off value, the sample is placed in the left tree branch. Otherwise, it is placed to the right and its peak intensity at the next m/z value is evaluated. Peaks that result in a maximum separation of the two groups, with a minimum of misclassification are chosen for the nodes. The branch consists of new nodes with an m/z value until a final classification can be made for the spectrum: originating from a colorectal cancer patient or from a healthy control. For every tree, the BPS performs a ten-fold cross-validation in the tree building process, in which ten times another tenth of the data set is used for testing of the tree and these results are combined to yield a cross-validation sensitivity and specificity as a measure for the tree's discriminative power. However, to obtain a more realistic sensitivity and specificity, classification trees built with one sample set as the training set were validated with the blinded data from the remaining set. In addition, both sample sets were combined to form a training set with two thirds of all samples keeping a random third behind in the tree building process for independent validation afterwards.

Biomarker purification and identification

Biomarkers detected in the profiling experiments were purified by fractionation of denatured serum on QhyperD beads (Biosepra; Ciphergen Biosystems), a strong anion exchange surface, with decreasing buffer pH. Subsequently, fractions containing the markers were concentrated on microcon YM-50 filters (Millipore, Billerica, MA, USA) and eluted with increasing concentrations of ACN + TFA (1: 0.001, v/v). The purification process was monitored by profiling each fraction on NP20 chips, containing a non-selective, silica chromatographic surface. Relevant eluates were evaporated and redissolved in loading buffer for SDS-PAGE. Gel electrophoresis was performed on Novex NuPage gels (Invitrogen, San Diego, CA, USA). Gels were stained using colloidal Coomassie staining (Simply Blue; Invitrogen) and protein bands of interest were excised and collected for either passive elution, followed by in-solution digestion or in-gel digestion with trypsin (Promega, Madison, WI, USA).

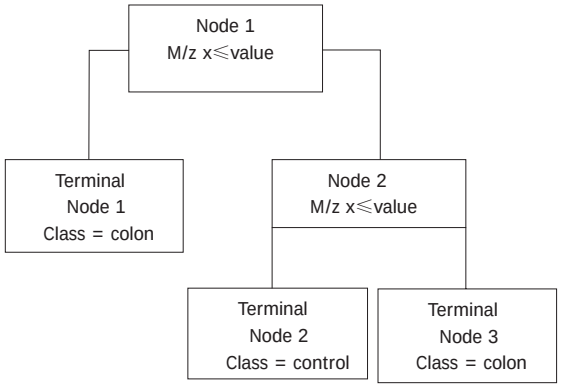

Figure 1 Example of a BPS-generated classification tree distinguishing colorectal cancer patients and healthy controls. If the peak intensity of an analyzed sample is below the cut-off value at the m/z in the node, the sample proceeds to the left. If not, it proceeds to the right, where its peak intensity at the next m/z is evaluated.

For passive elution, bands were washed twice with 300 mL/L ACN + 100 mmol/L NH_4HCO_3 (Sigma), followed by dehydration in ACN. Samples were heated at 50 °C and then eluted with 15 μL of formic acid/ACN/isopropanol/deionised water (4.5:3:1:1.5, v/v) under sonification for 30 min. The eluate was left for 3 h at room temperature before profiling on NP20 chips. Then, the eluate was left overnight. In-solution digests were obtained by evaporation of the supernatant in a SpeedVac, resuspending it in 20 mg/L trypsin in 100 mL/L ACN + 25 mmol/L NH_4HCO_3 and incubation for 4 h at room temperature.

In-gel digestion was performed after washing the excised band with methanol/acetic acid/deionised water (4:1:5, v/v) twice, followed by a wash with 300 mL/L ACN + 100 mmol/L NH_4HCO_3. Samples were dried on a SpeedVac and immersed in a 20 mg/L-solution of trypsin in 100 mmol/L NH_4HCO_3. Digestion was allowed for 12 h at room temperature. All tryptic digests were profiled on NP20 chips, using 1 μL 200 g/L CHCA (Ciphergen Biosystems) solution in 500 mL/L ACN + 5 mL/L TFA as matrix.

Peptides in the resulting digest were investigated with the MASCOT and ProFound search engines (http://www.matrixscience.com; http://prowl.rockefeller.edu/profound_bin/WebProFound.exe), using the Swiss-Prot

Table 1 Classification trees generated with the Biomarker Patterns Software

Tree	Included m/z's ($\times 10^3$ Da): cut-off intensity values and class assignment				Sensitivity (%)	Specificity (%)
	Node 1	Node 2	Node 3	Node 4		
I	3.3 ⩽ 15.035	-	-	-	77.8	73.3
	Colorectal cancer					
II	28 ⩽ 1.558	4.5 ⩽ 29.791	3.1 ⩽ 9.866	6.6 ⩽ 33.233	77.8	73.3
	Colorectal cancer	to Node 3	to Node 4	Colorectal cancer		
III	3.3 ⩽ 12.757	-	-	-	66.7	83.3
	Colorectal cancer					
IV	3.3 ⩽ 12.757	28 ⩽ 1.285	-	-	75.0	83.3
	Colorectal cancer	Colorectal cancer				
V	3.3 ⩽ 12.981	4.5 ⩽ 28.599	-	-	84.2	83.3
	Colorectal cancer	Healthy control				
VI	28 ⩽ 1.529	4.5 ⩽ 28.577	6.6 ⩽ 44.685	-	89.5	88.9
	Colorectal cancer	to Node 3	Colorectal cancer			

Sensitivities and specificities for trees I to IV were obtained by blinded testing with data from the remaining sample set.

and NCBI databases, respectively. Data were searched against the Homo sapiens subset of the database, defining fixed modification of the cysteine residues with propionamide and variable modification of methionine residues (oxidation). Peptide mass tolerance of the average MH^+ masses was 0.5 - 3 Da; the number of tryptic miscleavages allowed was 1 or 2.

Identification of proteins was confirmed either by immunoassay on protein A beads (Biosepra; Ciphergen Biosystems) with an appropriate antibody (Abcam Ltd, Cambridge, UK), or by sequencing of the most important peptides in the tryptic digest with tandem MS on both a Q-TOF™ II, (Micromass Ltd, UK) and a QSTAR ™ (AB/Sciex, Foster City, CA, USA), both equipped with a PCI 1000 interface (Ciphergen Biosystems). For the immunoassay, beads were loaded with antibody in phosphate-buffered saline (PBS, Sigma), and washed twice with PBS, followed by a 30-min incubation with whole serum, 5 subsequent washes with PBS and one with deionised water. Finally, bound proteins were eluted using 1 mol/L acetic acid and the eluate was profiled on NP20 chips.

Serum CRP, TRF and CEA quantification

Serum CEA was quantified using an electrochemiluminiscence immunoassay on a Modular analytics E170 analyser (Roche Diagnostics, Mannheim, Germany). A cut-off value of 5 μg/L was employed. Levels of the acute phase reactants C-reactive protein (CRP) and transferrin (TRF) were assessed by a near infrared particle immunoassay and a turbidimetric immunoassay, respectively, using the Beckman Synchron LX20 analyser (Beckman-Coulter Inc., Fullerton, CA, USA). CRP levels below 8 mg/L were considered clinically normal, as are TRF levels between 2.1 and 3.8 g/L. All statistical analyses for these data were performed with SPSS, version 11.0 (SPSS Inc., Chicago, IL, USA).

RESULTS

Biomarker detection

In the first and second sample set respectively, 15 and 6 proteins of which the expression differed in colorectal cancer patients compared to healthy controls ($P < 0.01$) were detected with the BMW application. Peaks below 2 000 Da were discarded, as they result mainly from the SPA matrix. In either sample set, m/z values of $3.2*10^3$, $3.3*10^3$, 6.4×10^3, 6.6×10^3, 6.8×10^3, and 28×10^3 were differentially expressed. Expressions of m/z 2.7×10^3, 3.1×10^3, 4.2×10^3, 4.3×10^3, 4.5×10^3, 8.0×10^3, 8.9×10^3, 14×10^3, and 16×10^3 significantly differed only in sample set A.

With the BPS several classification trees were built. Tree characteristics of the best-performing trees with accompanying sensitivities and specificities are described in Table 1. Tree I and II were generated from sample set A, tree III and IV from sample set B, and tree V and VI from the combination of sample sets A and B. Tree sensitivities and specificities for trees I to IV were obtained using the second sample set as validation set. For trees V and VI, the sensitivity and specificity were calculated by randomly choosing one third of all data to be excluded from the tree building process for use as validation data afterwards. As shown in Table 1, m/z 3.3×10^3 was the most frequently observed classifier among these best trees. When removing this classifier from the tree-building model, equally- or better-performing trees were seen with m/z 28×10^3 as main classifier (trees II and VI). Other biomarkers used in the trees include m/z 3.1×10^3, 4.5×10^3, and 6.6×10^3. Of these, m/z 3.1×10^3 and 4.5×10^3 were more abundant in colorectal cancer serum samples compared to healthy controls, whereas the others were less abundant. Parts of representative MS-spectra for patients and controls are shown in Figure 2.

Biomarker selectivity

To determine the selectivity of the observed protein profiles for colorectal cancer when compared to other cancer forms, additional samples from patients with other tumours were analyzed. This third sample set was analyzed concomitantly with 17 of the previously analyzed samples from colorectal cancer patients (10 from sample set A, 7 from B) and 20 previously analyzed control samples (10 from either sample set) using the same assay procedures.

When examining peak intensity differences between cancer patients and healthy controls by means of the Biomarker Wizard application, most of the biomarkers for

For each m/z value, mean peak intensities (SD) are given with their P-values for the intensity difference with healthy controls (HC). BC: breast cancer; NSCLC: non-small cell lung cancer; OC: ovarian cancer; PC: prostate cancer.

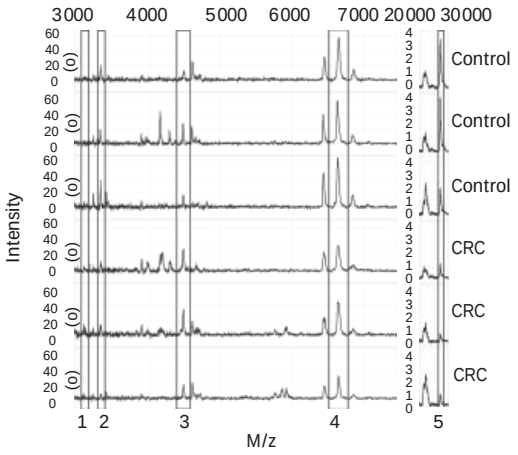

Figure 2 Spectra from colorectal cancer patients and controls. Biomarker proteins are boxed: 1=3.1×10³ Da, 2=3.3×10³ Da, 3=4.5×10³ Da, 4=6.6×10³ Da, 5=28×10³ Da.

colorectal cancer were found to be discriminative for other cancer forms as well (Table 2). Except for breast cancer samples, m/z 3.3×10³, 6.6×10³, and 28×10³ were markedly less abundant in all types of cancer compared to the control samples (P<0.01). For these tumour types, mean peak intensities were not significantly different from those for colorectal cancer, independent of patient characteristics (data not shown). There was a tendency for a significant increase of m/z 4.5×10³ in ovarian and prostate cancer (P<0.05). In breast cancer patients, no significance was reached for peak intensity differences of m/z 3.3×10³, and 4.5×10³ (P=0.10 and P=0.54, respectively). However, m/z 3.1×10³ was found to be significantly increased only in breast cancer samples (P=0.0011), but not in other cancer types.

A decision tree combining data from all tumour types was built with the BPS. Although most of the earlier observed biomarkers were discriminative for all other cancer forms as well, 76% of samples from colorectal cancer patients could be correctly distinguished from those of other cancers based on a classifier peak at m/z 5.9×10³. In samples from colorectal cancer, peak intensities for this m/z were slightly higher compared to the controls, whereas they were significantly lower than the controls in the other cancers (Table 2). In addition, data from the other tumour types were applied to the trees in Table 1. For all trees, more than 89% of patients with other cancers than colorectal cancer were classified as having colorectal cancer, except for tree VI, in which this was 78.4%.

Biomarker purification and identification

Fractionation of whole serum from colorectal cancer patients and controls resulted in elution of the 6.6×10³-Da marker mainly in the flowthrough (pH 9), and the 28*10³-Da marker in the pH 4 fraction. Following concentration on YM-50 filters, the 6.6×10³-Da marker was seen in the 200 mL/L- and 300 mL/L-ACN eluates mostly, more purified from surrounding masses in the latter. The 28×10³-Da marker was present in the filter wash (1 mL/L TFA).

SDS-PAGE of selected eluates was performed on a 120 g/L Bis-Tris gel for the 28×10³-Da marker and a 180 g/L Tris-glycine gel for the 6.6×10³-Da marker. For this marker, both the 200 mL/L- and 300 mL/L-ACN eluates were placed on gel. A clear band was seen for the 28×10³-Da protein, which was divided in half for both passive elution and in-gel digestion. For the 6.6×10³-Da marker, a number of faint bands was seen in the 6000-Da region, in both the 200 mL/L- and 300 mL/L-ACN eluates. All were excised. Bands from the 200 mL/L-ACN eluate were subjected to passive elution, and from the 300 mL/L-eluate to in-gel digestion. Profiling of gel eluates on NP20 confirmed the masses to be indeed 6.6×10³ and 28×10³ Da.

Peptide mapping results revealed the identity of the 28×10³-Da marker to be apolipoprotein A-I. The theoretical mass of this protein is 28 078.62 Da in the SwissProt database and its pI=5.27. The apolipoprotein A-I identity was confirmed by tandem MS of the 1 299.62-, 1301.71-, 1612.83- and 1386.77-Da peptides in the tryptic digest (Figure 3).

The 6.6×10³-Da marker was identified as apolipoprotein C-I, with a theoretical mass of 6 630.58 Da and pI=7.93. Spectra of this identification are shown in Figure 4. Confirmation of the apolipoprotein C-I identity was performed on protein A beads using a goat apolipoprotein C-I polyclonal antibody. The eluate's MS-spectrum clearly showed a large peak at 6.6×10³ and another prominent peak at 9.3×10³. The mass of the latter peak corresponded to that of apolipoprotein C-I precursor. In addition, the passive elution of the apolipoprotein C-I control (Figure 4A) showed a peak at 3.3×10³. The 3.3×10³-Da biomarker found in our sample sets A and B, as well as the set combined with other tumour types, consistently showed a high correlation with the 6.6×10³-Da one: the ratio of their

M/z 1504.70	MREWFSETFQK + Oxidation (M)

Figure 4 Identification of apolipoprotein C-I. **A:** Parts of the MS spectra of the gel eluates of an apolipoprotein C-I control and the 6.6×10^3-Da protein isolated from HC serum run on the same gel. **B:** Parts of the MS spectra of the in-gel digests of an apolipoprotein C-I control and the 6.6×10^3-Da protein isolated from HC serum and the results of sequencing of these two peptides with tandem MS. **C:** Part of the MS spectrum of the eluate from the apolipoprotein C-I antibody. Apart from the expected peaks at 9.3×10^3, apolipoprotein C-I precursor, and 6.6×10^3, a 6.4×10^3-Da peak is seen, which is a known fragment of apolipoprotein C-I missing two N-terminal amino acids. The mass at 7.8×10^3 is unknown and does not correspond to any of the apolipoproteins with which antibody cross-reactivity can occur. It is possibly an intermediate splice form of the precursor protein.

peak intensities was quite constantly ranging between 3.5 and 4.0 (Table 2). This supports the fact that the observed 3.3×10^3-Da marker is actually a doubly charged artefact of the 6.6×10^3-Da protein. The 3.1×10^3-Da protein was lost during the purification process and was therefore directly sequenced on-chip. It was identified as a 27-amino acid N-terminal fragment of albumin with sequence: DAHKS EVAHRFKDLGEENFKALVLIAF. The identity of the 4.5×10^3-Da protein is still under investigation.

Serum CRP, TRF and CEA levels

Evaluation of the extent of a possible acute phase reaction was done by measurement of CRP and TRF levels. Mean TRF levels in the patient and control group were 2.37 g/L (range, 1.20-3.60 g/L) and 2.59 g/L (range, 1.90-4.00 g/L), respectively (P=0.037, non-parametric Mann-Whitney U test). Mean CRP levels in either group were 29.0 mg/L (range, 0 - 213 mg/L) and 3.70 mg/L (range, 0 - 29.2 mg/L) (P<0.000, non-parametric Mann-Whitney U test). Although there was a significant difference in the levels of these acute phase reactants in the patients and controls, the mere presence of an acute phase response was not a good predictor for colorectal cancer: the sensitivities of CRP and TRF were 51.9% (40/77) and 22.1% (17/77), respectively, using the clinical cut-off values [specificities 88.8% (71/80) and 96.3% (77/80), respectively]. In addition, CRP and TRF levels were included in the BMW data files for the tree-building process with the BPS, in order to evaluate their capability to distinguish colorectal cancer patients and healthy controls. Neither CRP, nor TRF concentrations were as good a classifier as the m/z values in the generated trees.

Mean serum CEA in the colon group was significantly higher (mean 326.2 μg/L, range <1-9 452) compared to the control group (mean 2.23 μg/L, range <1-18.98) (P<0.001, non-parametric Mann-Whitney U test). Using a cut-off value of 5 μg/L, its sensitivity and specificity were found to be 75.3% and 95.0%, respectively, for all samples combined. This sensitivity was lower than that for the proteins in the classification trees generated with all samples (V and VI), but the specificity of CEA in this population was higher. Assessing CEA sensitivity in the total sample set according to colorectal cancer stage, using the 5 μg/L cut-off, resulted in correct classification of 0 of 1 Dukes' A, 0 of 2 Dukes' B, 3 of 12 (25.0%) Dukes' C, and 51 of 57 (89.5%) Dukes' D. In comparison, using the total sample set and the trees generated with the sets (V and VI), 1 of 1 Dukes' A, 1 of 2 Dukes' B, 11 of 12 (91.7%)

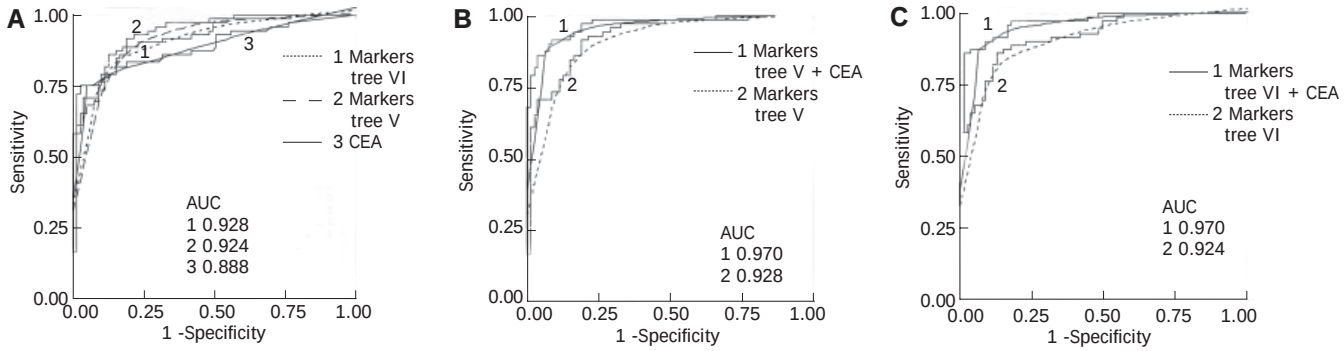

Figure 5 ROC curves for biomarker proteins from trees V and VI with and without log(CEA). Areas under the curve (AUC) are given for each model.

Dukes' C, and 47 of 57 (82.5%) Dukes' D were correctly classified. In addition, logistic regression was performed for CEA and the markers from tree V and VI, and receiver operating characteristic (ROC) curves were generated. As shown in Figure 5, combining the markers from each tree with log-transformed CEA values yielded a higher area under the ROC curve than for either alone.

DISCUSSION

In this study, five biomarker proteins were detected that were able to reliably distinguish colorectal cancer patients and healthy controls using the SELDI-TOF MS technique for protein profiling. Two of these were identified as apolipoprotein C-I (6.6×10^3 Da) and apolipoprotein A-I (28×10^3 Da). Using the ProteinChip Software, the 3.3×10^3-Da protein could be identified as a doubly charged form of the 6.6×10^3-Da apolipoprotein C-I, which was confirmed by its appearance in the MS spectrum of pure apolipoprotein C-I isolated from a gel. The m/z of 3.1×10^3 was found to be an N-terminal fragment of albumin. In addition, the detection of these biomarkers' expression difference was shown to be reproducible on two separate occasions, considering the obtained classification tree sensitivity and specificity between 65% and 90% when using the second sample set as a blinded validation set. Such reproducible detection is imperative for any future use as a clinical tool. Sensitivities and specificities obtained with data from the blinded sample set were comparable to those obtained by cross-validation within one sample set (data not shown), which supports the fact that there was no additional misclassification of samples due to experimental variability between the two sample sets.

Several reports have been made of differential expression of the same m/z values in colorectal cancer, even though different chip surfaces were used. Yu *et al*[17] reported a 3 329- and 6 669-Da protein to be differentially expressed on a hydrophobic chip surface, that were not selected in the final diagnostic pattern. In the same study, a 4 477-Da protein, which was a classifier in the final pattern, was also up-regulated in colorectal cancer patients[17,18]. The 6.6×10^3- and 3.3×10^3-Da proteins were detected by Yu *et al*[17] but not identified. It is likely that these are apolipoprotein C-I and its doubly charged form, since this is a very hydrophobic protein and retention on a hydrophobic chip surface is very plausible. In fact, in our study population, these m/z values were also seen on hydrophobic chips (data not shown). This appearance of (likely) the same colorectal cancer biomarkers in different laboratories underlines their validity. Also, a 5.9×10^3-Da protein was reported, which was an up-regulated biomarker in serum of colorectal cancer patients[17,18]. Despite lack of significance in our study, there was a tendency for our 5.9×10^3-Da protein to be higher in patients than controls, which is consistent with the result from Yu *et al*[17] and indicates this may be the same protein. Data from a proteomic study by our group[19] on breast cancer patients have shown a 5.9×10^3-Da down-regulated protein in this cancer type, which is in concordance with the 5.9×10^3-Da protein in the current study. The protein in the former study was identified as a fragment of fibrinogen alphaE chain.

Apolipoprotein C-I is primarily synthesised in the liver and, to a minor degree, in the small intestine. Its function resides mainly in lipoprotein metabolism[20]. It is originally formed as a pro-peptide of 9.3×10^3 Da, which generates the mature protein upon cleavage during translation. To our knowledge, no previous reports about apolipoprotein C-I down-regulation in cancer have been made as yet. However, a 6.6×10^3-Da protein was detected and identified as apolipoprotein C-I in another SELDI-TOF MS study, being decreased in hemorrhagic *versus* ischemic stroke and hemorrhagic stroke *versus* controls on a strong anion exchange surface at pH 9[21]. Apolipoprotein A-I is synthesised both in the liver and small intestine and is a major constituent of HDL apolipoprotein. It is a known negative acute phase reactant, of which decreased expression has been described in several cancers, including a SELDI-TOF MS study on ovarian cancer[22-25]. In the latter study an immunoassay was peformed. In contrast to our data, the authors found no decreased apolipoprotein A-I levels in colorectal cancer. However, apolipoprotein A-I levels assessed by immunoassay may reflect concentrations of both bound pro-apolipoprotein A-I and apolipoprotein A-I. Increased expression of apolipoprotein A-I has been described in tissue of both liver metastases and, to a lesser extent, primary tumours of colorectal origin[26]. The observed decrease in serum levels in our study thus may be due to decreased liver synthesis. Other human proteomics studies in which differential expression

of apolipoprotein A-I has been described include a SELDI-TOF MS analysis of plasma from patients with diabetes, and several studies using 2D-gel electrophoresis in old *versus* young brain tissue, cerebrospinal fluid of patients with Alzheimer's disease, serum during infection with hepatitis B virus, and plasma during acute coronary syndrome[27-31]. In all these diseases, decreased levels of apolipoprotein A-I were observed. To our knowledge, the albumin fragment that was found in this study has not been described in the literature before. Albumin is synthesised with an 18-amino acid signal peptide and a 6-amino acid pro-peptide. Over-expression of this specific fragment may be caused by enhanced proteolytic activity, as increased proteolysis is common in cancer invasion and metastasis[32]. However, for this fragment, a correlation with sample age was seen in the colorectal cancer group (data not shown). Thus, it cannot be ruled out that it is a product of protein degradation upon storage.

Although the identification of apolipoprotein C-I and apolipoprotein A-I as biomarkers suggests an acute phase response, comparison with routine markers for establishing such a response, CRP and TRF, shows that our biomarkers are much more sensitive for colorectal cancer than these. The value of our biomarkers for detection of colorectal cancer was also evaluated by comparison with the predictive value of CEA. Sensitivity of our biomarkers was higher than that of CEA considering all samples. Stratification by Dukes' stages showed a significant better sensitivity of our classification trees (91.7%, 11/12) compared to CEA (25.0%, 3/12) in Dukes' C colorectal cancer, although at stage D CEA performed better. Combining log-transformed CEA in a logistic regression model with the markers in the trees resulted in a higher AUC in the ROC curve than for either log(CEA) or the combined tree classifiers alone. This indicates that our markers provide additional information to CEA values. CEA sensitivity has been reported to be lower in earlier stages of colorectal cancer. Sensitivity has been reported to vary between 3% and 66.7% for Dukes' A to D staged disease[2,18,33]. No conclusions can be drawn on the performance of our classification trees at earlier stages of colorectal cancer due to limited samples, but 2 of 3 patient samples from stage A and B were correctly classified by the trees and none when using the clinical cut-off for CEA.

Our results showed that it is very important to compare any biomarkers found for a certain type of cancer with those for other tumour types. This is lacking in most of the SELDI-TOF MS studies published so far. We found that most of our biomarker proteins were differentially expressed in other cancers as well. Lack of a significant difference at m/z 3.3×10^3 and 4.5×10^3 in breast cancer patients could be explained by the large proportion of early disease (9 of 10 stage 2) in this group compared to the others (mainly stage 3 and 4). However, since m/z 3.3×10^3 is the doubly charged 6.6×10^3-Da protein, which was significantly less expressed in breast cancer, this lack of significance is more likely due to slight differences in ionisation of this protein in this group. The fact that the 3.1×10^3-Da protein is not significantly different in ovarian and prostate cancer may result from the limited sample size, as for the smaller colorectal cancer group in this analysis with comparable mean peak intensity no significant difference at m/z 3.1×10^3 was observed either, although in sample sets A and B it was.

Even though most of our biomarkers are not specific for colorectal cancer, a potential role for them lies in therapy evaluation, disease surveillance or prognosis, possibly combined with CEA or other available markers. At present, CEA is recommended for monitoring chemotherapy, but no studies showing any benefit on survival, quality of life, or reduction of costs are available, although serial CEA testing may lead to earlier detection of progressive disease[5]. In addition, specificity of CEA for treatment monitoring can be compromised by transient increases during treatment with various chemotherapeutic drugs, such as 5-flourouracil and levamisole[5]. Since the expression profiles of our reported markers reliably reflect presence of cancer, be it colorectal cancer or not, changes in expression levels may correspond to response to therapy or disease progression and provide additional information to CEA levels.

In conclusion, our results show that SELDI-TOF MS is a suitable technique to find new serum biomarkers for colorectal cancer. The markers we have found in this study reliably distinguish colorectal cancer patients from healthy persons. Although not specific for colorectal cancer, they have a potential role as markers in treatment monitoring, disease surveillance, or prognosis, possibly in combination with other available markers. To extend the study population and evaluate the ability of our biomarkers to detect early-stage tumours and polyps, a prospective study is currently ongoing.

Abstract

AIM: To examine the psychological impact of chronic hepatitis C (CHC) diagnosis in a large cohort of CHC patients as compared with other stressful life events and chronic diseases carrying a risk of life-threatening complications.

METHODS: One hundred and eighty-five outpatients with compensated CHC were asked to self-grade, using a 100-mm visual analogue scale (VAS), the degree of stress caused by the learning of CHC diagnosis and the perceived severity of their disease. Diagnosis-related stress was compared to four other stressful life events and perceived CHC severity was compared to four other common chronic diseases.

RESULTS: Learning of CHC diagnosis was considered a major stressful event (mean ± SD scores: 72±25), significantly less than death of a loved-one (89±13, $P < 0.0001$) and divorce (78 ± 23, $P < 0.007$), but more than job dismissal (68 ± 30, $P < 0.04$) and home removal (26±24, $P < 0.0001$). CHC was considered a severe disease (74±19), after AIDS (94±08, $P < 0.001$) and cancer (91±11, $P < 0.001$), but before diabetes (66±23, $P < 0.001$) and hypertension (62±20, $P < 0.001$). Perceived CHC severity was not related to the actual severity of liver disease, assessed according to Metavir fibrosis score. In multivariate analysis, diagnosis-related stress was related to perceived disease severity ($P < 0.001$), trait anxiety ($P < 0.001$) and infection through blood transfusion ($P < 0.001$).

CONCLUSION: Our results show the considerable psychological and emotional burden that a diagnosis of CHC represents, even in the absence of significant liver disease. They should be taken into account when announcing a diagnosis of CHC in order to reduce its negative effects.

Key words: Hepatitis C; Stressful life event; Perceived severity; Visual analogue scale

INTRODUCTION

Despite the fact that chronic hepatitis C (CHC) may lead to life-threatening complications such as cirrhosis, liver failure and hepatocellular carcinoma, most patients with CHC are asymptomatic and unaware of their liver disease prior to diagnosis. Nonetheless, these patients consistently report a significant reduction in health-related quality of life (HRQOL) as compared with population controls[1-6]. This impairment of HRQOL has been documented even in the absence of significant liver disease[3] and is usually improved after sustained viral clearance[4,5]. In addition, clinically significant emotional distress and depressive disorders have been reported in untreated CHC patients with a prevalence ranging from 11 to 53%[2,7-15], questioning the role of HCV itself in their occurrence[16]. Whether these disorders are due to the uncertainty of living with a chronic disease with potential life-threatening complications or to other psychosocial factors remains unclear. However, it has been recently shown that CHC patients aware of their diagnosis had worse HRQOL scores as compared with unaware seropositive patients[6,17], suggesting that the psychological impact of diagnosis knowledge may play an important role.

The aim of this prospective study was to examine the psychological impact of CHC diagnosis in a large cohort of CHC patients as compared with other stressful life events and chronic diseases carrying a risk of life-threatening complications.

MATERIALS AND METHODS

Study population

A total of 185 patients with a confirmed diagnosis of HCV infection (defined as detectable hepatitis C antibodies and HCV RNA in serum) attending the Hepatology Clinics at the University of Bordeaux were studied. Exclusion criteria were: age below 18 years, decompensated cirrhosis, co-infection by hepatitis B virus or human deficiency virus (HIV), current psychotic or manic disorders, obvious intellectual impairment, and inability to communicate in French.

Measures

Immediately prior to or following an outpatient clinic appointment, and after their written informed consent had been obtained, participants were asked to self-grade, using a 100-mm visual analogue scale (VAS), the degree of stress caused by the learning of CHC diagnosis. On that scale, the left endpoint 0 was defined as not stressful at all, the right endpoint 100 as extremely stressful. There were no further marks on the line. Instructions were as follows: "Put a mark on the line at the point that best describes how stressful you consider the learning of hepatitis C diagnosis". The degree of stress experienced was indicated by the distance in millimeters from the left endpoint. Perceived disease severity was assessed using the same method. VAS has been shown to be a reliable tool to assess subjective variables, such as stress[18], pain[19] and fatigue[20].

In addition to validate the reproducibility of measurements over time, a second assessment was performed 3 mo later in a subgroup of randomly selected patients.

Trait anxiety was assessed using the Spielberger State Trait Anxiety Inventory[21], a 20-item standardized self-report scale ranging from 20 (low tendency to be anxious) to 80 (high tendency to be anxious).

The influence on diagnosis-related stress of age, gender, marital status, educational level, route of HCV transmission, time since diagnosis, antiviral therapy, perceived severity of illness, actual severity of liver disease (assessed according to the fibrosis score of the METAVIR scoring system[22] in patients in whom a liver biopsy specimen was available), and trait anxiety was also studied.

Comparison with other stressful life events and chronic diseases

Using VAS mean scores, diagnosis-related stress was compared to four other stressful life events (i.e., home removal, job dismissal, divorce, or death of a loved-one) selected from the Paykel life-event scale[23]. Perceived CHC severity was compared to four other common chronic diseases carrying a risk of life-threatening complications (i.e., hypertension, diabetes mellitus, cancer and AIDS).

Statistical analysis

VAS scores for diagnosis-related stress and perceived disease severity were expressed as mean ± SD. Chi-square test was used for categorical variables and one-way analysis of variance (ANOVA) for continuous variables. A P value < 0.05 was considered statistically significant. Using paired Student's t-test, test-retest reliability was assessed for VAS mean scores in a randomly selected sample of patients. For the study of factors associated with diagnosis-related stress, ANOVA was used for both categorical (gender, educational level, marital status, route of transmission, antiviral therapy, and histological severity of liver disease) and continuous variables (age, perceived disease severity and trait anxiety). For the later, patients were divided into two groups according to the median value. Multivariate analysis was performed including variables significantly associated with diagnosis-related stress ($P < 0.10$).

Table 1 Characteristics of the 185 patients studied

	n = 185 (%)
Age (yr)	45±11
Gender (male/female)	111/74
Educational level	
No diploma	24 (13)
High school	83 (45)
College undergraduate	35 (19)
College graduate	43 (23)
Marital status	
Single/divorced	57 (31)
Married	92 (50)
Non-married couple	36 (19)
Routes of transmission for HCV	
Blood transfusion	74 (40)
Intravenous drug use	48 (26)
Others*	63 (34)
Histological severity (Metavir fibrosis score)	n=169
F0-1	39 (23)
F2	83 (49)
F3	19 (11)
F4	28 (17)
Trait anxiety (STAI)	45±11 (20-80)

RESULTS

Study population

The characteristics of the 185 patients are shown in Table 1. There were 111 men and 74 women with a mean age of 45±11 years. The study group had a broad distribution of educational background. Seventy-four (40%) patients were infected through blood transfusion, whereas 48 (26%) were infected through intravenous drug use. The mean time since CHC diagnosis was 2.9±2.6 years. Fifty-nine (32%) patients were receiving antiviral therapy at the time of the study. Of the 169 patients with available liver biopsy data, 28 (17%) had evidence of cirrhosis. The mean STAI-Y score for trait anxiety was 45±11 (range 22-80). This score did not differ from measures obtained in a community sample [24].

VAS scores for diagnosis-related stress and perceived disease severity

Mean±SD scores for diagnosis-related stress were 72±25 (range: 5-100). Mean±SD scores for perceived disease severity were 74±19 (range: 15-100). Three months later, the second assessment in a subgroup of 30 randomly selected patients showed that all VAS scores were reproducible over time (no difference was observed for

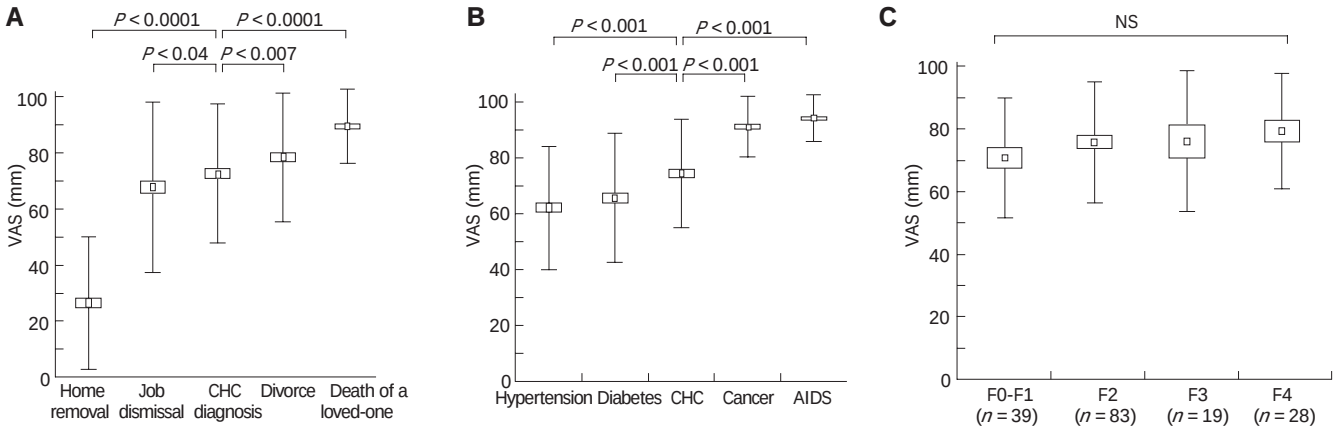

Figure 1 (**A**) Comparison between mean visual analogue scale (VAS) scores for chronic hepatitis C (CHC) diagnosis-related stress and four other stressful life events (i.e., home removal, job dismissal, divorce, and death of a loved-one) selected from the Paykel life-event scale[23] in the 185 patients. *P* values are for post-hoc comparisons made after significant one-way ANOVA ($F = 249.32$, $P < 0.0001$). (**B**) Comparison between mean visual analogue scale (VAS) scores for perceived chronic hepatitis (CHC) severity and four other common chronic diseases carrying a risk of life-threatening complications (i.e., hypertension, diabetes, cancer and AIDS) in the subgroup of 185 patients. *P* values are for post-hoc comparisons made after significant one-way ANOVA ($F = 173.81$, $P < 0.001$). (**C**) Mean visual analogue scale (VAS) scores for perceived chronic hepatitis (CHC) severity according to actual severity of liver disease assessed using METAVIR fibrosis score (F0: no fibrosis; F1: portal fibrosis without septa; F2: portal fibrosis and few septa; F3: numerous septa without cirrhosis; F4: cirrhosis) in the 169 patients with available liver specimen. In Figures A, B and C, the upper and lower limits of the boxes and the middle square indicate the standard error and the mean, respectively. The upper and lower horizontal bars indicate the standard deviation.

any item, using a paired *t* test).

Comparison with other stressful life events and chronic diseases

Mean±SD scores for stress were as follows: death of a loved-one (89±13), divorce (78±23), CHC diagnosis (72±25), job dismissal (68±30) and home removal (26±24) (Figure 1A). CHC diagnosis was significantly more stressful than job dismissal ($P < 0.04$) and home removal ($P < 0.0001$) but less than divorce ($P < 0.007$) and death of a loved-one ($P < 0.0001$).

Mean VAS scores for perceived disease severity were as follows: AIDS (94±08), cancer (91±11), CHC (74±19), diabetes mellitus (66±23) and hypertension (62±20) (Figure 1B). CHC was considered significantly more severe than diabetes mellitus ($P < 0.0001$) and hypertension ($P < 0.0001$) but less than cancer ($P < 0.001$) and AIDS ($P < 0.001$).

Relationship between perceived disease severity and actual severity

Mean VAS scores for perceived disease severity did not differ according to the Metavir fibrosis stages in the 169 patients in whom a liver specimen was available (Figure 1C).

Factors associated with diagnosis-related stress

In univariate analysis, diagnosis-related stress was associated with female sex ($P < 0.003$), infection through blood transfusion ($P < 0.002$), high perceived disease severity ($P < 0.001$) and high trait anxiety ($P < 0.001$) (Table 2). Stress tended to be higher in patients with low education level, although the difference did not reach statistical significance ($P = 0.07$). Scheffé post hoc tests revealed that stress scores were significantly higher in

Table 2 Factors associated with diagnosis-related stress in univariate analysis in the 185 patients

	Diagnosis-related stress (mean VAS scores)	*P*
Age (yrs)		
<46	73±25	
⩾46	72±24	NS
Gender		
Male	66±26	
Female	79±22	<0.003
Educational level		
< High school	75±24	
⩾ High school	69±25	0.07
Marital status		
Single/divorced	73±25	
In couple	72±24	NS

Educational level: (< high school:1, ⩾ high school:2)	-0.03	0.58
Anxiety (STAI-Y score)	0.30	< 0.001
Perceived disease severity (100mm VAS score)	0.43	< 0.001

[1]regression coefficient.
[2]Regression model: R = 0.60, R^2 = 0.36, adjusted R^2 = 0.35, F(5, 171) = 19.65, P < 0.001.

patients infected through blood transfusion than in those infected through intravenous drug use (P < 0.001). No difference was observed for patients infected through other routes of transmission. Stress did not differ between untreated and treated patients. In the latter patients, stress did not differ according to virological response.

In multivariate analysis, stress was related only to perceived disease severity (P < 0.001), trait anxiety (P < 0.001) and infection through blood transfusion (P < 0.01). These parameters accounted for 36% of the variance of diagnosis-related stress (R^2 = 0.36; P < 0.001; Table 3).

DISCUSSION

Our results show that learning one has contracted HCV infection, with its implications for future health and behaviour, is a major stressful event (with mean scores of 72 ± 25 on a 100-mm visual analogue scale). By comparison with other stressful life events selected from the Paykel life-event scale[23], ranging from minor (i.e., home removal) to major (i.e., death of a loved one), CHC diagnosis was considered less stressful than death of a loved one (89 ± 13, P < 0.0001) and divorce (78 ± 23, P < 0.007), but more than job dismissal (68 ± 30, P < 0.04) and home removal (26 ± 24, P < 0.0001). These results emphasize the considerable emotional and psychological burden that CHC diagnosis represents in patients' life. So far, the psychological issues that CHC patients face remain poorly understood. In the studies having reported clinically significant emotional distress and depressive disorders in patients with CHC[2,13-15], the psychological impact of diagnosis knowledge was not taken into account. However, it is important to distinguish between psychological reactions to the knowledge that one has been infected with HCV and the direct effects of the virus itself as evidenced by the results of the present study. Our findings are consistent with those of Rodger *et al*[6] who compared 15 patients who were aware of having HCV infection with 19 subjects who were unaware of having HCV infection, and found that the former had significantly poorer HRQOL scores. More recently, Dalgard *et al*[17] have confirmed these results in a cohort of 199 Swedish active drug user patients, showing that those who believed they were infected had a lower HRQOL scores than those who believed they were not infected. Taken together, these results provide evidence of the considerable negative impact of the knowledge of the diagnosis of CHC on patients' perception of their psychological well-being, known for other chronic diseases as the "labeling" effect[25]. Such an effect has recently been illustrated in a study by Zickmund *et al*[26], showing that stigmatization was common in patients with CHC and was associated with a lower quality of life and with a deterioration of social support.

There are increasing evidences that CHC infection may be associated with significant cerebral dysfunction. Several authors have reported cognitive impairment and central nervous system functional abnormalities in CHC patients compared with uninfected controls, using P300 event-related potentials, a sensitive electrophysiologist test of cognitive processing[27] or magnetic resonance spectroscopy[28-31]. Such findings suggest a direct biological effect of HCV infection on cerebral function. Whether cognitive dysfunction is an important determinant of impaired HRQOL in CHC remains to be determined.

As natural history of chronic HCV infection remains poorly defined[32], it is not surprising that CHC diagnosis, a disease with uncertain outcome, raises significant concerns about future health status. Indeed, CHC was perceived as a severe disease (74 ± 19), after AIDS (94 ± 08, P < 0.001) and cancer (91 ± 11, P < 0.001), but before diabetes (66 ± 23, P < 0.001) and hypertension (62 ± 20, P < 0.001). Interestingly, perceived CHC severity was not related to the actual severity of the disease, as assessed by the severity of liver histological lesions. This finding is consistent with the results of Foster *et al*[3] who showed that the significant impairment of HRQOL experienced by CHC patients could not be attributed to the histological severity of liver disease. It is also in keeping with studies[33-35] conducted in patients with hypertension or chronic respiratory diseases, showing that perception of a disease usually correlates poorly with its medically defined characteristics. In addition, the patients' perception of CHC severity seemed to have a more significant impact on their psychological status than did the histological severity of their liver disease as evidenced by multivariate analysis, showing that diagnosis-related stress was mainly related to perceived CHC severity, trait anxiety and infection through blood transfusion. An explanation for that latter finding may be the fact that patients infected through blood transfusion had no reason to expect such a health problem. By contrast, former drug users likely knew, given their past lifestyle, they were at risk of contracting severe diseases, such as HIV/AIDS, hepatitis B or C, with related-consequences for their future health.

Although our patient population does not represent a random sampling of CHC patients, we believe that it is representative of the general population of CHC patients. The demographic and clinical characteristics of our study population, including routes of transmission and proportion of patients with cirrhosis at the time of diagnosis, are similar to that reported in large surveys of patients with CHC in France[36,37]. In addition, all

VAS scores were reproducible over time in a sample of randomly selected patients. Although some of our patients received antiviral therapy (32%), diagnosis-related stress and perceived disease severity mean VAS scores did not differ between treated and untreated patients.

Finally, our findings may have important implications for clinicians who take care of patients with CHC. They highlight the importance of communication between patients and their physician and the crucial role of the specialist in providing adequate and accessible information for patients to cope with their condition[38].

In conclusion, our results show the considerable psychological and emotional burden that a diagnosis of CHC represents, even in the absence of significant liver disease. They should be taken into account when announcing a diagnosis of CHC in order to reduce its negative effects.

Abstract

AIM: To study the baculovirus/mammalian cell system for efficient expression of functional large hepatitis delta antigen (L-HDAg).

METHODS: A recombinant baculovirus expressing histidine-tagged L-HDAg (L-HDAgH) was constructed to transduce baby hamster kidney (BHK) cells by a simplified transduction protocol.

RESULTS: The recombinant baculovirus transduced BHK cells with efficiencies higher than 90% as determined by flow cytometry. The expression level was significantly higher than that obtained by plasmid transfection and was further enhanced 3-fold to around 19 pg/cell by the addition of 10 mmol/L sodium butyrate. Importantly, the expressed L-HDAgH was localized to the cell nucleus and correctly isoprenylated as determined by immunofluorescence labeling and confocal microscopy. Moreover, L-HDAgH interacted with hepatitis B surface antigen to form virus-like particles.

CONCLUSION: The fusion with histidine tags as well as overexpression of L-HDAgH in the baculovirus-transduced BHK cells does not impair the biological functions. Taken together, the baculovirus/mammalian cell system offers an attractive alternative for high level expression of L-HDAgH or other proteins that require extensive post-translational modifications.

INTRODUCTION

Hepatitis delta virus (HDV) is a subviral satellite and requires hepatitis B virus to supply envelope proteins (HBsAg) for its packaging, secretion and infection[1, 2]. HDV superinfection of HBV carriers can lead to fulminant hepatic failure and very likely the progression to liver cirrhosis[3], consequently HDV imposes a huge threat to the health of 350 million HBV carriers worldwide. However, effective vaccines or diagnostic assays remain unavailable. The RNA genome of HDV encodes the large and small forms of hepatitis delta antigens (L-HDAg and S-HDAg). The 24 kd S-HDAg and 27 kd L-HDAg are identical in sequence except that L-HDAg contains additional 19 amino acids at the C-terminus[1, 4]. The C-terminus extension of L-HDAg allows for the isoprenylation which is crucial for the interaction with S-HDAg and HBsAg for the formation of virions. It has been established that cell-mediated immunities are important in controlling HDV infection[5, 6], thus an effective T-cell stimulating HDV vaccine would be highly desired. In this regard, L-HDAg may represent an excellent vaccine candidate because L-HDAg (expressed by a DNA vaccine) induces significant titers of anti-HDV antibodies as well as strong cell-mediated immune responses in mice[7]. Moreover, L-HDAg is a dominant repressor for HDV replication[8], thus implicating its application as an anti-HDV drug in addition to being a vaccine. However, efforts to characterize and evaluate the immunological properties of L-HDAg have been hampered due to the lack of a proper method for efficient expression and purification of L-HDAg.

Baculovirus (*Autographa californica* multiple nuclear polyhedrosis virus, AcMNPV) has been widely utilized for protein expression in insect cells. Since the finding that baculovirus is capable of transducing mammalian cells in 1995, baculovirus has been developed as a vector for *in vitro* and *in vivo* gene therapy studies and many other applications (for review, see[9, 10]). Recently, the applications

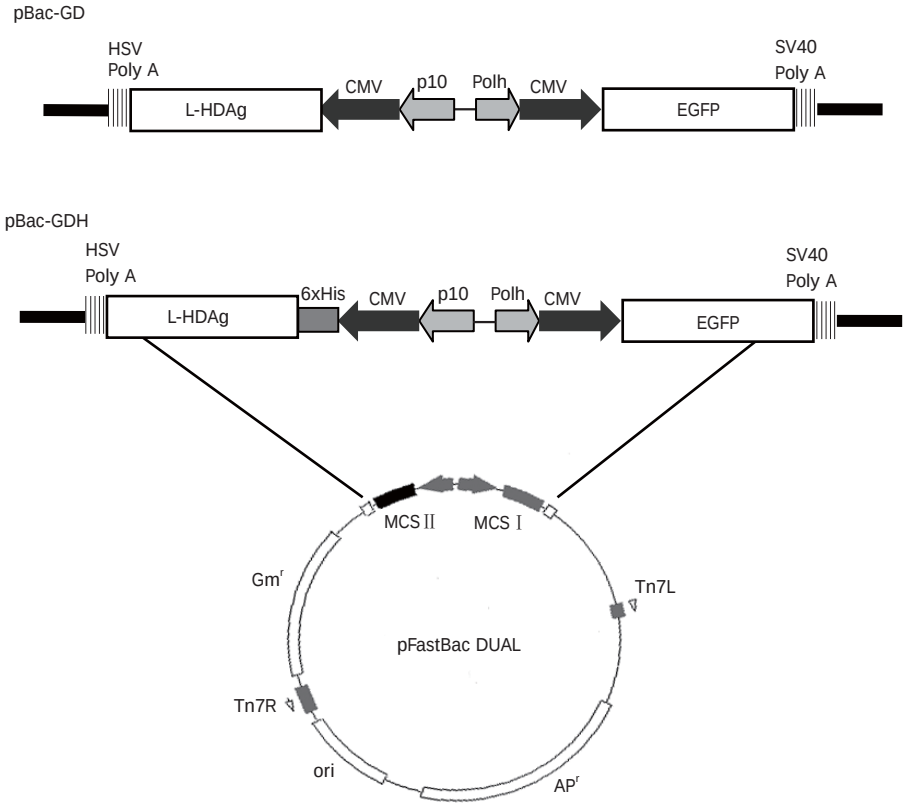

Figure 1 Schematic illustration of recombinant donor plasmids pBac-GDH and pBac-GD

of baculovirus have been further expanded to the identification of MHC class I mimotopes[11] and genetic modification of primary chondrocytes[12]. Furthermore, our group has also demonstrated the feasibility of producing HDV virus-like particles in Huh-7 cells[13]. All these studies suggest that baculovirus may be an ideal tool for the expression of functional, complex eukaryotic proteins owing to the following advantages: (1) Baculovirus transduction is highly efficient for many cell types and generally causes no appreciable cytopathic effect[10,14]; (2) The large AcMNPV genome (about 130 kb) confers the virus huge cloning capacity to harbor multiple genes or large inserts[15]; (3) The construction, manipulation and production of recombinant baculovirus are easy.

Considering the need for efficient expression of L-HDAg and the advantages of baculovirus/mammalian cell system, we constructed a recombinant baculovirus encoding histidine-tagged L-HDAg (L-HDAgH) for rapid and high level expression in transduced BHK cells. The high level expression and subsequent purification may allow us to obtain sufficient quantities of functional L-HDAgH for further evaluation of its immunological properties and its potential as a vaccine candidate. The success of this study supports the notion that the baculovirus/mammalian cell system can be a platform for efficient expression of eukaryotic proteins requiring post-translational modifications.

MATERIALS AND METHODS

Generation of recombinant baculoviruses

The transfer plasmid was generated using pFastBac™ DUAL (Invitrogen) as the backbone, which contained two multiple cloning sites (MCS). The gene encoding enhanced green fluorescent protein (EGFP), along with the upstream cytomegalovirus immediate-early (CMV-IE) promoter, was amplified by polymerase chain reaction (PCR) from pEGFP-C1 plasmid (Clontech) and inserted into MCS I under the polyhedrin promoter. The cDNA encoding L-HDAg was PCR-amplified from p2577-1L[16] and subcloned into pcDNA4/HisMax-TOPO (Invitrogen), thus a His_6 tag was fused at the N-terminus of L-HDAg under the control of CMV-IE promoter. The whole expression cassette was PCR-amplified again and subcloned into *Kpn* I site of MCS II. The resultant plasmid was designated pBac-GDH (Figure 1). Another plasmid, pBac-GD, was previously constructed to harbor the genes encoding L-HDAg and EGFP[13] (Figure 1). The recombinant baculoviruses were subsequently generated using the Bac-to-Bac® system (Invitrogen) and designated as Bac-GDH and Bac-GD. Another recombinant baculovirus co-expressing HBsAg and EGFP, Bac-GB, was constructed previously[13].

Cells and medium

BHK cells were cultured in Dulbecco's minimal essential medium (DMEM, Sigma) supplemented with 100 mL/L heat inactivated fetal bovine serum (FBS; Gibco), 2 mmol/L L-glutamine (Gibco) and non-essential amino acids (Gibco). The cells were maintained at 37 ℃ in a humidified incubator containing 5 % CO_2. Insect cell Sf-9 was maintained in TNM-FH medium (Sigma) supplemented with 10 mL/L FBS for baculovirus generation, amplification and titration according to standard protocols[17]. The viruses were not concentrated by ultracentrifugation. The titer of Bac-GDH was 8.3×10^8

plaque forming units per ml.

Baculovirus transduction

A simple process eliminating the need for virus ultracentrifugation[18] was adopted for transduction. Briefly, BHK cells cultured in 6-well plates (5×10^5 cells per well) were washed with PBS, and then transduced simply by adding 100 μL unconcentrated virus solution and 400 μL PBS. The plates (or dishes) were shaken on a rocking platform for 6 h at 25 ℃. After the virus incubation, the virus solution was aspirated. The wells were replenished with 2 mL complete medium with or without sodium butyrate and incubated at 37 ℃. The cells grown on 10-cm dishes were transduced similarly, except that larger volumes of virus (800 μL) and PBS (3.2 mL) were used.

Western blot analysis

BHK cells were singly transduced by Bac-GDH (or Bac-GD), or co-transduced by Bac-GDH and Bac-GB. To detect intracellular L-HDAgH (or L-HDAg), the cells were harvested at 2 dpt (days post-transduction) and resuspended in TE buffer containing phenylmethylsulfony lfluoride (PMSF). The proteins were released by sonication on ice and separated from debris by centrifugation. To detect secreted HBsAg and L-HDAgH, virus-like particles released into conditioned medium from co-transduced cells were concentrated by 200 g/L sucrose-cushioned ultracentrifugation as described previously[13]. The pellet was resuspended in TE buffer for Western blot. The intracellular or extracellular samples were resolved on 120 g/L gels and transferred onto nitrocellulose membranes. The L-HDAgH (or L-HDAg) was probed by human anti-HDV sera[19] or mouse anti-His_6 mAb (Amersham Biosciences). The HBsAg was probed by anti-HBsAg mAb (A10F1, a kind gift from Prof. S.C. Lee, National Taiwan University). The secondary antibodies were AP-conjugated goat anti-human or anti-mouse IgG (Kirkegaard and Perry Laboratories). The bands were developed using BCIP/NBT reagent (Sigma). The densitometry was performed by scanning the bands on the membranes and analyzing by Scion Image Shareware (Scion Corporation). For estimation of the product yield, serially diluted purified protein was used as the standard and analyzed by scanning densitometry.

Flow cytometry

The transduced cells were harvested by trypsin/EDTA, washed and resuspended in PBS for flow cytometry (FACSCalibur, Becton Dickinson) analysis according to the manufacturer's instruction. The percentage of cells emitting fluorescence (% GFP + cells) and mean fluorescence intensity (MFI) of each sample were measured 3 times by counting 10 000 cells in each measurement. The mean± standard deviation (SD) of 3 independent experiments are presented as arbitrary units (au).

Immunofluorescence labeling

BHK cells were seeded onto 22 mm×22 mm glass slides and transduced in duplicate by Bac-GDH at a multiplicity of infection of 280. The cells were fixed at 24 h post-transduction (hpt) with methanol/acetone (1:1) for 5 min at -20 ℃, rinsed with PBS and then blocked with PBS containing 20 g/L bovine serum albumin (BSA) for 30 min at 37 ℃. For the detection of subcellular localization, L-HDAgH was probed with 150 μL anti-HDAg mAb (HP6A1, 1:300 dilution)[16] for 1 h at 37 ℃ and washed with PBS 3×5 min. L-HDAgH was subsequently labeled using Cy3-conjugated goat anti-mouse IgG (1:25 dilution, Sigma). For simultaneous nuclear staining, SYBR green I (1: 40 000 dilution, BioWhittaker) was added together with the secondary antibody. For isoprenylation analysis, L-HDAgH was first probed with primary antibody solution containing HP6A1 and anti-farnesyl mAb (Sigma) for 1 h at 37 ℃, followed by the labeling with secondary antibody solution containing FITC-conjugated anti-mouse and TRITC-conjugated anti-rabbit mAb (Jackson ImmunoResearch) for 1 h at 37 ℃. The slides were washed with PBS 3×5 min, mounted using glycerol/PBS (3:1) mounting solution and observed by a confocal microscope (TCS SP2, Leica, Germany).

Protein purification

The His_6-tagged L-HDAg was purified by immobilized metal affinity chromatography (IMAC) under denaturing conditions. The cells were resuspended in 10 ml binding buffer A (20 mmol/L Tris-HCl, 500 mmol/L NaCl, 8 mol/L urea and 10 mL/L PMSF, pH 7.8), sonicated for 5 min and centrifuged (12000 r/min for 30 min). After centrifugation, the supernatant was loaded cyclically for 1 h at room temperature to the Fast-flow Protein Liquid Chromatography (ÄKTA FPLC, Amersham Biosciences) system in which the column contained 5 mL Ni^{2+}-coupled Chelating Sepharose Fast Flow resin. Bound proteins were eluted by a mixture of elution buffers A and B (20 mmol/L Tris-HCl, 500 mmol/L NaCl, 500 mmol/L imidazole, pH 7.8) at 1 mL/min at 4 ℃. The FPLC system generated step gradients by varying the volume ratios of buffers A and B so that the urea concentration decreased while the imidazole concentration increased stepwise. The eluate was collected in 1.5 mL fractions and then analyzed by Western blots and SDS-PAGE.

RESULTS

Confirmation of protein expression

The recombinant baculoviruses designed to express L-HDAg with or without His_6 tags were constructed and designated Bac-GDH and Bac-GD (Figure 1). To confirm the correct expression of L-HDAgH in BHK cells, the cells grown on 10-cm dishes were transduced by Bac-GD or Bac-GDH, harvested at 2 dpt and the cell lysates were analyzed by Western blot. Figure 2A depicts that the mock-transduced cells expressed no protein recognized by the anti-HDV serum, while the Bac-GD-transduced cells expressed a protein whose molecular mass (27 kd) corresponded to that of authentic L-HDAg, indicating the specificity of the serum. Similarly, the Bac-GDH-transduced cells expressed a protein recognized by the antibody, but with a slightly higher molecular mass (about 31 kd), thus suggesting the fusion of the His_6 tag to L-HDAg. The identities of the proteins were further

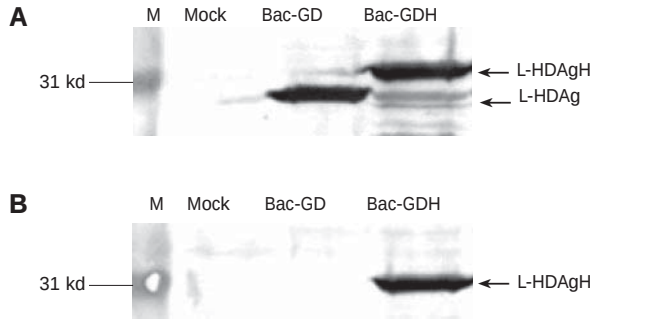

Figure 2 Western blot analysis of proteins expressed by mock-, Bac-GD- or Bac-GDH-transduced BHK cells. **A**: Anti-HDV sera; **B**: Anti-His$_6$ mAb.

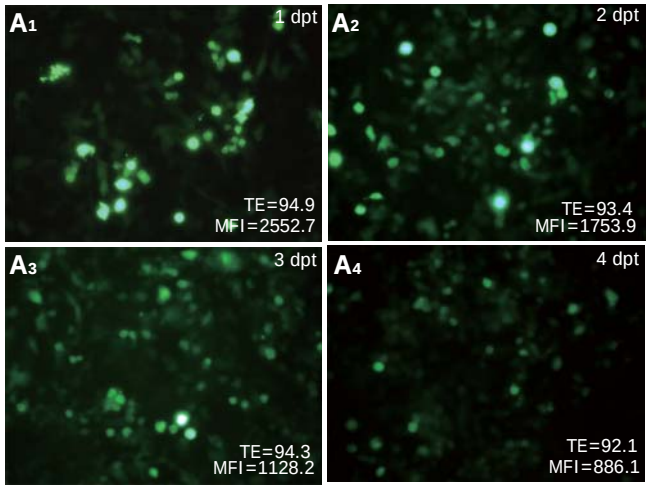

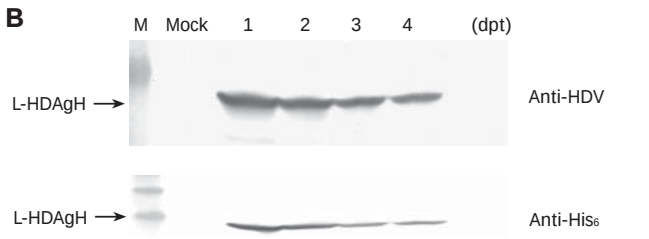

Figure 3 A: Variation of the transduction efficiency (TE) over time post-transduction. **B**: Time-course profile of L-HDAgH expression. Western blot using anti-HDV sera and anti-His6 mAb.

confirmed by analysis of the lysates using anti-His$_6$ mAb (Figure 2B). As expected, no His$_6$ tagged proteins were found in the mock- or Bac-GD-transduced cell lysates. In contrast, the 31 kd protein expressed by Bac-GDH was clearly visible. Figures 2A, B collectively confirme the expression of His$_6$ tagged L-HDAg in the BHK cells.

Transduction efficiency and time-course profile

To determine how efficiently the virus could transduce BHK cells and how the protein accumulation varied over time post-transduction, BHK cells were transduced and photographed using the fluorescence microscope. The percentages of GFP+ cells and the mean fluorescence intensities (MFI) were monitored over time by flow cytometry. As shown in Figure 3A, the percentage of GFP+ cells was up to 95 % at 1 dpt and remained higher than 90 % for 4 d, but the mean fluorescence intensities declined over time. Figure 3B shows the time-course profile of L-HDAgH expression and depicts that the expression reached the maximum rapidly at 1-2 dpt. The protein concentration declined slightly thereafter, but remained high at 4 dpt.

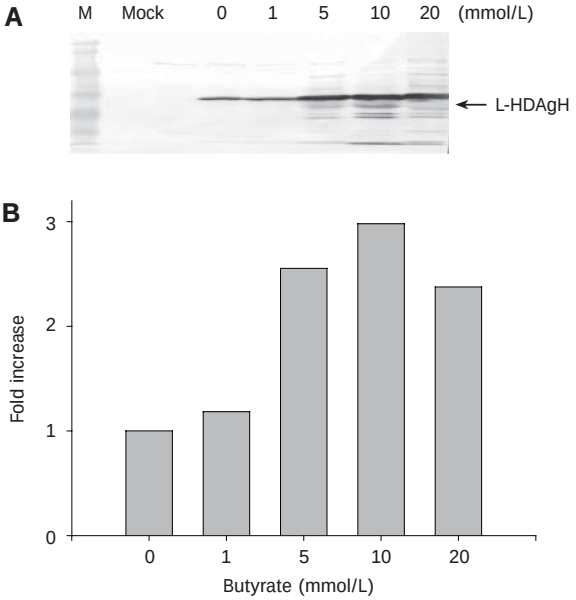

Figure 4 Effects of sodium butyrate on L-HDAgH expression. **A**. Western blot; **B**. The expression levels.

Enhancement of protein expression

To enhance the L-HDAgH expression, the cells were transduced on 10-cm dishes as described above, but varying concentrations of sodium butyrate, a histone deacetylase inhibitor shown to loosen the condensed chromosome and up-regulate the protein expression in mammalian cell system[20, 21], were supplemented to the medium after transduction. The cells were harvested at 2 dpt and the lysates were analyzed by Western blot. Figure 4A depicts a clear dependence of the L-HDAgH expression on the sodium butyrate concentrations. The scanning densitometry quantitatively revealed an about 3-fold enhancement in L-HDAgH expression by 10 mmol/L sodium butyrate, compared to the control without sodium butyrate (Figure 4B). The highest protein yield was roughly estimated to be about 19 pg/cell by scanning densitometry using serially diluted purified protein as the standard. At a higher concentration (i.e. 20 mmoL/L), the overall L-HDAgH expression dropped slightly probably due to high cytotoxicity associated with sodium butyrate[22].

Characterization of L-HDAgH

To determine whether baculovirus transduction and protein overexpression affected the cell physiology and deterred the correct protein localization, BHK cells were transduced by Bac-GDH, labeled by SYBR Green I and anti-HDAg mAb and examined by confocal microscopy. As shown, the nuclei were clearly marked by SYBR Green I (Figure 5A) while L-HDAgH was marked by clusters of

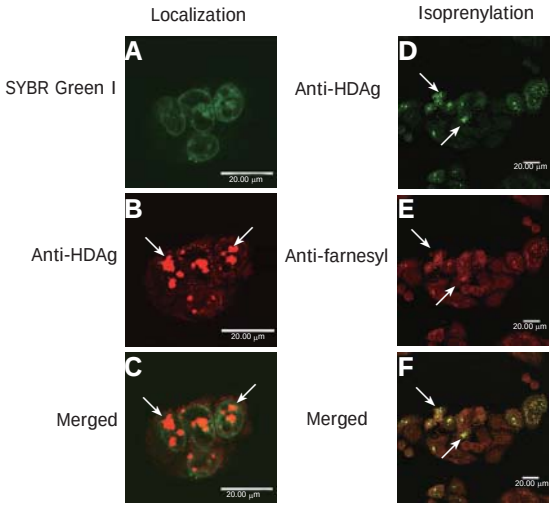

Figure 5 Subcellular localization and isoprenylation of L-HDAgH by immunofluorescence labeling. **A**: the presence of nuclei labeled by SYBR green I; **B**: L-HDAg detected using Cy3-conjugated goat anti-mouse IgG; **C**: merged photograph of A and B; **D**: the presence of L-HDAgH labeled by FITC-conjugated mAb; **E**: The presence of isoprenylation marked by TRITC-conjugated mAb; **F**: merged photograph of D and E. red dots (Figure 5B). The merged photograph (Figure 5C) clearly illustrates the co-localization of L-HDAgH with the nuclei, confirming that the expressed L-HDAgH was localized within the nuclei.

To evaluate whether L-HDAgH was properly isoprenylated, Bac-GDH-transduced BHK cells were subject to immunofluorescence double labeling using anti-HDAg and anti-farnesyl mAb. Figure 5D shows the green dots marking the presence of L-HDAgH using anti-HDAg mAb, while Figure 5E illustrates the detection of isoprenylation using anti-farnesyl mAb as evidenced by the red dots. The merged photograph (Figure 5F) clearly illustrates the co-localization of both red and green dots, indicating that the baculovirus-expressed L-HDAgH was isoprenylated.

Since the assembly of HDV virions or virus-like particles (VLP) is an important function of L-HDAg, whether L-HDAgH remained capable of assembling into VLP was investigated. It has been shown that L-HDAg along with HBsAg was necessary and sufficient for the assembly of HDV VLP[13], thus BHK cells were co-transduced by Bac-GB and Bac-GDH. The conditioned medium was collected, concentrated and analyzed by Western blot. Figure 6 shows that the pellet contained proteins recognized by anti-HBsAg, anti-HDAg and anti-His$_6$ antibodies, confirming the simultaneous secretion of both HBsAg and L-HDAgH into the medium. Because L-HDAgH alone was localized within the nucleus, the co-secretion proved the assembly and secretion of HDV VLP[23-25].

Purification of L-HDAgH

Thanks to the fused His$_6$ tag, L-HDAgH was purified by IMAC. Under the native conditions, however, the protein binding to the resin was very weak (not shown). Therefore, the protein was denatured by 8 mol/L urea and purified under denaturing conditions. The Western blot (upper panel, Figure 7) shows that the flow through contained no L-HDAgH, indicating significantly improved binding. The proteins were then eluted with a mixture of buffers A and B with decreasing urea concentration and increasing imidazole concentration. The L-HDAgH was eluted by 200 mmol/L imidazole buffer (4.8 mmol/L urea). The purity was 7 % as revealed by SDS-PAGE (lower panel, Figure 7).

DISCUSSION

As mentioned above, L-HDAg may represent an excellent vaccine candidate, but characterization and evaluation of the immunological properties of L-HDAg have been impeded due to the lack of a proper method for efficient expression and purification. Although attempts to express L-HDAg using *E coli* or baculovirus/insect cell systems have been made, both systems are not suited for L-HDAg expression because the former lacks post-translational modification while the latter results in rapid degradation of L-HDAg after 2 d post-infection[26]. Besides, L-HDAg expressed in insect cells induces cell cycle arrest[27]. The integration of L-HDAg gene into the chromosome of mammalian cells for stable expression may offer another option, but has not been reported probably because L-HDAg is a nuclear protein, the accumulation of which can result in significant cytotoxicity. Transient expression in mammalian cells mediated by other virus systems (e.g. vaccinia virus) may be possible as well, but these viruses lead to cell death and lysis, thus potentially undermining the post-translational modification at later stage. Owing to these restrictions, L-HDAg expression is mainly achieved by transfecting plasmids expressing L-HDAg into hepatoma cells (e.g. Huh-7 and HepG2). The plasmid transfection into hepatocytes, however, is notorious for

its low efficiency and low expression level, consequently, highly sensitive detection methods such as isotopic labeling and chemiluminescence enhancement are required to detect the expression.

To express functional L-HDAg efficiently and rapidly for research purposes, the baculovirus/mammalian cell system was employed. Using PBS as the surrounding solution, the efficiency of baculovirus-mediated gene delivery into BHK cells was up to 94 % (Figure 3A), which far exceeded 20 %-30 % normally achieved by plasmid transfection. The detection of L-HDAgH using anti-HDV sera and anti-His_6 mAb (Figure 2) confirmed that the expressed L-HDAgH possessed the fused His_6 tag and was similar in size and antigenic properties to those of authentic proteins. The expression level was apparently higher than that can be obtained using plasmid transfection, as evidenced by the easy detection using BCIP/NBT as the color developing reagent, which was significantly less sensitive than chemiluminescence enhancement. Under the transcriptional control of CMV-IE promoter, the L-HDAgH expression peaked at day 1-2 and gradually declined thereafter, which probably stemmed from cell proliferation and attenuation of promoter activity. Albeit this, the expression level could be up-regulated by sodium butyrate and reached the maximum (at about 19 pg/cell) at 10 mmol/L sodium butyrate (Figure 4A).

Besides the high transduction efficiency and high expression level, Figures 5A-C illustrate that L-HDAgH formed speckles localized within the nuclei of BHK cells, which is the subcellular location of authentic L-HDAg[28]. The formation of nuclear speckles is a sign of isoprenylation[29] and could have stemmed from 1) the formation of dimmers or multimers of L-HDAg between the coiled-coiled domains or 2) the interaction of L-HDAg with host proteins such as nucleolin and delta-interacting protein A[30]. The formation of aggregates has been previously observed for L-HDAg expressed in hepatoma cell lines via plasmid transfection[28], and explains the low binding of L-HDAgH to Ni^{2+}-coupled resin under native conditions and the low purity in subsequent purification steps. Further improvement in the purification process is required and is currently underway. Furthermore, Figures 5D-5F revealed that L-HDAgH underwent proper isoprenylation, which is a prerequisite for the interaction of L-HDAg with HBsAg (and hence the virion formation). The Western blot analysis of concentrated pellets (Figure 6) further confirmed the assembly and secretion of HDV VLP. The retention of isoprenylation as well as formation of VLP implied that the biological function of L-HDAgH was not impaired by the His_6 tag[31, 32].

In summary, our data solidly confirm that the overexpression of His_6 tagged L-HDAgH in baculovirus-transduced mammalian cells does not hamper the proper localization and processing. The data also suggest the maintenance of accurate structure and appropriate biological functions and hence validate the use of baculovirus/mammalian cell system for the production of eukaryotic proteins requiring extensive post-translational modifications. This is partly attributed to the fact that baculovirus does not cause cell lysis or induce cytotoxicity. Additionally, the baculovirus system enables protein production in BHK cells which is one of the few cell lines approved for biopharmaceutical production. Moreover, the transduction protocol eliminates the need for virus concentration by ultracentrifugation so that transduction can be carried out in the bioreactor simply by incubating the virus solution/PBS with the cells, which otherwise is difficult for plasmid transfection. Since process scale-up of BHK culture has been well established, large scale production of L-HDAg can be made possible simply by transferring this process to a bioreactor (e.g. a packed bed bioreactor).

Abstract

AIM: To investigate the severity of acute pancreatitis (AP) is associated to the intensity of leukocyte activation, inflammatory up-regulation and microcirculatory disruption associated to ischemia-reperfusion injury. Microvascular integrity and inhibition of pro-inflammatory mediators are key-factors in the evolution of AP. Relaxin is an insulin-like hormone that has been attributed vasorelaxant properties via the nitric oxide pathway while behaving as a glucocorticoid receptor agonist.

METHODS: AP was induced by the bilio-pancreatic duct-outlet-exclusion closed-duodenal-loops model. Treatment with relaxin was done at different time-points. Nitric oxide synthase inhibition by L-NAME and glucocorticoid receptor (GR) blockage by mifepristone was considered. AP severity was assessed by biochemical and histopathological analyses.

RESULTS: Treatment with relaxin reduced serum amylase, lipase, C-reactive protein, IL-6, IL-10, hsp72, LDH and 8-isoprostane as well as pancreatic and lung myeloperoxidase. Acinar and fat necrosis, hemorrhage and neutrophil infiltrate were also decreased. ATP depletion and ADP/ATP ratio were reduced while caspases 2-3-8 and 9 activities were increased. L-NAME and mifepristone decreased the efficiency of relaxin.

CONCLUSION: Relaxin resulted beneficial in the treatment of AP combining the properties of a GR agonist while preserving the microcirculation and favoring apoptosis over necrosis.

Key words: Acute pancreatitis; Relaxin; Nitric oxide; Glucocorticoid receptor; Necrosis; Apoptosis

INTRODUCTION

Acute pancreatitis (AP) is an acute inflammatory disorder associated with premature activation and increase in pancreatic enzymes in blood and urine that may progress to implicate other organs such as kidney, lungs and liver[1]. Inflammatory mediators induce complications that can range from local to systemic evolving to a severe form with high morbi-mortality[2].

The peri-vaterian duodenum (PV-D) has an extremely rich autonomic duodenum-pancreatic innervation therefore endoscopic maneuvers, gallstones, biliary sludge and/or hemobilia migrating and impacting on the peri-vaterian duodenum stimulate primary sensory neurons to unchain autonomous-arc-reflexes (AARs) responsible for the initial acute pancreatic neurogenic inflammation that may range from local and edematous to regional and necrotizing pancreatitis[3-6]. These autonomic nerve fibers are the starting point of autonomic-arc-reflexes which may integrate in the celiac ganglia complex or in the bulbar-hypothalamic autonomous nucleus to end in the intrapancreatic ganglion[6]. Therefore irritative stimuli induce impulses that travel through thin, unmyelinated, capsaicin-sensitive (type C) nerve fibers to generate in the somata of the afferent neurons vasoactive peptides such as substance P, neurokinin-A, VIP, SOM and DYN[7]. These sensory peptides synthesized in the somata are then transported to the nerve peripheral endings where they are released. Substance P and other sensory peptides can activate mast-cells that will liberate histamine and pro-inflammatory factors thus recruiting leukocytes that will exacerbate the inflammatory response associated to vasodialtation, edema, increased vascular permeability and neutrophil infiltration associated to this neuroimmune-

inflammatory interaction observed in the neurogenic inflammation[7].

Over-stimulation of receptors in the peri-vaterian duodenum trigger autonomic-arc-reflexes that induce a sympathetic hypertone followed by cathecolaminic discharges from nerve endings in the pancreas that affect capillaries and blood vessels leading to microcirculatory disturbances responsible for ischemia/ reperfusion injury associated to synthesis and release of pro-inflammatory factors together with leukocyte recruitment and activation that correlate with intracellular enzyme activation[7]. Under these circumstances the systemic inflammatory response syndrome (SIRS) may end in a multiorgan dysfunction syndrome (MODS) characterized by metabolic and homodynamic alterations, multifocal organic dysfunction and pluriparenchymatose failure[8]. The bilio-pancreatic-duct outlet exclusion closed duodenal loops (BPDOE-CDLs) model, that we have previously described and validated, mimics these circumstances[6].

Relaxin is a peptide hormone of ovarian origin that belongs to the insulin superfamily[9]. It has been reported that relaxin offers protection for reperfusion-induced cardiac injury increasing coronary blood flow favoring blood supply to the ischemic myocardium while it exerts a relaxant action on smooth muscle cells[10]. It has been shown that relaxin up regulates nitric oxide synthase (NOS) II expression thus inducing nitric oxide mediated vasodilatation by a controlled activation of endogenous nitric oxide biosynthesis[11]. By regulating nitric oxide relaxin inhibits neutrophil extravasation, adhesion, recruitment and activation[12]; decreases the expression of chemokines and adhesion molecules[13]; inhibits histamine release by mast cells[14]; depresses platelet aggregation[15]; alters Ik-B phosphorylation and degradation diminishing NF-kB activation and binding to DNA and enhances the activation of the glucocorticoid receptor (GR)[16]. Therefore, via the nitric oxide pathway relaxin exerts vaso-relaxant, anti-thrombotic and anti-inflammatory properties.

Relaxin has also been shown to bind and stimulate the glucocorticoid receptor that when activated will translocate to the nucleus where it inhibits NF-kB and AP-1 by transrepression and stimulates transcription of glucocorticoid response elements (GREs) of DNA inducing transcription of responsive genes by transcativation[16] . As an agonist of the glucocorticoid receptor relaxin will then possess anti-inflammatory properties inhibiting pro-inflammatory molecules.

Our aim was to investigate the influence of relaxin on the evolution of acute pancreatitis considering the relevance of the nitric oxide pathway and glucocorticoid receptor stimulation. Pancreatic, metabolic, kidney, liver and severity indicators were assessed.

MATERIALS AND METHODS

General concepts

The Bilio-pancreatic-duct-outlet-exclusion closed-duodenal-loops model (BPDOE-CDL) model was carried out in male inbred adult Wistar rats, weighing 250 - 350 g, free of pathogens, under controlled environmental conditions (room-temperature, 20-25 ℃; 12:12 light-dark cycle), with free access to standard rodent chow and water. The study was performed in accordance with national guidelines for the use and care of laboratory animals and was approved by the local animal care and use committee. Rats were randomly assigned to one of the three series: basal, control or experimental. Each of these series was divided into groups of 16 rats.

The animal series comprised eleven groups. *Group 1* (reference baseline values), consisted of un-fasted, healthy animals that did not undergo any surgery or treatment. *Group 2* (surgery control), only underwent the surgical maneuvers involved in triggering AP. *Group 3* (AP, BPDOE-CDLs model) acute pancreatitis was triggered by filling the closed-duodenal-loops at constant pressure with 8% sodium taurocholate [SIGMA, USA] and 200 uL of methylene blue to corroborate duodenal-reflux absence[6]. *Group 4* (PBS vehicle control and BPDOE-CDLs) acute pancreatitis was induced as for Group 3 and 100 uL PBS were injected sc 1h before and 4 h after the surgery. *Group 5* (LN+RLX, non-selective NOS inhibitor and relaxin) L-NAME (N^G-nitro-L-arginine methyl ester [SIGMA, USA]) at 10 mg/kg and 5 mg/kg and relaxin [Phoenix Pharmaceuticals Inc, USA] at 2.5ug/kg were administered sc 1h before and 4h after triggering acute pancreatitis. *Group 6* (MIF+RLX, GC receptor antagonist and relaxin) received mifepristone [SIGMA, USA] at 3 mg/kg and relaxin at 2.5 ug/kg sc 1h before and 4h after unchaining acute pancreatitis. *Group 7* (LN+MIF+RLX, non-selective NOS inhibitor associated to GC receptor antagonist and relaxin) L-NAME at 10 mg/kg and 5 mg/kg, mifepristone at 3 mg/kg and relaxin at 2.5ug/kg were administered sc 1h before and 4h after triggering acute pancreatitis. *Group 8* (RLX 1h pre BPDOE-CDLs) received 5ug/kg sc of relaxin 1h before the surgical maneuvers. *Group 9* (RLX 1h post BPDOE-CDLs) was injected with 5 ug/kg sc of relaxin 1h after the procedure. *Group 10* (RLX 1h pre and 4h post BPDOE-CDLs) was administered Relaxin at 2.5 ug/kg sc 1h before and 4h after unchaining acute pancreatitis. *Group 11* (RLX 4h post BPDOE-CDLs) was treated with 5 ug/kg sc of relaxin 4h after triggering acute pancreatitis. L-NAME and mifepristone were dissolved in saline solution, relaxin was dissolved in PBS. *Group 12* (RLX 12h &1h pre and 4h post BPDOE-CDLs) received relaxin at 5 ug/kg sc 12 h before the surgery and 2.5 ug/kg sc 1h prior to the procedure and a second administration 4h after it.

Experimental procedures

Bilio-pancreatic-duct-outlet-exclusion closed-duodenal-loops model (BPDOE-CDLs) We described the BPDOE-CDLs model in detail Figure 1, (reproduced with permission granted by the Journal of Pancreatology and S. Karger AG, Basel)[6]. The normally fed animals were anesthetized with sodium pentothal (5 mg/100 g) (Thiopental, Abbott, USA). A median laparotomy was done to exteriorize the antrum-duodenum-pancreas, and a double-tube double-hole intra-duodenal catheter was inserted, through which saline solution (3 mL) was instilled. Two closed-duodenal-loops were prepared: first two proximal pre-pyloric ligatures and one post-pyloric just above the common-bilio-pancreatic duct outlet

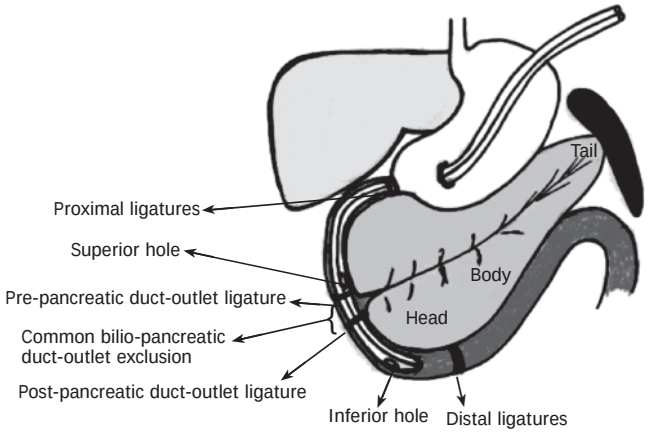

Figure 1 BPDOE-CDL model to trigger acute pancreatitis. Two closed-duodenal-loops were created in such a way that the entrance of the common bilio-pancreatic duct-outlet was absolutely excluded. To double check the absence of duodenal-reflux content or duodenal leakage, methylene blue was added to the sodium tauracholate which was instilled into the peri-vaterian duodenum through the superior and inferior holes (reproduced with permission granted by the Journal of Pancreatology and S. Karger AG, Basel)[6].

were placed. For the second loop, a ligature was placed just below the common-bilio-pancreatic-duct and two more ligatures were placed at the distal end of the peri-vaterian duodenum, thus excluding the common-bilio-pancreatic-duct outlet. Each closed-duodenal-loop was filled with 8% sodium taurocholate (1 mL) and 200 uL of methylene blue at constant pressure, following a 45-minute observation period. The closed-duodenal-loop content was aspirated, the ligatures removed and the laparotomy closed. The animal was then placed in an individual cage with microenvironmental temperature control and allowed to recover. After 12 h, the rat was exsanguinated under anesthesia by aortic puncture and a blood sample was obtained for biochemical tests. All procedures were done with aseptic techniques. If, despite exclusion of the common-bilio-pancreatic-duct, duodenal-content filtered through the ligatures and refluxed towards the bilio-pancreatic ductal tree, as evidenced from blue coloring of the pancreas, the rat was excluded from the study.

Macroscopic examination, dissection and weighing with a precision scale (Microgram-Series BH 300) of the pancreas were performed. The gland was subsequently divided into cephalic and splenic segments[6,17,18].

The liver, duodenum, kidneys, suprarenal glands, spleen and lungs were examined and dissected. Each organ was divided into smaller portions, one was fixed in formol-buffer and stained with hematoxylin-eosin, the others were wrapped individually in aluminum foil and preserved at -70 ℃. The cephalic and splenic segments of the pancreas and the lungs were studied in more detail.

Amylase and lipase activity measurement and protein quantification in pancreatic tissue Assays were done on each segment; the tissue was homogenized on ice in 2 mL of extraction buffer (20 mmol/L Tris-HCL pH 7.6-[Sigma, USA], 0.3 mol/L NaCl-[Merck, Germany], 0.5% Triton X-100-[Sigma, USA]; distilled water). Proteins were quantified in the homogenate according to the method described by Lowry[19]. The homogenate was centrifuged at 10000 r/min for 15 min at 4 ℃. The supernatant was assayed for amylase (kinetic method at 405 nm with defined substrate at 25 ℃-[Wiener, Arg.]) and lipase (turbidimetric method UV color at 25 ℃-[Randox, UK]).

Myeloperoxidase (MPO) activity in pancreas and lung tissue MPO, an enzyme found in neutrophils that represents the 5% of its dry weight, catalyzes the oxidation of electron donors (eg.halides) by hydrogen peroxide[20]. MPO was measured in both pancreatic segments and in lung tissue as a biochemical indicator of neutrophil infiltrate. To determine MPO activity the tissue was homogenized on ice with 1 mL hexadecyltrim ethylammonium bromide (HTAB) (0.5 % HTAB in 50 mmol/L phosphate buffer-pH 6.0). The homogenate was sonicated during 10 s at 200 W, and then centrifuged at 40000 r/min for 15 min at 4 ℃. MPO was assayed on the supernatant: 0.1 mL of the sample was combined with 2.9 mL of 5 mmol/L phosphate buffer, (pH 6.0, 0.167 mg/mL o-dianisidine hydrochloride and 0.0005% hydrogen peroxide). The change in absorbance at 460 nm was measured with a Clinicon 4010 spectrophotometer. One unit of MPO (UMPO) activity was defined as the amount that could degrade 1 μmol of peroxide per minute at 25 [21].

Caspase 2-3-8 and 9 activities in pancreas, liver and lung tissue Caspases 2-3-8 and 9 are early indicators of apoptosis in mammalian cells[22]. The CasPASE™ apoptosis activity assay kit [Genotech, MO-USA] is based on detecting the chromogenic and fluorogenic resulting molecule 7-amino-4-trifluromethyl cumarin (AFC) cleaved from the synthetic substrate, Z-VAD-fluoromethyl ketone (FMK) irreversibly and selectively inhibits the reaction. The excitation and emission wavelengths of AFC in a fluorometer are 360 nm and 510 nm respectively. Frozen tissues were homogenized at 4 ℃ in chilled lysis buffer and the lysates were then centrifuged at 15000 g for 30 min at 4 ℃, caspase activity was assessed on the supernatants. To calculate specific enzyme activity equal aliquots of supernatant were tested in presence of the Z-VAD-FMK inhibitor. Results were expressed as the specific cleavage of AFC per mg of protein per minute considering the nonspecific product formation coming from the substrate plus the inhibitor. All reagents were supplied by the kit and the assays were performed according to the manufacturer's instructions.

ATP and ADP/ATP ratio measurements in pancreas, liver and lung tissue ATP depletion allows to detect apoptosis, and when it is associated with the percentage of ATP loss and changes in the ADP/ATP ratio apoptosis can then be conveniently differentiated from necrosis[23]. Light formed from ATP and luciferin in the presence of luciferase can be measured at 560 nm. The tissue was homogenized in TCA (trichloroacetic acid) 6% for 1 min and centrifuged at 6000 g for 5 min at 4 ℃. The TCA in the supernatant was neutralized and diluted to a final concentration of 0.1% with Tris-Acetate pH 7.75 buffer. ATP concentration expressed as nmol/L per mg of protein and ADP/ATP concentration ratio were measured in the supernatant using the ENLITEN® ATP Assay System Bioluminescence Detection Kit [Promega, WI-USA] and ApoSENSOR™ ADP/ATP ratio assay kit (Alexis-Corp, Switzerland) respectively according to the manufacturer's instructions.

Extraction-purification-quantification of DNA The total mass of DNA in the pancreas, and lung tissue was used to standardize the units of enzymatic activity since it did not show significant quantitative variations in the BPDOE-CDL model.

The DNA was extracted and purified from tissue from both pancreatic segments and lung according to the manufacturer's instructions (Wizard Genomic- [Promega, USA]). Double stranded DNA concentration was measured at 260 nm.

Histologic evaluation Pancreatic tissue was graded on a scale of 0-4 each for: edema, hemorrhage, leukocyte infiltration, acinar necrosis and fat necrosis. Lung tissue was graded using a scale of 0-4 for leukocyte infiltration. Histologic changes were graded in a blinded manner by two independent observers counting frequency of foci per field seen at 40X (absent = 0, mild = 1, moderate = 2, severe = 3, overwhelming = 4).

Biochemical assays in blood samples *Loss of blood and hemoconcentration* were evaluated by the hematocrite. The *metabolic profile* consisted of glucose (enzymatic method in serum at 37 ℃-[Wiener, Arg.]), uric acid (enzymatic method in serum at 37 ℃-[Wiener, Arg]), proteins (enzymatic method in serum at 37 ℃-[Wiener, Arg.]) and calcium (direct colorimetric method in serum at 20 ℃-[Wiener, Arg.]). The *kidney profile* comprised urea (enzymatic method in serum at 37 ℃-[Wiener, Arg.]) and creatinine (end-point colorimetric method in serum at 37 ℃-[Wiener, Arg]). The *pancreatic profile* involved amylase (kinetic method at 405 nm with defined substrate in serum at 37 ℃-[Wiener, Arg.]) and lipase (UV turbidimetric method in serum at 37 ℃-[Randox, UK]). The *liver profile* consisted of AST and ALT (IFCC optimized UV method in serum at 37 ℃-[Wiener, Arg.]), bilirubin (colorimetric method to determine total and direct bilirubin in serum at 25 ℃, indirect bilirubin that results from the difference between them-[Wiener, Arg.]) and alkaline phosphatase (optimized DGKC-SSCC kinetic method at 405 nm in serum at 37 ℃-ALP 405-[Wiener, Arg.]) *Cellular injury* was assessed by LDH (DGKC optimized kinetic method in serum at 37 ℃-[Wiener, Arg.]). The *profile for cellular stress and inflammatory response associated to severity* involved leukocyte count, quantitative C reactive protein (immunoturbidimetric method in serum at 37 ℃ -PCR Latex Turbitest-[Wiener, Arg.]), heat shock protein (hsp) 72 (ELISA method for rat HSP 72 in plasma and serum-[StressGen Biotechnologies, USA)], IL-6 and IL-10 (ELISA technique in serum-[Assay Designs,USA]) and 8-Isoprostane (EIA method in plasma-[Cayman, USA]).

Statistical analysis

Biochemical assays in blood and organs The ANOVA test was used to establish differences between groups. The Dunnet test compared the difference between each group in relationship to group 1 (reference baseline level in control animals). The Student-Newman-Keuls test carried out after the ANOVA compared the groups between them and in relationship to group 1, evaluating the existence of homogeneous groups. Results are expressed as mean ± standard deviation (SD). Differences were considered statistically significant with $P < 0.05$.

Histopathological score The ANOVA test with two fixed factors (group and place: cephalic and splenic) was followed by the Dunnet test and Student-Newman-Keuls test. Results are expressed as mean ± SD. Differences were considered statistically significant with $P < 0.05$.

Correlation between MPO and leukocyte infiltrate In both pancreatic segments and in lung tissue, the Spearman correlation coefficient Rho was calculated to examine the correlation between MPO and leukocyte infiltrate[24].

RESULTS

Biochemical assays in blood and other tissues together with histopathological studies evaluated the influence of relaxin on the evolution of acute pancreatitis. Association with L-NAME and/or mifepristone pondered on the weight of the nitric oxide pathway and glucocorticoid receptor stimulation involvement in acute pancreatitis modulation by relaxin. These results are described in Tables 1-4.

Pancreatic and general biochemical assays in blood

To evaluate if relaxin helped to maintain pancreatic, metabolic, kidney and liver function after the initiation of acute pancreatitis, pancreatic and general biochemical assays in blood were performed (Table 1).

Cholestasis was absent in all groups. Uric acid, alkaline phosphatase, total - direct and indirect bilirubin showed no significant differences among the mean values for all groups, the rest of the assays did.

Amylase and lipase showed a significant increase for homogenous groups (3-4) that developed a severe acute pancreatitis, group 7 also exhibited a marked raise although not to the same extent and the values of the enzymes for homogenous groups (5-6) were slightly lower than for group 7. Relaxin treatment 12& 1h before and 4h after BPDOE-CDLs (group 12) was similar to the one corresponding to 1h pre and 4h post pancreatic maneuvers (group 10). These treatments resulted in the least increase in pancreatic enzymes. These same trend was observed for glucose, urea, creatinine, AST and ALT. The abnormal reduction profile in calcium and serum proteins presented the same course as the pathological augmentation observed for pancreatic enzymes. The hematocrite value, considering group 2 as the reference group due to blood loss during surgery, indicated that homogenous groups (10-12), developing mild acute pancreatitis did not manifest the hemoconcentration observed for homogenous groups (3-4).

2- Severity indicators in blood

We next wanted to assess if the severity of acute pancreatitis was ameliorated by relaxin treatment measuring blood parameters (Table 2 & Figure 2A). The raise in leukocyte count correlated ($R = 803$, $P < 0.05$) with the expression of inflammatory IL-6 and liver synthesized acute phase protein CRP. The significant increase observed for homogenous groups (3-4) was followed in order by that developed in group 7 and then by homogenous groups (5-6); these values were markedly diminished for homogenous groups (10-12). Inhibition of either the nitric oxide pathway or glucocorticoid receptor stimulation

In relationship to Reference Basal-Group 1, BPDOE-CDLs AP-Group 3 presents a significant difference in all the assays evaluated $P<0.05$. The pancreatic and general biochemical profile significantly improved with relaxin treatment particularly for Groups 10 &12 that corresponded to administration times 12h and/or 1h pre and 4h post surgery $P<0.05$. Homogenous groups for amylase and lipase:1-2-(12-10)-8-9-11-(5-6-7)-(3-4), $P<0.05$. HTO: hematocrite, Rlx: relaxin, LN: L-NAME, MIF: mifepristone.

Severe AP was developed in groups 3 & 4. This severity was ameliorated by treatment with relaxin. In relationship to reference basal-group 1, BPDOE-CDLs AP in group 3 presented a significant difference in all the assays evaluated while treated groups 10 & 12 were the ones to exhibit the best prognosis with a significant improvement for all markers $P<0.05$.Homogenous groups for severity indicators :1-2-(12-10)-8-9-11-(5-6-7)-(3-4), $P<0.05$. Rlx: relaxin, LN: L-NAME, MIF: mifepristone.

reduced the efficiency of relaxin treatment; inhibiting simultaneously both of them although leading to a more severe manifestation of the disease still showed better prognosis than that observed for homogenous groups (3-4) suggesting that there may be another mechanism by which relaxin may be also acting. Treatment with a single dose of relaxin 1h before, 1h after or 4h after unchaining acute pancreatitis although still beneficial was not as effective. Pro-inflammatory IL-6 and anti-inflammatory IL-10 exhibited the same profile as a consequence of the induction of the inflammatory response and attempt to counter-act it. Lipid peroxidation leading to elevated 8-isoprostane and synthesis of hsp72 aiming to protect from ongoing cellular stress followed the same trend.

Assays in pancreatic and lung tissue

We then wanted to investigate the enzymatic and inflammatory pancreatic and lung response (Table 3).

There were no significant differences between the mean value of the groups for DNA of the lung and the same pancreatic segment, but the mean values for the cephalic and splenic segments for each group were significantly different (data shown previously[6]).

The decrease in pancreatic amylase and lipase was inverse to their increase in blood. Pancreatic proteins showed a similar expression profile to that of pancreatic enzymes, the elevation for group 2 may result from the synthesis of acute phase pancreatic proteins.

Pancreatic and lung MPO activity reflecting neutrophil

Pancreatic amylase and lipase decreased significantly in severe AP group 3, $P<0.05$. Treatment with relaxin induced a significant improvement with an increase in pancreatic enzymes and proteins $P<0.05$, while there was a decrease in UMPO. This amelioration of the disease was even more remarkable for groups 10 & 12 indicating that treatment 12 and/or 1h pre and 4h post BPDOE-CDLs procedure had a protective role. The increase in pancreatic wet weight in groups with severe AP as a result of edema was significant $P<0.01$. Homogenous groups for pancreatic amylase-lipase and MPO: :1-2-(12-10)-8-9-11-(5-6-7)-(3-4), $P<0.05$; lung MPO: :1-2-(12-10)-8-9-11-(5-6-7)-(3-4), $P<0.05$. Rlx: relaxin, LN: L-NAME, MIF: mifepristone.

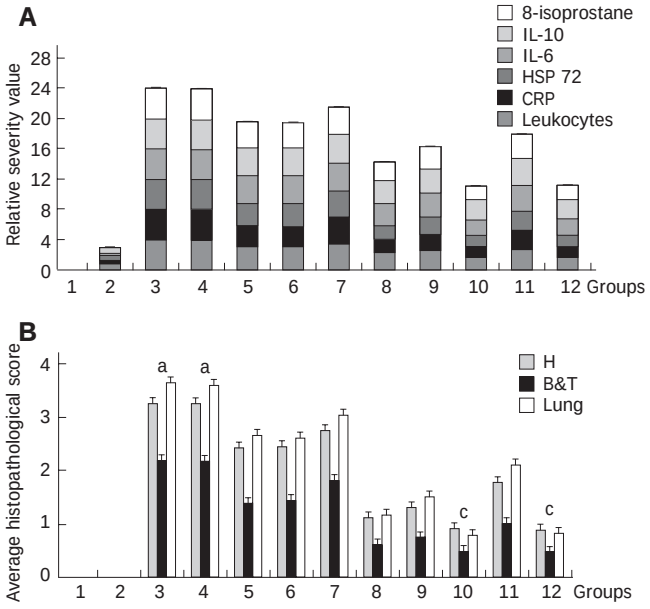

Figure 2 Relative severity value in blood and average histopathological score. **A**: Relative severity value in blood. To visualize the severity degree based on biochemical assays in blood, we arbitrarily established a single "relative severity value" of zero to group 1 (reference baseline value) and of four to group 3 (AP) per assay. To calculate the single "relative severity value" for the rest of the groups we used the following formula: "relative severity value" = [(X – reference baseline value) / (AP value – reference baseline value)] x 4. Introducing each mean value from table 2 (referred to in the above formula as X) we obtained six different single "relative severity values" for each group, whose contribution to the total "relative severity value" is shown in this graph. For those values in table 2 that were below the detection limit, the value assigned to X corresponded to that of the assay's sensitivity (IL-6: 112 pg/mL; IL-10: 12 pg/mL). Homogenous Groups are 1-2-(12-10)-8-9-11-(5-6-7)-(3-4), $P<0.05$. Results are shown as mean ± SD. **B**: Average histopathological score. To visualize the severity degree based on the score-associated to histopathological lesions, we averaged the means of the six parameters used in table 4 for each group. Homogenous groups are 1-2-(12-10)-8-9-11-(5-6-7)-(3-4), $P<0.05$. There was a significant increase in the assessed parameters for Groups 3&4 that developed severe AP $^{a}P<0.03$ while groups 10& 12 exhibited a significant improvement $^{c}P<0.05$ Results shown as mean ± SD.

infiltrate, was significantly higher for homogenous groups (3-4) while homogenous Groups (10-12) that had been treated with relaxin before and after triggering acute pancreatitis presented lesser UMPO values. The Spearman Correlation Coefficient between MPO activity and leukocyte infiltrate was significant for the pancreatic cephalic segment ($R=0.943$, $P<0.01$); for the pancreatic splenic segment ($R=0.831$, $P<0.001$); and for the lung ($R=0.871$, $P<0.01$).

The increase in pancreatic wet weight due to edema was more significant for homogenous groups (5-6)-7-(3-4) than for homogenous groups (10-12).

Histopathological scores in pancreas and lung tissue

Homogenous groups (10-12) that developed a mild acute pancreatitis exhibited edema as the main histopathological feature and a lower value for pancreatic and lung leukocyte infiltrate that correlated with MPO activity. Homogenous groups (5-6)-7-(3-4) were characterized by high scores for leukocyte infiltrate that correlated with MPO activity, pancreatic hemorrhage as well as acinar and fat necrosis. Necrotic foci presented a spotted pattern with higher frequency in the cephalic segment. group 11 that received relaxin 4h after triggering acute pancreatitis were characterized by hemorrhage. The average of pancreatic histopathological scores presented a significant lower value for homogenous groups (10-12) when comparing them to the average values obtained for homogenous groups (5-6)-7-(3-4). These results are described in Table 4 and Figure 2B.

General AP histopathology Groups with severe AP presented parenchymal necrosis with neutrophil infiltrate, fat necrosis, congestive blood vessels in peri-pancreatic fat, and intense hemorrhage. The duodenum exhibited lysis in the mucosa, subserosal blood vessel congestion and severe neutrophil infiltrate but there was no evidence of possible leakage towards the cephalic segment. These groups exhibited alterations in the liver, lung, kidneys, spleen and suprarenal glands. The liver showed necrosis, hemorrhage, blood vessel congestion, neutrophil infiltrate and steatosis.

Groups 3&4 that developed severe AP presented as main features leukocyte infiltrate, hemorrhage and acinar and fat necrosis and the histopathological scores were higher. Groups 10 & 12 that received relaxin 12 and/or 1h pre and 4h post surgery developed a mild AP and exhibited the lowest scores being the main feature edema. Homogenous groups for pancreatic edema, hemorrhage, acinar and fat necrosis and pancreatic and lung leukocyte infiltrate: :1-2-(12-10)-8-9-11-(5-6-7)-(3-4), $P<0.05$. Rlx: relaxin, LN: L-NAME, MIF: mifepristone.

The lungs were highly compromised exhibiting congestion of big blood vessels and alveolar capillaries with neutrophil infiltrate; the bronchial wall had reactive lymphoid hyperplasia and aspirative hemorrhage. The main features observed in the kidneys were congestion of cortical and medullar blood vessels and glomerular capillaries jointly with tubular and medullar acute necrosis. Suprarenal glands were characterized by edema and partial lipid loss while the spleen presented edema.

Caspases activity (2-3-8-9)

We next examined if treatment of pancreatic injury was associated to the activation of caspases 2-3-8-9 in the pancreas as primary site of injury and in the lung and the liver as relevant affected distant organs. Homogenous groups (10-12) that developed a mild acute pancreatitis manifested a greater activation of caspases 2-3-8-9 suggesting that the activity of both the initiator caspase 8 and the executor caspase 3 together with caspases 9 and 2 involved in the apoptosome or intrinsic pathways are stimulated by relaxin treatment suggesting that apoptosis is more significant in these groups than in homogenous groups (5-6)-7-(3-4) that developed a severe necrotizing acute pancreatitis (Figure 3).

Death due to apoptosis or necrosis

The next step was to elucidate whether relaxin treatment favored death by apoptosis over necrosis. Blood lactate dehydrogenase (LDH) is a marker of cellular injury and death. The raise in blood LDH due to acute pancreatitis was ameliorated in homogenous groups (10-12) (Figure 4A). To evaluate if the undergoing death process in the pancreas as primary site of injury and in the lung and the liver as relevant affected distant organs corresponded to apoptosis or necrosis we measured ATP concentration (Figure 4B) and then calculated the % of loss of ATP (Figure 4C) given the fact that the death process involves ATP consumption being an 85% or more ATP depletion associated to necrosis. Also the ADP/ATP ratio (Figure 4D) helped to differentiate between these two death mechanisms as a higher increase is indicative of necrosis while a lower one points towards apoptosis.

ATP depletion for homogenous groups (5-6)-7-(3-4) associated to a higher % of ATP loss and ADP/ATP ratio correlated ($R=0.842$; $P<0.05$) with the higher frequency observed in necrotic foci and severity indicators for these groups together with the elevated LDH value suggesting that for groups undergoing severe acute pancreatitis necrosis was the main form of cell death.

Homogenous Groups (10-12) that manifested a mild acute pancreatitis evidenced lesser ATP depletion with a % of ATP loss lower than 40% together with a lower ADP/ATP ratio. These results correlated with lower values for LDH ($R=0.798$, $P<0.05$) while edema was the principal histopathological feature. This suggested that for these groups apoptosis was the main form of cell death resulting in a more controlled process with less pro-inflammatory stimulation ameliorating the aggressiveness of the pathology.

Increased degree of severity

For each variable with significant differences between the groups' mean values, the relationship of these results were compared to the reference baseline level established in group 1. We then integrated this information to rank the groups in order of "increased degree of severity" (Table 5) showing that the severe acute pancreatitis developed by homogenous groups (3-4) was significantly ameliorated for homogenous groups (10-12).

DISCUSSION

According to the severity degree exhibited by acute pancreatitis will be the complexity of the pathology involving other organs apart from the pancreas that will lead to metabolic, liver, kidney and lung alterations

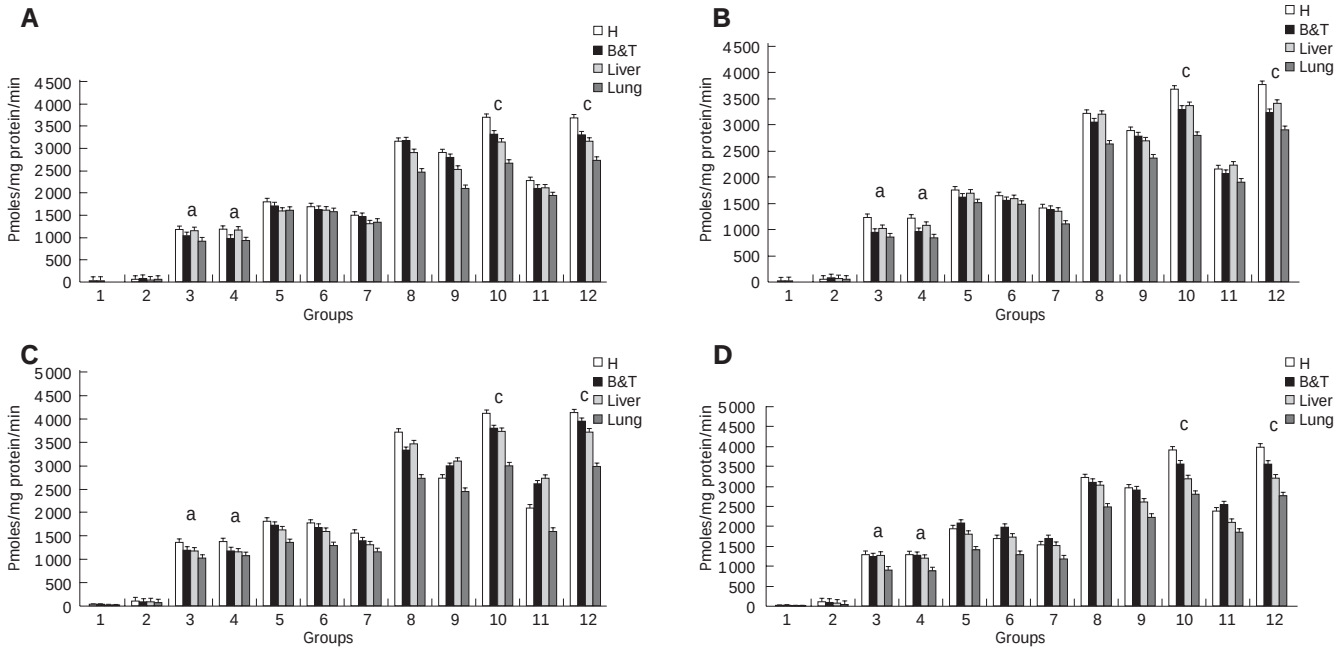

Figure 3 Caspase Activities. **A**: *Caspase 2 activity* was measured to evaluate the upstream activation of the intrinsic apoptotic pathway. Groups 10&12 presented a significant activation $^{c}P<0.05$ which was reduced for groups 3&4 $^{a}P<0.05$. Homogenous groups for caspase 2 activity are: 1-2-(12-10)-8-9-11-(5-6-7)-(3-4), $P<0.05$. H: pancreatic head, B&T: pancreatic body and tail. **B**: *Caspase 3 Activity* was measured to evaluate the activation of the executor caspase 3. Groups 10&12 presented a significant activation $^{c}P<0.05$ which was reduced for groups 3&4 $^{a}P<0.05$. Homogenous groups for caspase 2 activity are: 1-2-(12-10)-8-9-11-(5-6-7)-(3-4), $P<0.05$. H: pancreatic head, B&T: pancreatic body and tail. **C**: *Caspase 8 Activity* was measured to evaluate the activation of the initiator caspase 8. groups 10&12 presented a significant activation $^{c}P<0.05$ which was reduced for groups 3&4 $^{a}P<0.05$. Homogenous groups for caspase 8 activity are: 1-2-(12-10)-8-9-11-(5-6-7)-(3-4), $P<0.05$. H: pancreatic head, B&T: pancreatic body and tail. Results shown as mean±SD. **D**: *Caspase 9 Activity* was measured to evaluate the activation of the intrinsic pathway .Groups 10&12 presented a significant activation $^{c}P<0.05$ which was reduced for groups 3&4 $^{a}P<0.05$. Homogenous groups for caspase 9 activity are: 1-2-(12-10)-8-9-11-(5-6-7)-(3-4), $P<0.05$. H: pancreatic head, B&T: pancreatic body and tail. Results are shown as mean±SD.

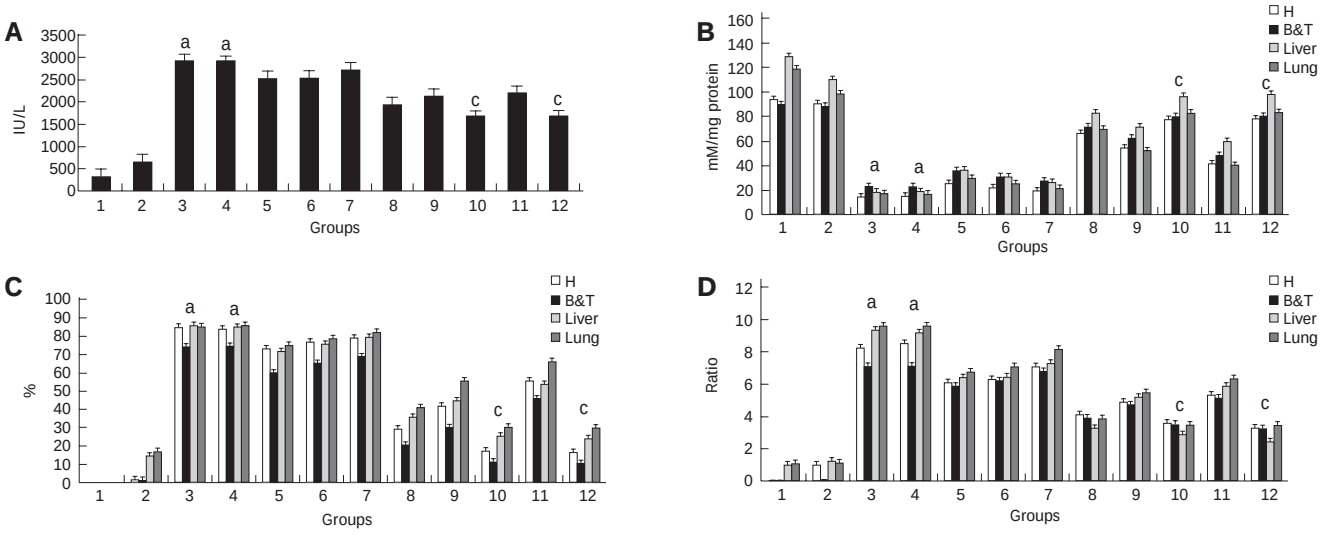

Figure 4 Apoptosis versus necrosis. **A**: Blood lactate dehydrogenase. As a marker of cellular injury and death significant high blood levels of LDH for groups 3&4 $^{a}P<0.005$ reflected the undergoing severe AP while groups 10&12 presented a significant reduction in the enzyme value $^{c}P<0.005$. Homogenous. Groups for LDH are:1-2-(12-10)-8-9-11-(5-6-7)-(3-4), $P<0.005$. **B**-**D**: ATP concentration. The significant decrease in ATP concentration that surpassed the 80% loss for groups 3&4 $^{a}P<0.005$,is the hallmark of the necrotic process that is being developed while groups 10&12 that underwent apoptosis did not manifest such extreme values $^{c}P<0.005$. This expression in the nucleotide levels is translated into the ADP/ATP ratio that is significantly increased $^{a}P<0.01$ for groups 3&4 that underwent necrosis while groups 10&12 that underwent apoptosis had significantly lower values $^{c}P<0.05$. Homogenous Groups are: 1-2-(12-10)-8-9-11-(5-6-7)-(3-4), $P<0.005$. Results are shown as mean±SD.

reflected in the histopathology and numerous biochemical parameters that require to be assessed in order to arrive to a proper classification of the disease.

It has been reported that relaxin can stimulate the nitric oxide pathway or the glucocorticoid receptor[7,14]. In our work we have evaluated the combined vasorelaxing and anti-inflammatory properties of relaxin on the evolution of acute pancreatitis, our results show that relaxin plays a highly beneficial role when administered within the first hour of the initiation of the noxa being this even more pronounced when the drug was given 1h pre and 4h post triggering acute pancreatitis, this would be particularly relevant for the prevention of post-ERCP pancreatitis providing basis for future studies where combined drug

Table 5 Order of groups according to the increase in the severity degree

GROUP NR.	GROUP DESCRIPTION
1	Basal Reference Control
2	Surgery Control
12	Relaxin administered 12h & 1h pre- BPDOE-CDLs and 4h post-BPDOE-CDLs
10	Relaxin administered 1h pre- BPDOE-CDLs and 4h post-BPDOE-CDLs
8	Relaxin administered 1h pre-BPDOE-CDLs
9	Relaxin administeres 1h post-BPDOE-CDLs
11	Relaxin administered 4h post-BPDOE-CDLs
5	Relaxin and L-NAME administered 1h pre- BPDOE-CDLs and 4h post-BPDOE-CDLs
6	Relaxin and Mifepristone administered 1h pre- BPDOE-CDLs and 4h post-BPDOE-CDLs
7	Relaxin, L-NAME & Mifepristone administered 1h pre- BPDOE-CDLs and 4h post-BPDOE-CDLs
3	BPDOE-CDLs AP model
4	Vehicle (PBS) control

The BPDOE-CDLs model induces a severe AP (group 3).Prophylactic treatment with relaxin, as shown for groups10&12, markedly reduces the severity of the pathology, being still useful although in a lesser degree even after AP was triggered.

treatments can be considered. When relaxin was received 4h after unchaining acute pancreatitis although still beneficial the efficiency of the treatment was reduced the reason probably being that additional supplemental therapies are required at this stage in order to restore the already altered hemodynamic and metabolic balance. The positive effect exerted by relaxin was significantly diminished by L-NAME and by mifepristone indicating that the nitric oxide pathway and glucocorticoid receptor stimulation are involved. The association of both inhibitors produced an even stronger reduction in the effect induced by relaxin however this group still presented less severe results than those observed for non-treated acute pancreatitis suggesting that there may be other pathways implicated.

While *apoptosis* is a programmed and controlled mechanism of cell death that is associated to reduced inflammation, *necrosis*, caused by irreparable cell injury causing membrane alterations that favor the release of enzymes that are responsible for degrading cellular structures and thus activating the inflammatory response[25]. Pancreatic hemorrhage and necrosis characterize severe acute pancreatitis being the consequence of dysfunctional tissue irrigation due to an initial hypoxia leading to an ischemia-reperfusion process due to alternative vasoconstriction followed by vasodilatation. These microcirculatory disturbances are linked to neutrophil activation and inflammation together with cellular stress that will convert cell death by apoptosis to necrosis, downregulating these factors by preserving pancreatic microvascular blood flow to ensure adequate tissue oxygenation and inhibiting pro-inflammatory mediators reduces the risk of necrotizing pancreatitis by favoring cell death by apoptosis over necrosis.

The fact that the severity of acute pancreatitis is inversely related to the degree of apoptosis suggests that this type of cell death may be a beneficial response to acinar cell injury particularly in acute pancreatitis. Clearly, the degree of inflammation and, therefore, the severity of pancreatitis are less in situations associated with acinar cell apoptosis than under conditions associated with acinar cell necrosis. The group of Steer[25] emphasizes then the notion that medications or other interventions that favor the development of apoptosis may minimize the severity of pancreatitis, and they could, therefore be of substantial clinical value. Together with Jones and Gores[26] they remark the concept that pharmacological induction of pancreatic apoptosis during the early stages of acute pancreatitis provides a relevant therapeutic strategy for the treatment of this disease.

The high density of neurons embedded in the pancreatic cephalic segment associated to the intimate relation between the peri-vaterian duodenum and the pancreas linked by the gastroduodenal plexus[27-29] emphasizes the relevance of the rich population of receptors in the peri-vaterian duodenum that when activated by irritative stimuli such as endoscopic maneuvers will unchain duodenopancreatic and duodenogastric autonomic-arc-reflexes. The BPDOE-CDLs model mimics this situation in which severe acute pancreatitis results from a sympathetic neurogenic overstimlaution that causes adrenergic hyper-reactivity responsible for the initial vasoconstriction and the subsequent ischemia/reperfusion injury. We propose that relaxin would, in first instance, counteract vasoconstriction arising from sympathetic-adrenergic stimulation by inducing vasodilatation through the nitric oxide pathway and exert anti-inflammatory properties by glucocorticoid receptor stimulation while favoring apoptosis over necrosis.

Severe acute pancreatitis induced by the BPDOE-CDLs model manifested kidney failure translated by the significant increase in urea and creatinine in blood associated to acute tubular necrosis; metabolic and liver alterations. The raise in severity factors indicating an intense inflammatory response defined by the increase in CRP and leukocyte count that correlated with neutrophil infiltrate in pancreatic and lung tissue associated to high activity values for MPO in these tissues suggested a SIRS in which the activation of neutrophils converted cellular death by apoptosis to necrosis as suggested by the high necrosis score in pancreatic tissue and the elevation of blood LDH describing organ injury. For this group caspases 2-3-8 and 9 activities were significantly reduced when comparing them to treated homogenous groups

(10-12). The dramatic depletion in ATP concentration, correlated with a loss of ATP that surpassed the 80 % thus inhibiting the initiation of the apoptotic pathway, and the increase in ADP/ATP ratio would be indicating a strong necrotic mechanism associated to a pro-inflammatory process as corroborated by the histopathology.

Groups that were treated with relaxin showed an improvement in blood metabolic parameters with reduced values for leukocyte count and CRP together with lower leukocyte infiltrate and MPO activity in pancreatic and lung tissue pointing to a milder inflammatory response. The increase in the activity of caspases 2-3-8 and 9 manifesting that both the intrinsic and the effector apoptotic pathways are activated is associated to a less drastic depletion of ATP that would not interfere with apoptosis and thus exhibit a reduced inflammatory reaction. Treatment with relaxin 4h after unchaining acute pancreatitis was beneficial however the best results were observed when relaxin was given within the first hour being optimal when administered 1h before and 4h after triggering acute pancreatitis as quite probably in this circumstance it could preserve microcirculation ensuring tissue oxygenation while inhibiting the expression of pro-inflammatory mediators associated with pro-apoptotic molecules, situation that is kept-up by the second dose, these results are relevant for the prevention of post-ERCP acute pancreatitis. There was no significant difference between homogenous groups 10 and 12 implying that starting treatment 12h or 1h prior to triggering acute pancreatitis exerts the same effect.

To evaluate the pathways involved in treatment with relaxin we associated the administration of relaxin 1h pre and 4h post BPDOE-CDLs procedure with L-NAME (NOS inhibitor) and/or mifepristone (glucocorticoid recptor antagonist). The inhibition of either the nitric oxide pathway or glucocorticoid receptor stimulation significantly reduced the positive effects described previously for homogenous groups (10-12). Surprisingly for group 7 when we associated both inhibitors the severity that was developed although greater than for homogenous groups (6-7) was still less than that displayed by homogenous groups (3-4) suggesting that there is another pathway involved in the treatment with relaxin.

We therefore conclude that relaxin plays a beneficial role in the evolution of acute pancreatitis triggered by the BPDOE-CDLs model as it induces an anti-inflammatory response via glucocorticoid receptor stimulation while favoring apoptosis over necrosis; simultaneously it helps to preserve pancreatic microcirculation by the nitric oxide pathway ensuring an appropriate blood flow and tissue oxygenation thus avoiding ischemia and the consequent ischemia/reperfusion injury while it reduces the expression and activation of pro-inflammatory factors and decreases neutrophil infiltration of the pancreas.

Abstract

AIM: To investigate the biological effects of cis-hydroxyproline (CHP) on the rat pancreatic carcinoma cell line DSL6A, and to examine the underlying molecular mechanisms.

METHODS: The effect of CHP on DSL6A cell proliferation was assessed by using BrdU incorporation. The expression of focal adhesion kinase (FAK) was characterized by Western blotting and immunofluorescence. Induction of endoplasmic reticulum (ER) stress was investigated by using RT-PCR and Western blotting for the glucose-related protein-78 (GRP78) and growth arrest and DNA inducible gene (GADD153). Cell viability was determined through measuring the metabolic activity based on the reduction potential of DSL6A cells. Apoptosis was analyzed by detection of caspase-3 activation and cleavage of poly(ADP-ribose) polymerase (PARP) as well as DNA laddering.

RESULTS: In addition to inhibition of proliferation, incubation with CHP induced proteolytic cleavage of FAK and a delocalisation of the enzyme from focal adhesions, followed by a loss of cell adherence. Simultaneously, we could show an increased expression of GRP78 and GADD153, indicating a CHP-mediated activation of the ER stress cascade in the DSL6A cell line. Prolonged incubation of DSL6A cells with CHP finally resulted in apoptotic cell death. Beside L-proline, the inhibition of intracellular proteolysis by addition of a broad spectrum protease inhibitor could abolish the effects of CHP on cellular functions and the molecular processes. In contrast, impeding the activity of apoptosis-executing caspases had no influence on CHP-mediated cell damage.

CONCLUSION: Our data suggest that the initiation of ER stress machinery by CHP leads to an activation of intracellular proteolytic processes, including caspase-independent FAK degradation, resulting in damaging pancreatic carcinoma cells.

INTRODUCTION

The prognosis of pancreatic carcinoma is uniformly fatal. Conventional cytostatic treatments for inoperable pancreatic cancer make little impact on the median survival. Therefore, the development of novel therapeutic concepts that activate proliferation-independent cell death are needed[1]. Cell damage by targeting protein biosynthesis may be a promising strategy for cancer therapy[2,3]. Previous studies have shown that cis-4-hydroxy-L-proline (CHP) as an analogue of L-proline inhibits the collagen synthesis and its extracellular deposition[4,5]. Furthermore, there are reports describing inhibitory effects of CHP on proliferation, adhesion, and migration of various cell types like fibroblasts, epithelial cells and tumor cells[5-8]. These data pointed to additional and/or other proteins whose synthesis might be affected by incorporation of the incorrect amino acid leading to disturbances of cellular mechanisms.

Based on the CHP-induced inhibition of cell adhesion, we hypothesized that the focal adhesion kinase (FAK) may be involved in the CHP-induced signal transduction. FAK is a 125 ku non-receptor tyrosin kinase that mediates different cellular responses to adhesion after clustering of transmembrane integrins at contact sites between the cell and the extracellular matrix (ECM) termed focal adhesions[9]. Frisch *et al*[10] have shown that constitutively activated FAK conferred protection against anoikis of epithelial cells. Consequently, the inhibition

of FAK resulted in apoptosis of fibroblasts as well as in detachment and cell death of human breast tumor cells, suggesting a pivotal role of FAK in the transmission of anti-apoptotic signals[11,12].

The incorporation of amino acid analogues into newly synthesized proteins has been shown to interfere with the correct protein folding leading to an accumulation of misfolded proteins in the endoplasmic reticulum (ER)[13]. The ER has emerged as an organelle that is exquisitely sensitive to alterations in homeostasis that initiates a diversity of molecular defence mechanisms referred to as 'ER stress'[14]. The complex ER stress response to a variety of different stimuli results eventually in adaptation for survival or induction of apoptosis[14]. Mechanisms activated upon accumulation of unfolded protein in the ER should ensure that only properly folded proteins abandon the ER lumen[15]. This quality control system includes the unfolded protein response (UPR) which is characterized by an up-regulation of chaperons, such as the glucose-regulated protein-78 (GRP)78, as well as by an induction of transcription factors like the pro-apoptotic growth arrest and DNA gene product (GADD)153[16].

The aim of this study was to characterize the biological effects of CHP on the rat pancreatic tumor cell line DSL6A. Addressing the question of the underlying molecular mechanisms, we investigated the participation of ER stress and FAK in the CHP effect on cell proliferation, adhesion, survival and apoptosis.

MATERIALS AND METHODS

Reagents

Dulbecco's minimal essential medium (DMEM) and fetal calf serum (FCS) were purchased from Biochrom (Berlin, Germany). Iscove's modified Dulbecco medium (IMDM) was purchased from PAA Laboratories (Cölbe, Germany). Nonessential amino acids, penicillin, streptomycin, trypsin, and all reagents for reverse transcription [Superscript RT, oligo(dT)$_{12-18}$, dNTP] were purchased from Invitrogen (Karlsruhe, Germany). Cis-4-hydroxy-L-proline were from Riemser Arzneimittel AG (Greifswald, Germany). Colorimetric 5-bromo-2'-deoxyuridine (BrdU)-labelling cell proliferation ELISA and apoptotic DNA ladder kit were obtained from Roche (Mannheim, Germany). CellTiter AQ$_{ueous}$ kit from Promega (Mannheim, Germany), RNeasy Mini RNA extraction kit and Taq polymerase from Qiagen (Hilden, Germany) were used. Primers for PCR were generated by using NCBI GenBank as the source for any sequences and were synthesized by BioTez (Berlin, Germany). Mouse monoclonal anti-FAK$^{(N354-534)}$ was purchased from Transduction, mouse anti-GRP78 from BD Biosciences, anti-β-actin from Sigma (Taufkirchen, Germany), anti-cleaved caspase-3 from anti-poly-(ADP ribose) polymerase (PARP), anti-cyclinD1 from Santa Cruz. Secondary horseradish peroxidase-labelled anti-mouse or anti-rabbit Ig antibodies, nitrocellulose membranes, ECL plus kit and hyperfilm ECL were purchased from Amersham (Freiburg, Germany). Alexa Fluor® 488 goat anti-mouse IgG was purchased from MoBiTec (Göttingen, Germany). Caspase-3 inhibitor Z-DEVD-FMK, general caspase inhibitor Z-VAD-FMK and the protease arrest reagent were purchased from Calbiochem (Schwalbach, Germany).

Cell culture

The rat pancreas carcinoma cell line DSL6A was cultured in DMEM supplemented with 100 mL/L FCS, 100 U/mL penicillin and 100 μg/mL streptomycin or in IMDM containing non-essential amino acids in addition to 100 mL/L FCS and antibiotics.

In contrast to IMDM, DMEM did not contain L-proline. To prevent cell adhesion, culture plates were coated with 20 g/L agarose as previously described[17].

Cell proliferation and cell survival

Cell proliferation was assessed using the colorimetric 5-bromo-2´-deoxyuridine (BrdU) DNA incorporation assay. Cells suspended in DMEM supplemented with 100 mL/L FCS were seeded into 96-well plates ($1x10^4$ cells/well). After becoming adherent, the cells were treated for 24 h and 48 h with different CHP concentrations dissolved in serum-free DMEM. BrdU labelling was performed during a further 20-h incubation. The BrdU incorporation was quantified using the ELISA kit according to the manufacturer's instructions[18].

For the detection of alive cells, the metabolic activity was measured by a colorimetric method based on the conversion of the tetrazolium salt MTS into formazan using the CellTiter AQ$_{ueous}$ kit according to the manufacturer's instructions. Cell cultivation and incubation was performed as described for BrdU labelling.

Apoptosis

Apoptosis was detected by the cleaved caspase-3 as well as the degradation of poly(ADP-ribose) polymerase (PARP) using the immunoblot technique. To show DNA laddering, cells were seeded into 12-well plates. Adherent cells were cultured in serum-free DMEM for 24 h and 48 h with or without 10 mmol/L CHP. At the end of the incubation, cells were harvested and DNA was extracted using the apoptotic DNA-Ladder kit according to the manufacturer' s instructions. Isolated DNA was electrophoretically separated on 15 g/L agarose gel containing ethidium bromide. The ethidium bromide fluorescence was visualised using an electronic camera.

RT-PCR

Total RNA was isolated using the RNeasy extraction kit. Three microgram of total RNA was reversed transcribed into cDNA as previously described[19]. Quantification of mRNA expression was preformed by using competitive PCR for the housekeeping gene β-actin and co-amplification with a defined concentration of a synthetic DNA fragment as internal standard[19]. On this basis, various cDNA samples were adjusted to equal input concentrations and electrophoretically separated on 18 g/L agarose gel containing ethidium bromide. Visualisation and measurement of resulting bands were performed with an electronic camera analysing the data with the EASY program (Herolab, Wiesloch, Germany). The primers for RT-PCR were as follows: for GRP78, GACATTTGCCCCAGAAGAAA (sense) and

ATGACCCGCTGATCAAAGTC (antisense), product size 375 bp; for GADD153, AGCTGAGTCTCTGCCTTTCG (sense) and TGTGGTCTC TACCTCCCTGG (antisense), product size 456 bp[20].

Western blot analysis

Cells were seeded into 60-mm dishes and grown to confluence. Protein extracts of DSL6A cells were prepared as previously described[18]. Proteins were electrophoretically separated on an 80 g/L SDS-polyacrylamide gel and blotted onto nitrocellulose membrane. Blots were incubated with the respective primary antibody for 2 h at room temperature. For visualization of the antibody binding, filters were exposed to a horseradish peroxidase (POD)-labelled anti-rabbit or anti-mouse Ig antibody and developed using the ECL Plus kit. The following primary antibody dilutions were used: FAK 1:1000, GRP78 1:500, cleaved caspase-3 1:500, PARP 1:1000, β-actin 1:1000. For re-probing with additional antibodies, membranes were stripped of bound antibodies by treatment with stripping buffer containing 62.5 mmol/L Tris (pH 6.7), 2 g/L SDS, 7 mL/L 2-mercaptoethanol for 30 min at 50 ℃.

Immunofluorescence

Cells were cultivated on glass cover slips as previously described[18]. For immunofluorescence staining, cells were fixed with ice-cold methanol, followed by incubation with a mouse monoclonal antibody (mAB) detecting FAK. Binding of the specific mAB was determined by Alexa Fluor anti-mouse IgG and visualized using the Confocal LASER scanning microscope (Leica TCS SP2 AOBS).

Statistical analysis

Results were expressed as mean ± SE. Data were analyzed using Wilcoxon's rank sum test. $P < 0.05$ was considered statistically significant.

RESULTS

CHP-induced morphological appearance of DSL6A cells

The incubation with 10 mmol/L CHP induced rounding up of adherently growing DSL6A cells resulting after 24 h in a complete detachment (Figure 1B). The CHP antagonist L-proline circumvented this CHP-induced loss of adherence (Figure 1C). Moreover, cells which had been rounded up through CHP treatment, spread out again after L-proline addition, forming finally a normal monolayer (Figure 1D).

Effects of CHP on cell proliferation and viability

Figure 2A shows the influence of CHP on the S phase of the cell cycle as measured by BrdU incorporation into the DNA of DSL6A cells. We observed CHP significantly inhibited the proliferation in a time- and dose-dependent manner. The determination of metabolically active DSL6A cells (Figure 2B) revealed a discrepancy between the efficiency of CHP in regard to cell proliferation and viability. While the BrdU incorporation after treatment with 10 mmol/L CHP for 24 h averaged only 20% of the controls (Figure 2A), cell viability was more than 50% (Figure 2B). The results obtained by BrdU incorporation

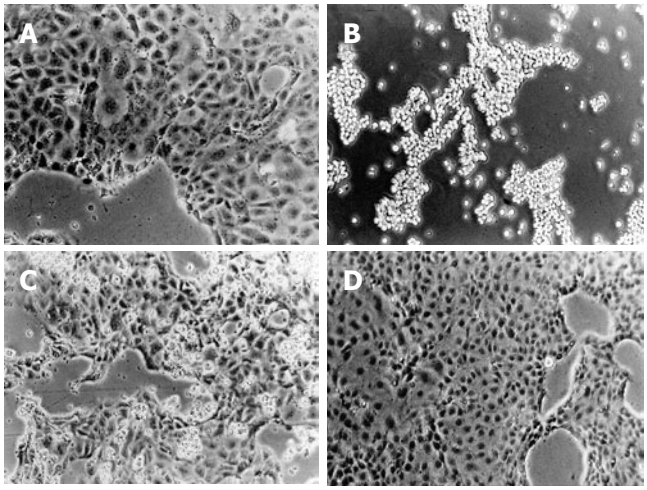

Figure 1 Effect of CHP on morphological appearance of DSL6A cell (Phase contrast microscopy, original magnification x200). A: Adherently growing controls; B: Incubation with 10 mmol/L CHP for 24 h caused rounding, followed by detachment of DSL cells; C: Addition of 20 mmol/L L-proline abolished the effects of CHP; D: CHP-treated cells cultured for further 48 h with 20 mmol/L L-proline, resulting in the re-adherence of the cells.

have been reflected on the molecular level analysing cyclin D1, a molecule substantially involved in the cell cycle progression[21]. As shown by immunoblotting, CHP triggered a decline of the cyclin D1 protein (Figure 2C). The CHP-caused growth inhibition could be prevented through addition of L-proline, indicating a competitive replacement of CHP by the correct amino acid (Figures 2A and 2B).

To examine whether the impaired cell functions could be restored, L-proline was added to the CHP-containing culture medium 24 h after beginning of the incubation with CHP. Cells were allowed to grow for further 24 h, followed by the measurement of BrdU incorporation. As shown in Figure 2D, the addition of L-proline induced a re-increase in BrdU incorporation.

In order to exclude the possibility that the restoring of proliferation was due to residual intact cells, we measured the BrdU uptake of cells remaining in the culture plates after removal of cells detached by CHP treatment. The BrdU incorporation was not significantly higher than immediately after CHP incubation (data not shown). These results suggested that CHP-induced DSL6A cell detachment is a reversible process.

Influence of CHP on FAK

The strong inhibition of cell adherence by CHP pointed to an involvement of the focal adhesion kinase (FAK) in the CHP-mediated molecular mechanisms[10]. Analysis of FAK using the Western blot technique revealed the expected 125 ku protein (Figure 3A). Treatment of the cells with CHP caused a time-dependent decline of the FAK signal and a simultaneous appearance of fragments of about 80 ku, suggesting a proteolytic degradation of the FAK molecule leading to a complete fragmentation during 48 h (Figure 3A).

Based on the hypothesis that CHP brought about FAK inactivation by proteolytic cleavage of the enzyme, we tested the influence of a broad spectrum protease inhibi-

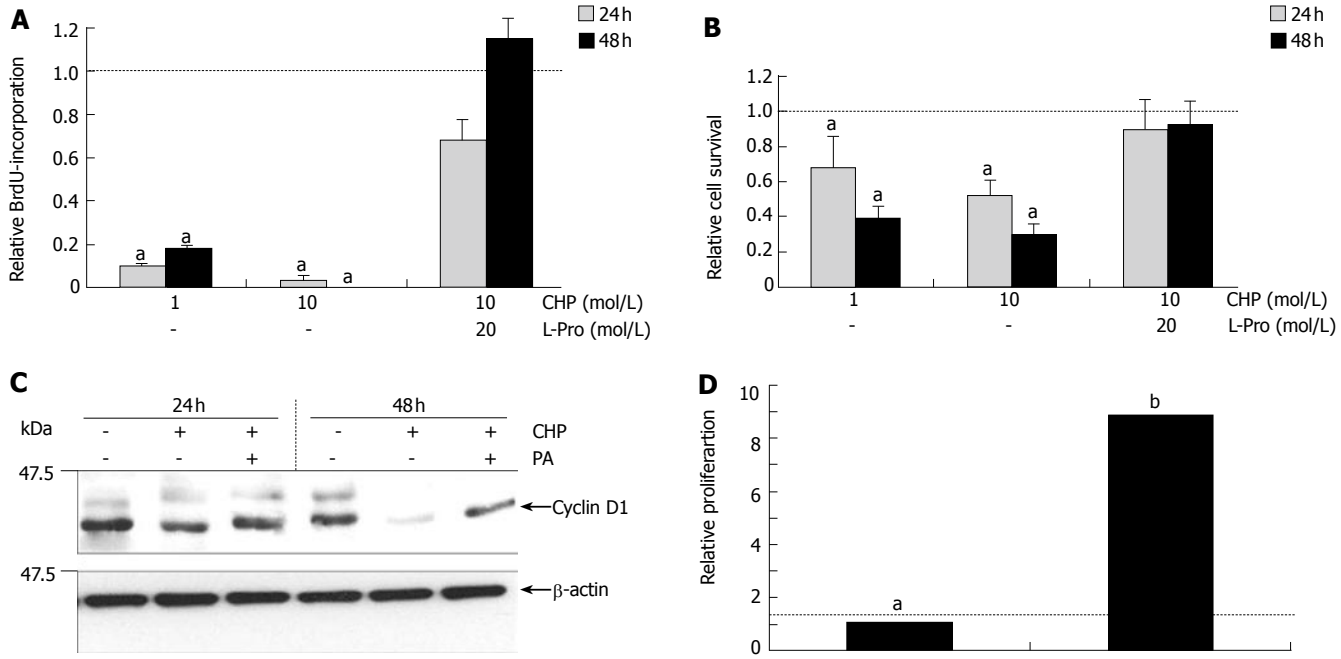

Figure 2 Inhibition of cell proliferation and survival by CHP. A: After the addition of BrdU, cells were cultured for further 20 h, followed by quantification of BrdU incorporation; B: Four hours after the addition of CellTiter AQueous solution, conversation of the MTT salt was measured. CHP-caused decrease of proliferation (A) and metabolically active cells (B) was prevented by the addition of L-proline. Results are expressed as mean±SE (n = 6, $^{a}P \leqslant 0.05$). C: Immunoblotting of total cell extracts from DSL6A cells using an anti-cyclin D1 antibody. Results are representative for three independent experiments. D: DSL6A cells were treated with 10 mmol/l CHP for 24 h before culture medium was (a) replaced by DMEM without CHP or (b) 20 mmol/L L-proline was added to the CHP-containing medium.

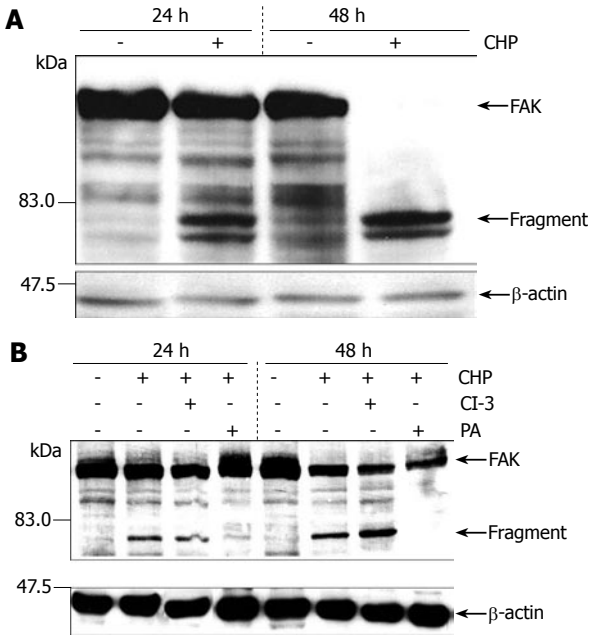

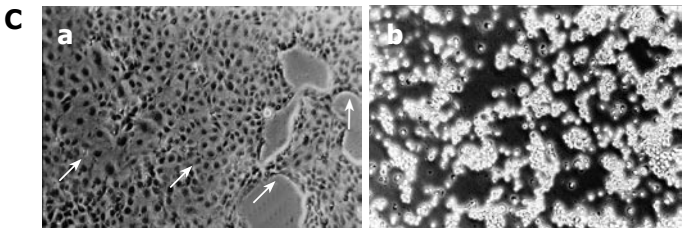

Figure 3 FAK fragmentations in DSL6A cells induced by CHP. A Immunoblotting of protein extracted from DSL6A cells after being incubated for 16 h and 48 h with or without 10 mmol/L CHP. CHP induced a time-dependent degradation of the 125 ku FAK protein, resulting in fragments of about 80 ku. B Simultaneous addition of the Protease Arrest Reagent (PI) to the CHP-treated cells attenuated fragmentation of FAK; in contrast, the caspase-3 inhibitor z-DEVD-fmk (CI-3, 100 μmol/L) was not able to abolish the CHP-induced FAK degradation. To show equal protein loading, the membranes were stripped and re-probed using an anti-β-actin specific antibody. C Effect of CHP on morphological appearance of DSL6A cells; (a) simultaneous addition of 10 mmol/L CHP and a broad spectrum protease inhibitor (PI, Protease Arrest Reagent) abolished the CHP-induced loss of adherence; (b) In contrast to the broad spectrum protease inhibitor, the caspase-3 inhibitor z-DEVD-fmk (CI-3, 100 μmol/L) had no effect on the CHP-induced loss of adherence (Phase contrast microscopy, original magnification x 200).

tor [protease arrest (PA) reagent]. The repression of the intracellular proteolytic activity was able to abolish the CHP-induced FAK degradation (Figure 3B). In addition, pre-incubation of DSL6A cell cultures with the protease inhibitor prevented the CHP-caused cell detachment (Figure 3Ca). Moreover, the cyclin D reduction in DSL6A cells treated for 48 h with CHP was attenuated by the PA reagent (Figure 2C)

In contrast, the inhibition of caspase-3 activity by Z-DEVD-FMK (CI-3) had neither an effect on CHP-mediated FAK degradation (Figure 3B) nor on cell detachment (Figure 3Cb). In addition, treatment with Z-VAD-FMK, a general caspase inhibitor including caspase-3, 7, 8, 10, could not abolish CHP-caused influences on DSL6A cells (data not shown).

Since FAK is localized in focal adhesions while the cell is in contact with extracellular matrix, we, using immunofluorescence staining, analysed the influence of CHP on the intracellular assembly of the enzyme. Results were visualized by laser scanning microscopy (Figure 4). We clearly observed the focal adhesions in adherently growing control cells (Figure 4A), whereas the CHP-caused cell

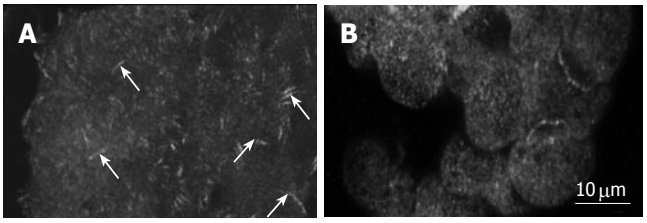

Figure 4 Immunocytochemical localisation of FAK. DSL6A cells grown on glass cover slips were cultured for 24 h without (A) or with 10 mmol/L CHP (B). Cell staining was performed by incubation with a mouse anti-FAK specific antibody. Binding of the primary antibody was detected by an AlexaFluorTM-labelled anti-mouse antibody. Arrows: focal adhesions; Bar: 10 μm.

Lane 1: DSL6A cells cultured without 10 mmol/L CHP for 6 h; lane 2: DSL6A cells cultured with 10 mmol/L CHP for 6 h; lane 3: DSL6A cells cultured with 10 mmol/L CHP for 24 h; lane 4: DSL6A cells treated for 24 h with CHP after the addition of 20 mol/L L-proline for further 6 h; lane 5: DSL6A cells treated for 24 h with CHP after the addition of 20 mol/L L-proline for further 24 h. B: Western blot analysis of GRP78 and FAK protein. Results are representative of at least three independent experiments.

rounding resulted in a loss of focal adhesions and a diffuse distribution of the FAK protein (Figure 4B).

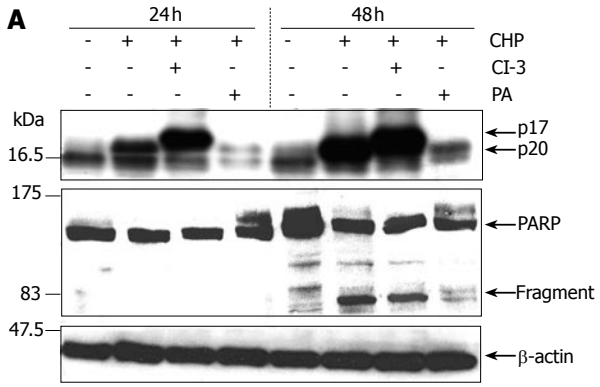
Influence on the expression of ER stress markers GRP78 and GADD153

CHP was earlier described as an inhibitor of normal collagen folding[22], a condition that inevitably affects the homeostasis of the endoplasmic reticulum (ER) referred to as ER stress[15]. In order to test whether CHP effects are mediated by ER stress, we analyzed the expression of GRP78 and GADD153 proteins whose up-regulation was defined as a component of the unfolded protein response (UPR)[18,15]. We found that CHP induced the mRNA expression of the both ER stress markers (Figure 5A). GRP78 transcript levels were found to be increased 3 h after the addition of CHP, while the up-regulation of GADD153 was detected only after 6 h. The CHP-induced GRP78 expression was confirmed on protein level by immunoblotting. A modest increase of the UPR component could be detected 3 h after the addition of CHP. The GRP78 protein levels in the cells increased during prolonged incubation with CHP reaching a maximum after 24 h (Figure 5B).

To test whether the L-proline-caused restoration of cell functions (Figure 2) was reflected on the molecular level, we investigated the time course of the expression of GRP78 and GADD157 during incubation with L-proline in CHP-treated cells. Six hours after the addition of L-proline, the transcript levels of both UPR components were reduced, reaching normal values during 24 h (Figure 6A). In contrast, the decrease of GRP78 protein levels could be detected only after 48 h (Figure 6B). Furthermore, L-proline-induced reversion of the CHP-mediated impairment of cell functions was accompanied by a time-dependent reconstitution of the FAK molecule associated with a reduction of the protein fragments (Figure 6B).

Impact of CHP on apoptosis

The reduction in cell viability pointed to the induction of apoptosis by CHP. Using the Western blot technique, we analyzed the processing of caspase-3 and poly-(ADP ribose) polymerase (PARP) to verify programmed cell death. The activation of apoptosis-executing caspase-3 occurs in a two-step proteolytic process. Initially, the procaspase-3 is cleaved into the subunits p12 and p20, followed by an autocatalytic fragmentation of the latter one, resulting in the fully active p17 enzyme[23]. Treatment of



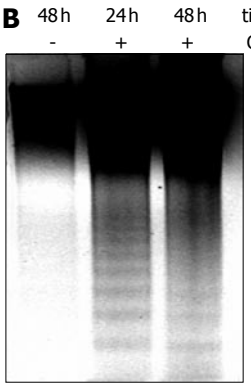


Figure 7 Induction of apoptosis by CHP. A: Immunoblotting using specific antibodies for cleaved caspase-3 or poly (ADP) ribose polymerase (PARP). B: DNA laddering induced by CHP. Results are representative of at least three independent experiments.

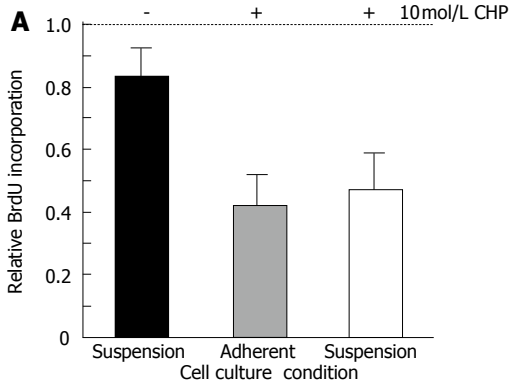

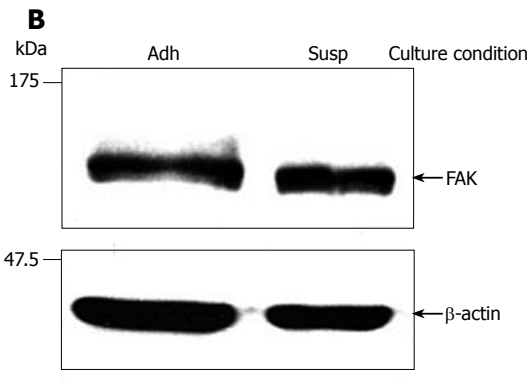

Figure 8 Survival of DSL6A cells cultured in suspension. A: Assessment of cell viability using the CellTiter AQueous assay. Adherent cells (adh.) and cells in suspension (susp.) were incubated for 24 h with or without 10 mmol/L CHP. Results are expressed as a percentage of living cells with regard to adherently growing, untreated control. Data are expressed as mean±SE (n=6). B: Western blot analysis of FAK protein levels.

DSL6A cells with CHP caused a time-dependent activation of caspase-3 represented by the p17 molecule (Figure 7A). Similarly, the cleaved PARP protein of 85 ku occurred during CHP treatment (Figure 7A). Intriguingly, the CHP-induced apoptotic DSL6A cell death, determined by the activation of caspase-3 and PARP, could be prevented by pre-treatment of the cells with the broad spectrum protease inhibitor PA (Figure 7A). These results together with the prevention of CHP-induced FAK degradation (Figure 3B) as well as cyclin D1 reduction (Figure 2C) by inhibition of intracellular proteolysis indicate a superior role of proteases in the CHP-mediated effects.

The caspase-3-specific inhibitor Z-DVED-FMK (CI-3) did not prevent the initial cleavage of procaspase-3 into the p20 fragment. Therefore, corresponding with the blockade of the subsequent autocatalytic processing generating the active p17 enzyme, the level of the p20 protein increased under the treatment with Z-DVED-FMK (Figure 7A).

Another characteristic sign of apoptosis is the degradation of genomic DNA into multiple fragments referred to as DNA laddering. Electrophoretical separation of DNA isolated from DSL6A cells treated for 24 h and 48 h with CHP exhibited the typical DNA ladder, whereas DNA degradation was not detected in untreated controls (Figure 4C). Interestingly, there was no effect of CHP on the anti-apoptotic factor bcl-2 (data not shown).

Loss of adherence and survival

To verify the hypothesis that CHP-induced cell death was not simply the consequence of the loss of adherence, cell survival was quantified in suspension cultures compared with adherently growing DSL6A cells. Indeed, the rate of metabolically active cells (17%) in suspension was lower than that in the adherent counterparts (Figure 8A). However, the portion of dead cells in monolayer cultures incubated with CHP for 24 h increased to about 60% as compared to the untreated controls. Moreover, there were no significant differences between adherent and suspension cultures in CHP-treated cells (Figure 8A). Interestingly, the FAK molecule in DSL6A cells bared from adhering remained intact (Figure 8B). Taken together, our data suggest that the CHP-mediated damage of DSL6A cell functions, including detachment, growth inhibition and apoptosis, is a consequence of molecular mechanisms initiated by intracellular proteolytic processes.

DISCUSSION

In this study, we have shown that cis-hydroxyproline initiates a stress machinery in the rat pancreatic cancer cell line DSL6A, leading sequentially to growth inhibition, loss of adherence and apoptosis. The capacity of CHP to inhibit cell proliferation is consistent with the results for fibroblasts, mammary carcinoma and retinal epithelium cells[6-8].

The CHP-induced damage of DSL6A cells was associated with proteolytic fragmentation and inactivation of FAK. Various studies have suggested that FAK is essentially implicated in integrin-mediated transfer of extracellular stimuli from the cell surface across the plasma membrane, resulting in the activation of several intracellular signalling pathways[22-24]. FAK activation by phosphorylation has been shown in a variety of cell types to be dependent on integrins binding to their extracellular ligands[27]. In addition, there are several reports regarding the regulation of FAK activity by limited cleavage of the

enzyme protein. Using human platelets, Cooray *et al*[28] could identify calpain as the FAK-hydrolysing protease. In a model of oncogenic cell transformation by retroviral gene transfer of v-src, Carragher *et al*[29] showed that cell detachment is associated with calpain-dependent FAK degradation. Furthermore, focal loss of adhesion followed by apoptosis after switching off v-src is accompanied by caspase-mediated FAK proteolysis[29]. The data and the different effects of specific protease inhibitors let the authors conclude that proteolysis of FAK might be a general phenomenon associated with disassembly of focal adhesions, but can be mediated by distinct proteases under different biological conditions[29]. We have shown that in addition to FAK cleavage, the CHP-induced cell detachment, cyclin D1 decline, and caspase-3 activation in DSL6A cells could be attenuated by proteolysis inhibition. The circumvention of the different molecular and functional effects by inhibition of intracellular proteolysis suggests that protease(s) might play a superior role in the execution of CHP-mediated cell toxicity. Furthermore, CHP induced the expression of GRP78 and GADD153, both of which have been defined to indicate the UPR, a pathway of the ER stress machinery[15].

As early as 1975, Uitto *et al*[22] found that non-helical CHP-containing pro-collagen is retained in the ER of chick embryo tendon cells. However, the molecular consequences of these observations could not fully be realised at this time. The CHP-initiated impairment of DSL6A cell functions might be likely attributed to more comprehensive cellular mechanisms rather than exclusively to the disturbance of collagen synthesis, especially because DSL6A cells do not express collagen type I but only traces of collagen type IV-specific transcripts (data not shown). Thus, an interference of CHP with the synthesis of proline-rich proteins involved in striking regulatory cell functions can be assumed[31].

L-proline is able to abolish CHP-induced disturbances of DSL6A cell functions. The mutual competitive replacement of the isomeric compounds proline and CHP has to be expected[5,8]. More interestingly, the addition of L-proline could arrest and even reverse the ongoing process of the CHP-induced ER stress. The restoration is accompanied by a decrease of the expression of the stress proteins, indicating the reversibility of the UPR. GRP78 transcript levels could be achieved during about 6 h of the starting status, while the normalization of the protein concentration takes more than 2 d. According to reports by Liu *et al*[32], the delayed protein decline is probably attributed to its half life time of more than 36 h.

Intriguingly, the L-proline-induced reversion of the CHP-mediated impairment of cell functions is accompanied by a time-dependent reconstitution of the FAK molecule. Furthermore, the survival of DSL6A cells maintained in suspension cultures suggests that the proteolytic FAK degradation is not resulted from apoptosis, but occurs downstream or even constitutes a component of the ER stress cascade. In addition to the proteolytic fragmentation of FAK shown by several studies[30,29], there are reports describing ER stress-mediated activation of caspases, leading to apoptotic cell death[33]. In contrast to these data, we showed that CHP-caused DSL6A cell injury could not be influenced by inhibition of caspases, suggesting that other and/or additional protease(s) trigger CHP-induced proteolytic activity. In this context, reports should be noted which suggest the existence of a physiological role of caspases, apart from that of death executioners[33].

Based on our data, we hypothesize that CHP initiates a signal cascade including sequentially the induction of ER stress, activation of protease(s) that catalyse the caspase-independent FAK fragmentation, followed by cell detachment and finally leading to apoptosis. Further investigations are necessary to identify proteases involved in the CHP-mediated mechanisms.

Interestingly, CHP-caused FAK inactivation leading to detachment of DSL6A cells is not directly associated with apoptosis, in general the cellular response to the loss of anchorage referred to as anoikis[34]. This anoikis-resistance of the DSL6A cells can be attributed most likely to their malignant phenotype[35].

Taken together, we have shown, probably for the first time, an ER stress-mediated cytotoxic effect exerted by CHP in pancreatic cancer cells. Since the molecular equipment may vary between different cell populations, further studies are needed to characterize the susceptibility of other cell types to CHP. Lastly, in order to test the practicability of CHP in cancer therapy, studies on animal models are under way.

ACKNOWLEDGMENTS

The authors thank Edith Prestin for the technical assistance. We are grateful to Peter Lorenz (Inst. of Immunology, University of Rostock) for excellent assistance with the laser scanning microscopy.

Abstract

AIM: To investigate the location alteration of Smad2 and Smad4 mRNAs in the liver during and after fibrogenesis in rats.

METHODS: Eighty male Wistar rats weighing approximately 200 g each were used. The rat models of experimental hepatic fibrosis were established by injection with carbon tetrachloride (CCl_4), normal rats and rats were injected with olive oil and served as control groups. *In situ* hybridization(ISH) was used to detect the Smad2 and Smad4 mRNA in liver.

RESULTS: *In situ* hybridization showed Smad2 and Smad4 mRNA expressions in the cytoplasm of hepatic stellate cells (HSC), fibroblasts and myofibroblasts around the central vein and hepatic sinus during and after fibrogenesis. Expression of Smad2, 4 mRNA was higher than that in normal and control rats.

CONCLUSION: In the process of and after hepatic fibrosis formation, HSC, fibroblasts and myofibroblasts are the major cells that express Smad2 and Smad4. The more serious the hepatic fibrosis is in the injured liver, the higher the level of Smad2 and Smad4 gene expression is during and after fibrogenesis respectively.

Key words: Smad2; Smad4; mRNA; Liver fibrogenesis

INTRODUCTION

Fibrosis is associated with many liver diseases, including hepatitis C virus infection, iron deposition, alcohol consumption, and nonalcoholic fatty liver disease. Hepatic fibrosis results from a net increased synthesis and decreased degradation of extracellular matrix (ECM) proteins. Type Ⅰ collagen is the most prevalent ECM protein deposited[1], with activated hepatic stellate cells(HSCs) serving as the primary source. Following a fibrogenic stimulus, HSCs are activated from their normal quiescent state, whereby they increase synthesis of procollagen type Ⅰ protein[1,2], and increase cellular proliferation, migration, and contractility[3,4]. Excess ECM accumulation results in scarring within the tissue[5].

In the progression of HSCs activation, many kinds of cytokines play important roles, including transforming growth factor-beta (TGF-β)[6]. TGF-β is a multifunctional cytokine with diverse effects on development, growth, and homeostasis in most tissues[7]. Signaling by TGF-β occurs through type Ⅰ and type Ⅱ transmembrane serine/threonine kinase receptors and intracellular Smad transduction molecules. The TGF-β ligand binds to its type II receptor, either directly or via coreceptors. Once activated by TGF-β, type II receptors recruit, bind, and transphosphorylate type I receptors, thereby stimulating protein kinase activity of the later. The activated type I receptors phosphorylate Smad2 or Smad3, which then bind to Smad4. The resulting Smad complex then moves into the nucleus, where it interacts in a cell-specific manner with various transcription factors to regulate the transcription of target genes[8].

It has been reported that there is a correlation between TGF-β and the formation of liver fibrosis[9,10]. TGF-β has a very important role in ECM production by HSC and many investigations have been done[11,12]. Antagonism of cytokines as a route to antifibrotic therapy, by blocking the interaction between TGF-β and its receptors, and the signal transduction mechanism for TGF-β, has been reported for the treatment of fibrosis[13,14]. Thus the investigation of the Smads signal transduction is indispensable for the study

of fibrosis and the development of its therapy. Until now, there have been no reports on the location and expression alteration of Smad2,4 during and after fibrogenesis. In this article, the expression and location of Smad2,4 mRNA were measured in rat livers with cRNA probes of Smad2,4 by *in situ* hybridization.

MATERIALS AND METHODS

Animal experiments

Eighty male Wistar rats weighing approximately 200 g each were used. Chronic liver injury was produced in 10 rats in each group by subcutaneous injections of 50% CCl_4 in olive oil at a volume of 2 ml/kg body weight twice weekly for 3, 6, 9, 12, 15, and 18 wk. Ten control rats similarly received olive oil alone as control group, and 10 other rats were not treated as normal group. All rats were maintained on a standard diet with water *ad libitum*. On the sixth day after the last treatment, 10 rats in each group were decapitated. Their livers were removed immediately, fixed in 4% paraformaldehyde at room temperature and snap-frozen in liquid nitrogen. The tissue specimens were stored at -80 ℃ until analysis.

Cloning of Smad2 and Smad4 cDNAs

Smad2 and Smad4 cDNAs were cloned in order to synthesize ISH riboprobes. The two cDNAs were obtained from rat liver total RNA by reverse transcription coupled to PCR by the use of the primers Smad2-up (5' GGTGGATCCGTGTCTCATCGGAAAGGG-3'), Smad2-GTGAATTCTGGAATGGAGTGGGTATAG-3') and Smad4-up (5'-AACCGGATCCATCTTCAGC ACCACCC-3'), Smad4-down (5'CGAATTCTTTGCCTA TGTGCAACCTTGC-3'), respectively. The two resulting fragments were digested with *BamH* Ⅰ and *Eco*R Ⅰ and cloned into the pSPT18 vector (Boehringer Mannheim) to obtain the pSPT18+/Smad2 and pSPT18+/Smad4 plasmids.

ISH riboprobe synthesis

The cDNA-containing plasmids were linearized as follows: pSPT18+/Smad2 and pSPT18+/Smad4 with *BamH* Ⅰ and *Eco*R Ⅰ. The linearized plasmids were then gel-isolated (Hua Shun Corp., China) and used as templates for anti-sense and sense digoxigenin (DIG)-labeled riboprobe synthesis(Boehringer Mannheim). The transcription mixture (20 μL) included 1 μg of linearized template cDNA , ATP, GTP and CTP at 1 mmol/L each, UTP 0.7 mmol/L, DIG-UTP 0.3 mmol/L, DTT 10 mmol/L, RNase inhibitor (1 U/μL of transcription mix), and T3 or T7 RNA polymerase (1 U/μL of transcription mix). Transcription was performed for at least 2 hr at 37 ℃. The template cDNAs were then digested by RNase-free DNase (2 μL at 1 U/μL, 15 min at 37 ℃), and all reactions were stopped by adjusting the reaction volume to 100 μL with EDTA (pH8.0). The riboprobes were then purified through two precipitation steps by addition of 100 μL LiCl (4 mmol/L) and 500 μL EtOH (100%), and centrifugation for 30 min at 4 ℃ in a microfuge. The pellet was resuspended in 100 μL DECP-treated water.

In situ hybridization

The serial paraffin sections (thickness 4 μm) were dried at 55 ℃, then deparaffinized by xylene and rehydrated in graded ethanol, incubated for 2×5 min in TBS containing 0.1% active DEPC (Fluka), acidified in 0.2 N HCl for 20 min at room temperature, and incubated for 2×5 min in TBS before digestion with proteinase K for 15 min, and then incubated for 2×5 min in TBS. After postfixation in 4% paraformaldehyde-PBS, sections were incubated for 2 ×5 min in TBS. And then sections were dehydrated with graded ethanol. After prehybridization at 42 ℃ for 2 h, the labeled RNA probes were added to the hybridization mix (Smad2 3.7 ng/μL, Smad4 2.3 ng/μL). The hybridization was carried out at 42 ℃ for 18 h with 20μL of hybridization mix on each section. The sections were washed with 2×SSC, 1×SSC, and TBST(TBS containing Tween20) respectively. After washed, the sections were incubated for 15 min at room temperature with Buffer I containing 1% blocking reagent (Boehringer Mannheim), and then at 37 ℃ with alkaline phosphatase-coupled anti-digoxigenin antibody(Boehringer Mannheim) diluted at 1:50 in Buffer I. Excess antibody was removed by 5×4 min washes in TBST, and the sections were equilibrated for 2× 5 min in Buffer I(Tris-HCl 100mmol/L, NaCl 100mmol/L, and $MgCl_2$ 100mmol/L, pH9.5). Color development was performed at 37 ℃ for 8 h in Buffer I containing NBT and BCIP(Promega). Staining was stopped by a 10 min washing in tap water, and non-special staining was removed in EtOH 95% with gentle agitation. Then the sections were rehydrated through successive baths of EtOH (70, 95, and 100%) and xylol (2×15 min each) and mounted in gum for microscopic examination and photography. Blank control: Smad2 and Smad4 cRNA probes for positive hepatic tissues were replaced by prehybridization solution. Negative control: *in situ* hybridization was performed in normal liver tissues. False positive control: *in situ* hybridization was performed in liver tissues injected with olive oil.

Pathology observation

The whole liver sections were stained with hematoxylin and eosin, and examined under microscope.

Statistic analysis

The *t* test was used to determine statistical significance between groups. *P* value of less than 0.05 was considered statistically significant.

RESULTS

Pathologic findings

During the hepatic fibrosis formation in the experimental rats, in liver tissues at 3 wk, infiltration of inflammatory cells was found around the portal area and central vein; at 6 wk, fatty degeneration and infiltration of inflammatory cells was detected; at 9 wk, hyperplasia of the lattice fibers and collagenous fibers was observed in portal area; at 12 wk, hyperplasia of the lattice fibers and collagenous fibers was observed in portal area and extended outwards, hyperplasia surrounding the central vein observed was

distributed along hepatic sinus and connected with each other, the hepatic lobules were encysted and separated by collagen bundles, the normal structure of lobules was destroyed, and pseudolobules formed, infiltration of inflammatory cells was found around the portal area and central vein; at 15 and 18 wk, excluding the findings of 12 wk, atypical hyperplasia was found in the epithelium of biliary capillary. The structure of liver tissues was normal in normal and control groups (Figures 1 and 2).

Smad2 and Smad4 location

Smad2 and Smad4 mRNAs in liver from experimental rats were detected mainly in the HSCs, fibroblasts and myofibroblasts around the portal area and central vein. Expressions of Smad2 and Smad4 mRNAs exhibited as blue particles in cytoplasm. No positive expression was found in nuclei. There was only mild positive expression in normal and control groups. Image pattern analysis showed that the expression in the experimental group was much stronger than that in the normal and control groups (Table 1, Figures 3 and 4).

DISCUSSION

To establish the model of liver fibrosis successfully is the key for detection of Smad2 and Smad4 mRNAs in the liver tissue during and after fibrogenesis. Researches for establishing the model of liver fibrosis with CCl_4 began in 1936. After that many methods to establish the model of liver fibrosis have been tried. Among them, liver fibrosis models induced by immune response or CCl_4 have been generally accepted mainly because they are more close to the disease characteristics in terms of the distinct stages of the disease of human body and a low mortality. In this study, the method of injecting CCl_4 was used to establish the model of liver fibrosis, and it was proved successful

by histochemical analysis of the sections stained with hematoxylin and eosin. According to the pathologic findings of this study, the exact time for establishment of rat hepatic cirrhosis by injecting CCl_4 may be at 12 wk. From 15 and 18 wk on, atypical hyperplasia was found in the epithelium of bile capillary. It may indicate that injecting CCl_4 may cause hepatic carcinoma.

TGF-β consists of a big molecular family that has a common structure including BMP and activin. These proteins have many roles in the cell structure and function, such as cell growth, differentiation, apoptosis and regulation of ECM production[15,16]. The main functions of the TGF-β super family are morphogenesis, inflammation, tissue recovery and oncogenesis[17]. Smads are intracellular signal transductive molecules of the TGF-β super family. These molecules were discovered as Mothers against dpp (Mad)[18,19], or sma[20] and named Smad in 1996[21]. According to the differences of structure and function, nine Smads have been reported and classified into three groups[7,22]. Smads 2 and 3 are named R-Smads in the

pathway and Smad 4 a Co-Smads for all these pathways. Smads 6, 7, 8 and Xsmad 8 are inhibitory factors of these Smads. When TGF-β binds to its receptor, Smad 2/3 is phosphorylated and binds with Smad 4, together they move into the nucleus for translation and expression of the target gene[7,23]. These mechanisms are thought to play a role in the process of liver damage, recovery, as well as liver fibrosis. In a damaged liver including chronic inflammation, in hepatitis B, TGF-β signaling was reported[24]. Not only Kupffer cells but also the HSC produce TGF-β by the autocrine system[25-28]. TGF-β1 stimulation evokes ECM production, which develops into liver fibrosis.

In this study, Smad2 and Smad4 mRNAs were investigated in rat liver during and after fibrogenesis caused by CCl_4 *in vivo*. With the method of *in situ* hybridization, we found Smad2 and Smad4 mRNAs were expressed obviously in HSC, myofibroblasts and fibroblasts of livers of liver fibrosis group, mostly in portal area and fibrous septum, while very mildly in vascular endothelial cells of livers from normal and control groups. While with the development of liver fibrosis, expressions of Smad2 and Smad4 mRNAs were increased also. These results indicate that Smad2 and Smad4 play an important role in the progression of liver fibrosis. In the sections of liver fibrosis at 15 and 18 wk, expressions of Smad2 and Smad4 mRNAs were higher in the epithelium of bile capillary than in normal and control groups. At this stage, there was atypical hyperplasia in the epithelium of bile capillary, indicating early stage of carcinoma. Therefore, Smad2 and Smad4 may be associated with cancerogenesis.

After stimulation of TGF-β, Smad2, 3 and 4 proteins translocate from cytoplasm to nucleus in MV1Lu cells, analyzed by immunofluorescence using specific antiserum[22]. Moreover, Smad3 seems to play the most important role in liver fibrosis, because Smad3 interacts with SP1 which increases expression of ECM by regulating COL1A2 gene[29]. By transfection of Smad3 expression plasmid in CF37 cells, ECM also increases by regulating COL1A2 gene. Nevertheless, COL1A2 transcription in CF37 cells is markedly increased by TGF-β after transfection with a Smad2 expression plasmid[30]. So Smad2 also plays an important role in liver fibrosis. Our findings are consistent with the above results. The difference is perhaps due to use of different cell lines or experimental conditions. Further researches are needed to confirm the results.

As the liver fibrosis is a complex process, involving many cytokines, cells, and signal transduction pathways, the mechanism cannot be fully explained by these experiments. However, it is clear that TGF/Smads signal transduction pathway plays an important role in liver fibrosis which has been proved by many researches. In our study, Smad2 and Smad4 mRNAs were detected in the plasma of HSC, fibroblasts and myofibroblasts around the portal area and central vein by *in situ* hybridization. Expressions of Smad2 and Smad4 mRNAs were higher during and after liver fibrogenesis than normal and control groups, indicating that they play an important role in liver fibrosis.

Abstract

AIM: To investigate the *c-kit* expression in biliary tract cancer cell lines and histological sections from patients with extrahepatic cholangiocarcinoma (CC) and to evaluate the efficacy of *in vitro* and *in vitro* treatment with imatinib mesilate.

METHODS: The protein expression of *c-kit* in the human biliary tract cancer cell lines Mz-ChA-2 and EGI-1 and histological sections from 19 patients with extrahepatic CC was assessed by immunoblotting, immunocytochemistry, and immunohistochemistry. The anti-proliferative effect of imatinib mesilate on biliary tract cancer cell lines Mz-ChA-2 and EGI-1 was studied *in vitro* by automated cell counting. In addition, immunodeficient NMRI mice (Taconic™) were subcutaneously injected with 5 x 10^6 cells of cell lines MzChA-2 and EGI-1. After having reached a tumour volume of 200 mm^3, daily treatment was started intraperitoneally with imatinib mesilate at a dose of 50 mg/kg or normal saline (NS). Tumor volume was calculated with a Vernier caliper. After 14 d, mice were sacrificed with tumors excised and tumor mass determined.

RESULTS: Immunoblotting revealed presence of *c-kit* in Mz-ChA-2 and absence in EGI-1 cells. Immunocytochemistry with *c-kit* antibodies displayed a cytoplasmatic and membraneous localization of receptor protein in Mz-ChA-2 cells and absence of *c-kit* in EGI-1 cells. *c-kit* was expressed in 7 of 19 (37%) extrahepatic human CC tissue samples, 2 showed a moderate and 5 a rather weak immunostaining. Imatinib mesilate at a low concentration of 5 μmol/L caused a significant growth inhibition in the *c-kit* positive cell line Mz-ChA-2 (31%), but not in the *c-kit* negative cell line EGI-1 (0%) ($P < 0.05$). Imatinib mesilate at an intermediate concentration of 10 μmol/L inhibited cellular growth of both cell lines (51% *vs* 57%). Imatinib mesilate at a higher concentration of 20 μmol/L seemed to have a general toxic effect on both cell lines. The IC_{50} values were 9.7 μmol/L and 11 μmol/L, respectively. After 14 d of *in vitro* treatment with imatinib mesilate, using the chimeric mouse model, *c-kit* positive Mz-ChA-2 tumors had a significantly reduced volume and mass as compared to NS treatment ($P < 0.05$). In contrast to that, treatment of mice bearing *c-kit* negative EGI-1 tumors did not result in any change of tumor volume and mass as compared to NS treatment.

CONCLUSION: *c-kit* expression is detectable at a moderate to low protein level in biliary tract cancer. Imatinib mesilate exerts marked effects on tumor growth *in vitro* and *in vitro* dependent on the level of *c-kit* expression.

INTRODUCTION

Protein kinases are functionally involved in a broad variety of human cancer[1,2]. In tumor cells, it is common that key tyrosine kinases are no longer adequately controlled, and excessive phosphorylation sustains signal transduction pathways in an activated state. Receptor tyrosine kinases (RTKs) are membrane bound proteins, consisting of a ligand-binding domain at the extracellular surface, a single transmembrane segment, and a cytoplasmic part harboring the protein tyrosine kinase activity. Ligand-induced dimerization, resulting in autophosphorylation of their cytoplasmic domains, is the major mode of activation of RTKs[3]. Many oncogenic mutations in RTKs involve either point mutations leading to constitutive dimerization of the receptors or translocations causing fusion of oligomeriza-

tion motifs to RTKs. Overexpression, probably caused by mutations in gene regulatory sequences or gene amplification, may lead to constitutive dimerization of RTKs. Moreover, mislocalization of RTKs due to fusion to other proteins may contribute to their oncogenic phenotype. Phosphorylated tyrosine residues in the receptor tails then function as recruitment sites for downstream signalling proteins containing phosphotyrosine-recognition domains, such as the SRC homology 2 (SH2) domain or the phosphotyrosine-binding (PTB) domain. These molecules act as relay points for a complex network of independent signalling molecules that ultimately affect gene transcription within the nucleus. *c-kit* (CD-117) is a transmembrane tyrosine kinase receptor in which the extracellular protein binds a ligand known as stem-cell factor (also known as Steel factor) and the intracellular portion contains the actual kinase enzymatic domain[4-6]. *c-kit* is similar in structure to several other RTKs with oncogenic capabilities, including platelet-derived growth factor receptor (PDGF-R) A and B, colony stimulating factor 1 receptor (CSF1-R), and fms-related tyrosine kinase 3 receptor (FLT3-R). *c-kit* is expressed at high levels in hematopoietic stem cells, mast cells, melanocytic cells, germ cells, and the interstitial cells of Cajal (ICC)[7-10]. The receptor forms homodimers upon ligand binding leading to receptor activation. This triggers activation of critical downstream signalling pathways, such as Ras/Raf/mitogen-activated protein kinase kinase (MAPKK)/mitogen-activated protein kinase (MAPK) (cell proliferation) and phosphatidylinositol 3-kinase (PI3K)/AKT (cell survival)[11,12]. There are receptor activating oncogenic *KIT* mutations which involve the extracellular (exon 9), juxtamembrane (exon 11) and kinase domains (exons 13 and 17). As a consequence, in hematologic neoplasms, the exact signalling pathways activated by the mutant *KIT* differ from those activated by normal *KIT*[13,14].

The clinical development of targeted tyrosine kinase inhibitors represents a breakthrough for cancer treatment. They are designed to take advantage of the molecular differences specific to tumor cells compared with normal tissues. The goal is to achieve tumor responses with better safety profiles than those associated with cytotoxic chemotherapies that exhibit narrow therapeutic indices and little selectivity for cancer cells over normal proliferating cells. Imatinib mesilate (STI-571, Gleevec™, Novartis), a 2-phenylaminopyrimidine, was primarily designed to treat chronic myeloid leukemia (CML) by inhibiting bcr-abl fusion protein, created by the t(9; 22) chromosomal translocation, which generates the distinctive Philadelphia (Ph) chromosome[15]. However, imatinib mesilate is not a specific bcr-abl inhibitor, its action extends to c-abl receptor, PDGF-R, and *c-kit*-R[15]. Moreover, it promotes NK cell activation[16] and downregulates telomerase activity[17]. Therefore, imatinib mesilate has been evaluated for the therapy of gastrointestinal stromal tumors (GISTs), because most of them characteristically show *c-kit* overexpression. For metastatic GISTs, imatinib mesilate is nowadays the therapeutical standard, based on a phase II study, including 147 patients with unresectable GISTs, which reported a partial response rate of 54 % and a rate of stable disease of 28 %[18]. A closer inspection of the data clearly displayed that *KIT* mutational status correlated with response to imatinib mesilate. Thus patients with activating *KIT* mutations in exon 11 had a partial response of close to 80%. In contrast, patients whose tumors expressed wild-type *KIT*, with no mutations, had a response rate of only 18%[19]. However, there are only a few published phase I and II studies investigating the effect of imatinib mesilate on gastrointestinal tumors, others than GISTs. Whereas three studies detected a modest level of biological effect of imatinib in hepatocellular carcinoma (HCC) and carcinoid tumor, there was no effect for the treatment of pancreatic carcinoma in two other studies[20-24]. In this study we investigated *c-kit* protein expression in biliary tract cancer cell lines and histological sections from 19 patients with extrahepatic cholangiocarcinoma (CC) and evaluated the efficacy of *in vitro* and *in vivo* treatment with imatinib mesilate.

MATERIALS AND METHODS

Materials

Human gallbladder cancer cell line Mz-ChA-2[25], human extrahepatic cholangiocarcinoma cell line EGI-1[26], and colorectal carcinoma cell line HT-29[27] were cultured as mono-layers in Dulbecco`s modified Eagle`s medium (DMEM, Invitrogen GmbH Karlsruhe, Germany) supplemented with 100 mL/L fetal bovine serum (FBS, Invitrogen GmbH Karlsruhe, Germany), 100 ku penicillin and 100 g/L streptomycin in humidified atmosphere of 900 mL/L air and 100 mL/L CO_2 at 37 ℃. Small cell lung cancer (SCLC) cell line NCI-H69[28] was kept in RPMI 1640 medium (Invitrogen GmbH Karlsruhe, Germany) containing 100 mL/L FBS and antibiotics in humidified atmosphere of 950mL/L air and 50mL/L CO_2 at 37 ℃. The 2-phenylaminopyrimidine derivative STI-571 (imatinib mesilate, Gleevec™) was provided by Novartis Pharma AG (Basel, Switzerland). Stock solution (10 g/L) was prepared in normal saline (NS) and stored at -20 ℃. Hoechst dye was purchased from Sigma (Sigma-Aldrich Chemie GmbH Munich, Germany), rabbit polyclonal c-kit antibody (CD117 Ab-6) from Neomarkers (Dunn Labortechnik GmbH, Asbach, Germany), and Cy™3-conjugated donkey anti-rabbit antibody from Jackson ImmunoResearch (Jackson ImmunoResearch Europe Ltd., Cambridgeshire, United Kingdom). Six to eight-week-old female athymic NMRI nude mice were supplied from Taconic (Taconic Europe, Ry, Denmark) and held under pathogen-free conditions. Human care was administered, and study protocols complied with the institutional guidelines.

Immunoblotting

Cell culture mono-layers were washed twice with ice-cold PBS and lysed with buffer containing Tris-HCl (20 mmol/L, pH 7.5), NP-40 (10 g/L), Triton-X (5 g/L), NaCl (250 mmol/L), EDTA (1 mmol/L), 100 ml/L glycerol, and one tablet of complete mini-EDTA-free protease inhibitor cocktail (Boehringer, Mannheim, Germany) (in 10 mL buffer). Protein concentration was determined by the Bradford protein assay (Bio-Rad, Munich, Germany). 30 μg of cell lysates were separated on SDS-polyacrylamide gels and electroblotted onto poly-

vinylidene difluoride membranes (Amersham Pharmacia Biotech, Freiburg, Germany). Membranes were then incubated in blocking solution (50 g/L BSA in 10 mmol/L Tris-HCl, 140 mmol/L NaCl, 1 g/L Tween-20) (TBS-T), followed by incubation with the primary antibody at 4 ℃ overnight. The membranes were then washed in TBS-T and incubated with HRPO-conjugated secondary antibodies for 1 h at room temperature. Antibody detection was performed with an enhanced chemoluminescence reaction.

Immunocytochemistry

For immunocytochemistry 1 x 10^5 tumor cells were seeded on coverslips of 12-well plates and incubated for one day. Then, medium was removed, cells were washed with PBS and fixed with 8 g/L formaldehyde in PBS for 2 h, washed again, and then permeabilized in 3 g/L Triton-X and 10 g/L DMSO in PBS for another 10 min. After nonspecific antibody binding was blocked by incubation with 50 ml/L donkey serum in 3 g/L Triton-X and 10 g/L DMSO in PBS at room temperature for 2 h, the primary antibody was added, followed by an incubation at 4 ℃ overnight. The omission of primary antibody served as negative control. The next day, cells were washed again and probed with Cy^{Tm}3-conjugated donkey anti-rabbit antibody at room temperature for 2 h. Then, extensive washing and nuclear staining was performed using Hoechst dye according to manufacturers instructions. Finally, coverslips were mounted on slides with 900 ml/L glycerol and slides were analyzed with a Zeiss LSM 510 laser scanning microscope (Carl Zeiss Jena GmbH, Jena, Germany).

Immunohistochemical staining

Paraffin-embedded tissue sections from resection specimens of 19 patients with extrahepatic CC were de-waxed, hydrated through graded alcohol, and immunostained with antibodies to c-kit using the avidin-biotin horseradish peroxidase method as previously described[29]. Immunoreactivity was revealed using True Blue^{TM} peroxidase substrate (KPL, Gaithersburg, USA). The sections were counterstained with hematoxilin and mounted with Permount (Fisher, Pittsburg, USA). For the tumor tissues, the percentage of positive cells was estimated and the staining intensity was semiquantitatively recorded as 1+, 2+, or 3+. For statistical analyses, the staining results were categorized into four groups according to Went *et al*[30]. Tumors without any staining were considered negative. Tumors with 1+ staining intensity in less than 60% of cells and 2+ intensity in less than 30% of cells were considered weakly positive. Tumors with 1+ staining intensity in ⩾ 60% of cells, 2+ intensity in 30% to 79%, or 3+ intensity in less than 30% were considered moderately positive. Tumors with 2+ intensity in ⩾ 80% or 3+ intensity in ⩾ 30% of cells were considered strongly positive. Only membranous or membranous plus cytoplasmic staining was considered for analysis because cytoplasmic staining alone proved to be false-positive in all preabsorption control experiments.

Inhibition of cell growth

The effect of imatinib treatment on cellular proliferation was assessed by automated cell counting (Schaerfe Casy 2.0 Cell Counter, Reutlingen, Germany) according to the manufacturers instructions. Briefly, 2 × 10^5 cells were seeded in T-25 cell culture flasks. Twenty-four hours after incubation, cells were treated with imatinib mesilate at 5 different concentrations (0, 1, 5, 10, and 20 μmol/L, respectively). After 6 d of incubation, cells were trypsinized, washed, and analyzed in triplicates by automated cell counting.

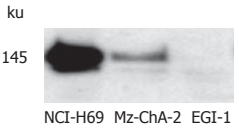

Figure 1 c-kit protein expression in biliary tract cancer cell lines.

Animal studies

Tumors were induced by injecting 5×10^6 Mz-ChA-2 or EGI-1 cells in 200 μL PBS sc into the flank region of NMRI nude mice (n = 40). Treatment was started when an average tumor volume of 200 mm³ was reached (usually after 2 wk). The verum group (n = 2×10) received imatinib mesilate, dissolved in normal saline (NS), ip once a day at 50 mg/kg, whereas the control group (n = 2×10) received NS only. Treatment was continued for 14 consecutive days, tumors were daily measured with a Vernier caliper and tumor volumes were calculated using the formula tumor volume = 0.5 × L × W^2, where L represents the length and W the width of the tumor. When treatment was finished, animals were sacrificed with tumors excised and weighed.

Statistical analysis

Statistical calculations were performed using SPSS, version 10.0 (SPSS Inc., Chicago, USA). Numeric data were presented as mean value with standard deviation (SD). Inter-group comparisons were performed with the Student t test. P< 0.05 was considered significant.

RESULTS

c-kit protein expression in biliary tract cancer cell lines

The expression of *c-kit* in both human biliary tract cancer cell lines Mz-ChA-2 and EGI-1 was assessed by immunoblotting. Cell lysate of SCLC cell line NCI-H69, which has been reported previously to express *c-kit*[28], served as positive control and showed an intense band at about 145 kDa, corresponding to *c-kit* receptor (Figure 1). In accordance with our previous study of *c-kit* m-RNA expression[31], immunoblotting of Mz-ChA-2 cell lysate demonstrated *c-kit* protein expression in this cell line as well. In contrast, *c-kit* expression was not detected in the m-RNA negative cell line EGI-1 (Figure 1). To further analyze *c-kit* expression in these cell lines, immunocytochemistry was performed. In this experiment, colorectal cancer cell line HT-29, which is known to express *c-kit*, served as positive control[27]. Immunocytochemical analysis showed a strong membraneous staining of the receptor protein in this cell line (Figure 2). In the tested biliary tract cancer cell lines, staining of *c-kit* revealed both cytoplasmatic and membraneous localization of receptor protein in Mz-

ChA-2 cells and absence of *c-kit* in EGI-1 cells (Figure 2).

c-kit protein expression in human biliary tract cancer tissue

In order to analyze the expression of c-kit in human biliary tract cancer, paraffin-embedded tissue sections from 19 patients suffering from extrahepatic hilar CC were immunostained with c-kit-antibodies using the avidin-biotin horseradish peroxidase method. The clinical characteristics of the study population were as follows: median age of patients was 61 years (range, 39-74 years); UICC IA, IB, IIA, IIB, III, and IV tumor stage (UICC 2002)[32] had 1, 3, 7, 6, 1, and 1 patients, respectively; Bismuth-Corlette[33] types I, II, IIIA, IIIB, and IV were found in 1, 1, 8, 2, and 7 patients, respectively; and 16 patients had well or moderately differentiated tumors. As a result, 2 of the 19 tissues samples displayed a moderate immunostaining (++), 5 a rather weak immunostaining (+), and 12 were negative (-). Thus, 7 of 19 (37%) of the histological sections of extrahepatic hilar CC tested showed moderate to weak expression of c-kit. The immunoreactivity of c-kit was found mainly in the cell membrane (Figure 3). Highly-differentiated tumors seemed to show a higher level of c-kit expression than low-differentiated tumors.

Inhibition of cellular growth by imatinib mesilate

To assess the effect of imatinib mesilate treatment on cellular proliferation of both biliary tract cancer cell lines, automated cell counting was performed, using the colorectal carcinoma cell line HT-29 as a positive control[27]. After 6 d of incubation, imatinib mesilate at a low concentration of 5 μmol/L caused a significant growth inhibition in *c-kit* positive cell line Mz-ChA-2 (31%±7%), a moderate growth inhibition in *c-kit* positive cell line HT-29 (7%±9%), and no growth inhibition in *c-kit* negative cell line EGI-1 (0%±10%) ($P<0.05$, Mz-ChA-2 *vs* EGI-1). Imatinib mesilate at an intermediate concentration of 10 μmol/L inhibited cellular growth of both biliary tract cancer cell lines significantly (51%±4% *vs* 57%±4%, Mz-ChA-2 *vs* EGI-1). However, this effect was even stronger for HT-29 (91%±19%) ($P<0.05$, HT-29 *vs* Mz-ChA-2 and EGI-1). Imatinib mesilate at a higher concentration of 20 μmol/L seemed to have a general toxic effect in all cell lines (99%±1% *vs* 99%±1% *vs* 100%, Mz-ChA-2 *vs* EGI-1 *vs* HT-29) (Figure 4). The resulting IC_{50} values were 9.7 μmol/L, 11 μmol/L, and 9.5 μmol/L, respectively.

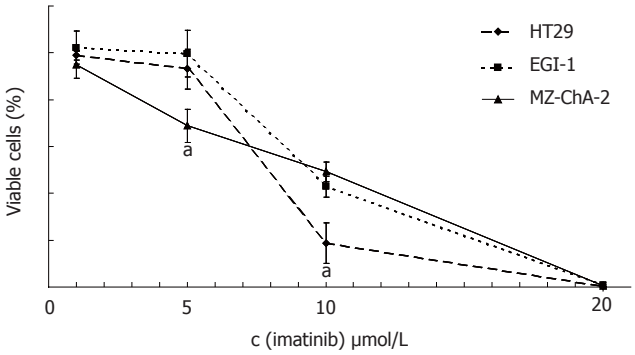

Figure 4 Inhibition of imatinib on cell growth ($^aP<0.05$).

Inhibition of tumor cell growth by imatinib mesilate in nude mice

To assess the antitumor activity of imatinib mesilate *in vivo*, tumors were induced in nude mice by subcutaneous injection of either Mz-ChA-2 or EGI-1 cells into the flanks of the animals ($n=20$ for each cell line). Treatment of mice consisted of daily ip injections of 50 mg/kg BW imatinib mesilate, and injection of NS served as control.

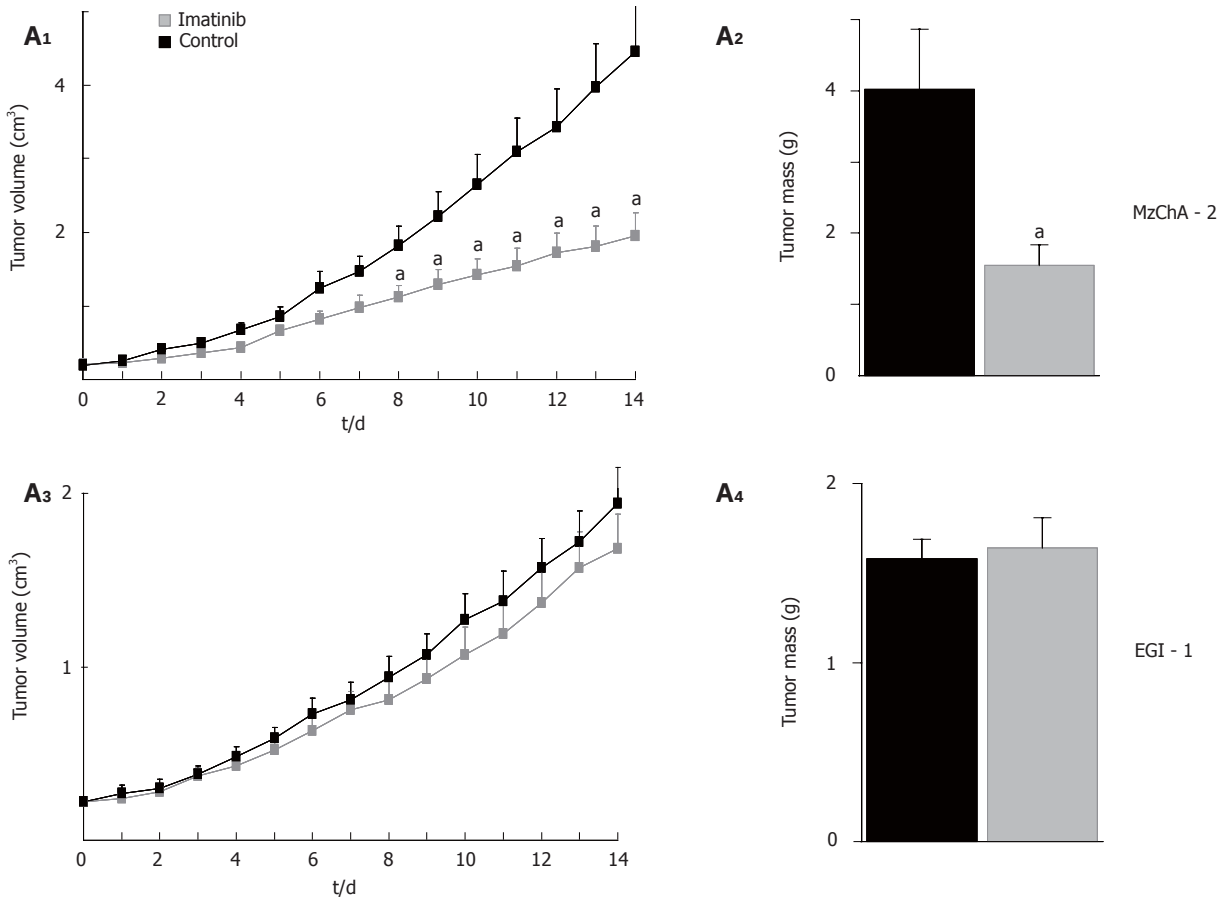

Figure 5 *In vivo* treatment with imatinib mesilate in chimeric mice; **A**: effect on tumor volume and tumor mass ($^aP<0.05$, imatinib *vs* control); **B**: hematoxilin-eosin stained paraffin-embedded tissue sections.

Eight to 14 d after beginning of treatment, Mz-ChA-2 cell tumors had a significantly reduced volume in comparison to control ($P<0.05$). At the end of the experiment (d 14) tumor mass was significantly diminished as compared to control ($P<0.05$). In contrast to that, imatinib mesilate treatment of mice bearing EGI-1 cell tumors did not result in any change of tumor growth compared to control (Figure 5A). Hematoxilin-eosin stained paraffin-embedded tissue sections from mouse tumors showed the typical features of low-differentiated adenocarcinoma (Figure 5B).

DISCUSSION

Non-resectable biliary tract cancer is associated with a poor prognosis due to wide resistance to chemotherapeutic agents and radiotherapy. It is therefore essential to search for new therapeutical approaches. Imatinib mesilate (STI571, Gleevec™), which was found to inhibit the *bcr-abl* tyrosine-kinase resulting from the translocation t(9;22) in chronic myeloid leukemia (CML), as well as *c-kit* and PDGF-R tyrosine kinases, may be an alternative[34]. We have previously shown expression of *c-kit* and PDGF-R m-RNA in 50% and 75% of 12 biliary tract cancer cell lines[31]. Activating mutations of *KIT* were not found, which is consistent with the data of Sihto *et al*[35]. This group screened 334 human cancers (32 histologic tumor types) for mutations with sensitive denaturing high-performance liquid chromatography (DHPLC) and found *KIT* mutations only in GIST tumors. In our study, *c-kit* receptor ligand SCF was present in all cells lines, respectively. We reasoned that the proliferation of these cells might be stimulated by an autocrine mechanism. In order

to test this hypothesis, we treated cell lines with different concentrations of imatinib mesilate. Imatinib mesilate at an intermediate concentration of 10 μmol/L and a higher concentration of 20 μmol/L reduced survival in all cell lines examined by manual cell counting after staining with trypan blue. The reduction was statistically significant higher in *c-kit* positive cell lines ($P < 0.02$) and was independent from PDGF-R status. At 50 μmol/L, a general non-specific toxic effect occurred in all cell lines. The average IC_{50} for growth inhibition of *c-kit* positive cell lines was estimated to be 10 μmol/L. 5-Fluorouracil (5-FU) alone (0.1 μg/mL) reduced cell growth by 40 % - 50 %, while the combination with imatinib mesilate reduced cell growth by another 20% (1 μmol/L) ($P = 0.008$) and 30% (10 μmol/L) ($P = 0.0001$), respectively. Additionally, treatment of cells with imatinib mesilate ± 5-FU had no modulating effects on S-phase fraction, but was associated with a significant induction of apoptosis[31].

However, at that time it was unclear whether *c-kit* could be detected at the protein level and how its distribution whithin the tumor cells was. Moreover, while this work was in progress, Chiorean *et al* were unable to detect *c-kit* at protein levels in human cholangiocarcinoma cell lines KMCH-1 and Mz-CHA-1[36]. In the present study, immunoblotting confirmed the results of our previous m-RNA analysis for Mz-ChA-2 and EGI-1 cells. Immunocytochemistry with *c-kit* antibodies displayed a cytoplasmatic and membraneous localization of receptor protein in *c-kit* positive Mz-ChA-2 cells, indicating a steady receptor turnover. Cell lysates of SCLC cell line NCI-H69 and colorectal cancer cell line HT-29 served as positive controls for immunoblotting and immunocytochemistry. Both cell lines displayed a stronger protein expression that might correlate with a higher sensitivity for imatinib mesilate treatment as shown in previous studies[27,28,37,38]. In order to verify that *c-kit* protein is not only expressed in cholangiocarcinoma cell lines, but also in human biliary tract cancer tissue, paraffin-embedded tissue sections from 19 patients suffering from extrahepatic hilar CC were immunostained with *c-kit*-antibodies using avidin-biotin horseradish peroxidase method. *c-kit* was expressed in 7 of 19 (37%) extrahepatic human CC tissue samples, 2 showed a moderate and 5 a rather weak immunostaining. This result is comparable to a previous analysis of 13 patients with intrahepatic cholangiocarcinoma which demonstrated an expression level of 31%[39]. In contrast, a study from Argentina detected only 6% *c-kit* expression in 50 specimens from gallbladder carcinoma[40]. Moreover, a weak to moderate *c-kit* expression was shown in 7 of 12 (58%) bile duct and gallbladder adenocarcinomas by Aswad *et al*[41]. Finally, a recent multitumor tissue microarray (TMA) analysis by Went *et al*, containing more than 3500 paraffin-embedded tumor samples representing more than 120 tumor types and subtypes, and a recent TMA analysis by Sihto *et al* showed negative results for gallbladder carcinoma ($n = 27$) and cholangiocarcinoma ($n = 3$)[30,35]. These controversial data could be explained by different antibodies used or different tissue selections. Using automated cell counting, we tried to confirm our manual cell counting data for the *c-kit* positive cell line Mz-ChA-2 and the *c-kit* negative cell line EGI-1 after treatment with imatinib mesilate. Imatinib mesilate at a low concentration of 5 μmol/L caused a significant growth inhibition in *c-kit* positive cell line Mz-ChA-2 (31%), but not in *c-kit* negative cell line EGI-1 (0%) ($P < 0.05$). Imatinib mesilate at an intermediate concentration of 10 μmol/L inhibited cellular growth of both cell lines (51% *vs* 57%), but was most effective in colorectal carcinoma cell line HT-29 (91%). Imatinib mesilate at a higher concentration of 20 μmol/L seemed to have a general toxic effect in both cell lines. The results for these particular cell lines indicate that: (1) at a concentration of 5 μmol/L imatinib mesilate seems to exhibit a *c-kit* receptor dependent cell growth inhibition. The different IC_{50} values of 9.5 μmol/L for HT-29, 9.7 μmol/L for Mz-ChA-2, and 11 μmol/L for EGI-1 may therefore be influenced by the different level *of c-kit* expression; (2) at a concentration of 10 and 20 μmol/L the inhibition by imatinib mesilate seems to be no longer *c-kit* receptor dependent. A possible explanation may be a significant decrease in epidermal growth factor receptor (EGF-R) and focal adhesion kinase (FAK) phosphorylation at these concentrations, as observed by Chiorean *et al* for cholangiocarcinoma cell line KMCH-1 which was associated with a reduction in Akt activity resulting in loss of Mcl-1, a potent anti-apoptotic Bcl-2 family member[36]. Whether an additional dose dependent inhibition of telomerase activity, as observed for *c-kit* positive Ewing sarcoma, melanoma, myeloma, breast cancer, Fanconi anemia, and *c-kit* negative murine pro-B cells, plays a role in cholangiocarcinoma has not been evaluated yet[17]; (3) the assumed general toxic effect of imatinib mesilate at a concentration of 20 μmol/L indicates that even a *c-kit* and PDGF-R negative cell line like EGI-1 can sometimes be destroyed at this concentration whereas our previous meta-analysis of 6 *c-kit* m-RNA negative biliary tract cancer cell lines demonstrated a general toxic effect only at 50 μmol/L with a potential inhibition at 20 μmol/L[31].

Even more important are therefore the results from our chimeric mouse model since so far there has been no animal model published for *in vivo* treatment with imatinib mesilate in biliary tract cancer. At the end of a 14 d treatment period with imatinib mesilate, *c-kit* positive Mz-ChA-2 tumors had a significantly reduced volume and mass as compared to NS treatment ($P < 0.05$). In contrast to that, treatment of mice bearing *c-kit* negative EGI-1 tumors did not result in any change of tumor volume and mass as compared to NS treatment. These results support the notion of a *c-kit* receptor expression dependency of sensitivity to imatinib mesilate *in vivo*. At the selected dose of 50 mg/kg, which was chosen according to a study by Druker *et al*[42], no toxic side effects occurred. As discussed by Druker *et al*[43], at steady state, a once-daily administration of 400 mg imatinib mesilate, the commonly used oral dose, translates into a mean maximal serum concentration of 4.6 μmol/L. Therefore, a daily oral dose of 600 mg may be reasonable for a study with patients suffering from biliary tract cancer. Drug-related adverse effects of imatinib mesilate include nausea, vomiting, myalgias, edema, diarrhea, and, less commonly, anemia, thrombocytopenia, neutropenia, and myelosuppression[43-45]. Moreover, there are concerns regarding the drugs liver toxicity in biliary tract cancer patients since it is primarily metabolized in the liver and tumor infiltration of the liver may reduce liver

function. Therefore, Eckel *et al* studied pharmacokinetics of imatinib mesilate in 17 patients with hepatocellular carcinoma and Child A-liver cirrhosis and compared the data with the data of 6 patients with CML and normal liver function[46]. As a result, they found no changes in pharmacokinetics in the first group of patients, thus letting assume the drugs safety in patients with hepatocellular carcinoma and Child A-liver cirrhosis. It is likely that these data can be transferred to patients with invasive biliary tract cancer. However, a phase I/II study is now required to further evaluate our preliminary in vitro and in vivo data. Therefore, our group has designed a clinical study for patients with biliary tract cancer that is now in progress.

In conclusion, *c-kit* expression is detectable by immunoblotting, immunocytochemistry, and immunohistochemistry at a moderate to low protein level in biliary tract cancer. Imatinib mesilate exerts marked effects on tumor growth *in vitro* and *in vivo* dependent on the level of *c-kit* expression. A phase I/II study has been designed to further study the role of imatinib mesilate treatment in patients with biliary tract cancer.

ACKNOWLEDGMENTS

The authors thank Mrs. Annett Kluge, Mrs. Ines Sommerer, and Dr. Michael Deininger for technical assistance and Novartis Pharma AG, 4002 Basel, Switzerland, for the provision of imatinib mesilate.

Abstract

AIM: To evaluate the effect of sumatriptan, a selective 5-HT$_1$ agonist, on anorectal function in irritable bowel syndrome (IBS) patients.

METHODS: Twenty-two IBS patients selected according to the Rome II criteria (F 15, M 7; mean age 29.3±6.8, range 22-44 years) were examined. The study was blind, randomized and placebo-controlled with a crossover design. Anorectal manometry and rectal balloon distension test were performed before and after the administration of placebo and sumatriptan.

RESULTS: The administration of sumatriptan caused a significant increase in the resting anal canal pressure from 9.2±2.0 kPa to 13.1±3.3 kPa (P<0.0001) connected with the increase in the anal sphincter length and high pressure zone. After sumatriptan injection a remarkable increase in the threshold for the first sensation from 27±9 mL to 34±12 mL (P<0.05) and urge sensation from 61±19 mL to 68±18 mL (P<0.01) was observed. Sumatriptan did not affect either the volume evoking the rectoanal inhibitory reflex or the results of the straining test.

CONCLUSION: 5-HT$_1$ receptors participate in the regulation of anorectal function. Elucidation of the role of 5-HT$_1$ receptors in the pathophysiological mechanisms of IBS may have some therapeutic implications.

Key words: Sumatriptan; 5-HT receptors; Irritable bowel syndrome, Anorectal function

INTRODUCTION

Serotonin (5-hydroxytryptamine, 5-HT) is one of the main neurotransmitters involved in the control of the gastrointestinal tract function and plays an important role in the pathophysiology of irritable bowel syndrome (IBS)[1,2]. A number of abnormal motor and sensory patterns reported in IBS patients is supposed to be a result of disturbances in serotonergic mechanisms. Different 5-HT receptor subtypes are involved in the regulation of enteric reflexes and signaling to the central nervous system[3]. Pharmacological data confirm that the specific 5-HT$_3$ antagonists and 5-HT$_4$ agonists are beneficial in the management of IBS[4-6]. Among new emerging serotonergic agents for functional gastrointestinal disorders the role of 5-HT$_1$ agonists was discussed[7]. Many IBS patients complain of various non-gastrointestinal symptoms and disorders such as headache, migraine, non-cardiac chest pain, back pain, dysuria, sleeping difficulties, chronic fatigue syndrome, fibromyalgia syndrome, anxiety and depression. From the clinical point of view frequent coexistence of IBS with headache reported by 23%-45% of IBS patients may also indicate the common pathogenetic and therapeutic link for these diseases, possibly related to the serotonin-dependent processes[8].

Sumatriptan is a selective 5-HT$_{1B/D}$ agonist used for migraine treatment. Recent research results on sumatriptan effects on the gastrointestinal tract function have shown that the drug alters oesophageal motility, favours transient lower oesophageal sphincter relaxations despite the increase in the lower oesophageal sphincter pressure, prolongs postprandial fundic relaxation delaying gastric emptying, and induces a premature intestinal third phase of the migrating motor complex in the jejunum. Encouraging results have been obtained in patients with dyspepsia and impaired postprandial gastric relaxation treated with sumatriptan[9,10]. A therapeutic potential for 5-HT$_1$ agonists in IBS patients has been also suggested according to the observation that sumatriptan causes a significant relaxation of the descending colon influencing the perception of colonic distension.

Anorectal function in IBS draws attention due to commonly reported symptoms by patients with this disorder including urgency, excessive straining or feeling of incomplete evacuation. Up to now, consistent association

between the above symptoms and anorectal dysfunction has not been clearly established. In some IBS patients anorectal manometry is performed to exclude abnormalities that may coexist with or imitate IBS. Moreover, assessment of anorectal function in IBS patients, particularly by use of anorectal manometry, presents an easily accessible way to evaluate the effects of drugs on the lower gastrointestinal tract function[11].

The aim of the present study was to test the hypothesis that sumatriptan influences anorectal function in patients with IBS.

MATERIALS AND METHODS

Subjects

Twenty-two IBS patients selected according to the Rome II criteria (15 women (F), 7 men (M); mean age 29.3± 6.8, range 22-44 years) participated in the study. Based on the bowel pattern, three subgroups of IBS patients were distinguished – constipation predominant IBS (C-IBS: 5 F, 0 M), diarrhea predominant IBS (D-IBS: 3 F, 4 M), and alternating IBS (A-IBS: 7 F, 3 M).

The organic causes for the symptoms were excluded by the evaluation of detailed medical history and physical examination, basic laboratory tests and normal colonoscopy within the five years preceding inclusion in the study. Patients who previously underwent abdominal or gastrointestinal surgery, except for appendectomy, were not included. Patients with ischemic heart disease, arterial hypertension, after myocardial infarction or cerebral stroke, and over 45 years of age were not included in the study, either. Blood pressure and heart rate values in all subjects were within the normal range. All patients had a normal electrocardiogram performed just before the study. The study was approved by the Ethics Committee of the Medical University Hospital and written informed consent was obtained from all subjects.

Recording methods

Anorectal manometry and rectal balloon distension were performed using a four lumen water-perfused catheter with a polyethylene balloon attached to the tip (Zinetics Manometric Catheter, Medtronic). Pressure was sensed by external pressure transducer connected to an analogue-digital converter (PC Polygraph, Synectics Medical, Synecpol). The system was calibrated at 0 and 6.67 kPa at the beginning of each study. The following measurements were derived from the manomertic recordings: the maximal anal resting pressure (MRP) and the maximal anal squeeze pressure (MSP); the anal sphincter length (SL) and high pressure zone (HPZ) within the anal canal, both during rest and squeeze. Moreover, strain, squeeze and cough tests as well as volume initiating the internal anal sphincter relaxation (rectoanal inhibitory reflex, RAIR) and volume required to elicit first sensation, urgency and discomfort or pain were evaluated.

The maximal resting and squeeze pressure along the anal canal was measured from the rectum to the anal margin by the dynamic pull-through technique. The procedure was performed both in the normal relaxed state and in the voluntary squeeze state by pulling a catheter through the sphincters at a speed of 10 mm/s. Three pulls in both states were performed. Evaluation of the strain and cough tests were carried out using the stationary pull-through technique. RAIR and sensory thresholds were measured by the intermittent, phasic rectal distension, starting with 10 mL of air and increasing in steps of 10 mL. The rectal balloon was emptied after each distension. The duration of the distension amounted to 60 s, with 40-60 s intervals between each inflation. During distensions subjects were asked to report and classify their sensation in terms of the first sensation, urge sensation and the maximal tolerable volume due to discomfort or pain. Whenever unbearable discomfort or painful sensation were experienced during any level of distension the experiment was immediately suspended.

Study protocol

Patients examined after an overnight fast without a cleansing enema in the left lateral position were allowed to acclimate to the assembly for 20 min. Patients were instructed not to take any analgesic, spasmolytic, anxiolytic, antidepressant, or anti-inflammatory agents within 72 h before the examination. Women participating in the study were examined within the first part of the menstrual cycle. The study was blind, randomized and placebo-controlled with a crossover design, in which each subject received placebo and drug on two separate days at least one week apart. After the baseline recordings sumatriptan 6 mg sc (Imigran, Glaxo Wellcome Group) or saline 0.5 mL sc was given in a random fashion. The second recordings were performed 30 min after the administration of the drug or placebo. Therefore, four recordings in each subject were performed (recording before and after sumatriptan injection, and recording before and after placebo injection). Blood pressure and heart rate were monitored during the study. All adverse events were noted.

Pressure data converted by PC polygraph were displayed, recorded, and analyzed on an IBM-compatible computer using Polygram software (Synectics Medical). Baselines were automatically set by the computer program. The amplitude was measured from the baseline to the peak of the resting and squeeze pressure area. The maximal resting anal pressure and the maximal squeeze anal pressure were defined as the mean of the three highest values observed at any site in the anal canal during three pulls in the relaxed state, and in the squeeze state, respectively. Each increase in the pressure during pull was later marked as an event in the tracing. The position of the event marked the position of the anal sphincter. The anal sphincter length is a product of the applied catheter pulling speed and time of the pressure increase during the pull-through procedure. The length of the zone with a pressure higher than the half of the maximal anal resting pressure value was defined as the high pressure zone.

The cough reflex was evaluated by measuring the mean of the three highest increments in the anal canal pressure during cough. The anal canal pressure during attempts to defecate was evaluated to assess the presence of pelvic floor dysynergia. RAIR was defined as a 20% reduction or more in the resting anal pressure in response to the rectal distension. The perception corresponding to each distend-

Table 1 Effect of sumatriptan on manometric and volumetric anorectal parameters in IBS patients (mean ± SD)

Anorectal parameter	Placebo	Sumatriptan
Maximal resting pressure	9.2±2.0 kPa	13.1±3.3 kPa[b]
Sphincter length during rest	4.0±0.5 cm	4.5±0.4 cm[b]
High pressure zone during rest	2.6±0.3 cm	3.1±0.5 cm[b]
Sphincter length during squeeze	5.1±0.4 cm	5.4±0.5 cm[b]
Urge sensation threshold	61±19 mL	68±18 mL[b]
First sensation threshold	27±9 mL	34±12 mL[c]
High pressure zone during squeeze	2.8±0.6 cm	3.0±0.7 cm[c]
Pain threshold: ≤100mL/>100mL (number of patients)	13/9	8/14
Rectoanal inhibitory reflex (RAIR)	21±8 mL	21±9 mL
Straining test results:		
Proper relaxation/lack of relaxation/ contraction (number of patients)	14/7/1	13/8/1
Maximal squeeze pressure	25.5±8.5 kPa	27.2±8.4 kPa
Maximal cough pressure/maximal resting pressure	2.9±0.8	3.1±1.1

[b]P<0.01, [c]P<0.05, *vs* Placebo.

Paired Student's t test was used in all cases except for analysis of straining test results and pain thresholds where chi-square test was used.

ing volume up to 100 mL was recorded.

Statistical analysis

Data are expressed as mean±SD unless otherwise stated. Statistical analysis was performed using paired Student's t test and the chi-square test, as well as EPIINFO statistical package ver. 3.2. Differences were taken to be significant for values of P<0.05.

RESULTS

Influence of placebo on anorectal function

The effect of placebo on the anal sphincter function and rectal perception thresholds was assessed in all 22 IBS patients participating in the study. Administration of placebo had no significant influence on the manometric parameters or on visceral perception thresholds. No changes in the distending volumes inducing the first rectal perception, urgency or pain sensations were observed. Lowered pain threshold (distending volume ⩽ 100 mL), considered as a sign of visceral hypersensitivity in IBS patients, was reported before and after the placebo administration in 12 and 13 patients (55% and 59%), respectively.

Effect of sumatriptan on the anal sphincter function

As compared with placebo, sumatriptan considerably increased the maximal resting pressure (MRP) from 9.2±2.0 kPa to 13.1±3.3 kPa (P<0.0001). The rise in the maximal squeeze pressure (MSP) was not statistically significant (P=0.0634, Table 1). After sumatriptan injection the increase in the anal canal pressure in response to cough (maximal cough pressure, MCP) was higher than after placebo injection. However, the increase in the MCP was proportional to the corresponding resting pressure, as the ratio MCP/MRP after the drug injection was not altered (P=0.245, Table 1). Manometric evaluation of the anal canal pressure during attempts to defecate revealed improper response in 9 patients (41%). Signs of pelvic floor dyssynergia appeared as paradoxical contractions of the anal sphincters in one subject and as a failure to relax the pelvic floor in 8 patients. The administration of the drug, as in the placebo case, did not change the results of the straining test. The anal sphincter length as well as high pressure zone of sphincter pressure evaluated by the pull-through technique during both rest and squeeze remarkably increased after sumatriptan injection (Table 1).

In comparison of the volume evoking the rectoanal inhibitory reflex (RAIR) after placebo and sumatriptan administration, which were respectively 21±8 mL and 21±9 mL, no significant difference was shown (P=0.665).

Effect of sumatriptan on visceral perception

According to the conscious rectal sensitivity thresholds, 30 min after sumatriptan injection significant increases in the thresholds for the first sensation from 27±9 mL to 34±12 mL (P< 0.05) and urgency from 61±19 mL to 68±18 mL (P< 0.01) were observed. During the baseline recordings lowered rectal pain sensation evoked with the distending volume up to 100 mL was observed in 13 IBS patients (59%) including 5 out of 7 D-IBS patients, 8 out of 10 A-IBS patients, and none of C-IBS patients. After the administration of the drug rectal pain threshold increased in 5 out of 13 patients, but in 8 (36%) it was still evoked by the distending volume up to 100 mL. The increase in the pain threshold was not significant (P=0.227).

Adverse events

After placebo administration in 5 out of 22 patients (23%) transient burning sensation in the place of injection was reported. No other adverse events were observed, except for one patient who complained of mild but long-lasting headache (about 7 d). A variety of side effects after the drug administration was reported in 20 out the 22 patients enrolled (91%). The majority of the adverse events were mild to moderate in severity. They began at a mean of 4 min (range 2-8 min) after sumatriptan injection and lasted for a mean of 12.5 min (range 1-25 min). The most commonly reported adverse events after sumatriptan injection were: burning sensation in the place of injection in 45% of patients; headache and throat tightness in 36%; weakness in 32%; tingling of lower and upper jaw or temple and formication of the head or face skin in 27%; flare in the place of injection, heaviness in chest, limbs, and in head in 23%; nose tightness, dyspnoea, bodily warmth, acroparesthesia, abdominal pain or discomfort in 9%; and nausea, drowsiness as well as total numbness in 4.5%. Many side effects occurred simultaneously, but the typical triad of symptoms, called "triptan sensations", i.e. throat tightness, heaviness in chest and bodily warmth, was not observed in any patient. In two patients after sumatriptan administration short-lasting proctalgia (about 1 min) occurred.

DISCUSSION

Based on the manometric evaluation, anorectal dysfunction in IBS patients included the signs of pelvic floor dysynergia observed in 41% of patients and lowered visceral pain thresholds in 59% of patients, particularly in

those with diarhoea predominant IBS and with alternating bowel pattern. According to the literature data an obstructive pattern of defecation is exhibited in about 20% of healthy subjects. Two times higher prevalence of improper response to the straining test in IBS patients, whether constipated or not, may suggest general changes in pelvic floor mobility in IBS. The presented results have shown that sumatriptan, a selective 5-HT$_{1B/D}$ agonist, noticeably affects anorectal function in IBS patients.

The drug administration in a standard therapeutic dose of 6 mg sc induces a considerable increase in the maximal anal resting pressure, and much less significant increase in the maximal anal squeeze pressure. The increase in the anal canal resting pressure observed after sumatriptan administration reflects mainly the internal anal sphincter contraction. On the contrary, squeeze pressure depends mostly on the external anal sphincter. Similarly, other manometric parameters characterising anorectal function and being connected with the anal canal pressure, such as the functional sphincter length and high pressure zone, increased as well. The maximal cough pressure after the drug injection was proportional to the corresponding resting pressure. Sumatriptan did not have any impact on the straining test results.

Interestingly, sumatriptan has also revealed its influence on visceral sensation thresholds. The increases in the first sensation and urge sensation thresholds were proved to be statistically important. During evaluation of rectal sensation, lowered pain threshold with the distending volume up to 100 mL was evoked in 59% IBS patients, which is in accordance with the literature data[12]. Visceral hypersensitivity was common in D-IBS and A-IBS, but not in C-IBS. After sumatriptan administration a tendency to lower visceral hypersensitivity in IBS patients was observed. The statistical analysis, however, did not confirm the significance of the increase in the pain threshold probably due to methodological limitations as with the maximal distending volume amounting to 100 mL not in all IBS patients pain or discomfort sensation was evoked. To evaluate precisely the influence of sumatriptan on rectal pain threshold another study would be needed, in which higher distending volumes and optimally a barostat or tensostat would be used. Regarding the results of the recent studies which have shown that sumatriptan affects the discomfort threshold during gastric and colonic distension, similar observation may be expected in the rectum. The influence of sumatriptan on colonic motility is important for further evaluation.

For better understanding of the role of 5-HT$_1$ receptors, the effect of sumatriptan on lower gastrointestinal tract function in the different subgroups of IBS patients as well as in healthy subjects should be investigated. From the methodological point of view, a crossover design of the study enabled us to avoid considerable interindividual variability common in functional testing such as anorectal manometry. However, an intraindividual variability could still have some impact on the manometric and volumetric parameters. Foster and colleagues used a similar protocol of the study evaluating the effect of sumatriptan on the oesophageal motility. All the women participating in the study were investigated in the follicular phase, as it has been shown that the menstrual cycle affects rectal sensitivity in IBS patients but not healthy volunteers[13]. Patients were examined after an overnight fast to eliminate the gastrointestinal reflexes and the postprandial increase in visceral sensitivity[14,15].

The majority of the adverse events were mild to moderate in severity and short-lasting. However, it cannot be totally excluded that they might stress the patients, and in this way affect the results to some extent.

Several recent studies dealt with the effect of sumatriptan on the upper part of the gastrointestinal tract[9]. Two observations were particularly important from the clinical point of view. The first one concerned chest symptoms, which occurred in 3-5% of patients using sumatriptan in the migraine treatment. Foster *et al* in the study on 16 healthy subjects have shown that a therapeutic dose of sumatriptan (6 mg, sc) altered oesophageal motility without affecting the ECG, supporting at the same time an oesophageal rather than cardiac cause for the sumatriptan-induced chest pain. However, contrary to what happened in healthy subjects, the drug failed to modify either the wave's amplitude or lower oesophageal sphincter tone in patients with ineffective oesophageal motility[16]. The second important observation having a potential therapeutic implication concerned the influence of sumatriptan on gastric fundic tone and sensitivity to distension[9]. Tack and co-workers[9] have shown that in some dyspeptic patients sumatriptan is able to restore impaired gastric accommodation to a meal and improve the early satiety symptom. A therapeutic potential for 5-HT$_1$ receptor agonist is suggested not only in functional dyspepsia, but in other functional gastrointestinal disorders, in particular IBS. The preliminary observation has revealed that sumatriptan causes a significant relaxation of the descending colon influencing the perception of colonic distension.

The present study has confirmed that sumatriptan affects not only the upper but also the lower part of the gastrointestinal tract, including anorectal function and rectal sensation thresholds. The sumatriptan-induced decrease in rectal sensitivity may have a therapeutic implication in IBS patients, particularly in patients with visceral hypersensitivity.

The effect of sumatriptan on the anal sphincter function should be also considered in patients using this drug in the form of suppository. In two patients after sumatriptan injection a short-lasting, transient proctalgia occurred. Hypothetically, it could result from the increase in the maximal resting pressure, or even spasm of the anal sphincter. However, no clinical observations have confirmed this hypothesis so far. On the other hand, various forms of the drug may differently affect gastrointestinal function. For example, it has been shown that, unlike the subcutaneous formulation, the intranasal administration of sumatriptan has no significant effect on gastric sensory and motor function, probably due to a low bioavailability of intranasally administered sumatriptan[17].

Since the resting anal canal pressure depends essentially on the internal anal sphincter (IAS) function the increase in its value after sumatriptan administration seems to result mainly from the IAS contraction. Up to now, research on neurological and pharmacological control of the IAS

function has evaluated quite precisely the role of the adrenergic and cholinergic systems. Recently, the role of non-adrenergic non-cholinergic (NANC) system involving nitric oxide (NO) as a neurotransmitter has been also investigated. Anorectal manometry and rectal sensitivity testing proved to be a useful method for evaluating the influence of pharmacological agents including serotonergic drugs acting on anorectal function in IBS patients[11]. It has been shown that serotonin induces contraction of the IAS, while ketanserin (a 5-HT_2 receptor antagonist) and cisapride (a 5-HT_4 receptor agonist and partial 5-HT_3 receptor antagonist) evokes the IAS relaxation in healthy subjects[18,19]. Prucalopride, a novel selective 5-HT_4 receptor agonist, seems not to influence the anorectal function either in IBS patients or in healthy controls[20], whereas tegaserod, the next 5-HT_4 receptor agonist, decreases sensitivity to rectal distension in healthy subjects[21]. In the study of Thumshirn *et al*[22] alosetron, a 5-HT_3 receptor antagonist, has no significant effect on gastrointestinal transit or rectal sensory and motor mechanisms in patients with non-constipated IBS. Interesting results have been obtained by Siproudhis *et al*[23] who investigated effects of two types of serotonergic antidepressants, amitriptyline and fluoxetine, on anorectal motility and visceral perception. Both antidepressants similarly relaxed the IAS, probably through a non-specific mechanism, without modifying visceral perception. Only amitriptyline relaxed the external anal sphincter[23].

The mechanisms underlying the sumatriptan-induced anorectal function changes remain unclear. The distribution of various types of 5-HT_1 receptors and particularly their role in the gastrointestinal function are also poorly identified. Anorectal function, and in particular visceral perception, are modulated at different levels of the brain-gut axis and theoretically, sumatriptan could be acting at each of these levels[24]. Potential mechanism for the effect of sumatriptan on anorectal function could occur via activation of the 5-$HT_{1B/D}$ receptors acting on enteric neurons. Alternatively, sumatriptan could be acting on sensory nerve terminals to modulate neurotransmitter release. A further possible mechanism could involve a central action of sumatriptan. However, pre-clinical data indicate that sumatriptan only poorly penetrates the blood-brain barrier making a central mechanism less probable.

A nitrergic pathway as a possible mechanism of the drug action on the gastrointestinal function has also been discussed. It has been already shown that the sumatriptan-induced relaxation of gastric fundus is partially mediated through the activation of an NANC mechanism, involving NO as a neurotransmitter, and the sumatriptan-induced relaxation of the gastric fundus is reversibly blocked by inhibition of NO synthase. However, regarding the fact that NO is the main neurotransmitter involved in the occurrence of RAIR, the lack of sumatriptan effect on the volume evoking RAIR might argue against the nitrergic mechanism. More likely a direct smooth muscle response may be modified. Sumatriptan induces not only the anal sphincter contraction, but as it has been shown in another study it causes also the increase in the lower oesophageal sphincter pressure.

Furthermore, it has been already shown that sumatriptan is able to induce endocrine secretion in men, and at the same time, for example somatostatin or glucacon can affect anorectal function. However, measurement of plasma somatostatin and glucagon concentration before and after administration of sumatriptan rules out their release as a mechanism by which sumatriptan may influence gastrointestinal function.

Sumatriptan may alter the perception of rectal distension due to its direct impact on the rectal tone. It has been already shown that the sumatriptan-induced gastric or colonic relaxations induce changes in visceral perception[9,10]. Likewise, higher volume thresholds during rectal sensitivity testing after sumatriptan administration may occur secondary to the drug-induced relaxation of the rectum. Therefore, further studies using a barostat or impedance planimetry are needed to explain this issue. The results obtained hitherto warrant further studies to clarify and verify the regulatory role of 5-HT_1 receptors in the gastrointestinal function and the mechanisms responsible for the effect of sumatriptan on the gastrointestinal sensorimotor function including receptor subtypes involved, and central *vs* peripheral mechanism. Selective and safe 5-HT_1 receptor ligands which are now lacking will be crucial for the future research.

In conclusion, the effect of sumatriptan on the anal sphincter function and rectal sensitivity thresholds indicates that 5-HT_1 receptors participate in the regulation of anorectal function. Better understanding of the role of these receptors in the pathogenesis of IBS may have some therapeutic implications, particularly in patients with visceral hypersensitivity. The possible application of anti-migraine drugs in the management of functional gastrointestinal disorders remains an open issue.

Preliminary results of this study have been presented in part at the 12th United European Gastroenterology Week held in Prague, Czech Republic, September 2004, and published as an abstract in *Gut* 2004; 53 (Suppl VI): A204.

Abstract

AIM: To investigate the expression of genes involved in the gemcitabine-induced cytotoxicity in human pancreatic cancer cells.

METHODS: A human pancreatic cancer cell line, PANC-1, was cultured. 1 x 10^4 PANC-1 cells were plated in 96-well microtiter plates. After being incubated for 24 h, gemcitabine was added to the medium at concentrations ranging 2.5 -1 000 mg/L. The AlamarBlue dye method was used for cell growth analysis. DNA fragmentation was quantitatively assayed using a DNA fragmentation enzyme-linked immunosorbent assay (ELISA) kit. *PAP* and *TP53INP1* mRNA expression was determined using the reverse transcription-polymerase chain reaction with semi-quantitative analysis. The expression of GSK-3β and phospho-GSK-3β proteins was examined with Western blot analysis.

RESULTS: The IC_{50} for the drug after a 48-h exposure to gemcitabine was 16 mg/L. The growth of PANC-1 cells was inhibited by gemcitabine in a concentration-dependent manner ($P < 0.0001$) and the cell growth was also inhibited throughout the time course ($P < 0.0001$). The DNA fragmentation rate in the gemcitabine-treated group at 48 h was 44.7 %, whereas it was 25.3 % in the untreated group. The *PAP* mRNA expression was decreased after being treated with gemcitabine, whereas the *TP53INP1* mRNA was increased by the gemcitabine treatment. Western blot analysis showed that phospho-GSK-3β^{ser9} was induced by the gemcitabine treatment.

CONCLUSION: Gemcitabine suppresses PANC-1 cell proliferation and induces apoptosis. Apoptosis is considered to be associated with the inhibition of PAP and GSK-3β, and the activation of *TP53INP1* and pospho-GSK-3β^{ser9}.

Key words: Gemcitabine; Pancreatitis-associated protein; TP53INP1; GSK-3β; PANC-1

INTRODUCTION

Pancreatic cancer is the fifth most common cause of cancer death in Japan[1]. It is estimated that there are 20000 cases every year, which is similar to the number of deaths from this disease. The reasons for its very high mortality rate include the lack of early diagnosis, a low resectability at the time of initial diagnosis, and the rapid recurrence after resection. Surgery is rarely a curative option in pancreatic cancers because of local extension and metastasis. Chemotherapy for advanced pancreatic cancer is palliative. The use of 5-FU in combination with radiation in the locally advanced setting has been shown to enhance survival. In a randomized trial between gemcitabine and 5-FU, gemcitabine showed significantly better results in terms of the clinical benefit effect and survival[2].

Gemcitabine (2', 2'-difluorodeoxycitidine) is a nucleoside analogue well known for its antitumor activity in several solid tumors[3]. It is one of the drugs effective for pancreatic cancers in the clinical treatment[4]. Various general mechanisms of gemcitabine have been described[5-7]. A primary mechanism of gemcitabine is the blocking of DNA synthesis by inhibiting DNA polymerase activity[8]. Gemcitabine itself is not active until it enters the cells. Its intracellular transport is mediated by facilitated diffusion[9]. Intracellularly, gemcitabine is phosphorylated to its active metabolites by deoxycitidine kinase to difluorodeoxycitidine monophosphate (dfdCMP), difluorodeoxycitidine diphosphate (dfdCDP) and difluorodeoxycitidine triphosphate (dfdCTP). All three of the metabolites interfere at different steps in the processing of DNA. The dfdCTP is incorporated into

DNA and as such can obstruct DNA replication and repair. The dfdCTP can also be incorporated into RNA and can inhibit CTP-synthetase. The dfdCMP can also inhibit dCMP-deaminase. The dfdCDP is an inhibitor of ribonucleotide reductase, and its action was shown to lead to the depletion of the DNA precursor pool, dNTP. Inhibition of DNA synthesis leads to growth inhibition or cell death. In previous studies, gemcitabine has been shown to play a major role in the apoptosis of certain tumor cell lines[10-12]. There are several pathways that relate to gemcitabine-induced apoptosis. Nicole *et al*[13] reported that gemcitabine-mediated apoptosis is caspase-dependent in pancreatic cancers; Jones *et al*[14] showed that gemcitabine-induced apoptosis is achieved through the blocking of NF-kB in non-small cell lung cancer cells (NSCLC). In addition, gemcitabine-induced apoptosis is also related to signal-regulated kinase (ERK), Akt, Bcl-2 and p38 mitogen-activated protein kinase (MAPK) pathways[15-17]. Achiwa *et al*[18] indicated that the increase in human equilibrate nucleoside transport (hENT) expression is a determinant of gemcitabine sensitivity in NSCLC cells. However, the molecular mechanism of gemcitabine-induced apoptosis has not been fully elucidated.

Pancreatitis-associated protein (PAP) is a secretory protein of pancreatic acinar cells. It is almost absent in the normal pancreas, but is induced in acute and chronic pancreatitis. We have reported the expression of *PAP* mRNA in cancer tissues and have measured *PAP* levels in the sera and pancreatic juice of patients with gastrointestinal cancers[19-21]. We found that serum *PAP* levels were increased in 40% of patients with pancreatic cancer. We also reported that *PAP* levels in endoscopically aspirated pancreatic juice were positive in 55% of pancreatic cancers. *PAP* levels were significantly higher in both the serum and pancreatic juice in cases of pancreatic cancer, compared to chronic pancreatitis. Cytokines such as tumor necrosis factor-α, interferon-γ, and interleukin-6 induce *PAP* mRNA expression in the pancreatic acinar AR4-2J cell line. We found that the enhanced expression of *PAP* in pancreatic adenocarcinoma is caused by both ectopic expression in cancer cells and induction in acinar cells[22].

TP53INP1[23] was previously called stress-induced protein (SIP)[24] or p53-dependent inducible nuclear protein (p53DINP1)[25]. *TP53INP1* is strongly induced in acinar cells during acute pancreatitis in mice, and is also overexpressed in response to various stresses in vitro. *TP53INP1* gene expression is wild-type p53-dependent[26]. There is a functional p53-response element within the promoter region of the *TP53INP1* gene, and *TP53INP1* mRNA expression is activated in cells expressing wild-type p53 in response to various stresses. One of the major functions of TP53INP1 is promoting cellular apoptosis. Glycogen synthase kinase 3β (GSK-3β) is a multifunctional serine/threonine kinase mediating various cellular signaling pathways. The particular pathway depends on its substrates for phosphorylation[27]. Since GSK-3β is also an important mediator of an apoptotic signal, it is plausible that the GSK-3β deregulation observed in cancer cells confers resistance to chemotherapy, which is a major cause of treatment failure in human cancers[28].

In this study we investigated the effect of gemcitabine on the PANC-1 cells in terms of apoptosis-related factors.

MATERIALS AND METHODS

Cell culture and gemcitabine treatment

A human pancreatic cancer cell line, PANC-1, obtained from the American Type Culture Collection (ATCC, MD, USA), was maintained in Dulbecco's modified Eagle's medium supplemented with 100 mL/L fetal calf serum, penicillin, and kanamycin at 37℃ in a 50 mL/L CO_2, 950 mL/L air atmosphere. Gemcitabine (Eli-Lilly Japan, Kobe, Japan) at a concentration of 50 mg/mL was dissolved in the serum free culture medium and stored at -20℃ in the freezer. The concentration range of the treatment was from 2.5 mg /L to 1 000 mg/L.

Cell growth evaluation

The Alamarblue dye method was used for cell growth analysis. The 1×10^4 cells were plated in 96-well microtiter plates. After being incubated for 24 h, gemcitabine was added to the medium. Twenty μL of AlamarBlue dye solution (Iwaki Glassware, Inc., Tokyo, Japan) was added to wells containing 200 μL of medium at the time 12, 24, 48, and 72 h. After being incubated for 3 h, the cell growth was evaluated as the absorbance (A) using a spectrophotometer (Dai-Nippon Pharmaceutical Co., Osaka, Japan). An excitation wavelength of 540 nm was used, and the emission was read at 620 nm. The color of AlamarBlue stock is violet, and changes to red when oxidized. Each treatment was applied to 6 wells, and the experiments were repeated 3 times.

DNA fragmentation assay

DNA fragmentation was quantitatively assayed using a DNA fragmentation enzyme-linked immunosorbent assay (ELISA) kit (Boehringer Mannheim GmbH, Mannheim, Germany) according to the protocol. Cells were cultured in flat-bottom, 96-well microplates. After incubation in gemcitabine-supplemented media for 24 h, the cells were detached from the wells. The cells were lysed with lysis buffer, and the lysate was processed for streptavidin-coated microtiter plates. After incubation with biotin-labeled antihistone antibody and peroxidase-labeled anti-DNA antibody, the amount of fragmented DNA was determined using 2, 2'-azino-bis-3-ethylbenzthiazoline-sulfonate (ABTS) as a substrate. The plates were read on a Labsystems integrated EIA (Dai-Nippon Pharmaceutical Co., Osaka, Japan) at wavelengths of 540 nm and 620 nm. Each treatment was added to duplicate wells, and the experiment repeated 3 times.

Total RNA was extracted from pancreatic cancer cells using a SV Total RNA Isolation system kit (Promega, Madison, WI, USA). RNA concentrations were determined with spectrophotometry. RT was performed using a PowerScript™ Reverse Transcriptase kit (Clontech Laboratories, Inc., Palo Alto, CA, USA). First strand cDNA was synthesized from 8 μg of total RNA at 65 ℃ for 5 min after RT; the reverse transcriptase was inactivated by incubating at 42℃ for 60 min and the reaction was terminated by heating at 70℃ for 25 min. Then, cycles

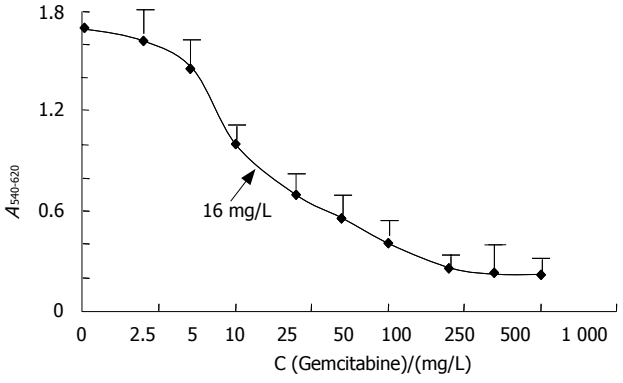

Figure 1 Effect of gemcitabine on the growth of PANC-1 cells.

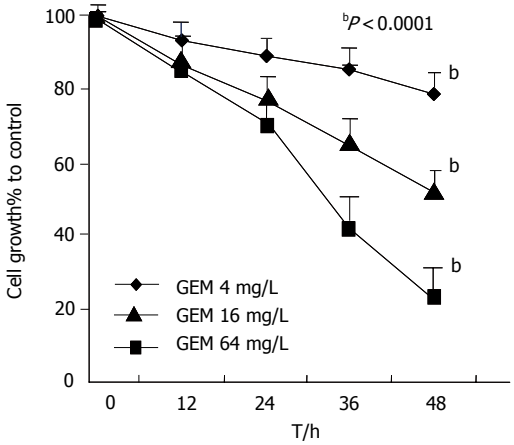

Figure 2 Inhibitory effect of gemcitabine on the growth of PANC-1 cells.

of amplification were performed on a DNA thermal cycler (Perkin Elmer Cetus, Inc., Norwalk, CT, USA) as follows: *PAP* primers were denatured at 91℃ for 60 sec, annealed at 54℃ for 60 sec, and polymerized at 72℃ for 45 sec. Then, extension was performed at 72℃ for 10 min. *TP53INP1* primers were denatured at 94℃ for 50 sec, annealed at 62℃ for 40 sec, and polymerized at 72℃ for 50 sec. The extension was performed at 72℃ for 10 min. The *PAP* primer pairs were sense: 5'-CTCCTGATTGCCTCCTCAAG -3' and antisense: 5'-AAACGTACCCTCTCTTTAGG -3', producing a fragment of 441 bp. *TP53INP1* mRNA was specifically amplified with the following primers: sense 5' -CATCCAGCCAAACTCTCAGTC -3' and antisense 5' -GCGACGAAGGCTATTTCTGT -3'. The size of the fragment was 703 base pairs (bp). The *GAPDH* of 452 bp was used as an internal control. Eight-microgram aliquots of the RT-PCR products were subjected to electrophoresis on a 20 g/L agarose gel and visualized with SYBR Gold (Molecular Probes, Inc., Eugene, OR, USA) at a 1:10000 dilution in dimethylsulfoxide, and exposed to ultraviolet 312-nm light.

Semiquantitative RT-PCR analysis

The gene expression of *PAP* and *TP53INP1* was semiquantitatively analyzed with an image analyzer (ATTO Densitograph ver. 3.02, ATTO, Inc., Tokyo, Japan). The relative expression intensity was calculated according to the following formula: PAP and TP53INP1 mRNA in a sample/GAPDH mRNA in a sample.

Western blot analysis

For Western blot analysis, 1×10^6 PANC-1 cells were lysed in a CelLytic™ mammalia tissue lysis/ extraction reagent buffer (Sigma-Aldrich, St. Louis, MO, USA). Aliquots were boiled for 5 minutes with Laemli buffer, resolved on a 125 g/L SDS-PAGE gel and eletrophoretically transferred to nitrocellulose membrane (Amersham, Buckingham, UK). Membranes were blocked for 1 h in TBS containing 50 g/L dry milk and 1 g/L Tween 20. Membranes were then incubated with either anti-rabbit phospho-GSK-3β (ser9) polyclonal antibody (Cell Signaling Technology, Inc. Beverly, MA, USA) or anti-mouse GSK-3β monoclonal antibody (BD Transduction Laboratories, Lexington, KY, USA) for one night at 4℃. After incubation with anti-rabbit or anti-mouse IgG second antibody labeled with peroxidase, the membranes were visualized with an ATTO image analyzer.

Statistical analysis

Experimental results were expressed as the mean ± SE. The difference between the means was evaluated with the Mann-Whitney *U* test. $P < 0.05$ was considered statistically significant. The statistical analysis was performed using StatView-5.0 (SAS Institute Inc. Tokyo, Japan).

RESULTS

Gemcitabine inhibited cell growth

The median 50% inhibitory concentration (IC_{50}) of gemcitabine after a 48-h exposure was 16 mg/L (Figure 1). We also measured the effect of 4, 16 and 64 mg/L gemcitabine at 12, 24, 36, and 48 h. The growth of PANC-1 cells was inhibited by gemcitabine in a concentration-dependent manner ($P < 0.0001$, Figure 2) and cell growth was also inhibited throughout the time course ($P < 0.0001$).

Gemcitabine induced apoptosis

1×10^4 PANC-1 cells were cultured in flat-bottom, 96-well microplates. After incubation in gemcitabine-supplemented media for 24 h, a DNA fragmentation assay was performed. The concentration of gemcitabine used in the DNA fragmentation assay was 16 mg/L. The DNA fragmentation rate in the gemcitabine-treated group was 44.7%, whereas the fragmentation rate in the untreated group was 25.3%. The fragmentation in the gemcitabine treated group was significantly higher than that in the untreated group ($P = 0.0157$).

Expression of PAP, TP53INP1 mRNA

We exposed the PANC-1 cells to 4, 16 and 64 mg/L gemcitabine for 48 h. The expression of *PAP* and *TP53INP1* mRNA was assessed using RT-PCR. The *PAP* mRNA expression was decreased after being treated with gemcitabine, and disappeared after being treated with 16 mg/L gemcitabine. The semiquantitative analysis showed the intensity of 16 mg/L gemcitabine-treated

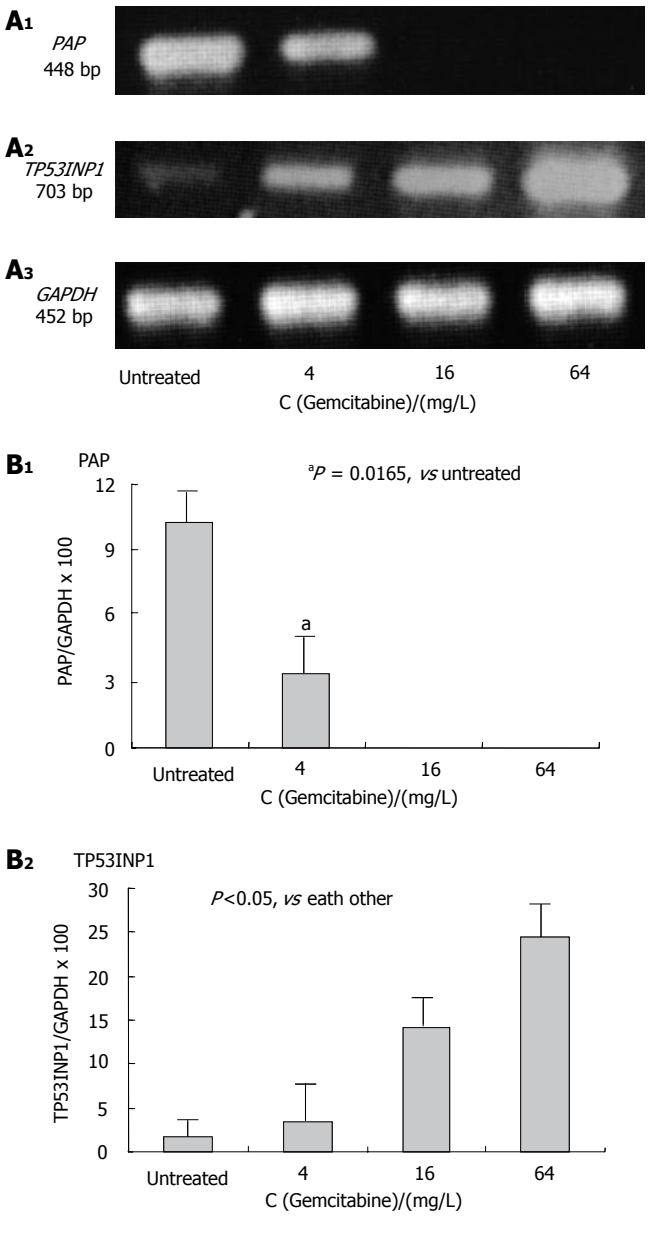

Figure 3 *PAP* mRNA expression after gemcitabine treatment.

cells to be significantly lower than that of the untreated cells ($P = 0.0165$, Figure 3). The *TP53INP1* mRNA was increased after exposure to gemcitabine. The intensity of the cells treated with 4, 16 and 64 mg/L gemcitabine was 2 times, 8.5 times and 14.6 times higher than in the untreated cells, respectively. The increasing density of *TP53INP1* mRNA was concentration-dependent. The *P* value of the interrelation of the untreated group to the 4 mg/L gemcitabine-treated group, 16 mg/L gemcitabine-treated group and 64mg/L gemcitabine-treated group were 0.0015, 0.0009 and 0.0352, respectively.

Expression of phospho-GSK-3β and GSK-3β proteins

The PANC-1 cell line showed no detectable phospho-GSK-3β^{ser9} in Western blotting analysis with a phospho-specific antibody, indicating GSK-3β activity in this cell line (Figure 4). On the other hand, phospho- GSK-3β^{ser9} was induced after 4 mg/L gemcitabine treatment, and gradually increased with the 16 and 64 mg/L gemcitabine

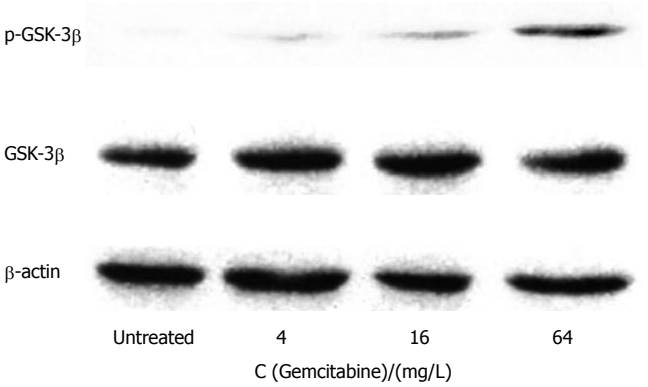

Figure 4 Effect of gemcitabine treatment on GSK-3β expression.

treatment. There was no significant difference in GSK-3β expression between the gemcitabine-treated and untreated groups.

DISCUSSION

Gemcitabine is a nucleotide analog that is converted to its triphosphate active form in cells and is subsequently incorporated into DNA to terminate strand elongation[13-17]. It shows a favorable clinical outcome in the treatment of pancreatic cancer and non-small cell lung cancer[14,18]. However, there have been few published *in vitro* analyses about gemcitabine. We therefore attempted to investigate the genes involved in the gemcitabine-induced cytotoxicity of pancreatic cancer cells. In the present study we showed that gemcitabine induced changes in expression of apoptosis-related genes in PANC-1 cells. The expression of anti-apoptotic pancreatitis-associated protein (PAP) was down-regulated, whereas the pro-apoptotic *TP53INP1* and p-GSK-3β were up-regulated after being treated with gemcitabine.

Apoptosis is believed to play an important role in tumors, and both pro- and anti-apoptotic factors are simultaneously activated in tumor development and progression. In this study, we showed that *PAP* expression was significantly decreased in the gemcitabine-induced anti-tumor process. The growth of human pancreatic cancer may require the up-regulation of *PAP* expression, which would suppress the apoptosis of cancer cells[19]. *PAP* is one of the effectors of antiapoptosis induced by tumor necrosis factor-α through NF-κB and MAP kinases in pancreatic acinar cells[29]. It was demonstrated that the activation status of the NF-κB, Akt and MAP kinase signaling pathways is often associated with anti-apoptotic signal transduction that is linked to chemotherapeutic agents[16]. NF-κB plays an important role in oncogenesis and promotes cellular resistance to anticancer therapy. Bandala *et al*[30] showed that gemcitabine treatment increased the activity of NF-κB, and Alexader *et al*[31] showed that the induction of NF-κB by gemcitabine was dose-dependent in five pancreatic cancer cell lines. In addition, gemcitabine specifically activates p38 MAP kinases in the human pancreatic cancer cell lines, PK-1 and PCI43[16]. Taken together, these findings confirmed that *PAP* is involved in the gemcitabine induced-apoptosis in a

dose-dependent manner.

Apoptosis is one of the major consequences of chemotherapy against malignancies. It is now established that the tumor suppressor p53 inhibits cell growth through the activation of cell cycle arrest and apoptosis. *TP53INP1* is a gene that is activated by wild type p53. It cooperates with HIPK2 to promote p53 phosphorylation at ser 46, and then induces apoptosis-inducing protein activation[25, 26]. In our conditions, we showed *TP53INP1* was up-regulated by gemcitabine treatment from 4 mg/L to 64 mg/L, in a dose-dependent manner. *TP53INP1* may be involved in gemcitabine-mediated apoptosis. The precise mechanism of the *TP53INP1* increase after gemcitabine treatment is unclear. It has been shown that phosphorylation of the NH_2-terminal residues of p53 mediates its stabilization and nuclear accumulation after anticancer drug treatment[28].

Beurel *et al*[28] has reported that GSK-3β is hyperphosphorylated on serine 9 in human hepatoma cell lines as well as in human and murine tumoral livers. We examined the impact of gemcitabine on GSK-3β activity in PANC-1 cells by measuring the phosphorylation level of GSK-3β at serine 9 as an indicator of GSK-3β inactivation. GSK-3β can act as a positive or negative physiological regulator of the p53 protein. During endoplasmic reticulum stress, p53 is inhibited through a mechanism involving its phosphorylation at ser 315 and ser 376 by GSK-3β. On the other hand, GSK-3β plays a crucial role in cell survival mediated by nuclear factor-kappaB (NF-κB) signaling. Phospho- GSK-$3\beta^{ser9}$ is an inactive form in normal tissues that suggests the regulation of the balanced expression of the active and inactive forms of this kinase. In our data, phospho- GSK-$3\beta^{ser9}$ was induced by gemcitabine treatment, indicating that GSK-3βgradually became inactive in the gemcitabine-treated cells. Our results are similar to those of Beurel *et al*[28], who showed that GSK-$3\beta^{ser9}$ phosphorylation by lithium treatment on tumor cells conferred resistance to anticancer therapy.

In conclusion, gemcitabine decreases cell proliferation of a human pancreatic cancer cell line, PANC-1, and promotes cellular apoptosis. The antiapoptotic gene, *PAP*, is down-regulated by gemcitabine treatment, whereas the pro-apoptotic *TP53INP1* gene and GSK-$3\beta^{ser9}$ protein are up-regulated. Gemcitabine can induce apoptosis in cancer cells through GSK-3β and *PAP* inhibition, and *TP53INP1* and GSK-$3\beta^{ser9}$ activation.

Abstract

AIM: To investigate the role of mangafodipir trisodium (MnDPDP) in focal pancreatic masses and mass-like lesions by evaluating contrast uptake features of the lesions and pancreatic parenchyma after contrast medium injection.

METHODS: A total of 37 patients with pancreatic mass or mass-like lesions were examined by unenhanced and MnDPDP-enhanced magnetic resonance imaging (MRI).

RESULTS: MRI was obtained 20-40 min after infusion of MnDPDP and homogeneous contrast enhancement was observed in normal pancreas parenchyma. In patients with atrophic pancreas there was no enhancement in pancreatic parenchyma on MnDPDP-enhanced MRI. In 37 patients with 41 pancreatic masses and mass-like lesions, contrast enhancement was observed at 5 lesions on MnDPDP enhanced MRI. Three of these 5 lesions were focal pancreatitis and the other 2 were adenocarcinoma. No contrast enhancement was determined in 36 pancreatic masses and mass-like lesions in 32 patients.

CONCLUSION: MnDPDP contrast-enhanced MRI, especially in cases with no parenchyma atrophy, can distinguish focal pancreatic lesion margins. Information about the function of pancreatic parenchyma can be obtained out of tumor. MnDPDP facilitates staging of pancreatic tumors by detection of metastatic lesions in the liver. In addition, diminished hetergenous uptake of MnDPDP in patients with pancreatitis may be helpful in differential diagnosis.

Key words: MnDPDP; Pancreas; MRI

INTRODUCTION

Diagnosis of focal pancreatic lesions is a significant challenge for radiologists and surgeons. Focal pancreatic lesions originate from the exocrine (mainly ductal adenocarcinomas) or endocrine part of gland (apudomas), cysts and/or inflammatory lesions. The diagnosis of apudoma is based on the elevated levels of circulating hormones, while the diagnosis of all other focal pancreatic lesions is mainly based on diagnostic imaging[1].

The relation of tumor with its surrounding structures can be described by cross-sectional techniques such as ultrasonography (US), CT and MRI. Ultrasonography has been proved as a first screening mode to depict the panceatic head and duct, the common bile duct and major vessels, but its value is limited by air in the digestive tract and its operator. Contrast enhanced triphasic spiral CT has an accuracy of only 70% for local staging[2]. Surgical procedures are therefore sometimes needed for diagnostic purposes[3,4]. Consequently there is a need for imaging methods with a higher sensitivity and specifity for identifying and staging pancreatic lesions to diminish the number of unnecessary laparotomies.

MnDPDP (Teslascan, Amersham, GE Heralth Care) is an organ-specific paramagnetic contrast agent that has been developed for imaging of the hepatobiliary system. Significant tissue uptake is seen mainly in the liver but much less in the renal cortex, adrenal glands, pancreas and other abdominal organs[5-7]. MnDPDP enables to get images with a higher signal-to-noise (S/N) ratio[8].

In this study, pancreatic mass and mass-like lesions were examined by MRI performed using MnDPDP. The aim of this study was to investigate the role of MnDPDP in focal pancreatic masses and mass-like lesions by evaluating features of their contrast uptake after contrast medium injection.

Table 1 Localization of pancreatic mass and mass-like lesions

	Patients (*n*)	Localization			Lesions (*n*)
		Head	Corpus	Tail	
Pancreas Ca	24	16	5	4	25[1]
Gastrinoma	1			1	1
Lymphoma	1			1	1
Lipoma	1			1	1
Focal pancreatitis	3	2		1	3
Pseudocyst	4	1	4	2	7[2]
Hydatid cyst	1	1			1
Choledochal cyst	1	1			1

[1]Two masses in a patient.
[2]Two masses in a patient and three masses in the other.

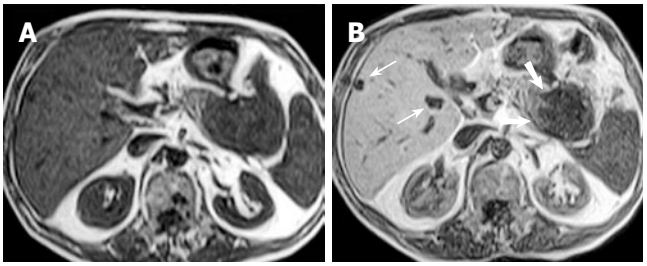

Figure 1 T1-weighted axial SE contrast-unenhanced (A) and MnDPDP-enhanced (B) images of pancreatic adenocarcinoma with liver metastases. MnDPDP enhancement was not determined in the lesion while the normal parenchyma of the pancreas showed homogeneous contrast enhancement. MnDPDP- enhanced image showed the better delination of the tumor (thick arrows). Tiny liver metastases (thin arrows) were not determined on unenhanced MR image but on MnDPDP-enhanced MRI.

MATERIALS AND METHODS

Pancreatic mass lesions or suspicious mass were determined in 37 patients (24 men, 13 women) with a mean age of 58.1 years (range 23-83 years) by US and CT. All patients underwent MnDPDP-enhanced and unenhanced MRI. The patients who received any contrast agent within 1 h before MnDPDP-enhanced MRI or had obstructive hepatobiliary disease or biliary stasis or severe renal impairment, or were contraindicative for CT or MRI or previously enrolled into this study, or defined as pregnancy or lactation, were excluded. The study was approved by the local ethical committee.

MR imaging was performed at 1.5 T (Picker Edge, Picker Internationals Highlands Height, OH) using a body coil. Sequences of axial T2-weighted fast-spin-echo (TR/TE: 8600-9700/96 msec matrix 192×256, slice thickness 3,5 mm, flip angle 90, FOV 40-55 cm), axial and coronal T1-weighted gradient echo (TR/TE: 155/8.1 msec, matrix 160x256, slice thickness 3 mm, gap 0,5 mm, flip angle 60, FOV 40-55 cm, breath-hold 15-20 sec) were applied in all patients before administration of contrast agent. Images of the coronal plane were obtained using only one of the three sequences (SE, gradient echo or fat sat gradient echo).

MnDPDP was injected intravenously at a dosage of 10 μmol/kg (2-3 mL/min) for 15 minutes. Postcontrast imaging was obtained using the same protocol and sequences (except for T2 weighted fast SE sequence) approximately 30 minutes after contrast administration. After contrast medium injection, the size, number, appearance, characteristics of the lesions were compared with normal pancreatic parenchyma. Also contrast uptake level in the lesions and pancreatic parenchyma were evaluated.

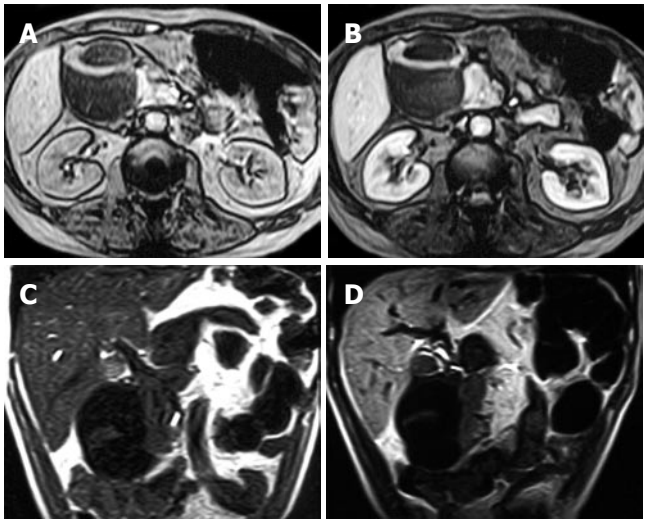

Figure 2 Unenhanced (A) and MnDPDP-enhanced (B) axial T1-weighted GRE images, unenhanced (C) and MnDPDP-enhanced (D) coronal T1-weighted SE images in pancreatic parenchyma out of lesion and liver parenchyma after MnDPDP infusion. Minimal contrast enhancement in the septa of mass was found on MnDPDP-enhanced images (B and D).

RESULTS

Diagnosis of all patients was confirmed by radiological, clinical and histopathological examination (Table 1). Twenty-three of the 37 patients underwent surgical intervention and percutaneous biopsy was performed in 5 patients with primary or metastatic lesions. In the remaining 9 patients, diagnosis was confirmed by clinical and radiological follow-up. Twenty-four patients with pancreatic carcinoma underwent MnDPDP-enhanced abdominal MRI. In 22 of 24 patients, contrast medium uptake in the mass lesions was not determined (Figure 1). Minimal heterogeneous contrast enhancement was seen in one of the 2 patients with contrast-enhanced masses and contrast enhancement of the septa was observed in the other patient with mucinous cystadenocarcinoma (Figure 2).

In patients with pancrea carcinoma contrast enhancement of pancreatic parencyhma out of the mass was evaluatedtic. Contrast enhancement was determined in 13 cases and no contrast enhancement was observed in 11 cases. Homogeneous contrast enhancement of pancreatic parencyhma was seen in 11 cases. MnDPDP-enhanced images revealed a significant improvement in the demarcation and depiction of pancreatic masses as compared to non-enhanced images. Contrast uptake of parenchyma out of mass was minimal in the other 2 cases. In these cases of pancreatic head carcinoma, pancreatitis was found with enlarged and heterogeneous contrast enhancement at the pancreatic parencyhma. In 11 patients with pancreas car-

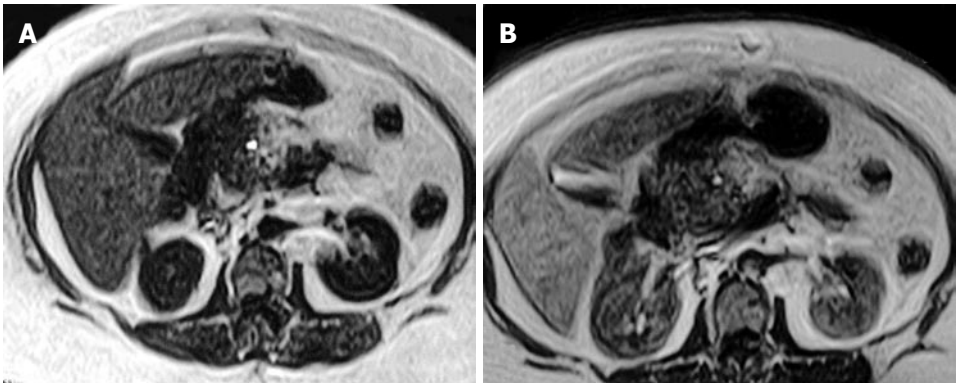

Figure 3 Contrast-unenhanced T1-weighted axial SE image demonstrating focal enlargement of the pancreatic head with a low signal intensity, simulating the appearence of pancreatic cancer (A) and MnDPDP-enhanced T1-weighted axial SE image showing heterogeneous and reduced contrast enhancement in this focal lesion (B).

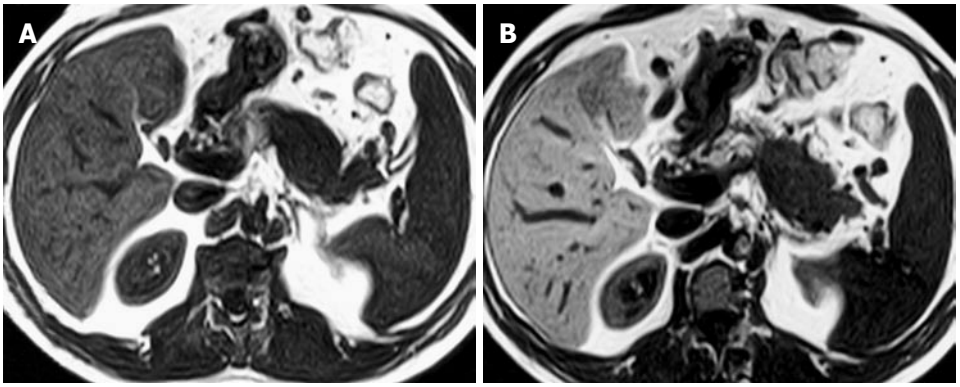

Figure 4 Unenhanced (A) and MnDPDP-enhanced (B) axial T1-weighted SE images showing better delineation of the tumor after MnDPDP infusion.

cinoma, pancreatic parencyhma was atrophic, indicating that these patients after MnDPDP infusion had no contrast enhancement in parencyhma out of the mass. In 3 patients with focal pancreatitis, the lesions were located at the tail in 1 case and at the head in 2 cases. Heterogeneous and reduced contrast enhancement in the focal lesions and homogeneous enhancement of parencyhma out of the lesion were observed in all the 3 cases after MnDPDP infusion (Figure 3). In patients with pancreas pseudocyst, metastatic lesion, hydatid cyst, aggressive type non-Hodgkin's lymphoma, lipoma, choledochal cyst and gastrinoma (Figure 4), no contrast enhancement was seen in all masses after MnDPDP infusion. In 37 patients with pancreatic masses or mass-like lesions, minimal contrast enhancement was established in 5 of 41 lesions (12.2%) by MnDPDP-enhanced MRI. No contrast enhancement was determined in 36 (87.8%) pancreatic masses or mass-like lesions in 32 patients.

DISCUSSION

Ductal adenocarcinoma of the pancreas comprises 75-90 % of all tumors of the pancreas[9]. Abdominal discomfort, back pain, obstructive jaundice and weight loss are the most common symptoms of pancreatic cancer[10]. The only potential cure for pancreatic neoplasms is surgery. Therefore early diagnognosis and assessment of tumor resectability are fundamental to achieve a successful treatment[11]. Bluemke *et al*[3] reported that ductal adenocarcinoma can be detected with helical CT and that further efforts to improve the preoperative staging of pancreatic ductal adenocarcinoma with helical CT should be directed toward improving the detection of small pancreatic ductal adenocarcinomas. Vellet *et al*[12] also reported that non-contour deforming small adenocarcinomas may not be detected by dynamic CT. Small pancreatic masses can be readily detected by MnDPDP-enhanced MRI and the sensitivity of MRI in staging of tumor is increased[13]. Gehl *et al*[14] reported that pancreatic enhancement is increased by 98% after MnDPDP injection. It was also found that after MnDPDP infusion, signal intensity of normal pancreatic parencyhma rises while tumor remains with less signal intensity[15].

Tumor-forming pancreatitis, also known as pseudotumorous pancreatitis or inflammatory pancreatic mass, is presented as a mass-like glandular enlargement. Focal enlargement of the pancreas typically involving head of the pancreas and common bile duct may occur, simulating the development of malignant neoplasms. Since the signal intensity and nonspecific contrast enhancement patterns of this tumor are similar to those of malignant tumor, their differential diagnosis is usually diffucult[16]. In our study, minimal heterogeneous contrast enhancement was observed in 3 patients with local pancreatitis by MnDPDP-enhanced MRI.

In patients with pancreatic adenocarcinomas, the contrast enhancement was compared to the proximal and distal part of tumor after MnDPDP infusion and less enhancement was found in the distal part of tumor. This may be caused by the obstruction of the pancreatic duct which is often found adjacent to the distal part of tumor[1]. In our study, pancreatic contrast enhancement at the distal part of tumor was poor in 2 cases because of pancreatitis adjacent to the distal part of tumor. Duct dilatation and atrophy of the pancreatic tail and body can be seen due to obstruction of the pancreatic duct in malignant tumor at the head of the pancreas. The parenchyma may have

a poor function even though atrophy does not occur, contrast enhancement of parenchyma becomes markedly less[8].

In our study, no uptake of contrast medium was observed in 11 patients with pancreatic malignant tumor by MnDPDP-enhanced MRI. Contrast enhancement of tumor was not observed in patients with tumor (out of 2 cases). On MnDPDP-enhanced T1-weighted images, minimal contrast-enhanced mass was detected in 1 patient with adenocarcinoma at the head of pancreas and contrast enhancement was observed in septa of mass of the other patient with mucinous cystadenocarcinoma, demonstrating that MnDPDP-enhanced MRI gives a better delineation of the tumor, especially in patients with no parenchyma atrophy. It may be difficult to distinguish the lesions simulating the occurrence of malignant neoplasms in patients with focal pancreatitis from malignant tumors. Diminished heteregenous uptake of MnDPDP of the lesions in patients with pancreatitis may be helpful in differential diagnosis.

MnDPDP is used as an organ specific contrast agent orginally designed for liver imaging. Since the agent is taken up by hepatocytes, increased contrast between normal liver parenchyma and metastatic liver lesions can be achieved. MnDPDP facilitates staging of pancreatic tumors by providing easily detection of metastatic lesions to the liver. MnDPDP may improve the staging of pancreatic cancer by increasing the sensitivity of MRI in the detection of liver metastases. MnDPDP-enhanced MRI can improve the accuracy of detection ratio and staging of focal pancreatic lesions, and is a safe and well tolerated noninvasive diagnostic method.

Abstract

AIM: To assess the hypercoagulability in PBC and its relationship with homocysteine (HCY) and various components of the haemostatic system.

METHODS: We investigated 51 PBC patients (43F/8M; mean age: 63±13.9 yr) and 102 healthy subjects (86 women/16 men; 63±13 yr), and evaluated the haemostatic process in whole blood by the Sonoclot analysis and the platelet function by PFA-100 device. We then measured HCY (fasting and after methionine loading), tissue factor (TF), thrombin-antithrombin complexes (TAT), D-dimer (D-D), thrombomodulin (TM), folic acid, vitamin B6 and B12 plasma levels. C677T 5,10-methylenetetrahydrofolate reductase (MTHFR) polymorphism was analyzed.

RESULTS: Sonoclot RATE values of patients were significantly ($P < 0.001$) higher than those of controls. Sonoclot time to peak values and PFA-100 closure times were comparable in patients and controls. TAT, TF and HCY levels, both in the fasting and post-methionine loading, were significantly ($P < 0.001$) higher in patients than in controls. Vitamin deficiencies were detected in 45/51 patients (88.2%). The prevalence of the homozygous TT677 MTHFR genotype was significantly higher in patients (31.4%) than in controls (17.5%) ($P < 0.05$). Sonoclot RATE values correlated significantly with HCY levels and TF.

CONCLUSION: In PBC, hyper-HCY is related to hypovitaminosis and genetic predisposing factors. Increased TF and HCY levels and signs of endothelial activation are associated with hypercoagulability and may have an important role in blood clotting activation.

INTRODUCTION

Primary biliary cirrhosis is deemed to be an autoimmune chronic cholestatic disorder of the liver that primarily affects middle aged women. Currently, the diagnosis of PBC is often made when the patient is still asymptomatic, with abnormal liver biochemistry and/or antimitochondrial antibodies (AMA). The symptomatic patients may have fatigue, generalized pruritus, osteoporosis, fat soluble vitamin deficiencies and portal hypertension[1,2]. The disease generally progresses slowly but survival is less than age- and gender-matched general population and natural history may vary greatly from patient to another[3].

Thrombosis of portal veins has been detected in 40% of PBC livers resected at orthotopic liver transplantation (OLTx) and is correlated with history of bleeding varices[4]. It has been hypothesized that portal veins thrombosis may be responsible for causing development of non-cirrhotic portal hypertension and progression of liver fibrosis[5,6]. A higher incidence of thrombosis of portal venous tree may be promoted by a hypercoagulable state[7] and recent evidence has demonstrated that PBC patients were hypercoagulable on thromboelastography[8,9]. Scarce data are available on the possible causes of this hypercoagulability. In particular, plasma coagulation factors have not been completely evaluated in these patients.

Hyperhomocysteinemia has been found to be associated with a hypercoagulable state and liver fibrosis[10,11]. It has been documented that mean basal and post-methionine load serum HCY levels are significantly higher in patients with PBC than healthy controls[12]. However these findings

need to be confirmed and no data are available on the genetic and acquired causes of such hyperhomocysteinemia and its relationship with hypercoagulability in patients with PBC.

The aim of this study was to investigate basal and post-methionine load serum homocysteine levels, various components of plasmatic coagulation, platelet function and their relationship with hypercoagulability in PBC patients.

MATERIALS AND METHODS

Subjects

Fifty-one consecutive patients with a diagnosis of PBC (43 women and 8 men; age: median 63±13.9 yr (range 20-76) referred to the Gastroenterology Unit of the University of Florence from December 2001 to July 2002, were enrolled. We divided the patients into four staging severity groups: 12 patients in stage I, 11 in stage II, 15 in stage III and 13 in stage IV. Exclusion criteria were renal insufficiency, consumption of alcohol, therapy with steroids, anticoagulants, NSAIDs or methotrexate, folic acid and vitamin B12 supplementation. All patients were stable with no history of bleeding or infectious complications at least 6 wk before evaluation. Routine laboratory investigations included aPTT, PT, fibrinogen, liver function tests (bilirubin, alkaline phosphatase, albumin, aspartate and alanine transaminases), creatinine, cholesterol, iron, calcium, and antimitochondrial antibodies (AMA). All cholestatic patients received vitamin K. All patients had a screening for thyroid-associated disease and intestinal bowel diseases.

One hundred and two healthy subjects with no previous history of liver disease, comparable for age and sex (86 women and 16 men; median 63±13 (range 18-75) yr), recruited from blood donors of our hospital and laboratory volunteers, were used as control group. Patients and controls gave their informed consent to use part of their blood samples for an experimental study.

Experimental procedures

Venous blood samples were collected from the basilical vein after discarding the first 2 mL of blood. We determined HCY plasma levels in the fasting state and 4 h after an oral load with methionine. One hundred mg/Kg of body weight of L-methionine was administered in approximately 200 mL of fruit juice immediately after the fasting phlebotomy.

Sonoclot™ analysis

The haemostatic process in whole blood has been measured by the Sonoclot™ (Sienco Company, Morrison, CO) analysis, a viscoelastic test on whole blood collected in tubes containing 0.129 M sodium citrate. (Saleem 83) Sonoclot analysis was performed within 30 min from the phlebotomy, with 360 μL citrated blood recalcified with 15 μL of calcium chloride (0.25 mol/L). The following variables were analyzed: (1) the clot RATE, i.e. the gradient of the primary slope measured as Clot Signal Units per minute which is an index of clot formation affected by both platelets and coagulation proteins; (2) the time to peak amplitude (TP) (minutes) which reflects the clot retraction away from the surface of the probe and is mainly influenced by the platelet function.

Platelet function analysis

Platelet function was evaluated by the PFA-100 ® device (Dade-Behring) on whole blood collected in tubes containing 0.129 M sodium citrate. The closure times (CT) were determined on duplicate samples (0.8 mL) within 2 hours of collection, using cartridges containing collagen-coated membranes with epinephrine (Col/Epi cartridge) or ADP (Col/ADP cartridge) as previously described[9].

Blood coagulation parameters

D-dimer (D-D), thrombin-antithrombin complex (TAT), tissue factor (TF) and thrombomodulin (TM) plasma levels were evaluated using ELISA method (D-D: Agen, Brisbane, Australia; TAT: Dade Behring, Marburg, Germany; TF: American Diagnostica, Greenwich,CT,USA; TM: Diagnostica Stago, Asnieres, France) on blood samples collected in tubes containing 0.129 M sodium citrate, immediately centrifugated at 4 ℃ and stored in plasma aliquots at -80 ℃ and assayed within two weeks.

Homocysteine assay

To determine HCY, whole blood was collected in tubes containing ethylenediaminotetracetate (EDTA) 0.17 mol/L, immediately put in ice and centrifuged within 30 minutes at 4 ℃ (15000 x g for 15 min). The supernatant was stored in aliquots at -80 ℃ until assay. Homocysteine plasma levels were detected by FPIA method (Abbott, Wiesbaden, Germany).

Vitamin pattern

Serum folic acid and vitamin B12 were measured by radioassay (ICN Pharmaceuticals, NY)). Serum vitamin B6 was measured with HPLC method and fluorescence detecting (Immundiagnostik, Benheim, Germany).

MTHFR polymorphism

Genomic DNA was extracted from peripheral blood leukocytes. C677T polymorphism in the MTHFR gene was carried out on genomic DNA by PCR amplification as already described[13].

Statistical analysis

All analyses were performed with SPSS 10.0 for Windows (SPSS, Chicago, IL, USA). The non-parametric Mann-Whitney test for unpaired data was used for comparisons between single groups. Spearman's rank correlation coefficient (for non-parametric data) was used for the correlation analysis. Fasting and post-methionine hyperhomocysteinemia were defined based on the 95th percentile cut-off of the control population (Fasting: M=15 μmol/L, F=13 μmol/L; Post-methionine: M=38 μmol/L, F=35 μmol/L).

For genetic analysis, Hardy-Weinberg equilibrium was assessed using χ^2 analysis. All probability values are two-tailed with values less than 0.05 considered to be

statistically significant.

RESULTS

Laboratory characteristics of patients investigated according to the stage of disease are shown in Table 1.

Blood Coagulation and Platelet Analysis

Sonoclot RATE values of PBC patients were significantly higher than those of controls ($P < 0.001$). In both the 29/51 (57%) PBC patients with a platelet count in normal range and the 22/51 (43%) PBC patients with thrombocytopenia as well as 26/51 (51%) PBC patients, the Sonoclot RATE value was higher than 95% of controls ($P < 0.001$) (Table 2).

Sonoclot TP values were significantly higher only in PBC patients with thrombocytopenia. Indeed, a significant difference of Sonoclot TP ($P < 0.001$) values was observed between PBC patients with a normal platelet count and with thrombocytopenia (Table 2). The hypercoagulable state and the increased TF circulating levels were independent of the disease's stage, and were presented even in the first stage of the disease (data not shown).

PFA-100 closure times after stimulation with epinephrine or ADP were comparable in patients with PBC and controls (Table 2). In 9/51 (17.6%) PBC patients, D-dimer plasma levels were higher than 95% of controls but the difference did not reach the statistical significance ($P = 0.16$).

TAT, thrombomodulin and tissue factor levels were significantly higher in patients than in controls (TAT 2.8±13.9 (1.5-87.3) μg/L *vs* 2.5±0.52 (1.1-4.2) μg/L; TM 23.7±3.5, (2.6-153.5) ng/mL *vs* 13.8±4.4 (7.6-23.1) ng/mL; TF 255.6±223.0 (81.4-1259.6) pg/mL *vs* 121.9±81.9 (24.8-466.1) pg/mL; $P < 0.001$).

Homocysteine

HCY plasma levels, both in the fasting state and post-methionine loading, were significantly higher in patients than in controls (Fasting: 12.1±8.76 (1.5-58.8) μmol/L *vs* 9.9±1.7 (6.4-18.0) μmol/L; Post-methionine 30.1±14.4 (9.2-99.6) μmol/L *vs* 28.0±5.23 (16.4-38.9) μmol/L, $P < 0.001$) (Table 3). Totally, hyperhomocysteinemia (defined as a concentration of fasting and/or post-methionine HCY above 95% of controls) was diagnosed in 23/51 patients (45.1%) (8 only fasting; 4 only PM; 11 both). No significant difference in plasma HCY levels was detected between four staging severity groups.

Folic acid, vitamins B12 and B6

Vitamin deficiencies (defined as a vitamin concentration below the 10th percentile of controls) were detected in 45/51 patients (88.2%).

Deficiency of folate (defined as a concentration less than 6.4 ng/mL) was documented in 39/51 (76.5%); deficiency of vitamin B12 (defined as a concentration less than 243.7 pg/mL) was found in 6/51 patients (11.8%). Deficiency of vitamin B6 (defined as a concentration less than 3.4 pg/mL) was found in 3/51 patients (5.8%). Three patients had low levels of both folic acid and vitamin B12, 1 patient of both vitamin B12 and B6 and 2 patients of both folic acid and vitamin B6.

Vitamins median values are shown in Table 3.

MTHFR C677T polymorphism

The allele frequency of the C677T polymorphism was 0.52 in patients and 0.45 in controls. The distribution of the three genotypes in controls was as follows: TT 17.5 %; CT 55.3%; CC 27.2%. The genotype distribution in patients was as following: TT 31.4%; CT 41.2%; CC 27.4%. The prevalence of the homozygous TT677 genotype was significantly higher in patients (31.4%) than in controls (17.5%) ($P < 0.05$).

Table 3 Homocysteine and vitamin levels in PBC patients and controls

	PBC Patients ($n = 51$)	Controls ($n = 102$)
Fasting HCY (μmol/L)	12.1 (1.8-58.8)[b]	9.9 (6.4-18.0)
Post-methionine HCY (μmol/L)	30.1 (9.2-99.6)[b]	28.0(16.4-38.9)
Folic Acid (ng/mL)	5.3(1.2-13.4)[b]	10.7(5.4-18.5)
Vitamin B12 (pg/mL)	335 (201-977)[a]	304.9(176-427.1)
Vitamin B6 (pg/mL)	6.6 (1-20)[b]	10.0 (3-17)

[a]$P < 0.05$ *vs* controls; [b]$P < 0.001$ *vs* control.

Table 4 TTMTHFR polymorphism and vitamin state in 51 PBC patients *n* (%)

MMTHFR	Low folate, normal HCY	Normal folate, high HCY	Low folate, high HCY	Normal folate, normal HCY	Total *No* patients
CT	8 (38)	0	10 (47.6)	3 (14.45)	21
CC	8 (57)	0	2 (14.5)	4 (28.5)	14
TT	3 (18.7)	2 (12.5)	9 (56)	2 (12.5)	16
Total	19	2	21	9	

Patients with the homozygous TT677 genotype had higher, but not statistically significant HCY levels than those with C677T and CC677 genotypes (TT = 13.3 (1.8-58.8) μmol/L; CT = 12.3 (7.9-42.6) μmol/L; CC = 10.2 (6.0-21.7) μmol/L).

TTMTHFR polymorphism and/or vitamin deficiencies were present in all hyperhomocysteinemic patients (Table 4). In other words, in patients with normal folic acid plasma levels homocysteinemia was normal except for two patients with TTMTHFR polymorphism.

Correlation between the parameters investigated

A significant correlation between Sonoclot rate values, TAT ($r = 0.44$, $P < 0.001$), TF plasma levels ($r = 0.30$, $P < 0.05$) and basal HCY ($r = 0.45$, $P < 0.001$) was observed. Sonoclot rate was significantly higher in patients with high fasting state and/or post-methionine than in the other patients [34 ± 7.4 (22-45) U/min *vs* 26 ± 5.4 (14-49) U/min (Figure 1)]. Moreover, a significant correlation was detected between HCY, TM ($r = 0.54$, $P < 0.001$) and TF ($r = 0.55$, $P < 0.05$).

TAT levels correlated significantly with TF ($r = 0.43$, $P < 0.05$) while HCY plasma levels correlated significantly with cholesterol plasma levels ($r = 0.55$, $P < 0.001$).

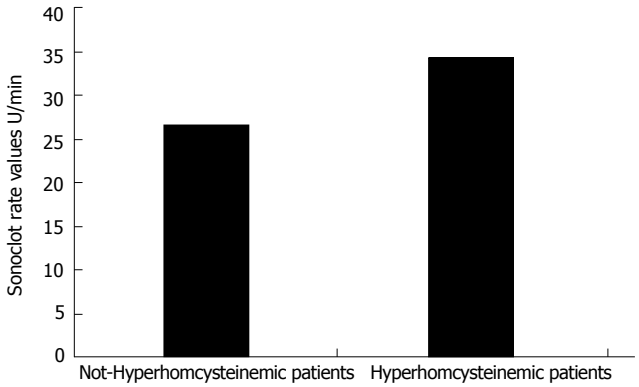

Figure 1 Sonoclot rate values in PBC patients with or without hyperhomocysteinemia.

DISCUSSION

Hypercoagulability in PBC has been previously documented with thromboelastography[8,9], and here we have confirmed this finding with Sonoclot, another technique of analysis of haemostatic process, and demonstrated high TAT circulating levels in 51 PBC patients.

Hypercoagulability may have two different roles in natural history of PBC: it could promote portal veins thrombosis and liver damage and on the other hand it could be responsible for a more favourable prognosis of variceal bleeding[14,15] and a lower blood loss at liver transplantation[11,16-19]. It has been hypothesized that portal veins thrombosis may be responsible for causing development of regenerative nodules and non-cirrhotic portal hypertension and progression of liver fibrosis[5,6]. In PBC patients hypercoagulability may contribute to the high incidence of oesophageal varices in early histological stages associated with the presence of regenerating nodules[20]. A recent study demonstrated that anticoagulant therapy with a thrombin antagonism can reduce fibrogenesis in rat liver[21], it could be interesting to evaluate if a correction of hypercoagulability could reduce the intrahepatic thrombosis formation and development of liver fibrosis and portal hypertension.

Moreover we found that TF might be involved in determination of thrombophilic status, in fact TF levels are higher in PBC patients than in healthy controls and are related to Sonoclot Rate values. TF is a glycoprotein present on the surface of the plasma membranes of monocytes, endothelial cells and smooth muscle cells[22,23], and it is the primary cellular trigger of the coagulation cascade. In our patients clinical conditions that may affect TF concentrations such as infections, neoplasia, or heparin administration have been ruled out. Lymphocyte activation is able to induce tissue factor expression by monocytes[23]. PBC is characterized by an intense biliary and systemic inflammatory CD4+ and CD8+ T cell response[23,25] and may be responsible for tissue factor expression and subsequent elevation of circulating levels.

Our data confirm the finding of elevated homocysteine levels in patients with PBC. Hyperhomocysteinemia has been found to be associated with a hypercoagulable state and liver fibrosis[10]. Here we demonstrated that HCY levels are associated with hypercoagulability and, as reported by others in the setting of thrombotic diseases[26,27], in this study we offer the "*in vivo*" demonstration that in PBC patients high levels of HCY are related to increased TF plasma concentration. TF expression by endothelial cells and monocyte-macrophages may be induced by HCY. This effect has been documented *in vitro* studies, in experimental animals and in hyperhomocysteinemic patients in a specific and dose-dependent manner[28]. HCY may be one of the mechanisms involved in the endothelial stimulation, as documented by the significant correlation with TM levels, which are significantly higher in patients than in controls.

Platelet function has been investigated by two parameters: Sonoclot TP value and PFA-100 closure time. Both of them have been found to be comparable or even higher than healthy controls values. These data are similar to those presented by Pihush *et al*[9].

As regards fibrinolysis, our data demonstrate that the hypercoagulable state in PBC patients is not associated with a comparable activation of fibrinolysis, as no difference in D-D levels was documented between patients and controls. Further studies are necessary to thoroughly investigate fibrinolysis, and in particular its main inhibitor, plasminogen activator inhibitor-1 (PAI-1), which may be released by stimulated monocytes and endothelial cells[29]. This behaviour of fibrinolytic system may contribute to determine a prothrombotic state.

In this study the main possible genetic and acquired alterations of HCY metabolism in PBC were investigated. We demonstrated the presence of vitamin deficiencies related to methionine metabolism (folic acid, vitamin B6 and vitamin B12) in about 90% of patients. In particular, the majority of patients had a folate deficiency. This is a novel finding that arises from the question about the potential clinical utility of a low-cost vitamin supplementation in these patients. It should be investigated if folate supplementation could correct hyperhomocysteinemia and/or hypercoagulability. Folate levels may be low due to inadequate dietary intake, malabsorption, increased utilization or to effects of drugs[30]; in our patients we excluded the presence of drugs able to interfere with folate absorption, such as methotrexate. Disease activity may contribute to increased demand for folate due to inflammation[32]. However, we found no correlation between disease activity, as measured by histological stage, and folate or HCY levels. Therefore, these data may point to inadequate intake as a significant factor that affects folate levels. Another hypothesis is the presence of an impairment of the folate enterohepatic circulation. This cycle plays an important role in the homeostasis of folic acid. It has been demonstrated that the interruption of bile circulation by bile drainage leads, to a rapid fall in serum folate levels to 30% of base line within 4-6 h[33]. Cholestasis could make this system of vitamin reutilization ineffective, and could induce folate low serum levels.

No data are available on the prevalence of C677T 5,10-methylenetetrahydrofolate reductase (MTHFR) polymorphism in PBC patients. This polymorphism is one of the most frequent genetic factors responsible for the alteration of HCY levels, especially in the presence of a suboptimal folate status[34,35]. We found a significant higher prevalence of the homozygous TT677 genotype in PBC patients. In these patients MTHFR has a reduced activity caused by a C-T substitution at nucleotide 677[36]. However, in order to investigate the prevalence of this genetic polymorphism in PBC further larger studies are needed.

In PBC serum cholesterol levels markedly increase with worsening of cholestasis[37,38]. In this study, as in others,[39,40] a significant in vivo association between HCY and cholesterol circulating levels was found, suggesting another possible explanation, together with cholestasis, for hypercholesterolemia in this disease.

Recently, in cultured human hepatocytes it was demonstrated that hyperhomocysteinemia determines an oxidative stress of the endoplasmic reticulum which activates the sterol regulatory element-binding proteins (SREBPs)[41]. The activation of SREBPs is associated with increased expression of genes responsible for cholesterol/triglyceride biosynthesis, and may be an explanation to our findings.

In conclusion, hypercoagulability and hyperhomocysteinemia exist in patients with PBC, and there is an association between these two parameters. TF may have a role in determination of blood clotting activation and hyperhomocysteinemia is related to hypovitaminosis and genetic predisposing factors. Further studies are needed to clarify if hyperhomocysteinemia and hypercoagulability may have a role in progression of liver damage and if they may be influenced by vitamin supplementation.

Abstract

AIM: To assess the early predictability of the soluble CD40L (sCD40L) in pancreatitis severity.

METHODS: Between February 2000 and February 2003, 279 consecutive patients with acute pancreatitis were prospectively enrolled in our study. In this report, 40 patients with mild and 40 patients with severe pancreatitis were randomly studied. sCD40L concentrations were measured 48 hours after admission.

RESULTS: sCD40L levels were significantly higher 48 hours after admission in severe pancreatitis than in mild pancreatitis. Using a cutoff of 1000 pg/L, the sensitivity and specificity of sCD40L to detect a severe course of the disease were 78% and 62% respectively compared to 72% and 81% for CRP. Logistic regression analysis found that CRP was the only statistically significant marker able to detect a severe course of the disease.

CONCLUSION: These findings indicate that CRP remains a valuable marker to determine the severity and prognosis of acute pancreatitis whereas sCD40L levels should be assessed in further studies.

Key words: Acute pancreatitis; Prognostic factor; sCD40

INTRODUCTION

Acute pancreatitis (AP) is a disease of variable severity. While approximately 80% of patients experience mild attacks, the remaining 20% still suffer from severe disease, with a mortality rate as high as 30%[1,2]. Since treatment of patients with severe disease is currently mostly supportive and directs at either prevention or control of the local and systemic complications, the early prediction of the severity of AP is the main goal of clinicians in charge of such patients[2]. Multifactorial scales including Ranson and APACHE II scoring systems have been used in acute pancreatitis since the 1980s. Ranson scale has been used in the 1980s in virtually all studies dealing with acute pancreatitis[3,4]. The list of 11 numerical parameters proposed by Ranson has no been fully discussed because only 5 criteria are obtained at admission and the remaining 6 during the subsequent 48 hour period, delay the performance of an early prediction. Moreover, the complexity of these scales and perhaps the fact that CT scanners are not available in every hospital account for the increasing interest in serum markers[5].

The pathophysiology of acute pancreatitis includes the activation and release of pancreatic enzymes in the interstitium, pancreatic autodigestion, and a multiple organ dysfunction following the release of these enzymes into the systemic circulation[6,7]. There is evidence that synthesis and release of pro-inflammatory cytokines and chemokines are also responsible for local and distant injuries[8,9]. If the concentration of these biological factors is correlated to the severity of the disease and if they are detected before the occurrence of multiple organ dysfunction, these factors might be important for the rapid scoring of the disease severity in the acute phase[5].

CD40, a proteic member of the tumour necrosis factor receptor family, is expressed on the membrane of a variety of cells, including B lymphocytes, monocytes, biliary and acinar cells as recently shown by our group[7,10]. CD40 binds to its ligand CD40L, a membrane glycoprotein, to mediate major immunoregulatory signals involved in auto-immune disease, graft rejection, inflammatory bowel disease, development of atherosclerosis and acute experimental pancreatitis[11]. We postulated that CD40-CD40L interactions might also play a role in the pathogenesis of human pancreatitis and that the soluble form of CD40L

Table 1 Characteristics of the population

	Control group	Mild pancreatitis	Severe pancreatitis	*P* value

Values are expressed as median values (CI 95%).

(sCD40L) levels might be correlated to the severity of the disease. The purpose of this study was to assess the early predictability of sCD40L in pancreatitis severity.

MATERIALS AND METHODS

The study protocol was approved by the local Ethics Committee. Upon admission, all patients with acute pancreatitis meeting the criteria of inclusion were identified and proposed to be included in the study. Before inclusion, each patient gave an informed consent. Between February 2000 and February 2003, 279 consecutive patients with acute pancreatitis were prospectively enrolled in our study. We assessed the role of sCD40L in the prediction of the severity of pancreatitis in this preliminary study. Consequently, 40 patients with mild and 40 patients with severe pancreatitis were randomly evaluated in the current study (Table 1). Ten healthy controls from our own divisions were also used for comparison. Inclusion criteria were typical abdominal pain associated with serum amylase twice the upper limit value (range: 26-128 U/L). The diagnosis was subsequently confirmed by CT scan with a Picker 1200 or a PQ-2000 instrument. Before scanning 150 ml of diluted oral contrast material (Telebrix Gastro, France) was administered to visualize the gastrointestinal tract. Intravenous contrast material (Omnipaque 350, Shering, Germany) was injected and multiple scans were obtained from the pancreas to the pelvis as previously described[12]. Pancreatic necrosis was considered significant if there was > 30% necrosis of the gland. Pancreatitis severity was defined according to the Atlanta classification and included organ failure (e.g.,shock, pulmonary insufficiency, renal failure), the presence of local complications (pancreatic necrosis, pseudocysts, abscess), or both[13]. Blood samples drawn 48 hours after admission were used to measure CRP and sCD40L using commercially available kits (Behring, Marburg, Germany and Bender MedSystems Vienna, Austria).

Statistical analysis

Serum markers were compared during severe and mild attacks by univariate analysis (Student' *t*-test, Mann-Whitney). SCD40L, CRP and Ranson scores were evaluated by receiver operating characteristics (ROC) curves for selected sCD40L and historically determined (CRP and Ranson) cutoff levels[3,4,5]. The cutoff for CRP (150 mg/L) and Ranson (severe > 3) was chosen according to the literature[4,5]. The cutoff for sCD40L was chosen according to its ROC curve. A logistic regression analysis for the binary outcome of mild or severe pancreatitis was performed. $P < 0.05$ was considered statistically significant. Statistics calculations were done using SPSS Software package (Chicago, USA).

RESULTS

The delay between the onset of abdominal pain and admission ranged from 7 hours to 2 d (Table 1). The aetiology of acute pancreatitis was biliary in 38 patients (48%), alcoholism in 30 (38%), drug-induced pancreatitis in 2 (3 %), hypertriglyceridemia in 1 (2 %) and idiopathic in the remaining 9 patients (11%) (Table1).

CT scan was obtained within 36 hours after admission in each patient and showed a normal pancreas in 5 patients, edema in 47 patients and necrosis in 28 patients (Table 1). Acute fluid collections were found in 35 patients (43 %) (Table1). The Ranson score established at 48 hours was $\geqslant 3$ in 27 patients (33 %), 19 of whom had severe pancreatitis and 8 mild pancreatitis. Sensitivity, specificity, positive predictive value, and negative predictive value of Ranson

Table 2 Performances of sCD40L, CRP and RANSON score

	Sensitivity (%)	Specificity (%)	Positive predictive value (%)	Negative predictive value (%)
sCD40L (cutoff 1000 pg/L)	77	62	63	74
CRP (150 mg/L)	72	81	80	74
RANSON Score (>3)	48	80	70	60

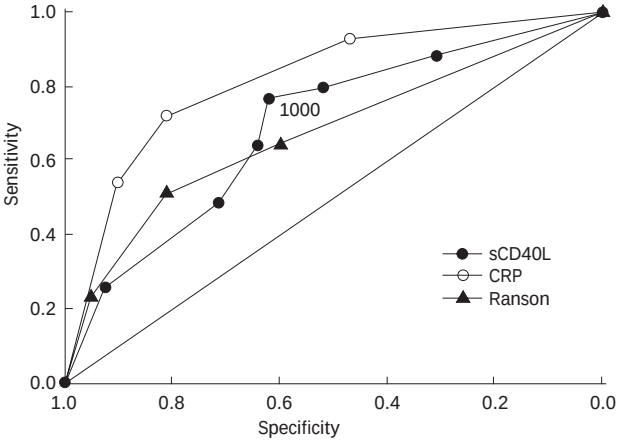

Figure 2 sCD40L (400, 800, 1000, 1200 1400 and 2000 pg/L), CRP (50, 150 and 200 mg/L) and Ranson (Ranson score of 2, 3 and 4) ROC curves with selected or historically determined cutoffs in patients with mild and severe pancreatitis.

score to predict a severe attack were 48% and 80%, and 70% and 60% respectively (Table 2). Three patients group with severe pancreatitis (7.5 %) died, two of whom were of biliary origin (Table 1).

Healthy controls had very low levels of sCD40L as well as CRP (Table 1). By comparison, levels of sCD40L and CRP were 795 pg/L (CI 95 %: 692-1301) and 42.5 mg/L (CI95%: 50-101) in patients with mild pancreatitis and 1215 pg/L (C I95% 1186-1753) and 225 mg/L (CI 95 % 199-319) ($P<0.0007$ and $P<0.0001$) in patients with severe pancreatitis respectively (Table 1 and Figure 1). No significant correlation was found between serum levels of sCD40L and the nature of the complications that occurred in patients with severe pancreatitis. There was only a trend towards correlation between sCD40L and the occurrence of multiple organ failure. The three patients who died from severe pancreatitis had intermediate levels of sCD40L (range from 184 to 236 pg/L). The sensitivity, specificity, positive predictive value, and negative predictive value of CRP to predict a severe attack were 72% and 81% respectively and 80% and 74% respectively (Table 2). Ranson score, CRP and sCD40L results were evaluated by their ROC curves for selected cutoff levels (Figure 1). Using a cutoff of 1000 pg/L for sCD40L as defined by the ROC curve, the sensitivity, specificity, positive predictive value and negative predictive value of sCD40L to predict a severe attack were 77% and 62% respectively, whereas the positive and negative predictive values were 63 % and 74% (Table 2). Logistic regression analysis for the binary outcome of mild or severe pancreatitis was performed to better delineate the performance of Ranson score, CRP and sCD40L (Figure 2). The forward stepwise analysis

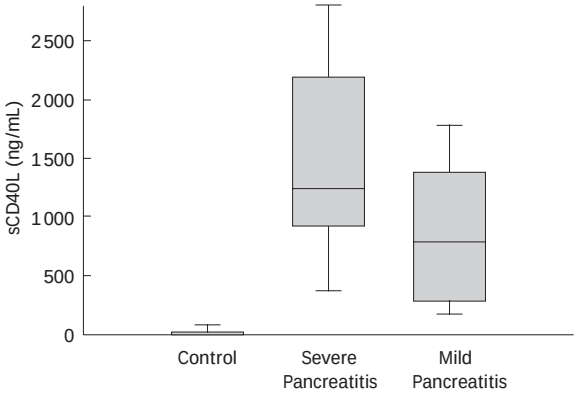

Figure 1 Soluble CD40L concentrations in healthy controls, severe and mild pancreatitis patients. Horizontal bars delineate the mean value.

found that CRP at d 2 was the only statistically significant parameter to predict a severe disease ($P<0.001$).

DISCUSSION

Predicting the course of acute pancreatitis remains a challenge for the physician[2]. Moreover, the 48-hour delay necessary to collect the standard scores and the complexity of multifactorial scales have prompted many physicians to investigate new markers[5]. CRP is an acute phase protein produced by the liver during inflammatory conditions that was first described in 1930[3]. In the mid-1980s, several studies showed that CRP could be considered as a valuable prognostic factor for severe pancreatitis[3,5,14]. Indeed, a better understanding of the pathophysiology of acute pancreatitis may contribute to a better selection of a specific prognostic marker. To this end, CD40-CD40L interaction, a major pro-inflammatory system widely distributed on a variety of leukocytes, has been recently studied in experimental rodent pancreatitis[7]. The expression of CD40 and its ligand were detected on pancreatic acinar cell surface, and peripheral T lymphocytes showed a progressive increase in the expression of CD40L during the course of experimental pancreatitis. Taken together, we thought that these findings might be applied to human pancreatitis. In the current report where 40 patients with mild and 40 patients with severe pancreatitis were randomly evaluated, we showed for the first time that the levels of the soluble form of CD40L (sCD40L) were higher in severe than in mild pancreatitis 48 hours after admission. The usefulness of this potential new marker has been compared to CRP, the most widely accepted serum marker that is used on a daily routine in almost all hospitals[3,7] and to Ranson score. We found that the sensitivity of sCD40L to predict a severe course was better than that by CRP. The negative predictive value of sCD40L that allows the physician to really exclude a severe disease was superior than that by CRP. A marker characterized by a better negative predictive allows cost savings since it can avoid useless observation time in emergency room or intensive care unit[15,16]. However, logistic regression analysis found that CRP was the only statistically significant marker able to identify a patient who developed a severe course of the disease. One explanation for this result is that our study was limited by the

small number of patients evaluated. Consequently, correlation between the levels of sCD40L and the occurrence of complications or death for example could not be studied.

Of note, Ranson score appeared insufficiently predictive of severe attacks, a feature already reported in several previous prospective studies[14,17,18]. To predict the severity of pancreatic disease itself, before the occurrence of multiple organ dysfunction, numerous other factors besides CRP have been evaluated so far with various performances. These factors are either enzymes released from the pancreas such as trypsinogen activation peptide[16] or mediators induced by inflammation in the pancreas itself or in remote organs such as procalcitonin[19], adhesion molecules[20] or cytokines[21]. For most of them, the higher the blood concentrations of these enzymes or mediators are, the more severe the disease is. Soluble CD40L could be one of the next markers of pancreatitis severity but further larger studies are needed to validate its clinical use in the early assessment of pancreatitis severity.

Abstract

AIM: To determine the association between the HLA-DRB1 alleles and perinuclear anti-neutrophil cytoplasmatic antibodies (p-ANCA) positive in Mexican patients with ulcerative colitis (UC).

METHODS: Ninety Mexican mestizo patients (45 females) with UC, confirmed by biopsy, were studied. High resolution HLA typing was performed by PCR-SSO reverse dot blot and PCR-SSP. Molecular typing techniques were applied to define HLA-DRB1 alleles. Enzyme-linked immunosorbent assay and immunofluorescence techniques were used to detect p-ANCA.

RESULTS: Forty-eight (53%) UC patients were positive for p-ANCA by ELISA and IF. We found that p-ANCA-positive UC patients had a significantly increased frequency of HLA-DR7 compared with p-ANCA-negative controls (22% *vs* 5.1%; pC = 0.02, OR = 5.2, CI 95%: 1.06-37.82). Disease activity was scored as severe in 20 patients, moderate in 8, mild in 14 and no activity in the remaining 38 patients according to the Truelove and Witts criteria. Subgroup analysis showed a significantly increased frequency of the HLA-DRB1*07 allele in 15 of 20 UC patients with severe activity of UC and p-ANCA positivity [100% *vs* 0%; pC = 0.0000001; OR = 35]. No significant differences were found between p-ANCA positive patients, HLA-DR alleles and other clinical features such as extraintestinal manifestations, proctocolectomy and extension.

CONCLUSION: The HLA-DRB1*07 is associated with p-ANCA positive UC Mexican patients.

Key words: HLA-DR; p-ANCA; Ulcerative colitis; Mexicans

Yamamoto-Furusho JK, Uscanga-Domínguez L, Lopez-Martinez A, Granados J. Association of the HLA-DRB1*0701 allele with perinuclear anti-neutrophil cytoplasmatic antibodies in Mexican patients with severe ulcerative colitis. *World J Gastroenterol* 2006; 12(10): 1617-1620

INTRODUCTION

Perinuclear anti-neutrophil cytoplasmic antibodies (p-ANCA) have been found consistently in patients with ulcerative colitis (UC)[1,2] however, their pathogenic role is still uncertain. The prevalence of p-ANCA in UC varies greatly from 39 to 80 percent in the ethnic group studied[2].

A genetic involvement in UC is supported by observations on familial aggregation of the disorder and concordance in monozygotic twins[3]. Considering the central role of the immune system in mediating the tissue damage in IBD, genes that participate in the development and regulation of the immune response, such as the HLA class II genes, are candidates for conferring the genetic susceptibility. Putative associations of UC with the polymorphic genes of the major histocompatibility complex (MHC) located on the short arm of the chromosome 6 suggest a role of these in the genetic susceptibility to develop UC in several populations of different ethnic and geographic background[4].

UC is a clinical and genetic heterogeneous disorder described in several ethnic groups[5-7]. An association between HLA-DR alleles and UC, in particular p-ANCA positive has been reported in patients from Italy[6], China[8] and United States[9].

Mexican mestizo individuals have a proportion of 56% native American Indian genes, 40% Caucasian genes, and 4% African genes[10], thus they are suitable to study the role of ethnicity in the susceptibility to develop UC and

p-ANCA positive in UC. Mestizo represents a complex mixture of European (Caucasian) and American native inhabitants (mongoloid) genetics, and constitutes the core of the Mexican and the Latin American populations.

The purpose of this study was to determine the association between the HLA-DRB1 alleles and p-ANCA positive in Mexican mestizo patients with UC.

MATERIALS AND METHODS

Patients

Ninety Mexican Mestizo patients with ulcerative colitis confirmed by histology were studied. Details of demographic and clinical characteristics of UC were obtained by a questionnaire, review of records and personal interview. No patient had a family history for UC. Disease extension was defined by colonoscopy. Thus, disease was classified either as extensive colitis (inflammation proximal to the splenic flexure) or distal colitis. Disease activity was scored by Truelove and Witts criteria[11].

Blood samples were obtained from 99 Mexican mestizo healthy, unrelated individuals with no family history of UC, ethnically matched to patients with UC as controls. Mexican mestizo individuals included in the present study accounted for 56% native American Indian genes, 40% white genes and 4% Black genes[11].

Methods

HLA typing Genomic DNA was isolated from peripheral venous blood by a modified "salting out" technique[12], precipitated with ethanol and resuspended in sterile distilled water at a final concentration 0.1-1.0 μg/μL before use.

Generic HLA-DRB1 typing was performed by PCR-SSO reverse dot blot hybridization (Amplicor, Hoffmann La Roche, Basel, Switzerland). High resolution HLA typing was performed by dot blot hybridization of amplified DNA with sequence-specific oligonucleotide probes labeled with digoxigenin di-deoxy-uridine-triphosphate (Dig-11-ddUTP). Information about DRB1 sequence was obtained from the 12th International Histocompatibility Workshop[13].

Indirect Immunofluorescence (IFL) Detection of ANCA was done according to the recommendations of the international workshop[14]. Human neutrophils were isolated from peripheral blood from patients and normal healthy volunteers by gradient centrifugation in 2% methylcellulose solution. The slides were fixed in 98% ethanol at 4℃ for 5 min and dried quickly in air. After wetting with phosphate-buffered saline (PBS) in a dilution of 1:40 and diluted two fold until dilution reached 1:320. Following incubation for 1 h at room temperature, the slides were washed three times with PBS and bound antibodies were incubated and detected with fluorescein isothiocyanate (FITC)-conjugated F(ab') rabbit anti-human IgG, diluted 1:100 in PBS for 30 min at room temperature. Subsequently, the slides were washed three times with PBS and covered with glycerin-phosphate-buffered saline. A titer $\geqslant$1:80 was considered positive, based on the results obtained from healthy controls.

Antigen-specific enzyme-linked immunosorbent assays (ELISA). This method was performed to identify the putative antigens recognized by the p-ANCA positive sera. Human Lf, MPO or cathepsin G was diluted to 2 μg/mL in carbonate buffer (pH 9.6) and 100 μL of each solution was placed in the wells of a 96-well microplate and left for 24 h at 4℃. After the plate was washed three times with PBS, 100 μL of diluted sera (1:100 in PBS containing 0.1 % Tween 20 and 0.1 % skim milk) was added to each well, and the plate was incubated for 1 h at 37℃. After washing, the enzyme reaction was performed, and color development was measured with a microplate colorimeter. Optical density values >2 SD were considered positive[15].

Statistical analysis Gene frequencies were compared using a 2×2 contingency table and Chi square test. Odd ratios have been calculated for the disease in carriers of specific alleles. Comparisons of allele frequencies between subgroups were performed using the EPI-INFO statistical package (Version 5.0; USD incorporated 1990, Stone Mountain, Georgia). All p values quoted were corrected by the Bonferroni test for multiple comparisons, while the number of alleles studied was taken into account. Statistical significance was considered when $P<0.05$.

RESULTS

Clinical features

The average disease duration was 7.2±6.6 years. Extensive colitis was present in 60% and distal colitis in 40%. Disease activity was scored as severe in 20 patients (25%), moderate in 8 (10%), mild in 14 (18%) and no activity in the remaining 38 patients (47%). Extraintestinal manifestations were present in 40%: arthritis (14.6%), primary sclerosing cholangitis (10.4%), sachroiliitis (6%), erythema nodosum (6%), ankylosing spondylitis (1.5%) and aphthous ulceration (1.5%). Fourteen patients (15.5%) required colectomy due to refractory medical therapy.

Positive p-ANCA

Positive p-ANCA was detected by IFL and ELISA methods in 48 of 90 patients with UC (53%) whereas c-ANCA was detected in 4 patients with UC. The frequencies of positive p-ANCA were increased significantly in the patients with UC as compared to controls. Titers of p-ANCA ranged 1:80-1:320.

HLA distribution

Patients with positive p-ANCA showed a significantly increased frequency of the HLA-DRB1*07 as compared to p-ANCA negative patients (pC = 0.02, OR = 5.2, CI 95 %: 1.06-37.82) and healthy controls (pC = 0.04, OR = 2.9, CI 95 %: 1.01-20.56). The remaining HLA-DR alleles did not show statistically differences between UC patients with positive p-ANCA and negative p-ANCA as shown in Table 1.

Subgroup analysis showed a significantly increased frequency of the HLA-DRB1*07 allele in patients with severe activity of UC and positive p-ANCA (15/15) as compared to 5 patients with severe disease and negative p-ANCA and no HLA-DRB1*07 [100 % *vs* 0%; pC = 0.0000001;

Table 1 Gene frequencies (g.f.) of HLA-DR alleles in patients with UC and healthy controls

HLA	p-ANCA + N = 96		p-ANCA – N = 84		Healthy controls N = 198	
	n	g.f.	*n*	g.f.	*n*	g.f.
DR7	21	0.218[1,2]	4	0.047	22	0.111

DR6	6	0.062	9	0.107	21	0.109
DR3	5	0.052	5	0.059	11	0.055
DR10	3	0.031	2	0.023	1	0.005

N = Number of chromosomes *n*= number of alleles.
[1]p-ANCA positive *vs* negative: pC = 0.02, OR = 5.2, CI 95%: 1.06-37.82.
[2]p-ANCA positive *vs* controls: pC = 0.04, OR = 2.9, CI 95%: 1.01-20.56.

OR=35]. No significant differences were found between p-ANCA positive patients, HLA-DR alleles and other clinical features such as extraintestinal manifestations, proctocolectomy and extension.

Disease activity

Data about disease activity were collected without knowledge of the results of ANCA testing. Interestingly, a significant association was found between severe activity of the disease and positive p-ANCA [75 % *vs* 25 %; pC = 0.00008; OR = 11; CI 95 %: 4.0-34.0]. No association was found between moderate, mild or inactive disease and the presence of p-ANCA (Table 2).

Extension We found that 22 UC patients with extensive colitis (47.8 %) were positive for p-ANCA while 19 patients with distal colitis were positive for p-ANCA (55.8 %). No statistical association was found between p-ANCA positivity and the extension of the disease [*P* = 0.47; OR = 0.72; CI 95 %: 0.27-1.94].

Proctocolectomy Seven patients with proctocolectomy were positive for p-ANCA as compared to 34 patients (51.5 %) who did not undergo the surgical procedure and were p-ANCA positive. No association was found between both groups [*P* = 0.91; OR = 0.94; CI 95 %: 0.26-3.43].

EIMs Futhermore, association was no found between each of the extraintestinal manifestations such as arthritis, primary sclerosing cholangitis, sachroiliitis, erythema nodosum, ankylosing spondilytis or aphthous ulceration and the presence of p-ANCA.

Type of treatment We followed up 80 patients treated with corticosteroids (local and systemic), 5-ASA (local and systemic) and azatioprin, and 10 untreated patients who served as controls. No association was found between p-ANCA positivity and any kind of medical treatment.

The prevalence of p-ANCA was higher in treated patients (45 %) than in untreated patients (6 %), probably reflecting the greater severity of the cases that required surgical treatment. After stratifying patients according to p-ANCA status, prevalence rates were not different as far as age, gender, age at first diagnosis, disease extension, surgery, extraintestinal manifestations were concerned.

No association was found between the number of clinical relapses and p-ANCA positive determination (data not shown).

Table 2 Clinical features of UC patients with positive and negative p-ANCA

Clinical feature	p-ANCA + *n* = 48	p-ANCA - *n* = 42	*P* value
Age at diagnosis (yr)	31 ± 8	33 ± 7	0.34
Gender (F/M)	23/25	22/20	0.62
Disease duration (yr)	7.4 ± 6.3	6.8 ± 6.2	0.45

Severe	15	5	0.000008

[a]OR = 11; CI 95%:4.0-34.0.
n = Number of patients.

DISCUSSION

This study provides evidence of the important role of MHC genes class II in the development of autoantibodies in patients with ulcerative colitis. The relevant finding was the increased frequency of the HLA-DRB1*07 allele in UC patients with positive p-ANCA compared with UC patients with negative p-ANCA. This association has not been reported in other ethnic groups. Several studies on Caucasians have demonstrated the association between the HLA-DR2 and the presence of p-ANCA positive UC patients from United States[16], Germany[17] and Italy[18]. In Chinese patients, a strong association is found between the HLA-DQ alpha 1c allele and the presence of ANCA positive[8].

On the other hand, other studies have not found association of the presence of positive p-ANCA and HLA-DR alleles in Jewish[2], French[18] and Korean[19] UC patients. Previous Mexican studies have reported association between HLA-DR1 and polymorphisms in the promoter region of tumor necrosis factor alpha and the genetic susceptibility to develop UC in this population[7,20].

The HLA-DRB1*07 has not been reported to have an association with positive p-ANCA in patients with UC from other ethnic groups. Interestingly, this allele is associated with chlorpromazine-induced lupus anticoagulant in patients with chronic psychiatric disorders[21]. We also found that the HLA-DR7 was associated with the production of anti-phospholipid antibodies in a group of Mexican mestizo patients with systemic lupus erythematosus[22]. The differences in the associated alleles could also be explained as a result in the genetic variation due to the role

of ethnicity in certain groups.

Finally, the association of the HLA-DRB1*07 allele with p-ANCA may be a result of immunoregulatory mechanisms related to the antigen presentation of protein fragments (autoantigens) to T cells, and may also play an important role in the development of autoimmunity, including the production of several autoantibodies such as lupus anticoagulant and anti-phospholipid antibodies as mentioned above.

This novel association between HLA-DRB1*07 allele and positive p-ANCA in Mexican UC patients suggests that this allele could be a marker of severe activity in patients with UC and plays a role as genetic marker for the production of different kind of autoantibodies in our population.

In conclusion, the HLA-DRB1*07 allele plays a genetic role in the production of p-ANCA in Mexican mestizo patients with ulcerative colitis.

Abstract

AIM: To investigate the role of cryofibrinogen (CF) in active inflammatory bowel disease (IBD).

METHODS: CF was assayed in 284 subjects: 61 with active and 63 with inactive ulcerative colitis (UC), 45 who had proctocolectomy, 35 with active and 20 with inactive Crohn's disease (CD), 40 with other diseases and 20 healthy controls. Trypsin inhibitor (TI) and TI antibody (TI-Ab) were measured in plasma and CF complex by ELISA.

RESULTS: CF in active UC was strikingly high compared with all other groups (χ^2<0.001). Similarly, CF was significantly higher in active CD than in inactive CD or in controls (χ^2<0.01). In UC, high CF and TI-Ab were associated with the need for operations. Further, high CF, CF/fibrinogen ratio, low TI and high TI-Ab in plasma were associated with disease activity or refractoriness to medication. Elevated CF was not associated with acute reactants like C-reactive protein and white blood cell counts except for erythrocyte sedimentation rate, suggesting that elevated CF was not a consequence of acute inflammation.

CONCLUSION: Elevated CF in active IBD appears to be morbigenous. CF promotes IBD via two main mechanisms, quenching of TI (an anti-inflammatory substance) and impairing microvascular perfusion by forming protein aggregates. CF may also serve as a biomarker of chronic IBD. Additional studies are warranted to fully evaluate the role of CF in IBD and the outcome should contribute to a better understanding of the pathogenesis of IBD.

Key words: Inflammatory bowel disease; Cryofibrinogen; Trypsin inhibitor; Trypsin inhibitor antibody; Acute colitis

INTRODUCTION

In 1955, Korst and Kratochivil[1] for the first time described "cryofibrinogen (CF)" as an abnormal protein, which is reversibly cold-precipitable in anticoagulated blood and could form fibrin and clot with thrombin. Now, CF is known as a cold-precipitable protein complex composed of fibrin, fibrinogen and fibrin split products found in plasma but not in serum of some individuals[2-4]. Further, cryofibrinogenaemia is now suspected to be associated with acute and chronic inflammatory diseases, lymphoproliferative disorders, and vascular complications[2-8]. However, it is true to say that up to now, CF has been best known as a risk factor for thrombo-embolic complications[2-9].

Regarding inflammatory bowel disease (IBD) and CF, several independent risk factors for thrombotic vascular diseases have recently been reported in IBD[9-13]. For example, it is known[11] that granulomatous vasculitis and fibrin deposition are components of the inflammatory process in Crohn's disease (CD). Similarly, presence of micro-thrombi in rectal biopsy specimens from patients with either ulcerative colitis (UC) or CD has been reported[12]; the incidence of systemic thrombo-embolic events in patients with IBD is known to be higher than that in the general population[13], reflecting a primary coagulation abnormality in patients with IBD[9-13].

Another biochemical substance, which was investigated in this study in relation to IBD, is trypsin inhibitor (TI). TI is best known for inhibiting trypsin to spare bystander tissues from unwanted damage[14]. Additionally, the literature provides convincing evidence for an anti-inflammatory action by TI as one of the body's naturally occurring immunoregulators[14-16] that include suppression of TNF generation[7]. In view of the above background, in

this study we hoped that finding the relationships between IBD, CF and TI might contribute to the understanding of the pathogenesis of IBD.

MATERIALS AND METHODS

Subjects

Between 1994 and 2001, a total of 284 subjects were investigated in this study. The demography of the study populations is presented in Table 1. There were 169 patients with UC (61 with active UC, 63 with remitted UC and 45 had proctocolectomy), 55 with CD (35 with active CD and 20 with remitted CD), 40 disease controls and 20 healthy controls.

Determination of disease severity and ongoing medications

Patients with active UC had bloody diarrhoea more than 6 times/d, a score of at least 14 on Lichtiger's clinical activity index (CAI)[17] and colonoscopy revealed Matts' s endoscopic grade 3[18]. Patients with active UC received total parenteral nutrition (all had severe UC) together with 5-aminosalicylic acid (5-ASA) or sulphasalazine orally and intravenous (iv) prednisolone (30-80mg/d) except for 5 patients who had their first UC episode before starting drug therapy. The remaining 45 patients with UC who had proctocolectomy with ileal pouch anal anastomosis (IPAA) at least 6 mo prior to this investigation represented the post-operative UC group. None of the 55 patients with CD received steroid therapy. Patients with active CD ($n=35$) had a mean Crohn's disease activity index (CDAI) of 266[19]. The subgroup with inactive CD ($n=20$) had a CDAI of less than 150 (clinical remission level). Forty age and sex matched hospital patients with other diseases were included as a disease control group (Table 1). Of these, 10 had non-IBD acute colitis caused by bacteria [enteropathogenic *Escherichia coli*, Vero toxin (-) in 6, *Salmonella enteritidis* in 3, and *Klebsiella peumoniae* in one], 4 with rheumatoid arthritis, 4 with primary biliary cirrhosis, 2 with autoimmune hepatitis, 2 with Bechet's disease, 2 with systemic lupus erythematosus, and 1 with polymyositis in autoimmune and collagen diseases, 4 with colonic polyps, 3 with chronic hepatitis C, 3 with hypercholesterolemia, 3 with peptic ulcers who were also *Helicobacter pylori* positive, and 2 with gastric cancer in non-acute and non-autoimmune state. Twenty healthy subjects who were in the same age range as patients were included as a healthy control group.

Measurement of fibrinogen and cryofibrinogen

Blood samples were obtained in the early morning fasting state. A 10 mL of whole blood was collected for cryoprecipitate measurements. The blood sample was pre-warmed at 37 ℃ in a plastic syringe and then was transferred into 2 plain glass tubes at 37 ℃; one tube contained 3.8% sodium citrate solution (9:1; vol/vol blood/citrate ratio), the other tube contained no anti-coagulant.[20] The tubes were incubated at 37 ℃ for 1 h and then were centrifuged at 1500g for 30 min to separate plasma or serum from cells.[21] Fibrinogen was measured by immunoturbidimetric assay according to a published method.[22] Total fibrinogen concentration in the plasma was measured before refrigeration. Plasma and serum samples were kept at 4 ℃ for up to 72h prior to assay of test substances. This was to allow precipitation of any abnormal fibrinogen into CF. Tubes were further spun at 1500g in a refrigerated centrifuge at 4 ℃ for 30 min. The supernatants were then rewarmed to 37 ℃ and used to measure fibrinogen and CF concentrations. The concentration of CF was measured as concentration differentials of fibrinogen before and after refrigeration.[22,23] The fibrinogen concentration was measured at 24 and 72 h after refrigeration. Sera samples were used for the detection and measurement of cryoglobulins (if present).

Assays of trypsin inhibitor and trypsin antibody

Trypsin inhibitor and trypsin inhibitor antibody (TI-Ab) in plasma and in CF[14] were measured by enzyme-linked immunosorbent assay (ELISA) in 18 patients with IBD (10 with UC, 8 with CD) as previously described.[24] These subjects were selected at random among the patients.

Ethics

All participants provided informed consent to be included in this study after they were informed of the purpose of the study and the nature of the procedures involved. Likewise the study protocol was reviewed and approved by our hospital Committee on the Ethics of Clinical Investigations Involving Humans.

Statistical analysis

Numerical data were presented as the mean ± SD values. Comparisons were made with the Chi square test (χ^2). Correlations between CF, TI and acute phase reactants including C-reactive protein (CRP), white blood cell counts (WBC), and erythrocyte sedimentation rate (ESR) were assessed by simple regression analysis or as indicated otherwise. $P<0.05$ was considered statistically significant.

RESULTS

Incidence and concentration of CF among groups

There was no significant difference in CF concentrations between 24 and 72h refrigeration. Therefore, only the results of 72h refrigeration were presented. A very high incidence of CF (upon storage of plasma at 4 ℃) and high CF concentrations were observed in patients with active IBD (Table 1 and Figure 1). This was most striking in patients with active UC (Figure 1). However, patients with UC who had operations or patients with non-IBD acute colitis (associated with infection) did not have abnormally high CF levels. Indeed, amongst the patients groups, the lowest CF concentration was found in patients with acute colitis; none of the 10 cases was CF positive. Thus in patients with UC, CF was still positive in 55.6% of patients with remitted UC, while patients with active CD had high CF levels, but the level in patients with inactive CD was not high (Figure 1). The only other group with high CF was patients with collagen disease, which is consistent with the literature[25]. In the disease control group, only 40% (12 of 40 patients) were positive for CF. In the healthy control group, only 1, (a 50-year-old man) was positive for CF, but the concentration of CF was not very high in this

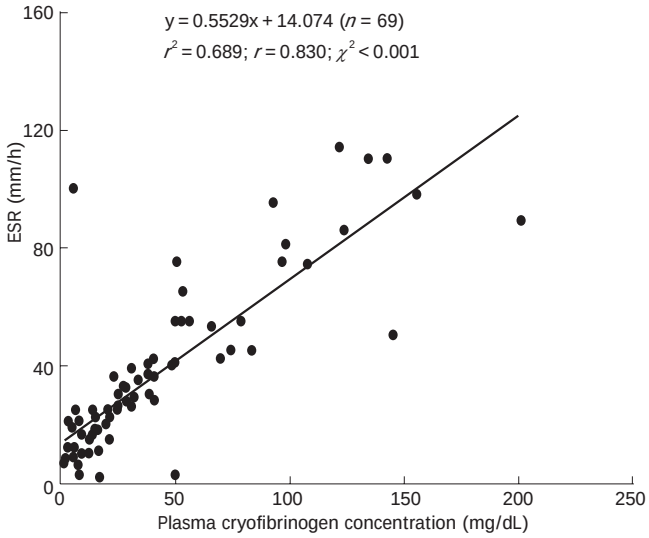

Figure 2 Simple regression analysis for relationship between plasma CF concentration and erythrocyte sedimentation rate (ESR) in 69 patients with active IBD.

patient (15.6 mg/dL). The CF/fibrinogen ratio was also determined for all subgroups of 284 patients. The results are presented in the Table 1. No cryoglobulinaemia was detected in IBD patients or in the healthy control group.

Relationship between CF and acute phase markers

To verify that high plasma CF was not associated with acute inflammation, its concentration was compared with concentrations of acute phase reactants like CRP, ESR, and WBC. Among these, only ESR showed a strong correlation with CF. (r=0.830, χ^2<0.001, Figure 2). There were no significant correlation between CF and CRP or between CF and WBC.

Relationship between CF and IBD clinical course

The relation between CF concentration, severity and duration of IBD were investigated. We divided the patients into 4 subgroups: (1) with more than 50 mg/dL CF; (2) with 10 to 50 mg/dL CF, (3) with less than 10 mg/dL CF; (4) with no CF. Both CAI/CDAI values and the duration of IBD were in this order: 1>2>3 or 4. We followed 44 patients who achieved remission among 61 with active UC and measured CF concentration to see if it follows patients' UC clinical course. Seven patients who became CF negative maintained their remission for over 5 years. In 33 patients in whom, CF concentration decreased by about 50%, 13 relapsed within 12 mo in addition to 4 patients who did not show any change in CF concentration.

Relationship between TI-ab and CF

It is thought that in the plasma, part of the CF complex acts as TI-ab and at 37℃ (the measurement temperature used in this study) and TI-ab dissociates from CF. Accordingly, TI-ab shown in both Figures 3 and 4 are believed to come from the CF complex. This means that a high plasma level of CF can reduce plasma levels of free TI. Figure 4 shows a simple regression analysis for the relationship between plasma CF and TI-ab in patients with

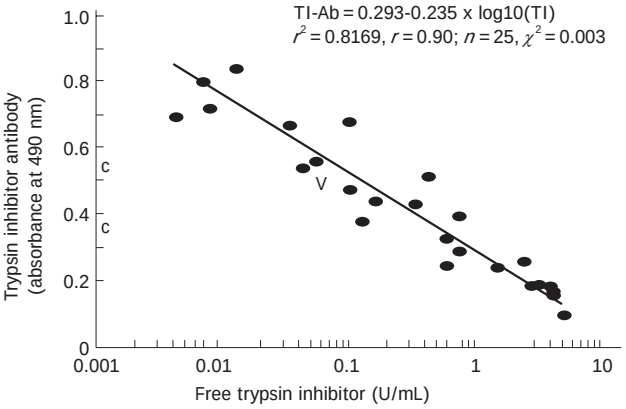

Figure 3 Logistic regression analysis to determine the relationship between TI and anti-TI-ab in patients with IBD.

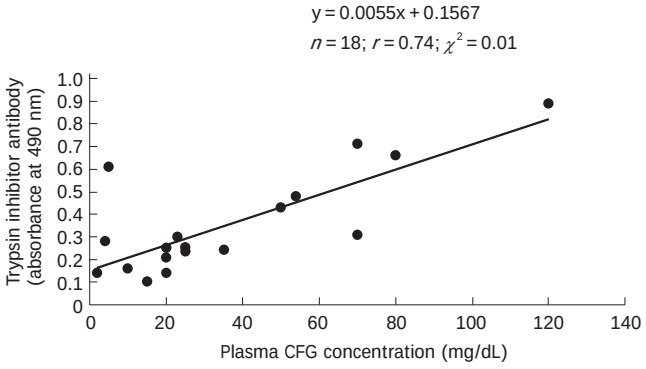

Figure 4 Simple regression analysis for the relationship between plasma CF concentration and TI-ab in 18 patients with active IBD.

active inflammatory bowel disease. As shown, there was a positive correlation between TI-ab and CF in the plasma (r= 0.74, χ^2 = 01).

DISCUSSION

For the first time this study reports the elevated plasma CF in patients with active IBD, with active UC showing the highest plasma CF. We also found that in most patients with active IBD, a marked fall in plasma CF was associated with disease remission. In contrast, persistently elevated CF was associated with medication-resistant and poor prognosis. Further, we could confirm that elevated plasma CF was not associated with typical acute phase reactants like CRP or WBC except showing strong correlation with the inflammatory marker, ESR. To ascertain that high plasma CF was one manifestation of active IBD, we included patient groups with diverse diseases together with a control group. Even in patients with acute colitis of non-IBD type, the concentration of CF was markedly lower compared with active UC of IBD. This observation convinced us that high plasma CF was indeed specific to active IBD. Further, elevated plasma CF was associated with IBD severity. Our impression is that elevated plasma CF is morbigenous; patients have severe and drug-refractory IBD.

Given that high plasma CF is seen during active IBD, and increases with IBD severity, the fundamental question if unequivocally addressed could significantly improve our understanding of the role of CF in IBD and the aetiology of IBD. First, is CF one cause or a consequence of active IBD? Second, exactly how CF contributes to active IBD (if at all)? At present, our data suggest that CF quenches TI thus depriving the immune system of an important natural anti-inflammatory factor (see the introduction section). But we should not forget that CF by precipitating cryoprotein aggregates is a major risk factor for vascular occlusion and impaired microvascular perfusion, which in IBD can delay ulcer healing.[3-8, 20, 25, 26] Additionally, high plasma concentration of CF can activate platelets in the same way as high plasma fibrinogen does[24] and block small vessels with micro-thrombi whereby compromising microcirculatory blood flow within the inflamed intestinal mucosa. Therefore, one mechanism of action of CF and its contribution to tissue injury and the perpetuation of IBD might be via vascular occlusion.

There are reports that treatment with immunosuppressive agents including corticosteroids, azathioprine, and cyclophosphamide is unsuccessful in preventing disease progression (non-IBD)[25-27]. However, the introduction of regular plasmapheresis together with cyclophosphamide therapy depletes plasma CF and this is associated with a marked improvement in the patients' clinical symptoms, Suggesting that extracorporeal circulation therapies such as plasma exchange and plasmapheresis, or cryofiltration[28-30] combined with conventional drug therapy may be effective in patients with refractory UC or CD who present with high plasma concentrations of CF, which we believe is a morbigenous factor in IBD.

Excess CF probably arises either from a misdirected synthesis or from post-synthetic alterations.[25,30,31] In IBD, it is likely that abnormal fibrinogen (CF) reflects a congenital abnormal production or an acquired abnormal production by the liver that is exposed to high cytokinaemia and proteases through portal vein from the intestine. If the elevated CF is caused by pro-inflammatory cytokines and proteases then its concentration in the inflamed intestinal lesions will be much higher compared with plasma.

In conclusion, high plasma CF in patients with active IBD appears to be morbigenous. The elevated plasma CF does not seem to be associated with typical acute phase reactants like CRP and WBC but showing strong correlation with ESR. Currently, our impression is that elevated CF promotes IBD via two main mechanisms quenching of TI (an anti-inflammatory substance) and impaired microvascular perfusion by forming protein aggregates. Further, CF may also serve as a new biomarker of chronic IBD. Clearly additional studies are warranted to fully evaluate the role of CF in IBD and the outcome should contribute to a better understanding of IBD aetiology.

Abstract

AIM: To determine the distal intramural spread (DIS) margin of rectal cancer.

METHODS: Sixty-one p53-positive specimens of rectal cancer were used. After conventional hematoxylin and eosin (H&E) staining, the DIS margin of rectal cancer in large specimens was examined by immunohistochemistry. The patients were divided into A, B, C, and D groups. After a long-term follow-up, the survival curves of the four groups were estimated using the life table.

RESULTS: Fifty-one of the sixty-one cases (83.6%) had DIS. The extent of DIS ranged 0.11-3.5 cm; meanwhile the mean of DIS measured by H&E staining was 0.13 cm. The significant difference was found between the means (t=5.622, P<0.0001). Only 1 of 51 patients had DIS greater than 3 cm. The DIS was less than 1.0 cm in most rectal cancer patients. The long-term results indicated that the survival rate of the patients whose DIS was greater than 1.0 cm was lower than that of the patients whose DIS was less than 0.5 cm.

CONCLUSION: Rectal cancer patients with DIS greater than 1.0 cm have poor prognosis.

Key words: Rectal cancer; Distal intramural spread; p53; Immunohistochemistry; Large specimen

INTRODUCTION

Defining the optimal distal surgical margin is very important for surgical oncologists during rectal cancer resection[1]. To ensure complete excision of cancer and maximum protection of normal tissue, we should define the length of DIS. Though a distal margin greater than 5 cm is advocated in the past[2], some studies proposed that a distal excision margin of 1 cm is sufficient[3-5], but the molecular clearance margin of DIS is unknown. Molecular techniques have been used to identify tumor markers and occult tumor cells in recent years[6] and the clear margin determined by molecular methods should be different from that by traditional histopathological methods. The accurate assessment of DIS could guide precise surgical resection, aid in estimating prognosis and predict recurrence site, but the molecular margin of DIS of rectal cancer is unknown. In this study, we used p53-immunostained large specimens of rectal cancer to measure the molecular margin of DIS and to clarify the influence of DIS margin on the long-term survival of patients after the resection of rectal cancer.

MATERIALS AND METHODS

Patients

By using conventional hematoxylin-eosin (H&E) and p53-immunostaining (LSAB), we identified 61 p53-positive cases in 97 rectal cancer patients who were surgically treated in our hospital between August 1996 and October 1997. The characteristics of the 61 patients are listed in Table 1.

Preparation of large specimens

Fresh specimens were opened longitudinally, straightened without stretching and pinned to a cork board. The distal margin (A1) was measured and fixed by 10% formalin for more than a week. The whole specimen including oral and anal edges of the tumor was cut longitudinally into 5-mm-thick giant sections. The sections were embedded in paraffin wax and then serial 8-μm-thick sections were cut from the giant sections on a large microtome. Routine H&E staining and p53-immunostaining (LSAB, 1:100 diluted mouse monoclonal antibody to p53, DO-7; DAKO Ltd, Denmark) were performed respectively. The distal margin was measured on large glass specimens (B1) and the extent of DIS was measured microscopically (b1). The microscopic extent of DIS was converted as the distance

of DIS in fresh specimen (a1) by the tissue shrinkage ratio by comparing the distal margin measured in fresh specimens before fixation (A1) to that measured on large sections macroscopically (B1) in each case (A1/B1=a1/b1). The data were converted data.

Statistical analysis

Both means of the DIS obtained by H&E staining and p53-immunostaining were compared by the paired sample statistic *t* test. According to the extent of DIS by p53-immunostaining, we divided the patients into four groups: A (DIS = 0.00 cm), B (DIS = 0.01-0.50 cm), C (DIS = 0.51-1.00 cm) and D (DIS > 1.00 cm) .The survival curves of the groups were generated by the life table and compared by Gehan test. SPSS software (8.0) was used for all statistical analyses. $P < 0.05$ was considered statistically significant.

RESULTS

Modalities of DIS in rectal cancer

Under microscope, no cancer cells were found on the edge of resection in the large specimens. By p53 immunostaining, DIS of p53-positive tumor cells was found in normal glandular epithelial tissue next to the tumor in 23 cases under the mucosa away from the tumor in 40 cases. Emboli of cancer cells were found in micro-veins and/or micro-lymph vasculature under the mucosa in 35 cases. Nest formation of cancer cells was found under the mucosa away from the tumor and a clear line between the tumor and the normal tissue was noted in 21 cases. Spread of cancer cells through the above four pathways was observed but there was a clear large space between the metastatic cells and the main tumor.

Comparison between the extents of DIS by H&E staining and p53 immunostaining

By H&E staining, no DIS was found in 32 cases, 29 cases had DIS (range: 0.10-1.39 cm, mean: 0.13 cm, 95%CI: 0.1-0.16 cm). By p53 immunostaining, only 10 cases had no DIS, 51 cases had DIS (range: 0.11-3.5 cm, mean: 0.59 cm, 95%CI: 0.5-0.67 cm). There was a significant difference between the means obtained by p53-immunostaining and H&E staining ($t = 5.622$, $P < 0.0001$, Table 2).

Follow-up results

By December 2003, the follow-up time ranged 266-2 485 d with a mean of 1 621.4 d. All cases were followed up. Twenty-nine patients died of cancer recurrence. There were 32 disease-free cases in the study.

Survival analysis

The 5-year survival rate of 61 patients was 57.78%. The 5-year survival rate of groups A, B, C, and D was 79.41%, 60.93%, 55.70%, and 31.88%, respectively. There was no statistical difference among the survival rates of groups A, B, and C. The survival rate of group D was significantly lower than that of groups A and B (Table 3 and Figure 1).

DISCUSSION

Different from other studies, the whole specimen was expanded with a similar pull force by surgeons during operation and pinned on a flat board. Then the specimen was fixed by 10% formalin for more than 7 d. The extent of DIS was measured on large specimens microscopically. A tissue shrinkage ratio between the distance measured in fresh specimens from surgical margin to distal tumor edge was used to convert the extent of DIS microscopically to the extent of DIS *in situ*[7]. The error of DIS measured microscopically caused by the shrinkage of tissue in formalin may be avoided by the above method. Moreover, missed diagnosis of DIS should be reduced because the continuous intramural spread can be observed on large specimens.

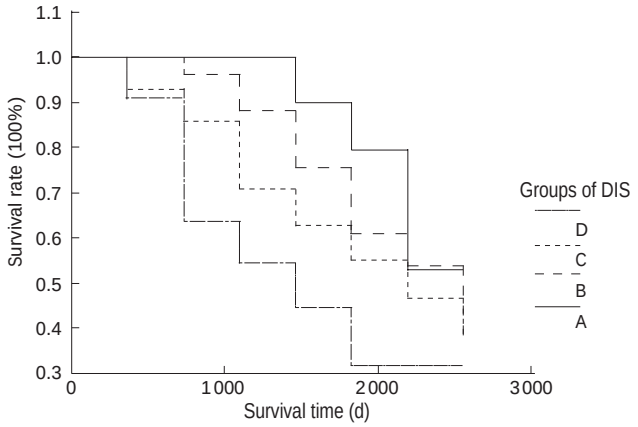

Figure 1 Survival curves of 61 rectal cancer patients.

Mutation of p53 gene is a late event of colorectal carcinogenesis[8]. Using molecular biological techniques, Brennan *et al*[9] and Hayashi *et al*[10] assessed the p53 gene mutation in clearance margins of 25 primary squamous cell carcinomas of the head and neck and local lymph nodes of 120 colorectal cancers. p53 gene mutation was found in some specimens without tumor residue, 40-70% patients with p53 gene mutation in clearance margins or lymph nodes had local recurrence and regional lymph node metastasis after the operation. No metastasis occurred in patients without p53 gene mutation. Their studies indicate that molecular biological analysis is more sensitive in finding hidden tumor cells by identifying tumor markers and can predict the site of local recurrence and the prognosis of patients.

Mutation of p53 gene results in the accumulation of p53 protein and p53 protein is regarded as a useful tumor marker[11]. p53-positive tumor cells that cannot be detected by H&E staining can be identified by immunohistochemical staining. Furthermore, hidden tumor cells usually are too small to be found by microscopy after conventional H&E staining.

In our study, we compared the extent of DIS by p53-immunostaining to that by H&E staining. The results between these two methods were similar, when DIS was less than 0.5 cm. In some cases, when DIS was greater than 0.5 cm, spread of single satellite cells in normal tissue was difficult to be identified by H&E staining. Therefore, H&E staining tends to cause false negative results compared to immune method. Because immunostaining is more sensitive than H&E staining, more positive diagnoses were made. The mean of DIS results was also higher by immunostaining ($P<0.05$, Table 2.).

Accurate identification of DIS of rectal cancer is very important for determining the clearance margin during the operation and preventing anastomosis recurrence[12]. According to the literatures published, DIS detected by H&E staining usually exists in 14.5-65.6% rectal cancer patients[3,7,8]. Because the results of DIS in rectal cancer are different in different studies[13], there is no universal agreement on the length of distal normal rectum that should be removed during radical resection[14]. Some authors suggested that 1-2 cm of distal removal of normal rectum is enough[4]. On the other hand, some cellular and molecular studies suggested that 2 cm is not safe[9]. In our study, though 83.6% (51/61) of the patients had DIS, the length of DIS in 78.4% (40/51) was less than 1 cm, in 6% (3/51) greater than 2 cm and only in 1.6% (1/51) greater than 3 cm, suggesting that 2 or 3 cm of the distal clearance margin is safe enough for most (95% or above) rectal cancers during radical resection.

It was reported that DIS is correlated to depth of cancer invasion and distal metastasis. Patients with positive DIS have a higher risk for developing metastasis after radical resection and their disease-free survival rate is lower than that of those with negative DIS[10]. In our study, patients with longer DIS had a lower survival rate (Figure 1). If DIS is greater than 1 cm, patient survival rate is markedly decreased regardless of distal normal rectum excision and negative tumor residue in distal surgical edge. The relationship between DIS and survival rate indicates that DIS is a prognostic factor of rectal cancer[15].

Abstract

We here report a case of a 18-year-old man with a history of recurrent abdominal pain and a previous episode of severe acute pancreatitis. Abdominal ultrasonography, contrast enhanced multislice computer tomography, endoscopic retrograde cholangiopancreatography, endoscopic ultrasonography and magnetic resonance imaging demonstrated a cystic mass lesion. Only on delayed phase magnetic resonance images after Gadolinium-BOPTA injection, it was possible to demonstrate the lesion's relationship with the biliary tree, differentiating the lesion from intraluminal duodenal diverticulum, and to achieve the diagnosis of duodenal duplication cyst, a recognized rare cause of acute pancreatitis. The diagnosis was confirmed by histology.

INTRODUCTION

Duodenal duplication cyst (DDC) is a benign congenital anomaly acquired during the digestive system embryonic development. It is a recognized rare cause of acute pancreatitis, usually diagnosed in the first two infancy years. In adults, the diagnosis is difficult because of symptom variety and non-specific nature[1,2]. DDC represents 5-12 % of all gastrointestinal tract duplications and often communicates with either the small bowel or the pancreatic duct, rarely with the biliary system. Duplication anomalies are usually adjacent to the involved bowel. The morphology is spherical or occasionally tubular and may communicate with the lumen[1]. Moreover, they are composed of a smooth muscle wall and an inner mucosal lining. The type III choledochocele by Todani *et al*[3] is an isolated cystic dilatation of the distal portion of the choledochus, eventually protruding into the duodenal lumen, whose imaging findings are similar to those of duodenal duplication communicating with the bile duct[4,5]. The differential diagnosis between these two entities is often preoperatively impossible. Once the lesion is excised, only the different inner mucosa permits to perform a diagnosis. According to the magnetic resonance cholangiopancreatography (MRCP) findings, we report a case for which we suggest two possible final diagnoses: duodenal duplication cyst or type III choledochocele both communicating with the bile duct. In both computer tomography (CT) and endoscopic ultrasonography (EUS), previously performed, the relationship between the cystic lesion and the biliary tree was not clear. As far as we know, this is the first case where magnetic resonance (MR) with Gd-BOPTA (a contrast medium partially excreted by the biliary system) is able to demonstrate the relationship between the cystic lesion and the bile duct, which presents an anomalous pancreatic-biliary junction.

CASE REPORT

A 18-year-old man was referred to emergency room for an episode of severe acute pancreatitis. The patient was already known for previous recurrent abdominal pain. Laboratory values indicated an acute pancreatitis (increase of serum amylase and lipase activity). Other laboratory results including liver enzymes and peripheral blood count, serum protein and creatinine concentration were within the reference ranges. The patient did not have any primary cause of pancreatitis (e.g. alcohol consumption or choledocholithiasis). Ultrasonography (US) showed a hypoechoic area at the head of the pancreas, finding compatible with focal necrosis in pancreatitis. Contrast-

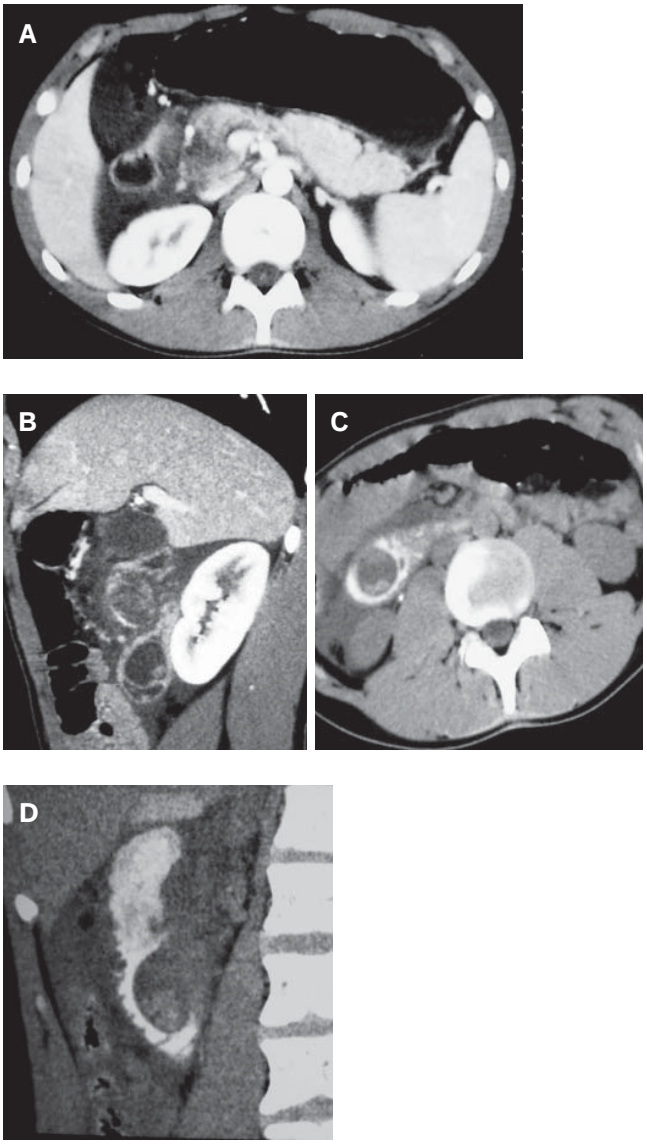

Figure 1 MSCT findings. **A** and **B**: On axial plane after i.v. injection of contrast medium the head of the pancreas presents a necrosis area, and on oblique plane the duodenum shows a cystic lesion filled with small stones; **C** and **D**: Oral contrast medium (diluted Gastrografin) fails to opacify the cystic lesion.

enhanced multislice CT (16 rows) confirmed the presence of necrotizing pancreatitis at the head (Figure 1A) and revealed a cystic lesion containing filling defects within the third portion of the duodenum (Figure 1B). After oral contrast agent (Gastrografin) administration, the cystic lesion was not filled up, suggesting the diagnosis of DDC (Figures 1C and D). The upper gastrointestinal series showed a four-centimeter intraluminal defect located in the medial wall between the second and the third portions of the duodenum. Endoscopic retrograde cholangiopancreatography (ERCP) was impossible to perform because the large submucosal mass was close to the major papilla, obstructing the bile ostium and pancreatic duct (Figure 2A).

EUS confirmed the presence of a submucosal cystic lesion at the inferior duodenal genu filled by calculi (Figure 2B), which was peculiar of choledochocele. Because of the site (duodenum medial wall) and the large size of the cystic

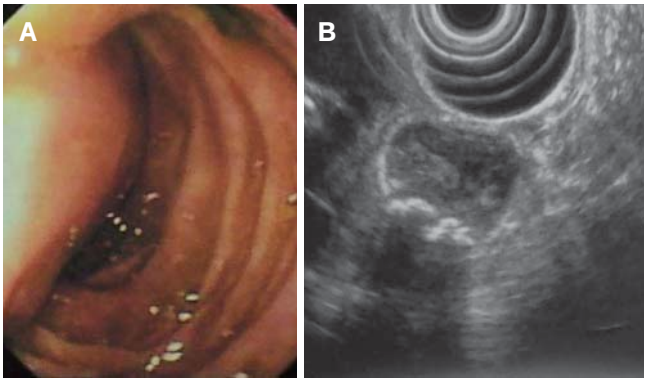

Figure 2 Endoscopic (**A**) and EUS (**B**) findings. By endoscopy the lesion appears as a submucosal mass obstructing the bile ostium and protruding into the duodenal lumen; EUS procedure was impossible to obtain further information because of the cystic lesion large size. The presence of calculi in the lesion was confirmed.

lesion it was impossible to demonstrate a linkage with the biliary system.

MR imaging was performed to solve the diagnostic discrepancy between CT and EUS and to better demonstrate the relationship between the cystic lesion and the bile duct. A 1.5 Tesla MR system with the following protocol was used: Breath Hold T1 GRE fat sat sequence (TR/TE 160/4,2), HASTE sequence TR/TE ∞/120 in the axial and coronal plane, RARE thick slab sequence (pre and post oral superparamagnetic contrast agent administration - Lumirem - Guerbet) and VIBE sequence in the coronal plane pre- and post-contrast agent administration (Gd-BOPTA), followed by a delayed phase at 120 min. The Gd-BOPTA is a mixed (interstitial and hepatocellular) paramagnetic contrast agent partially excreted through the biliary system, giving the opportunity like 99mTc-HIDA scintigraphy, to functionally evaluate the biliary excretion. All MR images showed a four-centimeter well circumscribed mass in the duodenal wall.

MRCP performed before and after a negative contrast agent oral administration, demonstrated that the cystic lesion was not directly in connection with the duodenal lumen. HASTE axial and coronal sequences, showed filling defects in the gravity-dependent position of the cystic lesion (Figure 3A). Heavily T2-weighted sequences (RARE thick slab) obtained in the coronal plane confirmed that the fluid content of the lesion was changing position with the peristalsis, without any definitive information about the relationship with the bile duct (Figure 3 B). Furthermore, on the delayed 3D VIBE images after intravenous (i.v.) injection of Gd-BOPTA, it was possible to demonstrate the direct passage of hyperintense bile fluid into the cystic lesion, confirming the existence of a linkage (Figure 4).

Once the patient recovered from the acute pancreatitis, one month after his first hospital admission, he underwent surgery. During laparotomy (Figure 5), after cholecystectomy and duodenotomy, two probes were inserted into the biliary tree through both cystic duct and ampulla: both the probes reached the diverticulum confirming the linkage between these anatomical structures. Then the diverticulum was opened, multiple stones were found and the wall

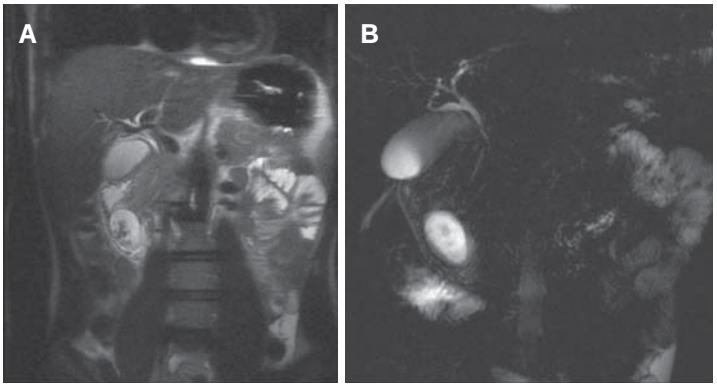

Figure 3 MRCP findings. **A**: Axial HASTE sequences demonstrate the intraluminal site of the duodenal cystic lesion with filling defects in the gravity dependent position; **B**: After superparamagnetic oral contrast medium administration the hyperintense cystic lesion does not change signal intensity.

Figure 4 MRCP findings after Gadolinium BOPTA injection. Coronal VIBE sequences obtained in the delayed phase (2h) reveal the presence of hyperintense bile simultaneously in the biliary tree and in the cystic lesion, confirming the relationship between these two structures.

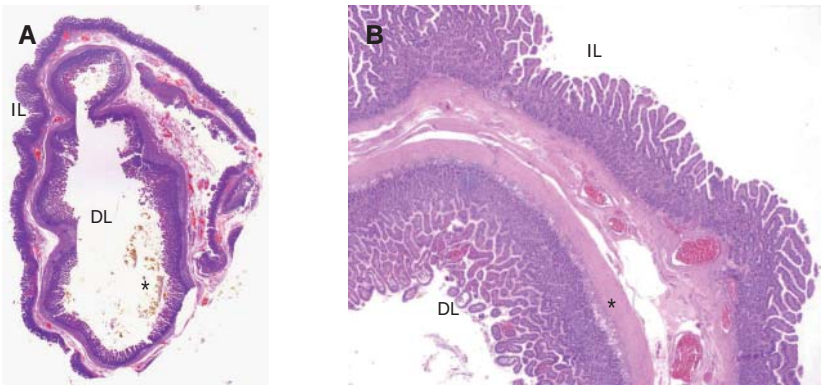

Figure 6 Mucosa, submucosa and muscle coats found in pathological ehamination. **A**: Gross transversal section of the specimen "in toto": inside it is possible to see the duplication lumen (DL) while the intestinal lumen is outside (IL). In the inner lumen there are bile plugs (*); **B**: Histology of the duodenal duplication. Microscopic low power view of the duplication wall (2x). The wall is composed of muscolaris propria extending into the septum between the duplicated segment and the mucosal lining. Intestinal mucosa is on both sides of the duplication, with a lot of macrophage cells (*) in the lamina propria of the internal one.

was completely excised up to the duodenal plane. The hole was closed with single layer stitches. Six days after surgery the patient was discharged.

Pathological examination of the excised cyst wall showed duodenal mucosa, submucosa and muscle coats. The pathologist made a diagnosis of duodenal duplication (Figures 6A and 6B) and found cholesterolosis in the cyst, in accordance with MR findings.

DISCUSSION

Clinical findings of DDC are either non-specific, such as mild abdominal pain, or specific, recalling acute or chronic pancreatitis. Two possible mechanisms might be responsible for pancreatitis: a transitory and mobility-related duodenal obstruction of the major papilla outflow by the cyst, and the migration of biliary sludge and/or microstones from the cyst to the biliary tree as observed in biliary pancreatitis[1]. As regards bile in- and out-flow, what we can imagine is a dynamic mechanism like gallbladder: the DDC wall is made of muscolaris propria, so there is peristalsis that outflows the bile. It is present a certain degree of stasis and demonstrated by the presence of stones. The pathogenesis of stones can be related more to the bile stasis in the cyst than to direct calculi drop down. Nevertheless the stasis, being intermittent due to peristalsis, does not automatically lead to a liver enzymes elevation, as in the literature[2,5,6]. The intraluminal mass has to be differentiated from a peduncled neoplastic lesion or an intraluminal duodenal diverticulum[6,7]. The cystic lesion is not an intraluminal duodenum diverticulum because the signal did not change after superparamagnetic contrast medium administration, remaining hyperintense in T2 weighted sequences. On opposite, the intraluminal duodenal diverticulum should become hypointense, due to the connection with the lumen. The differential diagnosis between these two different lesions is possible without administration of i.v. contrast medium[1]. Moreover MRCP alone cannot reveal the linkage between the cystic lesion and the bile duct, in particular if biliary anomalies are present. Following Gd-BOPTA injection, the presence of hyperintense biliary fluid on VIBE sequences can be demonstrated. The contrast agent fills both biliary tree and cystic duodenal duplication. In this case report the imaging findings of

duodenal duplication cyst communicating with the bile duct were comparable to that of choledochocele type III by Todani *et al*[3]. Considering the intraluminal site of the cystic lesion, it is possible to exclude other cystic diseases such as duodenal wall cystic dystrophy, pancreatic pseudocyst and other cystic masses belonging to the duodenal-choledochal-pancreatic area.

Regarding therapy, any surgical intervention should ensure complete resection of the duplication, in addition to its mucosa, in order to prevent malignant transformation[6].

CONCLUSION

Using both a negative oral contrast agent and an i.v. hepatospecific contrast agent with biliary excretion, MRI has a pivotal role in preoperative diagnosis to characterize duodenal cystic lesions eventually communicating with the biliary system and to differentiate duodenal duplication cyst from intraluminal duodenal diverticulum. In the case herein reported, distinction between choledochocele (type III) and duodenal duplication was only possible at pathological examination.

Abstract

We report here a case of multiple prolapsing mucosal polyps with diverticulosis in the sigmoid colon. A 52-year-old man was admitted to our hospital because of bloody diarrhea. Colonoscopy and barium enema showed multiple diverticula, markedly thickened mucosal folds and polypoid lesions with mucus on the top of them in the sigmoid colon. Endoscopic ultrasonography showed thickening of the mucosal and submucosal layers. Several endoscopic biopsy specimens were taken from the polypoid lesions. Histological examination revealed only chronic inflammatory cell infiltration. In order to obtain a definite diagnosis, we performed endoscopic jumbo biopsy for the polypoid lesions after obtaining informed consent. Histological examination revealed marked lymphocyte infiltration, hemosiderin deposits and fibromuscular obliteration in the lamina propria, features similar to those of mucosal prolapsing syndrome. After anti-diarrhetic treatment, clinical findings were improved. Thus, jumbo biopsy is useful for diagnosis and treatment of prolapsing mucosal polyps.

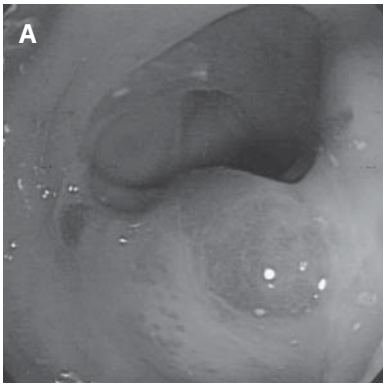
INTRODUCTION

Cases of colonic prolapsing mucosal polyps associated with diverticulosis have recently been reported in literature[1-3]. These polyps are histologically unclassifiable polyps resembling those in mucosal prolapse syndrome (MPS). Accurate differential diagnosis between neoplastic and non-neoplastic polyps is often difficult in these disease conditions. Many cases of colonic prolapsing mucosal polyps have been diagnosed retrospectively because of the low rate of pathological diagnosis of specimens obtained by the use of usual biopsy forceps. We report herein a case of unique non-neoplastic colonic mucosal prolapsing polyps with diverticulosis successfully diagnosed by using the jumbo biopsy method.

CASE REPORT

A 52-year-old man was admitted to our hospital in April 2003 because of abdominal discomfort, mucous discharge and bloody diarrhea. He had a history of frequent diarrhea from his twenties. Laboratory tests showed an increased number of peripheral leukocytes (13 800/mm^3). Barium enema showed polypoid lesions and multiple diverticula in the sigmoid colon. Colonoscopy showed multiple congested hyperemic mucosal folds and polypoid lesions with mucus on the top of them in the sigmoid colon. Slightly elevated red round patches were considered to be early minimal lesions of prolapsing mucosal polyps (Figure 1A). The surfaces of the polypoid lesions, considered to be advanced lesions, were smooth, and congested hyperemic mucosa contrasted sharply with the surrounding intact mucosa. Endoscopic examination with indigo-carmin dye spraying showed an intact mucosal pit pattern (Figure 1B). Endoscopic ultrasonography (EUS) of the early minimal lesions showed thickening of the first and second layers (mucosa) and irregular echoic lesions in the third layer (submucosa) with hypertrophy of the fourth layer (muscularis propria) (Figure 2A). EUS of the advanced lesions showed irregular low echoic lesions throughout the colonic wall (Figure 2B). Endoscopic



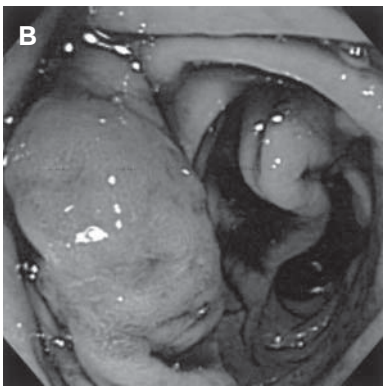


Figure 1 Colonoscopic examination of early minimal lesion (**A**) and advanced lesion (**B**) showing slightly elevated bright red round patches and congestive hyperemic polypoid lesion contrasted sharply with the surrounding mucosa (**B**: indigo carmine dye spraying view).

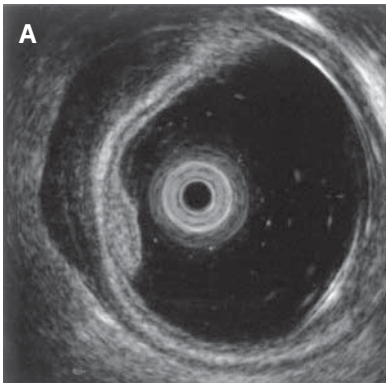

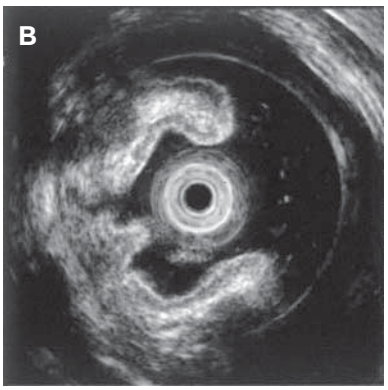

Figure 2 Endoscopic ultrasonographic examination of early minimal lesion (**A**) and advanced lesion (**B**) showing thickening of the first and second layers (mucosa) and irregular echoic lesion in the third layer (submucosa) with hypertrophy of the fourth layer (muscularis propria), and irregular low echoic lesion throughout colonic wall, respectively.

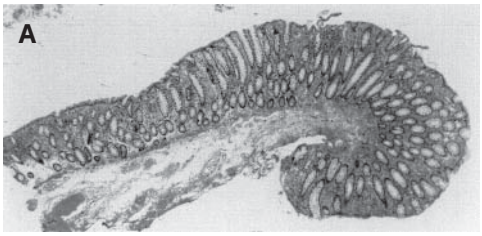

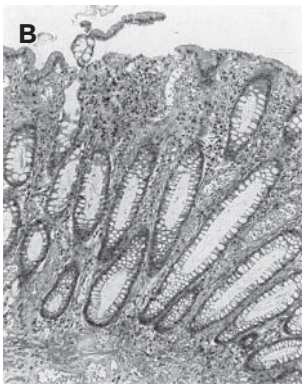

Figure 3 Hisological examination of prolapsing mucosal polyp showing mucosal hyperplasia (**A**) and chronic inflammatory cell infiltration, crypt elongation, congested vessels and fibromuscular obliterations observed in the lamina propria (**B**) (H&E, a: x40, b: x200).

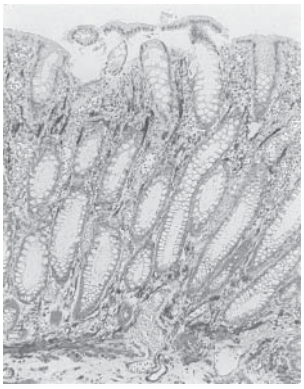

Figure 4 α-Smooth muscle actin (α-SMA) staining of prolapsing mucosal polyp showing smooth muscle fibers radiating from the thickened muscularis mucosa into the lamina propria (x200).

biopsy specimens were taken several times. Histology of biopsy specimens revealed no specific findings other than chronic inflammation. In order to obtain accurate diagnosis, we performed endoscopic jumbo biopsy for the polypoid lesions after obtaining informed consent. The jumbo biopsy specimen was taken by using a saline-solution-assisted snare resection technique that involved cutting with an Olympus SD-210-25 snare and an electro-surgical unit, OLYMPUS UES-20. Histology of the polypoid lesion showed mucosal hyperplasia (Figure 3A). Crypt elongation, chronic inflammatory cell infiltration, congested vessels and hemosiderin deposits were observed in the lamina propria (Figure 3B). Immunohistochemistry using a monoclonal antibody against anti-α smooth muscle actin showed smooth muscle fibers radiating from the thickened muscularis mucosa (fibromuscular obliteration) (Figure 4). Based on these findings, these lesions were diagnosed as prolapsing mucosal polyps with diverticulosis of the sigmoid colon. The patient was treated with anti-diarrhetic drugs and a fiber-enriched diet. Diarrhea was improved and the white blood cell count in peripheral blood decreased to within the normal range.

DISCUSSION

We experienced a patient who was diagnosed by using the jumbo biopsy method as having prolapsing mucosal

polyps with diverticular diseases. Cases of prolapsing mucosal polyps with diverticular disease have recently been reported by Franzin *et al*[1] and Mathus-Vliegen *et al*[2] These polyps are histologically unclassified polyps resembling those in mucosal prolapse syndrome (MPS). MPS including solitary rectal ulcer syndrome is characterized by the presence of polypoid or ulcerative lesions with the histological changes of glandular epithelium, fibromuscular obliteration and teleangiectatic blood vessels in the lamina propria. MPS is thought to result from chronic intermittent ischemia caused by overt or occult mucosal prolapse. Histological features of these polyps are crypt elongation, up-growth of muscle fibers from the muscularis mucosa (fibromuscular obliteration), and mucosal and submucosal vascular congestion, hemorrhage and hemosiderin deposition[3]. These polyps resemble 'cap polyposis'; however, there is a large amount of granulation tissue formation called fibrin-cap on the surface and less teleangiectactic changes in 'cap polyposis' than in MPS.

Endoscopy in our case showed slightly elevated red round patches, considered to be initial lesions, and smooth and congested hyperemic mucosal polypoid lesions. Tendler *et al*[4] reported that all prolapsing polyps occurred in the sigmoid colon usually in association with diverticular disease. Endoscopic ultrasonography (EUS) in our case showed thickening of the first and second layers (mucosa) and mixed hypoechoic lesions in the third layer (submucosa) with hypertrophy of the fourth layer (musclularis propria) in small patches, and moderate irregular hypoechoic lesions extended into the fourth layer (muscularis propria) with destruction of the first and second layers (mucosa) and the third layer (submucosa) in the polypoid lesion. It has recently been reported that EUS of polypoid prolapsing mucosal folds revealed thickening of mucosal and submucosal layers, demonstrating remarkably hyperemic and thickened mucosal folds[5]. These EUS findings resemble those described in previous reports of MPS[6,7]. In our case, the mixed hypoechoic pattern of early minimal lesions was thought to reflect mild fibromuscular obliteration and edema in the mucosal and submucosal layers. This irregular pattern was more apparent in advanced lesions throughout the colonic wall. These EUS findings demonstrated changes in the pathological development of these polyps. However, almost all cases of colonic prolapsing mucosal polyps have been diagnosed retrospectively after treatment. Only one case has been diagnosed by EUS findings and a normal surface pit-pattern before treatment[5].

Diagnosis of prolapsing mucosal polyps by examination of biopsy specimens obtained by using biopsy forceps can be difficult because of the sizes and depths of obtained specimens. Results of examination of biopsy specimens obtained several times from our case only showed chronic inflammation without fibromuscular obliteration. Warren *et al*[8] proposed the usefulness of diagnostic features of 'diamond-shaped' crypts in biopsy specimens. However, there were no such findings in our case. Jumbo biopsy is known to be a safe and useful method for diagnosis and treatment, and it is often used for not only endoscopic cure of early cancers, but also obtaining specimens for accurate pathologic staging[9]. In some cases, inflammatory change induces a "pseudo-malignant status". Colitis cystica profounda, a variant of mucosal prolapse syndrome, is sometimes difficult to distinguish from mucinous-producing carcinoma because of its formation by an aberrantly located gland-forming epithelium[10].

Treatment of prolapsing mucosal polyps is fundamentally conservative. Mathus-Viegen *et al*[2] reported the usefulness of a fiber-enriched diet for treatment of prolapsing mucosal polyps. Improvement was obtained in our case by a fiber-enriched diet and administration of an anti-diarrhetic drug. However, some patients with this disease require surgery because of intractable abdominal pain. It is important for endoscopists and pathologists to be familiar with and recognize the characteristic features of prolapsing mucosal polyps in order to avoid oversurgery for this disease because of its benign nature.

Abstract

In this case report we describe for the first time an association between autoimmune hepatitis (AIH) and uveitis, without any doubts about other possible etiologies, such as HCV, since all the old reports describe the association of AIH with iridocyclitis before tests for HCV-related hepatitis could be available. A 38-year-old businessman with abnormal liver function tests and hyperemia of the bulbar conjunctiva was admitted to the hospital. Six years before admission, the patient presented with persistent fever, arthralgias, conjunctival hyperemia, leukocytosis and increased ESR, referred to acute rheumatic fever. The presence of systemic diseases, most commonly associated with uveitis, was investigated without results and the patient was then treated with topical corticosteroids. His symptoms resolved. A test for anti-nuclear antibodies was positive, at a titre of 1:320, with a speckled and nucleolar staining pattern. Liver ultrasound showed mild hepatomegaly with an increased echostructure of the liver. Percutaneous liver biopsy was performed under ultrasound assistance. Histological examination showed necroinflammation over the portal, periportal and lobular areas, fibrotic portal tracts, with periportal fibrosis and occasional portal-to-portal bridgings, but intact hepatic architecture. Some hepatocytes showed barely discernible granules of hemosiderin in the lobular area. Bile ductules had not any significant morphological alterations. METAVIR score was A2-F3, according to the modified HAI grading/fibrosis staging. The patient was diagnosed to have AIH with mild activity and fibrosis and was discharged on 25 mg prednisone, entering clinical and biochemical remission, further confirming diagnosis. After discharge the patient continued to have treatment with corticosteroids as an outpatient at a dose of 5 mg. On January 2002 the patient was readmitted to the hospital. A test for anti-nuclear antibodies was positive, at a titre of 1:320, with a speckled and nucleolar staining pattern. Anti-smooth muscle antibody test was also positive (1:160), while anti-LKM antibodies were negative. Ophthalmologic examination revealed inflammatory cells and proteinaceous flare in the anterior chamber of the left eye, and a stromal lesion in the cornea. He was maintained on immunosuppressive therapy (5 mg prednisone plus topical antibiotic therapy for two weeks) and then discharged. A complete remission of the symptoms was registered on follow-up. At present (July 2005), the patient is on prednisone (5 mg) and has no symptoms. Liver function tests are also within the normal range.

Key words: Autoimmune hepatitis; Uveitis

CASE REPORT

A 38-year-old businessman was admitted to the Azienda Ospedaliero-Universitaria Careggi (Florence, Italy) on May 4th 2000, because of abnormal liver function tests and hyperemia of the bulbar conjunctiva.

The patient had no history of liver disease or jaundice, receipt of blood products, intravenous drug abuse, and exposure to alcohol or hepatotoxic drugs, seafood ingestion, any abdominal pain, excessive fatigue, rashes, or foreign travels. All his children were healthy. Family history of gastrointestinal or liver diseases was negative. His mother was affected by goitre and diabetes mellitus.

Six years before admission, the patient presented with persistent fever, arthralgias, conjuntival hyperemia, leukocytosis and increased ESR, which were referred to acute rheumatic fever, despite no evidence of recent group A streptococcal infection, since throat cultures were negative and streptoccal antibody test was normal. The patient was given salicylic acid up to 4 g for 2 mo. and prophylaxis with intramuscular benzathine penicillin G (1.2 g/mo. for 5 years). In 1998, conjunctival hyperemia recurred and iridocyclitis was diagnosed. The presence of systemic dis-

eases, most commonly associated with anterior uveitis, was investigated without results and the patient was treated with topical corticosteroids. His symptoms resolved. At admission for further studies on systemic alterations other than uveitis, the temperature was 36.6 ℃, the pulse was 84 bpm, and the respiration rate was 18/min. Blood pressure was 105/70 mmHg. At physical examination, the head, the neck and the extremities were normal. Auscultation of the heart and both lungs were normal. The abdomen was soft with normal bowel sounds and not distended; there was tenderness in the right upper quadrant, and also in the lower one, with rebound tenderness in the latter; the liver was enlarged (about 3 cm below the right costal margin); the spleen was not palpable; no hernia was detected. There was no evidence of edema, bleeding diathesis, or spider angiomata.

Main initial laboratory findings were as follows: hematocrit 48.2%, leukocytes 5 400/μL (39.5% neutrophils, 39.7% lymphocytes, 18.2% monocytes, 0.6% basophyls, 2.0% eosinophils), platelets 157 000/μL, reticulocyte count 1.35%, glucose 0.83 mg/dL, BUN 0.25 mg/dL, creatinine 1.0 mg/dL, proteins 72 g/L, albumin 42.3 g/L, globulins 29.7 g/L, IgG 1 590 mg/dL, IgA 224 mg/dL, IgM 83 mg/dL, AST 960 IU/L, ALT 1 510 IU/L, γ-glutamiltranspeptidase 112 IU/L, alkaline phosphatase 249 IU/L, total bilirubin 1.57 mg/dL, conjugated bilirubin 0.4 mg/dL, total cholesterol 116 mg/dL, serum calcium 8.4 mg/dL, serum phosphorus 2.6 mg/dL, serum iron concentration 276 μg/dL, serum ferritin 3 020 ng/mL, and haptoglobin 54 mg/dL; international normalized ratio for prothrombin time was 1.3, the activated partial thromboplastin time 39.6 s, and TSH 2.22 mU/L. Urinanalysis was normal. Hepatitis B surface antigen, anti hepatitis A, B and C virus (IgG) were undetectable. Anti-CMV IgG were positive (30 UA/mL), but IgM resulted negative. Serologic tests for brucella and mycobacterium sp (IgG and IgM) were negative. The direct and indirect Coombs tests were also negative. Serum circulating immune complexes were within the normal range (IgG binding C1q 2.6 μEq/mL and IgG binding C3 5.2 μEq/mL), C3 was 111, C4 22 mg/dL. A test for anti-nuclear antibodies was positive, at a titer of 1:320, with a speckled and nucleolar pattern of staining. Test for anti-smooth muscle antibodies was also positive (1:160), anti-LKM antibodies were negative. Titres of antithyroid peroxidase autoantibodies and anti-thyreoglobulin autoantibodies were 420 and 85.6 IU/mL, respectively.

Liver ultrasound showed mild hepatomegaly with an increased echostructure of the liver. Percutaneous liver biopsy was performed under ultrasound assistance. Liver biopsy showed necroinflammation over the portal, periportal and lobular areas, fibrotic portal tracts, with periportal fibrosis and occasional portal-to-portal bridgings, but intact hepatic architecture. Some hepatocytes showed barely discernible granules of hemosiderin in the lobular area. Bile ductules were without any significant morphological alterations. METAVIR score resulted A2-F3, according to the modified HAI grading and fibrosis staging as proposed by Ishak *et al*[1]. No stainable iron or copper deposits were found.

Ophthalmologic examination, performed to rule out Wilson's disease, revealed no diminished visual activity in both eyes; eye movements were normal, without diplopia; the globes were intrinsically normal, so as papillary light reflexes. The fundus oculi was normal, without signs of vasculitis. Biomicroscopy of the anterior segment of the eye was negative for iridocyclitis. No Kayser-Fleischer rings were noted.

Considering the clinical presentation, together with increased serum aminotransferase levels, absence of viral markers for hepatitis B, C, and other hepatotropic viruses, evidence on liver biopsy of chronic hepatitis with mild-

to-moderate fibrosis, the patients was diagnosed to have autoimmune hepatitis (AIH) with mild activity and discrete fibrosis. Patient was discharged on prednisone 25 mg and entered clinical and biochemical remission, further confirming diagnosis. After the discharge the patient continued to have treatment with corticosteroids as an outpatient at a dose of 5 mg.

On January 2002 the patient was readmitted to the hospital because of fever (39 ℃), occurring especially in the evening. He also complained photophobia, and blurred vision in both eyes. The blood pressure was 110/65 mmHg, the pulse rate was 87 bpm, and the respirations were 18/minute. Physical findings were unmodified in respect to the previous readmission.

Laboratory investigations showed the following data: hematocrit 39.7%, leukocytes 9 690/μL (65% neutrophils, 19.3% lymphocytes, 14.5% monocytes, 0% basophyls, 1.2% eosinophils), platelets 497 000/μL, reticulocyte count 1.35%, glucose 1.22 mg/dL, BUN 0.24 mg/dL, creatinine 1.2 mg/dL, proteins 84 g/L, albumin 33.9 g/L, globulins 50.1 g/L, IgG 1 670 mg/dL, IgA 273 mg/dL, IgM 64 mg/dL, AST 14 IU/L, ALT 16 IU/L, γ-glutamiltranspeptidase 26 IU/L, alkaline phosphatase 52 IU/L, total bilirubin 0.54 mg/dL, conjugated bilirubin 0.14 mg/dL, total cholesterol 96 mg/dL, serum calcium 9.1 mg/dL, serum phosphorus 2.4 mg/dL, serum iron concentration 82 μg/dL, serum ferritin 263 ng/mL, haptoglobin 1 120 mg/dL, international normalized ratio for prothrombin time 1.0, and the activated partial thromboplastin time 26.1 s. Flogosis indexes (ESR, C-reactive protein, fibrinogen) were elevated. TSH was 1.57 mU/L. Urinanalysis was normal. Direct and indirect Coombs tests were both negative. Serum circulating immune complexes were within the normal range; C3 was 196 mg/dL, C4 43 mg/dL, and serum immunoelectrophoresis showed increased IgG. A test for anti-nuclear antibodies was positive, at a titre of 1:320, with a speckled and nucleolar staining pattern. Test for anti-smooth muscle antibodies was also positive (1:160), anti-LKM antibodies were negative. Titres of antithyroid peroxidase autoantibodies and anti-thyreoglobulin autoantibodies were 420 and 85.6 IU/mL, respectively.

Serologic markers of viral infection (toxoplasma, EBV, mycobacterium sp, CMV, HAV, HBV, HCV and neurotropic viruses) were all negative. Antistreptococcal and anti-staphylococcal antibodies were undetectable (Table 1).

Ultrasound of the liver was normal. Ophthalmologic examination revealed inflammatory cells and proteinaceous flare in the anterior chamber of the left eye (Tyndall + - -), and a stromal lesion in the cornea. The right eye was unaffected.

He was maintained on immunosuppressive therapy (5 mg prednisone) plus topical antibiotic treatment for two weeks and then discharged. A complete remission of the symptoms was registered on follow-up. At present (July 2005), the patient is on prednisone (5 mg) and has no symptoms. Liver function tests are also within the normal range.

DISCUSSION

About 25% of patients with AIH have an acute onset. In most cases, however, the clinical presentation of AIH is characterized by the same signs and symptoms of chronic hepatitis of other aetiology. A specific feature of AIH is the association with extrahepatic immune-mediated syndromes, including autoimmune thyroiditis[2-5], scleroderma, rheumathoid arthritis, Sjögren's syndrome or diabetes mellitus (Table 2). An old report describes the association of chronic autoimmune hepatitis with iridocyclitis[2], but at that time tests for HCV-related hepatitis were not available[6].

The hallmark of acute anterior uveitis is the presence of inflammatory cells and proteinaceous flare in the anterior chamber of the eye. Symptoms include pain, photophobia, and blurred vision in the involved eye(s). Iridocyclitis may be part of a more generalized autoimmune and endogenous uveitis, such as Reiter's syndrome, more commonly observed in patients with HIV infection. Phacogenic uveitis, sympathetic ophtalmia and Vogt-Kaganayi-Harada syndrome can represent ocular autoimmune diseases suitable for a differential diagnosis, even if both phacogenic uveitis and sympathetic ophtalmia are post-traumatic granulomatous uveitis. In this patient, however, there is no history of physical or surgical trauma, ruling out the possibility of an involvement of the above disorders in this case. The Vogt-Kaganayi-Harada syndrome is an idiopathic, bilateral, inflammatory syndrome occurring in middle age and characterized by a typical granulomatous intraocular inflammation. The aetiology of this syndrome is unknown and the disorder is assumed to be an autoimmune hypersensitivity response to pigment. Poliosis (i.e. localized depigmentation of the hair) occurs in more than 90 percent of these patients, together with alopecia and vitiligo. Auditory disturbances occur in more than 75% of patients, and many other neurologic findings, including psychosis, have been sometimes reported. However, this disorder is very rare, and most cases have been associated with a previous penetrating ocular injury, which is absent in our patient.

We also considered, for the differential diagnosis, a possible ophtalmic localization of systemic diseases, either infectious or not[7]. Wegener's granulomatosis is characterized by fever, weight loss and other systemic manifestations, together with ocular and oropharyngeal signs. Moreover, ankylosing spondylitis and chronic inflammatory bowel diseases can both be complicated by anterior uveitis. Furthermore, viral infections can cause uveitis: toxoplasmosis is generally the most common cause of infective uveitis, and AIDS is also mostly associated with cryptococ-

cal chorioretinitis or posterior uveitis. A possible cause of uveitis can, finally, be represented by systemic lupus erythematosus, which is typically characterized by arthralgia, fever and ocular involvement, the presence of circulating antinuclear autoantibodies and no substantial remission after corticosteroid therapy.

AIH type I is the most common form of AIH worldwide and is associated with antinuclear antibodies and/or smooth muscle antibodies. This is a disorder characterized by hepatic and extrahepatic involvement; the most frequent extrahepatic associations of AIH are mentioned in the table above *(*Table 2*)*. In this case report, we have described, for the first time, an association between AIH and uveitis, without any doubts about other possible etiologies, such as HCV infection[8], since all the old reports describe the association of AIH with iridocyclitis before tests for HCV-related hepatitis could be available. Furthermore, this report concentrates on clinical attention to patients who may be at increased risk for potentially serious ocular disorders and for whom slit-lamp examination may be warranted on a regular basis.

The majority of patients affected by AIH require a long-term maintenance therapy, and the milder disease is associated with a better response to therapy[9]. Corticosteroid treatment is the best choice therapy for AIH and, even if it is usually followed by immunosuppression, thereafter[10], we preferred a low-dose steroid treatment, registering both remission of hepatitis and absence of any significant side effects. This is well documented in the literature[11]. Moreover, azathioprine has a significant early adverse reaction (EAR) profile, which includes an acute syndrome of constitutional symptoms, fever, rash, and acute pancreatitis and often requires discontinuation of drug. Some Authors report that EAR (early adverse reactions) precludes azathioprine use in patients with Crohn's disease (CD) and autoimmune hepatitis (AIH)[12]. Finally, we skip immunosuppressive treatment since it has been described an increased tumor risk under azathioprine therapy, especially in Vogt-Kaganayi-Harada (VKH) syndrome. Vogt-Kaganayi-Harada (VKH) syndrome was excluded in the differential diagnosis of our patient. Azathioprine treatment has been registered associated with increased risk of malignancies[13,14].

Abstract

A 79-year-old female patient with hepatitis C virus-related liver cirrhosis was diagnosed as having hepatocellular carcinoma (HCC) with a diameter of 2.0 cm. She refused therapy for HCC. Nine months after the diagnosis, she developed dermatomyositis when the HCC enlarged to a diameter of 6.0 cm. She underwent therapy for dermatomyositis, and then transcatheter arterial chemoembolization for HCC. Although the manifestations of dermatomyositis improved and entire tumor necrosis was achieved, she died of pneumonia 2 mo after the treatment of HCC. HCC and/or chronic hepatitis C virus infection might be involved in the pathogenesis of dermatomyositis.

Key words: Dermatomyositis; Hepatocellular carcinoma; Hepatitis C virus

INTRODUCTION

The cause of dermatomyositis remains unknown. However, some factors have been implicated in the pathogenesis of dermatomyositis. Many reports on the relationship between dermatomyositis and cancer or viral infection have been published[1-17]. We report herein a rare case of dermatomyositis that occurred during the natural course of hepatocellular carcinoma (HCC) in an elderly female patient with hepatitis C virus (HCV)-related liver cirrhosis.

CASE REPORT

A 79-year-old woman was treated for HCV-related liver cirrhosis at our hospital. She received medication for the liver disease (ursodeoxycholic acid) and for epilepsy (clonazepam) due to a past head injury. There was no family history of autoimmune disease or malignancy. In October 2003, a hepatic tumor with a diameter of 2.0 cm in the right anterosuperior segment was detected on dynamic computed tomography (CT): the tumor was shown to be a hypodense lesion in the basal study which was enhanced during the arterial phase and became hypodense during the delayed phase. The serum alpha-fetoprotein (AFP) and des-gamma-carboxy prothrombin (DCP) levels were 3.4 ng/mL (normal, <10 ng/mL) and 431 mAU/mL (normal, <40 mAU/mL), respectively. Based on these findings, the tumor was diagnosed as HCC. However, the HCC was not treated at that time because the patient refused therapy.

In July 2004, she began to develop progressive muscle weakness in the extremities and systemic erythema. She was admitted to the Department of Dermatology at our hospital. On admission, her height was 146 cm and her body weight was 60 kg. A heliotrope rash in the periorbital skin, Gottron papules on the metacarpophalangeal joints, and poikiloderma on the anterior neck and upper chest were observed. There was no skin thickening of the extremities or joint swelling. Muscle examination revealed symmetrical proximal weakness: she could not rise from a chair or raise her hands up to the level of her shoulders. Table 1 shows her laboratory data on admission. Elevated serum muscle enzymes were observed. HBsAg (enzyme immunoassay [EIA], Dinabot, Tokyo, Japan) was negative. Anti-HCV antibody (second generation, EIA, Dinabot) was positive with a high titer, and HCV RNA (reverse transcription-PCR, Sionogi, Osaka, Japan) was also positive. Hypergammaglobulinemia was observed. Antinuclear antibodies were positive (1:640, homogeneous, speckled), while rheumatoid factor, myeloperoxidase antineutrophil cytoplasmic antibodies, anti-DNA, anti-

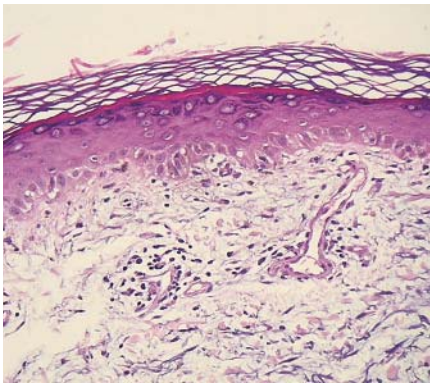

Figure 1 Hematoxylin-eosin staining of skin biopsy of the left forearm showing flattened epidermis and scattered inflammatory cell infiltration around the small vessels of the dermis (200 × magnifications).

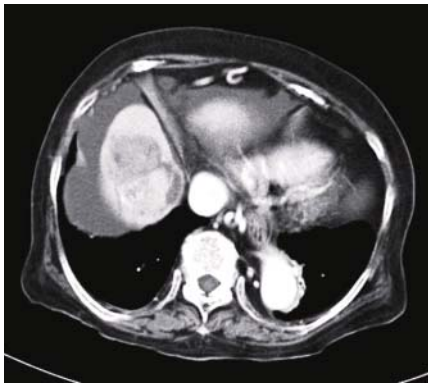

Figure 2 Contrast-enhanced computed tomography showing a hypervascular, in part, necrotic tumor in the right anterosuperior segment of the liver and ascites.

Jo-1, anti-RNP, anti-SSA, and anti-SSB were all negative. Electromyography of the right biceps brachii muscle showed fibrillation and low amplitude voltage of a short duration (less than 200 mV). Skin biopsy of the left forearm showed flattened epidermis, partial liquefaction of the basal layer, scattered inflammatory cell infiltration around the small vessels, and degeneration of collagen fiber of the dermis (Figure 1). Muscle biopsy of the left triceps failed to show remarkable findings. On the basis of these findings, the diagnosis of dermatomyositis was made. Initially, 50 mg of prednisolone per day was administered, and then the dosage was gradually decreased to 15 mg/d. Skin eruption almost disappeared completely and muscle power slowly improved. Muscle enzymes also improved to the normal range. During the treatment of dermatomyositis, the patient decided to undergo therapy for the HCC.

When she was referred to the Department of Internal Medicine in August 2004, the HCC nodule was enlarged to a maximal diameter of 6.0 cm, and ascites was observed (Figure 2). The serum AFP and DCP levels also increased to 2 130.2 ng/mL and 7 423 mAU/mL, respectively. Other serum tumor markers, including carcinoembryonic antigen, carbohydrate antigen 19-9, and carbohydrate antigen 125, were all negative. No other malignancies were identified by imaging studies, such as ultrasonography and CT or esophagogastroduodenal endoscopy. In August 2004, she underwent transcatheter arterial chemoembolization for the treatment of the HCC after the ascites was controlled. After transcatheter arterial chemoembolization, entire tumor necrosis was achieved; the serum AFP and DCP levels decreased to 46.7 ng/mL and 54 mAU/mL, respectively. The clinical course of dermatomyositis was not affected by the embolization. Unfortunately, the patient died of bacterial pneumonia in October 2004.

DISCUSSION

The relationship between cancer and dermatomyositis has been widely reported in the literature[1-9]. Recent

population-based studies have demonstrated that 15-32% of patients with dermatomyositis are associated with various types of cancers, such as ovarian, lung, pancreatic, stomach, and colorectal cancers[1,2]. However, there have been few reports on the association between dermatomyositis and HCC[3-9]. Although the rare association might be fortuitous, a recent report described the improvement of dermatomyositis without the need of corticosteroids after the resection of HCC, supporting the hypothesis that HCC can cause dermatomyositis through a paraneoplastic mechanism[8]. In the present case, dermatomyositis occurred when the HCC increased from a baseline diameter of 2.0 cm to 6.0 cm at 10 mo. In most other reported cases, advanced HCC, more than 6.0 cm in diameter or multiple, has been found at the diagnosis of dermatomyositis[4-9]. Those reports indicate that advanced HCC might induce an autoimmune response as the trigger of dermatomyositis.

Recent studies have demonstrated that antibodies to Mi-2, a component of the nucleosome remodeling-deacetylase complex, are strongly associated with dermatomyositis (frequencies up to 31%)[18,19]. An *in vitro* study has shown that a 169-bp cDNA product, which is 88.8% homologous to the human Mi-2beta antigen, is identified in H4IIE rat hepatoma cells[20]; and 100% homology is found at the protein level. Based on these findings, anti-Mi-2 antibodies might be cross-reactive with HCC. Unfortunately, anti-Mi-2 antibodies were not examined in the present case. Further studies on autoantibodies cross-reacting with HCC should be undertaken to shed light on the pathogenesis of dermatomyositis associated with HCC.

Occasional associations between dermatomyositis and HCV infection have been reported[6,7,9-14]. Thus far, there has been no direct evidence that HCV infection can cause dermatomyositis. A recent preliminary study has shown no significant higher incidence of HCV in patients with dermatomyositis as compared with the control population[10]. However, chronic HCV infection has been known to be associated with the presence of autoantibodies and various types of autoimmune diseases, leading to the hypothesis that chronic HCV infection could cause dermatomyositis through an autoimmune mechanism[21]. In the present case, antinuclear antibodies were strongly positive, suggesting that there might be some immune disorders related to the development of dermatomyositis. We speculate that antibodies against HCV or HCV-enzyme complex might cross-react with homologous area of host proteins and thus cause autoimmune diseases including dermatomyositis. Crowson *et al*[22] have reported that HCV RNA is expressed in a focal, weak fashion in endothelia and perivascular inflammatory cells in some HCV-infected patients associated with cutaneous eruptions. They postulated that parasitism by HCV can render endothelia autoantigenic through exposure of cryptic antigens via virally induced endothelia cell injury. Histopathologic examinations of HCV expression using skin biopsy specimens from patients with dermatomyositis associated with HCV infection might provide information on the role of HCV in the pathogenesis of dermatomyositis.

In the present case, other infectious agents including echovirus, adenovirus, and coxsackievirus, which are known to cause myositis, were not examined[15-17]. Therefore, there remains the possibility that dermatomyositis of the present case might be caused by such viruses.

In summary, this report suggests that HCC, in particular advanced HCC, and/or chronic HCV infection might be factors in the pathogenesis of dermatomyositis. The mechanisms of autoimmune responses induced by such factors should be studied in the future.

Abstract

Hepatic inflammatory pseudotumor (IPT) is a rare benign non-neoplastic lesion characterized by proliferating fibrous tissue infiltrated by inflammatory cells. The exact etiology of IPT remains unclear. Although the association of IPT with systemic inflammatory disorders has been well established, a specific relationship with cholangitis is distinctly rare. We report a case of spontaneous regression of hepatic IPT with primary biliary cirrhosis (PBC). To date, only two cases of IPT with PBC have been reported. In our case, however, IPT developed during the course of improvement of cholangitis of PBC induced by effective treatment, differing from two previously reported cases. Our case indicates that the development of IPT does not also relate to the activity of cholangitis and/or hyper gamma-globulinemia, since our case was confirmed radiologically to be free of IPT when biliary enzymes and immunoglobulins were much higher than the corresponding values on admission. Comparison of our case with the two previously reported cases suggests that IPT occurring with PBC does not represent the same disease entity or be a bystander for PBC.

Key words: Hepatic inflammatory pseudotumor; Primary biliary cirrhosis; Spontaneous regression; Ursodeoxycholic acid; Bezafibrate

INTRODUCTION

Hepatic inflammatory pseudotumor (IPT) is a rare benign non-neoplastic lesion characterized histopathologically by proliferating fibrous tissue infiltrated by inflammatory cells. The exact etiology of IPT remains unclear. Although the association of IPT with systemic inflammatory disorders has been well described, a specific relationship with cholangitis is distinctly rare[1-4]. Primary biliary cirrhosis (PBC) is a chronic cholestatic disease with cholangitis. We report a case of spontaneous regression of IPT associated with PBC. Our case was peculiar in view of detection of IPT during improvement of cholangitis of PBC, thus differing from the two previous reports of IPT with PBC[5,6].

CASE REPORT

The patient was a 71-year-old man. He was diagnosed in 2001 with PBC (Scheuer's histological stage II) based on histopathological findings of liver biopsy specimens and positive anti-mitochondrial antibody (AMA) and was followed with ursodeoxycholic acid (UDCA) in our department. He requested a check up for cancer and fluorodeoxyglucose positron emission tomographic study (FDG PET) was performed on his request on his 70th birthday. The whole-body images demonstrated a 3-cm-diameter spherical mass in the liver (Figure 1A, B). One year before FDG PET, no liver tumor was noted on enhanced computerized tomography (CT). He was admitted to our department for full examination and assessment. We had started treating the patient with bezafibrate, which was recently reported to be effective in improving PBC patients with elevated biliary enzymes[7], two months before detection of the liver mass because UDCA had not been fully effective. On admission, he was asymptomatic and physical examination was negative. Laboratory data on admission (Table 1) showed elevated

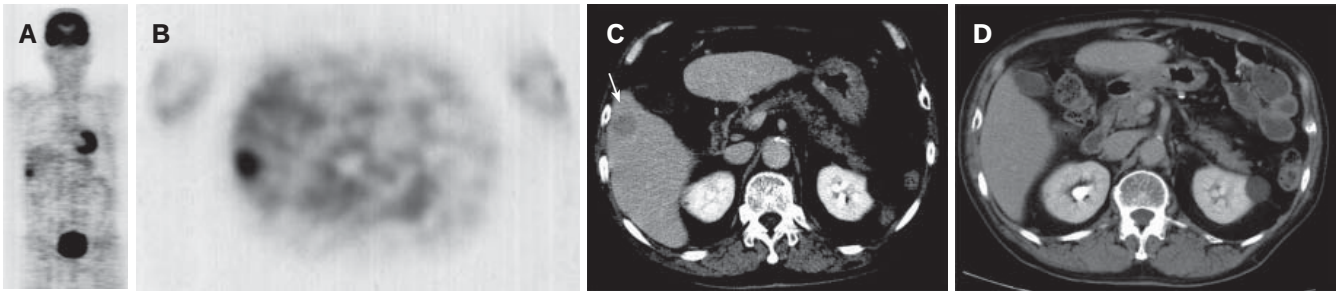

Figure 1 A, **B**: Whole body F-18 fluorodeoxyglucose (FDG) positron emission tomography (PET) scan showed a 3-cm spherical mass in the right lobe of the liver. **A**: Coronal sectional view, **B**: horizontal sectional view. **C**: Enhanced CT showed a 3-cm spherical low-density mass (arrow) in the right lobe of the liver. **D**: Another enhanced CT performed 3 mo after targeted liver biopsy showed complete resolution of the mass.

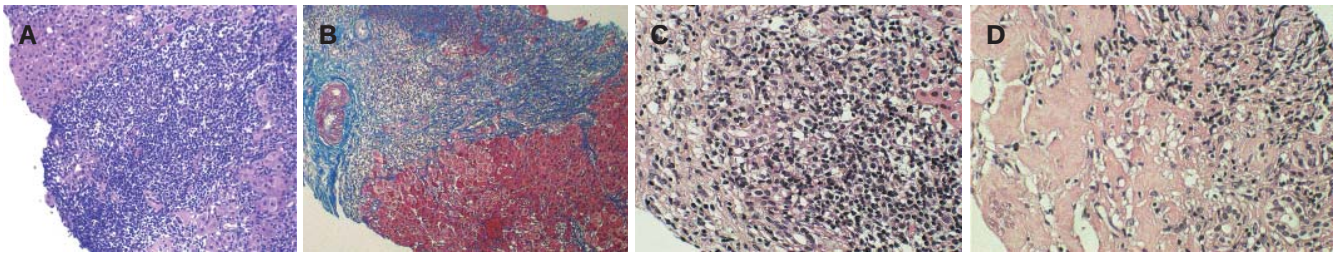

Figure 2 A: Liver biopsy specimen from the non-tumorous liver. Histopathological findings are consistent with primary biliary cirrhosis. The enlarged portal tract with damaged bile ducts in florid lesion of non-suppurative destructive cholangitis is infiltrated by inflammatory mononuclear cells. H&E, X100. **B**: Liver biopsy specimen shows clear-cut boundary between the "tumor" and liver parenchyma. Azan-Mallory, ×100. **C**:The "tumor" is composed of chronic inflammatory cells including lymphocytes and plasma cells. H&E, × 400. **D**: The "tumor" is composed of fibrous tissue, thick hyalinized collagen bundles with disappearance of liver parenchyma. H&E, ×400.

Table 1 Changes of Biochemical and immunologic Profile

	Before treatment of UDCA without detection of IPT	On admission	At the time of regression of IPT
Total bilirubin (mg/dL)	0.7	0.8	0.6
AST (IU/L)	46	22	25
ALT (IU/L)	391	16	15
ALP (IU/L)	682	159	141
γGTP (IU/L)	248	52	45
IgM (mg/dL)	1010	303	281
IgG (mg/dL)	2010	1360	1170
ANA	×5120	×160	×160
AMA (index)	181	205.6	173.2
CRP	<0.1	<0.1	<0.1

AMA (205.6 arbitrary unit), anti-nuclear antibodies (ANA, ×160), gamma-glutamyl transpeptidase (gamma-GTP, 52 IU/L) and IgM (303 mg/dL) levels and a normal value of alkaline phosphatase (ALP). The results of these tests showed satisfactory improvement compared with the data recorded when treatment was limited to UDCA only, thus reflecting the effectiveness of bezafibrate. Total bilirubin, aspartate aminotransferase, alanine aminotransferase, C-reactive protein, IgG levels, leukocyte count and gamma-globulin ratio of serum protein were normal. Serology for hepatitis B and C, alpha-fetoprotein, protein levels induced by the absence of vitamin K or antagonist-II and carcinoembryonic antigen were normal. Magnetic resonance cholangiopancreatography (MRCP) findings were normal. Enhanced CT showed a 3-cm spherical low-density mass in the right lobe of the liver (Figure 1C) corresponding to the mass on FDG PET. To rule out hepatocellular carcinoma, metastatic liver tumor, and cholangiocarcinoma, percutaneous needle biopsy was performed under CT because of the isoechoic lesion by ultrasonography. Histopathological examination showed marked infiltration of lymphocytes, plasma cells, fibrosis and loss of hepatic cells, findings consistent with IPT (Figure 2). Immunohistochemical staining for kappa- and lambda-light chains of immunoglobulin demonstrated the plasma cells contained both chains almost equally. The patient was followed up conservatively, and a repeat CT scan 3 mo after biopsy showed complete regression of IPT (Figure 1D). At this point, laboratory data (Table 1) showed normalization of gamma-GTP level and improvement of AMA (173.2 arbitrary unit) and IgM (281 mg/dL) levels except the same level of ANA (×160).

DISCUSSION

IPT is acute benign lesion that develops throughout the body. Hepatic IPT is relatively unique but has been recognized with increased frequency. It is difficult to make a specific diagnosis based on the findings of laboratory or imaging techniques because there is no specific laboratory marker and radiographic appearance. Therefore the vast majority of reported cases of IPT of the liver have been diagnosed after surgery or at autopsy[8-11]. Recently ultrasonography-guided percutaneus liver biopsy is reported to be useful[10,12].

The CT or MRI appearance of abdominal IPT are variable[13]. Moreover it has been reported that there are no specific signs of the disorder, in spite of the advances in imaging techniques (ultrasonography, endoscopic

retrograde cholangiography and angiography)[14-16], Yoon *et al*[17] reported that the area of low attenuation indicated the presence of chronic inflammatory infiltrations with foamy histiocytes, plasmacytes, and lymphocytes, while areas of iso- or high attenuation representes fibroblastic proliferation. Therefore the low attenuation of IPT on CT findings in our case may indicate a lower component of fibrosis and a higher component of cellular infiltration. Interestingly, to our knowledge, there is only one case of IPT detected by FDG PET, resulting from foreign body in abdominal cavity[18]. The tumor mass was identified as an inflammatory granuloma[18]. FDG PET may reflect inflammatory cell infiltrations in IPT in our case. The protean radiologic manifestations of IPT in our case may be the result not only of the variable morphologic structure including hyalinized collagen bundles or inflammatory cell infiltrations but the dynamic, rapidly changing nature of an inflammatory process.

While the exact etiology of hepatic IPT remains unclear, several mechanisms have been postulated such as infection, immune reaction, intraparenchymal hemorrhage and necrosis, occlusive phlebitis of intrahepatic veins, and secondary reaction to intrahepatic rupture of a biliary radical[19]. Cholangitis arising from various causes including infection with microorganisms, immunological or allergic reactions, and primary sclerosing cholangitis (PSC) has been also considered responsible for the development of hepatic IPT[1-4]. In only two recent reports[5,6], PBC was proposed as a possible cause of hepatic IPT. In both of these cases, hepatic IPT was detected with the simultaneous discovery of PBC or untreated PBC, associated with extremely high levels of biliary enzymes and autoimmune antibodies. Hyper gamma-globulinemia has been also suggested to contribute to the development of IPT[20-22]. The activity of cholangitis or hyper gamma-globulinemia as the etiological factor is, however, cannot be applied to our case because ANA (X5120), ALP (682 IU/L), gamma-GTP (248 IU/L), IgG (2010 mg/dL) and IgM levels (1010 mg/dL), measured when hepatic IPT had not been detected by CT before treatment of UDCA, were much higher than the corresponding laboratory data on admission (Table 1). At the time of regression of IPT, some of the laboratory data (Table 1) improved compared to those on admission probably due to effectiveness of UDCA add-on bezafibrate. However causal association between development or regression of IPT and improvement of laboratory data remains uncertain. Importantly, our case suggests IPT can develop at relatively inactive or recovery phase of PBC differing from previous reports[5,6] and on the contrary, IPT with PBC is probably not the same disease entity or a bystander for PBC.

The other finding exemplifying disease diversity is that the rapid resolution of some cases[4], including our case, may be related to the effectiveness of treatment of the underlying disease whereas in the other reported case[5] IPT regressed even though UDCA did not effectively improve the laboratory data. With regard to treatment of IPT, most reported patients underwent surgical resection because it is difficult to distinguish IPT from malignant liver tumors using only imaging modalities[9,23]. However, the prognosis of hepatic IPT is usually benign. Based on its spontaneous regression property, it is suggested that treatment of IPT should be conservative or noninvasive in patients diagnosed by imaging or needle biopsy[24]. As a treatment protocol, we recommend the use of medications first, such as UDCA and/or bezafibrate for patients with IPT and PBC or PSC after making a definite diagnosis. Once PBC is diagnosed, it is advised to follow such patients regularly and carefully by imaging studies to rule out the development of hepatic IPT during the clinical course, like our case. Since IPT rarely arises in PBC, but hepatocellular carcinoma often develops in cirrhotic patients with PBC, IPT may be one of hepatic tumors arising in PBC patients as a differential diagnosis during the clinical course. The coexistence of hepatic IPT and PBC, however, may be an accidental event. Further cases need to be diagnosed and studied in more detail.

Abstract

Phyllode tumor (PT) is extremely rare tumor of the breast. Distant metastasis occurs in 10-20% of patients with malignant phyllode tumor. The most common sites of metastases are the lungs and bones. Although theoretically any organ may have metastasis, an isolated duodenum metastasis has not been documented as yet in the English-language literature. We report herein a case with a isolated duodenal metastasis from PT of breast in a 31 year-old-woman who underwent right mastectomy 4 years before because of the recurrent malignant PT. She presented to our hospital with massive upper gastrointestinal bleeding. Clinical evaluation revealed a huge mass originated from duodenum. Urgent laparotomy and pancreaticoduodenectomy were carried out in order to remove the bleeding duodenal mass. The pathologic examination of the resected specimen showed a malignant spindle cell tumor consistent with metastatic malignant PT. Our case of gastrointestinal bleeding due to an isolated duodenal metastasis as a result of hematogenous spread from malignant phyllode tumor of breast is unique in the English literature and pancreaticoduodenectomy is a curative treatment for patients with isolated duodenal involvement.

Key words: Malignant phyllode tumor; Duodenal metastasis; Pancreaticoduodenectomy

INTRODUCTION

Duodenal metastases of malignant tumors are rare. Lung cancer, renal cell carcinoma, breast carcinoma, and malignant melanoma are the most common primary tumors that metastasize to the pancreaticoduodenal region[1]. The proportion of duodenal metastases from breast carcinoma has been reported in autopsy series as occuring in more than 15% patients, generally associated with extensive systemic spread, and clinical presentations from such metastases have been described in less than 1% of cases[2]. Lobular infiltrating carcinoma of the breast is the histological type that most frequently metastasizes to the duodenum[2]. Infiltrating ductal carcinoma of the breast has also been reported to metastasize to the duodenum[2,3]. However, gastrointestinal metastases from phyllode tumor of breast have rarely been reported in the literature[3,4]. To our knowledge, this report is the first case in the English literature of isolated duodenal metastases of phyllode tumor.

CASE REPORT

A 31-year-old female presented to the surgical clinic with severe upper gastrointestinal bleeding (hematemesis and melena). She was diagnosed of right breast phyllode tumor for which an excision of 4 cm mass was performed 6 years ago. Two years later she had a recurrence, and the excisional biopsy revealed malignant phyllode tumor, and hence she underwent a right mastectomy. She refused postoperative radiation therapy for malignant PT.

At the time she presented to our hospital, she was hypotensive with a blood pressure of 80/60 mm/Hg, and had temperature 36.2℃ (97.1°F), pulse 106 bpm, and respiratory rate 18 breaths/min. She appeared pale, weak, and in distress, with a dry oral mucosa. A huge firm mass was palpable on epigastrium and upper right side on physical examination. Results of laboratory testing on admission showed 8g/dL hemoglobin, 23.6% hematocrit, 38 mg/dL blood urea nitrogen, and 1.8 g/dL albumin level. The results of coagulation tests (prothrombin time and partial thromboplastin time) were within normal limits.

Upper gastrointestinal endoscopic examination revealed clotted blood in the stomach and an ulcerated duodenal tumor without active bleeding. Computed tomography scan showed that the huge mass (10 cm ×15 cm in dimension) originated from duodenum, and compressedthe liver, pancreas, kidney, inferior vena cava, and superior mesenteric vein (Figure 1). Throughout testing, the patient remained hemodynamically unstable. A central line was placed, and

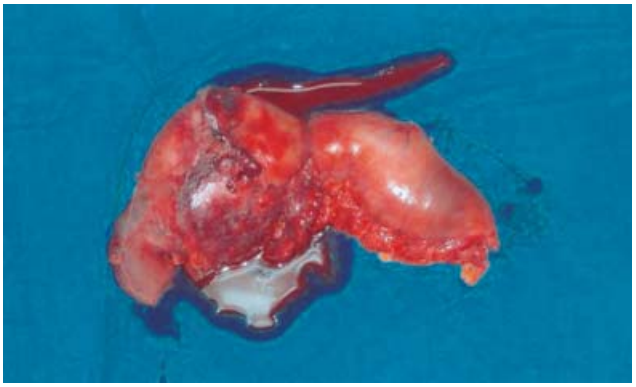

Figure 1 Specimen of the pancreaticoduodenectomy with negative margin.

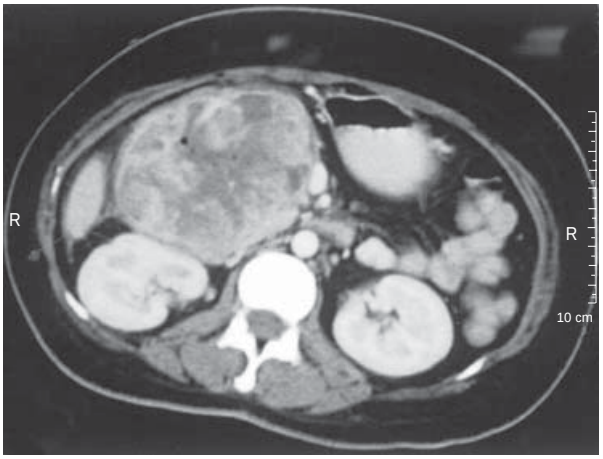

Figure 2 Computed tomography showing a 10 cm x 15 cm oval, mildly hypoechoic tumor with smooth margins.

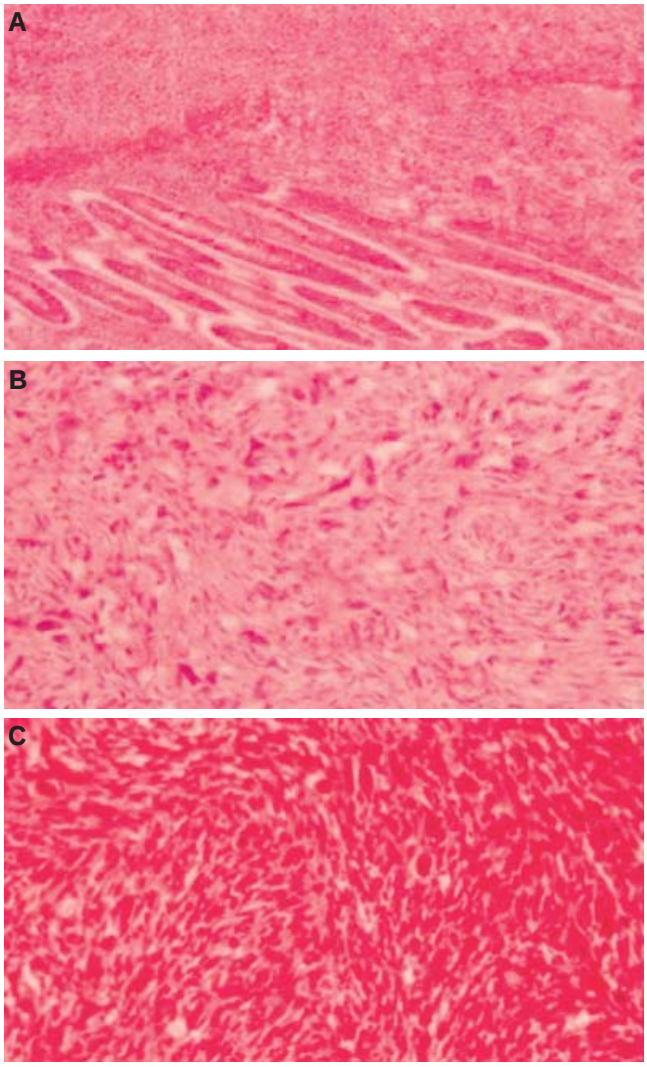

Figure 3 Neoplastic cells showing invasion of duodenal mucosa and submucosa (**A**) (H&E x 100); duodenal tumor consisted of haphazardly arranged pleomorphic spindle cells (**B**) (H&E x 200); breast tumor showing the similar histopathological findings with the duodenal tumor (**C**) (H&E x 200).

she received 8 units of packed erythrocytes. Since it was impossible to stop bleeding by embolisation of the huge mass, an urgent laparotomy and standard pancreaticoduodenectomy were carried out with the suspicion of primary duodenal tumor.

Gross examination of the resected specimen revealed a highly necrotic mass 15 cm×10 cm×10 cm in size within the wall of duodenum and pancreas with tumor-free resection margins (Figure 2). Histopathologically, tumor consisted of spindle cells with prominent nuclear pleomorphism and high mitotic index. Neoplastic cells showed invasion of all layers of duodenum, including mucosa (Figures 3A and 3B). Patient's mastectomy slides were obtained and compared to the duodenal tumor. Both tumors had the similar histopathological findings; atypical spindle cells showing an irregular cellular pattern without having an epithelial component (Figure 3C). Immunohistochemical analysis revealed only vimentin positivity in both tumors. The expressions of pan-cytokeratin, CD-117, smooth muscle actin, S-100, desmin and CD-34, CD-31 and CD-68 were all negative. Thus, a diagnosis of malignant spindle cell tumor consistent with metastatic malignant phyllode tumor was made.

The patient recovered uneventfully, and was discharged on the 10th postoperative day. The patient was alive and in good health 12 mo after surgery, with no evidence of disease at the moment.

DISCUSSION

Phyllode tumor is an uncommon fibroepithelial breast neoplasm that accounts for 0.5-1.0% of female breast tumor cases[5,6]. Phyllode tumors are generally classified into benign, borderline, and malignant tumors[5]. Malignant forms comprise nearly 25% of cases[7]. The rates of local recurrence and distant metastasis in patients with malignant PT range between 20-32% and 25-40%, respectively[5,6]. Positive or close surgical margin and large tumor size are important factors responsible for developing local recurrence[5,8]. They usually metastasize to the lung, pleura, bone, and liver but discrete localizations of metastases such as heart and central nervous system have also been reported[9,11]. The most reliable predictors for development of distant metastasis are stromal overgrowth, nuclear pleomorphism and high mitotic activity[6,7]. Mixed mesen-

chymal components (osteosarcomatosis, chondrosarcom *etc*.) have also been reported to be associated with worse prognosis[7]. Whether both local recurrence and tumor size contribute to the development of distant metastasis is still controversial[5,7,8]. In our case, the tumor size was 4 cm and the patient had a local recurrence 4 years ago.

Distant metastases of PT usually develop within 3 years of initial therapy, they may occur as soon as synchronous presentation or as long as more than ten years[7]. Because lungs are the most common site of metastasis for malignant phyllode tumors, all patients diagnosed with either a borderline or malignant lesion should undergo CT scanning of the chest prior to definitive surgery. This scan should include the liver, although liver metastases are less common. The primary goal for treatment of localized phyllode tumor is to achive wide, negative margin excision, this is generally agreed to include margins of 1 cm or greater.

We would like to stress that the preoperative diagnosis of a secondary gastrointestinal tumor begins with suspicion based on the history of a previously known non-gastrointestinal tumor[12,13]. In the presence of gastrointestinal mass in patients with a history of previous malignant PT, the physician should be aware of the possibility of gastrointestinal metastasis. The second primary tumor is known to be more common than isolated gastrointestinal metastasis. It is crucial to distinguish a metastatic gastrointestinal tumor from a primary one because of the therapeutic and prognostic implications[1,13]. Gastrointestinal metastasis can occur anywhere in the gut and can cause gastrointestinal symptoms, such as intestinal obstruction or bleeding. Radiological and endoscopic evaluations are usually nonspecific. Moreover, even histopathologically it is sometimes very difficult to distinguish a primary gastrointestinal stromal sarcoma or other sarcomas from a metastatic PT. In our case, we applied immunohistochemically a panel of antibodies to both duodenal and breast tumors. Results were not in concordance with other primary tumors. The histopathological findings were very similar to malignant PT, although we could not find any epithelial component, but it is a very well phenomenon that the metastases are commonly of stromal elements only in malignant PT[5].

To our best of knowledge, this is the first report of a PT metastasis to the duodenum. Currently, there are no clinical trials available to assess the best treatment regimen for metastatic PT. Experience with systemic therapy for metastatic PT is anecdotal. Chemotherapy may occasionally afford some palliation[14,15]. Ifosfamide is thought to be the most active agent. There is no demonstrated role for hormonal therapy. Given this limited experience, adjuvant systemic therapy cannot be recommended even for poor prognosis tumors. However, surgical treatment may become an ultimate option for patients who develop complication such as bleeding from the metastatic tumor, as seen in our case. Because of the therapeutic and prognostic implications, it is important to distinguish a metastatic gastrointestinal tumor from a primary one.

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*WJG, World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly journal of more than 48 000 circulation, published on the 7th, 14th, 21st and 28th of every month.

Original Research, Clinical Trials, Reviews, Comments, and Case Reports in esophageal cancer, gastric cancer, colon cancer, liver cancer, viral liver diseases, *etc*., from all over the world are welcome on the condition that they have not been published previously and have not been submitted simultaneously elsewhere.

Published by
The WJG Press

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297mm×210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page , Abstract, Introduction, Materials and Methods, Results, Discussion, acknowledgements, References, Tables, Figures and Figure Legends. Neither the editors nor the Publisher is responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part without the written permission of both the authors and the Publisher. We reserve the right to put onto our website and copy-edit accepted manuscripts. Authors should also follow the guidelines for the care and use of laboratory animals of their institution or national animal welfare committee.

Authors should retain one copy of the text, tables, photographs and illustrations, as rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for the loss or damage to photographs and illustrations in mailing process.

Online submission
Online submission is strongly advised. Manuscripts should be submitted through the Online Submission System at: http://www.wjgnet.com/index.jsp. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/wjg/help/instructions.jsp) before attempting to submit online. Authors encountering problems with the Online Submission System may send an email you describing the problem to wjg@wjgnet.com for assistance. If you submit your manuscript online, do not make a postal contribution. A repeated online submission for the same manuscript is strictly prohibited.

Postal submission
Send 3 duplicate hard copies of the full-text manuscript typed double-spaced on A4(297 mm×210 mm) white paper together with any original photographs or illustrations and a 3.5 inch computer diskette or CD-ROM containing an electronic copy of the manuscript including all the figures, graphs and tables in native Microsoft Word format or *.rtf format to:

Editorial Office

World Journal of Gastroenterology
Editorial Department: Apartment 1066, Yishou Garden,
58 North Langxinzhuang Road,
PO Box 2345, Beijing 100023, China
E-mail: wjg@wjgnet.com
http: //www.wjgnet.com

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using a word-processing software. All submissions must be typed in 1.5 line spacing and in word size 12 with ample margins. The letter font is Tahoma. For authors from China, one copy of the Chinese translation of the manuscript is also required (excluding references). Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page
Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was accomplished, disclosure of any financial support for the research, and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (removing all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s) and full family name.

Abstract
An informative, structured abstract of no more than 250 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipments, and the experimental procedures should be included. RESULTS: The observatory and experimental results, including data, effects, outcome, *etc.* should be included. Authors should present *P* value where necessary, and the significant data should accompany. CONCLUSION: Accurate view and the value of the results should be included.

The format of structured abstracts is at: http://www.wjgnet.com/wjg/help/11.doc

Key words
Please list 3-10 key words that could reflect content of the study mainly from *Index Medicus*.

Text
For most article types, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include in appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both.

Illustrations
Figures should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. No detailed legend should be involved under the figures. This part should be added into the text where the figures are applicable. Digital images: black and white photographs should be scanned and saved in TIFF format at a resolution of 300 dpi; color images should be saved as CMYK (print files) but not as RGB (screen-viewing files). Place each photograph in a separate file. Print images: supply images of size no smaller than 126 mm×76 mm printed on smooth surface paper; label the image by writing the Figure number and orientation using an arrow. Photomicrographs: indicate the original magnification and stain in the legend. Digital Drawings: supply files in EPS if created by freehand and illustrator, or TIFF from photoshops. EPS files must be accompanied by a version in native file format for editing purposes. Existing line drawings should be scanned at a resolution of 1200 dpi and as close as possible to the size where they will appear when printed. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes of atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...

Tables
Three-line tables should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each table. No detailed legend should be included under the tables. This part should be added into the text where the tables are applicable. The information should complement but not duplicate that contained in the text. Use one horizontal line under the title, a second under the column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations
Data that are not statistically significant should not be noted. $^{a}P<0.05$, $^{b}P<0.01$ should be noted ($P>0.05$ should not be noted). If there are other series of *P* values, $^{c}P<0.05$ and $^{d}P<0.01$ are used. Third series of *P* values can be expressed as $^{e}P<0.05$ and $^{f}P<0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or some other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.* in a certain sequence.

Acknowledgments
Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions are included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should code the references according the citation order in text in Arabic numerals, put references codes in square brackets, superscript it at the end of citation content or the author name of the citation. For those citation content as the narrate part, the coding number and square brackets should be typeset normally. For example, Crohn's disease (CD) is associated with increased intestinal permeability[1,2]. If references are directly cited in the text, they would be put together with the text, for example, from references [19,22-24], we know that...

When the authors code the references, please ensure that the order in text is the same as in reference part and also insure the spelling accuracy of the first author's name. Do not code the same citation twice.

PMID requirement

PMID roots in the abstract serial number indexed by PubMed (http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information of the journal citations is very important. Through reference testing system (http://www.aushome.cn/cgi-bin/index.pl), the authors and editor could check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in ASP file so that the readers can read the abstract of the citations online immediately.

Style for journal references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). Title of the cited article and italicized journal title (Journal title should be in its abbreviation form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634]

Note: The author should test the references through reference testing system (http://www.aushome.cn/cgi-bin/index.pl)

Style for book references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Format

Standard jounal article (list all authors and include the PubMed ID [PMID] where applicable)

1 **Das KM,** Farag SA. Current medical therapy of inflammatory bowel disease. *World J Gastroenterol* 2000; 6: 483-489 [PMID: 11819634]

2 **Pan BR**, Hodgson HJF, Kalsi J. Hyperglobulinemia in chronic liver disease: Relationships between *in vitro* immunoglobulin synthesis, short lived suppressor cell activity and serum immunoglobulin levels. *Clin Exp Immunol* 1984; 55: 546-551 [PMID: 6231144]

3 **Lin GZ,** Wang XZ, Wang P, Lin J, Yang FD. Immunologic effect of Jianpi Yishen decoction in treatment of Pixu-diarrhoea. *Shijie Huaren Xiaohua Zazhi* 1999; 7: 285-287

Books and other monographs (list all authors)

4 **Sherlock S,** Dooley J. Diseases of the liver and billiary system. 9th ed. Oxford: Blackwell Sci Pub, 1993: 258-296

Chapter in a book (list all authors)

5 **Lam SK.** Academic investigator's perspectives of medical treatment for peptic ulcer. In: Swabb EA, Azabo S. Ulcer disease: investigation and basis for therapy. New York: Marcel Dekker, 1991: 431-450

Electronic journal (list all authors)

6 **Morse SS.** Factors in the emergence of infectious diseases. Emerg Infect Dis serial online, 1995-01-03, cited 1996-06-05; 1(1):24 screens. Available from: URL: http//www.cdc.gov/ncidod/EID/eid.htm

Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those that are linked with a hyphen and the difference between the two numbers at two sides of the hyphen is more than 5. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered as inappropriate references. Authors should not cite their own unrelated published articles.

Statistical data

Present as mean ± SD and mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as γ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, *p*(B)= 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2 not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format about how to accurately write common units and quantum is at: http://www.wjgnet.com/wjg/help/15.doc

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further mention.

Italicis

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyr*A, *arg* 1, *c myc*, *c fos*, *etc.*

Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*

Biology: *Helicobacter pylori, H pylori, E coli, etc.*

SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. Author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, the final check list for authors, and responses to reviewers by a courier (such as EMS) (submission of revised manuscript by e-mail or on the *WJG* Editorial Office Online System is NOT available at present).

Language evaluation

The language of a manuscript will be graded before sending for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing; (4) Grade D: rejected. The revised articles should be in grade B or grade A.

Copyright assignment form

It is the policy of *WJG* to acquire copyright in all contributions. Papers accepted for publication become the copyright of *WJG* and authors will be asked to sign a transfer of copyright form. All authors must read and agree to the conditions outlined in the Copyright Assignment Form (which can be downloaded from http://www.wjgnet.com/wjg/help/9.doc).

Final check list for authors

The format is at: http://www.wjgnet.com/wjg/help/13.doc

Responses to reviewers

Please revise your article according to the comments/suggestions of reviewers. The format for responses to the reviewers' comments is at: http://www.wjgnet.com/wjg/help/10.doc

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Publication fee

Authors of accepted articles must pay publication fee.

EDITORIAL and LETTERS TO THE EDITOR are free of change.

World Journal of Gastroenterology ISSN 1007-9327

World Journal of Gastroenterology standard of quantities and units

Number	Nonstandard	Standard	Notice
1	4 days	4 d	In figures, tables and numerical narration
2	4 days	four days	In text narration
3	day	d	After Arabic numerals
4	Four d	Four days	At the beginning of a sentence
5	2 hours	2 h	After Arabic numerals
6	2 hs	2 h	After Arabic numerals
7	hr, hrs,	h	After Arabic numerals
8	10 seconds	10 s	After Arabic numerals
9	10 year	10 years	In text narration
10	Ten yr	Ten years	At the beginning of a sentence
11	0,1,2 years	0,1,2 yr	In figures and tables
12	0,1,2 year	0,1,2 yr	In figures and tables
13	4 weeks	4 wk	
14	Four wk	Four weeks	At the beginning of a sentence
15	2 months	2 mo	In figures and tables
16	Two mo	Two months	At the beginning of a sentence
17	10 minutes	10 min	
18	Ten min	Ten minutes	At the beginning of a sentence
19	50% (*V/V*)	500 mL/L	
20	50% (m/*V*)	500 g/L	
21	1 M	1 mol/L	
22	10 μM	10 μmol/L	
23	1N HCl	1 mol/L HCl	
24	1N H_2SO_4	0.5 mol/L H_2SO_4	
25	4rd edition	4^{th} edition	
26	15 year experience	15- year experience	
27	18.5 kDa	18.5 ku,18 500u or M_r18 500	
28	25 $g.kg^{-1}/d^{-1}$	25 g/(kg·d) or 25 g/kg per day	
29	6900	6 900	
30	1000 rpm	1 000 r/min	
31	sec	s	After Arabic numerals
32	1 pg $\cdot L^{-1}$	1 pg/L	
33	10 kilograms	10 kg	
34	13 000 rpm	13 000 *g*	High speed; *g* should be in italic and suitable conversion.
35	1000 *g*	1 000 r/min	Low speed. *g* cannot be used.
36	Gene bank	GenBank	International classified genetic materials collection bank
37	Ten L	Ten liters	At the beginning of a sentence
38	Ten mL	Ten milliliters	At the beginning of a sentence
39	umol	μmol	
40	30 sec	30 s	
41	1 g/dl	10 g/L	10-fold conversion
42	OD_{260}	A_{260}	"OD" has been abandoned.
43	One g/L	One microgram per liter	At the beginning of a sentence
44	*A*260 nm	A_{260} nm	*A* should be in italic.
	$^bP<0.05$	$^aP<0.05$	In Table, no note is needed if there is no significance instatistics: $^aP<0.05$, $^bP<0.01$ (no note if $P>0.05$). If ther is a second set of *P* value in the same table, $^cP<0.05$ and $^dP<0.01$ are used for a third set: $^eP<0.05$, $^fP<0.01$.
45	**F*=9.87, $^§F$=25.9, $^\#F$=67.4	^1F=9.87,^2F=25.9, ^3F=67.4	Notices in or under a table
46	KM	km	kilometer
47	CM	cm	centimeter
48	MM	mm	millimeter
49	Kg, KG	kg	kilogram
50	Gm, gr	g	gram
51	nt	N	newton
52	l	L	liter
53	db	dB	decibel
54	rpm	r/min	rotation per minute
55	bq	Bq	becquerel, a unit symbol
56	amp	A	ampere
57	coul	C	coulomb
58	HZ	Hz	
59	w	W	watt
60	KPa	kPa	kilo-pascal
61	p	Pa	pascal
62	ev	EV	volt (electronic unit)
63	Jonle	J	joule
64	J/mmol	kJ/mol	kilojoule per mole
65	$10\times10\times10cm^3$	10 cm×10 cm×10 cm	
66	N·km	KN·m	moment
67	*x*±s	mean±SD	In figures, tables or text narration
68	Mean±SEM	mean±SE	In figures, tables or text narration
69	*im*	im	intramuscular injection
70	*iv*	iv	intravenous injection
71	Wang et al	Wang *et al.*	
72	EcoRI	*Eco*RI	*Eco* in italic and RI in positive. Restriction endonuclease has its prescript form of writing.
73	Ecoli	*E.coli*	Bacteria and other biologic terms have their specific expression.
74	Hp	*H pylori*	
75	Iga	*Iga*	writing form of genes
76	*igA*	IgA	writing form of proteins
77	-70 kDa	~70 ku

Abstract

Carbohydrates are an important component of the diet. The carbohydrates that we ingest range from simple monosaccharides (glucose, fructose and galactose) to disaccharides (lactose, sucrose) to complex polysaccharides. Most carbohydrates are digested by salivary and pancreatic amylases, and are further broken down into monosaccharides by enzymes in the brush border membrane (BBM) of enterocytes. For example, lactase-phloridzin hydrolase and sucrase-isomaltase are two disaccharidases involved in the hydrolysis of nutritionally important disaccharides. Once monosaccharides are presented to the BBM, mature enterocytes expressing nutrient transporters transport the sugars into the enterocytes. This paper reviews the early studies that contributed to the development of a working model of intestinal sugar transport, and details the recent advances made in understanding the process by which sugars are absorbed in the intestine.

Key words: Glucose; Fructose; SGLT1; GLUT2; GLUT5; Transport; Intestine; Enterocytes; Sugar

INTRODUCTION

It has been known for decades that two different processes existed for intestinal glucose and fructose absorption. In studies using everted sacs of hamster small intestine, Crane and colleagues found that when the serosal and the mucosal side of the tissue were bathed in glucose, glucose accumulated on the serosal side[1]. This was not the case for fructose, and therefore the absorptive process was labelled as non-concentrating. The involvement of sodium (Na+) in glucose absorption was first proposed by Riklis and Quastel (1958)[2], although studies had previously demonstrated that the decrease in sugar absorption seen in adrenalectomized animals was prevented by adding NaCl to the drinking water[3]. The original Na^+/glucose cotransport hypothesis was presented by Crane in the 1960s[4]. This group showed that active glucose absorption by hamster small intestine required sodium (Na^+) in the bathing medium. Glucose transport was also blocked by ouabain that inhibits the Na^+K^+-ATPase in the basolateral membrane (BLM). This protein is responsible for maintaining the Na^+ gradient in the enterocytes, and driving Na^+ dependent transporters such as the sodium-dependent glucose transporter (SGLT1) in the brush border membrane (BBM).

Crane further developed the model of a mobile carrier in the BBM with two binding sites, one for glucose and one for Na^+[5]. He determined that the continuously maintained outward Na^+ gradient accomplished by the Na^+K^+-ATPase on the BLM was the primary asymmetry providing the driving force for active sugar transport. The phenomenon was considered to be "secondary active transport", as the hydrolysis of ATP was indirectly coupled to glucose transport via this electrochemical gradient. This pioneering work provided the framework for the further characterization of not only glucose transport, but also the transport of other co-transported solutes, and this concept is now considered to be a central tenet in cell physiology.

The pioneering work done by Crane was followed by the electrophysiological studies of Curran and colleagues[6-8] that further characterized transcellular Na^+ transport, and increased the understanding of Na^+ coupled co-transport. Further important advances were made in the 1980s. The method of expression cloning, developed by Wright and colleagues, resulted in SGLT1 being the first eukaryote cotransporter to be cloned. This technique takes advantage of the fact that Xenopus oocytes have the unique ability to translate foreign mRNA, and insert functional transporters into their plasma membrane. The researchers injected rabbit polyA RNA into the oocytes, and observed increases in glucose transport. Utilizing molecular techniques, they were able to isolate a single clone, and use it as a probe to identify human SGLT1[9].

With the continuing development of molecular techniques, the process of intestinal sugar absorption was developed further. The cloning and characterization of the sugar transporters GLUT2[10] and GLUT5[11]

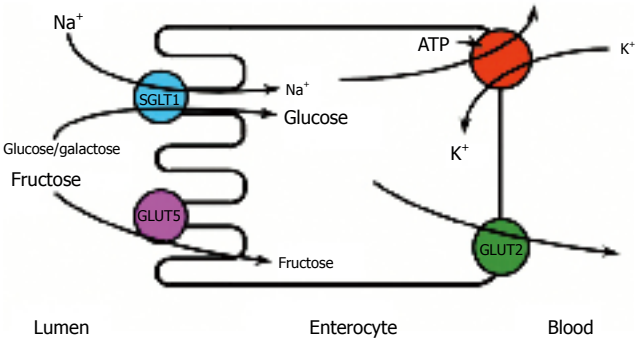

Figure 1 Classical model of intestinal sugar transport (from Wright, 1998). SGLT1 is the sodium dependent glucose/galactose transporter on the brush border membrane (BBM). The Na+K+-ATPase on the basolateral membrane (BLM) maintains the gradient necessary for the functioning of SGLT1. GLUT5 is a facilitative transporter on the BBM which transports fructose into the cell. GLUT2 on the BLM transports glucose, galactose and fructose out of the cell.

Table 1 Affinity constants of sugar transporters

Transporter	Km
SGLT1 (BBM)	Glucose:0.1-0.6 mmol/L (Wright *et al*, 2003)
GLUT2 (BLM)	Glucose:> 50 mmol/L Fructose: 66 mmol/L (Walmsley *et al*, 1998)
GLUT5 (BBM)	Fructose: 6-14 mmol/L (Walmsley *et al*, 1998)

soon followed, and the molecular aspects of the process of sugar absorption across the BBM and BLM were characterized. What is now known as the *"classical model of sugar absorption"* was developed (Figure 1), with SGLT1 actively transporting glucose and galactose across the BBM, and fructose crossing the BBM by facilitative diffusion via GLUT5. GLUT2, a low affinity transporter, was responsible for transporting these sugars across the BLM via facilitative diffusion.

SGLT1

The sodium/glucose cotransporter family (SLCA5) contains more than 200 members found in both animal and bacterial cells. There are 11 human genes expressed in tissues ranging from epithelia to the central nervous system. Hediger *et al* (1987) cloned the SGLT1 gene[9]. The cotransporter is a 73 kDa membrane protein with a Na^+-glucose stoichiometry of 2:1. The transporter has the same affinity for both glucose and galactose (Table 1), and transport is phloridzin sensitive (Ki = 0.1 mmol/L) (Table 2). The membrane topology of SGLT1 was determined using N-glycosylation scanning mutants and hydropathy plots. The transporter contains 14 transmembrane alpha-helices, with an extracellular N and C terminus[12-14]. The transporter contains a single glycosylation site between transmembrane 5 and 6; however, glycosylation is not required for functioning of the protein. Phosphorylation sites have been identified between transmembrane helices 6 and 7, and between transmembrane helices 8 and 9[15]. The importance of SGLT1 phosphorylation will be discussed below. SGLT1 is found in brush border membrane of mature enterocytes in the small intestine, with very small amounts detectable in the kidneys and the heart. Recently, SGLT1 has also been detected in the luminal membrane of intracerebral capillary endothelial cells, where it may participate in the transport of glucose across the blood-brain barrier[16].

Table 2 Inhibitors of sugar transporters

	Inhibitors
SGLT1	Phloridzin
GLUT2	Cytochalasin B Phloretin
GLUT5	Glyco-1, 3-oxazolidin-2-thiones, -ones (Girniene *et al*, 2003)
Na^+K^+-ATPase	Oubain

The process of intestinal sugar transport has been reviewed by Wright *et al* (2003)[17]. Initially, on the luminal side of the BBM, two Na^+ ions bind to SGLT1 and produce a conformational change that permits sugar binding. Another conformational change allows the substrates to enter the enterocyte. The sugar, followed by the Na^+, dissociates from SGLT1 because the affinity of the cytosolic sites is low, and also because the intracellular concentration of Na^+ is low (10 *vs* 140 mEq/L). Sodium can be replaced by H^+ or Li^+, but the affinity for glucose then decreases (apparent Michaelis affinity constant (Km) = 4-11 mmol/L).

The Na^+K^+-ATPase in the BLM is responsible for maintaining the Na^+ and K^+ electrochemical gradients across the cell membrane. The Na^+K^+-ATPase contains a 110 kDa α_1 catalytic subunit, as well as a highly glycosylated 55 kDa β_1 subunit[18,19]. The Na^+K^+-ATPase is up-regulated in experimental diabetes[20] and experimental ileitis [21], with post-translational modifications playing an important role in its regulation. This up-regulation may influence the functioning of SGLT1 and subsequently alter intestinal sugar uptake in these conditions.

Panayotova-Heiermann and Wright (2001) expressed various cDNA constructs of rabbit SGLT1 in Xenopus oocytes in order to determine the helices involved in sugar transport[22]. They found that helices 10-13 form the sugar permeation pathway for SGLT1, and they speculated that the N terminal region of SGLT1 (helices 1-9) may be required to couple Na^+ and glucose transport.

A number of factors influence the transport function of SGLT1 (Table 3). For example, the regulation of SGLT1 by dietary sugars was examined by Miyamoto *et al* (1993)[23]. Using Northern blotting, they showed that SGLT1 mRNA was increased by feeding rats 55% sugar diets containing glucose, galactose, fructose, mannose, xylose, or 3-O-methylglucose. Because 3-O-methylglucose is transported by SGLT1, but is not metabolized, and because SGLT1 does not transport fructose, mannose or xylose, the up-regulation of SGLT1 does not appear to

Table 3 Factors influencing transporter function

Factors influencing SGLT1 function	Factors influencing GLUT2 function	Factors influencing GLUT5 function

depend on either metabolism or transport of the sugar in question (Table 3).

Wright *et al* (1997) evaluated the role of SGLT1 phosphorylation[24]. They expressed rabbit SGLT1 in Xenopus oocytes, and activated protein kinase A (PKA) or protein kinase C (PKC) using 8-Br-cAMP and *sn*-1, 2-dioctanoylglycerol (DOG), respectively. PKA activation increased glucose transport by approximately 30%, while PKC activation reduced transport by 60%. The change in maximal transport rates (Vmax) was accompanied by alterations in the number of transporters in the plasma membrane, as well as changes in the surface area of the membrane. Since endocytosis and exocytosis alter the membrane surface area, the findings of the effects of PKA and PKC on SGLT1 suggest that these proteins may be involved in the regulation of glucose transport.

Similar increases in Vmax were obtained with activation of PKA in oocytes expressing rabbit, human, and rat SGLT1 isoforms. The effects of PKC, however, may depend on the sequence of the co-transporter, as there are conflicting reports of the effect of PKC on glucose transport. For example, PKC decreases sugar transport in Xenopus oocytes expressing rabbit and rat SGLT1[25,26], and increases sugar transport when human SGLT1 is expressed[27].

Veyhl *et al* (1993) demonstrated the presence of an intracellular regulatory protein (RS1) that may modify the activity of SGLT1[28]. Co-expression of RS1 and SGLT1 in Xenopus oocytes reduced both the Vmax for glucose transport as well as SGLT1 protein levels[26]. Plasma membrane surface area was also reduced, suggesting alterations in the endo- and/or exo-cytosis of membrane vesicles.

To investigate the role of intracellular trafficking in sugar transport, oocytes were injected either with cRNA of wild type, or mutant dynamin. Dynamin is a motor protein involved in receptor-mediated endocytosis, vesicle recycling, caveolae internalization and vesicle trafficking from the Golgi[29]. The inhibition of glucose uptake by RS1 was largely reduced after co-expression of the mutant dynamin protein. The investigators concluded that RS1 modulates dynamin-dependent trafficking to the BBM of intracellular vesicles containing SGLT1.

In order to further characterize the role of the RS1 protein in the regulation of intestinal glucose transport, a knockout mouse lacking the RS1 protein was recently developed: Osswald *et al* (2005) showed that RS1-/- mice developed obesity associated with increases in food intake, glucose transport and SGLT1 expression in the small intestine[30]. The effect of RS1 deficiency was tissue-specific and occurred through post-transcriptional mechanisms, as SGLT1 mRNA abundance was unchanged. These researchers speculated that therapeutic strategies aimed at reducing glucose uptake by increasing RS1 might potentially be used to treat obesity.

Heat shock proteins (hsp) may also play a role in regulating SGLT1 function (Table 3). A study done in renal epithelial cells showed that treatment with hsp70 increased glucose transport, but not the abundance of SGLT1 protein[31]. The increase in sugar transport was inhibited by an antibody directed against transforming growth factor β (TGF- β), leading the investigators to explore the effect of TGF-β on SGLT1: there was an increase in SGLT1 activity, as well as an increase in hsp70 protein when TGF-β was added to the culture media. The researchers speculated that hsp70 might stabilize SGLT1 expression in the membrane. This concept was supported by confocal microscopy studies, which demonstrated that TGF-β appears to move both SGLT1 and Hsp70 near the apical membrane site. However, the mechanism by which TGF-β exerts these effects on Hsp70 and SGLT1 is not known.

It is not known if SGLT1 is localized to specific microdomains within the BBM. In renal proximal tubular cells, SGLT1 was found in detergent-resistant membrane microdomains, also referred to as "lipid rafts"[32]. In this model, the absence of vimentin, an intermediate filament component, decreased glucose transport and caused a reduction in the amount of SGLT1 protein in these membrane microdomains. Furthermore, fluidization of the plasma membrane, or depleting the membrane of cholesterol, dramatically decreased glucose transport. This suggests that the activity of SGLT1 is optimal in a microenvironment characterized by low fluidity. Further research is required to determine if SGLT1 is localized to lipid rafts in the intestinal BBM, if this localization is mandatory for the functioning of SGLT1, and what are the factors that may regulate the localization of SGLT1 to these specialized microdomains.

The transcription factors hepatocyte nuclear factor-1 (HNF-1) and Sp1 may also regulate SGLT1. Martin *et al*, (2000) characterized the promoter region of the human SGLT1 gene by transfecting reporter constructs into

Caco-2 cells[33]. They demonstrated that three cis-elements, HNF-1, and two sites on the SGLT1 promoter ("GC boxes" to which Sp1 binds are required for maintaining basal transcription of SGLT1. Members of the Sp1 family bind to the GC boxes, and in the presence of HNF-1, synergistically activate the promoter. Some members of the Sp1 family have been implicated in tissue- and developmental- specific regulation of genes[34,35]. HNF-1 alters the expression of many small intestinal genes, including sucrase-isomaltase (SI) and lactase. It has also been implicated in the diurnal regulation of SGLT1 in rodents[36]. If HNF-1 was required for basal SGLT1 expression, glucose-galactose malabsorption would have been expected to be observed. Of interest, HNF-1 knockout mice experience life-threatening effects on the hepatic and renal systems, but no adverse effects on the gastrointestinal tracts were reported.

Katz *et al* (2004) identified a link between a mesenchymal factor and the regulation of a specific epithelial transport process[37]. *Foxl1* is a winged-helix transcription factor expressed in the mesenchymal cells bordering the crypts in the small intestine. Using the everted sleeve method coupled with Western blotting, the researchers showed that homozygous *Foxl1* null mice had decreased intestinal glucose uptake and decreased levels of SGLT1 protein. Growth retardation and abnormal small intestinal architecture were observed, characterized by short, broad and irregular villi. The effect of the loss of Foxl1 on SGLT1 was specific, as no changes in the expression of SI, lactase, GLUT2 or Na^+K^+ATPase were observed.

The transport of water across the intestinal epithelia has always been a subject of curiosity. The discovery of aquaporins by Preston *et al* (1992) renewed interest in this topic[38]. Although aquaporins may account for a portion of water absorption in the intestine, Wright and colleagues investigated the coupling of water transport to active Na^+-glucose cotransport. Overexpression of human or rabbit SGLT1 in Xenopus oocytes revealed that activation of the transporter was associated with an increase in volume of the cell (reflecting water transport), and this effect was blocked by phlorizin. If oocytes expressing SGLT1 were incubated in a sugar-free solution, no change in oocyte volume was observed. The increase in volume could be accounted for by a stoichiometry of two Na+ ions, one glucose molecule, and 249 water molecules[39]. The transport of water was independent of the osmotic gradient across the membrane, and may be a consequence of the conformational changes in SGLT1 that occur during Na^+/glucose transport. A channel formed by five C-terminal transmembrane helices of SGLT1 is thought to transport not only water, but also urea[22,40].

It is important to note, however, that others have suggested that local osmotic gradients fully account for water fluxes. Lapointe *et al* (2002) present evidence from experiments using Xenopus oocytes expressing human SGLT1 that contradicts the water cotransport hypothesis and suggests the passive movement of water across the plasma membrane[41].

Oral rehydration therapy (ORT) was developed in the 1970's to treat diarrheal dehydration[42]. The introduction of this very simple treatment has reduced mortality due to diarrhea in children under five years of age from 5 million in 1978, to 1.3 million in 2002 (http: //www.who.int/child-adolescent-health.2002; Victora *et al*, 2000). This success led to the proclamation that ORT was the most important medical advance of the 20th century, and earned Dr Hirschhorn and colleagues the first Pollin prize for Pediatric Research.

The goals of ORT are to replace fluids and minimize malnutrition. Starting in 1978, solutions containing a mixture of glucose, sodium, chloride, potassium and citrate were being commonly distributed by the World Health Organization. In fact, 800 million packets of ORT were distributed worldwide in 1991-1992[43]. Interestingly, controversy now exists over the optimal formulation, with reduced osmolarity formulas, rice-based formulas, or formulas containing amylase-resistant starch being favored by some researchers. For example, hypoosmolar rice-based formulas produced better results in cholera patients when compared to standard formulas[44]. The advantages of this rice-based formula are that it is cheap, offers more calories than standard ORT, and rice is readily available in many cholera-stricken regions. ORT formulas containing amylase-resistant starches may be favored due to the production of short chain fatty acids, which increase colonic Na+, Cl- and fluid absorption, and reduce colonic secretions[45-47]. These effects counteract the fluid losses and hypersecretion seen with infectious diarrhea.

Several features of carbohydrate digestion contribute to the efficacy of ORT. This life-saving therapy is based on the ability of SGLT1 to co-transport water. Na^+-dependent glucose absorption is not affected by the increased cAMP levels commonly seen with infections such as Cholera, and therefore this physiological fact can be exploited as a means to achieve glucose, Na^+ and water absorption, even in the presence of chloride and water secretion. Also, the oral administration of glucose or carbohydrates up-regulates SGLT1, thereby further increasing the intestinal transport of glucose, Na^+ and water. Since ORT is commonly administered to infants, it is important to utilize a transport system that is expressed and functional early in life. SGLT1 is expressed prenatally[48], and is functional at birth, making it an ideal candidate. In contrast to glucose, the use of fructose in these ORT solutions is contraindicated, as GLUT5 in the BBM is only expressed following weaning[49].

Glucose-galactose malabsorption (GGM) is a very rare autosomal recessive disease characterized by severe life-threatening diarrhea in the neonate, that resolves when the offending sugars (glucose, galactose and lactose) are removed from the diet[15,50]. Normal intestinal mucosal histology is observed, while phlorizin binding studies show reductions in SGLT1 protein in the BBM[51,52]. Electrophysiological studies and freeze fracture electron microscopy showed that this disease is due to a failure of the SGLT1 protein to traffic normally to the BBM[53]. Approximately 300 cases of GGM have been identified worldwide, affecting all racial and ethnic groups. The majority (70%) of patients are female, with two thirds coming from a consanguineous relationship[17]. Unlike genetic diseases like cystic fibrosis, in which a single

mutation accounts for most cases, in GGM each patient appears to have a unique mutation, ranging from missense mutations, to frame-shift mutations, to split-site-conservative mutations which produce truncated protein and mistrafficking of SGLT1 to the BBM[53-56]. This variety of mutations limits the usefulness of genetic testing for GGM, although prenatal diagnosis in a family at risk may be possible.

GGM is a difficult condition to diagnose. If GGM is suspected, the first step is the elimination of glucose, galactose and lactose from the infant's diet. Oral glucose tolerance tests in GGM patients produce a flat glucose response in the blood, as glucose is malabsorbed in the intestine. A hydrogen breath test performed following oral glucose produces abnormally high concentrations of H_2 in the breath (> 20 ppm) indicating glucose malabsorption, while oral fructose tolerance tests produce normal results. GGM is treated by using glucose-, galactose- and lactose-free formulas, and by eliminating the offending sugars from the diet[17]. Normal growth and neurological development are possible if infants receive fructose-based formula, and if dietary counselling is available[15,57].

GLUT5

GLUT5 is a 43 ku protein, with 12 transmembrane domains and intracellular N and C terminals. It was cloned by Burant and colleagues in 1992. GLUT5 was expressed in Xenopus oocytes, and its substrate specificity and kinetic properties were determined using radiolabelled substrates. Northern and Western blotting demonstrated the presence of GLUT5 in human small intestine and testis. Further work by Davidson *et al* (1992) focused on the developmental expression of GLUT5 in the human and fetal small intestine[58]. GLUT5 mRNA levels increase with age, and are highest in the adult small intestine. In adults, GLUT5 was localized to the BBM by Western blotting. Immunohistochemical techniques confirmed this finding, and further localized GLUT5 to only the mature enterocytes populating the upper half of the villus. This luminal localization provided further support for the notion that GLUT5 played a role in the intestinal uptake of dietary sugars.

Rand *et al*, (1993) characterized the expression of GLUT5 in rats[49]. GLUT5 mRNA was detected in the small intestine, kidney and brain by Northern blotting, and in the small intestine, testis, adipose and skeletal muscle using *in situ* hybridization. In the intestine, a proximal-distal gradient was observed, with GLUT5 mRNA levels being higher in the proximal small intestine when compared to the distal small intestine. A distinct pattern of expression was seen along the crypt-villous axis, with mRNA being highest in midvillus region.

The functional domain of GLUT5 was investigated by Buchs *et al*[59]. In order to ensure proper transport and insertion into the membrane, GLUT5-GLUT3 chimeras were created, and included various combinations of the GLUT3 and GLUT5 peptides. These chimeric GLUTs were expressed in Xenopus oocytes. This enabled the researchers to conclude that the regions necessary for fructose transport lie between the amino terminus and the third transmembrane domain, and between the 5th and 11th transmembrane domain.

The response of GLUT5 to dietary sugars was investigated by Miyamoto *et al*[23]. In this study, they fed sugar-enriched diets (55% D-glucose, D-galactose, 3-0-methylglucose, D-fructose, D-mannose or D-xylose) to male Sprague Dawley rats for 5 d. Northern blotting on intestinal samples showed that GLUT5 mRNA was increased only by dietary D-fructose, and was unaffected by the other sugars (Table 3). This was consistent with the suggestion that GLUT5 was a high affinity fructose transporter. Subsequent work by David *et al* (1995) showed that in 16 d old rats, feeding fructose but not glucose increased fructose uptake[60]. Furthermore, while both fructose and sucrose feeding enhanced absorption in older (21-60 d old) animals, glucose alone had no effect.

An interesting study by Castello *et al* (1995) demonstrated that GLUT5 mRNA in rats followed a circadean rhythm, with a 12-fold increase in mRNA at the end of the light cycle as compared to early in the light cycle[61]. BBM GLUT5 protein followed a similar pattern, which is also observed for other small intestinal genes such as BBM SI and lactase[62]. Although this pattern was thought to be a reflection of rodent feeding patterns, Corpe *et al* (1996) found that gene expression is hard-wired, because GLUT5 is up-regulated prior to the onset of feeding, even in the absence of dietary fructose[63]. Shu *et al* (1998) noted that this circadean rhythm was not developed at the time of weaning, possibly because the feeding patterns of suckling rats do not follow the same adult nocturnal patterns[64]. This diurnal variation in adult animals needs to be carefully considered when designing experiments in which levels of GLUT5 are measured, by performing studies in the morning in the early post-prandial period.

The regulation of GLUT5 was studied by Mahraoui *et al* (1994) using Caco-2 cells[65]. Treatment of the cells with forskolin, which stimulates adenylate cyclase and raises intracellular cAMP levels, increased fructose uptake 2-fold, and increased GLUT5 protein and mRNA 5-fold and 7-fold, respectively. Matosin-Matekalo *et al* (1999) used Caco2 cells transfected with a GLUT5 promoter inserted up-stream of the luciferase reporter gene[66]. They found that a region of the GLUT5 promoter binds the thyroid hormone receptor/retinoid X receptor heterodimers, and that both triiodothyronine (T3) and glucose increase GLUT5 mRNA.

Helliwell *et al*[67] looked at the regulation of GLUT5 by a number of signals that have well-established roles in the regulation of sugar transport. Isolated loops of rat jejunum were perfused with activators and inhibitors of the ERK, p38 and PI3K pathways. The findings suggest that the p38 pathway stimulates fructose transport, while the ERK and the PI3K pathways had little effect on fructose transport (Figure 3). Extensive cross-talk occurs between the pathways. For example, inhibiting the ERK pathway with PD98059 increased the sensitivity to anisomysin, which stimulates the p38 pathway. The authors concluded that the three pathways have the potential to regulate fructose transport during the digestion and absorption of a meal. They suggested that future work should focus on

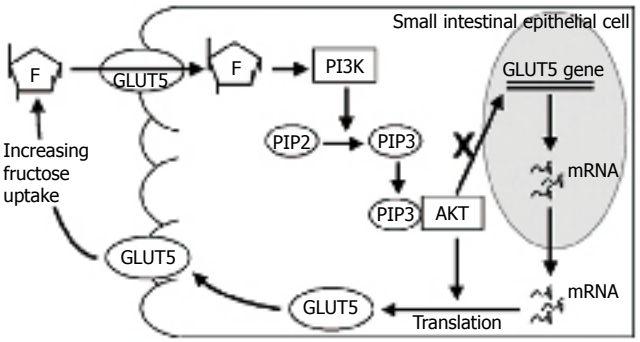

Figure 2 Proposed role of PI3K/Akt signalling pathway in the regulation of GLUT5 synthesis and trafficking (from Cui *et al*, 2005). Abbreviations: *F* = fructose, PIP3 = phosphatidylinositol-3, 4, 5-triphosphate, PIP2 = phosphatidylinositol-4, 5-biphosphate, PI3K = phosphatidylinositol 3-kinase.

Abbreviations: IRS=insulin regulatory subunit, ERK=extracellular regulated kinase, MEK=mitogen activated kinase kinases, PI3K=phosphatidylinositol 3-kinase, PD98059=ERK/MEK inhibitor, SB203580=p38 MAPK inhibitor, anisomycin=activator of p38 and jun kinase pathways.

determining the hormones that influence these pathways, and the molecular mechanisms that regulate the levels and activities of the sugar transporters.

Gouyon *et al*[68] used Caco-2 cells to investigate the mechanism by which fructose increases GLUT5 expression. Although both glucose and fructose increased the activity of the GLUT5 promoter, the effect of fructose was stronger and associated with higher cAMP concentrations. If cAMP signalling was blocked by a protein kinase A inhibitor, extensive GLUT5 mRNA degradation occurred, suggesting that the mRNA stability was influenced by PKA. A sugar response element was identified in the GLUT5 promoter. PABP-interacting protein 2, which represses translation[69,70], was identified as a component of GLUT5 3'-UTR RNA-protein complex, where it may act to destabilize transcripts. The differences between the effects of glucose and fructose on GLUT5 expression may be attributed to variations in their ability to increase cAMP levels, and to modulate the formation of protein complexes with GLUT5 3'-UTR.

Infection may also regulate fructose transport. Intravenous administration of Tumor necrosis factor-α (TNF-α) in rabbits significantly reduced jejunal fructose transport and GLUT5 protein[71]. This inhibition was related to the secretagogue effect of TNF-α, and both nitric oxide and prostaglandins were implicated in the inhibition of fructose uptake. Adaptive immunity also influences the expression of a number of developmentally regulated genes. In mice lacking in adaptive immunity (B cell deficient recombination-activating gene [RAG] mice), RNase protection assays demonstrated that GLUT5 was increased[72].

Recent advances have been made in understanding the signalling pathways involved in the regulation of GLUT5. Cui *et al*[73] have demonstrated that cAMP stimulates fructose transport in the neonatal rat intestine. Perfusing fructose (100mM) plus 8-bromo-cAMP in 22-d-old rats increased fructose uptake rates, while an inhibitor of adenylate cyclase abolished this effect. Despite the presence of two cAMP response elements in the human GLUT5 promoter region[65], GLUT5 mRNA was not affected by cAMP treatment. Interestingly, inhibitors of PKA did not prevent the fructose-associated increases in transport, suggesting that cAMP modulates fructose transport independent of PKA (Table 3).

Subsequent work by the same group has shown that fructose-induced increases in neonatal rat intestinal fructose uptake involve the PI3K/Akt signalling pathway[74]. In this study, PI3K inhibitors (wortmannin and LY94002) and an Akt inhibitor (SH-5) abolished the increase in fructose uptake, as well as the abundance of GLUT5 protein (but not mRNA) seen following fructose (100 mmol/L) perfusions in neonatal rats. Fructose perfusion increased phosphatidylinositol-3, 4, 5-triphosphate (PIP3), the product of PI3K, in the mid to upper regions of the villus, where most of the GLUT5 was located. The authors suggest that the PI3K/Akt pathway may be involved in the synthesis and/or recruitment of GLUT5 to the BBM in response to luminal fructose (Figure 2).

GLUT2

GLUT2 is a low affinity, high capacity facilitative transporter in the BLM that transports glucose, fructose, galactose and mannose[10,63,75-77]. It has 12 transmembrane domains, with intracellular N and C terminals. Using immunohistochemistry, Thorens *et al*[75] showed that GLUT2 expression increases as enterocytes migrate up from the crypt to the villous tip. Amino acid sequences in transmembrane segments 9-12 are primarily responsible for GLUT2's distinctive glucose affinity, whereas amino acid sequences in transmembrane segments 7-8 enable GLUT2 to transport fructose[78].

Luminal sugars[23,79] or vascular infusions of glucose or fructose[80,81] stimulate GLUT2 expression and activity. The response of GLUT2 to dietary sugars was investigated by Miyamoto *et al*[23]. In this study, they fed sugar-enriched diets to male Sprague Dawley rats for 5 d. GLUT2 mRNA was up-regulated by glucose, fructose and galactose. GLUT2 modulation required intracellular metabolism of the sugar, as it was unaffected by 3-O-methyglucose, a non-metabolized glucose analog.

In a study by Cui *et al*[82], the jejunum of 20-d-old anaesthetized rat pups was perfused with 100 mmol/L glucose or fructose. Increases in GLUT2 mRNA were

observed, and this effect was inhibited by actinomycin D, an inhibitor of transcription. Cycloheximide, an inhibitor of translation, did not block the enhanced expression of GLUT2 mRNA, suggesting that the synthesis of new proteins is not necessary for increases in GLUT2 mRNA. Because levels of GLUT2 mRNA and protein are tightly correlated, the regulation of GLUT2 may be transcriptional[83].

PASSIVE UPTAKE

For years there has been considered to be a "passive" component to sugar absorption. This traditional view has been challenged, with the suggestion that the kinetic characteristics of sugar uptake could also be described by a second high affinity, high capacity BBM transporter[83]. In order to better understand the new "GLUT2 trafficking model", we need first to consider the classic "passive permeation" model.

The fact that SGLT1 saturates at 30-50 mmol/L glucose was inconsistent with the observation that intestinal glucose absorption increases linearly with increases in luminal glucose concentrations up to several hundred millimolar[85]. This finding suggests the presence of two components: an active, phloridzin-sensitive component, and a phloridzin-insensitive, possibly passive component that does not appear to be saturable. Some studies have suggested that the "passive" component played a large role in glucose transport at high glucose concentrations, in some models contributing 3-5 times as much as the active component[86,87].

The passive component of glucose transport was characterized by Pappenheimer and Reiss (1987)[88]. The observation that high rates of water absorption accompany glucose absorption[89] provided a rationale for proposing that glucose in the intercellular spaces provided an osmotic force that resulted in bulk flow of nutrients. Pappenheimer and Reiss (1987) perfused isolated segments of hamster small intestine with 10-25 mmol/L glucose[88]. Structural studies using electron microscopy and freeze fracture analysis revealed large dilatations within junctions following glucose perfusion. They concluded that Na^+-coupled transport of solutes from the intestinal lumen to the cytosol of the enterocytes provides the driving force for the absorption of fluid and nutrients, and triggers the widening of intercellular junctions, thereby promoting the bulk absorption of nutrients by solvent drag. They calculated that the contribution of solvent drag exceeds that of active transport at luminal glucose concentrations greater than 250 mmol/L. Madara and Pappenheimer (1987) further demonstrated that the transport of glucose via SGLT1 caused dilatation of the tight junctions[90]. They concluded that passive glucose absorption is a result of paracellular solvent drag, and is indeed SGLT1 dependent. Therefore, like the more recent model suggested by Loo et al (2002)[39], these investigators suggest that the transport of water is SGLT1-dependent. However, this theory suggests the presence of a non-specific route, which could potentially allow passage of several solutes.

Ferraris and Diamond proposed an alternative theory, in which paracellular flow is negligible[91,92]. Based on the determination of up-dated kinetic constants for glucose absorption, and the determination of the usual free glucose concentrations in the intestinal lumen, they concluded that SGLT1 fully accounts for glucose absorption. Much of their work is based on studies examining long-term dietary adaptations, from which they concluded that BBM transporters are matched to dietary intake. Their model is supported by the findings of Lane *et al*[93], who demonstrated that paracellular flow in unanaesthetized dogs did not account for more than 2%-7% of total absorption.

Much of the controversy surrounding the role of the paracellular pathway stems from the discrepancies between the estimated concentrations of glucose in the intestinal lumen. Pappenheimer and Reiss[88] based their calculations on luminal glucose concentrations of 300 mmol/L, whereas Ferraris *et al*[92] did a detailed analysis of luminal glucose concentrations and concluded that physiological luminal values ranged from 0.2-48 mmol/L. Pappenheimer[94] used the rate of membrane hydrolysis of maltose to indirectly measure luminal glucose concentrations. They also point out that the techniques used by Ferraris *et al* (1990)[92], which involve glucose analysis of luminal contents, will underestimate the concentration found at the membrane following hydrolysis by disaccharidases. The actual physiological levels of glucose in the lumen remain a subject of debate.

The concept of more than one transport system for glucose was suggested by Malo[95]. Using human fetal and adult BBM vesicles, curvilinear Eadie-Hofstee plots and sodium activation curves were obtained when glucose concentrations were varied in the medium. These findings, coupled with determinations of phloretin-sensitive and -insensitive components, and the ability of the BBM vesicles to transport 3-O-methylglucose, suggested the presence of two transport systems: a high-affinity low-capacity system and a low-affinity high-capacity system[95,96]. This agrees with the observation that Na^+/glucose cotransport saturates at 30-50 mmol/L, yet absorption is linear from 50 mmol/L to several hundred mmol/L[85].

Although this concept was proposed many years ago, it was not until recently that interest in the area has re-emerged due to an alternative model of intestinal glucose transport proposed by George Kellett and his colleagues at the University of York, and by Edith Brot-Laroche and her colleagues at the University of Paris. Let us briefly explore this fascinating "voyage of discovery".

GLUT2 IN BBM

Several years ago, GLUT2 was detected in the BBM of enterocytes in diabetic animals, although at the time this was interpreted to be a pathological event[63]. More recently, Kellett and his colleagues proposed a model by which BBM SGLT1, in the presence of luminal glucose, promotes the rapid insertion of GLUT2 into the BBM via PKCβII and the MAP kinase-dependent signal transduction pathways[67,97,98]. PKCβII is located in the terminal web of mature enterocytes in the upper part of the intestinal villus[99]. Interestingly, these are the same cells that are responsible for glucose absorption.

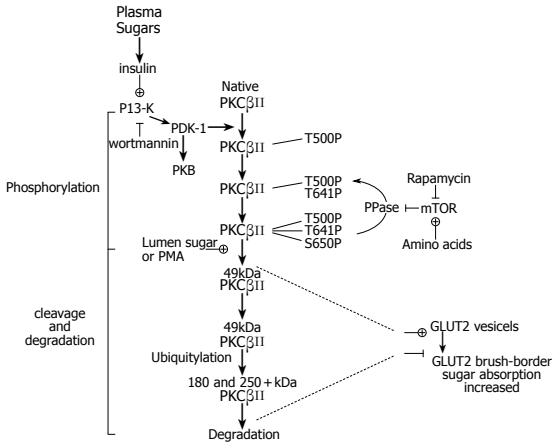

Figure 4 Potential signaling pathways for the regulation of GLUT2-mediated sugar absorption by insulin and amino acids through the control of PKC βII activity. (from Helliwell et al, 2003). Abbreviations: PMA= phorbol 12-myristate 13-acetate, PDK-1=protein-dependent kinase-1, PI3K=phosphatidylinositol-3-kinase, PKB=protein kinase B, mTOR=mammalian target of rapamycin, PKCβII=protein kinase C βII.

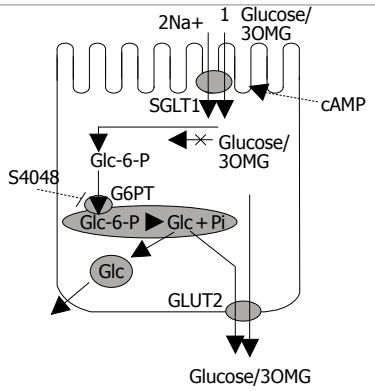

Figure 5 Proposed alternative mechanism for intestinal glucose transepithelial transport (from Stumpel et al, 2001). Abbreviations:Glc=glucose, Glc-6-P=glucose-6-phosphate, G6PT=glucose-6-phosphate translocase, 3-OMG=3-O-methylglucose, S4048=inhibitor of glucose-6-phosphate translocase, Pi=phosphate.

Using a luminal perfusion model, Kellett and coworkers measured the phloretin-insensitive (SGLT1) component and phloretin sensitive component (GLUT2) of glucose transport. They also showed using Western blotting that BBM GLUT2 increased 2.2 fold when the concentration of glucose in the perfusate increased from 0 to 100 mmol/L. Similarly, the BBM level of PKCβII increased with increasing glucose concentrations. This finding, coupled with the observation that PKCβII shows a saturation response and has a Km similar to that of SGLT1 (21-27 mmol/L), suggests that PKCβII is an important signal in the recruitment of GLUT2 to the BBM. PKCβII levels also correlate with levels of GLUT2 in the BBM, and this association offers further support for its role in the recruitment of GLUT2 to the BBM. The ability of the PKC inhibitor "chelerythrine" to block phorbol 12-myristate 13-acetate (PMA)-stimulated fructose transport and GLUT2 abundance in the BBM also supports this mode l[97].

Kellett's working hypothesis proposes that before a meal, when luminal concentrations of glucose are low, GLUT2 levels in the BBM are also low, which would minimize the escape of glucose from the cell (any glucose that did escape would be recycled by SGLT1, which can transport it against the glucose gradient). Once a meal is ingested and BBM enzymes hydrolyse disaccharides, luminal glucose concentrations increase. Glucose uptake via SGLT1 causes increases in enterocyte volume due to a rise in osmolarity (and the co-transport of water molecules by SGLT1), and may trigger the entry of Ca+, activating PKCβII and promoting the insertion of GLUT2 in the BBM. The involvement of SGLT1 in the recruitment of GLUT2 to the BBM agrees with observations that phloridzin (an SGLT1 inhibitor) fully blocks glucose uptake, and that patients with defective SGLT1 suffer from glucose-galactose malabsorption. Trafficking of GLUT2 is thought to be rapid, with a $t_{1/2}$ of less than 5 minutes. A rounding of the apical surface, due to a contraction of the peri-junctional actomyosin ring, allows luminal glucose to have increased access to the BBM enzymes and transporters. The authors recognize that there may also be an activation of the small amount of GLUT2 that is already present in the BBM.

Helliwell *et al*[67] investigated the role of several signalling pathways in intestinal fructose absorption. Using an *in vivo* perfusion model, they showed that fructose transport was mediated by both GLUT5 and GLUT2. Using PMA to stimulate a 4-fold stimulation of fructose transport, they saw a 4-fold increase in GLUT2 protein in the BBM that correlated with PKCβII activation. Only minor changes in GLUT5 levels were observed, suggesting that recruitment of GLUT2 to the BBM represents a mechanism by which absorptive capacity is matched to dietary intake.

Helliwell *et al*[100] also established a role for the PI-3K and the mTOR pathways in the phosphorylation, turnover and degradation of PKCβII. Using an *in vivo* perfusion model, they showed that inhibitors of these pathways (wortmannin and rapamycin, respectively) block GLUT2 trafficking to the BBM and inhibit sugar absorption. A role for insulin in the regulation of intestinal sugar absorption is suggested. In their model, they suggest that as sugar absorption increases, the plasma sugar concentration increases, stimulating the release of insulin, which activates PI 3-kinase, resulting in the phosphorylation of PKCβII (Figure 4).

They also proposed a model by which amino acids promote the formation of competent PKCβII by activating the mTOR pathway, which prevents dephosphorylation of PKCβII (Figure 4). Thus, the dynamic control of intestinal sugar absorption may be achieved by the rapid turnover and degradation of PKCβII.

Why haven't previous investigators been able to detect GLUT2 in the BBM? *In vivo* endogenous hormones and nutrients activate PKCβII. Kellett's group points out that the process of harvesting tissue for *in vitro* preparations causes the inactivation of PKCβII and the rapid trafficking of GLUT2 away from the BBM. This observation may help to explain why the passive component was more apparent in the *in vivo* studies, as compared to *in vitro* experiments. In order to minimize the loss of GLUT2 from the BBM, Kellett's group perform all stages of tissue harvesting and membrane vesicle preparations at 0-4℃

after perfusing the intestine with a sugar load.

Helliwell and Kellett [101] looked at perfusion conditions in order to determine if the so called passive component was SGLT1-dependent, as suggested by their work, or was SGLT1-independent, as suggested by earlier work by Debnam and Levin[102]. They concluded that the passive component is independent of the active component in high mechanical stress perfusions, suggesting that SGLT1-dependent recruitment of GLUT2 did not occur under these conditions. This may be related to the restrictions in blood flow and supply of endogenous nutrients and hormones caused by the high stress perfusions.

However, under conditions of low mechanical stress, inhibition of SGLT1 with phloridzin does decrease GLUT2 levels in the BBM. Clearly, the perfusion conditions affect the results of the experiment, and this may explain the discrepancies between various studies. Finally, Kellett and colleagues suggest that the term "facilitated" should be used rather than "passive" to more accurately describe the GLUT2 mediated component of sugar uptake.

The antibody used to detect GLUT2 is also critically important in being able to detect GLUT2 in the BBM. Currently, there are two commercially available antibodies that recognize GLUT2: one that recognizes the extracellular loop between transmembrane 1 and 2 (Biogenesis, Poole, England); and another that recognizes a portion of the C- terminus (Research Diagnostics, Flanders, NJ). The choice of antibody is important, as Au *et al* (2002) demonstrated that the biotinylation procedure they used to detect surface proteins interfered with the ability of the GLUT2 antibody to recognize the extracellular loop, forcing them to use the C-terminus antibody[103]. However, Thorens *et al*[103] were unable to detect GLUT2 in the BBM by immunohistochemistry using an antibody that recognizes the C-terminus[75]. In contrast, when using the antibody directed against the extracellular loop, Cheeseman's group was able to detect BBM GLUT2**.** In contrast, when using Western blotting on BBM vesicles, they were able to detect GLUT2 using either of the antibodies. Clearly, the choice of antibody depends on what method of detection is used.

Although earlier studies established a role for GLP-2 in modulating GLUT2 activity in the BLM[63,104], more recently Au *et al*[103] investigated the effect of GLP-2 on the transient expression of GLUT2 in the BBM. Using an *in vivo* perfusion model in rats, they showed that a one hour vascular infusion of GLP-2 (800 pM) doubled the rate of fructose absorption, and this enhanced absorption of fructose could be blocked by phloretin, an inhibitor of GLUT2. Immunohistochemistry localized GLUT2 to both the BBM and BLM, and identified a pool of transporter located just under the microvilli in the terminal web region. This raises the possibility that the cytoskeleton structure is involved in the insertion of GLUT2 into the BBM. Luminal glucose perfusion (50 mmol/L) or vascular GLP-2 infusion (800 pmol/L) increased GLUT2 in the BBM two-fold as determined by Western blotting of biotinylated surface proteins. Both Kellett and Cheeseman suggest that in addition to the insertion of GLUT2 in the BBM, the intrinsic activity of apical GLUT2 may also be regulated[103,105]. The concept of intrinsic activity and its regulation will be discussed in subsequent sections.

Gouyon *et al*[68] used confocal microscopy and immunofluorescence in mice to confirm the presence of GLUT2 in the BBM following five days of feeding a 65% sugar meal, or following an oral bolus of either fructose or glucose. Wild type and GLUT2 null mice were fed fructose, glucose or sucrose (65% glucose, fructose or sucrose)-rich diets for five days, or were fasted and then received a 40% fructose, glucose or sucrose bolus. The absence of GLUT2 did not significantly affect fructose absorption in animals fed a low-carbohydrate diet, suggesting that under these conditions GLUT5 is soley responsible for fructose uptake into the enterocyte.

In animals fed a high fructose diet, cytochalasin B (an inhibitor of GLUT2) inhibited fructose uptake 60% in wild type mice, whereas GLUT2 null mice were unaffected. A 40% reduction was observed in animals fed a high glucose diet. This suggests that under these conditions fructose enters the cell by both a cytochalasin B dependent process (GLUT2) and a cytochalasin B independent process (GLUT5). The trafficking of GLUT2 to the BBM may represent a mechanism by which sugar absorptive capacity is matched to dietary intake.

When GLUT2 null mice were challenged with oral fructose, transport was 60% lower than in wild type animals, indicating firstly that the absence of GLUT2 limited fructose uptake, and secondly that this could not be fully compensated for by GLUT5. Still, some compensatory changes were noted, as GLUT5 mRNA was found to be increased three-fold in the ileum, possibly indicating some fructose malabsorption in the GLUT2 null mice. Therefore, Gouyon's study demonstrates that while under control conditions GLUT5 is solely responsible for BBM fructose uptake, BBM GLUT2 may be responsible for 40%-60% of sugar uptake when the luminal sugar concentrations are high.

The role of AMP-activated kinase (AMPK), an intracellular energy sensor, in the regulation of intestinal sugar uptake has also been examined. Walker *et al*[106] demonstrated that the activation of AMPK resulted in the recruitment of GLUT2 to the BBM and a down-regulation of the energy-requiring SGLT1-mediated glucose uptake. The importance of this phenomenon, particularly in models of intestinal damage or stress, warrants further investigation.

The presence of GLUT2 in the BBM of humans has not been confirmed. Dyer *et al*[107] found GLUT2 expression was restricted to the BLM in humans, although critics of this work have speculated that this may be a result of the methods used to obtain and process biopsies, and the lack of feeding a high sugar diet or giving an oral sugar test prior to obtaining the biopsies[68].

In summary, the role of GLUT2 in the transport of sugars across the BBM remains controversial. The most recent data suggests that in specific situations, such as when luminal sugar concentrations are high, GLUT2 is recruited to the BBM and contributes to sugar uptake from the lumen. This may explain the discrepancies between studies and the inability of many researchers to detect GLUT2 in the BBM in their experimental models.

INTRINSIC ACTIVITY AND TRANSPORTER TRAFFICKING

A number of factors are involved in the regulation of intestinal sugar transport. These factors may modify sugar transport by altering the abundance of sugar transporters in the intestine. Alternatively, sugar transport may be regulated at an entirely different level. The intrinsic activity of the transporters (amount of substrate transported per unit of transporter protein) may be altered, in the absence of detectable changes in transporter abundance. Indeed, there has been a long history of reports of discrepancies between glucose uptake and the protein abundance of glucose transporters both in skeletal muscle[108], adipose[109] and in the intestine[67,103,110-114]. Changes in the intrinsic activity of glucose transporters have observed with hyperglycemia[110], diabetes[63], low luminal glucose concentrations[98] and following the activation of MAPK and PI3K[67]. The post-translational mechanism by which intrinsic activity is regulated is not known, but may involve phosphorylation or dephosphorylation of the transporter or the activation or inhibition of the transporter by a regulatory protein.

Kellett and his colleagues have shown that the PI3K pathway is involved in the modification of the intrinsic activity of GLUT2 and GLUT5[67]. Control of transport by the modulation of both the levels and activities of the transporters occurred as a result of extensive cross-talk between the extracellular signal-regulated kinase (ERK), p38, and phosphatidylinositol 3-kinase (PI 3-kinase) pathways. Activation of the p38 pathway stimulates fructose transport by increasing GLUT2 levels in the BBM, as well as increasing the intrinsic activity of GLUT2. In contrast, the ERK or PI 3-kinase pathways have regulatory effects on transporter trafficking and intrinsic activity, without having significant effects on fructose transport (Figure 3). However, these results are derived from independently modulating these pathways, when clearly there is extensive cross-talk. For example, when the ERK pathway is inhibited, fructose transport stimulated by the activation of the p38 pathway increases 50-fold, suggesting that the ERK pathway restrains the p38 pathway.

It is not known if PI3K/Akt modifies the intrinsic activity of SGLT1. However, a study by Alexander and Carey (2001) showed that orogastric IGF-1 treatment increased glucose uptake in piglets without increasing SGLT1 abundance, suggesting an effect on intrinsic activity of the transporter[115]. Inhibiting Akt blocked the increase in glucose uptake, possibly by modifying the activity of the transporter.

PI3K has also been implicated in the regulation of GLUT4 trafficking to the plasma membrane in adipocytes or muscle[108]. Despite this possibility, several studies have demonstrated that the trafficking of transporter protein to the BBM cannot fully explain changes in intestinal sugar uptake seen after IGF-1, GLP-2 or glucose administration [103,115,116]. Nevertheless, both alterations in trafficking and intrinsic activity may contribute to the changes seen in sugar uptake. Further work is required to further characterize the relative contributions of each of these mechanisms.

ALTERNATIVE THEORIES

The previously well-accepted role of GLUT2 as the sole BLM glucose transporter is also a subject of debate. The role of GLUT2 was originally based on it being immunolocalized to the BLM. However, this does not exclude the possibility of other basolateral transport pathways. Recently, GLUT2 null mice were developed, in which GLUT1 or GLUT2 was re-expressed in pancreatic β cells to enable survival. This was an important step in investigating the role of GLUT2 in sugar transport. In these animals, normal rates of glucose appearance in the tail vein blood were seen following an oral glucose load, suggesting that GLUT2 was not required for transepithelial glucose transport[117]. It is important to note that this paper has limitations, as the appearance of glucose in the tail vein is not a direct measure of intestinal sugar transport. Further work by Stumpel *et al*[118] using an isolated intestinal perfusion model demonstrated normal glucose transport kinetics despite a lack of GLUT2. This finding was noted under control conditions and following cAMP perfusion, which is known to increase glucose absorption via SGLT1[119]. Even with this accelerated apical uptake of glucose into the enterocyte, the basolateral transport of glucose did not appear to be rate-limiting.

Interestingly, sugar transport was dose-dependently inhibited by an agent that inhibits the glucose 6-phosphate translocase located in the endoplasmic reticulum (ER) membrane. Glucose 6-phosphate translocase transports glucose-6-phosphate from the cytosol into the lumen of the ER, where the active site of glucose-6-phosphatase is located. Furthermore, 3-O-methylglucose, which cannot be phosphorylated by the hexokinases, was not transported, despite the fact that it is a known substrate for both GLUT2 and SGLT1. Taken together, these findings suggest that a distinct pathway exists that involves glucose phosphorylation, transport to the ER, dephosphorylation, and release via a membrane-traffic based pathway (Figure 5). Interestingly, the expression of the glucose-6-phosphatase and the glucose-6-phosphate translocase, as determined by Northern blotting, were not increased in the GLUT2 null animals. This contrasts with the work of Gouyon *et al*[68], who used RT-PCR to demonstrate that GLUT2 null mice had increased mRNA expression of glucose-6-phosphatase.

Stumpel and colleagues[118] also noted that GLUT5 mRNA expression was increased in the GLUT2 null mice, while the expression of all other known GLUT transporters did not change. Human studies have demonstrated the presence of GLUT5 in the BLM of enterocytes[120]. The finding that fructose absorption was unaffected by GLUT2 status suggests that GLUT5 may have been present in the BLM, contributing to fructose release on the serosal surface of the enterocyte. However, the authors dismissed the possibility that fructose and glucose shared a common serosal transport system based on the observation that the release of glucose, but not fructose, was blocked by an inhibitor of the glucose 6-phosphate translocase.

Stumpel *et al*[118] also performed fructose perfusion experiments in GLUT2 null mice. The results showed

that intracellular fructose was not converted to glucose, further supporting the notion that this alternative pathway does not contribute to fructose efflux. The authors also discounted the possibility that the paracellular pathway significantly contributed to glucose absorption, as the SGLT1 inhibitor phloridzin greatly reduced glucose absorption. They concluded that a microsomal membrane traffic-based mechanism may be an important component of transepithelial glucose transport.

The investigators point out that the concept of a microsomal membrane-trafficking transport system is supported by the following observation: genes for glucose-6-phosphate translocase (G6PT1)[121] and glucose-6-phosphatase (G6PC)[122] are expressed in human intestinal cells, despite the fact that only minimal amounts of glycogen are found in jejunal biopsies[123]. Similarly, the high levels of hexokinase activity in intestinal cells [124] support the concept of an alternative transport system characterized by glucose phosphorylation and subsequent microsomal transport and trafficking.

Santer *et al*[125] re-evaluated the role of GLUT2 in intestinal sugar absorption in one patient with Fanconi Bickel syndrome (FBS). FBS is characterized by congenital GLUT2 deficiency. Oral glucose tolerance tests performed on this patient failed to demonstrate differences in breath hydrogen concentrations when compared to control subjects, indicating that sugar was not being malabsorbed, at least within the sensitivity limits of hydrogen breath testing. These findings also suggest that other mechanisms are in place to transport sugars across the basolateral membrane of enterocytes.

RECENT DISCOVERIES

The model of intestinal sugar transport is an ever-changing story. Recently, a new facilitative glucose transporter, GLUT7, has been cloned and characterized[126]. GLUT7 has a high affinity for glucose (Km = 0.3 mmol/L) and fructose (IC50 = 0.060 mmol/L), but not for galactose. GLUT7 mRNA is present in the human small intestine, colon, testis and prostate. GLUT7 protein was found in the intestine, mostly in the BBM. The transporter's high affinity led the researchers to speculate that it may be important in fructose absorption at the end of the meal, when concentrations of fructose in the intestinal lumen are low. The physiological relevance of GLUT7 is unknown, as it doesn't appear to compensate for the loss of SGLT1 in glucose-galactose malabsorption.

Tazawa *et al*[127] have also cloned SGLT4, a sodium-dependent sugar transporter found in the intestine, liver, and kidney. COS-7 cells expressing SGLT4 exhibited Na+-dependent α-methyl-D-glucopyranoside (AMG) transport activity (Km = 2.6 mmol/L), suggesting that SGLT4 is a low affinity transporter. Several sugars were able to inhibit AMG transport (D-mannose > D-glucose > D-fructose > D-galactose), suggesting that these sugars may also be substrates. However, only mannose was confirmed to be a substrate by studies demonstrating direct uptake of mannose into the cell. Because mannose is elevated in diabetes[128] and in the metabolic syndrome[128], the authors suggest that SGLT4 may be a potential therapeutic target for patients afflicted with these disorders. Further characterization of these novel intestinal transporters will add to understanding of intestinal sugar transport.

CONCLUSION

The process of intestinal sugar absorption remains a controversial topic. An increased understanding of this process will enable the development of better therapeutic strategies in conditions where the modulation of intestinal sugar transport could improve health. For example, reducing sugar absorption may be beneficial with regards to the treatment of diabetes or obesity. Conversely, stimulating sugar absorption may be desirable in patients with short bowel syndrome, or in malnourished elderly patients. Furthermore, the targeted delivery of drugs to tumour cells expressing glucose transporters is an exciting area of research that warrants further exploration.

Abstract

Numerous cellular and molecular events have been described in development of gastric cancer. In this article, we overviewed roles of *Helicobacter pylori (H pylori)* infection on some of the important events in gastric carcinogenesis and discussed whether these cellular and molecular events are reversible after cure of the infection. There are several bacterial components affecting gastric epithelial kinetics and promotion of gastric carcinogenesis. The bacterium also increases risks of genetic instability and mutations due to NO and other reactive oxygen species. Epigenetic silencing of tumor suppressor genes such as RUNX3 may alter the frequency of phenotype change of gastric glands to those with intestinal metaplasia. Host factors such as increased expression of growth factors, cytokines and COX-2 have been also reported in non-cancerous tissue in *H pylori*-positive subjects. It is noteworthy that most of the above phenomena are reversed after the cure of the infection. However, some of them including overexpression of COX-2 continue to exist and may increase risks for carcinogenesis in metaplastic or dysplastic mucosa even after successful *H pylori* eradication. Thus, *H pylori* eradication may not completely abolish the risk for gastric carcinogenesis. Efficiency of the cure of the infection in suppressing gastric cancer depends on the timing and the target population, and warrant further investigation.

Key words: Helicobacter; Cancer; Gastric acid; p53; Inflammation; Gastric atrophy; Intestinal metaplasia

INTRODUCTION

Gastric cancer is one of the most common neoplasmas worldwide, accounting for over 870 000 new cases and over 650 000 deaths annually[1]. Mortality from gastric cancer is the second most in death from malignancies, following to lung cancer. With exceptions in countries that have developed screening programs for early diagnoses, most patients reach treatment with cancers already in advanced stages[2]. Since surgery can be palliative, and gastric cancers are largely resistant to chemotherapy and radiotherapy, advanced gastric cancer has a poor prognosis. Therefore gastric cancer still remains a major clinical challenge and a great public health concern.

Extensive epidemiologic studies have shown that *Helicobacter pylori (H pylori)* infection is a major risk factor for developing gastric cancer and its precursor lesions[3]. The bacterium affects more than 50% of the world popultion[4]. The risk of patients with *H pylori* infection developing gastric cancer is in the order of two- to six-fold according to most retrospective case-control and prospective epidemiologic studies[5]. Furthermore, some of the trials eradicating *H pylori* have shown that cure of the infection reduces development of gastric cancer in high risk populations[6-8]. Thus, a hope is emerging and growing that cure of the *H pylori* infection may reduce incidence of gastric cancer.

The goal of this review is to clarify whether eradication *H pylori* results in eradication of gastric cancer. To accomplish this, we will discuss what types of cellular and molecular events occur in the *H pylori*-infected gastric mucosa; what bacterial factors are involved in the process of gastric carcinogenesis; and what host factors are able or unable to be reversed after the cure of the infection.

CELLULAR BASIS OF *H PYLORI*-RELATED GASTRIC CARCINOGENESIS

Histopathologic alterations

Chronic infection with *H pylori* causes active inflammation of gastric mucosa in majority of the population, although it is mostly asymptomatic. The bacterium also alters physiologic and histological behaviors of gastric mucosa, including hypochlorhydria, hyperchlorhydria, and changes in mucosal population of gastric epithelial cells that are specifically differentiated. In the hypochlorhydric population, hypergastrinemia occurs, while parietal cells do not respond to gastrin to produce acid, probably due to corpus inflammation. Apoptotic loss of superficial epithelial cells in the process of differentiation and migration in gastric glands increases[9], while proliferation of neck cells also increases possibly by some sort of compensation and by transactivation of growth stimuli in gastric mucosa[10]. In corpus mucosa, parietal cell population is also diminished in a long term, which is associated with alteration in population of other types of cells in each gland. Together with lowered density of glands partly due to inflammatory and edematous changes in subepithelial tissues, the above changes are known as gastric mucosal atrophy or atrophic gastritis. In addition, epithelial clones with incomplete and complete intestinal phenotypes emerge in the long-term process.

Currently, origins of the epithelial clones for the intestinal metaplasia have not yet been clearly determined. It is likely that epithelial clones for incomplete and complete intestinal metaplasia are developed from gastric epithelial cells by an activation of a series of genes including cdx-1/cdx-2[11-16]. In addition, bone marrow-derived adult somatic stem cells are involved in the regeneration of gastric glands, and may be another source of epithelial population[17]. Although our own study suggest that bone marrow-derived epithelial cells do not harbor permanently in a gastric gland, gastric adenocarcinomas are recently reported to be bone marrow-derived[18]. Stem cells in gastric glands locate neck region, whereas those in intestinal glands reside bottom region, a location completely different from the neck. Transdifferentiation of gastric gland cells to metaplastic cells remains an important question in gastric carcinogenesis.

Bacterial and/or host factors affecting the histologic alterations

Several pathogenic factors of *H pylori* have been demonstrated to be involved in the above alterations in gastric mucosa and the following development of gastric diseases.

Ammonia (NH_3), produced by *H pylori* urease, has been shown to cause acute gastric injury[19] in rats *in vivo* and to accelerate gastric epithelial cell death *in vitro*[19-21]. Chronic administration of NH_3, whose concentration is comparable to that found in *H pylori*-infected patients, increases epithelial cell replication and epithelial cell turnover, associated with accelerated epithelial cell death, cell exfoliation, preferential loss of parietal cells and gastric mucosal atrophy[22, 23]. The damaging effects of NH_3 on gastric mucosa are pH-dependent, while sodium hydroxide at the same pH does not cause significant mucosal injury[19]. Ammonia dissolves readily in water where it forms, and is in equilibrium with, ammonium ions (NH_4^+). With decreases in pH, NH_4^+ predominates, but increases in pH may materially increase levels of non-ionized NH_3[19]. On the other hand, *per os* administration with ammonium chloride (NH_4Cl) results in intragastric NH_4^+, and does not induce significant mucosal atrophy. Rather, NH_4Cl is reported to stimulate antral mucosa to increase gastrin release[24], which possibly induces gastric mucosal hypertrophy[25]. Therefore, not only *H pylori* but also gastric acid secretion of the host is an important determinant of gastric cell kinetics.

NH_3 also increases incidence and size of gastric adenocarcinomas in rats pretreated with N-methyl-N'-nitro-N-nitrosoguanidine (MNNG)[26, 27]. Prior administration of NH_3 followed by MNNG does not increase incidence of gastric adenocarcinomas in rats, indicating that NH_3 may act as a promoter in the chemically-induced gastric carcinogenesis. Immunohistochemical analysis using bromo deoxy-uridine (BrdU) demonstrates that NH_3 increases cell replication in gastric tumors as well as non-cancerous tissues surrounding the tumors. Thus, NH_3 and the consequent host epithelial responses play important roles not only in increased cell proliferation in untransformed gastric mucosa but also in promotion of gastric cancer.

The other virulence factors including CagA and other cag pathogenicity island (PAI) proteins, VacA and adhesions have been considered to be involved in wide diversity of *H pylori*-related diseases. For an example, strains containing the cag PAI have been reported to trigger signaling cascades in gastric epithelial cells, resulting in NF-κB activation and other cellular responses. Furthermore, CagA, which can be injected into the host cells, is able to be phosphorylated in the host, and to alter epithelial morphology probably through signaling pathway similar to that of HGF/c-met[28-31]. Roles of phosphorylated CagA protein in gastric epithelium are under extensive investigation and reviewed elsewhere[32]. Since it is related to gastric inflammation, cag PAI may stimulate indirectly excessive production of reactive oxygen species, including nitric oxide, and lead to programmed cell death. Indeed, studies show conflicting results for an association between cag PAI and apoptosis[33, 34].

VacA reportedly induces gastric epithelial cell apoptosis[35, 36]. It is found that VacA also induces apoptosis of marophages and suppresses T-cell responses[37-40]. Shibayama *et al*[41] showed that γ-glutamyl transpeptidase induces apoptosis. Furthermore, several apoptotic mediators such as TNF-α, FAS-ligand, TRAILs and their receptors are reported to be upregulated[42-44]. Thus, proapoptotic factors from either the bacterium or the host appear to be involved in altered cell kinetics as well as disturbed immunologic surveillance in gastric mucosa. Once certain clones acquire the resistance from apoptotic or immunologic surveillance, they begin to grow to form clusters of neoplastic phenotypes.

MOLECULAR ALTERATIONS OF *H PYLORI*-RELATED GASTRIC CARCINOGENESIS

Events promoting gastric carcinogenesis

Gastric cancer is divided into two histologic entities: 'in-

testinal-type' and 'diffuse-type'. These two types differ in epidemiology and clinical outcome. Molecular profiles are also distinct between these phenotypes[45-47], and actually consist of wide variety of alterations including mutations, loss of heterozygosity (LOH), and epigenetic changes of expression of unmutated genes(Table 1). It is not surprising that numerous reviews have been published regarding this topic[45-52], considering the size of population with gastric cancers or with *H pylori* infection. In diffuse-type gastric adenocarcinomas, DNA-repair errors, p16 suppression and cyclin E amplification occur frequently in early stages. In early stages of intestinal-type gastric adenocarcinomas, inactivation of APC due to LOH or mutation and nonfunctioning p53 frequently occur. Events due to changes in tumor microenvironments, *i.e.,* overexpression or transactivation of growth factors such as EGF-family growth factors (TGFα, EGF, HB-EGF, etc), insulin-like growth factors (IGF-1 and IGF-2), transforming growth factor-β, cytokines, and gastrin, also play important roles in phenotypic change in gastric epithelial cells [53, 54]. For an example, elevated gastrin may transactivate HB-EGF and its receptors, resulting in upregulation of mitogen-inducible cyclooxygenase (COX-2) and its products (prostaglandin E_2, etc)[55, 56].

Recently, COX-2[57-71] attracts attention of many oncologists and gastroenterologists. In fact, some epidemiologic studies have shown that a long-term NSAID-use results in significant reduction of incidence and mortality of digestive cancers including not only colon but also stomach[72, 73]. We have shown that the COX-2 overexpression alters cell kinetics, suppresses programmed cell death, induces invasive phenotypes, supports tumor angiogenesis and influences cell adhesion to endothelial cells[54, 70, 71, 74-79]. *H pylori* infection induces gastric COX-2 upregulation[71, 80-86], and cure of the infection reduces the COX-2 expression[70]. However, in mucosa with intestinal metaplasia, COX-2 is overexpressed even after the cure of the infection (Figure 1)[70]. Procarcinogenic effects of COX-2 on stomach could be only partially reversed by successful *H pylori* eradication. Similar findings were also observed in the case of expression of nitrotyrosine, a product of nitric oxide (NO), in precancerous gastric mucosa. Expression of nitrotyrosine is elevated in gastric mucosa in patients with *H pylori* gastritis, which is reversible after successful *H pylori* eradication. However, in gastric mucosa with intestinal metaplasia, nitrotyrosine continue to be overexpressed even after the cure of the *H pylori* infection, suggesting that NO and other reactive nitrogen species is highly produced in metaplastic lesions[70].

Mismatch repair deficiency

Microsatellite instability (MSI) is defined as the presence of replication errors in simple repetitive microsatellite sequences due to mismatch repair (MMR) deficiency[48]. It is classified as high-frequency (MSI-H), low-frequency (MSI-L) or stable (MSS)[87]. MSI has been recognized as one of the earliest changes in carcinogenesis and results in genomic instability. MSI is detected not only in gastric cancer but also in intestinal metaplasia from subjects both with and without gastric cancer[88], suggesting that MSI can be an early event in gastric carcinogenesis[89-91]. Further-

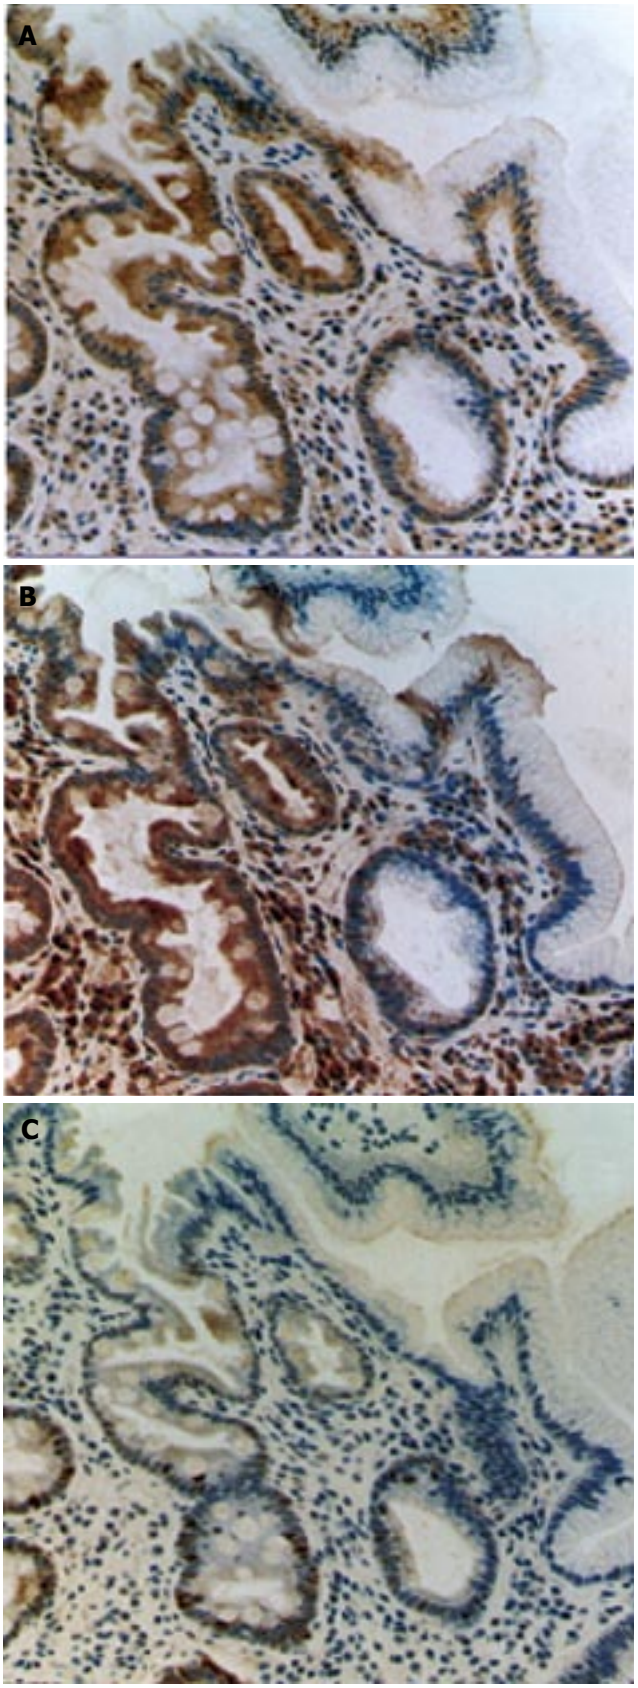

Figure 1 Expression of COX-2, nitrotyrosine and Ki-67 immunoreactivity in human gastric mucosa with intestinal metaplasia after cure of the H pylori infection. **A**: COX-2 immunostaining; **B**: nitrotyrosine immunostaining; **C**: Ki-67 immunostaining. The overexpression of COX-2 and nitrotyrosine, adduct of nitric oxide, are reported in gastric mucosa with *H pylori* infection[66, 68, 70, 71]. In these photographs, metaplastic gland with goblet cells (in the left side of each photograph) and non-metaplastic gastric glands (in the right side) are shown. COX-2 and nitrotyrosine immunoreactivities continue to exist in gastric mucosa with intestinal metaplasia after the successful *H pylori* eradication with PPI-triple therapy.

Table 1 Molecular alteration in the process of gastric carcinogenesis

Molecules	Major alterations	Comments	Category
p53	Mutation, LOH	Reported in diffuse-type and intestinal-type adenocarcinomas, as well as some precancerous lesions.	Tumor suppressor
APC	Mutation, LOH	Reported in diffuse-type and intestinal-type adenocarcinomas, as well as some precancerous lesions.	Tumor suppressor
DCC	LOH	Reported in intestinal-type adenocarcinomas. Related to cell adhesion	Tumor suppressor
CDH1	Mutation	Reported in diffuse-type adenocarcinomas.	Tumor suppressor
β-catenin	Mutation	Reported in intestinal-type adenocarcinomas.	Tumor suppressor
Fhit	LOH or deletion at chr. 3p14.2	Reported in diffuse-type and, in less frequency, intestinal-type adenocarcinomas, as well as some precancerous lesions.	Tumor suppressor
RUNX3	Hypermethylation	Related to TGF-β/SMAD signaling.	Tumor suppressor
K-ras	Mutation	Reported in intestinal-type adenocarcinomas. An element in signal transduction regulating cell proliferation, etc..	Oncogene
bcl-2	LOH	Reported in intestinal-type adenocarcinomas. Anti-apoptotic factor.	Oncogene
c-met	Amplification	Reported in diffuse-type and intestinal-type adenocarcinomas. The HGF receptor / tyrosine-kinase. Upregulation without mutation is also reported after mucosal injury.	Oncogene / Growth stimulus
c-erbB2	Amplification	Reported in intestinal-type adenocarcinomas. One of receptor-tyrosine kinases for EGF-family proteins.	Oncogene / Growth stimulus
Cyclin E	Amplification	Reported in diffuse-type and intestinal type adenocarciomas.	Cell cycle regulator
K-sam	Amplification	Reported in diffuse-type adenocarcinomas. One of bFGF receptor family proteins, FGFR2.	Oncogene
Mismatch repair (MMR) genes	Silencing due to hypermethylation	Reported in diffuse-type and intestinal-type adenocarcinomas, as well as some precancerous lesions. A possible source of mutations of other genes involving gastric carcinogenesis.	Determinants of microsatelite instability (MSI)
MMR genes	Mutation	Reported in diffuse-type and intestinal-type adenocarcinomas. There are conflicting data suggesting that mucosa with intestinal metaplasia is prone to and resistant to MSI.	Determinants of MSI
EGFR	Overexpression	Reported in diffuse-type and intestinal-type adenocarcinomas.	Growth stimulus
EGF	Overexpression	Reported in diffuse-type and intestinal-type adenocarcinomas.	Growth stimulus
TGF-α	Overexpression	Reported in diffuse-type and intestinal-type adenocarcinomas, as well as some precancerous lesions. Another EGF-family protein.	Growth stimulus
VEGF	Overexpression	Reported in diffuse-type and intestinal-type adenocarcinomas.	Angiogenic factor
iNOS	Overexpression	Reported in diffuse-type and intestinal-type adenocarcinomas, as well as some precancerous lesions and mucosa with H. pylori.	Enzyme
COX-2	Overexpression	Reported in diffuse-type and intestinal-type adenocarcinomas, as well as some precancerous lesions and mucosa with H. pylori. Cytokines and growth factors are possible inducer of COX-2.	Enzyme
ODC	Overexpression	Reported earlier in gastritis.	Enzyme
Telomerase	Activated	Enlongs telomere and prevents cell senescence.	Enzyme
CDXs	Overexpression	Reported in diffuse-type and intestinal-type adenocarcinomas, as well as precancerous lesions. Is involved in intestinal metaplasia.	Transcription factor
Ets1	Overexpression	A transcription factor involving angiogenesis.	Transcription factor
NF-κB	Overexpression	A transcription factor regulating expression of proinflammatory cytokines, chemokines, iNOS and COX-2.	Transcription factor
Sp-1	Overexpression	Reported in diffuse-type and intestinal-type adenocarcinomas.	Transcription factor
SC-1	Overexpression	Reported in diffuse-type adenocarcinomas.	Apoptosis receptor
Fas/CD95	Overexpression	Reported in diffuse-type adenocarcinomas.	Apoptosis receptor
E-cadherin	Mutation	Reported in diffuse-type and intestinal-type adenocarcinomas.	Cell adhesion
CD44	Splicing variant	Reported in diffuse-type and intestinal-type adenocarcinomas.	Cell adhesion
Gastrin	Elevation in serum	Elevation of amidated gastrin is reported. Transactivates EGF-family proteins.	Gut hormone

more, hypermethylation of CpG islands in the promoter region of the hMLH1 gene is associated with decreased hMLH1 protein, and often occurs in gastric cancer cases with MSI-H, indicating that epigenetic inactivation of hMLH1 may underlie MSI[92]. MSI in gastric cancer is associated with antral tumors, intestinal-type differentiation, and a better prognosis. Cancer cases with MSI exhibit mutations in BAX, hMSH3, hMSH6, E2F-4, TGF-β receptor II, and IGF-R II, which have simple tandem repeat sequences within their coding regions[93-99]. *H pylori* infection and following gastric mucosal alteration are closely related to MSI[100-102]. In particular, Park *et al*[100] recently reported an immunohistochemical study demonstrating that DNA MMR protein expression (hMLH1 and hMSH2) decreases in patients with *H pylori* infection. Cure of the infection resulted in significant increases in the percentage of hMLH1 (76.60 ± 20.27, 84.82 ± 12.73, $P = 0.01$) and hMSH2 (82.36 ± 12.86, 88.11 ± 9.27, $P < 0.05$) positive epithelial cells[100], suggesting that the effects of *H pylori* on MSI are reversible at least in a part. On the other hand, MSI results in frame-shift mutations of hMSH3 and hMSH6, and loss of hMSH1 and hMSH2 functions, which may lead gastric

Table 2 "p53" mutation in gastric cancers of early stages and precancerous gastric lesions. In gastric cancers of early stages and precancer gastric lesions, LOH and splicing are merely reported. Abbreviations for mutation: Del: deletion; Ins: insertion; F/S: frame shift. Abbreviati for lesion: EGC: early gastric cancer; AD: adenoma, CA/AD: carcinoma in adenoma; D: dysplasia; IM: intestinal metaplasia; N: muc without dysplasia, IM or carcinoma. Data are collected from references 104, 105, 113-118. (Modified from Tsuji *et al*[119, 120])

First author	Year	Case	G:C→A:T	G:C→T:A	A:T→G:C	A:T→C:G	A:T→T:A	G or C	Del	Ins	F/S	Lesions

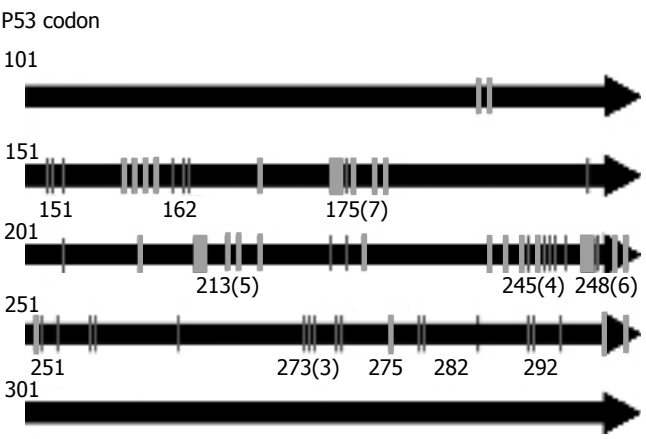

Figure 2 Location of point mutations of p53 in gastric cancers and premalignant lesions of the stomach. Horizontal lines mean codons of p53 gene. Thick and thin vertical lines respectively mean 5 and 1 mutations of the corresponding codon. Gray numbers indicate location of mutated codon followed by number of mutated cases in parentheses. As shown in this figure, codons 175, 213, 245, and 248 are preferably mutated in early stages of gastric cancer. Data are collected from references 104, 105, 113-118.

epithelial cells to further genetic instability that cannot be reverted by *H pylori* eradication. Therefore, the precise mechanism for *H pylori*-induced suppression on MMR protein has not yet been clarified and one of the important topics in *H pylori*-related gastric carcinogenesis.

Oncogenes

Certain EGF-like growth factors and their receptors are activated by membrane-type proteases called ADAMs (a disintegrin and metalloproteinase) following the stimulation including gastrin[56], endothelin and IL-8 that have G-protein coupled receptors[103]. IL-1β is also known to transactivate EGF-receptor via pathways dependent and independent of IL-8[103].

In addition, certain growth factors, their receptors and components of intracellular signaling have mutations or amplifications activating cell growth, inhibiting programmed cell death, and altering cell phenotypes. These oncogenes include HGF receptor (c-met), c-erbB2 (HER-2/neu), c-erbB3, K-sam, ras, c-myc and others, and have been reported to be mutated, amplified, or overexpressed in the process of gastric carcinogenesis[47, 52]. Once these oncogenes are mutated, it would be hardly possible for *H pylori* eradication to suppress oncogenes.

Tumor suppressor genes

Various tumor suppressor genes have been reported to be inactivated and involved in gastric carcinogenesis. For example, inactivation of p53 and p16 has been shown in both diffuse- and intestinal-type gastric cancers[52,104,105]. On the other hand, mutation of adenomatous polyposis coli (APC) gene occurs more often in intestinal-type gastric cancer. Another important tumor suppressor gene in intestinal-type gastric cancer is runt-related gene 3 (RUNX3) coding a subunit of polyomavirus enhancer binding protein 2[106-110], since expression of RUNX3 is greatly reduced in intestinal metaplasias in human stomachs[111] and Runx3-/- mouse gastric epithelial cells have a potential to differentiate into Cdx-2 positive intestinal type cells[112]. The product of the gene appears to interact with smad 2/3, which mediates TGF-β signaling pathway, and induces $p21^{WAF1/Cip1}$ expression.

Inactivation of these tumor suppressor genes includes, inactivating mutations, LOH, and epigenetic silencing. For example, hot spot mutations on CpG islands in p53 have been reported not only in gastric cancers at early stages but also in non-cancerous tissues with intestinal metaplasia [104, 105, 113-118]. In stomach, mutated p53 proteins are largely non-functioning and accumulate in the cells. Interestingly, p53 mutation frequently include G:C→A:T transition (Table 2, Figure 1)[119, 120], and NO is an important mutagen causing this type of mutation[120-122]. On the other hand, silencing of RUNX3 by promoter hypermethylation is frequently found in gastric cancers and in intestinal metaplasia. Although the silencing of tumor suppressor genes due to mutation may not be reversed, the epigenetic silencing may be reversed in methylation and demethylation processes. At present, there is no evidence indicating *H pylori per se* increases aberrant hypermethylation of tumor suppressor genes[123]: rather, Epstein-Barr virus-related gastric cancer is associated with a high frequency of DNA

hypermethylation, suggesting that viral oncogenesis might involve DNA hypermethylation with inactivation of tumor suppressor genes[124]. However, male gender, intestinal metaplasia and chronic inflammation with monocytic infiltration are strongly associated with increased methylation in non-cancerous gastric mucosa[123], and *H pylori* infection is one of the major causes of gastric inflammation. Thus, it remains an important question whether cure of the infection reduces the epigenetic alterations in tumor suppressor genes in non-transformed gastric epithelia.

Telomere and/or telomerase

Activation of telomerase that prevents shortening of telomeres during cell division may play an important role in immortalizing cells[47, 125-127]. In brief, telomeres cover the ends of chromosomes and are important in maintaining chromosomal integrity. In intestinal metaplasia, shortening of telomeres[52] as well as telomerase activation[127, 128] are observed, suggesting an important role in development of gastric cancer with intestinal type. Interestingly, it has been reported that *H pylori* infection reactivates telomerase[129, 130], and that cure of the infection appears to reduce telomerase activity[130]. Since clinical studies using human subjects may suffer from sampling errors, it remains an open question whether *H pylori* eradication reverses telomerase activation.

HOST GENETICS OF *H PYLORI*-RELATED GASTRIC CARCINOGENESIS

Genetic predisposition affecting inflammation and acidity of stomach

Genetic predisposition plays an important role in developing gastric cancer. The most widely reported are IL1B and NAT1 polymorphisms[131-138]. The association of IL1B polymorphism and gastric carcinogenesis was hypothetically explained by El-Omar *et al*[134] to be a strong acid-inhibiting and proinflammatory capacity of the gene product. Indeed, gastric acid secretion is known to be suppressed by IL-1β, which is mediated by nitric oxide[139]. These genetic factors may have strong association with *H pylori* infection, since the bacterium induces production of interleukins, inflammation, and elevates intragastric pH, which may result in increase of xenobiotic products. On the other hand, IL-1β and IL-8 were recently reported to transactivate EGF-receptor *via* ADAM-10 activation[103]. IL-1β is also known to up-regulate COX-2 in gastric epithelium[140]. Therefore, the reason for the association of IL1B polymorphisms and the risk for gastric cancer remains an open question and may require further investigation.

Genetic predisposition possibly independent of acidity of stomach

Another example of the genetic predisposition is families of hereditary nonpolyposis colorectal cancer (HNPCC) kindred of which have an excess of gastric carcinoma; complete intestinal metaplasia and chronic atrophic gastritis restricted to the antrum[141-143]. Interestingly, HNPCC patients frequently have a mutation in one of two DNA mismatch repair genes, hMSH2 or hMLH1, and demonstrate MSI-H. As mentioned earlier, *H pylori* has an ability to decrease MMR activity. Several genetic predispositions in MSI may share the same mutations to those found in *H pylori*-induced carcinogenesis. In these cases, the bacterial infection has a potent impact on gastric carcinogenesis, since it could lower the MMR activity more than the hereditary predisposition alone.

Hereditary gastric cancer due to germline mutation of the E-cadherin has been reported[144], which is a risk factor possibly independent of *H pylori* infection.

DOES *H PYLORI* ERADICATION ERADICATE GASTRIC CANCER?

Unlike the typical adenoma-carcinoma sequence of colon, development of gastric cancer appears to be a complex process. Due to the complexity of molecular events of gastric carcinogenesis, factors discussed here do not cover every aspect of gastric carcinogenesis. Rather, we tried to overview some of the possible factors initiating, promoting and supporting the development of gastric cancer. By doing so, we discussed what types of risks exists in *H pylori* positive subjects and what extent of these risks could be withdrawn after the cure of the infection.

Certain bacterial factors affect gastric epithelial cells directly to support establishment and development of metaplastic or dysplastic clones. Successful *H pylori* eradication withdraws these bacterial factors and therefore lowers the promotional effects on tumor development. The bacterium also increases genetic instability and risks of mutation. Some host factors such as NO and other reactive oxygen species are induced by *H pylori* and increase risks of mutation. Although cure of the infection may reduce these risks leading to epithelial mutagenesis, it does not abolish the risk completely. Particularly, in gastric mucosa with intestinal metaplasia and other phenotypically altered tissues, increases in MSI and NO synthesis, as well as COX-2 overexpression are unaltered after the cure of the *H pylori* infection. Thus, *H pylori* eradication is an effective strategy in reducing the risk of gastric cancer; however, it is not efficient enough to eradicate gastric cancer. Prevention of the infection, *H pylori* immunization, *H pylori* eradication in the youth, selection of the high risk population, and alternative chemopreventive measures may be essential for optimal management of malignancy of the stomach.

Abstract

Interleukin (IL)-10 is an important immunoregulatory cytokine produced by many cell populations. Numerous investigations suggest that IL-10 plays a major role in chronic liver diseases. IL-10 gene polymorphisms are possibly associated with liver disease susceptibility or severity. Recombinant human IL-10 has been produced and is currently tested in clinical trials. These trials may give new insights into the immunobiology of IL-10 and suggest that the IL-10/IL-10 receptor system may become a new therapeutic target.

Key words: Interleukin (IL)-10; Cytokine; Chronic liver diseases; Polymorphisms

BIOLOGICAL CHARACTERISTICS AND REGULATION OF INTERLEUKIN-10

Interleukin-10 (IL-10) first described as a cytokine synthesis inhibitory factor for T lymphocytes produced by T helper 2 (Th_2) cell clones, can inhibit interferon (IFN)-γ synthesis in Th_1 cell clones[1]. The human IL-10 gene, a homodimer with a molecular mass of 37 ku, is located on chromosome 1 and encodes for 5 exons. Each monomer consists of 160 amino acids. X-ray crystal-structure-analysis showed the two identical intertwining polypeptide chains of 160 animo acids are rotated by 180° to each other, forming two domains in a V- shape structure, each containing six helices[2-4]. Murine and human IL-10 exhibits a homology of about 80%. Various cell populations produce IL-10 in the body, including T cell subsets (Th_2, Tc_2, Tr_1, *etc*), monocytes, and macrophages. IL-10 is produced also by various cell types in other organs, including the liver[5-6]. Also, the stress axis plays a significant role in regulating IL-10 expression *in vivo*. Inflammation of the central nervous system or indirect activation of the stress axis by endotoxemia/bacteremia triggers the release of catecholamines that up-regulate IL-10 production in macrophages, particularly in the liver[7-8]. Within the liver, production of IL-10 has been documented within hepatocytes, sinusoidal endothelial cells, Kupffer cells, hepatic stellate cells and liver-associated lymphocytes[9]. These cells are stimulated to produce IL-10 through the cAMP/protein kinase A/CREB-1/ATF-1 signaling by several endogenous and exogenous factors such as stress, exdotoxin, tumor necrosis factor-α, catecholamines, and cAMP-elevating drugs. Recent data suggest that the p38 mitogen-activated kinase pathway also regulates the human IL-10 promoter via the activation of sp1 transcription factor[10]. IL-10 activity is mediated by its specific cell surface receptor-IL-10 receptor, which is expressed on a variety of cells, especially in immune cells[11]. Only a few copies of IL-10R are expressed on the surface of cells[12-13]. The expression is variable, but so far only a few regulating factors are known. IL-10R is composed of two different chains[14]. The interaction of hIL-10R with hIL-10 has been characterized recently and seems to be highly complex[15-16]. The IL-10Rβchain is essential for IL-10-mediated effects and CRFB4-deficient mice display the same phenotype as IL-10 deficient mice[17]. Only in cells expressing both IL-10R α and βchains, can the characteristic pattern of IL-10 signaling be observed[18]. The IL-10/IL-10R interaction activating the tyrosine kinases Jak1 and Tyk2, inhibiting the activity of NF-κB, results in transcriptional activation of several hundred genes[19]. The effects of IL-10 have been confirmed by experimental research in animals including IL-10 knockout mice[20] as well as by the effects of IL-10 observed in several inflammatory, autoimmune, and tumor models. IL-10 inhibits the ability of monocytes and macrophages to produce antigens to T cells[21-22] and monocytic production of IL-12. Inhibits proliferation and cytokine synthesis of $CD4^+$ T cells by exerting some direct effects of T cells, but does not exert potent direct inhibitory effects on $CD8^+$ T cells. IL-10 has various but weak stimulatory effects on B cells. IL-10 prevents apoptosis and enhances proliferation and differentiation of plasma cells as well as IgM synthesis, and inhibits the release of various chemokines by neutrophils. One of the most important properties of IL-10 is its anti-inflammatory action[23], which restrains the

immune response under various stimuli. Evidence of *in vivo* function of IL-10 indicates that inflammatory bowel disease is exacerated in the absence of IL-10.

EFFECTS OF IL-10 ON CHRONIC LIVER DISEASE AND LIVER FIBROSIS

Experimental data from animal models and clinical data from patients suggest that inflammation-associated cytokines including pro-inflammatory cytokines such as TNF-αand TGF-β, and anti-inflammatory cytokines such as IL-10 , are involved in the development of liver injury[24]. The effects of IL-10 have been observed in viral or autoimmune hepatitis, alcoholic liver disease, and animal models. Patients with a strong Th_1 response during acute HCV infection can clear the virus, while patients presenting with a Th_2 response (high levels of IL-10) evolve into chronicity[25]. In Con A-induced liver injury model[26-28], using a blocking IL-10 monoclonal antibody could lead to severe hepatic necrosis. On the other hand, administration of recombinant IL-10 in mice challenged with Con A could dramatically reduce secretion of pro-inflammatory cytokines, apoptosis of hepatocytes, hepatic neutrophil infiltrate and delay hepatic necrosis. In the model of liver injury induced by lipopolysaccharide (LPS) or staphylococcal enterotoxin B (SEB) in D-galactosamine (GalN)-sensitized mice[29-31], treatment with IL-10 could markedly reduce serum transaminase activities in a dose-dependent manner and hemorrhagic liver damage in sensitized mice exposed to toxins. IL-10 also inhibits increases in serum TNF-alpha and IFN-gamma concentrations with the toxins. Treatment with IL-10 could significantly reduce TNF-alpha mRNA and IFN-gamma mRNA expression in the liver and spleen after administration of the toxins to sensitized mice. These findings suggest that IL-10 is capable of regulating hepatic injury *in vivo* mediated by T cells macrophages. Injury of the liver requires the participation of proinflammatory cytokines and chemokines, many of which are regulated by the transcription factor, nuclear factor κB (NFκB). Other data suggest that IL-10 protects against hepatic ischemia/reperfusion injury by suppressing NFκB activation and subsequent expression of proinflammatory mediators[32]. IL-10 has been shown to be beneficial in the setting of liver transplantation[33], treatment with IL-10 can increase allograft survival. Current studies demonstrate that IL-10 may protect against surgery-or trauma related organ injuries secondary to hepatic ischemia-reperfusion. In human alcoholic liver disease or in rats fed with alcohol, defective production of IL-10 might result in chronic liver disease, suggesting that IL-10 might be of therapeutic value for alcoholic hepatitis by decreasing hepatocyte death[34]. In the model of CCl_4-induced chronic liver injury, IL-10 deficient animals had a persistently increased inflammatory infiltrate, and developed a more extensive fibrosis than the animals able to produce IL-10, indicating that IL-10 is involved in the control of fibrogenesis[35-37]. Several studies indicate that IL-10 might play an important role in antifibrogenesis during CCl_4-induced hepatic fibrogenesis[38-39]. Hepatic stellate cells (HSCs) are involved in liver fibrogenesis since, *in vitro* experiments have shown that HSCs express IL-10 receptor and produce IL-10[40-42]. In highly purified preparations of rat HSCs, messenger RNA (mRNA) for IL-10 can be detected by reverse-transcription polymerase chain reaction (RT-PCR). Long-term incubation of unstimulated mouse HSCs secrete IL-10 protein as detected by immunoblotting and specific enzyme-linked immunosorbent assay (ELISA). IL-10 protein is undetectable by immunohistochemistry in mouse HSCs during the first 3 d of culture. The percentage of IL-10-positive cells increases to 45% on d 7 and 100% on d 14, and IL-10 continues its expression in long-term culture of up to 120 d. These data indicate that IL-10 plays an important role in liver fibrosis by suppressing the function of HSC and promoting apoptosis of HSC[43-45]. IL-10 has a direct effect on the production of collagen and collagenases, modulates remodeling of the extracellular matrix[46-47], and indirectly limits the fibrogeneic response by controlling $TGF\beta_1$ secretion.

IL-10 GENE POLYMORPHISMS IN CHRONIC LIVER DISEASE

Genetic markers in cytokine genes are widely used in studies of immune-mediated diseases to determine disease susceptibility and severity[48]. In recent years, increasing attention has been paid to the role of cytokine levels in inflammatory and immune response., which may account for some of the heterogeneity observed in the outcome of chronic liver diseases, such as HBV and HCV infection, alcoholic and autoimmune hepatic disease. Possible linkage of IL-10 promoter haplotypes to disease susceptibility or severity has been reported[49]. The IL-10 promoter is highly polymorphie with two informative microsatellites, IL-10G and IL-10R. Single nucleotide polymorphisms (SNPs) in the promoter form SNP combinations (ATA, ACC, GCC) associated with differential IL-10 expression[50]. There are several lines of evidence that ATA haplotype in the IL-10 gene promoter is relevant to a genetically low capacity for IL-10 production, whereas GCC haplotype is identified as a high IL-10-producing phenotype, suggesting that the difference in disease progression of patients results from the inheritance of the IL-10 gene promoter polymorphisms. The influence of cytokine genotypes either on different clinical features of liver disease or in the response to antiviral therapy has been evaluated in several studies. Since inadequate expression of IL-10 seems to be of pathophysiological relevance in several diseases and the expression levels seem to have a genetic background. Increased serum levels of IL-10 are often observed in chronic HCV infection and inheritance of the interleukin-10 -1082 G/G may be associated with susceptibility to chronic hepatitis C infection and resistance to combined antiviral therapy[51-53], suggesting that chronic HCV infection patients with the haplotype conferring a high production of IL-10 have a lower rate of response to interferon therapy. IL-10 promoter allelic frequencies of T and A at positions -819 and -592, as well as the frequencies of ATA haplotype at positions -1082/-819/-592, are significantly higher in asymptomatic carriers than in patients with progressive chronic liver disease, suggesting that patients with haplotype

conferring a high production of IL-10 develop chronic progressive liver disease, while patients with a lower production of IL-10 tend to be asymptomatic carriers[54, 55]. Possession of the A allele at position -627 in the IL-10 promoter (low IL-10 expression) is associated with an increased risk of advanced liver disease in heavy drinkers[56, 57].

Genetic association analysis has revealed that one of the IL-10 haplotypes, IL10-ht2 (-1082A/-819T/-592C/+117T) is strongly associated with hepatocellular carcinoma (HCC) occurrence in a dose-dependent manner[58]. The frequency of susceptible IL10-ht2 is much higher in HCC patients and significantly increased in order of susceptibility to HBV progression from chronic to cirrhosis and HCC. In addition, the onset age of HCC is also accelerated among chronic hepatitis B patients who carry IL10-ht2. Increased IL-10 production mediated by IL10-ht2 suggests that up-regulation of IL-10 accelerates progression of chronic HBV infection, to HCC.

APPLICATION OF IL-10 AS A THERAPEUTIC AGENT

The promising results from IL-10 applied to several inflammatory diseases in experimental models induce the interest in clinical application of IL-10. So far human recombinant IL-10 has been tested in healthy volunteers, patients with Crohn's disease, rheumatoid arthritis, psoriasis, hepatitis C and HIV infection[59]. In phase I clinical trials, safety, tolerance, pharmacokinetics, pharmacodynamics, immunological and hematological effects of single or multiple doses of IL-10 administered by intravenous (i.v.) or subcutaneous (s.c.) route have been investigated in healthy volunteers[60]. IL-10 is well tolerated without serious side effects at the dose of 25 μg/kg and mild to moderate flu-like symptoms are observed in a fraction of recipients at the doses of 100 μg/kg.

Single i.v. or s.c. of IL-10 results in transient dose-dependent changes in white blood cell population, including increase of total white blood cells and neutrophils, lymphocytopenia and monocytosis as well as decrease in platelet counts are observed[61]. Following i.v. administration, IL-10 serum levels initially decline rapidly but yields a less steep terminal phase. IL-10 is cleared mainly through the kidneys as indicated by the increased $t_{1/2}$ and AUC of IL-10 in patients with moderate to severe renal insufficiency. Taken together, IL-10 application induces a number of immunological changes and is well tolerated[62]. IL-10 treatment does not result in significantly higher remission rate or clinical improvement for Crohn's disease compared with placebo treatment[63]. IL-10 can prevent postoperative recurrence of Chorine's disease but the clinical results are unsatisfactory[64]. The data from rheumatoid arthritis patients are rather discouraging, showing only marginal activity of the drug[65]. For psoriasis, IL-10 is likely to have antipsoriatic activity[66].

IL-10 is able to express antifibrotic properties in experimental models of liver cirrhosis[59]. It has been postulated that *in vivo* administration of IL-10 to patients with HCV infection may shift the intrahepatic immunologic balance away from Th1 cytokine predominance, thus exerting its anti-inflammatory and subsequent antifibrotic effect[67]. It was reported that long-term therapy with interleukin-10 decreases hepatic inflammatory activity and fibrosis, but leads to increased HCV viral levels[68].

IL-10 increases the susceptibility to infections due to its immunosuppressive activity and inhibition of bactericidal activity[69]. In the future, it may be used to target the delivery of IL-10 to avoid systemic side effects and low biodisponibility. IL-10 could be delivered locally with an adenovirus in the liver[70], suggesting that anti-inflammatory cytokines may have a future in the treatment of liver injury and the prevention of its complications.

ESOPHAGEAL CANCER

Association of smoking, alcohol drinking and dietary factors with esophageal cancer in high- and low-risk areas of Jiangsu Province, China

Abstract

AIM: To study the main environmental and lifestyle factors that account for the regional differences in esophageal cancer (EC) risk in low- and high-risk areas of Jiangsu Province, China.

METHODS: Since 2003, a population-based case-control study has been conducted simultaneously in low-risk (Ganyu County) and high-risk (Dafeng County) areas of Jiangsu Province, China. Using identical protocols and pre-tested standardized questionnaire, following written informed consent, eligible subjects were inquired about their detail information on potential determinants of EC, including demographic information, socio-economic status, living conditions, disease history, family cancer history, smoking, alcohol drinking, dietary habits, frequency, amount of food intake, etc. Conditional logistic regression with maximum likelihood estimation was used to obtain Odds ratio (OR) and 95 % confidence interval (95% CI), after adjustment for potential confounders.

RESULTS: In the preliminary analysis of the ongoing study, we recruited 291 pairs of cases and controls in Dafeng and 240 pairs of cases and controls in Ganyu, respectively. In both low-risk and high-risk areas, EC was inversely associated with socio-economic status, such as level of education, past economic status and body mass index. However, this disease was more frequent among those who had a family history of cancer or encountered misfortune in the past 10 years. EC was also more frequent among smokers, alcohol drinkers and fast eaters. Furthermore, there was a geographic variation of the associations between smoking, alcohol drinking and EC risk despite the similar prevalence of these risk factors in both low-risk and high-risk areas. The dose-response relationship of smoking and smoking related variables, such as age of the first smoking, duration and amount were apparent only in high-risk areas. On the contrary, a dose-response relationship on the effect of alcohol drinking on EC was observed only in low-risk areas.

CONCLUSION: The environmental risk factors, together with genetic factors and gene-environmental interactions might be the main reason for this high-risk gradient in Jiangsu Province, China.

Key words: Esophageal cacner; Case-control study; Smoking; Alcohol drinking; Dietary factors

INTRODUCTION

Esophageal cancer (EC) is the sixth most common cause of cancer mortality worldwide. The incidence of this disease shows a striking geographic variation in the world; a 20-fold variation is observed between high-risk China and low-risk western Africa[1]. Jiangsu Province, southeastern China is one of the highest EC incidence areas with a mortality rate of 30.0/100 000 between 1990-1992, which was significantly higher than the national average of 17.0/100 000[2,3]. EC has been the third leading cause of cancer mortality in Jiangsu Province since the 1970s[3]. Although the mortality rates of EC are high in most counties

of Jiangsu, national surveys conducted in the 1970s and 1990s have shown that rates differ considerably between different counties within the province, despite their similar geographic characteristics and socioeconomic status[3,4].

Comprehensive studies on the etiology and carcinogenesis of EC in high-risk areas have been carried out during the past decades. Epidemiological evidence suggests that the independent risk factors, tobacco smoking and alcohol drinking, are strongly associated with EC risk and have approximately multiplicative joint effects[5-7]. Dietary factors were also found to play an important role in the development of EC. Increased risk of EC was found to be associated with low intake of raw vegetables and fresh fruits, a deficiency in vitamins or protective antioxidants (e.g. Vitamin C and E, β-carotene, and selenium), high intake of carcinogens (frequent consumption of pickled vegetables and fungi toxins) and thermal injuries (fast eating speed for hot drinks and soups)[8-10]. While the contributory factors of EC are the high consumption of tobacco and alcoholic beverages in Western countries, the causative factors of EC in high-risk areas of China are nutrition deficiency, N-nitrosamines, fungi toxins and genetic factors[11].

Although numerous epidemiological studies have been conducted to explore the associations between environmental, lifestyle, dietary factors and the risk of esophageal cancer, few studies have been conducted to compare the association between risk factors and EC in apparently similar areas with a high risk gradient. Thus, a population-based case-control study has been conducted since 2003 in both low and high-risk areas of Jiangsu Province, China to study main environmental and lifestyle factors that account for regional differences in EC risk.

This paper reports the preliminary results on the independent and joint effects of smoking, alcohol drinking and dietary factors on EC risk and compares their associations with EC in both high-risk and low-risk areas.

MATERIALS AND METHODS

Study area

This study has been conducted in Dafeng and Ganyu counties since late 2003. Both counties are less developed coastal areas in northern Jiangsu Province, China, with 0.7 million and 1.1 million inhabitants, respectively. Dafeng is a high cancer incidence area and has a much higher mortality rate of EC than Ganyu. From 1996 to 2002, the yearly average age-adjusted mortality rate of EC in Dafeng was 36/100 000, whereas Ganyu had a considerably lower age-adjusted EC mortality rate of 24/100 000 during the same period ($P < 0.01$)[12].

Selection of cases and controls

Cases Newly diagnosed patients with primary esophageal cancer were recruited using data from regional cancer registry agencies. The cancer registry agencies in both counties were established in the late 1990s and are connected to the local Center for Disease Control and Prevention (CDC). All cases were coded according to the International Classification of Diseases, tenth revision (ICD-10, code C15.0 to C15.9). Secondary and recurrent cancers were excluded. All cases were restricted to local inhabitants of the two counties who have lived in either area for at least 5 years. In 2004, 45% and 72% of all newly registered EC cases were recruited and interviewed in Dafeng and Ganyu, respectively. The comparatively low response rate in Dafeng was partly due to the low involvement of local hospitals during the beginning of the study. A small number of cases were also unwilling to participate. Presently, the response rate in Dafeng is much higher. A system of rapid case recognition was used in the study. All regional hospitals were required by the local health authorities to report new EC patients shortly after diagnosis. As the cancer registry agencies are connected to the local CDC, the field investigators from the local CDC were able to identify and interview most patients within one month after their diagnosis. Of all the EC cases in Dafeng, 46% were histologically confirmed, 40% and 13% were diagnosed by endoscopy and radiology, respectively. In Ganyu, 30% of EC cases were histologically confirmed, 50% and 16% were diagnosed by endoscopy and radiology, respectively.

Controls Cases and controls were individually matched and derived from the same county. The criteria for the eligibility of controls were established as: controls had to be the same gender and within 5 years of age as the case, had to have lived in the area for at least 5 years, and had to have had good physical and mental health to answer questions reliably. Controls were randomly selected by a computer from the demographic database of the general population in the county police station. Local interviewers were responsible for locating and interviewing controls. If a selected control refused to participate, a replacement was found using the same recruitment criteria. The response rate of controls in both Dafeng and Ganyu was around 70%. Till March 2005, more than 400 EC cases were recruited in each county. However, the control recruitment rate is slower than the rate of case identification; thus only 291 and 240 pairs of cases and their matched controls were used in this analysis.

Data collection

Identical protocols and pre-tested standardized questionnaires were used. Data collection included a written informed consent, a face-to-face interview, a physical examination, and a 5 ml blood sample taken by professional interviewers from the local CDC in both counties. The questionnaire elicited detailed information on potential determinants of EC, including demographic information, socio-economic status, living conditions, disease history, family cancer history (any malignant neoplasm in first-degree relatives), smoking, alcohol drinking, dietary habits, and frequency and amount of food intake.

In our study, never-smokers were defined as having smoked fewer than 100 cigarettes in their lifetime. Current smokers and drinkers were defined as those who had the habit during the time of interview or those who stopped the habit because of health problems within one year of the date of interview. The dietary questionnaire used in this study included 90 food items. For each food item, the amount and frequency of consumption over the past year

were inquired. For cases, the amount and frequency of consumption referred to the year prior to the onset of the disease. In the final analysis, foods were categorized into several major groups: staple foods, preserved foods, meat, fish, eggs, soybean, and fruits and vegetables.

An anthropometric measurement and physical examination also took place at the time of interview to evaluate the subject's health status. Body mass index (BMI) was calculated as weight (kg) divided by height (m) squared (i.e., kg/m^2). BMI was grouped into quartiles according to the Chinese national standard (underweight: <18.5, normal: 18.5-23.9, overweight: 24~27.9, obesity: ⩾28)[13].

Statistical analysis

Data were double entered using Epidata 2.1b and cleaned and analyzed using SAS v8.2. Chi-square and Student *t*-tests were used to compare the distribution of relevant factors among the control groups between the two counties. Conditional logistic regression with maximum likelihood estimation of parameters was applied for both univariate and multivariate analyses. This was done by transforming each matched pair into a single observation, where the explanatory variable value was the difference between the corresponding values for the case-control pair [14]. Continuous variables such as income level and amount of food intake were divided into quartiles based on the frequency distribution among control groups.

The strength of the association was quantified as odds ratio (OR) obtained from conditional logistic regression. Statistical significance was set at 0.05, and accordingly, 95% confidence interval (CI) around the OR was used to address precision.

RESULTS

Subject characteristics

There were 291 pairs of cases and controls (200 male and 91 female pairs) in Dafeng and 240 pairs (181 male and 59 female) in Ganyu, respectively. By design, cases and controls had similar distributions in terms of gender and age in both two counties (Table 1). The differences in the distribution of the above-mentioned variables between the two counties were examined by comparing the two control groups. The proportion of patients who were older than 70 years of age and the proportion of illiteracy in Ganyu were higher than that of Dafeng ($P=0.002$ and $P<0.001$, respectively). There was also a geographic variation between the two counties between the proportion of BMI ($P=0.014$), occurrences of misfortunes such as fire disasters, lost of family members, divorces, etc in the past 10 years ($P=0.008$) and family history of cancer ($P<0.001$). On the other hand, there was no significant difference in past economic status, ever-smoking and ever-alcohol drinking habits between the two counties.

Socio-economic status

EC occurred less in higher socio-economic groups characterized by high levels of education and high economic status in both counties (Table 2). On the contrary, low levels of education, low economic status, family history of cancer in first-degree relatives (Dafeng OR: 1.53, Ganyu OR: 2.07), and occurrences of misfortune in the past 10 years (Dafeng OR: 1.26, Ganyu OR: 1.64) increased the risk of developing EC in both areas. In Dafeng, when compared to the lowest quartile (underweight people) of BMI, the second quartile (normal weight people, OR = 0.45) and the third quartile (overweight people, OR = 0.26) significantly showed a reduced risk of EC; whereas the OR increased in the highest quartile (obese people, OR = 0.49). A similar association between BMI and EC risk was also found in Ganyu, although the trend was not significant.

Tobacco smoking and alcohol drinking

Consistent smoking elevated the risk of developing EC in both counties (Table 3). In Dafeng, former smokers and current smokers have a 1.93- and 2.42- fold higher risk of developing EC than never-smokers. In Ganyu former smoking and current smoking also increased the risk of developing EC (OR = 1.28 and 2.36 respectively). We found in Dafeng that smoking at an earlier age (for trend $P=0.016$), long durations of smoking (for trend $P=0.006$), and large amounts of cigarettes per day (for trend $P=0.029$) were significantly associated with increased EC risk, with an apparent dose-response relationship. However, these associations were not significant in Ganyu.

In Ganyu, subjects who had drunk alcohol tended to have a higher risk of EC (OR = 1.71, 95% CI: 1.02-2.88). Moreover, drinking at an early age (for trend $P=0.012$) and long durations of drinking (for trend $P=0.061$) showed an increasing association with EC (Table 4). A high consumption of pure ethanol per week, 10 years ago, slightly elevated the risk of EC, but no significant dose-response relationship was found. We did not find any significant association between alcohol drinking and EC in Dafeng, despite its similar alcohol drinking prevalence as Ganyu. The joint effects by smoking and alcohol drinking were also explored in both counties, but no significant interaction was observed either in Dafeng ($P=0.900$) or in Ganyu ($P=0.870$).

Dietary factors

After adjusting for potential confounders in both Dafeng and Ganyu, subjects with fast eating speeds showed an increased risk of developing EC (Dafeng: OR=4.01; Ganyu: OR=3.09). On the other hand, high food temperatures, the possibility of being exposed to grain fungi pollution, and frequent intake of fresh garlic did not influence EC risk significantly (Table 5).

With regard to the consumption of major food groups, high consumptions of fish and seafood products significantly elevated the risk of developing EC in Dafeng (for trend $P=0.024$). Staple foods, preserved foods, fruits and vegetables, and soybean, however, were not apparently associated with EC risk in either county.

DISCUSSION

This population-based case-control study, conducted in high and low-risk areas of Jiangsu Province, China demonstrated an association between tobacco smoking, alcohol drinking, dietary factors and EC. These

[1] Some strata do not match the total because of missing values; [2] The *P*-value for comparing the distribution of factors between the two counties; [3] Never-smokers and ever-smokers were used for comparing the smoking habits between the two counties; [4] Because of the few numbers of former drinkers in both two counties, alcohol drinking status was categorized to never-drinkers and ever-drinkers for the comparison between the two counties and following analyses.

associations were compared separately in the two regions which had similar socioeconomic status and geographic characteristics. From our awareness, this is the first comparative population-based case-control study conducted in low-risk and high-risk areas simultaneously to compare the different associations of risk factors and EC in similar areas with high-risk gradients. Like other epidemiological researches, our study showed that EC was inversely associated with socioeconomic status, such as level of education and income. However this disease was more frequent among subjects with smoking and alcohol drinking habits and unhealthy dietary factors. Furthermore, a geographic variation of some associations was observed between the low-risk and high-risk areas. Smoking elevated the risk of EC in both areas concordantly, but the dose-response relationship of smoking and smoking related variables (age of first smoking, duration and amount) was apparent only in the high-risk area. On the contrary, the effect of alcohol drinking on EC and a dose-response relationship was only observed in the low-risk area.

Supporting previous studies, the risk of EC was inversely associated with socioeconomic status in the present study[15,16]. People with higher levels of education and better financial situations tend to have a lower risk of developing EC due to good living conditions and better health care access. Increased risk was found in people who had encountered misfortune in the past 10 years (Dafeng OR: 1.26, Ganyu OR: 1.64), or had a history of family cancer in first-degree relatives (Dafeng OR: 1.53, Ganyu OR: 1.57). These results were consistent in both high-risk and low-risk areas.

Associations between body mass index (BMI) and EC have been explored in several studies. Chow *et al*[17] reported a tendency towards a decreasing risk of esophageal squamous cell carcinoma with increasing BMI. Engeland found that low BMI increased the risk

[1] Matched by age and gender, further adjusted for level of education, past economic status (group) and alcohol drinking; [2] Never-smokers were used as the reference group.

of esophageal squamous cell carcinoma, while high BMI increased the risk of esophageal adenocarcinoma. In general, lowest BMI had the highest risk of EC[18]. Our study found similar results in both low-risk and high-risk areas. The risk of developing EC was significantly lower in normal and overweight groups when compared to the underweight group. However, the OR was high in the obese group. An increased risk of esophageal adenocarcinoma among obese persons has been explained by a dose-dependent association between increasing BMI and the risk of gastro-esophageal reflux symptoms, as observed by Nilsson *et al*[19].

Table 4 OR[1] and 95% CI of alcohol drinking in EC of Dafeng and Ganyu

Alcohol drinking	Dafeng (high-risk)	Ganyu (low-risk)
Alcohol drinking		
Never	1.00 (Referent)	1.00 (Referent)
Ever	1.01 (0.70-1.46)	1.71 (1.02-2.88)
P value	0.964	0.043
Age of first drink[2]		
<20	0.83 (0.44-1.58)	2.59 (1.03-6.50)
20-34	1.23 (0.79-1.91)	1.95 (1.08-3.53)
⩾35	0.81 (0.48-1.35)	1.18 (0.56-2.47)
P value for trend	0.815	0.012
Duration of drinking (yr)[2]		
1-24	0.96 (0.56-1.59)	1.28 (0.58-2.79)
25-34	0.89 (0.48-1.64)	1.48 (0.75-2.94)
35-44	1.57 (0.92-2.70)	1.47 (0.71-3.01)
⩾45	0.77 (0.43-1.40)	1.88 (0.95-3.75)
P value for trend	0.834	0.061
Alcohol consumption 10 years ago[2] (pure ethanol mL/wk)		
1-249	0.87 (0.49-1.54)	0.79 (0.36-1.74)
250-499	1.06 (0.60-1.89)	0.61 (0.30-1.25)
500-749	0.97 (0.52-1.79)	1.63 (0.77-3.43)
⩾750	1.10 (0.63-1.93)	1.27 (0.71-2.28)
P value for trend	0.74	0.223

[1] Matched by age and gender, further adjusted for level of education, past economic status (group) and tobacco smoking; [2] Never-drinkers were used as the reference group.

In conformity with other epidemiological studies shown in Western countries and some areas of Asia and Africa[20-22], increased risks of EC among former smoking and current smoking subjects were observed in both areas of our study. Tobacco smoke contains over 3000 constituents including 30 carcinogens, such as polycyclic aromatic hydrocarbons (PAHs), aromatic amines, and N-nitrosamines. The metabolites of these carcinogens may lead to gene mutation and cancer[23]. Age of first smoke, duration and dosage of tobacco use were also strongly associated with an elevated risk of developing EC in Dafeng, with an apparent dose-response relationship. Although Ganyu had a similar smoking prevalence, these time and dosage dependent results were not statistically significant in this area.

Several studies have reported a strong correlation between EC and alcohol abuse[24,25]. Alcoholic beverages also contain carcinogens and other compounds and may facilitate the absorption of esophageal mucosal cells and make them more susceptible to chemical carcinogens[26]. On the contrary of tobacco smoking, the positive association between alcohol drinking and EC was only found in Ganyu in our study (OR=1.71). Several studies

Table 5 OR and 95% CI of dietary habits, food consumption in EC of Dafeng and Ganyu

Dietary factor	County	Category				*P* value for trend
		1 (lowest)	2	3	4 (highest)

[1] Matched by age and gender, further adjusted for level of education, past economic status (group), smoking, alcohol drinking, BMI group, cancer family history, eating speed, food temperature and self-reported grain fungi pollution; [2] Matched by age and gender, further adjusted for education level, past economic status (group), smoking, alcohol drinking, BMI group, eating speed and family history of cancer; [3] Less than 3 times per week=1, 3 times per week and above=2; [4] Matched by age and gender, further adjusted for level of education, past economic status (group), smoking, alcohol drinking, BMI group, cancer family history, eating speed and food temperature; [5] Categorized by median among controls.

have reported a linear relationship between an overall daily ethanol consumption and EC risk[27,28]. However, in our study only the age of initial drinking and years of alcohol drinking were found to be associated with EC risk in Ganyu. No clear relationship between daily alcohol consumption and EC was found.

The interaction between tobacco smoking and alcohol drinking has been studied in many researches. It has been suggested that alcohol and tobacco interact in a multiplicative way[29,30]. In a large scale study, Castellsagué reported that the risk of EC in the highest joint level of alcohol and cigarette smoking increased 50.85-fold and 35.34-fold among men and women[7]. However the joint effect of smoking and alcohol was not found to be statistically significant in the high-risk area and the low-risk area in our study. The link between smoking, alcohol and EC in China are not as apparent as in Western countries. Several previous studies conducted in other high-risk areas of Jiangsu, China either did not find any relation or found only a weak association between smoking, alcohol drinking and EC[31,32].

Dietary factors are thought to play an important role in the pathogenesis of EC. Some epidemiological studies have suggested that the risk of EC is inversely associated with a higher intake of fruits and vegetables[10,33], while a detrimental effect was observed among high intake of certain types of meat, butter and saturated fatty acids[34]. Increased risk was related to N-nitrosamine compounds (mainly from preserved foods), foods contamination by fungus and the presence of toxins. Some unhealthy dietary habits such as fast eating speeds, consumption of hot foods and soups can cause the injury of esophageal mucosa and render the mucosa more susceptible to carcinogens.

An increased OR was found among fast eating subjects in both areas of this study (Dafeng OR: 4.01, Ganyu OR: 3.09). However, the associations between high food temperatures, the possibility of fungi pollution of grain, frequent intake of fresh garlic and EC was not statistically significant. In the food group analysis, after adjusting for potential confounders, we did not find any significant association between major food consumption and EC risk in either area. A positive association of fish and seafood product intake in Dafeng was found (for trend $P=0.024$). Fish is a rich dietary source of n-3 fatty acids. It has been reported that this long chain of fatty acid can suppress mutation, inhibit cell growth, and enhance cell apoptosis, thus reducing the risk of developing cancer[35]. The contradicting results found in our study of the increased risk found in the association between fish consumption and EC in Dafeng was probably due to water contamination or other unidentified confounders. However, this hypothesis needs to be further clarified and studied. Moreover, it may be more reasonable to study food composition and micronutrients in our future analysis rather than to use individual foods or food groups[36].

Ganyu has a high proportion of ageing and illiterate residents. The economic status of residents in Ganyu is also lower than Dafeng, although the difference is not significant (Table 1). As disease is more prevalent

among ageing populations and the level of education and economic situation are inversely associated with the risk of developing EC, it can be expected that the two counties would have a far higher risk gradient if they had a similar distribution of age and socioeconomic related factors.

As mentioned above, a heterogeneous association between smoking, alcohol drinking and EC was observed in the low- and high-risk areas in our study, despite their similar geographic characteristics and general socioeconomic statuses. A malignant tumor is the result of a series of DNA alterations in a single cell, which leads to a loss of normal functioning. A large number of gene coding for enzymes and receptors are involved in xenobiotic metabolism, with many of them showing polymorphisms. Many molecular epidemiological studies have proved that polymorphisms in activation and detoxification enzymes can interact with environmental carcinogens. It has been reported that GSTM1 null carriers may be especially susceptible to the action of tobacco with regards to EC[32], while inactive the ALDH2 genotype increases the risk of EC in alcoholics[37]. Genetic polymorphisms can interact with dietary factors. For example, cruciferous vegetables can inhibit the metabolic activation of phase I enzymes and induce the detoxification of carcinogens via phase II enzymes[38]. The polymorphism of one gene may also have an effect on other genes. Gene-gene interactions between GSTM1 0/0 and CYP1A1 and CYP1A2 enzyme induction have been observed in smokers[39]. Another example is that individuals with CYP1A1 Ile/Val alleles have greater CYP1A2 activity than those with wild type CYP1A1[40]. Furthermore, it has been suggested that genes can influence individual behaviours such as smoking, alcohol drinking and excess calorie intake, thereby having the potential to affect cancer risk[41].

Both environmental factors and human genes can show considerable regional variability. The variation in these factors together with their separate and joint effects ultimately determine the risk of cancer in different regions and may be the main reason for the large EC risk gradient between the counties in Jiangsu Province. Unfortunately scientific evidence on genetic polymorphisms, gene-environmental and gene-gene interactions remains inconsistent and inconclusive because of low statistical power and few candidate genes in previous studies. Moreover, no study has ever been conducted to compare the association between gene-environmental interaction and EC risk in apparently similar areas with a high risk gradient. Therefore, our future study will focus on genetic polymorphisms and their interactions with different environmental, lifestyle and dietary factors in the etiology of EC in high and low-risk areas, with a sufficient sample size and candidate genes.

Our present population-based case-control study has some limitations. Differences in the etiological factors between esophageal adenocarcinoma and squamous cell carcinoma may exist. Because of the low histological examination rate in China, it is difficult to differentiate between the subtypes of EC in a population-based study. Additionally, most risk factors in our study are based on self-reported data and may be subject to recall bias. Moreover, the relationship between BMI and EC was examined by using height and weight measurements obtained at the time of interview. Some cases might have begun to lose weight at an earlier time because of the disease. This factor could also have caused bias in our study.

In summary, the present study demonstrated the association between smoking, alcohol drinking, dietary factors and EC risk in the low-risk and high-risk areas of Jiangsu Province, China. Heterogeneous effects of smoking and alcohol drinking were found between the two areas, despite their similar geographic characteristics and general socioeconomic status. The variation in environmental risk factors, together with gene-environment and gene-gene interactions may be the main reason for these heterogeneous associations and may contribute to the large risk gradient of EC mortality in Jiangsu Province, China.

Abstract

AIM: To investigate the effects of tachyplesin and n-sodium butyrate on proliferation and gene expression of human gastric adenocarcinoma cell line BGC-823.

METHODS: Effects of tachyplesin and n-sodium butyrate on proliferation of BGC-823 cells were determined with trypan blue dye exclusion test and HE staining. Effects of tachyplesin and n-sodium butyrate on cell cycle were detected by flow cytometry. Protein levels of c-erbB-2, c-myc, p53 and p16 were examined by immunocytochemistry.

RESULTS: The inhibiting effects were similar after 2.0 mg/L tachyplesin and 2.0 mmol/L n-sodium butyrate treatment, the inhibitory rate of cellular growth was 62.66% and 60.19% respectively, and the respective maximum mitotic index was decreased by 49.35% and 51.69% respectively. Tachyplesin and n-sodium butyrate treatment could markedly increase the proportion of cells at G_0/G_1 phase and decrease the proportion at S phase. The expression levels of oncogene c-erbB-2, c-myc, and mtp53 proteins were down-regulated while the expression level of tumor suppressor gene p16 protein was up-regulated after the treatment with tachyplesin or n-sodium butyrate. The effects of 1.0 mg/L tachyplesin in combination with 1.0 mmol/L n-sodium butyrate were obviously superior to their individual treatment in changing cell cycle distribution and expression of c-erbB-2, c-myc, mtp53 and p16 protein. The inhibitory rate of cellular growth of BGC-823 cells after combination treatment was 62.29% and the maximum mitotic index was decreased by 51.95%.

CONCLUSION: Tachyplesin as a differentiation inducer of tumor cells has similar effects as n-sodium butyrate on proliferation of tumor cells, expression of correlative oncogene and tumor suppressor gene. It also has a synergistic effect on differentiation of tumor cells.

Key words: Tachyplesin; n-sodium butyrate; Gastric adenocarcinoma cell; Cell differentiation

INTRODUCTION

Tachyplesin, isolated from acid extracts of hemocytes of Chinese horseshoe crab (*Tachypleus tridentatus*), a sort of marine arthropod known as "live fossil", is a low-molecular-weight polypeptide [1]. This bioactive component has antitumor effect and induces tumor cell differentiation [2]. We used the small molecule polar compound n-sodium butyrate[3] as a parallel control to compare the effects on proliferation, cell cycle and expression of correlative oncogene and tumor suppressor gene of BGC-823 cells treated with tachyplesin, n-sodium butyrate and their combination. This research could provide information for further identification of antitumor low-molecular-weight crude bioactive peptides such as tachyplesin that can modulate the proliferation and differentiation of tumor cells.

MATERIALS AND METHODS

Tachyplesin isolation and extraction

Tachyplesin was isolated from acid extracts of Chinese horseshoe crab *(Tachypleus tridentatus)* hemocytes as previously described[4]. The crude extract was separated by SephadexG-50, CM-sepharose CL-6B column chromatography.

Cell culture

BGC-823 cells were cultured in RPMI-1640 medium supplemented with 20% heat-inactivated fetal calf serum,100 units/mL penicillin,100 mg/L streptomycin and 50 mg/L kanamycin at 37℃ in atmosphere containing 50 mL/L CO_2. BGC-823 cells were treated with culture medium containing inducers after seeded for 24 h.

Inducing treatment

The powder of tachyplesin obtained from separation, purification and lyophilization was dissolved in D-Hank's solution to prepare 100 mg/L concentrated solution. The mother liquor was prepared for solution of a given concentration with culture medium. N-sodium butyrate purchased from Sigma Co., was dissolved in appropriate concentration of D-Hank's solution to prepare 200 mmol/L concentrated solution. The concentrations of the three treatment solutions were as follows: 2.0 mg/L tachyplesin-treatment (Ta), 2.0 mmol/L n-sodium butyrate-treatment (Tb), and 1.0 mg/L tachyplesin + 1.0 mmol/L n-sodium butyrate for the combination treatment (Ta+Tb). The experimental groups were treated with the three reagents after medium was changed, while the control group was cultured continuously with fresh culture medium for future use.

Determination of cell growth curve

BGC-823 cells were collected in logarithmic phase, then suspension of BGC-823 cells was made in 5.0×10^4 cells/mL. The cells were seeded into 15 mL culture flasks with 2 mL per flask. After seeded for 24 h, the experimental groups were treated with the reagents containing different kinds of differentiation-induced gradients while the control group was cultured continuously in fresh culture medium. During the first seven days, untreated or treated cells were harvested from three flasks everyday, and the viable cells were counted by the trypan blue dye exclusion test to get average value. The similar results were found in triplicate experiments, the growth curve was derived from one of the results.

Determination of cell mitotic index

BGC-823 cells (5.0×10^4 mL) were seeded in to bottles containing little penicillin with cover slips. Treatments were performed after the cells were seeded for 24 h. During the first seven days, the cover slips were removed from two bottles of the untreated or treated cells everyday, fixed in Bouin-Hollande fixative, and stained with Hematoxylin-Eosin (HE). The mitotic cells in 1000 cells on each cover slip were counted, and the mitotic index curve was drawn.

Determination of cell cycle

BGC-823 cells were collected respectively from the treated groups and the control group after digested and centrifuged at 1000 r/min for 5 min. All the cells collected were rinsed three times with D-Hank's solution. The cells grown on cover slips were fixed in 75% pre-cooled ethanol at 4 ℃ overnight, centrifuged and resuspended in 100 mg/L RNase at 37℃ for 30 min. Then 50 mg/L propidium iodide was added into the suspended cells at 4 ℃ in dark for 30 min. The cell cycle was analyzed by flow cytometry (Bacton-Dickson Co.) and the data were analyzed by Cell FIT cell cycle analysis software（Version2.01.2）.

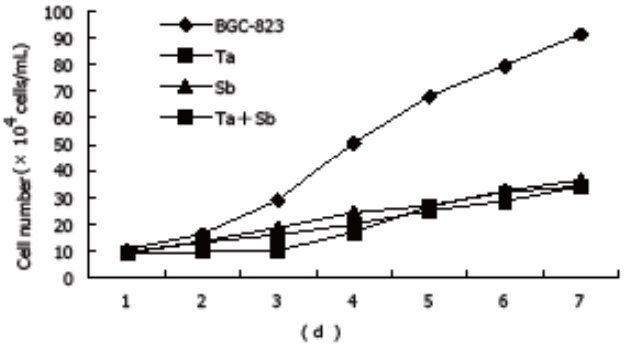

Figure 1 Cell growth inhibition in BGC-823 cells after tachyplesin, n-sodium butyrate and their combination treatment (×10^4 cells/mL).

Immunohistochemical analysis

BGC-823 cells (5.0×10^4/mL) and cells treated with different inducers were seeded into bottles containing little penicillin with cover slips for 36 h respectively. The cells grown on cover slips were rinsed with D-Hank's solution at 37℃. The changes in c-erbB-2, c-myc , p53 and p16 expression of treated and untreated BGC-823 cells were determined by SABC immunohistochemical assay. The reagent kit (Wuhan Boster Bioengineering Corporation) was used to determine the expression of these genes. PBS was used to take the place of primary antibody as the negative controls and positive specimens were used as positive controls.

RESULTS

Effects of tachyplesin and n-sodium butyrate on proliferation of BGC-823 cells

The cell growth curve determination showed that the proliferation of untreated BGC-823 cells was very fast. The cell number increased to 91.29×10^4/mL on the seventh day which was 18.26 times of that of the original 5.0×10^4/mL on the first day, with a doubling time of 45.82 h. However, after treated with tachyplesin or n-sodium butyrate, the growth rate of BGC-823 cells was inhibited. After treatment with 2.0 mg/L tachyplesin, the number of cells was 34.09×10^4/mL which was 6.8 times of that of the original number on the 7th day, with the doubling time prolonged to 75.7 h and the growth inhibitory rate increased to 62.77%. After treatment with 2.0 μg/mL n-sodium butyrate, the number of cells was 36.34×10^4/mL which was 7.27 times of that of the original number on the 7th day, the doubling time was 67.10 h and the growth inhibitory rate was 60.19%. After treatment with 1.0 mg/L tachyplesin + 1.0 mmol/L n-sodium butyrate, the number of cells was 33.87×10^4/mL on the 7th day, the doubling time was 69.75 h and the growth inhibitory rate was 62.29% (Figure 1).

The cell mitotic index determination showed that BGC-823 cells had vigorous proliferation capability, which reached to the divided peak on the fourth day and the maximum mitotic index was 38.5‰. However the mitotic

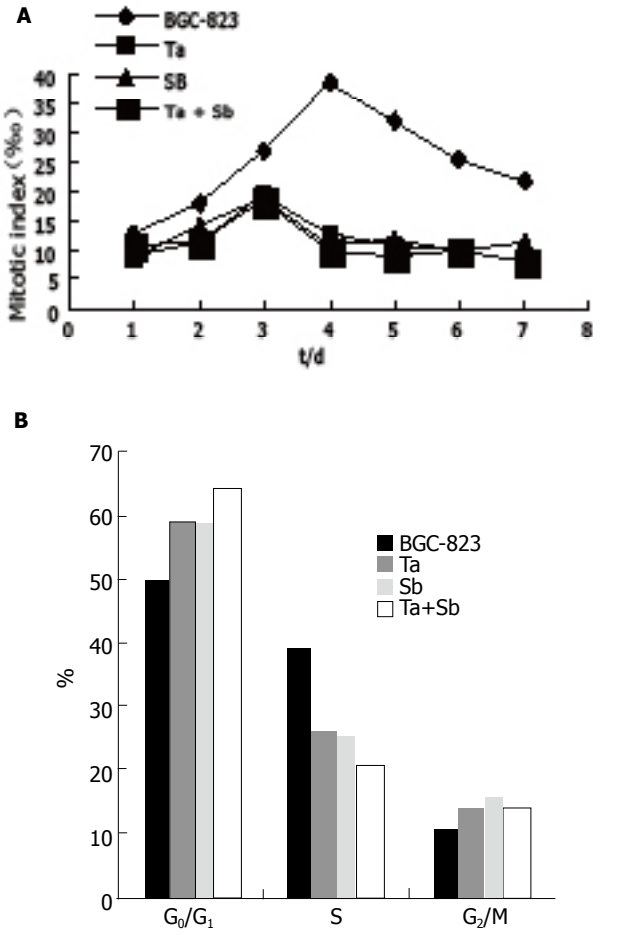

Figure 2 Influence of tachyplesin, n-sodium butyrate and their combination on mitotic index (**A**) and cell cycle (**B**) of BGC-823 cells.

index of cells treated with tachyplesin or n-sodium butyrate or their combination was only 19.5‰, 18.6‰ and 18.5‰ respectively at the divided peak, and declined by 49.35%, 51.69% and 51.95% respectively. The divided peak occurred on the third day after inducing treatment (Figure 2A).

Effects of tachyplesin and n-sodium butyrate on cell cycle of BGC-823 cells

Cell cycle of BGC-823 cells was analyzed by flow cytometry. The results showed that the cell cycle distribution of BGC-823 cells changed obviously when the cells were treated with tachyplesin or n-sodium butyrate. The proportion of untreated cells was 50.7% in G_0/G_1 phase, 39.1% in S phase and 10.2% in G_2+M phase. However, the proportion of cells at G_0/G_1 phase was 59.5%, 26.3% at S phase and 14.2% at G_2+M phase after treated with 2.0 mg/L tachyplesin. Similar changes occured in cells treated with 2.0 mmol/L n-sodium butyrate r the proportion of cells in G_0/G_1 phase was 59.2%, 25.2% in S phase and 15.6% in G_2+M phase. Meanwhile, the proportion of BGC-823 cells increased from 50.7% to 64.5% in G_0/G_1 phase and decreased from 39.1% to 20.9% in S phase(Table 1). The proportion of cells in G2+M phase increased from 10.2% to 14.6%(Figure 2B).

Effects of tachyplesin and n-sodium butyrate on expression of oncogene and tumor suppressor gene of BGC-823 cells

Immunocytochemistry showed that c-erbB-2 protein level in the control group was high. The dark brown-yellow granules were mainly detected in cytoplasm and membrane of BGC-823 cells. But in nuclei, the protein level was low, while a few unevenly-distributed buff granules could be detected (Figure 3A). After treated with tachyplesin, the positive rate of c-erbB-2 expression in BGC-823 cells decreased. The brown-yellow particles were mainly detected in cytoplasm around nuclear membrane but a few in nuclei (Figure 3B). After treated with n-sodium butyrate, relatively bigger brown-yellow granules were mainly detected in nuclei and cytoplasm around the nuclei but a few around the cell membrane(Figure 3C). After treated with the combination of the two inducers, the immunocytochemistry signal became weaker than after treated with n-sodium butyrate alone. The smooth and evenly-distributed brown-yellow granules were mainly detected in nucleoli and nuclear membrane of the cells (Figure 3D).

Immunocytochemistry showed that the c-MYC protein level in the control group was high, the brown granules were mainly detected in nuclei and cytoplasm around the nuclei of BGC-823 cells (Figure 3E). After treated with tachyplesin, the level of c-MYC protein in BGC-823 cells decreased. The light brown-yellow granules were mainly detected in karyoplasms around the nuclear membrane, while in nuclei, the protein level was very low (Figure 3F). After treated with n-sodium butyrate, the brown particles were mainly detected in nucleoli and cytoplasm, while in nuclei of the cells, the signal was almost negative (Figure 3G). After treated with combination of the two inducers, the signal became weaker than after treated with n-sodium butyrate alone. The evenly-distributed brown-yellow granules were mainly detected in nucleoli and cytoplasm while in nuclei of the cells, the signal could be scarcely detected (Figure 3H).

Immunocytochemistry showed that mtP53 protein level in the control group was high. The dark brown-yellow granules were mainly detected in nuclei, while a few granules were detected in cytoplasm of BGC-823 cells. Their distributing was irregular(Figure 3I). After treated with tachyplesin, the rate of positive expression of mtP53 in BGC-823 cells decreased. The light brown-yellow granules were mainly detected in cytoplasm, while in nuclei of the cells the expression was negative (Figure 3J). After treated with n-sodium butyrate, the light brownish-red granules

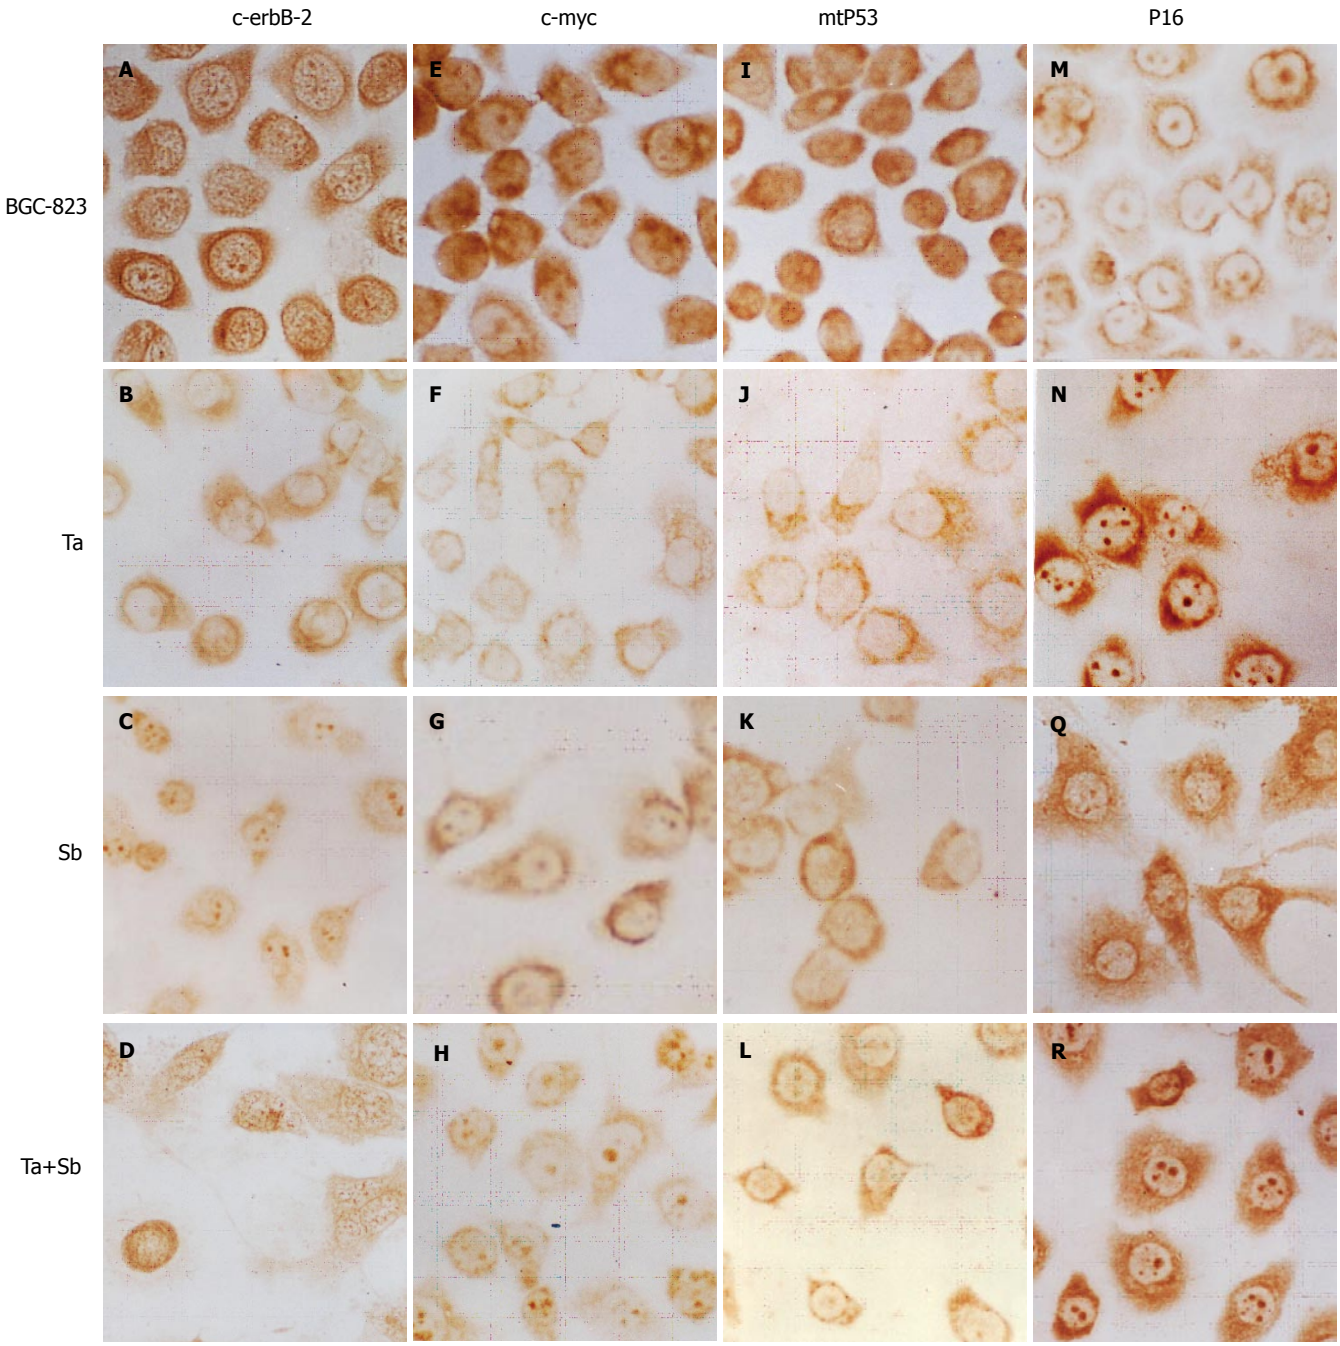

Figure 3 Expression of c-erbB-2 (A-D), c-myc (E-H), p53 (I-L), and p16 (M-R) in BGC-823 cells, tachyplesin-treated cells, n-sodium butyrate-treated cells, and tachyplesin + n-sodium butyrate-treated cells. ×536

were mainly detected in cytoplasm, while in nuclei of the cells, the mtP53 expression decreased greatly, and the signal became almost negative(Figure 3K). After treated with combination of the two inducers, the immunocytochemistry signal as a whole became weaker than after treated with n-sodium butyrate alone. The light brown granules were mainly detected in cytoplasm and could be hardly detected in nuclei of the cells (Figure 3L).

Immunocytochemistry showed that P16 protein level in the control group was low. The brown-yellow granules were detected in nucleoli and cytoplasm around the nuclear membrane of BGC-823 cells. The signal in cytoplasm and cell membrane was very weak (Figure 3M). However, after treated with tachyplesin, the P16 protein level in BGC-823 cells became very high. The evenly-distributed brown granules were detected in cytoplasm (Figure 3N). After treated with n-sodium butyrate, the P16 protein level became high. The brown granules were mainly detected in cytoplasm in a spare and dispersed manner. Some smaller granules were detected in marginal area of cytoplasm and protuberance of cells (Figure 3Q). After treated with combination of the two inducers, the P16 protein level became very high. The evenly-distributed brown granules were mainly detected in nucleoli and cytoplasm. The protein level in the combination treatment group was higher than in the group treated with n-sodium butyrate alone and the signal in nucleoli

became very strong (Figure 3R).

DISCUSSION

Sine continual division and constant proliferation are important characteristics of tumor cells, the proliferation of tumor cells is one of the significant indexes in identifying exogenous inducers of differentiation [5]. In our study, the cell growth curve, mitotic index and cell cycle indicated that BGC-823 cells had vigorous proliferation capability, the doubling time was 45.82 h, the maximum mitotic index was 38.5%, and the proportion of cells was 50.7% in G_0/G_1 phase and 39.1% in S phase. However the doubling time of cells treated with tachyplesin or n-sodium butyrate was 75.7 h and 67.1 h respectively, the rate of cell growth inhibition was 62.66% and 60.19% respectively, the maximum mitotic index decreased to 12.6% and 10.9% respectively, the proportion of cells in G_0/G_1 phase was 59.5% and 59.2% respectively, while the proportion of BGC-823 cells in S phase decreased to 26.3% and 25.2% respectively. The results demonstrated that the inhibitory effects of tachyplesin and n-sodium butyrate on proliferation of BGC-823 cells were significant. n-sodium butyrate, a small molecule polar compound, has been widely used in inducing differentiation of tumor cells [3, 6, 7]. The effects of n-sodium butyrate on cell growth and cell cycle are coincident with the reports about the anti-proliferative effects of n-sodium butyrate on the cell cycle arrest of human gastric, colonic and endometrial carcinoma cell lines [6-9]. Our experiment showed that the effects of tachyplesin and n-sodium butyrate on cell growth and cell cycle of BGC-823 were similar, indicating that tachyplesin has identical effects on inhibiting proliferation as chemical inducers of cancer cells.

The changes in expression of oncogenes and tumor suppressor genes play a role in cell carcinogenesis and reversal movement, amplification and inactivation of some associated genes such as c-erbB-2, c-myc, p53, p16 [10-11] are a main index in differentiation of human gastric carcinoma cells [11]. In our study, the levels of c-erbB2, c-myc, mtp53 proteins were high but p16 expression was low in untreated BGC-823 cells. However, after treated with tachyplesin or n-sodium butyrate, the level of c-erbB-2, c-myc, mtp53 proteins decreased and p16 protein expression increased significantly in BGC-823 cells, demonstrating that both tachyplesin and n-sodium butyrate can influence the expression of oncogenes and tumor suppressor genes. Previous studies showed that n-sodium butyrate could down-regulate the expression of oncogenes (c-erbB-2, c-myc, p53) and up-regulate the expression of tumor suppressor genes (p16) in endometrial and colonic carcinoma and melanoma[7,8,12,13], confirming that n-sodium butyrate has obvious effects on differentiation of BGC-823 cells. Our results also showed that tachyplesin had the same effect on up-regulating the expression of tumor suppressor genes and down-regulating the expression of oncogenes as n-sodium butyrate in BGC-823 cells.

The combination of different inducers may have a synergistic effect on differentiation and reduce toxicity and side effects by cutting down the dosage. It is not only an important subject in the field of differentiation, but also has a positive impact on the clinical application of different therapies for cancer [14]. Our study showed that at the concentration of 1.0 g tachyplesin + 1.0 mmol/L n-sodium butyrate, the growth inhibitory rate was 62.29%, the mitotic index decreased to 18.5‰ at the divided peak and the proportion of cells in G_0/G_1 phase increased to 64.5% and decreased to 20.9% in S phase. Immunocytochemistry also showed that the levels of c-erbB-2, c-myc, p53 proteins in BGC-823 cells treated with the combination were lower and the level of p16 protein was higher.

In conclusion, tachyplesin has synergistic effects with n-sodium butyrate and can be used in treatment of cancer.

Abstract

AIM: To evaluate contrast-enhanced ultrasonography (CEUS) using SonoVue® in the detection of liver metastases in patients with known extrahepatic primary tumors versus the combined gold standard comprising CT, MRI and clinical/histological data.

METHODS: It is an international multicenter study, and there were 12 centres and 125 patients (64 males, 61 females, aged 59 ± 11 years) involved, with 102 patients per protocol. Primary tumors were colorectal in 35%, breast in 27%, pancreatic in 17% and others in 21%. CEUS using SonoVue® was employed with a low-mechanical-index technique and contrast-specific software using Siemens Elegra, Philips HDI 5000 and Acuson Sequoia; continuous scanning for at least five minutes.

RESULTS: CEUS with SonoVue® increased significantly the number of focal liver lesions detected versus unenhanced sonography. In 31.4% of the patients, more lesions were found after contrast enhancement. The total numbers of lesions detected were comparable with CEUS (55), triple-phase spiral CT (61) and MRI with a liver-specific contrast agent (53). Accuracy of detection of metastatic disease (i.e. at least one metastatic lesion) was significantly higher for CEUS (91.2%) than for unenhanced sonography (81.4%) and was similar to that of triple-phase spiral CT (89.2%). In 53 patients whose CEUS examination was negative, a follow-up examination 3-6 mo later confirmed the absence of metastatic lesions in 50 patients (94.4%).

CONCLUSION: CEUS is proved to be reliable in the detection of liver metastases in patients with known extrahepatic primary tumors and suspected liver lesions.

INTRODUCTION

The continuous routine follow-up of cancer patients requires an easily available, reliable and cost-effective diagnostic method for the detection of liver metastases. Sonography is a widely used method for the detection of liver lesions, but is generally regarded as inferior to contrast-enhanced computed tomography (CT) and magnetic resonance imaging (MRI). The detection of liver

lesions with acoustic properties similar to those of the surrounding normal liver parenchyma has always been the significant limitation of grey scale (B-mode) imaging. To improve the detection of focal liver lesions, ultrasound imaging must also provide information on vascularity, exploiting the differences in blood flow between normal and pathological tissue. The concept of contrast-enhancing agents is not new, being derived from (bolus) dynamic computed tomography (CT) and magnetic resonance imaging (MRI).

Recent advances in contrast-enhanced techniques using high-mechanical-index imaging with Levovist® have improved the detection rate to a level similar to that attained using CT and MRI. This is clear from several, mostly single-centre, studies[1-5]. Owing to the high spatial resolution of sonography, CEUS may also detect subcentimetre metastases.

But there are still some important limitations since contrast-enhanced high-mechanical-index techniques must be performed intermittently and the examination technique is therefore difficult. It is expected that real-time scanning over the whole enhancement period of approximately three to five minutes using more stable contrast agents such as SonoVue® will facilitate routine use, making the examination easier and more reliable[6].

The purpose of this prospective international multicenter study using a real-time technique was to assess the ability of low-mechanical-index contrast-enhanced ultrasound (CEUS) to detect liver metastases in the presence of a known primary tumor versus a combined gold standard.

MATERIALS AND METHODS

The rationale of this study was to evaluate the diagnostic value of dynamic contrast sonography for the assessment of liver metastases versus established reference methods (CT and MRI) in combination with all clinical data except ultrasound techniques as a combined gold standard.

Study design

The study was a prospective, multicenter, open-label, intraindividual comparison. The new diagnostic procedure, dynamic contrast-enhanced ultrasound (CEUS), was compared with conventional sonography (without assessment of vascularity using contrast enhancement) and contrast-enhanced triple-phase CT, the method most commonly used in routine diagnosis. Furthermore, contrast-enhanced MRI was performed and the results from other diagnostic tests (biopsy, clinical data, etc.) were collected where available, to define the final diagnosis using the combined gold standard.

Patients

Between August 2001 and June 2002, 131 patients were enrolled at 12 European centres (see list of contributing centres). Included were male and female patients with known extrahepatic primary tumors and an indication for diagnostic assessment of possible liver metastases. Exclusion criteria were age < 18 years, pregnant or lactating women, known allergies to ingredients of the contrast agent, unstable medical conditions impairing the diagnostic procedure or contraindications to such a procedure, insufficient sonographic window for liver examination and participation in another investigational study.

Signed informed consent was obtained from all study patients before enrollment. The study protocol was approved by the ethics committee of the Landesärztekammer Baden-Württemberg and the local ethics committee of each centre. The study complied with Good Clinical Practice and the Declaration of Helsinki.

Methods and procedures

Ultrasonography

Ultrasound examinations were performed using a high-end sonographic scanner [Siemens Elegra (Ensemble Contrast Imaging), Acuson Sequoia (Coherent Contrast Imaging), Philips ATL HDI 5000 (Pulse Inversion Harmonic Contrast Imaging] with contrast-enhanced imaging software as indicated in square brackets. The contrast examinations were performed with low insonation power (low-MI imaging, mean MI = 0.22), to avoid destruction of microbubbles. Optimized pre-settings were provided for each type of machine, adjusting the imaging parameters to the contrast agent used.

BR1 (SonoVue®, Bracco International) was used as ultrasound contrast agent. BR 1 contains microbubbles of sulphur hexafluoride gas surrounded by a flexible phospholipid shell, allowing contrast-specific imaging at low insonation power. Owing to the size of the SonoVue® microbubbles (mean 2.5 μm), this contrast agent remains (as a so-called blood pool agent) within the vascular system, unlike current X-ray and MRI contrast agents which spread into the interstitial fluid. Thus contrast wash-in and wash-out can be assessed continuously during the whole enhancement phase.

Using a 20-gauge needle, BR1 was injected as an intravenous bolus of 2.4 mL (1 mL/second) into the cubital vein, followed by a 3-10 mL saline bolus for flushing. Additional injections of 4.8 mL (up to 3 contrast injections) were given, if required, to allow optimization of the procedure. There was an interval of at least 6 min between each injection of SonoVue®. To allow contrast clearance of the previous contrast injection the bubbles were destroyed by using high insonation power.

Prior to injection of the contrast agent (native) and throughout contrast enhancement (arterial and portal-venous phase), the entire liver tissue was examined by conventional B-mode ultrasonography as recently described[2,7]. Unenhanced and contrast-enhanced examinations (including the native and arterial and portal-venous enhancement phases) were evaluated separately.

All examinations were documented on S-VHS videotapes and some examinations were additionally digitally stored on magnetic-optical discs (MOD).

Computed tomography (CT)

Standard triple-phase spiral CT examinations were performed and evaluated in the radiology departments or associated radiology units of each centre. The CT examinations include native, arterial and portal-venous phase scans, using bolus injections of 123 mL (mean,

Table 1 Demographic data of the study population

Parameter	Mean	Range	
Age (yr)	59 ± 11	22-82

In 6 patients, several primary tumors were present		

range 100-370 mL, in one patient 60 mL) iodinated contrast agent (300-350 mg/mL). In most cases a multislice scanner was used. Examinations were performed with a slice thickness ⩽ 5 mm (in two patients 8 mm).

Magnetic resonance imaging (MRI)

Standard MRI examinations were performed and evaluated in the radiology departments or associated radiology units of each centre. The MRI examinations included native and liver-specific late-phase scans with T1 and T2 weighted images obtained by SE, TSE and/or GE sequences, using a liver-specific contrast agent (in 18 patients only dynamic phase with a Gd agent). Slice thickness was ⩽ 6 mm (in 10 patients up to 10 mm).

Final reference diagnosis

The final reference diagnosis was defined by combining all available information from imaging (CT and MRI examinations) plus additional information from histology (17), surgery (8) and other clinical examinations (4). Thus the final reference diagnosis includes all information available at the end of the diagnostic evaluation, with the exception of the results from the ultrasound examination (being the test method).

Follow-up examination

Patients with negative findings at the initial examination (i.e. no metastatic lesions detected in the liver) were asked to come back for a follow-up examination 3-6 mo after the initial examination, either US, CT or MRI. This follow-up examination was used as an additional reference standard for patients with negative initial contrast-enhanced sonography, to assess the predictive clinical value of contrast-enhanced sonography.

Safety and tolerability of the ultrasound contrast agent

All adverse events occurring during the examination and a 2 h post-examination observation period were collected and listed, irrespective of a causal relationship. Adverse events were assessed with regard to severity and causal relationship.

Statistical analysis

Unenhanced and contrast-enhanced sonographies were compared by calculating the percentage difference with the two-sided 95% confidence interval. A difference of 10% between methods was defined a priori as clinically significant. The assessment of contrast-enhanced sonography invariably included native (representing tissue) as well as contrast-enhanced sequences (representing vascularity), in parallel to the assessment of CT and MRI. This reflects clinical reality, where vascularity information is always assessed in combination with tissue information. Contrast sequences are performed as a supplement to native baseline sequences, not as an alternative.

For all methods sensitivity, specificity, accuracy, and negative and positive predictive values were calculated together with the respective 95% confidence intervals, using the combined final reference diagnosis as gold standard. Thus CT, MRI, histology, clinical data, etc, but not ultrasound were part of the gold standard. This could introduce a bias in favour of CT and MRI (for example, if sonography showed a small metastasis but all other CT + MRI did not, sonography was assessed as false positive), especially in cases where invasive confirmation was impossible for ethical reasons (6 lesions in 3 patients).

For the assessment of lesion numbers only patients having at most 8 lesions were considered, since in cases with a very high number of lesions the result is more indicative of the counting efforts and moreover there is no real clinical relevance. For the assessment of the presence of metastatic disease a patient was rated as positive if at least one lesion classifiable (on the basis of characteristic features mainly of the perfusion pattern, e.g. lack of portal-venous enhancement) as metastasis could be identified. Owing to the inclusion criteria, all patients had a current or previous primary nonhepatic tumor. The comparison of the methods included all patients for whom valid results from both methods were available, irrespective of the number of lesions. The assessment of follow-up data included all patients having negative metastatic disease at the initial examination (no metastases found with CEUS) and having follow-up data available.

As statistical tests the Wilcoxon signed rank test (comparison of lesion numbers) and the McNemar test (assessment of metastatic disease) were used. For the comparison of CEUS *vs* CT the test was performed as a two-sided test (testing equivalence) and as a one-sided test (testing non-inferiority of CEUS *vs* CT).

RESULTS

Study population

Epidemiological data are summarized in Table 1. All 131 patients enrolled had a primary extrahepatic tumor (Table 2). 125 of the 131 patients received an adequate dose of

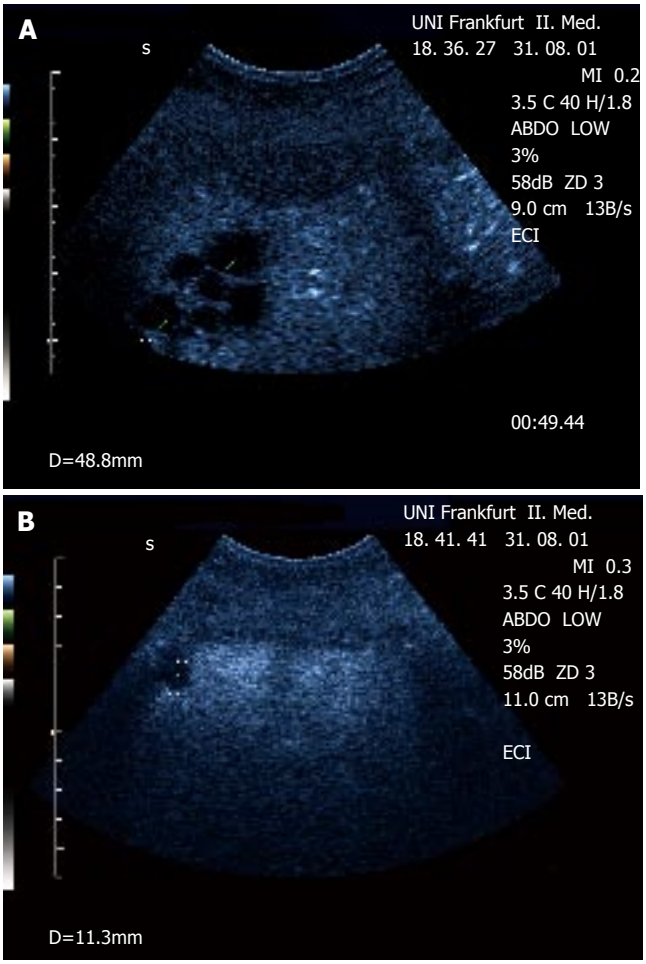

Figure 1 Demonstration of a focal (multicystic) lesion in a patient with cervix carcinoma using contrast-enhanced ultrasound (CEUS). **A**: The lesions can be delineated in the portal-venous phase as 'black spots' lacking portal-venous enhancement within normally enhanced liver tissue. **B**: An additional small lesion next to the diaphragm (not visible in native B-mode) was detected by CEUS but not with CT. Biopsy confirmed metastatic disease.

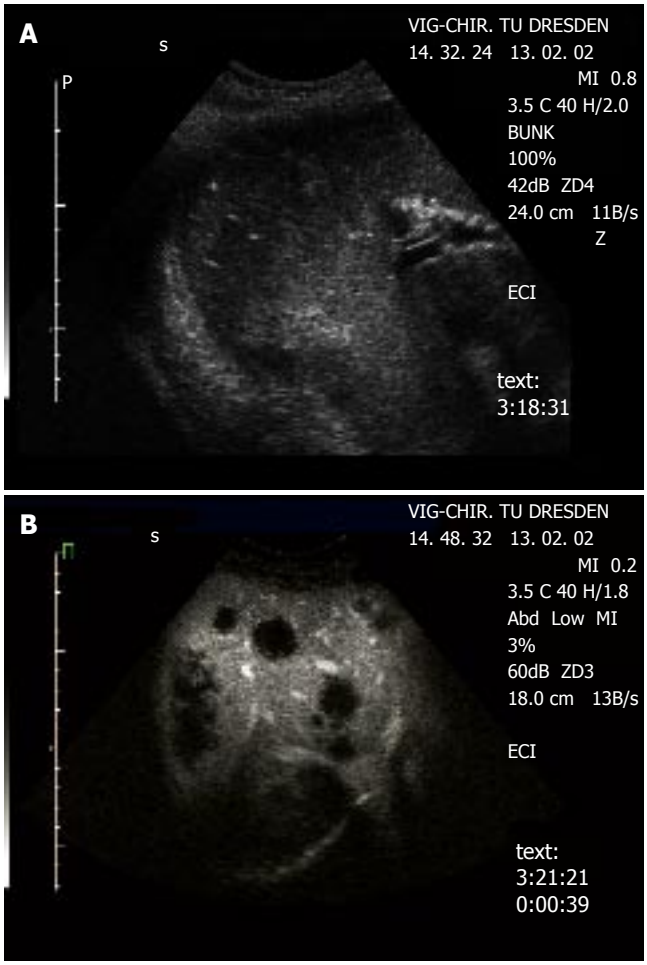

Figure 2 Detection of metastases in a patient with colorectal carcinoma **A**: Native B-mode sonography revealed 3 metastases (segment 6/7) in agreement with CT, MRI revealed 4 metastases (segment 6/7 and 4). **B**: Contrast-enhanced sonography identified diffuse metastatic disease in both liver lobes. the study medication (ultrasound contrast agent) and were considered eligible. 102 patients had no relevant protocol violations (per protocol population) and were used for the efficacy analysis. The reasons for exclusion from the primary efficacy analysis were (multiple instances possible): reference examination outside the stipulated time window of +/- 14 d (11 patients), reference examination missing or incomplete (8 patients), and inadequate visualization of the entire liver (5 patients).

The examination of the liver was performed as part of the initial staging in 63 patients (50.4%), as follow-up examination in 52 patients (41.6%), for presurgical diagnosis in 11 patients (8.8%) and for other purposes (abdominal pain, recurrent tumor staging, postsurgical assessment) in 3 patients (2.4%) (multiple reasons possible, percentage related to $n = 125$).

62 patients had negative contrast-enhanced sonography, i.e. no metastatic lesions were found at the initial examination. In 53 of these 62 patients, a follow-up examination was performed 3-6 mo after the initial examination and the absence of metastatic lesions was assessed additionally versus the information from follow-up.

Number of metastatic lesions

The metastatic lesions could be identified most clearly in the portal-venous phase, as lesions lacking portal-venous enhancement surrounded by normal liver tissue (Figure 1 and 2). Lack of portal-venous enhancement during CEUS occurred in 171 of 186 metastatic lesions (91.9%). In 60 of 186 lesions (32.3%) peripheral arterial enhancement could be detected (Figure 3). The number of lesions was assessable in 74 patients having fewer than 8 focal liver lesions. In 36 of these patients no metastatic lesion could be detected with any of the 3 imaging modalities (CEUS, CT, MRI). In the remaining 38 patients the number of metastatic lesions detected was 55 (CEUS), 61 (CT) and 53 (MRI). A comparison of the number of lesions per patient revealed that in 50 patients (67.6%) the same number of metastases was found with CEUS and CT. In 16 patients (21.6%) CT found more metastases, whereas in 8 patients (10.8%) CEUS found more metastases. However, since the histological gold standard was not available for every lesion, the rates of true and false positive lesions cannot be reliably defined. The differences between the numbers of metastases detected were not statistically significant (Wil-

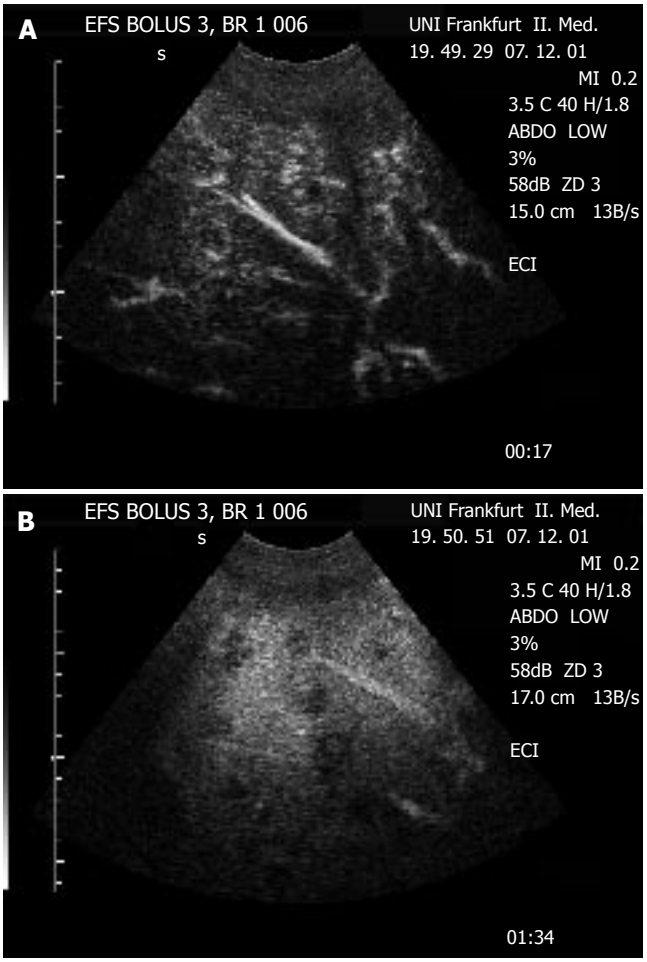

Figure 3 Detection of multiple metastatic lesions in the liver of a patient with sarcoma. **A**: In contrast-enhanced sonography, the lesions show a periperal enhancement in the arterial phase ("rim sign"), indicating the arterial blood supply to the peripheral proliferation zone of this metastatic lesions from a hypervascular tumor. **B**: During portal-venous phase, the lesions show lack of portal-venous enhancement ('black spot'), indication the absence of portal-venous blood flow typical for malignant liver lesions.

coxon signed rank test: $P = 0.28$ and $P = 0.95$ for CEUS versus CT and CEUS versus MRT, respectively). Thus with all 3 imaging modalities a comparable number of metastatic lesions could be found.

Assessment of metastatic disease

Contrast-enhanced ultrasound (CEUS) versus conventional (unenhanced) ultrasound On a patient basis, the detection of metastatic disease (i.e. of liver metastases irrespective of the number) was assessed and compared with the combined gold standard. With the use of contrast enhancement, the number of correctly classified patients rose from 83 out of 102 (native US) to 93 out of 102 (CEUS), showing clear superiority of contrast-enhanced sonography over unenhanced sono-graphy (Table 3). The superiority of CEUS was statistically significant (McNemar test: $P < 0.01$).

Contrast-enhanced ultrasound (CEUS) versus CT The correctly diagnosed number of patients with metastatic disease was 91 out of 102 patients in the case of triple-phase CT, compared with the 93 out of 102 patients who were correctly diagnosed using CEUS (Table 4). Thus contrast-enhanced ultrasound and spiral CT showed comparable accuracy for the detection of metastatic liver disease. The slight difference in favour of contrast-enhanced ultrasound was not statistically significant. The McNemar test revealed a two-sided 95% confidence interval [-6.2%; +10.1%],not clearly exceeding the stipulated 10% equivalence range.In comparison to the final reference diagnosis the sensitivi-ties were 84.6%, 88.5% and 92.3% and the respective specificities were 78.0%, 94.0% and 89.2% (unenhanced sonography, contrast-enhanced sonography and CT). Thus the accuracy for the detection of metastatic liver disease rose from 81.4% to 91.2% on use of contrast-enhancement for sonography, compared with 89.2% for spiral CT. Of the three methods, contrast-enhanced ultrasound showed the best specificity and accuracy for the detection/exclusion of metastatic liver disease.

Table 3 Patients with correct diagnosis (existence of metastatic disease) with unenhanced sonography and contrast-enhanced sonography (CEUS)

		CEUS Correct diagnosis		
		Yes	No	
Unenhanced sonography correct diagnosis	Yes	82	1	83
	No	11	8	19
		93	9	102

Table 4 Patients with correct diagnosis (existence of metastatic disease) with contrast-enhanced sonography (CEUS) and triple-phase spiral CT

		CEUS Correct diagnosis		
		Yes	No	
CT correct diagnosis	Yes	83	8	91
	No	10	1	11
		93	9	102
