## Abstract

Nutrient deficiencies are common in patients with inflammatory bowel disease (IBD). Both total parenteral and enteral nutrition provide important supportive therapy for IBD patients, but in adults these are not useful for primary therapy. Dietary intervention with omega-3 polyunsaturated fatty acids contained in fish oil may be useful for the care of IBD patients, and recent studies have stressed the role of PPAR on NF $\kappa$ B activity on the potential beneficial effect of dietary lipids on intestinal function.

## INTRODUCTION

Inflammatory bowel disease (IBD) is a term used to denote inflammation of the gastrointestinal mucosa of unknown

etiology. There are a number of hypotheses pertaining to the development and perpetuation of IBD. Three major theories emerge from the literature. The first implicates a persistent intestinal infection<sup>[1-3]</sup>; the second proposes that IBD is a consequence of a defective mucosal barrier to luminal antigens<sup>[4,5]</sup>; and the third suggests a dysregulated host immune response to ubiquitous antigens<sup>[4,6]</sup>. It is believed that IBD has both genetic and environmental components, and is immunologically mediated<sup>[4,7-9]</sup>. Data from IBD patients concerning cytokine profiles, permeability defects, response to treatment, and natural history of disease all indicate a heterogeneous group of illnesses that fall under the headings of ulcerative colitis (UC) and Crohn's disease (CD). Previous epidemiological data covering diet in UC and CD are conflicting, partly due to this heterogeneity of the diseases, difficulty in obtaining reliable data and publication bias such as negative structures of breastfeeding<sup>[10]</sup>.

## NUTRITION IN IBD

Specific antibody isotypes to major milk proteins are found in both UC and CD patients. In CD, the antibodies correlate with disease activity<sup>[11]</sup>. Although ethnic origin<sup>[12]</sup>, and not the IBD disease state, appears to be the main determinant of lactose intolerance, the avoidance of dairy products by IBD patients is extensive<sup>[13]</sup>. Lack of breastfeeding in infancy has been associated with CD but not UC. In addition, increased carbohydrate consumption has been documented in CD<sup>[14]</sup>. Others have alluded to a lack of dietary fiber as a predisposing factor for IBD<sup>[15]</sup>. The development of UC has also been associated with high intakes of monounsaturated fatty acids (MUFA), n6 polyunsaturated fatty acids (n6 PUFA), sulphur-containing diets and vitamin B6<sup>[16]</sup>.

## Deficiencies

IBD is associated with a number of nutritional deficiencies including anemia, hypoalbuminemia, hypomagnesemia, hypocalcemia and hypophosphatemia, as well as deficiencies in folic acid, niacin, Vitamins A, B12, C, and D as well as deficiencies of iron, zinc, copper<sup>[17]</sup>. It is not clear if low levels of micronutrients are one of the results of disease or one of primary importance. Plasma antioxidant concentrations are reduced in IBD patients, particularly those with active disease<sup>[18]</sup>. Antioxidant activity, assessed by measuring selenium concentrations and erythrocyte

glutathione peroxidase activity, is inversely correlated with inflammatory biomarkers, including  $\text{TNF}\alpha$ <sup>[19]</sup>. Hyperhomocysteinemia is more common in patients with IBD, and is associated with reduced serum concentrations of vitamin B12, folate and B6<sup>[20]</sup>.

Several mechanisms contribute to the malnutrition observed in IBD patients. Firstly, there is a decrease in the oral intake of nutrients because of abdominal pain and anorexia. Secondly, the mucosal inflammation and associated diarrhea leads to a loss of protein, blood, minerals, electrolytes and trace elements. Thirdly, multiple resections or bacterial overgrowth may have an adverse nutritional effect; and lastly, the pharmacological therapies may also lead to malnutrition. For example, sulfasalazine reduces folic acid absorption, and corticosteroids decrease calcium absorption as well as negatively affecting protein metabolism<sup>[21]</sup>. Alterations in energy metabolism may result in increased resting energy expenditure and lipid oxidation in IBD patients<sup>[22,23]</sup>. The consequences of malnutrition are numerous, and include reductions in bone mineral density<sup>[24]</sup>, as well as growth retardation and delayed sexual maturity in children<sup>[25]</sup>. Osteoporosis may also be implicated as a result of proinflammatory cytokine profiles.

Nutritional therapy can take on a number of forms which include Total Parenteral Nutrition (TPN) and Total Enteral Nutrition (TEN). The diets used are elemental, polymeric, and exclusion diets. Elemental diets contain nutrients reduced to their basic components: amino acids for proteins, glucose for carbohydrates, and short-chain triglycerides for fats. Polymeric formulas contain whole proteins for nitrogen, glucose polymers for carbohydrates and long-chain triglycerides for starch or fat, respectively<sup>[17]</sup>.

### **Total parenteral nutrition (TPN)**

The use of TPN for the management of IBD is based on certain theoretical advantages: bowel rest is beneficial because it diminishes motor and transport function of the diseased bowel<sup>[26,27]</sup>; a decrease in antigenic stimulation will eliminate the immunologic responses to food, especially in the presence of impaired intestinal permeability<sup>[28-30]</sup>; TPN fosters protein synthesis in the intestine which leads to cell renewal, healing, and reversal of impaired immunocompetence.

Ostro and co-workers<sup>[31]</sup> demonstrated remission rates of 63% to 89% with TPN in a large retrospective series of CD patients who were refractory to conventional medical management. However, Matuchansky *et al*<sup>[32]</sup> emphasized that there were high relapse rates (40%-62%) after 2 years. It has been suggested that TPN be used only in a nutritionally supportive role<sup>[33,34]</sup>. In UC, there is no evidence for better outcome with TPN<sup>[35,36]</sup>. Although remission rates of 9% to 80% have been reported, TPN given to patients with severe colitis appears to only be beneficial as perioperative nutritional support. In patients with mild disease, TPN is more effective but is not better than steroid therapy, and thus the invasiveness and cost of TPN are unjustified. Any benefits associated with TPN may be due to the administration of nutrients, and not bowel rest, as bowel rest alone has no effect on disease activity<sup>[37]</sup>.

Therefore, although TPN has a role in patients with a non-functioning intestine or the short bowel syndrome due to excessive resections, TPN is of limited use as a primary therapy in IBD. This is not intended to be an extensive review of TPN, but it should be cautioned that even in expert centres, TPN is associated with complications such as sepsis and cholestatic liver disease.

### **Total enteral nutrition (TEN), elemental and defined formula diets**

TEN excludes potential toxic dietary factors and antigenic exposure, since there are only amino acids, glucose or oligosaccharides and low lipid content. TEN is not associated with cholestasis, biliary sludge or gallstone formation, as is seen with TPN. Atrophy of the small intestinal mucosa has been observed in animal models receiving long-term TPN, but this atrophy is prevented with TEN. In addition, a 6-wk TPN treatment in dogs resulted in marked reduction in pancreatic weight, a decrease in small intestinal mass, and a decrease in intestinal disaccharidase activity in dogs<sup>[38]</sup>. For this reason, TEN is preferable to TPN.

The topic of nutrition in GI disorders occurring in IBD has been reviewed recently<sup>[39,40]</sup>. When compared to TPN, enteral nutrition yielded similar results of preventing and combating malnutrition<sup>[35,36,41]</sup>. Although Voitek *et al*<sup>[42]</sup> proposed that elemental diets may be an effective therapy for IBD, enteral nutrition as a primary therapy has failed to yield consistent results in numerous clinical trials. It is true that a number of trials have shown remission rates in CD patients receiving elemental diets, similar to the rates observed with steroid therapy<sup>[43-54]</sup>. However, it is noteworthy that significantly better remission rates were observed in patients receiving steroid treatment versus elemental diets when including all the diet group drop outs (i.e., on an intent-to-treat basis). The question remains as to the best way of analyzing the results when a large percentage of patients receiving diet therapy drop out because of unpalatability or intolerance. Furthermore, some studies have shown no difference with elemental diets when compared to steroid therapy<sup>[48,52]</sup>. In children, elemental diets were associated with greater linear growth, while in adults these diets preserve nitrogen balance<sup>[55,56]</sup>. The role of nutritional therapy in the context of pediatric onset illness has been reviewed<sup>[57]</sup>. Thus, enteral nutrition is easier to use, is less expensive, and is a better alternative to TPN. Unfortunately, its unpalatability limits patient compliance, but with strong encouragement this may be partially overcome.

The fat composition of enteral diets may influence the results which are obtained in the various clinical trials. Elemental diets have a low fat content, while most polymeric diets generally contain more fat including more linoleic acid, which is a precursor for the synthesis of potentially proinflammatory eicosanoids<sup>[58]</sup>.

Defined formula diets are usually more palatable and less expensive than are the elemental diets. While some investigators report no differences between elemental and defined formula diets in patients with acute CD<sup>[49,59,60]</sup>, Giaffer *et al*<sup>[61]</sup> found elemental diets to be more effective

in active CD. A randomized double-blind trial in Crohn's patients demonstrated that elemental and polymeric (defined) diets, differing only in their source of nitrogen, were equally effective in reducing the Crohn's disease activity index (CDAI), and in inducing clinical remission<sup>[62]</sup>. Although defined formula diets provide less bowel rest, they have the potential advantage of exposing the GI tract to the usual dietary substrates, which allow thereby for the full expression of intestinal, biliary and pancreatic activity<sup>[63]</sup>. In animal studies, it has also been observed that luminal nutrition has trophic influences on the gut<sup>[64]</sup>.

Is there a beneficial effect of supplementing polymeric formulas with TGF- $\beta$ 1<sup>[65]</sup>? In pediatric CD, reductions in proinflammatory cytokine concentrations and mRNA, paired with an up-regulation of TGF- $\beta$  mRNA, was associated with improved macroscopic and microscopic mucosal inflammation. A meta-analysis and a Cochrane review have demonstrated that in adults, corticosteroids are more effective than enteral diet therapy<sup>[48-50]</sup>. It is unclear what is the role of nutritional therapy in adults with CD<sup>[51-53]</sup>, although there is some evidence in Japan that enteral nutrition enjoys support as primary therapy<sup>[53]</sup>. In contrast to the generally agreed role in adults of enteral nutrition being useful to improve the patient's nutritional status as its main benefit, in children with CD enteral nutrition has a much clearer benefit to improve clinical, biochemical and growth parameters<sup>[55]</sup>, and may as well have a steroid sparing effect<sup>[56,57]</sup>.

### Glutamine, fiber and fatty acids

Diets high in glutamine, an important source of energy for enterocytes and the preferred fuel of the small intestine<sup>[66,67]</sup>, have been used with variable success. Glutamine probably exerts its trophic effects on the small intestine by increasing protein synthesis, and generating alanine as a substrate for enteric gluconeogenesis<sup>[68]</sup>. There is evidence that glutamine protects the small intestinal mucosa during critical illness<sup>[69,70]</sup>. However, oral glutamine supplements do not restore to normal the increased permeability seen in patients with CD, and these supplements do not beneficially affect the patients' CDAI or C-reactive protein (CRP) levels<sup>[71]</sup>. Similarly, a randomized controlled trial demonstrated that no benefit was associated with the intake of glutamine-enriched polymeric formulas in children with CD<sup>[72]</sup>.

In animal studies, dietary fiber has been implicated in maintaining the integrity of the intestine, and in preventing the bacterial translocation from the gut to the mesenteric lymph nodes<sup>[73,74]</sup>. Short chain fatty acids (SCFA, C1 to C6 organic fatty acids), are produced by the fermentation of dietary polysaccharides by the normal anaerobic bacteria in the colon. These SCFA are a source of energy for the colonocytes, in addition to their enhancing sodium and water absorption and promoting blood flow<sup>[75,76]</sup>. Reduced levels of SCFA, particularly butyrate, and a defect in the oxidation of butyrate by colonocytes, have been proposed as a mechanism in the pathogenesis of IBD<sup>[77,78]</sup>. Evidence to support this hypothesis includes the observation that the oxidation of <sup>13</sup>C-labelled butyrate is lower in patients with active UC as compared to healthy controls<sup>[79]</sup>. However, Simpson and co-workers failed to demonstrate differences

between UC patients and controls in the oxidation of rectally administered <sup>13</sup>C-labelled butyrate<sup>[80]</sup>.

TPN supplemented with SCFA enhanced functional adaptation to intestinal resection in rats. It remains to be determined if patients with short bowel syndrome may benefit from SCFA<sup>[81]</sup>.

Butyrate (C4 fatty acid) administered to UC patients resulted in remission rates comparable to corticosteroids and mesalamine<sup>[82]</sup>. In patients with CD, both intestinal biopsies and lamina propria cells cultured with butyrate had significantly reduced levels of inflammatory cytokines (TNF), possibly due to a reduction in NF $\kappa$ B activation and I $\kappa$ B degradation<sup>[83]</sup>.

Eicosanoids are inflammatory mediators, and have been implicated in the pathogenesis of chronic inflammatory lesions in the bowel. Specimens from patients with IBD show increased eicosanoid formation<sup>[84]</sup>. High dietary intake of omega-6 polyunsaturated fatty acids (PUFAs), which reduces omega-3 intake, may contribute to IBD development<sup>[85]</sup>. The benefits of fish oil, which contain n3 fatty acids, have been shown in some inflammatory diseases such as psoriasis and rheumatoid arthritis. Epidemiological observations of the low prevalence of IBD in Japanese and Inuit populations consuming high n3 fatty acid fish provided a rationale for the use of n3 fatty acids in IBD. The n3 fatty acids are believed to compete with n6 fatty acids as precursors of eicosanoid synthesis. The n3 products are series 5 leukotrienes, which have less physiological activity than do the arachidonate-derived series 4 counterparts. Thus, fish oil may have an anti-inflammatory effect.

Rats fed with fish oil which had TNBS-induced inflammatory lesions in the bowel showed less prostaglandin- and leukotriene-mediated immune response<sup>[86]</sup>. Parenteral lipid emulsions enriched with n3 fatty acids reduce diarrhea, attenuate morphological changes, and decrease colonic concentrations of inflammatory mediators in an animal model of acetic acid induced colitis<sup>[87]</sup>.

Loeschke *et al*<sup>[88]</sup> performed a placebo-controlled trial of n3 fatty acids in the prevention of relapse in UC. Patients in remission who received n3 fatty acids experienced fewer relapses than did those receiving placebo. Unfortunately, the beneficial results of this study did not persist throughout the length of the 2 year study, possibly due to decreased compliance over time. In a multicenter placebo controlled relapse prevention trial, Belluzzi *et al*<sup>[89]</sup> found a significant reduction in the relapse rate in CD patients given a special formulation designed to allow delayed ileal release of n3 fatty acids. A fish oil diet has been shown to increase eicosapentanoic and docosahexanoic acids in the intestinal mucosal lipids of IBD patients, as well as showing a decrease in arachadonic acid. An increase in the synthesis of leukotriene B5 as well as a 53% decrease of leukotriene B4 was shown in UC patients, whereas the fish oil treatment showed a nonsignificant trend to faster remission<sup>[90,91]</sup>. Fish oil supplementation results in clinical improvement of active mild to moderate disease, but was not associated with a significant decrease in leukotriene B4 production<sup>[84]</sup>. Thus, fish oil supplementation of the diet may provide some short-term benefit to patients with CD

or UC. The use of probiotics and prebiotics has received much attention; the interested reader is referred to recent reviews in this area<sup>[40]</sup>.

### Fatty acids and gene expression

The effect of fatty acids on gene expression was previously thought to result largely from alterations in membrane phospholipids or eicosanoid production. More recently, the discovery of nuclear receptors; such as peroxisome proliferator-activated receptors (PPARs), and their regulation by fatty acids, has changed this view. PPARs are ligand activated transcription factors that upon heterodimerization with the retinoic X receptor (RXR), recognize PPAR response elements in the promoter regions of various genes, and subsequently affect gene transcription. PPARs bind various ligands including nonsteroidal anti-inflammatory drugs (NSAIDs), thiazolidinediones (antidiabetic agents) as well as PUFAs and their metabolites<sup>[92-96]</sup>. Several subtypes of the receptor have been identified ( $\alpha, \delta, \gamma$ ) and these are differentially expressed in a variety of tissues. PPAR $\gamma$  is expressed in intestinal tissue, with the highest abundance detected in the colon<sup>[97]</sup>.

PPAR $\gamma$  has been implicated in the regulation of inflammation, and has become a potential therapeutic target in the treatment of inflammatory disorders, including IBD. It has been suggested that patients with UC have a mucosal deficit in PPAR $\gamma$  that may contribute to the development of their disease. Indeed, analysis of mRNA and protein from colonic biopsies shows reduced PPAR $\gamma$  in UC patients when compared to either Crohn's patients or healthy controls<sup>[98]</sup>.

Using colon cancer lines, it has been shown that PPAR ligands attenuate cytokine gene expression by inhibiting NF- $\kappa$ B via an I $\kappa$ B dependent mechanism<sup>[99]</sup>. A number of other studies suggest that PPAR activators inhibit COX2 by interference with NF- $\kappa$ B<sup>[100-102]</sup>. PPARs inhibit the AP-1 signaling pathway<sup>[103]</sup>, and interact with the Jun<sup>[104]</sup> and STAT signaling pathways<sup>[105]</sup>.

Animal studies support the role of PPAR in intestinal inflammation. Thiazolidinedione ligands for PPAR markedly reduced colonic inflammation in a mouse model of IBD<sup>[99]</sup>. PPAR+/- and RXR +/- mice display enhanced susceptibility to TNBS-induced colitis<sup>[106]</sup>. The administration of PPAR and RXR agonists synergistically reduce TNBS-induced colitis, with improved macroscopic and histologic scores, reductions in TNF $\alpha$  and IL-1 $\beta$  mRNA, and decreased NF- $\kappa$ B DNA binding activity.

Although clinical data is limited, the results of an open label study using rosiglitazone, a PPAR $\gamma$  ligand as therapy for UC, showed that 27% of patients achieved remission after 12 wk of therapy<sup>[107]</sup>. Thus, PPAR $\gamma$  ligands may represent a novel therapy for UC, and double-blind, placebo-controlled, randomized trials are warranted.

Of considerable interest, the ability to modulate PPAR nutritionally has been studied. Dietary PUFA have dramatic effects on gene expression through the regulation of several transcription factors, including PPAR. Fatty acid regulation of PPAR was first noted by Gottlicher *et al*<sup>[108]</sup>. A diverse array of fatty acids, eicosanoids, and fatty acid metabolites have been shown to activate PPAR<sup>[94-96]</sup>. Both

PPAR $\alpha$  and PPAR $\gamma$  bind mono- and polyunsaturated fatty acids at levels, which are found in human serum<sup>[95]</sup>. Thus, the anti-inflammatory effects of n3 PUFA may involve PPAR and interference with NF $\kappa$ B, rather than simply alterations in eicosanoid synthesis.

### Clinical Implications

It is widely accepted that nutritional deficiencies are common in patients with CD and UC, and these need to be anticipated, identified and treated. There are no specific diets which can be recommended for all patients with IBD; diet therapy needs to be individualized. TPN or TEN may be necessary to restore nutritional balance in selected IBD patients with malnutrition, but in adults these interventions do not provide a primary option to modify disease activity. The omega-3 PUFAs contained in fish oil may reduce disease activity in UC and CD when used in the short term in conjunction with standard medical therapy. Their mechanism of action may be to enhance the activity of the nuclear receptors PPAR (peroxisome proliferator-activated receptors) in the intestine, inhibiting the AP-1 signaling pathway and NF- $\kappa$ B, attenuating proinflammatory cytokine gene expression. Future research will focus on the identification and use of specific dietary lipids to reduce intestinal inflammatory activity and to maintain long-term disease remission.

## Abstract

More than 30 years after the discovery of human hepatitis B virus (HBV) this virus remains to be one of the major global health problems. In infected adolescents or adults, 5%-10% will lead to a chronic carrier state, whereas in infected neonates up to 90% develop chronicity. It is estimated that about 370 million people are chronic carriers of HBV worldwide. In many regions of the world, chronic HBV infection is still the major cause of liver cirrhosis and hepatocellular carcinoma. During the last 30 years, many steps of the viral life cycle have been unravelled, mainly due to cloning, sequencing and expression of the genomic DNA extracted from HBV virions. This has led to the development of a safe and efficient vaccine and sensitive tests for HBV surface protein (HBsAg) allowing reliable diagnosis and screening of blood products. More recently, a growing number of reverse transcriptase inhibitors have been developed. However, together with these improvements new deficiencies in prevention and cure of HBV infections are becoming apparent. Although HBV is a DNA virus, it is highly variable under immunity or drug induced selection pressure, resulting in vaccine-related escape mutants and drug resistance. To overcome these challenging problems new antivirals and optimised vaccines have to be developed.

<http://www.wjgnet.com/1007-9327/13/8.asp>

The discovery of the Australian antigen by Baruch S.

Blumberg, which is now known as “hepatitis B virus surface antigen” (HBsAg), in the late 1960’s opened the field of HBV research towards an understanding of an ancient scourge. During the following decades, many research groups all over the world worked successfully to unravel the life cycle of HBV. In Germany, the virologists Heinz Schaller, Peter H. Hofschneider, and Reiner Thomssen initiated HBV research and provided a profound impact on our understanding of the molecular biology of this virus. Among the clinicians; the names of Karl-Hermann Meyer zum Büschenfelde and Wolfgang Gerok are to be mentioned as founders of hepatitis B research. Moreover, in their labs, but also in other groups, students and scientists became inspired to work on this fascinating virus. Since then, an active and growing community of HBV virologists has been established in Germany. In this highlight topic a collection of reviews written by those scientists and clinicians is presented. The articles cover nearly all fields of hepadnaviral research, from attachment and entry to genome replication, maturation, pathology, animal models and antiviral therapy. The aim of this collection is to bring together recent findings in basic virological and clinical HBV research in order to provide a valuable reference for both hospital hepatologists and basic scientists.

Hepatitis B virus is the prototype member of the family *hepadnaviridae* that can be divided into the *orthohepadnaviruses* of mammals and the *avihepadnaviruses* of birds. To date, the *orthohepadnaviruses* are found only in humans and primates and in a special family of the *sciuridae*, namely North-American woodchucks and some squirrel species. Primate HBV were found in old world primates like chimpanzees, gorillas, gibbons, orangutans, and in one new world primate, the woolly monkey. In the review “Taxonomy and genotypes of Hepatitis B Virus”, Stephan Schaefer reports that HBV sequences from old world primates are closely related and cluster in monophyletic groups, while the HBV sequence isolated from woolly monkeys (WMHBV) is more divergent<sup>[1]</sup>. Human HBV is further subdivided into several genotypes. To date, 8 genotypes (called A-H) that differ by definition in at least 8% of their complete genome have been found. The genotypes can be further divided into 24 sub-genotypes that differ by at least 4% from each other. Interestingly, no sub-genotypes have been described for genotype E and G. The fact that genotype E is common in West Africa, but absent in Americans of African origin from Venezuela and Brazil has led to the speculation of a recent genesis of genotype E. The geo-

graphic origin of genotype G is less clear, however a high prevalence of this genotype has been described in Mexico. Both, the genotypes and sub-genotypes show distinct virological and epidemiological properties. As an example, liver cirrhosis was detected in a greater number of patients chronically infected with HBV genotype C than genotype B in Japan. The same was also detected for the prevalence of hepatocellular carcinoma in these patients. Interestingly, detailed analysis of HBV genomes revealed recombination events between different genotypes. Hybrids between genotype B and C, A and D are very common in certain regions and distinct intergenomic recombination breakpoint hotspots were detected (e.g. the preS1/S2 region and the 3'-end of the surface gene). B/C recombinants occur in Japan and C/D recombinants in Tibet. However, the mechanisms underlying these potential recombination events are still unknown. In contrast to HIV or RNA viruses, recombination during replication is unlikely, because reverse transcription of only one RNA genome occurs within the capsid. Thus, it seems also possible that the described changes are the result of an adaptation to distinct genetic disposition in different human populations. Taking into consideration that a chronic HBV carrier can produce up to  $10^{13}$  virions per day together with a high error rate of HBV reverse transcriptase, the HBV quasiespecies can substitute every nucleotide of the small 3.2 kb genome within one patient every day. This favours very fast adaptation of the virus to a changing environment, and may result in modular adaptations within distinct segments of the genome.

Soon after the discovery of hepatitis B virus, it was shown that not only humans but also chimpanzees may test positive for this agent. Furthermore, artificial infection of chimpanzees, but also other apes like gibbons and orangutans with serum from HBV-infected patients induces acute and chronic infections related to human disease. Nevertheless, a strong species specificity of hepatitis B virus was observed, since it was not possible to induce HBV-infection in other mammals. Since then, many efforts have been made to establish a small non-primate animal model for HBV infection *in vivo* as described in the review "Viral and cellular determinants involved in hepadnaviral entry" in this topic highlight<sup>[2]</sup>. The finding that *Tupaia belangeri*, a small non-primate mammal from Southeast-Asia is susceptible to HBV and HDV raises doubt in the strict host specificity of HBV. Besides the *in vivo* infection, which is usually self-limiting and does not lead to chronic infection, the use of primary *Tupaia* hepatocyte cultures for *in vitro* infection has greatly improved the field. For many years, primary human hepatocyte cultures, obtained after surgical liver resection were the only possibilities to study infectivity of HBV *in vitro*. However, working with these scarcely available cell cultures is not easy and optimal HBV infection is highly dependent on artificial additives like dimethylsulfoxide (DMSO) and polyethyleneglycol (PEG) for optimal infection. Furthermore, susceptibility of these cultures varies strongly. Primary hepatocyte cultures from *Tupaia belangeri* have overcome these limitations both in availability and susceptibility. Furthermore, the infection is possible without the addition of DMSO and PEG. Most established hepatoma cell lines allow HBV production,

but only after transfection of HBV DNA. Nevertheless, in 2001, a new hepatoma cell line called HepaRG was established that could be infected with HBV. However this feature is achieved only after prolonged cultivation in medium containing DMSO and other additives.

Experiments 20 years ago using synthetic peptides gave the first hint on the importance of the preS1 domain for viral infectivity. Later it was confirmed that the first 77 aminoacids of this domain are necessary for HBV infectivity, together with the N-terminal myristoylation at Glycin-2. Combining these important features, it turned out that these myristoylated preS1-peptides inhibited HBV infection at nanomolar concentrations *in vitro*. The exact role of myristoylation during the entry process of HBV is still not clear. It might enhance receptor recognition by insertion of the acyl chain into membranes of the receptor-complex. Interestingly, a so called myristoyl-switch is a well known element of viral entry mechanism used by non-enveloped viruses, like picornaviruses and reoviruses. Using a set of different myristoylated preS1-peptides the preS1 sequence responsible for this inhibition was further narrowed down to 10 aminoacids (NPLGFFPDHQ) in position 9-18 of preS1. Even single point mutations within this region abolish the inhibitory potential of preS1 peptides and when introduced into the viral surface proteins, also destroy infectivity of the virus completely.

The MHBs of HBV seem to be dispensable for infectivity of HBV and HDV. However, antibodies raised against the preS2 region that is an integral part of MHBs and LHBs could inhibit infection both *in vivo* and *in vitro*. Controversies exist about a role of a putative translocative motive (TLM) within the carboxyterminal part of preS2 and its importance for infectivity of HBV. However, no function of this sequence has been attributed to infection with HDV that uses HBV surface protein for infection.

The S-domain contributes to the main part of HBV surface proteins, but from the data obtained by use of myristoylated preS1 peptides, we know that the S-domain is not involved in initial binding to target cells. Nevertheless, antibodies raised against this domain are neutralising and contribute to protection against HBV infection in most cases. However, antibodies against the so-called antigenic domain (residues 100-160 that are also generated by the current S-containing vaccines) may not protect against naturally occurring escape-mutants that are frequently selected, e.g. by antiviral treatment. Since we now are aware that these antibodies will not counteract the binding of the virus to its target cells, the preS1 domain containing the minimal interaction site ought to be included into the vaccine. An unsolved problem is the identity of the still undetected high affinity receptor for HBV. An update of the still growing list of potential receptor candidates is listed in this reviews series, but none of them has ever been shown to be relevant for HBV infection.

Inspired by the presumption that the infection process of all hepadnaviruses may follow similar pathways, many labs used the more easy accessible duck hepatitis B virus (DHBV) infection system to study hepadnaviral entry *in vitro*. Although also restricted to primary hepatocyte cultures, this system is, compared to primary human hepatocyte cultures, relatively easy and accessible. Like in

HBV, the preS-domain of large surface protein of DHBV contributes to infection together with its N-terminal myristoylation. Furthermore, the preS-domain binds to a 180 kDa membrane protein and this binding can be inhibited by neutralizing preS-antibodies. Further work identified the gp180/p170 protein as carboxypeptidase D (CPD), a transmembrane protein with enzymatic activity. While substantial evidence supports the essential role of CPD for the DHBV infection process, expression of CPD in non-susceptible cells did not make these cells susceptible towards DHBV. Therefore, the first attachment partners for DHBV are still unknown. Furthermore, this molecule seems to be restricted to *avihepadnaviruses*, since the human homolog of CPD does not contribute to the HBV infection process. Therefore we have to be aware of the possible differences of entry mechanism of *avi*- and *orthohepadnaviruses*. Nevertheless with easy accessible *in vitro* infection systems for HBV available (primary Tupaia hepatocytes and the HepaRG cell line) it should now be possible to characterize cellular attachment factors and entry receptors for HBV.

After uptake, the viral genome has to be transported through the cytoplasm to the nucleus where active transcription can take place. As discussed by Kann *et al*<sup>[3]</sup>, evaluation of the transport modes of HBV from the plasma membrane to the nucleus is not easy since at least the early steps of attachment and entry are very species specific and usually need primary human or Tupaia hepatocytes. After uptake of the virus in a yet unknown compartment, the viral envelope proteins mediate fusion of viral and cellular membranes that results in delivery of the viral capsid into the cytoplasm. The capsid, harbouring the viral DNA, covalently linked to the viral polymerase must then be transported into the nucleus of the host cell. To study HBV capsid transport without an infection, isolated HBV capsids have to be either analysed within permeabilized cells or microinjected into *Xenopus laevis* oocytes. Both systems are very artificial and time-consuming. However, in the review of Kann *et al*, an easy *in vitro* system is described that allows analysis of intracellular transport after artificial entry of the capsids. The authors replaced the viral surface proteins of the virus by lipids, normally used for protein transfection. The lipids form an artificial membrane that allows fusion with the cellular plasma membrane and release of the viral capsid into the living cell. In fact, lipofection of HBV capsids isolated from virions allows “infection” of cells that are non-susceptible to the whole, complete virus. First, the core particles are transported *via* microtubuli towards the microtubule-organising centre, located at the perinuclear region of the cell. The viral capsid, containing a nuclear localisation signal interacts with the adaptor proteins importin alpha and beta. Importin beta facilitates contact with the nuclear pore and translocation into the nuclear pore. Interestingly, despite complete translocation, the core particles seem to be stuck at the end of their voyage through the nuclear pore, in a structure called “nuclear basket”. Within the nuclear basket, the breakdown of the capsid and the release of the viral DNA into the nucleus should be facilitated. However, many questions are still unanswered, e.g. what determines the arrest of the core

particle within the nuclear basket and genome release?

Once within the nucleus of the infected cells, the viral HBV genome is converted into a stable form that allows continuous production of progeny virus and is not lost during cell division. Jürgen Beck and Michael Nassal, give an overview of the hepadnaviral genome replication, starting from the conversion of the incoming viral genome with its circular, but only partially double stranded (rcDNA) to the very stable covalently closed circular DNA (cccDNA)<sup>[4]</sup>. The rc-DNA form of the HBV genome contains diverse modifications (e.g. the polymerase-protein covalently linked to the 5' end of the (-)-DNA strand) that have to be removed before generation of cccDNA that can serve as a matrix for proper transcription. Experimentally, this is difficult to investigate, since detection of cccDNA in the presence of high amounts of rcDNA is not trivial. Furthermore, cccDNA is present only in low amounts in infected hepatocytes (from 10-50 genomes per cells). Nevertheless, the episomal cccDNA is very stable (half-life > 30-60 d for DHBV infected ducks) and can therefore even persist during effective antiviral therapy. A detailed understanding of rc- to cccDNA conversion and its inhibition would therefore be desirable. The HBV cccDNA serves as the template for all viral RNAs that are transcribed by cellular RNA polymerase II. Interestingly, the reverse transcription step of HBV requires the specific packaging of the pregenomic HBV RNA together with the viral polymerase (containing reverse transcriptase, DNA polymerase and primase domains) into newly formed capsids. Therefore, the authors describe the newly formed capsid as a “dynamic replication machine” that puts the compartmentalization of genome amplification, known from other viruses, to its extreme. Besides the capsid, viral reverse transcriptase and pregenomic RNA, additional factors are essential for hepadnaviral replication. New methods that use *in vitro* reconstitution of purified components are beginning to reveal that cellular chaperones (e.g. heat shock proteins, hsp) are essential factors for viral polymerase-protein activation. Cell-free reconstitution systems will allow scientists to systematically study the factors necessary for hepadnaviral replication.

The review by Volker Bruss summarizes our current knowledge about hepatitis B virus morphogenesis<sup>[5]</sup>. Envelopment of mature core particles depends on the presence of HBV surface proteins that are synthesized at the endoplasmic reticulum (ER). HBV envelope proteins contain three related co-carboxyterminal surface proteins. Common to all three proteins is the 226 aminoacids long small surface protein (SHBs). Aminoterminal addition of the 55 aminoacid long preS2-domain results in the middle surface protein (MHBs), while further aminoterminal addition of the preS1-domain (109 or 118 aminoacids, depending on the genotype) are found in large surface protein (LHBs). During synthesis at the ER, the SHBs builds a conformation that results in exposure of aminoacids around 99 to 169 to the ER lumen resulting in N-glycosylation of half of the S proteins at asparagine (asn) 146. After budding, this loop is located at the surface of virions and subviral particles and carries the major conformational epitope of the HBV surface proteins. The M-Protein, in addition to the

S-domain, is always N-glycosylated at asn-4 in preS2 and also present on the viral surface. The preS2-domain is also O-glycosylated at threonine (thr) 37, but interestingly only in genotypes B-H, since genotype A lacks thr-37. However, the overall function of this O-glycosylation for the viral life cycle is still unknown. Moreover, the function of the M-protein by itself is still not clear. Absence of the M-protein does neither suppress virion formation nor impede viral infectivity. However, the M-protein seems to have an evolutionary advantage for the virus, since it is conserved through all *orthohepadnaviruses*. The preS2-domain is a further integral building block of the large surface antigen (LHBs) by further aminoterminal addition of the preS1-domain to the preS2-domain. The preS1-domain has a dual function: the aminoterminal domain is necessary for attachment and entry of the virus, while the carboxyterminus together with aminoterminal part of preS2 is used for envelopment. Interestingly, the preS-domains of the LHBs are cytosolic during translation but half of the preS chains of LHBs are believed to translocate after translation. How the preS domains cross the membrane is still unknown, however cytosolic and ER-specific chaperones are believed to be involved in this process. In addition, the preS1-domain is myristoylated at Glycin-2, a modification that is not necessary for viral morphogenesis, but important for efficient viral infection. Even without involvement of the core particle, the surface proteins can bud from a post-ER, pre-Golgi compartment and build subviral particles that do not contain a viral capsid or DNA and are therefore non-infectious. In the case of HBV, they are built in the form of spheres and filaments and can reach concentrations that are 10000-fold higher than the virions. Interestingly, the L-protein cannot build particles by itself, but needs S or M protein for proper segregation. Moreover, the LHBs can induce a dose-dependent inhibition of particle release even in the presence of SHBs. A massive storage of HBV envelope proteins in turn can lead to massive cell stress causing cell death or cancer. The significance of the secretion inhibition function of LHBs for the viral life cycle is still not clear. However, it seems to be dependent on the myristoylation of preS1 domain of LHBs since blocking of LHBs myristoylation abolishes the storage phenomenon of LHBs.

Hepatocellular carcinoma (HCC) is one of the most frequent malignant tumors world-wide. Behind lung and stomach cancer, HCC is the one of the leading cause of cancer death. In the review by Joachim Lupberger and Eberhard Hildt, titled "HBV Induced Oncogenesis", the authors discuss the relation of chronic HBV infections and HCC and describe the epidemiology of HBV-associated HCC<sup>[6]</sup>. Epidemiological data state that chronic HBV carriers have a more than 25 times higher risk of developing HCC, while the molecular mechanism underlying the development of HBV-associated HCC are still not clear. The authors distinguish between direct effects and indirect effects caused by the integration of HBV-DNA into the host genome. In contrast to retroviruses, integration of viral HBV-DNA is not necessary for the viral replication. However, almost all HBV-associated HCCs contain integrated HBV DNA.

The integrated viral genomes are rearranged or contain deletions, and cannot lead to viable progeny. However, they may exert an effect on key regulators of the cell cycle. Of special interest in this respect is the frequent integration of woodchuck hepatitis B virus into the N-myc2 gene of the host cells of North-American woodchucks in WHV-related HCC. In HBV-associated HCC however, site-specific integration of HBV genome is a rare event. One indirect effect of integrated HBV-DNA is transcription of HBV open reading frames that remain conserved even after integration. Of special interest is the HBx protein, a small polypeptide that is produced at very low levels in HBV infected hepatocytes. A large number of possible functions have been ascribed to this still enigmatic protein. Initially described as a transcriptional activator, the authors discuss interference of HBx with different signal transduction cascades. Furthermore, HBx was found to interfere with DNA repair and might therefore account for an increase of critical cellular mutations that might increase the risk of developing HCC. Besides the HBx, a special form of the HBV surface protein was found in HBV-infected hepatocytes of HCC patients. The middle surface protein (MHBs) was found to be C-terminally deleted in its S-domain (MHBst) that in turn results in an altered topology of the aminoterminal preS2 domain. While the preS2-domain of wildtype MHBs is located in the lumen of the endoplasmatic reticulum (ER) and is glycosylated at asparagine 4, the preS2-domain of the truncated form is in the cytoplasm. This results in interaction of preS2 with protein kinase C (PKC) and permanent activation of Raf/MEK/ERK signal transduction cascades that might exert a tumor promoter-like function. In line with this, transgenic mice expressing MHBst develop liver tumors. However, a more detailed understanding of the molecular mechanism in HBV-associated HCC development is needed.

In general the infection with HBV can lead to a wide spectrum of clinical manifestations, e.g. self-limited acute or fulminant hepatitis, asymptomatic infection, or chronic hepatitis with progression to liver cirrhosis that can lead to hepatocellular carcinoma (HCC). In their review, Baumert *et al*<sup>[7]</sup> focus on the impact of virus-host interactions for the pathogenesis of HBV infection and associated liver disease. Both, viral factors and host immune response are discussed. One of the major viral factors are certain HBV mutants that are associated with distinct clinical manifestations, altering the natural course of the infection and confer resistance to antiviral agents, e.g. inhibitors of HBV reverse transcriptase. The authors focus mainly on pre-core (pre-C) stop codon mutations resulting in loss of hepatitis B e antigen (HBeAg) and core-promoter mutations that enhance viral replication. The pre-C stop codon mutation is clinically recognized mainly in patients with chronic and fulminant hepatitis but is also detected in asymptomatic HBV carriers or self-limiting hepatitis. In all these patients, HBeAg, a soluble and secreted form of the core-protein cannot be synthesized any more, despite active viral replication. Therefore the authors argue that HBeAg may play an important role for the interaction of the virus with the host immune system, e.g. HBeAg might have an immunomodulatory function. In line with this, HBeAg might predispose neonates born to HBV-

infected mothers to develop persistent HBV infection by establishing T-cell tolerance to HBeAg and HBcAg *in utero*. Core-promoter mutations are mainly found in patients with an aggressive course of disease like fulminant hepatitis B. Those mutations result in a viral phenotype that shows enhanced viral replication in cell culture and might alter viral kinetics and influence cellular immune response *in vivo*. This might result in more severe liver injuries and possibly fulminant hepatitis. Despite the effect of viral variants, the host immune response is the key player in the onset of liver disease. The authors describe that HBV does not induce strong immune response during the early onset of infection. At the onset of HBV clearance an influx of T cells into the liver occurs, but this is not typically associated with strong liver disease, suggesting non-cytopathic mechanisms for viral clearance that is CD8+ dependent and IFN gamma associated. Weeks later, final elimination of HBV-infected liver cells occurs, presumably by a strong T-cell response with associated liver disease during acute self-limited HBV infection. The absence of a strong T-cell response is detected in patients with chronic hepatitis B. The precise mechanism that contributes to the failure of virus-specific T cell response is still not clear and is discussed by the authors.

Hepatitis B virus is the prototype virus of the family of *hepadnaviridae* that is further divided into the *orthohepadnaviruses* of the mammals and the *avibepadnaviruses* of the birds. The review of Funk *et al*<sup>[8]</sup>, describes avian hepatitis B viruses as an important animal model for the understanding of the life cycle of *hepadnaviridae*. Since the discovery of duck hepatitis B viruses (DHBV) in 1980 many other *avibepadnaviruses* have been characterized in various bird species including cranes and herons. The genomic and structural organization is very similar in human HBV and DHBV. Like HBV, DHBV replicate their DNA genome by reverse transcription of an RNA intermediate. Similar to HBV is their narrow host range, e.g. DHBV infects only distinct duck and goose species but not chicken. Both viruses infect mainly hepatocytes and share a similar life cycle. Nevertheless there are differences that have to be taken into consideration when comparing results obtained from HBV or DHBV systems. First of all, the transmission of infection in ducks occurs mainly vertically, while horizontal transmission is uncommon in contrast to human HBV. Although nearly all of DHBV infected ducks develop chronicity, none or very mild hepatitis is detected and no hepatocellular carcinoma occurs. Furthermore, the DHBV envelope is composed of only two surface proteins [large (L) and small (S) surface proteins] and lacks the middle surface protein (MHBs) found in HBV and other *orthohepadnaviruses*. Unlike the envelope proteins of HBV, DHBV L and S-proteins are not glycosylated, but the DHBV L-protein is phosphorylated, a modification that is absent in HBV L-protein. Another difference is the open reading frame (ORF) for the X-protein. For DHBV, only a cryptic X-like ORF has been described, but apparently lacks a functional role in DHBV *in vivo*. Despite these limitations, DHBV infection of ducks has been an important animal model for the understanding of the biology of hepadnaviral infections, due to the ready availability of susceptible ducks.

Because of the various limitations of the duck hepatitis B infection model like absence of a strong immune pathogenesis leading to the development of liver cirrhosis and HCC, infection of woodchucks (*Marmota monax*) with woodchuck hepatitis B virus (WHV) represents a well-accepted model for many aspects of pathogenesis of human HBV infection. In their review, the authors Stephan Menne and Paul J. Cote describe in detail the woodchuck animal model of orthohepadnaviral infections<sup>[9]</sup>. WHV, as HBV, is a member of the genus *orthohepadnavirus*. In nature, transmission of the virus occurs vertically and horizontally. Similar to HBV, infections of adult woodchucks with WHV results mainly in resolution and only 5% of infected animals progress to chronicity. Experimental infection of newborn woodchucks results in up to 75% to chronic infection, which is similar to the high properties of neonates born to HBV-infected mothers to develop persistent HBV infection. Chronic WHV infection is associated with life-long active viral replication and disease progression to chronic hepatitis and HCC in these animals. However, unlike chronic HBV infections, there is no naturally occurring e-antigen to anti-e seroconversion and step-down of viral replication. The high viral replication and the very high load of surface antigen and continuous presence of e-antigen in chronic WHV-infected woodchucks might therefore play a major role in disease progression that leads to a nearly 100% risk of these animals to acquire a HCC. However, even after recovery from acute WHV-infection a higher risk of HCC remains (up to 20%), when compared to uninfected woodchucks. Interestingly, the authors could show that WHV replication could be reactivated in serologically long-term resolved adult woodchucks by immunosuppression with cyclosporine A. These experiments support the hypothesis that replication-competent WHV (or HBV in humans) is able to persist years after recovery from acute hepatitis and is controlled by an intact host immune system. The observation in the woodchuck model is supported by recently described fatal reactivation of recovered HBV-infected persons during active immune suppression. The woodchuck could therefore be a very helpful model to study the mechanism of a possible long life persistence of HBV even after serological recovery from acute hepatitis. However, compared to humans, the immune system of woodchucks is not well characterized. Nevertheless, the woodchuck model has very much expanded our knowledge of immune pathogenesis of acute and chronic hepadnaviral infections. Chronically WHV-infected woodchucks have proven to be an invaluable tool for preclinical screening of antiviral drugs against chronic HBV infections of men. Of the many studies with nucleoside and nucleotide analogues tested so far in the woodchuck, telbivudine and clevudine are the most potent with a 8 log<sub>10</sub>/mL reduction in serum viremia after daily administration of 10 mg/kg for 4 wk, respectively. In addition, continuous treatment with clevudine also delayed the development of HCC significantly. The antiviral activity of tenofovir is much lower under same conditions with only 1.2 log<sub>10</sub>/mL reduction in serum viremia after 4 wk and is more or less comparable to those of lamivudine and adefovir in the woodchuck model. Furthermore, the authors describe in detail further immunological studies in neonatal

and adult WHV-infected woodchucks that might help to identify the factors responsible for the switch from acute to chronic infection. First results showed that under some conditions, a combination of long-term antiviral drug treatment and therapeutic vaccination can break humoral and cellular immune tolerance in chronic WHV-infected woodchucks, when compared with antiviral monotherapy. The woodchuck animal model of chronic HBV infection is therefore an invaluable tool to study viral pathogenesis and host immune responses.

Despite the existence of a HBV vaccine, more than 370 million people are chronically infected with HBV worldwide, leading to chronic liver disease and development of HCC in many cases. Therefore the overall goal of an antiviral therapy for these cases would be the cure of chronic HBV. However with the current antiviral drugs this might not be achievable in all cases within the near future. In the review by Hans L. Tillmann, the aims of today's antiviral therapy against chronic HBV are summarized<sup>[10]</sup>. That is, first of all, prevention of liver disease and development of HCC in these patients by control and suppression of HBV replication. The author discusses in detail the different types of chronic HBV and their treatment parameters. For antiviral therapy, only interferon alpha (IFN  $\alpha$ ) and inhibitors against the reverse transcriptase of HBV are currently available. With standard IFN  $\alpha$ , seroconversion from HBe to anti-HBe is induced in 20%-40% of patients 24 wk post-treatment. In chronic HBV patients with a HBeAg negative phenotype, patients showed a good response under IFN  $\alpha$  treatment for 6-12 mo but a sustained response was usually not observed in the majority of cases. Unfortunately, longer treatment is usually limited by strong side effects, e.g. flu-like symptoms. Pegylation of IFN  $\alpha$ , leading to a longer half life of the modified interferon has similar efficacy, but in general the sustained response for both, standard and pegylated interferon seems to be dependent on the HBV genotype. In contrast to the side effects of interferons, inhibitors of HBV reverse transcriptase can be used for prolonged antiviral therapy. Many of the nucleotides or nucleosides analogues against HBV were developed and used in HIV therapy. Lamivudine, also called 3TC, inhibits HBV reverse transcriptase very efficiently and usually results in viral suppression of 5-6 log<sub>10</sub> copies/mL after one year of treatment. Prolonged Lamivudine treatment may contribute to seroconversion of HBe to anti-HBe within 50% of patients after 4 years of therapy. The major problem with prolonged Lamivudine, but also other reverse transcriptase inhibitors is occurrence

of drug resistance due to the selection of HBV mutants. The mutations occur mainly within the YMDD-motive of the C-domain of the viral polymerase, however other mutations are also described. The high variability of the HBV reverse transcriptase together with a high replication rate of HBV and the slow kinetics of viral clearance lead to rapid selection of mutants under drug selection pressure that results in development of resistance during continuous therapy. For Lamivudine, up to 70% resistance has been described after 4 years of treatment. This leads to viral breakthrough and progression of liver disease. The author notes that it is therefore necessary to perform early diagnostics of drug resistance and to adapt antiviral therapy prior to breakdown of liver function. Even more important is that the new antiviral in use must not show cross-resistance to the HBV mutants selected by the former antiviral, e.g. telbivudine and emtricitabine have been reported to show a similar resistance mutation profile like Lamivudine.

For the future, it will be necessary to have antivirals on hand that inhibit different steps of the viral life cycle. Rational targets might be inhibitors of attachment and entry, conversion from rcDNA to cccDNA, capsid assembly, envelopment and secretion of viral particles. For attachment and entry, it has been shown that acylated preS1 peptides block HBV infection *in vitro* and in animal models. Based on these results a potent inhibitor of viral infection (Myrcludex B) is currently being developed.

## Abstract

Hepatitis B virus (HBV) is a member of the hepadnavirus family. Hepadnaviruses can be found in both mammals (orthohepadnaviruses) and birds (avihepadnaviruses). The genetic variability of HBV is very high. There are eight genotypes of HBV and three clades of HBV isolates from apes that appear to be additional genotypes of HBV. Most genotypes are now divided into subgenotypes with distinct virological and epidemiological properties. In addition, recombination among HBV genotypes increases the variability of HBV. This review summarises current knowledge of the epidemiology of genetic variability in hepadnaviruses and, due to rapid progress in the field, updates several recent reviews on HBV genotypes and subgenotypes.

## INTRODUCTION

Hepatitis B virus (HBV) is the prototype member of a steadily growing family of viruses called hepadnaviruses<sup>[1]</sup>. Hepadnaviruses can be found in both mammals (orthohepadnaviruses) and birds (avihepadnaviruses). HBV, the hepadnavirus infecting humans, is classified into eight genotypes today. HBV genotypes differ by at least 8%<sup>[2]</sup>. Since the first definition of the genotypes A, B, C and D<sup>[2]</sup>, genotypes E<sup>[3]</sup>, F<sup>[4]</sup>, G<sup>[5]</sup> and H<sup>[6]</sup> have been

detected. Due to the genetic diversity of HBV, numerous subgenotypes of HBV have been described<sup>[7]</sup> (Table 1). HBV subgenotypes differ by at least 4%<sup>[8]</sup>.

HBV genotypes and most subgenotypes show a distinct geographic distribution. In Asia, where there is a high prevalence of HBV carriers, strong evidence suggests that HBV genotypes influence the course of disease. Several recent reviews have summarised knowledge on different aspects of HBV genotypes<sup>[7-12]</sup> and on hepadnaviruses that infect species other than homo sapiens<sup>[13-15]</sup>. This review will update recent developments in understanding HBV genotypes and taxonomy.

## TAXONOMY

HBV is a partially double stranded virus that uses reverse transcriptase in its replication cycle. Thus, HBV is similar to many retroviruses found in animals and pararetroviruses in plants<sup>[16,17]</sup>.

After cloning and sequencing the HBV genome<sup>[18]</sup>, several related viruses were discovered in woodchucks (*Marmota monax*)<sup>[19]</sup>, ground squirrels (*Spermophilus beecheyi*)<sup>[20]</sup> and pekin duck (*Anas domestica*)<sup>[21]</sup>. Subsequently, numerous new viruses that are similar to HBV were found in mammals and birds and have been cloned (Tables 1 and 2). All these viruses are classified in the family of hepadnaviridae, including the genus orthohepadnavirus (mammals; Figure 1), and the genus avihepadnavirus (birds; Figure 2). In addition to the avihepadnaviruses listed in Table 2, five new hepadnaviruses were cloned from exotic duck and goose species; i.e., the Chiloe wigeon, mandarin duck, puna teal, Orinoco sheldgoose, and ashy-headed sheldgoose. Sequence comparisons revealed that 4 virus isolates were closely related to existing isolates of duck hepatitis B virus (DHBV), while the mandarin duck virus was closely related to Ross goose hepatitis B virus<sup>[22]</sup>.

In chimpanzees, gorillas, orangutans and gibbons new putative members of hepadnaviridae were discovered and sequenced completely<sup>[14]</sup>. It is now widely accepted that primate hepadnaviruses are indigenous to their hosts. Because hepadnaviruses isolated from apes are grouped as HBV genotypes in phylogenetic analyses, it has been suggested that isolates from apes should be named following the nomenclature used for immune deficiency viruses<sup>[23]</sup> (Table 1), e.g. HBV found in chimpanzees should be called HBVcpz. With only 5% divergence from the chimpanzee HBV isolates, the HBV isolate from gorilla is categorized in the HBV genotype (Figure 3, unpublished

**Figure 2** Phylogenetic tree of the genus avihepadnavirus.

results). Thus, three HBV genotypes from apes can now be differentiated. The chimpanzee and gorilla isolates from Africa are categorized as one genotype, i.e., HBVcpz. The isolates from the South-East-Asian apes, gibbon and orang-utan, are categorized into two genotypes, i.e., HBVgbn and HBVoru, respectively. These genotypes diverge by 8%. Within the gibbon genotype, distinct strains of HBV circulating in geographically separated populations have been described<sup>[24]</sup>.

Avihepadnaviruses are the most distant relatives of HBV with a nucleic acid homology of only 40%. WHV and GSHV as mammalian hepadnaviruses are more closely related to HBV and differ by only 17%. Complete WHV and GSHV genomes from GenBank show a high degree of homology and only one genotype is listed<sup>[25-27]</sup>. However, using degenerate primers, several variant WHV

isolates from wild-captured woodchucks were found that showed high divergence with sequencing of small parts of the genome<sup>[28]</sup>. DHBV has two genotypes, in contrast to WHV and GSHV, which have a narrow host range and geographical distribution<sup>[25,26]</sup>, DHBV is found in different avian species with independent isolates in many countries

**Figure 3** Phylogenetic tree of complete HBV genomes. An alignment of 601 complete HBV sequences was performed with Clustal X in the program DNASTar. The alignment was further analysed by boot-strapping using the Neighbourhood-Joining method contained in MEGA version 3.1<sup>[104]</sup>.

**Figure 4** Geographic distribution of HBV genotypes and subgenotypes.

around the world<sup>[29]</sup> (Figure 4).

Human HBV can be grouped into eight genotypes (based on more than 8% difference)<sup>[7,9-12]</sup>. Several attempts have been made to reconstruct the evolution of hepadnaviruses<sup>[30-34]</sup>. Estimating the rate of synonymous substitutions for HBV to be  $4.57 \times 10^{-5}$  per site per year, DHBV has been proposed to have diverged about 30 000 years ago from a common ancestor while GSHV and WHV should have diverged about 10 000 years ago from HBV and the HBV serotypes would be separated by about 3000 years<sup>[31]</sup>. However, as long as we are not able to accurately estimate the mutation rate of HBV over centuries or even millennia, it is not possible to calculate a time point for the separation of HBV genotypes or hepadnaviral species.

## HBV GENOTYPES AND SUBGENOTYPES

HBV genotypes differ by more than 8%<sup>[2,3]</sup>. Phylogenetic analyses using alignments of whole genomes have shown that 8 genotypes, called A, B, C, D, E, F, G and H, of HBV

**Table 3** Fundamental properties of genomes and differences between HBV genotypes

Genotype	Genome length in bp	ORF-differences
A	3221	Insertion of aa 153 and 154 in HBc
B	3215	
C	3215	
D	3182	Deletion of aa 1-11 in preS1
E	3212	Deletion of aa 11 in preS1
F	3215	Insertion of 12 aa in HBc Deletion of aa 11 in preS1
G	3248	
H	3215

	F3		Bolivia	[97,98]
	F4		Argentina	[97,98]

can be distinguished<sup>[7,11,12,35]</sup> (Figure 1). In general, HBV isolates found in apes diverge similarly to HBV genotypes in phylogenetic analyses and have been named HBVcpz, -oru, -gor and -gbn for their host's, i.e. chimpanzee, orang-utan, gorilla and gibbon, respectively (Table 1)<sup>[23]</sup>. However, as elucidated above, the isolate from gorillas is always categorized into the chimpanzee clade.

A prototypic HBV genome may have a length of 3215 nt, as found in HBV genotypes B, C, F and H. Due to deletions and insertions (Table 3), the other HBV genotypes differ slightly in length of genome (Table 3). Thus HBV genotype G with 3248 nt. is 66 nt longer than genotype D with 3182 bp.

Extensive phylogenetic analyses have shown that HBV genotypes can be further subdivided into subgenotypes (Table 4). HBV subgenotypes differ by at least 4%<sup>[8]</sup>. In

**Figure 5** Schematic genome organisation of recombinants between HBV genotypes. HBV recombinants were described from materials sampled in **A:** Vietnam<sup>[99]</sup>, **B:** Tibet<sup>[68]</sup>, **C:** Africa<sup>[100]</sup> and **D:** Asia<sup>[67]</sup>. The ORF coding for the HBV proteins are shown as arrows, the inner circle represents the HBV genome.

genotypes A, B and C, epidemiological data show that the respective subgenotype pairs A1/A2 (formerly termed Aa/Ae)<sup>[36]</sup>, B1/B2 (formerly Bj/Ba)<sup>[36]</sup> and C1/C2 (formerly Cs/Ce)<sup>[37-39]</sup> differ substantially in many virological and probably some clinical parameters. Subgenotypes also show distinct geographic distribution (Figure 3). However, this is not true for genotype D with subgenotypes D1, D2 and D3 being described as widespread in the world; e.g. D3 was found in Asia (East India)<sup>[40]</sup>, South Africa<sup>[41]</sup> and Europe (Serbia) (Stanojevic *et al*, unpublished results).

Except for genotype E and G, all HBV genotypes can be divided into subgenotypes. The absence of subgenotypes in HBV genotype E has been assumed to be the consequence of a recent genesis for genotype E<sup>[42-45]</sup>. Furthermore, genotype E is not present in Americans of African origin from Venezuela and Brazil<sup>[46,47]</sup>. The case for HBV genotype G appears to be less clear. Genotype G was originally found in the USA, France<sup>[5]</sup> and Germany<sup>[48]</sup>. Later, partial sequencing of HBV genes pointed to a high prevalence of HBV genotype G in Mexico<sup>[49]</sup>. Nevertheless, the geographic origin of HBV genotype G remains unknown<sup>[50]</sup>. To date only a limited number of complete HBV genotype G sequences have been deposited in GenBank that are not classified into subgenotypes.

## DOUBLE INFECTIONS AND RECOMBINANTS

Double infections with two different HBV genotypes have been known since typing was done serologically<sup>[51,52]</sup>. Subsequently, evidence of super infection with HBV isolates of the same or different genotype was described in

**Table 5** Examples for recombination events between of HBV genotypes

Genotype of Backbone	Insert	Recombination Breakpoint		No. in literature	Ref.

chronic HBV patients<sup>[53]</sup>. Super infection was accompanied by acute exacerbation of the chronic disease. Additional observations came from patients treated with interferon. Before treatment, HBV genotype A was prevalent. After treatment and relapse, a switch of the genotype to HBV genotype D was described<sup>[54,55]</sup>.

Using different methods for genotyping, several reports described high rates of double infection with two different HBV genotypes in all parts of the world. Using these methods double infections have been found in 4.4%<sup>[56]</sup>, 10.9%<sup>[57]</sup>, 12.5%<sup>[58]</sup>, 14.1% (Kirschberg *et al*, unpublished results), 17.3%<sup>[59]</sup> and 17.5%<sup>[60]</sup> of HBV infected patients. Even triple infections with HBV of genotype A, B and C have been described in 0.9% of HBV infected intravenous drug users<sup>[60]</sup>.

Infection with HBV of genotype G seems to be associated very often with an infection of HBV genotype A<sup>[61]</sup>. This was found in 4 individuals from the USA and in one patient from France<sup>[62]</sup>.

Coinfection with two different HBV genotypes in one patient may lead to an exchange of genetic material between the two strains. However, with current knowledge of HBV replication, the mechanism for this supposed recombination remains enigmatic. No mechanism can be envisioned that would allow an exchange of genetic material between two hepadnaviral genomes at the level of transcription. Nevertheless, numerous authors described changes in the genome of HBV that appear to be the consequences of a recombinatorial event (Figure 5 and Table 5).

Two recent works have comprehensively analysed the prevalence of events in the HBV genome that are reminiscent of recombinations<sup>[63,64]</sup>. About 87% of the putative recombinants were B/C (120) and A/D (29) hybrids. The other recombinants comprised A/B/C, A/C, A/E, A/G, C/D, C/F, C/G, C/U (U for unknown genotype) and B/C/U hybrids. Genotypes A and C showed a higher recombination tendency than did

other genotypes. The results also demonstrated region priority and breakpoint hot spots in the intergenotype recombination. Recombination breakpoints were found to be concentrated mainly in the vicinity of the DR1 region (nt 1640-1900), the preS1/S2 region (nt 3150-100), the 3'-end of the Core gene (nt 2330-2450) and the 3'-end of the Surface gene (nt 650-830)<sup>[63,64]</sup>.

Recombination events between human and chimpanzee<sup>[65]</sup> or gibbon<sup>[63]</sup> HBV sequences have also been described. Discrepant genotyping results from different parts of the genome are indicative of a recombination between genotype A and F<sup>[66]</sup>. Even mosaic genomes with sequences derived from three different genotypes have been described<sup>[59,64]</sup>.

Some recombinants among HBV genotypes have become the dominant subgenotype prevalent in certain geographic regions. Recombination between genotypes B and C has led to the generation of two different strains with distinct geographic distribution<sup>[67]</sup>. Strains of genotype B without recombination are found in Japan (subgenotype B1), whereas strains with recombination between genotype B and C are found throughout Asia (subgenotype B2), sparing Japan<sup>[67]</sup>. Recombinants between HBV genotypes C and D are the leading HBV subgenotype in Tibet<sup>[68-70]</sup>.

It remains open for discussion whether the observed exchanges are the consequence of direct genetic recombination taking place between two HBV strains or if they are the consequence of fast adaptation of HBV to a certain genetic and immunologic environment in different human populations in the world. The high replication capacity of HBV with a release of up to  $10^{13}$  viral particles per day<sup>[71,72]</sup> and the high error rate of the viral polymerase, lead to the production of HBV genomes with all possible single mutations and double mutations of every nucleotide of the HBV genome every day<sup>[72]</sup>. Thus, a fast adaptation of HBV to a new environment is also a possibility.

A hypothetical mosaicism of the HBV genome has already been proposed by Bowyer and Sim<sup>[73]</sup>. This work and later works described most HBV genotypes as a modular genome<sup>[63]</sup> that represents a mixture of small segments coming from many different HBV genotypes. If we expand on this observation, the HBV genome may be made up of a number of allelic modules with different properties; e.g. different binding sites for transcription factors or antigenic epitopes. Thus, a certain combination of these modules would make up an HBV genotype. The findings of Fischer *et al*<sup>[74]</sup> are in support of this speculation. The authors described genotype specific activation or repression of HBV enhancer II, preCore-pregenomic promoter by the transcription factor COUP-TF1.

## CONCLUSION

HBV has been recognised as a prototype member of a family of viruses infecting mammals and birds. Due to its high replication capacity and the high error rate of the viral reverse transcriptase, HBV is able to adapt to the host's environment. This adaptation has led to the emergence

of eight genotypes in humans and three closely related genotypes in apes. The human genotypes have further diverged into at least 24 subgenotypes, with certainly many more to come, and a plethora of recombinants. From the analysis of recombinants there are indications that at least one more genotype remains to be detected.

## Abstract

*Hepadnaviridae* is a family of hepatotropic DNA viruses that is divided into the genera *orthohepadnavirus* of mammals and *avihepadnavirus* of birds. All members of this family can cause acute and chronic hepatic infection, which in the case of human hepatitis B virus (HBV) constitutes a major global health problem. Although our knowledge about the molecular biology of these highly liver-specific viruses has profoundly increased in the last two decades, the mechanisms of attachment and productive entrance into the differentiated host hepatocytes are still enigmatic. The difficulties in studying hepadnaviral entry were primarily caused by the lack of easily accessible *in vitro* infection systems. Thus, for more than twenty years, differentiated primary hepatocytes from the respective species were the only *in vitro* models for both *orthohepadnaviruses* (e.g. HBV) and *avihepadnaviruses* (e.g. duck hepatitis B virus [DHBV]). Two important discoveries have been made recently regarding HBV: (1) primary hepatocytes from tree-shrews; i.e., *Tupaia belangeri*, can be substituted for primary human hepatocytes, and (2) a human hepatoma cell line (HepaRG) was established that gains susceptibility for HBV infection upon induction of differentiation *in vitro*. A number of potential HBV receptor candidates have been described in the past, but none of them have been confirmed to function as a receptor. For DHBV and probably all other avian hepadnaviruses, carboxypeptidase D (CPD) has been shown to be indispensable for infection, although the exact role of this molecule is still under debate. While still restricted to the use of primary duck hepatocytes (PDH), investigations performed with DHBV provided important general concepts on the first steps of hepadnaviral infection. However, with emerging data

obtained from the new HBV infection systems, the hope that DHBV utilizes the same mechanism as HBV only partially held true. Nevertheless, both HBV and DHBV *in vitro* infection systems will help to: (1) functionally dissect the hepadnaviral entry pathways, (2) perform reverse genetics (e.g. test the fitness of escape mutants), (3) titrate and map neutralizing antibodies, (4) improve current vaccines to combat acute and chronic infections of hepatitis B, and (5) develop entry inhibitors for future clinical applications.

## INTRODUCTION

The first step in virus infection is an energy independent attachment of the infectious particle to an accessible structure exposed at the host cell surface. Primary attachment, often characterized by low affinity and reversibility, is usually followed by the passage of the virion to a more specific receptor, which mediates further steps of entry. Both initial attachment and specific receptor recognition often contribute to host specificity and tissue tropism. For enveloped viruses, receptor binding is followed by fusion of the virus with either the plasma or an endosomal membrane. Fusion within intracellular vesicles is regularly triggered by acidification. The universal mechanism of membrane fusion requires conformational changes of virus-encoded fusion proteins leading to a physical approximation and finally merging of viral and cellular membranes<sup>[1]</sup>. A detailed understanding of receptor binding and membrane fusion is of general interest for molecular virologists and it also provides the basis for therapeutics that interfere with the early steps of infection, as has been successfully accomplished for HIV<sup>[2]</sup>.

HBV and related animal viruses form the family *hepadnaviridae*, which are small, enveloped DNA viruses that cause acute and chronic liver infection. They are

divided into the *orthohepadnaviruses* of mammals and *avihepadnaviruses* of birds<sup>[3]</sup> (see also the review on HBV taxonomy and genotypes by S. Schaefer in this series). HBV is a serious global infectious diseases and it is assumed that 2 billion people have had contact with that virus<sup>[4]</sup>. The infection can lead to a chronic carrier state in 5%-10% of immunocompetent adults and up to 90% of infected neonates. Chronic HBV infection is the major cause of liver cirrhosis and hepatocellular carcinoma in numerous regions of the world<sup>[5]</sup>. While the viral life cycle is still not fully understood, a safe and efficient vaccine has been developed and sensitive tests for HBV surface protein (HBsAg) now allow for reliable diagnosis and screening of blood products. Present therapeutic regimens for HBV address either the host immune system ( $\alpha$ -interferon [IFN $\alpha$ ]) or inhibit reverse transcription of the viral pregenomic RNA by nucleoside inhibitors (Lamivudine, Adefovir, Entecavir). The latter provoke the selection of resistant or even cross-resistant mutants that will become increasingly problematic to therapeutic control in the future (see also review "Antiviral therapy and resistance of hepatitis B virus infection" by H.L. Tillmann in this series).

To overcome these challenges, antiviral substances that target different replication steps; e.g. inhibitors of viral entry or improved vaccines that counteract the current escape-mutants, are becoming increasingly important. In the past, however, the lack of feasible HBV *in vitro* infection systems hampered investigations aiming in this direction. The only immunocompetent *in vivo* model that could be used for studies related to the infectivity of the virus was based on primary human hepatocytes (PHH) and those of the chimpanzee, which were limited in availability.

## ORGANIZATION OF THE HEPADNAVIRAL ENVELOPE

A hallmark of hepadnaviral infection is the constitutive secretion of nucleocapsid-free subviral particles (SVP), mainly composed of the hepadnaviral envelope proteins (large and small in the case of DHBV and large, middle, and small for HBV). HBV-SVPs exist as 22 nm spheres or filaments of the same diameter but variable in length. The HB virions appear in electron microscopy after negative staining as spheres of 45 nm. Virions and SVP contain variable proportions of the three co-carboxyterminal surface (glyco)-proteins; i.e., the large (LHBs), middle (MHBs) and small (SHBs) surface proteins (Figure 1). The SHBs protein is the major component of the virion envelope and the subviral HBsAg particles, while virions and filaments contain more LHB proteins than spheres<sup>[6]</sup>. In contrast DHBV and DHBV-SVPs are similar in size and shape (55-60 nm)<sup>[7]</sup> and contain a similar ratio of both envelope proteins (L:S = 1:5). In addition DHBV incorporates a processed version of the DHBs protein consisting of only the two N-terminal transmembrane domains of S and are therefore called S<sub>r</sub><sup>[8]</sup>. The hepadnaviral surface proteins are products of a single open reading frame and distinguished by three (HBV) or two (DHBV) domains. HBV comprises: preS1 (108 or 119 aa depending on the genotype) only in LHBs,

**Figure 1** Schematic presentation of human (HBV) and duck (DHBV) hepatitis B virus. The viral DNA is drawn as a single or double line. The viral polymerase is depicted with the primer domain (pr) and the reverse transcription domain (RT). The nucleocapsid (core or HBC/DHBC) is shown in black. Reported encapsidated cellular proteins are omitted. For HBV the surface proteins L, M and S are shown with the S-domain, the preS2-domain and the preS1-domain, whereas for DHBV, L- and S-surface proteins with preS and S-domain are depicted. St, truncated form of DHBV S-surface protein. Non-infectious subviral particles of HBV are shown in filamentous and spherical form and in larger spheroids in the case of DHBV.

preS2 (55 aa) in LHBs and MHBs, and S (226 aa) common to all three HBs proteins (Figure 2A). All three proteins bear within the S-domain a potential N-glycosylation site (NG) at Asn-146, which is only partially utilised. The second N-glycosylation site at Asn-4 in the preS2-domain is modified in MHBs but not in LHBs<sup>[6]</sup>. In addition to N-glycans, the preS2 domain of most *orthohepadnaviruses* contains O-glycans<sup>[9]</sup>. The preS2 domain of both LHBs and MHBs contains a single mucin-type O-glycan (OG) at Thr-37 in genotypes B-H. O-glycans are absent in genotype A, because the O-glycosylation site at Thr-37 is exchanged to Asp in genotype A for an unknown reason<sup>[10]</sup>. Although potential N- and O-glycosylation sites within the preS1 domain are present, none of them are used due to the cytoplasmic exposition of preS1 during synthesis. In contrast, the two DHBV envelope proteins L (preS+S) and S remain unglycosylated during secretion, but DHBV-L becomes phosphorylated<sup>[11]</sup> (for more details see review "Avian hepatitis B viruses: molecular and cellular biology, phylogenesis and host tropism" by Funk *et al* in this series). The N-termini of probably all hepadnaviral L-proteins contain recognition sequences that lead to myristoylation at Gly-2<sup>[12]</sup> while, at least in HBV, more carboxyterminal parts serve as envelopment signals for cytoplasmic core particles<sup>[13,14]</sup>. Several lines of evidence indicate that hepadnaviral L-proteins adopt dual topologies with half of their preS-domains located inside the particle,

**Figure 2** Surface proteins of HBV and DHBV. **(A)** Schematic organisation of the three surface proteins of HBV and the two surface proteins of DHBV. For HBV, used N- and O-glycosylation sites (NG and OG) are shown, (parenthesis indicate partial glycosylation). DHBV surface proteins are non-glycosylated, but the L-protein is phosphorylated at position 118 within its preS-domain. The L-protein of HBV and DHBV is myristoylated (Myr) at Gly-2 of the N-terminus of preS1 or preS, respectively. In case of HBV the preS1-domain encodes for 108 or 119 amino acids, depending on the genotype. The preS2-domain of MHBs is N-terminally acetylated (Ac) and is 55 amino acids long, while a preS2-domain and therefore a special M-protein is missing in DHBV. **(B)** Schematic presentation of preS-domains of HBV and DHBV important for virion formation and viral entry. The host-determining regions are depicted in green. The potential receptor binding site within the preS1-domain of HBV is shown with the essential domain (aa 9-18) and the two accessory domains (aa 28-39 and 39-48, respectively). For DHBV, the carboxypeptidase D (dCPD) binding site is depicted with the essential and stabilizing domains. Alpha helical domains are shown in blue ( $\alpha$ ). Reported trans-location motives (TLM) are marked in boxes. In DHBV preS, two TLMs are predicted (TLM1 and TLM2). TLM1 overlaps with the host-determining region, while TLM2 is located within the stabilizing sequence of the dCPD receptor binding site. In the case of HBV, the carboxyterminus of the 55 aa long preS2-domain was reported to contain a single TLM. The numbering of HBV preS1 is for genotype D (108 aa). P, phosphorylation site; OG, O-glycosylation; myr, myristoylation.

while the other half is located on the outside<sup>[15-18]</sup>. Virions and SVP particles bud to a lumen of a post-ER, pre-Golgi intermediate compartment. Therefore the particles contain lipids derived from intracellular compartments, rather than from the plasma membrane. The SHBs subunits of HBV and the subviral particles in the blood are highly cross-linked by disulfide-bonds and do not disassemble in the presence of detergents, unless the disulfide bonds are opened. Interestingly, this tight network of disulfide bridges is not found in DHBV particles. Those can easily be solubilised in mild detergents and both types of surface proteins do not form heterodimeric complexes (unpublished results).

## CELL CULTURE SYSTEMS FOR VIRUS PRODUCTION AND ENTRY ANALYSIS

It is known that after artificial delivery of replication

competent DNA constructs, later steps of the viral life cycle are not rigidly host-restricted. Transfection of hepatoma cell lines<sup>[19-21]</sup> or mouse liver cells<sup>[22]</sup> with replication-competent HBV/DHBV genomes results in the production and secretion of infectious virions. The same holds true for HBV transgenic mice<sup>[23]</sup>. Furthermore, lipofection of mature core particles, isolated from serum-derived virions into non-permissive hepatoma cells resulted in a full replication cycle of HBV<sup>[24]</sup>. This suggests that species-specificity of infection is determined at an early step; e.g. viral attachment, entry or fusion. Interestingly, productive infection not only depends on the species origin but also on the state of differentiation of the same cell line. This has been impressively demonstrated in HepaRG cells, which gain susceptibility towards HBV infection only several weeks after induction of differentiation<sup>[25]</sup>. In case of primary tupaia, human or duck hepatocyte cultures, susceptibility is achieved about one day after attachment

of the perfused and already differentiated hepatocytes, but is lost during prolonged culturing. Since binding and virus accumulation in HepaRG cells is similar in both, differentiated and undifferentiated cells (unpublished data) the restriction may not be caused by the bare presence or absence of a host entry molecule but might be complicated due to the polarisation state of the differentiated cell.

## PRIMARY HEPATOCYTE CULTURES AND RELIABLE MARKERS FOR INFECTION

For many years, cultures of primary human hepatocytes (PHH), obtained by immediate perfusion of liver pieces after surgical resection, were the only cells to study viral infectivity<sup>[26]</sup>. PHH are not easy to handle, cannot be propagated *in vitro* and need particular growth factors for maintenance of their differentiated state<sup>[27]</sup>. Moreover, the efficiency of HBV infection of PHH *in vitro* was reported to be low leading to only a few percent of cells being infected and a negligible spread within the cell culture. Thus, virus amplification is not achievable. This can be counteracted to some extent by the addition of dimethylsulfoxide (DMSO) during cultivation and the use of 4% polyethylene glycol (PEG) during infection<sup>[28-31]</sup>. In contrast, infection of PDH with DHBV leads to a spread of infection to virtually every cell in the culture even when very low initial virus titers were supplied. A major drawback of PHH is their limited availability and the heterogeneity in quality with different liver cell preparations resulting in varying susceptibilities towards HBV infection. Furthermore, susceptibility is limited during culture (5-7 d) when DMSO or hydrocortisone is omitted<sup>[26,29,30]</sup>. Fortunately, primary hepatocyte cultures from *Tupaia belangeri* (PTH) can be infected with HBV as efficiently as PHH cultures of good quality. In contrast to PHH, PTH can also be infected with a primate hepadnavirus from woolly monkey (WMHBV)<sup>[32]</sup>. Nevertheless, the host range of PTH is restricted to human and primate HBV, since productive infection with rodent hepatitis B virus (woodchuck hepatitis B virus, WHV) is not possible<sup>[32]</sup>.

Hepadnaviruses are non-cytopathic and do not induce conspicuous morphological changes of infected cells. Thus, detection and quantification of infectious virions cannot be achieved by simple virological methods; e.g. plaque test. In general, verification of *in vitro* HBV/DHBV infection should be done by quantification of different markers of an established HBV infection. Conversion of the relaxed circular (rc) DNA genomes of the incoming virus to covalently closed circular (ccc) DNA within the nucleus of an infected hepatocyte is the first marker of a productive HBV/DHBV infection, but is difficult to detect. The amount of cccDNA in just newly infected hepatocytes is very small compared to the large amounts of viral input DNA (as rcDNA), usually needed for efficient *in vitro* infection. Furthermore, DNA-containing particles are also taken up by cells that are not susceptible to infection. This is especially problematic when using embryonic duck hepatocyte preparations because they contain a high percentage of non-parenchymal cells (e.g. antigen-presenting liver sinusoidal endothelial cells). However, quantitative real-time PCR protocols

are available that amplify specifically cccDNA, but not rcDNA. With these protocols, specific detection of small amounts of cccDNA is possible, even in the presence of a large excess of rcDNA within infected hepatocytes<sup>[24,33]</sup>. Verification of specific HBV infection can also be achieved by detection of viral mRNA extracted from cells by either Northern Blot hybridisation or quantitative RT-PCR, usually resulting in higher sensitivity. Less demanding is the detection of secreted viral antigens; i.e., HBeAg or HBsAg, 9-12 d post infection, which could be done by commercially available ELISAs<sup>[33,34]</sup>. Especially when using enriched or highly purified viral inocula, HBeAg should be the marker of choice, since it is not present in the viral input, in contrast to HBsAg. However, since HBsAg can be detected with higher sensitivity than HBeAg it can be used as a marker, provided that several medium exchanges have been performed prior to the measurement, optimally between day 9-12<sup>[33,35]</sup>. This is necessary to get rid of input HBsAg, which is released from cells even after removal of the inoculum. There are several reports of alleged infections that determine HBsAg 2 d post infection in the supernatant spuriously assuming that this is progeny viral antigen<sup>[36,37]</sup>. Using optimized methods, the current detection limit in the PTH-system for purified HBV from human plasma is one HBV particle per hepatocyte in culture plates with 10<sup>5</sup> cells<sup>[33,34]</sup>. Addition of PEG and DMSO during infection is not necessary to achieve optimal infectivity in PTH<sup>[38]</sup>, as was reported to be beneficial to increase HBV infection of PHH<sup>[26,29]</sup>. Therefore, *Tupaia belangeri* represent a valuable tool to overcome the restrictions associated with PHH.

## HEPATIC CELL LINES

To become independent in the utilization of primary hepatocyte cultures, many groups explored the potentiality of human hepatoma cell lines for infection experiments. HepG2 cells were employed extensively for binding and infection experiments. HepG2-cells exhibit some features of differentiated liver parenchymal cells; e.g. expression of serum albumin<sup>[39]</sup>, and are successfully used for the production of virions after stable or transient transfection of HBV DNA<sup>[19,40]</sup>. Several studies reported specific binding and uptake of HBV by HepG2 cells<sup>[41-46]</sup>, however, no productive infection was observed by these researchers. In contrast, Bchini *et al*<sup>[47]</sup> and Paran *et al*<sup>[48]</sup> reported successful detection of viral antigens upon infection of HepG2 cells that were cultivated with, inter alia, DMSO and 5-aza-2'-deoxycytidine. Unfortunately, these results could not be reproduced by others. In order to search for an explanation for the refractoriness of HepG2 cells towards HBV, Qiao *et al*<sup>[43]</sup> supposed an inability of the incoming HBV core particles to reach the nucleus, while overexpression of serine protease inhibitor Kazal (SPIK) was suggested by another group<sup>[49]</sup>. The discovery that the addition of 2% DMSO into the culture medium of primary rat hepatocytes upholds their differentiated state through maintenance of hepatocyte specific detoxification enzymes (e.g. cytochrome P450) was a milestone for hepatic pharmacology<sup>[50]</sup>. Since hepadnaviral infection depends on the differentiated state of the hepatocyte, this method was

Table 1 Described binding partners for HBV preS1-domain. Numbering of aminoacids (aa) are given for HBV genotype D

Domain	aa	Described interaction partners/binding factors for HBV	Ref.
preS1	10-36	Hepatoma cells bind to preS1 peptide. Inhibition by peptide-antisera	[41]
	19-25	Binding of recombinant subviral particles containing preS1 to human liver. Inhibition by anti-preS1 aa19-25	[142]
	10-36	PreS1-peptide binding not limited to liver cells, also on extrahepatic sites	[143]
	10-36	Partial homology of preS1 aa10-36 with IgA. HBV entry via IgA-binding receptor?	[144]
	18-25	PreS1 aa18-25 crossreact with IgA alpha-1 chain, IgA and HBV use related receptors?	[145]
	10-36	PreS1 aa10-36 binding to 31 kDa protein on HepG2 cells	[146]
	10-36	PreS1-peptide aa10-36 binds to Interleukin 6 (IL6) but not IL3, IL5 and IL7	[147]
	10-36	CHO cells transfected with IL6 cDNA acquire binding sites for preS1 peptide aa10-36	[148]
	10-36	Isolation of 44 kDa protein (HBV-BP) from HepG2 plasma membranes. Homology to SCCA1, human squamous cell carcinoma antigen 1 (human serpin)	[46]
	preS1-GST	Isolation of p80 binding protein from human hepatocytes. Needs preS1 aa12-20/82-90 for binding. p80 binding also to rat hepatocytes	[149]
	preS1	Anti-idiotypic antisera of antibody inhibiting binding of HBV to HepG2. 35kDa protein homology to Glycerinaldehyde-3-phosphate-dehydrogenase (GAPD)	[150,151]
	preS1/ preS2	50 kDa serum glycoprotein interferes with binding of preS1 and preS2 mabs. Soluble form of plasma membrane protein on human hepatocytes	[152]
	preS1	Yeast two-hybrid assay I: preS1 domain and human liver cDNA library. Isolation of two unknown proteins.	[153]
	preS1	Yeast two-hybrid assay II: preS1 domain and human liver cDNA library. Isolation of cytoplasmic "nascent polypeptide-associated complex alpha polypeptide" (NACA)	[154]
HBV particles		Asialoglycoproteinreceptor (ASGPR) I : preS1-but not preS2-mabs inhibited binding of HBV to ASGPR. SHBs did not bind to ASGPR	[44]
HBV particles		Asialoglycoproteinreceptor (ASGPR) II : HBV uptake by HepG2 and HuH7 (ASGPR+), but not CHO (ASGPR-)	[45]
HBV particles		Asialoglycoproteinreceptor (ASGPR) III : Desialylated HBV only binds to HepG2. Uptake only by susceptible primary human hepatocytes	[155]
HBV particles		Asialoglycoproteinreceptor (ASGPR) IV: Increased HBV uptake by HepG2 after desialylation results in HBV infection	[156]

also successfully used for HBV and DHBV infection after preparation of human and duck hepatocytes<sup>[26,29,51]</sup>. While the method of induced HBV-susceptibility of long-term DMSO-treated hepatoma cell lines was not successful in established hepatoma cell lines (e.g. HepG2 or HuH7), evidence for this principle has been shown for a new hepatoma cell line (HepaRG). This cell line, established from a liver tumour of a female patient suffering from hepatocarcinoma and chronic hepatitis C infection, was shown to become susceptible to HBV and HDV infection upon treatment with DMSO and hydrocortisone<sup>[25,52]</sup>. The necessity of long term induction of HepaRG differentiation by DMSO and hydrocortisone prior to infection is time consuming, however, it provides the opportunity to decipher cellular determinants of hepatocyte differentiation and their influence on HBV infection for the first time.

In summary, the optimal system for the study of hepadnaviral attachment and entry *in vitro* are primary hepatocyte cultures of Pekin ducks and humans, the latter being very limited in supply and heterogeneous in quality and susceptibility to HBV. Primary hepatocyte cultures from *Tupaia belangeri* and the newly established HepaRG cells can overcome these limitations and provide a nearly unlimited supply of HBV-susceptible hepatic cells for various experimental settings.

## CELLULAR AND VIRAL BINDING FACTORS CRUCIAL FOR HBV INFECTIVITY

During the last 25 years, numerous reports on a variety of possible cellular HBV binding partners, involving all three HBV surface proteins, have been published (Tables

1 and 2). Many researchers tried to isolate HBV binding components from plasma membranes of either primary human hepatocytes or established hepatic cell lines (e.g. HepG2) with the help of HBV-peptides or complete (subviral-) particles. In contrast to the DHBV-model discussed later in this review, none of these potential HBV-binding factors has ever been convincingly shown to be essential in HBV entry<sup>[53]</sup>.

## FUNCTION OF THE PRES1 DOMAIN

In 1986, Neurath *et al*<sup>[41]</sup> reported that a synthetic preS1 peptide, comprising amino acids 21-47 and corresponding to amino acids 10-36 in genotype D, E and G binds HepG2 cells and also inhibits HBV binding to this cell line. Furthermore, antibodies directed against this peptide compete with binding of HBV particles to HepG2 cells. They could, however, not show the relevance of their findings for the infection process. These early data were consistent with functional studies of Le Seyec *et al*<sup>[54]</sup>, demonstrating that preS1 amino acids 3-77 of the HBV L-protein are essential for infectivity. In two independent studies, it was further shown that acylation of glycine 2 of preS1 with myristic acid is necessary for efficient hepadnaviral infection<sup>[55,56]</sup>. Interestingly, a synthetic peptide representing this essential 77 preS1-amino acids, including the N-terminal myristic acid moiety, was able to block HBV infection when added to the medium during infection<sup>[25]</sup>. Similarly, DHBV infection was sensitive against N-terminal preS-peptides DHBVpreS2-41. Surprisingly the inhibitory activity could be drastically increased by N-terminal myristoylation<sup>[57]</sup>. The effect of myristoylation

Table 2 Described binding partners for HBV preS2 and S-domains

preS2		Binds to polymerised human serum albumin (pHSA). pHSA has affinity to hepatocytes	[157]
		Preincubation of human liver membranes with pHSA induced binding of rec. HBsAg/preS2	[158]
		Natural pHSA only present in minor amount in serum	[159]
	3-16	Natural monomeric HSA binds to preS2 domain aa 3-16	[160]
	3-16	Binding site for pHSA	[161]
	2-24	Polyclonal antisera against preS2 peptide (2-24) neutralised HBV infection of chimpanzees	[71]
	14-32	Immunisation of chimpanzees with preS2 peptide (14-32) protected against infection	[162]
	3-16	PreS2 antisera against aa 3-16 inhibited infection completely, others only partially	[33]
S		Human apolipoprotein H (apo H) binds to small surface protein (SHBs)	[163,164]
		SHBs binds endonexin II, now called annexin V	[165]
		Overexpression of annexin V in rat hepatoma cells supported HBV-infection	[166]
		Yeast-derived SHBs alone did not bind to HBV-susceptible hepatocytes	[34]

on the inhibitory potential of preS1 lipopeptides for human HBV<sup>[25]</sup> was also shown using PTHs<sup>[34]</sup>, and HepaRG cells<sup>[58]</sup> confirming the fact that myristoylation of the preS-domain of hepadnaviral L-proteins is essential for infectivity, but also indicating that this modification seems to play a role in the context of extracellular inhibition by a peptide. Furthermore, it turned out that the inhibitory activity of the preS1 lipopeptides is dependent on the hydrophobicity of the N-terminal acyl residues. Stepwise increased inhibitory potential of the lipopeptides could be achieved by increasing the chain length from C5 (pentanoyl) to C14 (myristoyl), C16 (palmitoyl) and C18 (stearoyl)<sup>[34,58]</sup>. The role of the N-terminal myristoylation of preS1 during attachment and entry of HBV is still unclear. One explanation might be that the interaction of preS1 and its receptor might be enhanced by an insertion of myristic acid into the membranes or the receptor. Exposure of a myristoylated peptide or protein ("myristoyl-switch") after attachment is a known element of viral entry mechanisms for some nonenveloped viruses, such as picornaviruses<sup>[59]</sup> and reoviruses<sup>[60]</sup>.

Using a set of myristoylated HBV preS1 peptides of variable length, the attachment site of HBV was further narrowed down<sup>[34]</sup>. The data obtained using PTH suggest that: (1) residues containing the first 8 amino acids of preS1 (19 in genotype A) are dispensable, (2) residues in aa 9-18 are essential, (3) residues within aa 19-28 are dispensable, whereas iv) residues of aa 29-48 enhance infection inhibition (Figure 2B). Similar results were obtained in HepaRG cells and PHH in the presence or absence of PEG<sup>[58]</sup>. Introducing an *E. coli*-based expression system for the production of myristoylated preS-fusion proteins, Engelke *et al.*<sup>[35]</sup> verified that region 9-18 is essential for virion infectivity and identified single amino acids (aa 11, 12, 13 for geno-type D) within this region that are crucial for infection inhibition. Recombinant HBV particles carrying the same point mutations are not infectious. Interestingly, hepatitis delta virus (HDV), an RNA virus that replicates in HBV infected hepatocytes and packages its ribonucleoprotein into the HBV envelope (for a recent review see<sup>[61]</sup>) can be inhibited by acylated HBV preS-derived peptides with the same specificity<sup>[35]</sup>. Thus HDV uses at least one com-

mon step for entering hepatocytes and is therefore also suitable to study HBV entry events. Surprisingly, HBV-preS1 lipopeptides containing amino acids between aa 49 until aa 78 (the region that has been shown to be important for infectivity of virions<sup>[54]</sup>) did not further increase but weakened infection inhibition<sup>[34,58]</sup>. Thus this part of the L-protein may play a role in a different step of infection process. Segment 9-18 is highly conserved with only 3 exchanges in 330 positions of the eleven HBV-genotypes, while in the other segments of 10 aa between aa 1 and 48 there are 4-8 times more exchanges. The unexpected finding that internal deletions of the preS1 sequence 20-27, containing the epitope of the neutralizing monoclonal antibody (mab) MA18/7<sup>[6,62]</sup>, within lipopeptides 2-48, did not drastically affect infection-inhibition. PreS1-region 20-48 was speculated to contain major B-cell epitopes<sup>[63]</sup>. Indeed, mab KR359 neutralized HBV infectivity for PHH and binds to aa 19-26<sup>[64]</sup>, whereas another neutralizing mab KR127 binds to aa 37-45. Furthermore, humanised mab KR127 inhibited HBV infection in chimpanzees<sup>[65]</sup>. Obviously, the binding of mabs to these epitopes hinders the attachment although the essential sequence element needed for infection is elsewhere. While the behaviour of the inhibitory preS1-peptides was very similar in the Tupaia system<sup>[34]</sup> and PHH/HepaRG cells<sup>[58]</sup> one point was worth mentioning: the preS1 sequence 20-27 was necessary for full inhibitory potency of the preS1 (2-48) peptide in HepaRG cells. A possible explanation might be that the receptor molecule(s) on Tupaia hepatocytes has binding sites for aa 9-18 and 28-48 comparable to the human receptor(s) but differs with the human binding site at aa 20-27. In a similar approach, Barrera *et al.*<sup>[66]</sup> reported that the preS1-region involved in infection-inhibition of HDV spans residues 5-20 of preS1. However, they needed much higher concentrations of myristoylated preS1 peptides for inhibition in their study (> 5 µmol/L) than in the HBV studies using PTH<sup>[34]</sup>, PHH (< 1 nmol/L)<sup>[58]</sup> and HepaRG<sup>[35]</sup>. However this discrepancy might be related to the peptide preparation the authors used, since myristoylated recombinant preS1-proteins obtained from a baculovirus expression system had much higher and comparable specific activities.

The remarkable potency of infection-interference, using acylated preS1-peptide 2-48 at (sub-) nanomolar concentrations, was demonstrated by the kinetics of the peptides using both PTH and HepaRG cells. Even short preincubation periods (30 min) of peptides (100 nmol/L) with the cells are sufficient to block subsequent infection and to induce non-susceptibility of the cells for hours<sup>[34,58]</sup>. Interestingly, infection could also be blocked by myristoylated peptides (100 nmol/L) after attachment of the viral inoculum at 4°C had occurred<sup>[34]</sup>. These experiments supported the assumption that the peptides inhibited infection through binding to the hepatocytes (there possibly addressing a specific receptor), rather than with the virus, although we can presently not exclude the possibility that the peptide might address virions at a specific site on the cell. Using immunohistochemistry, we could demonstrate specific binding of HBV preS1 2-48 peptides to PTH, but not to primary rat hepatocytes or other hepatoma cell lines, such as mouse AML12<sup>[34]</sup>. The binding was considerably increased when using the respective acylated variants. The binding of the myristoylated HBV-preS-peptides could also prevent binding of highly purified HBV preS1-containing subviral particles, whereas preincubation with myristoylated preS peptides from avian hepadnaviruses did not<sup>[34]</sup>. However, inhibition of binding required micromolar concentrations of peptides, rather than nanomolar concentrations needed for inhibition of infection<sup>[34]</sup>. This discrepancy suggested presence of a more abundant low-affinity receptor for HBV on hepatocytes.

This low affinity receptor might be a sulphated glycan, because interaction of HBV and PHH is inhibited by heparin<sup>[67]</sup>. Furthermore, HBV binds to heparin *in vitro* and could be purified from the plasma of HBV-infected patients by heparin-sepharose columns<sup>[68]</sup>. Unfortunately, these reports could not clarify the relevance of this interaction for infection. Recently, we could show that HBV infection could be specifically blocked by preincubation of purified virus with heparin, or by treatment of PTH and HepaRG cells with heparinase (unpublished data). Since heparan sulphate proteoglycans (HSPGs) are enriched in the liver within the space of Disse, one may speculate that HBV is trapped by liver-specific HSPGs, serving as low-affinity receptors similar to the interaction and entry of apolipoprotein E lipoprotein remnants by liver HSPGs<sup>[69]</sup>. Specific entry of the virus may subsequently require passage to a yet undefined high affinity receptor(s), which can be blocked by the acylated preS1-derived peptides.

## FUNCTION OF THE PRES2 DOMAIN

The M protein of HBV is not essential for infectivity<sup>[70]</sup>, although antibodies against the N-terminal part of preS2 inhibited almost completely HBV infection in PTH cultures<sup>[33]</sup>. Similar results were reported for polyclonal antisera against HBV preS2 peptides (residue 1-24) *in vivo*<sup>[71]</sup>. The preS2-domain is present in both M- and L-protein (Figure 2A). However, due to the cytosolic orientation of the preS-domain in L-protein, N-glycosylation at Asn-4 of the preS2-domain occurs

only in the M-protein<sup>[16,72]</sup>. In accordance with this, one of several preS2-antibodies (Q19/10), recognizing aa 1-6 in a glycan dependent manner, strongly bound to the N-terminal part of preS2, but showed the lowest neutralisation potential of all preS2-mabs used in the study<sup>[33]</sup>. Possibly, the preferential binding of mab Q19/10 to the preS2-domain of MHBs is responsible for the strongly reduced neutralisation potential, which is in agreement with the dispensability of MHBs for infectivity<sup>[70]</sup>. Furthermore, the HBV M-protein is not essential for infectivity of hepatitis delta virus<sup>[73]</sup>. A direct role of the N-terminal part of preS2 domain of L-protein for infectivity is still under debate. The carboxyterminal part contains a cell permeable translocation motif (TLM), which was suggested to be involved in HBV entry (Figure 2B)<sup>[74]</sup>. However, recombinant HBV variants with disturbed or lacking TLM sequence within the preS2 domain of LHBs are still infectious in PHH cultures<sup>[75]</sup>. The dispensability of the TLM sequence during the entry process of HBV was also detected using the hepatitis delta virus system that uses HBV surface proteins for viral entry. The infectivity of recombinant hepatitis delta virus, containing only the large and small HBV surface proteins, was not affected by the absence or presence of a TLM-sequence within the preS2-domain of the LHBs (Sureau *et al*, Taylor *et al*, personal communication).

## FUNCTION OF THE S-DOMAIN

The observation that binding of HBV surface proteins to PTH cultures could be inhibited specifically by myristoylated preS1 peptides<sup>[34]</sup> argues against a predominant role of the S-domain in initial binding to hepatocytes. PreS1-rich subviral particles from human plasma bound specifically to more than 70% of cultured primary hepatocytes<sup>[33,34]</sup>, while subviral particles containing only S-protein, did not<sup>[34]</sup>. Addition of the preS1-sequence 2-48 to the S-domain of these particles restored the binding to PTH up to wild-type levels<sup>[34]</sup>. The main function of the S-domain is morphogenesis, but it contains several elements that participate in entry. The main point is that antibodies against the S-domain (as generated by current S-containing vaccines) could neutralise infection *in vivo* and *in vitro*<sup>[33,76-78]</sup>. Furthermore, the presence of escape-mutants in HBV-infected patients positive for anti-HBs<sup>[79,80]</sup> demonstrates the importance of the antigenic domain (residue 100-170) of SHBs for viral spread *in vivo*. Since the S-domain does not contribute directly to binding, the question arises how these antibodies are able to neutralize infection. The S-domain contains 8 Cys residues within the antigenic loop that form inter- and intramolecular disulfide bonds<sup>[81,82]</sup>, resulting in high molecular weight multiprotein complexes<sup>[83]</sup>, while the preS-domain does not contain Cys and forms linear epitopes. We found that a mab recognizing a conformational S-epitope could completely neutralise infection of PTH, while a mab recognising a linear S-epitope failed to inhibit infection completely (90% inhibition)<sup>[33]</sup>. Therefore, distinct amino acids within the correctly folded antigenic loop of the S-domain might be essential for the uptake process of HBV leading to productive infection. Support for this

assumption comes from infection experiments with HDV, carrying mutant HBV S-proteins in their envelopes. Although short internal deletions, within the antigenic loop of the S-domain (residues 104 to 163), had no effect on HDV morphogenesis, virions with S-deletions between residues 118 and 129 showed reduced infectivity on PHH and HepaRG cells. Single amino acid exchanges within this domain revealed a sequence 119 to 124 (GPCRTC) to be most important for infectivity<sup>[52]</sup>. This domain contains a CXXC-motive, known to be the active site in protein-disulfide isomerase and related enzymes, involved in catalyzing disulfide-bridge exchanges. In murine leukaemia virus surface proteins, the receptor-binding subunit (SU) domain contains a CXXC motive that is activated after receptor-binding of the envelope transmembrane (TM) subunit. This leads to isomerisation of SU-TM disulfide-bonds and fusion-activation within the TM subunit<sup>[84,85]</sup>. Whether a CXXC-motive is actively involved in fusion in the case of HDV or HBV, or whether this region binds to a (co)-receptor, is currently unclear.

A clear function in entry can be ascribed to the first transmembrane sequence of the S-domain. It has sequence similarity to type 1 fusion peptides and replacement of the corresponding sequence in influenza virus hemagglutinin with HBV transmembrane sequences confers hemifusion activity of the resulting chimeric influenza virus hemagglutinin<sup>[86]</sup>. As recently proven for DHBV only the S-domain of the L-protein but not the S-protein itself provides the function of fusion<sup>[87]</sup>. This observation suggests that the topology of the S-domain in L-protein is different from that of the S-protein. For HBV, this difference is also recognizable in the glycosylation pattern. 50% of SHBs, 30% of MHBs, but 90% of LHBs are N-glycosylated in the S-domain<sup>[6]</sup>.

## EARLY EVENTS IN DHBV INFECTION

For more than 20 years, the duck hepatitis B virus model system was successfully used to study hepadnaviral replication. Until recently, one of the exclusive advantages of this system was the possibility to systematically investigate the early events of infection. Even though difficult, a routine preparation of PDH from newly hatched Pekin ducklings, or embryonic hepatocytes from fertilized eggs, has been successfully established in many laboratories to perform *in vitro* infection and infection inhibition studies<sup>[51,88]</sup>. Guided by the supposition that insights into the DHBV entry process also illuminate the HBV early infection events, a series of studies have been performed, however, only some of them provided satisfactory answers so far. In the following pages we would like to concentrate on the following major issues: (1) What are the roles of the two multifunctional viral envelope proteins, L and S, in entering the hepatocyte and which of their subdomains are involved? (2) Which cellular components have been described to be functionally implicated in these processes? (3) How and where does fusion of the viral and cellular membranes occur and which part of the viral envelope protein acts as a fusion promoter? (4) Which endocytic route is mandatory for the virus in order to productively deliver its nucleocapsid

to the nucleus? (5) What determines host specificity of avian hepadnaviruses? (6) Why is the susceptibility of cells towards DHBV infection restricted to differentiated, resting hepatocytes? (7) Finally, taking into account the first functional insights into the HBV entry processes using the recently established *in vitro* systems (HepaRG cells and PTH), we would like to critically scrutinize the question whether there is justified hope that further insights into the DHBV entry processes are relevant for HBV, especially regarding the development of inhibitors for infection.

## THE ROLE OF THE DIFFERENT ENVELOPE PROTEINS IN DHBV ENTRY

Soon after the discovery of DHBV and the possibility of replicating the virus *in vitro* using PDH<sup>[89,90]</sup>, several groups characterized DHBV structural proteins biochemically and immunologically, including those that constitute the membranous envelope<sup>[91,92]</sup>. One approach was the recombinant expression of DHBV-preS fusion proteins to generate antisera. These sera detected two unglycosylated 35 and 37 kDa envelope proteins (the L-protein and its phosphorylated form), co-immunoprecipitated a 17 kDa protein under native conditions (which was identified as the DHBV S-protein by microsequencing) and were able to neutralize DHBV infection *in vitro*<sup>[92,93]</sup>. Further investigations concentrating on posttranslational modifications of L- and S-proteins and the possible functional implications for DHBV replication revealed, that the N-terminal Glycin-2 of the preS-domain of the DHBV L-protein becomes myristoylated during protein synthesis (Figure 2A)<sup>[94]</sup>. In addition to myristoylation the DHBV L-protein becomes partially phosphorylated preferentially at Serin 118 in its preS-domain (Figure 2B)<sup>[11,95,96]</sup>. Both modifications are not required for assembly and secretion of virions. However, while mutations in the phosphorylation sites did not interfere with infectivity of DHBV *in vitro* and *in vivo*<sup>[97]</sup> the prevention of myristoylation resulted in a loss of infectivity of the mutant in ducklings and a drastically reduced potential to infect PDH *in vitro*<sup>[94]</sup>, (our unpublished results). These findings indicate that at least parts of the DHBV-preS domain, including its N-terminal modification by myristic acid, are involved in virus entry. Functional epitope mapping of mouse mabs obtained after immunization with DHBV particles or recombinant proteins supported this idea<sup>[93,98-104]</sup>. Three epitopes within the preS domain recognized by neutralizing antibodies were characterized, the first one covering a central part including amino acids 82-109, the second one including a more N-terminal part, amino acids 12-30, and a third part between amino acids 123-137.

The first direct evidence for the participation of the preS-domain of the DHBV L-protein for virus entry came from infection competition experiments using recombinant SVPs composed of only the DHBV L- or DHBV S-protein. These particles were purified from yeast and displayed significant differences in their ability to compete with DHBV infection of PDH with only the L-particles being active<sup>[105]</sup>. The investigators further showed that only the preS/S-containing particles bind

hepatocytes, supporting the view that the preS-domain as a part of DHBV L plays a pivotal role in attachment and infection of hepatocytes. Following this experimental strategy, Urban *et al* demonstrated that *E. coli*-derived preS-polypeptides, devoid of both the N-terminal myristoyl moiety and the hydrophobic TM-containing S-domain, specifically inhibit DHBV infection *in vitro* with IC<sub>50</sub>s of about 800 nmol/L. Using a set of terminal and internal deletion mutants it became evident that an uninterrupted innermost preS-domain (amino acids 30-115), including epitopes recognized by neutralizing antibodies, is required for infection inhibition. Since the preS-polypeptide derived from the heron hepatitis B virus (HHBV) also competed with DHBV infection (despite an amino acid variation of 50%), it was evident that the addressed step cannot be responsible for the observed species specificity (see below) between these two avian hepadnaviruses. The striking correlation of the infection competition activity of DHBV-preS polypeptides with their ability to bind duck carboxypeptidase D (including the binding of HHBV preS to dCPD) suggested that it is this molecule which is addressed and inactivated at the surface of hepatocytes<sup>[106,107]</sup>. Interestingly a second peptide, consisting of the N-terminal 41 amino acids DHBV preS, devoid of CPD-binding and requiring myristoylation of Gly-2 for efficient inhibitory activity (IC<sub>50</sub> = 200 nmol/L), was identified subsequently<sup>[57]</sup>. Pre-incubation experiments showed that the peptide addresses a cellular component. Antibodies raised against this peptide and recognizing amino acids 12-23 were able to efficiently block DHBV infection and immunoprecipitate particles indicating that this N-terminal preS-part is exposed on the particle surface and required for infection<sup>[108]</sup>.

Until today, little is known about the role of the DHBV S-protein in DHBV entry. In contrast to the HBV S-protein, DHBV-S is smaller and does not include the antigenic loop, called *a* determinant, which bears epitopes involved in the protective immune response acquired upon vaccination against HBV. Indirect evidence for the involvement of DHBV-S in entry came from the observation that antibodies recognizing the DHBV S-protein, although rarely induced by immunization with DHBV particles<sup>[92]</sup>, can neutralize DHBV-infection of PDH<sup>[100]</sup>. However, it is not clear if the antibodies directly prevent molecular contacts needed for infection or if they interfere with the formation of preS-dependent interactions by steric hinderance. Both single point mutations within TM-1 of S, resulting in a reduction of hydrophobicity, or the complete replacement of DHBV TM-1 by the HBV TM-1 had no effect on DHBV infectivity (in contrast to the effect the same mutations had when introduced in the TM-1 of L)<sup>[100]</sup>. It has recently been shown that, besides L- and S-proteins, the DHBV envelope contains a third 10 kDa membrane protein termed S<sub>i</sub><sup>[8]</sup>. It is a truncated version of the DHBV S-protein, consisting of TM-1, the internal cystein loop and a part of TM-2. S<sub>i</sub>, however, seems to play a key role as a chaperone in L-protein translocation. Unfortunately, to date, no further systematic approaches aiming to identify S-specific amino acids that lead to non-infectious virions have been undertaken.

## CELLULAR MOLECULES INVOLVED IN DHBV ENTRY

Based on accumulating evidence that the preS-domain plays crucial roles in DHBV infection and also possibly mediates binding to the hepatocyte, Kuroki *et al*<sup>[109]</sup> performed a biochemical approach for receptor identification and detected a 180 kDa membrane protein in <sup>35</sup>S-labeled duck hepatocyte extracts that co-immunoprecipitated with DHBV particles or recombinant envelope proteins. They showed that binding requires only the DHBV-preS part and can be inhibited by neutralizing preS-antibodies. Continuous work by this group and independent efforts by Tong *et al* using GST-preS fusion proteins for affinity purification, identified gp180 or p170 (as named by Tong and co-worker) as the prototype member of a new class of regulatory trans-Golgi network (TGN)-resident carboxypeptidases, soon afterwards termed carboxypeptidase D (CPD)<sup>[110,111]</sup>. Duck CPD (dCPD) like all other CPDs identified so far, consists of three luminal/extracellular carboxypeptidase E like domains of about 50 kDa each, one transmembrane domain and a highly conserved cytoplasmic tail required for accurate retrieval to the TGN<sup>[110,112]</sup>. While two of the three luminal/extracellular domains bind Zn<sup>2+</sup>-ions and exhibit enzymatic carboxypeptidase activity towards yet unidentified cellular proteins that cross the secretory pathway<sup>[110,113]</sup>, the membrane proximal C-domain of dCPD is enzymatically inactive and binds DHBV preS with very high affinity<sup>[110,114,115]</sup>. However, although the C-domains of human CPD and mouse CPD are homologous to each other and to the dCPD-C domain<sup>[116]</sup> they do not interact with DHBV preS. Chicken CPD, by comparison, displays only a very weak binding<sup>[117]</sup>. Interestingly Spangenberg *et al*<sup>[117]</sup> succeeded in rescuing the binding of DHBV preS to the human CPD C-domain by the introduction of a short dCPD-C domain-derived sequence (amino acids 920-949). Thus, since dCPD is essential for DHBV infection, species specificity could at least partially be explained by the potential of the viral preS-domain to bind CPD.

There is striking experimental evidence that dCPD serves a crucial role in DHBV infection: (1) recombinant DHBV-preS peptides, which are able to bind dCPD *in vitro*, are also active as inhibitors of DHBV infection in PDH<sup>[106,107]</sup>. (2) soluble dCPD as well as antibodies against dCPD block DHBV infection<sup>[115,118]</sup>. (3) adenoviral transfer of a dCPD mutant lacking the cytoplasmic TGN-retrieval signal into PDH, abolishes DHBV infection of the transduced cells<sup>[119]</sup>. (4) dCPD is greatly and selectively down regulated in DHBV infected duck livers and in infected PDH, which is a possible way to exclude superinfection<sup>[120]</sup>, although there is evidence for a second dCPD-independent mechanism<sup>[121]</sup>. (5) a set of DHBV single point mutants that are deficient in dCPD binding lost their infectivity (unpublished data). However, despite this compelling evidence, it has not been possible to render non-susceptible cell lines that support replication of the viral genome (e.g. LMH cells) susceptible by expression of dCPD<sup>[106]</sup>. This indicates that either (an) additional factor(s) is/are missing in the dCPD-transduced cell line or that the remarkable and still enigmatic dependency of

hepadnaviral infections on a resting differentiated state of the hepatocyte provide additional constraints that must be overcome as well.

Following the identification of dCPD as a putative DHBV-receptor, extensive work from several groups addressed issues on the sequence requirements of the DHBV preS-domain in order to bind dCPD, as well as details in the mode of dCPD/DHBVpreS interaction<sup>[106,111,115,118,122]</sup>. Although the results of binding analyses are divergent to some extent, the variations are explainable by the dissimilar techniques that have been applied by the different authors. All findings, however, indicate that a central preS-sequence including amino acids 87-115 (containing major epitopes recognized by neutralizing antibodies) is indispensable for dCPD binding (Figure 2B). The disturbance of the integrity of this sequence abrogated binding entirely. Using quantitative real-time surface plasmon resonance spectroscopy, it became clear that sequences located N-terminal to this essential part (including amino acids 30-86) contribute to the complex stability in a sequence dependent manner, making the interaction of DHBV preS and the C-domain of dCPD to one of the strongest interactions between a viral ligand and a cellular protein<sup>[115]</sup>. Concerning the mode of interaction, two aspects are noteworthy: First, binding of preS induces conformational changes not only in the viral ligand but also in dCPD. Together with the unusual finding that preS binding to the dCPD C-domain occurs in close proximity to the cellular membrane, the preS-induced dCPD conformational changes indicate that dCPD may play an important role in the fusion of the viral and cellular membrane. If this holds true DHBV entry into hepatocytes would exemplify a novel type of a viral entry mechanism, involving the recruitment of a cellular protein to act as a fusion mediator. However, this hypothesis remains to be supported. Secondly, an extensive 2D NMR structural analysis of the DHBV preS-subdomain that binds dCPD (amino acids 30-115) revealed a mostly unstructured protein with only a short sequence within the essential binding site (amino acids 89-104,) exhibiting the tendency to form an alpha helix (Figure 2B). This is consistent with the observation that a DHBV preS-polypeptide can be treated repeatedly with denaturing agents without losing the ability to bind dCPD with an unaffected  $K_D$  of 1.5 nmol/L at 37°C<sup>[115]</sup>. Thus, the dCPD-binding domain of DHBV represents the first example of a viral protein belonging to the group of intrinsically unstructured/disordered proteins<sup>[123]</sup> and in that way differs from the well ordered structures found on the surfaces of other enveloped viruses; e.g. influenza virus hemagglutinin or HIV gp120. Structural analyses performed with the whole HBV preS1-polypeptide, as well as with myristoylated N-terminal preS1 peptide fragments, lead to similar results (unpublished data).

Immunization of mice using whole duck hepatocytes and subsequent screening of mAbs with respect to their potential to inhibit DHBV binding to and infection of PDH, Guo and Pugh isolated two IgMs exhibiting both activities<sup>[124]</sup>. They immunoprecipitated a 55 kDa cellular protein that is also detectable in other tissues of ducks and in other birds. Unfortunately, this interesting observation

has not been followed up and it therefore remains an open question if the 55 kDa protein represents a primary attachment factor that might be part of the viral entry machinery into hepatocytes.

Following the identification of dCPD as a putative receptor Li *et al.*<sup>[125]</sup> identified a 120 kDa protein preferentially found in liver, pancreas and kidney that displayed binding activity only to some N-terminally and C-terminally truncated variants of GST-preS fusion proteins. Binding depends on the two crucial arginine residues at positions 101 and 102. Purification and mass spectroscopic analysis of p120 identified it as the P-subunit of glycine decarboxylase (GDC), which is an enzyme involved in mitochondrial amino acid metabolism<sup>[126]</sup>. Recombinant expressed GDC was located to some extent at the cell surface and bound truncated preS-fusion proteins with comparable specificity as the endogenous GDC. Downmodulation of GDC-levels in PDH, either by prolonged cultivation or expression of antisense RNA, resulted in a reduced susceptibility towards infection. Duck GDC has therefore been proposed to act as a co-factor in DHBV infection after proteolytic processing of the DHBV L-protein<sup>[127]</sup>. Although, the proposed concept of proteolytic activation of the L-protein during entry is attractive, the role of GDC in DHBV infection cannot be exclusive since a DHBV mutant carrying the point mutation R101H is fully infectious, although the respective mutation abolished binding to GDC<sup>[108]</sup>.

## MOLECULES INVOLVED IN MEMBRANE FUSION OF DHBV WITH THE HEPATOCYTE MEMBRANE

In contrast to viruses enclosing type 1 fusion proteins on their surface (e.g. HIV, Influenza, Ebola virus), hepadnaviruses do not encode a classical fusion peptide sequence, which becomes proteolytically released from an envelope protein precursor during secretion. It has therefore been hypothesized that instead they use the internally located hydrophobic transmembrane domain 1 (TM-1) as a fusion peptide, similar to the type 2 fusion proteins found in HCV, and alphaviruses<sup>[128]</sup>. Evidence for this assumption came from experiments with DHBV subviral particles that, upon low pH-treatment, expose hydrophobic domains on their surface, thereby increasing their ability to bind membranes<sup>[129]</sup>. An elegant subsequent analysis, including reverse genetics, demonstrated that lowering the hydrophobicity of TM-1 in the L- but not the S-protein through alanine substitutions resulted in a loss of DHBV infectivity<sup>[87]</sup>. Thus, TM-1 serves (a) distinct function(s) in DHBV L- when compared to the DHBV S-protein, with clear involvement in the fusion process on the part of the L-protein.

Subsequent to the observation that a short, possibly amphipathic helix in the C-terminal part of the HBV preS2-domain consisting of amino acids 41-52 is capable of translocating fused proteins, such as GFP or nucleic acids across cellular membranes<sup>[74]</sup>, Stoeckl *et al.* predicted two such structural motifs (called trans-location motifs, TLM) also in the N-terminal third of the DHBV preS-domain

(amino acids 20-31 and 42-53, Figure 2B). These two sequence elements are notably conserved among all avian hepadnaviruses. Amino acids 22-41 have previously been shown to be important for a dCPD-independent inhibition of infection mediated by myristoylated DHBV and HHBV preS-peptides<sup>[57]</sup>. Exchange of 4 highly conserved amino acids in the first motif (D1-mutant) or 3 conserved amino acids in the second motif (D2-mutant) or the concurrent exchange of 7 amino acids (D-1/D2-mutant) resulted in a reduced secretion (D1 mutant) and a loss of infectivity (all mutants) in embryonic hepatocytes, emphasizing the importance of both segments for infection. Interestingly, all mutants bind to and are internalized into cells but cannot be released from an endosomal compartment. This observation supports the preceding idea that the N-terminal preS-part functions at an event downstream of receptor binding and uptake. Based on the loss of the TLM-activity of the mutated sequence, the authors hypothesize that escape from the endosome does not follow a classical fusion mechanism but proceeds via direct translocation of the nucleocapsid and generalize this mechanism for all hepadnaviruses. Although attractive as a model, this hypothesis lacks direct evidence (e.g. that introduction of other TLMs, such as HIV-Tat, can replace the DHBV sequence) and is also not supported by the observation that mutated virions lacking the preS2-containing TLM of the HBV L-protein are infectious *in vitro*<sup>[75]</sup>. It is also difficult to explain how amino acids 20-53 can contribute to host discrimination between DHBV and HHBV if they provide only a functional TLM in both avian hepadnaviruses (Figure 2B)<sup>[130]</sup>. Moreover, it has been shown that amino acids 42-51 of TLM-2 as part of DHBV preS does not form an alpha-helix<sup>[115]</sup>. Thus, the inability of the described DHBV mutants to escape the endosome might be a consequence of the disruption of the interaction with the proposed co-factor and not the disturbance of a TLM-function.

## ENDOCYTIC ROUTES USED BY DHBV

Although DHBV infection of PDH is efficient with respect to the percentage of cells that can be synchronously infected, our knowledge of the endocytic routes utilized by the viral particle is still rudimentary. This relates on the one hand to the fact that resting PDH cannot be efficiently transfected by routinely used protocols, making investigations with dominant negative mutants of the endocytic pathway complicated. On the other hand, the low percentage of virus particles that bind to hepatocytes, even when high multiplicities of genome equivalents "MGEs" are offered in the medium<sup>[105,131]</sup>, requires very sensitive methods for a direct visualization of DHBV uptake in hepatocytes by fluorescence microscopy<sup>[87]</sup>. Consequently, most of our knowledge on the DHBV uptake route comes from results with chemical drugs that are known to interfere with specific intracellular events, which have previously been used to decipher entry routes of other viruses (e.g. binding to charged surface molecules, endosomal acidification, trafficking along microtubules, actin cytoskeleton integrity).

Regarding the question whether productive DHBV infection requires endocytosis and intracellular trafficking events, including acidification as a prerequisite for fusion, early experiments using the lysomotropic reagents ammonium chloride, chloroquine and monensin lead to contradictory results. While Offensperger *et al*<sup>[132]</sup> showed that infection was abolished with ammonium chloride and chloroquine, Rigg and Schaller reported the contrary<sup>[133]</sup>. Following DHBV particle uptake using confocal microscopy, Chojnacki *et al* convincingly demonstrated recently that DHBV particles co-localize with fluorescently labeled transferrin in an endosomal compartment 2 h after attachment. The addition of bafilomycin A1, which is a potent inhibitor of vacuolar proton ATPases, at different time points during/after infection clearly showed that transit to the late endosomal compartment is required for infection<sup>[87]</sup>. Within this compartment, the activation of the DHBV envelope into a fusion competent state is probably not solely triggered by a pH decrease, explaining to some extent the earlier conflicting results, but might include events like CPD-binding and proteolytic cleavage of viral surface proteins. This is consistent with the observation by Breiner and Schaller who, while successfully applying an adenoviral transduction system for PDH, demonstrated that recombinant expression of CPD-mutants lacking the complete TGN retrieval signal abrogated DHBV infection<sup>[119]</sup>. PH-independent fusion and the dependence of productive infection on endosomal trafficking events have also been confirmed by an independent study<sup>[134]</sup>. Although there is still some debate on whether the authentic DHBV uptake route into hepatocytes proceeds via dCPD or if dCPD acts at a later stage, these results allow little doubt that accurate vesicular trafficking towards the late endosome, where fusion is expected to occur, is a prerequisite for productive DHBV infection. Using a semiquantitative PCR-based binding assay and chemicals that are known to interfere either with infection of hepadnaviruses or the formation and maintenance of microtubuli and the actin cytoskeleton, Funk *et al* showed that suramin, which is a highly charged urea-derivative and well-known inhibitor of DHBV, RSV and interestingly also HDV infection<sup>[135]</sup>, decreases binding of DHBV to hepatocytes. The authors estimated the number of DHBV binding sites on hepatocytes to be about  $10^4$ /cell, which is remarkably low when compared to other viruses<sup>[131]</sup>. They further showed that infection at some post-entry step depends on microtubular integrity and that spread in cell culture proceeds via polar egress of new virions from the infected cell<sup>[136]</sup>.

## WHAT DETERMINES HOST SPECIFICITY OF AVIAN HEPADNAVIRUSES?

Hepadnaviruses are principally characterized by a narrow host range, restricting *in vivo* infections to only closely related species of their natural hosts. Well-known examples are the restriction of natural HBV infection to humans and chimpanzees. Similar observations have also been made for avian hepadnaviruses. As far as we know, productive DHBV infection exclusively occurs in Pekin

ducks. Related species, such as the Muscovy duck, do not support *in vivo* infection. This *in vivo* species specificity is to some extent reflected by the restricted susceptibility of the respective hepatocyte cultures (e.g., DHBV infects hepatocytes of Pekin ducks but not those from Muscovy ducks or chickens). Interestingly, this is not observed when replication competent viral genomes are artificially transferred into cell lines of different origin. This is best exemplified by the observation that infectious DHBV particles can be produced even in the human hepatoma cell line HuH7<sup>[137,138]</sup>. It has therefore been assumed that some early step in infection (e.g., attachment, entry, fusion) determines the host range of hepadnaviruses and that the liver specific factors needed for genome replication and virus assembly are not decisive. Comparing the binding of DHBV particles to hepatocytes from Pekin ducks with hepatocytes from Muscovy ducks or chicken hepatocytes and fibroblasts, Pugh *et al* provided evidence for this assumption showing that the difference in susceptibility corresponds to the ability to bind virions and subviral particles. The loss of susceptibility towards infection during prolonged cultivation correlated with a reduction of binding capacity of cells.

The discovery of the heron hepatitis B virus (HHBV) and its property to be not infectious for Pekin ducks and PDH<sup>[139]</sup>, opened the way to investigate host specificity on a molecular level. In that line, Ishikawa and Ganem produced pseudotyped heron hepatitis B viruses (HHBV) with envelopes consisting of HHBV-S and chimeras of the DHBV and HHBV L-protein<sup>[130]</sup>. They showed that the replacement of the HHBV-preS domain with DHBV-preS rescued the infectivity of HHBV in PDH. This indicated that the preS-domain determines host range without the need for a species-specific “cross-talk” between L- and S-proteins. Further fine mapping revealed that a sequence element containing amino acids 22-37 is sufficient to overcome host restriction *in vitro*<sup>[130]</sup>, (Ishikawa, personal communication). Similar experiments have also been performed with HBV particles that were pseudotyped with chimeric L-proteins carrying WMHBV preS-sequences. Chouteau *et al*<sup>[140]</sup> found that HBV pseudotyped with a WMHBV envelope lost their infectivity for PHH *in vitro*. However, substitution of only the first 30 amino acids of HBV preS1 could restore infectivity of the chimera, indicating that a short N-proximal region in the L-protein harbors a determinant that contributes to the species specificity of HBV.

Although these data accentuate host restriction of hepadnaviruses as a general theme of this virus family, some unexpected recent observations complicate our understanding. One observation identifies a new hepadnavirus isolated from crown cranes which, despite its close relation to HHBV, infects PDH<sup>[12]</sup>. Another observation demonstrates that primary hepatocytes from *Tupaia belangeri*, belonging to the order *Scandentia*, are susceptible for HBV infection *in vitro*<sup>[32]</sup>. Taken together, host specificity of hepadnaviruses is to some extent determined by an early step in infection involving the adaptation of the N-terminal preS-domain of the L-protein to an unknown cellular factor. Moreover, there might be additional viral and host determinants that are to

be identified.

## WHY IS SUSCEPTIBILITY TOWARDS DHBV INFECTION RESTRICTED TO DIFFERENTIATED, RESTING HEPATOCYTES?

Another hallmark of hepadnaviral infection is its restriction to differentiated resting hepatocytes. Although some attempts have been undertaken there is no proliferating cell line available that supports DHBV infection. The recently described HepaRG cell line, which is the first to support the full replication cycle of HBV, is also not susceptible in a non-differentiated state<sup>[25]</sup>. HepaRG cells become susceptible for infection only after prolonged treatment with hydrocortisone and DMSO (this process needs at least 2 wk). This induced susceptibility does not correlate with enhanced binding of HBV to differentiated cells. In fact, other hepatoma cell lines, although not susceptible towards infection, bind and accumulate HBV much better than HepaRG cells (unpublished data). This remarkable behavior is supplemented by the observation that initial amplification of cccDNA after *in vitro* infection of embryonic duck hepatocytes increases by the progression of the cell cycle<sup>[141]</sup>. Thus we have to assume that, in addition to the bare presence or absence of receptor molecules, unknown differentiation-specific and cell cycle-dependent factors of hepatic origin are important key players that are involved in early restriction events.

## DO INSIGHTS INTO THE DHBV ENTRY PROCESSES HELP US TO UNDERSTAND HBV INFECTION?

Having now readily available *in vitro* systems to study HBV infection, important questions, such as the nature of the HBV receptor(s) or the characterization of the HBV entry pathway and its inhibition, can now be studied. These investigations are influenced by the results and concepts obtained from the DHBV studies. Just a few examples shall be mentioned: (1) The establishment of transduction systems for PTH, PHH and HepaRG cells will allow us to inspect the relevance of known endocytic pathways for HBV infection. (2) Using highly purified virus preparations, we may further be able to directly follow attachment and entry using sensitive microscopic techniques. (3) The application of microarray-based gene expression profiling will help us identify genes that are becoming up- or down-regulated during differentiation of HepaRG-cells and may therefore also be important regulators of the HBV replication cycle. (4) Having a set of well characterized preS-peptides that interfere with infection, it will be possible to identify the molecule(s) they address. However, it is of utmost importance to be aware of the possible differences in the uptake strategy that might have evolved in the two genera ortho- and avihepadnaviruses with their prototypic members HBV and DHBV, respectively. Two already known examples illustrate this. First, the discovery of dCPD as an important cellular factor for avihepadnavirus infection raised the

question of whether the human homologue plays a similar role in HBV infection. We have performed extensive studies related to that question (e.g., an infection inhibition experiment using soluble human CPD or anti-human CPD antibodies, investigations on whether transfection of human CPD promotes uptake of purified HBV, binding assays using HBV preS and human CPD *etc.*). None of these experiments gave any hint that this molecule is involved in HBV infection (unpublished data). Secondly, Chojnaki *et al*<sup>[87]</sup> provided unquestionable evidence that DHBV infection depends on the intracellular transport of virions from the early to the late endosome and is thereby blocked by bafilomycin A1. In contrast, HBV infection of HepaRG cells is not influenced by this drug (unpublished results) indicating, along with other evidence, that the two hepadnaviruses enter hepatocytes via different endocytic pathways.

## PERSPECTIVES

Since the cloning of the HBV genome, and the discovery of related viruses in the animal kingdom, many aspects of the hepadnaviral life cycle have been unravelled with the help of established hepatoma cell lines and the transfection of replication competent genomes. These cell lines were, however, not suitable for infection experiments, possibly due to the lack of one or more unknown factors required for infection. A huge and still growing list of binding partners for HBV and DHBV have been reported since then, however, none of them have been convincingly shown to be related to HBV infection, and only Carboxypeptidase D has been shown to play a crucial role for the infection of avihepadnaviruses. For over 20 years, primary human hepatocytes were the only possible *in vitro* system for studying HBV infections, which created strong limitations. These limitations have become obsolete with the discovery of the HepaRG cell line and the usability of PTH instead of PHH to study HBV infection in an accurate manner. Although both systems bear their specific difficulties (e.g., Tupaias have to be bred in captivity, and HepaRG cells require a laborious protocol in order to render them susceptible for infection) this should be manageable.

With these models it will be possible to characterise cellular attachment factors and entry receptors for HBV. It will further be possible to decipher the entry pathway(s) of HBV and thereby to relate this important pathogen to other viruses.

In light of the discovery of a crucial domain within the preS1 part of the L-protein, the available HBV vaccines have to be improved. Although the current vaccine has been shown to be safe and effective, it consists only of S-protein containing recombinant particles and relies solely on the generation of protective antibodies recognizing this part of the viral surface protein, which as we now know do not counteract binding of the virus to its target cells. This allows the emergence of escape mutants, frequently arising especially under antiviral therapy, with reverse transcriptase inhibitors (e.g. lamivudine). Inclusion of the preS1 sequences into vaccines should therefore directly protect against infection.

The discovery of HBV preS1-derived lipopeptides as potent inhibitors of HBV entry will not only stimulate further investigations aiming to decipher the early infection events, they also represent a novel antiviral approach for the treatment of acute and chronic hepatitis B and hepatitis delta, similar to the HIV-peptide entry-inhibitor T20 (also called *enfuvirtide* and *fuzeon*). However, compared to T-20, the most active HBV inhibitor (HBVpreS/2-48<sup>stearyl</sup> and also called Myrcludex B) approximately displays a 1000 fold higher specific activity. This substance, which is presently under preclinical development, could be very useful for post-exposure prophylaxis or the inhibiting of re-infection after liver transplantation. Whether efficient entry inhibition will also be beneficial in the treatment of chronic HBV and HDV infections, alone or in combination with current therapies, is an interesting objective to be addressed in a clinical trial in the near future.

### Abstract

For genome multiplication hepadnaviruses use the transcriptional machinery of the cell that is found within the nucleus. Thus the viral genome has to be transported through the cytoplasm and nuclear pore. The intracytosolic translocation is facilitated by the viral capsid that surrounds the genome and that interacts with cellular microtubules. The subsequent passage through the nuclear pore complexes (NPC) is mediated by the nuclear transport receptors importin  $\alpha$  and  $\beta$ . Importin  $\alpha$  binds to the C-terminus of the capsid protein that comprises a nuclear localization signal (NLS). The exposure of the NLS is regulated and depends upon genome maturation and/or phosphorylation of the capsid protein. As for other karyophilic cargos using this pathway importin  $\alpha$  interacts with importin  $\beta$  that facilitates docking of the import complex to the NPC and the passage through the pore. Being a unique strategy, the import of the viral capsid is incomplete in that it becomes arrested inside the nuclear basket, which is a cage-like structure on the karyoplasmic face of the NPC. Presumably only this compartment provides the factors that are required for capsid disassembly and genome release that is restricted to those capsids comprising a mature viral DNA genome.

### INTRODUCTION

Eukaryotic cells are divided into different compartments and viruses have to get access to the compartment that provides the cellular machinery for replication. Unlike bacteriophages that "just" have to pass the bacterial wall and membrane all viruses that infect eukaryotic cells have to travel through the cell to reach the place of replication. Dependent upon the virus and the type of genome, the machinery of DNA replication, transcription and RNA processing may be required. Gaining access to the nucleus where these factors are found requires active transport since passive diffusion is ineffective.

Although summarized by the term "intracellular transport" one has to differentiate between the intracytoplasmic transport towards the nucleus and the passage through the nuclear envelope into the karyoplasm. Nucleic acids are not karyophilic *per se*. Thus proteins attached to the viral genome must interact with cellular factors that facilitate the different transport processes. As intracytosolic and nuclear transport are based on different mechanisms it is evident that the interacting domains on the viral proteins have to be exposed in a coordinated manner. Moreover an effective virus, meaning a virus with a good particle-infectious unit ratio, has to release its genome from surrounding proteins only after termination of the various transport steps preventing abortion of the infection process. It has to be considered that the analysis of the underlying principles is not only important for analysis of potential drug targets for treatment of individual viral infections but also for creation of efficient vectors in gene therapy.

### OVERVIEW ON INTRACYTOSOLIC TRANSPORT PRINCIPLES

The need for active and directed intracytosolic transport results from the high viscosity of the cytoplasm. Protein concentrations of 170-350 mg/mL, RNA concentrations of 30  $\mu\text{g/mL}$ <sup>[1]</sup> and micro compartmentalization evoke a viscosity 10 to 100 fold higher than the viscosity of water<sup>[2]</sup>.

In consequence diffusion processes are enormously reduced so that only particles with diameters below 50 nm significantly diffuse<sup>[3]</sup>. Obviously such a passive movement is incompatible with efficient trafficking of organelles. Eukaryotic cells thus provide different active transport machineries that are not only used by large structures but even by small macromolecules as it was shown for the heat shock protein 90 (Hsp90)/glucocorticoid receptor  $\beta$  (GR $\beta$ ) complex<sup>[4]</sup> and the human tumour suppressor protein p53<sup>[5]</sup>. It is thus likely that structures as the HBV capsid with a diameter of 36 nm (80 % of the capsids that show a T = 4 symmetry, 20 % exhibit a T = 3 symmetry and a diameter of 32 nm<sup>[6,7]</sup>) use the same active cellular transport pathways towards the nucleus.

Most investigations on intracytosolic transport of viruses are done by adding inhibitors to cells during infection. To prevent misinterpretations it is important to realize the variety of cellular processes that are affected. Eukaryotic cells provide two active cytoplasmic transport systems based on microfilaments (MF) and microtubules (MT). Microfilaments have diameters of 5-9 nm and are double-stranded helical polymers of the ATPase actin. They form linear bundles, 2D networks and 3D gels and are most highly concentrated underneath the plasma membrane. Microfilaments are dynamic polar structures with a fast-growing plus-end and a relatively inert, slow-growing minus-end. They stabilize the cell structure and are involved in cell movement e.g. by filopodia and lamellipodia. With a velocity of 2-6  $\mu\text{m}/\text{s}$  transport via MF is slow<sup>[8,9]</sup> and generally thought to serve as the transport pathway for short distances.

Beside its role in transport actin is also involved in the internalization and/or formation of endocytic vesicles. In clathrin-mediated endocytosis a functional actin cytoskeleton enhances the internalization of the clathrin-coated vesicles but without being obligatory<sup>[10-12]</sup>. In phagocytosis and macropinocytosis local actin polymerization at the cytosolic site of the plasma membrane is required for vesicle formation as well as actin depolymerization<sup>[13-16]</sup>. Similarly, releasing of caveolin-coated vesicles into the cytoplasm depends on actin polymerization and depolymerization in caveolae-mediated endocytosis<sup>[17,18]</sup>.

Microtubules are hollow cylinders of 11-13 protofilaments made of the GTPase  $\alpha$ - and  $\beta$ -tubulin. MT are 25 nm in diameter and like MF they have a highly dynamic, fast-growing plus-end and a less dynamic minus-end, which is typically attached to a microtubule-organizing centre (MTOC). MT surround the nucleus and extend from the perinuclear MTOC to the cell periphery. They are thought to be the major long-range transport system<sup>[9]</sup> allowing a velocity of 3-5  $\mu\text{m}$  per hour (HSV 1 capsids, retrograde)<sup>[19]</sup>.

For both MT and MF two different mechanisms of transport exist (Figure 1) using polymerization (filament growth)/depolymerization (filament shrinkage) or motor proteins<sup>[20]</sup>. In the first mechanism the cargo binds dynamically *via* adapter proteins to one end of a growing or shortening filament and can be pushed or pulled in the given direction. Mitotic chromosomes for example bind at

**Figure 1** Participation of microtubules and microfilaments in transport processes. Transport processes are indicated as bold arrows. Microtubules (MT, bold lines) have a highly dynamic plus-end and a less dynamic minus-end that is located at the microtubule-organizing (MTOC). They participate in the transport of (1) organelles, e.g. endosomes, (2) direct retrograde transport of capsids via the dynein motor protein complex (adenovirus, HSV 1, parvoviruses), (3) direct anterograde transport of progeny HSV 1 capsids by conventional kinesins, and (4) participate in chromosome segregation upon mitosis. Microfilaments (MF), depicted as dotted lines participate (5) in separation of endocytic vesicles from the plasma membrane and (6) *via* polymerization in transport of e.g. *Listeria monocytogenes* and nuclear polyhedrosis virus (NPV).

its kinetochor *via* a dynein/dynactin-complex to the plus-end of the kinetochor-MT<sup>[21-23]</sup>. Depolymerization at the plus-end as well as depolymerization at the minus-end directs the chromosomes to the minus-end that is fixed at the spindle pole. Phagosomes<sup>[24,25]</sup>, macropinosomes<sup>[26,27]</sup> endosomes and lysosomes<sup>[27,28]</sup> are able to cross the cytosol by the help of a polymerizing actin tail comparable to the movement of the bacteria *listeria monocytogenes*<sup>[29-31]</sup> and the nuclear polyhedrosis virus (NPV) capsid<sup>[32-34]</sup>.

However the most commonly used transport strategy for macromolecules, mRNA, RNPs (ribonucleoprotein complexes), cellular organelles and vesicles along polar MF or MT involves motor protein complexes, namely myosins, kinesins and dyneins<sup>[20,35-38]</sup>. These cargo specific filament binding proteins exhibit a motor domain (ATPase) and move ATP-dependent and unidirectional along the stable filaments. Dependent upon the involved filament and transport direction different motor protein complexes are used. Class VI myosins are unconventional myosins which move towards the minus-end of MF<sup>[39]</sup>. They are involved in the transport of clathrin-coated vesicles from the plasma membrane into the inner cell<sup>[40,41]</sup>. Class I and class V myosins in contrast migrate towards the plus-end of MF<sup>[20,35]</sup>. Myosin I mediates transport of membranes whereas myosin V is responsible for the transport of organelles, as e.g. recycling endosomes towards the plasma membrane<sup>[20,42,43]</sup>. In addition myosin V can transport cargos along MT<sup>[44]</sup> thus linking both transport systems.

The MT specific kinesins can be distinguished upon the localization of the conserved motor domain into conventional kinesins, which have an N-terminal motor domain and that direct cargos in the anterograde direction

towards the plus-end of the MT (i.e. towards the cell periphery)<sup>[20,36]</sup>. They participate in the intracellular transport and localization of different cellular membrane organelles, as the extension of the ER (endoplasmic reticulum) from the nucleus towards the cell periphery<sup>[45,46]</sup>. In addition, conventional kinesins are used in directing progeny capsids of herpes simplex virus 1 (HSV 1) in the anterograde direction<sup>[47]</sup>.

Unconventional kinesins, which have a C-terminal motor domain move in contrast towards the minus-end of MT. They mediate axonal MT transport of vesicles and organelles<sup>[36]</sup>.

The cytoplasmic dynein is commonly associated with the cofactor dynactin (dynactin-complex)<sup>[48]</sup> transporting cellular vesicles (endosomes and caveolin-negative vesicles<sup>[49-52]</sup> and macromolecules (e.g. tumor suppressor protein p53<sup>[5]</sup>) in the retrograde direction towards MT minus-end (the MTOC). Apparently the dynein-complex is frequently used in transport of viral capsids towards the nucleus as it was shown for adenoviruses<sup>[53-55]</sup>, parvoviruses<sup>[56-59]</sup> and HSV 1 upon infection<sup>[47,60]</sup>.

## INTRACYTOSOLIC TRANSPORT OF HBV CAPSIDS

With the exception of NPV all viruses being analyzed so far make use of the MT transport system for their transport towards the nucleus<sup>[61]</sup>. This includes large viruses that have to travel long distances as the herpes simplex virus 1 (HSV 1;<sup>[47]</sup>) that has to be transported for centimeters between the axon end and the cell body and parvoviruses (18-26 nm)<sup>[56,58,62]</sup> that are below the diffusion limit inside the cytoplasm.

Evaluating the transport mode of hepatitis B virus is however not trivial as the entry mechanism is not fully understood. This is mainly caused by a lack of an appropriate and effective *in vitro* infection system that allows study of the early steps of the hepadnaviral life cycle. As described in "Viral and cellular determinants involved in hepadnaviral entry" hepadnaviruses enter the cells in vesicles<sup>[63]</sup> but do not need acidification for infection<sup>[64]</sup>. This step that normally occurs upon endocytosis has a major effect on viral structures as described for adeno- and parvoviruses<sup>[57,65,66]</sup>. The altered structure distinguishes capsids that have passed endocytosis from progeny capsids that are newly synthesized. The different exposed epitopes allow variant interactions so that incoming capsids are targeted to the nucleus while progeny capsids are not.

As such an acid-induced conformational change is missing in the hepadnaviral life cycle the viral capsids released from the endosomal pathway and the newly synthesized progeny capsids have the same structure. Consequently both types of capsid can participate in nuclear transport of the viral genome.

The restrictions of the experimental systems for analysis of hepadnaviral viral infections are most likely caused by an insufficient entry. It was thus a self suggested idea to replace the viral surface proteins by a lipid shell as it is done in protein transfection (lipofection)<sup>[67]</sup>. The lipids

fuse with the plasma membrane and release the capsids into the cytoplasm. For studying the intracellular transport of the hepadnaviral capsid lipofection has the advantage that no cellular transport vesicles are involved.

In fact lipofection of hepatoma cells yielded in a highly productive HBV infection similar to the *in vivo* efficiency.

As lipofection is independent upon receptors high amounts of capsids could be loaded on the cells. This allows one to follow the fate of the capsids and of the viral genomes by microscopical techniques<sup>[67]</sup> showing that the capsids accumulated at the nuclear envelope after 15 min. As diffusion can be assumed to take 1 h (for calculation see<sup>[9]</sup>), these data imply a directed active capsid transport towards the nucleus. Released viral genomes occurred exclusively inside the karyoplasm suggesting site-specific disintegration at the nuclear envelope. The use of the MT depolymerizing drug nocodazole inhibits accumulation of capsids at the nuclear envelope and the release of genomes suggesting that genome liberation requires transport to the nucleus.

The microscopical finding of an active MT-mediated transport towards the nucleus was supported analysing the effect of nocodazole on the hepadnaviral life-cycle. It was demonstrated that MT are essential for formation of nuclear DNA (cccDNA that occurs only after repair of the partially double stranded DNA genome within the nucleus) and for amplification of viral DNA via synthesis of progeny mature capsids.

The use of the MT transport system was confirmed in another experimental system in which capsids were injected into the cytosol of *Xenopus laevis* oocytes. Due to the longer transport distances 30 min are required for the capsids to reach the nucleus upon injection at the pole of the oocyte opposed the nucleus. Assuming a distance of 0.5 mm that has to be bridged this period is consistent with the cytosolic transport of HSV 1 capsids that traverse the cytoplasm with 3-5 mm per hour (retrograde transport,<sup>[9]</sup>). As electron microscopy was used as read-out for capsid localization these data could show that the capsids did not bind to undefined sites of the nuclear envelope but to the nuclear pore complexes (NPC)<sup>[68]</sup>. However, when anti tubulin-antibodies were preinjected the arrival of the capsids at the NPCs was inhibited confirming that even in cells only distantly related to human hepatocytes the same transport system is used.

Although conclusive, it must be considered that all the observations described above were not done in the "authentic primary" cells and that a liver-specific factor may alter e.g. the place of genome release and lead to another transport model that does not involve the capsid. However, the generation of capsids with a translocation motif (TLM) fused to the N-terminus of the capsid protein recently gave further support<sup>[69]</sup>. These capsids were still capable of encapsidating the polymerase and the pregenome so that mature DNA capsids were generated being able to initiate an HBV infection in primary human hepatocytes. Although the mode of uptake by a TLM remains controversial-directly penetrating the plasma membrane or using transporters<sup>[70]</sup>-a clear uptake of the capsids could be observed, resulting in accumulation in the

perinuclear region. This uptake was not observed when wild-type capsids were used being contradictory to most recent results of others<sup>[71]</sup>. Irrespectively of this divergence the location of the TLM capsids at the perinuclear region where the MTOC is situated supports that the MT were used for transport towards the nucleus.

An open question not being answered for any cargo that uses MT transport for reaching the nucleus is derived from the polarity and arrangement of the MT. As their minus-end is not directly located at the NPC but attached to the MTOC the cargo must cross the distance between the MTOC and the nucleus. There are observations that even for this short gap passive diffusion is not likely: HSV 1 capsids show an equal distribution around the nucleus after infection and do not accumulate at those NPCs adjacent to the MTOC<sup>[47]</sup>. However, the mechanism of this translocation remains open.

## GENERAL MECHANISM OF NUCLEAR TRANSPORT

Viruses that replicate in the nucleus of non-dividing cells have to traverse the nuclear envelope. For this reason nuclear proteins pass the nuclear pore complexes (NPCs). NPCs are large proteinaceous structures consisting of 30 different proteins<sup>[72]</sup>, collectively termed nucleoporins (Nups). Nucleoporins exist in multiples copies, forming a complex of estimated 125 MD<sup>[73]</sup>. Many nucleoporins contain distinct domains of phenylalanine-glycine (FG) repeats, which mediate the main interaction between nucleoporins and soluble transport receptors. The NPC consists of a central ring-like framework with 8-fold symmetry, representing the part of the complex that is embedded in the nuclear envelope (NE). Attached to a cytoplasmic ring moiety 8 cytoplasmic filaments form an initial docking side for transport complexes. On the karyoplasmic face, 8 fibres form the cage-like structure of the nuclear basket<sup>[74]</sup>. The central framework is a ring-like assembly built around a central pore through which the exchange of macromolecules occurs. The dimension of the nuclear pore restricts complexes to a diameter of 39 nm including their shell of transport receptors<sup>[68]</sup>; a size that is exceeded by most viruses or subviral particles.

NPCs regulate the traffic of proteins and nucleic acids into and out of the nucleus<sup>[75]</sup>. Substrates smaller than roughly 9 nm in size, including ions, metabolites and proteins, travel through the NPC in a diffusion-controlled and energy independent manner<sup>[76]</sup>.

Most nuclear cargos exhibit signals that interact with nuclear transport receptors of the importin  $\beta$  superfamily, comprising importins and transportins. All members of this family exhibit an N-terminal RanGTP-binding domain which is important for dissociating receptor and cargo (reviewed by<sup>[77]</sup>). There is a variety of different signals that are recognized as exemplified by the M9 domain, bound by transportin, polypeptides of basic amino acids that represent an importin  $\beta$  binding domain (IBB) and "classical" nuclear localization signals (NLSs) that show the consensus sequence K(K/R)X(K/R)<sup>[78]</sup>. The classical NLS does not directly bind to the transport-mediating receptor

importin  $\beta$  (Imp  $\beta$ ) but requires an adapter molecule, importin  $\alpha$  (Imp  $\alpha$ ), which connects NLS and - *via* its IBB- Imp  $\beta$ .

The driving force of nuclear import and export is determined by the different concentrations of RanGTP in the nucleus versus the cytoplasm. RanGTP that is enriched in the karyoplasm, interacts with the transport receptors of the import complex, leading to dissociation of cargo and receptor. While the cargo diffuses deeper into the karyoplasm, the RanGTP-receptor complex becomes exported to the cytoplasm.

Hepadnaviral genomes have to enter the nucleoplasm for replication. As hepatocytes are terminally differentiated cells that do not divide they cannot wait until the cell undergoes mitosis as most retroviruses-excluding HIV-do. As karyophilic proteins the capsids use the nuclear pore complex to get for access to the nucleoplasm.

## NUCLEAR IMPORT OF HEPADNAVIRAL GENOMES

Nucleic acids are not karyophilic *per se*. Therefore one or more proteins attached to the genome must interact with cellular nuclear import receptors. In case of the hepadnaviruses three models, each involving a different mediator, may play a crucial role in the nuclear import of the HBV genome: (1) The viral polymerase of the Hepatitis B virus. The enzyme is covalently attached to the viral genome and probably contains a hidden NLS. Expression of the polymerase in eukaryotic cells revealed that the protein stays cytoplasmic<sup>[79]</sup> but extraction of this complex from mature virions showed that it enters the nucleus<sup>[80]</sup>. However, the procedure of extraction requires harsh treatment and thus structure altering methods. (2) Some of the heat shock proteins as Hsc70 or Hsp90 activating the polymerase<sup>[81-84]</sup> and (3) the capsid proteins surrounding the viral replication complex.

The lipofection experiments described above, show that released viral DNA is exclusively present within the nucleus. The release is combined with the accumulation of capsids at the nuclear envelope. It thus has to be concluded that if the polymerase mediates nuclear import the release of the import complex must occur at the nuclear envelope, probably after docking of the capsids to the nuclear pore. Examples for such a pathway are the HSV 1 capsid that becomes opened upon the interaction of a penton with the NPC and adenovirus 2 that releases the complex of DNA and associated proteins at the pore<sup>[47,85-88]</sup>.

The polymerase-associated heat shock proteins may act in a similar manner. For example, the interaction with Hsc70 that exhibits a nuclear transport capacity is established<sup>[84]</sup>. The capsid-nuclear envelope interaction was more extensively investigated in cell biological assays and in microinjection experiments using oocytes of *Xenopus laevis*. Another experimental design is based on Digitonin permeabilized cells most commonly used in studying nuclear import reactions in detail. Digitonin permeabilizes only cholesterol containing membranes as e.g. the plasma membrane and membranes of mitochondria. Other membranes as the nuclear and ER membrane remain

unaffected<sup>[89]</sup>. In general adhesive cells are analysed under conditions where they attach to the surface of a glass cover slip thus the Digitonin has to be removed by washing steps. The washing removes the soluble cytosolic proteins (and some small nuclear proteins that rapidly diffuse out of the nucleus) including the cellular nuclear transport factors. Consequently these factors have to be replaced either by addition of selected import factors or in form of a cytosolic extract. However, as the nuclear transport capacity is conserved this process can be transferred to the *in vivo* situation presupposed that the subjected cargo with its modification is physiological.

Microinjection in the cytoplasm is another established technique. For electron microscopy *Xenopus laevis* oocytes are frequently used as the huge dimensions of the nucleus allow the analysis of multiple sections. Since nuclear import is phylogenetically well conserved the results are transferable to other cell types as long as no embryogenesis related processes are affected.

These assays and biochemical analyses have been used to analyse the nuclear import of the hepadnaviral genome in more detail. Using permeabilized cells it was shown that the HBV capsid protein contains an NLS within its C-terminal domain. This domain is hidden in the lumen of RNA-containing capsids expressed in *E. coli* and in eukaryotically expressed capsids devoid of the polymerase<sup>[90,91]</sup>. These capsids failed to interact with nuclei of permeabilized cells. However, the exposure of the C-terminus on the capsid surface was shown to be linked to genome maturation as *in vitro* studies revealed<sup>[90]</sup>. Interestingly, the exposure could be initiated in RNA-containing capsids expressed in *E. coli* when the C-terminus was *in vitro* phosphorylated by protein kinase C<sup>[92]</sup> or protein kinase A<sup>[93]</sup>. These observations strengthen the idea that phosphorylation and genome maturation are linked. The impact of the exposed C-termini for nuclear pore complex association becomes evident by cleavage experiments in which the C-termini were removed from mature capsids followed by subjection of the capsids to Digitonin-permeabilized cells. According with the hypothesis of a capsid-mediated NPC docking the capsids and the necessity of exposed NLS to the digested capsids failed to interact with the nuclei. Consistently with the identification of an NLS on the capsid protein importin  $\beta$  was found to be the mediator of NPC interaction, requiring importin  $\alpha$  as an adapter protein.

Most fascinating is the different import behaviour between capsids that have undergone genome maturation to a different extent. Capsids with an immature DNA genome interacted with the NPCs but remained associated with the pores while subjecting mature capsids to the permeabilized cells resulted in a nuclear capsid stain and released viral genomes within the nucleus.

Based on these data all three import models- polymerase, heat shock proteins or capsid mediation-could be true. The mature capsids could interact with the NPC releasing their genome followed by import of the genome mediated by the polymerase or heat shock proteins. The dissociated capsid subunits enter the nucleus as they apparently do in HBV infected individuals. The immature capsids could have been just more stable thus failing to

disintegrate and to release the genome.

Alternatively, only the mature capsids that expose more NLS may have become surrounded by enough nuclear transport receptors to pass a hydrophobic mesh caused by the crosslinking of hydrophobe FxFG repeats of nucleoporins. Only these capsids interact with the factors required for genome release.

To differentiate between the models further investigations were initiated to follow the fate of the capsids at the NPC. Surprisingly, electron microscopy after microinjection into *Xenopus laevis* oocytes showed that not only the mature capsids passed the pore and entered the nuclear basket but also immature capsids that apparently failed to diffuse deeper into the karyoplasm. Consistent with the experiments in permeabilized cells, RNA containing capsids did not interact with the NPCs.

For the model of nuclear import these findings implied that apparently the capsids mediated the passage through the nuclear pore into the nuclear basket. Here only the mature capsids disintegrated while the immature capsid stay arrested. Hypothetically this arrest can increase efficiency of HBV infection, assuming that genome maturation proceeds in these capsids.

## BEYOND NUCLEAR IMPORT

Hepadnaviral polymerases can only successfully synthesize the full length viral DNA when interacting with the capsid proteins. In fact, recent studies on the phosphorylation sites of the HBV capsid protein show that one serine residue (Ser 157) has to be phosphorylated for pregenome packaging while serine 164 is required for allowing DNA synthesis<sup>[94,95]</sup>. The highly efficient infections by hepadnaviruses thus imply that the genome release is well coordinated in that only capsids with a mature genome disintegrate. The factor however that apparently is only present within the nucleus remains unknown. Incubations of mature capsids with nuclear extracts failed to induce significant genome release while permeabilized hepatoma cells only require minutes to release thousands of HBV genomes per nucleus. Furthermore a liver-specific factor must be assumed as genome release is more efficient in permeabilized hepatoma- than in HeLa cells. *In vivo*, this conclusion is supported by observations of Untergasser *et al*<sup>[96]</sup>, who observed that cccDNA generation does not occur upon infection of dendritic cells with chimera of HBV and adenovirus.

Another open question is raised by the high copy number of empty capsids found in the nuclei of HBV infected hepatocytes or in hepatocytes of mice that are transgenic for HBV. Apparently they are not derived from capsids that have transported the genome into the nucleus as the half-life of the genome-as different data in the literature are (ranging from 3 d<sup>[97]</sup>, 55 d<sup>[98]</sup> to a non-relevant degradation<sup>[99]</sup>)-do not explain their frequent abundance. However, the capsid protein is strongly over expressed with regard to the number of viruses and capsids that participate in nuclear entry of the viral genome. Apparently capsid proteins have a nuclear transport capacity by their NLS, which is not hidden as long as

**Figure 2** Hepadnaviral trafficking within the cell. Capsids are drawn as grey icosahedra. Immat-Capsid, immature capsid, Mat-Capsid, mature capsid. The nucleic acid found within the capsids is depicted as a dotted line (RNA) or a full line (DNA). The arrows present movements (2, 4, 5, 8) or changes of the capsid (1, 7, 9, 10). Further explanations are given in the text.

they are not assembled to particles. Based on the results described above one must thus conclude that not capsids but the supernumerous capsid proteins or their assembly intermediates are imported. In accordance with consistent biochemical data of all groups studying the assembly process, it must be proposed that the capsid proteins do not need any other protein for assembly. The only driving force is the affinity to each other being supported by their interaction with other components as e.g. RNA. It is thus likely that after import of high numbers of capsid proteins into the nucleus the threshold concentration is reached resulting in rapid assembly to particles.

Nonetheless, one has to ask why the capsid proteins do not become arrested in the nuclear basket as the immature capsids. One can assume that assembled capsids can interact with at least eight basket proteins, most likely the nucleoporin 153<sup>[100]</sup>, that are arresting the capsid. Although the answer remains experimentally open a protein monomer in contrast is restricted to one interaction that is in competition with the thousands of proteins that pass the nuclear pore every second.

The meaning of the nuclear assembly is unsolved. It might be just a side effect caused by the intrinsic assembly ability of the capsid. However, as the capsid proteins interact preferentially with single stranded nucleic acids the assembly may prevent interference with the cellular transcription and RNA export machinery thus reducing toxicity of the virus and ensuring a long life of the

infected cell for persistent virus production.

## SUMMARIZING THE TRAFFICKING OF HEPADNAVIRAL CAPSID AND GENOME

The summary of the current knowledge on the nuclear import of the hepadnaviral genome is depicted in Figure 2. It must be considered however that there are several elements as e.g. the co-ordination of the transport processes that are yet unknown. (1) Upon genome maturation and phosphorylation the hepadnaviral capsids undergo a structural change that leads to exposure of increasing numbers of the C-termini that are part of the capsid protein. (2) The capsids are transported towards the microtubule-organizing centre (MTOC), which is located at the perinuclear region. (3) As the exposed C-terminal domain exhibits a nuclear localization signal the probability of an interaction with the adaptor protein importin  $\alpha$  increases. As in the physiological import of karyophilic proteins this complex is bound by importin  $\beta$ . Whether this acquisition already occurs during the MT-mediated transport or (4) during the unknown passage from the MTOC to the nucleus remains open. (5) Importin  $\beta$  next facilitates docking to the cytosolic fibres of the nuclear pore and translocation of the complex into the nuclear basket. (6) After dissociation of the nuclear import receptors from the capsid the capsid most likely interacts with a protein of the basket. (7) While immature capsids stay arrested and may continue with genome maturation, (8) mature capsids that are less stable release the genome with the associated proteins into the nucleus where genome repair takes place. (9) Supernumerous capsid proteins that result from disintegration can diffuse deeper into the karyoplasm where (10) they re-assemble after the capsid protein concentration reaches the threshold concentration for assembly.

## Abstract

Hepadnaviruses, including human hepatitis B virus (HBV), replicate through reverse transcription of an RNA intermediate, the pregenomic RNA (pgRNA). Despite this kinship to retroviruses, there are fundamental differences beyond the fact that hepadnavirions contain DNA instead of RNA. Most peculiar is the initiation of reverse transcription: it occurs by protein-priming, is strictly committed to using an RNA hairpin on the pgRNA,  $\epsilon$ , as template, and depends on cellular chaperones; moreover, proper replication can apparently occur only in the specialized environment of intact nucleocapsids. This complexity has hampered an in-depth mechanistic understanding. The recent successful reconstitution in the test tube of active replication initiation complexes from purified components, for duck HBV (DHBV), now allows for the analysis of the biochemistry of hepadnaviral replication at the molecular level. Here we review the current state of knowledge at all steps of the hepadnaviral genome replication cycle, with emphasis on new insights that turned up by the use of such cell-free systems. At this time, they can, unfortunately, not be complemented by three-dimensional structural information on the involved components. However, at least for the  $\epsilon$  RNA element such information is emerging, raising expectations that combining biophysics with biochemistry and genetics will soon provide a powerful integrated approach for solving the many outstanding questions. The ultimate, though most challenging goal, will be to visualize the hepadnaviral reverse transcriptase in the act of synthesizing DNA, which will also have strong implications for drug development.

## INTRODUCTION

A hallmark of hepatitis B virus (HBV) replication is protein-primed reverse transcription, related to, but mechanistically distinct from, retroviral replication. This review will focus on the various genome transformations that occur during the replication cycle, with emphasis on the cis-elements on the one hand, and the trans-acting factors known or thought to be involved on the other. A general outline of the chain of events during hepadnaviral replication has been established, mainly using transfection of cloned HBV DNA into a few suitable cell lines, and has been the subject of several reviews<sup>[1-6]</sup>. Much less clear than what happens is, however, how these various steps are achieved and regulated.

Several features of HBV make resolving such mechanistic questions exquisitely difficult: Foremost, until recently, no *in vitro* systems were available to reconstitute individual replication steps under controlled conditions; conversely, there are no simple infection systems to follow the consequences of mutation-induced *in vitro* phenotypes in the context of authentic virus replication. Secondly, for various of the viral components and mechanisms no precedents exist such that drawing conclusions *in silico*, or by analogy to experimentally more tractable systems, is of limited value. Finally, there is a general lack of structural information on the involved viral factors, in particular on P protein, the viral reverse transcriptase. Fortunately, duck HBV (DHBV), the type member of the *avibepadnaviridae*, provides a valuable model system<sup>[7]</sup>. Although it differs from HBV in some details, the general features of genome replication are highly conserved; in fact, that hepadnaviruses replicate through reverse transcription has been established with DHBV<sup>[8]</sup>. Beyond allowing feasible *in vitro* and *in vivo* infection studies, the crucial initiation step of DHBV reverse transcription has recently been

**Figure 1** Replication cycle of the hepadnaviral genome. Enveloped virions infect the cell, releasing RC-DNA containing nucleocapsids into the cytoplasm. RC-DNA is transported to the nucleus, and repaired to form cccDNA (1). Transcription of cccDNA by RNA polymerase II (2) produces, amongst other transcripts (not shown), pgRNA. pgRNA is encapsidated, together with P protein, and reverse transcribed inside the nucleocapsid (3). (+)-DNA synthesis from the (-)-DNA template generates new RC-DNA. New cycles lead to intracellular cccDNA amplification; alternatively, the RC-DNA containing nucleocapsids are enveloped and released as virions. PM, plasma membrane.

reconstituted in the test tube. On many occasions, we will therefore refer to data obtained with this model virus, and add what is available for human HBV.

## OVERVIEW OVER THE HEPADNAVIRAL GENOME REPLICATION CYCLE

Replication of the hepadnaviral genome can broadly be divided into three phases (Figure 1): (1) Infectious virions contain in their inner icosahedral core the genome as a partially double-stranded, circular but not covalently closed DNA of about 3.2 kb in length (relaxed circular, or RC-DNA); (2) upon infection, the RC-DNA is converted, inside the host cell nucleus, into a plasmid-like covalently closed circular DNA (cccDNA); (3) from the cccDNA, several genomic and subgenomic RNAs are transcribed by cellular RNA polymerase II; of these, the pregenomic RNA (pgRNA) is selectively packaged into progeny capsids and is reverse transcribed by the co-packaged P protein into new RC-DNA genomes. Matured RC-DNA containing-but not immature RNA containing-nucleocapsids can be used for intracellular cccDNA amplification, or be enveloped and released from the cell as progeny virions. Below we discuss these genome conversions, with emphasis on the reverse transcription step, and particularly its unique initiation mechanism.

### RC-DNA TO cccDNA CONVERSION

Persistent viral infections require that the viral genome be present in the infected cell in a stable form that is not lost during cell division, and which therefore can be used for the continuous production of progeny genomes. Many DNA virus genomes harbor replication origins allowing them to directly exploit the cellular replication machinery for amplification; retroviruses integrate a terminally duplicated linear version of their DNA genome into the host genome, such that it is replicated along with the chromosomes. For hepadnaviruses, the genome persists, instead, as a nuclear, episomal covalently closed

**Figure 2** HBV genome organization. The partially double-stranded, circular RC-DNA is indicated by thick black lines, with P covalently linked to the 5' end of the (-)-DNA, and the RNA primer (zigzag line) at the 5' end of (+)-DNA. The dashed part symbolizes the heterogeneous lengths of the (+)-strands. DR1 and DR2 are the direct repeats. The outer circle symbolizes the terminally redundant pgRNA with  $\epsilon$  close to the 5' end, and the poly-A tail at the 3' end. The precore mRNA is nearly identical, except it starts slightly upstream. The relative positions of the open reading frames for core (C), P, preS/S, and X are shown inside. TP, Terminal protein domain of P.

circle, i.e. the cccDNA. The circular form obviates the need for terminal redundancy in that, on the circle, the core promoter/enhancer II is placed in front of the start sites for the genomic RNAs; conversely, in typical HBV expression vectors the cloned hepadnaviral DNA is interrupted by plasmid sequences, such that the control regions need to be duplicated<sup>[9]</sup>.

Distinct features of the RC-DNA (Figure 2) are (1), only the (-)-DNA strand (with opposite polarity to the mRNAs) is complete whereas the (+)-strands comprise a cohort of less than full-length molecules; (2), the 5' end of the (-)-DNA is covalently linked to P protein; (3) the 5' end of the (+)-strand consists of an RNA oligonucleotide, derived from the pgRNA, which served as the primer for (+)-strand synthesis. For cccDNA formation, all these modifications need to be removed, and both strands need to be covalently ligated.

How this is achieved is not well understood, in particular because unambiguous cccDNA detection in the presence of excess RC-DNA is not technically trivial, not even by PCR approaches<sup>[10]</sup>. Also, whenever overlength HBV constructs are involved, e.g. upon transduction of cells with HBV carrying adeno-<sup>[11]</sup> or baculoviruses<sup>[12]</sup>, caution is indicated because homologous recombination could provide for a virus replication independent mechanism of cccDNA formation.

Direct infection avoids this problem but as yet only limited data are available. Earlier evidence obtained with the DHBV-primary duck hepatocyte (PDH) infection system suggested that the activity of the viral P protein is not required for cccDNA generation<sup>[13]</sup>; however, more recent data using infection with HBV of primary tupaia hepatocytes<sup>[14,15]</sup> indicate that reverse transcriptase inhibitors can strongly reduce, though not completely block, cccDNA formation<sup>[16]</sup>. This would be in line with a

role for P protein in the process, probably the completion of the (+)-strands. However, the other steps towards cccDNA are likely to require cellular activities, as suggested by the apparent lack of cccDNA, despite formation of infectious virions, in non-authentic host cells such as hepatocytes from HBV transgenic mice<sup>[17]</sup>. However, low level cccDNA generation in mice has been reported in certain experimental settings<sup>[18,19]</sup>.

Naturally hepadnavirus infected hepatocytes contain up to 50 or more copies of cccDNA<sup>[20]</sup>, probably in the form of histone-containing minichromosomes<sup>[21]</sup>. This amplification occurs intracellularly<sup>[22,23]</sup> in that progeny RC-DNA genomes, like the initially infecting genome, undergo nuclear import and cccDNA conversion (Figure 1). Together with the long half-life (30 to 60 d for DHBV<sup>[20,24]</sup>), this ensures that cccDNA is not lost during cell division, and even persists during effective antiviral therapy<sup>[25]</sup>. Nuclear transport, and enveloped virion formation appear to be competing events, such that late in infection, when sufficient amounts of envelope proteins become available, further cccDNA amplification ceases<sup>[26]</sup>. A recent analysis on the single cell level revealed that the cccDNA copy number in DHBV infected PDH is not uniform and fluctuates over time; about 90% of the cells contained between 1 and 17 copies, the rest more than 17 copies<sup>[27,28]</sup>. Cells with only one copy may allow segregation of daughter cells containing no cccDNA. This could explain the apparent, though probably less than complete<sup>[29]</sup>, disappearance of cccDNA during spontaneous clearance of HBV infection. However, therapeutic cccDNA elimination from the chronically infected liver remains a major issue even with the latest generation antivirals<sup>[30,31]</sup>; further investigations into the mechanism of cccDNA formation, and possibly breakdown, are clearly warranted.

## FROM cccDNA TO PREGENOMIC RNA

All known hepadnaviral RNAs, i.e. the subgenomic RNAs as well as the greater-than-genome length pgRNA and precore RNA, are transcribed by cellular RNA polymerase II (the enzyme responsible for cellular mRNA synthesis) using cccDNA as the template. All contain 5' cap structures, all are 3' terminally poly-adenylated at a common site, and all serve as mRNAs for viral gene products. Spliced transcripts do exist, and even can be packaged into progeny virions<sup>[32,33]</sup>, yet their functional role is still obscure although for DHBV splice site mutants appear to have defects<sup>[34]</sup>. The extent of splicing appears to be controlled in DHBV by a long-range RNA secondary structure<sup>[35]</sup>, and in HBV by the post-transcriptional regulatory element (PRE)<sup>[36]</sup>.

The transcript relevant for virus replication is the pregenomic RNA (pgRNA), encompassing the entire genome length plus a terminal redundancy of, in HBV, about 120 nt that contains a second copy each of the direct repeat 1 (DR1) and the  $\epsilon$  signal, plus the poly-A tail (Figure 3A). The pgRNA starts immediately after the precore initiator codon. Its first essential role is that as mRNA for the core protein and the reverse transcriptase;

**Figure 3** The pgRNA as substrate for P protein. **A:** pgRNA organization. The pgRNA is shown with some major cis-elements, i.e.  $\epsilon$  (hairpin structure), DR1, DR2, and DR1\*; DHBV, but not HBV, requires for encapsidation an additional cis-element (D $\epsilon$  region II). Binding of P protein to 5'  $\epsilon$ , but not 3'  $\epsilon$ , initiates pgRNA encapsidation and replication; **B:** In vitro priming assay. P protein with its Terminal protein (TP), reverse transcriptase (RT), and RNase H (RH) domains can be activated by reticulocyte lysate (RL), or individual factors (X, Y, Z), to bind  $\epsilon$ ;  $\epsilon$  may be supplied as small RNA covering just the hairpin structure. Upon addition of  $\alpha$ -<sup>32</sup>P-dNTPs, P uses  $\epsilon$  as template to copy 3 to 4 nt from the  $\epsilon$  bulge region; by the covalent linkage of the 5' nt to a tyrosine residue in TP, P protein becomes radioactively labeled, providing a sensitive assay for activity. In vitro priming does thus far not work with human HBV P protein and  $\epsilon$  RNA.

unlike retroviral Gag-Pol proteins, P is expressed as a separate polypeptide by an unconventional mechanism<sup>[37]</sup>. Secondly, pgRNA is the template for generation of new DNA genomes by reverse transcription. The 5' terminally extended precore RNA contains the initiator codon of the preC region and gives rise to the 25 kDa precore precursor protein of secreted 17 kDa HBeAg. It is unsuited as a pregenome, and is excluded from participating in replication on the level of encapsidation<sup>[38]</sup>.

Of note, RNA polymerase II transcription could contribute, in addition to reverse transcription, to hepadnaviral genome variability. Its extent is, however, unclear because the error rate of RNA polymerase II is not firmly established and strongly affected by some of the subunits in the holo-enzyme complex<sup>[39,40]</sup>.

## CAPSID-ASSISTED REVERSE TRANSCRIPTION OF pgRNA

The next crucial step in hepadnaviral replication is the specific packaging of pgRNA, plus the reverse transcriptase, into newly forming capsids. Key actors are cis-elements on the pgRNA, most notably the encapsidation signal  $\epsilon$ , and P protein which binds to  $\epsilon$ . This interaction, in a still poorly understood fashion, mediates recruitment of core protein dimers and thus leads to packaging of the pgRNA-P complex. Remarkably, the precore RNA is not packaged although it contains all of the sequence comprising the pgRNA. Likely, active translation from the upstream precore ATG through the  $\epsilon$  sequence prevents the P- $\epsilon$  interaction<sup>[38]</sup>. This implies, in turn, that P binding to  $\epsilon$  on the pgRNA interferes with

translation of the core ORF, and evidence supporting this view has been forwarded for DHBV<sup>[41]</sup>.

Once pgRNA and P protein are being encapsidated a second key function of the P- $\epsilon$  interaction is brought to bear, namely the initiation of reverse transcription. At this stage the first DNA nucleotide (nt) is covalently linked to P protein, extended into a complete (-) strand DNA, and (+) strand DNA synthesis ensues, giving rise to a new molecule of RC-DNA; the various immature DNA forms *in statu nascendi* are termed replicative intermediates, visible as a broad multiple band pattern in Southern blots from intracellular DNA.

Completion of reverse transcription before leaving the cell marks another fundamental difference to retroviruses which, except for foamyviruses<sup>[42]</sup>, are secreted as virions containing two copies of RNA; an evolutionary rationale may be that DNA synthesis in the infected cell allows hepadnaviruses the intracellular genome amplification cycle as an alternative to proviral integration for stable virus genome propagation. Yet another difference is that hepadnaviral reverse transcription occurs largely, if not exclusively, in intact nucleocapsids rather than in retrovirus-like reverse transcription complexes which typically lack a continuous core shell<sup>[43,44]</sup>.

Although compartmentalization of the genome amplification process is emerging as a common theme of several classes of RNA and reverse transcribing viruses<sup>[45]</sup>, the hepadnaviral strategy appears as an extreme variation, considering the space restrictions imposed on the replicating complex inside the geometrically defined capsid lumen. Either the RT must slide along the entire 3 kb template, or the template must be pulled through the RT's active site; at the same time the nucleic acid is most likely in contact with the Arg-rich C termini of the core protein subunits. In fact, capsids from core protein variants lacking part of this region still package pgRNA but appear unable to produce full-length RC-DNA; instead they preferentially reverse transcribe the fraction of spliced genomic RNAs<sup>[46,47]</sup>. Phosphorylation/dephosphorylation events at the S and T residues in the nucleic acid binding domain clearly accompany genome maturation<sup>[48]</sup>, and mutations affecting the core phosphorylation status<sup>[46,49]</sup> can influence DNA synthesis in various ways. Outside capsids, or in the absence of core protein, apparently no full-length DNA can be formed.

Together these observations support the view of the capsid as a dynamic replication machine. A recent cryo electron microscopic comparison between recombinant, bacterial RNA containing capsids and authentic genome harboring nucleocapsids indeed showed some structural differences<sup>[50]</sup>; a complementary study on mutant recombinant cores revealed an enormous flexibility of the capsid structure<sup>[51]</sup>. Switching between different structural states could well be involved in supporting the progress of DNA synthesis.

The heterogeneous lengths of the (+)-strand DNAs generated by capsid-assisted reverse transcription may result from a non-identical supply of dNTPs inside individual nucleocapsids at the moment of their enclosure by the dNTP-impermeable envelope. This predicts

that intracellular cores produced in the absence of envelopment should contain further extended (+)-DNAs. Alternatively, space restrictions in the capsid lumen could prevent (+)-strand DNA completion; in this view, further (+)-strand elongation after infection of a new cell might destabilize the nucleocapsid and thus be involved in genome uncoating.

## CIS-ELEMENTS AND TRANSACTING FACTORS ESSENTIAL FOR HEPADNAVIRAL REPLICATION

The absolute requirements for replication are a template nucleic acid, plus an enzyme that is able to read the template information and use it for synthesis of a complementary nucleic acid. Clearly, these basic components are the pgRNA (and later the (-)-strand DNA) and P protein. However, generation of a functional genome also depends critically on precise start and end points, provided by cis-elements on the template (Figure 3A); a further specialty of P protein is its strict dependence, for activity, on cellular factors, namely heat shock proteins (Hsp's) or chaperones (see below).

Most initial knowledge on the cis- and trans-factors involved in hepadnaviral replication was derived by transient transfection of mutant viral genomes into stable hepatoma cell lines. This system faithfully mimics several of the authentic replication steps, however its complexity precluded elucidation of many mechanistic details. The recent establishment of *in vitro* systems, culminating in the complete *in vitro* reconstitution of active DHBV replication initiation complexes from purified components<sup>[52-54]</sup>, overcame these restrictions (see below). It should be noted, however, that such minimal systems have their own limitations; for instance, the crucial role of the proper capsid environment for RC-DNA formation has not yet been modeled *in vitro*, and HBV P protein has thus far proven refractory to *in vitro* reconstitution of DNA synthesis activity. Hence which of the two approaches is more useful depends on the question addressed, and where ever possible they should be combined.

## STRUCTURE OF THE RNA ENCAPSIDATION SIGNAL $\epsilon$

The best understood cis-element on the hepadnaviral pgRNA is  $\epsilon$  (Figure 4), a stem-loop structure initially defined as the sequence from the 5' end of HBV pgRNA that P-dependently mediated encapsidation of pgRNA, and also of heterologous transcripts to which it was fused<sup>[55]</sup>; later, the P- $\epsilon$  interaction was found to constitute the first step in initiation of reverse transcription<sup>[56-58]</sup>, hence  $\epsilon$  also acts as the replication origin (Figure 3A).

The hairpin structure of  $\epsilon$  (Figure 4A) was confirmed by secondary structure analyses<sup>[59,60]</sup>, and its importance was established by following the effects of site-directed mutants on the packaging efficacy in transfected cells<sup>[59-63]</sup>. Furthermore, the  $\epsilon$  sequence is highly conserved in other mammalian hepadnaviruses, as well as between different

**Figure 4** Secondary structures of hepadnaviral  $\varepsilon$  signals. **A:** HBV  $\varepsilon$ . The entire hairpin, including in the upper stem region, is stably base-paired; formation of a stable tri-loop, as indicated, is confirmed by direct NMR analysis<sup>[68]</sup>. The conventional annotation for the loop sequence is high-lighted by grey shading. The bulge-templated DNA oligonucleotide and the priming Y63 are indicated; **B:** DHBV  $\varepsilon$ . The overall 2D structure is similar to that of HBV  $\varepsilon$ , including a largely base-paired upper stem<sup>[69]</sup>, as confirmed by preliminary NMR data. The boxed positions were randomized in a SELEX approach, and P binding individuals were selected from the corresponding RNA library<sup>[71]</sup>; **C:** HHBV  $\varepsilon$  ( $H\varepsilon$ ).  $H\varepsilon$  shows substantial sequence variation to **D:** (encircled nt), leading to a largely open upper stem structure; **D:** Generalized secondary structure of an avihepadnaviral  $\varepsilon$  signal. The scheme summarizes major determinants for productive interaction with P protein<sup>[71]</sup>. Grey background indicates nt positions that are probably in contact with protein. The bulge and its immediate vicinity, particularly the tip of the lower stem, are essential for P binding whereas the loop appears critically involved in the transition to a productive initiation complex<sup>[109]</sup>. U2590 > C or U2604 > G mutations abrogate, or strongly reduce, P binding whereas G2586 and C2594 do not affect binding but are important for priming. The major role of the nt termed N may be to provide a proper spacing to the bulge element; their sequence is not important as long as formation of highly stable base-pairing is prevented.

HBV isolates<sup>[64,65]</sup>. An illustrating example are the HBV precore variants in which HBeAg synthesis is prevented by stop mutations in the  $\varepsilon$  overlapping precore region. The only mutations causing this phenotype found in nature are those which maintain a stable  $\varepsilon$  secondary structure<sup>[66,67]</sup>.

It should be noted that RNA secondary structure (2D) analysis provides a mere description of the base-pairing pattern. Hence a true mechanistic understanding requires knowledge of the three-dimensional (3D) structure. The structure of the HBV  $\varepsilon$  upper stem, recently solved by nuclear magnetic resonance (NMR) techniques<sup>[68]</sup>, revealed that the apical loop consists actually of only 3 nt (as in Figure 4A). This analysis is currently extended to determining the 3D structure of the entire stem-loop, which seems to form a nearly contiguous double-helix (S. Flodell, M. Petersen, F. Girard, J. Zdunek, K. Kidd-Ljunggren, J. Schleucher and S. Wijmenga; submitted); of particular interest will be the structure of the bulge region which is the template for the first few nt of (-)-DNA (see below). Thermodynamic calculations as well as experimental melting curves indicate that the entire HBV  $\varepsilon$  structure, including the upper stem, is highly stable. Notably, however, in DHBV rearranging this structure is necessary for the RNA to act as a template (see below). Determining the  $\varepsilon$  RNA structure in the complex with P protein is therefore the ultimate, yet demanding, goal.

Despite limited sequence homology to HBV  $\varepsilon$ , DHBV  $\varepsilon$  ( $D\varepsilon$ ) has a similar secondary structure<sup>[69]</sup> with a bulge and an apical loop (Figure 4B), which suggested that this structure is a common trait of all hepadnaviruses. Surprisingly, the corresponding  $\varepsilon$  signal ( $H\varepsilon$ ) from the related heron HBV (HHBV) has much reduced base-

pairing in the upper stem region (Figure 4C), yet it functionally interacts with DHBV P protein *in vitro* whereas HBV  $\varepsilon$  does not<sup>[70]</sup>.

Selection, from a library of RNAs with partially randomized upper stems for individuals able to bind to *in vitro* translated DHBV P protein (see Cell-free reconstitution of hepadnaviral replication initiation) revealed the absence of base-pairing in the upper stem region as a common theme (Figure 4D)<sup>[71]</sup>. Some of the selected P-binding RNAs supported *in vitro* priming while others did not, confirming that a productive interaction, leading to DNA synthesis, requires more than mere physical binding (see below). Hence for avihepadnaviral  $\varepsilon$  signals an open upper stem structure is beneficial for both physical and productive binding to P; in fact, deliberate  $D\varepsilon$  stabilization strongly reduces P binding<sup>[71]</sup>. This is one line of evidence that structural reshaping of the upper stem is a crucial event for initiation of DNA synthesis. Independent support comes from preliminary NMR and melting curve data for wt  $D\varepsilon$  RNA, according to which the upper stem is the least stable region (F. Girard, O. Ottink, M. Tessari and S. Wijmenga, to be submitted). This marked difference to the highly stable HBV  $\varepsilon$  structure may be related to the *in vitro* inactivity of the HBV P protein<sup>[72]</sup>.

The functional consequences of mutations affecting  $\varepsilon$  and other recognized cis-elements are discussed in more detail below. Of note is, however, whereas the HBV  $\varepsilon$  stem-loop alone is sufficient to mediate encapsidation of heterologous RNAs<sup>[62,73]</sup>, DHBV pgRNA encapsidation requires additional elements. "Region II"<sup>[74]</sup>, several hundred nt downstream of 5'  $\varepsilon$ , and the intervening sequence<sup>[75]</sup> may be operative *via* long-range RNA

**Figure 5** Domain structure of P protein. **A:** Authentic DHBV P protein. Numbers are aa positions for DHBV P protein. The priming Tyr residue Y96 is indicated; **B:** Typical recombinant P protein construct. For solubility, a heterologous solubility enhancing domain (SED) such as NusA, GrpE, or GST is required, and a short stretch of C terminal aa must be removed. Deletion of the spacer has no negative effects on *in vitro* activity; **C:** Mini-RT2. This heavily truncated recombinant DHBV P protein requires mild detergent, but no chaperones for priming activity.

interactions<sup>[76]</sup>; why a similar element is dispensable for HBV pgRNA packaging is unclear.

Even HBV  $\epsilon$ , however, does not act as a completely autonomous encapsidation element. The 3' copy of  $\epsilon$  cannot substitute for 5'  $\epsilon$  in the context of otherwise authentic pgRNA<sup>[77]</sup> (although its DHBV counterpart is useable for DHBV P interaction in *in vitro* translation<sup>[78]</sup>). Furthermore, 5'  $\epsilon$  mediates encapsidation of heterologous RNAs only up to a limited distance from the 5' end (about 65 nt), and seems to require the 5' cap structure<sup>[79]</sup>. Hence the 5' cap and factors bound to it appear to have a role in the process, possibly in concert with the 3' poly-A tail and its associated cellular proteins<sup>[80]</sup>; this may explain why attempts to reconstitute encapsidation by simultaneous *in vitro* translation of P and core protein from uncapped, non-poly-adenylated RNAs in reticulocyte lysate (RL) were thus far unsuccessful.

An unexplored issue is whether the  $\epsilon$  hairpin, or other base-paired regions on the pgRNA, would be substrates for cellular dsRNA recognizing systems such as Toll-like receptor 3 (TLR3) or retinoic acid inducible gene I (RIG-I) which play important roles in innate immune responses against viral infection<sup>[81,82]</sup>, or for enzymes involved in processing of cellular hairpin RNAs such as the microRNA precursors<sup>[83]</sup>. Direct screens identified a 65 kDa nuclear protein<sup>[84]</sup> of unknown sequence and, more recently, a novel large RNA-binding ubiquitin ligase, hRUL138<sup>[85]</sup>, as potential cellular  $\epsilon$  RNA interaction partners. However, their roles in the viral life-cycle are not known. Also, any cellular  $\epsilon$ -binding factor would have to cope with the physical sequestration of pgRNA into nucleocapsids.

## P PROTEIN STRUCTURE

The P ORF, covering nearly 80% of the hepadnaviral genome (Figure 2), has a coding capacity of about 830 aa for HBV, and about 790 aa for DHBV (Figure 5). There is no indication for downstream processing of the primary translation products. In further contrast to retroviruses, hepadnaviral virions contain probably just one P protein molecule per particle<sup>[86]</sup>, in line with the covalent linkage to the genome. In transfected cells, P appears to be produced in excess, such that most molecules are not capsid associated<sup>[87-89]</sup>; they have a short half-life, and are bound to large cytoplasmic structures; their function, if any, is

unclear.

Bioinformatic<sup>[90]</sup> and genetic analyses showed the presence in all P proteins, of two conserved domains, namely the polymerase/reverse transcriptase (RT) domain, and the C-terminal RNase H (RH) domain. Both are necessary as structural components for pgRNA encapsidation<sup>[73]</sup>. An absolutely hepadnavirus-specific feature is, however, the Terminal Protein (TP) domain at the N terminus, separated from the RT domain by a highly variable, and dispensable, spacer<sup>[91]</sup>. TP was first identified as the (-)-DNA linked protein<sup>[92]</sup> and later was shown to provide a specific Y residue to which the first nt of the (-)-DNA becomes covalently linked (Y96 in DHBV TP<sup>[93,94]</sup>; Y63 in HBV TP<sup>[95]</sup>).

At present, no direct structural information on any hepadnaviral P protein is available although homology-based models for the RT<sup>[96]</sup> and RH domain<sup>[97]</sup> have been proposed. The RT model is in accord with drug resistance data, and it is supported by mutational analysis of the putative dNTP pocket of DHBV P protein where a single aromatic residue (F451) was shown to have a homologous role in dNTP versus rNTP discrimination as Y115 in HIV-1 RT<sup>[98]</sup>; replacement of the bulky F451 by smaller residues conferred to the protein a low but clearly detectable RNA polymerase activity. However, outside the active site the accuracy of the modeled structure is unknown. Hence direct structure determination of the RT and RH domains remains a major objective.

This holds even more for the TP domain, which shares no significant sequence similarity to any other protein in the data base, not even to the few other terminal proteins involved in viral genome replication, such as the VPg in picornaviruses<sup>[99]</sup>, or the terminal proteins of adenovirus<sup>[100]</sup> and the bacteriophage  $\phi$ 29<sup>[101]</sup>; moreover, those TP proteins are not covalently linked to their polymerases.

Structure determination requires a source for sufficient amounts of pure, soluble protein which proved to be immensely difficult for P protein. Eventually, this problem was partly overcome by slight modifications in the primary sequence of DHBV P and particularly by adding solubility mediating fusion partners such as GrpE, NusA, or GST<sup>[53,102,103]</sup>. However, although such fusions (Figure 5B) display activity (see below) they appear to be present as "soluble aggregates" which are unsuited for crystallization.

Particularly TP, when expressed in *E. coli*, is completely insoluble on its own, mostly due to a hydrophobic region

in the C terminal part. By selection from a pool of TP variants with random mutations we could isolate several TP variants, harboring fewer hydrophobic residues in this region, as monodispersely soluble proteins (J. Beck and M. Nassal, unpublished data). Interestingly, the same region was recently implicated to contain a molecular contact site, possibly for the RT domain<sup>[104]</sup>, as suggested by the ability of separate TP and RT/RH domains to trans-complement each other<sup>[53,95,105]</sup>. Since replacing several conserved hydrophobic regions at a time may affect TP function the challenge will be to find, for crystallization, mutants that combine solubility with functional activity. However, being at the heart of hepadnaviral replication, solving the structure of TP is one of the big current challenges.

## CELL-FREE RECONSTITUTION OF HEPADNAVIRAL REPLICATION INITIATION

Cell-free systems are inherently much more manipulatable than intact cells. The first such system to investigate the mechanism of hepadnaviral reverse transcription was based on the observation that DHBV P protein, *in vitro* translated in rabbit RL, became radioactively labeled when the translation reaction was supplied with  $\alpha$ -<sup>32</sup>P-dNTPs<sup>[78]</sup> - as expected if the initial step of reverse transcription, i.e. covalent attachment of the first nucleotide to P protein, had occurred ("in vitro priming"; Figure 3B). In fact, the 3' copy of Dε present on the P protein mRNA was shown to be the template for limited elongation; the role of ε, though only the 5' copy, as authentic genome replication origin was confirmed for DHBV<sup>[56,57]</sup>, and finally also HBV<sup>[58]</sup>.

The *in vitro* translation system has been used extensively to functionally analyze P protein as well as Dε mutants, particularly because Dε can be added as a separate short RNA covering just the hairpin structure ("trans-priming"). Human HBV P protein and ε, however, show no enzymatic activity in this setting.

## THE P-ε COMPLEX: DETERMINANTS FOR BINDING, PRIMING AND ENCAPSIDATION

A first - though not the only-requirement for a productive P-ε interaction is specific binding. In many RNA-protein interactions, structural diversity and hence specificity is achieved by deviations from a fully base-paired double-helical structure<sup>[106]</sup>, e.g. by interspersed single-stranded bulges and loops. Indeed, the Dε bulge structure (but not its actual sequence, unless it affects structure) is absolutely necessary for P binding. Mutants in the upper stem (see Figure 4B) which favor stable non-bulged structures do not bind to P<sup>[70]</sup>. Similarly critical is the sequence and structure at the junction between the lower stem and the bulge: Mutation of the unpaired U2604 opposite the bulge to G substantially reduced binding (and nearly abolished priming)<sup>[71]</sup>. At the tip base-pair of the lower stem, base identity of G2605, but not base-pairing itself, is important; in addition, most ribose residues in Dε could be replaced by deoxyribose residues, except in the two top base pairs

of the lower stem and in the bulge residue templating the first nt of (-)-DNA<sup>[107]</sup>. Hence this small region contains an essential base- and backbone dependent determinant for P-interaction (Figure 4D), likely because it forms, together with the bulge, a distinct three-dimensional recognition surface for P protein.

In the apical loop, various mutations had no drastic effects on P binding, suggesting the loop is not principally required for complex formation (though probably involved in forming a priming competent structure; see below). An exception is U2590 replacement of which by C abrogated binding<sup>[70,108]</sup>. However, deletion of this residue did not affect binding, and the negative effect of the U2590C mutation was partially rescued by an additional G to A mutation at the neighboring position 2589<sup>[61]</sup>. A direct 3D structure comparison between wild-type Dε, currently underway (S.S. Wijmenga, personal comm.), and the U2590C mutant RNA may help to explain this complex phenotype.

The existence of Dε RNA variants which bind P but have a much reduced or no template activity indicated that a productive P-ε interaction requires more than binding<sup>[61,70,71]</sup>. 2D structure comparisons of free versus P bound RNAs provide compelling evidence that the ability of an RNA to undergo a specific conformational shift is such a decisive additional feature<sup>[109]</sup>. Several base-paired nt in the upper stem of Dε become highly accessible to nucleases once bound to P; similar changes are not seen with priming-deficient variants. Hence it is likely that the RNA, after an initial binding step, must experience an induced-fit alteration into a new structure, and that only this is usable as a template. Non-productive complexes, by contrast, appear to be trapped at the initial binding stage. Foot-printing analysis further revealed that in productive, but not non-productive, complexes the 3' half of the loop plus 3' adjacent nt are protein bound, as are the unpaired U opposite the bulge and the nt at the tip of the lower stem (Figure 4D). Hence although the loop nucleotides may not be strictly required for initial binding, they probably provide a protein binding site that becomes crucial in the transition to a priming-active complex.

Also P protein undergoes structural alterations in this process. Proteolysis of *in vitro* translated DHBV P protein yielded a distinct proteolytic fragment only in the presence of priming-competent but not priming-inactive RNA variants<sup>[108,110]</sup>. Hence RNA and P protein mutually alter each others conformation, likely to properly arrange the ε template region and the priming Y residue of TP in the active site of the RT domain.

Notably, of the various P binding RNAs only those that are priming-active also support pgRNA encapsidation. Hence the abilities to initiate reverse transcription, to package pgRNA, and to adopt a distinct RNA-P protein complex conformation appear strictly coupled. In effect, this represents a quality control mechanism ensuring that only RNAs suitable as templates for reverse transcription are packaged. The current methods to analyze these replication-relevant structural changes have a very limited resolution; ultimately, biophysical examination of a priming-active complex will be required, and its

**Figure 6** Model for Hsp40/Hsp70 mediated in vitro activation of P protein. The low ATPase activity of Hsp70 is stimulated by Hsp40, yielding high substrate affinity Hsp70/ADP. A new cycle of substrate release and folding requires exchange of the ADP for new ATP which is stimulated by nucleotide exchange factors such as BAG-1. This ATP-dependent Hsp70 cycling applies to the chaperone's global folding activities but likely also to P activation: in the inactive state of P (1), the  $\epsilon$  RNA binding pocket is inaccessible; Hsp40/Hsp70 activation creates active P\* (2) which is able to bind  $\epsilon$  RNA (3); P\* is metastable, and decays to the inactive state (1) within minutes. Maintaining a steady-state level of P\* requires constant re-activation by Hsp40/Hsp70 and thus a continuous supply of fresh ATP. Complexes containing priming-competent  $\epsilon$  RNAs (3) undergo induced-fit rearrangements in the RNA and the protein, enabling them to initiate DNA synthesis upon dNTP addition (4). Several D $\epsilon$  variants bind P but do not act as template; most likely they are trapped at stage (3). The same may hold for human HBV P protein complexes with HBV  $\epsilon$  RNA.

comparison with non-productive complexes should be most revealing. However, several significant obstacles will have to be overcome for this approach, not the least being the strict dependence of DHBV P protein activity on additional cellular factors (see below).

This holds even more for active initiation complexes of human HBV. Insect cell expressed HBV P exerted a low but clearly detectable polymerase activity, with part of the DNA products covalently linked to TP as expected from authentic initiation<sup>[111]</sup>. The system revealed some important features, such as the priming role of Y63 in HBV TP<sup>[95]</sup>, trans-complementation between TP and RT/RH domains<sup>[95]</sup>, and even some nucleocapsid formation by co-expression of core protein<sup>[112]</sup>. Disturbingly, however, various of these activities were not strictly  $\epsilon$  dependent, and they could not be reconstituted after (partial) purification of the P protein. Whether insect cells contain some RNA that can substitute for  $\epsilon$  has not been clarified. *In vitro* translated HBV P protein shows no priming activity in reticulocyte lysate and not even in lysates from Huh7 cells (J. Beck and M. Nassal, unpublished data) which support replication when transfected with HBV. Recently, however, Hu *et al.*<sup>[72]</sup> reported a partial but important progress in that they were able to demonstrate specific binding-though not priming-for HBV P and  $\epsilon$  in an *in vitro* reconstitution system (see next paragraph).

## IN VITRO RECONSTITUTION OF REPLICATION INITIATION FROM PURIFIED COMPONENTS

One aspect for *in vitro* translation of P protein was, at the time, the lack of alternative ways to recombinantly produce the protein. Surprisingly, wheat germ extract versus rabbit RL translated DHBV P protein had a much reduced priming activity, suggesting the mammalian RL provided additional essential factors<sup>[113]</sup>. These turned out to be cellular chaperones, which are abundantly present in RL. Apart from Hsp60 chaperonins<sup>[114]</sup> (GroEL in bacteria), Hsp70 (DnaK in bacteria) and Hsp90 constitute the major chaperone systems. Hsp70 assists folding of many newly

synthesized polypeptides, refolding of misfolded proteins resulting, e.g., from heat-shock, and protein translocation through membranes<sup>[115-117]</sup>. Hsp90 has also broad but more specialized folding functions<sup>[118]</sup>, usually if not exclusively in concert with Hsp70; the two systems are linked *via* the Hsp70/Hsp90 organizing protein Hop. By analogy to the activation of nuclear hormone receptors<sup>[119]</sup> it was proposed that Hsp90 plus its small co-chaperone p23 are the essential factors for P protein activation<sup>[113,120]</sup>. However, the complex overall composition and the high chaperone content of RL compared to the minute amounts of P protein precluded a clear-cut distinction.

This was overcome when DHBV P protein became accessible in larger quantities by expressing, in *E. coli*, slightly modified variants<sup>[53,102]</sup>, in particular as fusions with solubility enhancing heterologous domains (Figure 5B). Such recombinant P proteins could now be added to the RL system and showed activity. Finally, because the translation function of RL was not required any longer, it became possible to systematically analyze the chaperone requirements for P protein activation with purified individual components.

In this way we could demonstrate that DHBV P can efficiently be activated *in vitro* by Hsp40 and Hsp70 plus ATP as an energy source, without the need for Hsp90 or other cofactors<sup>[54]</sup>. The primary reaction product is an RNA binding-competent form of P protein (P\*) that decays quickly in the absence of  $\epsilon$  RNA but, in its presence, accumulates in an initiation-competent form (Figure 6).

Maintaining P in its activated P\* form requires a constant supply of ATP<sup>[54]</sup>, and the same holds for the general folding activity of Hsp70<sup>[117]</sup>. This suggested that P activation represents a special form of Hsp70 mediated folding in which the chaperone, rather than helping P from an unfolded into a stable folded state, affects the equilibrium between the inactive P ground state and the metastable activated P\* form. Of note, bacterial DnaK has been shown to interact, physiologically, with a few folded, as opposed to misfolded, proteins such as the transcription factor  $\sigma 32$ <sup>[121,122]</sup>.

Hsp70 chaperoning is a cyclic ATP-driven process<sup>[117]</sup>.

Hsp70 binds ATP and in this form exerts low affinity to folding substrates (Figure 6, left). ATP hydrolysis then generates the high affinity Hsp70/ADP form. In the presence of substrate, the weak Hsp70 ATPase activity is stimulated up to 1000 fold by Hsp40 and related J-domain proteins (named after the prototypic *E. coli* Hsp40, DnaJ;<sup>[123]</sup>), explaining the important role of Hsp40. Initiating a new folding cycle requires reconversion of Hsp70/ADP into Hsp70/ATP, i.e. replacement of the bound ADP by fresh ATP; otherwise Hsp70 would be trapped and not be available for acting on new substrate molecules. Spontaneous nt exchange is slow but strongly enhanced by nucleotide exchange factors (NEFs). This predicted that addition of BAG-1, an established NEF of Hsp70<sup>[124]</sup>, to the minimal *in vitro* reconstitution system should enhance the formation of P\* molecules. Indeed, we observed a strong BAG-1 dependent increase in priming-active P molecules, but not with a BAG-1 mutant unable to interact with Hsp70. Hence ADP-ATP exchange on Hsp70 is the rate limiting step in the *in vitro* priming reaction (M. Stahl, M. Retzlaff, M. Nassal and J. Beck, submitted). A working model for the Hsp40/Hsp70 activation of DHBV P protein is shown in Figure 6.

Though these data are clear-cut, Hu and colleagues, using a similar experimental set-up though a different (i.e. GST) DHBV P fusion protein, reported that in their *in vitro* system P activation was strictly dependent on the additional presence of Hsp90 and the Hsp70/Hsp90 adaptor protein Hop, with the Hsp90 co-chaperone p23 enhancing the reaction rate<sup>[52]</sup>.

In our system, Hop and Hsp90 do have a stimulatory-but not an essential-effect (in a similar range as BAG-1), particularly at low P protein concentrations. In addition, the specific nature of the Hsp40 used can affect activation efficiency. Eukaryotic cells contain numerous Hsp40-like (or J-domain) proteins<sup>[125]</sup>; all contain the about 70 aa long J-domain which mediates interaction with Hsp70. Hsp70 activation of P protein appears to proceed selectively with the Hdj1 variant of Hsp40 but not Hdj2 or its yeast homolog Ydj1. With Ydj1, Hop and Hsp90 may become essential for detectable activation. Why different Hsp40s have different effects is currently unclear because all Hsp40s can stimulate the Hsp70 ATPase activity; however, there are different ways of how a substrate can enter the folding complex: either it is bound directly by Hsp70, or it is presented to Hsp70 by the Hsp40-like protein<sup>[123]</sup>. Therefore, the various additional domains present in different J-domain proteins could effect the formation of P\* *via* different pathways. Hence in summary, P activation *in vitro* is fundamentally dependent on Hsp70/Hsp40 but can be enhanced by additional factors, including Hop/Hsp90.

Interestingly, the strict chaperone dependence of DHBV P protein activity was relieved by an extensive C terminal truncation that removed the entire RH domain and some 75 aa from the RT domain; the only requirement for priming activity (though restricted to the very first DNA primer nt) of this truncated Mini-RT 2 protein (Figure 5C) was the presence of mild detergent<sup>[126]</sup>. This suggests that in full-length P protein C terminal parts

somehow block the  $\epsilon$  RNA binding site, and that this occlusion is removed by the chaperone action<sup>[102,127]</sup>.

Where exactly the chaperones bind to P and which conformational rearrangements they induce is unclear. Using *in vitro* translated DHBV P protein in RL Tavis *et al*<sup>[110]</sup> noted the  $\epsilon$ -dependent generation of a papain- and trypsin-resistant fragment covering mainly the RT domain. Taking advantage of the simple, defined composition of the *in vitro* reconstitution system we could directly investigate the effects of Hsp40 and Hsp70 on P protein conformation. Limited V8 protease digestion revealed specific chaperone- and ATP-dependent cleavages in the C terminal part of TP (between aa 164 and 199). Hence this TP region is inaccessible in non-activated P protein but becomes exposed in P\* (M. Stahl, J. Beck and M. Nassal, unpublished data). The functional relevance of this conformational alteration is supported by its correlation with the ability of P to bind  $\epsilon$  RNA, and the shielding of the same region from protease attack as long as the D $\epsilon$  RNA is bound; furthermore, the larger fragment encompasses two residues, K182 and R183, which are essential for RNA binding. These data support the model shown in Figure 6. Inclusion of Hop and Hsp90 in this assay should now allow one to monitor whether these, or additional factors, have differential effects on P conformation, or whether they mainly stabilize the changes already established by Hsp40/Hsp70.

Extending the scope of the *in vitro* reconstitution system, Hu and colleagues recently demonstrated that specific binding to  $\epsilon$  by the human HBV P protein also appears to be controlled by cellular chaperones<sup>[72,128]</sup>. On the  $\epsilon$  RNA side, the region immediately surrounding the bulge was essential but the apical loop was not. This was surprising given that the loop is essential for pgRNA encapsidation and initiation of replication in intact cells. However, in light of the above described DHBV data, it may just be a drastic manifestation that mere physical binding is not sufficient for a productive interaction; this is further supported in that only about half the P protein sequence was required for RNA binding, with even the catalytic YMDD motif being dispensable. Apparently, the crucial second step, which in D $\epsilon$  involves rearranging the upper stem and the loop, does not occur in the reconstituted HBV P protein- $\epsilon$  complexes, possibly due to the high stability of this region in HBV  $\epsilon$ . Finding conditions under which HBV P protein exerts authentic  $\epsilon$ -dependent *in vitro* priming-activity remains therefore another major challenge in HBV biology.

## IMPORTANCE OF CHAPERONES FOR HEPADNAVIRUS REPLICATION IN INTACT CELLS

Both the Hsp70 and the Hsp90 chaperoning activities are subject to regulation by a multitude of co-chaperones<sup>[117,129]</sup>. Hence which of the *in vitro* reconstitutible processes is the relevant one inside cells is not trivial to address, in particular because the chaperones are crucial for very many fundamental and regulatory cellular processes. For

**Figure 7** DNA primer translocation (first template switch). P copies 3 to 4 nt from the 5'  $\epsilon$  bulge, yielding the TP-linked DNA oligonucleotide which is translocated to the complementary motif in the 3' proximal DR1\*. **A:** Linear representation. DR1\* is nearly 3 kb apart from 5'  $\epsilon$  in primary sequence, and numerous other UUCA motifs are not used as acceptors.  $\phi$  denotes a newly identified cis-element with partial sequence complementarity to the 5' half of  $\epsilon$ . 3'  $\epsilon$  (light grey) is dispensable. The HBV specific sequences in the  $\epsilon$  bulge, and in DR1\* are shown below in capitals, flanking sequences in lower case; **B:** Models for juxtaposition of 5'  $\epsilon$  and DR1\*. A general mechanism would be closed loop formation<sup>[80]</sup> of the pgRNA by cap-binding and poly-A binding factors (ovals), e.g. via elongation initiation factor 4G (eIF-4G; large oval). More specifically,  $\epsilon$  might base-pair with  $\phi$ <sup>[146,147]</sup>, as indicated by the grey arrows. In such an arrangement, a small movement, rather than a big jump, of TP with the bound DNA primer (dashed outline) would suffice for specific translocation to DR1\*.

instance, geldanamycin (GA), an inhibitor of Hsp90, strongly interfered with DHBV replication in transfected cells at a concentration of 10 ng/mL whereas significant reduction of the *in vitro* priming activity required much higher concentrations<sup>[113]</sup>. Therefore, the antiviral effect in cells might be indirect, perhaps *via* one of the cellular kinases that are regulated by Hsp90<sup>[130]</sup>. Such effects on the cell make it also difficult to imagine that chaperone inhibitors could therapeutically be used against HBV infection without causing severe adverse effects. That GA analogs, nonetheless, exert tumor-specific therapeutic value<sup>[131]</sup> is probably due to the selective presence, in cancer cells, of Hsp90 in a high GA affinity state<sup>[132]</sup>. Whether this also holds for HBV infected cells is not known.

Various additional chaperones have, in part indirectly, been implicated in affecting P protein, for instance Hsp60<sup>[133-135]</sup> and the Hsp90 family member GRP94<sup>[136]</sup>; however, GRP94 is an endoplasmic reticulum (ER) resident protein for which a role in P protein activation is difficult to imagine. Overexpression of p50/cdc37, a co-chaperone of Hsp90 involved in activation of several signal transduction kinases, stimulated DHBV replication in transfected cells and a dominant negative mutant of p50/cdc37 inhibited DHBV P protein priming *in vitro*<sup>[137]</sup>. Again, the physiological relevance of these observations remains to be confirmed.

One possible solution would be to map the contact sites of the various chaperones on P protein using biochemical and biophysical methods, and then to generate P mutants with specific interaction defects. Monitoring their replication phenotypes in transfected, or better in infected, cells should then allow to narrow down which of the various reported interactions are truly significant for virus propagation *in vivo*.

Though we have stressed the uniquely strict chaperone-dependence of hepadnaviral P protein activation, there is accumulating evidence that other polymerases are also affected by chaperones. Probably the closest analogy exists to telomerase, the cellular reverse transcriptase that maintains chromosome end integrity<sup>[138,139]</sup>. However, also

the DNA polymerase of Herpes simplex virus<sup>[140]</sup>, and the RNA polymerases of flock house virus<sup>[141]</sup> and influenza virus appear to require chaperone assistance<sup>[142,143]</sup>. Closely watching progress in those areas might also provide clues as to the mechanism of chaperone-assisted hepadnavirus replication; however, for polymerases without a similarly sophisticated protein-primed initiation mode the chaperones could act at rather different levels.

## DNA PRIMER TRANSLOCATION AND (-)-DNA COMPLETION

In contrast to initiation, the subsequent steps for RC-DNA formation are currently not amenable to *in vitro* analysis, and they appear intimately related to the proper environment of intact nucleocapsids. Hence reverse genetics is still the most rewarding approach to address these equally puzzling and complex events.

The initial model of hepadnaviral (-)-DNA formation assumed that synthesis would start inside the 3' copy of DR1 (DR1\*), for HBV at the motif 5' UUCA. As discussed above, the complementary sequence 3' AAGT at the 5' end of (-)-DNA is instead copied from the UUCA motif in the  $\epsilon$  bulge (Figure 7A). Hence the oligonucleotide bound to TP must specifically be translocated to the 3' DR1\*, nearly 3 kb apart from 5'  $\epsilon$ . Given that there are about 20 further UUCA motifs on the pgRNA, and that even fewer than 4 nt of identity between the template region in  $\epsilon$  and the target site in DR1\* are sufficient for specific transfer<sup>[58]</sup>, additional elements ensuring proper translocation must be operating. One model is that DR1\* and 5'  $\epsilon$  are brought into close proximity (Figure 7B). A general mechanism would be closed-loop formation of the pgRNA *via* cellular proteins such as elongation initiation factor 4G (eIF-4G) which links 5' cap and 3' poly-A binding proteins<sup>[80]</sup>. A recent more specific model is a long-range RNA interaction between  $\epsilon$  and a new cis-element (" $\phi$ " or " $\beta 5$ ") slightly upstream of DR1\* that is involved in proper (-)-DNA synthesis<sup>[144-146]</sup>; it contains a sequence that

**Figure 8** RC-DNA formation. **A:** (-)-DNA completion. The DNA primer, still linked to TP, is extended from DR1\* to the 5' end of pgRNA. The RNA is simultaneously degraded by the RH domain, except for its capped 5' terminal region including 5' DR1; the fate of the poly-adenylated 3' end is unclear; **B:** RNA primer translocation (second template switch). The RNA primer translocates to DR2, and is extended to the 5' end of (-)-DNA. 3' r and 5' r denote an about 10 nt redundancy on the (-)-DNA. As above, several cis-elements appear to promote close proximity of the DR1 donor and the DR2 acceptor, as schematically indicated in the right hand figure; **C:** Circularization (third template switch). Having copied 5' r, the growing 3' end of the (+)-DNA switches to 3' r on the (-)-DNA, enabling further elongation. This reaction must involve juxtaposition of 5' r and 3' r. For easier comprehension, the switch is also depicted on the basis of the representation shown on the right of Figure 8B; both are topologically equivalent; **D:** RC-DNA. Extension on the (-)-DNA template creates a set of (+)-DNA strands of various length; **E:** Double-stranded linear (dsL) DNA. This minor DNA form originates when the RNA primer, having failed to translocate to DR2, is extended from its original position ("in situ priming").

is partially complementary to the 5' half of  $\epsilon$ . Mutations affecting the base-pairing potential between the two sequences can, indeed, influence the efficiency of (-)-DNA synthesis<sup>[147]</sup>. Exactly how an  $\epsilon$ - $\phi$  interaction would aid in primer translocation is unclear because base-pairing would simultaneously affect the proper  $\epsilon$  structure, implying some temporal regulation. Similar  $\phi$  elements have been proposed to be present in the other hepadnaviruses<sup>[146]</sup>; for DHBV we noted, however, that D $\epsilon$  mutants with reduced potential base-pairing to the supposed  $\phi$  element showed no obvious (-)-DNA synthesis defects<sup>[171]</sup> and K. Dallmeier, B. Schmid and M. Nassal, unpublished data).

The primer translocation process must also involve remodeling of the P- $\epsilon$  complex; the priming Y residue of TP must give way to the growing DNA oligonucleotide, then  $\epsilon$  must be replaced by DR1\* as the template. Hence P, like other protein-priming polymerases, must have distinct initiation and elongation modes. The recently solved structure of the bacteriophage  $\phi$ 29 DNA-dependent DNA polymerase with its (separately expressed) terminal protein<sup>[101]</sup> gives an impression of the dynamic changes that have to occur.  $\phi$ 29 uses for protein priming an S residue in one of three distinct TP domains. In the initiation mode, the priming domain mimics the primer-template nucleic acid that occupies the same site during elongation. The initiation reaction continues until 6 to 10 nt have been attached; at this time the priming domain is pushed out of the polymerase's active site, marking the transition to elongation mode. Similar events must happen in P protein. Notably, initiation of  $\phi$ 29 replication does not start at the very terminal template nt; rather the (identical) penultimate

nt is copied. Next, the copied nt slips back to the terminal template position, and the penultimate nt is copied again; adenovirus uses a similar mechanism<sup>[100]</sup>. Interestingly, such slip-back and re-copying can also occur with HBV P protein on mutant  $\epsilon$  templates<sup>[58]</sup>. A full understanding, however, will obligatorily require high resolution structural data on the hepadnaviral replication complex.

Notably, the single-stranded (-)-DNA is an intermediate that, as in retroviral replication, could be a target for cytidine deamination, and consequently inhibition of replication, by APOBEC enzymes<sup>[148]</sup>. APOBEC3G, one of several family members, has indeed been reported to interfere with HBV replication<sup>[149]</sup>, however, the mechanism does not involve editing<sup>[150]</sup>. Also, expression of the corresponding APOBEC mRNA is low in hepatic cells, although it might be inducible<sup>[151]</sup>. Further research is needed to clarify whether any of the APOBEC enzymes is genuinely involved in the innate response against HBV infection. At any rate, sequestration into intact nucleocapsids of this potentially vulnerable single-stranded DNA replication intermediate may be an efficient counter-defense of HBV.

## (+) -STRAND DNA SYNTHESIS AND CIRCULARIZATION

The end product of (-)-DNA synthesis is a unit length DNA copy of the pgRNA from its 5' end to, in HBV, the UUCA motif in the 3' DR1\* (Figure 8A); hence it contains a small, about 10 nt, terminal redundancy ("r"). Most of

the pgRNA template is degraded concomitantly to (-)-DNA synthesis by the RNase H domain of P. The fate of the non-copied 3' end of the pgRNA from DR1\* to the polyA tail is not exactly known. It seems to be underrepresented in the packaged RNA, both in DHBV<sup>[152]</sup>, and in HBV with mutations in the nucleic acid binding domain of the core protein<sup>[46]</sup>. Whether some of these 3' ends are never completely encapsidated, or whether they dissociate out of the capsid, has not yet conclusively been shown.

Well established is, however, that the 5' terminal about 15 to 18 nt of the pgRNA including the 5' DR1 sequence are spared from degradation, probably because the active site of RH is halted at this distance when the RT domain reaches the template 5' end<sup>[153]</sup>. This capped 5' RNA oligo is essential as primer for (+)-DNA synthesis. Extension of the RNA from its original position ("in situ priming") gives rise to a double-stranded linear (dsL) DNA (Figure 8E) which occurs to a small percentage in all hepadnaviruses<sup>[154]</sup>. Lacking the core promoter/enhancer for pgRNA translation upstream of the pgRNA start site it is unsuited for virus propagation but may be of pathogenic potential<sup>[155]</sup>. For RC-DNA formation, the RNA primer must be transferred to the 3' proximal DR2 (Figure 8B); pgRNAs with improper 5' ends, not containing the DR1 sequence in the RNA primer, fail to undergo this essential second template switch. Why the RNA primer predominantly jumps to DR2 although its complementarity to the initial site is larger (more than 15 versus 11 or 12 nt) is not obvious. An interesting explanation has been proposed for DHBV, according to which burying part of the 5' DR1 sequence in a competing intramolecular hairpin structure effectively shortens the sequence available for hybridization with the RNA primer<sup>[156]</sup>.

From its new location on DR2 the RNA primer is extended towards the P bound 5' end of the (-)-DNA, including the 5' r redundancy. Further elongation requires a third template switch, i.e. circularization (Figure 8C). In effect, the growing (+)-DNA end is transferred from 5' r to 3' r on the (-)-DNA template from where it can further be extended to yield RC-DNA (Figure 8D).

Though sequence identity between 5' r and 3' r is important, additional cis-elements are again required to ensure efficient RNA primer translocation and circularization. Using quantitative genetic techniques, the Loeb laboratory has defined, mostly in DHBV, several such cis-elements on the (-)-DNA<sup>[144,156-161]</sup>, e.g. 3E, M, and 5E, which are located at both termini and in the middle of pgRNA. Collectively, these data provide evidence that these cis-elements, *via* long range base-pairing, allow for a close juxtaposition of the corresponding donor and acceptor sites, and thus facilitate the proper template switches (Figure 8B, right panel). How this is achieved inside the replicating nucleocapsid is not easily envisaged. Also, we noted that chimeric heron-duck HBVs are less sensitive than DHBV to reduced base-pairing in some of these elements (K. Dallmeier and M. Nassal, unpublished). There is evidence, however, that similar potentially base-pairing cis-elements are present in human HBV<sup>[144,162]</sup> and assist in circularization (E. Lewellyn and D.D. Loeb, pers. comm.).

Hence intramolecular base-pairing is probably an important mechanism that ensures proper shaping of the viral genome for the various template switches that eventually yield RC-DNA. More details than is possible to show here can be found in informative schematic representations in references<sup>[144,160]</sup>.

## CONCLUSIONS AND PERSPECTIVES

Since the original discovery that hepadnaviruses replicate through reverse transcription numerous novel and unique aspects of the replication process have been unraveled by using reverse genetics in transfected cells. Indisputably, this system will continue to be an important tool in future HBV research; in some cases because even a cancer-derived stable cell line mimics many aspects of the complex natural environment for viral replication, allowing to look into the interplay between virus replication and cellular networks by genomics and/or proteomics; in others because we have currently no alternative due to the complexity of the interactions between the viral components themselves. An example is the control of the various template switches during RC-DNA generation by long-range nucleic acid interactions which apparently can only occur, and be monitored, in the context of assembled nucleocapsids.

For a mechanistic understanding, however, cell-free systems are indispensable. Two striking examples for their power are the discovery of the replication origin function of  $\epsilon$  and the chaperone-dependence of P protein activation; both would have gone unnoticed for a long time without the *in vitro* translation system. To disentangle these multifactorial processes on the molecular level, *in vitro* reconstitution from purified components is the approach of choice. Despite the bewildering complexity of the chaperoning systems, it will now be possible, starting from relatively simply composed systems, to systematically add-in additional factors and monitor their contributions to P protein activation; this should, *inter alia*, help answer the pressing question why human HBV P protein shows no enzymatic activity under conditions where its DHBV counterpart is active. An *in vitro* activity assay for HBV P protein would also be an important screening tool for better HBV antivirals. Similarly rewarding should be the development of *in vitro* systems that address other steps of the viral replication cycle, foremost perhaps inclusion of the core protein into the now available replication initiation systems.

Ultimately, structural biophysics needs to enter the field. At this time the HBV core protein, without its nucleic acid binding domain, is the only hepadnavirus component for which a high resolution structure is available<sup>[163]</sup>. Fortunately, 3D structural analyses of the  $\epsilon$  element are well underway, and at least individual domains of the P protein may become amenable to direct structure investigations. The most exciting, though also most challenging aim given its multifactorial composition, will be to obtain high resolution data for the P protein- $\epsilon$  RNA complex, caught in the act of DNA synthesis. However, the relevance of any such biophysical and biochemical

data will have to be corroborated in the context of the complete virus replication cycle, whenever possible in an *in vivo* setting.

Finally, although the complex interactions between viral, and viral and cellular, components may seem of foremost interest for basic HBV biology, they also hold the keys for novel, and more efficacious therapies of chronic hepatitis B. The few currently approved anti-HBV drugs are all nucleos(t)idic inhibitors of the reverse transcriptase. Their long-term efficacy is limited by the virtually unavoidable emergence of resistant HBV variants<sup>[30]</sup>; any new compounds with the same mechanism of action will also face this problem, which will be aggravated by cross-resistance, particularly against different analogs of the same natural nucleotide. Each of the steps in the HBV replication cycle that is now being elucidated in molecular detail provides new, unconventional targets for interference. Replication initiation alone depends on many specific interactions, including the TP and RT/RH domains of P protein,  $\epsilon$  RNA, and different chaperones. Blocking any of these interactions, e.g. by small molecules binding to, and altering the structure of  $\epsilon$  or preventing chaperone binding to P, would abolish reverse transcription by mechanisms entirely different from that of nucleoside analogs. Knowledge of the 3D structure of P would allow to design better nucleosidic as well as non-nucleoside inhibitors, and additional opportunities will certainly arise once the process of cccDNA formation is better understood. Especially in combination with conventional antivirals, such potential new drugs should greatly increase the chances for curing, rather than just controlling, chronic hepatitis B.

### Abstract

The hepatitis B virus (HBV) particle consists of an envelope containing three related surface proteins and probably lipid and an icosahedral nucleocapsid of approximately 30 nm diameter enclosing the viral DNA genome and DNA polymerase. The capsid is formed in the cytosol of the infected cell during packaging of an RNA pregenome replication complex by multiple copies of a 21-kDa C protein. The capsid gains the ability to bud during synthesis of the viral DNA genome by reverse transcription of the pregenome in the lumen of the particle. The three envelope proteins S, M, and L shape a complex transmembrane fold at the endoplasmic reticulum, and form disulfide-linked homo- and heterodimers. The transmembrane topology of a fraction of the large envelope protein L changes post-translationally, therefore, the N terminal domain of L (preS) finally appears on both sides of the membrane. During budding at an intracellular membrane, a short linear domain in the cytosolic preS region interacts with binding sites on the capsid surface. The virions are subsequently secreted into the blood. In addition, the surface proteins can bud in the absence of capsids and form subviral lipoprotein particles of 20 nm diameter which are also secreted.

### INTRODUCTION

*In vitro* systems for efficient production of hepatitis B virus

(HBV) capsids and subviral particles and for experimental examination of their morphogenesis are available. These systems allowed to draw a quite detailed, although still fragmentary, picture of these processes. However, *in vitro* production of virions by transfection of certain cell lines derived from hepatocellular carcinomas, such as HepG2 or Huh7, with cloned genomic HBV DNA<sup>[1,2]</sup> or by *in vitro* infection<sup>[3]</sup> is still quite inefficient, and this hampers many approaches to study the morphogenesis of the complete virus. In natural HBV infections one single hepatocyte in the liver releases 1 to 10 viruses per day<sup>[4]</sup>. *In vitro* the production rate seems to be similar. Therefore, the direct observation of HBV budding by electron microscopy or the characterization of the process by biochemical approaches is difficult to achieve<sup>[5]</sup>. It seems that the virus production rate in duck hepatitis B virus (DHBV) infection is higher at least *in vitro*, making these techniques suitable for studying DHBV morphogenesis<sup>[6]</sup>.

### THE HBV CAPSID FORMATION AND STRUCTURE

The C protein forming the shell of the HBV capsid consists of 183 or 185 amino acid (aa) residues depending on the genotype. The protein is relatively conserved among HBV isolates<sup>[7]</sup>. It can be expressed in a broad range of pro- and eukaryotic cell types and self-assembles into capsids. The first step is the formation of homodimers<sup>[8]</sup> linked by a disulfide bridge between the cysteine residue 61<sup>[9,10]</sup>. Higher oligomers containing chaperons have been described<sup>[11]</sup> but the pathway leading from dimers to complete capsids has not been elucidated in more detail. In the final capsid, the inter-dimer interactions are rather weak<sup>[12]</sup>. Two different types of capsids are formed<sup>[13]</sup>: particles with an icosahedral T = 3 symmetry have a diameter of 30 nm and consist of 90 C dimers, whereas particles with an icosahedral T = 4 symmetry are larger (the diameter is 34 nm) and contain 120 C dimers. Both particle species can also be found in infected human liver<sup>[14]</sup>. In infectious virions, T = 4 capsids have been found<sup>[15]</sup>.

The primary amino acid (aa) sequence of the C protein can be divided into two parts (Figure 1): the N-terminal 149 or 151 aa (depending on the genotype) form the so called assembly domain because this part of the protein is sufficient to direct the self-assembly of capsids. The C-terminal 34 aa are dispensable for capsid formation, rich in arginine residues, and involved in packaging of the pregenome/reverse transcriptase complex. Deletion of this domain abolishes the encapsidation of nucleic acid<sup>[16]</sup>.

**Figure 1** Linear map of the main structural HBV proteins. The C-terminal region (open box) of the capsid protein C is rich in arginine residues (+). The sequence of the small envelope S is also present at the C termini of the M and L protein. The two larger envelope proteins contain the additional N-terminal preS2 and preS2 + preS1 domain, respectively. The L protein is myristylated at glycine 2 (myr), the preS2 domain of M is N-glycosylated (filled circles), and the S domain of all 3 proteins is partially N-glycosylated (open circles).

Expression of the C-terminally truncated C protein in *E. coli* produces high amounts of  $T = 4$  capsids and relatively little  $T = 3$  particles<sup>[17]</sup>. Using this material a model for the folding of the C protein in the capsid first at lower resolution by cryo-electron microscopy<sup>[18,19]</sup> and finally after crystallization at a resolution of 3.3 Å<sup>[20,21]</sup> has been proposed. The C protein dimer forms a structure like an upside down “T”. The horizontal bar mediates the inter-dimer contacts with 5 and 6 dimers arranged around the 5-fold and quasi 6-fold symmetry axes, respectively, and the vertical bar forms a spike protruding outwards from the capsid surface (Figure 2). The tip of the spike forms the major epitope of the capsid antigen (HBcAg). The capsid shell contains pores with a diameter between 12 Å and 15 Å. These pores allow the diffusion of nucleotides into and out of the capsid lumen during the synthesis of the viral DNA genome.

The arginine-rich domain is not present in the capsid crystals but thought to interact with the viral genome in the lumen of the particle<sup>[16,22,23]</sup>. However, a monoclonal antibody directed against this region binds to intact HBV capsids<sup>[24]</sup>, and trypsin can clip off this domain from approximately half of the C protein chains in recombinant HBV capsids (Daniela Lieder, PhD thesis, Goettingen, 2002). It therefore seems possible that the C-terminal region of one fraction of C proteins reach into the lumen of the particle, while the domains from the other fraction appear on the external surface of the same particle. The peptide at the boundary between the assembly and arginine-rich domains of C forms a mobile array<sup>[25]</sup> and may allow an extreme mobility of the C terminal domain.

Capsid formation during recombinant expression of the C protein requires a higher concentration of C protein dimers relative to nucleocapsid formation in the context of an infection<sup>[26]</sup>. During authentic capsid formation, not only the viral pregenomic RNA bound to the viral P protein<sup>[27-30]</sup> but also cellular factors such as chaperones<sup>[31-33]</sup> and a protein kinase phosphorylating serine residues in the arginine-rich domain of C<sup>[34-37]</sup> are encapsidated. Apparently, the threshold concentration of C dimers needed for the initiation of capsid formation is lowered by one or more of these factors. This mechanism assures

**Figure 2** Crystal structure of a C-terminally truncated C protein dimer<sup>[21]</sup>. The spike protrudes upwards. The lumen of the capsid would be below the figure. Mutational analysis identified aa (shown in black) where the mutation was compatible with capsid formation and viral DNA synthesis in the lumen of the particle but blocked nucleocapsid envelopment<sup>[121]</sup>.

the efficient encapsidation of replication complexes and prevents that large amounts of empty capsids are formed in the presence of free replication complexes.

C proteins from human and woodchuck HBV can form mixed capsids, while this is not possible between human and duck C proteins<sup>[38]</sup> which are less homologous. Foreign protein domains can be incorporated into capsids when fused to the N or C terminus or at the tip of the spike<sup>[39-44]</sup>. The assembly of HBV capsids can be blocked by low molecular weight compounds, possibly offering new options for antiviral treatments in the future<sup>[45-48]</sup>.

## THE HBV ENVELOPE PROTEINS

The HBV envelope contains three related viral surface proteins. They are expressed from one open reading frame (ORF) referred to as E containing 389 or 400 codons depending on the genotype and three start sites for translation<sup>[49]</sup> (Figure 1). Transcription is initiated at a promoter upstream of the ORF and, in addition, at an internal promoter upstream of the second translation initiation site<sup>[50]</sup>. Translation of the larger mRNA yields the large envelope protein (L) consisting of 389 or 400 aa. Translation of the shorter transcripts gives rise to the middle sized, 281 aa long M protein and, in addition, to the small S protein consisting of 226 aa<sup>[51]</sup> depending on which translation initiation site is used. The aa sequence present at the C termini of L and M is identical to the S protein and is referred to as the S domain. The 55 aa long additional N-terminal domain of M being central in L is called preS2, and the 108 or 119 aa long N-terminal domain unique to L is named preS1. The E ORF of avian hepadnaviruses contains only 2 start codons, therefore, these viruses possess only two envelope proteins (L and S).

Like typical membrane proteins, the HBV envelope proteins are synthesized at the endoplasmic reticulum (ER). They gain a relatively complex topology (Figure 3). Insertion of the S protein into the ER membrane is initiated by an N-terminal signal sequence (aa 8 to

**Figure 3** Transmembrane topology of the HBV envelope proteins and model for envelope-capsid interaction. The transmembrane folding of the S protein is determined by an N-terminal and an internal signal shown as open boxes. The C-terminal domain is hydrophobic and probably embedded in the lipid bilayer (horizontal open bar). The C terminus is oriented towards the ER lumen. The folding of the M protein is similar to S. The preS2 domain of M (thinner line) is located in the ER lumen. In the initial folding of the L protein, the preS domains are located in the cytosol (i-preS). Whether the N-terminal myristate group (filled box) is inserted into the membrane as shown here is unknown. After refolding approximately half of the L chains expose the preS domains at the luminal side of the membrane (e-preS). Open and filled circles: see Figure 1. Asterisks indicate potential but unused N-glycosylation sites in preS of L. A domain in i-preS (boxed area) and in the cytosolic loop of S may interact with the capsid during budding. Immature capsids containing pregenomic RNA are not capable to bud. During viral DNA synthesis, the capsid shell changes (indicated by filled circles at the edges) and becomes competent for envelopment.

22) which is, however, not cleaved by the host's signal peptidase. A second signal (aa 80 to 98) directs the translocation of the peptide chain downstream of this signal through the ER membrane into the ER lumen<sup>[52]</sup>, whereas the region upstream of the signal remains in the cytosol. The signal itself anchors the protein as a transmembrane domain in the lipid bilayer. The C-terminal hydrophobic 57 aa of S are believed to be embedded in the ER membrane. Foreign domains fused to the C terminus of S are oriented towards the ER lumen, suggesting that the C terminus of S is also oriented toward this compartment<sup>[52]</sup>. This configuration causes the region between residues 23 and 79 to form a loop at the cytosolic side of the ER membrane, whereas the loop between aa 99 and approximately 169 is on the luminal side. The luminal loop carries the major conformational epitope of the HBV surface protein antigen (HBsAg) and is N-glycosylated in approximately half of the S molecules at asparagine (asn) residue 146<sup>[53]</sup>. After budding the HBsAg epitopes are located at the external surface of viral particles.

The transmembrane topology of the M protein is identical to S. The N-terminal preS2 domain (55 aa) is translocated into the ER lumen probably by the action of the first signal in the S domain<sup>[54]</sup>. The M protein is N-glycosylated at asn 4<sup>[55]</sup>. In addition, the preS2 domain is O-glycosylated in some but not all HBV genotypes<sup>[56]</sup>.

Glycine residue 2 of the L protein is myristylated<sup>[57]</sup>. The preS1 and preS2 domains at the N terminus of L initially remain at the cytosolic side of the ER membrane during L translation (i-preS conformation). The central

signal in the S domain of L anchors the protein in the ER membrane and causes the translocation of downstream sequences. Therefore, asn 146 in the S domain of L is partially N-glycosylated, while asn 4 of the preS2 as well as a further potential N-glycosylation site in preS1 remain unmodified (Figure 3). These sites are used when the N terminus of L is forced to cotranslationally translocate by the artificial fusion of a signal sequence to the N terminus of preS1<sup>[58]</sup>.

In about half of the L chains, the transmembrane topology changes after translation<sup>[59-63]</sup>. The preS domains then appear on the luminal side of the ER membrane (e-preS conformation). Probably the N-terminal signal in the S domain crosses the membrane in this conformation similar to the M and S proteins. How the preS domains move post-translationally through the membrane is not known. Cytosolic chaperones like Hsc70 bind to preS1 and deletion of the binding site causes cotranslational translocation of preS<sup>[64-66]</sup>. Luminal chaperones binding to the e-preS domain<sup>[67]</sup> could support this process. It might be possible that oligomerized S domains form a channel in the membrane for the preS transport<sup>[68]</sup>. For HBV, the S and M proteins are not required for the translocation process<sup>[69]</sup>, whereas the S protein is essential for DHBV<sup>[70,71]</sup>. In DHBV, a C-terminally truncated S protein has been described to fulfil a chaperone function during preS translocation<sup>[72]</sup>. These facts suggest that the preS translocation mechanism might be different between HBV and DHBV<sup>[73]</sup>. Both L isoforms have their own function: in the e-preS conformation, the preS1 and preS2 domains of L are exposed on the surface of virions and participate in virus receptor binding<sup>[74,75]</sup>, while in the i-preS conformation, the preS1 and preS2 domains of L are internal in the virion and probably important for contacting the nucleocapsid (see below). In addition, the i-preS domain can activate a variety of promoter elements<sup>[76]</sup>; however, the significance of this function is not clear.

The S domain but not the preS domain contains multiple cysteine residues. Cysteine residues in the luminal loop crosslink the envelope proteins with each other by multiple disulfide bridges. Shortly after synthesis, disulfide-linked homo- and heterodimers between S, M, and L proteins can be found<sup>[77,78]</sup>. The cytosolic loop contains 4 cysteine residues. Mutational analysis demonstrated that the exchange of 1 out of 3 of the 4 cysteine residues in this loop by a serine residue blocked subviral particle formation<sup>[79]</sup>. However, these cysteines are not involved in disulfide bridge formation in subviral particles<sup>[77]</sup>, and a covalent modification of these sites, for example, by fatty acid acylation, has not been found<sup>[57]</sup>. The DHBV L protein is partially phosphorylated<sup>[80,81]</sup>, mainly at serine 118<sup>[82]</sup>. However, mutational analyses could not demonstrate an essential role for this modification in the DHBV life cycle<sup>[83]</sup>. Phosphorylation of the HBV L protein could not be found.

## SUBVIRAL PARTICLES

The HBV surface proteins are not only incorporated into virion envelopes. Rather, they also bud very efficiently

from intracellular, post-ER pre-Golgi membranes<sup>[84,85]</sup> without envelopment of capsids, appear as subviral quasi-spherical or filamentous lipoprotein particles in the lumen of the compartment, and are released from the cell by secretion. The quasi-spherical particles have a diameter of 20 nm and an octahedral symmetry<sup>[86]</sup>, the filaments have variable lengths. Subviral particles are highly over-expressed relative to virions and reach a 10 000-fold higher concentration in serum. Subviral particles and virions carry identical surface antigens (HBsAg), although the protein composition is not identical. Spherical subviral particles contain only low amounts of L protein, whereas the relative amount of L is higher in filaments and even higher in the virion envelope<sup>[49]</sup>. It is assumed that the massive HBsAg overproduction influences the host's immune system in a way that is advantageous for the virus.

Recombinant expression of the S protein (e.g. in yeast) yields highly immunogenic intracellular 20-nm HBsAg particles which can be used as an active vaccine against hepatitis B<sup>[87]</sup>. S protein expressed in mammalian cells is efficiently secreted as 20-nm HBsAg particles. How the protein escapes the membrane and mobilizes lipid during subviral particle formation is unclear. Chaperons, such as calnexin<sup>[88]</sup> and BiP<sup>[67]</sup>, bind to S and support the maturation of the protein. The relative amount of lipid is only 25% by weight in subviral particles<sup>[89]</sup>, suggesting that the lipid is not organized as in a conventional membrane bilayer.

The M protein essentially behaves like the S protein with respect to subviral particle formation. However, the L protein can not be secreted from cells when expressed by itself. In fact, the L protein causes a dose-dependant inhibition of particle release when coexpressed with the S protein<sup>[90,91]</sup> and a storage of subviral particles in the ER lumen<sup>[88]</sup>. This can cause cell stress and even cell death or cancer<sup>[92,93]</sup>. The significance of the secretion inhibition function of L for the viral life cycle has remained unclear. This function can be abolished by blocking L myristylation (e.g. by a point mutation of the acceptor glycine residue) or by the deletion of the N-terminal 19 aa of preS1<sup>[94-96]</sup>. Also, the fusion of a secretion signal to the N terminus of L forcing the protein to exclusively generate the e-preS conformation abrogates secretion inhibition<sup>[58]</sup>. This, however, is different for the DHBV L protein<sup>[97]</sup>.

Host proteins are efficiently excluded during the morphogenesis of subviral particles. Even the HBV and DHBV S proteins sharing 25% identical aa do not form mixed particles during coexpression<sup>[98]</sup>. However, this is possible with the more closely related S proteins from HBV and the woodchuck hepatitis B virus (WHV). Apparently, the S protein subunits interact tightly with each other during 20 nm particle formation. However, foreign protein domains can be incorporated into subviral HBsAg particles when they are fused to the S protein<sup>[99,100]</sup>.

## CAPSID MATURATION

During HBV nucleocapsid formation, the RNA pregenome is packaged into the particle's lumen and first converted into single stranded and then into partially

double-stranded DNA. While nucleocapsids showing all stages of the viral DNA synthesis can be found within cells, secreted virions contain only rather mature circular, partially double-stranded DNA<sup>[101,102]</sup>. Therefore, it was proposed that early RNA-containing capsid can not be incorporated into virions and that the viral DNA synthesis is associated with a structural change in the capsid shell that allows only mature capsids to be enveloped<sup>[103]</sup>. This hypothesis was supported by several genetic experiments. C-terminal truncations of the DHBV core protein blocked viral DNA synthesis and also inhibited capsid envelopment<sup>[104]</sup>. Missense mutations inhibited the reverse transcriptase activity of HBV and DHBV P protein and locked nucleocapsids in an immature state. The incorporation of these capsids into virions was greatly reduced<sup>[105,106]</sup>. Using a synchronized DHBV replication system, it was shown that envelopment of capsids happened only late in the replication cycle<sup>[107]</sup>.

The nature of the maturation signal has only been described insufficiently. A comparison of capsids containing RNA and DNA by cryo-electronmicroscopy revealed structural differences<sup>[15]</sup>. There is also evidence that the phosphorylation state of the arginine-rich domain of the C protein might be part of the signal<sup>[108-110]</sup>. A validation of this hypothesis by a genetic approach is not suitable because substitutions of phosphorylation sites with alanine or glutamic/aspartic acid also influence pregenome packaging and DNA synthesis<sup>[111]</sup>. Interestingly, the point mutation of isoleucine 97 to leucine in the C protein caused the envelopment of immature capsids<sup>[112]</sup>. The side chain of this residue is located in the inner space of the spike and close to a hydrophobic pocket showing structural differences in mature *versus* immature capsids<sup>[15]</sup>. Possibly, the I97L mutation induces a conformational change causing a constitutive or early expression of the envelopment signal. An additional point mutation (P130T) in a quite distant area of the core protein restored the wild-type phenotype<sup>[113]</sup>, demonstrating the complex nature of the maturation signal for envelopment.

The exclusion of immature nucleocapsids from envelopment causes only replication-competent capsids to become part of virions. This may be one reason for the high specific infectivity of DHBV which is close to the optimum of 1 infectious particle per virion<sup>[114]</sup>. Also for HBV the specific infectivity seems to be very high<sup>[115]</sup>.

The disassembly of capsids occurs in the basket of nuclear pores upon nuclear transport of the viral genome<sup>[116]</sup> either during infection or intracellular amplification of the viral genome copy number. Capsid destabilization can also be induced by a tumor necrosis factor alpha-mediated non-cytopathic pathway and may play a role as an antiviral mechanism in natural infections<sup>[117]</sup>.

## CAPSID ENVELOPMENT AND VIRION FORMATION

In contrast to retroviruses or togaviruses, it is difficult to directly observe the envelopment of HBV capsid by electron microscopy probably because budding events are less frequent in the available *in vitro* expression systems.

It has even not been clarified whether the HBV envelope contains lipid, although this seems to be likely due to the composition of subviral HBsAg particles. Nevertheless, based on the molecular characterization of HBV formation (see below), it is assumed that hepatitis B virions are formed by budding in analogy to other enveloped viruses.

Mature hepadnaviral nucleocapsids originate in the cytosol. How the capsids move to post-ER, pre-Golgi membranes where the envelopment by the surface proteins supposedly occurs<sup>[84,85]</sup> is unknown. For DHBV capsids, there is evidence that mature capsids lacking C protein hyperphosphorylation, like capsids in virions, attach to intracellular membranes independent of viral envelope proteins<sup>[118]</sup>. Immature capsids are hyperphosphorylated and do not bind. This observation suggests that the discrimination between immature and mature capsids happens during the transport of the particle to budding sites before the contact to envelope proteins is established.

Several enveloped viruses utilize a host cell machinery for budding of vesicles into the lumen of so-called multivesicular bodies for their own virus budding<sup>[119,120]</sup>. Viral capsid proteins interact with the host factor of this pathway via so-called late domains. The HBV C protein contains the sequence PPAY (aa 129-132) exposed on the capsid surface<sup>[21]</sup> resembling the late domain motif PPXY. However, mutations at this site either blocked capsid formation or reproduced the wild-type phenotype<sup>[121]</sup>. Therefore, future experiments have to decide whether this pathway is involved in HBV morphogenesis.

The envelopment of HBV capsids strictly depends on viral envelope proteins<sup>[122-124]</sup> in contrast to type C retroviruses or lentiviruses where mutants blocked in envelope protein expression still release capsids wrapped with a lipid layer. A natural HBV point mutant unable to express the M protein was isolated from a patient and demonstrated that this protein is not required<sup>[125]</sup>, whereas suppression of L or S expression impeded virion formation<sup>[122,123]</sup>. An L construct with an N-terminally fused secretion signal generating only the e-preS conformation was secreted as a component of subviral particles<sup>[126]</sup> but failed to support virion formation<sup>[58]</sup>. Apparently, the i-preS conformation of L exposing the preS domain at the cytosolic side of the ER was essential for nucleocapsid envelopment. This finding is compatible to a model where this part of the L protein contains regions (matrix domains) mediating a contact to the capsid required for budding.

In DHBV, the L protein influences the fate of cytoplasmic capsids<sup>[124,127]</sup>. If the L protein is absent, capsids deliver the viral genome to the nucleus like in the initial infection of the cell and amplify the intracellular viral genome copy number, whereas capsids are mainly secreted as enveloped virions when the L protein is present. This function mapped to aa 116 to 137 of the 161 aa long DHBV preS domain<sup>[128]</sup>. A similarly short linear stretch between aa 103 and 124 (or aa 92 and 113 depending on the genotype) genetically mapping in HBV preS was found to be important for virion formation<sup>[129]</sup>. The exchange of two adjacent aa by alanine residues in this

area also prevented nucleocapsid envelopment.

Therefore, it is hypothesized that this part of L interacts with the capsid during envelopment and serves the function of a matrix domain similar to the cytoplasmic tail of the alpha virus E2 protein<sup>[130]</sup>. This model is supported by an HBV double point mutant where the I97L C protein mutation causing the envelopment of relatively immature capsids is suppressed by the A119F mutation in the putative matrix domain of L<sup>[131]</sup>. Also *in vitro* binding assays, using HBV envelope-derived peptides and liver-derived as well as recombinant capsids favour the model<sup>[132]</sup>. These results also suggest that the discrimination between immature and mature capsids might not occur on the level of capsid-envelope protein interactions. As aforementioned, this selection may happen during surface protein-independent membrane association of capsids.

The loop between the first and second transmembrane region in the S protein is also located at the cytoplasmic side of intracellular membranes and may establish a contact between envelope and capsid. Indeed, short deletions in the C-terminal half of this loop inhibited virion but not 20-nm particle formation<sup>[133]</sup>. However, point mutations (substitutions of two adjacent aa by alanine residues) in this area were not sufficient to block envelopment (V. Bruss, unpublished).

Potential binding sites on the capsid for envelope protein domains have also been mapped by mutational analyses. A screening of random insertions and deletions in the C protein<sup>[134]</sup> identified a few mutations allowing nucleocapsid formation and genome synthesis but blocking nucleocapsid envelopment<sup>[135]</sup>. A similar phenotype was found for naturally occurring HBV mutants isolated from chronically infected virus carriers<sup>[136]</sup>. Eleven point mutations generated on the basis of the crystal structure of the HBV capsid also induced a loss of nucleocapsid envelopment<sup>[121]</sup> (Figure 2). They are clustered around the base of the spike and in the groove between spikes. The minimal distance from the matrix domain in the preS region of L to the transmembrane region in the S domain of L allowing virion formation as mapped by deletion mutagenesis<sup>[137]</sup> is sufficient to allow the matrix domain to reach these sites on the capsid surface. Mutations at the tip or stem of the spike had no impact on capsid envelopment. However, HBV budding from transfected cells can be suppressed by a peptide binding to the tip of the spike<sup>[138,139]</sup>, possibly by steric hindrance.

As in the case of subviral 20-nm particles, the incorporation of foreign proteins into the virion envelope is strictly suppressed. Host membrane proteins could not be detected in virions and even envelope proteins from avian hepadnaviruses do not mix. However, the L protein from WHV can substitute with low efficiency for the HBV L protein in HBV morphogenesis<sup>[98]</sup>. The matrix domains of WHV and HBV L protein are highly conserved in contrast to the matrix domains of DHBV and HBV L. Foreign domains can be integrated into the HBV envelope by fusion to the N terminus of the S protein and addition of an N-terminal secretion signal<sup>[122]</sup>. This configuration results in a transmembrane topology similar to the M protein with the preS2 domain substituted by the foreign

sequence. When coexpressed with wild-type virus, the chimeric protein is phenotypically mixed into virions and the foreign domain is exposed on the virus surface.

## Abstract

Hepatocellular carcinoma (HCC) is one of the most common cancers in the world with an annual incidence of more than 500 000 in the year 2000. Its incidence is rising in many countries. Recently, it has been estimated that about 53% of HCC cases in the world are related to hepatitis B virus (HBV). The epidemiological association of HBV with HCC is well established. In recent studies, it was revealed that HBsAg carriers have a 25-37 times increased risk of developing HCC as compared to non-infected people. At present, HBV-associated carcinogenesis can be seen as a multi-factorial process that includes both direct and indirect mechanisms that might act synergistically. The integration of HBV DNA into the host genome occurs at early steps of clonal tumor expansion. The integration has been shown in a number of cases to affect a variety of cancer-related genes and to exert insertional mutagenesis. The permanent liver inflammation, induced by the immune response, resulting in a degeneration and regeneration process confers to the accumulation of critical mutations in the host genome. In addition to this, the regulatory proteins HBx and the PreS2 activators that can be encoded by the integrate exert a tumor promoter-like function resulting in positive selection of cells producing a functional regulatory protein. Gene expression profiling and proteomic techniques may help to characterize the molecular mechanisms driving HBV-associated carcinogenesis, and thus potentially identify new strategies in diagnosis and therapy.

## INTRODUCTION

With an estimate of more than 500 000 incidences in the year 2000 hepatocellular carcinoma (HCC) is one of the most frequent malignant tumors worldwide and its incidence is rising in many countries<sup>[1-4]</sup>. Despite being the 5<sup>th</sup> most frequent cancer in the world, HCC is the third leading cause of cancer death behind lung and stomach cancer. The high mortality associated with HCC is due to its unresponsiveness to treatment in many cases and symptoms of HCC often are recognized lately<sup>[5]</sup>. When viewed as estimated age-adjusted incidence rates of liver cancer per 100 000 men, the figures ranged as follows: in Asia, from 35.5 in Eastern Asia, 18.3 in South-eastern Asia to 5.6 in Western Asia; in Africa, from 24.2 in Middle Africa, 14.4 in Eastern Africa, 13.5 in Western Africa, 6.2 in Southern Africa to 4.9 in Northern Africa; in Europe, from 9.8 in Southern Europe, 5.8 in Eastern and Western Europe to 2.6 in Northern Europe; and to values of 4.8 in South America; 4.1 in North America; 3.6 in Australia/New Zealand and, finally, 2.1 in central America. In all regions, the rates recorded were two to three times higher in men than in women.

These significant differences in the geographic distribution of HCC incidence have led to identify chronic HBV infection as a leading risk factor for HCC<sup>[6-9]</sup>. Recently, it has been estimated that about 53% of HCC cases in the world are related to HBV<sup>[3]</sup>. The lifetime risk to develop a HCC was found to be increased even in patients that have cleared hepatitis B virus surface antigen (HBsAg) or with an occult HBV infection. Further risk factors include chronic HCV infection, exposure to aflatoxin B<sub>1</sub>, alcohol abuse, obesity and diabetes. Aflatoxin B<sub>1</sub> (AFB<sub>1</sub>) is a fungal metabolite that contaminates the food supply in certain areas of the world. It is produced by *Aspergillus flavus* and related fungi that grow on improperly stored foods, such as corn, rice and peanuts. AFB<sub>1</sub> requires metabolic conversion to its *exo*-8,9-epoxide in order to damage DNA. Coexistence of these risk factors, such as HBV and HCV infection or HBV infection and aflatoxin B<sub>1</sub>, increases the relative risk of HCC development<sup>[11-13]</sup>. While a variety of risk factors have been identified in the last years, here a short review describing the current state of knowledge of the molecular pathogenesis of HBV-associated HCC

is given. A focus of this review will be on the role of the HBV-regulatory proteins in this process.

## EPIDEMIOLOGY OF HBV-ASSOCIATED HCC

The epidemiological association of HBV with HCC is well established. In recent studies, it was revealed that HBsAg carriers have 25-37 times increased risk of developing HCC as compared to non-infected people<sup>[14,15]</sup>. Moreover, it was analyzed in more detail whether the viral status of the patients are correlated with the risk of developing HCC. HBV has been designated eight genotypes (A-H) based on genetic divergence. Each genotype has a distinct geographical and ethnic distribution. While genotypes B and C are prevalent in Asia, genotypes A and D occur frequently in Africa, Europe and India. There are conflicting data about the influence of HBV genotypes on HCC development<sup>[16-18]</sup>. Recent studies from Taiwan provide profound evidence for hepatitis B virus e antigen (HBeAg)-positive patients that HBV genotype C causes a more aggressive disease course as compared to genotype B<sup>[19-21]</sup>. On the other hand, there are reports from Taiwan describing that more than 50% of the HBV-related HCC patients are infected with genotype B. A study on Taiwanese pediatric patients with chronic HBV infection, who were followed for 15 years, showed that genotype B was identified in 74% of the children with HBV-associated HCC<sup>[22]</sup>. A further interesting observation is the prevalence of the T1762/A1764 mutation in the basal core promoter region which increases with the progression of liver disease. Since this mutation seems to be associated with HCC development, it might represent a helpful prognostic biomarker<sup>[23,24]</sup>.

The risk of HCC seems to be elevated with increasing HBV viral load<sup>[25]</sup>. Therefore, it is important to consider that most epidemiological analyses were based only on HBsAg positivity. A recent study revealed that the relative risk of HCC was increased by 6-fold among patients who were positive for both HBsAg and HBeAg, compared to those who were positive for HBsAg alone<sup>[15]</sup>. Based on this, it can be concluded that HBeAg could be an additional useful marker for risk of developing HCC, since HBeAg reflects productive HBV replication.

## DIRECT EFFECTS TRIGGERED BY THE INTEGRATION OF HBV-DNA INTO THE HOST GENOME

Integration is not essential for the viral replication but it allows persistence of the viral genome. Almost all of the HBV-associated HCCs harbor chromosomally integrated HBV DNA<sup>[26-28]</sup>. In many cases, these integrated viral genomes are characterized by rearrangements and/or partial deletions. HBV integration can induce deletions in the host chromosome at the integration site<sup>[29]</sup>. Based on these observations, it was tempting to speculate that the integration event *per se* causes a deregulation of key regulators of cell cycle control. This cis-hypothesis

(place of integration = place of function) seems to be supported by the woodchuck hepatitis B virus (WHV)-related HCC. Here, insertions of WHV-DNA into the c-myc or, preferentially the N-myc2 gene, have been frequently detected<sup>[30-34]</sup>. However, in case of the HBV-associated HCC, site-specific integration of the HBV genome or integration of the HBV genome into known oncogenes seems to be a rare event. Interesting examples are the integration of HBV DNA in a cyclin A gene<sup>[35]</sup>, in the retinoic acid receptor beta gene, in the mevalonate kinase gene or in the sarco/endoplasmic reticulum calcium ATPase1 gene<sup>[28,36]</sup>.

It was recently confirmed, using a PCR-based approach, that HBV insertion into cellular genes is a frequent event that occurs early during HBV infection even after acute self-limiting hepatitis<sup>[37]</sup> and that integration can occur in genes regulating cellular signal transduction cascades, proliferation control and cell viability. Recently, hTERT (human telomerase reverse transcriptase) that is part of the telomerase ribonuclear protein complex was found to be targeted in different HBV-associated HCCs<sup>[28,38,39]</sup>.

In light of these recent data, it will be an important issue to reconsider the role of the integration process for HBV-associated carcinogenesis. A helpful tool will be combining the analysis of putative HBV-specific integration sites with functional genomics of HBV-associated HCCs<sup>[40]</sup>.

## INDIRECT EFFECTS OF INTEGRATED HBV-DNA: HBx AND THE PREs2 ACTIVATOR FAMILY

### HBx

In most integrated subviral HBV genomes, the open reading frame for HBx or PreS2 regulatory protein is conserved and can be transcribed<sup>[41]</sup>. The HBx gene is conserved among all mammalian hepadnaviruses. HBx is a small polypeptide (17 kDa) that is produced at very low levels during chronic and acute hepatitis. Recently, a HBx-like regulatory protein was identified for duck hepatitis B virus (DHBV)<sup>[42]</sup>. Since the time when HBx initially was described to act as a transcriptional activator<sup>[43,44]</sup>, a variety of functions have been ascribed to the still enigmatic HBx<sup>[45,46]</sup>. While the X protein is essential for viral replication in case of WHV<sup>[47]</sup>, there are conflicting results about the relevance of HBx for the viral life cycle in case of HBV. There are reports describing that expression of the viral genome occurs independently from HBx functionality<sup>[48-50]</sup>; other papers describe a relevance of HBx for HBV replication<sup>[51]</sup>. In transgenic mouse models harboring an overgenomic HBV integrate, it could be observed that HBV replication does not depend on the presence of a functional HBx<sup>[52]</sup>. Comparable results were obtained in cell culture models based on huh-7 cells<sup>[48,50]</sup> while in case of HepG2 cells a reduction in HBx-deficient HBV genomes could be observed<sup>[53,54]</sup>. Moreover, infection experiments of primary *tupaia* hepatocytes revealed that HBx-deficient HBV particles are infectious (J. Köck, personal communication).

HBx activates a broad variety of different promoter elements. Based on the pleiotropic nature of the HBx-dependent transcriptional regulation, it was concluded that HBx interferes with signaling cascades upstream from the transcription complex. These signaling cascades trigger activation of transcription factors like AP-1 (activator protein-1), NF- $\kappa$ B (nuclear factor kappa B), SP1, and oct-1<sup>[46,55]</sup>. HBx affects the expression of a variety of genes that are involved in the control of the cell cycle, proliferation or apoptosis. From the beginning, HBx was considered as a crucial viral protein for the process of HBV-associated carcinogenesis<sup>[45,56-58]</sup> and this might have affected the focus of HBx research. In light of the putative role of HBx for viral carcinogenesis, the major focus of many research projects has been and is the interference of HBx with signal transduction cascades that affect the control of the cell cycle, proliferation or apoptosis. However, one should consider that selective over-expression of HBx reflects a situation that is different from the situation in an infected cell expressing the complete HBV genome. For example, it is well established that HBx is able to promote cellular proliferation<sup>[59]</sup>. On the other hand, it was shown that expression of the complete HBV genome that harbors the HBx and the PreS2 regulatory protein inhibits cell cycle progression<sup>[60]</sup> (Figure 1).

The analysis of HBx/protein kinase C (PKC) interaction is such an example for many reports analyzing the interference of HBx with signaling cascades and correlating this with a putative role of HBx for HBV-associated carcinogenesis. There are conflicting reports about the interference of HBx with PKC signaling. On the one hand, there are reports describing an HBx-dependent activation of PKC, mediated by an elevated DAG level in HBx-producing cells. In these studies, PKC is considered as an essential factor for the HBx-dependent activation of NF- $\kappa$ B or AP-1<sup>[61,62]</sup>. Other reports provide evidence that HBx neither affects activity of PKC nor that PKC is essential for HBx-dependent transcriptional activation<sup>[63-65]</sup>. The interesting aspect of an HBx-dependent activation of PKC is that a conclusive model for the role of HBx in the process of HBV-dependent carcinogenesis can be deduced. According to the two-step model of carcinogenesis<sup>[66]</sup> (initiation and promotion), the HBx-dependent activation of PKC could exert a tumor promoter-like function<sup>[61]</sup>. Independent from the point whether or not the HBx-dependent activation of PKC exerts a tumor promoter-like function, there is profound experimental evidence from experiments with transgenic mice that HBx indeed could exert a tumor promoter-like function. Irradiation of HBx transgenics or exposure of these transgenics to mutagens (diethylnitrosamine) caused a significant increase in the amount of pre-neoplastic lesions as compared to the wild-type control animals<sup>[67,68]</sup>. Apart from this, a variety of HBx transgenic mouse models were established, but only in one model system so far direct formation of liver cancer could be observed<sup>[69]</sup>.

A tumor promoter-like function of HBx does not necessarily require an activation of PKC. Other pathways as the activation of c-Raf-1-MEK/MAP2 (mitogen-activated protein kinase 2) kinase cascade could fulfill

**Figure 1** Major signaling pathways activated by the regulatory proteins HBx and PreS2 of HBV.

this function as well. Starting with the finding that HBx increases the Ras/GTP complex formation and thereby activates the c-Raf-1 signal transduction cascade<sup>[70]</sup>, more and more data were collected elucidating the interference of HBx with signaling cascades upstream of Ras. One of the next steps was the observation that Src is activated in HBx-producing cells<sup>[71,72]</sup>, followed by the observation that HBx is able to activate the cytosolic Ca<sup>2+</sup>-dependent praline-rich tyrosine kinase 2 (Pyk)<sup>[54]</sup>. Pyk is able to activate Src. A recent report describes an HBx-dependent activation of FAK (focal adhesion kinase), a well known regulator of Src kinases<sup>[53]</sup>. The activation of these signaling cascades requires the presence of HBx in an extranuclear compartment. On the other hand, there is evidence that a fraction of HBx is localized within the nucleus. The subcellular distribution of HBx is still a matter of debate. There are reports providing evidence that HBx is localized in the cytoplasm as well as in the nucleus<sup>[49,73]</sup>. The different localizations are associated with different functions. HBx localized in the cytoplasm is able to modulate intracellular signal transduction cascades as described above. Moreover, an association of HBx with the outer membrane of mitochondria that induces oxidative stress was described<sup>[74-76]</sup>. HBx localized in the nucleus is suggested to interfere directly with transcription factors or to exert a transcription factor-like function. A direct interaction with CREB (cAMP responsive element-binding protein) and ATF-2 (activating transcription factor 2) resulting in their increased DNA binding affinity<sup>[77]</sup> was reported as well as an interaction with RNA polymerase II in the transcription complex<sup>[78,79]</sup>.

In addition to the interaction of HBx with the transcription machinery, there is evidence that HBx interferes at multiple steps with DNA repair and so confers to an increase of critical mutations. HBx was found to bind to DDB1<sup>[80,81]</sup>, a subunit of the damaged DNA binding protein that is bound to damaged DNA, the first step in nucleotide excision repair. In cell culture experiments indeed the expression of HBx significantly inhibited the ability of cells to repair damaged DNA.

Therefore, it was tempting to speculate that HBx could confer by this to an increase in the amount of critical mutations in the host genome<sup>[80]</sup>. However, analysis of mutation frequency in HBx transgenic mice did not corroborate this hypothesis<sup>[82]</sup>. Other reports focus on the interaction of HBx with p53. On the one hand, it has been shown an indirect inhibition of p53 by HBx: HBx causes a transcriptional repression of the human p53 gene<sup>[83]</sup>. On the other hand, there is evidence for the capacity of HBx to bind to p53<sup>[84,85]</sup>. However, if the intracellular amounts of HBx and p53 are considered, there exists a tremendous excess of p53 as compared to HBx in the hepatocytes. The physiological significance of the direct p53/HBx interaction remains questionable.

### **The family of the PreS2 activators**

Apart from the HBx-regulatory protein, the HBV genome encodes a second family of regulatory proteins: the PreS2 activators. Based on a subcloned HBV integrate of the human hepatoma cell line huH4<sup>[86]</sup> and of an integrate isolated from an HBV-associated HCC<sup>[87]</sup>, preS/S genes that were truncated at the 3' end were identified<sup>[41]</sup>. These preS/S<sup>t</sup> genes encoded for C-terminally truncated surface proteins (MHBs<sup>t</sup>) that display a regulatory protein function. Initial analysis revealed that generation of the regulatory protein function requires at least deletion of the last transmembrane region in the S-domain (transmembrane region 3)<sup>[88-91]</sup>. This results in C-terminally truncated MHBs molecules that are endoplasmic reticulum (ER)-membrane associated by the remaining transmembrane regions I and II of the S domain<sup>[92,93]</sup>. A prototype of the ER-membrane-associated MHBs<sup>t</sup> activator is encoded by the integrate isolated from the human hepatoma cell line huH4<sup>[86]</sup>. This integrate is truncated at ntHBV 221 of the HBV genome resulting in a C-terminally truncated MHBs protein at amino acid (aa) 76 (MHBs<sup>t76</sup>). A detailed analysis revealed that a variety of differences exist between the structural protein MHBs and its C-terminally truncated variant MHBs<sup>t</sup>. In contrast to the structural protein MHBs and the regulatory variants, MHBs<sup>t</sup> are not secreted and lack the glycosylation at asparagine (asn) 4 of the PreS2 domain<sup>[92]</sup>. The intracellular retention of ER-membrane-associated MHBs<sup>t</sup> proteins gave raise to the hypothesis that the observed activator function is due to ER stress, induced by intracellular retention and subsequent accumulation in the ER<sup>[93-96]</sup>. More detailed analysis revealed, however, that the structural protein MHBs and the regulatory protein MHBs<sup>t</sup> differ in the topology of the PreS2 domain<sup>[97]</sup>. In case of the structural protein, the PreS2 domain faces the lumen of the endoplasmic reticulum and in accordance with this glycosylation at asn 4 can occur. In case of the activator protein MHBs<sup>t</sup>, the PreS2 domain directs into the cytoplasm. This explains the lack of N-glycosylation at asn 4. The PreS2 domain facing the cytoplasm interacts with cytosolic binding partners, thereby triggering intracellular signal transduction cascades. In accordance with this, a minimal PreS2 activator was identified lacking any membrane insertion domain (MHBs<sup>t55</sup>)<sup>[88,67,98]</sup>. This minimal activator encompasses the complete PreS2 domain and is localized within the cytoplasm. Since the

PreS2 domain is sufficient to exert the regulatory protein function, this class of regulatory proteins was designated PreS2 activator. The family of PreS2-regulatory proteins encompasses the membrane-associated regulatory proteins, such as MHBs<sup>t76</sup> or MHBs<sup>t167</sup>, and the non-membrane-associated short proteins, such as PreS2 domain (MHBs<sup>t55</sup>). There is no functional difference between the ER and the cytoplasmically localized PreS2 activators clearly arguing against the ER-overload hypothesis<sup>[97]</sup>.

The PreS1-PreS2 domain of the large hepatitis B virus surface protein (LHBs) displays a dual membrane topology<sup>[99-101]</sup>. In one fraction of LHBs, the first transmembrane region that is located at the beginning of the S-domain (aa 8-21) is used: in this case, the PreS1-PreS2 domain of LHBs faces the lumen of the endoplasmic reticulum. In case of the other fraction, this transmembrane region is not used, resulting in a PreS1-PreS2 domain that directs into the cytoplasm. As described above, the cytoplasmic orientation of the PreS2 domain in case of the MHBs<sup>t</sup> proteins is causative for their regulatory protein function. In accordance with this, LHBs displays a regulatory protein function<sup>[102]</sup> and belongs to the family of PreS2 activator proteins.

The PreS2 activators bind PKC- $\alpha$  in the cytoplasm. This interaction with PKC results in a DAG (1, 2, sn diacylglycerol)-independent activation of PKC and phosphorylation of the PreS2 domain. The activation of PKC is transduced by the c-Raf-1/MEK/ERK (extracellular signal-regulated kinase) signal transduction cascade<sup>[63]</sup>. This signal transduction cascade can exert a tumor promoter-like function according to the classical two-step model of carcinogenesis<sup>[66]</sup>. Indeed, transgenic mice expressing the PreS2 activator MHBs<sup>t76</sup> develop liver tumors at an age above 10 mo. Although the MHBs<sup>t76</sup> protein is produced in very small but clearly detectable amounts in the MHBs<sup>t76</sup> transgenic mice, a permanent activation of the Raf-1/MEK/ERK signal transduction cascade can be observed, resulting in an increased proliferation rate of the hepatocytes. The fact that MHBs<sup>t76</sup> is produced in very small amounts ensures that the observed effects are not due to any overload-associated effects. The tumor formation in these mice can be explained by the permanent activation signal transduction cascades that exert a tumor promoter-like function<sup>[63]</sup>. Since tumor formation is observed in older animals, it can be assumed that during the aging process critical mutations are accumulated (initiation) and then the tumor promoter function positively selects these cells.

In case of the LHBs-transgenics, tumor formation can be observed as well<sup>[103]</sup>. In these mice, a very strong overproduction of the LHBs protein occurs, resulting in an intracellular accumulation of the protein and subsequent formation of ground glass hepatocytes. This permanent accumulation results in a situation comparable to a storage disease. Tumor formation in these transgenics was explained by the resulting permanent inflammation<sup>[103-105]</sup>. In light of the observation that LHBs can act as a regulatory protein, however, the regulatory protein function that is immanent to LHBs should be considered as an additional factor conferring to tumor formation in these mice. The overload-associated stress

and inflammation results in the formation of critical mutations (initiation) and the permanent activation of the PKC/Raf/MEK/ERK signal transduction cascade which exerts a tumor promoter-like function.

### Immune pathogenesis of HCC

A major factor in the process of HBV-associated HCC development is the immune system<sup>[104,106,107]</sup>. The relevance of a chronic, virus-specific immune response for development of HBV-associated carcinoma was shown in an elegant experiment from F. Chisari's laboratory<sup>[108]</sup>. Transgenic mice that produce non-cytopathic amounts of HBsAg were used. In these mice, immunologic tolerance against the transgene product can be observed. In accordance with this, no evidence of the liver disease was observed. These mice were subjected to thymectomy and lethally irradiated. One group was reconstituted with the bone marrow and spleen cells derived from non-transgenic littermates that were vaccinated with a recombinant HBsAg encoding vaccinia virus resulting in HBsAg-specific cytotoxic T lymphocytes (CTLs) and antibodies. The other group was reconstituted with the bone marrow and spleen cells derived from transgenic donors that were immunologically tolerant.

In this animal model, the development of hepatitis and later of chronic hepatitis and finally HCC development could be exclusively observed in the mice that were reconstituted with the bone marrow and spleen cells derived from the vaccinated non-transgenic animals, but not in the control groups. Based on this, it was concluded that the immune system-mediated chronic inflammation of the liver, continuous cell death and subsequent cell proliferation might increase the frequency of genetic alterations and the risk of cancer<sup>[104,109-111]</sup>. This scenario is not exclusively restricted to HBV. Chronic inflammation, degeneration and regeneration are common to a variety of human liver diseases, such as glycogen storage disease or alcoholism or HCV infection, that can finally result in liver carcinoma development<sup>[5]</sup>. This means that an ineffective immune response can be the principal oncogenic factor during a chronic HBV infection in man. In other words, the same T-cell response can have complete different effects: if the T cell response is strong enough, HBV can be eliminated from the liver, if not, a pro-carcinogenic effect can be induced by permanently triggering necro-inflammatory disease without resulting in a final eradication of HBV from the liver. An interesting aspect is that the nucleoside analogue on lamivudine in patients with chronic hepatitis B can induce the recovery of antiviral T cell responses. However, restoration of HBV-specific T cell reactivity is only transient. The transient nature of the immune reconstitution may represent a favorable condition for virus reactivation once lamivudine therapy is withdrawn.

### CONCLUSION

At present, HBV-associated carcinogenesis can be seen as a multi-factorial process that includes both direct and indirect mechanisms that might act synergistically.

The integration of HBV DNA into the host genome occurs at early steps of clonal tumor expansion. The integration has been shown in a number of cases to affect a variety of cancer-related genes and to exert insertional mutagenesis. The permanent liver inflammation resulting in a degeneration and regeneration process confers to the accumulation of critical mutations in the host genome. In addition, the regulatory proteins HBx and the PreS2 activators that can be encoded by the integrate can exert a tumor promoter-like function, resulting in positive selection of cells producing a functional regulatory protein.

Based on new technologies, including gene expression profiling and proteomics, it should be possible to further reveal the molecular mechanisms underlying HBV-associated HCC development and to identify novel diagnostic markers as well as therapeutic and preventive targets.

## Abstract

Infection with hepatitis B virus (HBV) leads to a wide spectrum of clinical presentations ranging from an asymptomatic carrier state to self-limited acute or fulminant hepatitis to chronic hepatitis with progression to cirrhosis and hepatocellular carcinoma. Infection with HBV is one of the most common viral diseases affecting man. Both viral factors as well as the host immune response have been implicated in the pathogenesis and clinical outcome of HBV infection. In this review, we will discuss the impact of virus-host interactions for the pathogenesis of HBV infection and liver disease. These interactions include the relevance of naturally occurring viral variants for clinical disease, the role of virus-induced apoptosis for HBV-induced liver cell injury and the impact of antiviral immune responses for outcome of infection.

## MOLECULAR VIROLOGY OF HEPATITIS B VIRUS INFECTION

Hepatitis B virus (HBV) is a small DNA virus and

belongs to a group of hepatotropic DNA viruses (hepadnaviruses)<sup>[1,2]</sup>. The virus consists of a nucleocapsid and an outer envelope composed mainly of three hepatitis B surface antigens (HBsAg) that play a central role in the diagnosis of HBV infection. The nucleocapsid contains hepatitis B core antigen (HBcAg), a DNA polymerase-reverse transcriptase, the viral genome as well as cellular proteins<sup>[1,2]</sup>.

The genome consists of a partially double-stranded circular DNA molecule of about 3200 base pairs in length with known sequence as well as genetic organization. The pre-surface 1 [pre-S1]/pre-surface 2 [pre-S2]/and surface genes [S] code for the various HBsAg. The protein encoded by the pre-core [pre-C]/core gene [C] undergoes post-translational modification to yield hepatitis B e antigen (HBeAg), which is a seromarker for high viral replication<sup>[2]</sup>. The core gene codes for HBcAg, the major structural protein of the nucleocapsid. Finally, the X gene codes for the hepatitis B x antigen (HBxAg). HBxAg has been shown to be a potent transactivator of cellular and viral genes. A variety of interactions with cellular proteins has been proposed as potential targets of HBxAg. The precise functions of HBxAg, however, in the viral life cycle and the natural course of HBV infection remain to be established. In addition to the known viral genes, several *cis*- and *trans*-acting genetic elements involved in the fine control of gene expression, RNA packaging and viral replication have been identified<sup>[1,2]</sup>.

The viral DNA polymerase-reverse transcriptase is encoded by the polymerase gene [P] and is of central importance for viral replication. Different from all known mammalian DNA viruses, hepadnaviruses replicate *via* reverse transcription of a RNA intermediate<sup>[3,4]</sup>, the pregenomic RNA, which is a strategy central to the life cycle of RNA retroviruses. Similarities and differences between retroviral and hepadnaviral replication have been defined<sup>[1]</sup>. Based on the unique replication cycle of HBV, antiviral therapeutic strategies aimed at the reverse transcription of HBV RNA or at HBV reverse transcriptase have been successfully used as antivirals to treat HBV infection<sup>[5-13]</sup>.

## VIRAL VARIANTS AND PATHOGENESIS OF INFECTION

Evidence has been accumulating that certain HBV mutants are associated with unique clinical manifestations, may affect the natural course of the infection and confer

resistance to antiviral agents (Table 1)<sup>[14-17]</sup>. Naturally occurring mutations in the context of various genotypes have been identified in the structural and non-structural genes as well as regulatory elements of the virus. The best characterized mutants are the pre-core (pre-C) stop codon mutations resulting in a loss of hepatitis B e antigen<sup>[18]</sup>, defined clusters of mutations in the core promoter resulting in enhanced viral replication<sup>[19-21]</sup>, and mutations in the reverse transcriptase/polymerase genes conferring resistance to antivirals<sup>[16,22]</sup>. Furthermore, several mutations in the HBV surface gene have been identified which alter the antigenicity of the viral surface proteins (HBsAg) and structure of the viral envelope<sup>[15,23]</sup>.

### **HBeAg variants and HBeAg-seronegativity**

One of the first HBV mutations clinically recognized and functionally characterized was the pre-C stop codon mutation, resulting in a loss of HBeAg. Not all patients with chronic hepatitis B become HBV DNA negative, despite seroconversion from HBeAg to anti-HBe. Numerous studies have shown that these patients are infected with a pre-C/C mutant<sup>[24,25]</sup>. This mutant has a translation stop codon at the end of the pre-C gene. Thus, the pre-C/C fusion protein, a precursor of HBeAg, cannot be synthesized. In these patients, therefore, viral replication may persist despite elimination of HBeAg and seroconversion to anti-HBe. While the loss of HBeAg appears irrelevant for the biology of the virus, it may play an important role in the interaction of the virus with the immune system. Secreted HBeAg has been proposed to have an immunoregulatory function *in utero* by establishing T-cell tolerance to HBeAg and HBcAg that may predispose neonates born to HBV-infected mothers to develop persistent HBV infection<sup>[26]</sup>. Recent studies have further demonstrated an immunomodulatory role of HBeAg in antigen presentation and recognition by CD4<sup>+</sup> T-cells<sup>[27]</sup>. The selection of HBeAg mutants in the host may be due in part to immunomodulatory properties of HBeAg resulting in a survival advantage for the virus<sup>[28]</sup>. Whether and how this mutation - either alone or in combination with other mutations - affects the clinical course of HBV infection is still unclear.

Of interest in this respect is the observation that pre-C stop codon mutants are found not only in patients with fulminant hepatitis<sup>[18,29-32]</sup> or chronic active hepatitis B<sup>[24,25,33-35]</sup>, but also in asymptomatic HBV carriers<sup>[32]</sup> or acute, self-limited hepatitis<sup>[36]</sup>. In the woodchuck model, the pre-C stop codon mutation was found to exert no effect on viral replication or the severity of liver disease. Infections with the pre-C stop codon mutant, however, did not take a chronic course<sup>[37]</sup>. Interestingly, in the duck hepatitis B virus model the pre-C stop codon mutant replicates less well and is overgrown by wild-type virus during the natural course of coinfection<sup>[38]</sup>.

### **Core promoter variants and enhanced viral replication**

During the last couple of years mutations have been identified in regulatory genetic elements of the HBV genome. Several independent studies have identified and functionally characterized distinct mutations clustered in

**Table 1** HBV variants and their potential impact for pathogenesis of HBV infection

HBV region	Mutation	Molecular phenotype	Clinical relevance
Pre-S/S	Pre-S1/ pre-S2/ S-promotor	Misassembly	Fibrosing cholestatic hepatitis
	S	Alteration of B- and T-cell epitopes	Vaccine escape
	S splicing		Immune escape Diagnostic escape
Pre-C	Pre-C-stop	Loss of HBeAg	Severe hepatitis HBeAg-deficiency
Core	Core	Alteration of T-cell epitopes	Viral persistence Severe hepatitis
RT/Pol	Pol	Replication deficiency	Viral latency Viral persistence
	Pol	Resistance to antivirals	Therapy escape
Regulatory Elements	Core promotor	Enhanced replication and core expression	Severe hepatitis Modulation of drug resistance
		Decreased HBeAg synthesis	HBeAg seronegativity
	Enhancer I	Decreased replication	Chronic hepatitis

HBV genomic region, mutation, molecular phenotype and clinical relevance are indicated.

enhancer II of the HBV core promotor. Core promoter mutations are predominantly found in patients with a more aggressive course of disease such as fulminant<sup>[19,39-41]</sup> or chronic hepatitis B<sup>[21,33,42-45]</sup>. Some of the patients have a decrease or loss of HBeAg<sup>[39,43]</sup>.

A common hallmark of core promoter mutations is the biological phenotype of enhanced viral replication in transfected hepatoma cell lines<sup>[19,21,33,39-44]</sup> and primary hepatocytes<sup>[20]</sup>. The most prevalent mutant comprises a double mutation (A to T at nucleotide 1764 and G to A at nucleotide 1766, nucleotide numbering according to<sup>[46]</sup> located at the 3'-end of enhancer II of the basal core promotor being present in up to 80% of individuals chronically infected with HBV<sup>[47]</sup>.

Several other core promoter mutations in immunocompromized patients and severe or fulminant liver disease have been identified<sup>[41,42,45]</sup>. A common phenotype of these mutations seems to be the enhanced viral encapsidation by altering the balance between pre-C and C RNA transcript levels<sup>[42]</sup>. Several of these mutations have been shown to create additional transcription factor (HNF-1, HNF-3, HNF-4 or C/EBP) binding sites<sup>[41,42,48]</sup>. The magnitude of mutant-induced enhancement of viral replication seems to be dependent on the HBV subtype/genotype<sup>[40,49]</sup>.

The phenotype of enhanced viral replication may be the reason why core promoter mutants seem to be selected in immunosuppressed patients or patients with chronic hepatitis. Interestingly, one study suggested the presence of core promoter mutations was significantly associated with the development of hepatocellular carcinoma (HCC)<sup>[50]</sup>. Furthermore, the high-replication phenotype of viral strains containing core promoter mutations may play a role in the pathogenesis of more aggressive or severe disease associated with these mutations. Interestingly, the

transmission of a high-replication strain containing two core promotor mutations and the pre-C mutation to HBV-naïve patients has resulted in an outbreak of fulminant fatal hepatitis<sup>[19]</sup>. Enhanced viral replication with the concomitant increase in viral protein expression may result in a differential immune response as well as a more rapid and widespread infection in naïve patients<sup>[19,20,40]</sup>. Altered viral kinetics accompanied by a more vigorous cellular immune response may be important mechanisms resulting in more severe liver injury and potentially fulminant hepatitis. Another factor contributing to fulminant hepatic failure associated with defined core promoter mutations may be hepatocyte apoptosis induced by the HBV variant<sup>[20]</sup>. Since not all patients with fulminant hepatitis are infected with HBV strains exhibiting a high-replication phenotype<sup>[51]</sup> additional mechanisms for the pathogenesis of fulminant hepatitis likely exist<sup>[52]</sup>.

### Variants of HBsAg and immune escape

A variety of mutations have been identified in the HBV structural genes resulting in differential antigen recognition and immune response<sup>[53]</sup>. During the course of a passive-active HBV immunization program in southern Italy, several children were infected with HBV despite a primary response to the HBsAg vaccine. Molecular analyses showed that one of these children was infected with a HBV mutant<sup>[54,55]</sup>. This mutant exhibited a defect in the S region of the HBV genome (glycine (Gly) to arginine (Arg) at amino acid position 145) with loss of the group-specific antigenic determinant a, which is the main target of the vaccine response. Further biological characterization of this mutant in the context of replication-competent viral genomes revealed that this mutation also results in impaired S secretion and decreased virion stability<sup>[56]</sup>. This viral mutant was able to escape the immune surveillance and thereby resulted in an infection despite the presence of anti-HBs antibodies ('vaccine escape mutant'). Similar mutants have been detected in Japan<sup>[57]</sup> and the Gambia<sup>[58]</sup> and presumably occur world-wide<sup>[53]</sup>. Consistent with these initial observations, a recent study demonstrated the accumulation of HBsAg a determinant mutants during the implementation of universal vaccination programs in Taiwan<sup>[59]</sup>. In contrast to these epidemiological observations, a study in the chimpanzee model using currently available US-licensed HBV vaccines demonstrated protection against the 'classical' vaccine escape (Gly-145-Arg) mutant *in vivo*. This study provides strong evidence that immunization with recombinant HBV vaccines stimulates anti-HBs that is broadly reactive and protects the host efficiently from infection with HBV strains containing the Gly-145-Arg mutant<sup>[60]</sup>. Since this study only evaluated the protective properties of licensed HBV vaccines against the Gly-145-Arg mutant, it does not exclude the possibility that other genuine vaccine escape mutants result in immunization failure<sup>[60]</sup>. Further studies are needed to address this issue. In addition to immune escape on the B cell level, vaccine escape mediated by defined HBsAg epitopes can occur on the T cell level<sup>[61]</sup>. Taken together, these findings indicate, that careful epidemiologic monitoring of vaccine failure caused by infection with HBV mutants may be crucial for the success

of global immunization strategies.

'Immune escape mutants' have also been reported in patients after liver transplantation for HBV-related chronic liver disease who had received monoclonal or polyclonal anti-HBs antibodies to prevent reinfection of the graft<sup>[62-65]</sup>. 'Immune escape mutants' have also been identified in anti-HBs positive individuals<sup>[57,66]</sup>.

In addition to 'vaccine escape mutants' and 'immune escape mutants', 'diagnosis escape mutants' have been described, since most of the HBsAg detection assays are based on anti-HBs antibodies<sup>[57,67]</sup>. Diagnostic escape may also be the result of a posttranscriptional effect of viral mutations on HBsAg expression as described by Hass *et al* in an elegant study isolating a naturally occurring mutation targeting splicing of subgenomic RNA<sup>[68,69]</sup>. The emergence of these variants may potentially contribute to occult HBsAg-negative HBV infection<sup>[70]</sup>.

Mutations have further been detected in the pre-S1 or pre-S2 regions of the HBV genome. Their clinical significance is as yet unknown, however. Since the preS1 region appears to be important for the very first steps of viral infection<sup>[71,72]</sup>, it is conceivable that variants affecting this region may also affect the biological phenotype of the virus by altering its ability to bind or infect hepatocytes. A pre-S2 defective HBV variant has been associated with fulminant hepatitis B<sup>[73]</sup>. A cluster of mutations in the S promotor (two deletions and a point mutation in the regulatory element CCAAT) isolated from a patient with fibrosing cholestatic hepatitis after HBV reinfection of the transplanted liver has been shown to result in virus retention and misassembly<sup>[74,75]</sup>. Furthermore, a recent study demonstrates evidence that patients with progressive liver disease have a higher frequency of pre-S deletion<sup>[76]</sup>. HBsAg variants resulting in a defect or impairment in virion secretion have also been described in severe and fulminant hepatitis B<sup>[56,77]</sup>.

### Mutations conferring resistance to antiviral therapy

In recent years polymerase gene mutants have been identified in patients treated with antiviral drugs, resulting in drug resistance, respectively<sup>[78]</sup>. Lamivudine, a nucleoside analogue, is a potent inhibitor of HBV replication and is clinically used as an antiviral for the treatment of chronic hepatitis B and advanced HBV-induced liver disease<sup>[11,12,79,80]</sup>. Adefovir is an alternative nucleotide analogue previously licensed for the treatment of chronic hepatitis B<sup>[9,10]</sup>. Other nucleoside analogues currently under clinical investigations include entecavir, emtricitabine, clevudine and telbivudine<sup>[16,78]</sup>. Several of these drugs act as chain-terminators during the synthesis of the nascent DNA strand, thereby terminating viral replication<sup>[16]</sup>. Other nucleoside or nucleotide analogues such as adefovir and entecavir interfere with priming and minus-strand DNA elongation<sup>[16]</sup>. Adefovir and-to a lesser extent-lamivudine also target initial plus-strand DNA repair<sup>[81]</sup>.

The selection of drug resistant mutants depends on several factors. As the viral polymerase is subjected to a spontaneous error rate, viral mutants accumulate during the natural course of the disease. When an antiviral pressure is applied, the mutations exhibiting the best replication capacity in the presence of the drug

are selected. The mutant spread depends on its level of intrinsic resistance and on its replicative fitness<sup>[16]</sup>. This may explain in part why the peaks of drug resistance observed with lamivudine (23% at year one and up to 65% at year five of treatment<sup>[82,83]</sup>) and with adefovir dipivoxil (2% at two years and 3.9% at three years of treatment<sup>[84,85]</sup>) are different.

These mutant viral genomes are characterized by selective amino acid changes in various domains of the HBV reverse transcriptase/polymerase. In particular, lamivudine resistance has been extensively studied. The reverse transcriptase polymerase of HBV and HIV share a common and highly conserved tyrosine, methionine, aspartate, aspartate (YMDD) nucleotide-binding motif in the catalytic domain of the enzyme. Similar to the development of lamivudine-resistant HIV mutants, lamivudine treatment of patients with chronic HBV infection results in drug-resistant strains, characterized by YMDD to YIDD (tyrosine, isoleucine, aspartate, aspartate; "M204I") or YVDD (tyrosine, valine, aspartate, aspartate; "M204V") mutations in the catalytic C-domain of the reverse transcriptase<sup>[16,86]</sup>. Interestingly, the mutant genomes exhibited lower levels of replication when compared with wild-type genomes<sup>[87]</sup>. Further studies identified additional mutations in the neighboring B domain (V173L and L180M<sup>[88]</sup>). Interestingly, these mutations can restore partially the replication capacity of the C-domain mutations<sup>[88]</sup>.

In contrast to lamivudine, viral resistance to adefovir appears to be mediated pre-dominantly by a mutation in the D-domain<sup>[84]</sup>. The N236T mutation confers only a 5-10-fold resistance to adefovir<sup>[84]</sup>, which may explain the delayed emergence of this mutant<sup>[16]</sup>. Another mutation A181V located in the B-domain has been described<sup>[16]</sup>. Three recently isolated cases of primary adefovir resistance were due to a mutation comprising I233V. Interestingly, the viral variants containing this mutation were sensitive to tenofovir<sup>[22]</sup>. Drug resistance due to viral mutations in the reverse transcriptase/polymerase represents an important clinical issue in the management of chronic hepatitis B and may ultimately require the development of novel treatment approaches including the combination of various antiviral strategies<sup>[16,78]</sup>.

In summary, a large variety of HBV mutations associated with various pathological conditions as well as drug resistance have been isolated and described in detail<sup>[15]</sup>. Studies *in vitro* as well as *in vivo* have defined the functional relevance of several viral mutants. Furthermore, these studies provided important clues for the understanding of the impact of these mutants on the pathogenesis of disease and the molecular characterization of drug resistance. Functional studies of mutants in established and emerging HBV *in vivo* models<sup>[89]</sup> may ultimately allow confirmation of the relationship between defined mutations and their clinical relevance<sup>[15]</sup>.

## MECHANISMS OF HBV-INDUCED LIVER DISEASE: APOPTOSIS

The induction of apoptosis is a hallmark of many viruses

infecting humans. Although HBV is considered as a non-cytopathic virus<sup>[14]</sup>, hepadnavirus-induced apoptosis and cytopathic effects have been described in several experimental model systems: First, a duck hepatitis B variant containing a single amino acid change in the large surface antigen resulting in accumulation of cccDNA resulted in a strong cytopathic effect in hepatocytes *in vitro* and *in vivo*<sup>[90-92]</sup>. In this system, the level of viral replication and cccDNA formation correlated with cytopathic effects in infected hepatocytes<sup>[90]</sup>. Second, intracellular retention of the HBV large surface protein has been shown to induce apoptosis in cell lines<sup>[93,94]</sup>. In this model overexpression of the large surface antigen resulted in cellular vacuolization and apoptosis of transfected hepatoma cells<sup>[94]</sup>. Third, the HBX protein has been suggested to induce apoptosis in both a p53-dependent and p53-independent manner<sup>[95-97]</sup>. Exploring the mechanism of these previous observations, a recent study has elegantly demonstrated that HBX interacts with c-FLIP, a key regulator of the death-inducing signaling complex<sup>[96]</sup>. Recruitment of c-FLIP to the death-inducing signaling complex is inhibited by HBX resulting in hyperactivation of caspase-8 and caspase-3 by death signals<sup>[96]</sup>. Finally, a viral variant containing two core promoter mutations associated with fulminant hepatitis has been shown to induce apoptosis in primary Tupaia hepatocytes<sup>[20]</sup>. Interestingly, in the latter model induction of apoptosis was independent of viral replication suggesting that viral protein synthesis was sufficient for the virus-induced hepatocyte cell death. Since the two core promoter mutations resulted in two amino acid changes of the HBX protein, the HBX protein may be a potential candidate mediating this effect<sup>[20]</sup>. Further studies in animal model systems are needed to elucidate the impact of HBV-induced apoptosis for HBV-induced liver injury<sup>[20]</sup>.

## IMMUNOPATHOGENESIS OF HBV INFECTION

Apart from direct biological effects of viral variants (Table 1) there is growing consensus that the host immune response, especially the virus-specific T cell response<sup>[98]</sup>, is the key determinant influencing the course of disease and the onset of liver disease.

### Successful immune response.

A genomic array analysis using liver RNA obtained at multiple time points after HBV infection in chimpanzees demonstrated that HBV did not induce any genes during entry and expansion<sup>[99]</sup>, suggesting it is a stealth virus early in the infection. In contrast, a large number of T cell-derived IFN-gamma-regulated genes were induced in the liver during viral clearance<sup>[99]</sup>, reflecting the impact of an adaptive T cell response that inhibits viral replication and kills infected cells, thereby terminating the infection. These results are in agreement with several studies performed in acutely infected patients suggesting an important role of the adaptive T cell response<sup>[98,100-105]</sup>. Indeed, several studies have shown that the peripheral blood cytotoxic T lymphocyte (CTL) response to HBV is polyclonal and multispecific in patients with acute viral hepatitis and that

it persists indefinitely after recovery, when it is maintained by continued antigenic stimulation by residual virus that persists, apparently harmlessly, in healthy convalescent individuals<sup>[106]</sup>. In contrast, the CTL response to HBV is relatively weak in patients with chronic HBV infection, except during spontaneous disease flares or interferon (IFN) induced recovery, when it is readily detectable<sup>[101,104]</sup>. These earlier studies have been confirmed by using new techniques, such as the tetramer technology. By using this approach, Maini *et al*<sup>[100]</sup> could, for example, show that multispecific HBV-specific CD8<sup>+</sup> T cell responses are detectable during the acute phase of self-limited infection and decline thereafter. Of note, a recent study could also demonstrate that HBV-specific CD8<sup>+</sup> T cells accumulate in the infected organ, i.e., the liver, where they remain detectable at high frequencies even after HBsAg seroconversion<sup>[107]</sup>.

Studies in the HBV transgenic mouse model revealed that, in addition to causing viral hepatitis, virus-specific T cells as well as NK and NKT cells can abolish HBV expression and replication without killing the hepatocytes and that this antiviral activity is mediated by interferon gamma (IFN $\gamma$ ) and tumor necrosis factor alpha (TNF $\alpha$ )<sup>[104,108,109]</sup> (Figure 1). Importantly, studies in the chimpanzee model indicated that the same events are operative during natural infection. Indeed, in these studies it was shown that the early phase of HBV clearance was temporally associated with the appearance of CD3, CD8 and IFN $\gamma$  in the liver, which reflects the influx of T cells into the liver<sup>[110]</sup>. Of note, there was only limited liver disease during this time although almost 100% of hepatocytes were infected, clearly suggesting that noncytotoxic mechanisms were active during this early phase of viral clearance. In contrast, the final elimination of the virus that occurred several weeks later occurred in the presence of significant liver disease, indicating the presence of cytopathic effector functions that are probably mediated by virus-specific T cells<sup>[110]</sup>.

To determine which subset of T cells is responsible for viral clearance and liver disease, the course of HBV infection in chimpanzees that were depleted of its CD4<sup>+</sup> or CD8<sup>+</sup> cells was monitored<sup>[111]</sup>. Depletion of CD4<sup>+</sup> cells did not significantly alter the course of infection. In contrast to the minor effects observed during CD4-depletion, CD8-depletion greatly prolonged the infection and delayed the onset of viral clearance and liver disease until CD8<sup>+</sup> T cells reappeared in the circulation and virus-specific CD8<sup>+</sup> T cells entered the liver<sup>[111]</sup>. Indeed, in the absence of CD8<sup>+</sup> cells, the duration of peak infection was prolonged and the time of onset of the initial decrease in HBV DNA levels and increase in serum ALT activity was delayed. In addition, the time required for both the first phase of viral clearance and for the final elimination of the virus was markedly delayed and prolonged in the CD8-depleted animal. It is important to note that the reappearance of CD8<sup>+</sup> cells correlated with the appearance of IFN $\gamma$  producing virus-specific CD8<sup>+</sup> T cells in the liver, the onset of a mild liver disease, the appearance of IFN $\gamma$  mRNA in the liver and a 50 fold reduction in total liver HBV DNA<sup>[111]</sup>. These results suggest that HBV

**Figure 1** Cytopathic and non-cytopathic T cell responses against HBV infection.

replication is inhibited early and non-cytopathically in a CD8 dependent and probably IFN $\gamma$  associated manner. The final elimination of the virus occurred several months later and was associated with a rebound of CD8<sup>+</sup> cells to baseline levels, a surge of the intrahepatic CD8<sup>+</sup> T cell response, a surge in intrahepatic IFN $\gamma$  mRNA and a surge in sALT activity. Thus, these results demonstrate that intrahepatic HBV-specific CD8<sup>+</sup> T cells are required for rapid viral clearance during acute HBV infection. In addition, the data suggest the existence of dual antiviral functions that overlap temporally during natural infection but can be clearly separated by CD8 depletion: a primarily noncytolytic CD8<sup>+</sup> dependent mechanism that may be mediated by IFN $\gamma$  and a primarily cytolytic mechanism that clears the remaining infected cells. It is also important to note that virus-specific CD8<sup>+</sup> T cells display oscillating effector functions during the course of infection that seem primarily influenced by the interaction of the T cells with the antigen-presenting cells<sup>[112,113]</sup>.

### T cell failure

In contrast to the strong and multispecific T cell responses observed during acute self-limited HBV infection, patients with chronic hepatitis B tend to have weak and narrowly focused immune responses<sup>[98]</sup>. The mechanisms that contribute to the failure of the virus-specific T cell response in chronically infected patients are only poorly understood and may include T cell deletion, anergy, exhaustion, ignorance and T cell dysfunction. HBV establishes chronic hepatitis mainly by vertical transmission from HBV infected mothers to neonates. The immunomodulatory effects of the HBeAg might play a role in this setting since it has been shown to be tolerable to T cells in transgenic mice. An important mechanism for the development of viral persistence in adults may be the development of viral escape mutations. Of note, mutational inactivation of B-cell and T cell epitopes has been demonstrated in chronic HBV infection but it seems to occur much less compared to the hepatitis C virus<sup>[101,104,114]</sup>. Little information is currently available about the intrahepatic T cell response during chronic HBV infection. Of note, one study showed functional, tetramer positive CD8<sup>+</sup> T cells in the blood and the liver of

chronically HBV infected patients. However, the number of intrahepatic HBV-specific, tetramer-positive T cells did not differ between HBeAg negative patients with normal ALT levels and HBeAg positive patients with increased ALT levels, even though the intrahepatic cellular infiltrate was greater in the latter group<sup>[115]</sup>. These results suggest a differential contribution of HBV-specific and HBV non-specific bystander lymphocytes in the pathogenesis of chronic hepatitis. T cell dysfunction might also contribute to viral persistence. For example, Reignat *et al.*<sup>[116]</sup> have shown that HBsAg-specific CD8<sup>+</sup> T cells display abnormal HLA/ peptide tetramer binding properties in contrast to HBcAg-positive CD8<sup>+</sup> T cells. A high viral load may be one important factor that contributes to T cell failure. In this regard, it is important to note that antiviral treatment can overcome CD8<sup>+</sup> T cell hypo-responsiveness in subjects with chronic HBV infection, suggesting that the T cells are present but suppressed<sup>[117,118]</sup>. First evidence suggests that next to high viral loads and a lack of virus-specific CD4<sup>+</sup> T cell help, regulatory T cells may contribute to this T cell suppression<sup>[119,120]</sup>. Clearly, additional studies are required to better understand the complex host-virus interactions that determine the outcome of HBV infection.

## CONCLUSION

Virus-host interactions, especially the virus-specific T cell response, are the key factors accounting for the pathogenesis of HBV infection. Viral variants may influence the course of disease and deserve special attention in the setting of antiviral therapy, immune escape and reactivation during immunosuppressive therapy.

### Abstract

The human hepatitis B virus (HBV) and the duck hepatitis B virus (DHBV) share several fundamental features. Both viruses have a partially double-stranded DNA genome that is replicated via a RNA intermediate and the coding open reading frames (ORFs) overlap extensively. In addition, the genomic and structural organization, as well as replication and biological characteristics, are very similar in both viruses. Most of the key features of hepadnaviral infection were first discovered in the DHBV model system and subsequently confirmed for HBV. There are, however, several differences between human HBV and DHBV. This review will focus on the molecular and cellular biology, evolution, and host adaptation of the avian hepatitis B viruses with particular emphasis on DHBV as a model system.

### INTRODUCTION

Full understanding of the molecular biology of the human hepatitis B virus (HBV) is hampered by a variety of experimental restrictions. There is no small animal model system available for infection studies and only few aspects of the viral life cycle are accessible to biochemical methods. A complete viral infection cycle mimicking natural HBV infection *in vitro* could only be achieved until recently with primary human hepatocytes. The disadvantages of this system are: (1) restricted accessibility to the cells, (2) infection inefficiency and (3) high variability in infection assays. The recent establishment of the HepaRG cell line is therefore a major breakthrough and allows HBV infection studies under defined conditions for the first time<sup>[1]</sup>.

This review will focus on one of two established animal virus models; i.e., the DHBV model system. The human HBV and DHBV share several fundamental features. Both viruses have a partially double-stranded DNA genome that is replicated via an RNA intermediate and the coding open reading frames (ORFs) overlap extensively. In addition, the genomic and structural organization, as well as replication and biological characteristics, are very similar in both viruses. They both infect hepatocytes preferentially and have a very similar life cycle. Most of the key features of hepadnaviral infection were first discovered in the DHBV model system and subsequently confirmed for HBV. This includes replication of the viral genome by reverse transcription of a RNA intermediate<sup>[2]</sup>, mechanisms of covalently closed circular (ccc) DNA formation and amplification<sup>[3]</sup>, details of reverse transcription<sup>[4]</sup>, and determinants of host tropism<sup>[5]</sup>.

In light of the above mentioned austerities for HBV, the DHBV model of hepatitis B virus infection remains a convenient and reliable system that offers several unique advantages. Most importantly, steady availability and highly reproducible infection of primary duck hepatocytes (PDHs) provide the optimal basis for *in vitro* and *in vivo* studies of the molecular and cellular biology of hepatitis B virus infection under defined and controlled conditions. In addition, the chicken hepatoma cell line LMH produces progeny virus after transfection with cloned, mutant or wt DHBV genomes, which can be used to infect PDHs or ducks<sup>[6]</sup>.

Thus, the DHBV model system is a unique system that allows elucidation of the hepadnaviral life cycle in considerable detail. However, there are several differences

Table 1 Comparison of HBV and DHBV

	HBV	DHBV
Natural host	Human	Pekin duck
Related viruses	WM-HBV, WHV	HHBV, SGHBV
Pathogenicity		
Chronic infection	yes	yes
Liver injury	yes	no
Experimental systems		
Cell transfection	yes	yes
<i>In vitro</i> infection	yes	yes
Transgenic mouse	yes	no
Small animal model	no	yes

WMHBV: woolly monkey HBV; WHV: woodchuck HBV; HHBV: heron HBV; SGHBV: snow goose HBV.

between human HBV and DHBV. First of all, DHBV infection normally results in chronicity since the virus is transmitted from the hen to the egg (see<sup>[7]</sup> and references therein). This infection usually does not lead to liver injury and the infected duck remains healthy throughout life. When an adult duck is infected, the infection is usually eliminated. When HBV is transmitted from mother to child, it also often results in chronic infection. However, in a large number of cases, this leads to liver injury and development of hepatocellular carcinoma or cirrhosis. When an adult is infected, this can either result in fulminant, acute or chronic hepatitis when the virus is not eliminated. Another difference between DHBV and HBV is expression of the X protein (for further differences see Table 1). This regulatory protein, with not fully understood function, is expressed by HBV from a conventional ORF, but in DHBV, an unusual cryptic ORF is used.

In the last two decades, parts of the hepadnaviral life cycle, especially the replication strategy, could be undecieved in considerable detail. In contrast, there is very little information available on the infectious entry or secretion pathway. The cellular partners involved in cell-virus interactions at these stages of infection remain unidentified and the molecular determinants of host specificity, hepatotropism and the nature of the receptor complex still await discovery.

For more information about human HBV and the other corresponding model systems please see the comprehensive reviews in this issue.

## AVIAN HEPATITIS B VIRUSES

The duck hepatitis B virus was discovered in 1980 by William Mason and colleagues<sup>[8]</sup>. They found a virus very similar to HBV in about 10% of Pekin ducks from two different sources in the USA and they pointed out that no abnormal level of mortality or signs of hepatitis were found in the infected ducks. Naturally occurring DHBV infections have been reported in Pekin ducks and related species from China, USA, Canada, Europe, India, and South Africa<sup>[9-11]</sup>.

Since then, avihepadnaviruses have been detected in various duck species<sup>[10]</sup> including exotic ducks and geese<sup>[10]</sup> (DHBV), in snow geese<sup>[12]</sup> (SGHBV), a Ross' goose

**Figure 1** Phylogenetic tree of avian hepadnaviruses and related hosts. Phylogenetic relationship of all known avian hepadnaviruses based on preS/S gene sequence. The corresponding natural hosts are also indicated.

(RGHBV, GenBank Acc.No. M95589), white storks<sup>[13]</sup> (STHBV), demoiselle and grey crowned cranes<sup>[14]</sup> (CHBV) as well as grey herons<sup>[15]</sup> (HHBV). Like their mammalian counterparts, avihepadnaviruses have a rather narrow host range. For instance, DHBV infects only certain duck and goose species but neither infects Muscovy ducks nor chickens<sup>[16]</sup>. Little is known about the host range of HHBV or STHBV. Despite its substantial sequence homology with DHBV, HHBV does not infect ducks and only very inefficiently primary duck hepatocytes<sup>[15]</sup>. Recently, we reported that cranes are naturally infected with a hepatitis B virus, designated CHBV<sup>[14]</sup>. Cranes are phylogenetically very distant from ducks and are more closely related to herons and storks (Figure 1). Interestingly however, CHBV infects primary duck hepatocytes with similar efficiency as DHBV. Collectively this and related data suggest that the host range of hepadnaviruses cannot be simply predicted based on the evolutionary relatedness of their respective hosts. For a comprehensive sequence comparison and a phylogenetic tree of the host birds see<sup>[14]</sup>.

Phylogenetic analysis of the various isolates demonstrated a rather high variability among DHBV strains, whereas genomes from other avihepadnaviruses, such as stork or crane hepatitis B virus, appear less variable. HHBV infection occurs not only in captive grey herons, but also with high prevalence in free-living birds. We have detected HHBV in another heron species (great blue heron) as well as in two of its sub-species (great white heron and Würdemann's heron). Thus, the virus persists in free-living birds and is an endogenous virus of several heron species.

DHBV will certainly remain the most important avihepadnavirus for research purposes since the infection system with PDHs and the important research tools are well established. It is possible to generate mutant viruses after transfection of cloned DHBV genomes into the chicken hepatoma cell line LMH<sup>[6]</sup>. Thus, different mutations can be studied not only concerning their effects

on replication but also on infection efficiency and events. In addition, *in vivo* infections can be performed in ducks without the need to establish expensive handling facilities and without risk. In these ducks not only the host range of hepadnaviruses can be studied in considerable detail (in addition to *in vitro* studies), but also the activity and toxicity of antiviral substances can be addressed<sup>[17]</sup>.

## THE AVIHEPADNAVIRAL LIFE CYCLE: AN OVERVIEW

Avian hepatitis B viruses belong to the family of DNA viruses that replicate their DNA genome by reverse transcription of an RNA intermediate. Thus, they belong, together with the cauliflower mosaic virus, to the group of pararetroviruses that do not integrate their genome into host cell chromosomes.

A schematic view of the DHBV genome and structure of virions is shown in Figure 2. The genome of DHBV has an unusual design. It consists of a ca. 3000 bp partially double-stranded DNA. The circularity of the genome is achieved by overlapping cohesive 5' ends<sup>[18]</sup>. The coding negative strand is complete and even has a short terminal redundancy but is not covalently closed. Its 5' end is covalently attached to the viral polymerase P<sup>[19]</sup>. The positive strand is not complete but encompasses between 40% and 85% of the genome<sup>[20]</sup>. However, the length of the gap varies among different hepadnaviruses and is smallest in DHBV<sup>[18]</sup>. Attached at the 5' end of the positive strand is a short ribooligonucleotide, which is a remnant of the pregenomic RNA (pgRNA)<sup>[21]</sup>. Both 5' terminal structures function as primers during viral replication<sup>[21]</sup>. As another particularity, the viral genome has two direct repeats (DR) with a length of 11 base pairs that have important functions in replication.

The viral genome organization is very compact and economic. All nucleotides have a coding function in at least one of the four open reading frames (ORFs). Regulatory sequences such as enhancers and promoters, as well as several cis-acting elements, overlap with coding regions. The first ORF encodes the surface proteins L and S, the second codes for the capsid protein as well as the e-antigen, the third for the polymerase and a cryptic fourth for the X protein<sup>[22]</sup>.

Two different types of spherical viral particles can be detected in the serum of infected ducks: infectious virus particles (virions) with a diameter between 40 and 60 nm and subviral particles (SVPs) with a diameter between 30 and 60 nm, which lack the 27 nm nucleocapsid, including the viral genome<sup>[23]</sup>. After transfection of cell lines, a third particle entity can be detected in the cell culture supernatant. These cells secrete so called 'naked capsids' lacking the viral envelope for unknown reasons.

The virus is surrounded by a lipid envelope, which presumably originates from the host cell endoplasmic reticulum (ER) membrane, and contains both viral surface proteins. For HBV, it has been shown that the membrane is rich in phosphatidyl choline (60% of all lipids) as well as cholesterol (30% of all lipids)<sup>[24]</sup> and thus differs from the lipid composition of the cellular ER membrane,

**Figure 2** Virion structure and genome organization of avian hepadnaviruses. The viral envelope is derived from hepatocellular membranes and contains the viral surface proteins S and L. It covers the nucleocapsid harbouring the viral genome with the covalently linked terminal protein domain (TP, orange circle) of the polymerase (P, red circle) and cellular proteins like Hsc70. The genome is organized as depicted. The various transcripts are indicated by thin lines with the small arrowhead indicating the start sites. The partially double stranded, viral DNA with the covalently bound TP domain of P (red circle) is symbolized by the thicker lines. The numbered circles 1 and 2 on the viral DNA represent the direct repeats (DR). Enh represents the enhancer domain. The ORFs encoding core (C), polymerase (P), and the surface proteins (preS and S) are symbolized by thick arrows. Epsilon (De) is the stem loop structure on the pgRNA which acts as an encapsidation signal and replication origin. The second encapsidation element Dell is unique to avian hepatitis B viruses, since the mammalian counterparts lack this RNA structure. SD and SA represent the major splice donor and acceptor sites, respectively.

implicating that lipids are actively selected for the viral membrane. In total, the amount of lipids in comparison to the amount of protein is very small, in SVPs the weight ratio is about 1:4<sup>[25]</sup>. Thus, the lipids in the viral envelope are presumably not forming a lipid bilayer but protein aggregates seem to be separated through short lipid regions<sup>[26]</sup>. This strongly restricts the lateral mobility of the envelope components. The lipid composition of the DHBV envelope remains to be determined.

SVPs largely consist of the viral surface proteins S and L, which are incorporated into the envelope. They do not contain viral DNA and are thus not infectious. This entity is secreted from infected cells in excess compared to virions. It is assumed that per virion 1000 to 10000 SVPs are secreted<sup>[27]</sup>. SVPs can compete with viral binding and thus infection<sup>[28]</sup>. In contrast, it has been shown that SVPs enhance infection when a very low multiplicity of infection (MOI) is used, which indicates an important role in the viral life cycle<sup>[29]</sup>.

Complete virions contain an icosahedral capsid inside the envelope, which is about 35 nm in diameter as seen in cryo-electron microscopy or 27 nm in negative stain pictures and consists of 240 subunits of core protein<sup>[30]</sup>. The nucleocapsid holds the viral DNA genome with the covalently attached polymerase.

Cellular components can additionally be packed into viral particles. This is the case for Hsc70, which was detected in large amounts<sup>[31]</sup>. The identity and function of other proteins of cellular origin are still unknown.

A schematic view of the viral life cycle is shown in Figure 3. The life cycle of DHBV starts with attachment of the viral particles to their receptor/receptor complex on the surface of the target host cell. This is mediated by the preS domain of the viral L protein that binds to

**Figure 3** Model of the hepadnaviral life cycle. The hepadnaviral particle binds the hepatocyte via a specific receptor complex/molecule. It then enters the cell via endocytosis and is transported intracellularly in a MT-dependent fashion. After release out of the endosomal compartment, the nucleocapsid containing the viral DNA binds the nuclear pore complex and the viral genome is released into the nucleus. It is also possible that the whole nucleocapsid enters the nucleus and releases the viral DNA inside. Afterwards, the viral rcDNA is converted into cccDNA and viral transcripts are made. These are exported into the cytosol where the pgRNA is packaged together with the viral polymerase into the nucleocapsid. Inside the capsid, the RNA is reverse transcribed into the viral DNA genome. These matured nucleocapsids can then either be transported to the nucleus to add to the cellular cccDNA pool or they interact with viral surface proteins on the cellular ER membrane. There, the nucleocapsid buds into the lumen of the ER and is then transported in a yet undefined fashion to the cell surface where the viral particle is released into the cell exterior.

unknown cellular receptor compounds. After binding, viral particles are taken up into the cell by receptor-mediated endocytosis<sup>[32-34]</sup>. Then, the nucleocapsid is released from the endosomal compartment into the cytosol. It is currently under discussion whether a low endosomal pH is necessary for this release. The cytoplasmic nucleocapsids are then transported to the nucleus to initiate productive infection. This transport strongly depends on active microtubules (MT) but not on actin<sup>[27]</sup>.

After reaching the nuclear membrane, the core protein is presumably phosphorylated and exposes a nuclear localization signal. This results in binding of nuclear factors; e.g., importins, to the capsid, which leads to uptake of the whole complex into the nucleus<sup>[35]</sup>. However, disassembly of the capsid near the nuclear membrane and subsequent transport of the viral DNA into the nucleus

cannot be excluded.

In the nucleus, the relaxed form of the viral genome, the rcDNA (relaxed circular), is converted into the covalently closed, circular form (cccDNA). This is only possible after removal of the 5'-terminal structures (protein and RNA), repair of the gap and covalent ligation of the strands by cellular proteins. The cccDNA is usually not incorporated into the host genome but is organized in nucleosomes in the form of an episome<sup>[36]</sup>.

Transcription of the viral genome is mediated by the cellular RNA polymerase II<sup>[37]</sup>. *In vivo*, three different viral RNA classes could be identified, which are all polyadenylated and possess a cap structure<sup>[21]</sup>. They all have the same 3' end since only one polyadenylation site is present in the viral genome but have different 5' ends due to different transcription initiation sites. The different viral

RNAs are transported into the cytoplasm and translated. The two longest RNAs (3.5 kb), which stretch the whole genome, have two different functions. They code for the viral proteins core, the polymerase and e-antigen but one also serves as the pregenome<sup>[21]</sup>. Part of the 3.5 kb mRNA is spliced and serves as mRNA for L protein synthesis. A second class of viral RNAs (2.1 kb) encodes for the large surface protein, and the third class (1.8 kb) codes for the small surface protein, which is the most abundant one. The identity of the X-encoding RNA is unknown.

After export into the cytosol, the viral RNAs are translated and the viral surface proteins are directly inserted into the ER membrane. Once inserted, they can autonomously form subviral particles or interact with capsids to form virions.

In the cytosol, core protein dimers interact with each other and self assemble with the viral polymerase and the pgRNA into ribonucleoprotein complexes<sup>[38]</sup>. The pgRNA is packaged upon a chaperone-mediated interaction of the polymerase with the stem loop structure epsilon (ε). This structure also serves as the replication origin for the reverse transcription. Prior to packaging, the core protein is phosphorylated<sup>[39]</sup>. It is currently unclear whether reverse transcription initiates during ribonucleoprotein complex formation or after assembly of the capsid. However, when the pgRNA is inside the capsid, the particles mature, e.g. the RNA is reverse transcribed into the viral DNA genome and the core proteins are dephosphorylated<sup>[2,40]</sup>. The mature capsids interact with the viral surface proteins at the membrane of the ER and bud into the lumen, thus forming complete virions. The enveloped virions are then presumably transported through the constitutive secretion pathway to the cell surface and are released there. Alternatively, mature capsids can be transported to the nucleus and add to the cccDNA pool. After a successful infection, between one and 20 cccDNA molecules can be detected inside the nucleus<sup>[41]</sup>. This re-infection cycle preferentially occurs during establishment of an infection when the levels of large surface protein are low<sup>[42]</sup>. After a successful infection, the levels of L inside the cell rise and capsids preferentially form virions and are secreted.

In the absence of mature capsids and due to the autonomous budding activity of the viral surface proteins, subviral particles are formed. S as well as L proteins seem to accumulate in membrane domains of the ER where they reach quite high densities. When they reach a critical density, they presumably bud into the ER lumen and form subviral particles.

## DHBV PROTEINS AND THEIR BASIC FUNCTIONS IN VIRAL ENTRY, REPLICATION, AND MORPHOGENESIS

### Core protein and e-antigen

The viral core protein fulfils several opposing functions during the different stages of the viral life cycle; e.g., nucleic acid binding and assembly opposed to disassembly and nucleic acid release. These diverse functions are partly regulated by: (1) subcellular localization, (2) quaternary structure and (3) posttranslational modification by phos-

phorylation and dephosphorylation of its C-terminus.

The viral nucleocapsid is composed of dimeric subunits of the viral core protein (DHBc) with a molecular weight of 32 kDa. The N-terminal region of the core protein (up to about 144 aa) is acetylated<sup>[43]</sup> and sufficient for assembly of the capsid shell<sup>[44,45]</sup>. The carboxyterminal end of the protein, the so called C-terminal domain (CTD), is extremely basic and binds nucleic acids. This is essential for packaging of the pgRNA into the nucleocapsid as well as progression of reverse transcription within<sup>[44,46]</sup>. In addition, a nuclear localization signal is present between aa 184 and 226 along with a nuclear export signal<sup>[47]</sup>.

The major phosphorylation sites in the core protein are mapped to the arginine-rich C-terminus. This domain contains consensus sequences for different cellular kinases, such as PKC, SRPK1 and SRPK2 (Figure 4). Furthermore, Thr174 is highly conserved and is a cdc2 kinase phosphorylation site. Compared to the extracellular core protein, intracellular core is highly phosphorylated. Mutational analysis of the major phosphorylation sites revealed that individual or combined substitution had no overt effect on pgRNA packaging. However, the S245A mutant was deficient in genome maturation<sup>[48]</sup>. It has been shown that the CTD contains several phosphosites, which are heterogeneously phosphorylated intracellularly and hypophosphorylated or non-phosphorylated in the secreted virion<sup>[40,43]</sup>. This dephosphorylation, which occurs as nucleocapsids mature (meaning that the pgRNA is reverse transcribed into the rcDNA genome), is thought to be a maturation signal that results in secretion of only fully matured virions containing the DNA genome<sup>[43]</sup>. In addition, it has been shown that binding of hepadnaviral capsids to the nuclear pore complex depends on the phosphorylation status of the core protein<sup>[35]</sup>. The kinases or phosphatases implicated in these steps are not known. This is also true for the fate of the nucleocapsids after nuclear binding; it is not known whether they disassemble at the nuclear pore and thereafter release the viral DNA or if they are transported through the nuclear pore and then disassemble.

DHBc has the autonomous ability to assemble into particulate structures, which is dependent on the DHBc concentration<sup>[49]</sup>. The nucleocapsid is a dynamic structure and subject to regulated conformational transitions. Formation of progeny virions requires stable

nucleocapsids, whereas during viral entry, the incoming viral structure must disassemble and release the viral genome. Furthermore, reverse transcription of the viral genome occurs within the capsid and it is thought that this is linked with structural rearrangements in the capsid.

The ultrastructural analysis of the HBV core protein revealed that the monomeric form is dominated by a long alpha-helical hairpin structure<sup>[45]</sup>. The first step of capsid formation is the homodimerization of two core protein monomers that arrange in a way that leads to an antiparallel order, which results in an almost exact twofold symmetry. As a result, the characteristic spike on the capsid surface is formed by a compact four helix bundle. These spikes are the regions that interact in the virion with the viral envelope structures. Preliminary 3D reconstruction of the DHBV capsid suggests that the protein forms T-shaped dimers similar to the human core protein (M. Nassal, personal communication).

The open reading frame that encodes DHBc also codes for a nonstructural viral protein, which is the DHBc or precore. This e-antigen is, compared to the DHBc, truncated at the C-terminus and extended on the N-terminus. In addition it contains a type I signal recognition sequence. It is translocated into the ER during synthesis where the signal recognition sequence is cleaved and the C-terminus removed. After this processing, e-antigen is transported through the Golgi complex and secreted from the infected cell<sup>[50,51]</sup>. It has been shown that the e-antigen is glycosylated<sup>[50]</sup>. The glycosylation pattern seems to differ among the different avian hepadnaviruses and even among different isolates of DHBV due to the presence of different numbers of N-glycosylation sites. This is, for instance, obvious in a recent study of HHBV e-antigen that has one glycosylation site. This resulted in two bands in immunoblot analysis (one for glycosylated and for non-glycosylated e-antigen), while CHBV e-antigen with two N-glycosylation sites showed three bands on the immunoblot<sup>[14]</sup>.

DHBc can be detected in the serum of infected ducks<sup>[52]</sup> and serves as a marker for efficient viral replication. Its exact function is unknown, but it has been shown that it plays no essential role in viral replication, morphogenesis or infectivity<sup>[53]</sup>. However, it seems to play a role in the establishment of chronic infections<sup>[54]</sup> and its absence may confer a growth advantage of precore-minus mutants over wildtype virus<sup>[55]</sup>.

### Polymerase

The viral polymerase is a multifunctional protein of about 90 kDa in size. It has a DNA-dependent DNA polymerase activity/domain to fill the gap in the viral DNA during replication<sup>[56]</sup> and an RNaseH activity/domain to selectively digest RNA from an RNA-DNA-hybrid molecule<sup>[57]</sup>, as it has been shown for HBV. It also has reverse transcriptase (RT) activity to transcribe the RNA pregenome into the DNA genome during replication<sup>[2]</sup>. The polymerase homology domain is centrally located, whereas the RNaseH homology domain is located near the C-terminus of the protein. Viruses with point mutations in these regions are either defective for viral DNA synthesis or only allow negative-strand but not positive-strand DNA

synthesis<sup>[56]</sup>. Most N-terminal sections of the polymerase domain are spacer regions without any other apparent function<sup>[58]</sup>. Most N-terminal sections are the region implicated in the covalent linkage of the P protein to the viral DNA often referred to as terminal protein.

In the process of viral genome replication, during which the pregenomic RNA is transcribed into the genomic DNA, the different domains can assert their different functions. The pgRNA is transcribed from the viral cccDNA by cellular polymerase II. This RNA is then transported into the cytosol and binds the viral polymerase and the core proteins. The polymerase recognizes the epsilon and another downstream region on the viral RNA and binds there with the help of cellular proteins like Hsp90<sup>[59]</sup>. Inside the particle, the RNA is transcribed into the negative strand DNA by the RT domain of the polymerase. This process is primed by the protein itself and tyrosine 96 of the P protein serves as a primer<sup>[60]</sup>. This results in covalent attachment of the nascent DNA strand onto the terminal protein part of the polymerase. After attachment of about 4 nucleotides, this DNA product is transferred to the DR1 sequence on the viral pgRNA. This is possible since the epsilon signal and the DR1 share a 4 nucleotide identity. From this position, the DNA negative strand is elongated by the conventional mechanism<sup>[61,62]</sup>. As this elongation proceeds, the template RNA is degraded by the RNaseH activity of the viral polymerase<sup>[2,63]</sup>. The end product of this reaction is a negative-stranded DNA, which is terminally redundant by about 8 nucleotides.

Positive strand synthesis is initiated at DR2 and primed by a short oligoribonucleotide, which is a remnant from the pgRNA<sup>[64]</sup>. This primer is transferred to a complementary region at the 5' end of the negative strand DNA for positive strand synthesis. From there, synthesis of the positive strand proceeds.

Sometimes (in about 1% to 5% of cases) the primer fails to translocate. This results in a process called *in situ* priming, where a fully duplex linear DNA is the end product<sup>[65]</sup>. This is a dead end for viral replication but may be the cause for integration of some viral genomes into the chromosomal DNA of the host cell.

Elongation of the positive strand proceeds until the 5' end of the negative strand is reached. Then, an intramolecular strand transfer is needed to complete positive strand synthesis. This happens after circularization of the genome, which is possible because of the short redundancies at each strand end. After the circularization, positive strand synthesis can proceed. Usually elongation does not proceed until the end of the template is reached. In the case of DHBV, normally about 80% of the positive strands complete elongation<sup>[20]</sup>.

### Envelope proteins

The multiple functions of the viral envelope proteins are reflected by the domain organization and unique biochemical features. The DHBV envelope proteins are encoded by a single ORF consisting of the preS and S domain. The viral envelope proteins are inserted into the membrane of the virus that originated from intracellular membranes (presumably the ER) of the infected cell. In the case of DHBV, these envelope proteins are the small

protein S, which constitutes about 80% of total envelope proteins, and the large protein L, which constitutes about 20%<sup>[66,67]</sup>. S protein is thus the most abundant protein in the viral envelope. It determines the envelope curvature and is indispensable for both budding and secretion of viral particles. Both viral surface proteins are unique compared to other viral surface proteins in their relatively complex structure and topology<sup>[68]</sup>. They have a molecular weight of 18 and 36 kDa, respectively, and are anchored in the membrane by several transmembrane domains. The C-terminus of both proteins are identical, while L is N-terminally extended by 161 aa compared to S. The length of this extension varies with the isolate. This unusual organisation results from differential transcription of a single ORF<sup>[67]</sup> (Figure 2).

The L protein is modified with myristic acid at its N-terminal glycine after removal of the first amino acid methionine, which presumably anchors the protein in the membrane in addition to the transmembrane domains<sup>[69]</sup>. This myristoylation is required for infectivity of the virus but not for assembly<sup>[69]</sup>. Unlike the envelope protein of HBV, DHBV L and S are not modified by N-glycosylation although they contain consensus glycosylation sites. In contrast, it has been shown that the DHBV L protein (p36) is the only surface protein that is phosphorylated<sup>[70,71]</sup>. This phosphorylation occurs at serine 118 by an ERK-type MAP kinase and is not essential for viral replication, particle formation or infectivity<sup>[71]</sup>.

As transmembrane proteins, L and S are incorporated cotranslationally into the ER membrane. The proteins have four transmembrane domains (TM1 to TM4) that anchor them in the membrane and consist of membrane-spanning hydrophobic alpha-helices (Figure 5). In addition, the preS domain of the L protein contains two translocation motifs (TLM), which are 12 amino acid encompassing domains that form an amphipathic alpha helix<sup>[32]</sup>. TLMs mediate an energy- and receptor-independent transfer of peptides, nucleic acids and proteins when fused to them across membranes without affecting their integrity<sup>[72]</sup>. The DHBV-TLMs are located between amino acids 20-31 (TLM1) and 42-53 (TLM2) and required for viral infectivity.

Worth mentioning is the dual topology of the L protein<sup>[73]</sup>. After cotranslational insertion of the protein into the cellular membrane, part of the proteins changes the topology (Figure 5). This leads to exposure of the N-terminus to the cytosolic side of the membrane in about half of the L proteins while the other half has the N-terminus directed to the luminal side<sup>[74]</sup>. In this way, the protein can fulfil two different functions: it can interact with the cellular receptor on the outside of the virus and it can interact with the nucleocapsid on the inside. Whether S also adopts a dual topology remains to be determined.

The viral surface proteins are able to autonomously form subviral particles without the help of an interacting nucleocapsid. The exact mechanism of this phenomenon is not known, yet it is assumed that the proteins interact with each other to form microdomains in the ER membrane from which they bud when they reach a critical density. A prerequisite for this budding activity would be a tight interaction of the viral surface proteins with the membrane lipids and a membrane bending activity. When

**Figure 5** Dual topology of the viral surface protein L. The L protein is inserted into the ER membrane during synthesis with transmembrane domain 2 being inserted into the membrane. Half of the proteins then change their topology and insert the transmembrane domain 1 into the ER membrane. After this change and formation of the virus, L can exert its two basic functions: interaction with the nucleocapsid on the cytosolic preS domain and interaction with the host cell receptor on the surface of the viral particle.

L protein is expressed without the S component, particles are formed inside the cells, but are not secreted. This retention and secretion defect can be overcome by co-expression of the S protein<sup>[75]</sup>. This implies an important function for the S protein in secretion of viral particles.

Another function of the L protein is regulation of cccDNA amplification. As mentioned above, cccDNA is the replication template for all hepadnaviruses. It is a prerequisite for maintaining chronic infection of hepatocytes and is the main obstruction during antiviral therapy since it is mostly not eliminated from the cells. The amount of cccDNA inside the host cell nucleus is thus of great importance for the virus. To maintain its replication template in the nucleus, it re-infects and this process is regulated in an elaborate manner by the large viral surface protein<sup>[76]</sup>. During the early stage of infection when the amount of L protein is low inside the cell, mature core particles preferentially infect the nucleus to add to the cccDNA pool. Concomitant with the increase in cccDNA, the levels of L increase. This leads to redirection of the mature capsids into the secretory pathway and reduces cccDNA amplification.

The L protein is also responsible for superinfection exclusion, which prevents hepadnaviral infection of already infected hepatocytes<sup>[77]</sup>. This phenomenon was first ascribed to downregulation of the putative viral receptor protein gp180. This has not been confirmed and it has been suggested that superinfection exclusion may result from a role of L as a regulator of intracellular trafficking<sup>[77]</sup>.

The L protein not only plays a role in viral morphogenesis or cccDNA amplification, but it is also implicated in additional regulatory functions such as signalling<sup>[71]</sup>. The cytosolically exposed preS domain of the L protein has the potential to activate gene expression from cellular promoter elements in *trans*. It is also phosphorylated by ERK2 at serine 118, which is induced by various stimuli and may play a role in intracellular virus-host crosstalk<sup>[71]</sup>.

### X protein

One major difference between the avian and mammalian hepatitis B viruses is the presence of an ORF called X in the latter. The function of this regulatory protein is still far from being understood. Recently it has been reported

**Figure 6** Current model for entry and intracellular trafficking of DHBV. The hepadnaviral life cycle starts with the attachment of virions to specific binding sites on the surface of hepatocytes mediated by the preS region of the large viral envelope protein L. Afterwards the virus enters the cell via endocytosis and resides in an endocytic vesicle which is transported in a MT-dependent and probably polar fashion. The endosomal release of the incoming particle requires the activity of the vacuolar H<sup>+</sup>-ATPase and presumably the cholesterol of the viral envelope. After release, the particle is transported in a MT-dependent fashion mediated by dynein/dynactin to the nucleus and initiates infection after release of the viral genome at the nuclear membrane or within the nucleus. However, the majority of viral particles is missorted and degraded by the proteasome and other cellular proteases.

that X protein enhances the replication of transfected HBV genomes<sup>[78]</sup>. DHBV lacks an apparent X-ORF. But a cryptic X-like ORF has recently been reported<sup>[22]</sup>. *In vivo* experiments have suggested no functional role for this gene product in DHBV short term infection<sup>[79]</sup>.

## DHBV INFECTION

### *In vitro* infection

Hepadnaviruses can only efficiently infect primary hepatocytes with the exception of the recently published HepaRG cell line, which can be infected with the human HBV<sup>[1]</sup>. Thus, primary hepatocyte cultures have to be established for use with hepadnaviruses. In the case of DHBV, either primary fetal or adult hepatocytes can be used. Fetal hepatocytes can be obtained easily from the livers of non-hatched duck embryos. These are digested with collagenase, washed and plated. This results in a mixed culture containing hepatocytes as well as other cells of the liver, which are the non-parenchymal cells, such as macrophages, sinusoidal endothelial cells, and fibroblasts. Alternatively, primary duck hepatocyte cultures can be obtained from adult ducks by liver perfusion. This results in a rather homogenous suspension of cells containing high amounts of hepatocytes (up to 90%) compared to

non-parenchymal cells. Compared to primary human hepatocytes, PDHs are about 20 times more permissive to hepadnaviral infection.

The cells are cultured in a standard medium containing hydrocortisone, insulin as well as DMSO. The DMSO is important for maintaining differentiation and thus infectability of the cells<sup>[80]</sup>. Under these culture conditions, the cells remain infectable for up to 2 weeks in culture and viral spread occurs. The DMSO as well as omitting serum from the cell culture medium are essential conditions for maintaining cellular infectability since addition of serum to the cultures decreases the amount of cellular receptor proteins on the cell surface<sup>[81]</sup>.

Research with the *in vitro* model of DHBV infection has lead to the discovery of many different features of the hepadnaviral life cycle. However, while factors involved in the early and most vulnerable steps of the viral life cycle (Figure 6) have been identified for a variety of viruses, little is known for hepadnaviruses (for a review see<sup>[7]</sup> and references therein).

Hepatoma cell lines, which can replicate the viral DNA and produce progeny virus after transfection of the viral genome into the nucleus, are not permissive for infection with the virus itself<sup>[82]</sup>. This phenomenon led to the assumption that the absence of a viral receptor or

receptor complex on the cell surface of these cells is the major determinant for infection. Great effort was invested to identify these molecules. But to date, the molecules responsible for the viral uptake that leads to productive infection are still unknown, although carboxypeptidase D (gp180) has been shown to specifically interact with the viral L protein and leads to internalization of viral particles after heterologous expression<sup>[83-85]</sup>. However, this did not lead to productive infection of these cells. In addition, the protein has been shown to not only bind DHBV, but also the viral surface protein from heron HBV, which does not infect PDHs, and this protein is not liver specific. It thus cannot be the determinant for viral host range or tissue specificity. This shows that either additional factors are required for the infection or that gp180 plays no role in the productive uptake and binding of the virus.

Initial binding of hepadnaviral particles seems to involve a component with low affinity without saturation and a component with high affinity and saturation<sup>[28]</sup>. This indicates that the binding involves at least two determinants and thus components. Several competition experiments with recombinant preS peptides, neutralizing antibodies and SVPs showed that the preS region of the viral L protein is essential for viral binding and the establishment of an infection<sup>[26,28,86,87]</sup>. In addition, it has been shown that preS peptides that were myristoylated were much more efficient in preventing DHBV infection than non-myristoylated peptides, which indicates that the myristoylation of L plays an important role during infection<sup>[86]</sup>.

To gain more insight into the enigmatical early steps of hepadnaviral infection, we recently characterized the early attachment and entry events of DHBV infection in PDHs<sup>[27]</sup>. To do so, we established a sensitive, PCR-based assay that allowed us to investigate viral binding and entry. This binding and entry assay showed that only a small proportion of the inoculum binds to the cell surface of hepatocytes. Also the overall number of particles that bind to the cell surface is quite low, after 2 h at 4°C, only up to 10 virions and 10 000 SVPs per cell were detectable. This indicates that the number of hepatocellular surface binding sites is about 10 000 per cell. Binding was prevented by the use of neutralizing antibodies as well as suramin, which also prevented viral infection showing that the detected binding sites are relevant for productive infection.

The steps after viral binding also remain quite elusive. It was shown years ago that the kinetics of DHBV uptake is unusual since binding and entry seem to be very slow. For a maximal infection efficiency, cells have to be incubated with the virus up to 16 h<sup>[80]</sup>. We have recently shown that viral uptake indeed needs an unusually long time period<sup>[27]</sup>. 1 h after attachment only about 70% of bound DHBV was taken up and internalization was complete within 3 h. This shows that virus uptake itself takes a relatively long time period, but since after 3 h all bound virions were internalized, uptake is very efficient. In contrast, viral trafficking inside the cell does not seem to be efficient since a high proportion of viral particles are degraded after viral entry into the cell and thus cannot establish infection<sup>[34]</sup>.

It has been shown previously that DHBV entry into

PDHs requires energy, which indicates that cellular and/or viral processes actively take place and that DHBV is presumably entering the cell via endocytosis<sup>[33,34]</sup>. Studies addressing the pH-dependency of DHBV infection by the use of chemical substances that increase endosomal pH led to contradicting results<sup>[33,88-90]</sup>. However, the weight of data favours pH-independent entry as well as an endocytic mechanism and shows that the virus does not require passage through a highly acidic compartment. The effect of the vATPase inhibitors seem to be due more to effects on viral trafficking inside the cell than on the endosomal pH alone<sup>[34]</sup>.

After the virus is taken up by the cell via endocytosis, it has to be transported to the nucleus to establish infection. In the nucleus, the viral rcDNA is converted into the cccDNA. This conversion is detectable within the first 24 h after virus inoculation<sup>[27,91]</sup>. Thus, after efficient viral uptake there is an unusually long gap of 13 to 17 h before the appearance of nuclear viral cccDNA. This gap suggests that there is a rate-limiting post entry step that precedes cccDNA formation, which involves viral uncoating and nuclear genome transport, or is required for rc- to cccDNA conversion. The intracellular transport has been shown to be independent of the actin skeleton, which in contrast seems to restrict entry, and is strictly dependent on the microtubule (MT) network of the cell<sup>[27]</sup>. Overexpression of dynamin, a cofactor subunit of the motor protein complex dynactin-dynein, which mediates transport along microtubules, also reduced DHBV infection (our unpublished data). To date it remains unknown whether the MT-dependent transport of the virus (or the nucleocapsid alone) occurs only at the stage of the endosome or if the virus alone also interacts with microtubules.

To deliver the viral DNA into the nucleus, it has to be released from the viral particle and, prior to that, the viral particle has to be released from the endosomal compartment it resides in. It has been shown that this involves an unusual mechanism that depends on the integrity of a so called TLM<sup>[32]</sup>. The TLM thus mediates release of the viral particle out of the endosome into which it initially entered.

The infectious entry pathway of hepadnaviruses appears to involve a series of highly coordinated and directional steps leading to the nuclear delivery of viral genomes essential for the establishment of a productive infection. These steps may, alone or in combination, determine the species and host cell tropism common to all hepadnaviruses.

### ***In vivo infection***

DHBV-infected ducks exhibit age-related outcomes of infection, which is similar to HBV-infected humans. In principle, hepadnaviruses have the ability to cause either a transient or chronic infection. When infected with DHBV, young ducks develop persistent infection whereas adult ducks become transiently infected and eliminate the virus<sup>[92]</sup>. These different outcomes are viral dose dependent; persistent infection in young ducks develops more frequently with higher doses of virus<sup>[92]</sup>. In some cases, dependent on age and infection with a given mutant,

experimental infections can cause symptoms of a liver inflammation<sup>[93]</sup>. It has been shown that one genome equivalent is sufficient to infect a duckling and that spread of the virus within the liver is very efficient: 14 d after inoculation, virtually all hepatocytes were infected<sup>[94]</sup>. In addition, it has been shown that the difference between the infection outcome in older and neonatal ducks depends on the production of neutralizing antibodies against the virus<sup>[95]</sup>. The rapid production of neutralizing antibodies in older ducks led to an efficient inhibition of viral spread in the liver.

The duck hepatitis B virus infects Chinese domestic and American pekin ducks as well as geese. Normally, infection takes place through vertical transmission from the infected hen to the eggs and results in a chronic infection that is without symptoms and is tolerated by the immune system<sup>[23]</sup>. The virus then replicates in the egg yolk sack and is transferred to the embryonic hepatocytes by day 6 of development<sup>[96]</sup>. Thus, all offspring from an infected hen are DHBV-positive.

When DHBV infection is persistent in the duck, viral replication mainly occurs in the hepatocytes of the liver. Usually, the level of viral replication is then very high, with most hepatocytes infected and expressing the viral antigens. This is also reflected in the amount of viral antigens circulating in the blood stream. Up to  $10^{10}$  virions and  $10^{13}$  SVPs can be detected per ml of serum<sup>[97]</sup>.

*In vivo* infections with DHBV are often used to study the growth kinetics of viral mutants<sup>[79]</sup>. This allows elucidation of specific mutations in the viral genome on the behaviour of this respective mutant in their natural host. In contrast to the *in vitro* situation, the role of the immune system and the spread of the virus within the infected liver can be assessed.

It has been shown that the addition of lipopolysaccharides (LPS, endotoxin) to PDH cultures inhibited DHBV replication efficiently<sup>[98]</sup>. This was due to the release of interferon alpha and gamma from non-parenchymal cells (i.e. Kupffer cells, resident macrophages of the liver). The exact mechanism behind this phenomenon is not known.

## HOST SPECIFICITY

All known hepadnaviruses are strongly, but not exclusively, cell type specific and have a narrow host range restricting them to their natural host and a few closely related species (Figure 1). DHBV, for example, infects only certain duck and goose species, but either does not or very inefficiently infects chicken or Muscovy ducks, respectively. Despite its substantial sequence homology with DHBV, the heron HBV (HHBV) does not infect PDHs. Although ducks and duck-derived primary hepatocytes are virtually non-permissive for HHBV, substitution of a region of the HHBV-specific preS domain of the L protein by the corresponding sequence from DHBV overcomes this species barrier. As a consequence, the pseudotyped HHBV virions can efficiently infect primary duck hepatocytes<sup>[5]</sup>. The same is true for mammalian hepadnaviruses, as shown for woolly monkey hepatitis B virus pseudotyped with a small stretch of preS1 sequence from HBV, which was

then infectious for human hepatocytes. Thus, although the sequence of this region is very divergent among the different hepadnaviruses, the biological functions seem to be conserved. The so called host-determining region (HDR) in the preS part of the avian L protein was mapped to amino acids 22 to 90, and an exchange of this small region also changed the species specificity<sup>[5]</sup>. These studies clearly indicate that the block to cross-species infection by hepadnaviruses is destined at the level of infectious viral entry. A small domain within the preS region of the L protein plays a pivotal role in host discrimination.

We showed that cranes are naturally infected with a novel hepadnavirus, designated crane HBV (CHBV)<sup>[14]</sup>. Phylogenetically, cranes are very distant from ducks and are closely related to herons and storks. However, we found that CHBV infects PDHs with similar efficiency as DHBV, indicating a rather broad host range of this virus at least *in vitro*. Whether CHBV can establish chronic infection in ducks *in vivo* and is as non-pathogenic as DHBV remains to be elucidated. Interestingly, comparison between the HDR of DHBV and the HDR of CHBV reveals a short insert of 3 amino acids (PMP) in the CHBV L protein, a sequence similar but not identical to the analogous region of HHBV and STHBV, whereas all other known duck and goose hepadnaviruses have no such insert (Figure 7). It remains to be shown which sequence features of the L protein are responsible for the unusual broad host range of CHBV and at which level of infection the block in cross-species infection is determined.

Accordingly, comparative genomic and subgenomic sequence alignment from different avihepadnaviruses facilitates the prediction of specific properties of each virus and helps to gain insight into the mechanisms controlling species specificity and host adaptation.

## CHEMOTHERAPY AND VACCINATION

Antiviral drugs currently in use for therapy of chronic hepatitis B are nucleoside analogues and interferon. These therapies are unsatisfactory since the virus is usually not eliminated from the infected patient and resistant viruses frequently appear after treatment with nucleoside analogues. These data show the need for additional therapies and therapeutic strategies. The therapeutic effect of new vaccination strategies as well as chemotherapeutic agents can be assessed with the DHBV model system.

A long-term study showed that treatment of persistently infected ducks with 0.1 mg/kg per day of entecavir resulted in a rapid 4-log drop in serum DHBV

surface antigen<sup>[99]</sup>. However, a rapid rebound of levels of DHBV DNA and antigens in serum and liver was observed when entecavir was discontinued. When entecavir was administered at the time of DHBV inoculation, it was not effective to prevent infection but it led to a significant suppression of viral spread even after withdrawal of the drug<sup>[100]</sup>. Thus, short term suppression of DHBV infection shortly after infection provides the opportunity for the immune response to successfully control the infection.

Immunotherapy using DNA vaccines has been proposed as a way to improve viral clearance via the induction of an effective immune response. It has been shown that a DNA vaccine expressing DHBV surface antigens induces high levels of antibodies directed against these antigens, which protected or partially protected the animals against a challenge with DHBV<sup>[101]</sup>. This suggests that DNA vaccines may be an alternative to conventional vaccines for inducing immune response and protection against infection.

## ACKNOWLEDGMENTS

We apologize to those authors whose work we could not cite directly due to space limitations. The authors are indebted to Claudia Franke (Heinrich-Pette-Institute, Hamburg, Germany) for providing the picture of core protein phosphorylation.

## Abstract

This review describes the woodchuck and the woodchuck hepatitis virus (WHV) as an animal model for pathogenesis and therapy of chronic hepatitis B virus (HBV) infection and disease in humans. The establishment of woodchuck breeding colonies, and use of laboratory-reared woodchucks infected with defined WHV inocula, have enhanced our understanding of the virology and immunology of HBV infection and disease pathogenesis, including major sequelae like chronic hepatitis and hepatocellular carcinoma. The role of persistent WHV infection and of viral load on the natural history of infection and disease progression has been firmly established along the way. More recently, the model has shed new light on the role of host immune responses in these natural processes, and on how the immune system of the chronic carrier can be manipulated therapeutically to reduce or delay serious disease sequelae through induction of the recovery phenotype. The woodchuck is an outbred species and is not well defined immunologically due to a limitation of available host markers. However, the recent development of several key host response assays for woodchucks provides experimental opportunities for further mechanistic studies of outcome predictors in neonatal- and adult-acquired infections. Understanding the virological and immunological mechanisms responsible for resolution of self-limited infection, and

for the onset and maintenance of chronic infection, will greatly facilitate the development of successful strategies for the therapeutic eradication of established chronic HBV infection. Likewise, the results of drug efficacy and toxicity studies in the chronic carrier woodchucks are predictive for responses of patients chronically infected with HBV. Therefore, chronic WHV carrier woodchucks provide a well-characterized mammalian model for preclinical evaluation of the safety and efficacy of drug candidates, experimental therapeutic vaccines, and immunomodulators for the treatment and prevention of HBV disease sequelae.

## INTRODUCTION

Infection of adult humans with the hepatitis B virus (HBV) results characteristically in self-limited hepatic disease with recovery based on serological and clinical parameters. Progression to chronic HBV infection occurs infrequently in infected adults, but HBV infections often persist in unvaccinated infants born to HBV-carrier mothers. Chronic HBV infection can lead to chronic hepatitis, liver cirrhosis, and hepatocellular carcinoma (HCC) later in life. Estimates indicate that more than 2 billion people worldwide have serological evidence of previous or current HBV infection, with at least 350 million chronic carriers, and an overall mortality rate from HBV-induced liver disease of 1.2 million deaths per year<sup>[1]</sup>. Although highly effective vaccines are licensed and have been in use since the early 1980's to prevent HBV infection in neonates and adults, the large reservoir of chronic HBV

carriers currently remaining could benefit immensely from the timely development of effective antiviral and/or immunotherapies that cure the infection or reduce the risk of disease progression.

Evidence from HBV-infected humans, and from animal models of HBV (i.e., HBV-transgenic mice, chimpanzees, pekin ducks, and woodchucks), indicate that the success or failure of humoral and cellular immune responses to the virus determine the initial outcome of acute HBV infection (i.e., as self-limited versus chronic), and that defective responses appear to play a role in the progression of chronic HBV infection (i.e., to chronic hepatitis, cirrhosis, and possibly HCC)<sup>[2-10]</sup>. Self-limited infections by HBV involving successful immune responses represent by far the more favorable outcome. Chronic HBV infections, where immune responses have failed or are sub-optimal for virus clearance, represent a daunting challenge to successful therapy against a background of continuing disease progression. Current treatment strategies for chronic HBV infection are suboptimal when compared to the curative process observed in self-limited HBV infection. Understanding the prevention and pathogenesis of HBV infection has advanced greatly through clinical studies in humans, and through experimental studies in the chimpanzee model of HBV infection; however, neither of these models is well-suited for the routine testing of therapeutic strategies for treatment of chronic HBV infection.

Woodchuck hepatitis virus (WHV) is a naturally occurring hepadnavirus of the Eastern woodchuck (*Marmota monax*) (Figure 1). WHV was described initially in 1977 at the Penrose Zoo in Philadelphia in a colony of woodchucks where high rates of chronic hepatitis and HCC had been observed<sup>[11]</sup>. Several strains of WHV have been identified since then, which are all very closely related genetically<sup>[12-16]</sup>, but which may induce differing proportions of chronic infections in neonatal woodchucks<sup>[17]</sup>. WHV, and another HBV-like virus, the duck hepatitis B virus (DHBV)<sup>[18-20]</sup> have been used most extensively in the modeling of HBV infection and antiviral therapy (for previous reviews see<sup>[21-24]</sup>).

Research using the woodchuck began in 1978 and it was developed further into a laboratory model by 1980 when a woodchuck breeding colony was established at Cornell University. Early progress in model development at the Georgetown and Cornell Universities involved: (1) the production and validation of reagents and assays for WHV and for disease markers, (2) the characterization of infectious WHV inocula that induced predictably high rates of chronic infection when inoculated in neonatal woodchucks, and (3) basic studies of the natural history of virologic responses and tumor development associated with experimental infection of neonatal and adult woodchucks. Since 1988, the neonatal chronic WHV infection model has been applied primarily in the testing of antiviral nucleoside analogues for chronic HBV infection (for previous reviews see<sup>[10,25-30]</sup>).

Early studies in woodchucks also involved the testing of conventional vaccines for the prevention of acute, self-limited WHV infection in neonatal and adult

**Figure 1** Eastern woodchuck (*Marmota monax*).

woodchucks<sup>[28]</sup>, and also for prevention of the chronic outcome and HCC in the vaccinated neonates challenged with higher doses of inoculum to enable breakthrough infections<sup>[31,32]</sup>. Immunomodulation of acute and chronic WHV infections using immunosuppressive drugs, such as cyclosporine A<sup>[33,34]</sup>, was performed to gain an initial understanding of the role of the woodchuck immune response in the outcome and maintenance of WHV infection. The focus of investigations using the woodchuck has ranged widely since 1980, with flexible emphasis on both model development and model application in many areas of HBV research. These included viral and disease pathogenesis, and the prevention and treatment of HBV infection and disease sequelae (including HCC) using vaccines, antiviral drug candidates, and immunomodulators alone and in combination. The purpose of this review is to highlight the woodchuck as an animal model for pathogenesis and therapy of chronic HBV infection.

## NATURAL HISTORY OF WHV INFECTION AND DISEASE

Experimental infection of woodchucks with WHV is a well-accepted model for many aspects of the pathogenesis of human HBV infection<sup>[7,10,26-29,35-38]</sup>. Recent studies of the host response of woodchucks to WHV infection and therapy have revealed numerous parallels to the immunopathogenesis of HBV infection. Certain immune markers in woodchucks cannot be analyzed currently to the same extent as those in mice and in humans. However, the patterns and profiles of those immune responses measured thus far in the woodchuck model are highly consistent with the underlying immunologic mechanisms defined in humans.

Experimental infection of neonatal or adult woodchucks with WHV7P1<sup>[17]</sup>, a well characterized inoculum of WHV, produces predictable proportions of acute, self-limited (i.e., resolved) infections versus chronic infections. This mimics the effects of age on outcome of HBV infection in humans<sup>[3,4]</sup>. In adult woodchucks, WHV7P1 infections result mainly in resolution, with less than 5% of woodchucks progressing to chronicity<sup>[17]</sup> (Figure 2).

**Figure 2** Schematic profiles for serum viremia in adult and neonatal models of experimental WHV infection. **A:** Adult woodchucks. Adult woodchucks born to WHV-negative dams are infected with  $1 \times 10^7$  woodchuck infectious doses 50% of a defined WHV inoculum by the intravenous route. The proportions of chronic and resolved outcomes of adult woodchucks usually are less than 5% and more than 95%, respectively. The lifetime risk for the development of HCC in established chronic and resolved WHV infections is 100% and 15%-20%, respectively; **B:** Neonatal woodchucks. Neonatal woodchucks born to WHV-negative dams are infected with  $5 \times 10^6$  woodchuck infectious doses 50% of a defined WHV inoculum by the subcutaneous route. The proportions of chronic and resolved outcomes range between 60%-75% and 25%-40%, respectively. The lifetime risk for the development of HCC in established chronic and resolved WHV infections is 100% and 15%-20%, respectively. HCC in uninfected, WHV-negative woodchucks is not observed. Approximate time intervals for the development of innate and acquired immunity are shown.

However, transient suppression of cellular immune responses with cyclosporine A (CsA) during the incubation and acute phase of adult WHV infections results in 92% of these infections progressing to the chronic outcome; with CsA given only during the incubation period and very early acute stage (0 to 4 wk post infection), the result is up to 50% chronic outcomes in adult WHV infections<sup>[33,34]</sup>. This shows the importance and timing of early immune responses in the resolution of acute WHV infection. Experimental immunosuppression, however, does not necessarily mimic natural processes associated with the progression to chronic infection.

Most chronic HBV infections occur as a result of neonatally-acquired infection<sup>[39-41]</sup>. Experimental infection of neonatal woodchucks with WHV7P1 usually results in a 60%-75% frequency of chronic carriers and a 25%-40% frequency of naturally recovered infections<sup>[17]</sup> (Figure 2). Viral and host response kinetics are relatively uniform when neonatal woodchucks are inoculated with WHV7P1 in the spring of the year, thus enabling statistical modeling of serologic and hepatic responses using samples collected in successive years. Such features also enable co-temporal comparisons of early acute phase immune responses before the self-limited and chronic outcomes become evident serologically, which can help to differentiate and identify the underlying mechanisms involved in the onset versus maintenance of chronic WHV infection<sup>[42-46]</sup>

(Figure 3).

Chronic WHV infection involves life-long active viral replication and inevitable disease progression to chronic hepatitis and HCC<sup>[35,47-50]</sup>. In chronically infected woodchucks, there is no naturally occurring e-antigen to anti-e seroconversion and associated step-down of viral replication (i.e., as is commonly seen in chronic HBV infection; e.g.,<sup>[51-54]</sup>). In general, the high viral replication and high surface antigen and e-antigen loads present in the chronic WHV carrier appear to play a role in the maintenance of immunologic tolerance, and are associated with disease progression to HCC<sup>[43-45,55-57]</sup>.

Self-limited WHV infection involves a relatively complete shut down of viral replication and a nearly complete clearance of virus from the system with full recovery. It has been suggested that trace amounts of residual WHV genomes often detected in long-term recovered woodchucks in liver, serum, and in peripheral blood mononuclear cells (PBMC), could actually represent an alternate form of persistent viral infection<sup>[58-65]</sup>. Residual HBV DNA has been documented also for humans recovered from self-limited HBV infection (e.g.,<sup>[66-71]</sup>). In woodchucks, even recovery from acute WHV infection incurs a discernable lifetime risk of HCC (5%-20%) when compared to control seronegative woodchucks (i.e., uninfected with WHV); however, this risk is significantly lower compared to the lifetime risk of HCC in chronic

**Figure 3** Schematic profiles for viremia, acute hepatitis, and disease progression in the neonatal model of experimental WHV infection. **A:** Self-limited, resolved WHV infection; **B:** Chronic WHV infection. Neonatal woodchucks born to WHV-negative dams are infected experimentally at 3 d of age with  $5 \times 10^6$  woodchuck infectious doses 50% of a defined WHV inoculum by the subcutaneous route. Approximate time intervals for self-limited acute hepatitis and progressive chronic hepatitis are shown. Use of the neonatal WHV infection model enables co-temporal comparisons of acute self-limiting and chronic outcome of WHV infections as they develop. Comparison of acute phase events at early time points before or near the times when self-limited, resolved and chronic outcomes begin to segregate based on serologic criteria allows the definition of immune mechanisms involved in progression toward recovery versus chronicity. Comparison at later time points enables the investigation of mechanisms that are important in the maintenance of the established WHV infection state and that lead to disease progression and tumor development. During this time the established chronic WHV carrier woodchucks are used mainly for the testing of antiviral nucleosides, immunotherapeutic strategies, and for the prevention of onset and development of HCC.

WHV carrier woodchucks, which is essentially 100%<sup>[58,72]</sup> (Figure 2). Such results provide direct experimental evidence for the carcinogenicity of WHV and, by analogy, for HBV where chronic infection also is associated with HCC.

In a recent study, we examined the reactivation of WHV replication and the generation of infectious WHV in long-term resolved adult woodchucks during experimental immunosuppression with CsA (Menne *et al.*, unpublished data). Administration of CsA to serologically recovered woodchucks with evidence of residual WHV DNA in liver and PBMC, and with durable recall cellular immune responses of PBMC to WHV antigens, resulted in a transient reactivation of WHV replication during CsA treatment. This supports the idea that replication-competent WHV (and by analogy, HBV) can persist for many years after recovery from acute viral hepatitis, possibly as part of a continuing process. That is, the virus may be controlled by virus-specific immune responses that are primed continuously by trace amounts of virus and viral antigens. In any case, the presence of long-term recall cellular immune responses with mutual persistence of residual WHV covalently closed circular DNA (WHV cccDNA) is significant to the durability of recovery responses over the long term for the stable control of replication and shut down of the infectious process. The

apparent lack (or need) of such immune responses with the apparent loss of WHV cccDNA is significant to the extent of viral immune clearance possible in recovery. One implication from the above studies is how much a relatively successful antiviral and/or immunotherapy for chronic HBV or WHV infection will improve the prospects for disease outcome beyond that observed in natural recovery from infection.

## MOLECULAR VIROLOGY STUDIES

WHV is classified as a member of the genus *Orthohepadnavirus*, family *Hepadnaviridae*<sup>[73]</sup>. The genetic organization of WHV is similar to that of HBV and other mammalian hepadnaviruses, and their biological properties and replicative strategies are essentially the same<sup>[74]</sup>. Filaments and spherical particles are found in the serum of WHV-infected woodchucks which are composed of the envelope protein of the virus. Complete virions are 42 to 45 nm in diameter and are composed of an exterior envelope protein (WHV surface antigen; WHsAg), an inner nucleocapsid or core protein (WHcAg), and, within the nucleocapsid, the DNA genome<sup>[75,76]</sup>. The replicative cycle of WHV seems to be identical to that of HBV<sup>[75-78]</sup>. The role of cccDNA as the template for viral transcription, the mechanism of replenishment of the cccDNA pool,

and the control of this pathway by surface antigen, have been investigated mainly using DHBV. For some studies, full-length clones of the WHV genome, cut and ligated to form a supercoiled cccDNA, have been used for *in vivo* molecular studies since direct injection into the hepatic parenchyma of woodchucks results in productive WHV infection<sup>[79]</sup>. Only a brief overview is provided below for background purposes.

During infection, HBV enters the hepatocyte, but the mechanism is poorly understood. No hepatocyte receptor has yet been defined for HBV, although studies suggest that the virus-cell recognition may be mediated all or in part by specific sequences located in the pre-S1 region of the large envelope protein. However, with numerous other potential envelope recognition sites for the cell suggested from *in vivo* neutralization studies with monoclonal antibodies, and the fact that antibodies elicited by vaccines to only the small envelope protein provide protective immunity, we are a long way from understanding the mechanisms of antibody-mediated neutralization of HBV attachment, entry, and uncoating during infection. It is known that the circular, partially double-stranded DNA genome makes its way to the nucleus where the partial DNA strand (i.e., positive strand) is completed via the endogenously linked virion reverse transcriptase-DNA polymerase, and the now fully circularized double strand is then ligated into a cccDNA. The cccDNA serves as the key template for viral mRNA transcription via the cellular RNA polymerase II. One of the viral mRNAs (slightly larger than the genome length transcript) becomes encapsidated into maturing core particles along with the virion polymerase, where it is then reverse transcribed into the viral negative strand DNA *via* the RNA-dependent DNA polymerase activity of the encapsidated enzyme. The viral polymerase then uses its DNA-dependent DNA polymerase activity to partially complete the positive strand DNA to about 50%-75%, and this non-covalently closed circularized DNA is found in mature virions of HBV and WHV. Envelope acquisition occurs at the endoplasmic reticulum (ER) and mature virions are secreted from hepatocytes. Hepadnaviruses are not directly cytotoxic to infected cells.

Amplification and replenishment of cccDNA in the nucleus of the infected hepatocyte occurs when a portion of the maturing core particles complete positive strand DNA synthesis and are cycled back to the nucleus (i.e., instead of through the ER) where the new double strand DNA is processed into cccDNA. In HBV, most immunostaining of core is found in the nucleus, whereas in WHV, the core staining is primarily cytoplasmic, and not detected in the nucleus. This suggests a process of newly synthesized cytoplasmic core particles carrying out reverse transcription, partial or complete positive strand synthesis, and occasional re-entry into the nucleus for amplification of cccDNA (alternatively, cytoplasmic core staining may reflect incoming virus, but this seems far less likely). For HBV, cytoplasmic cores may go undetectable by immunostaining, and the denser staining of core particles within the nucleus may reflect maturation of HBV core particles there, with exit to the ER for envelope

acquisition via a different cellular pathway. In established carrier woodchucks, WHV virions often circulate in 10- to 100-fold greater concentrations than do HBV virions in human chronic carriers. This may relate to the differential immuno-localization of core particles in the two models.

Transition of viral DNA to RNA during the life cycle of WHV has similarities to that of retroviruses<sup>[75,78]</sup>, but integration of viral DNA into the host genome is not, however, essential for replication of hepadnaviruses, as is the case with retroviruses. Persistence of episomal cccDNA in infected hepatocytes is considered stable and this is problematic for its removal from the system, which appears to require elimination of the infected hepatocyte. It therefore represents the main target for attaining complete eradication of hepadnavirus from the system. When hepadnaviral DNA does integrate into host cell DNA, it is usually truncated and rearranged, and can target any number of sites in cellular DNA<sup>[80,81]</sup>, some or all of which may be important in hepatocarcinogenesis. Morphological and molecular virological studies of the liver have shown that virtually 100% of hepatocytes become infected after experimental WHV infection<sup>[82]</sup>. Although replicative forms are cleared rapidly during recovery, WHV cccDNA persisted in a certain proportion of woodchucks long after evidence of WHV replication had ceased. That said, recovery is indeed durable and protective against disease progression in the vast majority of cases. On the other hand, persistence of the episomal cccDNA in chronic HBV (and WHV) infections remains a major conundrum in attempts to clear the virus via various therapeutic approaches (see below).

HBV generally is considered a hepatotropic virus, but hepadnavirus DNA can also be detected in extrahepatic tissues. For example, DHBV is often found replicating in the pancreas of ducks. HBV and WHV appear to infect the lymphatic system, although the exact significance of this observation is not well understood<sup>[58,60-63,65,83-86]</sup>. Some studies suggest that WHV replication and spread in the lymphatic compartment can proceed independently, even before infection of the liver<sup>[60,86]</sup>. Quiescent (non-replicating) WHV DNA molecules in PBMC from chronic WHV carriers can be activated to form replicative intermediates by stimulation of PBMC with lipopolysaccharide (LPS)<sup>[62]</sup>. The cell-free supernatants from LPS-stimulated WHV carrier PBMC (but not those from the unstimulated carrier PBMC) contain newly replicated infectious WHV that induce-acute hepatitis in WHV-susceptible adult woodchucks<sup>[84]</sup>.

WHV quiescence versus replication in the lymphatic compartment may vary depending on the state of the host lymphatic target cell (i.e., resting, dividing, circulating in blood, within lymphatic tissue, *etc.*). WHV DNA can be detected in bone marrow cells as early as one month post neonatal WHV infection, but the first signs of WHV replication in PBMC, lymph nodes, and spleens occur during the acute stage of hepatic infection<sup>[83]</sup>. During recovery lymphatic WHV replication subsides to a quiescent state (or approaches complete elimination). In chronic infections, WHV replication also becomes quiescent in circulating PBMC, but often continues in the

spleen<sup>[83]</sup>, and the quiescent WHV in PBMC often can be activated upon *ex vivo* stimulation using LPS, as indicated above<sup>[62,84]</sup>. More recent published studies indicate that long-term recovered woodchucks can also harbor infectious DNA in PBMC<sup>[58]</sup>.

From the above, woodchucks recovering from acute WHV infection and those progressing to chronicity seem to have similar PBMC infection profiles, and in both cases the PBMC respond robustly in proliferation assays to polyclonal mitogens such as ConA, PHA, and LPS<sup>[44,55,87-89]</sup>. Even with similar PBMC WHV DNA profiles, the PBMC proliferative responses to viral antigens are generally more robust in the recovery outcome compared to the chronic outcome<sup>[44,55,56,87-90]</sup>. Thus, immune response function in viral infection does not appear to be affected adversely by the ongoing lymphatic infection. In fact, lymphatic infection by WHV, either acutely or in chronic WHV carriers, does not result in any lymphadenopathy, lymphopenia, lymphoma, or generalized immunodeficiency enabling opportunistic infections. As with natural recovery, therapy of chronic WHV infection presumes to target all reservoirs and molecular forms of the virus in both the lymphatic system and liver.

## IMMUNOLOGICAL STUDIES

Resolution of experimental WHV infection in both neonatal and adult woodchucks involves a self-curative process with appropriate virus-specific immune responses in the periphery and liver (Figure 3). Natural recovery perhaps represents a benchmark for the possible induction of antiviral and/or immunotherapeutic effects in chronic WHV carriers. Specific activation of humoral and cellular immune responses is a prerequisite for viral clearance during acute HBV infection in adult patients, as reported in numerous studies<sup>[2-4,9,91]</sup>. However, the kinetic development of these responses during the early incubation and acute stages of adult HBV infection, and their influence on the course and outcome of infection, are less well characterized in humans, since patients usually do not present with clinical symptoms immediately after HBV transmission (except for a few rare cases involving known exposure times; e.g.,<sup>[92]</sup>).

Studies of self-limited WHV infection reveal numerous virus and host response patterns analogous to self-limited HBV infection<sup>[61,79,82,83,85,88,89,93-105]</sup>. In general, resolution of WHV infection in both the neonatal and adult settings is characterized by: (1) a transient peak of WHV DNA and antigen detection in serum and liver during the acute phase of infection, (2) timely and appropriate cell-mediated immunity (CMI) to viral antigens, (3) acute viral hepatitis with limited liver injury, (4) a transient peak and subsequent normalization of serum aminotransferases, and (5) seroconversion to virus-neutralizing antibodies, all leading to a substantial clearance of virus and viral antigens from the blood and liver. The humoral immune response to viral antigens (i.e., WHcAg and WHsAg) during resolution is associated with the development of robust titers of anti-core (anti-WHc), and of virus-neutralizing, protective, anti-surface antibodies (anti-WHs)

with the onset and waning of the acute phase, all usually within several weeks after experimental infection<sup>[17,42]</sup>.

In adult woodchucks, the CMI associated with recovery is characterized by activation of PBMC detected by *in vitro* stimulation of PBMC with WHsAg, WHcAg, and synthetic peptides of both antigens<sup>[87-90,93,94,106]</sup>. The successful PBMC response to WHcAg is associated contemporarily with viral clearance from serum, and this has been mapped extensively to several key epitopes of the WHcAg<sup>[87,93]</sup>. In fact, immunization with the dominant WHcAg epitope sequence between amino acids 97 to 110 significantly dampens acute WHV infections in adult woodchucks following experimental challenge with WHV, when compared to infections in unvaccinated control woodchucks<sup>[87]</sup>. Mapping of the PBMC responses to WHsAg and WHV x antigen (WHxAg) during the acute phase of resolution have been in progress.

The CMI to viral antigens during the acute phase in neonatal woodchucks experimentally infected with cWHV8P1 (from which neonates resolve more frequently) is similar to that in resolving adult woodchucks, which is independent of the WHV inoculum used<sup>[44]</sup>. Robust PBMC responses to WHcAg, WHsAg, and WHxAg, and to several non-overlapping core peptides, are associated temporally with the clearance of WHV DNA and WHsAg from serum. Detailed analysis of the WHcAg-specific PBMC responses revealed a broad recognition of several WHcAg epitopes representing apparently distinct regions of this antigen. Similar to adult WHV infections, neonatal woodchucks develop PBMC responses to important WHcAg peptides (residues 97 to 110, residues 100-113)<sup>[44]</sup>.

In the liver, the CMI during resolution of adult WHV infection is characterized by moderate to marked hepatic inflammation and liver injury involving increased CD3- (cluster of differentiation 3) positive T lymphocyte accumulation, and apoptosis and regeneration of hepatocytes<sup>[96,97]</sup>. These events are accompanied by marked elevations of CD3, CD4, and CD8 mRNA expression and increased expression of the T-helper lymphocyte (Th)-type 1 cytokine mRNAs interferon gamma (IFN- $\gamma$ ) and tumor necrosis factor alpha (TNF- $\alpha$ ), and of the IFN- $\gamma$ -inducible oligoadenylate synthetase (2'-5'-OAS) mRNA<sup>[96,97]</sup>. *In vitro* testing of cell-mediated killing of hepatocytes revealed activation of both FasL- (ligand for the apoptosis-inducing factor Fas) and perforin-dependent pathways during resolution, and a comparative analysis demonstrated that acute hepatitis, but not established chronic WHV infection, is associated with elevated hepatocyte killing as a consequence of increased activation of the perforin-dependent pathway<sup>[95]</sup>. Further acute phase studies of adult self-limiting WHV infections are in progress to better define the kinetic interrelationships between mRNA expression in liver and PBMC mRNA expression *ex vivo* or following *in vitro* stimulation with antigens.

Neonatal WHV infections can be studied prospectively, in proportionate and adequate numbers of woodchucks, as the dichotomy in outcome proceeds dynamically in real time toward recovery versus chronicity. As with recovering WHV infections in adult woodchucks, resolution of

neonatal WHV infection is associated with moderate hepatic inflammation and liver injury and accumulation of CD3-positive T-lymphocytes<sup>[42,43]</sup>. Hepatic inflammation is characterized further by significant accumulation of CD3, CD4, and CD8 mRNAs, with elevated expression of the Th-type 1 cytokine mRNAs IFN- $\gamma$  and TNF- $\alpha$ , and of the intracellular transcription factor STAT4 (signal transactivator of transcription) and T-bet (T box expressed in T lymphocytes) mRNAs, and also of Fas ligand and perforin mRNAs. When taken together, the results indicate that both non-cytolytic and cytolytic clearance of WHV-infected hepatocytes is occurring<sup>[43,45,46]</sup>. The results from the above studies suggest further that early virus-specific CMI in both the periphery and liver play a pivotal role in resolution of acute WHV infection in neonatal and adult woodchucks, and that the responses to WHcAg and to selected core peptides are instrumental in controlling viral infection.

Although immune responsiveness has been well-characterized in the periphery and liver of established HBV chronic carriers during chronic hepatitis, the actual acute phase responses associated with the early onset of chronic HBV infection are less well understood. Lack of immune responsiveness to HBV antigens in some HBV carriers may ensue with the establishment of the carrier state and have little to do with the early onset at a time when other individuals may recover normally. Moreover, chronic hepatitis is defective by definition, when compared with the acute hepatitis that results in recovery, because the chronic inflammation is incapable of clearing the hepatic infection and lends itself only to progressive liver disease. Adult patients presenting with acute hepatitis B are often well into the infection and only rarely progress to chronic infection. Studies of the early onset of chronic HBV infection in humans after neonatal transmission have obvious limitations. While studies in established chronic HBV carriers show defective immune responses associated with tolerance and chronic hepatitis and a failure to clear the infection<sup>[2-4,9,91]</sup>, it is unclear whether such deficient responses are representative of the primary acute phase responses that predispose to the chronic outcome. Understanding how the chronic infection first becomes established kinetically near the time of the acute stage of infection could lead to the identification of important cause-effect relationships that will facilitate the rational development of therapies for successfully treating established chronic infections.

For testing the hypothesis that chronic WHV infection develops due to a diminished host response to acute infection, co-temporal comparisons were performed in the neonatal WHV infection model<sup>[7,17,42-46,107-109]</sup>. Using a bank of control and WHV-infected liver specimens that were obtained surgically at two acute phase time points of neonatal WHV infection (wk 8 and 14) and that were assigned to recovered or carrier woodchucks once outcome was known based on later serological profiles, the early onset of the chronic WHV carrier state (compared to co-temporal resolving infections) was characterized by: (1) higher acute phase viral loads in liver (at wk 8 and 14 post infection), (2) diminished acute hepatitis (at wk

14), (3) detectable but significantly diminished hepatic inflammation (at wk 14), and (4) reduced liver injury (at wk 14)<sup>[42,43,45,46]</sup>. This was associated further with: (1) absent or suboptimal intrahepatic accumulation of CD3, CD4, and CD8 mRNAs, and (2) reduced expression of Th-type 1 cytokine mRNAs, especially IFN- $\gamma$  and TNF- $\alpha$ , along with the key Th-type 1 transcription factor T-bet<sup>[43,45,46]</sup>. This represented an early primary deficiency in the Th-type 1 response in liver to acute WHV infection, and was not associated with any local antagonistic Th-type 2 immunoregulation<sup>[45]</sup>.

Studies in the peripheral blood using serial measurements of PBMC responses in neonatal woodchucks experimentally infected with WHV7P1 or cWHV8P1 have shown thus far that all neonates with resolving infections had robust acute phase PBMC responses to WHcAg and to the key epitope of this antigen (core residues 97-110), with the majority of woodchucks also responding to WHsAg and WHxAg<sup>[44]</sup>. In contrast, prospective carriers responded less frequently or not at all, with only about one-third responding to WHcAg, and among these, only about half responded to the key core epitope and to other WHV antigens. Detailed mapping of the PBMC responses to WHcAg revealed that the epitopes recognized were localized to distinct regions of this antigen and were different from those recognized during resolving WHV infections<sup>[44]</sup>. In the prospective carriers with minimal acute phase PBMC responses to WHcAg, viremia and antigenemia developed later, and viral and antigen loads were lower compared to those seen in prospective carriers without any evidence of virus-specific PBMC responses<sup>[44]</sup>. In any case the levels of viremia and antigenemia in these prospective carriers were much higher than in neonates with resolving WHV infections<sup>[44]</sup>. Interestingly, the fact that virus-specific PBMC responses were undetectable in the majority of prospective carriers indicates an early genesis for the CMI defect commonly observed later in established chronic WHV infection<sup>[55,56,87-90,94]</sup>. Further studies to correlate the molecular immunologic responses of PBMC based on leukocyte surface marker and cytokine mRNA expression with outcome of neonatal WHV infection are in progress.

Established chronic HBV infection is associated with increased viral load and risk of severe liver disease sequelae<sup>[2-4,9,91]</sup>. Chronic HBV infections resulting from neonatal transmissions are characterized by T cell immunotolerance to viral antigens throughout most of life until end-stage disease, but may exhibit occasional exacerbations of liver disease before this time<sup>[51,110-114]</sup>. T cell proliferative responses to viral antigens in adult-acquired chronic HBV infections can be variable during disease progression, but are usually less responsive, except during periodic transient flare reactions and with seroconversion to anti-e antibodies (e.g.,<sup>[52-54,115,116]</sup>).

Studies in woodchucks indicate that viral antigen-specific CMI during established chronic WHV infection is also defective, similar to that observed in HBV infection<sup>[45,55,56,87-89,94]</sup>. In the neonatal woodchuck, following an occasional, early and transient, but suboptimal acute hepatitis, WHV chronic carriage is characterized for some

time with minimal chronic persistent hepatitis, and little or no liver injury based on serum enzyme markers up through at least 15 mo post infection<sup>[46]</sup>. This progresses subsequently to more active hepatitis and liver injury just before or at the time of HCC onset and tumor growth<sup>[46,47,49,50,55,57]</sup>. PBMC remain essentially immunotolerant to WHV antigens throughout all of the chronic phase of neonatal WHV infection, including end stage disease<sup>[55,56,87,89,90,94]</sup>. The baseline expression of Th-type 1 cytokines in liver that is usually observed during the chronic phase can sometimes increase above normal with progressive chronic hepatitis (usually with increased TNF- $\alpha$  and less IFN- $\gamma$ )<sup>[45,97]</sup>, but without affecting clearance of the infection. Less is known of the CMI in documented adult-acquired chronic WHV infections, but the apparent greater degree of chronic hepatitis in this setting may suggest some exception to the fully tolerant state as leading to and maintaining the chronic infection<sup>[96]</sup>. Indeed, some leukocyte surface and cytokine markers become elevated in liver during acute hepatitis in adult woodchucks that eventually become chronic carriers, although to a lesser extent than seen during the acute phase of woodchucks that resolve.

## THERAPEUTIC STUDIES

### Antiviral drugs

Woodchucks with experimentally induced chronic WHV infection have been used successfully in the empiric screening and preclinical assessment of antiviral drugs being developed for treatment of chronic HBV infection (for previous reviews see<sup>[21,24,25,30,35,117]</sup>). Current strategies aim to suppress viral replication in liver and the concentration of viral DNA in serum during chronic HBV infection (i.e., reduce viral load) by treatment with nucleoside and nucleotide analogues. As indicated above, it has been difficult to target the viral cccDNA directly in this process, and so potent inhibition of viral replication is the main means to reduce viral load in blood and tissues, and perhaps diminish replenishment of cccDNA indirectly, until cells harboring this intermediate can turnover or be eliminated by immune responses. Accordingly, lifelong therapy with antiviral drugs is currently the accepted procedure, even though this often results in the selection of drug-resistant mutants (i.e., mutations of the polymerase gene), which has been observed and modeled in the woodchuck (e.g.,<sup>[118-122]</sup>).

Before testing in woodchucks, potential drug candidates are screened for antiviral activity against HBV in the 2.2.15 cell system, a HepG2 cell line that is engineered to produce HBV constitutively<sup>[123]</sup>. Drugs with significant antiviral activity *in vitro* also have been tested in a HBV-transgenic mouse model designed and validated for this purpose<sup>[124]</sup>. However, drug efficacy in an *in vivo* infection model is most usually assessed in the woodchuck model. Most nucleoside analogues with intermediate antiviral activity *in vitro* against HBV had comparable antiviral activity against WHV in woodchucks, but some exceptions exist. For example, fialuridine (D-FIAU) had modest activity *in vitro*, and potent antiviral activity in woodchucks; however, this

was associated with a marked and delayed hepatotoxicity characterized by microvesicular steatosis and mitochondrial injury<sup>[125]</sup>, similar to the unfortunate hepatotoxic effects this drug had in humans, where it was first tested<sup>[126]</sup>.

In recent years, numerous nucleoside and nucleotide analogues designed to inhibit HBV replication were tested in the woodchuck model (e.g.,<sup>[125,127-140]</sup>). Some of these nucleoside analogues had demonstrated antiviral efficacy in chronic WHV carrier woodchucks, such as lamivudine (3TC, Epivir)<sup>[21,120,141-143]</sup>, adefovir dipivoxil (ADV, Hepsera)<sup>[144,145]</sup>, and entecavir (ETV, Baraclude)<sup>[139,146]</sup>, and are now approved by the FDA for treatment of chronic HBV infection. Other nucleoside analogues, also having activity in woodchucks against WHV, are used for the treatment of human immunodeficiency virus (HIV), such as tenofovir disoproxil fumarate (TDF, Viread)<sup>[147]</sup> and emtricitabine (FTC, Coviracil)<sup>[148-150]</sup>, and still others are in advanced clinical testing, such as telbivudine (LdT)<sup>[151-153]</sup>, valtorcitabine (val-LdC)<sup>[151-153]</sup>, and clevudine (L-FMAU)<sup>[55,56,122,150,154-156]</sup>. FDA approval of these drugs for treatment of chronic HBV infection is expected in the near future (in fact, telbivudine was approved most recently). Table 1 summarizes the antiviral activities of these second and third-generation nucleosides in chronic WHV carrier woodchucks that were reported in selected studies. We note here in these experiments that viral recrudescence following cessation of drug is often a function of being unable to completely suppress viral replication sufficiently during a given treatment, or significantly enough over time in order to allow cells containing cccDNA to turnover or be eliminated by the immune response.

Lamivudine is a moderately potent antiviral drug in woodchucks and is without toxicity during daily, oral administration for up to 24 wk<sup>[21,141,157]</sup>, and even longer<sup>[142]</sup>. The average reduction in serum WHV DNA after 4 or 12 wk of treatment with different doses (1, 5, or 15 mg/kg bodyweight) was approximately 2.5 and 1.5 logs, respectively. The average time to recrudescence of viral replication after drug withdrawal was within 1 to 2 wk. In woodchucks, lamivudine also has been shown to act synergistically both with alpha-interferon and with famciclovir<sup>[141,157]</sup>. An antiviral activity comparable to lamivudine has been reported for adefovir<sup>[144]</sup>. Daily oral administration of adefovir for 12 wk with doses of 5 and 15 mg/kg resulted in a reduction in serum viremia of 1.7 or 2.5 logs, respectively. Viral recrudescence after drug withdrawal occurred within 6 wk. No toxicity associated with administration of adefovir was observed. The antiviral activity of tenofovir in woodchucks<sup>[147]</sup> is comparable to those of lamivudine and adefovir. The reduction in serum WHV DNA observed after 4 wk of daily, oral treatment with tenofovir doses of 5 and 15 mg/kg was 1.5 or 1.2 logs, respectively. After drug withdrawal viral recrudescence occurred within 1 to 4 wk and treatment was without any evidence of drug-associated toxicity.

A higher antiviral activity on chronic WHV infection was reported for emtricitabine<sup>[149]</sup>. Daily oral treatment for 4 wk with doses of 10 or 30 mg/kg reduced serum viremia by 3.2 and 4.9 logs, respectively. Recrudescence of viral replication occurred within 1 to 2 wk after drug withdrawal.

Table 1 Antiviral activities of second and third-generation nucleosides and nucleotides in the woodchuck model of chronic HBV infection

Antiviral drug	Oral dose (mg/kg per day)	Treatment duration (wk)	Follow up duration (wk)	Serum WHV DNA reduction (log)	Time to viral recrudescence (wk)	Drug-associated toxicity	Other viral markers	Ref.
Lamivudine	1	24	24	1.5	within 1-2	none	WHV RI red. (3-fold) no WHV RNA red. no serum WHsAg red.	[141]
	5	4	12	3.4	within 1	none	WHV RI red. (4-fold) no WHV RNA red. no serum WHsAg red.	[21]
	5	12	12	1.9	within 1-2	none	WHV RI red. (3-fold) no WHV RNA red. no serum WHsAg red.	[157]
	15	4	12	5.4	within 1	none	WHV RI red. (12-fold) no WHV RNA red. no serum WHsAg red.	[21]
Adefovir	5	12	6	1.7	within 6	none		[144]
	15	12	6	2.5	within 6	none		[144]
Entecavir	0.02	12	12	7-8 <sup>1</sup>	within 2-10	none	WHV RI red. in individual animals to undetectable levels	[139]
	0.1	12	12	7-8	within 6-10	none	WHV RI red. in most animals to undetectable levels	[139]
Tenofovir	5	4	12	1.5	within 1-4	none	no WHV RI red. no WHV RNA red. no serum WHsAg red.	[147]
	15	4	12	1.2	within 1-4	none	no WHV RI red. no WHV RNA red. no serum WHsAg red.	[147]
Emtricitabine	3	4	12	1.4	within 1-2	none	WHV RI red. (3-fold) no WHV RNA red. no serum WHsAg red.	[149]
	10	4	12	3.2	within 1-2	none	WHV RI red. (13-fold) no WHV RNA red. no serum WHsAg red.	[149]
	30	4	12	4.9	within 1-2		WHV RI red. (80-fold) no WHV RNA red. no serum WHsAg red.	[149]
	20 <sup>2</sup>	4	4	1.4	within 1-2	none		[148]
	30 <sup>2</sup>	4	4	1.8	within 1-2	none	WHV RI red. (2-fold)	[148]
Telbivudine	10	4	8	8	within 4-8	none	serum WHsAg red.	[151-153]
Valtorcitabine	10	4	8	4-6	within 1-8	none		[151-153]
Clevudine	3	4	12	9.2	within 2-10	none	WHV RI red. (28-fold) no WHV RNA red. serum WHsAg red. (2-fold)	[154]
	10	4	12	8.2	within 8-12 <sup>3</sup>	none	WHV RI red. (68-fold) WHV RNA red. (2.7-fold) serum WHsAg red. (4-fold) WHV cccDNA red. (2-6-fold or to undetectable levels)	[154]

<sup>1</sup>Two of 6 woodchucks with modest reduction in serum WHV DNA of approximately 2.0 logs were not included. <sup>2</sup>Dosage was given twice daily by intraperitoneal administration. <sup>3</sup>One woodchuck had suppressed serum WHV DNA at the end of the study. WHV RI, hepatic WHV DNA replicative intermediates; WHV RNA, intrahepatic WHV RNA; red., reduction.

A dose of emtricitabine of 3 mg/kg in this study was less efficacious, but was comparable to those observed with 20 and 30 mg/kg, administered twice daily, intraperitoneally, for 4 wk<sup>[148]</sup>. There was no toxicity associated with this drug treatment. A more remarkable antiviral activity was obtained with valtorcitabine in chronic WHV carrier woodchucks after daily oral administration for 4 wk with a dose of 10 mg/kg<sup>[151-153]</sup>. In this case, serum WHV DNA became reduced by 4 to 6 logs with no evidence

of drug-associated toxicity at the dose used. The time to recrudescence of viral replication after drug withdrawal was as little as 1 wk, but extended to 8 wk in many of the animals. Entecavir had an even higher antiviral activity in woodchucks<sup>[139]</sup>. Daily oral administration of entecavir for 12 wk at a dose of 0.02 mg/kg resulted in a reduction in serum viremia of 7 to 8 logs in 4 of 6 treated woodchucks (2 of the 6 treated woodchucks had only a modest antiviral effect). Recrudescence of viral replication after drug

withdrawal occurred in as little as 2 wk, but was extended to 10 wk in several of the animals. Administration of entecavir at a dose of 0.1 mg/kg reduced serum viremia by 7 to 8 logs and viral recrudescence was observed within 6 to 10 wk. No toxicity associated with drug treatment was reported.

The most potent antiviral drugs that have been tested so far in woodchucks are telbivudine and clevudine. Daily oral administration of telbivudine for 4 wk at a dose of 10 mg/kg resulted in an 8 log reduction in serum viremia and viral recrudescence was observed within 4 to 8 wk after drug withdrawal<sup>[151,152]</sup>. Daily oral administration of clevudine for 4 wk at doses of 3 or 10 mg/kg reduced serum viremia by 9.2 and 8.2 logs, respectively<sup>[154]</sup>. With the lower dose of clevudine viral recrudescence after drug withdrawal was observed within 2 to 10 wk. The higher dose delayed viral recrudescence and serum WHV DNA concentrations reached pretreatment levels within 8 to 12 wk, and in one woodchuck, serum viremia was still suppressed at the end of the study. No toxicity was associated with the above short-term treatments using either telbivudine or clevudine.

The above studies in the woodchuck model demonstrate that a significant antiviral effect on chronic WHV infection could be achieved with all drugs. The relative antiviral efficacy against WHV, at the doses administered and for the duration of treatment used, was clevudine  $\geq$  telbivudine  $\geq$  entecavir  $>$  valtorcitabine  $\geq$  emtricitabine  $\geq$  tenofovir = adefovir = lamivudine. A prolonged suppression of WHV replication after drug withdrawal was achieved with clevudine, telbivudine, entecavir, and valtorcitabine, and the magnitude of these responses was often associated indirectly with transient or sustained reductions in WHV cccDNA potentially enabling some turnover of residually infected cells. The favorable safety and efficacy profile obtained thus far in the woodchuck model using relatively short-term treatments with clevudine, telbivudine, and valtorcitabine suggest that these drugs should be of value in the long-term control of chronic HBV infection in humans and support their continued clinical development.

The preclinical evaluation of antiviral drugs for treatment of lamivudine-resistant HBV infection has been modeled in woodchucks by the experimental induction of lamivudine-resistant WHV with nine or more months of lamivudine treatment, followed by continued therapy with lamivudine along with the new drug candidate of interest<sup>[122,145]</sup>. Prolonged treatment with lamivudine led to the establishment of drug-resistant WHV mutants, characterized mainly by mutations in the B domain of the WHV polymerase gene (i.e., HBV mutations occur in B and C domains). Supplemental daily oral treatment of these circulating B domain mutants with adefovir or clevudine (10 mg/kg per day, 12 wk and 7 wk, respectively) demonstrated that both drugs could suppress replication of these lamivudine-resistant WHV mutants. In a different study, lamivudine-resistant mutants of WHV were found to be cross-resistant to treatment with clevudine<sup>[122]</sup>. Studies are in progress using engineered lamivudine-resistant mutants of WHV that mimic the additional

polymerase C domain mutants observed in human HBV patients treated with lamivudine.

In addition to the testing of drugs in woodchucks for antiviral effects, applications also have been extended to the testing of entecavir, clevudine, or lamivudine for efficacy against disease progression<sup>[30,142,146,155]</sup>. Extended lamivudine treatment of woodchucks with chronic WHV infection delayed the development of HCC and significantly extended survival of woodchucks in one study<sup>[142]</sup>. In that study, twenty 8-mo-old chronic WHV carrier woodchucks were treated throughout the rest of their lifetime with lamivudine (5 mg and then 15 mg/kg, orally, daily). Twenty placebo control WHV carrier woodchucks were included for comparison. Serum WHV DNA decreased by 4 to 5 logs in lamivudine-treated carrier woodchucks, with an antiviral effect that was sustained for more than one year with continued treatment. Importantly, there was a significant delay in time to onset of HCC and death due to HCC among lamivudine-treated woodchucks compared to placebo controls. In another study of lamivudine in WHV carrier woodchucks, no delay in hepatocarcinogenesis was observed with treatment, most likely because drug treatment began when woodchucks were at an older age, was of shorter duration, and less of an antiviral effect on serum WHV DNA was observed<sup>[120]</sup>. In both studies, lamivudine resistance developed that was associated with a high frequency of mutation in the WHV polymerase gene B domain<sup>[118,121]</sup>.

In another study, long-term oral treatment with entecavir<sup>[146]</sup> in 8-mo-old woodchucks at 0.5 mg/kg per day for 8 wk, and then with a weekly dose of 0.5 mg/kg for 14 or 36 mo, produced sustained antiviral responses in half of the woodchucks treated for 14 mo, and in 80% of the woodchucks treated for 36 mo (i.e., reduced serum viremia of 5 to 8 logs). Here, the drug-treated woodchucks had marked reduction in viral load and did not develop HCC during the next 2 years follow-up. Compared in this case with historical controls, entecavir treatment significantly delayed the development of HCC and prolonged survival.

In another study, clevudine was administered orally to chronic WHV carrier woodchucks at 10 mg/kg per day for 32 wk<sup>[30,55,56,155]</sup> starting at 1 to 2 years of age. Half of the clevudine-treated woodchucks and half of the placebo recipients then received 4 doses of a conventional WHsAg vaccine (alum-adsorbed, formalin-inactivated WHsAg) during the next 16 wk. Combination treatment with clevudine and vaccine resulted in a sustained antiviral effect with reductions in serum viremia of more than 8 logs in many cases (Figure 4), and prevented the development of HCC altogether in up to 38% of treated woodchucks. In a subset of the woodchucks studied, where clevudine or placebo treatment was initiated at 1 year of age (and the data analyzed independent of combination with WHsAg vaccine), the development of HCC in clevudine-treated woodchucks was delayed significantly and long-term survival after 4 years likewise was increased significantly compared to woodchucks that did not receive clevudine. These studies show that chemotherapy with antiviral drugs can delay and reduce disease progression in chronic carrier woodchucks, and also show the correlation between

**Figure 4** Combination treatment with clevidine and WHsAg vaccine suppresses serum viremia and antigenemia and induces a humoral response in chronic WHV carrier woodchucks. Changes in serum WHV DNA, serum WHsAg, and anti-WHs antibodies of chronic carriers in response to treatment with placebo (CLV-V-), vaccine (CLV-V+), drug (CLV+V-), and combination of drug and vaccine (CLV+V+) are shown. Horizontal bars denote the period of clevidine (CLV) administration for 32 wk. Arrowheads represent the 4 immunizations (V) using 50  $\mu$ g doses of an alum-adsorbed, formalin-inactivated WHsAg vaccine at wk 32, 36, 40, and 48. WHVge, WHV genomic equivalents (virion or WHV DNA-containing particles).

reduced viral load and reduced disease progression, with noteworthy implications for HBV therapy in humans.

In addition to nucleoside or nucleotide analogues, various other compounds of organic and plant origin have been tested in woodchucks for their antiviral activity (e.g.,<sup>[141,158-161]</sup>), but these will not be discussed in detail in

this review. Direct testing of anti-tumor agents against established HCC in woodchucks is also possible<sup>[162-164]</sup>, but has not been fully developed to date.

### Immunotherapy

The main goal of basic immunological studies described above in neonatal and adult WHV-infected woodchucks is to identify and differentiate factors that cause and maintain chronic infection from those that result from chronic carriage. By better defining cause-effect relationships, it should be possible to develop and test rational immunotherapies that can induce immune responses in the established chronic carrier that mimic those in recovery from WHV infection. In this way, it should be possible to enhance the immune elimination of cells harboring viral cccDNA (and/or control its level and expression), as occurs with successful immune responses leading to recovery.

As indicated in the sections above, chronicity as an outcome of neonatal WHV infection appears to result from a failed or suboptimal primary immune response relatively early during the acute phase of infection in the periphery and in the liver. The onset of chronic infection (compared to resolution) is characterized by deficiencies in the CD8-positive cytolytic T lymphocyte (CTL) response, and reduced expression of Th-type 1 cytokines and intracellular transcription factors, minimal acute hepatitis, and humoral and cellular immunologic tolerance to viral antigens<sup>[42-46]</sup>. Negative immunoregulation of the intrahepatic Th-type 1 response by excessive intrahepatic Th-type 2 immune responses is not a defining factor in this outcome<sup>[45,46]</sup>. Chronicity then appears to develop due to reduced immune-mediated clearance of infected hepatocytes by both non-cytolytic and cytolytic processes<sup>[45,46]</sup>. The above studies indicate further that early induction of immune tolerance may be a factor in the onset of chronic neonatal WHV infection, and a similar mechanism may be involved in the onset of chronic HBV infection in unvaccinated infants born to HBV-carrier mothers. This may include the deletion of higher affinity virus-specific T cells by negative selection of precursor T cells in the thymus (central tolerance), or clonal anergy or exhaustion of virus-specific T cells that escaped early negative selection in the thymus, which are then rendered unresponsive due to higher viral and antigen loads (peripheral tolerance).

Several studies have used WHV-naïve woodchucks for testing experimental vaccines, including conventional and DNA vaccines, and adjuvants, for later therapeutic vaccination of chronic WHV carrier woodchucks. In these studies antibody responses against WHsAg or WHcAg were induced<sup>[31,55,87,165-172]</sup>, and partial or full protection against viral infection and disease by challenge with WHV was observed<sup>[31,87,165,166,168-172]</sup>. A few studies also determined that cellular immune responses were induced in addition to the humoral responses<sup>[87,168-171]</sup>.

Unlike when WHV-naïve woodchucks are immunized, the detection of free anti-WHs in serum of WHV carriers vaccinated with WHsAg is more problematic due to an excess of WHsAg in the serum samples. However, positive

Table 2 Immunotherapeutic approaches in the woodchuck model of chronic HBV infection

Treatment	Outcome	Additional results	Ref.
Vaccination			
WHsAg vaccine/adjuvant	Anti-WHs response	CMI to WHsAg	[55,56,155]
WHsAg vaccine/adjuvant	Anti-WHs response (antibodies mainly directed against preS region)		[173]
WHsAg vaccine/Th peptide epitope	Anti-WHs response Transient serum WHV DNA red. in a few animals (1 log)	Two woodchucks died	[174]
Cytokines			
IFN- $\alpha$ (adenoviral vector)	Transient serum WHV DNA red. (1 log)	Transient WHV RI red. (1 log)	[181]
IFN- $\alpha$ (adeno-associated viral vector)	Transient serum WHV DNA red. (2 logs) Sustained serum WHV DNA red. in 2 animals		[182]
IFN- $\gamma$ (adenoviral vector)	No antiviral effect		[181]
Adoptive immunotransfer			
Liver transplantation	Serum WHV DNA red.	WHV RI red., WHV RNA red.	[188]
Combination treatment			
Lamivudine + WHsAg vaccine/ Th peptide epitope	No additional benefit beyond lamivudine-induced antiviral effect	CMI to WHsAg/WHcAg	
Lamivudine + $\beta$ -galactosidase (adenoviral vector)	Transient but sustained serum WHV DNA red. (> 1 log) in addition to lamivudine-induced antiviral effect	WHV RI red., WHV cccDNA red., WHV RNA red.	[191]
Clevudine + $\beta$ -galactosidase/+ IFN- $\gamma$ /+ IFN- $\alpha$ (adenoviral vector)	Transient but sustained serum WHV DNA red. in addition to clevudine-induced antiviral effect	WHV RI red.	[156]
Clevudine + emtricitabine + IFN- $\gamma$ (adenoviral vector)	No additional benefit beyond clevudine + emtricitabine-induced antiviral effect	Increased liver inflammation with IFN- $\gamma$	[150]
Clevudine + WHsAg vaccine	Anti-WHs response Sustained serum WHV DNA red. (> 6 to 8 log)	WHV cccDNA red., CMI to WHsAg/WHcAg Delay in onset of disease progression	[55,56,155]

signals for anti-WHs can often be detected by enzyme immunoassay under these conditions, even though it may be complexed in native serum. This is because of the exchange of bound anti-WHs between WHsAg in the sample solution, and the WHsAg adsorbed to the solid phase assay matrix. Unvaccinated WHV carriers rarely if ever show detectable anti-WHs of this nature, even though they may have some complexed anti-WHs in serum. Thus, the vaccination of WHV carriers with WHsAg most likely increases the levels of anti-WHs in complex, which enables its subsequent detection (at generally low levels) in the various enzyme immunoassay formats. Assays able to detect anti-WHs in complex with WHsAg are being developed to better study such responses.

One approach to immunotherapy is to modulate the deficient humoral and cellular immune responses of chronic HBV carriers by conventional vaccination (Table 2). In one study chronic WHV carrier woodchucks received up to 6 immunizations with a serum-derived WHsAg vaccine that was adsorbed to aluminum salt and contained monophosphoryl lipid A<sup>[173]</sup>. Following immunization, all of the carrier woodchucks developed an antibody response against WHsAg that was directed mainly against the WHV preS region, but there was little in the way of positive CMI to the antigen used in the vaccine. Despite the induction of anti-WHs antibodies, serum levels of WHV DNA and WHsAg in vaccinated carriers remained unchanged. This was consistent with another study in which four doses of

an alum-adsorbed, formalin-inactivated WHsAg vaccine were administered<sup>[55,56,155]</sup>. In the latter study, CMI to WHsAg and WHsAg peptides was detected in the majority of vaccinated carriers, but, again, there was little effect on serum viral load (Figures 4 and 5). Therapeutic vaccination of chronic WHV carrier woodchucks with a serum-derived WHsAg in combination with an experimental adjuvant (i.e., a peptide carrying a Th epitope from sperm whale myoglobin) induced anti-WHs antibody responses and minor transient reductions in serum WHV DNA in a few of the vaccinated carriers<sup>[174]</sup>. Caution in the use of this therapeutic WHsAg vaccine was recommended, however, since some of the carriers died during the vaccinations. Such adverse effects could have been related to the experimental adjuvant and/or to liver disease present in the woodchucks at entry into the study. The results from these studies indicate that immunization of chronic WHV carrier woodchucks with WHsAg can partially induce (or boost) B cell responses to WHsAg. Additional modulation, however, seems necessary for inducing a response profile that resembles that observed during resolution of WHV infection.

Another approach to immunotherapy of chronic HBV infection involves direct reconstitution of the deficient Th-type 1 immune responses in the liver to mimic natural recovery from infection. Cytokines such as IFN- $\gamma$  and TNF- $\alpha$  have been reported to have direct, non-cytolytic antiviral effects in HBV transgenic mice<sup>[8,175-177]</sup>. However,

**Figure 5** Combination treatment with clevudine and WHsAg vaccine enhances and expands the pattern of cell-mediated immune responses to WHV antigens in chronic WHV carrier woodchucks. Changes in the PBMC responses to WHsAg, WHcAg, WHeAg, and WHxAg of chronic carriers in response to treatment with placebo (CLV-V-), vaccine (CLV+V-), drug (CLV-V+), and combination of drug and vaccine (CLV+V+) are shown. Horizontal bars denote the period of clevudine (CLV) administration for 32 wk. Arrowheads represent the 4 immunizations (V) using 50  $\mu$ g doses of an alum-adsorbed, formalin-inactivated WHsAg vaccine at wk 32, 36, 40, and 48.

increased expression of these cytokines can occur in established chronic WHV carriers with progressing chronic hepatitis and liver injury<sup>[45,96,97,178]</sup>, but with little concurrent reduction in viral replication. This indicates that additional responses would be important to developing a more complete therapeutic effect resembling recovery. Recent studies have shown that woodchuck IFN- $\gamma$  (and TNF- $\alpha$ ) does not significantly deplete WHV RNA or WHV DNA replicative intermediates *in vitro* in virus-infected primary hepatocytes from chronic carriers<sup>[179]</sup>. Other studies in primary hepatocyte cultures from established WHV carriers suggest that expression of IFN- $\gamma$  from a transfected plasmid (and also of TNF- $\alpha$ ) can induce partial host response profiles with similarity to recovering liver, and also impair a later step in viral replication by a non-cytolytic mechanism that is probably mediated by TNF- $\alpha$ <sup>[180]</sup>.

The effects of woodchuck IFN- $\alpha$  and IFN- $\gamma$  on WHV replication were determined *in vivo* in a recent study in chronic WHV carrier woodchucks using an adenoviral vector for the expression of these cytokines<sup>[181]</sup>. Following vector administration directly into the liver, a slight but

transient reduction in intrahepatic WHV DNA replication and in serum WHV DNA of about 1 log was obtained with the IFN- $\alpha$  expressing vector. The intrahepatic expression of IFN- $\gamma$ , however, had no effect on WHV, thus leading to the conclusion that hepatocytes of chronic WHV carrier woodchucks may be functionally altered in their response to IFN- $\gamma$  or resistant to this cytokine. In another study, the administration of woodchuck IFN- $\alpha$  using an adeno-associated viral vector for intrahepatic delivery of this cytokine into chronic WHV carrier woodchucks had a significant antiviral effect in that serum WHV DNA was reduced by 2 logs on average (range 1.5 to 4 logs)<sup>[182]</sup>. The antiviral effect observed was transient in the majority of woodchucks, but two woodchucks appeared to have sustained suppression in serum WHV DNA concentration. The results from these studies indicate that *in vivo* therapeutic gene delivery to augment the deficient Th-type 1 cytokine responses in liver may restore some of the failed antiviral and immunologic functions in human chronic HBV infection.

Another approach to immunotherapy of chronic HBV infection involves the restoration and stimulation

of higher-affinity Th and CTL clones in the periphery (or locally in the liver). Rather than to supplement a specific cytokine deficiency, it may be possible to reconstitute a complete and successful cellular immune response to acute infection by transfer of autologous or histocompatible T cell clones. The efficacy of the latter approach has been demonstrated in recent clinical studies of lymphocompatible bone marrow or PBMC transplantation from HBV-recovered or anti-HBV immunized donors into chronic carrier recipients (e.g.,<sup>[183-187]</sup>). Studies of cell-based therapies in chronic WHV carrier woodchucks involving adoptive lymphocyte transfer from vaccinated or WHV-resolved donors are in progress using neonatal-infected carrier woodchucks made lymphocompatible with their sires by co-injection of parental bone marrow and/or lymphocytes at birth. Later, after the neonates become established WHV carriers, they are re-administered parental lymphocytes therapeutically that were primed in the parent by immunization or recovery from acute WHV infection (Menne *et al.*, unpublished data). Recently, another approach involving adoptive immunotransfer *via* liver transplantation from vaccinated WHV-naïve woodchucks into chronic carrier woodchucks was tested<sup>[188]</sup>. Following vaccination of donor woodchucks with DNA plasmids encoding WHcAg, WHsAg, and WHAg in combination with a plasmid expressing IFN- $\gamma$  livers were transplanted into recipient woodchucks, and the therapeutic effect determined. Two of 3 recipient carriers demonstrated a reduction in serum WHV DNA below the limit of detection by Southern hybridization analysis immediately following transplantation that lasted for up to 7 wk. WHV DNA in serum samples was detected when a more sensitive PCR assay was used. Nevertheless, the reductions in serum viremia were consistent with parallel reductions in intrahepatic levels of WHV RNA and DNA replicative intermediates.

### Combination therapy

The high viral and antigen loads in serum during the chronic phase of infection are believed to maintain immunologic tolerance in established carrier woodchucks<sup>[55,56]</sup>. In some cases, treatment with antiviral drug alone may unmask host immune responses as seen during treatment of adult-acquired chronic HBV infection with lamivudine<sup>[189,190]</sup>; however, such responses appear sub-optimal for bringing about a complete recovery phenotype. To facilitate the emergence of the host immune response from a tolerant state maintained by high antigen load, combination therapy with a nucleoside analogue followed by modulation of the deficient immune responses represents a promising approach. Such an approach might even be able to improve upon natural recovery by creating optimal conditions for more rapid and complete eradication of viral cccDNA from the system.

In one study, chronic WHV carrier woodchucks were treated with lamivudine at a relatively high daily dose of 200 mg/kg given orally for 23 wk<sup>[143]</sup>. At the time, WHV DNA and WHsAg serum levels had declined by 3 to 5 logs or 1 log, respectively, woodchucks were vaccinated with three doses of a serum-derived WHsAg in combination

with a peptide carrying a Th epitope from sperm whale myoglobin. In contrast to a previous study<sup>[174]</sup>, therapeutic vaccination did not induce detectable anti-WHs antibody responses in carriers; the levels of viremia and antigenemia remained nearly unchanged from that achieved by drug treatment, and they returned to pretreatment levels following drug withdrawal. One important finding of this study was that the combination of lamivudine and vaccine, but not treatment with drug alone, induced CMI to WHsAg and WHcAg, presumably by shifting the cytokine profile from Th-type 2 to that of Th-type 0/1.

In another study chronic WHV carrier woodchucks received lamivudine treatment for 6 mo, again at a relatively high dose (200 mg/kg per day, oral) in order to reduce serum WHV DNA by 1 to 3 logs, and were then superinfected with an adenoviral vector expressing  $\beta$ -galactosidase<sup>[191]</sup>. Compared to control woodchucks, combination treatment resulted in further reductions of serum WHV DNA (10-20-fold) in the majority of woodchucks. The vector itself induced local immune responses in liver, and a bystander antiviral effect was observed on intrahepatic WHV DNA, WHV cccDNA, and WHV RNA that correlated with the inflammatory responses involving increased intrahepatic expression of woodchuck leukocyte markers and cytokines. The suppression of WHV replication was transient, but prolonged compared to woodchucks receiving lamivudine monotherapy. Similar results were obtained following superinfection of chronic WHV carriers with adenoviral vectors expressing IFN- $\gamma$ , TNF- $\alpha$ , or  $\beta$ -galactosidase in combination with orally administered clevudine at 10 mg/kg per day<sup>[156]</sup>. Adenovirus superinfection led to declines in the intrahepatic WHV DNA levels, but a long-term benefit of combination treatment over clevudine alone was not observed. However, in contrast to monotherapy with lamivudine<sup>[191]</sup>, recrudescence of WHV replication was delayed until 14 wk after withdrawal of clevudine.

The antiviral effect of a combination of two nucleoside analogues in addition to an adenoviral vector expressing IFN- $\gamma$  also has been tested in chronic WHV carrier woodchucks<sup>[150]</sup>. Woodchucks received clevudine and emtricitabine simultaneously at daily oral doses of 10 mg/kg and 30 mg/kg, respectively, for 8 wk, with two intravenous injections of the vector at wk 4 and 8. Combination treatment with clevudine and emtricitabine resulted in an antiviral effect on WHV replication, with reductions in serum viremia by 4 logs, and associated declines in intrahepatic levels of WHV DNA replicative intermediates and WHV cccDNA. The antiviral effect was sustained in a few woodchucks following drug withdrawal. The additional administration of the adenoviral vector led to increased liver inflammation, but enhancements of the antiviral effect compared to combination treatment with clevudine and emtricitabine were not observed.

In our study in chronically WHV-infected woodchucks described above<sup>[55,56,155]</sup>, combination therapy with clevudine (10 mg/kg per day, oral, 32 wk), followed by 4 doses of a conventional WHsAg vaccine (alum-adsorbed, formalin-inactivated WHsAg), enhanced the virus-specific CMI to WHsAg, and resulted in additional

collateral responses to other viral antigens (Figures 4 and 5). Vaccination alone elicited low-level antibody responses to WHsAg in most woodchucks but did not affect serum WHV DNA or WHsAg levels compared to placebo-treated control woodchucks. Chronic WHV carrier woodchucks treated first with clevudine to reduce serum WHV DNA (> 6 to 8 log reduction) and WHsAg (> 50- to 500-fold reduction), and then vaccinated, developed a more robust anti-WHs antibody response. After vaccination, WHsAg-specific CMI was shown in both vaccinated groups, but was significantly enhanced in woodchucks treated initially with clevudine, and was broadened to include responses to WHcAg and to selected peptide epitopes of WHcAg and WHsAg.

Thus, the long-term drug treatment combined with therapeutic vaccination was shown to break humoral and cellular immune tolerance in treated WHV carrier woodchucks better than the component monotherapies, and to produce a more complete immune response profile resembling that in recovery from acute WHV infection, including an associated and marked reduction in the concentration of WHV cccDNA in liver. While the inclusion of vaccine after clevudine treatment did not result in a significant further antiviral effect beyond that of clevudine alone (i.e., clevudine is so potent that further antiviral effects would be difficult to measure), the combination therapy did have an additive benefit over the monotherapies in delaying the onset and occurrence of disease progression, including chronic hepatitis and HCC<sup>[30,155]</sup>. The results of this study suggest that the delay in the onset of chronic hepatitis and HCC is due to the uniformly high degree of suppression of viral load, especially the expression of viral antigens in serum and liver, any of which could act to maintain immune tolerance during chronic carriage. Longer term protection against the onset or development of HCC then appeared to be a function of the improved cellular and humoral immune responsiveness to viral antigens, which could no longer serve as endogenous tolerogens after reduction by drug.

## CONCLUSIONS

The woodchuck animal model of chronic HBV infection has been valuable in determining the mechanisms of hepadnavirus replication and for studies of viral pathogenesis including associated disease sequelae and host immune responses. Continued modeling of early acute phase immune responses leading to resolution versus chronicity in the neonatal woodchuck may help to identify useful predictive markers of outcome that will facilitate the early identification of the carrier state, and the rational development of antiviral and/or immunotherapies for established chronic HBV infection. Colony-born woodchucks infected as neonates with well-characterized inocula also enable the evaluation of efficacy and toxicity of new types of prophylaxis or therapy under controlled experimental conditions in a relevant animal model within a reasonable time frame. Continued testing of new therapeutic approaches empirically and rationally in the woodchuck model will ultimately improve the chances for

successful therapeutic eradication of established chronic HBV infection and its disease sequelae.

### Abstract

Hepatitis B virus (HBV) infection is still the most common cause of hepatocellular carcinoma and liver cirrhosis world wide. Recently, however, there has been quite dramatic improvement in the understanding of HBV associated liver disease and its treatment. It has become clear that high viral replication is a major risk factor for the development of both cirrhosis and hepatocellular carcinoma. Early studies have shown lamivudine lowers the risk of HBV associated complications. There are currently three nucleos(t)ides licensed, in addition to interferon, and there are more drugs coming to the market soon. Interferon or its pegylated counterpart are still the only options for treatment with defined end points, while nucleos(t)ides therapy is used mostly for long term treatment. Combination therapies have not been shown to be superior to monotherapy in naïve patients, however, the outcome depends on how the end point is defined. Interferon plus lamivudine achieves a higher viral suppression than either treatment alone, even though Hbe-seroconversion was not different after a one year treatment. HBV-genotypes emerge as relevant factors, with genotypes "A" and "B" responding relatively well to interferon, achieving up to 20% HBsAg clearance in the case of genotype "A". In addition to having a defined treatment duration, interferon has the advantage of lacking resistance selection, which is a major drawback for lamivudine and the other nucleos(t)ides. The emergence of resistance against adefovir and entecavir is somewhat slower in naïve compared to lamivudine resistant patients. Adefovir has a low resistance profile with 3%, 9%, 18%, and 28% after 2, 3, 4, and 5 years, respectively, while entecavir has rarely produced resistance in naïve patients for up to 3 years.

**Key words:** Hepatitis B; Antiviral therapy; Resistance;

### INTRODUCTION

Even though hepatitis B virus (HBV) infection is a preventable disease through vaccination, an estimated 2 billion people are HBV infected, with more than 350 million HBsAg positive and considered as carriers or actively infected<sup>[1]</sup>. As with hepatitis C, only about one third of the patients that are HBsAg positive require antiviral therapy because of active HBV replication and associated liver disease determined by elevated liver enzymes. Recently, it was demonstrated that, at least in Asian males older than 30 years of age, there is a viral load related risk of hepatocellular carcinoma<sup>[2]</sup>. This would suggest that antiviral therapy might be indicated even in the absence of active liver disease to decrease the risk of developing hepatocellular carcinoma.

There are different potential mechanisms for how HBV can be inhibited. Mechanisms include an antiviral and immune modulating approach with substances like interferon, a purely antiviral approach inhibiting the HBV polymerase with substances like acyclovir, ganciclovir, and more recently lamivudine, adefovir, entecavir, telbivudine, and several not yet licensed drugs. Interestingly, most of the antivirals studied for HBV were derived from herpes virus or HIV drug development. Thus many of these substances are active against both HBV and HIV, as HBV likewise to HIV replicates *via* an error-prone viral reverse transcriptase. This cross-reactivity must be kept in mind because patients with an HIV infection must never be treated with a monotherapy for HIV, i.e. lamivudine, tenofovir. The reverse transcriptase of HBV and HIV displays similarities, including a so called YMDD motif. Thus, in any patient undergoing HBV-specific treatment, which might also act against HIV, an HIV test should be recommended. Furthermore, if HBV needs to be treated while HIV does not need to be treated, entecavir, telbivudine, and interferon are the primary options. Future options also might include new approaches such as the inhibition of

**Figure 1** HBsAg seroconversion occurs more frequently on HBV genotype "A" compared to the other Genotypes. Date given in percent (%). Adapted from Lau GK, et al. *N Engl J Med* 2005.

viral entry by using a peptide that is competitive with HBV binding.

Among the earliest substances to be used in man were interferon, acyclovir (previously shown to ameliorate Herpes Simplex Virus I associated encephalitis), as well as vidarabine and ARA-A<sup>[3-5]</sup>. Even though promising, these agents, except for interferon, were subsequently shown to have minor potency in controlled trials and/or had significant side effects prohibiting further development<sup>[6,7]</sup>. Similarly, a combination of interferon with these "antiviral" agents did not improve the efficacy of interferon<sup>[8]</sup>. Ganciclovir, which is effective against cytomegalovirus, has also been evaluated for effectiveness against HBV<sup>[9]</sup>, but was subsequently not developed further because more potent drugs were emerging.

## GOALS OF THERAPY FOR HBV INFECTION

The main goal of antiviral therapy is to prevent the development of liver failure, due to either acute fulminant hepatitis or chronic hepatitis B with subsequent liver cirrhosis, the emergence of hepatocellular carcinoma, and HBV transmission. All of these can likely be achieved by suppressing HBV replication, which thereby leads to the remission of liver disease activity and infectivity.

In patients with wild type virus infection, the primary goal of antiviral therapy is to achieve seroconversion from HBeAg to the corresponding anti-HBe antibody (i.e. HBe seroconversion) because this immunologic event is associated with reduced risk for progression of liver disease<sup>[10]</sup>. Noteworthy, a prior decline in viral load is mandatory to obtain HBe seroconversion, which is subsequently required to also achieve seroconversion from HBsAg to the homologous anti-HBs antibody (i.e. HBs seroconversion). This, however, is achieved less frequently and its likelihood, as that of HBe-Seroconversion, might be genotype related (Figure 1)<sup>[11]</sup>.

HBeAg can be negative in the presence of ongoing high viral replication. In patients with HBeAg negative chronic hepatitis B, pre-core mutants can be detected, which are characterised by an inability to produce HBeAg in detectable quantities (Core-promoter mutations) or show a failure to produce HBeAg (start codon mutations or mutations towards a stop codon typically in the second

to last codon of the pre-core region). Available antiviral agents are effective in suppressing HBV replication but in many cases they are not capable of inducing a sustained response after treatment cessation. Therefore, the main objective of therapy is to control viral replication to prevent ALT flares and/or induce remission of disease.

## TREATMENT OUTCOME PARAMETERS

Treatment responses have been poorly defined in the past and different studies use different endpoints, thereby making clear comparisons troublesome. In an approach to unify treatment outcome measurements, the European consensus conference in 2002 defined different types of responses<sup>[12]</sup>; i.e., an initial response, an on-treatment or maintained response, and the sustained response when antiviral treatment has been stopped. The virological response is defined by the decline in HBV DNA below  $10^4$  or  $10^3$  copies/mL, the biochemical response by the normalization of ALT levels, and the histological response (HAI score) by the improvement in the inflammatory activity or fibrosis indices. The combined response is defined by the improvement in ALT levels and decrease in viral load while the complete response is characterized by the combination of the decrease in viral load, the normalization of ALT levels, the occurrence of an HBe- or HBs-seroconversion, and an improvement of liver disease at histology.

The treatment response is also defined based on the duration of therapy. An initial response is characterized by at least 1 log<sub>10</sub> copies/mL decrease in viral load compared to the baseline value at wk 12 of therapy. The maintained response is defined by a low viral load during therapy. Depending on the use of nucleoside analogue or interferon, there is no agreed threshold to define the maintained response. Usually, a decrease of viral load below  $10^4$  copies/mL is associated with an improvement of liver histology. However, with nucleoside analogs, the lower the viral load, the lower the risk to develop viral drug resistance. It seems to emerge that viral load shall decrease to  $< 3 \log_{10}(10^3)$  copies/mL. The end of treatment response is defined by the response observed at the end of therapy, if there was a decision to stop treatment. A relapse is defined by the increase in viral load after treatment

cessation. The sustained response is conventionally defined by the maintenance of the response 6 mo after drug withdrawal. Finally, a breakthrough is an increase of the viral load of at least 1log after initial response (see also resistance).

To enable better comparison of different studies in the future the following data should always be reported within a given study: HBeAg loss & HBeAg seroconversion to anti-HBe; HBsAg loss & HBsAg seroconversion to anti-HBs; End of treatment results, and if applicable at 6 mo follow-up; HBV-DNA log reduction within defined time points e.g. at wk 12 and 24; Number of patients not achieving a 1 or 2 log reduction within 12 and 24 wk; Mean and median log reduction; Achieved HBV DNA reduction to absolute values, such as below 400 copies (100 IU/mL) and below 50 copies (12.5 IU/mL); HBV-Genotypes.

If new assays become available, the studies should report data in a way that is comparable to former studies.

## INDICATION OF ANTIVIRAL THERAPY

Treatment goals and knowledge of the natural history of disease are important for deciding who needs treatment. Two studies have shown that Asian males who are older than 30 years and HBeAg positive<sup>[13]</sup> or have a high viral load have a 10% risk of developing a hepatocellular carcinoma or cirrhosis<sup>[2,122]</sup>. In these patients, antiviral strategies seem justified even in the absence of liver disease. In contrast to HCV, HBV can lead to hepatocellular carcinoma in absence of advanced fibrosis/cirrhosis. However, whether these data that were derived from an Asian population can be translated to other regions of the world with different HBV genotypes and ethnic backgrounds appears questionable. There was no difference in survival and liver related death in European HBsAg positive blood donors vs HBsAg negative blood donors<sup>[14]</sup>. Based on the present knowledge of the natural history of chronic HBV hepatitis and on the efficacy of antiviral drugs, antiviral therapy of chronic HBV infection is indicated in patients with chronic hepatitis B in the immunotolerant phase characterized by high levels of viral replication and elevated serum ALT levels (Table 1). Liver histology usually shows inflammatory activity and variable degrees of liver fibrosis depending on the duration of the disease. Since continuing HBV replication and elevation of ALT levels reflect a significant risk of disease progression towards liver cirrhosis and hepatocellular carcinoma<sup>[15,16]</sup>, antiviral therapy is indicated to decrease viral load, normalize ALT levels and induce a remission of the liver disease.

There are two main forms of chronic HBsAg positive hepatitis, which are distinguished by their HBeAg status. The HBeAg positive form is associated with a so-called wild type virus infection, HBsAg and HBeAg positivity, high HBV DNA levels, usually  $> 10^6$  copies/mL, and elevated ALT levels. The HBeAg negative form is associated with core promoter and/or pre-core mutant virus infection, HBsAg positivity and HBeAg negativity (most patients have anti-HBe antibody), HBV DNA levels that are fluctuating but are usually  $> 10^4$  copies/mL, and elevated ALT levels that may also fluctuate over time.

Table 1 Indication for observing and treating HBV

	HBV-DNA levels	ALT status	Therapy/Observation	
HBeAg +	$> 10^5$	Normal	Observe	
HBeAg +	$> 10^5$	Elevated	Yes	IFN, Antivirals
HBeAg +	$> 10^4$	Normal	Observe	
HBeAg -	$> 10^4$	Elevated	Yes	Antivirals, IFN
HBeAg -	$> 10^4$	Normal	Observe	
Pregnancy	$> 10^9$ geq/mL	Irrelevant	Yes	Antivirals
HBsAg + chemotherapy	Irrelevant	Irrelevant	Yes	Antivirals
HBsAg -				
Anti-HBc + chemotherapy	Positive	Irrelevant	Observe, treat in case of HBsAg appearance	Antivirals
Advanced fibrosis	irrelevant	Elevated	Always	Antivirals
Transplanted patients	$> 10^4$		Consider Treatment	Antivirals
Asian male	$> 10^{5/6}$	Irrelevant	Yes	Antivirals

Treatment endpoints differ depending on the form of chronic hepatitis B.

It is currently not recommended to treat patients who are in the immunotolerant phase. They are defined serologically by HBsAg positivity, HBeAg positivity, high HBV DNA levels (usually higher than  $10^8$  copies/mL), and normal serum ALT levels. They usually have no liver damage or only minimal liver disease at liver biopsy examination, but they are highly infectious. The results of clinical trials for interferon alpha or nucleoside analogs indicate that patients with high HBV DNA load and normal ALT levels have almost no chance of HBeAg seroconversion. However, patients should be monitored on a regular basis to diagnose a break in immune tolerance characterized by an elevation in ALT levels and a decline in viral load, which may reflect the onset of liver damage and represent an indication for antiviral therapy. In addition, being a 30 years old Asian male with a viral load above  $10^6$  might also serve as an indication because of the 10% change of developing a HCC or liver cirrhosis in ten years<sup>[2,121]</sup>. However, this prediction probably cannot be transferred to women and to European patients.

The other category of patients with chronic HBV infection who should not be treated are HBsAg inactive carriers. Their virologic profile is characterized by HBsAg positivity, HBeAg negativity, anti-HBe antibody positivity, persistently low HBV DNA levels ( $< 10^4$  copies/mL), and normal ALT levels. Liver histology usually shows no or minimal damage and the risk of progressing liver disease is considered to be minimal as long as ALT levels remain normal and viraemia is below  $10^4$  copies/mL. It is currently recommended that these patients should not be treated but should be followed carefully every 3 to 6 mo to promptly diagnose reactivation of viral replication and ALT exacerbations. When their values have been stable for 2 years, one can consider extending their monitoring intervals to 12 mo intervals.

In the case of advanced fibrosis, the recommendation

**Figure 2** Pre-emptive lamivudine is associated with lower frequency and lower severity of hepatitis during chemotherapy. Data given in percent (%). Adapted from Li YH, et al. *Cancer* 2006.

is to initiate every patient on antivirals to prevent further deterioration of their liver disease independent of disease activity at least in the presence of HBV-DNA. Certainly, when fibrosis regresses during treatment an interruption might be considered.

Another clear indication for antiviral treatment is prevention of reactivation on chemotherapy, where lamivudine has been associated with lower frequency and lower disease severity of hepatitis (Figure 2)<sup>[17]</sup>. To a lesser extent, antiviral therapy seems indicated in late pregnancy in women with a high viral load<sup>[18,19]</sup>, but formal clinical studies have not yet been published.

### General outcome predictors

Some pre-treatment factors have been identified that predict responses to therapy. They may be useful in treatment decisions and drug choices. The results of clinical trials have shown that high ALT values ( $> 3 \times \text{ULN}$ ) are always predictive of a higher chance of HBeAg-seroconversion. In addition, a low viral load ( $< 10^7$  copies/mL equivalent to 35 pg/mL) is predictive of a favourable response to standard or pegylated interferon. In addition, likewise to HCV though to a lesser extent, there is emerging evidence that HBV-genotypes are associated with treatment responses. While genotypes seem to be of no relevance for nucleos(t)ide therapy, there is ample evidence that the HBV genotypes A (versus D) and B (versus C) are associated with a better response to interferon therapy. HBsAg-seroconversion might be strongly associated with genotype A<sup>[20]</sup>.

## STANDARD INTERFERON ALPHA

A sustained response, defined by HBe seroconversion 24 wk post-treatment, is induced by subcutaneous administration of standard interferon in 20% to 40% of patients depending on patient characteristics; while only 5% to 10% of patients seroconvert in the placebo group<sup>[21,22]</sup>. Spontaneous HBe seroconversion is part of the natural history of the disease and is believed to be driven by the host immune response; in all clinical trials the spontaneous rate of HBe-seroconversion ranges from 5% to 10% per year. Patients with high ALT levels, a high HAI score, and low HBV DNA levels have a higher chance of HBe seroconversion ( $> 40\%$ ). While responses to HCV associated

interferon therapy are usually associated with an immediate drop in both HCV-RNA and ALT, response to interferon with HBV is, especially in responders, associated with a marked increase of ALT in conjunction with a decrease of serum HBV DNA during the second or third month of therapy. The former reflects the immunological response leading to clearance of the virus and might also be associated with the vanishing immunosuppression caused by HBV itself. Clearance of HBsAg and seroconversion to anti-HBs is a late event; the percentage of patients who became HBsAg-negative after seroconverting to anti-HBe varied widely (7%-65%) for follow-ups of 3-4 years<sup>[23,24]</sup>. The European consensus conference recommended using a regimen of 5 MU daily or 10 MU thrice weekly for 24 wk<sup>[12]</sup>. However, due to the frequency of side effects at these high doses of interferon, 5-6 MU interferon thrice weekly may be an optimal choice to allow the continuation of therapy. Side effects are frequent and numerous but usually mild and reversible after treatment withdrawal.

HBeAg negative patients with active hepatitis B are mostly infected with the so called pre-core mutant. Trials using 6-12 mo of interferon therapy in that patient population showed that, regardless of interferon dosage, there was a good response while on therapy (inhibition of HBV-DNA, normalization of ALT) but relapses post-therapy were common and observed in a majority of patients. These initial studies indicated that therapy, therefore, should not rely on courses of interferon less than 1 year. Long-term administration for at least 2 years showed clinical benefit in terms of viral suppression and ALT normalization. Approximately 30% of patients may present a sustained response after treatment withdrawal when the interferon course was sufficiently long to maintain the suppression of viral replication<sup>[25]</sup>. However, side effects and poor tolerance to interferon administration limit its prolonged use in this form of chronic hepatitis B.

## RESULTS OF PEGYLATED INTERFERON ALPHA

Pegylation is binding a pegylated side chain to interferon leading to a 12 or 40 kD molecule, i.e., PEG-IFN- $\alpha 2b$ , and Peg-IFN- $\alpha 2a$  respectively, which increases the half life of interferon making a once weekly application feasible and sufficient. These pegylated interferons have proven

**Figure 3** Viral load reduction at the end of treatment and at 24 wk follow-up in the different treatment arms. Adapted from Lau GK, et al. *N Engl J Med* 2005.

to not only increase convenience by enabling once weekly dosing but they have also improved efficacy dramatically in hepatitis C. Thus, it was a logical consequence to also evaluate them in Hepatitis B. A phase II study evaluated the efficacy of 90, 180 and 270 µg of PEG-IFN-α2a for 24 wk in comparison to a standard interferon-α2a 4.5MU three times per week<sup>[26]</sup>. This dose of standard interferon 3 times per week, however, has to be considered to be inappropriate at that time.

In the subsequent phase III trials the antiviral effect of pegylated IFN-α2a (40 kDa) or -α2b (12 kDa) administration was evaluated for 48 wk (versus 24 wk used previously and considered as standard care). These trials have shown a HBe seroconversion rate of approximately 30% 6 mo post-treatment<sup>[11,27]</sup>. However, standard interferon was not a comparator in that study; only lamivudine was tested. Interestingly, a HBs seroconversion rate of 3%-5% was observed at the end of follow-up, while clearance of HBsAg was observed in up to 7% of patients with high genotype dependence (Figure 1). Tolerance and the nature and frequency of side effects for pegylated interferon alpha were generally similar to that of standard interferon in historic controls. Flu like syndrome, inflammatory skin reaction at the injection site and neutropenia were more frequent with pegylated than with standard interferon. Interestingly, depression, which occurs in about 30% of HCV patients during treatment, was reported to be lower than 3%. Even though viral suppression at the end of follow-up was similar for Peg-IFN-α2a and Peg-IFN-α2a plus lamivudine, the end of treatment viral suppression was significantly more pronounced in combination therapy (Figure 3) based on the given confidence intervals.

## NUCLEOS(T)IDE ANALOGUES

While interferon usually leads to some side effects, such as flu like symptoms, the various nucleos(t)ides are characterised by few side effects, at least at the licensed dose.

### Famciclovir

The first nucleos(t)ide studied in a larger trial was famciclovir, which was developed as a treatment for acyclovir

**Figure 4** Different response pattern on famciclovir. Adapted from Tillmann HL et al. *Hepatology* 1998.

resistant herpes simplex virus I infection. Famciclovir was subsequently shown to also have some HBV-activity *in vitro* and was thus developed for HBV therapy. In both liver and heart transplant patients, famciclovir has proven to ameliorate liver disease, despite only moderate virological response in most of the patients<sup>[28-30]</sup>. Basically three different patterns of response were determined in our transplant patients. A third of the patients responded well, a third showed slow response and another third did not show any response (Figure 4). Interestingly, the responders showed a clear virological response, which rarely exceeded one log reduction within three months, while transaminases and liver function deterioration were ameliorated.

A controlled trial also proved efficacy<sup>[31]</sup>, but the drug is relatively expensive to produce and lamivudine was emerging as a more potent and less expensive drug. Nevertheless there was a clinical response despite relatively moderate viral suppression of 70%, which is equivalent to less than a 1 log reduction. Some of the patients showed marked and clear improvement in liver function after having had a continuous decrease in liver function prior to initiation of famciclovir (Figure 5).

Despite promising results in liver<sup>[28,29]</sup> and heart transplant<sup>[30]</sup> patients, famciclovir was not developed further after the potency of lamivudine became evident. All of the patients responding slowly or not responding to famciclovir showed immediate and more marked response to lamivudine, as did the patients developing resistance on famciclovir<sup>[32]</sup>.

### Lamivudine

Lamivudine (3TC) has been developed for inhibiting the reverse transcriptase of HIV<sup>[33]</sup>, but as HBV's life cycle also requires a functioning reverse transcriptase, lamivudine was investigated and proven to be effective in inhibiting HBV as well, both *in vitro* and *in vivo*<sup>[34]</sup>. Several phase III trials have demonstrated the antiviral efficacy of lamivudine administration in patients with HBeAg positive<sup>[35,36]</sup> and HBeAg negative chronic hepatitis B in doses of 100 to 300 mg/d<sup>[37]</sup>. The higher doses used in HIV have not proven to be more efficacious<sup>[38-40]</sup>, even though their potential in preventing resistance has not been determined. Advantages of lamivudine are oral administration, an excellent safety

**Figure 5** Improvement on famciclovir in a patient with continuous deterioration prior to initiation of famciclovir therapy. Arrow indicates start of famciclovir, where after Bilirubin slowly normalised, and both Quick test (Marker for impaired clotting function) and cholinesterase (CHE) stabilised indicating stabilisation of liver function. (unpublished).

profile, a rapid antiviral effect, and a relatively low cost of therapy. Viral load declines by 3-5  $\log_{10}$  copies/mL after a year of therapy compared to baseline values. The antiviral effect is accompanied by a significant decrease in ALT levels, and an improvement in the histology activity index. An improvement of liver fibrosis has also been observed during lamivudine therapy<sup>[41]</sup>. However, the primary goal of therapy, i.e. HBe seroconversion, is obtained only in approximately 20% of patients after 1 year of treatment, which was nevertheless significantly higher than in patients receiving placebo (5%-10%). Continuous lamivudine therapy is indicated in patients who do not seroconvert. It avoids a rebound of viral replication and exacerbations of liver disease. Continuing lamivudine therapy is associated with a progressive increase in the number of patients who undergo HBe seroconversion, reaching approximately 50% after 4 years of therapy<sup>[42]</sup>. A factor influencing the durability of HBe seroconversion is the duration of lamivudine therapy after seroconversion. In HBeAg negative patients, long-term lamivudine treatment is required because rebound is immediate after cessation<sup>[37]</sup>.

### Emtricitabine

Emtricitabine (FTC) is a L-deoxycytidine analogue as is lamivudine. Emtricitabine was also developed for HIV therapy, where it is often used in a fixed combination with tenofovir. Emtricitabine was evaluated in phase II and phase III trials. In a study randomising 98 patients to receive emtricitabine at 25, 100, or 200 mg daily for 48 wk and then 200 mg until wk 96, the dose of 200 mg daily provided the best results. After 2 years, 53% of the patients had serum HBV DNA below 4700 copies/mL, 33% seroconverted to anti-HBe and 85% had normal ALT levels. Resistance mutations were observed in 18% of patients after 96 wk of therapy<sup>[43]</sup>.

A 200 mg dose of emtricitabine has been shown to be superior to placebo for histologic improvement (103

of 167 (62%) patients receiving FTC *vs* 20 of 81 (25%) receiving placebo;  $P < 0.001$ ). Serum HBV DNA less than 400 copies/mL was achieved in 91 of 167 (54%) patients in the FTC group *vs* 2 of 81 (2%) in the placebo group ( $P < 0.001$ ). Resistance towards FTC was detected in 20 of 159 FTC treated patients (13%, with a 95% confidence interval of 8%-18%). The safety profile of emtricitabine was found to be similar to that of placebo during treatment<sup>[44]</sup>. Being an L-nucleoside, FTC shows cross resistance to Lamivudine<sup>[45]</sup>.

### Telbivudine

Telbivudine is also an L-analogue, such as lamivudine, and it shares a similar resistance profile to lamivudine. However, resistance to telbivudine is associated with the YIDD mutation, leaving entecavir fully active. The safety, antiviral activity, and pharmacokinetics of telbivudine have been assessed in 43 adults with hepatitis B and antigen-positive chronic hepatitis B<sup>[46]</sup>. This placebo-controlled dose-escalation trial investigated six telbivudine daily dosing levels (25, 50, 100, 200, 400, and 800 mg/d); treatment was given for 4 wk. There was more than a 2 log reduction in all dose groups within one week, with disclosing higher potency of the  $> 400$  mg dose only in the second phase. Telbivudine was well tolerated at all dosing levels, with no dose-related or treatment-related clinical or laboratory adverse events. Antiviral activity was dose-dependent, with a maximum at doses of 400 mg/d and or more. In the 800 mg/d cohort, the mean HBV DNA reduction was 3.75  $\log_{10}$  copies/mL at wk 4, comprising a 99.98% reduction in serum viral load. Subsequently, large phase III studies have shown the superiority of telbivudine compared to lamivudine in the suppression of viral load (by 6.5  $\log_{10}$  versus 5.5  $\log_{10}$ ) and improvement of liver histology<sup>[47]</sup>. A 24 wk study also showed telbivudine to be more active than adefovir with a 6.3 *vs* 4.97 log reduction of HBV-DNA<sup>[48]</sup>. Telbivudine resistance was observed in

**Figure 6** Reduction in HBV-DNA, as well as histological improvement in inflammation and fibrosis according to the Knodell score after 48 wk therapy with 10, 30 mg ADV. Adapted from Marcellin P, *et al. N Engl J Med* 2003.

approximately 5% of patients after 1 year of therapy and associated with a M204I mutation, as expected, within the “YMDD”-motif in the viral polymerase<sup>[49]</sup>. However, the M204V mutation, which is frequently associated with additional mutations at 180 and 173, has not been detected with telbivudine<sup>[50]</sup>. This might be another advantage in addition to its higher antiviral activity. Importantly, pharmacokinetics indicate no alteration with impaired hepatic function<sup>[51]</sup>.

### Adefovir

In the early 1990s, adefovir was shown to inhibit HBV and HIV in cell cultures<sup>[52,53]</sup>. Its development for HIV was halted because the dose required for HIV inhibition was associated with significant nephrotoxicity beyond 24 wk of treatment<sup>[54]</sup>. However, HBV was inhibited with lower doses of adefovir and it could even be used safely in renal impaired patients<sup>[55]</sup>. It was shown that a 10 mg dose provided a smaller decrease in viral load than a 30 mg dose (Figure 6) but there was a higher creatinine increase with the 30 mg dose and therefore only the 10 mg dose was developed further<sup>[56]</sup>.

In a large phase III trial, 515 patients with HBeAg positive chronic hepatitis B were treated with adefovir 10 mg ( $n = 171$ ), adefovir 30 mg ( $n = 173$ ) or placebo ( $n = 167$ ) for 48 wk. HBe seroconversion was achieved only in a minority of patients, i.e. 14% in the 30 mg daily and 12% in the 10 mg daily dosing group of patients receiving adefovir dipivoxil versus 6% in the placebo group. ALT levels normalized in 48% and 55% of patients receiving adefovir 10 and 30 mg adefovir respectively, versus 16% in the placebo group. Reduction of HBV-DNA and liver inflammation and fibrosis improved significantly in patients given adefovir (Figure 6)<sup>[57]</sup>. Tolerance for the daily dose of 10 mg adefovir was comparable to placebo. Extended administration of adefovir dipivoxil showed an increased rate of HBe seroconversion over time: 14% of 296 patients, 33% of 231 patients, and 46% of 84 patients after 1, 2, and 3 years of therapy, respectively<sup>[57,58]</sup>.

Similar to HBeAg positive patients, adefovir administration for 48 wk in HBeAg negative patients induced histologic improvement more frequently in adefovir treated (64%) *vs* placebo treated patients (33%,  $P < 0.001$ ), and reduced serum HBV DNA below  $< 400$

copies/mL [51% (63 of 123) *vs* 0%;  $P < 0.001$ ]<sup>[59]</sup>. HBV DNA was below 1000 copies/mL in 51%, 71% and 79% patients after 48, 96 and 144 wk, respectively<sup>[59-60]</sup>. Interestingly, in the majority of patients who were switched from adefovir to placebo, the benefit of treatment was lost, indicating that antiviral therapy with nucleoside analogs must be prolonged in this patient population to avoid viral reactivation and ALT flares. Side effects after 144 wk were similar to those observed at wk 48. It has been presented recently that 22/33 anti-HBeAg negative patients showed sustained response when adefovir was stopped after 4 to 5 years of continuous adefovir therapy<sup>[122]</sup>.

### Entecavir

Entecavir was developed as an anti-herpes drug, but proved to display only moderate activity, which eventually led to discontinuation of development for this indication. However, Bristol-Myers Squibb discovered that entecavir was extremely potent against HBV through inhibition of HBV-DNA polymerase, with relatively low toxicity. Entecavir is the first HBV-specific antiviral to be licensed that seems to lack both HIV and herpesvirus cross-reactivity<sup>[61]</sup>, which is especially attractive for HIV-HBV co-infected patients not yet requiring HIV-treatment. Entecavir has been evaluated for naïve patients in two controlled phase III trials involving 715 HBeAg positive and 648 HBeAg-negative patients with chronic HBV infection, detectable HBV DNA, persistently elevated ALT levels and chronic inflammation on liver biopsy. Entecavir administered 0.5 mg orally once daily for 52 wk was shown to be superior to lamivudine (100 mg orally once daily for 52 wk) for the primary efficacy endpoint of histological improvement and for secondary endpoints, such as the reduction in viral load ( $6.9\log$  *vs*  $5.4\log$ ,  $P < 0.001$  for HBeAg+;  $5.0$  *vs*  $4.5\log$ ,  $P < 0.001$  for HBeAg-) and normalization of ALT (68 *vs* 60%,  $P = 0.02$  for HBeAg+; 78 *vs* 71%;  $P = 0.045$  for HBeAg-)<sup>[62,63]</sup>. After 2 years of treatment, 81% of patients receiving entecavir had a viral load below 300 copies/mL versus only 39% of patients receiving lamivudine, 31% seroconverted to anti-HBe versus 26% in the lamivudine group, and 5% showed a clearance of HBsAg versus 3% in lamivudine treated patients<sup>[64]</sup>. The second year, however, was limited to 307 of the initial 709 patients. In lamivudine refractory

patients, entecavir administered at 1 mg once daily induced a significant viral load reduction and histological improvement, by comparison with the control group treated with lamivudine<sup>[65]</sup>. Entecavir was approved in 2005 by the US FDA for the treatment of chronic HBV infection in adults with evidence of active viral replication and either evidence of persistent elevation in serum ALT or histologically active disease. Entecavir resistant mutants have been described mainly in patients with lamivudine resistance<sup>[66]</sup>. Approximately 9% of lamivudine resistant patients treated with entecavir develop resistance to entecavir after 2 years of therapy. The resistant mutants are then resistant to both lamivudine and entecavir.

### Tenofovir

Tenofovir is licensed for the treatment of HIV infection but has known activity against HBV as well. It is less nephrotoxic and therefore it can be used in a higher dose (300 mg) unlike adefovir, which is licensed for a 10 mg dose.

Tenofovir's anti-HBV activity has been studied *in vitro* and *in vivo* mostly in HIV infected patients coinfecting with HBV. In this patient population, tenofovir administration decreased HBV load significantly both in lamivudine naïve and lamivudine resistant patients<sup>[67-69]</sup>. There is good evidence from non-randomized<sup>[70]</sup>, but also a small randomised study, that tenofovir is more potent than adefovir in reducing HBV load<sup>[71]</sup>. Phase III trials are ongoing to compare the anti-HBV activities of tenofovir and adefovir in HBV mono-infected patients and in HIV-HBV co-infected patients. Currently, even though it has higher potency and lower cost compared to adefovir, tenofovir cannot be prescribed. This can be considered as a drawback of modern bureaucratic medicine, which prohibits using a drug that has a better safety profile and higher activity at lower costs, but has not been specifically evaluated for that indication.

### Clevudine

Clevudine is an artificial beta-L nucleoside analogue that shows cross-resistance to lamivudine<sup>[45]</sup>. It seems to have an advantage in that viral load rebound after therapy cessation is not immediate<sup>[72]</sup>. A specific attractive aspect of clevudine is its activity against delta virus infection, at least in the woodchuck model<sup>[73]</sup>.

### Pradefovir (Remofovir)

There is evidence that the safety of ADV could be improved if liver-specific targeting could be achieved, thereby allowing higher liver-associated concentration without increase of systemic exposure with nephrotoxic consequences. One such prodrug is pradefovir, formerly remofovir<sup>[74]</sup>, which is under clinical development. 10, 20 and 30 mg of pradefovir seem to be more potent than 10 mg of adefovir (-4.22, -4.33, -5.06log *vs* -3.66)<sup>[75]</sup>. However, it needs to be determined whether it is more effective than tenofovir.

### ANA380

ANA380 is a prodrug of ANA317, another recently reported substance with activity against lamivudine resistant HBV. Patients treated with ANA 380 at 30 mg, 60 mg, 90

mg, 150 mg and 240 mg dose levels experienced reduction in plasma HBV viral DNA at 12 wk of 2.8 log, 3.2 log, 3.9 log<sub>10</sub>, 3.9 log<sub>10</sub> and 4.1 log<sub>10</sub> units, respectively<sup>[76]</sup>.

### Myrcludex B: an acylated PreS1 peptide

It was found that the preS1 amino acids 2-48 mediate attachment of the virus to its target cells. Furthermore amino-terminally acylated peptides containing amino acids 2-18, and even more efficiently with 2-48 of the PreS1 domain, can be used to block hepatitis B virus infection<sup>[77]</sup>. Using this concept, Urban *et al.*, developed a peptide that was shown to inhibit HBV-infection *in vitro* and in animal models and is currently being developed as an antiviral approach. It is currently not clear whether it will inhibit infection in a post exposure approach, i.e. after needle stick injury or liver transplantation of HBV-positive patients, to prevent re-infection or whether it might have antiviral activity in chronic hepatitis B.

## COMBINATION THERAPY

Several studies have evaluated the efficacy of a combination of interferon alpha 2a or 2b with lamivudine and more recently a combination of Peg-IFN alpha 2a or 2b with lamivudine in comparison with pegIFN alone and/or lamivudine alone<sup>[11,27]</sup>. It was concluded that the efficacy of combined Peg-IFN plus lamivudine is not different from Peg-IFN alone if both are given for 48 wk. However, this depends on what you are observing. HBeAg seroconversion actually was even lower, though not significantly different, 24 wk post-treatment. Similarly the viral load reduction and normalisation of transaminases was similar between Peg-IFN plus lamivudine *vs* Peg-IFN monotherapy 24 wk after the end of therapy<sup>[78]</sup>.

The decline of viral load was higher, however, in the combination group than in the single treatment group during therapy (Figure 3). The rate of lamivudine resistance was lower in patients who received a combination of lamivudine with pegIFN compared to lamivudine monotherapy, and following the state of art, one would not have stopped lamivudine therapy at 48 wk. Thus, it may be premature to state that Peg-IFN should not be combined with lamivudine, but this certainly would need further study.

Likewise, a very small study suggested that ccc-DNA reduction was augmented when adefovir is combined with Peg-IFN *vs* adefovir alone<sup>[79]</sup>. Whether this can eventually lead to higher HBsAg seroconversion rates needs to be determined in future studies.

A combination therapy approach is also suggested with use of some of the more recently developed antivirals. It had been shown that adefovir plus emtricitabine is superior to adefovir alone<sup>[80]</sup>. Given the similarity but superiority of tenofovir versus adefovir, the combination of tenofovir with emtricitabine appears especially promising, and since this combination is one of the backbones of HIV-antiretroviral therapy and there is already an excellent track record.

Recently, emtricitabine was also combined with 10 mg clevudine (1.8 to 2.3 log reduction) and results showed a superiority for the combination versus emtricitabine alone

**Figure 7** Prevalence of resistance on different antivirals, up to 2 (A) and up to 5 (B) year data.

(1.4 to 2.0 log reduction)<sup>[81]</sup>. These viral load reductions, however, were still lower than those reported on 50 mg clevudine monotherapy (s. clevudine above). Thus, in the combination trials each drug should also be tested as monotherapy to exclude the “combination effect” of higher potency for one of the drugs.

## DRUG RESISTANCE

HBV replicates *via* an error prone viral reverse transcriptase resulting in a large pool of quasiespecies with mutations interspersed throughout the genome. During antiviral drug selection pressure (e.g., lamivudine, adefovir, or entecavir), HBV mutants are selected from the preexisting pool of quasiespecies and over time become the dominant species.

Drug resistant mutants emerge as a function of at least six factors: (1) the viral mutation frequency (annual error rate), (2) the intrinsic mutability of the antiviral target site (some mutants are lethal and cannot replicate), (3) the selective pressure exerted by the drug (the stronger the more likely a resistance emerges), (4) the magnitude and rate of virus replication (the higher the viral load, the more likely resistance emerges), (5) the overall replication fitness of the mutant (some mutants are replicating very poorly and some require addition compensatory mutations), and (6) the availability of replication space (the amount of cccDNA harboured in a cell is limited; if there is no space for new cccDNA the likelihood of resistance is reduced).

HBV resistance to antivirals can be defined at different

levels, which usually develop sequentially: (1) genotypic resistance is the detection of polymerase gene mutations known to confer resistance to the drug, (2) virologic breakthrough has been defined as an increase of at least one log<sub>10</sub> copies/mL compared to the lowest value during treatment, associated with the presence of resistance mutations following genotypic resistance, (3) clinical failure is defined as viral breakthrough and increase in ALT levels and subsequently progression of liver disease usually following the virological breakthrough. Very rarely increased replication of viruses can be observed after emergence of resistance<sup>[82]</sup>, which was first described 40 years ago for enteroviruses<sup>[83]</sup>, and some years ago for HIV<sup>[84,85]</sup>, which has, however, minor clinical relevance because of the multiple drug approach in HIV.

One of the clear advantages of interferons is their inability to significantly induce mutations, which would subsequently abolish interferon activity. In contrast, all nucleos(t)ide given for more than 48 wk have been shown to induce mutations with various frequencies after 1 to 2 years and during longer treatment (Figure 7A and B), which leads to impaired sensitivity towards the appropriate antiviral. The first antiviral leading to some clinical improvement but also to mutations was famciclovir. Its signature mutation was L528M<sup>[32]</sup> (now corresponding to rtL180M, as numbering was changed to start at the start of the reverse transcriptase of HBV-DNA polymerase with the highly conserved EDWGPCDEHG motif<sup>[86]</sup>) thereby eliminating different numbering for different HBV

genotypes. Patients with such a L528M/rtL180M mutation were shown to be sensitive to lamivudine, at least until YMDD mutations due to lamivudine became known as well<sup>[32]</sup>.

New drugs have become available and knowledge of the *in vitro* cross-resistance profile has provided the rationale for their use in patients with treatment failure. The rescue treatment of patients with drug resistance has improved significantly in recent years.

The major problem of long-term lamivudine therapy is the occurrence of drug resistance. The spontaneous variability of the HBV genome and the slow kinetics of viral clearance, are the biological basis for the selection of drug resistant mutants. The results of phase III clinical trials and of cohort studies have shown an incidence of lamivudine resistance of approximately 20% per year<sup>[87]</sup>. Lamivudine resistance develops in up to 70% of patients after 4 years of therapy<sup>[88,89]</sup>, leading to an increase in viral load (viral breakthrough) that is followed by an increase in ALT levels (biochemical breakthrough), a reduced HBe seroconversion rate in HBeAg positive patients, and a progression of liver disease<sup>[87]</sup>. In some patients, especially those with liver cirrhosis or severe fibrosis, the biochemical breakthrough that follows lamivudine resistance may cause a severe and acute exacerbation of liver disease that may precipitate liver failure<sup>[88,90-92]</sup>.

Long-term studies have shown that antiviral efficacy and histological improvement is progressively lost with time because the prevalence of resistance mutations increases as liver disease continues. This was observed in some patients with YMDD mutations but none without those mutations<sup>[93]</sup>. ALT levels increase progressively with the duration of infection with the YMDD mutants and it was reported that no patient who developed lamivudine resistance mutation for 24 mo had normal ALT levels<sup>[94]</sup>. It is therefore necessary to make an early diagnosis of drug resistance to adapt rescue antiviral therapy prior to the degradation of liver functions<sup>[92,95]</sup>.

In a retrospective nationwide analysis of lamivudine therapy in Italy, the development of clinically important events after virological breakthroughs depended on the severity of the underlying liver disease; severe hepatitis flares at the emergence of YMDD were noted in patients with child B and C cirrhosis but not in patients with non-cirrhotic chronic hepatitis<sup>[96]</sup>, which is in agreement with previous studies<sup>[91,92]</sup>. Interestingly, the rate of HCC was diminished even in multivariate analysis in patients with maintained response *vs* those with breakthrough<sup>[96]</sup>.

Mutations conferring resistance to lamivudine are mainly located in the C domain of the reverse transcriptase within the YMDD motif, i.e. M204V or M204I, and may be associated with compensatory mutations in the C domain, i.e. V173L or L180M. After 1 year of treatment, lamivudine resistant mutants emerged in 22% of patients, increasing to 38% after 2 years, 53% after 3 years, 66% after 4 years, and 69% after 5 years<sup>[87,89,97]</sup>. However, this also means that approximately 30% of patients seem to never develop resistance against lamivudine. *In vitro* and *in vivo* studies showed that the main lamivudine resistant mutants remain sensitive to adefovir<sup>[98,99]</sup>, tenofovir<sup>[70]</sup>, and entecav-

ir<sup>[62,100]</sup>, even though susceptibility to entecavir was reduced *in vitro*<sup>[101]</sup>.

Comparing the addition of adefovir to ongoing lamivudine and the switch from lamivudine to adefovir did not reveal any difference in viral load decline in these two treatment groups. However, recently Lampertico *et al*<sup>[102]</sup> presented data showing very pronounced viral load reduction if adefovir was added when viral resistance emerged instead of when clinical resistance with elevated liver enzymes was evident. In addition, the risk of resistance to adefovir was significantly less frequent in patients receiving adefovir in addition rather than as a substitute for lamivudine<sup>[103]</sup>. Thus, because of the lack of cross-resistance between the two drugs, there is now a consensus among experts that adefovir should be added to lamivudine in patients with lamivudine failure to prevent or delay the subsequent selection of new resistant mutants.

Because of the reduced susceptibility of the lamivudine resistance mutant to entecavir *in vitro*, entecavir was given to patients with lamivudine failure at a dose of 1 mg daily instead of 0.5 mg, which was given to naïve patients. Entecavir induced a significant decline in viral load in these lamivudine refractory patients<sup>[65]</sup>. Noteworthy, cases of entecavir resistance were described so far only in lamivudine resistant patients, suggesting that some level of cross-resistance between these two drugs is responsible for the selection of mutants resistant to both drugs. Based on these findings, follow-up studies are required to better determine the indication of entecavir in patients with prior lamivudine resistance.

Telbivudine and emtricitabine share the same resistance mutations as lamivudine except that telbivudine seems to not induce mutations at L180M and 173 as frequently. The year one resistance data within the GLOBE-study indicate that the telbivudine resistance is associated with a M250I mutation and not with a M250V mutation.

In patients treated continuously with adefovir 10 mg/d as a monotherapy, drug-resistant mutants emerged in 2%, 5.9%, 18%, and 29% of patients after 2-5 years, respectively. Resistance to adefovir is most frequently conferred by the selection of a rtN236T mutation in the D domain of the HBV polymerase or a rtA181V mutation in the B domain of the polymerase<sup>[104-106]</sup>. This may be accompanied by liver failure<sup>[107]</sup>. *In vitro*, the rtN236T mutation is sensitive to both lamivudine and entecavir and the rtA181V showed a decreased susceptibility to lamivudine, which can be confirmed *in vivo*<sup>[106,107]</sup>. Adefovir resistance can probably be significantly reduced if treatment is combined with lamivudine. In addition, it has been suggested that resistance to adefovir is more likely to develop in lamivudine resistant patients with 10% *vs* 0% after one year adefovir<sup>[108]</sup>, which is in agreement with another Korean study reporting a resistance rate of 6.4% and 25.4% after 1 and 2 years adefovir therapy, respectively<sup>[109]</sup>. Mutant HBV with resistance against both adefovir and lamivudine can emerge<sup>[106]</sup>.

Recently, it was suggested that a mutant/variant rtI233V is naturally occurring even before therapy in some HBV patients<sup>[110]</sup> and might be associated with reduced susceptibility to adefovir. Resistance was proven for that

mutation *in vitro* after it had been observed in three patients not responding to adefovir<sup>[111]</sup>. Surprisingly, this mutation has not been observed in patients developing virological breakthrough. This mutation has not, however, been seen in any of the 20 patients with insufficient response to adefovir from another institution<sup>[112]</sup>. Since 10% of patients with normal rt sequence have an insufficient response to adefovir, this may be more related to drug transporter polymorphisms, since they have been related to nephrotoxicity, but could also account for the insufficient response.

Entecavir resistance was observed mainly in the therapy of lamivudine refractory patients. The resistance rate appears to be approximately 10% after 2 years and 25% after 3 years in patients with lamivudine failure and 0.8% in naïve patients over 3 years<sup>[123]</sup>. The main resistance mutations are rtT184G, rtS202I, rtM250V on a background of lamivudine resistance mutations<sup>[113]</sup>. These mutants are resistant to lamivudine but appear to be susceptible to adefovir *in vitro*<sup>[114]</sup>. Clinical data are awaited to provide recommendation for the treatment of entecavir resistant patients. The emergence of entecavir resistance seems to be bound to the presence of a M250V mutation, thus leaving entecavir as a full option in case of telbivudine resistance.

### Monitoring of antiviral therapy

Monitoring during antiviral therapy could serve different purposes: (1) estimation of the response based on early viral kinetics; and (2) early recognition of the development of viral resistance with an increase in the viral load after initial reduction or by mutation monitoring.

It was initially shown by Puchhammer-Stockl *et al*<sup>[115]</sup> that patients showing an early viral response are less likely to develop resistance with lamivudine, which was recently confirmed prospectively for telbivudine<sup>[116]</sup>. Nevertheless monitoring viral resistance by observing the emergence of mutations known to confer resistance would be the most sensitive way to monitor patients who remain viraemic on current treatments. Based on experience, it is not recommended to wait until an increase in viral load associated with ALT-elevation is evident, since these patients are less likely to respond as well as those placed on an alternative additional antiviral therapy earlier. In addition, this approach harbours the risk of hepatic decompensation. With any nucleos(t)ide there will always be a risk for the emergence of drug-resistance, which mandates monitoring patients on antiviral therapy. The rationale for the timing of monitoring derives from the consideration that the biochemical breakthrough usually occurs with a delay of several weeks after the virological breakthrough and that the clinical impact is usually different in non-cirrhotic than in cirrhotic disease. In the former, the ALT breakthrough most often has no major clinical consequences and in the latter it may precipitate liver failure and death. Monitoring should be performed by measuring the viral load with quantitative HBV DNA testing and certainly transaminases. If the residual viraemia remains high (see below) treatment should be switched to alternative therapy, if possible.

The antiviral response at wk 24 of therapy was found

to be a predictor of subsequent efficacy (HBeAg loss, HBV DNA < 200 copies/mL, ALT normalization, and viral breakthrough) in patients treated with lamivudine or telbivudine<sup>[117]</sup>. In the 5-year study of adefovir administration in HBeAg negative chronic hepatitis, patients with a viral load lower than 3 log<sub>10</sub> copies/mL after 1 year of therapy had a significantly lower risk of developing resistance by year 3 of treatment (< 3%) compared to a risk of 26% and 66% for those having a viral load between 3 and 6 log<sub>10</sub> copies, and > 6 log<sub>10</sub> copies/mL, respectively<sup>[118]</sup>. On the other hand, this suggests that those who do not achieve a viral load reduction should be given rescue therapy before the development of true resistance.

During long-term treatment, a 3 or 6 monthly assessment of viral load and serological markers is required to monitor antiviral treatment efficacy and determine whether the response is maintained or whether drug resistance is developing. Certainly drug compliance is important, as any drug interruption may lead to a rebound of viral replication and ALT flares. The detection of polymerase mutations can be performed by sequencing, line probe assay, and DNA chip technologies. Detection may become more complex when additional treatment options become available, since there is emerging evidence that the cross-resistance profile is different from one mutant to another<sup>[119,120]</sup>. The line probe assay is more sensitive than sequencing of PCR products but cannot detect new mutations.

New tools may become available in the future to monitor the efficacy of antiviral therapy, such as the quantification of intrahepatic cccDNA or the quantification of serum HBsAg as a surrogate marker. Furthermore, with the development of new drugs and the increasing complexity of the resistance profile, phenotypic assays to determine drug susceptibility of the clinical isolates may prove useful in tailoring antiviral therapy to the virological situation of the patient, as already shown in HIV.

### CONCLUSIONS

Patients with minimal disease, whether in the immunotolerant phase or with inactive infection, should not be treated. However, if it is confirmed that the risk of HCC is 10% within 10 years for patients with more than 10<sup>6</sup> viral load, these patients should receive antiviral treatment irrespective of the activity of their liver disease. In patients with chronic hepatitis proven by ALT elevation and abnormal liver histology, antiviral therapy is indicated because all studies have shown that antiviral therapy decreases the risk of liver disease progression compared to the natural history of the disease. In patients who are HBeAg positive, the primary goal of antiviral therapy is to obtain HBe seroconversion. If the patient is young and has predictive factors of favourable response, a finite course of pegylated interferon should be tried as a first line option in genotype A and B patients. In other cases (including non-responders to IFN, patients intolerant to interferon and those with factors of poor response to interferon), long-term therapy

Table 2 Treatment options for chronic hepatitis B and their profile

	Standard Interferon PegIFN	Lamivudine	Adefovir	Entecavir
Viral suppression	4.5 log <sub>10</sub> copies/mL	5-6 log <sub>10</sub> copies/mL	3-4 log <sub>10</sub> copies/mL	6-7 log <sub>10</sub> copies/mL
Long term therapy	(6 to) 12 mo in HBe pos. Patients 24 mo in HBeAg neg. patients	+ (continuous)	+ (continuous)	+ (continuous)
Side effects	+	- to very low	- to very low	- to very low
HBe seroconversion	30%	15%-20% at 1 yr, 25%-30% at 2 yr	10%-15% at 1 yr	20% at 1 yr, 30% at 2 yr
Predictive factors for seroconversion	High ALT, low HBV DNA levels	High ALT	High ALT	?
Clearance of HBsAg	+	-	-	?
Cost	++ per months	+	++	(++)
Sustained response	< 30% HBeAg - ca. 30% in HBeAg +	Maintained response 30%-35% (3 yr)	Maintained response ≥ 70% (5 yr)	Maintained response?
Maintained response	Not applicable	Maintained response 30%-35% (3 yr)	Maintained response ≥ 70% (5 yr)	Maintained response?
Clearance of HBsAg	+ (Genotype dependent)	low	low	low
Resistance	No resistance but non-response	20% per year	0% at 1 yr up to 29% at yr 5	0% at 1 & 2 yr (2% at 1 and 10% at 2 yr in lam resistant patients)

with nucleos(t)ide analogues is usually needed.

Long-term therapy is probably required in patients who are HBeAg negative. Nucleoside analogues are better tolerated than pegylated interferon, but the therapeutic choice must take into account the risk of drug resistance (Table 2).

Likely future therapy is to begin with an inexpensive antiviral and then adding or switching to another in the case of insufficient response. In patients with severe liver disease, i.e. decompensated liver cirrhosis or HBV recurrence on the liver graft, one might consider combining nucleoside analogues lacking cross-resistance from the start to provide the best chance of long-term control of viral replication and disease progression.

Finally, it is recommended that physicians should be brought back into the position of prescribing licensed drugs, even if they are only licensed for another treatment, when there is evidence for superiority of such an approach. One such example is tenofovir, which has been licensed for HIV and displays higher efficacy and a better safety profile than adefovir.

### Abstract

**AIM:** To demonstrate the change and effect of nociceptin/orphanin FQ in the colon of rats with cathartic colon.

**METHODS:** The cathartic colon model was established by feeding rats rhubarb for 3 mo, the changes of colonic electromyography were investigated by both suspension muscle strips test and serosal recordings of colonic myoelectrical activity. Immunohistochemical staining (S-P methods) and image analysis were used to determine the changes of nociceptin/orphanin FQ in the proximal colon and distal colon of rats with cathartic colon.

**RESULTS:** Suspension muscle strips test *in vitro* showed OFQ ( $10^{-9}$ - $10^{-6}$  mol/L) concentration dependently caused an immediate tonic contraction in the isolated colon. But the increase of tension in cathartic colon was less than control groups ( $P < 0.01$ ). Intravenous administration of OFQ (1  $\mu$ g/kg) caused phasic contractions in the proximal colon, while the amplitude of phasic contractions caused by OFQ in cathartic colon was much lower than that in the control groups ( $2.58 \pm 0.41$  vs  $4.16 \pm 0.53$ ,  $t = -2.6$ ,  $P = 0.012$ ). OFQ was highly expressed in the myenteric plexus of the rat colon but not in the muscle cells. The immunoreactivity of OFQ in the proximal colon in cathartic colon rats decreased significantly compared with the control group ( $P = 0.001$ ).

**CONCLUSION:** Colonic smooth muscle of cathartic colon showed low sensitivity to the stimulation of OFQ, suggesting that it might be caused by the abnormal distribution of OFQ or the abnormalities of receptors, leading to the disorganization of dynamic and incoordinated contractions.

### INTRODUCTION

Slow transit constipation (STC) is a common syndrome in idiopathic constipation. It is a severe disorder of colonic motility. Because of lack of understanding of the etiology, current medical treatments for STC are often ineffective<sup>[1]</sup>. It has been shown that predominant symptoms in STC correlate with the enteric nervous system (ENS) abnormalities<sup>[2]</sup>. Animal experiments have shown that stimulant laxatives can damage the ENS and cause changes of some enteric neurotransmitters and thus slow gastrointestinal tract transit occurs<sup>[3]</sup>.

The peptide nociceptin, also called orphanin-FQ (N/OFQ), is a 17-amino-acid peptide and was identified in 1995<sup>[4]</sup>. Because it binds an opioid receptor like 1 (ORL1)receptor with a high affinity, it has been reported to be an endogenous agonist for ORL1 receptor. *In situ* hybridization studies have revealed the wide distribution of the ORL1 receptor mRNA in the central nervous system of rats<sup>[5]</sup>, especially in the coli involved in pain control, so most of the researches focused on the role of N/OFQ in analgesics. However, by the activation of the ORL1 receptor, N/OFQ can also influence reward, anxiety, feeding and memory processes<sup>[6,7]</sup>, cardiovascular and renal functions<sup>[8,9]</sup>, gastric and intestinal motility<sup>[10,11]</sup> and secretions<sup>[12,13]</sup>.

The gastrointestinal tract is an important model system for the research of pharmacological characterization of opioid receptors. Therefore, if N/OFQ can also act as a brain-bowel peptide like classical opioid, it may play a role in the regulation of gastrointestinal tract functions. In this study, with a rat model of cathartic colon, we determined the effects of OFQ on mechanical activity of the rat colon and conducted immunohistochemical studies on rat colon to assess the changes of OFQ.

### MATERIALS AND METHODS

#### Experimental animals

Fifty Wistar rats of either sex, obtained from the

Experimental Animal Center, Lanzhou University (Lanzhou, China), weighing  $290 \pm 50$  g, were divided randomly into control group ( $n = 25$ ) and cathartic colon group treated with rhubarb ( $n = 25$ ). Rats were housed in cage, one per cage under standard laboratory conditions (room temperature, 18-28°C, relative humidity, 40%-80%). Control rats were given soft chows, while the rats in rhubarb group were given chows premixed with rhubarb powder. The initial rhubarb dosage was 200 mg/kg-d, and another 200 mg/kg was added every day until it reached 1000 mg/kg-d for several days until loose stool disappeared. Then, rhubarb was added at 200 mg/kg-d again to 3600 mg/kg-d for 3 mo.

### Materials

Tetrodotoxin (TTX) and naloxone were obtained from Sigma Co. USA. OFQ (1-17) was obtained from Physical Laboratories, School of Life Science, Lanzhou University (Lanzhou, China). Rabbit antinociceptin antiserum (Chemicon Pharmaceuticals Inc, 1:500. Goat anti-rabbit biotinylated secondary antibody (Rocland Laboratories, USA, 1:15000).

### Motility studies

Wistar rats (body weight,  $290 \pm 50$  g) were starved overnight and killed by head-strike, longitudinal muscle strips were isolated from proximal colon, muscle strips (10 mm in length and 3 mm in width) were suspended between 2 platinum electrodes in a 30 mL organ bath filled with Krebs-Henseleit buffer containing 118 mmol/L NaCl, 4.8 mmol/L KCl, 2.5 mmol/L  $\text{CaCl}_2$ , 25 mmol/L  $\text{NaHCO}_3$ , 1.2 mmol/L  $\text{KH}_2\text{PO}_4$ , 1.2 mmol/L  $\text{MgSO}_4$ , 11 mmol/L glucose and 0.1% bovine serum albumin. Krebs-Henseleit buffer solution was continuously gassed with 95%  $\text{O}_2$ -5%  $\text{CO}_2$  and maintained at 37°C and pH 7.4. Mechanical activity was recorded on a polygraph through isometric transducers. Muscle strips were stretched in 1-mm increments and repeatedly exposed to  $10^{-6}$  mmol/L carbachol to determine  $L_0$ , the length at which the maximal active tension response developed. The resting of tension was kept constant during the equilibration period, dose-response curves were constructed after applying OFQ ( $10^{-9}$ - $10^{-6}$  mol/L) to longitudinal muscle stripes from proximal colon. Doses of OFQ were administered at 20-min intervals. To investigate the neural pathways responsible for the contractile action of OFQ, we examined the effects of TTX and naloxone on OFQ-induced contractions. Muscle strips were preincubated with each antagonist for 10 min followed by incubation with OFQ ( $n = 8$ ).

### Response of colon in anesthetized rats

Colonic motility studies in anesthetized rats were carried out according to the procedures described previously (Nagasaki *et al*, 1989.) In brief, rats were fasted for 20 h and anesthetized with urethane (1.2 g/kg s.c.). After midline laparotomy, a strain gauge force transducer (F-081S, Star Medical, Japan) was sutured on the serosal surface of the proximal colon to record the circular muscle contraction. For intravenous administration of drugs, the right femoral

vein was cannulated. After the contractile response to bethanechol (30 mg/kg i.v) became stable, OFQ (1  $\mu\text{g/kg}$ ) was administered intravenously ( $n = 7$ ).

### Immunohistochemistry

The animals were deeply anaesthetized with 5% isoflurane and perfused transcardially with aerated calcium-free Tyrode's solution, followed by a fixative containing 4% paraformaldehyde and 0.2% picric acid in 0.1 mol/L phosphate buffer (pH 7.2-7.4). The proximal and distal colons were removed immediately after perfusion, post-fixed in the same fixative for 4h and then cryoprotected in 10% sucrose in phosphate-buffered saline (PBS, pH 7.4) overnight.

A series of sections were cut and mounted on gelatin-subbed slides. Elimination of endogenous peroxidase activity was performed with 0.3% hydrogen peroxide in PBS at room temperature for 30 min. The sections were pre-blocked with 3% normal goat serum, 0.5% triton X-100, and 1% bovine serum albumin in PBS for 30 min. Then incubated in rabbit antinociceptin antiserum (Chemicon Pharmaceuticals Inc, 1:500) at 4°C overnight. The sections were rinsed with PBS and incubated for 1h with goat anti-rabbit biotinylated secondary antibody (Rocland Laboratories, USA, 1:15000). Then they were incubated in an avidin-biotin complex coupled to horseradish peroxidase for 10 min at room temperature. Finally, after rinsing with PBS, the nociceptin-positive neurons and nerve fibers were visualized using 3, 3'-diaminobenzidine (DAB, Maixin Chemical Co. Fuzhou, China). The slides were then dried, dehydrated in ethanol (70%-100% gradually), cleared in xylene, and coverslipped with mounting solution. Immunohistochemical image analysis was made to assess the changes of OFQ both in proximal and distal colons in two group rats ( $n = 10$ ).

All animal experiments were carried out in accordance with the National Institutes of Health Guide for the Care and Use of Laboratory Animals.

### Statistical analysis

Results were expressed as mean  $\pm$  SE. Data were analyzed by SPSS10.0. Differences were analyzed by one-way analysis of variance ANOVA and independent *t* test. Probabilities of  $P < 0.05$  were considered significant.

## RESULTS

### Motility studies

*In vitro* studies using longitudinal muscle revealed that OFQ ( $10^{-9}$ - $10^{-6}$  mol/L) induced contractions in the colon. The threshold concentration of OFQ to induce contractions was  $10^{-9}$  mol/L. In the proximal colon of two group rats, OFQ ( $10^{-9}$  to  $10^{-6}$  mol/L) induced contractions in a dose-dependent manner (Figure1A), but the increase of tension in cathartic colon was lower than in the control groups (Figure1B). To determine if OFQ activity was mediated by neural pathways or if it was a direct myogenic effect, OFQ-induced contractions were examined in the presence of TTX. In the presence of TTX, OFQ failed to elicit additional contractions (Figure 1C). The contractions

**Figure 1** Effects of OFQ ( $10^{-9}$ – $10^{-6}$  mol/L) on colon of rats *in vitro*. **A:** Effects of OFQ on the contractile activity of longitudinal muscle strips obtained from the rat proximal colon; **B:** Different effects of OFQ ( $10^{-9}$ – $10^{-6}$  mol/L) on increment of tension in two groups of rats. <sup>a</sup> $P < 0.05$  vs  $1 \times 10^{-9}$  mol/L; <sup>b</sup> $P < 0.01$  vs  $1 \times 10^{-9}$  mol/L; **C:** In the presence of TTX ( $10^{-6}$  mol/L), OFQ ( $10^{-6}$  mol/L) failed to evoke additional contractions; **D:** The response to OFQ ( $1 \times 10^{-6}$  mol/L) was not affected by naloxone ( $1 \times 10^{-6}$  mol/L).

induced by OFQ ( $1 \times 10^{-6}$  mol/L) were not affected by classical opioid antagonist, naloxone ( $1 \times 10^{-6}$  mol/L) (Figure 1D).

Intravenous administration of OFQ caused phasic contractions in the proximal colon (Figure 2A), it was not affected by classical opioid antagonist, naloxone ( $1 \times 10^{-6}$  mol/L) (Figure 2B), but the amplitude of phasic contractions caused by OFQ in cathartic colon was much lower than control groups (Figure 2C,  $2.58 \pm 0.41$  vs  $4.16 \pm 0.53$ ,  $t = -2.6$ ,  $P = 0.012$ ).

### Immunohistochemistry

Immunohistochemistry of OFQ in the rat gastrointestinal tract showed that Orphanin FQ immunoreactive (OFQ-IR) neurons and nerve fibers were visualized in the myenteric plexus of the rat colon (Figure 3A). The immunoreactivity of OFQ in the myenteric plexus in the proximal cathartic colon of rats decreased significantly as compared with

**Figure 2** Effects of OFQ on colon of rats *in vivo*. **A:** Intravenous administration of OFQ ( $1 \mu\text{g/kg}$ ) caused phasic contractions in the colon. **B:** Naloxone ( $300 \mu\text{g/kg}$ ) has no effects on phasic contractions caused by intravenous administration of OFQ ( $1 \mu\text{g/kg}$ ) in the proximal colon. **C:** Intravenous administration of OFQ ( $1 \mu\text{g/kg}$ ) caused phasic contractions in the proximal colon in two groups.

the control group. ( $176.42 \pm 5.792$  vs  $137.367 \pm 25.508$ ,  $P = 0.001$ ) (Figure 3B, 3C). The negative control showed no staining of OFQ-IR in the myenteric plexus of the gastrointestinal tract.

### DISCUSSION

Due to the diet and social-psychological changes, constipation has become an important factor affecting the quality of human life in modern society, therefore the morbidity is getting higher and higher. STC is a common syndrome in idiopathic constipation. It is a severe disorder of colonic motility characterized by a reduction in the frequency, amplitude and duration of propulsive contractions in the large bowel. Because of lack of understanding of the etiology, current medical treatments on STC are often ineffective. Animal experiments have shown that stimulant laxatives can damage ENS and cause the changes of some enteric neurotransmitters and thus the slow gastrointestinal tract transit occurs.

The innervation of the gastrointestinal tract is unique among the visceral organs. Neurons originating in the enteric ganglionated plexuses within the gut wall coordinate intrinsic reflexes associated with intestinal motility, epithelial secretion, and mucosal blood flow<sup>[14]</sup>. The myenteric plexus lies between the longitudinal and circular smooth muscle layers and regulates intestinal motor function. Bowel motility is controlled by a local network of intramural nerves<sup>[15]</sup>. Effects of opioid peptides on GI motility have been studied. Morphine can cause constipation due in part to slowing of GI transit and inhibition of active intestinal secretion, which was the normal side effect in clinical practice<sup>[16]</sup>.

Despite its being homologous to classical opioids, dynorphin A, the OFQ/ORL1 system represents a new peptide-based signaling pathway, which is pharmacologically distinct from the opioid system<sup>[17]</sup>. Probing into the distribution and function of N/OFQ and ORL1 receptor in the gastrointestinal tract of the animal model will contribute to the overall understanding of the characteristics of this neuronal system, accelerating

**Figure 3** A: Expression of OFQ in the myenteric plexus of colon in control group. SP  $\times$  200; B: Strong positive expression of OFQ in colon of control group. SP  $\times$  400; C: Weaker positive expression of OFQ in colon of model group. SP  $\times$  400.

related researches of the gastrointestinal motility regulated by OFQ/ORL1 receptor system and promote the general comprehensiveness of the opioid system. Thus, the model of rats with cathartic colon was established by feeding the rats with rhubarb for 3 months so as to illustrate the etiology of STC.

Our *in vitro* studies showed that OFQ induced contractions of colonic longitudinal muscle strips. In the proximal colon, OFQ ( $10^{-9}$ - $10^{-6}$  mol/L) induced contractions in a dose-dependent manner (Figure 1). But the increase of tension in cathartic colon was lower than the control groups (Figure 2). The mechanisms underlying OFQ-induced contractions were further investigated in the proximal colon. To determine if OFQ activity was mediated by neural pathways or if it was a direct myogenic action, OFQ induced contractions were examined in the presence of TTX, it has been supposed that TTX can abolish neuronal transmitter transition<sup>[18]</sup>.

In the presence of TTX, OFQ failed to evoke additional contractions, suggesting that action of OFQ is mediated by neural pathways. It was coincidental with the present study that OFQ was highly expressed in the myenteric plexus of the rat colon, but not in the muscle cells. The *in vitro*, inhibitory effects of OFQ on EFS-evoked muscle contractions has been reported for mouse vas deferens and guinea pig ileum<sup>[19]</sup>. EFS-evoked muscular contractions were significantly reduced by 50% in guinea pig ileum by OFQ ( $10^{-7}$  mol/L) and was significantly reduced in mouse vas deferens by OFQ. Thus, the mechanisms and sites of action of OFQ may differ among different regions of gastrointestinal tract and different species.

Our study *in vivo* showed that intravenous administration of OFQ (1  $\mu$ g/kg) significantly increased muscle contractions in the proximal colon. These observations indicate that OFQ also stimulates colonic motility *in vivo*. The effects cannot be affected by classical antagonist, naloxone, but can be abolished in the presence of TTX, suggesting that the action of OFQ is nerve mediated. Currently, the physiological role of OFQ in colonic motility is unknown. However, Takahashi *et al*<sup>[20]</sup> in an *in vivo* study showed that intravenous administration of OFQ (3 pmol/kg to 3 nmol/L) significantly increased muscle contractions in the proximal colon. Furthermore, OFQ (1 nmol/L, subcutaneously) accelerated the colonic transit by promoting migrating colonic contractions in rats<sup>[21]</sup>. These observations also indicate that OFQ can stimulate colonic motility *in vivo*.

The immunoreactivity of OFQ in the myenteric plexus in the proximal region of the cathartic colon of rats decreased significantly compared with the control group. It has been suggested that OFQ preferred to be located in the stimulating motor neuron<sup>[22]</sup>. Colonic smooth muscle of cathartic colon showed low sensitivity to the stimulation of OFQ and this suggested it might be caused by the abnormal distribution of OFQ or the abnormalities of receptors, leading to the disorganization of dynamic and uncoordinated contractions.

In conclusion, OFQ seems to modulate the colonic transit independently from the classical opioid peptides<sup>[23]</sup>. We confirmed that OFQ is present in the gastrointestinal tract and has an effect on colonic motility. The physiological role of the nociceptin-QRL1 system in the colon is not clear but it may be significant to pathophysiological processes that underlie motor dysfunction of the bowel<sup>[24]</sup>. These findings indicate that OFQ is a brain-gut peptide and plays a role in the control of gastrointestinal functions<sup>[25]</sup>. The abnormalities of enteric nervous system are responsible for slow transit constipation. It also indicates that chronic application of stimulant laxatives can induce disorganization and damage the enteric nervous system<sup>[26,27]</sup> and accelerate the pathological changes of STC. But the pathophysiology of STC is complex and not easily approached through the data from animals alone. Further studies according to the clinical characteristics of STC patients could provide additional insight into this issue. It is necessary to investigate the mechanism underlying the biological actions of N/OFQ on GI. Because OFQ seems to exert

its stimulatory action in the colon<sup>[28,29]</sup>, in the future, synthesized analogues of OFQ may be used to treat constipation secondary to colonic inertia<sup>[30]</sup>.

ity, mortality from malignant neoplasms, non-Hodgkin's lymphoma and digestive system disorders were significantly higher in gluten sensitive patients compared to the Northern Ireland population.

**CONCLUSION:** Patients with coeliac disease or gluten sensitivity had higher mortality rates than the Northern Ireland population. This association persists more than one year after diagnosis in patients testing positive for anti-gliadin antibodies. Breast cancer is significantly reduced in the cohort of patients with gluten sensitivity.

### Abstract

**AIM:** To determine the risk of malignancy and mortality in patients with a positive endomysial or anti-gliadin antibody test in Northern Ireland.

**METHODS:** A population-based retrospective cohort study design was used. Laboratory test results used in the diagnosis of coeliac disease were obtained from the Regional Immunology Laboratory, cancer statistics from the Northern Ireland Cancer Registry and mortality statistics from the General Registrar Office, Northern Ireland. Age standardized incidence ratios of malignant neoplasms and standardized mortality ratios of all-cause and cause-specific mortality were calculated.

**RESULTS:** A total of 13 338 people had an endomysial antibody and/or an anti-gliadin antibody test in Northern Ireland between 1993 and 1996. There were 490 patients who tested positive for endomysial antibodies and they were assumed to have coeliac disease. There were 1133 patients who tested positive for anti-gliadin antibodies and they were defined as gluten sensitive. Malignant neoplasms were not significantly associated with coeliac disease; however, all-cause mortality was significantly increased following diagnosis. The standardized incidence and mortality ratios for non-Hodgkin's lymphoma were increased in coeliac disease patients but did not reach statistical significance. Lung and breast cancer incidence were significantly lower and all-cause mortal-

### INTRODUCTION

Coeliac disease (CD) is an autoimmune disorder characterised by inflammation and villous atrophy of the small intestine, resulting in the malabsorption of vitamins and nutrients. It is caused by an immune response to wheat gluten (gliadin). Ireland is thought to have one of the highest incidences of CD in the world with a prevalence in Northern Ireland of at least 1 person per 122 in the population<sup>[1]</sup>. Diagnosis is normally confirmed by duodenal biopsy; however, highly sensitive and specific blood tests for CD are available including the transglutaminase antibody test (93% sensitive, > 99% specific) and the endomysial antibody (EMA) test (93% sensitive, > 98% specific)<sup>[2]</sup>. Another test the anti-gliadin antibody (AGA) test is not as sensitive or specific for CD. It is a measure of the immune response to gliadin and may detect people with gluten sensitivity who don't have clinically detectable CD. Patients testing positive for CD are advised to adhere to a strict gluten free diet for life<sup>[3,4]</sup> to avoid symptoms such as diarrhoea, anaemia and weight loss associated with this condition.

In addition to the significant morbidity that can be associated with this condition, CD is thought to be associated with an increased risk of malignancy and mortality. A recent European multi-centre study reported more than

a three-fold increased risk of non-Hodgkin's Lymphoma (NHL) in patients with clinically diagnosed CD<sup>[5]</sup>. Other studies have also reported an increased incidence and/or mortality of NHL in patients with CD<sup>[4,6-12]</sup>. Estimates of the standardised incidence ratio range from 3.3<sup>[5]</sup> to 18.0<sup>[10]</sup>, although Card *et al*<sup>[7]</sup> suggest that the risk of NHL is at the lower end of these estimates.

CD has been associated with an increased risk of other cancers including cancers of the gastrointestinal tract<sup>[7-9,11]</sup>, in particular cancers of the small intestine<sup>[7,9-11]</sup>. However, West *et al*<sup>[8]</sup> in a recent study including 4732 people with CD found that most cancers, except NHL, were reported within one year of diagnosis of CD.

Studies have also reported that CD may be associated with reduced risks of some cancers including breast cancer<sup>[8,11,13]</sup> although the reason for this association remains unknown. West *et al*<sup>[8]</sup> reported that lung cancer was less common in patients with CD with one possible explanation of the proposed protective effect of cigarette smoking<sup>[14]</sup>.

Overall, mortality was higher in patients with CD compared to the population<sup>[8,10,15]</sup>. Metzger *et al*<sup>[15]</sup> reported a standardised mortality ratio (SMR) of all-cause mortality of 2.53 (95% CI 1.50-4.25) with an increased mortality from malignant neoplasms. West *et al*<sup>[8]</sup> observed that the association between all-cause mortality and CD remained significant more than one year after diagnosis.

The aim of this study was to identify the incidence of malignancy and mortality in patients with CD (positive EMA test) or patients with gluten sensitivity (positive AGA test) in a retrospective cohort study in Northern Ireland.

## MATERIALS AND METHODS

### Exposure measurement

A serological dataset of all patients investigated for suspected coeliac disease tested for IgA EMA and/or IgA AGA between 1993 and 1996 was obtained from the Regional Immunology Laboratory, Royal Group of Hospitals, Belfast. If patients had EMA/AGA tests on more than one occasion their date of inclusion in the study was the date of the first positive EMA or AGA result. Duplicates were removed and records with no date of birth excluded. Cases were defined as patients with 'coeliac disease' (positive EMA result) or 'patients with an intolerance to gliadin in the diet' (positive AGA, result more than  $100 \times 10^3$  EU/L). No information was available on the EMA test results for 4585 patients who had an AGA test. These patients were excluded from the AGA positive, EMA negative analysis.

### Outcome measurement - incidence

Researchers within the Northern Ireland Cancer Registry (NICR)-LAA, LJM, CF; who are experienced in the procedures involved in linking datasets, used forename, surname, date of birth and when available hospital number or General Practitioner name to match patients in the serological database to patients within the NICR database. EMA and AGA positive patients were followed-up for between 7 and 11 years until the end of December 2003. Exact and "fuzzy" matching algorithms were used to link

patients in the two databases. "Fuzzy" matching used phonetic codes for the forename and surname to match similar sounding names which had different spellings (i.e. Smyth and Smith). If dates of birth were similar (i.e. 01/03/1975 and 03/01/1975) they were considered as potential matches. All "fuzzy" and potential matches were checked manually using all available information before being included in the study.

The main outcome measures were classified according to the International Classification of diseases (ICD) 9 before 2002 and ICD 10 thereafter: (1) Any malignant neoplasm (ICD 9: 140-208, 230-234; ICD 10: C00-C97); (2) NHL (ICD 9: 200, 202; ICD 10: C82-C85); (3) Gastrointestinal tract cancer (ICD 9: 150-154; ICD 10: C15-C21); (4) Small bowel cancer (ICD 9: 152; ICD 10: C17); (5) Lung cancer (ICD 9: 162-163; ICD 10: C34); (6) Breast cancer (ICD 9: 174-175; ICD 10: C50); (7) Prostate cancer (ICD 9: 185; ICD 10: C61); (8) Liver cancer (ICD 9: 155; ICD 10: C22).

### Outcome measurement - mortality

The serological database was also linked by forename, surname and date of birth to death records held by the Registrar General's Office (GRO), Northern Ireland until the end of December 2003. These files contain cause-specific mortality data on all deaths occurring within Northern Ireland. Exact matching and "fuzzy" matching algorithms were used and potential matches were checked manually. Outcome measures included all-cause and cause-specific mortality. Ethical committee approval for this study was obtained from the Research Ethics Committee of the Queen's University Belfast to match the databases.

### Statistical analysis

Total person-years of follow-up for the cohort of patients with a positive EMA test and for the cohort of patients with a positive AGA test were calculated by collating the person-years of follow-up for each patient from the date of entry into the cohort (1993 to 1996) until the date of death or 31st December 2003, whichever was earlier.

Indirect standardization was used to calculate standardised incidence ratios (SIRs) for all malignant neoplasms and for each cancer type (including NHL, gastrointestinal cancers, small bowel, breast, prostate, liver and lung cancer) for patients with a positive EMA test, for patients with a positive AGA test and for patients with a positive AGA test but a negative EMA test. The SIRs were calculated by taking the total number of observed cancers within the cohort of patients with a positive EMA or AGA test and dividing this by the expected number of cancers, calculated by applying age and sex-specific incidence rates within the Northern Ireland population to each cohort. CIs were estimated using the Poisson distribution. Standardised mortality ratios were calculated in a similar manner to the SIRs using all and cause-specific mortality figures obtained from the General Registrar Office, Northern Ireland.

## RESULTS

Of the 13338 patients in Northern Ireland who under-

Table 1 Number of EMA and AGA positive and negative patients

went EMA and/or AGA tests between 1993 and 1996 490 were EMA positive (5.6% of EMA tests), 1,133 AGA positive (8.5% of all AGA tests) and 456 patients were AGA positive and EMA negative (5.2% of those tested for both EMA and AGA) (Table 1).

The average age (age range) of patients with a positive EMA or AGA test were 45 (0-88) years and 50 (0-91) years respectively. Included in the database were 46 children (< 18 years) with a positive EMA test (9.2% of cohort) and 71 children with a positive AGA test (6.3% of cohort). In total 68.2% of EMA positives and 63.2% of AGA positives were male. The average AGA score in those testing positive was  $215.4 \times 10^3$  EU/L (range 100-1163  $\times 10^3$  EU/L).

#### Standardised incidence ratios-EMA

In total 24 (4.90%) of the EMA positive patients developed a malignant neoplasm during the follow-up period, 6 of which were diagnosed within 12 mo of the test. There were no significant associations between a positive EMA test and developing a malignant neoplasm (Table 2). Due to the small number of EMA positive patients developing malignancy the confidence intervals for the site specific cancers are large resulting in no significant associations despite a raised SIR being found for NHL [SIR 7.47 (95% CI 0.00-17.83)], small bowel cancer [SIR 23.33 (95% CI 0.00-69.07)] and primary liver cancer [SIR 31.62 (95% CI 0.00-75.45)]. Lung cancer appeared to be less common in EMA positive patients than in the Northern Ireland population [SIR 0.39 (95% CI 0-1.14)].

#### Standardised incidence ratios - AGA

In total 96 (8.47%) of the AGA positive population de-

veloped a malignant neoplasm. There were no significant associations between a positive AGA result and the development of malignant neoplasms (Table 2). However, malignancy was significantly raised in the AGA positive, EMA negative group [SIR 1.82 (95% CI 1.39-2.26)] (Table 2). This association was confined to males, SIR 2.90 (95% CI 2.11-3.69), and remained significant 6 and 12 mo after the AGA test, SIR 2.16 (95% CI 1.48-2.84) and SIR 1.91 (95% CI 1.27-2.55), respectively. Overall incidence of malignant neoplasms occurring 6 and 12 mo after the AGA test were significantly reduced in females SIR 0.60 (95% CI 0.27-0.92) and SIR 0.51 (95% CI 0.19-0.83) respectively. There was a significant inverse relationship between lung and breast cancer and a positive AGA result; however, only breast cancer was significantly reduced in the AGA positive EMA negative group. The SIR was raised for both small bowel and liver cancer but the results were not statistically significant.

#### Standardised mortality ratios - EMA

Overall mortality was significantly higher in the EMA positive population compared to the Northern Ireland population (Table 3). However, the statistically significant association did not remain when deaths within 6 mo or 1 year of the EMA test were excluded from the analysis. Although there were no other statistically significant associations mortality from NHL, endocrine deaths and urinary deaths appeared increased.

#### Standardised mortality ratios - AGA

Overall, mortality was higher in the AGA positive and in the AGA positive/EMA negative populations than in the Northern Ireland population (Table 3). This association

Table 3 Standardised mortality ratios (SMR) of all cause and cause-specific mortality

	EMA +ve			AGA +ve			AGA +ve, EMA -ve		
	<i>n</i>	Expected <i>n</i>	SMR (95% CI)	<i>n</i>	Expected <i>n</i>	SMR (95% CI)	<i>n</i>	Expected <i>n</i>	SMR (95% CI)
All cause mortality	46	26.01	1.77 (1.26-2.28)	234	101.25	2.31 (2.01-2.61)	114	47.25	2.41 (1.97-2.86)

All cause mortality (> 12 mo after diagnosis)	32	25.91	1.24 (0.81-1.66)	165	100.09	1.65 (1.40-1.90)	75	46.59	1.61 (1.25-1.97)
Malignant neoplasms	9	7.05	1.28 (0.44-2.11)	52	32.28	1.61 (1.17-2.05)	27	14.55	1.86 (1.16-2.56)
NHL deaths	2	0.29	6.89 (0.00-16.44)	8	1.12	7.12 (2.18-12.05)	3	0.51	5.88 (0.00-12.53)
Endocrine deaths	1	0.16	6.10 (0.00-18.07)	2	0.24	8.19 (0.00-19.53)	1	0.58	1.73 (0.00-5.14)
Nervous system	1	0.25	3.96 (0.00-11.72)	2	2.92	0.69 (0.00-1.63)	1	2.92	0.34 (0.00-1.01)
Circulatory system	9	12.11	0.74 (0.26-1.23)	42	59.95	0.70 (0.49-0.91)	22	28.65	0.77 (0.45-1.09)
Respiratory system	3	2.67	1.12 (0.00-2.40)	35	25.18	1.39 (0.93-1.85)	2	1.45	1.38 (0.00-3.29)
Digestive system disorders	2	0.58	3.42 (0.00-8.17)	19	4.12	4.61 (2.54-6.68)	10	1.90	5.26 (2.00-8.52)

remained significant even when deaths occurring within 6 mo and one year of the test were excluded. Mortality caused by malignant neoplasms was also significantly raised in both groups as was mortality from digestive system disorders. Mortality from NHL was significantly higher and mortality from circulatory system disease was significantly lower in the AGA positive group but not in the AGA positive/EMA negative group.

## DISCUSSION

In this retrospective cohort study the incidence of malignant neoplasms in patients with CD (positive EMA test) was similar to that of the Northern Ireland population. However, patients with gluten sensitivity (positive AGA test) had an increased incidence of malignant neoplasms within six months of diagnosis. In keeping with the findings of other studies all cause mortality was significantly raised in patients with CD; however, this was limited to the six month period following diagnosis. Patients with gluten sensitivity had a significantly raised SMR; this association remained significant more than 12 mo after diagnosis. Compared to the general population breast and lung cancer incidence were significantly lower in patients with gluten sensitivity. Mortality from malignant neoplasms, NHL and digestive system disorders was significantly increased.

The main strength of this study is its population-based design. All patients within Northern Ireland with clinical symptoms suspicious of CD and who also had a positive EMA and/or AGA test during the study period (1993 to 1996) were included. Since a wide spectrum of patients were included in the study the results should be more generalisable to patients with gluten sensitivity than the results of studies where CD was diagnosed in hospital or at referral centres<sup>[9-11,16,17]</sup>. It is likely that cases diagnosed as hospital in-patients or at referral centres have more severe disease and therefore cancer incidence and mortality may be higher in this group of patients than in all CD patients. CD may go undetected in the population and without screening it is difficult to generalise any of the results to all patients with CD within the population.

Population-based registers of cancer incidence and cause-specific mortality facilitated the matching process. Incomplete matching of patients on the serological database to the NICR and/or GRO database may result in an underestimation of the risk of malignancy and/or mortality compared to the general population. To minimize the possibility of observer bias the staff was blinded to the positive/negative result status of the patients during the matching process. Cancer incidence and mortality in EMA positive, AGA positive and AGA positive/EMA negative patients were compared to the rates in the Northern Ireland population. Other studies have used population-based controls<sup>[8]</sup> or population rates for comparison<sup>[7,10-12]</sup>; however, the study by Collin *et al*<sup>[17]</sup> used hospital outpatients undergoing upper gastrointestinal endoscopy as controls. These patients are likely to have been under investigation because of upper gastrointestinal symptoms and are unlikely to be representative of the general population. One of the proposed explanations for previous reports of increased gastrointestinal cancer incidence in CD patients<sup>[7-9,11]</sup> is that CD was diagnosed coincidentally when the patients were under investigation for tumour related symptoms. Several studies have reported cancer incidence and/or mortality rates with lag periods of between 1 and 5 years<sup>[7,10-12,16]</sup> after diagnosis of CD. We, therefore, included SIRs and SMRs excluding patients with an event in the 6-or 12-mo period post diagnosis.

There were 3908 person years of follow-up for malignancy and 3718 person years of follow-up for mortality in the cohort of patients with CD. Bias may have been introduced by loss to follow-up although emigration rates are low in Northern Ireland; data from the GRO (Northern Ireland) estimates that less than 0.1% of the population migrated from the province per year during the 1990s<sup>[18]</sup>. One of the potential weaknesses of this study was the lack of histological confirmation of CD. Although it is likely that jejunal biopsies were taken from patients with a positive EMA test gaining access to these records without patient consent would have required further ethical considerations. However, the sensitivity and specificity of the EMA test are high<sup>[2]</sup> and it is, therefore, likely to give a relatively accurate measure of the incidence of CD in the

cohort. The EMA test detects antibodies to an antigen (tissue transglutaminase) present in the endomysial lining of smooth muscle cells. The AGA test measures antibodies to gliadin which do not remain in patients who adhere to a strict gluten free diet. The assay will become negative if the patient is compliant with a gluten free diet. Therefore some patients with CD may not be detected within the cohort. The study by Logan *et al*<sup>[13]</sup> showed that cancer incidence was decreased in those who were diagnosed early and placed on a gluten-free diet. If this is the case then the incidence of malignancy in CD patients may be lower than reported. However, we had no way to determine whether or not the patients included in the study adhered to a strict gluten-free diet.

Another issue is that multiple comparisons may inflate the possibility of a Type 1 error occurring (i.e. the apparent association resulting by chance). However, only malignant neoplasms/causes of mortality where there had been a previous association or where there was an a priori hypothesis were investigated.

One issue with using these datasets and using a retrospective cohort design is that potential confounding variables were not collected at the time the cohort was established and therefore these could not be adjusted for in the analyses. Potential confounding variables could include co-existing medical conditions, smoking, body mass index, diet, age, sex, *etc.* For example, diabetes is associated with CD and possibly with endocrine deaths which were non-significantly raised and smoking which is less common in patients with CD<sup>[14]</sup> is associated with lung cancer incidence. There was a significantly reduced risk of lung cancer in patients with a positive AGA test and a non-significant reduced risk in patients with a positive EMA test. West *et al*<sup>[8]</sup> was the only study to attempt to adjust for potential confounding variables. Adjusting for BMI and smoking did not dramatically alter the observed associations; however, the authors suggest that data on potential confounders may be incomplete as it was obtained from routinely collected information.

Although some AGA positive/EMA negative patients may have CD there were a larger number that were AGA positive than expected according to the sensitivity of the EMA test. Therefore, some of these patients may be gluten sensitive but as yet have no damage to the endomysial muscle. If this is the case then this is the first study to investigate the risk of malignancy and mortality in this group of patients, who were excluded from the recent large study by West *et al*<sup>[8]</sup>. Mortality was significantly increased in this group of patients and remained elevated more than one year after the positive AGA test. Mortality from digestive system disorders was increased which was not surprising as a positive AGA test may be a marker for other gastrointestinal disorders. Interestingly, it is in this group of patients that breast cancer appears to be reduced. Other studies have reported reduced risks of breast cancer in patients with CD<sup>[8,11,13]</sup> although there were no significant associations between breast cancer and a positive EMA test in this study. Although the reason(s) for this association remain unknown Askling *et al*<sup>[11]</sup> suggest that the reduced risk of breast cancer may be a consequence of immune system dysfunction.

The size of the current study is smaller than the more recently published studies e.g. the study by West *et al*<sup>[8]</sup> who used the General Practice Research Database which had 4,732 CD patients. Malignancy was increased in patients in the first year after diagnosis but not beyond one year of follow-up. In the current study malignancy was not increased in patients with a positive EMA test but was in patients with a positive AGA test. Other studies have also reported no overall increased risk of malignancy in CD patients<sup>[7,16]</sup>. The size of the current study meant that there was insufficient power to detect any associations between cancer type and CD. However, the risk of NHL appeared to be increased which is in keeping with the results of other studies<sup>[3-5,7-12]</sup>. There was a significant increased risk of NHL deaths in patients with a positive AGA test. This group of patients is likely to include some patients with CD as there were a number of patients that had no EMA record in the database.

Malignancy and mortality were not significantly increased in patients with CD more than one year after diagnosis; however, overall mortality and mortality from malignant neoplasms were increased in patients who were gluten sensitive with a negative EMA test. If these patients do not have the histological characteristics of CD then it is important to determine the cause of the increased mortality. If this is limited to other digestive system disorders then patients with a negative EMA test but with symptoms should be further investigated for other digestive system disorders. Further investigations into this area are warranted to determine if it is gluten sensitivity that is associated with increased mortality and malignancy or to determine if it is just a marker for other gastrointestinal conditions.

In addition, it is important to determine the risk of malignancy and mortality in patients with a histological confirmation of CD. This study could be extended further by collecting pathology reports on all patients within the study and looking for evidence of villous atrophy. Information on confounding variables such as smoking status could also be collected. However, it is unlikely that patients could be approached because of data confidentiality issues. It is possible that cancer incidence and mortality change depending on the length of time since diagnosis. Therefore, an extension to this study would be to follow-up the patients for a longer period of time. The association with reduced breast cancer incidence is interesting and further studies to investigate this association may identify factors that are associated with reduced breast cancer incidence.

### Abstract

**AIM:** To examine the changes in the histomorphology of the gastric, jejunal and colonic wall of dogs due to physiological aging.

**METHODS:** Full thickness biopsies were taken from the gastrointestinal tracts of 28 dogs of different ages. The thickness of the different layers of the wall was measured and the numbers of proliferating cells as indicated by immunohistochemical detection of Ki67 were counted.

**RESULTS:** In the three excision sites, the thickness of all subepithelial layers increased with rising age. The strongest correlation between age and thickness of the intestinal wall was found in the first 10 years of life and in the jejunum ( $r = 0.6-0.71$  for the deep lamina propria mucosa, the muscularis mucosa, and the circular layer of the tunica muscularis). The number of proliferating cells decreased during aging, with the strongest correlation in the lamina propria mucosa and lamina muscularis mucosa of the jejunum and in the colonic submucosa ( $r = -0.61$  to  $-0.71$ ). Epithelial proliferation was only weakly correlated to the age.

**CONCLUSION:** The morphology of the deeper layers and the proliferation of mesenchymal cells of the intestinal wall of healthy dogs are correlated with age. Gastrointestinal epithelial proliferation is only weakly age-correlated.

### INTRODUCTION

Canine models are well known in the development of gastrointestinal drugs. On the other hand, an increasing number of biopsy samples are taken from the intestines of pet dogs with gastrointestinal symptoms and delivered to pathological diagnostic institutions for evaluation. Lesions, usually found in those specimens, however, are in most cases quantitative aberrations of normal morphology and cellular distribution rather than of a distinct qualitative kind. So a correct diagnosis is largely dependent on the experience of the examiner and the differentiation between physiological and pathological influences on the morphology. Data on the histological changes in the intestinal morphology in dependence on physiological processes, however, are very sparse. Suckling puppies exhibit rapid changes in the mucosal morphology that reach a comparatively stable state by the 42<sup>nd</sup> d of life<sup>[1]</sup>. In old dogs, Lafora body-like polyglucosan bodies have been described in the smooth musculature<sup>[2]</sup> and amyloid in the vessel walls of the large and small intestine without functional or neurological abnormalities<sup>[3]</sup>. Because of the usage of endoscopic biopsies, however, most examinations are limited to the mucosa<sup>[4]</sup>. The aim of this study was to characterize morphological alterations during the physiological course of aging including the different layers of the intestinal and gastric wall of dogs.

### MATERIALS AND METHODS

#### Subjects

Tissue samples were obtained from 28 dogs of different age and breed (Table 1), which were patients of the Small Animal Clinic and were euthanatized for diseases unrelated to the gastrointestinal tract. Under general anesthesia, full thickness biopsies of the gastric, jejunal and colonic wall were surgically excised and immediately fixed in 100 mL/L

neutral formalin. After fixation, the samples were routinely embedded in paraffin, cut, and stained with hematoxylin and eosin.

### Evaluation of slides

All measurements were performed in a blind fashion, i.e., without knowledge of the animals' age. Distances and structural measurements were performed using a computer sustained manual system (ASM 68k), in which a line was projected into the microscopic ocular, that could be manually adjusted to the outlines of the respective structure to be determined. The resulting length of the line was calculated by the supporting computer system.

The following parameters were determined: in the stomach, depth of foveolae (epithelial length from the surface to the isthmus), length of whole gastric glands (epithelial length from the surface to the base of the gland), estimated percentage of chief cells and parietal cells in the pars principalis, number of fiber layers between the gland base and the lamina muscularis mucosa, thickness of the lamina muscularis mucosa, submucosa, and, because of the inconsistent orientation and borders of the single muscle layers in the stomach, of the tunica muscularis as a whole (Table 2); in the jejunum, villus length (length from the tip following the central lymphatic vessel to the crypt mouth), villus mid and base width (shortest distance from epithelial surface to epithelial surface in the middle of the villus

and at the crypt mouth, respectively), crypt depth (length from the crypt mouth to the crypt base following the crypt lumen), thickness of the stratum compactum (distance between crypt base and lamina muscularis mucosa), lamina muscularis mucosa, submucosa, circular and longitudinal layer of the tunica muscularis mucosae (Table 3); in the colon, crypt depth, thickness of the lamina muscularis mucosa, submucosa, circular and longitudinal layer of the tunica muscularis mucosa (Table 4). All measurements were performed at four points of a well oriented section, which were equally distributed over its total length.

### Immunohistochemical assay

In the jejunum and colon, where the most obvious changes in the thickness of wall layers were found, immunohistochemical detection of Ki67 was carried out to determine the proliferative index. The immunohistochemical reaction was performed as follows: Paraffin-embedded sections were dewaxed and treated with 50 mL/L H<sub>2</sub>O<sub>2</sub> in ethanol for 30 min to inhibit endogenous peroxidase, followed by rinsing three times in phosphate-buffered saline (PBS). Antigen-retrieval was achieved by microwave treatment (20 min, 0.01 mol/L citrate buffer, pH 6). After demasking, the slides were incubated overnight with the first antibody (MIB-1, DAKOCytomation, Glostrup, Denmark) diluted 1:100 in PBS with 10 g/L bovine serum albumin. Binding of primary antibody was detected with a biotinylated second antibody (goat anti-mouse, diluted 1:200 in PBS) and the ABC-reagent (both Vector Laboratories, Burlingame, USA) according to the manufacturer's instructions using diaminobenzidine as chromogen. Finally, the slides were counterstained with hematoxylin. Negative control was performed with an identical procedure without the first antibody in the PBS/serum incubation step. An internal

positive control for the proliferation marker was present in all sections in the epithelial renewal zone of crypts and gastric pits.

#### Evaluation of Ki67-positive cells

In the jejunum and colon, the number of Ki67-positive cells (i.e. proliferating cells) was examined for the epithelia. Myocytes, myofibrocytes and fibrocytes could not be properly differentiated by morphological means in the immunohistochemically stained slides. For this reason, the number of proliferating cells per area comprises all cells of the lamina propria mucosa, lamina muscularis mucosa, submucosa, circular and longitudinal layer of the tunica muscularis, except round cells, especially leucocytes. All epithelial cells of approximately the lower 40% of the crypts stained positive for Ki67. Hence, comparison was made between the relative and absolute length of this compartment of the crypts. For the other layers, the absolute numbers of positive cells were counted in one whole section and set in relation to the total area of this layer in the respective section (Tables 5 and 6).

#### Statistical analysis

Values were checked for normal distribution.  $r$  is the Pearson product moment correlation coefficient as calculated by OpenOffice.org Calc.

## RESULTS

#### General considerations

In the examined sections, no qualitative changes, such as scars or amyloid deposits, were found irrespective of the age of the dogs.

**Stomach:** In the fundic mucosa, only minor changes

could be noted with increasing age. A tendency towards a relatively increased depth of foveolae could be noted and the lamina muscularis mucosa became thicker (Table 7). The relationship between age and lamina muscularis mucosa thickness was highest in dogs younger than 10 years ( $n = 14$ ).

**Jejunum:** The mean thickness of all layers of the jejunum increased in size during aging (data not shown). The most significant changes were detected in the deeper layers of the intestinal wall during the first 10 years of life ( $n = 12$ ), most obviously in the deepest part of the mucosal lamina propria in the jejunum. The distance between the crypt base and the lamina muscularis mucosa showed a strong correlation with the age of the examined dogs (Table 8). While villus length and crypt depth did not show any clear relationship with the age, the whole mucosal thickness increased with aging, mainly in the first 10 years of life. In the lamina muscularis mucosa, submucosa and circular layer of the tunica muscularis, the thickness also increased with age. In addition, in the lamina muscularis mucosa and circular layer, these changes displayed a stronger relationship in dogs less than 10 years. The longitudinal layer of the tunica muscularis did not show age-related changes.

**Colon:** The circular layer of the tunica muscularis displayed an age-related increase (Table 9). In contrast to the findings in the jejunum, only weak correlations between age and the thickness of the other mucosal or submucosal layers could be found.

#### Immunohistochemistry

**Jejunum:** In all layers of the intestinal wall, the numbers of proliferating cells were highest in young dogs, particularly those less than 3 years (data not shown). A

marked correlation between age and number of Ki67-positive cells could be found in dogs younger than 10 years ( $n = 12$ ) for the lamina propria between crypts and between lamina muscularis mucosa and crypt base, for the lamina muscularis mucosa, for the submucosa and for the tunica muscularis (Table 9). Including the older dogs ( $> 10$  years), correlation between age and thickness of the lamina muscularis mucosa remained strong. In contrast

to the mesenchymal tissues, no clear correlation could be detected between age and epithelial proliferation.

**Colon:** As in the jejunum, the number of proliferating cells decreased with age. The strongest correlations were found, again, until the age of 10 ( $n = 13$ ). In particular, the thickness of the lamina propria between crypt base and lamina muscularis mucosa, of the lamina muscularis mucosa and of the submucosa revealed a strong age-

**Table 7** Strength of correlation between age and diameter of different layers in the stomach wall of dogs

	All ages	< 10 yr
Absolute foveolar depth	0.44	0.05
Relative foveolar depth	0.54	0.11
Lamina muscularis mucosa	0.17	0.58
Submucosa	0.35	0.17
Tunica muscularis	-0.04	0.01

**Table 8** Strength of correlation between age and diameter of different layers in the jejunal wall of dogs

	All ages	< 10 yr
Villus length	-0.01	0.17
Crypt depth	-0.15	-0.2
Whole mucosa	0.5	0.1

Submucosa	0.46	0.13
Circular muscle layer	0.59	0.6
Longitudinal muscle layer	0.12	0.12

dependency in the number of proliferating cells (Table 10). In the submucosa, the correlation remained strong throughout the lifetime. The tunica muscularis and lamina propria between crypts showed only moderately age-related proliferation ( $r = -0.34$  and  $-0.43$ , respectively).

## DISCUSSION

The layers of the gastrointestinal wall beneath the mucosa comprise the major part of intestinal tissue. However, apart from pathological conditions, these tissues are thought to remain unchanged throughout lifetime. This study revealed that in dogs without gastrointestinal diseases, a continuous thickening of the deeper intestinal layers occurs, mainly during the first 10 years of life. In dogs, this period is regarded as young to middle-aged. Hence senile change in nutritional behavior and metabolism is unlikely to be the primary driving force in this development.

The strongest correlation between age and morphology could be detected in the jejunal lamina propria mucosa between crypt base and lamina muscularis mucosa. In textbooks of veterinary histology, this site is often referred to as stratum compactum<sup>[5]</sup>, when it is easily discernable from the overlying lamina propria, as in the proximal small intestine. In the examined sections, no morphologically distinct stratum compactum could be detected, even in those dogs that presented with a very large distance between the crypt base and the lamina muscularis mucosa. This might be due to the more distally located excision site. This layer is thought to prevent perforation of the intestinal wall by food containing bones<sup>[4]</sup>. Similarly, the observed proliferation of this zone during lifetime in this study might have been stimulated by mucosal distension and alteration by sharp bone fragments. However, detailed anamnestic data about the diet fed to these dogs during

**Table 9** Strength of correlation between age and diameter of different layers in the colonic wall of dogs

Tunica muscularis	-0.29	-0.56	-0.36	-0.34

their whole lifetime were not available.

Observations of alterations in the size of the lamina muscularis mucosa are restricted to experimental conditions, e.g. an increase in thickness after partial jejunectomy<sup>[6]</sup> in rats. The observed increase in the thickness of the muscular layer during lifetime is paralleled by observations in the jejuna of rats<sup>[7,8]</sup>. A possible explanation might be an increased workload for the musculature caused by a decrease in neuronal coordination as a result of the neuronal cell loss during aging, which has been described in humans<sup>[9]</sup> and rats<sup>[10]</sup>. If the increased muscular thickness is the result of a hypertrophy of muscle fibers or of the proliferation of connective tissue between fibers needs further, preferentially electron microscopic investigations.

In rats, epithelial cell proliferation increased in the first postnatal week and decreased or remained unaltered in the following months<sup>[7,11,12]</sup>. Differentiation of the brush border enzymes follows a similar course with a maximal development in young adulthood<sup>[13]</sup>. Examination of the mechanisms involved pointed to involvement of proliferation, apoptosis and crypt fission in the development of the intestinal mucosal epithelium<sup>[14,15]</sup>, but delivered contradictory results in particular with regard to alteration of the apoptotic rate in aging rats<sup>[14,16-18]</sup>. In contrast to these findings, the epithelial proliferation in the canine tissues in this study and a study of the jejunal mucosal morphology in dogs of different weights and ages<sup>[19]</sup> remained stable throughout lifetime. This observation was also made in mice<sup>[20]</sup>. The discrepancy in the proliferative rate might be explained by different methods applied. While bromodeoxyuridine<sup>[11,6]</sup> and Ki-67

(this investigation) cover a small time span of the cycling process, proliferating cell nuclear antigen is expressed during a long period exceeding mitosis. The increased number of proliferative cells in aging rats found in the study using the latter method<sup>[18]</sup> might indicate rather decreased degradation of the detected enzyme than increased number of cycling cells. The deeper layers of the present study, however, contained a decreasing number of proliferating cells with rising age. This reduced speed of cellular turn-over might lead to a lower adaptability towards a changed digestibility of diet and a slower healing after damage in older dogs.

In conclusion, all layers of the canine jejunal and colonic wall, except for the epithelial monolayer, increase in thickness during aging, while the number of proliferating cells decreases. The underlying mechanisms and possible functional consequences need further investigation.

## ACKNOWLEDGMENTS

We would like to thank Dr. K Rohn, Department of Biometry, Epidemiology and Information Processing, University of Veterinary Medicine Hannover, for assistance with the statistical analyses.

Tovey FI. Congratulation on *World Journal of Gastroenterology*. *World J Gastroenterol* 2007; 13(1): 158

<http://www.wjgnet.com/1007-9327/13/158.asp>

Dear Professor Lian-Sheng Ma,  
Professor Michael Hobsley and I have greatly enjoyed

reading the account of all you have done towards the development of "The *World Journal of Gastroenterology*", as described in the article by Zhen-Xi Li in the November 21st. issue of the Journal. It is an amazing achievement! Yours is the only international gastroenterological journal to come out weekly! The standard of the articles is extremely high and the Journal is equal in size to "Gut" (Leaderette: 2005 Impact Factor-Gastroenterology & Hepatology list:1 GASTROENTEROLOGY 12.386; 2 HEPATOLOGY 9.792; GUT 7.692), which comes out only monthly. You have achieved all this in a matter of only 10 years-truly a wonderful achievement. We do congratulate you.

Liu Y. President Lian-Sheng Ma met with Dr. Parimal Chowdhury, Professor of University of Arkansas for Medical Sciences. *World J Gastroenterol* 2007; 13(1): 159

<http://www.wjgnet.com/1007-9327/13/159.asp>

President Lian-Sheng Ma, Editor-in-Chief of *World Journal of Gastroenterology* (WJG), met with Dr. Parimal Chowdhury, from the University of Arkansas for Medical Sciences, member of WJG Editorial Board, and his wife in Beijing on November 29, 2006. The two sides held cordial and friendly talks.

President Ma extended his warm welcome to Mrs. Chowdhury. He firstly introduced to the guests the development of the journal. Currently, the editorial board of the WJG consists of 903 members from 52 countries, there are 5 science editors, 27 language editors located in 16 countries, 22 copy editors from 8 countries and 5 electronic editors. Totally 1223 articles were published in WJG from issue No.1 to issue No.42 in 2006, with authors distributed in 58 countries and regions, articles coming from outside China accounted for 77.35%, and the rejection rate was 46.44%. WJG is the only weekly journal in the fields of gastroenterology and liver diseases among SCI journals in the world. WJG was hit 13090137 times and downloaded 1313719 times online from April 15<sup>th</sup>, 2003 to November 1<sup>st</sup>, 2006. WJG was cited 2595 times in 2005 by 765 SCI journals, including 412 (15.87%) self-citations. WJG is an international academic journal of its kind published in English in China. Based on rapid development of basic research both in basic and clinical gastroenterology as well as growth of international exchange in science and technology, WJG converted to a weekly journal from 2005. PubMed and WJG electronic version of the text became available beginning from 1998 (ASP, PDF), and readers have free access to read the full texts of WJG. In this point, authors can make a timely and broad dissemination of their work to the world, and this has greatly expanded the international influence of the journal and attracted more high-quality manuscripts from

Parimal Chowdhury (middle of front seat), Professor of University of Arkansas for Medical Sciences, and his wife (left of front seat) met with Lian-Sheng Ma (right of front seat), President of WJG, in Beijing, China, on November 29, 2006. The other in turn (from right of rear seat) are Jing Wang, Ye Liu, Yan Jiang, Jing-Yun Ma, Gai-Ping Wang, who are editors of WJG. (WJG Photo).

different parts of the world.

Dr. Chowdhury was grateful for the hospitality given by President Ma and his staff and expressed his appreciation for the achievements and development of WJG. He mentioned that WJG is an open journal wide-ranging in contents and timely publication. Furthermore, it has the potential capacity of competing with similar international journals. Dr. Chowdhury also mentioned that Dr. Mark Donowitz, President of the American Gastroenterological Association (AGA), visited Hong Kong recently, is also very concerned about the development of WJG. He had a great admiration for the rich content, high quality of editing and printing and fast publishing frequency of WJG. It was his pleasure to work with WJG, said Dr. Chowdhury, adding that as one of the editorial board members of WJG, he will continue to contribute to WJG development.

Finally, President Ma expressed his gratitude to Dr. Chowdhury for his support and for his comments on WJG, for writing reviews, and organizing a series of articles as topic highlights in the past. Ma also expressed that WJG will continue to follow international standards and improve the academic quality in all aspects including peer review, copy editing, printing, etc. WJG will target to be the most outstanding international journals with respect to academic level be quality of editing from a scientific perspective and to be one of the top academic international journals in the next 3 to 5 years with the strong support of our country, the authors, readers, all editorial members and the international community.

## ACKNOWLEDGMENTS

# Acknowledgments to Reviewers of World Journal of Gastroenterology

Many reviewers have contributed their expertise and time to the peer review, a critical process to ensure the quality of *World Journal of Gastroenterology*. The editors and authors of the articles submitted to the journal are grateful to the following reviewers for evaluating the articles (including those published in this issue and those rejected for this issue) during the last editing time period.

### Kyoichi Adachi, MD

Department of Gastroenterology and Hepatology, Shimane University, School of Medicine Shimane, 89-1 Enya-cho, Izumo-shi Shimane 693-8501, Japan

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (WJG, *World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly journal of more than 48 000 circulation, published on the 7<sup>th</sup>, 14<sup>th</sup>, 21<sup>st</sup> and 28<sup>th</sup> of every month.

Original Research, Clinical Trials, Reviews, Comments, and Case Reports in esophageal cancer, gastric cancer, colon cancer, liver cancer, viral liver diseases, etc., from all over the world are welcome on the condition that they have not been published previously and have not been submitted simultaneously elsewhere.

#### Indexed and abstracted in

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, *Index Medicus*, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, *Nature Clinical Practice Gastroenterology and Hepatology*, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

#### Published by

The WJG Press

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297 mm × 210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, acknowledgements, References, Tables, Figures and Figure Legends. Neither the editors nor the Publisher is responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part without the written permission of both the authors and the Publisher. We reserve the right to put onto our website and copy-edit accepted manuscripts. Authors should also follow the guidelines for the care and use of laboratory animals of their institution or national animal welfare committee.

Authors should retain one copy of the text, tables, photographs and illustrations, as rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for the loss or damage to photographs and illustrations in mailing process.

#### Online submission

Online submission is strongly advised. Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/index.jsp>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. Authors encountering problems with the Online Submission System may send an email you describing the problem to [wjg@wjgnet.com](mailto:wjg@wjgnet.com) for assistance. If you submit your manuscript online, do not make a postal contribution. A repeated online submission for the same manuscript is strictly prohibited.

#### Postal submission

Send 3 duplicate hard copies of the full-text manuscript typed double-spaced on A4 (297 mm × 210 mm) white paper together with any original photographs or illustrations and a 3.5 inch computer diskette or CD-ROM containing an electronic copy of the manuscript including all the figures, graphs and tables in native Microsoft Word format or \*.rtf format to:

#### Editorial Office

##### *World Journal of Gastroenterology*

Telephone: +86-10-85381892  
Fax: +86-10-85381893

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using a word-processing software. All submissions must be typed in 1.5

line spacing and in word size 12 with ample margins. The letter font is Tahoma. For authors from China, one copy of the Chinese translation of the manuscript is also required (excluding references). Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was accomplished, disclosure of any financial support for the research, and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (removing all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s) and full family name.

#### Abstract

An informative, structured abstract of no more than 250 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipments, and the experimental procedures should be included. RESULTS: The observatory and experimental results, including data, effects, outcome, etc. should be included. Authors should present *P* value where necessary, and the significant data should accompany. CONCLUSION: Accurate view and the value of the results should be included.

The format of structured abstracts is at: <http://www.wjgnet.com/wjg/help/11.doc>

#### Key words

Please list 5-10 key words that could reflect content of the study mainly from *Index Medicus*.

#### Text

For most article types, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include in appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both.

#### Illustrations

Figures should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. No detailed legend should be involved under the figures. This part should be added into the text where the figures are applicable. Digital images: black and white photographs should be scanned and saved in TIFF format at a resolution of 300 dpi; color images should be saved as CMYK (print files) but not as RGB (screen-viewing files). Place each photograph in a separate file. Print images: supply images of size no smaller than 126 mm × 85 mm printed on smooth surface paper; label the image by writing the Figure number and orientation using an arrow. Photomicrographs: indicate the original magnification and stain in the legend. Digital Drawings: supply files in EPS if created by freehand and illustrator, or TIFF from photoshops. EPS files must be accompanied by a version in native file format for editing purposes. Existing line drawings should be scanned at a resolution of 1200 dpi and as close as possible to the size where they will appear when printed. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes of atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...

#### Tables

Three-line tables should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each table. No detailed legend should be included under the tables. This part should be added into the text where the tables are applicable. The information should complement but not duplicate that contained in the text. Use one horizontal line under the title, a second under the column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

#### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup>*P*<0.05, <sup>b</sup>*P*<0.01 should be noted (*P*>0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P*<0.05 and <sup>d</sup>*P*<0.01 are used. Third series of *P* values can be expressed as <sup>e</sup>*P*<0.05 and <sup>f</sup>*P*<0.01. Other notes in tables or under

illustrations should be expressed as  $^1F$ ,  $^2F$ ,  $^3F$ ; or some other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, etc. in a certain sequence.

### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions are included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should code the references according the citation order in text in Arabic numerals, put references codes in square brackets, superscript it at the end of citation content or the author name of the citation. For those citation content as the narrate part, the coding number and square brackets should be typeset normally. For example, Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>. If references are directly cited in the text, they would be put together with the text, for example, from references [19,22-24], we know that...

When the authors code the references, please ensure that the order in text is the same as in reference part and also insure the spelling accuracy of the first author's name. Do not code the same citation twice.

### PMID requirement

PMID roots in the abstract serial number indexed by PubMed (<http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed>). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information of the journal citations is very important. Through reference testing system, the authors and editor could check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in ASP file so that the readers can read the abstract of the citations online immediately.

### Style for journal references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). Title of the cited article and italicized journal title (Journal title should be in its abbreviation form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634]

Note: The author should test the references through reference testing system (<http://www.wjgnet.com/cgi-bin/index.pl>)

### Style for book references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

### Books

*Personal author(s)*

- 10 **Sherlock S**, Dooley J. Diseases of the liver and biliary system. 9th ed. Oxford: Blackwell Sci Pub, 1993: 258-296

*Chapter in a book (list all authors)*

- 11 **Lam SK**. Academic investigator's perspectives of medical treatment for peptic ulcer. In: Swabb EA, Azabo S. Ulcer disease: investigation and basis for therapy. New York: Marcel Dekker, 1991: 431-450

*Author(s) and editor(s)*

- 12 **Breedlove GK**, Schorfheide AM. Adolescent pregnancy. 2nd ed. Wiczorek RR, editor. White Plains (NY): March of Dimes Education Services, 2001: 20-34

*Conference proceedings*

- 13 **Harnden P**, Joffe JK, Jones WG, editors. Germ cell tumours V. Proceedings of the 5th Germ Cell Tumour Conference; 2001 Sep 13-15; Leeds, UK. New York: Springer, 2002: 30-56

*Conference paper*

- 14 **Christensen S**, Oppacher F. An analysis of Koza's computational effort statistic for genetic programming. In: Foster JA, Lutton E, Miller J, Ryan C, Tettamanzi AG, editors. Genetic programming. EuroGP 2002: Proceedings of the 5th European Conference on Genetic Programming; 2002 Apr 3-5; Kinsdale, Ireland. Berlin: Springer, 2002: 182-191

**Electronic journal** (list all authors)

**Morse SS**. Factors in the emergence of infectious diseases. Emerg Infect Dis serial online, 1995-01-03, cited 1996-06-05; 1(1): 24 screens. Available from: URL: <http://www.cdc.gov/ncidod/EID/eid.htm>

**Patent** (list all authors)

- 16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

### Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those that are linked with a hyphen and the difference between the two numbers at two sides of the hyphen is more than 5. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered as inappropriate references. Authors should not cite their own unrelated published articles.

### Statistical data

Present as mean  $\pm$  SD or mean  $\pm$  SE.

### Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\gamma$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

### Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p*(B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5  $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub> not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format about how to accurately write common units and quantum is at: <http://www.wjgnet.com/wjg/help/15.doc>

**Abbreviations**

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further mention.

**Italics**

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kbo I*, *Kpn I*, etc.

Biology: *H pylori*, *E coli*, etc.

**SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED**

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. Author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, the final check list for authors, and responses to reviewers by a courier (such as EMS) (submission of revised manuscript by e-mail or on the *WJG* Editorial Office Online System is NOT available at present).

**Language evaluation**

The language of a manuscript will be graded before sending for revision.

(1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing; (4) Grade D: rejected. The revised articles should be in grade B or grade A.

**Copyright assignment form**

Please download CAF from <http://www.wjgnet.com/wjg/help/9.doc>.

We certify that the material contained in this manuscript:

**Ms:**

**Title:**

is original, except when appropriately referenced to other sources, and that written permission has been granted by any existing copyright holders. We agree to transfer to *WJG* all rights of our manuscript, including: (1) all copyright ownership in all print and electronic formats; (2) the right to grant permission to republish or reprint the stated material in whole or in part, with or without a fee; (3) the right to print copies for free distribution or sale; (4) the right to republish the stated material in a collection of articles or in any other format. We also agree that our article be put on the Internet.

**Criteria for authorship:** The *WJG* requests and publishes information about contributions of each author named to the submitted study. Authorship credit should be based on (1) direct participation in the study, including substantial contributions to conception and design of study, or acquisition of data, or analysis and interpretation of data; (2) manuscript writing, including drafting the article, or revising it critically for important intellectual content; (3) supportive work, including statistical analysis of data, or acquisition of funding, or administration, technology and materials support, or supervision, or supportive contributions. Authors should meet at least one of the three conditions. The *WJG* does not publish co-first authors and co-corresponding authors.

We hereby assign copyright transfer to *WJG* if this paper is accepted.

Author Name in full (Full names should be provided, with first name first, followed by middle names and family name at the last, eg, Eamonn MM Quigley). Handwritten names are not accepted.

Author Name in abbreviation (Family name is put first in full, followed by middle names and first name in abbreviation with first letter in capital, eg, Quigley EMM). Handwritten names are not accepted.

**Final check list for authors**

The format is at: <http://www.wjgnet.com/wjg/help/13.doc>

**Responses to reviewers**

Please revise your article according to the comments/suggestions of reviewers. The format for responses to the reviewers' comments is at: <http://www.wjgnet.com/wjg/help/10.doc>

## Contents

<b>EDITORIAL</b>	165	Role of endosonography in non-malignant pancreatic diseases <i>Noh KW, Pungpapong S, Raimondo M</i>
	170	Pancreatitis-associated protein: From a lectin to an anti-inflammatory cytokine <i>Closa D, Motoo Y, Iovanna JL</i>
<b>TOPIC HIGHLIGHT</b>	175	Early diabetic neuropathy: Triggers and mechanisms <i>Dobretsov M, Romanovsky D, Stimers JR</i>
	192	Advances in small animal mesentery models for <i>in vivo</i> flow cytometry, dynamic microscopy, and drug screening <i>Galanzha EI, Tuchin VV, Zharov VP</i>
<b>REVIEW</b>	219	Differential diagnosis between functional and organic intestinal disorders: Is there a role for non-invasive tests? <i>Costa F, Mumolo MG, Marchi S, Bellini M</i>
	224	Importance of performance status for treatment outcome in advanced pancreatic cancer <i>Boeck S, Hinke A, Wilkowski R, Heinemann V</i>
<b>LIVER CANCER</b>	228	Interferon- $\alpha$ response in chronic hepatitis B-transfected HepG2.2.15 cells is partially restored by lamivudine treatment <i>Guan SH, Lu M, Grünewald P, Roggendorf M, Gerken G, Schlaak JF</i>
<b>BASIC RESEARCH</b>	236	Correlation between <i>in vitro</i> and <i>in vivo</i> immunomodulatory properties of lactic acid bacteria <i>Foligne B, Nutton S, Grangette C, Dennin V, Goudercourt D, Poiret S, Dewulf J, Brassart D, Mercenier A, Pot B</i>
	244	Rescue of the albino phenotype by introducing a functional tyrosinase minigene into Kunming albino mice <i>Xiao D, Yue Y, Deng XY, Huang B, Guo ZM, Ma Y, Lin YL, Hong X, Tang H, Xu K, Chen XG</i>
	250	Antiproliferation and apoptosis induction of paeonol in HepG <sub>2</sub> cells <i>Xu SP, Sun GP, Shen YX, Wei W, Peng WR, Wang H</i>
<b>CLINICAL RESEARCH</b>	257	Detection of disseminated pancreatic cells by amplification of cytokeratin-19 with quantitative RT-PCR in blood, bone marrow and peritoneal lavage of pancreatic carcinoma patients <i>Hoffmann K, Kerner C, Wilfert W, Mueller M, Thiery J, Hauss J, Witzigmann H</i>
	264	Efficacy of long term cyclic administration of the poorly absorbed antibiotic Rifaximin in symptomatic, uncomplicated colonic diverticular disease <i>Colecchia A, Vestito A, Pasqui F, Mazzella G, Roda E, Pistoia F, Brandimarte G, Festi D</i>
	270	Proximal gastric motility in critically ill patients with type 2 diabetes mellitus <i>Nguyen NQ, Fraser RJ, Bryant LK, Chapman M, Holloway RH</i>

- 276** Role of ciprofloxacin in patients with cholestasis after endoscopic retrograde cholangiopancreatography  
*Ratanachu-ek T, Prajanphanit P, Leelawat K, Chantawibul S, Panpimanmas S, Subwongcharoen S, Wannaprasert J*

- RAPID COMMUNICATION 280** Twenty-four hour intra-arterial infusion of 5-fluorouracil, cisplatin, and leucovorin is more effective than 6-hour infusion for advanced hepatocellular carcinoma  
*Nagai H, Kanayama M, Higami K, Momiyama K, Ikoma A, Okano N, Matsumaru K, Watanabe M, Ishii K, Sumino Y, Miki K*
- 285** Totally laparoscopic trans-hiatal gastroesophagectomy for benign diseases of the esophago-gastric junction  
*Dulucq JL, Wintringer P, Mahajna A*
- 289** Impact of endoscopic ultrasound-guided fine needle biopsy for diagnosis of pancreatic masses  
*Iglesias-Garcia J, Dominguez-Munoz E, Lozano-Leon A, Abdulkader I, Larino-Noia J, Antunez J, Forteza J*
- 294** Immunogenicity of recombinant hepatitis B virus vaccine in patients with and without chronic hepatitis C virus infection: A case-control study  
*Daryani NE, Nassiri-Toosi M, Rashidi A, Khodarahmi I*
- 299** Ginkgo biloba extract (EGb 761) attenuates lung injury induced by intestinal ischemia/reperfusion in rats: Roles of oxidative stress and nitric oxide  
*Liu KX, Wu WK, He W, Liu CL*

- CASE REPORTS**
- 306** Are heat stroke and physical exhaustion underestimated causes of acute hepatic failure?  
*Weigand K, Riediger C, Stremmel W, Flechtenmacher C, Encke J*
- 310** Jejunum-jejunal invagination due to intestinal melanoma  
*Resta G, Anania G, Messina F, de Tullio D, Ferrocci G, Zanzi F, Pellegrini D, Stano R, Cavallero G, Azzena G, Occhionorelli S*
- 313** An unusual cause of cholecystitis: Heterotopic pancreatic tissue in the gallbladder  
*Elpek GÖ, Bozova S, Küpesiz GY, Ögüş M*
- 316** A case of interstitial pneumonitis in a patient with ulcerative colitis treated with azathioprine  
*Nagy F, Molnar T, Makula E, Kiss I, Milassin P, Zollei E, Tiszlavicz L, Lonovics J*
- 320** Gallbladder lymphangioma: A case report and review of the literature  
*Kim JK, Yoo KS, Moon JH, Park KH, Chung YW, Kim KO, Park CH, Hahn T, Park SH, Kim JH, Jeon JY, Kim MJ, Min KS, Park CK*

## Abstract

Endoscopic ultrasound (EUS) has emerged as a valuable tool in the evaluation of benign and malignant pancreatic diseases. The ability to obtain high quality images and perform fine-needle aspiration (FNA) has led EUS to become the diagnostic test of choice when evaluating the pancreas. This article will review the role of EUS in benign pancreatic diseases.

Noh KW, Pungpapong S, Raimondo M. Role of endosonography in non-malignant pancreatic diseases. *World J Gastroenterol* 2007; 13(2): 165-169

<http://www.wjgnet.com/1007-9327/13/165.asp>

## INTRODUCTION

Endoscopic ultrasound (EUS) was developed in part to better evaluate the pancreas. As the ultrasound probe lies in close proximity of the pancreas, high quality images can be obtained and FNA can be performed under ultrasound guidance. EUS is considered safer and less invasive than endoscopic retrograde pancreatography (ERP). Thus, EUS is an important diagnostic test when evaluating the pancreas, especially in the setting of benign pancreatic diseases.

## CHRONIC PANCREATITIS

### EUS appearance

The diagnosis of chronic pancreatitis *via* EUS is based on parenchymal and ductal criteria on examination of the pancreas. The presence of 5 or more criteria is generally considered highly suggestive or diagnostic of chronic

pancreatitis and the presence of 2 or less criteria generally rules out the diagnosis of chronic pancreatitis.

To make the EUS diagnosis of chronic pancreatitis, one must understand the “normal” sonographic features of the pancreas. Several features were initially established by standard transabdominal ultrasound examinations of the pancreas. A “normal pancreas” was determined through studies such as that of Ikeda *et al*<sup>[1]</sup> who reported features of the pancreas in a large screening program in Japan. The pancreatic parenchyma in the absence of disease should appear homogeneous and have a “salt and pepper” appearance (Figure 1). The pancreatic duct should be seen as a smooth tubular structure coursing through the center of the pancreas. Side branches should not be visible.

The features of chronic pancreatitis can be divided into those that pertain to the parenchyma and the duct. These have been previously described by Lees<sup>[2,3]</sup> and Wiersma<sup>[4]</sup>. The parenchymal features include: hyperechogenic foci, hyperechogenic strands, lobulation, cysts, and calcifications; the ductal features include: main duct dilation, main duct irregularity, hyperechogenic main duct margins, and visible side branch ducts (Table 1).

Hyperechogenic foci and strands are bright echoes or string-like structures that may correlate histologically with thickened fibrous deposits<sup>[5]</sup>. These findings can be seen in patients with a normal pancreas, especially in older individuals. When hyperechogenic strands form a distinct “lobule”, this is called lobulation (Figure 2). The pancreas thus appears inhomogeneous. This feature is more strongly associated with chronic pancreatitis as compared to hyperechogenic foci and strands alone. Calcifications of the pancreas are seen as hyperechoic or bright areas with acoustic shadowing. This feature is almost pathognomonic of chronic pancreatitis. Cysts are anechoic round or oval structures. Pancreatic cysts will be discussed further in the later sections of this article.

The size of a normal pancreatic duct is considered to be less than 3 mm in the head, 2 mm in the body and 1 mm in the tail of the pancreas. A larger duct is considered to be abnormal except in older patients when found as an isolated finding. An irregular duct correlates with focal dilation and narrowing of the main pancreatic duct. If a side branch is visible, this is considered a feature of chronic pancreatitis.

The threshold for EUS diagnosis of chronic pancreatitis can be varied. A lower threshold such as greater than 3 criteria will produce a high sensitivity, but a low specificity. By contrast, using a higher threshold such as greater than 5 criteria will produce a low sensitivity and a high specificity. Thus, if the purpose of the examination

Figure 1 Normal pancreas.

Figure 2 Lobular pancreas.

Table 1 Features of chronic pancreatitis

EUS criteria	Appearance	Histological correlate
Hyperechoic foci	Small distinct focus of bright echo	Focal fibrosis
Hyperechoic strands	Small string like bright echo	Bridging fibrosis
Lobularity	Rounded homogenous areas separated by hyperechoic strands	Fibrosis, glandular atrophy
Cyst	Abnormal anechoic round or oval structure	Cysts, pseudocyst
Calcification	Hyperechoic lesion with acoustic shadowing	Parenchymal calcification
Ductal dilation	> 3 mm in head, > 2 mm in body, > 1 mm in tail	Duct dilation
Side branch dilation	Small anechoic structure outside the main pancreatic duct	Side branch dilation
Duct irregularity	Coarse uneven outline of the duct	Focal dilation, narrowing
Hyperechoic duct margins	Hyperechoic margins of the main pancreatic duct	Periductal fibrosis

is to exclude disease, a low threshold should be used. However, if the purpose is to establish the diagnosis chronic pancreatitis, a higher threshold should be used.

Another important fact is that not all factors are equal when diagnosing chronic pancreatitis. The features of lobulation and calcification are suggestive of chronic pancreatitis even in the absence of other criteria. As mentioned earlier, some features such as a dilated duct can be a “normal” finding in older individuals<sup>[1]</sup>. Currently, there is no accepted scoring system to take these factors into consideration.

Recent experimental evidence suggests the complementary role of increased levels of an inflammatory mediator such as the interleukin 8 (IL-8) in pancreatic juice and EUS to diagnose chronic pancreatitis<sup>[6]</sup>. In this study, the specificity of the combination of tests (both increased pancreatic juice levels of IL-8 and abnormal EUS) reached 100%. Until these data are confirmed in larger studies, clinical judgment must be used to make a diagnosis of chronic pancreatitis.

The lack of a gold standard for diagnosis other than histology has pressed some investigators to explore the role of EUS-FNA in chronic pancreatitis. Hollerbach *et al*<sup>[7]</sup> performed EUS-FNA in 27 patients with different degrees of severity (as measured by ERP criteria). EUS was 97% sensitive but only 60% specific for the diagnosis of chronic pancreatitis. The only advantage of EUS-FNA in this study was represented by an increased negative predictive value. Few patients developed self-limited abdominal pain after the procedure, but no major

complications were observed.

More recently, DeWitt *et al*<sup>[8]</sup> published their experience with EUS-FNA using the trucut needle which provides a core biopsy of the pancreas for histology. The results were compared with EUS and ERP. The authors observed poor agreement between EUS and EUS with trucut biopsy and only fair agreement between ERP and EUS with trucut biopsy. Therefore, the results of these studies induce caution when considering EUS-FNA (including the trucut needle) to diagnose chronic pancreatitis.

Conversely, EUS with trucut biopsy may have a significant role when considering the diagnosis of autoimmune chronic pancreatitis. Though the most characteristic endosonographic finding of this condition is diffuse pancreatic parenchyma enlargement (so-called sausage shape), there may be overlap with the non-autoimmune form of the disease or with cases of a pseudotumorous pancreatitis. Levy *et al*<sup>[9]</sup> reported their experience on 19 patients with autoimmune pancreatitis. In 10 patients who had EUS-FNA, the material retrieved was not adequate for the cytopathologist to make the diagnosis. However, the combination of the trucut needle and the immunohistochemistry staining for IgG 4 allowed the Authors to reach the correct final diagnosis of chronic autoimmune pancreatitis in virtually all patients. The authors concluded that though the EUS with trucut helps to make the diagnosis of autoimmune pancreatitis, this condition has still a low prevalence and a high suspicion of the disease with appropriate clinical presentation is necessary.

## PANCREATIC CYSTS

### EUS appearance

Improved imaging techniques and more frequent imaging of the abdomen has led to increased discovery of pancreatic cysts. These cysts pose a diagnostic and therapeutic challenge as the pathology ranges from benign pseudocysts to malignant cystic neoplasms. EUS plays an important role in the diagnosis and management of pancreatic cysts as allows for high quality images and the ability to perform fine needle aspiration.

Pseudocysts account for approximately 90% of pancreatic cystic lesions. Serous cystadenomas (SCA), mucinous cystadenomas (MCA) and intraductal papillary mucinous neoplasms (IPMN) account for the majority of the remaining 10% of cysts. Pseudocysts and SCA have little or no malignant potential as opposed to MCA and IPMN which are potentially malignant or malignant. Thus, it is important to identify mucinous cystic lesions.

Pseudocysts are inflammatory fluid collections that arise in the setting of acute or chronic pancreatitis. These cysts are anechoic, thick walled structures. Septations are rare and regional inflammatory lymph nodes may be seen. Aspiration of cyst fluid will reveal dark, thin fluid containing inflammatory cells and high levels of amylase.

SCA are benign cystic lesions of the pancreas<sup>[10]</sup> with the exception of a few case reports<sup>[11-13]</sup>. They have a female predilection and are most commonly discovered in the 7<sup>th</sup> decade of life<sup>[10,14,15]</sup>. These cysts are generally microcystic, but solid and macrocystic variants have been described<sup>[16-19]</sup>. This leads to a honeycomb appearance in cross-section. Central or “sunburst” calcification is considered pathognomonic, but is found in less than 20% of cases<sup>[15,20]</sup>. Cytology obtained from EUS guided FNA of these cysts is often non-diagnostic<sup>[21]</sup>. However, when an adequate sample is obtained, this will reveal cuboidal cells without the presence of mucin.

MCA are generally macrocystic, composed of a small number of discrete compartments greater than 2 cm in size<sup>[15]</sup>. The septations are thick, irregular and occasionally a peripheral area of calcification is present<sup>[22]</sup>. It has a female predilection, mostly present in the body-tail region of the pancreas and occur most commonly in the 5<sup>th</sup> to 7<sup>th</sup> decade of life<sup>[15,20,23]</sup>. The presence of mural nodules is suggestive of invasive carcinoma. The cyst fluid of MCA is viscous and clear. Cytology will reveal mucin rich fluid with columnar mucinous cells<sup>[15]</sup>.

The EUS appearance of IPMN includes segmental or diffuse dilation of the main pancreatic duct or multiple pancreatic cysts that arise from the branch ducts of the main pancreatic duct. There is an equal or slightly higher incidence of IPMNs among males than in females. The peak incidence is in the 6<sup>th</sup> and 7<sup>th</sup> decade of life<sup>[15,24]</sup>. Like MCA, the cyst fluid is viscous, clear and will contain mucinous epithelial cells<sup>[15]</sup>.

### Cyst fluid analysis

Cyst fluid analysis of tumor markers has been studied to differentiate among benign and pre-malignant pancreatic cysts. In the Cooperative Pancreatic Cyst Study, the authors compared the findings of pancreatic cyst fluid of one

hundred twelve patients obtained *via* EUS-FNA to surgical histology. EUS morphology, fluid cytology and cystic fluid tumor markers were evaluated. The results demonstrated that cyst fluid CEA levels (optimal cut-off 192 ng/mL) provided the greatest accuracy in differentiating mucinous versus non-mucinous pancreatic cysts. In addition, the accuracy of cyst fluid CEA was higher than that of EUS morphology, cyst fluid cytology or any combination of tests<sup>[25]</sup>. However, cyst fluid tumor marker values alone cannot definitively discriminate between mucinous and non-mucinous pancreatic cysts as there is overlap of CEA levels in these cysts<sup>[25,26]</sup>.

### New techniques

Trucut biopsy of the pancreatic cyst wall has been investigated as a possible method of diagnosing pancreatic cysts. Levy *et al*<sup>[27]</sup> performed EUS guided trucut biopsies (EUS-TCB) in ten patients. In seven patients, a diagnosis was established and no complications were reported. Although promising, EUS-TCB can be difficult to perform in the head of the pancreas given the risk of puncturing surrounding vasculature. In addition, the curvature of the scope may not allow for effective firing of the biopsy needle.

The role of pancreatic cyst fluid molecular analysis in predicting the pathology of the pancreatic cysts has been investigated. Khalid *et al*<sup>[28]</sup> analyzed pancreatic cystic fluid obtained *via* EUS-FNA in thirty-six patients with confirmed surgical histology. The authors hypothesized that polymerase chain reaction (PCR) amplification of DNA from whole or lysed cells shed into the cyst fluid may be predictive of cyst pathology. A high level of mutational damage would predict an underlying malignancy. In addition, as malignant cysts would have high cell turnover, cyst fluid DNA content may be higher in malignant cysts. Ten of the eleven malignant cysts carried multiple mutations as compared to no mutations in all ten benign cysts. The total amount of DNA in the malignant cysts was significantly higher than in the benign cysts.

## INTERVENTIONAL EUS

### Celiac plexus block

Pain associated with chronic pancreatitis can be difficult to control<sup>[29]</sup>. Often narcotic pain medications are required, but these are associated with significant adverse effects including constipation, nausea, vomiting and dependence. As pancreatic pain is mainly transmitted through the celiac plexus, celiac plexus neurolysis or block has been employed to manage pain related to pancreatic cancer or chronic pancreatitis. Initially, this was performed surgically or percutaneously. EUS-guided celiac plexus neurolysis was introduced by Wiersema *et al*<sup>[30]</sup> which was found to be as effective as the surgical or percutaneous approaches for the management of pancreatic cancer related pain. This technique was applied to manage pain from chronic pancreatitis<sup>[31,32]</sup>. Gress *et al*<sup>[31]</sup> reported a series of ninety patients with chronic pancreatitis who underwent EUS-guided celiac plexus block using Bupivacaine and Triamcinolone. Fifty-five percent of patients reported

a decrease in pain symptoms at 4 and 8 wk. A smaller percentage of patients experienced pain relief at 12 and 24 wk. The study was limited by a lack of a placebo arm which allows for potential bias. The use of celiac plexus block for the management of chronic pancreatitis pain remains uncertain and further studies are necessary.

### Drainage of pseudocyst

Pancreatic pseudocysts may develop as sequela of acute or chronic pancreatitis. They can be asymptomatic and often resolve with time. However, when they become symptomatic or enlarge to greater than 6 cm in size, drainage is indicated. Traditionally, drainage of pseudocysts was performed surgically. However, percutaneous and endoscopic techniques have gained favor given the mortality and morbidity of surgery. The location of puncture for transgastric and transduodenal drainage of pseudocysts was determined by the bulge caused by the pseudocyst into the lumen. In the absence of a bulge, puncture of the cyst was a "blind" process increasing the risk of perforation and hemorrhage<sup>[33,34]</sup>. EUS allows for transgastric or transduodenal drainage of the pseudocyst under real time ultrasound guidance and thus minimizes the risk of complications. Various techniques have been described in the literature<sup>[34-42]</sup>.

## CONCLUSIONS

EUS is an essential tool in evaluating benign pancreatic diseases. Chronic pancreatitis and cystic lesions of the pancreas pose a diagnostic challenge. EUS carries an advantage over CT scans and endoscopic retrograde pancreatography in the diagnosis of chronic pancreatitis as it has the ability to detect parenchymal changes evident in early chronic pancreatitis. In the cases of pancreatic cysts, EUS allows for direct sampling of cyst fluid under ultrasound guidance to differentiate between cystic lesions of the pancreas. Overall, the ability to obtain important information regarding the pancreas through high quality images and FNA in a relatively safe manner is the main advantage of EUS.

### Abstract

Pancreatitis-associated protein (PAP) was discovered in the pancreatic juice of rats with acute pancreatitis. PAP is a 16 kDa secretory protein structurally related to the C-type lectins although classical lectin-related function has not been reported yet. Then, it was demonstrated that PAP expression may be activated in some tissues in a constitutive or injury- and inflammation-induced manner. More recently, it has been found that PAP acts as an anti-inflammatory factor *in vitro* and *in vivo*. PAP expression can be induced by several pro- and anti-inflammatory cytokines and by itself through a JAK/STAT3-dependent pathway. PAP is able to activate the expression of the anti-inflammatory factor SOCS3 through the JAK/STAT3-dependent pathway. The JAK/STAT3/SOCS3 pathway seems to be a common point between PAP and several cytokines. Therefore, it is reasonable to propose that PAP is a new anti-inflammatory cytokine.

### INTRODUCTION

In 1984, Keim and co-workers reported the presence of a new protein in pancreatic juice of rats after induction

of acute pancreatitis<sup>[1]</sup>. This secretory protein was absent in control rats but appeared early after induction of pancreatitis and remained over-expressed for the following 3-4 d. The protein was detected also in pancreas homogenate and in zymogen granules. Due to the relationship with the induction of pancreatitis, the protein was denominated "pancreatitis associated protein" or PAP. Four years later, Tachibana and colleagues described the peptide 23 as a protein from the rat pituitary gland, which synthesis was stimulated by the growth hormone-releasing hormone and inhibited by somatostatin<sup>[2]</sup> but its primary structure remained unresolved at the time. The sequence of PAP was deduced after cloning the corresponding mRNA from rat<sup>[3]</sup> and human pancreas<sup>[4]</sup>. Only four years later Katsumata and co-workers reported that in fact, peptide 23, identified in 1988, was identical to PAP<sup>[5]</sup>. Finally, Lasserre and colleagues found that the PAP mRNA was overexpressed in 7 of 29 hepatocellular carcinomas<sup>[6]</sup> and named the encoded protein HIP. Therefore, peptide 23, HIP and PAP are three names for the same protein. In this review we will call it PAP because it is the first name adopted for this protein.

In healthy pancreas, PAP is constitutively expressed in the  $\alpha$ -cells of Langerhans islets<sup>[7]</sup>. By contrast, in the exocrine pancreas, PAP is only expressed when the acinar cells are harmed<sup>[4]</sup>. In fact, PAP expression is activated in pancreatic acinar cells in response to many injuries such as acute and chronic pancreatitis<sup>[4]</sup>, hypoxia<sup>[8]</sup>, toxins<sup>[9]</sup>, diabetes<sup>[10]</sup>, lipopolysaccharides<sup>[11]</sup>, hypotransferrinaemia<sup>[12]</sup>, and in the transplanted tissue<sup>[13]</sup>. However, its expression is not restricted to pancreatic tissue, and could be observed in several organs. This includes the intestine during chronic inflammatory diseases such as Crohn's disease and ulcerative colitis<sup>[14,15]</sup> and in animal models of inflammatory bowel disease (IBD)<sup>[16]</sup>. PAP is also expressed in the brain tissue of Alzheimer patients<sup>[17,18]</sup>, in the luminal epithelial cells of the uterus<sup>[19]</sup> and in a sub-population of developing motoneurons and, after peripheral injury, in sensory neurons and motoneurons<sup>[20,21]</sup>. Moreover, PAP mRNA expression was found activated in about 80% of the pancreatic adenocarcinomas of ductal origin and in 30% of mucinous cystadenomas<sup>[22]</sup>. The levels of PAP mRNA expression correlated with nodal invasion, presence of distant metastases and short survival. Also, in some cases peritumoral regions overexpressed PAP<sup>[23]</sup>, indicating that both tumor and peritumoral cells contribute to the high PAP serum level observed in patients with pancreatic cancer. In the liver, PAP was found strongly activated in about 30% of the primary hepatocarcinomas,

**Figure 1** Schematic protein domains in the different C-type lectins. Sequences are aligned on the C-type lectin-like domain (CTLD). Note that PAP is the smallest protein member, containing only the CTLD linked to a short N-terminal peptide (SNTP).

but the forced expression of PAP in this organ does not induce tumor development<sup>[24]</sup>.

## PAP IS A LECTIN-RELATED PROTEIN

Computer analysis of the PAP sequence suggests a structural relationship with lectins<sup>[3]</sup>. Identities between PAP and the other animal and human lectins range from 16% to 26%. Homologous domain includes the conserved amino acids of the consensus carbohydrate binding domain of the  $\text{Ca}^{2+}$ -dependent lectins (C-type lectins) (Figure 1). However, initial attempts to characterize a carbohydrate binding activity, including erythrocyte agglutination or adsorption to affinity columns specific for different carbohydrates, failed<sup>[3]</sup>. The structural organization of the PAP gene reveals new clues to the evolutionary development of the lectin genes. The PAP coding sequence spans over six exons and the putative carbohydrate-recognition domain is encoded by exons IV, V and VI. This gene organization suggests that PAP belongs to a new group of lectins which have evolved from the same carbohydrate-recognition domain ancestral precursor through a different process<sup>[25]</sup>. It is interesting to note that PAP is the smallest protein reported among the C-type lectins. In fact, it comprises a single carbohydrate-recognition domain linked to a signal peptide<sup>[26]</sup> whereas other C-type lectins contain the sugar-binding consensus combined with a variety of other protein domains which confer specific functions of lectins. In contrast, PAP does not have additional functional domains.

## PAP IN PANCREATIC DISEASES

Early after its discovery it becomes clear that acinar

cells of the pancreas are the main source of PAP in pathological situations. Using an experimental model of acute pancreatitis in rat, Morisset and co-workers found the induction of PAP and its localization in zymogen granules<sup>[27]</sup>. Bodeker and co-workers described the pattern of PAP up-regulation in exocrine pancreas during the progression of the disease<sup>[28]</sup>. The profiles obtained by Northern blot analysis with pancreatic RNAs, Western blot in pancreatic protein extracts and immunodetection are equivalent to that observed in human disease and in animal models. The absence of PAP in healthy pancreas and its strong induction observed during the early phase of the disease suggest that PAP could be a stress protein or an acute phase protein induced upon cell insult. This is of interest since pancreatic acute phase response, characterized by sudden changes in protein expression is a clear indicator of injury or infections in the pancreatic gland. Since PAP is overexpressed by pancreatic cells in response to cellular stress, it has been evaluated whether serum PAP could be an indicator of different pancreatic diseases. In an initial retrospective study<sup>[29]</sup>, it has been suggested that PAP might be a useful serum marker in the following of acute pancreatitis. In particular, a continuous elevation of serum PAP concentrations indicates that pancreatitis is still in progress. Nevertheless, other studies revealed that despite severity of pancreatitis correlated with serum levels of PAP, the sensitivity of PAP did not allow distinguishing severe from mild acute pancreatitis, better than C reactive protein<sup>[30]</sup>. In the case of pancreatic cancer, PAP was also overexpressed and could be observed in malignant ductular structures in pancreatic carcinomas<sup>[22]</sup>. Other reports revealed that PAP was strongly expressed in acini adjacent to the invasive adenocarcinoma, suggesting that the main source of PAP release in the pancreatic

juice is acini<sup>[23]</sup>. Since overexpression of PAP significantly correlated with nodal involvement, distant metastasis, and short survival, it has been suggested that its expression in human pancreatic ductal adenocarcinoma could be an indicator of tumor aggressiveness<sup>[22]</sup>.

## PHYSIOLOGICAL FUNCTIONS OF PAP

The fact that PAP is secreted by pancreatic acinar cells into the pancreatic juice initially suggested a role for this protein in pancreatic juice homeostasis. Several data are in line with this. Pancreatic juice is supersaturated in  $\text{CaCO}_3$  and, in the absence of physiological inhibitors, this salt will precipitate in crystal formation. Interestingly, lithostathine, another member of the PAP protein family, inhibits  $\text{CaCO}_3$  crystal growth *in vitro*<sup>[31]</sup>. On the other hand, it has been shown that PAP can bind and aggregate several bacterial strains from the intestinal flora including Gram positive and Gram negative, aerobic and anaerobic bacteria, although without inhibiting their growth<sup>[3]</sup>. This fact suggests that PAP could act as an endogenous anti-bacterial agent that could play a protective role preventing infectious complications in acute pancreatitis. Another suggested function for PAP is related to the fact that PAP conferred significant resistance to apoptosis induced by  $\text{TNF}\alpha$ <sup>[32]</sup> or by low doses of  $\text{H}_2\text{O}_2$ <sup>[33]</sup>, indicating that during acute pancreatitis PAP generation could be part of a mechanism of pancreatic cell protection against apoptosis. This anti-apoptotic effect of PAP was also observed in liver in which PAP protects hepatocytes against  $\text{TNF}\alpha$ -induced apoptosis<sup>[24]</sup>. An interesting role for PAP has also been observed in motoneurons. It has been reported that PAP expression is activated in developing and regenerating motoneurons<sup>[20]</sup>. This effect is related to ciliary neurotrophic factor (CNTF), which is an important survival factor for motoneurons. In cultured motoneurons, CNTF induces PAP expression which acts as an autocrine/paracrine neurotrophic factor in a subpopulation of motoneurons, by stimulating a survival pathway involving PI3 kinase, Akt kinase and  $\text{NF}\kappa\text{B}$ <sup>[34]</sup>. Despite the obvious interest of these observations, it is difficult to link these effects with the enormous amount of PAP released by pancreas during acute pancreatitis or cellular stress. Consequently, other physiological functions, more closely related with pancreatic diseases, have been investigated.

## PAP AS AN ANTI-INFLAMMATORY MEDIATOR

The initial indication that PAP could act as a modulator of the inflammatory response has been provided by Heller and co-workers<sup>[35]</sup>. Using an *ex-vivo* model of lung perfusion, these authors observed that PAP reduces the severity of some features associated with N-formyl-methionyl-leucyl-phenyl-alanine (FMLP)-induced activation of leukocytes. This includes the generation of thromboxane  $\text{B}_2$  and the tissue edema formation in the lung. Since PAP generation has been observed in diseases related with inflammatory processes (pancreatitis, Crohn's disease, etc.), it was speculated that PAP could act as a cell response to the inflammatory

stress. This is in line with the fact that induction in the pancreas of an acute-phase response, in which PAP expression was activated, prior to triggering necrotizing pancreatitis, significantly improved the survival of the animals<sup>[36]</sup>. Studies demonstrated that the administration of anti-PAP antibodies in an experimental model of taurocholate-induced acute pancreatitis in rats was associated with increased inflammation in the pancreas, evidenced by more abundant necrosis, increased pancreatic myeloperoxidase (MPO) levels and more prominent neutrophil infiltration<sup>[37]</sup>. Similar results were observed in another study using PAP antisense oligodeoxyribonucleotides to block the expression of PAP prior to induction of pancreatitis. With this approach, pancreatitis-induced PAP expression was reduced by 55% and markers of inflammatory cell damage were increased. These include serum amylase activity, pancreas edema, serum C-reactive protein, leukocyte infiltration and fat necrosis. In addition, the expression of *IL-1 $\alpha$* , *IL-1 $\beta$*  and *IL-4* was increased in peripheral blood mononuclear cells<sup>[38]</sup>. Pre-treatment with PAP of the *in vitro*  $\text{TNF}\alpha$ -stimulated macrophages results in a dose-dependent inhibition of *IL-6* and *TNF $\alpha$*  mRNA expression<sup>[37]</sup>. The inhibitory effect of PAP has been observed in different cell lines, including rat pancreatic acinar AR42J cells and human HT29 colon derived cells<sup>[39]</sup>. In these models, PAP prevented  $\text{NF}\kappa\text{B}$  translocation/activation in response to  $\text{TNF}\alpha$ , indicating that inhibition by PAP occurs, at least in part, upstream of  $\text{NF}\kappa\text{B}$  pathway. It is of clinical interest that the anti-inflammatory effect of PAP could be observed in other organs than pancreas. For example, increased serum levels of PAP expression has been observed in IBD-affected patients and these levels correlated with clinical and endoscopic parameters. In addition, *ex vivo* experiments showed that intestinal PAP synthesis and secretion was increased in active IBD and correlated with endoscopic and histological severity of inflammatory lesions. Remarkably, PAP reduced the proinflammatory cytokines secretion of the incubation of intestinal mucosa from active Crohn's disease in a dose dependent manner<sup>[39]</sup>. Consequently, it could be suggested that the anti-inflammatory role of PAP is not restricted to the pancreas and could be a more general response of the epithelial cells against the inflammatory processes.

## ANTI-INFLAMMATORY ACTIVITY OF PAP IS MEDIATED BY STAT3 ACTIVATION

The inhibitory effect of PAP on the pro-inflammatory  $\text{NF}\kappa\text{B}$  pathway seems to be dependent on protein synthesis. This has been demonstrated in AR42J cells by using cycloheximide into the culture medium to prevent *de novo* protein synthesis<sup>[40]</sup>. As indicated above,  $\text{TNF}\alpha$  induces overexpression of the *TNF $\alpha$*  gene itself and this autocrine loop could be blocked by PAP. However, PAP lost its ability when protein synthesis was inhibited by cycloheximide. This protein synthesis dependence to act as an anti-inflammatory factor shows similarities to *IL-10* and *IL-6*, which depend in part on the synthesis of suppressor of cytokine signalling (SOCS) proteins<sup>[41,42]</sup>. Both *IL-10* and *IL-6* receptors are related to the JAK/STAT signal

**Figure 2** Anti-inflammatory pathway activated by PAP.

transduction pathways. Therefore, the relationship between PAP and JAK/STAT has also been evaluated. In a recent paper, it has been reported that PAP treatment of the AR42J cells results in a rapid and transient phosphorylation and nuclear translocation of STAT3 protein<sup>[40]</sup>. In addition, pre-treatment with JAK-specific inhibitors results in the blockage of the inhibitory effects induced by PAP. Finally, the PAP-dependent activation of STAT3 results in a strong activation of its gene target SOCS3 that in turn could be the mediator of the PAP anti-inflammatory effect. Altogether, these results indicate that PAP exerts their effects through the synthesis of a protein induced by the activation of the JAK/STAT signalling pathway. SOCS3 will be the best candidate.

PAP can be strongly induced by IL-6 and IL-10 and IL-10-related cytokines through a STAT3-mediated pathway. Interestingly, expression of PAP itself appears to be induced in pancreatic acinar cells by the presence of PAP in the medium. This is also related to the activation of STAT3 pathway since at least two functional STAT-responsive elements have been reported in the promoter of the PAP gene<sup>[43]</sup>. This self-induction suggests the existence of a positive feedback mechanism in pancreatic acinar cells *via* a PAP receptor and a cross-talk with other cytokines (Figure 2).

## CONCLUDING REMARKS

PAP has been found as a 16 kDa secretory protein specifically induced in pancreas with acute pancreatitis. It has been demonstrated that PAP is activated in some tissues in a constitutive or injury- and inflammation-induced manner. PAP is structurally related to the C-type lectins although not classical lectin-related function has been reported. More recently, it has been found that PAP acts as an anti-inflammatory factor *in vitro* and *in vivo*. PAP expression can be induced by several pro- and anti-inflammatory cytokines and by itself through a JAK/STAT3-dependent pathway. PAP is able to activate the expression of the anti-inflammatory factor SOCS3 through the JAK/STAT3-dependent pathway. JAK/STAT3/SOCS3 pathway seems to be a common point between PAP and several cytokines. Therefore, it is reasonable to believe that PAP is a new anti-inflammatory cytokine.

### INTRODUCTION

Diabetes mellitus is a complex of metabolic disorders associated with insufficiency of insulin secretion, insulin action or both, and is manifested by hyperglycemia<sup>[1-3]</sup>. Diabetes is diagnosed when fasting blood glucose exceeds 6.9 mmol/L, or casual or 2-h glucose in a glucose tolerance test exceeds 11 mmol/L<sup>[4]</sup>. Control of blood glucose in vertebrate organisms is accomplished essentially by the action of two pancreatic hormones, i.e., insulin and glucagon, with the participation of epinephrine, ACTH, growth hormone and glucocorticoids occurring under special circumstances, such as stress. Insulin is released by islet beta cells in response to an increase of blood glucose (usually after a meal). It suppresses glucose production and stimulates the uptake and storage of glucose in skeletal muscle and liver (Figure 1). It also suppresses lipogenesis in the fat tissue and stimulates amino-acid synthesis in skeletal muscle. During a fasting state, when blood glucose is low or during stress requiring mobilization of energy, insulin secretion is suppressed and glucagon is released into the circulation by pancreatic  $\alpha$  cells, opposing the action of insulin to increase the release of stored energy resources for use by the organism (Figure 1)<sup>[5,6]</sup>.

The metabolic effects of insulin are mediated by activation of its cognate receptors that are expressed in target tissues (skeletal muscle, liver, fat) in large excess compared to the amount needed for normal regulation of glucose metabolism (spare receptors<sup>[7-10]</sup>). This lays a background for and signifies the paramount importance of the glucose control mechanisms. Indeed, in type 1 diabetes, which is usually associated with idiopathic autoimmune attack and destruction of islet beta cells, more than 90% of islet cells need to be destroyed or less than 10% of insulin production should remain for overt hyperglycemia to manifest<sup>[11]</sup>. Similarly, in type 2 diabetes, associated in its early stages with decreased sensitivity of insulin-responsive

### Abstract

Peripheral neuropathy, and specifically distal peripheral neuropathy (DPN), is one of the most frequent and troublesome complications of diabetes mellitus. It is the major reason for morbidity and mortality among diabetic patients. It is also frequently associated with debilitating pain. Unfortunately, our knowledge of the natural history and pathogenesis of this disease remains limited. For a long time hyperglycemia was viewed as a major, if not the sole factor, responsible for all symptomatic presentations of DPN. Multiple clinical observations and animal studies supported this view. The control of blood glucose as an obligatory step of therapy to delay or reverse DPN is no longer an arguable issue. However, while supporting evidence for the glycemic hypothesis has accumulated, multiple controversies accumulated as well. It is obvious now that DPN cannot be fully understood without considering factors besides hyperglycemia. Some symptoms of DPN may develop with little, if any, correlation with the glycemic status of a patient. It is also clear that identification of these putative non-glycemic mechanisms of DPN is of utmost importance for our understanding of failures with existing treatments and for the development of new approaches for diagnosis and therapy of DPN. In this work we will review the strengths and weaknesses of the glycemic hypothesis, focusing on clinical and animal data and on the pathogenesis of early stages and triggers of DPN other than hyperglycemia.

**Figure 1** Hormonal regulation of systemic blood glucose.

tissues to the action of the hormone (insulin resistance) and compensatory hyperinsulinemia, no clinical diabetes develops before muscle and fat tissue sensitivity to insulin is decreased below 50%-35% of normal<sup>[9]</sup>. In rats, and similarly in humans, plasma insulin may vary over the range of 1 to 4 ng/mL with fasting blood glucose exceeding the diabetic threshold of 6.9 mmol/L (solid line in Figure 2)<sup>[12-17]</sup> only in rare cases. In most cases, insulin must decrease to less than 0.5 ng/mL level (15% of control, 3.5 ng/mL level) in order to manifest overt hyperglycemia and diabetes.

Such a large safety factor for glucose control is of critical biological importance; however, clinically the impairment of insulin signaling in this disease process starts long before it manifests in overt hyperglycemia. With the discovery of insulin and improvement in techniques for blood glucose measurement, diabetes is not a life threatening disease by itself<sup>[18]</sup>. Therefore the long pre-clinical progression of diabetes could be a relatively minor issue; however, diabetes is associated with a variety of life threatening complications, among which distal peripheral neuropathy (DPN), cardio-vascular disease (CVD), retinopathy and renal disease are most frequent<sup>[2]</sup>. The problem is signs of these complications are frequently present prior to overt hyperglycemia and diabetes (Figure 2). Realization of this fact led to the definition of pre-diabetes as a state with moderate impairment of blood glucose control and high risk of development of overt diabetes, retinopathy and CVD<sup>[3,19]</sup>. Pre-diabetes is diagnosed when fasting blood glucose exceeds 5.6 mmol/L and/or 2-h glucose in a glucose tolerance test (GTT) exceeds 6.9 mM (impaired fasting glucose (IFG) and impaired glucose tolerance (IGT) dashed and solid horizontal lines in Figure 2, respectively)<sup>[4]</sup>.

Establishing the correct lower limit for diagnosis of pre-diabetes is important because it determines whether clinical tests for complications should be performed and recommendations in life style and diet modifications should be presented to patients. In a recent study of young adult men, it was shown that fasting glucose exceeding 4.82 mmol/L constitutes an independent risk factor for developing type 2 diabetes in otherwise healthy subjects<sup>[20]</sup>. In another study of adult healthy men without diabetes or pre-diabetes, progressive loss of

**Figure 2** Relationships between rat plasma insulin and fasting blood glucose concentrations. Data are from normal and streptozotocin-injected adult Sprague-Dawley rats (the authors' unpublished observations). STZ-rats having moderate pancreatic impairment and moderately decreased plasma insulin (vertical dashed lines) do not develop overt hyperglycemia.

$\beta$ -cell function and decrease in the first-phase of insulin secretion were detected at fasting glucose between 5.0 and 5.4 mmol/L<sup>[21]</sup>. Another clinically important issue is to understand the pathogenesis of diabetic complications, starting with pre-diabetic patients. This knowledge is required for early detection, prognosis and treatment of diabetic complications. Here we will discuss data and hypotheses for the triggers and progression of one such complication, which is distal peripheral neuropathy.

## DISTAL PERIPHERAL NEUROPATHY

The prevalence of peripheral neuropathy in diabetic subjects approaches 70% and about 50% of these are cases of DPN<sup>[22-24]</sup>. The disease usually progresses to involve cardiac autonomic nerves, and as a result it is a major factor in mortality of diabetic subjects. DPN is also the major reason for loss of protective limb mechanical sensations, traumatic ulceration injures and therefore amputations<sup>[23,24]</sup>. Finally, about 11% of DPN cases are associated with chronic pain symptoms that severely diminish the quality of life and are frequently associated with depression<sup>[22,23]</sup>. The etiology of DPN is unknown and prediction of progression and treatments of the symptoms of DPN are limited<sup>[22,25-27]</sup>.

Perhaps the largest problem associated with DPN, complicating its classification and treatment, is the variety of clinical presentations of this disease (Figure 3)<sup>[28-30]</sup>. Aside from a generally bilateral manifestation, distal to proximal advance and prevalence of sensory over motor impairment signs and symptoms, any two randomly selected cases of DPN may have nothing in common at the time of diagnosis and, to the extent it is known, their history and the pattern of their future progression may be very different. There are two broad categories of sensory symptoms of DPN, positive and negative<sup>[26,29]</sup>. Positive symptoms include pain, paresthesias and aberrant, exaggerated sensitivity to normally painless or moderately painful stimuli (allodynia and hyperalgesia). Negative

**Positive sensory symptoms:**

Chronic or Acute/Remitting:

Spontaneous:

Painless paresthesias:

numbness, tingling, pricking, burning, or  
creepingPain/dysesthesia: burning,  
electric, sharp, or dull/aching

Evoked pain/dysesthesia: allodynia or

hyperalgesia, mechanical/  
or thermal

tactile

**Negative sensory signs/symptoms:**Decrease in sensory nerve amplitude/conduction  
velocity

Decrease or loss of perception:

Vibratory stimuli

Thermal stimuli (warming or cooling)

Tactile perception (light touch)

Nociception (hypoalgesia):

Thermal (heat or cold)

Mechanical (pin-prick)

Loss of tendon reflexes

**Motor signs/symptoms**Decrease in motor nerve amplitude/conduction  
velocity

Muscle wasting

**Figure 3** Signs and symptoms of distal peripheral neuropathy. Categories of symptoms most frequently manifested in humans with diabetes are given in bold.

symptoms consist of loss of sensory perception in one or several modalities. Motor symptoms, if present, manifest as muscle weakness, and thus they are also negative. Finally, a classical electrophysiological, and also negative, sign of DPN is a decrease in nerve conduction velocity (NCV) and amplitude of compound action potentials (APs) in peripheral sensory and motor nerves<sup>[23,24,26,27,31]</sup>. Furthermore, three categories of DPN, acute painful remitting neuropathy, chronic painful neuropathy and painless neuropathy with ulcer can be outlined as separate clinical entities<sup>[24,32,33]</sup>. The relationships among these entities, however, if any exist, are not known. Within each of these groups, signs of demyelination of large peripheral fibers (decrease in NCV) may or may not co-exist with signs and symptoms of large fiber axonopathy (decrease in amplitude of compound APs, loss of vibration sensation and/or loss of stretch reflexes). Loss of warm and cold perception, impairment of unmyelinated and small myelinated fibers, may or may not co-exist with signs of large fiber abnormalities<sup>[24,31,32,34-36]</sup>. Furthermore, the pain normally conducted by small unmyelinated peripheral axons may or may not be present at the same time with any of the above mentioned symptoms<sup>[22-24,26,36,37]</sup>. Finally, the modalities of pain and the degree of involvement of autonomic nervous system impairment constitute another large set of variables<sup>[22,24,33,38-40]</sup>.

From experiments in animals, and by analogy with other neuropathies, it can be suggested that the pathogenesis of negative symptoms and signs of DPN is likely to be associated with demyelination and axonal atrophy and degeneration<sup>[41,42]</sup>. Failure of re-innervation will make these symptoms essentially irreversible<sup>[42-44]</sup>. Mechanisms of neuropathic pain, paresthesias and

**Figure 4** Hypotheses on distal-to-proximal progression of DPN. In normal PNS (top), neurons synthesize proteins in the cell body and transport them down the axon at the rate determined by axonal structural and functional needs. Impairment of synthesis or axonal transport of proteins will result in dying-back neuropathy, in which neurons with longest processes are affected first (middle). Alternatively, the neuropathy may result from effect of random local insults to the axon, with probability of accumulation of a critical number of such insults being higher for neurons having longer axons (bottom). Short arrows indicate non-specified axonal or neuronal injuries. Long solid or dashed arrows indicate normal or compromised axonal transport (respectively).

hyperalgesia are less understood<sup>[27,40]</sup>. However, it is generally accepted that abnormally intense spontaneous input from primary afferent fibers to the spinal cord is a primary trigger of these symptoms<sup>[24,27,45,46]</sup>. At least three usually overlapping conditions, resulting in such abnormal activity of peripheral axons, are well established. First is impairment of endoneurial circulation and following it ischemia<sup>[47,48]</sup>. Second is impairment of axon-glia relationships and segmental or paranodal demyelination<sup>[49,50]</sup>. The third condition is an axonal injury and following it Wallerian degeneration and neuroma<sup>[51,52]</sup>. In addition, increased excitability of regenerating, and therefore not yet properly myelinated, nerve fibers may add to the generation of aberrant peripheral discharge and pain<sup>[53,54]</sup>. At least at advanced stages, evidence for axonal, glial and vascular injuries are detectable in most cases of DPN<sup>[41,55]</sup>.

Further insight into the pathogenesis of DPN is provided by its diffuse, bilateral presentation and distal to proximal progression. The former suggests that systemic rather than local conditions underlie the clinical pathology, while the latter could indicate two possibilities (Figure 4). First, DPN may be a manifestation of dying back degeneration, with the primary insult consisting of the impairment of synthesis or efferent axonal transport of proteins, therefore affecting the function of the longest axons in the body that are most dependent on these mechanisms<sup>[42]</sup>. Failure of protein synthesis, including synthesis of some important neurotrophic molecules, in diabetes could result in impaired nerve regeneration and dying back axonopathy<sup>[43,44,55,56]</sup>. Alternatively, accumulation of the effects of multiple injuries randomly located along the axon, for example demyelinating injuries, may result in a clinical picture that is practically indistinguishable from dying back neuropathy<sup>[41,42,57]</sup>. The longest axons in the body will most likely be hit by a critical number of such local insults and their function will fail first.

Micro-vascular disease followed by local impairment of blood supply to the nerve fascicles may be a basis for random demyelinating insults progressing later to axonal degeneration<sup>[58-60]</sup>. It is also conceivable that both mechanisms are operating at the same time. Both demyelination and axonal degeneration were detected in human DPN by electrophysiological tests and biopsy studies<sup>[24,41,61]</sup>. Peripheral axons are the longest in the human body, and this might be an important factor explaining PNS involvement superseding the CNS complications. Another potentially important reason for the high vulnerability of PNS to diabetic injury is the relatively weak anti-oxidative defenses of peripheral neurons (see Section 3).

While the discussion above appears to encompass all the major features of DPN, multiple questions related to the pathogenesis of DPN remain unresolved. Thus whether or not dying back axonopathy or multiple local injuries or both mechanisms lead to the disease, it is not clear why, in most cases of neuropathy, sensory symptoms prevail over signs of impairment to motor axons innervating the same distal areas of the human body. Furthermore, neither of these mechanisms explains a variety of clinical presentations of DPN nor answers the question of why some diabetic patients live without any symptoms of DPN for years<sup>[62]</sup>. Finally, major questions that remain to be answered include identifying pathogenic triggers of DPN, pathogenesis of individual symptoms, and relationships among different symptoms and signs of the disease<sup>[22,24]</sup>.

To illustrate the importance of the latter question, two hypothetical scenarios of DPN are shown in Figure 5. In the first scenario (Figure 5, top), there is a single pathogenic process triggering and maintaining the disease. The course of the disease and its clinical manifestations at the time of diagnosis and neurological evaluation (ovals in the Figure 5) will be determined by the duration of DPN and individual differences in the genetic backgrounds of patients. From the point of view of the symptoms revealed by a neurological exam, the second scenario (Figure 5, bottom) is identical to the first one; the critically important difference, however, is that different sets of symptoms in this scenario are triggered and driven by entirely independent pathogenic mechanisms (symptoms "a", "c", and "d" vs symptom "b"). Some of the branches of the pathogenic process ("b" in the first scenario) may enter an irreversible stage. Therefore, the early detection of DPN is an obligatory condition for the successful treatment of this disease. The cartoons demonstrate also that identification of all participating triggering mechanisms and symptoms associated with them is another critical step for the efficient treatment of DPN.

## CHRONIC HYPERGLYCEMIA AND PATHOGENESIS OF DPN

DPN follows both type 1 and type 2 diabetes, and systemic hyperglycemia is the most obvious symptom that these types of the disease have in common<sup>[24,63,64]</sup>, suggesting hyperglycemia as a universal trigger for DPN. Indeed,

**Figure 5** Hypothetical branching (top) and multi-trigger (bottom) pathogenesis of DPN. In the first scenario (top) all manifestations of the disease result from the unique branching pathogenic process, and symptom "b" discovered at the time of neurological exam B is not corrected by treatment because it has already progressed to an irreversible stage (dashed lines). Earlier diagnosis and institution of treatment (at time A) may critically change the outcome of therapy in this scenario. Alternatively (lower scenario), several independent factors may trigger and maintain the progression of DPN. In this case the therapy may fail to treat symptoms not because they are irreversible, but because the correct cause of the pathology is not identified and is not treated (dashed lines).

insulin treatment or treatment with insulin-sensitizing drugs to control hyperglycemia reverses some symptoms of DPN and delays its progression in general<sup>[65,66]</sup>. The Diabetes Control and Complications Trial (DCCT) data show that strict control of hyperglycemia in type 1 diabetes patients without clinical neuropathy decreased development of DPN in 60% of cases over 5 years of follow up study<sup>[67,68]</sup>. Well within the framework of the glycaemic hypothesis, the failure to prevent all cases of DPN could be explained by the fact that glucose control can never be perfect. Type 1 and 2 patients are, on average, euglycemic for only about 62% of the day, while during the remaining 30% and 8% of the day they have various degrees of hyperglycemia and hypoglycemia, respectively<sup>[69]</sup>. Therefore, to avoid hypoglycemic crisis, the acceptable target value for blood glucose in controlled subjects is usually set to values above normal (6.7 to 10 mmol/L in DCCT and 6 mmol/L in U.K. Prospective Diabetes Study; of type 2 diabetic patients<sup>[65,68]</sup>). Another explanation for incomplete efficacy of glucose control is that, after long-standing diabetes, some neuropathic mechanisms may enter either an irreversible stage or a stage of progression that is already independent of the original trigger. With the limitations imposed by generally late diagnosis of diabetes and DPN<sup>[24,70,71]</sup>, slowing of NCV, paraesthesia and painful symptoms appear to be the earliest (closest to the initiating pathogenic insult) manifestations of DPN. Therefore, it appears to be in good agreement with the glycaemic hypothesis that in patients with newly diagnosed diabetes, NCV slowing and paresthesias (hyperglycemic neuropathy) can be frequently completely recovered with the establishment of euglycemia<sup>[31,42]</sup>.

Further support for the glycaemic hypothesis comes from research in animals, specifically rat models of type

**Figure 6** Hyperglycemia, derangement of cell metabolism and oxidative/nitrosative stress. Hyperglycemia associates with accumulation of fructose-6-phosphate and hexosamine pathway (1) to N-acetylglucosamine, accumulation of dihydroxyacetone phosphate and associated activation of PKC (2), activation of polyol sugar pathway (3), and glucose autooxidation and non-enzymatic protein glycation (4). These metabolic events are either regular physiologically important components cell metabolism (1, 2 and 3) or are normally under strict control of intrinsic intracellular defense mechanisms (4). However, under conditions of chronic hyperglycemia activation of these pathways leads to a global derangement of the cell and tissue homeostasis, which culminates in an uncontrolled cascade of abnormal protein modifications, oxidative/nitrosative stress and pro-inflammatory conditions.

1 diabetes (STZ-induced or spontaneous in BB-rats) and spontaneous type 2 diabetes in Zucker fatty rats<sup>[66,72]</sup> that appear to be the best studied animal models with regard to neuropathy. The short life span of rodents severely limits evaluation of chronic human diseases in these animals. Another limitation is that in behavioral tests, evoked pain manifested by limb withdrawal can be tested, but neither spontaneous pain nor changes in non-nociceptive sensory thresholds can be reliably measured in animals. Nonetheless, in general agreement with both clinical data on the earliest signs and symptoms of human DPN and the glycemic hypothesis, slowing of sensory<sup>[73-76]</sup> and motor<sup>[74,75,77-83]</sup> NCV and manifestations of evoked pain (hyperalgesia<sup>[75,84-87]</sup> and allodynia<sup>[85]</sup>) were shown to develop within the first month of onset of hyperglycemia in diabetic rats. With a longer time allowed (six to twelve months of diabetes) signs of axonopathy, demyelination and nerve degeneration can also be detected in diabetic animals<sup>[56,74,80,82,88-90]</sup>. Finally, early in the course of diabetes in rat models impairment of endoneurial blood flow and micro- and macrovascular reactivity are reported by many investigators<sup>[75,91-94]</sup>. Skin and arterial blood flow is abnormal early in diabetic patients<sup>[95-98]</sup>, but no reduction in sural nerve blood flow was detected in humans with

diabetes and mild DPN<sup>[99]</sup>. Thus, it is not clear whether impaired endoneurial blood flow represents a rat-specific component of DPN or if it is missed in humans because of its transient character and usually late detection of DPN in diabetic patients. In agreement with the glycemic hypothesis, all abnormalities found in rat models are reversible with normalization of blood glucose in insulin replacement experiments, and some of them (decreased pain pressure threshold) can be induced in normal rats by chronic *in vivo* perfusion of a DRG, or a segment of sciatic nerve with hyperglycemic solution<sup>[100,101]</sup>.

Finally, support for the glycemic hypothesis is provided also by studies of cellular pathology associated with experimental diabetes. These studies show that practically all signs and symptoms of DPN observed in animal models may be linked to hyperglycemia-induced metabolic impairment of nerve, glial and endothelial cells in PNS. A detailed description of these studies is beyond the scope of the present work and can be found in a number of recent reviews<sup>[94,102-109]</sup>. The purpose of Figure 6 is only to provide a brief outline of cell metabolic abnormalities associated with diabetes and emphasize the findings directly relevant to the following discussion of triggers of early DPN.

Although the scheme in Figure 6 is simplified and omits many essential steps for the cascade of events [the poly (ADP-ribose) polymerase (PARP)<sup>[108]</sup>; activation and consequences of lipid peroxidation<sup>[110]</sup> are not shown], it clearly demonstrates the complexity of this cascade. Some events appear to be more specific to one type of cell than to another, and there is as yet no agreement on which events (for example activation of polyol pathway<sup>[111]</sup> or abnormally intensified oxidative phosphorylation<sup>[106]</sup>) plays a leading role in cellular impairment. Nonetheless, most of the data available indicate that all the various pathways activated by hyperglycemia converge in generation of excess reactive oxygen species (ROS). This process eventually overwhelms the intrinsic anti-oxidant mechanisms of the cell and ends in oxidative/nitrosative stress and pro-inflammatory conditions in the tissues<sup>[112-115]</sup>. The efficacy of treatment with anti-oxidants in correction of DPN in animals and humans supports this view<sup>[116-119]</sup>.

In diabetic animals, oxidative stress injury develops in parallel in all major cellular elements of PNS. Injury to glial cells is responsible for the demyelination component of DPN, which may explain the decrease in NCV and painful manifestations of the disease. Oxidative stress in neurons might be responsible for axonopathy, impaired regenerative capacity of axons and negative symptoms of DPN. Glial cell injury will affect the nerve neurotrophism adding to the progression of neuronal defects. Finally, oxidative stress and impairment of nitric oxide (NO) production in the endothelium of epi- and endoneurial blood vessels results in impairment of endoneurial circulation and endoneurial hypoxia, exaggerating and speeding up the direct effect of hyperglycemic conditions on glial cells and neurons. Oxidative stress is pro-inflammatory, which affects the production of cytokines by glial cells, and provokes the recruitment of immune response cells into the affected tissue. This might be another important component of the pathogenesis and progression of DPN. Thus, combining these data and observations lays the foundation for a view of the natural history of DPN similar to that depicted in Figure 7 according to an expanded view of the glyemic hypothesis.

Perhaps the most attractive aspect of such a view of the pathogenesis of DPN is that while it suggests a unifying trigger and mechanism (hyperglycemia and oxidative stress) for all symptoms of DPN, it nevertheless remains flexible enough to leave room for individual variability in the rates of progression and spectrum of manifestations of the disease. Indeed, the actual effects of uniform pro-oxidative and pro-inflammatory conditions may differ sharply depending on differences of individual cells and tissues in their intrinsic anti-oxidant defenses and individual organisms in their immune defenses. The injuries to a single myelinating or non-myelinating Schwann cell, endothelial cell or neuron will unlikely have even subclinical significance. The death of several myelinating cells will result in a decrease of NCV in a given axon and injury to several endothelial cells may cause the closure of a given capillary. Yet there are many axons and there is regeneration of damaged axons, and there are many capillaries and regeneration of damaged and collateral capillaries. It is only after cellular defenses

**Figure 7** Pathogenesis of DPN with hyperglycemia as a major trigger of PNS injury.

against the oxidative stress are overwhelmed in many cells that the sub-clinical signs of the disease may be expected to appear, and it is anticipated to take an even longer time before clinical manifestations will themselves appear. In agreement with this, *en mass* CNS cells appear to have a much higher capacity for anti-oxidative mechanisms than do PNS cells and this might be one of the reasons why diabetic neuropathy affects the CNS much later than it affects peripheral nervous functions<sup>[90,113,120]</sup>.

## DIFFICULTIES OF THE GLYCEMIC HYPOTHESIS

While apparently logical and consistent with many clinical observations and the results of animal studies, the glyemic hypothesis cannot completely explain all the data. Thus, experiments in rodents consistently demonstrate that the polyol pathway (conversion of glucose to sorbitol by aldose reductase and then to fructose by sorbitol dehydrogenase; pathway 3 in Figure 6) is an important source of reactive oxygen species, and inhibition of aldose reductase prevents or reverses many signs of DPN seen in diabetic animals<sup>[121]</sup>. The same treatment in humans, however, has shown questionable efficacy so far<sup>[27,53,122,123]</sup>. Other problems include the failure of a pre-clinical slowing of NCV<sup>[24,124]</sup> or increase in glycosylated hemoglobin<sup>[22]</sup> (HA1c, integral measure of persistent hyperglycemia; pathway 4 in Figure 6) to predict development or severity of symptoms of DPN. Also, the finding of an inverse correlation between hyperglycemia and pain severity in diabetic patients with remitting painful neuropathy at presentation<sup>[33]</sup> is inconsistent with the glyemic hypothesis. These and other similar inconsistencies certainly could be attributed to the complexity of the disease, differences in studied patient populations, or inadequate design of drug trials in terms of timing, duration or dose<sup>[121]</sup>. Similarly, the lack of absolute efficacy in glucose control in preventing DPN in humans with diabetes<sup>[68]</sup> could also be explained within the framework of the glyemic hypothesis considering the difficulty of maintaining blood glucose concentrations within the relatively narrow range of normal values, which suggests that the actual threshold for neuropathic effects of hyperglycemia is lower than was

previously thought. Therefore, recent findings of increased incidence of DPN in patients with pre-diabetes, many of whom have an impaired glucose tolerance (IGT) but not fasting hyperglycemia<sup>[22,25,70,71,125-127]</sup>, appear to present the most serious challenge for the glycemic hypothesis.

The possibility that PNS injury may be triggered by exaggerated and prolonged postprandial hyperglycemic episodes, without necessarily requiring chronic hyperglycemia, should be considered to reconcile the glycemic hypothesis with observations of DPN in glucose intolerant patients<sup>[70,128-130]</sup>. Indeed, indices of large fiber function (ankle and knee reflexes and vibratory perception thresholds) were shown to decay with impairment of glucose tolerance in humans without diabetes and neuropathy<sup>[131]</sup>. Furthermore, pain is a frequent symptom of pre-diabetic DPN. An acute glucose infusion, which could be considered as an analog to a postprandial glucose surge, decreased thresholds to electrical stimulation in healthy adult volunteers<sup>[132]</sup> and decreased pain pressure thresholds in type 1 diabetic patients without clinical neuropathy<sup>[133]</sup>. In the latter study, however, no association between acute hyperglycemia and heat pain, warmth/cooling or vibration perception thresholds, was found<sup>[133]</sup>. Inconsistent with the idea that postprandial glucose changes have a neuropathic effect, no correlation was detected between short-term fluctuations in blood glucose and pain scores or heat pain thresholds in the study of type 1 and type 2 diabetic subjects with painful neuropathy<sup>[134]</sup>. Furthermore, no correlation between the number of glycemic excursions and the number of painful episodes was found in the study of type 1 patients with painless neuropathy<sup>[135]</sup>.

Difficulties with the glycemic hypothesis are not unique to the human clinic. Thus in the STZ-rat model of diabetes, NCV could be corrected by a low level of insulin therapy below that required to correct hyperglycemia<sup>[89,136]</sup>. Pain pressure and von Frey filament thresholds studied in the same model demonstrate no correlation with the degree of hyperglycemia<sup>[84,101,137]</sup>. Furthermore, aldose reductase inhibitors (blockers of the polyol sugar pathway; Figure 6), given at doses sufficient to correct nerve sorbitol and fructose and heat pain thresholds, do not correct von Frey filament threshold in STZ-hyperglycemic rats<sup>[138,139]</sup>. As another example, pain pressure thresholds in type 2 diabetic Zucker rats could be corrected with insulin-like-growth factor II (IGF-II) that has no effect on blood glucose<sup>[86]</sup>. All these examples are taken from experiments in overtly diabetic and hyperglycemic animals. Therefore, formally the possibility remains that hyperglycemia was the triggering event for the observed abnormalities, but it is not required for the progression and maintenance of these pathologies. Whether DPN develops in pre-diabetic rats as it does in humans has not yet been studied. Since previous work has focused on diabetes, little attention has been devoted to the development of pre-diabetic animal models and studies of DPN in these models. Nonetheless, neuropathic decreases of mechanical and thermal nociceptive thresholds<sup>[140]</sup> and slowing of motor NCV<sup>[141]</sup> were observed in studies in Zucker-fatty rats. Since these are insulin-resistant but normoglycemic animals (type 2 pre-diabetes) the impaired glucose tolerance could

be responsible for DPN in these animals. Recently, we described decreased pain pressure threshold in rats that were injected with STZ but remained normoglycemic<sup>[84]</sup>. These rats also had normal glucose tolerance, maintained normal levels of HbA1c, and normal concentrations of sorbitol in the nerve, suggesting that not only fasting but casual glucose also was maintained within physiological limits (Figure 8).

Thus there is solid evidence that hyperglycemia is an important factor of DPN. However, there are also both clinical and animal studies indicating that in addition to chronic and/or postprandial hyperglycemia, other pathogenic mechanisms must exist that trigger and maintain at least some of the symptoms of DPN. Identification of these factors is of critical importance for our understanding of both the natural history of pre-diabetic DPN and the pathogenesis of diabetic DPN in general<sup>[27,88]</sup>.

## INSULIN SIGNALING AND DPN

In the search for triggers of DPN other than hyperglycemia, it is important to note that successful reversion or postponing of DPN in clinical glucose control trials does not necessarily prove the glucose hypothesis<sup>[142]</sup>. Glucose metabolism is regulated by insulin *via* type B receptors (IR-B) abundantly expressed by liver, skeletal muscle and fat cells. Insulin receptors, however, are also expressed in central and peripheral nervous systems<sup>[143,144]</sup>. Furthermore, in PNS the highest densities of IRs are located on endothelial cells, paranodal loops of Schwann cells and medium and small size primary sensory neurons<sup>[143,144]</sup>. All these locations are strategically critical points of PNS function considering what is known about the pathogenic mechanisms of DPN. While the nervous system has mostly type A receptors (IR-A), the insulin affinities of these and IR-B receptors are similar ( $K_{0.5}$  is 3 to 6 ng/mL<sup>[145]</sup>) and well within the range of circulating concentrations of insulin (1 to 6 ng/mL<sup>[12-17]</sup>). Thus, it is very possible that correction of insulin levels in treatments for Type 1 diabetes or insulin-sensitizing therapy in cases of type 2 diabetes not only corrects glucose metabolism, but also has independent effects on the function of PNS. Serious consideration of this hypothesis is warranted, first because it provides an explanation for at least some failures of glycemic controls to reverse DPN, and second because it may explain the development of DPN in pre-diabetic patients.

### **Insulinopenia (Type 1 diabetes and pre-diabetes)**

As described in the Introduction, overt type 1 diabetes is preceded by a state of partial pancreatic damage and moderate insulinopenia in which insulin production is still satisfactory for blood glucose control<sup>[11]</sup>. The type 1 pre-diabetic state is probably short and little is known about neuropathy in these patients. The results of a recently completed follow-up to DCCT study of type 1 diabetic patients, however, has shown that regardless of the level of glycemic control, neuropathy is less prevalent in the group of patients that maintained intensive vs. conventional insulin therapy<sup>[146]</sup>. Further support for the

**Figure 8** Pain pressure thresholds are not correlated with hyperglycemia. Weight (A), blood glucose (B), nerve sorbitol (C) and pain pressure thresholds (D) in control, STZ-normoglycemic and hyperglycemic rats (white, grey and black columns respectively; 2 wk after injection of 65 mg/kg STZ).

possibility of a direct role of insulinopenia in DPN comes from experiments in the STZ-rat model of type 1 diabetes. It was demonstrated that local insulin application to the nerve prevents motor NCV slowing in STZ-hyperglycemic rats<sup>[147]</sup>. Similarly, systemic<sup>[136]</sup> or intrathecal<sup>[89]</sup> application of insulin can correct sensory and motor NCV in STZ-treated rats without having an effect on hyperglycemia. Finally, in our experiments in rats that were injected with STZ and developed moderate insulinopenia but not fasting hyperglycemia (Figure 8), pressure pain thresholds were decreased in proportion to the degree of insulinopenia, and low dose insulin-replacement therapy corrected this defect without changes in the systemic blood glucose level (Figure 9). Taken together these data suggest that at least some signs of neuropathy (slowing of NCV, pressure-evoked pain in rats) may indeed be triggered by insulinopenia with no relevance to the blood glucose level. Another notable aspect of these experiments is that correction of nerve conduction<sup>[89,136,147]</sup> and pain pressure thresholds (Figure 9) with insulin treatment could be achieved without changes in systemic blood glucose levels, leading to an important implication that the thresholds of “metabolic” and “neuropathic” effects of insulinopenia may differ.

To date, detailed information on the relation between insulin and nerve conduction is not available. However, comparison of better studied “dose-response” relationships between insulin, blood glucose and pain pressure thresholds (Figure 10A) allows speculation that in the rat, control of glucose metabolism may tolerate at least

five times lower insulin levels than does nerve function. Given that this difference was confirmed in both animals and humans, the outcome of these studies is of a great importance. This finding may explain the development of neuropathy in pre-diabetes and also suggests that neuropathy may start at stages preceding pre-diabetes, and some therapeutic interventions to correct insulin levels or insulin resistance (see next section) are warranted in pre-diabetic patients.

Differences in threshold concentrations of a ligand are usually determined by the differences in receptor properties. However, insulin affinities of IR-B and IR-A isoforms of the insulin receptor expressed in cells of organs responsible for glucose metabolism and in nerve tissue are too close to account for apparent differences in the concentrations of hormone required for maintaining normal blood glucose concentrations and normal pain pressure thresholds<sup>[145]</sup>. On the other hand, strong correlative relationships between insulin and pain pressure thresholds (Figure 9A) suggest a nearly direct link between insulin regulation and pressure pain mechanisms. The hypothesis of spare receptors<sup>[7,8,10]</sup> is the easiest way to explain this discrepancy. Thus as shown in Figure 10A, both metabolic and neuropathic effects of insulin may be described adequately within the concept of insulin binding with the same affinity ( $K_{0.5} = 1$  ng/mL) in nerve and in glucose controlling organs, if 65% of the receptor occupancy is needed to control nerve function, and only 10% of occupancy is required for glucose metabolism. Hill equations were used in this simulation; however, since the

**Figure 9** Insulin-dependence of pain pressure threshold in STZ-normoglycemic rats. Two weeks after injection of STZ pain pressure threshold of STZ-NG rats is decreased in proportion to the plasma insulin level ( $R = 0.97$ ; **A**). Insulin replacement initiated one week after STZ injection (horizontal bar in panel **B**) does not change PPT of control or hyperglycemic rats, but corrects it in STZ-normoglycemic animals (empty and filled circles, and filled triangles, respectively). Insulin replacement, does not affect blood glucose (**C**), but normalizes plasma insulin level (**D**) in STZ-NG rats. In **C** and **D** white, grey and black columns represent control, STZ-NG and STZ-HG rats, respectively.

purpose was merely to illustrate the potential possibility of the given scenario, parameters of the equations were adjusted by a trial and error approach and no attempt was made to optimize the parameters. Some alternatives to this scenario will be discussed in section 6.1 of this review.

### Insulin resistance

Prevalence of type 2 to type 1 diabetes is about 9 to 1 and most of the cases of human pre-diabetes are type 2 pre-diabetes or metabolic syndrome cases<sup>[24,125]</sup>. Over the long-term, insulin production is impaired in type 2 diabetes further increasing the incidence of DPN in this population by mechanisms described above. In a ten-year study of the natural history of type 2 diabetic patients, it was found that decreased serum insulin and increased blood glucose concentrations are independent predictors of DPN<sup>[148]</sup>. However, in early type 2 diabetes and pre-diabetes there is a compensatory hyperinsulinemia. Because of this hyperinsulinemia type 2 pre-diabetes usually spans a much longer period of time than does type 1 pre-diabetes. Thus, after 5 years only 20% to 35% of patients with impaired fasting glucose or impaired glucose tolerance develop overt hyperglycemia (see<sup>[70]</sup>). Despite this compensatory hyperinsulinemia, however, many type 2 pre-diabetic patients do develop DPN<sup>[125,126]</sup>. This latter observation

suggests that in terms of neuropathic outcome, insulin resistance and insulinopenia may be equivalent states. It also suggests that increased production of insulin may fail to compensate for decreased sensitivity of PNS to regulation by insulin.

Not much experimental data exists to verify the validity of either of these suggestions. In studies in normal human volunteers, warmth detection threshold correlated with insulin but not fasting or 2-h GTT glucose, leading the authors to suggest that insulin resistance may determine some sensory functions of PNS<sup>[149]</sup>. This is also supported by observations of decreased NCV<sup>[141]</sup> and pressure pain thresholds<sup>[86]</sup> and the authors' unpublished observations in the Zucker fatty rat model of type 2 pre-diabetes. However, whether it is possible that hyperinsulinemia is effective in regulating glucose metabolism but fails to compensate for nerve insulin resistance is at this time absolutely not known. Furthermore, it is unknown if this mechanism plays a role in DPN associated with type 2 diabetes. In theory such a possibility does exist, and Figure 10B illustrates the scenario that we believe provides a useful working hypothesis for future experiments. Using "dose-response" relations as a starting point, shown in Figure 10A, the insulin resistant state that leads to type 2 diabetes may be modeled as a decrease in affinity of

**Figure 10** Putative "insulin-glucose metabolism" and "insulin-nerve function" relationships in normal and insulin-resistant rats. In **A**: Normal rats: Empty circles represent fasting glucose and filled circles pain pressure thresholds measured in control, STZ-NG and STZ-HG rats, pooled together and normalized to show relative changes of these parameter between control and diabetic animals. The data were fitted by Hill curves calculated based on the assumption that insulin binds to the receptor with an affinity of 1 ng/mL (dotted curve) and 10% and 65% occupancy of these receptors is required for maximum metabolic (intersection with dashed curve) and nerve (intersection with solid curve) effect of the hormone, respectively. In **B**: Insulin-Resistant Rats: Insulin resistant state was simulated by increasing  $K_{0.5}$  of insulin binding to the receptor to 20 ng/mL. Points of intersections of the dotted curve with the dashed and solid curves recalculated with the new  $K_{0.5}$  parameter show (arrows and labels) that maintaining glucose metabolism now requires about 6 ng/mL of plasma insulin, and nerve function requires at least 28 ng/mL of the hormone.

IR from 1 to 20 ng/mL, which leads to proportional rightward shifts of insulin-glucose metabolism and insulin-nerve function relationships. If the requirements of 10% and 65% occupancy of IR remain unchanged, maintenance of normal glucose metabolism under these new conditions will need about 6 ng/mL of circulating insulin and nearly 30 ng/mL insulin concentration will be the minimum needed to maintain normal PNS function. The calculated 6 ng/mL insulin concentration is in the range of insulin concentrations measured in Zucker fatty rats (5.1 to 11.7 ng/mL; model of compensated insulin resistance<sup>[150-152]</sup>). These latter numbers are, however, significantly lower than predicted by the model insulin concentration needed to maintain nerve function. Therefore, it may be speculated that the "set-point" or natural goal of compensatory hyperinsulinemia is merely to correct glucose metabolism, which is vitally important for the organism, with no concern about the less significant problem of nerve function.

### Cellular mechanisms

Thus, while the connection remains speculative, the data above suggest that impairment of insulin signaling in PNS (because of decreased insulin production, insulin

resistance or both) may be an important factor in the pathogenesis of DPN. Further studies are needed to confirm this hypothesis and further studies are also needed to understand the cellular mechanisms of insulin action in PNS.

Glucose is a major fuel for neurons of peripheral and central nervous systems. However, unlike that in major target tissues of insulin regulation, uptake of glucose in nervous tissue is an insulin-independent process. Therefore, the simple explanation of the neural effects of insulin to regulate the energy supply does not appear to be applicable. There should be some other role of IR in the nervous system. In the CNS, these receptors are involved in the insulin control of feeding behavior, reproductive and cognitive functions and neuromodulation<sup>[27,153]</sup>. Insulin also clearly has neurotrophic functions. It stimulates neurite outgrowth, is involved in peripheral nerve regeneration and is required for survival of sympathetic neurons (see<sup>[27]</sup>). These effects are likely very important for regeneration, which is suppressed in long-term DPN. For short term diabetes, the possibility of insulin regulation of axon-glia relationships, vascular permeability, and function of nociceptive primary afferent neurons<sup>[143,144]</sup> may be of importance. The possibility of a selective acute effect of

insulin on endoneurial blood flow (decrease) was also demonstrated by experiments in normal rats<sup>[154]</sup>.

Note also that the negative cellular effects of hyperglycemia and insufficiency of insulin signaling seem to converge at some point. Pain pressure thresholds are decreased in rat models of local hyperglycemia with a time course and to a degree that is very similar to those in STZ-normoglycemic rats<sup>[101]</sup>. Since many studies support oxidative/nitrosative stress as a central event of hyperglycemic impairment, it is reasonable to suggest that oxidative/nitrosative stress can interfere with insulin regulation in some or all of the hyperglycemia-induced steps of the pathogenic cascade depicted in Figure 6. Insulin directly regulates inner mitochondrial membrane potentials and may affect oxidative phosphorylation<sup>[136]</sup>. Insulin also suppresses expression of NADPH oxidase<sup>[155]</sup> and controls expression of  $\text{Nf-}\kappa\text{B}$  and associated inflammatory reactions<sup>[155,156]</sup>. In fact, the anti-inflammatory effects of insulin have been known since the discovery of the benefits of insulin therapy in systemic inflammatory responses to trauma or bacterial infection<sup>[157]</sup>. Insulin signaling also was shown to be linked to the regulation of Na, K-ATPase<sup>[158,159]</sup> and endothelial NO production<sup>[158,160]</sup>. These data suggest that insulinopenia does have the potential to produce the same or very similar neuropathic effects as were attributed previously solely to hyperglycemia.

## OTHER FACTORS OF SIGNIFICANCE

While the above outlined insulin-signaling hypothesis of DPN appears compelling, it will certainly be corrected and modified in many of its segments to conform to the results of future studies. It can also be stated here, without reservation, that no complete picture of the pathogenesis of DPN will be created unless the roles of insulin-like growth factors and C-peptide are considered in addition to hyperglycemia and insulin signaling in PNS<sup>[142]</sup>.

### Insulin-like growth factors (IGFs)

IGFs are produced in the kidney, spinal cord, skeletal muscle and peripheral glia. IGFs possess multiple neurotrophic functions, including control of neuronal survival, neurite outgrowth and regeneration, and expression of genes encoding axonal cytoskeletal proteins (tubulins and neurofilaments)<sup>[142,161-166]</sup>. Interestingly, IGF-1 appears to be involved in the regulation of resistance to oxidative stress<sup>[167]</sup>. IGFs primarily act *via* specific receptors, but since IGFs are present in the circulation in a 100-fold excess compared to insulin, they may also bind to and activate IR, mimicking some but not all effects of insulin<sup>[168,145,165]</sup>. It might be important in this regard that, in peripheral nerve, IGF-I receptors are co-localized with IR in sensory neurons<sup>[169,170]</sup> and Schwann cells<sup>[171]</sup> and a large fraction of them are likely hybrids composed of protein subunits of both IR-A and IGF-I receptors<sup>[143,169]</sup>. These hybrid IR/IGF receptors have substantially higher affinity to IGF-I than to insulin<sup>[172,173]</sup>. However, even when present in physiological concentrations, insulin may still bind to and activate some portion of hybrid as well

as homomeric IGF-I receptors<sup>[161,174]</sup>. In addition, IGF-I may act by suppressing growth hormone and improving insulin sensitivity and insulin production in type 1 and type 2 diabetic subjects<sup>[174-178]</sup>. Insulin on the other hand, may modify kidney production of IGFs, and *via* regulation of IGF binding proteins, it may control the activity of circulating IGFs<sup>[161,175,176]</sup>. Whether, any of these multiple mechanisms participate in the apparent dissociation of the metabolic and neuropathic effects of insulinopenia remains to be determined.

Abnormal expression and levels of circulating IGFs and/or changes in expression of receptors for IGF were measured in diabetic human subjects<sup>[174]</sup>, in STZ-rats (see<sup>[179-181]</sup>), and in the type 2 diabetes Zucker diabetic fatty (ZDF) rat model<sup>[86]</sup>. Furthermore, in obese Zucker rats, both insulin- and IGF-I resistances were shown to develop and mediate impaired glucose tolerance in this model of pre-diabetes<sup>[182]</sup>. Thus potentially, *via* impairment of protein synthesis, insufficiency of IGFs may add to the pathogenesis of regenerative capacity, neurodegeneration and irreversible stages of DPN<sup>[142]</sup>. This suggestion is supported by observations of recovery of NCV and reversion of atrophy of myelinated sensory axons in the sural nerve of STZ rats treated with intrathecal IGF-I<sup>[89]</sup>. In addition, the defect in IGFs or IGF-receptor expression could also add to the pathogenesis of early symptoms of DPN either directly or through modulation of insulin production or nerve sensitivity to insulin. Indeed, down-regulation of IGF-I receptors, which is observed in nerves of STZ-diabetic rats, occurs comparatively early, within 1 week after the onset of hyperglycemia<sup>[181]</sup>. Furthermore, continuous subcutaneous infusion of IGF- II was shown to recover pain pressure thresholds to a normal level after 6 wk of diabetes in the ZDF rat model<sup>[86]</sup>. The latter observation is interesting because, in STZ-diabetic rats, a similar magnitude and early decrease in pain pressure thresholds seems to result from insulinopenia (see previous section). Affinity of IGF- II binding to brain type insulin receptors or to IGF-I-R is two-three times lower than that of respective natural ligands<sup>[145]</sup>. Therefore, the effect of IGF- II on mechanical hyperalgesia may still be explained within the framework of our insulin signaling hypothesis of early neuropathy. However, the possibility of a more complex regulation of pain pressure thresholds cannot be excluded. It is important also that in all the examples above the effects of treatments with IGFs occurred with no measurable changes in the glycemic status of studied animals; once again suggesting that the pathogenesis of DPN is multifactorial.

### C-peptide

C-peptide is a segment of the proinsulin molecule sliced off to form insulin. Acting through both its own receptors and modulating activity of insulin receptors, C-peptide produces multiple insulin and IGF-like effects<sup>[27,183,184]</sup>. C-peptide also enhances autophosphorylation of IR and effects of insulin, and treatment with C-peptide reverses decreased expression of IGF-I, NGF and neurotrophin-3 receptors in type 1 spontaneously diabetic rats<sup>[27,183,185]</sup>. Considering these effects and the fact that

**Figure 11** Modified scheme of pathogenesis of diffuse diabetic neuropathy with inclusion of insulin signaling. According to this view, the disease process starts before impairment of glucose metabolism becomes apparent. Derangement of insulin signaling in PNS triggers and maintains the neuropathy at this stage. Postprandial and chronic hyperglycemia is not the least important factor of DPN, but they become involved at relatively advanced stages of DPN. C-peptide and IGFs insufficiencies represent another important set of pathogenic mechanisms; however, the role of these mechanisms in early DPN remains undetermined.

C-peptide is secreted in equimolar concentrations with insulin, it can be concluded that C-peptide insufficiency may have an important role in the pathogenesis of type 1 diabetes<sup>[75,183,184]</sup>. In agreement with this implication, in patients with recently diagnosed type 1 diabetes, C-peptide treatment was shown to correct sensory NCV and vibration perception<sup>[186]</sup>. C-peptide treatment also corrects skin microcirculation in diabetic patients<sup>[187]</sup> and endoneurial blood flow and NCV slowing<sup>[75]</sup>, thermal hyperalgesia, atrophy and degeneration of C-fibers<sup>[185]</sup> in BB/Wor type 1 diabetes rat model.

As expected, no differences in plasma C-peptide levels were found in pre-diabetic patients and patients with type 2 diabetes of short duration (less than 5 years from diagnosis), even though the number and severity of the signs and symptoms of DPN differed substantially between these groups<sup>[128]</sup>. What is less clear in the same study is a lack of detectable deficiency of C-peptide in advanced type 2 diabetes patients (more than 5 years) who could have been expected to start developing insulinopenia. In general, however, multiple questions remain to be resolved in relation to C-peptide and its role and mechanisms of action in DPN. Similar to conditions of chronic or postprandial hyperglycemia or impaired insulin- or IGF-signaling, C-peptide deficiency appears to affect activity of Na,K-ATPase, NO production and neurotrophism, but the C-peptide mediated regulation does not appear to depend on oxidative stress, which is apparently important in the pathogenesis of these conditions<sup>[75,188]</sup>. It is also not clear whether any of the symptoms may be directly attributed to C-peptide insufficiency in DPN. Endoneurial blood flow, NCV and heat nociception appear to be the foremost candidates<sup>[186,187]</sup>, but antioxidant treatments and insulin replacement correct these abnormalities in STZ rats at least as efficiently as does C-peptide replacement in the BB/Wor rat model of type 1 diabetes.

## CONCLUSION

DPN is a frequent and troublesome complication of diabetes mellitus. Diabetes manifests in a case-specific variety of signs and symptoms, and associates with complex biochemical, functional and structural abnormalities of the peripheral nervous system. While the obvious hyperglycemia present in diabetes can explain the development of these abnormalities, data suggest that other factors may also contribute. We have discussed the evidence for insu-

linopenia in type 1 diabetes or insulin resistance in type 2 diabetes as causal factors in the development of DPN. We have suggested that these two cases actually represent a single cause of impaired insulin signaling. Considering the role of insulin signaling in DPN more completely explains the changes in nerve function in pre-diabetic or early diabetic patients and animal models. This does not preclude hyperglycemia also as a factor in DPN, but allows a more complete picture of the disease process (Figure 11). In addition to insulin signaling, some evidence also exists for a role of IGF and C-peptide in mediating DPN. The pathogenesis of DPN is obviously multifactorial, and despite long-standing efforts, remains poorly understood. This work has also suggested that insulin signaling has effects that occur with different levels of receptor occupancy. Thus insulin action on nerve function requires a higher level of receptor occupancy than does insulin action on glycemic control. This could be explained by different levels of receptor coupling to second messenger signaling pathways in nerve versus liver or muscle. Future studies should elucidate these mechanisms so that a clearer picture of DPN can be obtained, especially in pre-diabetes where early detection could improve therapeutic outcomes.

## Abstract

Using animal mesentery with intravital optical microscopy is a well-established experimental model for studying blood and lymph microcirculation *in vivo*. Recent advances in cell biology and optical techniques provide the basis for extending this model for new applications, which should generate significantly improved experimental data. This review summarizes the achievements in this specific area, including *in vivo* label-free blood and lymph photothermal flow cytometry, super-sensitive fluorescence image cytometry, light scattering and speckle flow cytometry, microvessel dynamic microscopy, infrared (IR) angiography, and high-speed imaging of individual cells in fast flow. The capabilities of these techniques, using the rat mesentery model, were demonstrated in various studies; e.g., real-time quantitative detection of circulating and migrating individual blood and cancer cells, studies on vascular dynamics with a focus on lymphatics under normal conditions and under different interventions (e.g. lasers, drugs, nicotine), assessment of lymphatic disturbances from experimental lymphedema, monitoring cell traffic between blood and lymph systems, and high-speed imaging of cell transient deformability in flow. In particular, the obtained results demonstrated that individual cell transportation in living organisms depends on cell type (e.g., normal blood or leukemic cells), the cell's functional state (e.g., live, apoptotic, or necrotic), and the functional status of the organism. Possible future applications, including *in vivo* early diagnosis and prevention of disease, monitoring immune response and apoptosis, chemo- and radio-sensitivity tests, and drug screening, are also discussed.

## INTRODUCTION

It is difficult to access the gastrointestinal tract with powerful intravital high-resolution optical microscopy. One unique exception is the mesentery, which has as its main functions maintaining digestive organs in their proper positions while simultaneously providing routes for nerves and for blood and lymph vessels. To date, small animal mesentery is a well-established experimental model for studying blood and lymph microcirculation *in vivo*.

Historically, the first microscopic observation of the mesenteric lymph microvessels of a guinea pig was performed by Arnold Heller in 1869<sup>[1]</sup>. During the first 30-50 years of the 20th century, extensive *in vivo* studies of mesenteric microcirculation were undertaken<sup>[2-4]</sup>. In particular, the basics of capillary circulation were first studied in rat mesentery<sup>[3]</sup>. Later, this model was successfully used to study the fundamentals of the microvascular physiology of blood (i.e., microvascular rheology, hemodynamics, vasomotion, hematocrit, permeability of the vascular wall, flow velocity) and lymph (i.e., phasic contractile activity, flow velocity, and the diameter of small lymphatics) systems<sup>[5-26]</sup>. Using rat mesentery, Sekizuka *et al*<sup>[24]</sup> performed real-time videoanalysis of contractile lymphatic motion in rat mesentery and determined quantitatively the dynamics of the frequency of these contractions. Benoit *et al*<sup>[22]</sup> and Dixon *et al*<sup>[26]</sup> obtained basic data about relationships among lymphatic contractile activity, vessel diameter, and lymph flow velocity<sup>[23]</sup>. In particular, they established the correlation between cyclic fluctuations of lymph velocity

and vessel wall motion during the phasic contraction. Most of the results related to microvessel diameter and contractile activity were obtained with conventional transmission optical microscopy alone.

The mesentery model has also been used to study the effects of various hormones, mediators, drugs, and other environmental impacts on microcirculation, including the influence of histamine, norepinephrine, dopamine, dobutamine, PO<sub>2</sub>, substance P, L-NAME, methylene blue, leukotrienes, histamine, platelet activating factor, temperature, low-power laser radiation, X-radiation, and others<sup>[3,20,27-34]</sup>. In particular, this model was used in the first study of the effects of nitric oxide (NO) on lymph microvessels *in vivo*. Shirasawa *et al.*<sup>[35]</sup> showed the influence of a NO synthase inhibitor on lymphatic diameter and contractile activity, which was reversed after applying an endogenous NO donor (L-arginine). This model has also been employed to study microcirculation disturbances in experimental models of diseases such as diabetes, ischemia, hemorrhage, shock, inflammation, tumor, edema, and others<sup>[2,4,13,21,22,36,37]</sup>.

Recent discoveries in cell biology (e.g., identification of the genes, such as VEGF-C and VEGF-D, expressed by endothelium or endothelial growth factors for lymphatics), along with advances in optical techniques (e.g., lasers, high-speed digital cameras, powerful software) have increased interest in this model and its capabilities for studying the fundamentals of blood and lymph microcirculation, including its potential for the molecular imaging of individual cells *in vivo*<sup>[38-40]</sup>. Nevertheless, some methods used in most experiments have limitations. For example, the majority of the results about platelets [e.g., platelet thrombosis, or their interaction with white blood cells (WBCs) or vessel walls], red blood cells (RBCs), and tumor cells were obtained with what are currently the most powerful techniques, such as fluorescent labeling<sup>[12,13,21,41-43]</sup>. However, despite significant progress in the development of new labels<sup>[44-46]</sup> (e.g., quantum dots, fluorescent-specific antibodies<sup>[47]</sup>), these techniques *in vivo* (as in many other experiments *in vitro*) are potentially subject to photobleaching (despite the short exposure time), or cytotoxicity. Moreover, growing evidence shows that fluorescence labeling may seriously distort genuine cell properties, even without evident toxicity, and cellular physiologic functions. For example, acridine orange and Rhodamine 6G, traditional fluorescent dyes for leukocytes, have been demonstrated to be mutagenic and carcinogenic, and possibly cause phototoxic effects<sup>[48-51]</sup>. Fluorescence imaging of lymphatics by injecting fluorescein isothiocyanate (FITC)-dextran into the interstitial space led to elevated interstitial pressure and altered lymph viscosity<sup>[52]</sup>. These findings may raise some concern about the kinetics of labeled cells in flow, particularly about the main cause and the real rate of cell elimination from circulation, the actual properties of apoptotic or cancer cells, or the strong influence of the tags due to phagocytosis, or the interaction of tags with other cells<sup>[53-55]</sup>. All these concerns gain importance in *in vivo* studies in humans, and add to interest in developing label-free imaging. The mesentery model with advanced optical technique can provide a good quality of label-free

imaging of moving cells.

In mesenteric microvessels, the imaging of flowing cells *in vivo* without any staining or labeling was realized mainly with transmission microscopy for slow moving, rolling (30-70  $\mu\text{m/s}$ ), and adhesive WBCs<sup>[10,12,14,15,17]</sup>. The monitoring of single RBCs and their small aggregates has usually been performed in two modes: 1) in selected microvessels (small venules or capillaries) with slow flow using a frame rate of 20-30 frames per second (fps), or 2) using a short time-exposure mode ( $\sim 0.1$ -1 ms) by which only single images of fast-moving cells can be captured<sup>[56-58]</sup>. Only a few studies demonstrated relatively high-speed imaging for measuring flow velocity in the range of 750-2500 fps in blood flow, and approximately 500 fps in lymph flow<sup>[19,26,59]</sup>. Due to motion distortion, these speeds are not quite fast enough to image shape and subcellular structures of individual fast-moving cells. For example, imaging in blood microvessels, with typical flow velocities of 5-10 mm/s, requires imaging speed ranges of 5000-10 000 fps<sup>[58]</sup>. Additionally, simultaneous high-speed imaging with high optical resolution of individual moving cells has not yet been developed *in vivo*. This is crucial for *in vivo* flow cytometry (FC).

In this review, which is based on our 15 years of experience in this area, we summarize both our previous data, which are scattered or presented in difficult-to-access publications, as well as our latest achievements in *in vivo* label-free FC, high-speed imaging, and vessel dynamics, focusing on real-time monitoring of circulating and migrating blood and cancer cells in blood and lymph systems, and especially on our studies of microlymphatic function in normal and pathological states and under the impact of different therapeutic interventions.

## FEATURES OF THE LYMPHATIC SYSTEM

Unlike the circular blood network, the lymphatic vasculature is an open-ended system that transports lymph from tissue to the blood system<sup>[60,61]</sup>. The initial lymphatics collect fluid and cells from the interstitial space of tissue and form the afferent (prenodal) lymph, which is transported through valvular prenodal lymphatics to the lymph nodes. In the lymph nodes, some fluid, debris, and pathogens are removed from lymph, while cells (mainly lymphocytes) are added to lymph. Lymph leaves the lymph node by efferent collecting lymphatics, and passes through the thoracic duct and enters into the inferior vena cava. During this process, some cells and proteins can re-circulate in the blood system-tissue-lymph system-blood system pathway. In contrast to blood, which is moved by one motor, the heart, the motion of lymph is primarily maintained by rhythmic contractions of vessel walls, called phasic contractions. Such contractions are initiated by pacemakers along vessels. Additionally, lymph vessels have well-developed bicuspid funnel-shaped valves (collagen sheets with filaments covered on both sides by endothelium), which are dispersed at regular intervals along the vessel and divide it into functional units-lymphangions (the fragment of the lymph vessel between input and output valves). The valves can block lymphatic lumen to prevent (at least partially) backflow and contribute to a

unidirectional flow. Some external forces, such as muscle contractions, respiratory movements, and intestinal peristalsis, can also maintain lymph motion. In general, lymph flow is turbulent, has an oscillating character, and is slower than blood motion. The lymphatics in an entire living organism have multi-level regulation, including the central nervous system, hormones, and local substances such as mediators, pH, and Ca ions<sup>[1,24,26,29,60-69]</sup>.

Compared to the well-studied blood system, our understanding of lymph function is limited; however, rat mesentery, with its unique structure that we describe here, may help to fill knowledge gaps in this under-explored system. Below, we present a brief comparison of different animal models emphasizing the advantage of rat mesentery for monitoring single-cell transport under normal and pathologic conditions.

## ANIMAL MODELS

Microcirculation has been successfully studied using optical microscopy in various animal models (e.g., rabbit or mouse ear, hamster or mouse dorsal skin-flap window or skin-fold chamber, or open cremaster muscle)<sup>[52-55,59,63,70-73]</sup>. The use of these models for high-resolution imaging of individual flowing or static cells may be somewhat limited because of significant light scattering from surrounding tissue (e.g., skin or muscles) and/or the relatively deep location of vessels below the skin. Image quality in these

particular models can be improved in two ways: (1) by using thin hairless skin (e.g. ear of nude mouse ~270 μm thick), or (2) by decreasing light scattering using a recently developed optical clearing method combined with spectral selection (e.g. use a “green” filter to increase blood vessel contrast)<sup>[74-77]</sup>.

Figure 1 illustrates our few attempts using these models and transmission microscopy to obtain high-resolution images of individual cells in blood flow without staining. In particular, we compared images of blood microvessels of ordinary (i.e. with hair, Figure 1A-D) and nude (i.e., hairless, Figure 1E-H) ear skin of rats and mice, and with mouse dorsal skin-fold chamber (Figure 1I-L). The best results were obtained with the nude mouse ear model in combination with optical clearing and a spectral filter in the range of the maximum absorption of hemoglobin, around 570-580 nm (Figure 1F-H). The dorsal skin-fold model provided a poorer quality image of an individual cell as compared with the RBC images of the skin-fold chamber (Figure 1L) and with RBC images of nude mouse ear (Figure 1H), and required an invasive procedure. In general, even after many improvements, all of these models provide monitoring of individual cells only in selected capillaries with single-file flow (RBCs travel in one line with the same velocity). In addition, the images of colorless lymphatics in skin can be obtained mainly with additional labeling with fluorescent or absorbing contrast agents (e.g. FITC-dextran and dyes such as isosulfan blue,

**Figure 2** Imaging of lymph vessels using contrast agents in different rat models. Lymphatics labeled by a 1% solution of lymphazurin in muscles of (A) abdomen wall, (B) tongue, and (C) pad.

lymphazurin, and others; Figure 2)<sup>[52,78-80]</sup>. However, these procedures do not provide information on cell dynamics in flow or valve functioning.

In general, the best targets for conventional transmission microscopy are relatively transparent animal structures such as zebrafish, and vascular nets of the hamster cheek pouch<sup>[63,81-84]</sup>; however, these models are not ideal for studying lymph or blood vessels. The zebrafish (tropical fish) model is very different from human anatomy and physiology, and while the hamster cheek pouch model is good for visualizing blood microvessels, the lymphatics in the hamster cheek pouch are not well developed, preventing us from simultaneously studying blood and lymph systems, if desired.

To date, the best optical images of both lymph and blood microvessels have been obtained in the mesentery of small cold-blooded (frog) and mammalian (mouse, cat, rabbit, guinea pig, and rat) animals. However, the capillaries of frog mesenteric microvessels are relatively larger in diameter and their sensitivity to environmental impacts is markedly less than that of mammals<sup>[3]</sup>. Of the mammalian models, the rat is an excellent model in terms of size, physiology, and pharmacokinetics for broadening medical applications, including single-cell diagnostics<sup>[85-88]</sup>. Additionally, some rat models are able to mimic select human diseases. This is particularly important for understanding common mechanisms of microvessel physiology and pathology (edema, inflammation, tumor), as well as for studying specific features of mesenteric microvasculature under normal conditions (to maintain homeostasis in the abdominal space) and in mesentery-related diseases (e.g. mesothelioma, sclerosing mesenteritis, panniculitis, acute mesenteric vein thrombosis, tumor metastasis).

Mesentery consists of thin (8-15  $\mu\text{m}$ ), relatively transparent, duplex connective tissue, which is divided into triangular, relatively transparent windows by arteries (400-500  $\mu\text{m}$  in diameter) and veins (600-700  $\mu\text{m}$  in diameter) obscured by adipose tissue (Figure 3D)<sup>[3,89-91]</sup>. The smaller branches of these vessels leave the adipose regions and pass into the microvascular net (Figure 3E), which spreads out into transparent areas. On the venous side of the capillaries, there is an accumulation of initial lymphatics (Figure 3E-G). These initial lymphatics then pass into larger valvular lymphatics, which are located

parallel with and very close to the venules (Figure 3E, H).

Thus, rat mesentery triangulars contains all the typical components of a microvascular net: a blood microvessel network including arterioles (diameter, 7-60  $\mu\text{m}$ ; velocity, 5-10 mm/s), venules (10-70  $\mu\text{m}$ ; 0.5-3 mm/s), and capillaries (5-9  $\mu\text{m}$ ; 0.1-1.4 mm/s), as well as well-developed microlymphatic vessels (diameter, 50-250  $\mu\text{m}$ ; velocity 0-7 mm/s) and clearly distinguishable initial lymphatics with migrating cells<sup>[3,24,26,58,66,92-94]</sup>. Figure 3 shows typical images obtained with the optical schematics portrayed in Figure 4.

The specific functional features of mesenteric vasculature involve a considerable gradient of venular permeability, a preponderance of fluid filtration, and a relatively low proportion (~15%) of re-absorption of interstitial fluid by capillaries<sup>[95,96]</sup>. Additionally, rat mesenteric blood microvascular is characterized by many communications between the capillary loops arising from neighboring arterioles with well-developed arterio-venous anastomoses, which shunt blood from arteriola to venula<sup>[3]</sup>. This structure can facilitate adaptation and maintenance of blood flow under different conditions.

For medical imaging, the main advantage of mesenteric microcirculation is that a single layer of blood and well-developed lymph microvessels lies in one plane (Figure 4B), which facilitates continuous observation of all components of the microvascular network (from arteriola to venula, together with lymph microvessels, Figure 3H), as well as label-free, high-resolution imaging of individual cells with almost ideal optical conditions (Figure 3I-N). Light is slightly attenuated, mainly in the relatively thin vessel wall, without any influence from other tissues, as it is in other models. The refractive indexes in the typical spectral range of 400-700 nm used for studies are lower for rat mesenteric tissue ( $n = 1.38$ ) than for rat skin ( $n = 1.40$ -1.42) and, especially, for the epidermis ( $n = 1.55$ ) for humans; thus, it is close to that of water ( $n = 1.33$ )<sup>[97]</sup>. As a result, these optical and geometric features significantly reduce unwanted scattered light, allowing the use of a microscopic objective with a high numerical aperture (up to 1.4) and high magnification (60 $\times$  - 100 $\times$ ). Optical reflectance spectra from lymph vessels obtained *in vivo* with a fiber optic spectrometer (Model 1000, Ocean Optics, Inc., USA) demonstrated slight spectral features and time-dependence within 1-2 s (Figure 5), which can

**Figure 3** *In vivo* monitoring of microcirculation using rat mesentery. **A, B:** Sections of a single lymph node at different magnifications (4 × and 100 ×, respectively); **C:** liver section (10 ×); **D:** section of intestine with mesentery; **E:** schematic of typical tissue microvascular unit; **F, G:** initial lymphatic (4 × and 100 ×); **H:** section of mesenteric tissue with valvular lymph vessel and surrounding blood vessels (10 ×); **I:** high-resolution imaging of single WBCs and RBCs, as well as their aggregates in lymph flow (100 ×); **J:** valve tip with fast-flowing cells (100 ×); **K:** transmission, photothermal, and fluorescence images of individual WBC, RBC, and K562 leukemic cell in lymph flow; **L:** capillary at different magnifications, (left) high-resolution images of RBCs, platelets, and endothelial cells (EC) in capillary wall (100 ×) and (right) parachute-like RBCs at low magnification (10 ×); **M:** rolling WBC in venula (100 ×, 10 ×); **N:** four sequential high-resolution images of RBC shapes in fast arteriolar flow (velocity of 5 mm/s; 40 ×); **O:** high-resolution images of adipocyte, mast cell, and RBCs in the interstitial space (100 ×).

**Figure 4** Integrated, multispectral FC *in vivo*. **A:** Typical transmission image of rat mesentery segment with lymph and blood microvessels; **B:** Schematic of the mesentery cross-section.

be explained by specific lymph flow oscillations<sup>[98]</sup>. An additional advantage of the mesenteric model is the good penetration of the reagents into the mesenteric lining. Thus, the responses of the microvascular network to different environmental impacts can be studied relatively easily using a simple topical application.

The well-developed procedure for preparing rat mesentery for studying microcirculation include anesthetizing the rat (ketamine/xylazine, 50/10 mg/kg, i.m.), followed by a laparotomy by mid-abdominal incision (~1 cm), gently exteriorizing the intestinal loop with mesentery from the abdomen and positioning it on a customized thermostabilizing microscope stage, which maintains the body temperature at approximately 37.7°C [2,3,22-28,35,58,66,94]. The mesentery is bathed with a constant diffusion of warm Ringer's solution with a phosphate buffer and 1% bovine serum albumin (37°C, pH 7.4). In principle, these procedures may introduce some limitations and artifacts related to the anesthesia, the minimal but invasive surgical intervention, and periodic small vibrations of the mesentery due to intestinal motion<sup>[19,99]</sup>. However, according to experimental data gathered during at least 2-3 h of acute observation after microsurgery, these procedures do not produce marked changes in microvessel function (diameter, phasic activity, valve function, lymph flow) or in metabolic or respiratory parameters. Furthermore, the short timeframe during which the rapidly circulating cells are in the microvessels of the exposed mesenteric area significantly reduces the influence of this exposure on the properties of the flowing cells. Additionally, to decrease the effects of the surgical manipulations and to stabilize the microvascular parameters, the monitoring of cells in blood and lymph flow begins approximately 15 min after the laparotomy<sup>[93]</sup>. Coating the intestinal loop with oxygen-impermeable plastic foil helps maintain stable physiological

**Figure 5** Time-resolved reflection spectra from the same point on the lymphatic vessel (D = 128  $\mu\text{m}$ ) at different times.

parameters for up to 5 h<sup>[100]</sup>. Our data also demonstrate that it is possible to repeat the surgical procedure to periodically monitor the same microcirculation area during the development of chronic pathology, even over a 2-mo timeframe<sup>[101]</sup>. To exclude the influence of microsurgery itself on the microcirculation, the data from experimental groups were usually compared with those from the corresponding control group, which undergo a mid-abdominal microincision without any other interventions.

In general, based upon our experience and the experiences of other groups, this easy-to-access mesentery microvessel model, which has significant features and advantages (see above) with only a few minor limitations, is a very promising vehicle for real-time monitoring, with the highest optical resolution, of individual static, migrating, and circulating cells (e.g. WBCs, RBCs, cancer cells, and

many others). Such a model is essential for studying immune function and the transport of proteins, cells, and liquid between the blood and lymph systems under normal and pathologic (lymphedema, metastasis, and many other lymph-related diseases) states.

## INTEGRATED IMAGING SYSTEM

Recent progress in optical techniques enabled the development of a multi-module, multi-functional experimental system that integrates transmission digital microscopy (TDM), a photothermal (PT) method, a highly sensitive fluorescent and speckle technique with advanced charge-coupled device (CCD) or complementary metal oxide semiconductor (CMOS) cameras (Figure 4). The primary application of this system was for *in vivo* FC. Indeed, although *in vitro* FC is a powerful, established diagnostic method<sup>[102]</sup>, only an *in vivo* study can assess physiologic and pathologic processes involving cell metabolism and cell-cell interactions (e.g., adhesion, aggregation, rolling effects, migration through vessel walls) in the real, complex environment of living organisms<sup>[53-55,84,99,103]</sup>. Further, invasive isolation of cells from their native environment and their processing may not only introduce artifacts, but also make it impossible to examine the same cell population over long time periods. Adaptation of FC for *in vivo* studies required overcoming problems related to light scattering by vessel walls and surrounding tissues, fluctuation of cell velocity, cell position in a vessel, and precautions with labeling procedures<sup>[53,54]</sup>.

### TDM module

TDM was built on the technical platform of an upright Olympus BX-51 microscope and provides the following functions: (1) imaging of relatively large structures such as lymph and blood microvessels with relatively low magnification ( $4 \times$  -  $10 \times$ , Figure 3H); (2) quantitative dynamic evaluation of blood and lymph microvessel diameter, parameters of lymphatic phasic contractions and valve activity, and cell concentration in flow; (3) determination of cell velocity in lymph flow by video-recording cell movement [so-called particle image velocimetry (PIV)];<sup>[18,19]</sup> (4) navigation of the pulse laser beams on the desired area of the mesentery in other optical methods; and (5) single-cell identification at high magnification ( $40 \times$ ,  $60 \times$ , and  $100 \times$ , water immersion)<sup>[58,94,104]</sup>. In particular, the mesentery model provides a unique opportunity to simultaneously image *in vivo*, with the highest optical resolution ( $\sim 300$  nm), individual cells in blood microvessels (Figure 3L and M) and small lymphatics (Figure 3F, G, I-K), tissue interstitium (Figure 3O), and lymph nodes (Figure 3A and B) located in the root of the mesentery and even in the liver.

The images were recorded with several digital cameras: a black-and-white Cohu 2122 and a color Nikon DXM1200, with speeds up to 25 fps and a minimal exposure time of 0.04 s. These speeds were sufficient to image relatively slow-moving individual cells, such as rolling leukocytes ( $30$ - $70$   $\mu\text{m/s}$ ), in blood flow (Figure 3M). We also used a highly sensitive CCD camera (Cascade

650, Photometrics) with speed of up to 500 fps and with a minimal exposure time of 0.1 ms. A high-speed CMOS camera (model MV-D1024-160-CL8; Photonfocus, Switzerland), with speeds of 10 000 fps for an area of  $128 \times 128$  pixels and 39 000 fps for an area of  $128 \times 16$  pixels, provided high-resolution imaging of fast-moving RBCs in blood flow ( $2$ - $10$  mm/s in arterioles and large venules, Figure 3N) and WBCs in valvular lymphatics (ranging from 0 to 7 mm/s). Scion Image (Scion Corp.), Nikon software (ACT-1), and WinX/32 V2.5.18.1 (Roper Scientific) were used for processing, capturing, measuring, and editing images of the moving cells.

Using TDM in the bright-field mode, the combination of light absorption and scattering effects on cells made it possible to visualize and identify most blood cells without conventional labeling and vital staining. In particular, due to relatively strong light absorption by RBCs, these single cells in flow appeared mostly as dark objects in the trans-illumination mode, while weakly absorbing WBCs and platelets appeared either as light objects (e.g., in the presence of many more strongly absorbing RBCs in blood flow or with dominant scattering effects) or, in contrast, as slightly dark objects (e.g., in the transparent plasma without RBCs). In the "packed" flow, RBCs sometimes exhibited bright margins or were seen as light objects due to multiple scattering effects. This is because the light, during propagation through many other RBCs and before reaching the plane of focus, was significantly scattered and attenuated through absorption, resulting in dominant scattering light around imaged cells.

The integration of high-resolution and high-speed monitoring improves PIV in the dynamic range and enhances spatial resolution and measurement accuracy. In particular, our technique enables us to measure the velocity of individual cells up to 10 mm/s without marked optical distortion of cell images in packed multi-file blood flow<sup>[104]</sup>. However, the low absorption sensitivity of TDM makes it impossible to differentiate individual cells with slight differences in absorption in fast flow *in vivo* (e.g. different WBCs or cancer cells).

### PT module

To detect low-absorbing cells, PT methods were used with no cell labeling and inheritance to scattered light. With these methods, absorption by non-fluorescent cellular components (most of which are naturally weakly fluorescent) is measured by monitoring thermal (due to picosecond-scale non-radiative relaxation of the absorbed energy) and accompanying effects directly in cells<sup>[105-109]</sup>. For non-fluorescent samples, PT methods currently offer the highest sensitivity for the absorption coefficient, on the order of  $10^{-5}$ - $10^{-6}$   $\text{cm}^{-1}$ , which makes it possible to non-invasively (a short-term temperature elevation  $\leq 1$ - $5^\circ\text{C}$ ) detect a single, unlabeled biomolecule with a sensitivity comparable to that of laser-fluorescence methods (i.e. with labeling)<sup>[109-111]</sup>. This absorption sensitivity threshold of the PT technique is at least four to five orders of magnitude better (e.g.,  $10^{-2}$ - $10^{-3}$   $\text{cm}^{-1}$  for single cells) than that of TDM, with the capability to measure absorption spectra at the subcellular level in weakly absorbing cells (e.g. WBCs

**Figure 6** Typical positions of probe (red) and pump (green) laser beams during PT imaging. **A:** Circular beams in a blood capillary (cell velocity,  $\sim 0.5$  mm/s; magnification, 100  $\times$ ); **B:** Overlapping pump and probe pulses in an artery (cell velocity,  $\sim 2$  mm/s; magnification, 10  $\times$ ); **C:** an ellipsoidal beam geometry in a blood vessel (cell velocity,  $\sim 5$  mm/s; magnification, 10  $\times$ ).

or cancer cells).

Briefly, in the first PT imaging (PTI) mode, individual cells were irradiated with a short, focused pump laser pulse of a tunable optical parametric oscillator (OPO) laser (wavelength, 420–2300 nm; pulse width, 8 ns; pulse energy, 0.1–10<sup>3</sup>  $\mu$ J; Lotis Ltd., Minsk, Belarus; Figure 6)<sup>[109,112,113]</sup>. Time-resolved monitoring of temperature-dependent variations of the refractive index around the absorbing cellular structures or whole cells was accomplished with thermal-lens (thermolens) or phase-contrast imaging (Olympus BX51 microscope with a CCD camera; AE-260E, Apogee Inc.) using a second, collinear laser pulse of a Raman shifter (wavelength, 639 nm; pulse width, 13 ns; pulse energy, 10 nJ). In particular, in the phase contrast mode, a customized phase-contrast microobjective (20  $\times$ ) with a Zernike coaxial quarter-wave filter was used to image the probe laser beam. The diameters of the pump- and probe-beam spots were varied 20–40  $\mu$ m and 15–25  $\mu$ m, respectively.

A second thermolens mode made it possible to record a whole cell's time-resolved integral PT response *via* the defocusing effects of a collinear, intensity-stabilized He-Ne laser probe beam (wavelength, 633 nm; diameter, 15  $\mu$ m; energy, 2 mW) as detected with a photodiode through a pinhole (0.5 mm). The PT response was recorded with a Tektronix TDS 3032B oscilloscope. In the presence of gaps between neighboring cells in lymph and blood flow (typical for small lymphatics and blood capillaries), we used a circular laser-beam geometry (Figure 6A). At short distances, selected experiments were performed with an elliptical beam shape (Figure 6C).

In contrast to TDM, the PT technique was able to identify low-absorbing cells (e.g. normal and apoptotic WBCs or cancer cells) in blood and lymph flow *in vivo* on the basis of their differences in integral and local absorption associated with specific heme proteins<sup>[58,77,94,114–118]</sup>.

### Laser speckle microscopy (LSM) module

Because of the varying velocities and trajectories of cell motion in cross-sections of vessels, time-consuming TDM is not well suited for rapidly estimating mean cell velocity in the presense of many cells in flow. The limitations of TDM were partially solved using the LSM technique (Figure 7)<sup>[66,68,98,119–122]</sup>. Laser radiation from a focused He-Ne laser beam (633 nm) scattered by a diffusely scattering

object has a specific, speckle structure (Figure 7A and B), resulting from the interference of independent contributions from a large number of randomly distributed scattering centers. Detection of the speckle fluctuation's intensity (Figure 7C) with a photodetector provides information of flow velocity estimated through the width of the power spectrum of these fluctuations or from the width of their autocorrelation function (Figure 7D and E). Figure 7D illustrates the spectrum recorded for the central part of a vessel (axial lymph flow), while Figure 7E demonstrates spectra obtained at points placed near the vessel wall. Such changes indicate that velocity decreases from a vessel's center to its periphery, which enables monitoring of the profile patterns of lymph-flow velocity for microlymphatics.

To increase its ability to measure the absolute value and direction of flow, we also used the speckle-correlation mode, which uses two photodetectors to record the intensity in fluctuations of the speckle field at two points<sup>[123,124]</sup>. The described algorithm was verified *in vivo* by measuring lymph flow in a lymphatic vessel with LSM (Figure 7F curve 1) and TDM (Figure 7F curve 2). There was relatively good correlation (coefficient of linear regression = 0.72) between the two methods; however, the LSM mode had advantages, such as rapid calculation of lymph-flow velocity (compared to TDM). On the other hand, combining LSM with TDM allowed us to: (1) monitor the quantitative dynamics of cell velocity in lymph or blood flow; (2) verify data from the speckle method; (3) obtain a profile of lymph velocity through the changing shapes of the speckle signal from the center region to the near-wall region; and (4) determine the dynamic relationships among changes in lymph flow velocity and other functional activities of lymphatics. This integrated schematic also has the potential for speckle-imaging of mesenteric structures at cellular and subcellular levels, including detection of individual cell rotation and functional state (e.g., live, apoptotic, and necrotic) in flow<sup>[118]</sup>.

### Fluorescent module

A fluorescence module was added to the integrated system to verify PT data and for independent applications using specific fluorescent tags to identify different cells with similar shapes and sizes (e.g. lymphocytes and leukemia

**Figure 7** Integration of laser speckle and transmission microscopies for studying lymph flow dynamics. **A:** A laser beam was focused into a small-diameter spot ( $\sim 5\ \mu\text{m}$ ) on axial lymph flow (microvessel diameter  $55\ \mu\text{m}$ ); **B:** Lymph flow randomly modulated the focused Gaussian beam to provide scattered dynamic speckles images; **C:** Scattered intensity fluctuations were detected by a photodetector and transformed into an electrical output signal. **D and E:** Spectral shapes from scanning the lymphatic cross-section: **(D)** the spectrum when the laser beam was focused in axial flow and **(E)** when the laser beam was focused in flow near the lymphatic wall; **F:** Real-time dynamics of lymph-flow velocity in a lymph microvessel, recorded with a laser speckle technique (curve 1) and by processing the video recording (curve 2).

cells)<sup>[116,94]</sup>. Fluorescent imaging was performed with CCD cameras (Cascade 650, Photometrics, color Nikon DXM1200) and a super-sensitive PentaMAX camera with an intensifier (Princeton Instruments, Inc.).

## STUDY OF MICROLYPHATIC DYNAMICS

### Label-free time-resolved lymphography

An essential ingredient in studying the functional activity of lymph microvessels is to know when the observed functions approximate normal conditions. The previously described imaging system allowed us to obtain such basic information on intact lymph microcirculation, including quantitative measurements such as indices of phasic contraction and valve function, the numbers of microvessels with lymph flow, the numbers of cells in lymph, and lymph flow velocity<sup>[58,66,101,125]</sup>.

TDM images of rat mesentery at two relatively small magnifications ( $4\times$ , field of view  $250\times 350\ \mu\text{m}$  and  $10\times$ , field of view  $125\times 175\ \mu\text{m}$ ) allowed us to visualize the initial (Figure 3F) and valvular lymphatics (Figure 3H), the

vessel wall, lymphatic valves, and cells in lymph flow, as well as neighboring blood microvessels. In particular, we studied small valvular lymphatics with mean diameters of  $147\pm 3\ \mu\text{m}$ . Half of these lymphatics in a normal state had spontaneous phasic contractions<sup>[101]</sup>.

The rate (frequency) of contractions and contraction amplitude (the percentage difference between maximum and minimum diameters during contraction) vary significantly<sup>[66]</sup>. Benoit *et al*<sup>[22]</sup> found that the lymphangions with phasic contractions have mean end diastolic diameters of  $69.2\pm 6.5\ \mu\text{m}$  and systolic diameters of  $39.4\pm 5.6\ \mu\text{m}$  (i.e. an amplitude of 43%). In another paper, the same authors showed that lymphatics with mean end diastolic diameters of  $106.9\pm 13.7\ \mu\text{m}$  have a systolic diameter of  $69.8\pm 8.8\ \mu\text{m}$  (i.e. amplitude of 35%)<sup>[30]</sup>. From our data, lymphangions had mean diastolic diameters of  $147\pm 3\ \mu\text{m}$  and amplitudes of  $29\%\pm 9\%$ <sup>[58]</sup>. Thus summarized, these data indicate that the larger lymphatics have smaller amplitudes of phasic contractions. Our detailed analysis of relationships between diameter and amplitude revealed that the lymphangion with larger diameters have less amplitude

(Figure 8, unpublished), which is in line with the results presented above. In addition, we believe that the amplitude of phasic contractions should be analyzed in relation to valve activity; indeed, the amplitude of phasic contractions in lymphangions with active valves was  $31\% \pm 4\%$ , while in lymphangions with non-active valves it was only  $6\% \pm 2\%$ <sup>[66]</sup>.

The majority of lymphatics with phasic contractions (78%) have active valves, which periodically open and close. An average activity rate (frequency of closing-opening cycles per minute) was 9-12/min<sup>[58,66,101,125]</sup>.

Cells are moved in 85% of lymphangions and they are not found in 15% of lymphangions<sup>[66,125]</sup>. It is well known that some parts of blood capillaries do not work normally<sup>[61]</sup>. We speculate that the same situation may occur in lymphatics, in which activity can start under some specific circumstances, for example during disease development (e.g., lymphedema).

Lymph flow velocity is usually estimated by measuring cell velocity. Our measurements with a conventional video camera (25-30 fps) revealed that mean cell velocity in an axial flow in the non-valvular central part of mesenteric lymphangions (i.e. approximately equal distance between input and output valves) is  $211\text{--}262 \mu\text{m/s}$  on average, with a maximum of  $1\text{--}2 \text{ mm/s}$ <sup>[58,66,101,125]</sup>. When lymph flow goes through the valve, the phase contraction leads to acceleration of flow because of the narrow valve nozzle. In turn, this leads to significantly increased cell velocity.

Lymph usually moves in the forward direction for a short period of time; then, the motion is interrupted and the lymph stops for up to 1-1.5 s. After that, the lymph flow starts in the reverse direction. Usually, cells oscillate at a rate of 50-70 oscillations per minute<sup>[126]</sup>. Figure 9 shows oscillations during 15 s in a non-valvular part of an individual lymphangion (mean diameter in the investigated site =  $170 \pm 5 \mu\text{m}$ ; mean cell velocity during the investigated time =  $168 \pm 6 \mu\text{m/s}$ )<sup>[126]</sup>. In some rare microvessels, the time-averaged velocity of lymph flow equaled zero. In this case, lymphocytes only oscillated relative to a position without the leak-back of lymph. Using a high-speed videotape recorder (2000 fps), Sekizuka *et al.*<sup>[24]</sup> demonstrated that maximum cell velocity in rat mesenteric lymphatics was 2-3 mm/s. Later, using a relatively high-speed camera (500 fps), Zawiewa *et al.* determined that maximum cell velocity in some mesenteric lymphatics may reach 7 mm/s and their oscillations correlate with phasic contractions<sup>[26]</sup>. Probably, such variability of cell velocity may result from different experimental conditions.

It is important that the analysis of lymph flow requires that we estimate both cellular and plasma velocities (analogous to blood flow). In fact, Starr *et al.*<sup>[8]</sup> found that the blood flow in cat mesenteric microvessels *in vivo* is characterized by a discrepancy between RBC and plasma velocities. This discrepancy is dependent on the elastic properties of RBCs and flow dynamics, including plasma shear and pressure field. We expect a similar phenomenon in lymph flow, especially due to its oscillating character; however, these effects require further quantitative verification.

Depending on lymph flow velocity and vessel structure, cell distribution in the cross-section of the lymphangion varies<sup>[58,66,125]</sup>. Most often, at relatively low velocities and/or

**Figure 8** Diameter-amplitude relationship in rat mesenteric lymphangion. Cycles-experimental data, solid curve-approximation ( $A = 109.3 - 0.96 \times D + 0.0024 \times D^2$  where A: amplitude and D: diameter).

in the non-active valves (80% of cases), cell distribution was relatively uniform. However, at high velocities and/or in functioning valves (20% of cases), most cells were concentrated near the vessel axis.

It is well known that lymph has markedly lower concentrations of cells than blood. However, there is relatively little data about cell concentration in prenodal lymph. In particular, cell concentrations range from 200 to 1000 cells/ $\mu\text{L}$  in prenodal sheep's lymph and 100 cells/ $\mu\text{L}$  in prenodal rabbit's lymph<sup>[127,128]</sup>. It was found that approximately  $1 \times 10^6$  cells/h ( $1.7 \times 10^4$  cells/min) go through a single prenodal (afferent) sheep's lymphatic<sup>[129,130]</sup>.

According to our data, the cell concentration in rat mesenteric prenodal lymphatics is larger. Specifically, we measured the number of cells in a  $50 \mu\text{m} \times 50 \mu\text{m}$  square in the central part of a lymphangion from a rat mesenteric microvessel using 2D-imaging<sup>[66]</sup>. Because the depth of field was approximately  $28 \mu\text{m}$ , the number of cells was determined in a  $50 \mu\text{m} \times 50 \mu\text{m} \times 28 \mu\text{m}$  volume (i.e.,  $7 \times 10^{-5} \mu\text{L}$  of lymph). Data is summarized in Table 1 (taking into account distribution of cells in a cross-section of a lymphangion, see above). Finally, the mean concentration of cells in the lymph flow of intact mesenteric microvessels was estimated as approximately  $0.5\text{--}1 \times 10^5$  cells/ $\mu\text{L}$ . From these data, the average percent of cell fraction in lymphatics was 5.5%. This parameter is analogous to hematocrit in the blood system, and may be called lymphocrit. It is interesting that a 5%-6% level of hematocrit can be found only in blood capillaries, as compared to that in arterioles with diameters from 60-70  $\mu\text{m}$ , in which the hematocrit achieved 20%-30%. Cell flux in the prenodal lymph was estimated to be 10-50 cells/s. The cell concentration in flow is usually higher in vessels with higher lymph flow velocities, and is somewhat correlated with the amplitude of phase contractions and rate of valve activity<sup>[66]</sup>. Recent data obtained by Dixon *et al.*<sup>[131]</sup> with a high-speed video system and by capturing multiple contraction cycles in rat mesenteric lymphatic preparations with smaller diameters ( $91 \pm 9 \mu\text{m}$ ) revealed that lymphocyte densities were  $12\,000 \pm 5200$  cells/ $\mu\text{L}$ .

**Figure 9** Real-time dynamics of cell velocity in axial lymph flow within the non-valvular segment of a lymphangion (mean diameter of  $170 \pm 5 \mu\text{m}$ ) without phasic contractions and valve activities, measured by processing the video recording ( $\mu\text{m/s}$ ) for 15 s.

**Table 1** Relationship between lymphocrit and other parameters of microlymphatic function

	Cell concentration, cells/ $\mu\text{L}$	Lymphocrit %	Proportion of Lymphangions %	Diameter $\mu\text{m}$	Parameters of phasic contractions		Valve activity per minute	Cell velocity ( $\mu\text{m/s}$ )
					Amplitude (%)	Count of contractions per minute		
Group 1	$< 3.75 \times 10^4$	$< 2$	22	$106 \pm 9^{a,b}$	$50 \pm 15^{a,b}$	$12 \pm 2$	$8 \pm 0.5^b$	$161 \pm 191$
Group 2	$3.75 \times 10^4$ - $12.2 \times 10^4$	2-6	45	$141 \pm 8^a$	$28 \pm 7^{a,c}$	$12 \pm 1$	$11 \pm 1$	$254 \pm 151$
Group 3	$> 12.2 \times 10^4$	$> 6$	33	$165 \pm 9^b$	$14 \pm 5^{b,c}$	$15 \pm 1$	$16 \pm 2.5^b$	$214 \pm 19$

<sup>a</sup> $P < 0.05$ , vs Group 2; <sup>b</sup> $P < 0.05$ , vs Group 3; <sup>c</sup> $P < 0.05$ , vs Group 3.

and cell flux was  $990 \pm 260$  cells/min.

The relationship between lymphocrit and pathologies is still unknown. There are indications that the leg massage of healthy rabbits stimulates lymph flow and increases cell concentration, while leg edema due to venous pressure rising is not accompanied by an elevation in cell concentration<sup>[128]</sup>.

Data about cell composition in afferent lymph are very limited and have been obtained in *in vitro* tests. In particular, 80%-90% of cells in normal prenodal lymph are related to mature lymphocytes, 5%-20% to macrophages and dendritic cells, and 0%-10% to other cells (e.g. basophilic blast cells, RBCs)<sup>[127]</sup>. The composition of WBC types changes based upon the pathology. For example, it is estimated that there is a significant appearance of neutrophils in experimental peritonitis in sheep. Other important problems are the mechanisms by which different cells (e.g. metastatic tumor cells) enter into peripheral lymphatics. Recently, Azzali studied tumor-associated absorbing lymphatics in the peritumor area of fixed tissue specimens (adenocarcinoma, melanoma, colorectal cancer) using light microscopy, transmission electron microscopy, and histochemistry with 3-D image reconstruction<sup>[132]</sup>. He found that cancer cells can enter into lymphatics through intraendothelial channels ( $1.8$ - $2.1 \mu\text{m}$  in diameter and  $6.8$ - $7.2 \mu\text{m}$  in length). These results are very promising, but such a mechanism remains to be proven in living cells *in vivo*.

### Lymph and blood flow cytometry *in vivo*

We demonstrated the first application of the PT techniques for lymph and blood PT flow cytometry (PTFC) *in vivo* integrated with TDM<sup>[94,115,116,133]</sup>. To

minimize cell image distortion due to spatial cell-radial fluctuations in lymph flow (up to  $50 \mu\text{m}$  in  $150\text{-}\mu\text{m}$ -diameter lymph vessels), cells were imaged immediately after passing through a lymphatic valve, which played the role of a natural nozzle, focusing the cells near the vessel axis (Figure 3J). Thus, lymphatic valves provided a natural type of "hydrodynamic focusing" (a term used in *in vitro* FC involving an artificial nozzle) to limit lateral fluctuation of cells up to a few micrometers.

High-resolution and high-speed TDM imaging provides a real-time monitoring of individual cells in blood (Figure 3L-N) and lymph flow (Figure 3I-K), as well as static and migrating cells in the interstitium (Figure 3O), lymph nodes (Figure 3A and B), and even in liver (Figure 3C)<sup>[58,94]</sup>. The high spatial resolution offered by TDM ( $300$ - $500 \text{ nm}$  at  $40\times$  -  $100\times$  magnification with water immersion) makes it possible to identify some types of moving cells based upon their sizes and shapes (e.g. WBCs and RBCs; Figure 3K). We can even monitor the rotation of a single RBC (Figure 10A-C) and visualize intralymphatic cell aggregates of different sizes in intact microlymphatics (Figure 10D-F).

PT module in integrated FC allows us to obtain PT images of flowing cells (e.g., lymphocytes, RBCs, and leukemic cells) with an absorption sensitivity approximately four orders of magnitude greater than the sensitivity of transmittance microscopy (Figure 3K, left and middle columns)<sup>[94]</sup>. In particular, PT images revealed the subcellular structures of these cells (Figure 3K, middle column) associated with the spatial distribution of cytochromes in lymphocytes and cancer cells and of hemoglobin in RBCs, which were not clearly visible with

**Figure 10** High-resolution monitoring of cell behavior in lymph flow. Top row (A-C): three sequential images of an individual RBC's rotation in lymph flow (lymphatic diameter 185  $\mu\text{m}$ , mean cell velocity 220  $\mu\text{m/s}$ , magnification 100  $\times$ ). Bottom row: moving aggregates of different sizes in lymph flow; D: Unstable aggregate of a few cells in intact lymphatic; E: large aggregate of RBCs in lymph flow resulting from venous insufficiency; F: rouleaux formation when numerous RBCs appeared in lymph flow due to laser-induced hemorrhage (magnification 100  $\times$ ).

TDM (Figure 3K, left column). Fluorescence images, obtained with a high-sensitivity CCD camera with an intensifier (PentaMAX, Princeton Instruments, Inc.), showed high image contrast (Figure 3K, right column) similar to that of PT images, although inconvenient staining procedures were required. Specifically, leukocytes were labeled with Rhodamine 6G. RBCs and K562 cells were labeled with FITC and MitoTracker Red, respectively. Because of differences in the optical properties of normal and cancerous cells, especially mitochondrial distribution<sup>[134,135]</sup>, which can be visualized with the PT technique, we can assume that PTFC has the potential to distinguish these cells after further improvements.

PT-signal tracings from flowing cells in blood (Figure 11A) and lymph (Figure 11B-E) microvessels were obtained as a function of time<sup>[116,94]</sup>. Due to their different absorption properties, the significant (40-60-fold) differences in the integral PT amplitudes from RBCs and WBCs (lymphocytes) allowed us to distinguish cells using only the thermolens mode (i.e. even without imaging). Cells were also identified through differences in cooling times (6-10  $\mu\text{s}$  for RBCs, and 20-25  $\mu\text{s}$  for lymphocytes). PT signals from RBCs in blood flow showing a purely positive component indicate a linear positive PT response from the cells at a low laser energy level with no cell damage (temperature increase is usually 5-10°C, Figure 11A). The amplitude differences indicate differences in average absorption and reflect the natural heterogeneity of RBCs. The negative signal component from cells in lymph flow presented in Figure 11D is related to laser-induced photodamage through bubble formation around strongly absorbing cellular zones that have been overheated. The presence of both positive and negative components in the PT-signal amplitude tracing (Figure 11E) indicated a noninvasive condition for lymphocytes (which have a

**Figure 11** Typical PT-signal tracings from blood cells in blood and lymph flow: A: RBCs in blood flow; B: rare RBC in lymph flow; C: growing number of RBCs in lymph flow during laser-induced hemorrhage; D: laser-induced damage of RBCs in lymph flow and lymphocytes in lymph flow in linear and nonlinear PT modes; and E: lymphocytes and RBCs in lymph flow. Laser parameters: wavelength, 525 nm; energy/amplitude/time scale/division: (A), 0.3  $\mu\text{J}/50$  mV/100 ms; (B), 0.5  $\mu\text{J}/20$  mV/1 s/div; (C) 0.6  $\mu\text{J}/100$  mV/200 ms/div, (D) 5  $\mu\text{J}/500$  mV/4 s/div; and (E) 145  $\mu\text{J}/100$  mV/10 s, respectively.

high photodamage threshold) and an invasive condition for RBCs (which have a low photodamage threshold) at the same energy level. Decreasing the laser energy level

**Figure 12** High-resolution, high-speed monitoring of cells in blood flow. RBCs are indicated by conventional arrows and triangle; rolling WBCs by arrows originating from filled circles; and direction of flow by dashed lines. **A-C**: behavior of normal RBCs and WBCs in flow (1250-2500 fps; 40 ×); **D**: The shapes of normal (left) and diamide-treated (middle) RBCs in single-file flow of small venula (diameter ~10 μm), and (right) adhesion of diamide-treated RBCs to wall of the relatively large venula (diameter ~40 μm).

allows us to selectively identify rare RBCs in lymph flow. For example, Figure 11B shows the detection of single RBCs at a low laser energy level. This level did not produce notable PT signals from the many lymphocytes in lymph flow because of their low absorption. Laser-induced vessel injury led to a fast-growing number of RBCs in lymph flow (Figure 11C). The next tracing shows that the PT signals from RBCs at a relatively high laser energy level led to cell damage (Figure 11D).

## HIGH-SPEED IMAGING OF INDIVIDUAL CELLS IN FAST BLOOD FLOW

This technique, using an advanced high-speed CMOS

camera, reveals the high deformability of parachute-like RBCs as they are squeezed at 0.6 mm/s through a narrow gap between the vessel wall and rigid adherent cells on the opposite wall (Figure 12A)<sup>[104]</sup>. It also shows how quickly the relatively fast-flowing RBCs (~1 mm/s) change shape as they interact with the much more slowly moving (so-called rolling) leukocytes (~0.1 mm/s; Figure 12B). We also observed significant dynamic deformation of two RBCs in merging flow streams in a bifurcation zone (Figure 12C), and extremely fast stretching (0.4 ms at 2500 fps) of initially discoid RBCs to ~0.7-0.9 μm (Figure 3N). Our technique has provided relatively good contrast images of both slow- (20 μm/s, Figure 3L, left) and fast-flowing (2.5 mm/s) single platelets in blood microvessels. The best-quality images of platelets were obtained in the RBC-free

space of the microvessel lumen.

We also performed time-resolved monitoring of cell deformability. In particular, diamide (20 mg/kg) was injected in a rat's tail vein to increase the rigidity of RBCs *in vivo*. We observed a drug-induced decrease in the deformability of RBCs in fast blood flow (up to 5 mm/s) compared to RBCs in normal conditions, with maximum centrifugal forces acting on cells in curved capillaries (Figure 12D, left and middle). In addition, diamide led to adhesion of abnormal RBCs to vessel walls (Figure 12D, right). To our knowledge, this was the first time that these phenomena have been observed with high-speed, high-resolution imaging *in vivo*. After additional study, potential applications of this technique may include fundamental studies of dynamic cell-cell interactions in native flow or the identification of abnormal cells (e.g., cancerous cells or sickle RBCs) using their different dynamic deformability as new biological markers that are sensitive to disease development or to different interventions.

## IMAGE CYTOMETRY OF STATIC CELLS AND TISSUE STRUCTURES

### Interstitium

Figure 3O shows typical high-resolution TDM images of mast cells, adipocytes, and slow-moving RBCs in mesenteric interstitium<sup>[58,101]</sup>. This technique also provides distinct images of fibrils, as well as other static and migrating cells. In some cases, the phase-contrast images demonstrated better contrast of margins and sub-cellular structures for selected single cells in interstitium than does non phase-contrast at high magnification (100 ×, with water immersion), which prevents overlapping refractive heterogeneities of connective tissue (see images of mast cell and adipocytes in Figure 3O).

### Lymph and blood microvessel walls

With TDM, we obtained high-resolution images of (1) distinct individual blood endotheliocytes (EC) of the capillary wall (Figure 3L, left); (2) the initial lymphatic wall with cells (e.g. leukocytes) migrated from interstitium (Figure 3G); and (3) lymphatic wall and valvular cusp structures of larger vessels<sup>[58]</sup>.

### Lymph node

Using a minimally invasive procedure, we demonstrated real-time, *in vivo* monitoring of individual cells in different domains of mesenteric lymph nodes (e.g., medullary sinus, light and marginal zones of marginal sinus) in their native state (unpublished data, Figure 3B)<sup>[94]</sup>.

## STUDY OF ENVIRONMENTAL IMPACTS ON LYMPHATICS

To date, the effects of environmental and therapeutic interventions on blood microcirculation have been studied in appropriate detail in humans and in different animal models, including the rat mesentery; however, the lymphatic system has received much less attention in spite of the many biological and medical problems associated with

microlymphatic functioning and its disturbance in different diseases, including cancer metastasis, venous insufficiency, infections, inflammation, lymphatic malformations, and especially lymphedema<sup>[29,40,62]</sup>. To partially fill this knowledge gap, we used a rat model with an integrated optical technique to quantitatively study lymph and blood dynamics under different impacts, including chemical, drug, and physical interventions. In our study, we chose interventions that have effects on lymphatics that are unknown (dimethyl sulfoxide); incompletely known ( $\beta$ -adrenoceptor agonist and  $\beta_1$ - and  $\beta_2$ -adrenoceptor antagonists, donors of NO, low-power laser radiation); or controversial (inhibitors of NO-synthase). These effects were studied by real-time monitoring of the diameters and parameters of phasic contractions, and changes in lymph flow velocity, valve activity, and cell behavior in microvasculature.

### Effects of adrenergic agonists and antagonists

One of the most important regulators of the vasculature is adrenergic regulation through  $\alpha$ - and  $\beta$ -adrenoreceptors<sup>[61]</sup>. The effects of adrenergic agonists and antagonists on diameter and phasic contractions of microlymphatics have been described in *in vitro* or *in vivo* tests<sup>[22,29,30]</sup>. It is known that norepinephrine applied topically or injected intravenously instantly reduces the diameter and increases the contraction frequency of rat mesenteric lymphatics, while isoproterenol has opposite effects<sup>[29]</sup>. Moreover, the attempts to study the effects of  $\alpha$ -adrenoagonists and antagonists on lymph flow in microvessels were made using calculated parameters of lymph outflow (as calculated with the following assumptions: strongly cylindrical, unchanging geometry of lymph vessel with unidirectional lymph flow)<sup>[22,30]</sup>. It was shown that  $\alpha$ -adrenergic regulation of lymph outflow in mesenteric lymphatics is through  $\alpha_1$ -receptors<sup>[30]</sup>.

In our tests, we clarified the effects of a  $\beta$ -adrenoceptor agonist and antagonist (and their subtypes) on cell flow velocity *via* the direct monitoring of lymph flow, and determined the relationships between cell velocity and other parameters of microlymphatic function (diameter, amplitude and rate of phasic contractions, rate of valve activity) (Table 2). Isoprenaline, a  $\beta$ -adrenoceptor agonist, ( $10^{-5}$  mol/L, 15 min of topical application) caused dose- and time-dependent responses: 5 min following topical application, the percentage of contracting lymphangions was decreased from 60% to 33% and lymph flow velocity was inhibited from  $134 \pm 13$   $\mu\text{m/s}$  to  $82 \pm 19$   $\mu\text{m/s}$  ( $P < 0.05$ ). Then, at 15 min, 40% of lymphangions exhibited lymphostasis accompanied by vessel constriction and depression of phasic activity. The adrenoceptor antagonists metoprolol ( $\beta_1$ ) and butoxamin ( $\beta_2$ ) were also applied topically at the same parameters ( $10^{-5}$  mol/L, 15 min). Both antagonists stimulated phasic contractions in non-active lymphangions. However, the effect of metoprolol was more marked, increasing the proportion of microlymphatics with contractile activity to 66%, while butoxamin stimulated phasic activity in only 32% of non-active lymphangions. As a result, metoprolol's action significantly increased lymph flow velocity (from  $136 \pm 14$   $\mu\text{m/s}$  to  $198 \pm 24$   $\mu\text{m/s}$ ,  $P < 0.02$ ), while it did not change with butoxamin. Based upon this data, we assume

Table 2 Effects of 15-min topical application of different vasoactive drugs on lymph microvessel functions

Drug	Diameter	Phasic activity	Lymph flow velocity
Sodium Nitroprusside ( $10^{-5}$ mol/L)	Dilation	Slight short-time inhibition	Unchanged
N-Nitro-L-Arginine ( $10^{-4}$ mol/L)	Unchanged	Stimulation	Stimulation
Isoprenaline ( $10^{-5}$ mol/L)	Constriction	Inhibition	Inhibition up to stasis
Metoprolol ( $10^{-5}$ mol/L)	Unchanged	Stimulation	Stimulation
Butoxamin ( $10^{-5}$ mol/L)	Unchanged	Slight stimulation	Unchanged
Dymethyl Sulfoxide, (30%)	Constriction	Stimulation	Stimulation in 50% of lymphangions Inhibition in 39% of lymphangions (without phasic contractions)

Table 3 Effects of 30% DMSO at the topical application on blood microvessel diameter

	Arterioles		Venules		
Before application	16.5 ± 0.49	25.3 ± 0.69	16.1 ± 0.79	24.9 ± 0.74	34.8 ± 0.66
After DMSO application					
1 min	17.4 ± 0.67	25.8 ± 1.09	18.6 ± 0.98 <sup>a</sup>	29.6 ± 1.29 <sup>a</sup>	39.0 ± 2.25
2 min	16.9 ± 0.83	28.1 ± 0.80 <sup>a</sup>	19.2 ± 1.11 <sup>a</sup>	28.9 ± 1.33 <sup>a</sup>	38.8 ± 1.53 <sup>a</sup>

Significant differences from state before application, <sup>a</sup> $P < 0.05$ .

that lymph microvessels (and probably similar large lymph vessels), have  $\beta_1$ - and  $\beta_2$ - adrenoceptors.

### No effects

Another essential regulative substance of lymph mesenteric microvessel function *in vivo* is nitric oxide (NO)<sup>[53,66,136,137]</sup>. According to our data, intravenous injection of an NO donor (sodium nitroprusside, 100  $\mu$ g/kg, i.e. drug concentration in blood is  $5 \times 10^{-5}$  mol/L) caused slight dilation of lymphatics within 30 min<sup>[136]</sup>. However, sodium nitroprusside does not affect lymph flow. The response of lymphatics to direct topical application of sodium nitroprusside ( $10^{-5}$  mol/L, 30 min) was similar but more intense: dilation of lymphangions for  $25 \pm 2.5$   $\mu$ m was accompanied by slight transient inhibition of the proportion of lymphatics with phasic contractions and active valves<sup>[137]</sup>.

While the hyper-production of NO does not change lymph flow, the inhibition of NO synthesis stimulated lymph motion (Table 2). Topical application of N-nitro-L-arginine, a known inhibitor of NO ( $10^{-4}$  mol/L, 30 min), first caused (fifth minute of application) a short-term decrease in the amplitude of phasic contractions (from  $23\% \pm 3\%$  to  $11\% \pm 1\%$ ,  $P < 0.001$ ) and stimulation of valve activity (rate of valve activity increased from  $6 \pm 1$  to  $11 \pm 2$  per min,  $P < 0.05$ )<sup>[66,137]</sup>. Then, from the tenth minute, we observed permanent stimulation of phasic activity and lymph flow. Shirasawa and coauthors concluded that a 15-min application of an NO donor and an inhibitor of NO synthase portray the direct effects of NO on microvessel walls<sup>[35]</sup>. Therefore, we speculate that NO can regulate lymph flow in microvessels due to (at least, partly) the direct action of NO on the endothelium and the smooth muscles of lymph microvessel walls.

### Pharmacological effects of dimethyl sulfoxide (DMSO)

DMSO has a wide spectrum of biological activities,

including high penetrating activity and significant vasoactive effects on blood vessels<sup>[138,139]</sup>. It is used for local treatment of trauma, arthrosis, and rheumatoid arthritis<sup>[140,141]</sup>. The effects of DMSO on the microlymphatic system are unknown. Experimental studies have revealed that a 30-min topical application of 30% DMSO caused specific, dynamic microvascular changes in blood and lymph<sup>[66,142]</sup>. Immediately after application (within the first minute), there was stasis within 100% of venules and 85%-95% of arterioles, with significant dilation (dilation began earlier and the diameter increased more in venules than in arterioles) and hemorrhaging around venules (Table 3). The marked responses of lymphatics started later (15 min of DMSO application), and appeared as a significant increase in lymph-flow velocity from  $190 \pm 12$   $\mu$ m/s (before DMSO application) to  $233 \pm 20$   $\mu$ m/s ( $P < 0.05$ ) accompanied by stimulation of phasic contractions in 21% of lymphangion and decreasing of diameter. In parallel, the 39% of lymphatics is characterized by lymphostasis development (Table 2). Obtained on DMSO's impacts on lymph and blood microvascular function can be used for assessment the possible side effects of this drug.

### Effect of low-power laser irradiation

Publication of the positive clinical effects of low-power laser therapy, including lymphedema treatment, stimulated our interest in studying lymphatic response to this radiation<sup>[143-145]</sup>. The effects of low-power laser radiation (He-Ne laser) on intact lymph microvessels were studied at three radiation intensities-450 mW/cm<sup>2</sup>, 45 mW/cm<sup>2</sup>, and 14 mW/cm<sup>2</sup>-each with an exposure time of 15 min<sup>[66,136,146]</sup>. Laser power of 14 mW/cm<sup>2</sup> did not have a significant effect on lymph microvessel function. After 5 min of irradiation at 45 mW/cm<sup>2</sup>, 70% of lymphatics were dilated an average of  $8 \pm 1$   $\mu$ m ( $P < 0.01$ ). After 15 min, the proportion of microvessels

**Figure 13** The percentage of lymphangions exhibiting phasic contractions during 30 min of irradiation with a He-Ne laser (450 mW/cm<sup>2</sup>).

that were dilated (60%-70%) did not change, and phasic contractions appeared in 21% of lymphatics. When the lymphatics were irradiated at the highest laser power (450 mW/cm<sup>2</sup>), similar dilation of the majority of microvessels was observed. Simultaneously, 15 min of laser radiation at 450 mW/cm<sup>2</sup> significantly stimulated contractions within a larger number of vessels (45%) than did irradiation at 45 mW/cm<sup>2</sup>. The mean contractile amplitude of irradiated vessels was 1.5-fold greater than that of intact lymphatics (44%  $\pm$  5% compared to the amplitude of spontaneous contractions of 29%  $\pm$  9%). Increasing the irradiating time up to 30 min at 450 mW/cm<sup>2</sup> did not change the degree of lymphatic dilation and just slightly increased the proportion of lymphatics with phasic contractions (Figure 13). These laser effects were maintained up to 30 min after irradiation. None of the doses of laser radiation affected how the valve functioned. Thus, our data is in line with the results of Carati *et al.*<sup>[32]</sup> in that low-power laser radiation may improve lymph drainage by stimulating phasic contractions and by dilation of microvessels.

#### High-power laser treatment of vascular abnormalities

Rat mesentery microvasculature is very useful as a model for laser treatment of port-wine stains and other vascular abnormalities. In particular, in one study, rat mesenteric blood vessels were irradiated with a laser pulse (585 nm, 0.2-0.6 ms pulse duration, 0.5-30 J/cm<sup>2</sup> radiant exposure)<sup>[147]</sup>. Video microscopy was used to assess vessel dilation, formation of intravascular thrombi, bubble formation, and vessel rupture. Changes in reflection during a laser pulse were measured by simultaneously recording the temporal behavior of the incident and reflected light. A threshold radiant exposure of approximately 3 J/cm<sup>2</sup> was found to produce changes in the optical properties of blood *in vivo*, confirming previous *in vitro* results. Often, laser exposure induced a significant increase in vessel diameter, up to three-four times the initial diameter within 200 ms after laser exposure. Sometimes, immediately after the pulse, round structures, interpreted as being gas bubbles, were seen within the vessel lumen.

We obtained similar results in our study with a 10 ms laser pulse (585 nm, 0.5-30 J/cm<sup>2</sup> radiant exposure). In addition, local hemorrhaging around venules with rupture

of venular walls occurred at lower radiant exposures than in arterioles with smaller diameters (due to the more effective cooling effects in smaller vessels; Figure 14A and B). For the first time, significant constriction of neighboring lymphatics was observed, up to obliteration of lumina and lymph stasis (Figure 14C and D). Additionally, hemorrhage in the interstitium led to the entry of many RBCs (visualized as distinct red points by TDM) into the lymph flow. The PT mode of integrated PTFC proved this fact. In particular, PT-signal tracing specific for RBC laser energy levels showed a growing number of RBCs in lymph flow during laser-induced hemorrhage (Figure 11C).

Preliminary data from intravenous injection of 100-nm gold nanoparticles followed by laser irradiation of the mesentery demonstrate a decrease in the blood vessel damage threshold (approximately 3-5 times) compared to the damage induced without nanoparticles, despite the sub-optimal parameters of the laser used [wavelength was outside the maximum absorption of the nanoparticles (~525 nm), and of relatively long pulse duration]. Nevertheless, to our knowledge, this was the first demonstration of the application of nanotechnology to treat blood vessels with laser-activated gold nanoparticles and their nanoclusters<sup>[148-154]</sup>.

#### Combined action of laser and drugs

Sodium nitroprusside increased the sensitivity of lymph microvessels to low-power He-Ne laser radiation<sup>[136]</sup>. After intravenous injection of sodium nitroprusside (100  $\mu$ g/kg), application of He-Ne laser radiation at the lowest power (14 mW/cm<sup>2</sup> for 15 min) stimulated phasic contractions in 44% of lymph microvessels against a background of stable dilation caused by the drug. Contractions occurred at a rate of 6-25/min and had amplitudes of 8-22  $\mu$ m. In comparison, this dose of laser radiation alone had no notable effect on the phasic contractions of intact microvessels. Such an approach could have great potential for developing innovative therapies for some diseases (e.g., lymphedema).

#### Nicotine intoxication

Nicotine, an important component of cigarette smoke, was shown to be indirectly responsible for inducing

**Figure 14** Effect of a laser pulse (585 nm, 10-ms pulse duration, 0.5-30 J/cm<sup>2</sup> radiant exposure) on blood and lymph microvessels *in vivo*. **A:** Intact venule (V) and arterioles (A1 and A2) with good blood flow; **B:** Damage to these microvessels immediately after laser pulse: local hemorrhage (arrow) around the venule (V) and stasis in a small arteriole (A2); **C:** Intact lymphatic (L) before laser pulse (black dash line shows internal margin of lymphatic wall); **D:** Laser-induced constriction of the lymphatic, which coincided with stasis in neighboring venules.

pathology in many tissues, both human and animal<sup>[155-157]</sup>. Exposure to cigarette smoke increases the nicotine level in the blood to a maximum in less than 10 s. Therefore, the immediate responses of the vascular network to the action of nicotine appear to be important in the development of acute pathology. The pathological effects of nicotine on blood microcirculation have been reported in sufficient detail, but its impact on the lymphatic system remains obscure.

We uncovered the first experimental evidence of potential active participation of lymph microvessels in the mechanisms of nicotine's effects *in vivo*<sup>[158]</sup>. The influence of nicotine on microlymphatics was determined using three routes of nicotine administration: (1) direct topical application in various concentrations (0.001 mmol/L, 10 mmol/L, and 100 mmol/L solutions) for 15 min; (2) acute injection of nicotine solution (10 mmol/L) through a cannulated vein; and (3) chronic administration for 14 d *via* subcutaneous injection from a mini-osmotic pump (10 mmol/L solution; 0.5 µL/h delivery rate).

The topical application showed that the most significant responses of microlymphatics to nicotine's impact were at 10 mmol/L and 100 mmol/L doses. In particular, the concentration of 10 mmol/L caused a significant, immediate short-term (12-40 s) constriction of 100% of the lymphangions. The effect started within 3-5 s of application (67% of cases) or after ~3 min of nicotine exposure (33% of cases). The lymphatic diameter was decreased by 34% ± 7% (more than ~2 times the amplitude of spontaneous phasic contractions before nicotine application). In all cases with the highest

concentration of nicotine (100 mmol/L), the same immediate constrictions were associated with the slowing of lymph flow, local stable constriction of lymph microvessels, asynchronous motion of the lymphatic wall, stasis in blood microvessels, and disturbances of respiration. Thus, under the direct impact of nicotine, there were significant changes in small lymphatic function *in vivo*, which were dose and time dependent. We hypothesize that the obtained effects were the result of the direct action of nicotine on lymph microvessels and probably reflect specific endothelial dysfunction and/or injury of the contractile ability of the lymphatic wall.

Acute nicotine intoxication delivered intravenously slightly relaxed the lymphatics and was sometimes accompanied by slowing of lymph flow and short-term stasis in blood microvessels. Chronic intoxication using a 10 mmol/L concentration (effective at the topical application) did not markedly change the function of lymphatic and blood microvessels and did not differ markedly from that in the intact state. The absence of effects may be the result of adaptation of the microcirculation to the action of nicotine.

Thus, nicotine induces marked changes in small lymphatic function *via* its acute, direct impact *in vivo*. The observed microlymphatic disturbances due to the action of nicotine may be an important mechanism in the complex, immediate reaction of a healthy organism to cigarette smoke. The acute lymphatic damage caused by nicotine could be more crucial in some pathologies or treatments, and suggests that nicotine may contribute to vascular abnormalities and tissue edema.

## EXPERIMENTAL MODELING OF DIFFERENT PATHOLOGIES

Damage to lymph microcirculation is an important mechanism underlying the development of many diseases (e.g., tumor, inflammation, infections, intoxications, lymphedema, lymphatic malformation) and often determines their severity<sup>[29,40,62,159]</sup>. Because rat mesentery is a highly informative *in vivo* model for functional analysis of lymph microdynamics, this animal model was used by us to study the mechanisms of microlymphatic disturbances resulting from different pathologies, such as models of staphylococcal intoxication, pathological stress, lymphedema, and venous insufficiency.

### Staphylococcal intoxication

It is well known that  $\alpha$ -toxin ( $\alpha$ -hemolysin) is the protein produced by *Staphylococcus aureus* and causes serious blood circulatory disturbances with its appearance in blood during staphylococcal diseases; however, its effect on lymph microcirculation is still poorly understood<sup>[160-162]</sup>. In our study, we used an exotoxin complex (ETC) produced by culture *Staphylococcus aureus* O-15<sup>[66,142,163-166]</sup>. The main component of this complex is  $\alpha$ -toxin (titer  $\sim 1:640$ ); additionally, it contains a small amount of  $\delta$ -toxin (titer  $\sim 1:64$ ). Endotoxins, enterotoxins, and protein A are completely absent.

The staphylococcal intoxication was introduced by intravenous injection of ETC (0.2 mg/100 g) into the tail vein, after which we monitored microcirculation for 30 min. This dose caused serious intoxication. Animals with acute exotoxic shock (those dying within 30 min of ETC introduction) were excluded from the analysis. Disturbances of lymph microcirculation began immediately; after 1 min, the diameters of 75% of the lymphatics were slightly decreased (by  $7 \pm 2 \mu\text{m}$ ). Between the fifth and tenth minutes of observation, in parallel with vasoconstriction, ETC induced pathologic phasic contractions, characterized by asynchronous wall motion, in half of the lymphatics. After 30 min, lymphatic disturbances were expanded by the development of lymphostasis in 53% of cases.

The resulting effects were due primarily to the direct action of the toxic complex on the lymphatics, as the topical application of ETC in the investigated microlymphatics caused similar microvascular disturbances during a 60-min period. In particular, after a short latent period ( $58 \pm 9 \text{ s}$ ), ETC induced marked decreasing of lymphangion diameters ( $36 \pm 11 \mu\text{m}$  from the initial diameter) and stimulated pathologic phasic contractions in 60% of cases. Pathologic phasic activity is characterized by irregular motion of lymphatic walls and defective relaxation (after contraction, the diastolic diameter is sometimes less than it was before). We observed simultaneous abnormalities in blood microvasculature (slowing down of blood flow in venules; increasing migration of leukocytes through venular walls into tissue; and local accumulation of leukocytes around blood microvessels and, as a result, compression of venules into irregular shapes). From the thirtieth to the sixtieth minute of observation, the pathologic constriction of lymph

microvessels progressed to complete obliteration of the lymphatic lumen, inhibition of phasic contractions, and gradual development of lymphostasis in 90%-98% of lymphatics. In parallel, we observed blood flow slowing up to stasis and small hemorrhages around venules.

The underlying mechanisms of microlymphatic disturbances include the well-known ability of  $\alpha$ -toxin to form the specific  $\text{Ca}^{2+}$  channels in cell membranes and, correspondingly, to disturb the transport  $\text{Ca}^{2+}$  in the smooth muscles of the vascular wall and, probably, in the pacemaker cells<sup>[167,168]</sup>. Thus, these data revealed that an important mechanism of staphylococcal vascular disturbances is damage to the lymph microcirculation. Therefore, therapies for staphylococcal pathology require the correction of microlymphatic dysfunction.

Pathologic effects on lymph microvessels are partially reversible by He-Ne laser radiation and some vasoactive drugs (Euphyllin, Verapamil, DMSO)<sup>[66,142,165,166]</sup>. In particular, irradiation of the mesentery (450 mW/cm<sup>2</sup> during the first 15 min following ETC application) attenuates typical toxin constriction. In contrast, preliminarily irradiating *in vitro* ETC (20 mW/cm<sup>2</sup>, 60 min) attenuates development of lymphostasis: a 60-min application of non-irradiated ETC causes lymphostasis in 88% of lymphangia, while irradiated ETC led to lymphostasis in 57% of lymph microvessels. Thus, low-power laser radiation can attenuate lymphotoxic action *via* its effect on microlymphatic walls, as well as on the properties of ETC itself<sup>[166]</sup>.

However, the most effective corrections of microlymphatic disturbances can be achieved by DMSO. It has been noted above that the effects of DMSO after ETC application (dilation of lymphatics, inhibition of pathologic phasic activity, restoration of lymph flow) are different from the effects on intact lymphatics. Moreover, these local, positive effects are associated with an increase in the duration of animal life, which has been demonstrated in experiments on mice injected with lethal doses of ETC<sup>[66,142,165]</sup>.

### Study of experimental lymphedema

Lymphedema is a complication of lymphatic drainage decompensation that may happen during congenital lymphatic dysplasia, hepatic cirrhosis, venous insufficiency, obstruction or surgical extirpation of lymph nodes<sup>[159,169,170]</sup>. In particular, post-mastectomy lymphedema (PML) develops in 25%-50% of cases after breast cancer treatment<sup>[171]</sup>. Generally, lymphedema damages the local lymphovascular network (e.g. in affected extremities) causing insufficient and abnormal lymph transport and, correspondingly, accumulation of protein-rich fluid in the interstitial space (tissue edema)<sup>[159,169,172]</sup>. Because the microvascular network is the principal site for fluid exchange between blood, lymph, and interstitial space, detailed studies of lymph microvessel disturbances during lymphedema have great importance. The efficacy of existing therapeutic treatments for PML is controversial, and clear scientific data have not emerged on the mechanisms of lymphedema development<sup>[143,170,171]</sup>.

Obtaining data from human subjects involves many difficulties (e.g., unpredictability of the time of clinical

onset of PML, limitations of diagnostic methods, etc.)<sup>[170,173]</sup>. In experimental studies in rat, dog, and rabbit extremities, the multi-layers of lymph vascular networks, the rapid development of a good collateral network, and sufficient angiogenesis permit quick restoration of lymph pathways and drainage function, leading to prompt resolution of even acute edema without the appearance of long-term or chronic edema<sup>[174-177]</sup>. This precludes an informed study of chronic or long-term edema.

In light of these facts, the development of lymphedema in rat mesentery may make the detailed study of lymph and blood microvessel function in acute and chronic edema, because the single layer of vessels in this animal model reduces the opportunity for rapid development of collateral lymph flow. In our study, experimental lymphedema was created by microsurgical removal of regional lymph nodes (lymphadenectomy) or ligation of the collecting vein<sup>[101,126,178,179]</sup>. Then, the direct quantitative measurement of tissue water was performed in parallel to monitoring blood and lymph vessel activity, including mapping individual cell transport in microvessels and tissue.

After lymphadenectomy, dynamic observation of amounts of water revealed increasing edema from 30 min to 1 wk; the greatest degree of edema occurred at 1 wk with a gradual decrease in edema from 1 to 11 wk<sup>[101]</sup>. At the thirtieth minute post lymphadenectomy, these effects were accompanied by acute constriction of lymph vessels and slowing of lymph flow velocity from  $302 \pm 41 \mu\text{m/s}$  before extirpation to  $155 \pm 30 \mu\text{m/s}$  after extirpation ( $P < 0.01$ ). After 1 wk of lymphedema, the lymphatics were overloaded (diameter increased from  $133 \pm 6 \mu\text{m}$  in their intact state to  $147 \pm 4 \mu\text{m}$  after lymphadenectomy,  $P < 0.05$ ) with slowing lymph flow. Four weeks after lymphadenectomy, the amount of water in tissue included a range from significant compensation to progressive development of edema. In spite of this, lymph microvessels of all experimental animals (with compensation or with decompensation of edema) revealed significant dysfunction and structure damage (dilation, slowing of lymph flow, degenerative changes in the microlymphatic wall). Eleven weeks after lymphedema, we observed various microvascular disturbances, including lymphatic fibrosis at edema decompensation and significant dilation of lymph microvessels or lymphangiogenesis at edema compensation.

We obtained experimental evidence of the significant role of blood microvessels during lymphedema development after lymphadenectomy, which before was either not clear or was controversial. Marked changes in blood microvessels started at the stage of well-developed tissue edema and marked lymphatic disturbances. We observed dilation of blood microvessels, venules, and expansion of the microvascular network without significant hemorrhage in the interstitium<sup>[101]</sup>.

Acute venous insufficiency (30 min after vein ligation) led to significant edema<sup>[101,126,178,179]</sup>. The comparison of acute lymphedema after lymphadenectomy and venous insufficiency revealed several similar changes, including inhibition of lymph flow and phasic activity. The specific disturbances after vein ligation included marked dilation of

the blood vascular network; slowing (up to stasis) of blood flow in venules; and multiple hemorrhages adjacent to the venules and, as a result, the presence of many RBCs in the lymph.

Thus, unknown mechanisms of microvascular damage as well as the correlation between the functions of lymph microvessels, blood microvessels, and tissue edema in dynamic lymphedema development *in vivo* was established, which is important both for understanding mechanisms of lymphedema and for developing new treatment strategies.

### Experimental model of sound-related stress

Experimental pathologic stress (2 h of immobilization and interrupted sound, 120 dB, 150-500 Hz) on rats led to significant (20%) increase in microlymphatic diameters ( $P < 0.01$ ); intensification of lymph flow (mean cell velocity increased from  $227 \pm 8 \mu\text{m/s}$  in intact rats to  $295 \pm 12 \mu\text{m/s}$  in the stressed animals,  $P < 0.001$ ), and stimulation of phasic contractions in 75% of lymphatics<sup>[179-181]</sup>. The resulting changes in lymph microvessel function probably stimulate lymph drainage and, therefore, play an adaptive role in this pathology.

## REAL-TIME QUANTITATIVE MONITORING OF INDIVIDUAL CELL TRANSPORT *IN VIVO*

Normal rat lymphocytes, rat basophilic leukemia (RBL-1) cells, K562 human leukemia cells, and rat RBCs (for each cell type,  $10^7$ - $10^8$  cells/mL) were labeled with FITC and introduced separately by bolus injection (100  $\mu\text{L}$ ) into the tail vein of rats with normal blood circulation or with acute venous insufficiency (ligation of collecting mesenteric vein). Over the next 30-60 min, we monitored in real-time the fluorescently labeled circulating, rolling, and adhesive cells in mesenteric blood vessels (diameter, 30-50  $\mu\text{m}$ ) and lymph microvessels (diameter, 120-180  $\mu\text{m}$ ), as well as visualized the distribution of the cells in mesenteric interstitial space. Simultaneous fluorescence and transmission imaging allowed us to distinguish the position of a single labeled cell. Accumulation of cells in mesenteric lymph nodes and the right lobe of the liver was monitored *in vivo* 60-90 min after the injections; each organ had been carefully exposed through a mid-abdominal incision and placed on a thermostabilizing microscope stage. To minimize light scattering by tissue and obtain deep, clear images of lymph nodes, we applied optical immersion technology (optical clearing method) using glycerol, which is an osmotic chemical<sup>[182,183]</sup>. In addition, the concentration of labeled cells in the systemic blood circulation was estimated by sampling blood through a catheter.

### Normal and leukemic cell transport: a comparative analysis

We observed a significant number of rat RBCs, WBCs (lymphocytes), and leukemic cells in blood microvessels immediately after injection; 85%-95% of the cells were cleared from the microcirculation within the first 30 min (Figure 15A and B). In comparison, only a few human leukemia cells were found in the blood circulation within

**Figure 15** **A:** Monitoring of labeled rat lymphocytes, and rat (RBL) and human (K562) leukemia cells in blood vessels of rat mesentery; **B:** Simultaneous monitoring of RBCs in blood and lymph systems under normal conditions and with venous insufficiency; **C, D:** *In vivo* imaging of liver with **(C)** lymphocytes and **(D)** RBL leukemia cells. Monitoring RBC migration from blood vessel **(E)** through interstitium to **(F)** lymph vessel and **(G)** lymph node.

the first 5-10 min (Figure 15A), probably because 95% of the cells were cleared by a strong immune response immediately after injection. These cells then migrated into the interstitial space and were quickly destroyed. No cells appeared in lymphatic vessels during the first 60 min of observation.

In the first 5 min after bolus injections of WBCs or RBCs labeled with FITC ( $10^6$  cells of each type in bolus), 50 times more RBCs were present in the circulation than were normal WBCs. Normal WBCs were detected in blood flow more often than rat leukemia cells (RBL-1 cells). RBL-1 cells, being  $\sim 1.5$ -2 times larger than normal WBCs, probably plugged small microvessels, thus decreasing the number of cells detected. In particular, Figure 15A shows that the number of WBCs was slightly higher than that of RBL-1 cells, although fewer WBCs ( $10^6$  cells in bolus) than RBL-1 cells ( $10^7$  cells in bolus) were injected. At 60-90 min of observation, both types of cells had accumulated mainly in the liver (Figure 15C and D). WBCs were visualized in liver as clearly distinguishable individual cells (Figure 15C), whereas RBL-1 cells appeared as a fluorescent spot (Figure 15D), probably because cells were destroyed in the liver, and only the rest of the dye was visible. However, both types of cells were identified after 3 h of observation in blood samples from large vessels; there were more WBCs than RBL-1 cells ( $10^3$  vs  $10^2$ ). Thus, although the migrations of leukemic cells and normal cells in the same living organism represent some shared properties, they also display significantly distinct features. In the future, these distinct features may be used as diagnostic criteria for

leukemia. Since the presented approach is able to analyze the transport of lymphocyte (important participants of immune response) it offers the potential to study *in vivo* immune responses at cellular and molecular levels.

#### Cell transport dynamic from blood to lymph during edema

The modeling of acute venous insufficiency and tissue edema caused marked changes in normal cell migration<sup>[101]</sup>. In particular, after injection of labeled RBCs, we observed a 5-min increase in the absolute number of labeled cells in the slowing blood flow of edematous tissue compared with normal blood flow (Figure 15B). Then, the slow-down of blood flow at the edema led to the output of many RBCs (10-15 min of observation) from blood vessels in mesenteric interstitium, where the trajectory of their motion is represented as episodic zigzag lines with mean velocities of 10-20  $\mu\text{m/s}$ . As a result, RBCs moved through the interstitium to the lymphatics. After 30 min of monitoring, RBCs were identified in lymph flow (Figure 15F), and then in mesenteric lymph nodes (40-60 min of observation; Figure 15G). Thus, our integrated optical technique demonstrates unique capabilities for real-time monitoring of labeled cells in blood and lymph flow, as well as the migration of these cells into tissue interstitium and regional lymph nodes.

#### In vivo detection of flowing apoptotic cells

Apoptosis is referred to as programmed physiological cell death. *In vivo* study of apoptosis is crucial for understanding the fundamentals of cell biology; optimization of

**Figure 16** A: Apoptotic (arrowhead, red) and normal (two arrow triangles, green) cells in two blood vessels (dashed lines); B: Apoptotic cells (arrowhead, red) in interstitium (arrow shows one vessel); C: Normal (arrow, green) and apoptotic (red) cells in a lymph node (dashed line).

radiation therapy and chemotherapy; diagnosis of many diseases (e.g., metastasis development, cardiovascular diseases, hematological diseases, autoimmune diseases, neurodegenerative diseases, Alzheimer's disease); and assessment of acute organ transplant rejection or the effect of immunosuppressive drugs<sup>[134,184-195]</sup>. Despite significant progress in studying apoptosis *in vitro* with many powerful assays, adapting these assays to *in vivo* study of apoptosis is extremely difficult<sup>[184,185]</sup>.

In our experiments, WBCs extracted from a rat underwent apoptosis after exposure to dexamethasone. They were then labeled with rhodamine 6G (red fluorescent emission). In addition, normal WBCs were labeled with FITC (green emission). A 50/50 mixture of labeled apoptotic and normal WBCs was injected into a rat's tail vein, and the appearance of the WBCs was monitored in rat mesentery venules with integrated PTFC. The fluorescence measurements (obtained by counting the number of cells in images) demonstrated the appearance of both normal and apoptotic cells in blood microvessel flow during the first minute (Figure 16A), and rapid clearing of apoptotic cells from circulation, with a half-life of ~8 min. We also observed: (1) rolling apoptotic cells in small venules within 10 min after the injections, (2) the appearance of apoptotic cells in the interstitium after 15 min (Figure 16B), and (3) significant accumulation of apoptotic cells in mesenteric lymph nodes (Figure 16C) after 30 min (see details of node location in Figure 3A and B).

Thus, the obtained results demonstrate that individual cell migration in living organisms depends on: (1) the morphological type of normal and abnormal cells (e.g. WBCs versus RBCs, WBCs versus leukemic cells), (2) the functional state of the cell (e.g. living versus apoptotic cells), and (3) the functional status of the entire organism (e.g. in norm versus in acute venous insufficiency at tissue edema). The high sensitivity of the PT technique to nanoscale morphologic events during apoptosis demonstrated *in vitro*<sup>[112-113]</sup>, in combination with conventional fluorescent assays, makes it possible to apply this technique for detection of apoptotic cells *in vivo*.

## IR ANGIOGRAPHY AND LYMPHGRAPHY

Indocyanine green (ICG) is a well-known, relatively

harmless dye for IR blood angiography and IR imaging of lymph nodes in human and animals<sup>[196-201]</sup>. Within the first seconds after intravenous injection, there is a shift in the absorption spectrum of ICG from 780 nm to 805 nm (spectral stabilization) due to two processes: polymerization of ICG molecules and their binding to plasma proteins and lipoproteins<sup>[196]</sup>. Plasma clearance of ICG is biphasic, showing a rapid first phase with a half-life of 4-6 min and a secondary phase with a half-life of more than 1 h<sup>[197]</sup>. ICG is eliminated from an organism by the enterohepatic route<sup>[197]</sup>.

The imaging of blood vasculature by ICG is a well-known conventional approach; however, identification of the lymph microvascular network with ICG has not been previously studied. Recently, we performed first experiments with microlymphatics. Using TDM and fluorescent microscopy, we monitored typical microvascular units (venula, arteriola, and lymph microvessel of rat mesentery; Figure 17) after intravenous ICG injection (0.2 mL/100 g in rat's tail vein). Excitation at a wavelength of 805 nm, 0.25 mW/cm<sup>2</sup>, was provided by continuous diode laser, and the re-emitted fluorescence was filtered at 830 nm and then detected using an intensified highly sensitive camera (PentoMAX, Roper Scientific). Our preliminary studies demonstrated that the first IR image of the venula appears 70-80 s after injection; then, in a short period of time (first 2 min after injection), dye appeared in the arteriola (Figure 17B). Forty to fifty minutes after injection, ICG accumulated (at least partly) in lymph microvessels (Figure 17C). Thus, ICG may potentially be used for study of blood and lymph microcirculation (IR angiography and lymphography), including a monitoring traffic dye in blood and lymph vascular nets.

## CONCLUSIONS

As demonstrated in this paper, rat mesentery, in combination with advanced optical techniques, is an attractive animal model for *in vivo* lymph- and blood flow cytometry, high-resolution high speed cell imaging, IR time-resolved angiography and lymphography, real-time monitoring of cells traffic through tissue in norm, during diseases or in response to therapy.

Specifically, the capabilities of this model may include:

**Figure 17** ICG IR blood and lymph microangiography. Transmission image before ICG injection (venula: short arrow, arteriola: triangle, lymph microvessel: long arrow) (A). Fluorescence images (excitation 805 nm; emission 830 nm) at the (B) 15th and (C) 45th min after ICG injection.

(1) analysis of cell pathways in tissue (blood microvessel, interstitium, afferent lymphatics) with migration through microvessel walls and accumulation in lymph nodes and liver; (2) quantitative monitoring of changes in the number of normal or abnormal cells in blood and lymph flow (blood and lymph FC); (3) identification of moving and static cells, including rare abnormal cells and apoptotic cells, through their size, shape, and specific sub-cellular structures; (4) high-resolution, high-speed monitoring of lymph and blood microrheology (e.g. transient deformability, cell aggregation), and interactions between different moving cells and between moving cells and endothelial cells of the vessel wall; (5) quantitative assessment of the clearance rate of circulating cells in lymph and blood flow; (6) analysis of *in vivo* immune responses at cellular and molecular levels; (7) *in vivo* monitoring of the circulation and migration of chylomicrons, bacteria, and viruses; (8) monitoring of dynamic thrombus and blood clot formation (with and without platelet participation); (9) label-free IR microvessel angiography and lymphography.

These advantages are crucial, both for understanding basic cell biology (e.g. metabolism and apoptosis), cell flow dynamics, and for conducting clinical studies of early disease diagnoses (e.g., cancer, sickle diseases, leukemia, edema, inflammation, infections) or assessment of innovative therapeutic interventions (pharmaceuticals, nicotine, lasers, or  $\gamma$ -radiation). Other potential applications may include radio and drug screening *in vivo* based on the previously described, promising *in vitro* techniques.

It is hoped that this review will serve not only as a helpful progress report and to provide certain leads for further research, but will also help attract the scientific interest and support that are required to solve these problems.

## ACKNOWLEDGMENTS

The authors thank Grigory E Brill, PhD, DSc (Saratov Medical State University, Russia); Sergey S Ulianov, PhD, DSc (Saratov State University, Russia); Qingming Luo, PhD (Institute for Biomedical Photonics, Huazhong University of Science and Technology, China); Ivan V Fedosov, PhD (Saratov State University, Russia); Anastasia V Solovieva, PhD (Saratov Medical State University, Russia). We thank Tatiana V Stepanova for assisting with animal experiments, Dmitri O Lapotko, PhD for his significant contribution

in the development of the PT setup, and Scott Ferguson, for assisting with laser measurements. We also thank the Office of Grants and Scientific Publications at the University of Arkansas for Medical Sciences for editorial assistance during the preparation of this manuscript.

### Abstract

Abdominal pain and bowel habits alterations are common symptoms in the general population. The investigation to differentiate organic from functional bowel disorders represents a considerable burden both for patients and public health service. The selection of patients who should undergo endoscopic and/or radiological procedures is one of the key points of the diagnostic process, which should avoid the abuse of invasive and expensive tests as well as the underestimation of potentially harmful diseases. Over the coming years, clinicians and researchers will be challenged to develop strategies to increase the patient's compliance and to reduce the economic and social costs of the intestinal diseases.

### INTRODUCTION

For the sake of simplicity, bowel diseases have been divided into organic (OBD) and functional (FBD) disorders. In the past, FBD was merely considered an “umbrella” for many clinical pictures where the term functional reflected an unknown etiology and/or pathogenesis and their existence was even denied by some physicians<sup>[1,2]</sup>. In the last years, the fast-growing insight into the pathogenesis of intestinal

diseases has been narrowing the field of disturbances “not explained by structural or biochemical abnormalities”, in parallel with the progress of diagnostic tools and the development of novel technologies. Recent evidences, such as the role of serotonin in visceral functions<sup>[3-5]</sup>, the post-infective onset of irritable bowel syndrome (IBS)<sup>[6]</sup> or data about potential neuroendocrine dysfunctions<sup>[7]</sup> shed light on the phenomena underlying FBD. The “biopsychosocial model” focused on the complex interplay among genetics, environment, psychosocial and physiological factors, significantly contributed to clarify the true genesis of “functional” symptoms and to modify both treatment and clinical outcome<sup>[8]</sup>. However, while the new scenario of pathogenesis suggests an overlapping between morphologic and functional abnormalities, in clinical practice the distinction is maintained in prognostic terms, as “functional” identifies scarcely evolutive and virtually harmless conditions.

As the intestine reacts to different stimuli with a limited array of symptoms, the investigation to differentiate OBD and FBD represents a considerable burden for both the patients and public health service.

The selection of patients who should undergo endoscopic and/or radiological procedures is one of the key points of the diagnostic process, which should avoid the abuse of invasive and expensive tests as well as the underestimation of potentially dangerous diseases. In particular, we should take into account the high prevalence and increasing incidence of colo-rectal cancer which, at an early stage, can be successfully treated by endoscopic resection. Nevertheless, colonoscopy is not advisable in all patients with abdominal complaints in the absence of “red flag” features (age > 45 years, anaemia, bleeding, fever, weight loss, etc.) (Figure 1). Chronic or recurrent abdominal pain and bowel habit alterations are common symptoms in the general population. Because a wide range of etiologies may underlie these symptoms, they do not allow a differential diagnosis between OBD (neoplasm, infectious enteritis, Crohn's disease, celiac disease, etc.) and FBD. Moreover, patients may present overlapping syndromes as OBD and FBD, are not mutually exclusive and can be present in the same patient. FBD, mainly IBS, which affect 5%-20% of general population, are the most common intestinal disorders in both primary and secondary care<sup>[9-11]</sup>. Most patients are diagnosed and treated by general practitioners (GPs) and only those unresponsive to conventional treatment<sup>[10,12]</sup> are eventually referred to a gastroenterologist<sup>[9,13]</sup>.

In order to improve the positive identification of

**Figure 1** Suggested approach to the diagnosis of chronic abdominal symptoms.

patients affected with FBD, the Rome classification system has been developed. Although these guidelines have raised controversies about duration, frequency, severity and terminology itself of symptoms, they have created a common language for FBD and are now considered the gold standard. Unfortunately, Rome criteria have been developed by and for specialists working in the secondary care setting; they are ignored by many GPs and considered by others, as well as by many specialists, too complex and time-consuming and/or restrictive, suitable only for the tertiary care setting and for research purposes<sup>[14]</sup>. Therefore, many GPs and gastroenterologists are confident of making a correct diagnosis based on their personal criteria<sup>[14,15]</sup> and, in the absence of any biological or instrumental marker, FBD is still an exclusive diagnosis which often require extensive investigation. The recent Rome III criteria appear to be simpler and less restrictive and hopefully will help the diagnosis of FBD on clinical basis<sup>[16]</sup>.

When FBD is suspected, the clinical criteria can be combined with a number of non-invasive diagnostic tools. Unfortunately serological biomarkers of inflammation such as erythrocyte sedimentation rate, C-reactive protein, white cell count, platelet count, are not sufficiently sensitive or sufficiently specific because they do not directly reflect

the level of local inflammation<sup>[17-19]</sup>. The faecal occult blood test is of little use in detecting inflammatory bowel diseases (IBD) and has a low sensitivity for the diagnosis of colon cancer, especially at an early stage<sup>[20,21]</sup>. Therefore, in recent years considerable effort has been devoted to find alternative solutions. The latest knowledge about the pathogenesis of FBD (infection, food allergy or intolerance)<sup>[22-24]</sup>, have focused attention on the role of microscopic inflammation, bacterial overgrowth, altered immunity and even more subtle alterations, whose effects are detectable in non-invasive manner, by analysing stools, breath samples and blood.

## FAECAL MARKERS

### Neutrophil-derived proteins

Faecal neutrophil-derived proteins (mainly calprotectin and lactoferrin) assessment is receiving increasing attention as promising tools to differentiate OBD and FBD; although their clinical use needs definitive confirmation especially in the work-up of FBD, they could be the putative ideal test for non-invasive assessment of intestinal inflammation<sup>[25-27]</sup>.

Calprotectin is a 36-kDa calcium and zinc binding protein that accounts for about 60% of total proteins in the cytosol fraction of neutrophil granulocytes<sup>[28,29]</sup>. An

increase in faecal calprotectin levels in IBD, colorectal cancer and non-steroidal anti-inflammatory drugs enteropathy has been reported<sup>[30-33]</sup>. In a study of Dolwani, faecal calprotectin was superior to small bowel barium follow-up in identifying patients with organic diseases<sup>[34]</sup>. In Crohn's disease (CD) and ulcerative colitis (UC), its levels closely correlated with the faecal excretion of <sup>111</sup>In-labelled leukocytes, which is considered to be the gold standard for measuring intestinal inflammation<sup>[35]</sup> and recently it has been reported that a high faecal calprotectin concentration may identify those IBD patients in remission who are at risk of early relapse<sup>[36,37]</sup>. Calprotectin has a high negative predictive value for intestinal inflammation. It has low specificity for intestinal pathology but, at a cut-off of 30 mg/L (150 µg/g of faeces by the new method), it showed a sensitivity of 100% in discriminating between active Crohn's disease and IBS<sup>[27]</sup>. The combined use of presence/absence of alarm features, Rome criteria and calprotectin test proved to be a non-invasive, effective mean of screening patients for organic intestinal disease<sup>[38]</sup>.

Lactoferrin is an iron-binding protein contained in organic fluid, intestinal mucus and in neutrophils. Similarly to calprotectin, faecal lactoferrin proved to be a simple, sensitive marker of intestinal inflammation<sup>[25,39,40]</sup>.

## DNA

The molecular genetics of colorectal cancer provided the basis for the analysis of faecal DNA<sup>[41]</sup>. Colonoscopy is the best tool for the diagnosis of colorectal cancer but it cannot be proposed for a systematic screening of the entire population > 50 years of age. The recent availability of faecal-based, multi-target DNA panel has allowed a better sensitivity than faecal occult blood test for the detection of colorectal cancer<sup>[21]</sup>. This panel consists of different mutations (*K-ras* gene, *APC* gene, *p53* gene), markers of microsatellite-instability and markers of disordered apoptosis, clearly involved in the progression of colorectal cancer. Although the performance of faecal DNA testing is not comparable to colonoscopy, it is simple and non-invasive, therefore its use at frequent intervals might compensate for the lower diagnostic accuracy<sup>[21]</sup>.

## Pancreatic elastase

Chronic pancreatitis is a frequent cause of abdominal pain and diarrhoea whose diagnosis often requires complex and expensive procedures. The assessment of pancreatic elastase on stools seems to offer a better performance than previous non-invasive tests (i.e. serology, Pancreolauryl test, faecal tests for pancreatic enzyme) with a high sensitivity for moderate and severe pancreatic insufficiency<sup>[42,43]</sup>; this faecal test, like faecal neutrophil-derived protein assessment, is easy to perform, requires a single stool sample and offers a great advantage in terms of patient's compliance. Although most authors reported poor sensitivity for mild disease, its use has been recommended as a first choice test in patients with chronic diarrhoea of putative pancreatic origin<sup>[44]</sup>.

If these experimental data are confirmed in large controlled studies, the routine use of faecal tests might contribute to the selection of patients with abdominal

complaints both in the first diagnosis and in the follow-up avoiding invasive and expensive procedures.

## BREATH TESTS

Breath analysis is a simple and safe alternative to invasive tests to investigate digestive functions. Exhaled hydrogen (H<sub>2</sub>) and carbon (C) can be employed to assess malabsorption, gastrointestinal motility and *H. pylori* infection. H<sub>2</sub> in humans is produced only by bacterial fermentation of carbohydrates<sup>[45]</sup>. This process has been related to the onset of symptoms such as diarrhoea, bloating and abdominal pain<sup>[46,47]</sup>. Different hydrogen breath tests are currently used to detect carbohydrate malabsorption. Lactose, fructose, sorbitol are the most commonly tested carbohydrates, although their role in symptoms of FBD is controversial, and the prevalence of lactose, fructose and sorbitol malabsorption in IBS patients is not different from healthy subjects<sup>[48]</sup>.

Small intestinal bacterial overgrowth (SIBO) is a malabsorption syndrome characterized by more than 10<sup>5</sup> colonic type bacterial/mL of jejunal juice described in case of structural bowel alterations (surgical blind loop, stenosis, etc), motility disturbances (pseudo-obstruction, diabetic autonomic neuropathy, scleroderma) and also present in chronic diseases (liver cirrhosis, chronic pancreatitis, chronic renal failure)<sup>[49]</sup>. Recent data also indicate that an altered gut flora may play a pathogenic role both in IBS and IBD<sup>[50,51]</sup>. It has been shown that eradication of SIBO eliminates IBS symptoms in 48% of patients<sup>[52]</sup>. Although jejunal culture is considered the gold standard for the diagnosis of SIBO, some drawbacks limit its widespread use; thus, glucose and lactulose breath tests are commonly employed. Breath tests based on the excretion of CO<sub>2</sub> subsequently measured by a mass spectrometer have been developed; they employ a variety of <sup>13</sup>C substrates to investigate the exocrine pancreatic function (<sup>13</sup>C triolein, <sup>13</sup>C mixed chain triglyceride)<sup>[53]</sup>, gastric emptying (<sup>13</sup>C octanoate)<sup>[54]</sup>, as well as in the diagnosis of *H. pylori* infection (<sup>13</sup>C urea)<sup>[55]</sup>.

The simplicity and the safety of breath tests encouraged a widespread use, but the data on their low diagnostic accuracy should be taken into account and their use on regular basis cannot be recommended in clinical practice<sup>[56]</sup>.

## SERUM

Recent literature highlighted that approximately 4% of patients diagnosed as IBS are affected with celiac disease<sup>[57]</sup>. Altered bowel habits and abdominal pain, the clinical hallmark of IBS, are common in celiac patients, and serological assessment for anti-endomysial and anti-transglutaminase antibodies should be performed as a first level test when IBS is suspected. Many patients suffering from abdominal pain and/or bowel habit changes perceive their symptoms as related to some form of dietary intolerance and show a good response to an exclusive diet. Nevertheless, any attempt to correlate food-specific IgE production and chronic abdominal symptoms has been disappointing<sup>[24,58]</sup>. Although it has been reported

that sometimes IgE-mediated reactivity can present with chronic abdominal complaints, the measurement of food-specific IgE antibody concentrations to ascertain food intolerance in FBD is not justified and should be discouraged<sup>[59]</sup>. Preliminary data showed that high titres of food-specific IgG4 antibodies are present in IBS patients suggesting a diagnostic role in those cases of IBS who could benefit mostly by an exclusive diet<sup>[60]</sup>. Their clinical follow-up and further research are needed to clarify the importance of these findings and their role in clinical practice.

## CONCLUSION

Likely the near future will lead to a deep revision of the concept of “functional disorder”. The striking progress in our knowledge of the molecular basis of diseases is identifying new models for FBD pathogenesis, which tend to be less “functional” and more “organic”.

These new evidences will have a relevant effect on the clinical management of intestinal diseases. We are not far from the time when the development of minimally or non-invasive techniques will allow an accurate diagnosis, a serial monitoring and a “real time” adjustment of therapy.

## Abstract

Despite progress in the treatment of advanced and metastatic pancreatic cancer (PC), the outcome of this disease remains dismal for the majority of patients. Given the moderate efficacy of treatment, prognostic factors may help to guide treatment decisions. Several trials identified baseline performance status as an important prognostic factor for survival. Unfit patients with a Karnofsky performance status (KPS) below 70% only have a marginal benefit from chemotherapy with gemcitabine (Gem) and may often benefit more from optimal supportive care. Once, however, the decision is taken to apply chemotherapy, KPS may be used to select either mono- or combination chemotherapy. Patients with a good performance status (KPS = 90%-100%) may have a significant and clinically relevant survival benefit from combination chemotherapy. By contrast, patients with a poor performance status (KPS  $\leq$  80%) have no advantage from intensified therapy and should rather receive single-agent treatment.

## INTRODUCTION

Advanced pancreatic cancer (PC) is an incurable disease and without appropriate treatment survival is limited to 3-4 mo. Since Burris *et al*<sup>[1]</sup> demonstrated the superiority of gemcitabine (Gem) over bolus 5-fluorouracil (5-FU), single-agent Gem has evolved as a standard of care. Numerous trials consistently support the notion that Gem alone may induce a median overall survival (OS) of 5-7 mo and a 1-year-survival of 11%-25%<sup>[2]</sup>. A great effort has been undertaken to improve these results by use of combination chemotherapy. Up to now, only two combinations, Gem plus erlotinib<sup>[3]</sup> and Gem plus capecitabine<sup>[4]</sup> have provided a significant prolongation of survival when compared to Gem alone.

Due to the moderate progress derived from chemotherapy, the question arises if subgroups of patients can be identified who benefit most from specific treatment strategies. Previous studies already tried to identify prognostic factors such as pre-treatment CA 19-9 levels<sup>[5,6]</sup>, inflammatory response markers like C-reactive protein (CRP) or cytokines<sup>[7,8]</sup>, serum-albumin levels<sup>[9]</sup> or pre-treatment performance status<sup>[10-12]</sup>. In this overview we analysed Karnofsky performance status (KPS) as a prognostic factor to define a patient group which may benefit from more intensive therapy as opposed to those patients who should rather receive single-agent treatment.

## CLINICAL TRIALS

### Single-agent therapy

The clinical importance of the KPS for the outcome of PC patients treated with Gem was first elucidated by Storniolo and co-workers<sup>[13]</sup>. Within an investigational new drug treatment program 3023 patients were evaluated. The analysis of baseline efficacy factors indicated that patients with a KPS  $\geq$  70% had a median survival of 5.5 mo as compared to only 2.4 mo observed in patients with a KPS < 70%. Also median time to disease progression (TTP) was greater in the good performance group (2.9 *vs* 1.7 mo, respectively). Interestingly, best tumor response was comparable between the two groups (12% *vs* 10%) supporting the notion that in PC response to therapy is only a poor surrogate endpoint for survival. In view of this analysis, it appears unlikely that patients with a KPS < 70% actually benefit from therapy and the conclusion may be drawn that chemotherapy with Gem should rather be withheld in patients with a very poor performance status.

**Table 1** Influence of performance status on median survival in randomized phase III trials

	Overall Survival (mo)		Reference
	KPS 60-80	KPS 90-100	
Gemcitabine + Cisplatin	4.9 <sup>1</sup>	10.7	Heinemann <i>et al</i>
Gemcitabine	4.8 <sup>1</sup>	6.9	
Statistical significance	$P = 0.64$	$P = 0.051$	
Gemcitabine + 5-FU/FA	3.4	8.5	Riess <i>et al</i>
Gemcitabine	4.9	6.2	
Statistical significance	$P = 0.62$	$P = 0.172$	
Gemcitabine + Capecitabine	5.3	10.1	Herrmann <i>et al</i>
Gemcitabine	7.0	7.5	
Statistical significance	$P = 0.22$	$P = 0.024$	

KPS = Karnofsky performance status, <sup>1</sup>subgroup with poor performance status defined as KPS 70%-80%.

**Figure 1** Randomized phase III trial comparing gemcitabine (Gem) vs gemcitabine plus cisplatin (Cis): Subgroups KPS 70%-80% and KPS 90%-100%; Progression-free survival (PFS) by treatment arm (HR = hazard ratio).

### Gemcitabine plus Cisplatin

The combination of Gem and cisplatin is based on a synergistic cytotoxic interaction of the two agents, namely the propensity of Gem to inhibit repair of cisplatin-induced DNA damage. In a randomized phase III trial Gem plus cisplatin was compared to single-agent Gem<sup>[14]</sup>. In the combination arm, Gem (1000 mg/m<sup>2</sup>) and cisplatin (50 mg/m<sup>2</sup>) were both applied in a biweekly fashion, while in the single-agent arm Gem was given at a dose of 1000 mg/m<sup>2</sup> weekly times three in a 4-wk regimen. One hundred ninety-five patients with histologically confirmed advanced PC (KPS > 70%) were randomized and survival was evaluated as the primary end-point.

**Figure 2** Randomized phase III trial comparing gemcitabine (Gem) vs gemcitabine plus cisplatin (Cis): Subgroups KPS 70%-80% and KPS 90%-100%; Overall survival (OS) by treatment arm (HR = hazard ratio).

In a post-hoc analysis of this trial, patients were divided into groups with good (KPS = 90%-100%) and poor performance status (KPS = 70%-80%). Patients with a poor performance status at base-line (KPS 70%-80%) had no benefit from combination therapy as compared to Gem alone and comparably disappointing results were obtained for progression free survival (PFS: 2.8 *vs* 2.9 mo,  $P = 0.69$ ) and OS (4.9 *vs* 4.8 mo,  $P = 0.64$ ) (Table 1). By contrast, patients with a good KPS (90%-100%) who underwent treatment with Gem/cisplatin had a significantly longer PFS compared to patients treated with single-agent Gem (7.7 *vs* 2.8 mo,  $P = 0.013$ ) (Figure 1). This prolongation of PFS also translated into a prolonged median OS (10.7 *vs* 6.9 mo), that reached a borderline level of statistical significance ( $P = 0.051$ ) (Figure 2).

In the univariate analysis for prognostic factors, KPS (HR = 0.52,  $P = 0.006$ ) and stage of disease (HR = 1.55,  $P = 0.0048$ ) had a significant impact on survival, while age, gender, tumor grading and treatment arm did not. These data were confirmed in a multivariate analysis which identified KPS (HR = 0.59,  $P = 0.0051$ ) and stage of disease (HR = 1.65,  $P = 0.022$ ) as independent determinants of overall survival<sup>[14]</sup>.

### Gemcitabine plus 5-FU

The CONKO-002 trial compared the combination of Gem plus folinic acid (FA) and 5-FU to single-agent Gem<sup>[15]</sup>. In this randomized phase III trial Gem was given at a dose of 1000 mg/m<sup>2</sup> together with FA 200 mg/m<sup>2</sup> and 5-FU 750 mg/m<sup>2</sup> weekly times four every six weeks. In the comparator arm, single-agent Gem was applied ac-

cording to the Burris regimen (1000 mg/m<sup>2</sup> weekly × 7 followed by two weeks rest and a subsequent application on d 1, 8, and 15 every four weeks<sup>[1]</sup>). Both treatment arms induced nearly identical results for tumor response rates (Gem/FA/5-FU *vs* Gem: RR = 4.8% *vs* 7.2%), median time to tumor progression (TTP = 3.5 *vs* 3.5 mo), and median survival time (OS = 5.9 *vs* 6.2 mo). Also in this trial, the subgroup analysis indicated that patients with a poor performance status (KPS = 60%-80%) responded in a different way compared to the good performance group (KPS = 90%-100%). In patients with a poor performance status, combination treatment induced a worse survival than gemcitabine alone (3.4 *vs* 4.9 mo). By contrast, a strong trend towards an improved survival was observed in the good performance group treated within the combination arm (8.5 *vs* 6.2 mo, *P* = 0.172) (Table 1).

### Gemcitabine plus Capecitabine

Herrmann and co-workers performed a randomized trial comparing Gem (1000 mg/m<sup>2</sup>, d 1 + 8, q 3 wk) plus capecitabine (650 mg/m<sup>2</sup> po bid d 1-14 q 3 wk) to Gem given according to the Burris-regimen<sup>[16]</sup>. While the combination induced a higher median PFS than Gem alone (4.8 *vs* 4.0 mo) and a longer median OS (8.4 mo *vs* 7.3 mo), these results failed to reach the level of statistical significance. In the unfavorable KPS group (60%-80%), survival with Gem/capecitabine was inferior to Gem alone (5.3 *vs* 7.0 mo), while in the good performance group the combination induced a significantly superior survival time (10.1 *vs* 7.5 mo, *P* = 0.024) (Table 1).

## CONCLUSION

Despite recent advances in systemic treatment of patients with advanced PC, the prognosis still remains poor. Thus, pre-treatment patient selection, based on prognostic factors, for different therapeutic options (e.g. supportive care only, single-agent chemotherapy, combination chemotherapy) may turn out to gain clinical importance. Additionally, these prognostic factors may also be a useful for the design of future trials in advanced PC.

In the present review, we summarized the clinical importance of performance status as a prognostic factor for OS. In a randomized trial comparing Gem plus cisplatin to Gem alone potential prognostic factors such as stage of disease, KPS, treatment arm, age, sex, and pathological tumor grade were evaluated in a univariate analysis. Only pre-treatment KPS and distant metastasis could be identified as significant prognostic factors for OS. In a multivariate analysis, both could be confirmed as independent prognostic factors for PFS and OS<sup>[14]</sup>. The importance of performance status has already been observed by Louvet and co-workers who compared the Gem plus oxaliplatin combination to single-agent Gem<sup>[12]</sup>. He reported that distant metastasis and a poor PS (ECOG 2) at baseline were independent negative prognostic factors. These data were further supported by van Cutsem *et al*<sup>[9]</sup> who investigated the efficacy of Gem plus tipifarnib in a large randomized phase III trial. ECOG performance status and stage of disease (locally advanced *vs* metastatic) were, besides tumor differentiation and albumin levels, highly significant prog-

nostic factors for survival in a univariate analysis.

Once performance status is defined as a clinically relevant prognosticator for patient outcome, the question needs to be asked if performance status can also be used to guide adequate treatment selection. Storniolo *et al*<sup>[13]</sup> clearly demonstrated that the benefit from single-agent Gem is very low if patients with a KPS < 70% are treated. More often than not these patients will rather benefit from optimal supportive care.

Once, however, the decision is taken that a patient should receive chemotherapy it needs to be clarified if combination or single-agent chemotherapy is likely to provide an optimal therapeutic result. The relevance of KPS in this particular question was investigated based on a randomized trial comparing the Gem/cisplatin combination to Gem alone. In a retrospective subgroup analysis, patients with a good KPS (90%-100%) had a clear benefit from the Gem/cisplatin combination with regard to PFS (7.7 *vs* 2.8 mo, *P* = 0.013) and OS (10.7 *vs* 6.9 mo, *P* = 0.051). Outcome of patients with a poor KPS (70%-80%) was, however, not affected by the choice of treatment. Similar observations were also reported in two further phase III trials<sup>[15,16]</sup>. While none of them demonstrated a significant superiority of combination chemotherapy for the whole study population, both trials could show a clinical relevant benefit for patients with a good performance status.

In conclusion, Gem-based combination regimens have the potential to prolong survival in patients with a good KPS, whereas patients with a poor KPS have no advantage and may as well receive single-agent Gem. Consideration of the performance status may, therefore, help to select adequate treatment strategies and thus may provide a reasonable step towards individualized therapy. Individualization of treatment becomes necessary since the benefit from more intensive combination chemotherapy can only be expected in defined subgroups of PC patients.

## Abstract

**AIM:** To characterize the IFN-response and its modulation by the antiviral compound lamivudine in HBV-transfected HepG2.2.15 cells.

**METHODS:** HepG2.2.15 and HepG2 cells were stimulated with various concentrations of IFN- $\alpha$ 2a in the presence or absence of lamivudine. Then, total RNA was extracted and analysed by customised cDNA arrays and northern blot for interferon-inducible genes (ISGs). In addition, cellular proteins were extracted for EMSA and western blot. HBV replication was assessed by southern blot or ELISAs for HBsAg and HBeAg.

**RESULTS:** Two genes (MxA, Cig5) with completely abolished and 4 genes (IFITM1, -2, -3, and 6-16) with partially reduced IFN-responses were identified in HepG2.2.15 cells. In 2 genes (IFITM1, 6-16), the response to IFN- $\alpha$  could be restored by treatment with lamivudine. This effect could not be explained by a direct modulation of the Jak/Stat signalling pathway since EMSA and western blot experiments revealed no suppression of Stat1 activation and ISGF3 formation after stimulation with IFN- $\alpha$  in HepG2.2.15 compared to HepG2 cells.

**CONCLUSION:** These results are consistent with the assumption that chronic hepatitis B may specifically modulate the cellular response to IFN by a selective blockage of some ISGs. Antiviral treatment with lamivudine may partially restore ISG expression by reducing HBV gene expression and replication.

## INTRODUCTION

Hepatitis B (HBV) is a hepatotropic DNA virus capable of causing both acute and chronic hepatitis in humans. It is estimated that over 350 million people are chronically infected with HBV worldwide. Currently approved therapeutic strategies for treatment of HBV include interferon-alpha (IFN- $\alpha$ ), the nucleoside analogue lamivudine and the nucleotide analogue adefovir<sup>[1,2]</sup>. However, only a minority of patients treated with IFN- $\alpha$  has a long-term sustained response with 'eradication' of the virus. Patients with a high viral load, in particular, rarely respond to IFN therapy. Treatment with lamivudine, on the other hand, is complicated by a high rate of viral resistance and a high relapse rate after cessation of therapy, respectively<sup>[3]</sup>. Both the emergence of viral resistance and relapse after therapy are often associated with a hepatitis flare, which can sometimes be fatal. Thus, novel strategies are needed to improve treatment for this disease.

To develop new regimens it is necessary to gain further insights into the interactions between HBV and the main antiviral system of the host, the IFN-system. It has been shown that type I and type II interferons are able to suppress HBV-replication in livers from HBV-transgenic mice<sup>[4-6]</sup>. This could also be demonstrated *in vitro* by using immortalized hepatocyte cell lines from these animals<sup>[7]</sup> and involves elimination of pregenomic RNA-containing capsids, inhibition of DNA replication and reduction of steady-state levels of HBV transcripts. The effector mechanisms that have been associated with IFN-induced suppression of HBV-replication include MxA<sup>[8]</sup> and proteasome mediated activities<sup>[9,10]</sup>. Additional data suggest a role for GTP-binding proteins, signalling and various other molecules in the control of HBV replication<sup>[11]</sup>. HBV can

counteract these antiviral effector mechanisms by inhibiting proteasome activities in an HBX-dependent manner<sup>[12]</sup> and by suppressing MxA expression at the promoter level<sup>[13]</sup>. Furthermore, it has been shown that HBV replicated at higher levels in HBV-transgenic mice crossed with IRF-1 or PKR deficient mice while replication was unchanged in transgenic mice crossed with RNase L deficient mice<sup>[14]</sup>.

Assuming that HBV may interfere with the expression of ISGs, one would predict that the ISG expression in cell lines with and without HBV may be different and this would be modulated by inhibition of HBV gene expression and replication. The present study was performed to test this hypothesis. Using customized cDNA arrays for ISGs, we could identify 2 ISGs (MxA and Cig5) that are completely abolished in HBV-transfected HepG2.2.15 cells and 4 genes (IFITM1, -2, -3 and 6-16) with partially reduced responses. This suppression could partially be restored in 2 genes (IFITM1, 6-16) by treatment with the nucleoside analogue lamivudine suggesting an additional therapeutic mechanism for this drug.

## MATERIALS AND METHODS

### Cell culture

HepG2.2.15 cells were kindly provided by G. Acs (Mount Sinai Medical Cancer, New York, NY) and maintained in Dulbecco's Modified Eagle's Medium, supplemented with 2 mmol/L L-glutamine 50 IU/mL of penicillin, 50 mg/L of streptomycin, 500 mg/L of G418, 5% (vol/vol) fetal bovine serum, at 37°C in humidified incubators at 5% CO<sub>2</sub>. The cells were seeded at a density of  $8 \times 10^5$  cells and maintained in a confluent state for 2 to 3 d before being treated with antiviral compounds. At first, various concentrations from 0.04  $\mu$ mol/L to 100  $\mu$ mol/L of lamivudine were used to reach the suitable drug concentration, which profoundly suppressed HBV replication without cytotoxicity. At the same time, a time course of drug action also was evaluated. Over a period of 10 d lamivudine was added to the medium daily, then the cells were stimulated by addition of IFN- $\alpha$  for 6 h. Thereafter, the media were collected and DNA or RNA was extracted for further analysis.

### Analysis of secreted HBV particles

Detection of HBsAg and HBeAg was carried out by using a commercially available kit (Dade Behring) according to the manufacturer's instructions. Medium samples collected from HepG2.2.15 cells were centrifuged at 1200 rpm for 10 min to remove cellular debris, transferred to clean tubes and stored at -20°C until analysed. HBsAg and HBeAg amounts were evaluated from absorbance reading values (450 nm) compared to the constructed controls.

### HBV DNA analysis

**Extracellular virion HBV-DNA analysis:** Medium of HepG2.2.15 cells was collected and centrifuged (10 min, 2000  $\times$  g), and polyethylene glycol ( $M_r$ , 8000) was added to the supernatant at a concentration of 10% (wt/vol) followed by overnight precipitation at 4°C. The virions

were pelleted (30 min, 10 000  $\times$  g), and the pellet was re-suspended in lysis buffer (10 mmol/L Tris-Cl, 5 mmol/L EDTA, 150 mmol/L NaCl, 1% SDS) at room temperature for 15 min. Proteinase K was added at a concentration of 500  $\mu$ g/mL and the suspension incubated for 2 h at 56°C. The digest was extracted with phenol/chloroform, 1:1 (vol/vol) or chloroform, respectively, and the DNA was precipitated with 2.5 vol. of ethanol. The DNA pellet was dissolved in TE solution and then spotted onto Hybond-N+ membranes. Alternatively, the DNA was electrophoresed in 1.2% agarose gel followed by blotting onto Hybond-N+ membranes. The bolt was hybridized with a <sup>32</sup>P-labeled HBV DNA probe (digested by Nsi I from plasmids that contained the full length HBV genome sequence dimer and labelled with a Rediprime™ II Random prime labelling system), washed with 2  $\times$  SSC/0.1% SDS at room temperature for 20 min, twice, and 0.1  $\times$  SSC/0.1% SDS at 60°C for 45 min, and then autoradiographed. The intensity of the autoradiographic dots or bands was quantitated using the Cyclone Storage Phosphor System (Packard Instrument Company, Median, Conn.). All drug concentrations were tested in duplicate or triplicate, with antiviral effects being scored as the amount of HBV DNA present in the media relative to that in untreated controls.

### Intracellular HBV replicative intermediates (RI)

**analysis:** HepG2.2.15 cells were consecutively treated with various concentrations of lamivudine for 10 d. The cytoplasmic preparations containing HBV core particles were isolated from the treated cells. Cells were lysed with lysis buffer (50 mmol/L Tris-Cl, PH 7.4, 150 mmol/L NaCl, 5 mmol/L MgCl<sub>2</sub>, 0.5% NP-40) at room temperature for 5-10 min. The cytoplasmic fraction was separated from the nuclear fraction by centrifugation. Unprotected DNA was removed by adjusting cytoplasmic preparations so that they contained 10 mmol/L MgCl<sub>2</sub> and 500  $\mu$ g/mL of DNase I (Roche, Germany) followed by a 1 h incubation at 37°C. To extract replicative intermediates (RI), EDTA, sodium dodecyl sulfate (SDS), NaCl and proteinase K (QIAGEN) were added separately and sequentially to final concentrations of 10 mmol/L EDTA, 1% SDS, 100 mmol/L NaCl and 500 mg/L of proteinase K. The sample was incubated for 1.5 h at 56°C and then subjected to sequential phenol and chloroform extraction and isopropanol precipitation. Precipitated nucleic acids were resuspended in a small volume of TE solution and digested with 100 mg/L of RNase (Roche, Germany) for 1 h at 37°C. Twenty micrograms of cytoplasmic preparations containing HBV replicative intermediates DNA (RI) were then analysed by electrophoresis in 1.2% agarose gels, followed by blotting onto Hybond-N+ membranes. The bolt was hybridized with a <sup>32</sup>P-labeled HBV DNA probe (digested by Nsi I from plasmids which contain full length HBV genome sequence dimer, and labelled with a Rediprime™ II Random prime labelling system), washed with 2  $\times$  SSC/0.1% SDS at room temperature for 20 min, twice, and 0.1  $\times$  SSC/0.1% SDS at 60°C for 45 min, and then autoradiographed as described above.

### RNA extraction

Total RNA was isolated from cells using Trizol according

to the manufacturer's instructions. RNA quantity and quality was assessed by determination of the optical density at 260 and 280 nm using spectrophotometry and additional visualisation by agarose gel electrophoresis.

#### **Gene expression profiling by customized cDNA macroarrays**

Radiolabelled cDNA was generated from 20 µg total RNA by reverse transcription with Superscript II (Gibco, MD) in the presence of  $^{32}$ P-dCTP. Residual RNA was hydrolysed by alkaline treatment at 70°C for 20 min and the cDNA was purified using G-50 columns (Amersham Pharmacia, UK). Before hybridisation to the macroarrays the labelled cDNA was mixed with 50 µg COT-DNA (Gibco) and 10 µg Poly-A DNA (Sigma), denatured at 95°C for 5 min and hybridised for 1 h to minimise non-specific binding. Preparation of the macroarrays (representing 150 known ISGs), hybridisation of the radioactive cDNAs and scanning and analysis of the macroarrays were carried out as described previously<sup>[15]</sup>.

#### **Northern blot analysis**

5 µg of total RNA was electrophoresed through a 1.2% agarose gel containing formaldehyde and then transferred to Hybond-N+ membranes. The immobilized RNA was hybridized with a  $^{32}$ P-labeled DNA probe (IMAGE clones PCR products, purified with Gel Extract kit, QIAGEN).

#### **Electrophoretic Mobility Shift Assay**

At 80% to 90% confluence, cells were stimulated with IFN- $\alpha$  for 6 h. Preparations of nuclear extracts were performed according to the instruction of the manufacturer (PIERCE, NE-PERTM Nuclear Extraction Reagent). Nuclear extracts/DNA binding reactions were performed in 20 µL containing 15 µg nuclear extract protein and 4 µL Gel Shift Binding 5 × Buffer (20% glycerol, 5 mmol/L MgCl<sub>2</sub>, 2.5 mmol/L EDTA, 2.5 mmol/L DTT, 250 mmol/L Tris-Cl, PH 7.5, 0.25 mg/mL Poly (dI-dC) · Poly (dI-dC)). ISRE/GAS consensus oligonucleotides (5'-AAG TAC TTT CAG TTT CAT ATT ACT CTA-3') from the promoter region of the IFN- $\alpha$  responsive genes were used. Mutant oligonucleotides (5'-AAG TAC TTT CAG TGG TCT ATT ACT CTA-3') were used as control. The probes were end-labeled with  $\gamma$ - $^{32}$ P-ATP (U K, 3000 Ci/mol) at room temperature for 20 min. Complexes were separated from the probe in 4% naive poly-acrylamide gel in 0.5 × TBE buffer. The gels were subsequently dried and autoradiographed.

#### **Western blot analysis**

After interferon treatment, cells were washed once with ice-cold phosphate-buffered saline. Cells were lysed on ice for 30 min in 0.5 mL lysis buffer containing 50 mmol/L Tris, pH 8.0, 10% Glycerol, 0.5% NP40, 150 mmol/L NaCl, 1 mmol/L DTT, 1 mmol/L EDTA, 1 mmol/L Sodiumorthovanadate, 170 mg/L phenylmethylsulfonyl fluoride, 2 mg/L Aprotinin, 1 mg/L Leupeptin. Lysates were cleared by centrifugation in a microcentrifuge at high speed for 30 min at 4°C. Protein concentration of the supernatant was measured with Bradford reagent. Equal amounts (100 µg) of proteins were suspended in

sodium-dodecyl sulphate (SDS)-sample buffer, boiled for 5 min and separated by electrophoresis (NuPAGE 4%-12% Bis-Tris Gel, Invitrogen). The separated proteins were transferred to a polyvinylidene difluoride membrane (Hybond-P<sup>TM</sup>, Amersham Biosciences). After blocking for 1 h at room temperature in 10% non-fat dry milk in Tris-buffered saline with 0.1% Tween-20 (TBST) or 1% BSA for antibodies specific for phosphorylated epitopes, membranes were incubated with anti-p38, anti-pp38 (Santa Cruz), anti-Stat1, anti-Stat1(pY701) and anti-ERK1, anti-ERK1/2(pT202/pY204) (BD Biosciences) overnight at 4°C, and thereafter with horseradish peroxidase-conjugated anti-rabbit or anti-Mouse IgG (1:5000) (Amersham Biosciences) for 1 h at room temperature. The proteins were detected with enhanced chemiluminescence reagent (ECL, Amersham).

#### **Southern blot analysis**

Twenty micrograms of cytoplasmic preparations containing HBV replicative intermediates (RI) DNA were analysed by Southern blotting as above.

## **RESULTS**

#### **Differential expression of ISGs in HepG2.2.15 and HepG2 upon stimulation with IFN- $\alpha$**

Type 1 IFNs are known to induce an intracellular antiviral state against many viruses. Therefore, we developed a customized cDNA array methodology to study the expression of IFN stimulated genes (ISGs). At present, this system permits the analysis of several hundred genes of interest. A substantial spectrum of known ISGs is analysed with this macroarray (Table 1). The sensitivity of this method has also been assessed previously<sup>[15]</sup>. Conventionally, in most micro- and macroarray systems a 2-fold change in the expression level is regarded as being significant.

In the established hepatoma cell line, hepG2.2.15 with stably transfected HBV genomes<sup>[16]</sup>, ISG expression was examined using the cDNA macroarrays (Table 2). While many ISGs, e.g., 2-5 OAS, IFI 17, and RING4, were normally stimulated by IFN- $\alpha$ , several other ISGs were expressed at a lower level compared with the ISG expression in HepG2 cells. The induction of 2 ISGs, MxA and Cig5, was completely inhibited in HepG2.2.15 cells, while a partial inhibition was observed for 4 ISGs, IFITM1, IFITM2, IFITM3, and 6-16 (Table 1, Figure 1). Thus, only a subgroup of ISGs was down regulated in HepG2.2.15.

#### **Analysis of the IFN response in HepG2.2.15 and HepG2 cells**

The results above suggested that the IFN-signalling pathway is only partially inhibited in HepG2.2.15. Western blotting and EMSA and were carried out to analyse Stat1 activation and ISGF3 formation in HepG2 and HepG2.2.15 cells. The phosphorylated form of Stat1 was detected by western blot in IFN- $\alpha$  treated cells (Figure 2). The phosphorylation of Stat1 was enhanced in HepG2.2.15, compared with HepG2. Furthermore, Figure 3 showed that the formation of ISGF3 in HepG2.2.15 cells occurred after IFN- $\alpha$  stimulation, as occurred in HepG2 cells.

Genes of interest were selected from the UniGene database. These genes comprise known ISGs and genes of intrinsic interest which might or might not be induced by IFNs in different cell systems. They include genes involved in cell proliferation, immune responses and the responses to a variety of cytokines. 5' IMAGE clones with 0.5-0.8 kb length were chosen and obtained from RZPD, Berlin, Germany.

**Figure 1** Northern blot analysis of ISG expression and its modulation by lamivudine in HepG2 and HepG2.2.15 cells. HepG2 and HepG2.2.15 cells were cultured in the absence or presence of 2  $\mu$ mol/L of lamivudine for 10 d. Then, the cells were stimulated with 100 or 1000 IU/mL of IFN- $\alpha$  for 6 h. Total cellular RNAs were isolated for Northern blotting hybridization. Lam: lamivudine.

Cells were stimulated with 100 U/mL IFN- $\alpha$  for 6 h with or without pre-treatment with 2  $\mu$ mol/L lamivudine for 10 d. Then, RNA was isolated and assayed by cDNA macroarray. Data are shown as fold induction compared to the untreated control. Lam: Lamivudine.

These data clearly show that the IFN-signalling pathway is generally not blocked in HepG2.2.15 cells. The results consistently show that both steps were evenly enhanced in HepG2.2.15. In addition, activation of ERK and p38 MAPKinase was not altered in HepG2.2.15 cells (data not shown).

### Reduction of the production of HBV proteins and the HBV replication by lamivudine treatment

The difference in ISG expression in HepG2 and HepG2.2.15 cell lines may be partly due to the presence of HBV replication in the later one. Consequently, the ISG expression in HepG2.2.15 would change if the HBV gene expression or replication is suppressed. To test this hypothesis, we determined the optimal condition to reduce HBV gene expression and replication using the nucleoside analogue lamivudine. HepG2.2.15 cells were treated with lamivudine at various concentrations from 0.04  $\mu$ mol/L to 100  $\mu$ mol/L. The antiviral activity was determined by quantitation of secreted HBsAg and HBeAg particles, extracellular virions and intracellular HBV replicative intermediates (RI). Figure 4A shows that treatment with lamivudine led to a significant reduction of secreted HBsAg and HBeAg in the supernatant of HepG2.2.15 cells. Parallel to the reduction of HBsAg and HBeAg production, the extracellular virion DNA in the culture supernatant of HepG2.2.15 cells and intracellular HBV replicative intermediates (RI) decreased after treatment with 2  $\mu$ mol/L or 20  $\mu$ mol/L of lamivudine for 10 d (Figure 4B and C). Maximal levels of suppression of HBV were observed after 10 d of lamivudine treatment. At that time, levels of RI were not more than 1.5% of controls in cultures of the 2  $\mu$ mol/L treatment group. Based on these results, we chose

**Figure 2** Analysis of Stat1 phosphorylation after IFN- $\alpha$  stimulation in HepG2 and HepG2.2.15 cells. Cells were stimulated with 100 U/mL of IFN- $\alpha$  for the indicated time points. Then, nuclear proteins were extracted and analysed by western blot. Data were quantified using Imagequant and are shown as relative units.

**Figure 3** Analysis of ISGF3 formation after IFN- $\alpha$  stimulation in HepG2 and HepG2.2.15 cells. HepG2 and HepG2.2.15 cells were stimulated with 1000 IU/mL of IFN- $\alpha$  for 6 h followed by isolation of nuclear extracts (NE-PER<sup>TM</sup> reagent kits) for EMSA analysis.

a concentration of 2  $\mu$ mol/L and duration of 10 d to suppress HBV replication in our system to study the modulatory effects of lamivudine on the IFN-response.

### The IFN response in HepG2.2.15 and HepG2 cells after lamivudine treatment

The effect of lamivudine on ISG expression in HepG2.2.15 and HepG2 was investigated by using gene macroarrays. No effect was observed for the stimulation of MxA and Cig5 expression by lamivudine treatment (Table 2). Both genes did not respond with an increased expression upon IFN- $\alpha$  stimulation. An increase of the IFN- $\alpha$  concentration to 1000 units per mL or a prolonged incubation with IFN- $\alpha$  did not change the expression of MxA and cig5. The reduced induction of IFITM 2 and IFITM 3 expression could not be enhanced by lamivudine treatment. In contrast, IFITM1 and 6-16 expression could

be restored by lamivudine treatment of HepG2.2.15 cells (Table 1, Figure 1). This indicates that lamivudine can only partially normalize the IFN-response in HBV-transfected HepG2.2.15 cells at concentrations that profoundly inhibit viral replication and secretion of viral particles. Lamivudine had no effect on ISG expression in HepG2 cells and did not enhance the induction of many other ISGs, such as 2.5 OAS and Mx<sub>B</sub>.

## DISCUSSION

In the present work, we found that HepG2.2.15 and HepG2 respond differently to IFN- $\alpha$ . Several ISGs were not induced in HepG2.2.15 while they were expressed in HepG2 cells after IFN- $\alpha$ . There may be multiple reasons for the different ISG expression profiles in these cell lines, though HepG2.2.15 was derived from HepG2<sup>[16]</sup>. Previous data indicated that the expression of the IFN-inducible gene MxA was specifically inhibited by HBV proteins in HBV-transfected HepG2 or HuH7 cells<sup>[13]</sup>, and this was accompanied by diminished antiviral activity of IFN<sup>[17]</sup>. In our study, we confirmed this finding with MxA expression being completely diminished in HBV-transfected HepG2.2.15 cells. In addition, we showed that additional ISG (Cig5, IFITM1, -2, -3 and 6-16) expression was completely abolished or partially reduced by HBV. The majority of ISGs, however, are expressed and inducible in both HepG2 and HepG2.2.15 cells, indicating that the HBV gene expression and replication had no effect on these ISGs. Consistently, Rosmorduc *et al*<sup>[17]</sup> demonstrated that 2'5OAS expression is not affected by HBV. Our results support the view that the HBV-mediated inhibition of the IFN-response, if any, represents a specific rather than global effect. The Stat1 activation or ISGF3 formation in HepG2.2.15 cells appeared to be normal, indicating that the Jak/Stat signalling pathway is intact and functional. These findings are corroborated by the data from Fernandez *et al*<sup>[13]</sup> who demonstrated that the inhibition of MxA induction in HepG2 cells occurs at the promoter level.

We then asked the question whether the HBV-mediated suppressive effect on the IFN-response could be reverted by treatment with the nucleoside analogue lamivudine, which is an effective inhibitor of HBV replication *in vitro*<sup>[18]</sup> and *in vivo*<sup>[19,20]</sup>. Lamivudine is phosphorylated within the cell and then incorporated into nascent viral DNA by the HBV polymerase during replication<sup>[21]</sup> resulting in the termination of HBV DNA elongation. Lamivudine also inhibits reverse transcriptase activity directly through competitive inhibition. Although some reports indicate that lamivudine exerts synergistic effects with IFN, the underlying mechanisms are not clear<sup>[22,23]</sup>. To answer this question we first established the optimal conditions for *in vitro* treatment of HepG2.2.15 cells with lamivudine. The results indicated that lamivudine exerted potent antiviral activities in our system as it strongly suppressed the formation of HBV replicative intermediates and extracellular HBV DNA at concentrations that correspond well to plasma levels found in patients that are treated with this drug. However, HBsAg and HBeAg secretion was only down regulated and not completely blocked. After treatment with lamivudine for 10 d, the induction of IFITM1

**Figure 4** Antiviral effects of lamivudine in HepG2.2.15 cells. **A:** HepG2.2.15 cells were cultivated with various concentrations (0 to 100 μmol/L) of 3 TC for 10 d. Then, supernatants were harvested and assayed for the presence of HBsAg and HBeAg by ELISA; **B:** HepG2.2.15 cells were treated with 2 or 20 μmol/L of lamivudine for 4, 7 and 10 d, respectively. Then, supernatants were collected and extracellular HBV-DNA was analyzed by dot blot hybridization; **C:** HepG2.2.15 cells were treated with various concentrations of lamivudine for 10 d. Then, intracellular HBV replicative intermediates were isolated for southern blotting. Lane 1: control, lane 2: 0.04 μmol/L, lane 3: 0.2 μmol/L, lane 4: 5 μmol/L, lane 5: 25 μmol/L, lane 6: 125 μmol/L, RC, relaxed circular HBV-DNA; DS, double stranded linear HBV-DNA.

and 6-16 expression could be enhanced while MxA, Cig5, IFITM2 and IFITM3 induction remained unchanged. This indicates that lamivudine can at least partially improve the impaired IFN response in HBV-transfected cells. IFITM 1 to 3 and 6-16 belong to a family called small ISGs<sup>[24]</sup>. IFITM 1 to 3 are classified as members of the 1-8 group while 6-16 is a member of the ISG12 group. These genes were under the control of multiple elements responding to IFN- $\alpha$  stimulation including ISGF3 and interferon. It is likely that the lamivudine treatment partially reduces HBV gene expression and therefore contributes to the improved

ISG expression. On the other hand, the continuing HBV protein production may still dominantly interfere with the expression of many ISGs, such as *cig5* and *IFITM3*.

These findings are corroborated by our study that shows an improved IFN response of PBMC from HBV patients after treatment with adefovir. Some reports have also suggested a restoration of weak T helper cell and CTL responses after initiation of lamivudine therapy<sup>[25,26]</sup>. Although it is certainly a possibility, it still remains to be determined whether this effect can be explained by an enhanced responsiveness to IFNs.

In conclusion, our results suggest that HBV specifically modulates the IFN response in HepG2 cells by a selective suppression of certain ISGs. This suppression is at least partially reversible by antiviral treatment with the nucleoside analogue lamivudine.

### Abstract

**AIM:** To investigate the correlation between the *in vitro* immune profile of probiotic strains and their ability to prevent experimental colitis in mice.

**METHODS:** *In vitro* immunomodulation was assessed by measuring interleukin (IL)-12p70, IL-10, tumor necrosis factor alpha (TNF $\alpha$ ) and interferon  $\gamma$  (IFN $\gamma$ ) release by human peripheral blood mononuclear cells (PBMCs) after 24 h stimulation with 13 live bacterial strains. A murine model of acute TNBS-colitis was next used to evaluate the prophylactic protective capacity of the same set of strains.

**RESULTS:** A strain-specific *in vivo* protection was observed. The strains displaying an *in vitro* capacity to induce higher levels of the anti-inflammatory cytokine IL-10 and lower levels of the inflammatory cytokine IL-12, offered the best protection in the *in vivo* colitis model. In contrast, strains leading to a low IL-10/IL-12 cytokine ratio could not significantly attenuate colitis symptoms.

**CONCLUSION:** These results show that we could predict the *in vivo* protective capacity of the studied lactic acid bacteria (LAB) based on the cytokine profile we established *in vitro*. The PBMC-based assay we used may thus serve as a useful primary indicator to narrow down the number of candidate strains to be tested in murine models for their anti-inflammatory potential.

### INTRODUCTION

Probiotic lactobacilli and bifidobacteria are increasingly recognized as a way to prevent and/or treat intestinal disorders<sup>[1]</sup>. Probiotic treatment has been successful in a limited number of clinical inflammatory bowel disease (IBD) trials<sup>[2,3]</sup>, as well as in various experimental rodent models for acute and chronic intestinal inflammation<sup>[4]</sup>. Cytokines are key regulators of inflammation in IBD, and several pro-inflammatory and immune regulatory cytokines are dysregulated in the mucosa of IBD patients. Probiotic-mediated immunomodulation represents an interesting option in the management of IBD<sup>[5]</sup> and it was shown that both the systemic and mucosal immune systems can be modulated by orally delivered bacteria<sup>[6-8]</sup>. However, not all candidate probiotics have been proven equally efficient due to the differences in survival and persistence of the strain in the gastro-intestinal tract, and/or to strain-specific interactions of the probiotic with the host immune system<sup>[9-11]</sup>. The selection of a successful protective strain may therefore rely on the proper screening of a large number of candidate strains for their technological and immunomodulatory performance.

However, it remains challenging to set up *in vitro* tests with a fair predictive value that would allow us to narrow down the number of candidate strains to be tested in animal models. Until now, results of *in vitro* studies have rarely been linked to *in vivo* effects<sup>[12,13]</sup>. This could possibly be explained by the variety of parameters that may interfere in the systematic comparison of strains such as the bacterial preparations used (viability, growth phase, dose and timing of administration), possible time effects (early *versus* late

immune responses), or physiological status and type of eukaryotic cells used. When testing human peripheral blood mononuclear cells (PBMCs), the *in vitro* experiment may also be influenced by the method of PBMC preparation as well as the variable responsiveness of the donors<sup>[10,14,15]</sup>. Once identified, however, these parameters/factors can be controlled by using standardized methodologies<sup>[16]</sup>, allowing, on the one hand, to classify strains according to the *in vitro* differences in their interaction with human immunocompetent cells and, on the other hand, to confirm *in vivo* the “protective capacity” of the best candidate strains (showing between 30% and 70% reduction of the inflammatory score)<sup>[16,17]</sup>. In this paper we addressed the question whether prophylaxis by oral consumption of live non-pathogenic lactic acid bacteria (LAB) in experimental colitis actually matches their *in vitro* stimulation profile on human PBMCs. Cytokine profiles released *in vitro* by human PBMC stimulated with 13 bacterial strains were compared with the protection they offered in a murine trinitrobenzene sulfonate (TNBS) model of acute colitis. The results of this study demonstrate that the *in vitro* immune profiling of the strains is indeed predictive of their *in vivo* protective effect in a mouse colitis model. These findings support the idea that promising LAB strains for IBD alleviation may be discriminated from non-protective ones using *in vitro* and *in vivo* assays.

## MATERIALS AND METHODS

### Bacterial strains and growth conditions

Bacterial strains and their origin are shown in Table 1. *Lactobacillus* strains were grown under limited aeration at 37°C in MRS medium (Difco) and *Bifidobacterium* strains were grown anaerobically in MRS supplemented with 0.05% L-cysteine-hydrochloride (Sigma). *Lactococcus lactis* MG1363 was grown at 30°C in M17 medium supplemented with 0.5% glucose. *E. coli* and *S. gordonii* were grown at 37°C in LB and BHI medium (Difco), respectively. The number of live bacteria (CFU) was deduced from the absorbance at 600 nm ( $A_{600}$ ), using a calibration curve for each strain. For immune cell stimulation, bacterial cells were grown till stationary phase, washed and resuspended at  $1 \times 10^9$  CFU/mL in phosphate buffered saline (PBS) containing 20% glycerol and stored at -80°C until used for assays. For *in vivo* experiments, bacteria were grown for 18 h, washed twice in sterile PBS (pH 7.2) and resuspended at  $1 \times 10^9$  CFU/mL in 0.2 mol/L NaHCO<sub>3</sub> buffer (pH 8.8) containing 2% glucose.

### PBMC isolation

PBMCs were isolated from peripheral blood of healthy donors as previously described<sup>[18]</sup>. Briefly, after a Ficoll gradient centrifugation (Pharmacia, Uppsala, Sweden), mononuclear cells were collected, washed in RPMI 1640 medium (Live technologies, Paisley, Scotland) and adjusted to  $2 \times 10^6$  cells/mL in RPMI 1640 supplemented with gentamicin (150 µg/mL), L-glutamine (2 mmol/L), and 10% foetal calf serum (FCS) (Gibco-BRL).

### Induction of cytokine release

PBMCs ( $2 \times 10^6$  cells/mL) were seeded in 24-well tissue

Table 1 Strains used with their origin

Bacterial species /subspecies	Strain designation	Type of isolate, source and/or reference
<i>Lactobacillus salivarius</i> subsp <i>salivarius</i>	Ls33	Commercial strain
<i>Lactobacillus rhamnosus</i>	Lr32	Commercial strain
<i>Lactobacillus casei</i>	Bl23	ATCC <sup>1</sup> 393, plasmid-cured
<i>Lactobacillus acidophilus</i>	NCFM	Human, commercial strain
<i>Lactobacillus acidophilus</i>	IPL <sup>3</sup> 908	Commercial isolate
<i>Lactobacillus plantarum</i>	NCIMB 8826	Human, NCIMB <sup>2</sup> collection

culture plates (Corning, NY). Twenty microliters of a thawed bacterial suspension at  $10^9$  CFU/mL were added (bacteria:cell ratio of 10:1). PBS containing 20% glycerol was used as a negative (non-stimulated) control. On the basis of preliminary time-course studies, 24 h stimulation corresponded to the best time point for cytokine responses of bacteria stimulated-PBMCs. After 24 h stimulation at 37°C in an atmosphere of air with 5% CO<sub>2</sub>, culture supernatants were collected, clarified by centrifugation and stored at -20°C until cytokine analysis. Neither medium acidification nor bacterial proliferation was observed. Cytokines were measured by ELISA using BD pharmingen antibody pairs (BD Biosciences, San Jose, Ca, USA) for tumor necrosis factor alpha (TNFα), interleukin (IL)-10, interferon γ (IFNγ) and IL-12p70, according to the manufacturer's recommendations.

### Induction of colitis and inflammation scoring

Animal experiments were performed in an accredited establishment (number 59-35009; Institut Pasteur de Lille, France) and approved guidelines, according to French Ethical Committee and European Union Normatives (number 86/609/CEE). BALB/c and C57/Bl6 mice (female, 8 wk) were obtained from Charles River (St Germain sur l'Arbresle, France). A standardized murine TNBS colitis model was used in which sublethal levels of inflammation were induced<sup>[16]</sup>. Briefly, a 50 µL solution of 100 mg/kg (BALB/c mice) or 180 mg/kg (C57Bl6 mice) TNBS (Sigma) in 50% ethanol was slowly administered in the colon *via* a 3.5 F catheter. Bacterial suspensions (100 µL), containing  $1 \times 10^9$  CFU/mL in NaHCO<sub>3</sub> buffer (or buffer alone for controls) were administered intragastrically to mice each day, starting 5 d before until d 1 after TNBS administration. The mice were weighed and killed 48 h after TNBS administration. Colons were removed, washed and opened. Inflammation grading was performed by two

**Figure 1** Strain-specific patterns of IL-10 (A) and IL-12p70 (B) release for various bacterial strains and IL-10/IL-12 ratios (C) for 6 to 12 independent healthy donors. Bars represent the mean  $\pm$  SE values in pg/mL for 6 to 12 independent healthy donors. Ranked box and whisker plots show the median values and first to third quartiles in boxes. Different letters indicate significant differences according to Mann-Whitney *U* test ( $P < 0.05$ ).

blinded observers, using the Wallace scoring method<sup>[19]</sup>. Results are expressed as % protection, corresponding to the reduction of the mean macroscopic inflammation score of bacteria-treated mice ( $n = 10$ ) in comparison to the mean score of TNBS-treated control mice (NaHCO<sub>3</sub> buffer-treated mice,  $n = 10$ )<sup>[16]</sup>. Histological analysis was performed on hematoxylin/eosin-stained 5  $\mu$ m tissue sections from colon samples fixed in 10% formalin and embedded in paraffin.

### Statistical analysis

Results were analyzed by the non-parametric one-way analysis of variance and Mann-Whitney *U* test. Differences were judged to be statistically significant when the *P* value was  $< 0.05$ . For *in vivo* experiments, only protection levels exceeding 30% (positive and negative) were considered to be relevant, as previously described<sup>[16]</sup>. For the calculation of the IL-10/IL-12 ratio, all undetectable IL-12 values (below 50 pg/mL) were arbitrarily set at 50 pg/mL level to normalize aberrant quotients. Association of variables was analyzed by the *P* value-assigned Spearman rank correlation coefficient.

## RESULTS

### Cytokine release by PBMCs is strain specific

The *in vitro* immunostimulation by 13 live bacterial strains (Table 1) of PBMCs collected from 6 to 12 independent donors, revealed distinct and typical patterns of cytokine

release. TNF $\alpha$  release was quite uniform for the different LAB investigated, while IFN $\gamma$  showed variations tending to parallel IL-12 profiles (data not shown). IL-10 and IL-12 levels displayed a strain-specific pattern (Figure 1A and B). Variations in IL-10 concentrations were substantial with values ranging between 200 and 3000 pg/mL depending on the bacterial strain. For IL-12, we also observed significant variations between strains, covering a range of cytokine levels of 50 to 1200 pg/mL. As IL-10 and IL-12 appeared to be the most discriminative cytokines, we used the IL-10/IL-12 ratio (Figure 1C) to distinguish between strains exhibiting a "pro-" versus "anti-inflammatory" profile (low versus high IL-10/IL-12 ratio, respectively). This approach was found to be useful to identify strains with marked opposite profiles, but did not allow discrimination of strains with median cytokine ratios.

The variation in absolute cytokine concentrations released by PBMCs derived from different donors was examined by conducting successive experiments with a limited set of 6 strains (*E. coli* TG1, *L. salivarius* Ls33, *L. casei* BI23, *L. plantarum* NCIMB 8826, *L. lactis* MG1363 and *L. acidophilus* NCFM). In general, for a variety of individual donors, the ranking of strains was quite reproducible: the most potent "anti-inflammatory" strains induced the highest IL-10 responses in all donors, while other strains were stronger IL-12 inducers in most donors. As an example, Figure 2A and B shows the IL-10 and IL-12 expression profiles for four donors in response to the six "reference" strains used. Relative differences

**Figure 2** IL-10 (A) and IL-12p70 (B) release in 4 distinct individual human PBMC donors and the expression level of IL-10 (C) and IL-12p70 (D). Individual values are represented in pg/mL while IL-10 and IL-12p70 levels are expressed as % of the highest inducer strain. <sup>a</sup> $P < 0.05$ .

between two strains, expressed as a percentage of the highest inducer, taken as internal control, were quite constant for all donors (Figures 2C and D). For example, we consistently found 35% and 82% difference ( $P < 0.05$ ) between the strains *L. salivarius* Ls33 and *L. acidophilus* NCFM, for IL-10 and IL-12 induction, respectively. Based on these observations, both strains could be compared in a semi-quantitative way, using their average IL-10 and IL-12 release patterns upon stimulation of PBMCs from four different donors. To that extent we calculated a full matrix of  $P$ -values for the IL-10/IL-12 ratios obtained from several overlapping studies with reference strains as well as new isolates, for at least 4 PBMC donors, which allowed us to rank strains from an “anti-inflammatory” to a “pro-inflammatory” profile.

When applied to the 13 strains used in this study, this methodology established a semi-quantitative ranking, which could classify strains *L. salivarius* Ls33, *L. casei* BI23, *L. rhamnosus* Lr32, *L. acidophilus* IPL908 as more anti-inflammatory than the three bifidobacteria and the two *L. plantarum* strains. *L. lactis* MG1363, *S. gordonii* V288 and *L. acidophilus* NCFM® strains showed a slightly pro-inflammatory profile with a very low IL-10/IL-12 ratio.

#### Protection of TNBS-induced colitis was strain-specific

We investigated the protective effect of the 13 strains studied *in vitro* against TNBS-induced colitis in mice (Figure 3). Ls33, Lr32, BI23, IPL908 and BL04 strains consistently led to a considerable attenuation of colitis (data represent the result of usually 2 to 4 distinct experiments),

with reduced weight loss, improved clinical parameters (rectal bleeding, stool consistency, *i.e.* liquid pasty stool and diarrhoea, lethargy; data not shown) and reduced macroscopic inflammation scores. Considering the % protection as the reduction of the mean macroscopic inflammation score of bacteria-treated mice ( $n = 10$ ) in comparison to the mean score of TNBS-treated control mice, the *Lactobacillus plantarum* strains and the BB02 and BI07 bifidobacterial strains induced moderate but significant levels of protection. In contrast, no improvement in colitis was observed for the strains *L. acidophilus* NCFM, *L. lactis* MG1363 or *S. gordonii* V288 and for the non-pathogenic *E. coli* TG1. None of these strains, however, aggravated the symptoms of colitis. Histological analysis corroborated these findings, showing dramatic improvement in epithelial lesions of the animals receiving protective strains, with a significant decrease in goblet cells and crypt loss (data not shown), and reduced inflammatory infiltrates (mainly neutrophils) accompanied with a reduction of the colon wall thickness to almost normal levels (Figure 4).

Additional experiments confirmed this strain-specific protection in mice with a different genetic background (C57/Bl6 mice). The protection observed in BALB/c mice with *L. salivarius* Ls33 ( $56.5\% \pm 7.2\%$ ,  $P < 0.01$ ) was confirmed in C57/Bl6 mice ( $47\%$ ,  $P < 0.01$ ), whereas the *L. acidophilus* NCFM® and *E. coli* strains alleviated colitis neither in BALB/c mice ( $-12.5\% \pm 2.7\%$ , NS; and  $+19.4\% \pm 3.7\%$ , NS, respectively) nor in C57/Bl6 ( $+26\%$ , NS; and  $-6.4\%$ , NS, respectively).

**Figure 3** Protective effect of LAB strains against TNBS-induced colitis in BALB/c mice. Results are expressed as a % reduction of the mean macroscopic inflammation of mice treated with LAB as compared to the mean score of non-treated mice. Colitis index was assessed 48 h after TNBS administration. Each bar represents an independent experiment and corresponds to the ratio of control and LAB-treated mice groups ( $n = 10$ ). <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  vs TNBS-control group. The horizontal dashed lines indicate the 30% threshold of the uncertain statistical significance.

### In vivo / In vitro correlation

Considering both *in vitro* and *in vivo* results, it was evident that strains displaying the highest *in vitro* anti-inflammatory profile (a high IL-10/IL-12 ratio) were the most protective in the *in vivo* colitis model, while those leading to intermediary *in vitro* IL-10/IL-12 ratios showed limited protection. In contrast, bacteria characterized by a low anti-inflammatory potential (low IL-10/IL-12 ratio) did not improve inflammation at all. As a result, with the exception of the Gram-negative *E. coli*, the ranking of all Gram-positive bacteria investigated, based on the *in vitro* cytokine profiling, closely matched the ranking based on the improvement of colitis symptoms. Although this link could not be expressed as an “exact linear” association between % protection and IL-10/IL-12 ratio, it was found to be highly significant using the Spearman rank correlation coefficient ( $r_s = 0.825$ ,  $P < 0.001$ ) (Figure 5).

## DISCUSSION

Immunomodulation through probiotics represents one of the current treatment options for IBD<sup>[5,20]</sup> and specific strains may stimulate immunomodulatory mediators, inhibit pro-inflammatory cytokines and influence the phenotypes of immunocompetent cells with subsequent events such as migration of dendritic cells and induction of regulatory T cells<sup>[15,21]</sup>. The mechanisms of action of probiotics are most probably multi-factorial, involving a variety of effector signals, cell types and receptors<sup>[22]</sup>, and strains may differ in their respective ability to trigger these signals considering both immunocompetent and intestinal epithelial cells<sup>[23]</sup>. It has been proposed that some probiotics are able to prevent or restore intestinal homeostasis after an immune dysregulation, improving mucosal barrier functions as well as down-regulating inflammatory responses<sup>[24,25]</sup>.

In this study, we aimed at developing a simple and

**Figure 4** Hematoxylin/eosin staining of representative cross-sections of murine (BALB/c) distal colon (HE, x 20). **A:** Normal appearance of the colon from a negative control mice; **B:** Thickening of the colon wall accompanied with massive inflammatory infiltrate and muscular necrosis 2 d after TNBS-induction of colitis; **C:** Reduction of histological damage in *L. salivarius* Ls33-treated mice after TNBS administration; **D:** Lack of histological improvement of colitis in *L. acidophilus* NCFM-treated mice after TNBS administration.

standardized *in vitro* test allowing preliminary classification of candidate probiotic strains according to their immune modulation capacity that would be predictive of their *in vivo* effect. To this end, we ranked 13 LAB strains with reference to the IL10/IL12 cytokine ratio induced on human PBMCs and further assessed their protective effect against TNBS-induced colitis in mice.

We observed strong strain-specific variations of the *in vitro* cytokine induction profiles after stimulation of immunocompetent cells, which confirms the results reported in previous studies<sup>[9-11,15,26]</sup>. We also noted that differences between blood donors did not prevent us ranking the strains based on their cytokine responses as the relative responses of PBMCs to various LAB were consistent from one donor to another. PBMCs from healthy donors can thus be used to screen the immunomodulatory activity of candidate probiotic strains and this test/assay appears to be a good indicator of *in vivo* anti-inflammatory strains. Despite the fact that this assay does not clarify the physiological mechanism(s) involved, it seems to mimic how the immune system may sense the bacterial strains and consequently polarise the immune response. Strains leading to a high IL-10/IL-12 ratio would more easily slow down an early Th1 response.

In accordance with this hypothesis, we found differences in the *in vivo* protective capacity of the 13 studied strains against TNBS-induced inflammation<sup>[27]</sup>. This strain-specificity has already been described in other experimental models of colitis<sup>[28-31]</sup>. The variations we observed between different LAB strains in this respect cannot simply be explained by differences in persistence, especially when daily administrations maintain the level of bacteria in the gastro-intestinal tract. Of note, we have previously verified whether the anti-inflammatory profiles could in any way be linked to *in vitro* properties such as gastric juice (pepsin/pancreatin) and bile salt resistance, epithelial cell adhesion and *in vivo* intestinal persistence (unpublished data). However, no link was found between them.

Above all, we have demonstrated in this study that the ranking of strains obtained on the basis of an *in vitro* IL-10/IL-12 cytokine induction ratio closely matches the ranking of the *in vivo* ability of the strains to attenuate experimental colitis. The concordance between the *in vitro* and *in vivo* assays has been illustrated in the case of a cell-wall mutant of *L. plantarum*<sup>[18]</sup>. The importance of the IL-10/IL-12 ratio has also recently been highlighted by Peran *et al.*<sup>[32]</sup> who showed that administration of a specific strain of *Lactobacillus salivarius* subsp. *salivarius* could improve the recovery of inflamed tissue in a TNBS model of rat colitis. This strain was selected among 30 LAB strains for eliciting the best IL-10/IL-12 and IL-10/TNF $\alpha$  ratios. Unfortunately, no strains exhibiting a moderate or low IL-10/IL-12 profile were included in the *in vivo* study, which could have validated the proposed screening strategy. Similarly, *in vitro* tests on immunocompetent cells have been used successfully to study the effect of distinct bacterial fractions (intact cell walls, protoplast and polysaccharide-peptidoglycans) of the strain *Lactobacillus casei* Shirota<sup>[33]</sup>. Using the ability of this strain to inhibit the LPS-induced IL-6 in mice bone marrow derived-DCs and PBMCs isolated from ulcerative colitis patients, the authors could establish that the polysaccharide-peptidoglycan complex was the most efficient compound to improve chronic colitis and ileitis in their mice model. Another example attesting similar links between *in vitro* macrophage stimulation and related protection in a murine TNBS model of colitis was reported for the anti-inflammatory

**Figure 5** Correlation between the average protection against experimental colitis and the mean IL-10/IL-12 ratios obtained *in vitro*, for all investigated strains. Spearman coefficient ( $r_s = 0.825$ ,  $P < 0.001$ ). The horizontal dashed lines indicate the 30% threshold of unprotectiveness.

drug “catapolside”<sup>[34]</sup>, leading to clinical trials in IBD patients in Korea.

Recently, the PBMC IL-10/IL-12 ratio has also been used to follow the immunomodulatory properties of probiotics in a clinical study on irritable bowel syndrome (IBS)<sup>[31]</sup>. Despite different aetiology and characteristics, IBD and IBS share some aspects of immune dysregulation, and IBS has been documented to be associated with low-grade inflammation. Concomitantly to alleviation of the main IBS symptoms, the authors showed normalization of the PBMC IL-10/IL-12 ratio in patients receiving probiotics *versus* placebo, showing that *in vivo* probiotic efficiency can be correlated to specific *in vitro* assays.

Despite the positive correlation observed between *in vivo* protection and *in vitro* cytokine ratio, some restrictions are clear. First of all, the link is not valid for Gram-negative bacteria. Gram-negative bacteria, including both non-pathogenic and pathogenic strains, are well known to be potent inducers of monocytic IL-10, while Gram-positive species preferentially stimulate IL-12<sup>[10]</sup>. These observations do not exclude Gram-negative strains from being anti-inflammatory. For example, bacteria such as the *E. coli* strain Nissle<sup>[55]</sup> or virulence-attenuated *Yersinia pseudotuberculosis* mutants<sup>[36]</sup> have been shown to be able to reduce colonic lesions and inflammatory mediators in murine models of experimental colitis. Secondly, it is not excluded that *Lactobacillus* strains may moderate colitis by non immune-related modes of action, as for example by acting on barrier integrity or influencing the oxidative pathway<sup>[37]</sup>. Alternatively, LAB strains with a rather pro-inflammatory profile may have other health benefits which substantiate their probiotic status<sup>[38,39]</sup>.

The methods described in this paper can be used to screen a larger set of potential probiotic strains for their immunomodulatory properties, since they are relatively simple and quite reproducible. We are currently building a reference database including both *in vitro* cytokine profiles, as well as protection levels measured in the TNBS mice model for selected reference strains. This database encompasses strains and blends used in former clinical trials in IBD (i.e. *L. rhamnosus* GG, VSL#3 and *E. coli* strain Nissle<sup>[2,3,40,41]</sup>), which could further support

and validate the predictive value of the screening strategy presented in this paper.

In conclusion, our results linked *in vitro* and *in vivo* anti-inflammatory properties of a series of LAB and confirm that potential probiotic strains can be pre-screened *in vitro* for their immunomodulating potential, before animal and clinical investigations. This allows pre-selection of probiotics able to modulate the host immune system in a specific way while reducing considerably the use of animals for screening purposes. Besides these ethical considerations, the comparative study of strains carefully selected for either pro- or anti-inflammatory properties will assist further investigation of the mechanism(s) by which specific probiotics signal to the host.

## COMMENTS

### Background

Evidence exists for the protective role of selected probiotic strains in inflammatory bowel disease. Probiotic strains have clearly been shown to differ in their *in vitro* interaction with immunocompetent cells, especially in terms of cytokine responses. No clear link has been established so far between the *in vitro* immunomodulation potential (e.g. on PBMC's) of the probiotic strain and its ability to prevent experimental colitis in mice (e.g. in TNBS- induced colitis). The use of simple *in vitro* methods to select the most efficient strains for possible clinical trials will improve the quality and reduce the costs of this type of research.

### Research frontiers

Improving gastrointestinal function is important for IBD patients and fundamental research is needed to develop new treatments for such pathogenesis. Probiotics are generally accepted to be one of these alternative methods. Few original research papers, however, have evaluated the potential of this approach by focusing on the level of the bacterial strain or strains used.

Probiotic-mediated immunomodulation represents an interesting option in the management of IBD and there is evidence that the immune system can be modulated by orally delivered bacteria. However, in some animal and clinical studies, probiotics did not show the expected beneficial effect. The selection of a successful protective strain may rely on a proper screening of a large number of candidate strains for their technological and immunomodulatory performance, as recently published in *WJG*. Together with proper *in vitro* analytical methods, the use of a reliable animal model is therefore indispensable. Using a well-standardized animal model, we have demonstrated that consistent differences in anti-inflammatory potential of several orally administered lactic acid bacteria could be observed in TNBS-induced colitis.

In the present study we linked for the first time the results of *in vitro* and *in vivo* anti-inflammatory readouts for 13 selected LAB, and confirmed herewith the strain-specific nature of the potential of probiotics to modulate the host's immune system and in assisting in the alleviation of intestinal disorders, IBD in particular.

### Innovations and breakthroughs

Linking *in vitro* and *in vivo* anti-inflammatory properties of a series of LAB can confirm the interest of screening potential probiotic strains using *in vitro* assays, before launching animal and clinical investigations. This allows not only the pre-selection of probiotics able to modulate the host's immune system in a specific way while reducing considerably the use of animals for screening purposes, but also results in a classification of microorganisms that could be useful for the study or comparison of other probiotic properties. So, besides ethical considerations, the comparative study of strains carefully selected for either pro- or anti-inflammatory properties will assist further investigation of the mechanism(s) by which specific probiotics signal to the host.

### Applications

The use of probiotic strains in IBD treatment has been controversial, because of some major drawbacks. The first is the type of inflammatory disease targeted (Crohn's disease on the one hand, with low success levels, *versus* ulcerative colitis and pouchitis where treatment was more successful). The second is that a comparison between a therapeutic preventive application in combination with or without traditional medication, is not always clear. The third is that the choice

of strains or the mixture thereof is often made rather artificially and driven by available commercial preparations which are not necessarily developed or suitable for this type of medical application. Using the described selection procedure, the influence of well-selected strains (e.g. with expected positive and negative performance as anti-inflammatory agent) in different conditions (with or without traditional medication) of a selected animal model (prophylactic or therapeutic) can be evaluated unequivocally. The results should not only allow to select the best possible conditions for the follow-up clinical study but will also help to understand the underlying mechanisms and factors that influence the efficiency of the application.

### Terminology

The TNBS mouse model of colitis is a hapten-induced experimental model (TNBS = 2, 4, 6-trinitrobenzene sulfonic acid), which has proven to be a very useful model for studying certain forms of human inflammatory bowel disease. This model has e.g. been used to show that an IL-12-driven, Th1 T cell-mediated inflammation of the colon is not only prevented by systemic administration of anti-IL-12 antibody, but can also be treated this way. Consequently anti-IL-12 is currently used in the treatment of Crohn's disease. Other studies with this model have established that mucosal inflammation and/or its prevention depend partially on a balance between pro-inflammatory Th1 T cell responses and anti-inflammatory TGF- $\beta$  and IL-10 responses.

### Peer review

This is an interesting study showing that *in vitro* assays using human PBMCs can partially translate to murine models of colitis giving an indication of the level of expected protection of this particular model of colitis using IL-10/IL-12 ratios. It would be interesting to discover whether this held out if colitis was induced before administration of the probiotic (perhaps a more physiological approach for therapy). However, this does offer some insight into prophylactic approaches for managing patients in remission.

### Abstract

**AIM:** To use the tyrosinase minigene as a visual marker to perform microinjection training and improve the techniques related with transgene to greatly elevate the efficiency of gene transfer.

**METHODS:** A mouse tyrosinase minigene, i.e., TyBS, in which the 2.25-kb authentic genomic 5' non-coding flanking sequence of mouse tyrosinase was fused to a mouse tyrosinase cDNA, was introduced into the fertilized eggs of outbred Kunming albino mice.

**RESULTS:** Of the 11 animals that developed from the injected eggs, two mice (P1 and #8) exhibited pigmented hair (P1) and eyes (P1 and #8), as confirmed by PCR analysis for the tyrosinase minigene integrated into the genome. When founder P1 was bred to Kunming male mouse, six progeny out of 11 offspring inherited the transgene and the pigmented-eye phenotype.

**CONCLUSION:** Taken together, these results suggest that this minigene encodes the active tyrosinase protein and that its 5' flanking region contains the sequences regulating the expression of mouse tyrosinase gene as expected. We have rescued the albino phenotype by introduction and expression of a functional tyrosinase

### INTRODUCTION

Visible pigmentation in the mammals results from the synthesis and distribution of melanin in skin, hair bulbs and eyes<sup>[1-3]</sup>. Tyrosinase is the first and rate-limiting enzyme in the pathway for melanin production in melanocytes of the skin and eyes<sup>[1-3]</sup>. Mutation of the tyrosinase gene is a common cause of a similar phenotype in all vertebrates, known as albinism, due to a lack of melanin pigment<sup>[1,3]</sup>. In mouse, the albino phenotype is characterized by a total absence of pigmentation due to a mutation in the tyrosinase gene; several point mutations within the tyrosinase gene have been found, which can inactivate its function to result in oculocutaneous albinism (OCA)<sup>[1,3]</sup>. In mouse, the classical albino (*c*) mutation corresponds to a single-point mutation in the first exon of the tyrosinase gene, which brings about an amino acid mutation Cys103Ser, leading to the accumulation of a non-functional protein<sup>[4,5]</sup>. When mice are homozygous (*c/c*) for mutations that inactivate the tyrosinase gene, mice are albino regardless of the genotype at the other loci<sup>[1,3]</sup>. The entire common albino inbred strains of laboratory mice, such as FVB/N, BALB/c, etc, belonging to OCA, have the same point mutation in the tyrosinase gene, indicating that these strains are derived from a common ancestor<sup>[5]</sup>. The albino phenotype has been successfully corrected through the tyrosinase transgene, which can express the active tyrosinase in transgenic mice<sup>[5-18]</sup>, rabbits<sup>[19]</sup>, fish<sup>[20-22]</sup> and other vertebrates

expressing tyrosinase functional transgenes<sup>[23]</sup>.

The Human and Model Organism Genome Projects have revealed the sequence information of many genes. A significant challenge for scientists over the next few decades is to annotate the human and model organism genomes with functional information. Genetically engineered mice will play a vital role in the study of the functional genome.

The production of transgenic mice, involving an intensive sequence of procedures in genetics, molecular biology, embryology and animal science, is usually time-consuming and labor-consuming. One problem with learning to do microinjections is that it can be a long wait between the time the microinjections are done and the time that the results are known, particularly if one waits until the microinjected embryos have developed into weaning age mice before screening. How to easily and rapidly assay for a successful pronuclear? There are a number of constructs that are particularly useful when learning to do microinjections. Among them, tyrosinase can be used to allow the visual identification of transgenic mice at birth in the first and all subsequent generations. Microinjection of a tyrosinase minigene into embryos from an albino mouse strain can result in gene cure of the albino defect and the pigment synthesis<sup>[5,6,18]</sup>. Pigmented mice with dark eyes can be easily identified by simply visible inspection at birth. In fact, the pigment epithelial cells of the retina begin to synthesize melanin by P10.5 of embryonic development<sup>[8,26]</sup> so that transgenic mice can be typically identified by visual inspection of the fetuses 2 wk after microinjection. The microinjection can be done using albino inbred strains (such as FVB/N and BALB/c) and inexpensive outbred albino strains (such as ICR and Kunming mice). Another advantage of the tyrosinase minigene is the fact that it is not detrimental to the health of the transgenic animals.

Therefore, we decided to use the tyrosinase minigene as a visual marker to perform microinjection training and improve the techniques related with transgene to greatly elevate the efficiency of gene transfer in our center.

## MATERIALS AND METHODS

### Production of the tyrosinase minigene transgenic mice

The tyrosinase minigene TyBS<sup>[5]</sup> used for microinjection was generously provided by Dr. P.A. Overbeek (Howard Hughes Medical Institute, Department of Cell Biology, Baylor College of Medicine, Houston, TX, USA) and Dr. F Beermann (Swiss Institute for Experimental Cancer Research, Switzerland).

Transgenic mice were generated by microinjection of single cell embryos using standard techniques<sup>[27]</sup>. The Kunming mouse strain, supplied by Center of Experimental Animals, Sun Yat-Sen University, was used as the source of embryos for the micromanipulation and for the subsequent breeding trials. For microinjection, the 4.1-kb fragment of tyrosinase minigene (Figure 1) was released free from the vector backbone of pTyBS<sup>[5]</sup> via digestion with *EcoR* I and *Kpn* I, thereafter isolated and purified using the QIA quick gel extraction kit (Qiagen, Hilden, Germany), diluted to a final concentration of 2

**Figure 1** The structure of tyrosinase minigene construct TyBS used for microinjection. The construct contains a 2.25-kb tyrosinase promoter, i.e., 5' non-coding flanking sequence of mouse tyrosinase, as a single thick line plus 65 bp of tyrosinase exon I (to the *Xho* I site) and 1.785-kb *Xho* I-*EcoR* I fragment (shaded) (derived from Tyrs-J) containing tyrosinase cDNA and 3' non-coding flanking sequence. TyBS encodes cysteine at amino acid 103 and glycine at amino acid 346. The 4.1-kb injected fragment was obtained by pTyBS digestion with *Kpn* I and *EcoR* I. The restriction sites are: E, *EcoR* I; K, *Kpn* I. The primers specific for TyBS used in PCR reaction (small arrows) and the expected size of PCR products are indicated.

μg/mL DNA in injection buffer (10 mmol/L Tris/0.1 mmol/L EDTA, pH 7.4), and then microinjected into the pronuclear of one cell-stage fertilized embryos [Kunming mouse (♀) × Kunming mouse (♂)]. About 20-25 DNA-injected fertilized eggs that survived microinjection were implanted into the oviducts of one recipient pseudopregnant Kunming mouse 2-3 h after injection or the next day as previously described<sup>[27]</sup>. Potential transgenic founders were weaned at 3 wk of age. The offsprings were firstly screened for the presence of the transgene via pigmentation phenotypes derived from the existence of the functional tyrosinase minigene, followed by PCR analysis performed on the tail genomic DNA prepared with standard protocols<sup>[28]</sup>. All animal care and experimentation were performed according to the Study and Ethical Guidelines for Animal Care, handling and termination established by the Subcommittee of Sun Yat-Sen University on laboratory animal care. The presented work was approved by the ethical committee of Sun Yat-sen University and is covered by Chinese animal husbandary legislation.

### Genotype analysis by PCR

PCR was performed on tail genomic DNA to further identify which mice have tyrosinase minigene integrated into their genome. The sequences of the forward primer (FP) within exon 1 and reverse primer (RP) within exon 4 used to amplify a 767-bp fragment of the tyrosinase minigene were: 5'-GGTTTCAACTGCGGAAACTG-3' (forward) and 5'-TGTGAGTGGACTGGCAAATC-3' (reverse) (Figure 1). PCR conditions were as follows: pre-denaturation at 94°C for 7 min, followed by 30 amplification cycles of denaturation at 94°C for 1 min, primer annealing at 58°C for 1 min, and extension at 72°C for 1 min 30 s, and finally an additional extension at 72°C for 10 min. TyBS construct DNA was used as the positive control for each PCR reaction, and genomic DNA from normal Kunming mice was employed as a negative control for each PCR test. DNA samples were considered positive for a particular transgene if a band of the predicted size in the test samples was present with no amplification occurring in the control sample. Endogenous genomic

tyrosinase sequence was not amplified under this PCR conditions chosen here.

### **Mouse propagation and transmission**

At 6-8 wk of age, founders shown to be transgenic for the tyrosinase minigene were mated with normal Kunming mice to generate F1. Pigmented F1 animals derived from founder, as well as albino non-transgenic littermates were further analyzed for the inheritance of the tyrosinase transgene by PCR using tyrosinase-FP/RP primers. PCR protocols for TyBS were noted above.

## **RESULTS**

### **Rescue of the albino phenotype by tyrosinase transgene**

Within the coding sequences of the tyrosinase gene, a G to C transversion at nucleotide 308, leading to a cysteine (Cys) to serine (Ser) mutation at amino acid 103, is sufficient to abrogate pigment production in mice<sup>[5]</sup>. This same base pair change is fully conserved in the classical albino strains of laboratory mice, such as FVB/N and BALB/c<sup>[5]</sup>. Albino Kunming mice are an outbred mouse strain that is homozygous mutant at the albino (*c*) locus. An albino mutation carried in the Kunming mouse strain should be also the result of a base substitution from G to C in exon I. It is, therefore, reasonable to expect that the albino phenotype can be rescued by introducing a functional tyrosinase minigene, such as TyBS, into albino embryos.

The tyrosinase minigene TyBS construct<sup>[5]</sup> used for microinjection is illustrated in Figure 1. As the expression of the tyrosinase minigene is easily detected by the pigmented phenotype, this gene can be used as a visual marker for the production of transgenic animals.

Of the 45 embryos transferred to the recipient females, 11 embryos developed to term. Two individuals of 11 siblings were transgenic, as demonstrated by pigmentation phenotype in the eyes (Figure 2A-D, F and G) and coat (Figure 2C, D and F), and PCR analyses (Figures 3A and B).

Furthermore, two TyBS transgenic mice, i.e. P1 (Figure 2A and B) and #8 (Figure 2G) which died 48 h after birth, had dark eyes at birth, and were immediately identifiable as transgenic mice. Although the extent of the coat pigmentation was non-standard like the wild-type phenotype, founder P1 exhibited the partially pigmented phenotype (Figure 2C, D and F). Over time, the coat of P1 with nearly black eyes (Figure 2A-D, F) became more heavily pigmented (light grey to dark grey) (Figure 2C, D and F), while the eye and fur phenotypes of non-transgenic littermate controls remained pink and albino throughout life (Figure 2C-E), respectively.

### **Transmissibility of the foreign transgene**

To determine whether the TyBS transgene was transmitted to the next generation, at 6 wk of age female P1 was back-crossed to the parental mouse strain to give F1 generation. The progeny of P1 was analyzed for the inheritance of the transgene by eye phenotype, coat pigmentation and PCR.

From the cross between P1 and normal Kunming mouse, 11 offspring were obtained. Although all of littermates from P1 died immediately at birth, it was found

that six out of the 11 siblings exhibited the pigmented eyes at birth (Figure 2H), as verified by PCR (Figure 3C).

Non-mosaic transgenic mice with one site of integration should transmit the transgenic DNA in a Mendelian fashion to about 50% of their offspring, whereas mosaic mice generally show a frequency of transmission of 25% or less. Note that founder mice that have more than one site of integration can produce litters where 75% or more of the offspring are transgenic, although the percent transmission for any one site of integration is expected to be average 50% or less<sup>[29,30]</sup>. It was concluded that founder P1, successfully transmitting the transgene in a Mendelian fashion to about 55% (6/11) of its progeny, is non-mosaic transgenic mouse.

Taken together, these data demonstrate that founder P1 can transmit the transgene to subsequent generation and its progeny show an inherited characteristic phenotype of pigmented eyes.

## **DISCUSSION**

### **Coat color of the tyrosinase transgenic mice**

Pigmentary genes are the first mammalian genes to be studied, mostly because of the obvious phenotypes associated with their mutations<sup>[23]</sup>. In this study, founder P1, harboring the tyrosinase minigene TyBS, exhibited light pigmentation, but non-standard wild-type coat color in the skin, although over time, P1 coat became more heavily pigmented. Similarly, the transgenic mice carrying TyBS construct showed considerable variation in the intensity of pigmentation, the coat colors were found to range from grayish to brownish, and none of the mice were black<sup>[5]</sup>.

Actually, all these standard tyrosinase constructs, including TyBS, driven by the limited amount of 5' tyrosinase upstream regulatory sequences (ranging from 270- to 5500-bp promoter sequences) displayed a high degree of variability in coat pigmentation between independent lines<sup>[14,30-34]</sup>, and the coat pigmentation did not reach the normal levels observed in the wild-type phenotype<sup>[6,18,30-32,35,36]</sup>. For example, in an evaluation of 39 transgenic founder animals and 44 transgenic lines, 5 phenotypic patterns of pigmentation were consistently observed, including albino, dark, light, mottled and Himalayan<sup>[32]</sup>. In fact, the tyrosinase minigene which is sufficient to produce normal levels of both eumelanin and pheomelanin can give normal black or brown pigmentation on the appropriate non-agouti genetic backgrounds<sup>[5,32]</sup>. These abnormally expressional patterns might have been explained by position effects. In summary, these findings demonstrate that other regulatory regions within the tyrosinase gene are required to sustain the faithful expression of tyrosinase transgene, independent of integration site.

By flanking a tyrosinase minigene with tandem copies of the chicken  $\beta$ -globin 5' HS4 insulator, there is a significant reduction in variability among transgenic lines, with the resulting mice exhibiting the similar levels of coat pigmentation, which, in turn, improves the yield of phenotypically expected transgenic founders resulting from each microinjection session, and consequently reduces

**Figure 2** Eye and coat colors of tyrosinase minigene transgenic Kunming albino mice. One foster mother gave birth to six F0 pups (A-F); among the littermates, only one mouse (referred to as P1) had the pigmented eyes at birth. On July 15, another foster mother produced three F0 pups (G); of three siblings, only one mouse (referred to as #8) indicated the pigmented eyes at birth. P1 (♀) was crossed with normal Kunming albino mouse to give birth to 11 F1 offspring (H). All of the common albino strains of laboratory mice, such as FVB/N, BALB/c, and Kunming mouse (in China), have pink eyes and albino skin. (A and B) The 2-d-old littermates. At birth, one pigmented mouse (P1) with dark eyes could be easily and immediately identified as a transgenic mouse by simple visual inspection. (C) The 4-wk-old littermates and Kunming albino foster mother. Founder P1 exhibited black eyes and light grey fur when compared to the non-transgenic littermate controls and Kunming albino foster mother with pink eyes and albino skin. No differences in phenotypes between transgenic mouse and the controls and foster mother except for melanization in eyes and hairs. Actually, the Kunming albino mouse was also used as a recipient strain for TyBS transgene in this project. (D) Eye color of the 4-wk-old P1 mouse compared with one of the non-transgenic littermates. One of the non-transgenic littermates (right of the middle map) had pink eyes, while at this age the heterozygote P1 (left of the middle map, upper and lower) had nearly black eyes. (E and F) The 8-wk-old non-transgenic littermate control and the adult P1 mouse (8-wk old), respectively. The non-transgenic littermate control (E, left) had pink eyes and albino coat, while at this age the heterozygote P1 mouse (F, right) had nearly black eyes and dark grey coat. Over time, the coat of P1 mouse became more heavily pigmented, while the eye and fur phenotypes of non-transgenic littermate control remained pink and albino throughout the life, respectively. (G) Eye color of the 1.5-d old #8 compared with its littermates. At birth, #8 with dark eyes could be easily and immediately identified as transgenic mice by simple visual inspection. Unfortunately, #8 as well as non-transgenic littermates without dark eyes were killed by foster mother 1.5 d after birth. (H) Eye color of F1 offspring (11) developed from mating of P1 and normal Kunming albino mouse. Founder P1 (♀) was back-crossed to normal Kunming albino mouse to produce eleven F1 generation. Unluckily, all of F1 offspring (11), born on September 8, died immediately at birth. P1 also deceased one month after delivery as it did not recover from giving birth to pups. Of the 11 animals that developed from the mating aforementioned, six mice exhibited pigmented eyes. → and → indicate the pigmented eyes and non-pigmented eyes (pink), respectively.

Lane M1: DL 2000 DNA Marker (TaKaRa); lane PC: positive control (TyBS as template); lane NC: negative control using genomic DNA from normal Kunming mice as template. The arrows indicate the positions of PCR products amplified by the primers shown in Figure 1. (**A**) Littermates (F0, six mice) were verified for the transgene presence by PCR analysis. Lanes 1-6: genomic DNA from the potential founder(s) of 6 littermates; Lane 2: 767-bp band amplified from genomic DNA of P1 with pigmentation in the eyes. (**B**) Littermates (F0, three mice) were confirmed for the transgene presence by PCR analysis. Lanes 1-3: genomic DNA from the potential founder(s) of three siblings. Lane 1: 767-bp band amplified from genomic DNA of #8 with pigmentation in the eyes. Other details are as in Figure 2G. (**C**) Littermates (F1, 11 mice) were examined for the transgene presence by PCR analysis. The founder P1 (♀) was crossed with normal Kunming mouse to produce 11 littermates (F1) with six mice with pigmented eyes. Lanes 1-11: genomic DNA from F1 offspring derived from P1; Lanes 1, 3-5, 7, 10: 767-bp specific band amplified from genomic DNA of F1 offspring exhibiting pigmented eyes.

animal requirements for transgenic production<sup>[37]</sup>.

### Co-injection strategy for visually identifying the transgenic mice

Screening transgenic animals is usually time-consuming and labor-consuming. It would be very helpful if the transgenic animals could be identified by the visible inspection at birth. The functional tyrosinase gene introduced into an albino mouse strain leads to pigmentation in eyes and skin with high penetrance, and pigmented mice with dark eyes can be immediately identified by simply visible inspection at birth<sup>[23]</sup>, as further confirmed by this study.

When two or several transgenic constructs are co-injected into single-cell fertilized embryos, the co-injected constructs typically co-integrate into the genome, where the transgene can independently express<sup>[38]</sup>. Theoretically, co-injection of tyrosinase transgenic construct with any other construct(s) should result in a certain percentage of transgenic mice carrying both transgenes at a single chromosomal site<sup>[23]</sup>. Additionally, co-injection experiments with the agouti transgenes and other transgenes demonstrated co-integration of the two constructs at the same chromosomal site in approximately 95% of F1 progeny, allowing transgene inheritance to be visibly detected<sup>[39]</sup>. The direct and visual detection of pigmentation in tyrosinase transgenic animals generated in the albino genetic backgrounds was repeatedly proposed by independent teams as a visual marker in co-injection strategies for the rapid detection of the successful transgenesis<sup>[12,30-33,35]</sup> and by our practices (data not shown). The utility of tyrosinase minigene co-injection with other construct(s) of interest is a useful adjunct to allow rapidly visual identification of transgenic mice at birth.

Moreover, another advantage of co-injection strategy is the fact that homozygous mice in most families can

be identified by simply visual inspection, since the homozygous mice have darker coat colors, reflecting the increased gene dosage<sup>[32]</sup>.

The co-injection strategy improves the yield of phenotypically desirable transgenic founder mice resulting from each microinjection session, and consequently reduces animal requirements for the transgenic production and routine genetic validation of transgenic lines.

In summary, we have successfully rescued the albino phenotype by introducing a functional tyrosinase gene into Kunming albino mouse. It should be pointed out here that TyBS and other tyrosinase transgenic constructs can be fused with any of the other genes and microinjected into fertilized eggs from albino murine strains in order to produce melanin pigments as an excellently visible marker for the generation and breeding of transgenic mice.

### ACKNOWLEDGMENTS

We thank Dr. CY Fan (Department of Pathology and Otolaryngology, University of Arkansas for Medical Sciences, USA) for his unstinting advices and technical guidance in making transgenic mice, for his supportive and friendly attitude toward our projects. We thank Dr. F Beermann (Swiss Institute for Experimental Cancer Research, Switzerland) for kindly gifting the plasmids of ptrTyr5 and pTyBS, Dr. PA Overbeek (Howard Hughes Medical Institute, Department of Cell Biology, Baylor College of Medicine, Houston, TX, USA) for providing the vectors (e.g., pTyBS and pTy811C), and Professor G Schutz [Deutsches Krebsforschungszentrum (DKFZ), Heidelberg, Germany] for providing the plasmid ptrTyr5. We are also indebted to the expert technical assistance of JY Han, HH Zhang, GG Qiu, WG Huang, FY Chen, FR Ni, JY Xie and JH Wang, Center of Experimental Animals, Sun Yat-Sen University.

**CONCLUSION:** Pae had a significant growth-inhibitory effect on the human hepatoma cell line HepG<sub>2</sub>, which may be related to apoptosis induction and cell cycle arrest. It also can enhance the cytotoxicity of chemotherapeutic agents on HepG<sub>2</sub> cells, and the S phase arrest induced by Pae may be one of the mechanisms of these interactions.

### Abstract

**AIM:** To investigate the antiproliferative effect of paeonol (Pae) used alone or in combination with chemotherapeutic agents [cisplatin (CDDP), doxorubicin (DOX) and 5-fluorouracil (5-FU)] on human hepatoma cell line HepG<sub>2</sub> and the possible mechanisms.

**METHODS:** The cytotoxic effect of drugs on HepG<sub>2</sub> cells was measured by 3-(4, 5-dimethylthiazol-2-yl)-2, 5-diphenyltetrazolium bromide (MTT) assay. Morphologic changes were observed by acridine orange (AO) fluorescence staining. Cell cycle and apoptosis rate were detected by flow cytometry (FCM). Drug-drug interactions were analyzed by the coefficient of drug interaction (CDI).

**RESULTS:** Pae (7.81-250 mg/L) had an inhibitory effect on the proliferation of HepG<sub>2</sub> cells in a dose-dependent manner, with the IC<sub>50</sub> value of (104.77 ± 7.28) mg/L. AO fluorescence staining and FCM assays showed that Pae induced apoptosis and arrested cell cycle at S phase in HepG<sub>2</sub> cells. Further, different extent synergisms were observed when Pae (15.63, 31.25, 62.5 mg/L) was combined with CDDP (0.31-2.5 mg/L), DOX (0.16-1.25 mg/L), or 5-FU (12.5-100 mg/L) at appropriate concentrations. The IC<sub>50</sub> value of the three drugs decreased dramatically when combined with Pae ( $P < 0.01$ ). Of the three different combinations, the sensitivity of cells to drugs was considerably different.

### INTRODUCTION

Hepatocellular carcinoma (HCC) is the fifth most common cancer and the third leading cause of cancer-related death worldwide<sup>[1]</sup>. Eighty percent of the burden is borne by countries in Asia and Sub-Saharan Africa<sup>[2]</sup>. Although recent advances in management with a multidisciplinary approach results in improved local and regional disease control, the 5-year survival rate is still less than 10%<sup>[3]</sup>. Thus it is imperative to develop more effective and low-toxic chemotherapy agents.

Chinese herbal medicines are now attracting great attention in the world, which also show promising effects in treatment of cancers, including HCC<sup>[4]</sup>. Paeonol (Pae, 2-hydroxy-4-methoxyacetophenone, Figure 1), is a natural product extracted from the root of *Paeonia Suffruticosa* Andrew<sup>[5]</sup>. In our previous study, the antineoplastic activity of Pae has been demonstrated both in various cell lines<sup>[6]</sup> and in animal models<sup>[7,8]</sup>. The present study was designed to investigate the antiproliferative effect of Pae used alone or in combination with chemotherapeutic drugs [cisplatin (CDDP), doxorubicin (DOX) and 5-fluorouracil (5-FU)] on human hepatoma cell line HepG<sub>2</sub> and the possible mechanisms.

### MATERIALS AND METHODS

#### Cells and culture conditions

Human hepatocellular carcinoma cell line HepG<sub>2</sub> was

**Figure 1** Structure of Pae (2-hydroxy-4-methoxyacetophenone).

purchased from Shanghai Institute of Hepatocarcinoma. HepG<sub>2</sub> cells were cultured in Dulbecco's modified Eagle's medium (DMEM) supplemented with 10% fetal bovine serum (FBS) and incubated at 37°C in a humidified atmosphere with 5% CO<sub>2</sub>.

### Drugs and reagents

Pae Injection was purchased from the First Pharmaceutical Factory of Shanghai, China (Cat. No. 990402, 10 mg/2 mL); CDDP Injection was purchased from Nanjing Pharmaceutical Co. Ltd, China (Cat. No. 20050602, 20 mg/20 mL); DOX was provided by Wanle Pharmaceutical Inc., Shenzhen, China (Cat. No. 0407E1, 10 mg/ampoule); 5-FU Injection was supplied by Shanghai Haipu Pharmaceutical Factory, China (Cat. No. 031109, 0.25 g/10 mL); DMEM was purchased from GIBCO BRL, Life Technologies Inc. (New York, USA); 3-[4, 5-dimethylthiazol-2-yl]-2, 5-diphenyltetra-zolium bromide (MTT) and acridine orange (AO) were from Sigma Co., USA. DNA-Prep-Reagents Kit was provided by Beckman Coulter Co. USA (Cat. No. 760279K).

### In vitro cytotoxicity assay

HepG<sub>2</sub> cells were seeded in 96-well plates at a density of  $1-5 \times 10^3$  cells/well in 100  $\mu$ L DMEM containing 10% FBS overnight. Nonadherent cells were removed by gentle washing. Then cells were treated with various concentrations of the drugs. After 44 h of drug exposure, 20  $\mu$ L MTT solution (5 g/L) was added to each well for another 4 h at 37°C. The formazine was solved in 150  $\mu$ L/well dimethyl sulfoxide (DMSO) and the absorbance was detected at 490 nm using ELx800 Strip reader (Bio-Tek, USA). The percentage of cytotoxicity was calculated as follows: Cytotoxicity (%) =  $(1 - A_{490} \text{ of experimental well}) / A_{490} \text{ of control well}$ . The median inhibitory concentration (IC<sub>50</sub>) (defined as the drug concentration at which cell growth was inhibited by 50%) was assessed from the dose-response curves.

### Analysis of in vitro drug interaction

The coefficient of drug interaction (CDI) was used to analyze the synergistically inhibitory effect of drug combinations<sup>[9]</sup>. CDI is calculated as follows:  $CDI = AB / (A \times B)$ . According to the absorbance of each group, AB is the ratio of the combination groups to control group; A or B is the ratio of the single agent groups to control group. Thus CDI value less than, equal to or greater than 1 indicates that the drugs are synergistic, additive or antagonistic, respectively. CDI less than 0.7 indicates that the drugs are significantly synergistic.

**Figure 2** Dose-dependent cytotoxicity of Pae in HepG<sub>2</sub> cells. Data are presented as mean  $\pm$  SE (error bar) of triplicate experiments.

### AO fluorescence staining

Cells were cultured in 6-well plates containing cover slips overnight. After incubation with Pae for 24 h, the cover slips were washed twice with PBS, fixed with 95% ethanol for 15 min, acidified with 1% acetic acid for 30 s, dyed with 0.1 g/L AO for 10 min, differentiated with 0.1 mol/L CaCl<sub>2</sub> for 2 min, and then washed with PBS 3 times. The cover slips were sealed and observed under a fluorescence microscope (OLYMPUS, Japan).

### Flow cytometry assay

Cells were cultured in 6-well plates and allowed to grow to 75%-80% confluency. Nonadherent cells were removed by gentle washing, and the media were removed and replaced with fresh medium containing Pae at the desired concentrations. After exposure to drugs for 24 h, cells were collected and centrifuged at 1500 r/min in a 15 mL tube for 10 min. The cells were washed twice with PBS and resuspended in 50  $\mu$ L fixing buffer at a room temperature for 20 s, then 500  $\mu$ L propidium iodide (PI) staining buffer was added in the dark at room temperature for 30 min (according to the procedure program of the DNA-Prep Coulter reagents kit). A minimum of  $1 \times 10^5$  cells for each group was analyzed using an EPICS XL-MCL model Coulter counter. Cell cycle distribution was analyzed using Mcycle software.

### Statistical analysis

Biostatistical analyses were done using the SPSS 11.5 software package. All experiments were repeated at least three times. Results of multiple experiments are given as the mean  $\pm$  SE. Non-parametric Kruskal-Wallis test was used to detect differences among the different experimental groups. Mann-Whitney *U* test was subsequently used for statistical evaluation in two-group comparisons. Pearson correlation coefficients were used for continuous independent and dependent variables. A level of  $P < 0.05$  was accepted as statistically significant.

## RESULTS

### Effect of pae on the proliferation of HepG<sub>2</sub> cells

We first examined the effect of Pae on the proliferation of HepG<sub>2</sub> cells. As shown in Figure 2, a dramatic dose-

**Figure 3** Effect of Pae on apoptosis in HepG2 cells. **A:** Morphological changes of HepG2 cells treated with Pae 62.5 mg/L ( $\times 320$ ); **B:** Flow cytometry analysis of HepG2 cells treated with Pae for 24 h. (a). Control; (b).Pae 31.25 mg/L; (c).Pae 62.5 mg/L; (d).Pae 125 mg/L.

dependent reduction of cell viability was seen in cells incubated with Pae at concentrations of 7.81-250 mg/L for 48 h. The  $r$  value of dose-effect curves was 0.959 ( $P < 0.01$ ) and the  $IC_{50}$  value of Pae was  $(104.77 \pm 7.28)$  mg/L ( $P < 0.01$ ).

#### Effects of Pae on apoptosis in HepG2 cells

Morphological evidence of apoptosis was demonstrated by AO fluorescence staining. AO could be seen in all cells and the nuclei appeared green and chromatin was stained yellow (Figure 3A). Cells treated with Pae showed typically apoptotic changes, such as chromatin condensation,

membrane blebbing, deformed and fragmented nuclei.

FCM assay was performed to analyze apoptosis in HepG2 cells treated with various concentrations of Pae for 24 h. It was found that the sub-G<sub>1</sub> peak appeared before G<sub>1</sub> phase, which represents apoptotic cell population (Figure 3B), in a dose- and time-dependent manner (Figure 4).

#### Effects of Pae on cell cycle in HepG2 cells

Mcycle software was used to analyze the kinetic changes of cell cycle distribution. In untreated HepG2 controls, cells were present in G<sub>0</sub>/G<sub>1</sub> ( $71.79\% \pm 2.76\%$ ), S ( $20.31\%$ )

**Figure 4** Effect of Pae on cell cycle in HepG<sub>2</sub> cells. The distribution of cells in the sub-G<sub>1</sub>, G<sub>0</sub>/G<sub>1</sub>, S, and G<sub>2</sub>/M phases of the cell cycle were calculated and plotted. (A): Dose-dependent curve of cell cycle distribution induced by Pae. (B): Time-dependent curve of cell cycle distribution induced by Pae 31.25 mg/L. Each point represents triplicate experiments. Bars  $\pm$  SE.

$\pm 0.58\%$ ), and G<sub>2</sub>/M ( $7.16\% \pm 0.57\%$ ) phases. For HepG<sub>2</sub> cells exposed to various concentrations of Pae, the S-phase fraction increased while G<sub>0</sub>/G<sub>1</sub> fraction decreased in a dose-dependent manner (Figure 4A). And the percentages of cells in S phase increased to  $24.98\% \pm 1.63\%$ ,  $26.54\% \pm 1.53\%$ ,  $31.72\% \pm 4.85\%$  after 24, 48, and 72 h, respectively, when compared with untreated control cells, which was accompanied by a concomitant decrease of cells in the G<sub>0</sub>/G<sub>1</sub> phase of the cell cycle (Figure 4B). It indicated that Pae might arrest the cell cycle at the S phase, and this blockage of cell cycle may prevent cells from entering M phase.

#### Pae enhancing the cytotoxicity of chemotherapeutic drugs on HepG<sub>2</sub> cells

Growth-inhibition assays were performed to investigate whether Pae can enhance the antiproliferative effects of chemotherapeutic agents on HepG<sub>2</sub> cells. Three doses of Pae (15.63, 31.25 and 62.5 mg/L) were combined with different concentrations of CDDP, DOX, and 5-FU, respectively. For each experiment, a dose-response curve of each single chemotherapeutic agent and its combination with Pae was drawn, which showed that Pae increased the cytotoxicity of CDDP, DOX, and 5-FU on HepG<sub>2</sub> cells. The IC<sub>50</sub> value of the three drugs decreased dramatically at different extents when combined with Pae. For example, in the presence of 15.63, 31.25 and 62.5 mg/L Pae, the IC<sub>50</sub> of CDDP reduced from  $0.591 \pm 0.053$  mg/L to  $0.366 \pm 0.011$ ,  $0.161 \pm 0.018$ ,  $0.007 \pm 0.002$  mg/L, respectively. That of DOX reduced from  $0.489 \pm 0.124$  mg/L to  $0.175 \pm 0.043$ ,  $0.037 \pm 0.012$ ,  $0.032 \pm 0.005$  mg/L. And that of 5-FU reduced from  $310.783 \pm 13.094$  mg/L to  $161.759 \pm 9.507$ ,  $8.646 \pm 2.331$ ,  $5.021 \pm 0.962$  mg/L, respectively ( $P < 0.01$ , Figure 5A-C).

We analyzed the nature of the interaction between Pae and the three drugs using CDI, which quantitatively measures the interaction of two drugs. As shown in Figure 5D, Pae and CDDP yielded synergistic interactions across a wide concentration range. The synergistic effect was most prominent when 15.63 mg/L Pae was combined with 1.25

mg/L CDDP (CDI  $< 0.7$ ). While a significant synergistic effect was only obtained when Pae concentration reached 31.25 and 62.5 mg/L in combination with 0.16 mg/L and 0.31 mg/L DOX, respectively. When DOX reached 1.25 mg/L, the interaction was antagonistic (Figure 5E). Pae had a relatively weak activity to enhance the antiproliferative effect of 5-FU in HepG<sub>2</sub> cells. If the concentrations of drugs were too high or too low, the synergistic cytotoxic effects could not be achieved. The combinations of Pae at 31.25 mg/L and 5-FU at 12.5 and 25 mg/L exhibited significantly synergistic activity against HepG<sub>2</sub> cells, while an antagonistic effect was observed at 62.5 mg/L of Pae in combination with 25-100 mg/L of 5-FU (Figure 5F).

## DISCUSSION

Currently, a variety of cytotoxic and antiproliferative agents have been tested in HCC treatment, which are used alone, or in combination with other drugs or other treatment modalities<sup>[10]</sup>. Agents with partial response rates near or above 10% include DOX, CDDP and 5-FU<sup>[11-13]</sup>. However, high doses of these drugs lead to severe toxicities, which have a negative effect on patients' survival. The use of less toxic doses in combination with other anti-proliferative agents would be desirable<sup>[14-17]</sup>.

Pae is isolated from the herb *Pycnostelma paniculatum* (Bunge) K.S., and the root of the plant *Paeonia Suffruticosa* Andrew<sup>[5]</sup>. It is a white needle crystal with a relatively low-melting point of 51°C-52°C. The molecular weight of Pae is 166.18 ku and the molecular formula is C<sub>9</sub>H<sub>10</sub>O<sub>3</sub><sup>[18]</sup>. Pae possesses extensive pharmacological activities such as sedation, hypnosis, antipyresis, analgesic, antioxidation, antiinflammation, and immunoregulation<sup>[19]</sup>. Additionally, Pae had minimal systemic toxicity (LD<sub>50</sub> 3430 mg/kg) when it was orally administrated to mice<sup>[20]</sup>. In our previous study, the antineoplastic activity of Pae has been demonstrated both in cell lines, such as human erythromyeloid cell line K562, breast cancer gene cell line T6-17, human hepatoma cell line Bel-7404, and cervical

**Figure 5** The synergistically antiproliferative effect of Pae combined with CDDP (A), DOX (B), or 5-FU (C) on HepG<sub>2</sub> cells. The dots represent the concentrations of chemotherapeutic drugs as 0 on the dose-response curves which means treatment with Pae alone. Data are presented as mean  $\pm$  SE of triplicate experiments. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$ , vs chemotherapeutic drugs alone. And CDI for the combination treatment of Pae with CDDP (D), DOX (E), or 5-FU (F) on HepG<sub>2</sub> cells.

cancer cell line Hela<sup>[6]</sup>, and in animal models bearing HepA hepatocarcinoma<sup>[7,8]</sup>. Ji *et al*<sup>[21]</sup> demonstrated that Pae at a low concentration had synergetic effects with 5-FU, MMC and CDDP on inhibiting the proliferation of human colorectal cancer cell line HT-29.

In the present study, Pae exhibited growth inhibition to HepG<sub>2</sub> cells in a dose-dependent manner, with the IC<sub>50</sub> value of 104.77 ( $\pm$  7.28 mg/L) mg/L. Although the exact mechanism of the cytotoxicity of Pae against HepG<sub>2</sub> cells

is not entirely clear, many potential mechanisms have been proposed for the growth inhibition of Pae in cultured cells and animal models. These mechanisms include induction of apoptosis<sup>[22-23]</sup> and immunoregulation such as promoted lymphocyte proliferation, IL-2 production by splenocytes, and TNF- $\alpha$  production by PM $\phi$  from the model mice<sup>[7,8]</sup>. Apoptosis is a mechanism by which cells undergo death to control cell proliferation or in response to DNA damage. A tumor occurs when the balance of

cell proliferation and cell death is broken<sup>[24]</sup>. Induction of apoptosis is an effective strategy for cancer therapy<sup>[25]</sup>. In the present study, the cells treated with Pae showed typical characteristics of apoptosis. Similarly, apoptotic peak appeared before G<sub>1</sub> phase after treatment with Pae, which resulted from the internucleosomal degradation of DNA, in a dose- and time-dependent manner. Moreover, the HepG<sub>2</sub> cells exposed to Pae for 24 h showed depletion of the G<sub>0</sub>/G<sub>1</sub> fraction and accumulation in S-phase. Accumulation in S-phase has also been reported by Liu *et al*<sup>[22]</sup>, in which Pae could induce cell cycle disturbance and S phase of the HT-29 cells was increased, while G<sub>0</sub>/G<sub>1</sub> and G<sub>2</sub>/M phase of the cells were decreased. The S phase arrest and apoptosis induction of Pae on HepG<sub>2</sub> cells might be its main mechanism.

Meanwhile, HepG<sub>2</sub> cells were treated with the combinations of Pae and different chemotherapeutic agents. The results indicated that the growth inhibitory effect of CDDP, DOX, or 5-FU, respectively, was enhanced significantly by Pae at appropriate concentrations. Among the three agents examined, CDDP showed the most wide synergistic effect with Pae. The synergistic effect was most prominent (CDI < 0.7 =) when 15.63 mg/L Pae was combined with 1.25 mg/L CDDP. This indicated that the combination of Pae and CDDP at certain concentrations might help reduce nausea, vomiting and serious kidney toxicity of CDDP. Similar results that Pae in combination with anticancer drugs had synergistic effects at lower concentrations and had antagonistic effects at higher concentrations were observed in DOX and 5-FU, but with different sensitivities. The S phase arrest of Pae may be one of the mechanisms related with these interactions. 5-FU belongs to cell cycle specific agents, which acts specifically on cells in S phase<sup>[26]</sup>. The cytotoxic effects of CDDP and DOX are generally considered to be non-cell-cycle specific<sup>[27-28]</sup>. Nevertheless, DOX has the most killing effect on S phase cells<sup>[28]</sup>. CDDP is most specific to G<sub>1</sub> phase cells, while it also has strong effects on cells in S phase<sup>[29]</sup>. Further studies are needed to investigate the mechanisms of these synergisms, which favor the reasonable application of Pae to HCC treatment.

## COMMENTS

### Background

Hepatocellular carcinoma (HCC) is a major contributor to cancer incidence and mortality in the world. No effective treatment is available by now. Therefore, there is a critical need to develop more strategies for chemotherapy of hepatoma.

### Research frontiers

Currently, a variety of cytotoxic and antiproliferative agents have been tested in HCC treatment, which are used alone, or in combination with other drugs or with different modalities of treatment. Chinese herbal medicines are now attracting great attention in the world, which also show promising effects in HCC therapy. Paeonol, a natural product extracted from the root of *Paeonia Suffruticosa* Andrew, has shown antineoplastic activities both in cell lines and in animal models.

## Innovations and breakthroughs

This is the first report on the antiproliferation, induction of apoptosis and cell cycle arrest by Pae in HepG<sub>2</sub> cells.

## Applications

Pae may be expected to be effective and useful as a new agent in hepatoma chemotherapy.

## Peer review

The authors examine the cytotoxic effect of Pae only in HepG<sub>2</sub> cells. It remains unclear whether the effect of Pae in HepG<sub>2</sub> cells can be generalized to other hepatoma cells. The authors should examine the effect of Pae using a panel of hepatoma cell lines; The data in Figure 4 suggested that Pae induces S-phase arrest in HepG<sub>2</sub> cells. However, the molecular basis for S-phase arrest is not clearly shown. The authors should examine whether Pae has an effect in cells arrested at G<sub>1</sub>/S phase using pre-treatment of cells such as hydroxyurea. It would be important to examine the expression of p21, p27 CDK1 and cyclinA after treatment with Pae.

## Abstract

**AIM:** To evaluate the diagnostic potential of cytokeratin-19 (CK-19) mRNA for the detection of disseminated tumor cells in blood, bone marrow and peritoneal lavage in patients with ductal adenocarcinoma of the pancreas.

**METHODS:** Sixty-eight patients with pancreatic cancer ( $n = 37$ ), chronic pancreatitis ( $n = 16$ ), and non-pancreatic benign surgical diseases ( $n = 15$ , control group) were included in the study. Venous blood was taken preoperatively, intraoperatively and at postoperative d 1 and 10. Preoperative bone marrow aspirates and peritoneal lavage taken before mobilization of the tumor were analyzed. All samples were evaluated for disseminated tumor cells by CK-19-specific nested-PCR and quantitative fluorogenic RT-PCR.

**RESULTS:** CK-19 mRNA expression was increased in 24 (64%) blood samples and 11 (30%) of the peritoneal lavage samples in the patients with pancreatic cancer. In 15 (40%) of the patients with pancreatic cancer, disseminated tumor cells were detected in venous blood and bone marrow and/or peritoneal lavage. In the peritoneal lavage, the detection rates were correlated with the tumor size and the tumor differentiation. CK-19 levels were increased in pT3/T4 and moderately/poorly differentiated tumors (G2/G3). Pancreatic cancer patients with at least one CK-19 mRNA-positive sample showed a trend towards shorter survival. Pancreatic cancer

patients showed significantly increased detection rates of disseminated tumor cells in blood and peritoneal lavage compared to the controls and the patients with chronic pancreatitis.

**CONCLUSION:** Disseminated tumor cells can be detected in patients with pancreatic ductal adenocarcinoma by CK-19 fluorogenic RT-PCR. In peritoneal lavage, detection rate is correlated with tumor stage and differentiation. In the clinical use, CK-19 is suitable for the distinction between malignant and benign pancreatic disease in combination with other tumor-specific markers.

## INTRODUCTION

Pancreatic cancer is one of the top five causes of cancer death in the Western world. The 5-year survival rates are around 4%<sup>[1,2]</sup>. Tumor resection is associated with prolonged survival and postoperative adjuvant chemotherapy may further improve long-term results<sup>[3,4]</sup>. However, curative treatment of most patients fails due to local recurrence and hepatic metastases occurring within two years after surgery<sup>[5,6]</sup>. Occult micro-metastases caused by disseminated tumor cells are the most limiting factor for the improvement of mortality rates. Their influence on prognosis and development of new therapeutic strategies has not yet been completely elucidated.

Disseminated tumor cells are not ascertainable with current staging methods. Additional to cytology, immunohistochemical analysis is the standard for identification of tumor cells. Despite improvement of detection rates by conventional cytology, conflicting result regarding the prognostic relevance have been reported<sup>[7]</sup>. Several studies focused on molecular biological approaches for the qualitative or semi-quantitative verification of tumor cell dissemination in pancreatic cancer<sup>[8-12]</sup>. Reverse transcriptase polymerase chain reaction (RT-PCR) has a high sensitivity and allows the identification of approximately 1 tumor cell in 10<sup>7</sup> normal peripheral mononuclear blood cells<sup>[13]</sup>. Using qualitative PCR methods, varying frequency of gene transcripts and false positive results have been reported<sup>[14-16]</sup>. Therefore, tumor cell detection in patients with ductal adenocarcinoma of the pancreas is still a matter of debate.

Nowadays CEA and CA 19-9 are established as clinical markers for pancreatic cancer. However, expressions of these antigens have also been reported in cholangitis, chronic pancreatitis and various gastrointestinal tumors<sup>[17]</sup>. Various studies used cytokeratin-19 (CK-19) for pancreatic cell detection. CK-19 has been identified as a reliable marker for epithelial cell differentiation<sup>[18]</sup>. It is specific for undifferentiated pancreatic ductal cells and homogenously expressed at high levels in primary pancreatic adenocarcinoma and pancreatic carcinoma metastases<sup>[19,20]</sup>. CK-19 is not expressed in hematopoietic cells and therefore suited for detection of disseminated pancreatic cells in the peripheral blood<sup>[19,21]</sup>.

Here, we report on the expression of CK-19 mRNA in blood, bone marrow and peritoneal lavage in 68 patients. Nested-PCR and quantitative fluorogenic RT-PCR were used to detect dissemination of pancreatic cells in patients with pancreatic cancer, chronic pancreatitis and non-pancreatic benign surgical diseases. The purpose of this study was to evaluate the potential of qualitative nested-PCR and quantitative RT-PCR for the detection of disseminated pancreatic cells and the differentiation between chronic pancreatitis and pancreatic cancer.

## MATERIALS AND METHODS

### Patients

This prospective study was approved by the Ethical Commission of the University of Leipzig and informed written consent was obtained from each patient. Peripheral blood samples, bone marrow aspirations and peritoneal lavage of 68 patients were analyzed. Thirty-seven patients with histologically confirmed primary pancreatic cancer, 16 patients with chronic pancreatitis and 15 controls with non-pancreatic benign surgical diseases participated in the study. In all patients, diagnosis was confirmed by the resected specimen or tumor biopsy for non-resectable cancers ( $n = 11$ ). Patients with pancreatic cancer were staged according to the UICC guidelines 2005<sup>[22]</sup>. According to the UICC stage, 4 (10%) patients had stage I, 3 (8%) stage II, 19 (51%) stage III, and 11 (29%) stage IV pancreatic cancer. The survival time of the patients ranged between 3 and 48 mo (median survival: 12 mo). Patients

with cancer of the common bile duct, the ampulla of Vater or the duodenum were excluded from the study.

### Samples

Four blood samples were obtained from each patient through central venous catheter 30 min preoperatively, intraoperatively after mobilization of the pancreas and 24 h as well as 10 d after the operation. Bone marrow samples were obtained after induction of general anesthesia by aspiration from the iliac crest and heparinized. Peritoneal lavage was performed immediately after exploration of the abdominal cavity. About 500 mL of sterile isotonic sodium chloride solution was instilled, removed after irrigation and then EDTA buffer was added.

### RNA extraction and cDNA synthesis

All samples were diluted and washed with 10 mL of erythrocyte lysis buffer. The mononuclear cell fraction was isolated by Ficoll-Isopaque (Amersham, Braunschweig, Germany). Total RNA was extracted using guanidinium-isothiocyanate-phenol-chloroform-based method (Trizol, Gibco BRL, Life Technologies, Gaithersburg, USA). RNA integrity was checked electrophoretically and quantified spectrophotometrically. First strand cDNA was generated from 3 µg of total RNA diluted with 10 µL of RNase-free water using 1 µL of Random Hexamer Primer (Roche Diagnostics, Basel, Switzerland) and incubated for 10 min at 68°C. After chilling on ice, 7 µL of master mixture, according to Superscript II kit (Invitrogen, Carlsbad, USA), was added and after 60 min of incubation at 42°C, the reaction was inactivated for 10 min at 80°C.

### Qualitative nested-PCR

Qualitative analysis of CK-19 expression was carried out using nested-PCR. Two different pairs of primer (n-PCR1/n-PCR2) were designed. The second set of primers amplifies inside the amplification sites of n-PCR1 primers to improve the specificity of PCR. Then 5 µL of cDNA was diluted with 45 µL of mixture containing 1 µL of each n-PCR1 primer, 10 × PCR buffer, dNTP PCR, AmpliTaq polymerase (Perkin Elmer Life and Analytical Sciences, Boston, USA) and DNase-free water for first round PCR. The conditions for PCR step one and two were one cycle at 95°C for 3 min, followed by 40 cycles at 57°C for 20 s, 72°C for 50 s and a final extension at 72°C for 10 min. For second round PCR, 1 µL of aliquot of the first round PCR product was added to 49 µL of master mixture containing 1 µL of each n-PCR2 primer. Two negative controls were included per run. Ten microliters of all PCR products were electrophoresed on 20 g/L agarose gels and visualized after ethidium bromide staining (Table 1).

### Quantitative RT-PCR

CK-19 and housekeeping genes beta-actin primers and fluorogenic probes were designed using Primer Express software (Primerexpress Version 2.0, Perkin Elmer) (Table 1). PCR primers and probes have been positioned to span exon-intron boundaries. Amplification and detection of CK-19 a and b pseudogen are unlikely because probe and

Table 1 Sequences for quantitative RT-PCR and nested-PCR primers and fluorescent probes

	Forward primer	Reverse primer	Length (bp)

primer contain several mismatches. mRNA quantification was carried out using the one tube, one enzyme fluorogenic RT-PCR protocol<sup>[23]</sup>. Ten microliters of cDNA was diluted with 40  $\mu$ L of master mixture containing TaqPolymerase, dNTP mixture and 10  $\times$  AmpliTaq buffer A, 200 nmol/L probe, 900 nmol/L primer and 25 mmol/L MgCl<sub>2</sub>. After 10 min of denaturation at 95°C, PCR was carried out for 40 cycles at 95°C for 15 s and extension at 60°C for 60 s in the presence of the probe. RT-PCR monitoring was achieved by measuring the fluorescent signal of the probe at the end of the annealing phase of each cycle. mRNA quantification was recorded and analyzed with the ABI 7700 Prism Sequence detection system (Perkin Elmer Applied Biosystems, Foster City, CA, USA). Two no-template controls were used to monitor contamination in every run. Accurate quantification was achieved through generation of standard curves by serial dilution of CK-19 and beta-actin RNA transcribed by RNA polymerase. The sensitivity of the technique was evaluated by serial control analysis obtained in dilution experiments with CK-19-expressing cancer cell lines (CaPan2, PANC1). It was possible to detect the CK-19 mRNA expression of one cell of the cell lines in 1 mL of normal peripheral blood.

### Evaluation criteria

For nested-PCR, the samples were tested twice. If a CK-19 signal was detected, the sample was judged positive. The fluorogenic RT-PCR assay was done twice for each sample. The average value of both duplicates for each sample was used as quantitative value. Samples were excluded from the investigation if the expression of the house-keeping gene beta-actin was below 10<sup>6</sup> copies. The ratio of copies of CK 19 mRNA per 10<sup>6</sup> copies of beta-actin mRNA was used for further analysis. The introduction of a cut-off was required, due to high illegitimate background transcription in the control group. The samples which exceeded the maximum value of the CK-19 mRNA expression in the control group were defined as CK-19 mRNA-positive.

### Statistical analysis

Mann-Whitney rank sum test was used for quantitative analysis to assess the differences in the means. Fisher's exact test was used for qualitative analysis. Two-tailed *P* value less than 0.05 was considered statistically significant. Kaplan-Meier and log-rank test were used for analysis of survival. Statistical analysis was carried out using SigmaStat 1.0 software (Jandel Scientific Corp., Erkrath, Germany).

Figure 1 Quantitative values of cytokeratin-19 transcription in blood, bone marrow and peritoneal lavage of the patients with pancreatic cancer. <sup>1</sup>Cut-off: Maximal expression of CK-19 mRNA in healthy control patients.

## RESULTS

### Qualitative nested-PCR

CK-19 mRNA expression was detectable in the blood in 65% (24/37) of the patients with pancreatic cancer, 53% (8/16) of the patients with chronic pancreatitis and 18% (3/15) of the control group. The analysis of the bone marrow samples revealed detectable CK-19 mRNA in 56% (21/37) of pancreatic cancer patients, 46% (7/16) of chronic pancreatitis patients and 66% (10/15) of the control group. In 51% (19/37) of the patients with pancreatic cancer and 46% (7/16) of the patients with chronic pancreatitis and 46% (7/15) of the control group, CK-19 mRNA was detectable in the peritoneal lavage. There was no statistically significant difference between the groups.

### Quantitative real-time RT-PCR

Blood, bone marrow and peritoneal lavage samples of 37 patients with pancreatic cancer were analyzed by CK-19 fluorogenic RT-PCR. CK-19 mRNA transcripts were detected in 70% (26/37) of blood samples, 67% (25/37) of bone marrow aspirates and 54% (20/37) of peritoneal lavage samples. In 40% (15/37) of the patients, PCR result was obtained from at least two compartments. We found that 64% (24/37) of the blood samples and 30% (11/37) of the peritoneal lavage samples showed CK-19 mRNA expression above the cut-off value and were defined as CK-19 mRNA-positive (Figure 1).

The CK-19 signal exceeded the cut-off value in 21% (8/37) of the pre-operatively and 19% (7/37) of the

**Figure 2** Quantitative analysis of CK-19 expression in blood (mean  $\pm$  SD). <sup>a</sup> $P < 0.05$  vs pancreatic cancer.

intraoperatively taken blood samples. Likewise, 13% (5/37) of the samples taken at the first postoperative day and 10% (4/37) of the samples taken at the 10<sup>th</sup> postoperative day showed expression of CK-19 mRNA. The median mRNA expression was significantly increased in the patients compared to the control group at the four time points ( $P < 0.05$ ) (Figure 2). The CK-19 levels showed a trend to increase intraoperatively and decrease at the 1<sup>st</sup> and 10<sup>th</sup> postoperative days below the pre-operative level ( $P = 0.07$ ). We found 64% (24/37) of the bone marrow samples exhibited detectable CK-19 mRNA expression. None of the samples exceeded the CK-19 mRNA expression of the control group. The detection rate was not statistically different. In the peritoneal lavage, CK-19 signal was detected in 54% (20/37); 30% (11/37) of these samples exceeded the maximum level of the control group and were found to be CK-19 mRNA-positive. Compared to the control group, the median CK-19 mRNA expression was at least 10-fold increased ( $533 \pm 121$  copies CK-19/ $10^6$  copies beta-actin *vs*  $6262 \pm 557$  copies CK-19/ $10^6$  copies beta-actin,  $P < 0.01$ ) (Figure 3).

The correlation analysis of marker detection and stage of disease was performed for blood, bone marrow and peritoneal lavage. In peritoneal lavage, CK-19 mRNA levels correlated with the tumor size and were increased 3 times in the patients with a pT3/pT4 tumor compared to the patients with pT1/pT2 tumors ( $874 \pm 87$  copies/ $10^6$  copies beta-actin *vs*  $2884 \pm 473$  copies/ $10^6$  copies beta-actin ( $P < 0.05$ ). Detection rates were increased for the patients with moderate or poorly differentiated tumors (pG2/pG3) compared to the patients with well differentiated tumors (pG1) ( $3560 \pm 302$  copies CK-19/ $10^6$  copies beta-actin *vs*  $1055 \pm 88$  copies CK-19/ $10^6$  copies beta-actin,  $P < 0.05$ ) (Figure 4). The detection rates were not significantly different regarding the N stage or in blood and bone marrow samples. At the endpoint of the study, 14 patients had died of metastasized disease or tumor recurrence; 57% (8/14) of these patients had at least one CK-19 positive sample. No significant difference in the median survival was observed between the patients with positive CK-19 mRNA expression and negative CK-19 mRNA expression (10 mo *vs* 15 mo,  $P = 0.15$ ).

**Figure 3** Quantitative CK-19 expression in peritoneal lavage of the patients with pancreatic cancer (mean  $\pm$  SD, <sup>a</sup> $P < 0.05$  vs pancreatic cancer).

**Figure 4** Quantitative CK-19 expression in peritoneal lavage of the patients with tumors (mean  $\pm$  SD). <sup>a</sup> $P < 0.05$  vs pT1/2; <sup>c</sup> $P < 0.05$  vs pG1.

Blood, bone marrow and peritoneal lavage samples of 31 patients without malignancies (15 patients of the control group and 16 patients with chronic pancreatitis) were evaluated. CK-19 expression was detectable in 80% (12/15) of the samples taken from the control group. The highest detectable CK-19 signal was used as the base line for the cut-off values which were as follows: blood preoperatively 1064 copies CK-19 per  $10^6$  copies beta-actin, intraoperatively 984 copies CK-19 per  $10^6$  copies beta-actin, 1<sup>st</sup> and 10<sup>th</sup> postoperative days 1179 copies CK-19 per  $10^6$  copies beta-actin; bone marrow 4200 copies CK-19 per  $10^6$  copies beta-actin; and peritoneal lavage 1600 copies CK-19 per  $10^6$  copies beta-actin.

CK-19 mRNA could be detected in 80% (12/16) of the blood samples, 53% (8/16) of the bone marrow aspirates and 60% (9/16) of peritoneal lavage of the patients with chronic pancreatitis. No analyzed sample exceeded the maximal CK-19 mRNA expression of the control group. We observed a five-fold lower CK-19 signal in the peripheral blood compared to the patients with pancreatic cancer ( $142 \pm 138$  copies/ $10^6$  copies beta-actin *vs*  $741 \pm 278$  copies/ $10^6$  copies beta-actin). The gene expression was significantly different at the four investigated time points ( $P < 0.01$ ) (Figure 2). Analysis

of the bone marrow samples did not reveal any obvious difference in the CK-19 mRNA expression between the investigated groups. Compared to the patients with pancreatic cancer, the median CK-19 mRNA expression in the peritoneal lavage was 10-fold lower in the patients with chronic pancreatitis ( $261 \pm 134$  copies/ $10^6$  copies beta-actin *vs*  $3319 \pm 484$  copies/ $10^6$  copies beta-actin,  $P < 0.01$ ).

## DISCUSSION

The long-term survival rates for patients with pancreatic cancer remain low. Without treatment, the 5-year survival rates are 0.4% to 4%<sup>[1,24]</sup>. Up to 80% of patients develop recurrent disease within 2 years after tumor resection<sup>[5]</sup>. Despite progress in adjuvant therapy and application of new chemo-radio-immunotherapy protocols, the high recurrence rate is the most limiting factor for the improvement of the patients prognosis<sup>[3,25]</sup>. Therefore, more sensitive staging methods are needed for this kind of tumor. Minimal residual disease caused by the spread of tumor cells into the circulation either before or during surgery is discussed as a main reason for early metastases and local recurrence in pancreatic cancer<sup>[26,27]</sup>. To detect tumor cells in the circulation, several studies have focused on cytokeratins and their potential role as tumor-specific markers<sup>[11,12,20,28-32]</sup>. However, conventional cytology, immunohistochemistry and molecular biological approaches reported conflicting results regarding the prevalence of CK-19 positive disseminated tumor cells and the impact on the prognosis of patients<sup>[12,33]</sup>. A reason for this is the target gene expression by non-neoplastic cells. False-positive results caused by illegitimate background transcription of CK-19 as seen in this study pose a major problem for qualitative PCR analysis. Gene transcription of CK-19 in healthy control groups and patients with benign disease has been reported in up to 80% of the analyzed samples<sup>[14,16]</sup>. In order to prevent false-positive results and increase the specificity, samples in this study were analyzed by quantitative RT-PCR. This approach facilitated the definition of cut-off values representing the maximal target gene expression in the control group. Regarding the results of nested-PCR in our study group, the qualitative PCR analysis of CK-19 expression can not be recommended for the detection of disseminated pancreatic cells.

Despite detection rates between 4%-100% using K-ras, CEA and cytokeratins as markers, up to now, tumor cell dissemination in the blood is not identified as an independent prognostic marker in pancreatic cancer<sup>[12,34-39]</sup>. In our sample series, 64% of peripheral blood samples taken from the patients with pancreatic cancer were detected to be CK-19-positive by quantitative fluorogenic RT-PCR. To reflect the dynamics of tumor cell dissemination during surgical intervention, blood samples were analyzed at four different time points showing target gene detection rates significantly higher compared to the control group. As described for K-ras and CEA mRNA, the amount of detectable CK-19 transcripts showed a trend to increase intraoperatively and decrease postoperatively below the preoperative level<sup>[26,36,37]</sup>.

In consistent with Aihara *et al*<sup>[29]</sup>, the CK-19 mRNA expression in the peripheral blood in our study showed higher levels.

Various studies have focused on the detection of disseminated pancreatic tumor cells in the bone marrow. Though positive detection rates have been reported between 24% and 58% for different markers, the tumor cell detection in the bone marrow does not correlate with tumor stage and is not an independent prognostic marker<sup>[11,12,34,35]</sup>. There is only one study by Soeth *et al*<sup>[36]</sup> demonstrating a benefit in survival in patients with CK-20-negative bone marrow aspirates. The data obtained in our study confirm the results of Dimmler *et al*<sup>[14]</sup>, who dissuade from use of CK-19 for analysis of bone marrow due to high levels of illegitimate background expression in healthy controls. In contrast, peritoneal lavage was identified to be suitable to represent the actual state of tumor dissemination. The immunohistochemical analysis of the peritoneal lavage reported detection rates between 20% and 58% for marker-positive pancreatic cells<sup>[34,35,37-39]</sup>. Compared to the analysis by Inoue *et al*<sup>[40]</sup> who reported 10% of K-ras mRNA-positive cells, our detection rate of CK-19 positive cells was 30%. To the best of our knowledge, this sample series is the first report that shows a correlation between the CK-19 mRNA expression in the peritoneal lavage and the tumor size and tumor differentiation. A correlation between positive tumor cell detection and impaired patient survival as reported for cytological analysis by Yachida *et al*<sup>[37]</sup> and Makary *et al*<sup>[41]</sup> could not be detected.

Besides the detection of dissemination of neoplastic cells, the differentiation between malignant and benign pancreatic disease is of major interest for clinicians. Up to now, several markers such as K-ras, p53 and CEA failed as serum marker for a differential diagnosis<sup>[17,42]</sup>. CK 19-9 is the best characterized serum marker but has no absolute specificity. This is the first study that evaluates CK-19 mRNA expression in different compartments for the potential to differentiate between pancreatic cancer and chronic pancreatitis. In our study, the patients with pancreatic cancer showed an unequivocally increased CK-19 expression compared to the patients with chronic pancreatitis. Ten-fold higher expression levels in the peripheral blood as well as in the peritoneal lavage from the pancreatic cancer patients compared to the chronic pancreatitis patients indicated that quantitative fluorogenic RT-PCR is suited for the distinction between malignant and benign pancreatic disease.

In conclusion, our data suggest that CK-19-positive tumor cells can be detected in patients with pancreatic carcinoma in venous blood and peritoneal lavage by using fluorogenic RT-PCR. The prevalence of isolated tumor cells in peritoneal lavage increases significantly with the tumor stage and differentiation. The application of highly sensitive RT-PCR technique may improve the staging of patients and the monitoring of the residual tumor cell burden within the context of adjuvant systemic therapies. For the clinical use, the combination of tumor-specific markers is indispensable to increase the specificity of this test.

## COMMENTS

### Background

Pancreatic cancer is one of the top five causes of cancer death in the Western world. Occult micro-metastases caused by disseminated tumor cells are the most limiting factor for the improvement of mortality rates.

### Research frontiers

Additional to cytology, immunohistochemical analysis is the standard for identification of disseminated tumor cells. Nevertheless, conflicting results regarding the prognostic relevance have been reported. Molecular biological approaches, such as reverse transcriptase polymerase chain reaction (RT-PCR), have a high sensitivity and specificity and might be more suitable for the analysis of disseminated tumor cells.

### Innovations and breakthroughs

Various studies used cytokeratin-19 (CK-19) for pancreatic cell detection that has been identified as a reliable marker for epithelial cell differentiation and is homogenously expressed at high levels in primary pancreatic adenocarcinoma and pancreatic carcinoma metastases. Until now, CK-19 mRNA expression has not been identified as an independent prognostic indicator in pancreatic cancer.

### Applications

Our data suggest that CK-19-positive tumor cells can be detected in patients with pancreatic carcinoma in venous blood and peritoneal lavage by using fluorogenic RT-PCR. The prevalence of isolated tumor cells in peritoneal lavage increases significantly with the tumor stage and differentiation. The application of highly sensitive RT-PCR technique may improve the staging of patients and the monitoring of the residual tumor cell burden within the context of adjuvant systemic therapies. For the clinical use, the combination of tumor-specific markers is indispensable to increase the specificity of this test.

### Peer review

The authors demonstrate that quantification of CK-19 seems to be a reliable marker for the differential diagnosis of ductal pancreatic cancer and for staging. The Material and Methods, Results and Discussion are adequate and the paper provides new information for the investigators in this field.

### Abstract

**AIM:** To comparatively evaluate the long term efficacy of Rifaximin and dietary fibers in reducing symptoms and/or complication frequency in symptomatic, uncomplicated diverticular disease.

**METHODS:** 307 patients (118 males, 189 females, age range: 40-80 years) were enrolled in the study and randomly assigned to: Rifaximin (400 mg bid for 7 d every month) plus dietary fiber supplementation (at least 20 gr/d) or dietary fiber supplementation alone. The study duration was 24 mo; both clinical examination and symptoms' questionnaire were performed every two months.

**RESULTS:** Both treatments reduced symptom frequency, but Rifaximin at a greater extent, when compared to basal values. Symptomatic score declined during both treatments, but a greater reduction was evident in the Rifaximin group ( $6.4 \pm 2.8$  and  $6.2 \pm 2.6$  at enrollment,  $P = \text{NS}$ ,  $1.0 \pm 0.7$  and  $2.4 \pm 1.7$  after 24 mo,  $P < 0.001$ , respectively). Probability of symptom reduction was higher and complication frequency lower (Kaplan-Meier method) in the Rifaximin group ( $P < 0.0001$  and  $0.028$ , respectively).

**CONCLUSION:** In patients with symptomatic, uncomplicated diverticular disease, cyclic administration of Rifaximin plus dietary fiber supplementation is more effective in reducing both symptom and complication frequency than simple dietary fiber supplementation. Long term administration of the poorly absorbed antibiotic Rifaximin is safe and well tolerated by the patients,

### INTRODUCTION

Diverticular disease of the colon represents the most common disease affecting the large bowel in the Western world<sup>[1]</sup>; the disease is more frequent in USA than in Europe and it represents a rare clinical condition in Africa<sup>[2]</sup>. Prevalence of diverticular disease is largely age-dependent and is uncommon, with a rate less than 5%, in subjects under 40 years of age, increasing up to 65% in those aged 65 years or more<sup>[3]</sup>. Diverticular disease and its clinical consequences have recently become increasingly prevalent, paralleling western patterns of living and eating, the ageing population, and economic and industrial development<sup>[4]</sup>. Although a large majority of patients with diverticular disease will remain entirely asymptomatic for their entire life, 20% of them may manifest clinical illness<sup>[4,5]</sup> and a worse quality of life<sup>[6]</sup>. Furthermore, since available data<sup>[2,3]</sup> suggest that the incidence of diverticular disease is increasing and that its prevalence increases with age, the identification of a management strategy for the disease represents an healthy priority. Several guidelines are actually available to manage diverticular disease<sup>[7,8]</sup>; there is a consensus that conservative treatment is indicated in patients with a first attack of uncomplicated diverticulitis, since about 70% of patients treated for a first episode recover and have no further problems<sup>[9]</sup>. However, a 60% risk of developing complications has been reported in patients with recurrent attacks<sup>[2]</sup>. Conservative treatment is aimed at the relief of symptoms and at preventing

major complications<sup>[8,9]</sup>. Available evidence<sup>[10]</sup> suggests that antibiotics, and namely topical antibiotics, and dietary fibers represent useful treatments for uncomplicated diverticular disease and for preventing disease complications. Different antibiotics have been tested, but the possibility of side effect development due to their long-term use have discouraged their employment<sup>[10]</sup>.

Rifaximin is a rifamycin analogue with a broad spectrum of activity similar to that of rifampicin and it is poorly absorbed in the gastrointestinal tract<sup>[11]</sup>, thus conferring to this drug a high safety profile. Due to these properties, Rifaximin has been tested in different gastrointestinal diseases, and in diverticular disease too<sup>[12,13]</sup>. Two randomized clinical trials<sup>[14,15]</sup> performed in patients with uncomplicated diverticular disease showed that Rifaximin plus dietary fiber supplementation was more effective in improving symptoms than dietary fibre supplementation alone after 12 mo of treatment.

Since the uncertainties regarding the natural history of the disease, and in particular the predictors for the progression from uncomplicated to complicated disease, and the lack of a definite indication for long term management of uncomplicated disease, data on long-term treatment with topical antibiotics and dietary fibers would be necessary.

Therefore, the aim of the present study was to evaluate the long-term efficacy of cyclic administration of Rifaximin plus fiber supplementation versus fiber supplementation alone on symptoms and clinical manifestations in patients with symptomatic, but uncomplicated, diverticular disease.

## MATERIALS AND METHODS

### Study design

This was a multicenter, open, prospective, randomized, controlled study. Patients were randomly assigned to one of the two treatment regimens: one group received Rifaximin (400 mg bid for 7 d every month) plus dietary fiber supplementation (at least 20 gr/d) (Rifaximin group) and the other group simple dietary fiber supplementation (at least 20 gr/d) (fiber group). The study duration was 24 mo.

Patients were consecutively assigned to one group or to the other by a computer-generated randomization scheme. Informed consent was obtained from each patient and the study protocol was approved by the local Ethics Committee.

### Patients

Consecutive patients with symptomatic, uncomplicated diverticular disease were enrolled. Inclusion criteria for the study were: age between 40 and 80 years, endoscopic or radiological evidence of diverticular disease of the sigmoid and/or descending colon, presence of symptoms attributable to the diverticular disease of the colon such as lower abdominal pain/discomfort, bloating, tenesmus, diarrhea and abdominal tenderness. Patients who referred the continuous presence of three, or more, of these symptoms for at least 1 mo before the enrolment entered in the study.

Exclusion criteria were represented by the presence of a solitary diverticulum of the right colon, signs of

complicated diverticular disease, previous colonic surgery, neoplastic or haematological diseases, immunodeficiency, pregnancy and questionable ability to cooperate. Patients who assumed antibiotics in the previous 4 wk were also excluded.

### Clinical evaluation

At enrolment and every 2 mo until the 24 mo patients underwent clinical examination; a questionnaire inquiring about the presence and severity of abdominal symptoms was also performed. Five clinical variables (lower abdominal pain/discomfort, bloating, tenesmus, diarrhea and abdominal tenderness) were graded according to the following scale: 0 = no symptoms; 1 = mild symptoms, easily tolerated; 2 = moderate symptoms, sufficient to cause interference with normal daily activities; 3 = severe, incapacitating symptoms, with inability to perform normal daily activities. Consequently the global score could range from 0 (absence of symptoms) to 15 (presence of all symptoms with the higher degree of severity).

Biochemical tests were performed at enrolment, and after 12 and 24 mo of treatment.

### Statistical methods

On the presumption of a 40% reduction at 24 mo in the frequency of symptoms with dietary fiber and a 65% reduction with Rifaximin plus fiber treatment, and considering the delta between the frequencies to be either equal to or at least 25%, a two-tail significance test, a significance level of  $\alpha = 0.05$ , a 99% power and a 3:2 allocation ratio (in order to better satisfy the secondary end-point), the number of patients to be enrolled was 177 patients for the Rifaximin group and 110 for the fibers group. Presuming a 10% of drop-out, it was necessary to enrol 307 patients (185 for the active group and 122 for the control group)<sup>[16]</sup>.

$\chi^2$  test or Fisher's exact test were used to compare the distribution of categorical or absolute variables within the studied groups. Parametric tests (Levene's test, *t* test, one- and two-way analysis of variance and repeated-measure ANOVA) were used to analyze continuous parameters. Non-parametric tests, one-way analysis of variance (Friedman's test) and Wilcoxon test were applied to analyze the same parameters in subgroups of patients in whom a distribution normality of character being studied could not be presumed<sup>[17]</sup>.

Kaplan Meier curves were used to estimate the probability of a reduction in symptom score and of complication development in the two groups of patients; differences between the two branches were evaluated by means of Log-rank test. Results were expressed as mean  $\pm$  SD and a *P* value less than 0.05 was considered as statistically significant. Data analysis was performed using SPSS version 13.0.

## RESULTS

### Patients

Three-hundred and seven (307) patients were enrolled, 118 males and 189 females.

Table 1 shows demographic and clinical characteristics

**Table 1** Demographic and clinical characteristics of study patients

	Rifaximin plus fibers ( <i>n</i> = 184)	Fibers ( <i>n</i> = 123)	<i>P</i>

Diarrhoea	35.9%	32.5%	<sup>1</sup> NS
Abdominal tenderness	71.2%	69.1%	<sup>1</sup> NS
Symptoms score	6.4 ± 2.8	6.2 ± 2.6	<sup>1</sup> NS

<sup>1</sup> $\chi^2$  test with continuity correction; <sup>2</sup>*t* test; <sup>3</sup> $\chi^2$  test.

of the enrolled patients: no difference was found between the two groups of patients in terms of gender, age and colonic distribution of the disease as well as frequency of abdominal symptoms and global symptom score. Diagnosis of diverticular disease was performed by colonoscopy in 46.2% of patients treated with Rifaximin and in 53.7% of patients treated with fibers, and by barium enema in 60.9% and 48.8% of patients, respectively (*P* = NS). Again, no difference was present at baseline between the two groups of treatment as far as biochemical parameters are concerned (Table 2).

Fourty-eight (48) patients did not complete the study, 25 patients of the Rifaximin group and 23 patients of the fibers group; 28 patients (17 of the Rifaximin group and 11 of the fibers group, *P* = NS, Fisher's exact test) were drop-outs: in the Rifaximin group 14 patients refused to continue the study, 2 patients died for cardiovascular disease and 1 patient for causes unrelated to diverticular disease, while in the fibers group 10 patients refused to continue the study and 1 patient underwent surgery for gallstone disease. Side effects (mainly represented by nausea, headache and weakness) occurred in 4 patients of the Rifaximin group and in 3 patients of the fibers group (*P* = NS). Frequency of complications was significantly different (*P* = 0.041) between the two groups: in fact complications occurred in 4 patients of the Rifaximin group (2 cases of rectal bleeding, and 2 of diverticulitis) and in 9 of the fiber group (4 cases of intestinal infections, 1 of rectal bleeding and 4 of diverticulitis).

The effect of treatments on clinical signs and symptoms is illustrated in Table 3: both treatments induced a significant reduction in symptom frequency in all patients after 12 mo. After 24 mo of treatment, Rifaximin was able to further reduce symptoms as lower abdominal pain, bloating, tenesmus and abdominal tenderness while no difference was observed in patients treated with fibers alone

<sup>1</sup> $\chi^2$  test; <sup>2</sup>Fisher's Exact test.

between the results observed at the 12<sup>th</sup> and the 24<sup>th</sup> mo.

The effect of treatments on the symptomatic score is shown in Figure 1: although both treatments were able to significantly reduce the symptom score, this result was differently reached: at baseline the symptom score was similar, while at the end of the study period a significant difference (*P* < 0.01) was present between the Rifaximin treated group and the fiber group (1.0 ± 0.7 and 2.4 ± 1.7, respectively).

The clinical effect of the two treatments evaluated according to the Kaplan-Meier method is shown in Figure 2: the probability of symptom remission in symptomatic patients was significantly higher (*P* < 0.0001) in the Rifaximin group than in the control group. Although the overall clinical efficacy of the two regimens is different, a similar behaviour can be observed: the cumulative survival progressively declined during the first 12 mo of treatment, remaining constant during the following 12 mo. Rifaximin treatment was also able to induce a lower frequency of recurrence of symptoms: six (3.2%) Rifaximin treated patients had a further episode of abdominal symptoms, while in the fibers group the corresponding figure was three (9.6%) patients (*P* < 0.03).

No significant alterations in biochemical tests were observed in the two groups of patients (Table 4). The probability of developing complications during the study in the two groups of patients evaluated according to the

*t* test for paired data, corrected for multiple comparison.

**Figure 1** Changes in symptoms score after Rifaximin plus fiber supplementation and fiber supplementation alone (mean ± SD). *t* test for independent samples corrected for multiple comparison: <sup>a</sup>*P* < 0.05; <sup>b</sup>*P* < 0.01; <sup>d</sup>*P* < 0.001.

**Figure 2** Probability of symptom reduction in patients treated with Rifaximin plus fibers or with fiber supplementation alone. Kaplan-Meier method: Test Log Rank: *P* < 0.0001.

Kaplan-Meier method is illustrated in Figure 3: as observed for symptoms, Rifaximin administration documented a more favourable effect, being significantly lower (*P* < 0.028) the probability of developing complications with respect to fiber supplementation. Although with a different rate of probability, both treatments induced a progressively reduced frequency of complications during the whole study period.

## DISCUSSION

The present study suggest that the cyclic, long term administration of the non-absorbable antibiotic Rifaximin associated with dietary fiber supplementation is more effective than dietary fiber supplementation alone in reducing the clinical manifestations of patients with symptomatic, uncomplicated diverticular disease. Furthermore, Rifaximin treatment is more effective than fiber administration influencing the clinical course of the disease, since both probability of symptom recurrence and development of disease complications are significantly reduced.

Diverticular disease of the colon is common in developed countries and its prevalence is correlated

with advancing age<sup>[1-4]</sup>. Studies on the natural history of the disease<sup>[3,5,9]</sup> have indicated that most patients with colonic diverticula remain entirely asymptomatic for their lifetime. Actually there are no definitive data to support any therapeutic recommendation, or routine follow-up regimen, for asymptomatic subjects, although it is reasonable to recommend a life-style characterized by regular physical activity and a diet high in fruit and vegetable fibers<sup>[18]</sup>. According to available guidelines<sup>[7,8]</sup> in symptomatic, but uncomplicated, diverticular disease treatment is aimed at symptom-relief and at prevention of complications (diverticulitis, hemorrhage). Different agents have been proposed, such as bulking agents, antispasmodics, topical antibiotics, on the basis of different potential pathophysiological mechanism/s, i.e. abnormal colonic motility, inadequate intake of dietary fibers, intestinal bacterial overgrowth and mucosal inflammation<sup>[10,19-23]</sup>.

The efficacy of fiber supplementation in the treatment of symptomatic diverticular disease remains controversial, although it is considered a mainstay for treatment<sup>[10]</sup>. The efficacy of dietary fibers in reducing symptoms and in improving intestinal function is probably related to its ability to hold water, to increase luminal intestinal mass,

to relax the intestinal wall and to lower the intraluminal pressure<sup>[24,25]</sup>.

Antibiotics are routinely used in the treatment of inflammatory complications of diverticular disease. In symptomatic, but uncomplicated diverticular disease, the use of antibiotics seems without a rationale. However, recent studies have suggested the presence, at least in a sub-group of patients, of an intestinal bacterial overgrowth<sup>[21]</sup>, a condition that may allow an excessive production of bowel gas with secondary development of abdominal pain, bloating and tenderness. Furthermore, intestinal bacterial overgrowth may contribute to maintain a chronic, low-grade mucosal inflammation, as suggested in irritable bowel syndrome<sup>[26]</sup>, which could be responsible for symptom development<sup>[19]</sup>.

Rifaximin has been tested in both uncontrolled<sup>[12,13]</sup> and controlled<sup>[14,15]</sup> clinical studies to treat symptomatic, uncomplicated diverticular disease, with encouraging results.

The mechanism by which Rifaximin improves symptoms in uncomplicated diverticular disease is unclear. It has been suggested a synergistic effect of Rifaximin and high fiber diet in reducing proliferation of gut microflora, with a consequent decrease in bacterial hydrogen and methane production and/or in expanding faecal mass, due to a decrease in bacterial degradation of fibers<sup>[15,27]</sup>.

Furthermore, Rifaximin may improve symptoms and lower the frequency of disease complications reducing intestinal bacterial overgrowth<sup>[19,21]</sup>. Rifaximin may also enhance faecal bulking and faecal weight, as shown for other antibiotics<sup>[28]</sup>, and decrease the intraluminal colonic pressure, one of the pathogenetic mechanisms for diverticula development<sup>[20]</sup>. Due to the therapeutic uncertainties of both Rifaximin and fiber supplementation, in the present study we decided to comparatively evaluate these two agents. The results we obtained confirm and extend to a longer period previous observations by Papi *et al*<sup>[14]</sup> and Latella *et al*<sup>[15]</sup>, who found that administration for 12 mo of Rifaximin plus dietary fiber supplementation was more effective in improving symptoms than dietary fibre supplementation alone. The present study documents that the efficacy of Rifaximin plus fiber supplementation is not only maintained, but it is more evident after 24 mo of treatment than fibers alone. According to the probability curves, the beneficial clinical effect of Rifaximin treatment is more pronounced during the first 12 mo, but it may last up to 24 mo. This observation is important, since it suggests a positive effect of Rifaximin treatment on the natural history of diverticular disease. Up to now, no definitive data are available regarding the way to prevent the development/maintenance of disease symptoms and complications. As far as the last point is concerned, the present study indicates that Rifaximin treatment significantly reduces the probability of complication development and that this effect is constant during the whole study period.

In conclusion the present study documents that in patients with symptomatic, uncomplicated diverticular disease, cyclic administration of Rifaximin plus fiber supplementation is more effective in reducing symptom persistence/recurrence and complication development

**Figure 3** Probability of complication development in patients treated with Rifaximin plus fibers or with fibers supplementation alone. Kaplan-Meier method. Test Log Rank:  $P = 0.028$ .

than dietary fiber alone. Cyclic, long term administration of this non-absorbable antibiotic is safe and well tolerated by the patients, confirming the clinical usefulness of this therapeutic strategy in the overall management of diverticular disease. Further studies are needed to better identify the mechanism/s of action of both Rifaximin and of its association with dietary fibers.

### Abstract

**AIM:** To investigate the proximal gastric motor response to duodenal nutrients in critically ill patients with long-standing type 2 diabetes mellitus.

**METHODS:** Proximal gastric motility was assessed (using a barostat) in 10 critically ill patients with type 2 diabetes mellitus ( $59 \pm 3$  years) during two 60-min duodenal infusions of Ensure® (1 and 2 kcal/min), in random order, separated by 2 h fasting. Data were compared with 15 non-diabetic critically ill patients ( $48 \pm 5$  years) and 10 healthy volunteers ( $28 \pm 3$  years).

**RESULTS:** Baseline proximal gastric volumes were similar between the three groups. In diabetic patients, proximal gastric relaxation during 1 kcal/min nutrient infusion was similar to non-diabetic patients and healthy controls. In contrast, relaxation during 2 kcal/min infusion was initially reduced in diabetic patients ( $P < 0.05$ ) but increased to a level similar to healthy humans, unlike non-diabetic patients where relaxation was impaired throughout the infusion. Duodenal nutrient stimulation reduced the fundic wave frequency in a dose-dependent fashion in both the critically ill diabetic patients and healthy subjects, but not in critically ill patients without diabetes. Fundic wave frequency in diabetic patients and healthy subjects was greater than in non-diabetic patients.

**CONCLUSION:** In patients with diabetes mellitus, proximal gastric motility is less disturbed than non-diabetic patients during critical illness, suggesting that these patients may not be at greater risk of delayed gastric emptying.

### INTRODUCTION

In the community, approximately 50% of patients with type 1 or 2 diabetes mellitus (DM) have gastroparesis<sup>[1]</sup>. Although gastric emptying of either a solid or semi-solid meal is consistently slow in these patients, gastric emptying of liquid meals is variable<sup>[1-4]</sup>. The aetiology of slow gastric emptying and the variable rate of liquid emptying are unclear, but may be related to hyperglycemia or autonomic neuropathy<sup>[1,5-7]</sup>, factors that result in motor dysfunction of both the proximal and distal stomach<sup>[1,7,8]</sup>.

Delayed gastric emptying is also common in critically ill patients<sup>[9-11]</sup> and is associated with disturbed motility of both the proximal and distal stomach<sup>[10,12,13]</sup>. In health, the proximal stomach is a major determinant of liquid gastric emptying and is regulated by feedback from the small intestine. In health, the fundus relaxes in response to the presence of nutrient in the duodenum<sup>[14]</sup>. Critically ill patients without DM have been reported to have impaired proximal gastric relaxation, reduced fundic wave activity and a failed recovery of proximal gastric volume to pre-stimulation level<sup>[12]</sup>. Currently, there are no data on the impact of DM on gastric motor function or emptying during critical illness, despite the fact that one-third of patients admitted to critical care units have DM<sup>[15]</sup>. Given that both DM and critical illness are risk factors for disturbed gastric motility, we hypothesized that critically ill patients with DM would have abnormal proximal gastric motor activity during fasting and in response to duodenal nutrient infusion, compared to non-diabetic critically ill patients and healthy humans.

### MATERIALS AND METHODS

#### Subjects

Studies were performed in 25 sedated and mechanically ventilated critically ill patients, who were admitted to a level-3 mixed intensive care unit between January and September 2004. All patients required enteral nutrition. Ten

patients had documented type 2 DM with a mean duration of  $7.9 \pm 1.8$  years. Seven of the diabetic patients had required insulin therapy prior to ICU admission. Formal testing for the presence of autonomic neuropathy was not performed. Fifteen critically ill patients without diabetes mellitus served as patient controls. Exclusion criteria for all patients were (1) recent major abdominal surgery, (2) any contra-indication to passage of an enteral tube, (3) administration of opioid analgesia, benzodiazepines or prokinetic therapy within the previous 24 h, and (4) previous gastric, oesophageal or intestinal surgery. All patients received an insulin infusion for blood glucose control according to a standardized protocol that started on admission and aimed to maintain blood glucose concentrations between 5.0 and 7.9 mmol/L. Data from both patient groups were compared to 10 healthy volunteers, who had no history of systemic or gastrointestinal disease and were not taking any medication. Healthy volunteers were instructed to refrain from smoking for 24 h prior to the study.

Written informed consent was obtained from healthy subjects and the next of kin of patients prior to enrolment into the study. The protocol was approved by the Human Research Ethics Committee of the Royal Adelaide Hospital.

### Measurement of proximal gastric motility

Proximal gastric motility was measured using an electronic gastric barostat<sup>[16]</sup> (Distender Series II; G&J Electronics, Ontario, Canada). A thin flaccid-walled bag with a maximum capacity of 1000 mL was attached to the distal end of the assembly, which was connected to the system *via* pressure and volume ports. Changes in proximal gastric volume were measured indirectly by changes in the volume of the polyethylene bag.

Data were stored onto a Powermac 7100 computer (Apple Computer, Cupertino, CA), using custom-written data-acquisition software (Labview: National Instruments, Austin, TX). This software was also used to program the barostat to perform distensions in stepwise increments. Recorded data were imported into a display and analysis program (Acqknowledge, Biopac System, Goleta, CA) for manual analysis.

### Blood glucose concentrations

Marked hyperglycaemia may alter small intestinal feedback and adversely affect gastric motility<sup>[5-7]</sup>. Blood glucose concentrations were measured using a portable glucometer (Precision Plus, Abbott Laboratories, Bedford, USA) immediately before and every 20 min during nutrient infusion.

### Protocol

All subjects were studied after at least 6 h fasting and in a 30 degree recumbent position. To standardise the sedative regimen in patients, propofol alone was used, and opioids, benzodiazepines or prokinetic agents were not administered for 24 h prior to and during the study. In patients, placement of both the barostat catheter and post-pyloric feeding tube were performed at the bedside with endoscopic assistance, without additional sedation to that required for ventilation. A 12 French  $\times$  114 cm naso-duo-

denal feeding tube (Flexiflo, Abbott, Ireland) was inserted into the duodenum over a guidewire (THSF-35-260, Cook, Australia). The barostat catheter was then guided through the mouth into the stomach by the endoscope. The barostat bag was inflated with 400 mL of air and gently retracted into the fundus under direct vision. Gastric contents (air and fluid) were aspirated completely prior to withdrawal of the endoscope. Correct placement of the feeding tube was confirmed by measurement of the duodenal trans-mucosal potential difference (TMPD)<sup>[16]</sup> and subsequently by radiography<sup>[13]</sup>.

In healthy subjects, the barostat assembly and feeding tube were swallowed and allowed to pass into the correct position spontaneously, without the assistance of endoscopy. Duodenal nutrient infusion was achieved by inserting a silicon-rubber catheter (Dentsleeve, Adelaide, Australia) with a central feeding lumen and lead-weighted tip into the stomach. The tube passed spontaneously into the duodenum using phase 2 and 3 of the migrating motor complex. Movement of the catheter into the correct position was monitored continuously by measurement of the antro-duodenal TMPD gradient<sup>[16]</sup>. Radiological confirmation was not performed in healthy subjects. The barostat catheter was then inserted to a depth of 55 cm, the bag inflated with 400 mL of air and the assembly pulled back until resistance was felt<sup>[17]</sup>.

Following confirmation that both assemblies were positioned correctly, air in the barostat bag was aspirated manually and the catheter was connected to the barostat pump. The minimum distending pressure (MDP), defined as the first pressure level that provided an intragastric bag volume of more than 30 mL, was determined<sup>[17]</sup>. The intrabag pressure for the study was set at  $MDP + 2 \text{ mmHg}$ <sup>[17]</sup>. All studies began with a 15-min baseline recording, during which normal saline (0.9% NaCl) was infused into the duodenum at a rate of 240 mL/h (baseline 1). Each subject then received two 60 minute duodenal infusions of Ensure<sup>®</sup> (Abbott Laboratories, Ohio, USA; nutrient content: 13% protein, 64% carbohydrate, 21% fat; energy density: 1 kcal/mL) at 1 and 2 kcal/min, in a randomised order. Ensure<sup>®</sup> was diluted with normal saline to 1:4 for the 1 kcal/min infusion and to 1:2 for 2 kcal/min infusion, and infused at a rate of 240 mL/h. The nutrient infusions were separated by a 2 h 'washout period', consisting of 90 min of no infusion, followed by 30 min of intraduodenal saline infusion (baseline 2). Blood samples for the measurement of blood glucose concentration were collected at baseline and every 20 min during nutrient infusion. Barostat recordings were performed continuously over 4 h. The study protocol is outlined in Figure 1.

### Data analysis

Intra-bag volumes were determined at 2-min intervals and the mean baseline volume was measured over 10 min before each infusion. Changes in intra-bag volume during nutrient infusion were calculated as the difference between the actual volume and the mean baseline volume. The serial changes in bag volume during the infusions were plotted and compared. Proximal gastric relaxation was indirectly inferred by an increase in bag volume<sup>[17]</sup>. The time course for the proximal stomach to return to baseline volume af-

**Figure 1** Schematic outline of study protocol.

ter nutrient stimulation was assessed by analysis of the 2 h “no-infusion” period; and was defined as the time taken for the relaxed fundus to return to pre-stimulation level for  $> 5$  min. Assessment of fundic slow volume waves (FW) was also performed. These were defined as changes in proximal gastric volume of greater than 30 mL that reverted in less than 2 min to a volume within 50% of the previous level<sup>[17]</sup>. The number and amplitude of FWs (per 10 min) was determined during fasting and in response to duodenal nutrient infusion.

### Statistical analysis

Data are expressed as mean  $\pm$  SE. Differences in demographic characteristics, baseline volumes, MDP, FW frequency, peak volume response and the time required for the proximal stomach to return to baseline volume, were compared between the three groups using Student's unpaired *t*-test. ANOVA was used to compare the proximal gastric volume, fundic wave and blood glucose responses to nutrient infusion between the groups, with time and treatment as the factors. A *P* value  $< 0.05$  was considered statistically significant.

## RESULTS

Oral intubation of the assembly was tolerated well by all subjects and no complications occurred in any group. Demographic characteristics of the study groups are summarized in Table 1. The MDP was higher in both patient groups compared to healthy subjects ( $P < 0.05$ ), but was similar between diabetic and non-diabetic patients (Table 2). Baseline proximal gastric volumes were similar between the three groups.

### Proximal gastric volume response to duodenal nutrients

In response to duodenal nutrients, healthy volunteers demonstrated a “biphasic” proximal gastric volume response. Following an initial rapid relaxation, the fundus partially contracted and then exhibited a sustained relaxation throughout the remainder of the infusion (Figure 2). In non-diabetic critically ill patients, there was an overall impairment of both the initial and later phase of the response. In diabetic patients, however, there was an absence of the initial response in the first 20 min during both 1 and 2 kcal/min infusions. Thereafter, the proximal gastric volume increased to the level observed in healthy volunteers.

During the 1 kcal/min infusion there was no difference in the proximal gastric volume response between diabetic critically ill patients and the other two groups. However, during the first 20 min of the 2 kcal/min infusion, the

<sup>a</sup>*P*  $< 0.05$  vs healthy subjects; <sup>c</sup>*P*  $< 0.05$  vs diabetic patients and healthy subjects.

proximal gastric volume was significantly smaller in diabetic critically ill patients than in non-diabetic critically ill patients and healthy subjects. Thereafter, the proximal gastric volume of diabetic patients was greater than that of non-diabetic patients and similar to healthy subjects (Figure 2).

### Recovery of proximal gastric volume after nutrient stimulation

The proximal gastric volume returned to baseline level within 60 min following cessation of nutrient stimulation in all diabetic patients and healthy subjects, but in only 2 of the 15 non-diabetic patients. In diabetic patients, the time taken for the proximal gastric volume to return to baseline level was significantly shorter than in non-diabetic patients and longer than healthy subjects (Table 2).

### Fundic volume wave frequency

At baseline, the mean frequency of FWs in diabetic patients (10.2  $\pm$  1.7 waves/10 min) was similar to that of healthy subjects (11.8  $\pm$  0.9 waves/10 min; *P* = 0.38), but was higher than non-diabetic patients (7.0  $\pm$  0.8 waves/10 min; *P*  $< 0.05$ ; Figure 3).

**Figure 2** Changes in proximal gastric volume during duodenal nutrient stimulation (1 and 2 kcal/min) in critically ill patients and healthy subjects. <sup>a</sup> $P < 0.05$ , ICU patients vs healthy subjects during 0–30 min; <sup>c</sup> $P < 0.05$ , non-DM patients vs diabetic patients and healthy subjects during 30–60 min.

**Figure 3** Frequency of fundic slow wave contractions at baseline and during duodenal nutrient infusion (1 and 2 kcal/min) in critically ill patients and healthy subjects. <sup>a</sup> $P < 0.05$  vs healthy subjects and diabetic patients at baseline; <sup>c</sup> $P < 0.05$  vs healthy subjects and diabetic patients during 1 kcal infusion; <sup>e</sup> $P < 0.05$  vs healthy subjects during 2 kcal infusion.

The impact of duodenal nutrient stimulation on the frequency of FWs in diabetic patients was similar to that of healthy subjects but differed from non-diabetic patients (Figure 3). Nutrient stimulation with 1 kcal/min infusion did not reduce the mean frequency of FWs in either diabetic patients ( $9.0 \pm 2.0$  waves/10 min) or healthy subjects ( $9.9 \pm 1.0$  waves/10 min), in contrast to non-diabetic patients ( $4.4 \pm 0.9$  waves/10 min;  $P < 0.05$ ). However, in all 3 groups the 2 kcal/min nutrient infusion significantly reduced the mean frequency of FWs compared to baseline (diabetic:  $3.9 \pm 1.1$  waves/10 min,  $P < 0.05$ ; healthy:  $7.6 \pm 0.8$  waves/10 min,  $P < 0.001$ ; non-diabetic:  $4.2 \pm 0.9$  waves/10 min,  $P < 0.05$ ). The magnitude of reduction in FW frequency during 2 kcal/min was greatest in diabetic patients ( $-6.6 \pm 1.7$  waves/10 min), compared to healthy subjects ( $-4.0 \pm 0.7$  waves/10 min,  $P < 0.05$ ) and non-diabetic patients ( $-1.9 \pm 0.6$ ,  $P < 0.001$ ; Figure 3).

Overall, the frequency of FWs in diabetic patients during 1 kcal/min infusion was similar to that of healthy subjects, but was higher than non-diabetic patients. In contrast, due to the greater magnitude of reduction in FW frequency by a higher nutrient load, fundic wave activity during 2 kcal/min infusion in diabetic patients was similar to that of non-diabetic patients, but less than that of healthy subjects (Figure 3).

### Blood glucose concentrations

Overall, both fasting and nutrient-stimulated blood glucose

concentrations were higher in critically ill patients than in healthy subjects (Figure 4). There were no significant differences in blood glucose concentrations between diabetic and non-diabetic patients, reflecting the use of an insulin infusion protocol in all patients.

## DISCUSSION

This is the first study to examine proximal gastric motor activity in critically ill patients with type 2 diabetes mellitus. The results show that the response to intestinal nutrient feedback is characterized by an initial absence of proximal gastric relaxation, after which the volume increased to a level similar to that seen in healthy volunteers. Furthermore, the delayed volume response was associated with a nutrient load-dependent reduction in fundic wave activity and a slightly impaired recovery of the proximal gastric volume to baseline level. This is in contrast to non-diabetic critically ill patients, who demonstrated a sustained impairment of proximal gastric relaxation, a reduction in fundic wave activity even during 1 kcal/min infusion and a failure of the fundus to recover to baseline volume. These findings support a recent retrospective study, which suggested that type 2 diabetes mellitus may not be a risk factor for delayed gastric emptying in critical illness<sup>[18]</sup>.

A notable feature of the proximal gastric response to nutrient stimulation in diabetic patients was the complete absence of proximal gastric relaxation during the first 20 min of nutrient infusion, however the reason for this re-

**Figure 4** Blood glucose concentration at baseline and during nutrient infusion in critically ill patients and healthy subjects. <sup>a</sup> $P < 0.05$  vs critically ill patients at baseline; <sup>c</sup> $P < 0.05$  vs critically ill patients during nutrient infusion.

sponse remains unclear. In health, gastro-enteric feedback is regulated by neuro-hormonal pathways<sup>[14,16-19]</sup>, and proximal gastric tone is modulated by a balance between the excitatory cholinergic nerves and the inhibitory nitrergic neural inputs from the vagus<sup>[20]</sup>. As autonomic dysfunction is common in patients with diabetic autonomic neuropathy<sup>[8]</sup> and during critical illness<sup>[21]</sup> the greater degree of impaired relaxation in our diabetic patients may relate to an adverse 'additive-effect' of both factors on the autonomic nervous system<sup>[20-22]</sup>. Formal testing for autonomic neuropathy was not performed in the current study as this was not feasible in the acute critical care setting. A prevalence of autonomic neuropathy of more than 50% would be expected, based on a previous study in diabetic patients with a similar mean duration of disease<sup>[23]</sup>. Furthermore, disturbances in the metabolism of nitric oxide, a key transmitter in the regulation of gastrointestinal motor function, may also be important<sup>[22]</sup>. Impaired proximal gastric relaxation is associated with altered levels of nitric oxide<sup>[1,8]</sup>, and has been reported in both patients with diabetes mellitus<sup>[1]</sup> and critical illness<sup>[24]</sup>. Whilst increased cytokine production<sup>[25]</sup> and drug usage<sup>[26]</sup> can also contribute to impaired relaxation, the impact of these factors are likely to be similar between diabetic and non-DM critically ill patients and probably do not account for the differences in gastric motility seen between the groups.

Following the initial impairment of relaxation, the proximal gastric volume in diabetic critically ill patients increased to a level comparable to that of healthy subjects. This finding has not been previously reported in either patients with critical illness or diabetes mellitus alone. In the later, proximal gastric motor responses to gastric but not duodenal nutrients have been evaluated and further studies to assess this may provide useful information. The mechanisms underlying this normalization of proximal gastric motility are unknown. Despite the use of a standardized insulin protocol in all patients during the study, a small degree of hyperglycaemia occurred in diabetic patients during the latter half of the 2 kcal/min infusion (Figure 4). Although hyperglycaemia has been shown to induce proximal gastric relaxation<sup>[7]</sup>, the absolute increase in blood glucose level was small and therefore unlikely to have contributed significantly to the subsequent response. The diabetic patients had a higher BMI than the healthy volunteers, however no differences in either proximal gastric volume

or compliance have been reported between obese and lean subjects<sup>[27,28]</sup>. Thus, a higher BMI in diabetic patients seems unlikely to have contributed to the differences in proximal gastric motility. Opiate drugs such as morphine were excluded 24 h prior to the study, hence are unlikely to explain our findings<sup>[29]</sup>.

To standardize the nutrient stimulation and enable a reliable assessment of the entero-gastric feedback response, feeds were delivered directly into the duodenum at a rate consistent with normal gastric emptying. Intra-gastric delivery of nutrients was not used in the current study because gastric emptying is frequently impaired in the critically ill. Furthermore, both gastric motility and emptying of a liquid meal may be altered by the presence of a barostat balloon<sup>[30]</sup>. In addition, intra-duodenal nutrient stimulation with 1 and 2 kcal/min nutrient loads enabled examination of the dose-dependency of the proximal gastric motor response<sup>[16,17,19]</sup>.

Previous studies in critically ill patients have suggested enhanced entero-gastric feedback in response to duodenal nutrient stimulation<sup>[12]</sup>. In contrast to the non-diabetic patients, diabetic critically ill patients had a dose-dependent reduction in fundic wave activity, similar to the healthy subjects. The different responses in fundic wave activity during the 1 and 2 kcal/min nutrient loads between the diabetic and non-diabetic patients suggest that entero-gastric feedback is not increased in diabetic patients. Furthermore, apart from an initial delay in relaxation, the overall proximal gastric motor responses to nutrients in diabetic critically ill patients were similar to those of healthy subjects. As the proximal stomach is a major determinant of liquid gastric emptying<sup>[16,17,19]</sup>, these findings may explain the relatively normal gastric emptying observed in this group of patients<sup>[14]</sup>.

Whether differences in the 'accommodative' response to nutrients between the two patient groups affect their ability to tolerate bolus or continuous gastric feeds remains to be determined and requires further study. It is conceivable that slow continuous feeds may be better tolerated in non-diabetic critically ill patients as proximal gastric relaxation is small and slow during nutrient stimulation<sup>[9,11]</sup>. In contrast, the relatively normal 'biphasic' proximal gastric response in the diabetic critically ill patients may allow better tolerance to bolus gastric feeds.

In conclusion, proximal gastric motor responses to

duodenal nutrient are relatively normal in type 2 diabetic patients during critical illness. These motor findings support data which suggests these patients may have normal gastric emptying<sup>[18]</sup> and may be less prone to developing naso-gastric feed intolerance than non-diabetic, critically ill patients.

### Abstract

**AIM:** To determine the role of ciprofloxacin in reducing cholangitis in cholestatic patients with adequate biliary drainage after endoscopic retrograde cholangiopancreatography (ERCP).

**METHODS:** A randomized, controlled trial was performed in 48 cholestatic patients at Rajavithi Hospital (Tertiary Referral Center for ERCP: 600 cases per year). All the 48 patients received 200 mg ciprofloxacin intravenous injection for 30 min before starting any procedures, and then were randomly divided in two groups. Twenty-two patients in study group continually received ciprofloxacin until 48 h after ERCP. Causes of biliary obstruction, bacteriology of bile and blood (in cholangitis) and clinical cholangitis were recorded.

**RESULTS:** Forty-eight patients were enrolled and divided into continuous ciprofloxacin treatment group ( $n = 22$ ) and discontinuous ciprofloxacin treatment group ( $n = 26$ ). During ERCP, stones were found in 22 patients, malignant diseases in 24 patients and other pathologic lesions in 5 patients. One (4.5%) of the 22 patients who received ciprofloxacin and 2 (6.3%) of the 26 patients who discontinued ciprofloxacin after ERCP developed cholangitis (relative risk = 0.71; 95% CI = 0.14-3.65;  $P = 0.88$ ). Bacterobilia was found in 27 (56.3%) out of 48 patients. *E. coli* and *Streptococcus viridans* were the most common organisms.

**CONCLUSION:** Continual use of ciprofloxacin in patients with cholestasis after adequate biliary drainage procedures plays no role in reducing cholangitis.

### INTRODUCTION

Endoscopic retrograde cholangiopancreatography (ERCP) is widely used in diagnosis and treatment of biliary and pancreatic diseases<sup>[1,2]</sup>. Acute cholangitis and septicemia remain serious complications related to this technique<sup>[3]</sup>. The incidence of cholangitis is 0.8%-19%, and its mortality rate is 10%<sup>[4]</sup>.

The role of prophylactic antibiotics after ERCP has been recently assessed in several placebo-controlled randomized trials<sup>[5-9]</sup>. This procedure plays an essential part in high risk patients with prosthetic valve and history of endocarditis, obstructed bile duct, pancreatic cystic lesion and inadequate common bile duct drainage<sup>[3,10]</sup>. To date, no antibiotic regimen has emerged. Most of the bacterial flora in bile of patients with cholangitis and asymptomatic bacterobilia are Gram-negative organisms such as *E. coli*, *Klebsella spp.* and Gram-positive organisms such as *Enterococcus faecalis*<sup>[5-6,11-13]</sup>. The choice of an antibiotic regimen should be able to cover the Gram-negative bacteria and effectively penetrates the obstructed biliary tree. Ciprofloxacin attains a concentration in bile of approximately 20% of the mean peak level in serum, even in an obstructed biliary system. This drug level is still 10 times higher than MIC of the Gram-negative bacteria and is the most effective antibiotic against the Gram-negative bacteria, as indicated in the standard guidelines<sup>[3,5,7,10,12-13]</sup>.

Ciprofloxacin is highly effective against cholestasis. However, no previous clinical study has reported the role of continuous use of ciprofloxacin in cholestatic patients after ERCP. Although many professional gastrointestinal societies recommend prophylactic use of antibiotics in the treatment of obstructive jaundice patients after ERCP, no guideline has been established after adequate biliary drainage.

The aim of this study was to evaluate the effect of

ciprofloxacin in reducing the incidence of cholangitis after adequate endoscopic biliary drainage.

## MATERIALS AND METHODS

### Subjects

This study was a randomized, controlled trial approved by the Ethics Committee of Rajavithi Hospital. Cholestatic patients in Rajavithi Hospital (Tertiary Referral Center for ERCP), Bangkok, Thailand, admitted between June 2005 and May 2006 were included in this study. Inclusion criteria included age of 18 years or older, cholestasis (at least two from 4 criteria of total bilirubin > 2 mg/dL, serum alkaline phosphatase more than twice of normal value, alanine transaminase > 40 mmol/L and ultrasound or CT-scan showing dilated bile duct). All the patients underwent ERCP and gave their written informed consent to participate in the study. Patients were excluded from the study if they refused to participate in the study, or had endocarditis or vulvular heart disease, history of allergy to fluoroquinolone group, cholangitis or sepsis, use of antibiotics within 7 d before ERCP.

### Methods

All cholestatic patients received 200 mg ciprofloxacin intravenous injection about 30 min before ERCP. Bile was aspirated before contrast medium was injected and sent to cultivation. Those who did not have biliary drainage after ERCP were excluded from this study, and ciprofloxacin was given until infection subsided. All patients who had adequate biliary drainage (defined as total relief of bile duct obstruction by stone extraction, sphincterotomy or stent replacement), were randomly divided into two groups: continuous ciprofloxacin treatment group and discontinuous ciprofloxacin treatment group. Ciprofloxacin (200 mg) intravenous injection every 12 h was given to the continuous ciprofloxacin treatment group for 48 h after ERCP, and discontinued if no infection signs and symptoms were found. The discontinuous ciprofloxacin treatment group was not given any ciprofloxacin after an adequate biliary drainage. If cholangitis occurred in any group, 200 mg ciprofloxacin intravenous injection every 12 h or other proper antibiotics (following blood or bile culture and sensitivity) were given until the infection subsided (no fever and  $WBC < 10 \times 10^9/m^3$ ) (Figure 1).

Vital signs were monitored every 8 h, liver function test and CBC count were performed once a day. Hemoculture was done if body temperature was above 38°C. Monitoring was continued until the doctor decided to discontinue it based on the following criteria, including stable vital signs, body temperature below 38°C, improvement in cholestasis and jaundice, and absence of abdominal pain.

ERCP was performed in all patients by the same endoscopist (Dr. Thawee Ratanachu-ek) under TJF-160 endoscope. After successful cannulation of the common bile duct, bile samples were obtained for bacteriological culture, and the definitive treatment for obstruction was performed. After each endoscopic procedure, endoscopes were manually washed by trained nurses according to the manufacturer's instructions.

Figure 1 Flow chart of cholestasis management.

### Statistical analysis

All statistical analyses were performed using the Yates' modified chi-square test and Student's *t* test, and expressed as mean  $\pm$  SD.

## RESULTS

During June 2005 and May 2006, 48 patients after ERCP were enrolled in the study. All the patients received prophylactic ciprofloxacin, and divided into two groups: continuous ciprofloxacin treatment group ( $n = 22$ ) and discontinuous ciprofloxacin treatment group ( $n = 26$ ). The clinical characteristics and demographics in both groups were similar (Table 1). Stones were the most common cause of cholestasis in both groups. Diagnosis and intervention during ERCP are presented in Table 1.

Cholangitis was found in one (4.5%) out of 22 patients in the continuous ciprofloxacin treatment group and 2 (7.7%) out of 26 patients in the discontinuous ciprofloxacin treatment group. No sepsis and death occurred in this study.

The incidence of cholangitis was also similar in ciprofloxacin-treated patients after ERCP and controls (the relative risk = 0.71, 95% CI = 0.14 to 3.65). The total incidence of bacterobilia was 56.3% (27/48). The incidence of bacterobilia was 59.1% (13/22) in the continuous ciprofloxacin treatment group and 53.8% (14/26) in the control group (relative risk = 1.12, 95% CI = 0.60 to 2.11) (Table 2).

Gram-negative organisms were the most commonly found in the bile cultures. The bacteriology of bile cultures from both groups is illustrated in Table 3.

Three (11.1%) out of 27 patients with bacterobilia who developed cholangitis were found to have Gram-negative organisms in their blood culture. One female patient in the continuous ciprofloxacin treatment group had hepatocellular cancer, and a stent was inserted to the right anterior segment of the liver. She was febrile on the second day after ERCP, indicating that she had

Table 1 Clinical characteristics of 48 patients undergoing ERCP

Characteristic	Ciprofloxacin (n = 22)		None-ciprofloxacin (n = 26)	
	n	%	n	%

leukocytosis (WBC count was  $10.8 \times 10^9/\text{m}^3$ ). She received 2 g ceftriazone intravenous injection daily for 11 d until infection subsided.

Two patients developed cholangitis in the discontinuous ciprofloxacin treatment group. Both received proper antibiotics until infection subsided. The results of bile cultures and hemocultures are shown in Table 4.

## DISCUSSION

Bacteremia and cholangitis are the important complications of ERCP, and their incidence varies from 0.8%-19%<sup>[4]</sup>. It is known that prophylactic antibiotic treatment before ERCP plays a crucial role in the treatment of high risk patients with bile duct obstruction, pancreatic pseudocyst and inadequate cholestatic drainage<sup>[3,10-11]</sup>. However, the efficacy of such extensive use of antibiotics after ERCP has not been previously demonstrated, thus leading to the design of our study.

All the patients had mild or moderate cholangitis. This might be due to a benefit of the routine use of prophylactic ciprofloxacin in cholestatic patients before ERCP. Loperfido *et al*<sup>[14]</sup> found that small center, jaundice and male sex were risk factors for developing cholangitis after ERCP. We had only one male patient out of 3 cholangitis patients who had obstructive jaundice in our hospital (Tertiary Referral Center for ERCP: 600 cases per year).

In our study, cholangitis incidence after ERCP was lower than that in previous studies<sup>[8,9,15]</sup>. This might be attributed to the low natural incidence of the disease<sup>[4]</sup>,

Table 3 Bacterial species in cultures of bile from 48 patients

Bacterial culture	Antibiotic (22)		P
	n (%)	No antibiotic (26) n (%)

standard sterile technique used in our hospital, and all procedures done by the same endoscopist, and our technique in collecting the bile before injecting contrast media. All these suggest that bacteriologic study and release of biliary tract pressure can reduce the incidence of pressure-induced sepsis.

*E. coli*, *Streptococcus viridans* and *Klebsiella spp.* are the most frequently isolated organisms from bile. Rung R *et al*<sup>[13]</sup> have found a similar incidence of bacterobilia (56.3%). Ciprofloxacin was chosen in our study because of its efficacy against most Gram-negative organisms (*E. coli* and *Klebsiella spp.*) which are the pathogens most frequently found in biliary tract infection<sup>[5-6,12-13,16-17]</sup> and its penetration into the obstructive biliary tree<sup>[6]</sup>.

We found 12 Gram-positive bacteria in bile cultures (*Streptococcus viridans* and *Enterococcus spp.*) of the 27 bacterobilia specimens (56.3%), which is consistent with previous studies on bacteriology of bile in patients with obstructive jaundice, showing that *Streptococcus viridans* and *Enterococcus spp.* are the most common Gram-positive bacteria in bile cultures<sup>[18-23]</sup>. Clark *et al*<sup>[24]</sup> have found the same results and recommended ampicillin/sulbactam for all biliary obstructions with positive bile *Enterococci*. We conclude that once Gram positive bacteria are detected, perioperative use of appropriate antibiotics is mandatory to reduce postoperative septic complications.

The results of our trial showed no difference in the incidences of cholangitis between the two groups (4.5% in the continuous ciprofloxacin treatment group and 7.7% in discontinuous ciprofloxacin treatment group, relative risk = 0.71, 95% CI = 0.14 to 3.65, *P* = 0.88).

Alvey CG *et al*<sup>[25]</sup> used 750 mg of ciprofloxacin taken

orally in 47 jaundice patients about 90 min before ERCP to prevent sepsis and we used the same sample size (48 patients). Our suggestion is that if a larger sample size is employed, this outcome may be strongly enforced.

In conclusion, extensive use of antibiotics after adequate drainage by ERCP in cholestatic patients does not substantially reduce the incidence of cholangitis. Continuous use of antibiotics is unnecessary in these patients. The results of this study may contribute to decreasing the drawbacks of the widespread use of antibiotics including cost, adverse effects, and emergency of resistant strains of bacteria.

### Abstract

**AIM:** To evaluate the time dependence of intra-arterial 5-fluorouracil (5-FU) therapy for advanced hepatocellular carcinoma (aHCC).

**METHODS:** Thirty-seven adult Japanese patients who had aHCC and liver cirrhosis were treated with combined intra-arterial 5-FU, cisplatin (CDDP), and leucovorin (LV). The Japan Integrated Staging score (JIS score) of each patient was 3 or more. The patients were divided into two groups, after which the 15 patients in group S were treated with 6-h infusion chemotherapy (LV at 12 mg/h, CDDP at 10 mg/h, and 5-FU at 250 mg/m<sup>2</sup> per 4 h) and the 22 patients in group L were treated with 24-h infusion chemotherapy (LV at 12 mg/h, CDDP at 10 mg/h, and 5-FU at 250 mg/m<sup>2</sup> per 22 h). Continuous infusion chemotherapy was performed *via* the proper hepatic artery every 5 d for 4 wk using an implanted drug reservoir.

**RESULTS:** The percentages of patients with a partial response after 4 wk of chemotherapy were 6.7% in group S and 31.8% in group L. The survival of group L was significantly better than that of group S, with the median survival time being 496 d in group L and 226 d in group S ( $P < 0.05$ ).

**CONCLUSION:** Continuous 24-h intra-arterial infusion is more effective for aHCC and can markedly prolong survival time as compared to 6-h infusion.

**Key words:** 5-fluorouracil; Cisplatin; Advanced hepato-

### INTRODUCTION

The majority of patients with advanced hepatocellular carcinoma (aHCC) survive no longer than 6 mo from the day of initial diagnosis<sup>[1]</sup>. It was reported that improvement of implanted drug delivery systems has made it possible to administer repeated hepatic arterial infusion of anticancer agents to patients with aHCC and that hepatic arterial infusion therapy not only improved survival but also the quality of life (QOL)<sup>[2]</sup>. Continuous local arterial infusion of 5-fluorouracil (5-FU) and cisplatin (CDDP) using an infuser pump and an implanted reservoir has been shown to prolong the survival of patients with severe advanced HCC<sup>[2-4]</sup>. Leucovorin is a biochemical modulator of 5-FU<sup>[5-7]</sup>. A randomized study showed that the regimen using CDDP, 5-FU, and leucovorin (LV) was significantly better than that of the low-dose CDDP and 5-FU alone<sup>[8]</sup>. However, there were differences of the response rate and the regimen used in these studies, such as 250 mg of 5-FU for 5 or 24 h. For staging of HCC, Cancer of the Liver Italian Program (CLIP) score<sup>[9]</sup> has been reported to be very useful<sup>[10-12]</sup>. However, it was also reported that the stratification ability and prognostic power of the Japan Integrated Staging (JIS) score<sup>[13]</sup> were superior to those of the CLIP score for staging of HCC<sup>[14]</sup>. Accordingly, this study was performed to evaluate the time dependence of intra-arterial 5-FU therapy for aHCC by using the JIS score.

### MATERIALS AND METHODS

#### Patients

Thirty-seven adult Japanese patients who had aHCC and

**Table 1** Clinical characteristic of the 37 patients with advanced HCC and HCV cirrhosis

Mean age	Group S: 68.3 yr Group L: 66.6 yr
Gender	Group S: 10 males, 15 females Group L: 15 males, 7 females
Child-Pugh classification	Group S A: 6, B: 7, C: 2 Group L A: 11, B: 9, C: 2
Stage	Group S III: 2, IVA: 12, IVB: 1 (Vp3: 4, Vp4: 1, vv2: 0) Group L III: 1, IVA: 14, IVB: 7 (Vp3: 3, Vp4: 0, vv2: 1)
JIS score	Group S 3: 7, 4: 7, 5: 1 Group L 3: 12, 4: 8, 5: 2

liver cirrhosis due to HCV infection (C-LC) were treated with combined intra-arterial 5-FU, CDDP, and LV at Omori Hospital, Japan between 2000 and 2005. According to the computed tomography (CT) findings, the tumors were inoperable, with a JIS score of 3 or more in all patients.

### Chemotherapy regimen

The patients were divided into two groups. Group S comprised 15 patients (10 men and 5 women) who were treated with 6-h infusion chemotherapy (LV at 12 mg/h, CDDP at 10 mg/h, and 5-FU at 250 mg/m<sup>2</sup> per 4 h), while group L included 22 patients (15 men and 7 women) who were treated with 24-h infusion chemotherapy (LV at 12 mg/h, CDDP at 10 mg/h, and 5-FU at 250 mg/m<sup>2</sup> per 22 h). Doses of the chemotherapy were according to a previous report<sup>[8]</sup>. Continuous infusion chemotherapy was performed *via* the proper hepatic artery every 5 d for 4 wk using a catheter connected to a subcutaneously implanted drug delivery system. Subsequently, the same chemotherapy was continued for as long as possible.

### System placement technique

In all patients, an intra-arterial catheter was inserted *via* the femoral artery and was attached to a subcutaneously implanted reservoir<sup>[15]</sup>. In principle, the gastroduodenal artery and the right gastric artery were occluded with steel coils to prevent gastroduodenal injury from anticancer agents. Written informed consent was obtained from each patient or family members after the possible complications of reservoir implantation and arterial infusion chemotherapy had been fully explained.

### Evaluation of therapeutic effect

On CT scans obtained after 4 wk of treatment, the size of the intrahepatic tumors was measured as the product of the two longest perpendicular diameters of the largest tumor. CT images were acquired according to the same method as performed for pretreatment workup. The response criteria defined by the Liver Cancer Study Group of Japan were used. A complete response (CR) was defined as disappearance of the tumor and no evidence of new lesions for at least 4 wk, while a partial response

**Table 2** Objective response and survival in the both group (%)

	Group	JIS score		
		3	4	5
1-yr	Group S	14.3	0.0	0.0
	Group L	50.0	16.7	16.7
2-yr	Group S	0.0	0.0	0.0
	Group L	16.7	0.0	0.0
3-yr	Group S	0.0	0.0	0.0
	Group L	16.7	0.0	0.0

Objective response rate: Group S 6.7% (1/15 cases) CR: PR: SD: PD = 0: 1: 3: 11; Group L 31.8% (7/22 cases) CR: PR: SD: PD = 0: 7: 9: 6.

(PR) was defined as reduction of the product of the two longest diameters by more than 50%. An increase of the product by more than 25% was defined as progressive disease (PD), and the changes in between PD and PR were defined as stable disease (SD). The response was also evaluated by measuring serum alpha-fetoprotein (AFP), AFP-L3, and PIVKA-II levels in the patients with elevated levels of these markers. The survival period was defined as the interval between the start of treatment and death.

### Statistical analysis

The Mann-Whitney test was used to compare the patient characteristics between the two groups. Survival was evaluated by the Kaplan-Meier method, and the significance of differences in survival was determined by the log rank test. *P* value less than 0.05 was considered statistically significant.

## RESULTS

The group S comprised a total of 10 men and 5 women aged 54 to 79 years (mean  $\pm$  SD, 68.3  $\pm$  7.4 years), while the group L comprised 15 men and 7 women aged 52 to 76 years old (mean  $\pm$  SD, 66.6  $\pm$  7.8 years). There was no significant difference between the both groups. The Child-Pugh class was A for 6 patients in group S and 11 patients in group L, while it was B for 7 and 9 patients, respectively, and C for 2 patients in each group. Two patients had stage III, 12 stage IVA, and one patient stage IVB disease in group S, while the respective numbers were 1, 14, and 7 in group L. Seven patients had a JIS score of 3, seven patients had a JIS score of 4, and one patient had a JIS score of 5 in group S, while the respective numbers were 12, 8, and 2 in group L. In group S, one patient had tumor thrombi in major branches of the portal vein and four patients had tumor thrombi in the first portal branch. In group L, there was also one patient with tumor invasion into the right hepatic vein and four patients with tumor thrombi in the first portal branch (Table 1).

### Response

Table 2 summarizes the response to treatment and the survival of the aHCC patients, all of whom had a JIS score  $\geq$  3. In group S, one of the 15 (6.7%) patients achieved PR, but no patient achieved CR. Also, 11 of the 15 (73.3%)

**Figure 1** Survival curves plotted by the Kaplan-Meier method. The survival of group L was significantly better than that of group S. The median survival time was 496 d in group L versus 226 d in group S ( $P < 0.05$ , Kaplan-Meier method and log-rank test).

**Figure 2** Changes of serum AFP following treatment in the both groups. In group L, the serum AFP level decreased significantly after treatment compared with before treatment ( $P < 0.05$ , Mann-Whitney test).

patients showed PD and 3 (20.0%) patients had SD. In group L, seven of the 22 (31.8%) patients achieved PR, although none of the patients achieved CR. Six of the 22 (27.3%) patients showed PD, but 9 (40.9%) patients had SD. The response rate in group L was significantly better than that in group S ( $P < 0.05$ , Mann-Whitney test).

**Figure 3** Changes of the white blood cell count following treatment in the both groups. There were no significant differences in either group.

### Survival

In group S, the 1-year survival rates for the patients with a JIS score of 3, 4, and 5 were 14.3%, 0.0%, and 0.0%, respectively. There were no survivors for 2 years or more. In group L, the 1-year survival rates for the patients with a JIS score of 3, 4, and 5 were 50.0%, 16.7%, and 16.7%, respectively, while the 2-year survival rates for those patients were 16.7%, 0%, and 0%, respectively. None of the patients in either group survived for 3 years (Table 2). The survival of group L was significantly better than that of group S, with the median survival time being 496 d in group L and 226 d in group S ( $P < 0.05$ ) (Figure 1).

### Tumor markers

Figure 2 summarizes the changes of serum AFP following treatments in both groups. In group L, the serum AFP level decreased significantly after treatment compared with that before treatment. However, there was no significant change of the serum AFP level in group S. Moreover, there were no significant changes of the serum AFP-L3 and PIVKA-II levels in both groups (data not shown).

### Hematologic toxicity

Figure 3 summarizes the changes of the white blood cell count following treatment in both groups, showing that there were no significant differences in either of the groups. Similarly, there were no significant changes of

**Figure 4** Changes of neutrophil and monocyte counts following treatment in the both groups. In group L, the neutrophil and monocyte counts were significantly decreased after treatment as compared with before treatment (\* $P < 0.05$ , Mann-Whitney test).

lymphocyte or platelet count before and after treatment in either group (data not shown). However, the neutrophil and monocyte counts were significantly decreased after treatments in group L compared to group S (Figure 4).

## DISCUSSION

The majority of patients with advanced hepatocellular carcinoma (aHCC) live no longer than 6 mo from the day of diagnosis<sup>[1]</sup>. It was also reported that the average survival of patients with aHCC was 4 mo from the onset of symptoms and 2 mo from the time of admission<sup>[16]</sup>. In the present study, one of 15 (6.7%) patients in group S achieved PR, while seven of 22 (31.8%) patients in group L reached a state of PR. The survival of group L was significantly better than that of group S, with the median survival time being 496 d in group L *versus* 226 d in group S. Moreover, the serum AFP level decreased significantly after treatment in group L, although this change was not observed in group S. Regarding hematologic toxicity, the neutrophil and monocyte counts were significantly decreased after treatment in group L, while these changes were not observed in group S. In the present study, the severity of disease was assessed by the JIS score, making it possible to observe effect of continuous intra-arterial infusion for 6 and 24 h in C-LC patients with aHCC of similar severity. It was demonstrated that the method of continuous intra-arterial infusion for 24 h was more effective and could prolong survival compared to 6-h infusion. Both treatments were effective for aHCC in the patients with C-LC, when we excluded the patients with a JIS score  $\leq 2$  in this study. However, 24-h infusion caused a greater decrease of the neutrophil and monocyte counts compared to 6-h infusion.

5-FU and CDDP have been the most commonly used drugs in combination regimens because CDDP amplifies the effect of 5-FU by biochemical modulation in addition to its own action<sup>[6,17,18]</sup>. Moreover, LV has a synergistic effect in promoting the biochemical modulation of 5-FU. It has been reported that chemotherapy using 5-FU, CDDP, and LV is superior to other treatments (5-FU alone, CDDP alone, and 5-FU plus LV) with respect to controlling tumor growth, even if the concentrations of 5-FU and LV are reduced by half<sup>[8]</sup>. Therefore, we selected

the combination of 5-FU, CDDP, and LV for intra-arterial infusion to treat aHCC, based on the employment of CDDP and LV as modulators of 5-FU. 5-FU has been reported to exhibit its anticancer effects *via* the following mechanisms: (1) Inhibition of deoxyribonucleic acid (DNA) synthesis through inactivation of thymidylate synthase (TS) by formation of a complex between methyle netetrahydrofolate ( $\text{CH}_2\text{FH}_4$ ) and 5-fluoro-2'-deoxyuridine 5'-monophosphate (FdUMP), which is synthesized from 5-FU. (2) Interference with ribonucleic acid (RNA) metabolism by the uptake of phosphated 5-fluorouridine 5'-triphosphate into RNA<sup>[19]</sup>. It was also reported that a single dose of 5-FU is more effective for causing RNA dysfunction, while continuous infusion causes more DNA damage<sup>[20]</sup>. Another study showed that 5-FU was almost undetectable in the peripheral blood when 5-FU and low-dose CDDP were continuously infused *via* a central vein or *via* the hepatic artery in patients with advanced or metastatic HCC<sup>[21]</sup>. These reports indicate that the method of continuous intra-arterial infusion for 24 h would cause more damage to tumor DNA in our C-LC patients with aHCC compared with 6-h infusion, although 24-h infusion had stronger hematologic toxicity than 6-h infusion. Our results might also be supported by the report that 5-FU has a time-dependent anticancer effect and shows stronger cell-killing activity *in vitro* when exposure is continued for a longer period<sup>[22]</sup>.

In conclusion, continuous 24-h intra-arterial infusion is more effective and can prolong survival as compared with 6-h infusion in C-LC patients with aHCC, although 24-h infusion is associated with stronger hematologic toxicity.

## Abstract

**AIM:** To prospectively present our initial experience with totally laparoscopic transhiatal esophagogastric resections for benign diseases of the cardia and distal esophagus.

**METHODS:** Laparoscopic gastric mobilization and tubularization combined with transhiatal esophageal dissection and intrathoracic esophagogastric anastomosis accomplished by a circular stapler was done in 3 patients. There were 2 females and 1 male patient with a mean age of  $73 \pm 5$  years.

**RESULTS:** Two patients were operated on due to benign stromal tumor of the cardia and one patient had severe oesophageal peptic stenosis. Mean blood loss was  $47 \pm 15$  mL and mean operating time was  $130 \pm 10$  min. There were no cases that required conversion to laparotomy. All patients were extubated immediately after surgery. Soft diet intake and ambulation times were  $5.1 \pm 0.4$  d and  $2.6 \pm 0.6$  d, respectively. There were no intraoperative and postoperative complications and there were no perioperative deaths. The average length of hospital stay was  $9.3 \pm 3$  d. All procedures were curative and all resected margins were tumor free. The mean number of retrieved lymph nodes was  $18 \pm 8$ .

**CONCLUSION:** Laparoscopic transhiatal esophagogastric resection for benign lesions has good effects and proves feasible and safe.

## INTRODUCTION

In recent years, the incidence of adenocarcinoma of the lower esophagus and cardia has increased<sup>[1]</sup>. Surgery remains the treatment of choice for these cancers, since it provides definitive treatment and long-term survival for some patients and offers splendid palliation for many others. The most common surgeries for resectable lesions are total gastrectomy with distal esophagectomy, Ivor Lewis esophagectomy and the blunt transhiatal procedure<sup>[2,3]</sup>. These traditional approaches are frequently associated with significant morbidity and mortality rates ranging from 5% to 10%<sup>[4-6]</sup>. With the development of minimally invasive surgery during the last decade, attempts were made to use alternative minimally invasive methods for esophageal dissection, which avoid an open thoracotomy incision and therefore reduce the associated morbidity<sup>[7-11]</sup>. However, combined methods using thoracoscopic dissection with conventional abdominal approaches have not achieved a significant reduction in respiratory morbidity, mostly due to the upper midline abdominal incision<sup>[12,13]</sup>. Better outcomes were achieved by the use of laparoscopic gastric mobilization combined with transhiatal or thoracoscopic esophageal mobilization and cervical or thoracic anastomoses<sup>[14,15]</sup>.

The present study reports on our initial experience with laparoscopic gastric mobilization and transhiatal oesophageal dissection with intrathoracic esophagogastric anastomosis without abdominal, cervical or thoracic incisions for benign diseases of the cardia and distal esophagus prospectively.

## MATERIALS AND METHODS

### Patients

The clinical records of patients who underwent laparoscopic gastroesophagectomy in the Department of Abdominal Surgery of the Institute of Laparoscopic Surgery (ILS, Bordeaux) were collected prospectively. All patients underwent preoperative workup including upper gastrointestinal barium swallow, endoscopy with biopsies, endoscopic ultrasonography and dynamic CT scanning

of the chest, abdomen and pelvis, in order to establish the diagnosis and determine the extent and staging of the disease. Twenty-eight patients with a malignancy underwent combined laparoscopic and thoracoscopic Ivor Lewis esophagectomy and were excluded from this study. For precise laparoscopic resection in one case of a small intraluminal lesion, we used preoperative endoscopic location and applied metal clips identified by intraoperative X-ray control. Prior to the operations, all cases were reviewed at a meeting attended by staff surgeons, oncologists, gastroenterologists and pathologists. Patients were informed which procedure was expected and the possibility of conversion was discussed. All patients were put on antithrombotic prophylaxis by low-weight heparin and given elastic stockings. Postoperatively, all patients were given total parenteral nutrition for the first 5 d. A hydrosoluble contrast swallow was performed on the 5<sup>th</sup> postoperative day and if normal, enteral feeding was started.

### Studied data

The patients' demographic data, surgeries, postoperative courses and outpatient follow-up were studied. The following data were collected prospectively: age, sex, preoperative work-up, types and locations of the tumor, duration of surgery, blood loss, intraoperative complications, pathological findings and nodal status, postoperative complications, hospital stay, recurrence and distant events. Variables are presented as mean and standard deviation.

### Surgical techniques

The patient was placed in a 25° reverse-Trendelenburg position with split legs; the operating surgeon stood between the legs, the assistant surgeon stood on the left side of the patient and the camera holding assistant was on the right side. A total of five operating trocars were used: a 0° videoscope was introduced through a 10 mm supraumbilical trocar, two 12 mm working ports were placed to the right and left of the midline, and two 5 mm exposure trocars were in sub-xiphoid and left lateral position (Figure 1). Laparoscopic explorations were done by creating a pneumoperitoneum with CO<sub>2</sub> to a maximum pressure of 12 mmHg. After exploration of the peritoneal cavity the greater curvature was mobilized by dissection of the greater omentum from the transverse colon using scissors and Ligasure® (Valleylab, Tyco Healthcare Group Lp, Boulder, CO 80 301-3299, UK) or harmonic scalpel (Ethicon Endo-surgery, Cincinnati, OH, USA). The left gastric vessels were exposed and clipped and divided at their roots while the lymph nodes were dissected. The greater curvature mobilization was continued in a distal to proximal direction while the right gastric and gastroepiploic arteries were preserved. A Kocher maneuver was performed followed by gastric tubularization: After definition of the distal margin of the specimen, an endoscopic linear stapler (Ethicon Endo-surgery, Cincinnati, OH, USA) was used to divide the small curvature and create a tube of the greater curvature that would later allow anastomosis with the esophagus. The right diaphragmatic crus was dissected to

10 mm Trocar ○ 5 mm Trocar ○ 12 mm Trocar ○

Figure 1 Trocar placement for transhiatal esophagogastrectomy.

expose the lower mediastinum. The fundus and abdominal esophagus were mobilized by division of the gastrophrenic peritoneal reflection and separation of the gastroesophageal junction from the left and right crus. The hiatus was entered and the mediastinal esophagus was dissected. The dissection limits were between the left and right parietal pleuras, the pericardium and left pulmonary vein anteriorly and the aorta posteriorly. The anterior and posterior vagal nerves were identified and divided and finally the esophagus was transected 2 to 3 cm above the lesion with free margins.

For reconstruction a 25 mm circular stapler (Ethicon Endo-surgery, Cincinnati, OH, USA) was used to perform intracorporeal esophagogastric anastomosis. The anvil was prepared by tying a thread with a needle to the tip and then inserted into the peritoneal cavity through a port-site. The anvil was introduced through the lateral esophageal wall 1.5 cm proximal to the transection line, the needle exited through the esophageal wall and then the esophageal stump was closed by a linear endo GIA stapler. The circular stapler was introduced by enlarging one of the left sided trocar sites, entered into the still attached lesser curvature, then passed into the gastric tube. After the stapler was connected to the anvil, the esogastric anastomosis was created, and the stapler removed. The tissue doughnuts were carefully checked. The gastric tube was transected with a linear stapler proximal to the anastomosis, making sure to leave at least 1 cm of tissue so as not to create ischemia. The resected specimen was placed inside a bag (Endo Catch II, Auto Suture European Services Center, S.A., 78990 Elancourt, France) and was removed through enlargement of one of the port wounds.

## RESULTS

### Patients' characteristics

Between April 2002 and January 2005, we performed laparoscopic gastroesophagectomy in 3 patients. There were 2 female and 1 male patients with a mean age of  $73 \pm 5$  years. The presenting syndromes were abdominal pain and dyspepsia in the first patient, upper gastrointestinal bleeding in the second patient, and dysphagia and weight loss in the last patient. Patients' preoperative risk was evaluated

Table 1 Patient demographics and presenting symptoms

No.	Age (yr)	Gender	ASA	Symptoms	Pathologic site	Pathology
1	67	M	1	Abdominal pain and dyspepsia	Gastroesophageal junction	Gastrointestinal stromal tumor
2	79	F	2	Upper gastrointestinal bleeding	Gastroesophageal junction	Gastrointestinal stromal tumor
3	73	F	2	Dysphagia and weight loss	Distal esophagus	Severe fibrosis

ASA: American Society of Anesthesiologists physical status score.

according to the American Society of Anesthesiologists physical status score (ASA) (Table 1).

### Perioperative data

The perioperative data were as follows: Mean blood loss was  $47 \pm 15$  mL and mean operating time was  $130 \pm 10$  min. There were no cases that required conversion to laparotomy. All patients had their tracheal tube removed immediately after surgery. Mean stay time in Intensive Care Unit was  $2.3 \pm 0.5$  d. Resumption of soft diet intake and ambulation times were  $5.1 \pm 0.4$  d and  $2.6 \pm 0.6$  d, respectively. There were no intraoperative or postoperative complications and there were no perioperative deaths. The average length of hospital stay was  $9.3 \pm 3$  d.

### Pathologic findings

Two patients were operated on for benign lesions, which were gastrointestinal stromal tumors of the gastroesophageal junction. One patient had severe fibrosis causing severe stenosis of the distal esophagus due to prolonged gastroesophageal reflux.

All procedures were curative and all resected margins were disease or tumor free. The mean tumor size of the surgical specimens was  $3.1 \pm 1$  cm and the mean number of retrieved lymph nodes was  $18 \pm 8$ . The patients were cured of lesions and symptoms during a follow-up of  $25 \pm 12$  mo.

## DISCUSSION

In spite of modern surgical techniques and improved perioperative care, conventional surgical approaches for benign and malignant lesions of the esophagus and cardia have not significantly lowered the postoperative morbidity and mortality rates. The mortality rates from esophagectomy ranged from 8% in high volume-centers to as high as 23% in low-volume centers<sup>[16]</sup>. Respiratory complications associated with thoracotomy and prolonged deflation of the right lung during the operation, as well as infections due to anastomotic leaks are the major causes of perioperative morbidity in these surgeries. The high morbidity rates lead to increased cost, prolonged hospital stay, and occasionally, to mortality. Therefore, patients with esophageal cancer, in particular, older patients and those with co-morbid conditions may not be referred for operation at all.

During the 1970s Orringer introduced the technique of transhiatal esophagectomy, which avoids thoracotomy<sup>[3]</sup>. However, the use of an open approach has not clearly demonstrated reduction of the risk of postoperative respiratory complications or postoperative mortality. In addition,

part of the dissection is “blind” with the consequent risk of bleeding, particularly from the azygos vein, and damage to the trachea and bronchi.

With the advent of minimally invasive surgical techniques, various minimally invasive surgical approaches to esophagectomy were introduced. The initial one was thoracoscopic esophagectomy combined with a laparotomy<sup>[13,17-19]</sup>. In contrast to expectations, no clear benefits were shown and in some of the early series it was clear that postoperative pulmonary complications were common following this approach<sup>[13]</sup>. Many other groups who performed thoracoscopic esophagectomy noted respiratory complications. Cuschieri noted pulmonary consolidation in 12% of 26 patients<sup>[7]</sup>. Gossot and colleagues had a 17% incidence of atelectasis requiring prolonged ventilation<sup>[20]</sup>, Collard and co-workers described a 17% incidence of pneumonitis<sup>[21]</sup>, and Dexter and associates reported that 3 of 13 respiratory complications were fatal<sup>[9]</sup>. A study from Hong Kong comparing thoracoscopy and open thoracotomy found no significant difference in cardiopulmonary complications<sup>[17]</sup>.

Considering that postoperative pulmonary complications are mainly caused by the prolonged deflation of the right lung during the operation and that midline abdominal and thoracic incisions compromise respiratory ability, we tried to avoid laparotomy and thoracotomy using the laparoscopic transhiatal approach. This approach could reduce postoperative morbidities and speed recovery. We performed laparoscopic gastric mobilization and transhiatal esophageal dissection with intrathoracic esophagogastric anastomosis to treat benign cardiac and distal esophageal tumors. Laparoscopic transhiatal esophagogastric anastomosis was described recently by Costi and colleagues<sup>[22]</sup>, who found that this approach minimizes postoperative complications and gives good results. The technique described by Costi *et al* is quite similar to ours while the main difference is the esophago-gastric anastomosis: Costi *et al* tied the stapler's anvil to the end of an oro-gastric tube which was inserted orally down to the esophageal stump.

Our preliminary results showed that laparoscopic transhiatal esophagogastric anastomosis without abdominal or thoracic incisions were feasible and safe. There was no need to convert to open surgery, the estimated blood loss was minimal and there were no intraoperative complications. The operative time was shorter than in the other approaches, which necessitated patient's position change and two working fields. There were no intraoperative ventilation difficulties, all patients were extubated immediately after surgery and there were no postoperative pulmonary complications. The patients were ambulated early and the postoperative course

was uneventful in all cases. The mean hospital stay was 11 d (Hospital stay in France, unlike US or other countries, is influenced not only by medical, but also cultural and patient related factors.). We used a narrow gastric tube without pyloroplasty, to avoid the potential problems associated with dumping as supported by previous studies<sup>[23]</sup>. One concern usually raised regarding the treatment of malignant diseases by minimally invasive approaches is whether these approaches provide an adequate cancer resection, allowing free tumor margins and extensive lymph node dissection, while being minimally invasive. Previous studies concluded that the use of laparoscopic assisted transhiatal dissection for distal esophageal cancer allows enhanced tumor and nodal clearance compared with the standard transhiatal approach<sup>[24]</sup>. A randomized study comparing an extended thoracic approach and transhiatal approach in 220 patients with adenocarcinoma of the esophagus found no significant difference in survival between the 2 groups<sup>[25]</sup>. There are no randomized studies comparing the laparoscopic and open transhiatal approach for malignant lesions. Despite that all resected margins in our study were tumor free and the mean number of retrieved lymph nodes was  $18 \pm 8$ , which is comparable with the thoracoscopic and open surgery series, our strategy for malignant lesions of the cardia and distal esophagus is to perform combined laparoscopic and thoracoscopic Ivor Lewis esophagectomy with en bloc mediastinal lymphadenectomy.

In conclusion, our preliminary results demonstrate that laparoscopic transhiatal esophagogastrrectomy for benign lesions of the cardia and distal esophagus has good effects and is feasible and safe. Further studies with a larger number of patients and longer follow up are needed to establish this approach.

### Abstract

**AIM:** To evaluate the diagnostic accuracy of histological evaluation of pancreatic tissue samples obtained by a modified method for recovering and processing the endoscopic ultrasound (EUS)-guided fine needle aspiration (FNA) material in the differential diagnosis of pancreatic solid masses.

**METHODS:** Sixty-two consecutive patients with pancreatic masses were prospectively studied. EUS was performed by the linear scanning Pentax FG-38UX echendoscope. Three FNAs (22G needle) were carried out during each procedure. The materials obtained with first and second punctures were processed for cytological study. Materials of the third puncture were recovered into 10% formol solution by careful injection of saline solution through the needle, and processed for histological study.

**RESULTS:** Length of the core specimen obtained for histological analysis was  $6.5 \pm 5.3$  mm (range 1-22 mm). Cytological and histological samples were considered as adequate in 51 (82.3%) and 52 cases (83.9%), respectively. Overall sensitivity of both pancreatic cytology and histology for diagnosis of malignancy was 68.4%. Contrary to cytology, histology was able to diagnose tumours other than adenocarcinomas, and all cases of inflammatory masses. Combination of cytology and histology allowed obtaining an adequate sample in 56 cases (90.3%), with a global sensitivity of 84.21%, specificity of 100% and an overall accuracy of 90.32%. The complication rate was 1.6%.

**CONCLUSION:** Adequate pancreatic core specimens for

### INTRODUCTION

Differential diagnosis of pancreatic masses is a frequent clinical challenge. Therapeutic decision in this context is mainly based on the ability to establish or exclude malignancy<sup>[1]</sup>. Although ductal adenocarcinoma is the most frequent cause of pancreatic masses, other neoplasms (e.g. lymphoma, cystic tumours) and benign conditions (e.g. chronic pancreatitis) with different prognoses and treatment options can arise within the pancreas. A histological diagnosis becomes therefore highly relevant for an optimal therapeutic decision<sup>[2]</sup>.

Endoscopic ultrasound (EUS)-guided fine needle aspiration (FNA) has been proved to be a safe and useful method for tissue sampling of intramural and extramural gastrointestinal lesions including the pancreas<sup>[3,4]</sup>. Cytological study of the materials obtained by FNA allows the evaluation of cellular findings suggestive of malignancy, such as anisonucleosis, nuclear membrane irregularity and nuclear enlargement. Unfortunately, inflammation causes a reactive and regenerative process leading to cellular changes that can be difficult to distinguish from well-differentiated neoplasias. Histological study of tissue samples allows the assessment of tissue architecture and cell morphology, as well as the performance of immunohistochemical analysis<sup>[5,6]</sup>, thus usually providing with a higher diagnostic accuracy than cytology.

Retrieving pancreatic tissue fragments with different EUS-guided techniques has been explored. In this context,

needles of different diameters and trucut needles have been used with variable success and complication rates<sup>[7-11]</sup>.

The aim of the present study was to evaluate the diagnostic accuracy of the histological evaluation of pancreatic tissue samples obtained by a modified method for recovering and processing the EUS-guided FNA material in the differential diagnosis of pancreatic solid masses.

## MATERIALS AND METHODS

### Subjects

Sixty-two consecutive patients (mean age 57 years, range 20 to 83 years, 35 males and 27 females), who underwent an EUS-guided FNA for the evaluation of solid pancreatic masses were prospectively included in the study over a two-years period.

### Methods

In addition to abdominal ultrasound, all patients had a previous evaluation of the pancreatic mass by CT scan. Lesions were located in the head of the pancreas in 45 cases, in the body in 15 cases, and in the tail in two cases. Once the corresponding signed informed consent was obtained, EUS was performed under conscious sedation by a single operator (JIG). A standard blood coagulation analysis was performed before EUS-guided FNA, and an uncorrectable coagulation profile (prothrombin time < 60%) was considered as a contraindication for the procedure.

EUS was performed using a convex array echoendoscope (Pentax FG-38UX<sup>®</sup>), connected to an ultrasound equipment Hitachi-E6000<sup>®</sup>. FNA was performed with a standard 22-gauge needle (Sonotip II<sup>®</sup>, Mediglobe, Germany). This needle is equipped with a round nitinol stylet covered by a 118 cm protective metal spiral coil sheath. The needle can be advanced up to 8.5 cm from the spiral sheath. The target lesion was endosonographically visualized and the region was scanned for vessels using colour and pulsed Doppler. FNA was performed from the duodenum or the stomach according to the location of the lesion in the head or the body/tail of the pancreas, respectively. Before puncture, the stylet was withdrawn several millimeters, thereby exposing the sharp needle tip. The needle was then advanced into the target tissue under endosonographic guidance (Figure 1). Once the lesion was penetrated, the stylet was advanced to the original position to “unplug” the needle, and to push out any potentially needle-clogging tissue or body fluids. The stylet was then removed and suction was applied using a 5 mL syringe while moving the needle to and fro within the lesion. Suction was released before removing the needle. This procedure was repeated three times and the material obtained was recovered as follows: (1) The samples obtained after the first and second punctures were expelled on microscope slides by pushing the needle stylet and injecting air through the needle. The material was then spread on the slides, fixed in 96% ethanol and processed for cytological study by Papanicolau staining (Figure 2). Cytology samples were evaluated for cellular preservation, background substance, cellularity, architectural integrity, and cytoplasmic and nuclear details. Cytology diagnoses were categorized into non-diagnostic,

**Figure 1** Endoscopic ultrasound image of a mass in the body of the pancreas. Fine needle aspiration of the mass (White arrow: pancreatic mass; Dotted arrow: FNA needle).

**Figure 2** Cytological evaluation of a pancreatic sample obtained by EUS-guided FNA. The presence of marked cellular atypia (arrows) supports the diagnosis of adenocarcinoma of the pancreas (Papanicolau staining  $\times 40$ ).

negative for malignancy, and positive for malignancy, based on published criteria<sup>[12]</sup>. (2) Samples obtained after the third puncture were recovered into a tube containing a 10% formol solution by injecting 2 ml of saline solution through the needle (Figure 3). Samples were then embedded in paraffin. Tissue sections of 3 to 4  $\mu$ m were stained by the classical haematoxylin-eosin technique for morphological evaluation. The sample was considered adequate if a coherent core tissue specimen from the target lesion was obtained (Figure 4).

No pathologist was present in the endoscopy room during the procedure. Samples were initially processed by the endoscopist, who was specifically trained with this aim by pathologists. Thus, no microscopic evaluation of sample adequacy was performed at that time. Two experienced pathologists examined both cytological smears and histological specimens. Cytological and histological findings were compared with the surgical specimen as gold standards in patients who were further operated upon. In non-operated patients, a clinical, morphological (EUS and CT scan) and biochemical evaluation (including serum levels of Ca 19.9) over a minimum follow-up

**Figure 3** Core of pancreatic tissue obtained by expelling the content of the needle into a tube with 10% formal solution by careful injection of saline solution after EUS-guided FNA.

of at least 6 mo was considered as gold standards. The criteria for establishing a benign course of disease were thus a subjective well-being, absence of weight loss, no progression of the disease on imaging studies and no elevation of serum tumour markers.

### Statistical analysis

Sensitivity, specificity, overall accuracy and positive and negative predictive values for malignancy were calculated. Data from histology and cytology are shown as percentages and 95% confidence intervals and compared by the Fisher's exact test.  $P < 0.05$  was considered as significant.

## RESULTS

Pancreatic masses were secondary to a malignant condition in 38 cases (61.3%), and to benign diseases in 24 cases (38.7%). Distribution of patients according to the final diagnosis based on the gold standards is shown in Table 1. A total of 27 patients underwent surgery, including 20 pancreatic adenocarcinomas, one patient with an endocrine tumour, and 6 patients with an inflammatory mass related to a chronic pancreatitis. The remaining 35 patients were followed up for a median of 10 mo (range 6-20 mo).

The length of the core specimen obtained for histolog-

B cell lymphoma	1	0	1	1
Endocrine carcinoma	1	0	1	1
Inflammatory process	24	17	24	24
Total	62	42	55	56

**Table 2** Accuracy of EUS-guided FNA for detection of malignancy in pancreatic solid masses in cases of adequate FNA sampling (95% CI)

	Cytology	Histology	<i>P</i>
Sensitivity	76.5% (60.0-87.6)	92.85% (77.3-98.0)	0.097
Specificity	100% (81.6-100)	100% (86.2-100)	NS
Negative predictive value	68.0% (48.4-82.8)	92.3% (75.9-97.9)*	$< 0.05$
Positive predictive value	100% (87.1-100)	100% (87.1-100)	NS
Overall accuracy	84.3% (72.0-91.8)	96.1% (87.0-98.9)	0.05

NS: not significant. \* $P < 0.05$  vs cytology.

ical analysis was  $6.5 \pm 5.3$  mm (range 1-22 mm). Cytological and histological samples were considered as adequate in 51 (82.3%, 95% CI, 71.0%-89.8%) and 52 cases (83.9%, 95% CI, 72.8%-91.0%), respectively (not significant). Global sensitivity of both pancreatic cytology and histology for diagnosis of malignancy was 68.4% (52.5%-80.9%).

Diagnostic accuracy of both techniques in cases of adequate sample is shown in Table 2. In this context, histology tended to be more sensitive and accurate, and showed a significantly higher negative predictive value for malignancy than cytology.

Histological evaluation provided a correct diagnosis in all 24 cases of inflammatory masses, compared with 17 cases correctly classified by cytology (Table 1). Although both techniques were similarly sensitive for the diagnosis of pancreatic adenocarcinomas, histology was the only one able to diagnose other tumours like lymphomas, endocrine tumours and small cell lung cancer metastasis (Table 1). The combination of cytology and histology allowed obtaining an adequate sample in 56 cases (90.3%, 95% CI, 80.4%-95.5%), and a correct diagnosis in all 24 cases of inflammatory masses and 32 cases of pancreatic malignancy (Table 1). Thus, the global sensitivity of EUS-guided FNA was 84.21% (95% CI, 69.6%-92.6%), specificity of 100% (95% CI, 86.2%-100%), and overall accuracy of 90.32% (95% CI, 80.4%-95.5%).

The complication rate of the procedure was 1.6%, and only one case of mild acute pancreatitis that resolved within three days of conservative treatment was observed. No patient died because of the procedure.

## DISCUSSION

Recovery of pancreatic EUS-guided FNA specimen into a 10% formol solution by careful injection of saline through the needle allows obtaining an adequate tissue sample for histological diagnosis of pancreatic masses in most cases. Compared to cytology, histology provides a significantly higher negative predictive value for malignancy, and tends to be more accurate. In addition, tumours other than adenocarcinomas are more easily diagnosed by histology.

Several studies have evaluated the accuracy of cytology after EUS-guided FNA for the diagnostic assessment of pancreatic masses. According to those reports, an adequate cytological specimen can be obtained in 82% to 91% of cases, with a sensitivity for malignancy ranging from 64% to 96%<sup>[13-25]</sup>. In our series, the sensitivity of cytology for the diagnosis of malignancy was 68.4%, which improved up to 76.5% when only adequate samples were considered, similar to the previous report.

In previous studies showing high diagnostic yields of cytology, 3 to 6 needle passes through the lesion<sup>[16-23,26]</sup> and on-site evaluation of the FNA sample adequacy by a cytopathologist<sup>[10,27-29]</sup> was considered essential. We were able to obtain an adequate sample in 90% of cases by performing three passes, two for cytological evaluation and one for histological evaluation.

Compared to cytology, histological evaluation of a tissue sample seems to have several advantages, such as a better distinction between well-differentiated adenocarcinoma and chronic pancreatitis, an appropriate cellular subtyping and architectural analysis for the diagnosis of tumours (i.e. lymphoma), as well as the possibility of using special stains<sup>[5,6]</sup>. In our series, obtaining a core specimen for histological evaluation allowed us to categorize malignant lesions that, although rare, were impossible to be diagnosed by cytology (i.e., pancreatic lymphomas, small cell lung cancer metastasis and endocrine carcinomas). Histological analyses were also able to properly diagnose benign pancreatic lesions in all patients. However, we had difficulties in acquisition of adequate samples from pancreatic adenocarcinomas, which might be explained by the tissue features of this solid tumour, characterized by infiltrating duct-like and tubular structures embedded in a highly desmoplastic stroma<sup>[30]</sup>.

Different needles and different needle diameters have been evaluated to obtain core tissue specimens for histopathological analysis<sup>[7-11]</sup>. Binmoeller *et al*<sup>[7]</sup> were able to obtain adequate tissue core specimens in 40 out of 45 patients with pancreatic masses using an 18-gauge needle. Despite that, the sensitivity for detection of a malignancy was only 53%<sup>[7]</sup>. In a more recent retrospective study, Levy *et al*<sup>[9]</sup> reported an accuracy of 85% for the diagnosis of different pancreatic and non-pancreatic lesions using a 19-gauge trucut needle, compared to a 60% accuracy achieved by the standard fine needle aspiration technique. Varadarajulu *et al*<sup>[10]</sup> compared a 19-gauge trucut needle with the standard 22-gauge needle with fine needle aspiration, and no difference in the diagnostic accuracy between both techniques was found (78% *vs* 89%). The diagnostic yield of the trucut needle biopsy is strongly limited to lesions located in the head of the pancreas<sup>[11]</sup>. This is due to

the impossibility to reach within the duodenum the degree of deflection of the echoendoscope tip required to bring the target lesion to an adequate position for puncture. Larghi *et al*<sup>[11]</sup>, despite performing trucut needle biopsy only in lesions accessible for the transgastric approach, were able to obtain materials in only 74% of cases, with an overall diagnostic accuracy of 61%. Contrary to these, the method described in the present study allowed us to achieve a high diagnostic accuracy for pancreatic masses located both in the head and in the body and tail of the pancreas.

Despite the advantages of obtaining tissue core specimens for histological analysis, two cases in our series of malignant pancreatic masses were only detected by cytology. This strongly argues in favour of obtaining specimens for both cytological and histological evaluation. Similar data were reported by other authors<sup>[7,9]</sup>. In fact, this approach allowed obtaining an adequate sample (either for histology and/or cytology) in 90.3% of cases, with an overall diagnostic accuracy for a malignancy as high as of 90.3%.

EUS-guided biopsy of the pancreas is a safe technique<sup>[31,32]</sup>, with a slightly higher complication rate related to the use of trucut needles<sup>[10]</sup>. In fact, the risk of pancreatitis and bleeding has been reported to be higher with trucut needles than with the standard FNA needles<sup>[10]</sup>, even though this was not confirmed by other authors<sup>[7,11]</sup>. A case of mild acute pancreatitis was the only complication observed in the present series after EUS-guided FNA of the pancreas. This low complication rate is similar to that reported previously using a standard 22G needle<sup>[21-25]</sup>.

In conclusion, pancreatic core specimens for histological examination can be obtained by EUS-guided FNA with a 22-gauge needle by careful injection of saline through the needle and by expelling the tissue samples into a tube containing 10% formol solution. The samples obtained by this procedure are highly adequate for histological analyses allowing an appropriate evaluation of pancreatic solid masses. This technique is mainly useful for the diagnosis of different types of pancreatic tumours as well as for the evaluation of benign diseases. Combination with cytology tends to increase the sensitivity of histology for the diagnosis of pancreatic adenocarcinomas.

## COMMENTS

### Background

Differential diagnosis of pancreatic masses is a frequent clinical challenge. Endoscopic ultrasound (EUS)-guided fine needle aspiration (FNA) has been proved to be a safe and useful method for tissue sampling of pancreatic solid masses. Histological study of tissue samples allows the assessment of tissue architecture and cell morphology, as well as the performance of immunohistochemical analysis, thus usually providing with a higher diagnostic accuracy than cytology.

### Research frontiers

Further research is needed in order to improve the diagnostic yield of EUS-guided biopsy, and to provide with better material from pancreatic lesions. Availability of adequate pancreatic tissue samples may allow performing immunohistochemical studies, molecular analysis, and evaluation of genetic mutations, thus providing the basis for a better knowledge of pancreatic diseases.

### Innovations and breakthroughs

Our study demonstrates that a core specimen from pancreatic solid masses can

be obtained using a standard 22 gauge needle, thus allowing the histological evaluation of pancreatic lesions. Retrieving pancreatic tissue fragments has been explored using different types of needles (e.g., trucut needles) and different ways of sample processing. In contrast to trucut needles, our technique allows access to lesions located at the head of the pancreas with a low complication rate.

### Applications

Obtaining samples of pancreatic tissue allows the histological evaluation of pancreatic solid masses, which may be of help for the diagnosis of different pancreatic tumours as well as for the evaluation of benign diseases like chronic pancreatitis.

### Peer review

This paper provides support for the use of this modified method when performing fine needle biopsy of solid pancreatic masses.

## Abstract

**AIM:** To compare the response of standard hepatitis B virus (HBV) vaccination between patients with chronic hepatitis C virus (HCV) infection and healthy individuals.

**METHODS:** This is a prospective case-control study. A total of 38 patients with chronic HCV infection and 40 healthy controls were included. Vaccination was performed by injection of 20 µg recombinant HBsAg into the deltoid muscle at mo 0, 1 and 6. Anti-HBs concentration was determined 3 mo after the last dose and compared between the two groups. The response pattern was characterized as (1) high-response when the anti-HBs antibody titer was > 100 IU/L, (2) low-response when the titer was 10-100 IU/L and (3) no-response when the titer was < 10 IU/L.

**RESULTS:** In the patient group, there were 10/38 (26.3%) non-responders, 8/38 (21.1%) low-responders and 20/38 (52.6%) high-responders. The corresponding values in the control group were 2/40 (5.0%), 7/40 (17.5%) and 31/40 (77.5%), respectively. The response pattern was statistically different between the two groups. In multivariate analysis, smoking was a significant confounder, while HCV infection lost its significant correlation with lower antibody response.

**CONCLUSION:** Patients with chronic HCV infection tend to respond weakly to HBV vaccination compared to healthy individuals, though this correlation is not independent according to multivariate analysis.

## INTRODUCTION

One major transmission route for both hepatitis C virus (HCV) and hepatitis B virus (HBV) is the parenteral route, and the sources of infection include administration of blood or blood products<sup>[1,2]</sup>, intravenous drug use<sup>[3,4]</sup> and needle-stick accidents<sup>[5,6]</sup>. According to the analysis of the Third National Health and Nutrition Survey, more than 25% of HCV-positive patients in the United States had hepatitis B markers, a proportion nearly six times that in the HCV-negative group<sup>[3]</sup>. However, the actual prevalence of HBV infection in patients with HCV infection is probably underestimated<sup>[7,8]</sup>. Although it has been shown that superinfection of either HBV or HCV may suppress the other's replicative levels, coinfection with both viruses has synergistic effects with regard to histological lesions, progression to cirrhosis and cancer development<sup>[9-13]</sup>. As such it has been recommended by the National Institutes of Health (NIH) that individuals with HCV be vaccinated against HBV infection to prevent such an outcome<sup>[14]</sup>.

HBV vaccination at standard doses (20 µg for adults at mo 0, 1, and 6) results in an effective antibody response in 90% to 98% of healthy individuals<sup>[15,16]</sup>. However, reduced immunogenicity of the vaccine has been established in persons with chronic liver disease, patients receiving hemodialysis, patients with HIV infection and those awaiting transplantation<sup>[17-21]</sup>. To the best of our knowledge, only a few studies, with inconsistent results, have compared the immunogenicity of standard HBV vaccination in chronic hepatitis C patients with that in healthy individuals through a case-control study<sup>[22-24]</sup>. Therefore, we found it valuable to compare the response of standard HBV vaccination between patients with chronic HCV infection and healthy individuals in a prospective case-control study.

## MATERIALS AND METHODS

### Subjects

Between April 2005 and August 2006, 38 patients with

chronic hepatitis C infection (patients group) and 40 healthy individuals (control group) referred to our clinic were enrolled in this case-control study. Totally there were 50 males and 28 females with a mean age of  $37.6 \pm 12.8$  years. All participants gave written informed consent and the study protocol was approved by the Ethical Committee of Tehran University of Medical Sciences. Inclusion criteria for the patient group were: age  $> 18$  years, HCV infection diagnosed by positive HCV serological markers assessed by ELISA (Abbott Laboratories, North Chicago, IL, USA) and confirmed by the presence of serum HCV RNA detected by PCR, chronic infection diagnosed by serum alanine aminotransferase (ALT) levels of at least twice the upper normal values ( $> 90$  IU/L) for at least two times within a period longer than 6 mo and/or a liver biopsy showing evidence of chronic hepatitis. The control group was selected from healthy adults older than 18 years. Exclusion criteria were: pregnancy, lactation, known bleeding diathesis, current intravenous drug use, alcohol consumption  $> 30$  g/d, history of cancer or transplantation, receiving immunosuppressive medications (excluding interferon), previous hepatitis B vaccination, history of allergy to vaccine components, current or previous hepatitis B infection (positive HBs Ag, anti-HBc Ab/anti-HBs Ab by ELISA), laboratory or clinical evidence of other chronic liver diseases including cirrhosis of any etiology, presence of HIV infection, chronic renal failure (serum creatinine  $> 2.5$ ) or hemodialysis.

The following variables were recorded for all participants: age (year), sex, body mass (kg), height (m), smoking, alcohol use, history of intravenous drug use. Body mass index (BMI) was calculated by dividing mass (kg) by squared height ( $m^2$ ). Liver biopsy during two years before vaccination showing the stage and grade of liver involvement according to Ishak *et al.*<sup>[25]</sup> and HCV genotype (determined by PCR-RFLP) was available for 31 and 34 patients, respectively. Baseline ALT (IU/L) was determined by commercial kits for all patients.

### Methods

Vaccination was performed by injection of 20  $\mu$ g recombinant HBsAg (Euvax B, LG Chem, Korea) into the deltoid muscle at mo 0, 1 and 6. Anti-HBs concentration was determined 3 mo after the last dose and expressed as IU/L. The response pattern was characterized as (1) high-response when anti-HBs antibody titer was  $> 100$  IU/L, (2) low-response when the titer was 10–100 IU/L and (3) no-response when the titer was  $< 10$  IU/L. Patients were monitored after each vaccine dose for the occurrences of local (pain, induration, flush) and general (headache, fatigue, fever) side effects.

### Statistical analysis

The results are presented as mean  $\pm$  SD.  $\chi^2$  test with Fisher's exact test was used to compare qualitative variables between the groups. Student's *t* test and analysis of variance (ANOVA) were used to compare the quantitative variables between two and multiple groups, respectively. The independent predictive factors of vaccine response were identified by multivariate analysis using multiple

logistic regression. Statistical analysis was conducted with SPSS 11.5 software (SPSS Inc., Chicago, IL, USA). Throughout analysis, *P*  $< 0.05$  was considered statistically significant.

## RESULTS

### Characteristics of patients and controls

Patients were significantly older than healthy subjects (*P* = 0.017). Also, patients were more frequently males (*P* = 0.010), smokers (*P*  $< 0.001$ ) and previous intravenous drug users (*P* = 0.001) (Table 1).

### Antibody response

A total of 28/38 (73.7%) chronic hepatitis C patients responded to the vaccination course (anti-HBs  $> 10$  IU/L) compared with 38/40 (95.0%) controls (*P* = 0.012). In the patient group, there were 10/38 (26.3%) non-responders, 8/38 (21.1%) low-responders and 20/38 (52.6%) high-responders. The corresponding values in the control group were 2/40 (5.0%), 7/40 (17.5%) and 31/40 (77.5%), respectively (Figure 1). The response pattern was statistically different between the two groups (*P* = 0.021). The frequency of non-responders was significantly higher in the patient group (*P* = 0.024 after Bonferroni's correction). However, the frequency of low-responders (*P* = 0.778) and high-responders (*P* = 0.064) was not significantly different between the two groups. Since

**Table 2** Characteristics of hepatitis C patients according to vaccine response (mean  $\pm$  SD)

Characteristics	Non-responder (n = 10)	Responder (n = 28)	P
Age (yr)	41.5 $\pm$ 11.3	41.0 $\pm$ 10.2	0.897
Male/Female	8/2	22/6	1.000
BMI (kg/m <sup>2</sup> )	26.6 $\pm$ 6.0	24.2 $\pm$ 4.1	0.192
Smoking n (%)	9 (90.0)	16 (57.1)	0.118
Alcohol n (%)	2 (20.0)	4 (14.3)	0.644
Hx of iv drug use n (%)	2 (20.0)	7 (25.0)	1.000
ALT (IU/L)	177.1 $\pm$ 293.9	78.3 $\pm$ 165.3	0.199
Liver disease			
HAI grade (0-18) <sup>1</sup>	5.4 $\pm$ 2.1	5.6 $\pm$ 1.9	0.773
HAI stage (0-6) <sup>1</sup>	2.3 $\pm$ 1.1	2.6 $\pm$ 1.6	0.669
HCV genotype n (%)	8	26	
1a	6 (75.0)	14 (53.8)	0.422
Other than 1a	2 (25.0)	12 (46.2)	

<sup>1</sup>According to Knodell's histological activity index (HAI) as modified by Ishak *et al*<sup>[25]</sup>. Non-responder (anti-HBs < 10 IU/L); Responder (anti-HBs > 10 IU/L). Hx:history.

the patient and control groups were not matched in age, sex, smoking and history of iv drug use, binary logistic regression was performed to adjust for these parameters. Response (anti-HBs > 10 IU/L) was considered as the dependent variable, while hepatitis C infection, age, sex, smoking and history of iv drug use were included as covariates. None of hepatitis C infection ( $P = 0.448$ ), age ( $P = 0.078$ ), sex ( $P = 0.480$ ) and history of iv drug use ( $P = 0.127$ ) were independently correlated with lower antibody response in the patient group. However, smoking was a significant confounder ( $P = 0.024$ ; odds ratio: 25.64; 95% confidence interval: 1.54-500).

### Characteristics of hepatitis C patients according to vaccine response

The comparison of characteristics of patients between responders and non-responders to HBV vaccine showed no significant difference regarding age, sex ratio, BMI, smoking, alcohol use, history of iv drug use, baseline ALT level, stage and grade of liver disease and genotype (1a *vs* others, Table 2). When patients were categorized into three groups of non-, low- and high-responders, none of the variables except genotype ( $P = 0.038$ ) had a significant correlation with response category anymore (Table 3). Genotype 1a was more frequently observed in non-responders. However, when Bonferroni's correction was applied for subgroup analysis, this correlation was no longer significant. In summary, no correlation was found between the variables studied and response in either type of analysis.

### Side effects

No severe side effects following vaccination were observed in chronic hepatitis C patients. Local adverse effects (erythema, pain at injection point, induration) following vaccination were observed in 4/38 (10.5%) patients. Systemic side effects such as flulike syndrome, headache, fever and fatigue occurred several days following vaccine injections in 1/38 (2.6%) patients.

**Table 3** Characteristics of hepatitis C patients according to vaccine response

Characteristic	Non-responder (n = 10)	Low-responder (n = 8)	High-responder (n = 20)	P

Non-responder (anti-HBs < 10 IU/L); Low-responder (10 IU/L < anti-HBs < 100 IU/L); High-responder (anti-HBs > 100 IU/L). <sup>a</sup> $P < 0.05$  comparison between three groups.

## DISCUSSION

In the present study, the antibody response to standard HBV vaccination with a dose of 20  $\mu$ g at mo 0, 1 and 6 in individuals with non-cirrhotic chronic hepatitis C infection was evaluated and compared with healthy controls. The frequency of high-responders, low-responders and non-responders in the patient and control groups was 52.6%, 21.1%, 26.3% and 77.5%, 17.5%, 5.0%, respectively ( $P = 0.021$ ). Non-responders were significantly more common in the patient group ( $P = 0.024$ ). However, this correlation was not significant in multivariate analysis anymore when age, sex, smoking and history of iv drug use were controlled as potential confounders. In our patient group, there was no correlation between antibody response and variables such as age, sex, BMI, smoking, alcohol use, history of iv drug use, baseline ALT levels, stage and grade of liver disease and genotype.

Several studies have compared the immunogenicity of hepatitis B vaccination with different protocols between healthy individuals and hepatitis C patients. Some of them, like our study, have failed to demonstrate a significant correlation between chronic hepatitis C and antibody response<sup>[22,26-28]</sup>. However, some authors have shown that responses were weaker in patients than in controls<sup>[23,24,29,30]</sup>. Hence the results still remain controversial. Among the above mentioned studies, only three have used the same vaccination protocol as ours<sup>[22-24]</sup>. Lee *et al*<sup>[22]</sup> compared the immunogenicity of HBV vaccination between 26 hepatitis C patients and 35 controls. The groups were similar in age, but the control group was significantly younger than the patient group. One month after the last dose, 88.5% of patients and 91.4% of controls responded to vaccination with anti-HBs > 10 IU/L. The difference was not statistically significant<sup>[22]</sup>.

In another study of 48 patients and 11 controls, Chlabicz *et al*<sup>[23]</sup> showed that 72.9% of patients and 90.9% of controls responded (anti-HBs > 10 IU/L) to HBV vaccination one month after the last dose. The groups

were similar in age, sex, BMI and smoking frequency but the difference in antibody response was not significant either. One year after the last dose, there was a significant reduction in antibody response among patients so that only 34.1% of them remained responders. The corresponding value in the control group was 90% at the same time ( $P < 0.05$ ).

Finally, Mattos *et al*<sup>[24]</sup> reported in their study of 85 patients and 46 healthy adults that 55.3% of patients and 97.8% of controls responded (anti-HBs  $> 10$  IU/L) to HBV vaccination one month after the third vaccine dose. Non-responders were significantly more common in the patient group ( $P < 0.001$ ). The patient and control groups were matched in sex, BMI, alcohol use and smoking, but the patient group was significantly older than the control group. In multivariate regression to control for age as a potential confounder, HCV positivity remained significantly correlated with the lower antibody response ( $P = 0.0013$ ). The patient group in this study included both cirrhotic and non-cirrhotic individuals. Considering that cirrhosis is associated with a lower antibody response<sup>[26,31]</sup>, inhomogeneity of the patient group might have had a role in the significant correlation in this study<sup>[24]</sup>.

We only considered non-cirrhotic patients in our study. The results of multivariate regression showed that hepatitis C infection did not play an independent role in decreasing antibody response. Rather, smoking was a significant confounder ( $P = 0.024$ ; odds ratio: 25.64; 95% confidence interval: 1.54-500). This finding is in agreement with previous studies<sup>[32,33]</sup>. When patients were categorized into two (responder and non-responder) or three groups (non-, low- and high-responder), no variables studied had a significant correlation with antibody response. Previous studies, as well as ours, failed to show a significant correlation between antibody response and age, sex, BMI, smoking, alcohol use, iv drug use, baseline ALT level or liver histology (grade, stage)<sup>[24,29,30]</sup>. Mattos *et al*<sup>[24]</sup> showed that the percentage of non-responders was significantly higher in patients with genotype 1 ( $P = 0.04$ ). Considering that they had three subgroups of patients according to their response, subgroup analysis with a Bonferroni's correction (which changes the  $P$  value to  $P_i = 0.08$ ) seemed to be necessary to make a justifiable conclusion. We did not achieve a significant correlation, which was supported by Leroy *et al*<sup>[29]</sup>.

No clinically significant adverse effect was seen in our patients. Local side effects following vaccination were observed in 10.5%, while systemic side effects such as flulike syndrome, headache, fever and fatigue occurred in 2.6% of patients. These rates are almost similar to those reported in other studies<sup>[22,26,30]</sup>. In conclusion, patients with chronic hepatitis C infection tend to respond weakly to HBV vaccination compared to healthy individuals, though this correlation is not independent according to multivariate analysis.

## COMMENTS

### Background

Several studies have compared the immunogenicity of hepatitis B vaccination between healthy individuals and hepatitis C patients. Some of them have failed

to demonstrate a significant correlation between chronic hepatitis C and antibody response. However, some authors have shown that responses were weaker in patients than in controls.

### Research frontiers

Coinfection with both hepatitis B and C viruses has synergistic effects with regard to histological lesions, progression to cirrhosis and cancer development. Therefore, it may be very beneficial to prevent HBV superinfection in hepatitis C patients.

### Innovations and breakthroughs

Considering the various vaccination protocols used in HCV patients and also controversial results, we found it valuable to compare the response of standard HBV vaccination between patients with chronic HCV infection and healthy individuals in a prospective case-control study. The results showed that hepatitis C infection does not decrease the immune response to HBV vaccination.

### Applications

Based on the results of this study, in the absence of factors known to weaken the immune response, hepatitis C patients do not seem to need additional doses of HBV vaccine or antibody titration after standard HBV vaccination. However, these considerations should be taken into account when vaccinating a hepatitis C patient in general, i.e. one with commonly coexisting immunity-related risk factors.

### Terminology

Multivariate analysis: When compared groups are not similar in some possibly important features such as sex or age, performing a multivariate analysis using multiple logistic regression can adjust groups for such potential confounders.

Bonferroni's correction: A method to adjust the level of significance when multiple comparisons are made.

### Peer review

If we accept that HBV vaccine may be useful in HCV patients, the basic steps of research should be: to evaluate the rate of response in HCV carriers and to verify whether this rate is acceptable in terms of cost benefit. The patients and controls were significantly different in age, sex, smoking frequency and intravenous drug use.

Moreover, EGb 761 markedly increased SOD activity, reduced MDA levels and MPO activity, and suppressed NO generation accompanied by down-regulation of iNOS expression ( $P < 0.05$  or  $0.01$ ).

**CONCLUSION:** The results indicate that EGb 761 has a protective effect on lung injury induced by II/R, which may be related to its antioxidant property and suppressions of neutrophil accumulation and iNOS-induced NO generation. EGb 761 seems to be an effective therapeutic agent for critically ill patients with respiratory failure related to II/R.

## Abstract

**AIM:** To investigate the effect of ginkgo biloba extract (EGb 761) on lung injury induced by intestinal ischemia/reperfusion (II/R).

**METHODS:** The rat model of II/R injury was produced by clamping the superior mesenteric artery for 60 min followed by reperfusion for 180 min. The rats were randomly allocated into sham, II/R, and EGb + II/R groups. In EGb + II/R group, EGb 761 (100 mg/kg per day) was given *via* a gastric tube for 7 consecutive days prior to surgery. Rats in II/R and sham groups were treated with equal volumes of the vehicle of EGb 761. Lung injury was assessed by light microscopy, wet-to-dry lung weight ratio (W/D) and pulmonary permeability index (PPI). The levels of malondialdehyde (MDA) and nitrite/nitrate ( $\text{NO}_2^-/\text{NO}_3^-$ ), as well as the activities of superoxide dismutase (SOD) and myeloperoxidase (MPO) were examined. Western blot was used to determine the expression of inducible nitric oxide synthase (iNOS).

**RESULTS:** EGb 761 markedly improved mean arterial pressure and attenuated lung injury, manifested by the improvement of histological changes and significant decreases of pulmonary W/D and PPI ( $P < 0.05$  or  $0.01$ ).

## INTRODUCTION

Intestinal ischemia/reperfusion (II/R) injury is a grave condition resulting from acute mesenteric ischemia, hemorrhagic, traumatic or septic shock, or severe burns and some surgical procedures including small bowel transplantation and abdominal aortic surgery<sup>[1]</sup>. It is well-known that II/R not only causes injury of the intestine itself, but also involves severe destruction of remote organs and even multiple organ dysfunction<sup>[2,3]</sup>. Of these remote organ injuries, lung injury has been well-characterized as an acute inflammation with sequestration of leukocytes and their enzymatic products in lung tissue, increased microvascular permeability, perivascular and interstitial edema, and pulmonary edema<sup>[4]</sup>. These pulmonary processes incited by remote II/R injury frequently lead to the clinical picture of acute respiratory distress syndrome<sup>[5]</sup>.

The mechanisms of lung injury induced by II/R are very complex. It is well-established that lipid peroxidation is one of the major factors causing lung injury<sup>[6,7]</sup>. In

addition, evidence showed that overproduction of nitric oxide (NO) generated by inducible nitric oxide synthase (iNOS) not only aggravates oxidative damage<sup>[8,9]</sup>, but leads to pulmonary microvascular dysfunction as well<sup>[10]</sup>. Thus, the therapeutical strategy by removing free radicals and reducing NO overproduction should be potential effective strategies for the protection against lung injury following  $\Pi$ /R.

Extracts from the leaves of ginkgo biloba have been widely used therapeutically in China and Western countries for years. Standard ginkgo biloba extract, EGb 761, contains 22%-27% flavonoids and 5%-7% terpenoids, which are the most important active substances in the extract<sup>[11]</sup>. Today, EGb 761 is widely prescribed for treatment of disorders such as Alzheimer's disease and neuronal hypoxia, both of which have etiologies associated with oxidative stress<sup>[11-13]</sup>. In the cardiovascular system, it can protect the heart against ischaemia/reperfusion damage<sup>[14]</sup> and alleviate vascular endothelial cell injury<sup>[15]</sup>. Thus, currently, EGb 761 is also widely used in treating cardiovascular diseases<sup>[16]</sup>.

EGb 761 has a broad spectrum of pharmacological activities. However, most of the investigations were focused on cardio-cerebral vascular diseases. Recently, several studies showed that EGb 761 decreases malondialdehyde (MDA) and myeloperoxidase (MPO, an indicator of tissue neutrophil accumulation) levels<sup>[17]</sup> and protects against histological damage in intestinal mucosa after  $\Pi$ /R<sup>[18]</sup>. However, there is no report about the effect of EGb 761 on lung injury induced by  $\Pi$ /R.

Based on the above findings, we postulate that EGb 761 can exert a protective effect on  $\Pi$ /R-induced lung injury. Thus, the present study was undertaken to confirm the above hypothesis and elucidate the mechanisms related to pulmonary lipid peroxidation, neutrophil sequestration and nitric oxide (NO) production regulated by induced nitric oxide synthase (iNOS) expression.

## MATERIALS AND METHODS

### Animal preparation

The current study was approved by the Animal Care Committee of Sun Yat-sen University and performed in accordance with the guidelines for the use of experimental animals by the Ministry of Health. Twenty-four adult pathogen-free male Wistar rats weighing between 230-302 g were housed in individual cages in a cohorted temperature-controlled room with alternating 12 h light/dark cycles, and acclimated for a week before the study. Food was removed 8 h prior to the study, and all rats had free access to water.

### Establishment of intestinal ischemia/reperfusion rat models

All rats were anesthetized with pentobarbital (30 mg/kg body weight, intraperitoneally). A polyethylene catheter (PE-10) was inserted into the left carotid artery. The catheter was connected to MacLab digital data acquisition system (PowerLab/4SP ADI Instruments, Ugo Basile Comerio, VA, Italy) *via* a pressure transducer (TSD104A Biopac Systems, 2 Biological Instruments, Besozzo,

VA, Italy) for monitoring mean arterial pressure (MAP). Periodically, the cannula was flushed with normal saline (100  $\mu$ L) to maintain recording fidelity. The rat model was established according to our previous method<sup>[19]</sup>. The small intestine was exteriorized by midline laparotomy and the superior mesenteric artery (SMA) was occluded by microvascular clip. After 60 min of ischemia, the SMA was reperused for 180 min. Ischemia was determined by the existence of pulseless or pale color of the small intestine. The return of pulse and restoration of pink color were assumed to be due to the reperfusion of the intestine.

### Experimental protocol

The rats were randomly allocated into one of 3 equal groups ( $n = 8$ ): Sham,  $\Pi$ /R and EGb +  $\Pi$ /R. The surgical sham group underwent full surgical preparation including the isolation of SMA without the occlusion. In EGb +  $\Pi$ /R group, EGb 761 (100 mg/kg per day) was given *via* gastric tube for 7 consecutive days prior to surgery. EGb 761 was dissolved in normal saline at the concentration of 100 mg/mL. Rats in  $\Pi$ /R group and sham group were treated with equal volumes of the vehicle (normal saline solution) of EGb 761. EGb 761 was supplied by Zhejiang Kangenbei Pharmaceutical Company, China (No. 21003). It contains 24% ginkgo-flavonole glycosides and 6% terpenoids.

### Sample collection of blood and lung tissues

After 3-h reperfusion, blood samples were taken from carotid artery. A median sternotomy was performed, and the left main bronchus and right lower lobe bronchus were clamped. The trachea was cannulated and the right upper and middle lobes were lavaged three times with 2 mL of saline containing 0.07 mmol/L EDTA. The collected blood and bronchoalveolar lavage (BAL) fluids were centrifuged at 3000 r/min for 15 min, and the supernatant was stored at -80°C for subsequent measurement of protein content. The right lower lung lobe was divided into two parts for histology examination and the assessment of pulmonary edema. The left upper and lower lung lobes were used for biochemical and Western blotting analyses, respectively.

### Lung histology examination

Part of the right lower lung lobe was harvested and fixed in 10% formalin. After embedded in paraffin, sections of 8 mm were stained with hematoxylin and eosin for light microscopy.

### Assessment of pulmonary vascular permeability and pulmonary edema

Pulmonary permeability index (PPI) served as indicators of high pulmonary vascular permeability. PPI was assessed by the ratio of protein concentration in BAL fluid to that in plasma. The protein concentrations of blood and BAL fluid were detected by Coomassie brilliant blue method according to the manufacturer's instructions (Nanjing Jiancheng Corp., China). The severity of pulmonary edema was estimated by wet-to-dry lung weight ratio (W/D). After the wet weight of the lungs was measured, the lungs

were completely dried in a vacuum oven (DP22; Yamato Scientific, Tokyo, Japan) at 95°C for 48 h to remove any gravimetrically detectable water.

#### Detection of myeloperoxidase activity in lung tissue

Myeloperoxidase (MPO) activity was detected according to the method described by Barry *et al.*<sup>[20]</sup>. After weighing, the lung assay sample was homogenised in 5 mL of 0.5% hexadecyltrimethyl ammonium bromide (Sigma, U.K.) in 50 mmol potassium phosphate buffer (pH 6). The homogenate was freeze-thawed twice, and then centrifuged at 13 000 *g* for 5 min. The resulting supernatant was assayed spectrophotometrically for MPO activity by incubating 0.1 mL of the supernatant with 2.9 mL of solution B. Solution B was prepared by dissolving 2.9 mL of O-dionisidine hydrochloride (Sigma, U.K.) in 90 mL of distilled water and addition of 10 mL of 50 mmol potassium phosphate buffer (pH 6) and hydrogen peroxide (final concentration 0.0005%). The change in absorbance with time at 460 nm was then recorded continuously (Philips PU/VIS specvasculature trophotometer). One unit of MPO was defined as that degrading 1  $\mu$ mol peroxide per minute at 25°C. Results were expressed as units per gram of lung tissue.

#### Detection of oxidative stress in lung tissue

Lung tissues were homogenized on ice in normal saline. The homogenates were centrifuged at 4000 *r/min* at 4°C for 10 min. MDA levels in the supernatants were determined by measurement of thiobarbituric acid-reactive substance levels using MDA assay kit (Nanjing Jiancheng Corp., China) according to the manufacturer's instructions. The results were calculated as nmol per 100 mg of protein (nmol/100 mg). SOD activity in the supernatants was evaluated by inhibition of nitroblue tetrazolium (NBT) reduction by O<sub>2</sub><sup>-</sup> generated by the xanthine/xanthine oxidase system in accordance with the manufacturer's instructions (Nanjing Jiancheng Corp., China). The results were expressed as U/100 mg protein.

#### Detection of nitrite/nitrate in lung tissue

Lung tissues (100 mg) were weighed and made into 10% homogenates with 0.9 mL normal saline. After centrifugation for 10 min at 10 000 *r/min*, the supernatant was placed in boiling water for 3 min and then centrifuged for 5 min at 10 000 *g*. The supernatant (0.1 mL) was taken for the detection of nitrite/nitrate (NO<sub>2</sub><sup>-</sup>/NO<sub>3</sub><sup>-</sup>) production, an indicator of NO synthesis, with an NO assay kit (Nanjing Jiancheng Corp., China) following the manufacturer's instructions. Results were calculated as micromoles per 100 grams of protein ( $\mu$ mol/100 mg protein).

#### Western blotting analysis for inducible nitric oxide synthase in lung tissue

The left lower lung lobe was homogenized with PBS (pH 7.2) and centrifuged at 4°C, 18 000 *r/min* for 10 min. After precipitation, the unsolubilized fraction was discarded. The protein concentration in the supernatant was determined by Coomassie blue dyebinding assay (Nanjing Jiancheng Corp. China). Aliquots (30 mg) of

**Figure 1** Effects of EGb 761 (arrow indicates the starting point of reperfusion) on mean arterial pressure (MAP) after II/R in anaesthetized rats. A rapid drop in MAP was recorded immediately after the beginning of reperfusion of the ischemic bowel. Data are the means of 8 rats (SD not shown). EGb 761 markedly increased MAP. There were significant differences in MAP at all time points after reperfusion between II/R and EGb + II/R groups ( $P < 0.01$ ).

proteins from each sample were electrophoresed on a 120 g/L SDS-polyacrylamide gel for 4 h at 100 V. The protein samples were transferred onto a nitrocellulose membrane (Amersham, USA). The membrane was then probed with polyclonal rabbit anti-rat inducible nitric oxide synthase (iNOS) antibody (1:50 dilution, Santa Cruz Co., USA) for 2 h at 37°C. After 3 washes with TPBS, blots were visualized with the use of an amplified HRP kit (Wuhan Boshide Corp, China). The presence of iNOS was indicated by the presence of brown color.

#### Statistical analysis

Statistical analysis was performed using SPSS (version 10.1; SPSS for Windows, Chicago, IL) software. Data were expressed as mean  $\pm$  SD. One-way analysis of variance was used for multiple comparisons and least significant difference test (LSD-t) was used for intra-group comparison.  $P < 0.05$  was considered statistically significant.

## RESULTS

#### Changes in MAP

There was no death of any rats during the experiment. There were no significant differences in the weight of the rats and the temperature in the laboratory among the groups. Figure 1 illustrates the time course of MAP in the three experimental groups. A rapid drop in MAP was recorded immediately after the release of the arterial occlusion and the beginning of reperfusion of the ischemic bowel. EGb 761 significantly improved MAP. There was a significant difference in MAP at all time points after reperfusion between II/R and EGb + II/R groups ( $P < 0.01$ ).

#### Pathological changes of lung tissue

The histological structure of alveolar and mesenchymal cells was normal in the lungs of sham group (Figure 2A), while the lung tissues from II/R group were significantly damaged with pulmonary edema, hemorrhage and

**Figure 2** Light microscopic observation of the lung tissues after II/R with pretreatment of EGb 761 in rats. **A:** The normal lung tissue structure was found in sham group ( $\times 100$ ); **B:** Lung edema, hemorrhage and inflammatory cell sequestration were found in II/R group ( $\times 200$ ); **C:** Decreased morphological changes induced by II/R were found in EGb + II/R group ( $\times 200$ ).

inflammatory cell infiltration (Figure 2B). Pretreatment with EGb 761 could attenuate significantly the lung injury as shown by light microscopy (Figure 2C).

#### Changes in W/D and PPI in lung tissues

Compared with the sham group, the lung W/D and PPI in II/R group were increased significantly ( $P < 0.05$ ,  $P < 0.01$ ). Compared with the II/R group, the lung W/D and PPI in EGb + II/R group were significantly decreased ( $P < 0.05$  or  $0.01$ ) (Table 1).

#### Changes in MPO activity in lung tissues

MPO activity in II/R group was significantly higher than that in the sham group ( $P < 0.01$ ). Compared with II/R group, MPO activity in EGb + II/R group was markedly reduced ( $P < 0.01$ ), but still higher than that in the sham group ( $P < 0.05$ ) (Table 2).

**Table 1** Changes in W/D and PPI in lung tissues (mean  $\pm$  SD)

	<i>n</i>	Sham	II/R	EGb + II/R
PPI ( $\times 10^{-3}$ )	8	1.08 $\pm$ 0.42	4.02 $\pm$ 0.82 <sup>b</sup>	2.23 $\pm$ 0.45 <sup>a,c</sup>
W/D (%)	8	13.75 $\pm$ 5.18	29.62 $\pm$ 3.39 <sup>a</sup>	16.34 $\pm$ 6.45 <sup>d</sup>

<sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  vs sham group; <sup>c</sup> $P < 0.05$ , <sup>d</sup> $P < 0.01$  vs II/R group. W/D: Wet-to-dry lung weight ratio, PPI: pulmonary permeability index.

**Table 2** Changes in the activities of SOD and MPO, the levels of MDA and NO<sub>2</sub><sup>-</sup>/NO<sub>3</sub><sup>-</sup> in lung tissues (mean  $\pm$  SD)

	<i>n</i>	Sham	II/R	EGb + II/R
MDA (nmol/100 mg)	8	41.34 $\pm$ 6.45	68.52 $\pm$ 8.69 <sup>b</sup>	44.56 $\pm$ 6.13 <sup>d</sup>
SOD activity (U/100 mg)	8	101.8 $\pm$ 10.32	61.09 $\pm$ 6.52 <sup>b</sup>	84.36 $\pm$ 8.25 <sup>a,c</sup>
NO <sub>2</sub> <sup>-</sup> /NO <sub>3</sub> <sup>-</sup> ( $\mu$ mol/100 mg)	8	40.36 $\pm$ 9.68	78.54 $\pm$ 12.36 <sup>b</sup>	44.13 $\pm$ 8.56 <sup>d</sup>
MPO activity (U/g)	8	3.26 $\pm$ 0.78	6.93 $\pm$ 0.79 <sup>b</sup>	4.14 $\pm$ 0.76 <sup>a,d</sup>

<sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  vs sham group; <sup>c</sup> $P < 0.05$ , <sup>d</sup> $P < 0.01$  vs II/R group. MPO: Myeloperoxidase; NO<sub>2</sub><sup>-</sup>/NO<sub>3</sub><sup>-</sup>: nitrite/nitrate; MDA: malondialdehyde; SOD: superoxide dismutase.

#### Changes in lung MDA levels and SOD activity in lung tissues

MDA levels in II/R group were significantly higher than that in the sham group ( $P < 0.01$ ). Compared with II/R group, MDA levels in EGb + II/R group were markedly decreased ( $P < 0.01$ ). SOD activity in II/R group was markedly lower than that of the sham group ( $P < 0.01$ ). It was increased significantly in EGb + II/R group ( $P < 0.01$ ), but still lower than that of the sham group ( $P < 0.05$ ) (Table 2).

#### Changes in lung NO<sub>2</sub><sup>-</sup>/NO<sub>3</sub><sup>-</sup> levels in lung tissues

Compared with the sham group, lung NO<sub>2</sub><sup>-</sup>/NO<sub>3</sub><sup>-</sup> levels in II/R group were increased significantly ( $P < 0.01$ ). Compared with the II/R group, NO<sub>2</sub><sup>-</sup>/NO<sub>3</sub><sup>-</sup> levels in EGb + II/R group were decreased significantly ( $P < 0.01$ ) (Table 2).

#### Changes in iNOS expression in lung tissues

Western blotting showed that very weak positive signals were found in the lung tissues of the sham group. Significant increases of iNOS protein expression were seen in the II/R group. There were still notable positive signals in EGb + II/R group, but it was weaker for the II/R group (Figure 3).

## DISCUSSION

Currently, EGb 761 is commonly used in treating cardiovascular diseases and cerebral vascular diseases in many countries. As far as we know, the present study is the first to investigate its effects on II/R-induced lung injury. The results showed that EGb 761 can markedly improve MAP and attenuate lung injury, manifested by the improvement of the histological damage and significant decreases of pulmonary W/D and PPI (variables related to lung injury). These findings suggest that the administration

**Figure 3** Western blotting analysis of iNOS in rat lung. 1. Sham group; 2. II/R group; 3. EGb + II/R group. The intensity of the bands was greater in II/R group compared with EGb + II/R group. A prominent band of iNOS protein was demonstrated at approximately 70 Kd.

of EGb 761 may be a potential effective therapeutical approach for the prevention from II/R-induced lung injury.

The mechanisms of lung injury after II/R are complex and poorly understood. It is thought that the damage of intestinal mucosal barrier following II/R causes the dislocation of bacteria or endogenous endotoxins, leading to systemic inflammatory reactions<sup>[20-22]</sup>. The neutrophil and their enzymatic products are sequestered in lung tissues, which causes increased microvascular permeability, perivascular and interstitial edema, and pulmonary edema<sup>[4,22,23]</sup>.

MPO is a haem-containing enzyme located within the azurophil granules of neutrophils, and its activity is known as an indicator of tissue neutrophil accumulation<sup>[24]</sup>. The present study showed that EGb 761 markedly reduced MPO activity, suggesting that its protective effect on II/R-induced lung injury might be related to the suppression of neutrophil accumulation. Our findings are well supported by previous studies, in which EGb 761 suppressed neutrophil sequestration in hepatic and renal tissues evidenced by decreased MPO activity<sup>[25,26]</sup>. Previous studies also demonstrated that EGb 761 increases peripheral and cerebral blood flow and improves microcirculation, and reduces capillary permeability<sup>[27,28]</sup>, indicating the effect of EGb 761 on neutrophil accumulation. However, the related mechanisms need further investigation.

It is well documented that lipid peroxidation due to II/R is one of the main causes for lung injury<sup>[6,7]</sup>. MDA is the direct product of lipid peroxidation. Therefore, the extent of lipid peroxidation can be assessed by measuring MDA levels in tissues<sup>[29]</sup>. SOD is the major enzyme for scavenging oxygen free radicals, and its activity can reflect its functional status<sup>[30]</sup>. Previous studies have shown that EGb 761 can interact as a free radical scavenger and an inhibitor of lipid peroxidation with all, or nearly all, reactive oxygen species<sup>[27]</sup>. In the present study, EGb 761 was demonstrated to inhibit MDA production and increase SOD activity, suggesting that the inhibition of lipid peroxidation may be one of the mechanisms attributable to the protective effects of EGb 761 on II/R-induced lung injury.

Several recent observations implicate that NO may be an important participant in the pulmonary response to II/R<sup>[31]</sup>. It has been suggested that NO, produced from endothelial constitutive nitric oxide synthase (ecNOS), may be an important protective molecule at the onset of II/R. In this regard, inhibitors of endogenous NO production greatly exacerbate the increase in epithelial permeability and cardiovascular dysfunction in the reperfused post-

ischemia intestine<sup>[31,32]</sup>. Excessive NO production has been attributed to the second NOS (inducible NOS, iNOS) that is not present under normal conditions but can be induced in response to systemic inflammatory states, including II/R. The induction of iNOS has been implicated in the pathogenesis of II/R and it was reported that the inhibitions of iNOS activity and NO production could attenuate II/R injury<sup>[10,33]</sup>. In the present study, we further studied the contribution of iNOS to II/R-induced lung injury. The results showed that 60 min of intestinal ischemia followed by 180 min of reperfusion significantly upregulated the lung iNOS expression, accompanied by marked elevation of pulmonary nitrate/nitrite (stable metabolites of NO) levels. This is consistent with the findings of Virlos *et al*<sup>[10]</sup>, who demonstrated that pulmonary iNOS activity in rats subjected to II/R was significantly increased and of Zhou *et al*<sup>[8]</sup>, who showed that systemic inflammatory response and lung injury occur following II/R with an overproduction of NO accompanied by the increases of iNOS expression and the formation of peroxynitrite in the lungs. The mechanisms of the cytotoxic actions of excessive NO production have not been fully understood. It has been suggested that the superoxide ions react with NO to produce peroxynitrite, which then causes accentuated lipid peroxidation, proteic and DNA modifications resulting in cellular damages<sup>[34]</sup>. Taken together, the iNOS-NO-peroxynitrite dependent pathway may be one of the mechanisms of II/R-induced lung injury.

The effect of EGb 761 on NO generation in lung tissue following II/R was studied for the first time in the present study. The results showed that EGb 761 significantly reduced the generation of NO accompanied by the down-regulation of iNOS expression. Varga *et al* showed that EGb 761 directly acts as an NO scavenger and concomitantly inhibits the expression of iNOS mRNA in myocardial tissues, thus improving the recovery of postischemic cardiac function after myocardial ischemia/reperfusion<sup>[35]</sup>. In addition, EGb 761 inhibits NO production in lipopolysaccharide/gamma interferon (LPS/IFN- $\gamma$ )-activated macrophages by concomitantly scavenging NO and inhibiting iNOS mRNA and enzyme activity<sup>[36,37]</sup>. Although the experimental models employed in previous studies are different from the present study, these findings can, at least in part, support our current conclusion that the protective effect of EGb 761 on lung injury may be attributable to its suppression on the iNOS-NO dependent pathway.

There is little information on the mechanisms of the effect of EGb 761 on the iNOS-NO dependent pathway. A most recent study showed the preventive effect of EGb on the lipopolysaccharide-induced expressions of iNOS *via* the suppression of nuclear factor-kappaB (NF- $\kappa$ B) in RAW 264.7 cells. Thus, the suppression of NF- $\kappa$ B might be the potential mechanism underlying the findings that EGb 761 reduces NO production and concomitantly inhibits iNOS expression in lung tissues following II/R<sup>[38]</sup>.

There are some limitations in the present study. First, EGb 761 is a specific and complex product prepared from ginkgo leaves. EGb 761 used in this study contained 24% ginkgo-flavonole glycosides and 6% terpenoids. Which

components produce the protective effect or work more in protecting against II/R-induced lung injury in the present study remains to be elucidated. Second, we did not employ selective inhibitor of iNOS to strengthen the present conclusion, because we focused on investigating the protective effect of EGb 761 on lung injury and thus only preliminarily studied the related mechanisms.

In conclusion, the present study indicates that EGb 761 has a protective effect on lung injury induced by II/R, which may be related to its antioxidative property and the suppressions of neutrophil accumulation and iNOS-induced NO generation. EGb 761 appears to be an effective therapeutic agent for some critically ill patients with respiratory failure related to II/R, although its mechanisms remain to be elucidated.

We thank Dr. You-Kai Zhu and Dr. Ming-Qi Zhao for their help with experimental techniques.

## COMMENTS

### Background

EGb 761 is widely used in treating cardio-cerebral vascular diseases mainly due to its action of anti-oxidative damage; however, there is no report about its effect on lung injury induced by intestinal ischemia/reperfusion. The present study was undertaken to confirm the above hypothesis and elucidate the mechanisms related to pulmonary lipid peroxidation, neutrophil sequestration and nitric oxide (NO) production regulated by induced nitric oxide synthase (iNOS) expression.

### Research frontiers

EGb 761 has been reported to be effective for the disorders such as Alzheimer's disease and neuronal hypoxia and to protect the heart against ischaemia/reperfusion damage and to alleviate vascular endothelial cell injury, which all have etiologies associated with oxidative stress.

### Innovations and breakthroughs

Previous studies showed the protective effect of EGb 761 on cardio-cerebral ischemia/reperfusion injury and intestinal mucosa injury following intestinal ischemia/reperfusion (II/R). The present study indicates that EGb 761 has a protective effect on lung injury induced by II/R and the mechanism may be related to its antioxidative property and the suppressions of neutrophil accumulation and iNOS-induced NO generation.

### Applications

Remote lung injury induced by intestinal ischemia reperfusion (II/R) due to acute mesenteric ischemia, hemorrhagic, traumatic or septic shock, or severe burns and some surgical procedures including small bowel transplantation and abdominal aortic surgery often leads to the clinical picture of acute respiratory distress syndrome. EGb 761 has been demonstrated to have the protective effect on lung injury and thus appears to be an effective therapeutic agent for some critically ill patients with respiratory failure related to II/R.

### Terminology

Excessive production of nitric oxide (NO) is attributed to the upregulation of inducible nitric oxide synthase (iNOS) expression that is not present under normal conditions, but can be induced in response to systemic inflammatory states, including II/R. NO can react with superoxide ions to produce peroxynitrite, which then causes accentuated lipid peroxidation, proteic and DNA modifications, resulting in cellular damages. This is described as an iNOS-NO-peroxynitrite dependent pathway.

### Peer review

This manuscript is very interesting. The title accurately reflects the major contents of the article. The results provide sufficient experimental evidences from which

conclusions are drawn. The conclusions are scientifically reliable and valuable.

## Abstract

While cardiopulmonary symptoms are common in patients undergoing classical or, due to physical exercise, exertional heat stroke, the failure of other organs is a rarely described phenomenon. Here we present two cases of acute hepatic failure, one due to classic heat shock, while the other occurred while the patient was doing a marathon-type running. Both cases presented with very high transaminases and significantly elevated international normalized ratio (INR). No other causes for liver failure could be identified but physical exhaustion and hyperthermia.

## INTRODUCTION

Heat stroke is a life-threatening condition that can be fatal if proper assessment and treatment are not initiated rapidly<sup>[1,2]</sup>. A variable degree of organ involvement is present in heat stroke<sup>[3]</sup>. At the beginning, there is heat exhaustion, characterized by nonspecific symptoms such as malaise, headache and nausea. Untreated this illness results in heat stroke, a serious disease possibly involving central

nervous system dysfunction, rhabdomyolysis, arrhythmias, disseminated intravascular coagulation and hepatic failure, not uncommon followed by death<sup>[4]</sup>.

The current model of heat stroke favors hyperthermia as trigger, while endotoxaemia drives the disease. However, the pathology is not fully understood<sup>[2]</sup>. In athletes undergoing intense training a variety of immune and gastrointestinal disturbances can occur. We here describe two completely different causes of heat stroke resulting in acute and severe liver failure as leading symptom.

## CASE REPORTS

### Case one

A 23-year old male was delivered to our intensive care unit (ICU) after he collapsed running a half-marathon. He had no former medical history and was in good physical shape. He took no medication and was negative for an obtained drug screening. By admission he felt fatigue and complained about nausea and vomiting. The laboratory results showed elevated levels of 12427 U/L creatinine kinase (CK) (normal < 145 U/L), 5821 U/L lactate dehydrogenase (LDH) (normal < 248 U/L), 8378 U/L aspartate aminotransferase (AST) (normal < 31 U/L), 9765 U/L alanine aminotransferase (ALT) (normal < 34 U/L), 40 mg/dL bilirubin (normal < 1.0 mg/dL) and 2.8 international normalized ratio (INR) (normal < 1.2) (Figure 1). The other basic laboratory parameters were within normal range. The patient was monitored and treated with intravenous fluid (5 to 6 liters per 24 h).

To exclude other causes for acute hepatic failure, virus serologies were obtained. Besides positive IgG of hepatitis A and B due to immunization, there were no serological findings for acute or chronic hepatitis A, B, C or human immunodeficiency virus (HIV). Also acute infection with cytomegalovirus (CMV), herpes simplex virus (HSV) or Epstein-Barr virus (EBV) was ruled out. The autoimmune antibodies (ANA, ANCA, SMA, LKM, mitochondrial antibodies) were also negative. In addition, protein electrophoresis gave no pathologic findings. Serum levels for alpha-1-antitrypsin, iron and transferrin were within normal range. Ferritin was raised to 29490 µg/L (normal 30-300 µg/L), probably due to destruction of hepatocytes. Because of lowered caeruloplasmin (serum) and copper (serum and 24-h urine) levels, a liver biopsy was performed. The histology showed intact architecture of the lobules. Portal fields showed no signs of fibrosis or inflammatory infiltration. Accentuated centrilobular

**Figure 1** Basic laboratory parameters of a 23-year-old male patient presenting with liver failure after exertional heat stroke. **A:** Creatinine kinase (CK), lactate dehydrogenase (LDH), aspartate aminotransferase (AST) and alanine amino-transferase (ALT) at admission and during progression in a linear scale; **B:** Creatinine and urea in a logarithmic scale; **C:** Bilirubin and international normalized ratio (INR) in a linear scale.

**Figure 2** HE-staining of a liver biopsy derived from a 23-yr-old male presenting with liver failure after exertional heat stroke. Microscopy showed liver tissue with intact architecture of the lobules. Portal fields showed no signs of fibrosis or inflammatory infiltration. Accentuated centrilobular necrosis was accompanied with fatty degeneration of hepatocytes. Additionally, focal bile inclusions were found without Mallory bodies, iron debris and atypical cellular proliferation. Altogether, the morphological picture does not fit acute Wilson's disease, hemochromatosis or infection, but ischemic liver disease.

necrosis and fatty degeneration of hepatocytes were seen. Additionally, focal bile inclusions were found. Altogether, the morphological picture did not fit acute Wilson's disease, hemochromatosis or infection, but ischemic liver disease (Figure 2).

Abdominal ultrasound including duplex sonography, besides a slight hepatosplenomegaly, demonstrated no abnormal findings. To exclude a cardiac reason for the patient's collapse, both a 24-h electrocardiogram and an echocardiogram showed normal heart function and structure.

The patient stayed in the ICU for 5 d, while the laboratory results were declining (Figure 1) (208 U/L LDH, 676 U/L AST, 1438 U/L ALT, 2.2 mg/dL bilirubin, 1.1 INR). Initially, the CK did rise to levels higher than 30 000 U/L, but on d 5 after admission it dropped to 4948 U/L. Renal function was normal at all times due to high fluid application and keeping the urine-pH above 7.5. On d 6, the patient was transferred from ICU to a regular ward in good health and mostly recompensated laboratory

parameters for further monitoring. At follow-up one week later the patient was in good health and showed normal laboratory parameters.

### Case two

A 46-year old male was delivered to our ICU after he had collapsed due to heat shock. His working place was below a roof window and it was a very hot day. In the after-noon, after working all day, he finally suffered from a seizure and was found cardiorespiratory stable but unconscious with his temperature of 42°C.

By admission laboratory findings demonstrated a clinical picture of acute hepatic failure with very high levels of transaminases (15 929 U/L AST, 10 050 U/L ALT), bilirubin (1.9 mg/dL) and malfunction in liver synthesis (1.9 INR) (Figure 3). Further laboratory parameters showed an elevated LDH (15 831 U/L), CK (6452 U/L), Troponin T (1.18 µg/L, normal < 0.03 µg/L), creatinine (1.78 mg/dL, normal < 1.3 mg/dL) and urea (50 mg/dL, normal < 45 mg/dL). All other basic parameters were within normal range.

Besides a seizure in 1989 due to an intra-cerebral bleeding, the patient had no past medical history. We started to treat him with intravenous fluid (5 to 6 liters per 24 h). Because of acute renal dysfunction he was treated two times with hemodialysis.

To exclude other reasons for acute hepatic failure he received further examinations. An abdominal ultrasound including duplex sonography showed no alterations. No pathologic serum markers for alpha1-antitrypsin, caeruloplasmin, copper, iron, ferritin, AFP or autoimmune antibodies (ANA, ds-DNA, ANCA, LKM, SMA, mitochondrial antibodies) were observed. Virus serologies were positive for HSV-IgG, VZV-IgG, EBV-IgG, but negative for IgM, as a parameter for acute infection. Hepatitis A was IgG positive due to immunization. All other infectious causes tested, like CMV, influenza A and B, hanta virus, hepatitis B and C, HIV and leptospirosis, were negative. Additionally, an obtained drug screening was negative.

The patient was further monitored in our ICU and received treatment of cooling and intravenous fluid. The

**Figure 3** Basic laboratory parameters of a 46-year old male presenting with liver failure due to classic heat stroke. **A:** Creatinine kinase (CK), lactate dehydrogenase (LDH), aspartate aminotransferase (AST) and alanine amino-transferase (ALT) at admission and during progression in a linear scale; **B:** Creatinine and urea in a logarithmic scale; **C:** Bilirubin and international normalized ratio (INR) in a linear scale.

patient regained consciousness within 36 h after therapy was started and the abnormal laboratory parameters excluding creatinine and urea, returned slowly to normal within a few days. Because of the elevated myocardial enzymes at admission, an echocardiogram and an electro cardiogram (ECG) were obtained. While the ECG was normal, the echocardiogram showed a very mild hypertrophic obstructive cardiomyopathy (HOCM), unknown so far, but a good right and left ventricular function and no contraction disorders of the myocardium. Also, the patient did not suffer from chest pain or dyspnoea at all times.

Six days after admission the patient had lowered laboratory parameters (Figure 3) (512 U/L LDH, 620 U/L AST, 1889 U/L ALT, 1.7 mg/dL bilirubin, 4376 U/L CK, 0.35  $\mu$ g/L TNT, 1.0 INR), but still high urea and creatinine levels. He was transferred to a nephrology ward where he continued to get hemodialysis, until the kidney function was resolved. Twenty-three days later he presented again at the outpatient clinic with almost normalized laboratory parameters (Figure 3).

## DISCUSSION

Described in this paper are two cases of acute hepatic failure due to physical exhaustion/heat shock. While the first patient had no other organ disorders, the second suffered from multi-organ failure including heart, kidneys and brain, and mainly liver malfunction.

It has been rarely reported that physical exhaustion can lead to hyperthermia, coma, rhabdomyolysis and organ failure<sup>[5,6]</sup>. Classic heat stroke however, is a more common disease with the life-threatening core body temperature higher than 40.5°C. Its associated clinical manifestations are exsiccosis, fatigue, nausea, vomiting, disorientation and coma<sup>[7]</sup>. Possible complications are cardiopulmonary dysfunction, acid-base or electrolyte disorders, as well as failure of other organs. Recently, a study demonstrated that 21 of 28 patients with heat stroke developed organ dysfunctions. Acute respiratory distress syndrome is the frequently encountered complication<sup>[8]</sup>, while liver malfunction has not been reported. Our two cases indicate

that liver failure may be more often than expected. Liver failure due to heat stroke begins with the same common symptoms, like nausea and exhaustion. When collapse, hyperthermia and multi-organ failure occur, it may be diagnosed<sup>[9]</sup>, indicating that a rise in liver enzymes is an important predictive factor<sup>[8]</sup>. In our cases, liver failure was the leading symptom, causing cerebral disorders and renal dysfunction. Liver transplantation is the only possible treatment for severe hepatic damage. Recently, the first long-term follow-up of liver transplantation for hepatic failure due to heat stroke has been reported<sup>[10]</sup>.

The recommended treatment for such severe cases is fluid application and rebalancing acid-base and electrolyte disorders as well as close monitoring, except for liver transplantation. Other treatments, like application of human umbilical cord blood cells as described in rats, to lower intracerebral changes due to heat stroke, remain speculative and under experiment at present<sup>[11]</sup>.

The mechanism underlying liver failure in heat shock patients is not totally understood. An earlier study showed that systemic or intrahepatic circulatory disturbance as seen in disseminated intravascular coagulation (DIC), may be the cause<sup>[12]</sup>. In one case, a portal vein thrombosis has been found<sup>[9]</sup>, which could result in liver and other organ failure. However, in our cases, the duplex sonography showed no big vessel thrombosis, whereas DIC could not be excluded. Although DIC could explain the raised liver enzymes in our second case, the cardiac problems due to HOCM contributing to the liver failure could not be ruled out. Nevertheless, we think that a cardiac reason is unlikely, because the right and left ventricular function of the patients was excellent at all times.

It has been reported that the intracranial pressure rises and cerebral ischemia occurs due to lower arterial pressure during heat stroke, resulting in lower blood flow and intracranial pO<sub>2</sub><sup>[11]</sup>. It remains for further study if the same mechanism is responsible for liver damage. If so, this could result in a therapeutic application of vasoactive substances to increase intrahepatic blood flow in patients with severe liver damage after heat stroke.

Another review published in 2004 has discussed a possible function of immune response in organ failure

of patients suffering from hyperthermia during physical exercise<sup>[13]</sup>. Since a reduced splanchnic blood flow which can result in gastrointestinal barrier dysfunction and increased permeability can be measured, endotoxin causing immune reactions could enter internal organs and drive organ damage. This may lead to the assumption that application of immune suppressive medication could be tested.

Besides liver malfunction, renal problems were the leading cause of liver failure in our cases. This is most likely explained by exsiccosis. Nevertheless, it is also possible that the high CK is an additionally cause of renal disorder.

In conclusion, patients with hepatic failure due to physical exhaustion or heat stroke should be closely monitored and severe problems like bleeding, hepatic coma and acute renal malfunction should be recognized as early as possible.

## Abstract

Cutaneous melanoma is one of the most studied neoplastic lesions in biology and clinical oncology. It has been well documented that this type of neoplasm presents a high metastatic rate, and is able to involve nearly every tissue. Non-cutaneous melanoma represents an unusual pattern of melanoma, and the small intestine is an uncommon anatomic localization. Herein we report an extremely rare clinical case of a young woman affected by a bleeding jejunal melanoma, whose early clinical presentation was an intestinal invagination.

Resta G, Anania G, Messina F, de Tullio D, Ferrocchi G, Zanzi F, Pellegrini D, Stano R, Cavallesco G, Azzena G, Occhionorelli S. Jejuno-jejunal invagination due to intestinal melanoma. *World J Gastroenterol* 2007; 13(2): 310-312

<http://www.wjgnet.com/1007-9327/13/310.asp>

## INTRODUCTION

Cutaneous melanoma is a malignancy characterized by a high mortality rate. It can metastasize to all organs, although the gastrointestinal tract is an unusual metastatic localization. In 50% of cutaneous melanomas, in fact, metastases in the gastroenteric tract are diagnosed upon autopsy, and only in 5% of cases, they are diagnosed clinically<sup>[1,2]</sup>. Intestinal metastases of cutaneous melanomas

are linked to a baleful prognosis, with a survival average of 6-10 mo after surgery<sup>[3,4]</sup>.

Many studies have demonstrated that only surgery can lead to a control of chronic anemia related to intestinal melanoma bleeding and resolution of the episodes of intestinal sub-occlusion. Surgery on melanoma metastases moreover, can guarantee an increase of survival, in addition to an excellent improvement in quality of life<sup>[5-7]</sup>. Intestinal metastases represent the occurrence of an occult skin melanoma in only 3%-5% of cases, in which a spontaneous regression of the cutaneous lesion happens<sup>[8]</sup>. Intestinal metastasis bleeding is extremely rare<sup>[9,10]</sup>.

In order to add more information about surgical presentation of intestinal occult melanoma herein we describe a case of a young woman affected by bloody jejunal metastasis of occult cutaneous melanoma, complicated by intestinal invagination-an extremely rare case in the adult population.

## CASE REPORT

A 45-year old woman complained of continual nausea and biliary vomiting, associated with a weight loss of 5 kg. Due to localized abdominal pain, mainly in the right hypochondrium and episodes of hematemesis, the patient was admitted to our hospital. Blood tests revealed sideropenic anemia with 81 g/L haemoglobin, serum iron 100 pg/L, ferritin 23 µg/L, and fecal occult blood test (FOBT) positive in three fecal samples. A gastroscopy was performed, which showed the presence of grade I esophagitis, moderate hiatal hernia and chronic erosive gastritis. The colonoscopy was incomplete due to the presence of colic stools. Abdominal ultrasonography highlighted a distension of the intestinal loops without signs of parenchymatous organ pathology. The patient therefore received an abdominal CT, which suggested the presence of a gastric distension with duodenum-jejunal distension and the presence of a jejunal loop with thickened walls. A second hyperdense image inside the intestinal lumen, forming a target-shaped image was also present: typical feature of intestinal invagination (Figure 1). We therefore decided to proceed to urgent surgical operation after blood transfusion. During surgery, intra-peritoneal fluid was found and samples were removed for cytological testing. Invagination at the third jejunal loop (Figure 2) was evidenced. The presence of hypertrophic lymphatic tissue with intestinal mesenteric lymphadenomegalia was also present. Manual resolution of the invagination was carried out. This procedure highlighted the presence of a hyperchromic ulcerated neo-

**Figure 1** Duodenum-jejunal distension and the presence of a jejunal loop with thickened walls, with a second hyper-dense image inside the same lumen, forming a target-shaped aspect characteristic of intestinal invagination.

**Figure 4** Ileal wall infiltrated with metastatic melanomatous cells with nuclear pseudoinclusions and nucleoli, in nest and trabecular arrangement (HE x 10).

**Figure 2** Invagination at the third jejunal loop.

**Figure 3** Presence of a hyperchromic ulcerated neoformation, with signs of recent bleeding of the serosa.

formation, with obvious signs of recent bleeding coming from the serosa (Figure 3).

Thorough exploration of the abdominal cavity did not detect further replicative lesions. Resection of the third jejunal loop containing the neoformations and the whole underlying mesentery with its lymph nodes, was performed. The intestinal continuity was restored through a latero-lateral jejuno-jejunal anastomosis.

The post-operative course was uneventful and the patient was discharged after 10 postoperative days. The definitive histological examination showed the presence of an intestinal metastasis of cutaneous melanoma of unknown origin (Figures 4 and 5). The patient was then re-

**Figure 5** Strong positivity at immunohistochemical assay for HMB45.

ferred to an oncologic centre for the search of the primary melanoma localization. At three, six months and a year follow-up, the patient is alive and no signs of skin melanoma have been detected.

## DISCUSSION

The peculiar rarity of this clinical case represents the principal reason for our interest. In spite of the clinical manifestation and the diagnostic-therapeutic approach adopted, this case presents many conditions that have been previously poorly documented in international literature.

Our patient presented a chronic anemia and repeated biliary vomiting that were related to the erosive gastritis and esophagitis identified by the gastroscopy, even if this did not necessarily exclude chronic bleeding from neoplastic lesions. The pre-operative CT scan of parajejunal lymphadenomegalia prompted us to suspect the presence of a neoplastic lesion causing the jejunal invagination. Jejunal invagination in an adult, in fact, can cause 1%-3% of surgically treated intestinal occlusion but is mainly due to peritoneal adhesion or to the presence of intestinal anastomosis<sup>[11]</sup> and less frequently to a neoplasm. Melanoma intestinal metastasis is clinically diagnosed only in 3%-5% of cases, and is usually found to affect the stomach or the colon. Jejunal location is much less frequent<sup>[12]</sup> and, if present, does not show clinical signs till diagnosed at autopsy. A diagnosis based on the finding of metastatic

lesions, without identification of the primary cutaneous source, as described in our report, is carried out in only 3% of melanomas. Even if the etiology of primary gastrointestinal melanomas remain undefined, some authors suggest that primary gastrointestinal melanomas are derived from melanoblastic cells of the neural crest which, migrating through the omphalomesenteric canal or APUD cells, reach the intestinal tract, undergoing neoplastic transformation<sup>[13]</sup>. Non-cutaneous melanomas represent a rare form of melanoma. In a review of 84 836 cases of melanoma, 91.2% were cutaneous, 5.2% ocular, 2.2% of unknown primary site and only 1.3% of gastrointestinal mucosa<sup>[14]</sup>. Melanomas that arise on mucosal surfaces appear to be more aggressive and are associated with worse prognosis than cutaneous melanomas. The poorer prognosis may be related to the delay in diagnosis, to their more aggressive behaviour, or to earlier dissemination because of the rich lymphatic and vascular supply of the gastrointestinal mucosa<sup>[15,16]</sup>.

Our case shows that the presence of an early complication due to intestinal occlusion, through a sequential and appropriate instrumental diagnostic evaluation, gave us the opportunity to identify a rare melanotic lesion. Moreover, the right surgical approach has given us the opportunity to improve the length and quality of the life of this unlucky patient.

### Abstract

Gallbladder localization of heterotopic pancreas (HP) is uncommon and very rarely gives rise to symptoms. Herein we report a case of HP found in the gallbladder neck presented with signs and symptoms of cholecystitis. The patient was a 40-year old male, suffering from epigastric pain, abdominal fullness and fever. On physical examination, the right upper abdomen was tender with a positive Murphy's sign. Ultrasonographic examination showed a hydrotic gallbladder without stones and he underwent a cholecystectomy. Pathological examination revealed an intramural nodule (9 mm) in the neck region which is consisted of acini, ducts and islet cells of an aberrant pancreatic tissue. Although HP is encountered rarely in the gallbladder and is found incidentally during pathological studies, this case emphasizes that HP might cause symptoms and present clinically as cholecystitis. For this reason, in patients presenting with symptomatic gallbladder diseases, including cholecystitis without any other pathology, HP should be taken into consideration before it is diagnosed as "idiopathic".

### INTRODUCTION

Heterotopic pancreas (HP) is defined as the presence of pancreatic tissue lying outside its normal location and

lacking anatomical or vascular continuity with the pancreas proper<sup>[1]</sup>. In 85% to 90% of reported cases, HP has been found in stomach, duodenum, upper jejunum, whereas its presence in the gallbladder is very rare<sup>[1-3]</sup>. Similar to HP of other organs, HP of the gallbladder itself has no clinical importance and is found incidentally in most cases. However, there have been some reports of symptomatic gallbladder disease<sup>[4-7]</sup>. Herein we report a case of HP in the neck of the gallbladder who presented with clinical findings of cholecystitis.

### CASE REPORT

A 40-year old male presented to the hospital with epigastric pain, abdominal fullness and fever three days ago. On physical examination, the right upper abdomen was tender with a positive Murphy's sign. His laboratory data revealed total bilirubin = 1.5 mg/dL, direct bilirubin = 0.8 mg/dL, ALP = 398 U/dL, SGOT = 70 U/dL, SGPT = 60 U/dL, GGT = 90U/dL. Ultrasonographic (US) examination showed a hydrotic gallbladder without stones. A cholecystectomy was performed. The macroscopic findings were as follows: gallbladder measuring 80 mm × 50 mm × 40 mm, wall thickness 3-12 mm. In the neck region, a yellowish-white intramural nodule measuring 9 mm × 8 mm × 8 mm was observed. Microscopic examination revealed aberrant pancreatic tissue consisting of acini, ducts and chromogranin A expressing islet cells. No direct connection with the gallbladder lumen was observed (Figure 1). The whole specimen was embedded stepwise for further microscopic evaluation, but any other pancreatic tissue was not detected. The diagnosis was thereby established as chronic cholecystitis with heterotopic pancreas. All symptoms disappeared following cholecystectomy and the patient recovered completely.

### DISCUSSION

Although HP is the second most prevalent pancreatic anomaly, the incidence in gastrointestinal tract is estimated to be from 0.55% to 13.7% on autopsy, and 0.2% in laparotomy<sup>[6]</sup>. Despite the frequent occurrence of HP in the stomach, duodenum and upper jejunum, the gallbladder localization is extremely rare. Since the first publication by Poppi in 1916, only 29 more cases of HP worldwide in the gallbladder have been reported in a review of the literature up to the present<sup>[8]</sup>. In these cases there is a higher incidence of female patients between 40 and 50 years of age<sup>[9]</sup>. However, similar to our case, its

**Figure 1** Histological sections of HP showing dilated ducts (arrows, H&E x 100) and acini (A), acinar and islet cells (asterisk, H&E x 250) (B), and chromogranin A expressing islet cells (Mayer's haematoxylin x 250) (C) in submucosa of gallbladder neck.

occurrences have been reported in men. In half of the reported cases, HP is preferentially localized close to the neck of the gallbladder<sup>[9]</sup>. Parallel to this observation, in our patient HP was located in the neck region.

HP in the gallbladder is very rarely symptomatic. In most reported cases, it is an incidental pathological findings and coexists with gallstones<sup>[9,10]</sup>. However, there have been some reported symptomatic gallbladder diseases due to HP<sup>[4-7]</sup>. In one case HP has been found to cause perforation of the gallbladder and lead to peritonitis<sup>[5]</sup>. Similar to our case, in two cases HP has been found to stimulate cholecystopathy with all symptoms disappearing following cholecystectomy<sup>[4,7]</sup>. Inceoglu *et al*<sup>[6]</sup> have reported a case of HP in the cystic duct with hydrops of the gallbladder and chronic pancreatitis of the ectopic tissue. In all cases including the case presented here, because of its rare occurrence as a symptomatic lesion, HP is not taken into consideration in the clinical differential diagnosis. Indeed, as in other organs, the preoperative diagnosis of HP in gallbladder is difficult<sup>[10,11]</sup>. Symptomatology and clinical findings in most cases suggest gallbladder disease, mainly lithiasis and cholecystitis<sup>[9]</sup>. It was pointed out that HP located especially in the neck region might prevent bile flow like a stone and cause hydrops of the gallbladder mimicking the clinical findings of these diseases<sup>[6]</sup>. From this point of view, in our case localization of HP in the neck region might explain the clinical findings of cholecystitis related to hydrops of the gallbladder without cholelithiasis. Recently it was indicated that, despite its high resolution, US is not specific for HP and impossible to distinguish HP from other lesions such as cholesterol polyps, adenoma and carcinoma<sup>[9,11]</sup>. Parallel to these observations, in our case while US examination revealed a hydropic gallbladder without stones, it failed to detect HP. For these reasons, we suggest that the rare occurrence of HP in the gallbladder and its presence as an incidental finding in cholecystectomy materials do not exclude its consideration in the differential diagnosis of symptomatic gallbladder diseases.

Our histopathological examination revealed a HP constituted of acini, ducts and islet cells, corresponding to the total heterotopia<sup>[8]</sup>. Although pancreatitis may occur in HP, the present case had no histopathological findings of pancreatitis<sup>[6]</sup>.

The origin of heterotopic pancreatic tissue is controversial but two theories have been proposed. One suggests that pancreatic tissue is separated from the main pancreas during embryonic rotation<sup>[5,6]</sup>, the other is that during the growth of the ventral pancreatic bud a proportion is transported by the longitudinal growth of the intestines<sup>[5,6]</sup>. Therefore its presence in the gallbladder might indicate derivation from the ventral diverticulum. On the other hand, the site of organ/tissue formation is also determined by strictly coordinated developmental programs involving interplay between extracellular signaling and intracellular transcriptional factor networks. It has been demonstrated that in mammals the developmental decisions according to the state of the immediate neighbors are controlled through the Notch signaling system<sup>[12]</sup>. Several studies indicate that this system also plays an essential role in the precise orchestration of cell-fate decisions in the developing pancreas<sup>[13]</sup>. Hes-1 (Hairy enhancer of split), a main effector of Notch signaling is required for region-appropriate specification of the pancreas in the developing foregut endoderm<sup>[14]</sup>. In experimental studies, ectopic pancreas formation has been observed in Hes-1 knockout mice and the plasticity of endodermal progenitors of the gut, bile duct, and pancreas has been suggested<sup>[14,15]</sup>. In light of these observations, we consider that besides two proposed theories, abnormalities in the Notch signaling system, especially in Hes-1 expression during embryogenesis may also contribute to the formation of HP of the gallbladder.

In conclusion, HP of the gallbladder is a very rare condition which is diagnosed incidentally, but may cause clinical symptoms such as cholecystitis and should be taken into consideration in patients with symptomatic

gallbladder disease without any other specific clinical and laboratory findings before it is diagnosed as idiopathic.

## Abstract

The early hypersensitivity reaction and late bone marrow depression are well-known side-effects of azathioprine, whereas interstitial pneumonia is a rare complication. A 40-year old male patient had been treated with azathioprine in consequence of extensive ulcerative colitis for 10 years. He then complained of 7 d of fever, cough and catarrhal signs, without symptoms of active colitis. Opportunistic infections were ruled out. The chest X-ray, CT and lung biopsy demonstrated the presence of interstitial inflammation. Azathioprine therapy was discontinued as a potential source of the pulmonary infiltrate. In response to steroid therapy, and intensive care, the pulmonary infiltrate gradually decreased within 4 wk. Three months later, his ulcerative colitis relapsed, and ileo-anal pouch surgery was performed. In cases of atypical pneumonia, without a proven infection, azathioprine-associated interstitial pneumonitis may be present, which heals after withdrawal of the drug.

## INTRODUCTION

Azathioprine (Imuran® Glaxo-SmithKline) (AZA), one of the most commonly prescribed immunosuppressive drugs, is mainly administered in the treatment of immune-mediated diseases. AZA has been used to combat inflammatory bowel diseases (IBD) such as ulcerative colitis and Crohn's disease since the 1960s<sup>[1]</sup>. It has been shown to reduce the number of lamina propria plasma cells, to alter the function of lymphocytes and natural killer cells and to exert an anti-inflammatory effect<sup>[2]</sup>. In IBD, azathioprine is used in both steroid-dependent and steroid-resistant cases. The clinical efficacy starts within 3-6 mo after the initiation of therapy. It is effective in more than half of the patients<sup>[3]</sup>. The early hypersensitivity reaction (nausea, fever, hepatitis and pancreatitis) and late bone marrow depression (leukopenia and macrocytosis) are relatively common side-effects<sup>[4]</sup>, but interstitial pneumonitis is rare.

## CASE REPORT

A 41-year old male patient with known ulcerative colitis since 1988 was referred to the Department of Medicine by his GP in June 2003 with symptoms and signs of relapse. His pancolitis had been treated with AZA (1.8 mg/kg per day) since 1993 because of frequent relapses. During the therapy only mild (1-2 blood-streaked stools) and rare (for 1-2 wk periods, once or twice yearly) relapses occurred. The patient was in good physical condition for his age and he was able to work. Six weeks before his admission, there was a severe relapse. He complained of anorexia, a weight loss (15 kg) and frequent bowel movements (10-12 times/d), accompanied with colicky pain and blood in the stools. Fever, dyspnoea and cardiac symptoms were not present. His treatment on admission was: 1 g olsalazine, 150 mg azathioprine, 12 mg methylprednisolone daily. Physical examination of the cardiorespiratory system was negative and diffuse abdominal tenderness was detected. His weight was 91 kg, his height was 182 cm, and his temperature was normal. The blood chemistry at the time of admission was as follows: ESR = 76 mm/h, serum sodium = 132 mmol/L, potassium = 3.7 mmol/L, haematocrit = 32%, hb = 111 g/L, TIBC = 55 µmol/L, white blood cell count = 4.400 G/L, and platelets = 368.000 G/L. Liver function tests were normal. Colonoscopy revealed severe active extensive ulcerative colitis involving the whole transversal colon. In response to parenteral corticosteroid treatment, his condition improved. He was discharged in good condition after

**Figure 1** Chest X-ray (2003-09-09) showing moderate reticular enhancement with ring-like consolidation in both lungs (but predominantly the right), without cardiac or aortic abnormalities.

**Figure 2** Chest X-ray (2003-09-14) showing significant progression and volume loss in both lungs. A palm-sized homogeneous consolidation developed in the central part of the lung, a marked interstitial enhancement was seen in other parts of the lung. The radiological image suggested ARDS. The heart was enlarged.

11 d on 48 mg/d oral methylprednisolone and 150 mg/d AZA.

After a remission period, which lasted throughout the summer, he presented to the Department of Medicine in September 2003 with complaints of weakness, weight loss, coughing and fever, the latter appearing every evening for a week. He did not cough up blood. He had 2-4 stools daily, without blood. He had no abdominal symptoms. His daily treatment on admission was 150 mg AZA, 16 mg methylprednisolone and doxycycline (prescribed by his GP). The results of physical examinations (cardiovascular and respiratory systems and abdomen) were normal. Septic fever was present. Blood chemistry values were as follows: ESR = 125 mm/h, haematocrit = 31%, hb = 10.7 g/L, white blood cell count = 4.100 G/L, platelets = 325.000 G/L, CRP = 351 mg/L, and uric acid = 471  $\mu$ mol/L. The haemoculture was negative and procalcitonin was 0.07 ng/mL. The bacteriology (pharynx, sputum and urine) and virology (CMV, EBV, Coxsackie and adenovirus) tests were negative.

The chest X-ray (2003-09-09) revealed moderately increased interstitial shadowing with a ring-like consolidation in both lungs (predominantly in the right), without cardiac or aortic abnormalities. The follow-up chest X-ray revealed progression (Figure 1). Despite the discontinuation of AZA, progressive interstitial inflammation was detected in both lungs. The patient was treated with 1 g/d clarithromycin intravenously and 12 mg methylprednisolone orally. He was transferred to the intensive care unit because of the possibility of a severe opportunistic infection or an autoimmune disease. AZA-associated pneumonitis was also suspected.

His respiratory failure was treated in the intensive care unit. Dyspnoea occurred on minor exertion, the patient had orthostatic hypotension, and he was weak. On physical examination, the liver was palpable 2 cm beyond the costal margin. Except for dyspnoea nothing abnormal was detected. Blood chemistry showed ESR = 120 mm/h, haematocrit = 26%, hb = 90 g/L, white blood cell count = 2.970-3.200 G/L, platelets = 426.000 G/L, SGOT = 246 U/L, SGPT = 91 U/L, gamma GT = 600 U/L, LDH = 1125 U/L, and procalcitonin = 0.07 ng/L. Nasal oxygen

supplementation was initiated, and a bronchial lavage sample was collected from the lower respiratory tract under anaesthesia. Arterial blood gas analyses displayed pH = 7.455, pCO<sub>2</sub> = 33.0, pO<sub>2</sub> = 50.9 mmHg, and sO<sub>2</sub> = 86.2%. Two days later the corresponding values of pH, pCO<sub>2</sub>, pO<sub>2</sub>, and sO<sub>2</sub> were: 7.394%, 41.7%, 75.1% and 94.0%, respectively. Neither typical nor atypical pathogens were detected in bacteriology samples. CMV PCR and Legionella IgM-IgG were also negative.

The follow-up chest X-ray examination (Figure 2), revealed a significant progression of the interstitial shadowing in both lungs. A palm-sized homogeneous consolidation was seen in the hilar area and marked interstitial shadowing in the remaining parts of the lungs. The radiological appearance was suggestive of acute respiratory distress syndrome (ARDS). Cardiac enlargement was demonstrated.

The chest CT examination revealed a 2-cm wide pleural effusion with increased alveolar/air-space shadowing bilaterally. The X-ray and CT examinations suggested ARDS. A needle biopsy was performed from the apex of the right lung. The histology showed intraluminal myxoid polyps (Masson bodies) in the alveoli (Figures 3,4,5). Vasculitis and *Pneumocystis carinii* infection were excluded. The results of the histology and immuno-histochemistry suggested a diagnosis of bronchiolitis obliterans organizing pneumonia (BOOP), but hypersensitivity pneumonitis was also regarded as a possibility. After sulphamethoxazole/trimethoprim and methylprednisolone therapy, his condition gradually improved (Figure 6), and his liver and renal functions became normal. At the time of discharge, he was treated with 3 g sulphasalazine, 1 g sulphamethoxazole/trimethoprim and 8 mg methylprednisolone daily.

Three months later (2004-09-01) only mild dyspnoea occurred on exertion, but he had 8-10 liquid stools daily, occasionally with some blood on the surface of faeces. He had neither fever nor extraintestinal symptoms. The results of chest and heart examination were normal, but the sigma was tender. Corticosteroid therapy was restarted with 64 mg/d methylprednisolone. Blood chemistry

**Figure 3** Histology of lung needle biopsy (HE, 112 ×).

**Figure 4** Histology showing the pathognomic Masson bodies for BOOP and polypous proliferation of new connective tissue in the alveolus (trichrome, 224 ×).

**Figure 5** Immunohistochemistry for the expression of CK 7. Interstitial fibrosis and proliferation of type II pneumocytes are apparent (224 ×).

showed serum Fe = 21.3  $\mu\text{mol/L}$ , uric acid = 461  $\mu\text{mol/L}$ , gamma GT = 121 U/L, cholesterol = 7.75 mmol/L, triglyceride = 2.3 mmol/L, white blood cell count = 7.870 G/L and platelets = 223.000 G/L. Pulmonary functions were VC = 110%, RV = 109%, spirometry FVC = 104%, FEV<sub>1</sub> = 112%. The diffusion capacity values (DLCO = 74%, DLCO/VA = 60%) suggested a slightly decreased diffusion capacity. The chest X-ray revealed a further improvement of the lung volume. Interstitial shadowing was still present in the perihilar region of the lungs. Colonoscopy could only be carried out to 20 cm because of the pain and active colitis. The surface of mucosa was reddish, vulnerable and ulcerated, corresponding to active ulcerative colitis. In view of his previous history, proctocolectomy had to be considered. The first surgical intervention was carried out a month later and, after the ileal-pouch anal anastomosis (IPAA), the temporary anus prae was closed in August 2004. He had no complaints after the operation, produced 4-5 stools daily and was not on any medication.

## DISCUSSION

In IBD patients, AZA treatment is worth starting if the patient is steroid-refractory (the effective dose does not lead to remission) or steroid dependent (discontinuation of the steroid causes a relapse)<sup>[5]</sup>. The first clinical results were inhomogeneous as concerns efficacy, because of the long time until the onset of action. Hawthorne *et al*<sup>[6]</sup> have proven the beneficial effect of the medication on

the maintenance of remission in ulcerative colitis. In their study, seventy-nine patients who had been taking AZA for 6 mo were then divided into two groups. One of the groups continued to receive the therapy while placebo was administered to the patients in the other. The relapse rate was 36% in the AZA-treated group and 59% in the placebo group.

The mechanism of action of AZA is unknown. In IBD, the drug decreases the number of lamina propria plasma cells and alters the functions of lymphocytes and natural killer cells.

The therapeutic effect has been explained by the apoptosis-inducing behaviour of the drug. Tiede *et al*<sup>[7]</sup> considered that 6-thioGTP, a metabolite of AZA, could alter the apoptosis of T cells. The metabolite inhibits the activation of certain genes inside the cells, and induces apoptosis via a mitochondrial path.

Bedrossian *et al*<sup>[8]</sup> have noted bilateral lung infiltration with a reduced pO<sub>2</sub> in 7 kidney-transplanted patients treated with AZA, which was not cured by antibiotic therapy. In their study, lung biopsy revealed an abnormal histology, which varied from diffuse alveolar damage to interstitial pneumonia and pulmonary fibrosis. No immune deposition, eosinophilia, vasculitis or granuloma could be detected, and the bacteriological findings were negative. When AZA was withdrawn from the treatment, the infiltration was significantly diminished in 2 patients who exhibited diffuse alveolar damage, but 4 patients diagnosed as interstitial pneumonitis, died of ARDS. The biopsies revealed hyaline membranes, intraalveolar oedema and damage to

**Figure 6** Chest X-ray (2003-10-15) showing improvement of lung volumes. Reticular enhancement of the middle part of the lungs is still present.

the alveolar epithelium in those who received low doses of AZA, and atypical epithelial hyperplasia, reorganization of the distal air spaces and fibrosis in the cases treated with high doses of AZA. Histologically the changes observed could not be distinguished from the characteristic changes caused by other pulmonary toxic drugs.

In our case, AZA treatment, initiated because of the common and serious relapses of extensive ulcerative colitis, ensured a good condition for almost 10 years. The patient was hospitalized because of a severe relapse in June 2003, but at that time no pulmonary abnormality was found. Remission was achieved with intravenous corticosteroid therapy. Three months later (2003-09-09), the patient presented with cough, catarrhal signs and pulmonary infiltration. We initially thought of concomitant infection, which may be expected during immunosuppressive treatment. In consequence of earlier therapy the pancolitis was in remission. After admission, the dose of AZA was reduced, and doxycycline was changed to chlarythromycin. However, despite his good general condition and the conventional treatment, the pulmonary infiltration rapidly deteriorated. Dyspnoea developed, which necessitated intensive care. Concomitant infection was not confirmed

by the diagnostic examinations, and broad-spectrum antibiotics were proven ineffective. The lung biopsy results and the clinical features strongly suggested that he had AZA-associated interstitial pneumonia. Other causes of BOOP, such as eosinophilic pneumonia, vasculitis, irradiation, nitrofurantoin, gold, amiodarone and methotrexate, were excluded. In view of the results, AZA treatment was discontinued, oral corticosteroid medication was continued and the patient's condition gradually improved. Three months later (December 2003), ulcerative colitis relapsed. In view of the clinical course of ulcerative colitis (frequent recurrences and AZA-induced interstitial pneumonitis), proctocolectomy was recommended. After surgery, the patient's condition normalized without any further treatment.

In summary, in cases of atypical pneumonia without a proven opportunistic infection, AZA-associated interstitial pneumonitis may be present, which heals after withdrawal of the drug.

## Abstract

Lymphangiomas are rare, benign tumors of the lymphatic system, usually present in children aged 5 years and younger. Because they are asymptomatic until the mass enlarges to cause symptoms, most lymphangiomas are diagnosed at adulthood incidentally. We experienced a case of a 60-year-old man diagnosed with a cystic lymphangioma of the gallbladder, which was successfully resected without any complication. Magnetic resonance imaging and magnetic resonance cholangiopancreatography were very helpful for the diagnosis of the cystic lesion around the gallbladder as were ultrasonography and computed tomography scan. These showed a multi-lobulated cystic mass with intact cystic duct and bile duct in the gallbladder fossa. The patient underwent an open cholecystectomy and the histological findings were consistent with a cystic lymphangioma of the gallbladder. We here report the case of cystic lymphangioma of the gallbladder with a review of the literature.

## INTRODUCTION

Lymphangiomas are uncommon benign congenital malformations of the lymphatic system<sup>[1-3]</sup>. About 95% lymphangiomas occur in the skin and the subcutaneous tissues of the head, neck and axillary region and the remaining 5% appear in other parts of the body such as lungs, pleura, pericardium, esophagus, stomach, jejunum, colon, pancreas, liver, gallbladder, kidney, and the mesentery<sup>[3-5]</sup>. Because most lymphangiomas are multicystic, lobulated lesions, they may be confused with other lesions, such as intrahepatic simple cysts, ductal ectasia, liver hemangiomas, pericholecystic cystic tumors or angiosarcomas. Various imaging studies are often required for accurate diagnosis and to differentiate gallbladder lymphangiomas from other lesions<sup>[3,6,7]</sup>. Recently, magnetic resonance imaging (MRI) and magnetic resonance cholangiopancreatography (MRCP) have been shown to be helpful for the characterization of the lesions as well as an evaluation of the relation to the adjacent organs. Complete surgical resection is the treatment of choice for gallbladder lymphangioma, and recently successful laparoscopic resection also has been reported<sup>[8]</sup>.

## CASE REPORT

A 60-year-old man was admitted to Hallym University Sacred Heart Hospital for treatment of aspiration pneumonia. He presented a high fever, chills and coughing, and had no abdominal pain or discomfort. Chest computed tomography (CT) scan for evaluation of the pneumonia unexpectedly showed a large lobulating low density lesion in the liver near the gallbladder in addition to pneumonic infiltration of the lungs. The patient was referred to our department for evaluation of the large cystic lesion. Abdominal ultrasonography (US) showed a hypoechoic mass encircling the gallbladder lumen in the liver (Figure 1). Abdominal CT showed an approximately 5.2 cm-sized multi-lobulated cystic mass, insinuating gallbladder lymphangioma, between the liver and the gallbladder bed (Figure 2). Abdominal MRI was performed for the characterization and anatomical evaluation of the lesion. Axial T2-weighted image showed an intact lumen

**Figure 1** Abdominal ultrasonography showing multi-loculated cystic mass and intact gallbladder lumen.

**Figure 2** Abdominal computed tomography (CT) image showing a low-density multilocular cystic lesion with septation originated from the gallbladder fossa.

**Figure 3** Axial T2-weighted magnetic resonance (MR) image showing a thin multi-septated cystic mass (high-signal intensity) with scalloping margin.

**Figure 4** Magnetic resonance cholangiopancreatography (MRCP) image showing gallbladder encapsulated by variable sized multi-cystic lesions, which have no communication with biliary system.

of the gallbladder (low-signal intensity) surrounded by a thin multi-septated cystic mass (high-signal intensity) with scalloping margin (Figure 3). This finding strongly suggested a lymphangioma arising from the lymphatic tissue of the gallbladder wall. MRCP also clearly showed a large multi-cystic gallbladder lymphangioma in the gallbladder fossa (Figure 4). Characteristically, the cystic duct and bile duct were completely separated from the lymphangioma, and were well preserved. Additionally, the gallbladder was obviously visualized and its contraction was grossly normal (ejection fraction = 89%) on hepatobiliary DISIDA scan.

An open cholecystectomy was performed after resolution of the pneumonia. At surgical exploration, a well-defined multi-lobular cystic tumor encapsulating the gallbladder was observed. Grossly the tumor was measured 5.5 cm × 4.3 cm × 3.5 cm in size and was clearly separated from the liver. When the tumor was cut off from the surface, the gallbladder mucosa was intact and various-sized multiple cysts were shown. Each cyst was filled with serous or hemorrhagic lymphatic fluid. Histological evaluation revealed a flat endothelial lining encircling each cyst and multiple lymphocyte aggregations beside the cyst (Figure 5). This demonstrated that the cyst was a lymphatic

space. The lesion was diagnosed as a cystic lymphangioma of the gallbladder because it had no connection with adjacent normal lymphatics. CT at 12 mo following the surgical resection showed no evidence of recurrence.

## DISCUSSION

Lymphangiomas are benign tumors that may appear in any organ of the body except the brain. It more commonly involves the skin and soft tissue of the head and neck (95%), and lymphangioma occurring in the gastrointestinal tract is rare. A lymphangioma arising from the gallbladder is extremely rare, representing only 0.8%-1% of all intra-abdominal lymphangiomas<sup>[1-5]</sup>, and only a few cases have been reported. Lymphangiomas are classified as simple, cavernous, and cystic types based on their histological findings<sup>[3,6,9-11]</sup>. The simple type is usually situated superficially in the skin and is composed of small thin-walled lymphatic vessels. The cavernous type is composed of dilated lymphatic vessels and lymphoid stroma, and has a connection with spaces of various normal adjacent lymphatics. The cystic type consists of lymphatic spaces

**Figure 5** Gross appearance of resected specimen showing a well-margined multi cystic lesion filled with yellowish fluid, and microphotograph from the cholecystectomy specimen showing a lymphatic space lined with flat endothelium (hematoxylin and eosin staining,  $\times 12.5$ ).

of various sizes that contain fascicles of smooth muscle and collagen bundles, but has no connection with adjacent normal lymphatics<sup>[11,12]</sup>.

The etiology of lymphangiomas could be explained by several theories<sup>[1,6]</sup>. The most powerful one is that it is a congenital abnormality of the lymphatic system. Failure to establish connection with the normal drainage vessel causes sequestration of lymphatic tissue during embryogenesis. This theory would explain why lymphangioma occurs primarily in children. However, other views suggest that secondary causes such as abdominal trauma, lymphatic obstruction, inflammatory processes, surgery, or radiation therapy may lead to the formation of lymphangiomas<sup>[1,6]</sup>.

Clinical presentations of these tumors are variable. Most cases are asymptomatic or have non-specific symptoms, such as nausea, vomiting, dyspepsia, abdominal discomfort or a palpable mass. In the past it was somewhat difficult to diagnose a lymphangioma before surgical or histological identification. Preoperative diagnosis of gallbladder lymphangioma remains difficult because it is very rare, and sometimes imaging studies such as US and CT cannot distinguish it from other lesions. The findings of US and CT show a large cystic lesion, but it is difficult to find where the lesion originates from and to understand its relation to surrounding organs.

However recently, various advanced imaging studies, especially MRI and MRCP, can support the diagnosis of lymphangiomas more easily before exploration<sup>[1,6,7]</sup>. US seems to be useful in defining the mass as a multilocular cystic lesion, but often does not distinguish between a hepatic lesion and a pericholecystic lesion. CT shows a simple or multilocular cystic lesion with the density of water. The septa of the cysts are of uniform thickness. Administering contrast agents intravenously can enhance the wall of the cysts<sup>[6]</sup>. However, the findings of CT of previous reports only showed cystic lesion in the gallbladder fossa or inferior to the liver, but could not show that the lesion was arising from the gallbladder. Moreover, the gallbladder was not visible due to cystic lesions in most of them, as was evident in the present case. Although hemorrhage within the lymphangioma was readily noted on follow-up CT, it might have been difficult to differentiate it from an intracystic solid lesion if the case was initially presented after hemorrhage<sup>[6]</sup>.

In our study, MRI and MRCP are very helpful for making the correct diagnosis. One recent report described the MR findings of gallbladder lymphangiomas based on the findings of splenic cystic lymphangiomas<sup>[6]</sup>. This report suggested that characteristic MR findings would be very helpful for the differential diagnosis of gallbladder lymphangioma, and characterizing the mass even if the cystic lesion was complicated by intracystic hemorrhage. Axial T1- and T2-weighted and coronal MR images clearly depicted the lumen of the gallbladder and the multiseptated cystic mass originating in the gallbladder wall. MR imaging, including MRCP, clearly defined the mass and its relation to the gallbladder. The characteristic thin-walled multilocular cystic appearance was clearly depicted on MR imaging and was helpful for making the correct diagnosis<sup>[1,3,6,7]</sup>. MRCP characteristically showed that the cystic duct and bile duct were well preserved and were completely separated from the lymphangioma, as the finding of the present case. This was the typical feature of such lymphangiomas that had no communication between the mass and the biliary system. Therefore, if a gallbladder lymphangioma is suspected, MRI and MRCP should be recommended.

For the management of lymphangiomas, complete total surgical excision is known to be the standard treatment. If the mass grows large to compress surrounding structures and vessels, it can cause significant symptoms and morbidities. Furthermore, if it progresses to be complicated, intra-abdominal infection, rupture, torsion or hemorrhage can occur. A recent report suggested that two cases of gallbladder lymphangiomas were successfully treated by laparoscopic cholecystectomy, even though their size was more than 15 cm in diameter<sup>[8]</sup>. While we did not perform laparoscopic cholecystectomy, laparoscopic resection was possible because the lesion was relatively small compared to the previous report and was easily separated from the adjacent organs at surgical exploration. However, in a recent case, *en bloc* resection of the extrahepatic bile duct including the gallbladder was necessary because a huge cystic lesion adhered to the entire extrahepatic bile duct anteriorly and posteriorly, and part of the cyst also adhered to the right hepatic artery<sup>[1]</sup>. Therefore, laparoscopic resection was preferably

performed after evaluation of the extent of the cystic mass and its relation to adjacent organs. Recurrence has been reported with incomplete resection, but if the lesion is completely resected, long-term prognosis is excellent<sup>[12]</sup>.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (WJG, *World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly journal of more than 48 000 circulation, published on the 7<sup>th</sup>, 14<sup>th</sup>, 21<sup>st</sup> and 28<sup>th</sup> of every month.

Original Research, Clinical Trials, Reviews, Comments, and Case Reports in esophageal cancer, gastric cancer, colon cancer, liver cancer, viral liver diseases, etc., from all over the world are welcome on the condition that they have not been published previously and have not been submitted simultaneously elsewhere.

#### Indexed and abstracted in

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, *Index Medicus*, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, *Nature Clinical Practice Gastroenterology and Hepatology*, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

#### Published by

The WJG Press

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297 mm × 210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, acknowledgements, References, Tables, Figures and Figure Legends. Neither the editors nor the Publisher is responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part without the written permission of both the authors and the Publisher. We reserve the right to put onto our website and copy-edit accepted manuscripts. Authors should also follow the guidelines for the care and use of laboratory animals of their institution or national animal welfare committee.

Authors should retain one copy of the text, tables, photographs and illustrations, as rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for the loss or damage to photographs and illustrations in mailing process.

#### Online submission

Online submission is strongly advised. Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/index.jsp>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. Authors encountering problems with the Online Submission System may send an email you describing the problem to [wjg@wjgnet.com](mailto:wjg@wjgnet.com) for assistance. If you submit your manuscript online, do not make a postal contribution. A repeated online submission for the same manuscript is strictly prohibited.

#### Postal submission

Send 3 duplicate hard copies of the full-text manuscript typed double-spaced on A4 (297 mm × 210 mm) white paper together with any original photographs or illustrations and a 3.5 inch computer diskette or CD-ROM containing an electronic copy of the manuscript including all the figures, graphs and tables in native Microsoft Word format or \*.rtf format to:

#### Editorial Office

##### *World Journal of Gastroenterology*

Editorial Department: Apartment 1066, Yishou Garden,  
58 North Langxinzhuang Road,  
PO Box 2345, Beijing 100023, China  
E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)  
<http://www.wjgnet.com>  
Telephone: +86-10-85381892  
Fax: +86-10-85381893

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using a word-processing software. All submissions must be typed in 1.5

line spacing and in word size 12 with ample margins. The letter font is Tahoma. For authors from China, one copy of the Chinese translation of the manuscript is also required (excluding references). Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was accomplished, disclosure of any financial support for the research, and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (removing all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s) and full family name.

#### Abstract

An informative, structured abstract of no more than 250 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipments, and the experimental procedures should be included. RESULTS: The observatory and experimental results, including data, effects, outcome, etc. should be included. Authors should present *P* value where necessary, and the significant data should accompany. CONCLUSION: Accurate view and the value of the results should be included.

The format of structured abstracts is at: <http://www.wjgnet.com/wjg/help/11.doc>

#### Key words

Please list 5-10 key words that could reflect content of the study mainly from *Index Medicus*.

#### Text

For most article types, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include in appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both.

#### Illustrations

Figures should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. No detailed legend should be involved under the figures. This part should be added into the text where the figures are applicable. Digital images: black and white photographs should be scanned and saved in TIFF format at a resolution of 300 dpi; color images should be saved as CMYK (print files) but not as RGB (screen-viewing files). Place each photograph in a separate file. Print images: supply images of size no smaller than 126 mm × 85 mm printed on smooth surface paper; label the image by writing the Figure number and orientation using an arrow. Photomicrographs: indicate the original magnification and stain in the legend. Digital Drawings: supply files in EPS if created by freehand and illustrator, or TIFF from photoshops. EPS files must be accompanied by a version in native file format for editing purposes. Existing line drawings should be scanned at a resolution of 1200 dpi and as close as possible to the size where they will appear when printed. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes of atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...

#### Tables

Three-line tables should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each table. No detailed legend should be included under the tables. This part should be added into the text where the tables are applicable. The information should complement but not duplicate that contained in the text. Use one horizontal line under the title, a second under the column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

#### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup>*P*<0.05, <sup>b</sup>*P*<0.01 should be noted (*P*>0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P*<0.05 and <sup>d</sup>*P*<0.01 are used. Third series of *P* values can be expressed as <sup>e</sup>*P*<0.05 and <sup>f</sup>*P*<0.01. Other notes in tables or under

illustrations should be expressed as  $^1F$ ,  $^2F$ ,  $^3F$ ; or some other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, etc. in a certain sequence.

### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions are included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should code the references according the citation order in text in Arabic numerals, put references codes in square brackets, superscript it at the end of citation content or the author name of the citation. For those citation content as the narrate part, the coding number and square brackets should be typeset normally. For example, Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>. If references are directly cited in the text, they would be put together with the text, for example, from references [19,22-24], we know that...

When the authors code the references, please ensure that the order in text is the same as in reference part and also insure the spelling accuracy of the first author's name. Do not code the same citation twice.

### PMID requirement

PMID roots in the abstract serial number indexed by PubMed (<http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed>). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information of the journal citations is very important. Through reference testing system, the authors and editor could check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in ASP file so that the readers can read the abstract of the citations online immediately.

### Style for journal references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). Title of the cited article and italicized journal title (Journal title should be in its abbreviation form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634]

Note: The author should test the references through reference testing system (<http://www.wjgnet.com/cgi-bin/index.pl>)

### Style for book references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

**Patent (list all authors)**

- 16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

### Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those that are linked with a hyphen and the difference between the two numbers at two sides of the hyphen is more than 5. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered as inappropriate references. Authors should not cite their own unrelated published articles.

### Statistical data

Present as mean  $\pm$  SD or mean  $\pm$  SE.

### Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\gamma$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

### Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p*(B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6  $24.5 \mu\text{g/L}$ ; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub> not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format about how to accurately write common units and quantum is at: <http://www.wjgnet.com/wjg/help/15.doc>

### Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further mention.

### Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kbo I*, *Kpn I*, etc.

Biology: *H pylori*, *E coli*, etc.

### SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. Author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, the final check list for authors, and responses to reviewers by a courier (such as EMS) (submission of revised manuscript by e-mail or on the *WJG* Editorial Office Online System is NOT available at present).

### Language evaluation

The language of a manuscript will be graded before sending for revision.

(1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing; (4) Grade D: rejected. The revised articles should be in grade B or grade A.

### Copyright assignment form

Please download CAF from <http://www.wjgnet.com/wjg/help/9.doc>.

We certify that the material contained in this manuscript:

**Ms:**

**Title:**

is original, except when appropriately referenced to other sources, and that written permission has been granted by any existing copyright holders. We agree to transfer to *WJG* all rights of our manuscript, including: (1) all copyright ownership in all print and electronic formats; (2) the right to grant permission to republish or reprint the stated material in whole or in part, with or without a fee; (3) the right to print copies for free distribution or sale; (4) the right to republish the stated material in a collection of articles or in any other format. We also agree that our article be put on the Internet.

**Criteria for authorship:** The *WJG* requests and publishes information about contributions of each author named to the submitted study. Authorship credit should be based on (1) direct participation in the study, including substantial contributions to conception and design of study, or acquisition of data, or analysis and interpretation of data; (2) manuscript writing, including drafting the article, or revising it critically for important intellectual content; (3) supportive work, including statistical analysis of data, or acquisition of funding, or administration, technology and materials support, or supervision, or supportive contributions. Authors should meet at least one of the three conditions. The *WJG* does not publish co-first authors and co-corresponding authors.

We hereby assign copyright transfer to *WJG* if this paper is accepted.

Author Name in full (Full names should be provided, with first name first, followed by middle names and family name at the last, eg, Eamonn MM Quigley). Handwritten names are not accepted.

Author Name in abbreviation (Family name is put first in full, followed by middle names and first name in abbreviation with first letter in capital, eg, Quigley EMM). Handwritten names are not accepted.

### Final check list for authors

The format is at: <http://www.wjgnet.com/wjg/help/13.doc>

### Responses to reviewers

Please revise your article according to the comments/suggestions of reviewers. The format for responses to the reviewers' comments is at: <http://www.wjgnet.com/wjg/help/10.doc>

### Abstract

Currently, pharmaceutical preparations are serious contributors to liver disease; hepatotoxicity ranking as the most frequent cause for acute liver failure and post-commercialization regulatory decisions. The diagnosis of hepatotoxicity remains a difficult task because of the lack of reliable markers for use in general clinical practice. To incriminate any given drug in an episode of liver dysfunction is a step-by-step process that requires a high degree of suspicion, compatible chronology, awareness of the drug's hepatotoxic potential, the exclusion of alternative causes of liver damage and the ability to detect the presence of subtle data that favors a toxic etiology. This process is time-consuming and the final result is frequently inaccurate. Diagnostic algorithms may add consistency to the diagnostic process by translating the suspicion into a quantitative score. Such scales are useful since they provide a framework that emphasizes the features that merit attention in cases of suspected hepatic adverse reaction as well. Current efforts in collecting bona fide cases of drug-induced hepatotoxicity will make refinements of existing scales feasible. It is now relatively easy to accommodate relevant data within the scoring system and to delete low-impact items. Efforts should also be directed toward the development of an abridged instrument for use in evaluating suspected drug-induced hepatotoxicity at the very beginning of the diagnosis and treatment process when clinical decisions need to be made. The instrument chosen would enable a confident diagnosis to be made on admission of the patient and treatment to be fine-

### INTRODUCTION

Idiosyncratic liver disease caused by drugs or toxins is a major challenge of modern hepatology, and is a somewhat neglected field as well. The reasons for this are varied. Firstly, hepatotoxicity is rarely encountered in standard clinical practice because of its relatively low incidence compared to other hepatic diseases and the difficulties in confidently diagnosing the condition. Secondly, there have not been substantial advances in recent decades in the understanding of its pathogenesis, which is mostly due to the lack of validated animal models for investigating idiosyncratic hepatotoxicity. As such, susceptibility factors that can predispose individuals to adverse hepatic reactions to drugs have not been conclusively identified, nor has there been any development of reliable and standardized markers for the identification and measurement of toxic liver damage<sup>[1]</sup>. Co-operative efforts are being encouraged so as to prospectively collect bona fide cases from which quality data and biological samples could be obtained for genome-wide studies<sup>[2,3]</sup>.

Hepatotoxicity has a considerable impact on health because many of the hepatic reactions induced by pharmaceutical preparations can be very severe. A survey from the Acute Liver Failure Study Group (ALFSG) of the patients admitted in 17 US hospitals showed that prescribed drugs (including acetaminophen) accounted for > 50% of cases of acute liver failure<sup>[4]</sup>. Indeed, drug-induced hepatotoxicity is still the main reason for cessation of further drug development and, as well, for post-approval drug regulatory decisions including removal of several culprit drugs from the market<sup>[5]</sup>. Recent examples

in the USA and Europe are troglitazone, bromfenac, trovafloxacin, ebrotidine, nimesulide, nefazodone and ximelagatran<sup>[6-8]</sup>.

## CLINICAL PRESENTATION OF DRUG-INDUCED HEPATOTOXICITY

In standard clinical practice, drug-induced hepatotoxicity may present in several ways (clinical and pathological) that simulate known forms of acute and chronic liver diseases; the severity ranging from sub-clinical elevations in liver enzyme concentrations to acute liver failure. Gastroenterologists need to bear hepatotoxicity in mind when conducting a differential diagnosis in every patient who presents with liver dysfunction. Mainly, drugs tend to induce acute hepatitis, cholestasis or a mixed condition. A clinical picture resembling acute viral hepatitis with jaundice, malaise, anorexia, nausea and abdominal pain is the principal presentation but, because every liver cell may be the target of drug-induced toxicity, many other expressions of hepatotoxicity may be evident including chronic hepatitis, cirrhosis, sinusoidal obstruction syndrome or neoplasm<sup>[9]</sup>.

Liver histology (although not very specific and at best resulting in "compatible with") is the ideal tool to date for defining the pattern of hepatotoxicity. However, since a liver biopsy specimen is often not available, the pattern of drug-related liver injury is, from a practical standpoint, classified according to laboratory data. This mainly includes the activity of serum alanine aminotransferase (ALT) and alkaline phosphatase (AP) with the increase in activity being expressed with respect to the upper limit of normal (ULN) and the ratio of the measured activities<sup>[10]</sup>. This classification is somewhat arbitrary and insufficient in classifying all types of drug-induced liver damage (e.g. vascular lesions and chronic damage, in general), however, the system does have some prognostic value.

Acute hepatocellular (e.g., cytotoxic, cytolytic) liver injury is defined by ALT > 2-fold that of ULN (2N) or an ALT/AP ratio  $\geq 5$ <sup>[10]</sup>. Patients with this particular type of liver damage have non-specific clinical features, and jaundice is not always evident. Sometimes there are clues of drug allergy, such as fever, rash or peripheral eosinophilia. Serum levels of aminotransferase are markedly increased. Liver histology shows variable degrees of cell necrosis and inflammation, mainly in zone 3 of the hepatic acini together with an abundance of eosinophils in the infiltrate, which is consistent with a toxic etiology<sup>[9,11-14]</sup>. These expressions of hepatotoxicity are observed with many drugs (Table 1). Patients with acute hepatocellular injury related to drugs are at risk of acute liver failure. The observation by Hyman Zimmerman, known as "Hy's rule"<sup>[9]</sup>, predicts a mean mortality (or its surrogate marker, liver transplantation) of 10% for jaundiced patients with acute toxic hepatocellular damage (providing total bilirubin is not elevated as a result of other causes such as biliary obstruction or Gilbert syndrome). Two recent studies<sup>[3,15]</sup> have validated this observation using multivariate analysis, and they indicated that, apart from total bilirubin and the hepatocellular-type of injury, other variables such older age, female gender and AST levels were independently

associated with a poor outcome<sup>[3,15]</sup>.

Acute cholestatic injury, defined as an increase in serum AP > 2N or by an ALT/AP  $\leq 2$  is classified into two subtypes: pure, "bland" or canalicular cholestasis; and acute cholestatic or hepatocanalicular hepatitis. Patients with acute cholestasis usually present with jaundice and itching. The canalicular pattern is characterized by an increase in conjugated bilirubin, AP and  $\gamma$ -glutamyl transpeptidase ( $\gamma$ -GT) with minimal, if any, impairment in serum transaminases. Liver biopsy shows hepatocyte cholestasis and dilated biliary canaliculi with bile plugs, but with little or no inflammation and necrosis<sup>[14]</sup>. Anabolic and contraceptive steroids typically produce this expression of hepatotoxicity.

Symptoms in the hepatocanalicular type of damage include abdominal pain and fever and, as such, resemble acute biliary obstruction. However, the associated hypersensitivity features that sometimes occur are an important clue toward the diagnosis of hepatotoxicity. Liver biopsy reveals variable degrees of portal inflammation and hepatocyte necrosis, in addition to marked cholestasis of centrilobular predominance<sup>[9,11,14]</sup>. Older age has been found to increase the likelihood of drug-induced hepatotoxicity being expressed as cholestatic damage<sup>[3,16]</sup>. Typical examples of drugs that cause this variety of liver damage are amoxicillin-clavulanate, macrolide antibiotics and phenothiazine neuroleptics, but many others have a similar capacity (Table 2).

In mixed hepatic injury the clinical and biological picture is intermediate between the hepatocellular and cholestatic patterns, and features of either type may predominate. By definition, the ALT/AP ratio is between 2 and 5. Allergy reactions are often present, as well as a granulomatous reaction in the liver biopsy specimen. When faced with a mixed hepatitis clinical picture, the gastroenterologists should always seek a culprit medication since this type of injury is far more characteristic of drug-induced hepatotoxicity than of viral hepatitis<sup>[9]</sup>. Almost all drugs that produce cholestatic injury are also capable of inducing a mixed pattern.

Although drug-induced cholestatic and mixed lesions progress to acute liver failure less frequently than hepatocellular types, their resolution is generally slower. For example, a long-term follow-up of a large cohort in a Registry demonstrated a significantly higher trend towards becoming chronic in cholestatic/mixed cases compared to hepatocellular-type disease<sup>[17]</sup>.

## DIAGNOSIS IN THE CLINICAL SETTING

A straightforward diagnosis of hepatotoxicity in clinical practice is seldom possible. An exception is when symptoms of hepatitis rapidly ensue following the obvious exposure to an over-dosage of intrinsic hepatotoxins, such as acetaminophen. In these circumstances, blood concentrations of the compound could be used to confirm the suspicion. In a few other instances the diagnosis can be easily established if liver damage becomes apparent after re-exposure to a drug that had been suspected as being the cause of previous hepatitis. This topic of re-challenge is discussed in more detail later.

**Table 1** Medications, herbal products and illicit drugs related to the hepatocellular-type of damage

Compound	Other injury	Comments
Acarbose		FHF
Allopurinol	Granuloma	Hypersensitivity
Amiodarone	Phospholipidosis, cirrhosis	
Amoxicillin, Ampicillin		
Anti-HIV: (Didanosine, Zidovudine, protease inhibitors)		
NSAIDs (AAS, Ibuprofen, Diclofenac, Piroxicam, Indometacin)		Nimesulide; withdrawn
Asparaginase	Steatosis	
Benzazepam	Chronic hepatitis	
Chlormethizole	Cholestatic hepatitis	FHF
Cocaine, Ecstasy and amphetamine derivatives		FHF
Diphenytoin		Hypersensitivity
Disulfiram		FHF
Ebrotidine	Cirrhosis	FHF
Fluoxetine, Paroxetine	Chronic hepatitis	
Flutamide		FHF
Halothane		
Hypolipemics; Lovastatin, Pravastatin, Simvastatin, Atorvastatin		
Isoniazid	Granuloma, chronic hepatitis	FHF
Ketoconazole, Mebendazole, Albendazole, Pentamidine		FHF
Mesalazine	Chronic hepatitis	Autoimmune features
Methotrexate	Steatosis, fibrosis, cirrhosis	
Minocycline	Chronic hepatitis, steatosis	Autoimmune features
Nitrofurantoin	Chronic hepatitis	
Nefazodone		FHF, withdrawn
Omeprazole		
Penicillin G	Prolonged cholestasis	
Pyrazinamide		
Herbal remedies		FHF
Germander ( <i>Teucrium chamaedrys</i> ), senna		
Pennyroyal oil, kava-kava		
Camellia sinensis (green tea); Chinese herbal medicines		
Risperidone		
Ritodrine		
Sulfasalazine		Hypersensitivity
Telithromycin		
Terbinafine	Cholestatic hepatitis	FHF
Tetracycline	Micro-steatosis	FHF
Tolcapone		FHF, withdrawn
Topiramate		
Trazodone	Chronic hepatitis	
Trovafloxacin		FHF, withdrawn in Europe
Valproic acid	Micro-steatosis	
Venlafaxine		
Verapamil	Granuloma	
Vitamin A	Fibrosis, cirrhosis	
Ximelagatran		FHF, discontinued

Features of hypersensitivity include fever, rash and eosinophilia; FHF: Fulminant hepatic failure.

Direct evidence for idiosyncratic hepatotoxicity is rarely available. This includes, for a few drugs, the detection of serum circulating autoantibodies to specific forms of cytochrome P450 (Table 3). Most of these drugs have been withdrawn from the market. This circumstance, in addition to uncertainty regarding sensitivity and specificity of the autoantibody test, makes such a situation irrelevant in current clinical practice<sup>[18]</sup>.

Another tool that has been used in the search for evidence of drug allergy is the lymphocyte-stimulation

test. This comprises counting of lymphocyte proliferation following exposure of peripheral blood mononuclear cells (monocytes) from the patient to the suspected drug *in vitro*. Using radiolabel led thymidine incorporation in the presence of a prostaglandin inhibitor (such as indometacin), prevents the suppressive influence of activated monocytes on T-cells<sup>[19,20]</sup>. However, a positive response merely indicates sensitization towards a certain drug and cannot actually be related to effector mechanisms (symptoms) while, on the contrary, a negative test does

Table 2 Medications associated with the cholestatic-type damage

Compound	Other injury	Comment
Cholestasis without hepatitis (canalicular/bland/pure jaundice)		
Estrogens, contraceptive steroids and anabolic-steroids (Budd-Chiari, adenoma, carcinoma, peliosis hepatitis, adenoma, carcinoma)		
Cholestasis with hepatitis (hepatocanalicular jaundice)		
Amoxicillin-clavulanic acid	Chronic cholestasis	VBDS
Atorvastatin	Chronic cholestasis	
Azathioprine	Chronic cholestasis	
Benoxaprofen (withdrawn)		
Bupropion	Chronic cholestasis	
Captopril, enalapril, fosinopril		
Carbamazepine	Chronic cholestasis	VBDS
Carbimazole		
Cloxacillin, dicloxacillin, flucloxacillin		
Clindamycin	Chronic cholestasis	
Ciprofloxacin, norfloxacin		
Cyproheptadine	Chronic cholestasis	VBDS
Diazepam, nitrazepam		
Erythromycins	Chronic cholestasis	VBDS
Gold compounds, penicillamine		
Herbal remedies:		
Chaparral leaf ( <i>Larrea tridentate</i> ); Glycyrrhizin, greater celandine ( <i>Chelidonium majus</i> )		
Irbesartan	Chronic cholestasis	
Lipid lowering agents ("statins")		
Macrolide antibiotics		
Mianserin		
Mirtazapine	Chronic cholestasis	
Phenothiazines (chlorpromazine)	Chronic cholestasis	
Robecoxib, celecoxib		
Rosiglitazone, oiglitazone		
Roxithromycin	Chronic cholestasis	
Sulfamethoxazole-trimethoprim	Chronic cholestasis	VBDS
Sulfonamides	Chronic cholestasis	
Sulfonylureas (Glibenclamide, Chlorpropamide)		
Sulindac, piroxicam, diclofenac, ibuprofen		
Terbinafine	Chronic cholestasis	VBDS
Tamoxifen	Hepatocellular, peliosis	
	Chronic cholestasis	
Tetracycline	Chronic cholestasis	
Ticlopidine & Clopidogrel	Chronic cholestasis	
Thiabendazole		VBDS
Tricyclic antidepressants (Amitriptyline, Imipramine)	Chronic cholestasis	VBDS
Sclerosing cholangitis-like	Floxuridine (intra-arterial)	
Cholangiodestructive (primary biliary cirrhosis)	Chlorpromazine, ajmaline	

VBDS: Vanishing bile duct syndrome.

not exclude drug allergy<sup>[21]</sup>. Finally, these *in vitro* tests are difficult to standardize, are poorly reproducible between laboratories, and have not gained general clinical acceptance<sup>[20,21]</sup>.

Hence, in the absence of an acceptable and convenient gold standard, the diagnosis is subjective and is made with varying levels of confidence based on a combination of factors including temporal associations and with respect to latency, the rate of improvement after cessation of the drug, and the definitive exclusion of alternative possible causes<sup>[22]</sup>. Confounding features include multiple drugs

Table 3 Autoantibodies specific to drug-induced hepatotoxicity

Autoantibody	Example
Anti-mitochondrial (anti-M6) autoantibody	Iproniazid
Anti-liver kidney microsomal 2 antibody (anti-LKM2)	Tienilic acid
Anti CYP 1A2	Dihydralazine
Anti CYP 2E1	Halothane
Anti-liver microsomal autoantibody	Carbamazepine
Anti-microsomal epoxide hydrolase	Germander

CYP: Cytochrome P450.

Figure 1 Approaching a suspicion of drug-induced hepatotoxicity.

prescribed for many patients, lack of information on doses consumed as well as stop and start dates<sup>[23]</sup>. A careful "step-by-step" approach should proceed according to the outline in Figure 1<sup>[24]</sup>.

### Screening for drug exposure and assessment of its hepatotoxic potential

A thorough drug and chemical history is essential, including prescribed and over-the-counter medications as well as consumption of illicit (recreational) drugs. Soliciting medication containers or a written medication plan, when available, assists the patient's recall and reduces errors<sup>[3]</sup>. In unconscious or confused patients or in those who are able to collaborate with the physician, the relatives or care-givers should be consulted.

The question that needs to be addressed is whether the treatment had commenced well before symptom presentation or in the early phase of hepatitis. This is because the suspected drug could actually have been prescribed to alleviate the first symptoms of hepatitis, such as gastrointestinal complaints or malaise. If this is not the case, duration of therapy with the suspected drug must be screened. Liver tests, if performed before starting the drug, can be very valuable in the patient's assessment. The latency period of different drugs varies widely. However, there is a relatively consistent "signature" for each drug

which is linked to the mechanism of damage involved. Details can usually be elicited from the patient. For instance, intrinsic hepatotoxins induce overt liver damage within a few hours of exposure. In most idiosyncratic cases, the latency period is roughly between 1 wk and 3 mo. In general, allergic hepatic reactions are likely to occur within 1 to 5 wk of taking the drug.

A delay of > 3 mo is typically seen with compounds that act by non-allergic mechanisms; i.e. “metabolic idiosyncrasy”. While drug-induced acute hepatitis seldom occurs after > 12 mo of exposure, these long latency-periods are still possible in unusual forms of chronic liver damage (such as steato-hepatitis, fibrosis and chronic hepatitis) in which the expression of hepatotoxicity is symptom-less and which allows the contra-indicated treatment to continue<sup>[25-31]</sup>, or simply because the type of lesion requires prolonged exposure to become manifest (e.g. vascular lesions and tumors)<sup>[32,33]</sup>.

In some instances the role of a drug is difficult to recognize because of a considerable delay (up to 3 or 4 wk) between the interruption of therapy and clinical presentation of the condition. Examples include amoxicillin-clavulanate<sup>[34]</sup>, midecamycin<sup>[35]</sup> and trovafloxacin<sup>[36]</sup>. The reasons for this are unclear and could be that such an unusual time-course might combine a late immune response to the drug if its retention in the body is protracted<sup>[37]</sup>.

There is no clear rule in identifying the culprit drug if the patient is taking various medications simultaneously. Attention should be paid to the latest drug introduced into the patient's regimen since this is the one that is likely to have stimulated the reaction. However, when a known hepatotoxic drug antedates the latest medication introduced then it seems reasonable to ascribe the clinical picture to the combination of the drugs because of the possibility of pharmaco-kinetic interaction<sup>[3,38]</sup>.

With respect to the hepatotoxic potential of screened drugs, their potentials for causing liver damage are not the same, and almost all marketed medications have been incriminated in incidences of hepatotoxicity<sup>[39]</sup>. For instance, some drugs like isoniazid, diclofenac, and amoxicillin-clavulanate are well-known hepatotoxic agents<sup>[3]</sup> while others such as digoxin rank very low on the list of hepatotoxins<sup>[9]</sup>. The main causative group of drugs, in a large cohort of hepatotoxicity cases collected in the Spanish Registry, was antibiotics followed by non-steroidal anti-inflammatory drugs (NSAIDs)<sup>[3]</sup>. Further, among the drugs most-frequently associated with idiosyncratic acute liver failure reported by the ALFSG, were antibiotics (particularly isoniazid), non-steroidal analgesics, anti-seizure medications and herbal preparations<sup>[40]</sup>.

Valuable information can be accessed from databases of hepatotoxic drugs, such as HEPATOX from France<sup>[39]</sup>, lists in reference textbooks<sup>[9,11,41]</sup> or more up-to-date resources such as MEDLINE-PubMed database of the National Library of Medicine where MESHing the name of the drug together with the terms “hepatotoxicity,” “hepatitis,” “drug-induced hepatotoxicity,” or simply “liver” can provide useful details.

If the patient has been taking a newly marketed drug, the data on its hepatotoxic potential, if known, would

only be available in pre-approval clinical trials (usually involving 1500-2500 patients). This size of trial would not have the power to detect significant (clinically overt) liver disease since finding hepatotoxicity with an incidence of 1:10 000 (the approximate incidence of most idiosyncratic reactions) would require 30 000 patients to be treated in the trial (“rule of threes”)<sup>[42]</sup>. Nevertheless, the appearance of less prominent signals of liver damage in pre-approval studies should be carefully noted. These include the incidence of asymptomatic ALT and bilirubin elevations. An ALT  $\geq$  8N or a  $\geq$  1.5 fold increase in direct bilirubin, especially if it is accompanied by a raised ALT, deserves special attention since this rarely occurs in ostensibly normal populations.

### **Exclusion of other causes of liver damage**

Diagnostic evaluation of any patient with acute liver disease of unknown origin should comprise a careful history to exclude alcohol abuse, recent episodes of hypotension, epidemiological risk factors of infectious hepatitis, specific serology and molecular biology studies for common viruses involved in viral hepatitis, as well as screening for autoimmune hepatitis. All patients should also have an abdominal ultrasound examination to exclude mechanical biliary obstruction.

The appropriateness of additional investigation would depend on the presence of particular symptoms or analytical features (Table 4). Patients with the cholestatic or mixed pattern of hepatic injury may require complementary imaging by magnetic resonance cholangiography or endoscopic retrograde cholangiography, despite normal abdominal ultrasound findings, so as to exclude benign or malignant obstruction of the biliary tract.

### **Features suggesting toxic liver damage**

Once alternative causes of liver damage have been ruled out, the suspicion of drug-induced hepatotoxicity can be confirmed by a careful scrutiny of co-existing features of drug-allergy, by noting the course following drug cessation and following a re-challenge dose, as well as through biopsy findings or biochemical patterns compatible with toxic liver damage<sup>[24]</sup>. Drug-allergy manifestations are associated with widely variable hepatotoxicity rates depending, mainly, on the drug class. Features that suggest drug-allergy include, skin rash, fever, peripheral eosinophilia, short latency period (1 mo or less) and rapid symptoms recurrence on re-challenge. Hematological features including granulocytopenia, thrombopenia or hemolytic anemia as well as renal and pancreatic involvement may also accompany some instances of drug-induced immuno-allergic hepatic injury<sup>[43,44]</sup>. In rare cases the extreme skin involvement of Steven-Johnson syndrome or the Lyell syndrome are strong clues to drug hypersensitivity<sup>[9]</sup>. However, because these manifestations occur in a minority of cases of hepatotoxicity, their absence is not necessarily a helpful sign. In our Spanish Registry<sup>[3]</sup>, some of the hallmarks of hypersensitivity (e.g., fever, rash, eosinophilia, cytopenia) were present only in 106 of 446 cases (23%) with idiosyncratic hepatotoxicity.

In some instances, typical hypersensitivity symptoms

Table 4 Clinical work-up to identify other possible causes of liver disease

Test	Condition	Commentary
Viral serology IgM anti-HAV IgM anti-HBc Anti-HCV, RNA-HCV (RT-PCR) IgM-CMV IgM-EBV Herpes virus	Viral hepatitis	Less frequent in older patients, especially Hepatitis A, search for epidemiologic risk factors, outcome may be similar to that of DILI following de-challenge.
Bacterial serology: Salmonella, Campylobacter, Listeria, Coxiella	Bacterial hepatitis	If persistent fever and/or diarrhea
Serology for syphilis	Secondary syphilis	Multiple sexual partners. Disproportionately high serum AP levels.
Autoimmunity (ANA, ANCA, AMA, ASMA, anti-LKM-1)	Autoimmune hepatitis, Primary biliary cirrhosis	Women, ambiguous course following de-challenge. Other autoimmunity features.
AST/ALT ratio > 2	Alcoholic hepatitis	Alcohol abuse. Moderate increase in transaminases despite severity at presentation
Ceruloplasmine, urine cooper	Wilson's disease	Patients < 40 yr
Alfa-1 antitrypsin	Deficit of $\alpha$ -1 antitrypsin	Pulmonary disease
Transferrin saturation	Hemochromatosis	In anicteric hepatocellular damage. Middle-aged men and older women.
Brilliant eco texture of the Liver.	Non-alcoholic steatohepatitis	In anicteric hepatocellular damage. Obesity, Metabolic syndrome.
Transaminase levels markedly high	Ischemic hepatitis	Disproportionately high AST levels. Hypotension, shock, recent surgery, heart failure, antecedent vascular disease, elderly
Dilated bile ducts by image procedures (AU, CT, MRCP and ERCP)	Biliary obstruction	Colic abdominal pain, cholestatic/ mixed pattern.

ALT: alanine aminotransferase; AP: alkaline phosphatase; AST: aspartate aminotransferase; AU: abdominal ultrasound examination; Anti-HAV: Hepatitis A antibody; Anti-HBc: Hepatitis B core antibody; Anti-HCV: Hepatitis C antibody; anti-LKM-1: Liver-kidney microsomal antibody type 1; AMA: antimitochondrial antibody; ANA: antinuclear antibody; ANCA: perinuclear antineutrophil cytoplasmic antibody; ASMA: antismooth muscle antibody; BPC: Biliary primary cirrhosis; CMV: cytomegalovirus; CT: computed tomography; EBV: Epstein-Barr virus; ERCP: Endoscopic retrograde cholangiography; MRCP: Magnetic resonance cholangiography.

are absent. However, clues pointing toward an immuno-allergic reaction might come from the presence of more subtle features, such as detectable serum autoantibodies and antinuclear and anti-smooth-muscle antibodies<sup>[12,31]</sup>. It is very likely that immunologic and metabolic idiosyncrasies operate concurrently in many cases of drug-induced hepatic injury<sup>[9,18]</sup>.

The value of hypersensitivity features as indirect evidence of drug-allergy is currently under debate. In a large cohort of patients with drug-induced idiosyncratic liver disease, a link between HLA-DRB1\*15 and-DQB1\*06 alleles and the cholestatic/mixed injury (but not hepatocellular injury) was established. The frequency of DRB1\*07 and DQB1\*02 alleles was also reduced in the cholestatic/mixed injury group<sup>[45]</sup>. Conversely, there were no differences in HLA-class II allele distributions between hepatotoxicity patients who had and those who had not any hypersensitivity features. This would suggest that the majority of cholestatic/mixed cases might have an allergy pre-disposition that was genetic, irrespective of whether they have accompanying signs of drug-allergy. This is less certain in hepatocellular cases with hypersensitivity features<sup>[46]</sup>.

Rapid improvements in biochemical values following withdrawal of drug therapy raises the possibility of a toxic etiology, even though this outcome may be seen in viral hepatitis as well. For hepatocellular injury, the involvement of a drug has been defined as being "highly likely" if there is a decrease of at least 50% in the levels of liver enzymes in the first 8 d following cessation of the therapy<sup>[9]</sup>.

Although less conclusive, expert consensus still considers drug involvement "suggestive" (and positively weighted on the clinical scale) if such a decrease occurs within 30 d following cessation of the therapy<sup>[10]</sup>.

Gastroenterologists assessing suspected drug hepatotoxicity should be aware that other atypical outcomes make laboratory scrutiny following drug withdrawal less categorical. In general, cholestatic reactions subside more slowly, with abnormal enzyme levels persisting for long periods of more than one year in some instances<sup>[47,48]</sup>.

Particularly confusing is the clinical evolution of some severe cases in which the injury may progress over several days despite drug cessation, or even progressing to fulminant hepatic failure<sup>[49,50]</sup>. Conversely, the phenomenon of "adaptation" to injury can occur with some drugs (e.g. statins). This can be responsible for the spontaneous improvement in liver function tests, despite the drug treatment being continued<sup>[42]</sup>.

Currently, the only way to confidently confirm idiosyncratic drug-induced hepatotoxicity is by demonstrating a recrudescence of liver injury following re-challenge with the suspected agent. Strictly, a positive response following re-exposure can be defined as a doubling of ALT and AP values for hepatocellular and cholestatic reactions, respectively. From a practical standpoint, however, it is hard to demonstrate this in most circumstances in which unintentional re-exposure occurs. Conversely, with careful inquiry a history of inadvertent re-challenge may be sometimes elicited because jaundice

**Table 5** Rationale for performing liver biopsy in a case suspected of having drug-induced hepatotoxicity

Clinical setting	Presentation
Any clinical context	Putative drugs not previously incriminated in liver toxicity
Acute or chronic liver disease	Female, autoantibody sero-positive High serum gammaglobulin and immunoglobulin G levels at presentation Incomplete or ambiguous de-challenge
Chronic alcoholism	Acute deterioration during aversive therapy (disulfiram, carbimide calcium)
Any acute liver deterioration in a patient with cirrhosis or chronic hepatitis C.	e.g. worsening of liver function in a patient with primary biliary cirrhosis receiving rifampicin or a chronic hepatitis C patient receiving ibuprofen
Chronic impairment in liver tests in non-jaundiced patients.	Especially if constitutional symptoms and/or clinical signs of portal hypertension are disclosed.
Young patients with sero-negative acute hepatitis or chronic liver disease.	Moderate decrease in ceruloplasmin levels or slight increases in urinary copper excretion.

had not accompanied the index episode and the symptoms were non-specific at the time (e.g., malaise, gastrointestinal complaints) and were thus easily overlooked. In such cases, what was believed to be the first instance of hepatitis was, in reality, a re-challenge episode<sup>[24]</sup>.

Intentional re-challenge implies several practical problems. Firstly, re-challenge is strictly contra-indicated in drug-induced hepatocellular hepatitis with associated hypersensitivity features because there is the risk of inducing a more severe, or even fulminant, clinical picture. Secondly, the amount of drug required to provoke the reaction is not known. Arbitrarily, a single dose needs to be chosen. Arguably, however, several doses may be necessary to reproduce liver damage in “metabolic” (non-allergic) drug-induced hepatotoxicity. This false negative response to re-challenge has been demonstrated for isoniazid<sup>[9]</sup> and, probably, applies to many other drugs operating under similar mechanisms. Finally, and most importantly, re-exposure of the patient to the suspected drug cannot be ethically supported purely for diagnostic purposes. Re-exposure should be attempted only when the drug being used is deemed essential for disease treatment, such as in the treatment of tuberculosis with isoniazid. Written informed consent needs to be obtained from the patient. Nevertheless, taking into consideration the consequences of misdiagnosing hepatotoxicity in pre-approval clinical trials<sup>[12]</sup>, we believe that testing clinical or sub-clinical hepatitis in the trial setting might be an additional indication for re-challenge<sup>[24]</sup>.

A common misconception among clinical gastroenterologists is the need to have a liver biopsy specimen to establish a diagnosis of drug-induced hepatotoxicity with confidence. Rather, since there are no histological findings specific for toxic damage, liver biopsy should not be performed routinely for this indication<sup>[14,51]</sup>. Indeed, a liver biopsy specimen, which is often taken several days after the clinical presentation of the symptoms when the pathological features are beginning to wane, may generate perplexity and confusion in cases in which chronological sequence criteria are critical and when exclusion of alternative causes appear to incriminate the drug.

Currently, a reasonable approach for performing a liver biopsy in patients with suspected drug-induced hepatotoxicity is restricted<sup>[13]</sup> to when the patient may

have an underlying liver disease and, hence, it is difficult to ascribe the picture to the candidate drug or to a recrudescence of the disease (Table 5) or, alternatively, to characterize the pattern of injury with those drugs that had not been previously incriminated in hepatotoxicity<sup>[12,30,36]</sup>. We believe that a liver biopsy is also justified for identifying more severe or residual lesions (e.g. fibrosis), which could have prognostic significance. For instance, in some chronic variants of hepatotoxicity, clinical and laboratory features reflect the severity of the liver injury<sup>[30,31]</sup> poorly and a liver biopsy may clarify its true magnitude. Further, severe bile duct injury during cholestatic hepatitis has been shown to be predictive of clinical evolution into chronic cholestasis<sup>[52]</sup>, and, in a retrospective study, the presence of fibrosis in the index liver biopsy had been related to the development of chronic liver disease<sup>[53]</sup>.

Since a liver biopsy is not available in most cases, focus on the biochemical expression of hepatic damage may help in incriminating a specific medication. Each drug appears to have its own “signature” in relation to a more-or-less specific pattern of liver injury<sup>[7,42]</sup>. Although this is true for some drugs (e.g., estrogens induce cholestatic injury and seldom any present with any other pattern of damage), for most other drugs such consistency is not so clear. For instance, amoxicillin-clavulanate tends to produce cholestatic or mixed damage, although hepatocellular damage has been reported frequently as well<sup>[16,54]</sup>. Hepatocellular and cholestatic or mixed injury have been noted with nimesulide<sup>[55]</sup> or troglitazone<sup>[56,57]</sup>, among others. Hence it is important for gastroenterologists to view a suspicion of drug-induced hepatotoxicity with caution and with awareness that any given drug can produce diverse types of injury<sup>[58]</sup>.

## CAUSALITY ASSESSMENT METHODS: IN SEARCH OF GREATER OBJECTIVITY

Clinical judgment is a necessary first step in the identification of any hepatic disease suspected of being caused by a drug or toxin. Diagnostic precision and objectivity are essential from the perspective of the practicing clinician who must decide whether to continue, or to stop, a therapy even though it may be the most appropriate for the disease under treatment and which might induce new events in the future if not correctly

identified. Except for the very rare circumstances in which an unintentional positive re-challenge may confirm the putative involvement of a drug, the evidence that is usually collected is often circumstantial, based on subjective impressions from previous experiences, and can lead to inaccurate diagnosis<sup>[59]</sup>. The process is time-consuming and delays clinical judgment; at least until other possible causes of liver disease have been excluded.

An approach that does not follow objective guidelines that complement standard clinical practice, results in causation categories that may be defined as drug-related (e.g. acetaminophen overdose, instances of positive re-challenge), not drug related (an alternative explanation found) or when the role of a medication may appear conditional<sup>[22]</sup>. This last judgment in which subjectivity prevails does, indeed, represent the bulk of situations in standard clinical practice. In addition, this judgment depends closely on the attending physician's skill and attitude towards the disease under consideration. Hence, agreement among physicians who evaluate a given case of drug-suspected hepatotoxicity may differ considerably. Variations in data consistency, completeness, and subjective weighting of causality arguments would, presumably, contribute to these differences.

### Algorithms or clinical scales

Over the last three decades, several groups have developed methods to improve the consistency, accuracy and objectiveness in causality assessment of adverse drug reactions. The qualities required for any scoring system are, usually, reproducibility and validity<sup>[60]</sup>. Reproducibility ensures an identical result when the scales are applied irrespective of the user. Validity refers to the capacity to distinguish between cases when the drug is responsible, and cases when the drug it is not responsible.

There are two possible categories of approach: the probabilistic approach<sup>[61]</sup> based on Bayesian statistics, which is rarely used in routine clinical practice because the approach requires precisely-quantified data to model the probability distributions for each parameter. The alternative approach is the widely used algorithm or clinical scale<sup>[62]</sup>. The key features of an adverse reaction are identified and integrated into an objective rating scale based on the sum of weighted numerical values assigned to individual axes of a decision strategy. The scores are translated into categories of suspicion. The different causality assessment methods developed can produce different numerical scales that may or may not be super-imposable and with non-identical categories of suspicion. This complicates any comparisons among the different scales<sup>[62]</sup>.

The Naranjo Adverse Drug Reaction Probability Scale (1981) proposed for adverse reactions to drugs (not restricted to hepatotoxicity) offers the advantage of simplicity and wide applicability<sup>[63]</sup>. This scale involves ten "yes", "no" or "not known or inapplicable" answers to questions concerning several disease-related areas: temporal relationship, competing causes, de-challenge/re-challenge results, and knowledge of the drug's reactions. In addition, universally-accepted criteria are introduced: placebo challenge, drug concentrations and objective measurement of adverse drug reaction. An adverse drug

reaction is described as a probability category based on the total score. The categories are: definite ( $\geq 9$  points scored), likely (5 to 8 points), possible (1 to 4 points), and doubtful ( $\leq 0$  points). The scale has been validated and has resulted in improved reproducibility of patient evaluations. The main source of inter-observer disagreement has been the question of alternative causes and reflects, perhaps, the complexity of the clinical situation and differences in clinical training among observers. Despite the lack of specificity with respect to hepatotoxicity, use of the Naranjo scale is a requirement by some journals when adverse drug-related events are reported<sup>[63,64]</sup> and, as well, in reporting to national drug monitoring bodies.

In 1992, under the auspices of the Council for International Organizations of Medical Sciences, a working group developed and implemented a standardized method for drug causality assessment and the scales are named after the organizers of the consensus meeting: CIOMS or RUCAM (Roussel Uclaf Causality Assessment Method)<sup>[65,66]</sup>. This method provides a standardized scoring system in which the limits and contents of most criteria were decided by consensus among experts on the basis of organ-oriented characteristics. The time-to-onset and duration are evaluated separately for hepatocellular versus cholestatic/mixed reactions since the latter can occur long after the cessation and may be resolved much more slowly (Table 6). The CIOMS/RUCAM scale provides a scoring system for 6 axes in the decision strategy. The categories of suspicion are "definite or highly probable" (score  $> 8$ ), "probable" (score 6-8), "possible" (score 3-5), "unlikely" (score 1-2) and "excluded" (score  $\leq 0$ ). One of the advantages of this system that is of note is that there are very few questions that require a subjective response. The scale can assign a definitive diagnosis of drug-induced hepatotoxicity in patients even without re-challenge. Also, it performs well with newly-marketed drugs or for a previously-unreported liver injury associated with an older drug. The major drawback is its complexity. It requires training in its administration and is less efficient when a user is unfamiliar with the format. The scale may seem cumbersome and while reading across the page, care needs to be taken to not misunderstand the questions; otherwise careless errors can be made. Recently, experts have criticized the weighting attributed to certain of the risk factors (e.g., age of the patient  $> 55$  years, alcohol consumption, pregnancy) which, at best, would be significant only for a limited number of drugs<sup>[23,42]</sup>.

More recently, Maria and Victorino from Portugal developed a simplified scoring system to overcome the above-mentioned problems. Called the Clinical Diagnostic Scale<sup>[67]</sup> (also termed the M&V scale) it uses several features of the CIOMS/RUCAM scale while omitting and adding others (Table 6). Five components were selected for inclusion in the scale: temporal relationship between drug intake and the onset of clinical symptoms, exclusion of alternative causes, presence of extra-hepatic manifestations (e.g., rash, fever, arthralgia, eosinophilia  $> 6\%$  and cytopenia), intentional or accidental re-exposure to the drug, and previous reports in the literature. The sum of the points for each parameter can vary from -6

**Table 6** Comparison of the scores for individual axes of the CIOMS and Maria & Victorino diagnostic scales

CIOMS criteria	Score	Maria & Victorino criteria	Score
Chronology criterion		Chronology criterion	
From drug intake until event onset	+2 to +1	From drug intake until event onset	+1 to +3
From drug withdrawal until event onset	+1 to 0	From drug withdrawal until event onset	-3 to +3
Time-course of the reaction	-2 to +3	Time-course of the reaction	0 to +3
Risk factors		Exclusion of alternative causes	-3 to +3
Age	+1 to 0		
Alcohol	+1 to 0	Extra-hepatic manifestations	0 to +3
Concomitant therapy	-3 to 0	Literature data	-3 to +2
Exclusion of non-drug-related causes	-3 to +2	Re-challenge	0 to +3
Literature data	0 to +2		
Re-challenge	-2 to +3		

to +20. Concordance with the five classic degrees of probability of adverse drug reactions is established on the basis of the tabulated score as follows: “definite” (score > 17), “probable” (score 14-17), “possible” (score 10-13), “unlikely” (score 6-9) and “excluded” (score < 6). The authors highlighted some limitations of the scale: The instrument performs poorly in atypical cases of drugs with unusually-long latency periods or chronic outcome. There is room for improvement in the exclusion of alternative causes of liver injury by more clearly specifying the clinical conditions to be excluded, as well as including detailed criteria for exclusion. The main advantage of the M&V scale is its ease of application in standard clinical practice.

### Comparison of assessment methods in hepatotoxicity

The merits of the CIOMS and the M&V scales and their degree of concordance were compared in a population of 215 patients included in a registry of hepatotoxicity<sup>[68]</sup>. Causality in this population had been verified previously by 3 experts as being drug-induced (185) or as non-drug (30 cases). Complete agreement between the M&V scale and the CIOMS scale was obtained in only 42 cases (18%). Discrepancies in the assessment of causality occurred in 186 ratings; in each of these cases the CIOMS scale ascribed a higher level of certainty than the M&V scale. The M&V system classified only about one third of the cases as “probable” or “definite”, and tended to underestimate the probability of causality. Indeed, the performance of the M&V scale was poor in reactions with long latency periods (more than 15 d; for example amoxicillin/clavulanic acid), clinical progression to chronic status following withdrawal (cholestatic pattern), or death.

The concordance of assessment was low because the two methods assigned different weightings to the assessment criteria and, as such, the reasons for discordance could be clearly identified. For example, a time-lapse of > 15 d between drug withdrawal and event onset can be rectified by subtracting 3 points from the score on the M&V scale. A time-lapse of > 6 mo between drug withdrawal and normalization of laboratory values (in cholestatic or mixed type of injury) or 2 mo (in hepatocellular damage) precluded a “definite” or “probable” diagnosis being reached. Unknown reactions to drugs marketed for > 5 years preclude a “certainty” diagnosis. Conversely, the best correlation between the

two scales was found for drug-induced liver injury that included a probable immuno-allergic mechanism. This is because the M&V scale includes questions that apply only to cases with extra-hepatic features. It would appear, therefore, that the CIOMS instrument shows better agreement with “common sense” clinical judgment. Aside from its clinical validity, the usefulness of the CIOMS scale is that it provides a framework that emphasizes topics that need to be addressed in cases of suspected hepatic adverse reaction in order to improve the consistency of judgment<sup>[68]</sup>.

The Clinical Diagnostic Scale (CDS or M&V) was further evaluated in the causality assessment of 135 hepatotoxic adverse drug reaction reports<sup>[69]</sup>. Initially, the CIOMS criteria were used to classify reactions as “drug-related”, “drug-unrelated” and “indeterminate.” Reports classified as drug-related (49 reactions) scored higher on the clinical scale, with a median score of 12 (range 8-15). Of those, no reactions were classified as “definite”, 20 were classified as “probable” and 23 as “possible”. It is important to note that 6 patients were classified as “unlikely”. The authors suggested that a cut-off score > 9 (falling into the category of “possible”) be used in clinical decision-making. It is of further note that “possible” is a fairly low category adjacent to “unlikely” and this makes the cut-off score somewhat unreliable for decision-making. In addition, the authors did not assess or compare the merits of the two systems in any detail<sup>[70]</sup>. Six patients whose hepatotoxicity was considered drug-related on the basis of the consensus classification (four of these patients having a positive re-challenge) scored < 10 (“unlikely”). Two patients had flucloxacillin-induced cholestasis that first appeared > 15 d following drug withdrawal, and in two other patients the reactions were fatal and therefore precluded an accurate assignment of cause. Two other patients with a long latency period scored only 1 point each for the onset-of-reaction score. These examples confirm the limitations of the clinical scale, as highlighted by the authors themselves and which are in accordance with the conclusions reached by Lucena *et al*<sup>[68]</sup>.

These comparative studies clearly show that the CIOMS scale, although far from being a perfect instrument, provides a uniform basis from which to develop a more precise approach in determining the causes of drug-induced hepatotoxicity. Indeed, medical

journals should insist on the application of the scale as a quality control prior to accepting reports of hepatotoxicity. Nevertheless, rules for assigning causality in drug-induced liver injury are no substitute for clinical judgment. For instance, when more than one drug could be the culprit, a “blind” application of the scale can lead to a somewhat misleading causality assessment if only chronological criteria are taken into account<sup>[38]</sup>. To avoid this, attention should be paid to major drug metabolic mechanisms in relation to potential pharmacokinetic interactions with the drug<sup>[71]</sup>.

## FUTURE DIRECTIONS

Apart from the development of unequivocal diagnostic biomarkers in the near future, it would be feasible in the short term to develop some refinements to make the CIOM scale more realistic; more relevant data can be incorporated and low-impact items need to be deleted from the scoring system. This task will be helped by using large databases of *bona fide* cases of hepatotoxicity. The DILIN network is developing and testing such a causality assessment method by a complex computer-based process for gathering and distributing relevant information<sup>[72]</sup>. This analysis would be useful to confirm or discard alcohol, age >55 years and pregnancy as general risk factors for hepatotoxicity, while evaluating the roles of other candidate susceptibility factors such as obesity (a condition that is associated with an increased expression of CYP2E1)<sup>[1]</sup>. Further, the age cut-off point does not consider the pediatric age range as a risk factor for toxicity of some drugs. Other known risk factors for individual drugs when present in the appropriate setting should be incorporated (e.g. HIV infection in sulfonamide use, co-infection with hepatitis B/hepatitis C virus and antiretroviral drugs, female gender for diclofenac).

In real practice, to make a definite diagnosis of drug-induced hepatotoxicity, clinicians pay much attention in assigning causality to a concordance between the actual biochemical profile of the patient and that which is provided by consensus guidelines relating to the suspected drug (for instance, cholestatic damage with amoxicillin-clavulanate use). As well, the presence of hypersensitivity features is considered by practicing physicians of crucial value in the attribution of culpability to a specific drug. Neither biochemical “signature” nor hypersensitivity features are weighted in the CIOMS scale<sup>[73]</sup> and these discrepancies await resolution.

Apart from these important questions, there is the need to validate a new instrument with an abridged scale that would provide a better approximation to the truth; i.e., the likelihood that a given case of hepatitis is due to a specific drug, at the very beginning of the patient evaluation process when key clinical decisions need to be made. The diagnosis needs to be made with confidence on admission of the patient and maintained while further confirmatory information is gathered. This would be the goal of a clinical assessment tool for the evaluation of drug-induced hepatotoxicity.

## Abstract

**AIM:** To identify tumor associated genes of rectal cancer and to probe the application possibility of gene expression profiles for the classification of tumors.

**METHODS:** Rectal cancer tissues and their paired normal mucosa were obtained from patients undergoing surgical resection of rectal cancer. Total RNA was extracted using Trizol reagents. First strand cDNA synthesis was indirectly labeled with aminoallyl-dUTP and coupled with Cy3 or Cy5 dye NHS mono-functional ester. After normalization to total spots, the genes which background subtracted intensity did not exceed 2 SD above the mean blank were excluded. The data were then sorted to obtain genes differentially expressed by  $\geq 2$  fold up or down in at least 5 of the 21 patients.

**RESULTS:** In the 21 rectal cancer patients, 23 genes were up-regulated in at least 5 samples and 15 genes were down-regulated in at least 5 patients. Hierarchical cluster analysis classified the patients into two groups according to the clinicopathological stage, with one group being all above stage II and one group all below stage II.

**CONCLUSION:** The up-regulated genes and down-regulated genes may be molecular markers of rectal

cancer. The expression profiles can be used for classification of rectal cancer.

## INTRODUCTION

Colorectal cancer (CRC) is one of the most common causes of cancer related deaths, the majority of which are secondary to liver metastasis. Whereas significant improvements have been made in patient survival, the mortality is still quite high in patients with metastatic cancer<sup>[1]</sup>. Clinical trials of new therapeutic agents are constantly ongoing and drug effectiveness is improving. However, a complete cure for patients with advanced colorectal cancer awaits new targets and strategies. To achieve this goal, a comprehensive understanding of the mechanisms of colorectal carcinogenesis is essential. In the last two decades these mechanisms have been intensively studied. At the molecular level, activation of oncogenes<sup>[2]</sup> and inactivation of tumor suppressor genes are processes known to be involved in colorectal cancer<sup>[3,4]</sup>. CRC typically develops over decades and involves multiple genetic events. This has led to the development of a multi-step model of colorectal tumorigenesis<sup>[5]</sup>. It is generally accepted that one of the initiating steps in colorectal carcinogenesis is mutation in APC tumor suppressor gene<sup>[6]</sup>.

APC is known to bind to a cell signaling/transcription factor  $\beta$  catenin. Activation of the Wnt pathway normally signals the association of  $\beta$ -catenin with members of the T-cek factor/lymphocyte-enhancer factor family and translocation to nucleus<sup>[7,8]</sup>. This complex can activate the transcription of a variety of target genes including c-Myc<sup>[9]</sup> and cyclin D1<sup>[10,11]</sup>. Loss of APC function leads to an abnormal accumulation of  $\beta$ -catenin and dys-regulates Wnt signaling<sup>[12]</sup>. Traditional methods of identifying novel targets that are involved in colon cancer progression are based on the studies of individual

genes. The developments of oligonucleotide or cDNA microarrays have made it possible to permit the expression levels of tens of thousands of genes to be monitored simultaneously and rapidly. These new methods have been used to identify the genes involved in colorectal cancer development. By using cDNA microarray with different number of elements, many genes have been identified. Kitahara<sup>[13]</sup> identified 235 genes of differential expression in 9216 human genes by using laser-capture microdissection. These differentially expressed genes include those associated with signal transduction, metabolic enzymes, production of reactive oxygen species, cell cycle, transcription, mitosis and apoptosis<sup>[13]</sup>. In another study, Williams identified 2632 genes (574 up-regulated and 2058 down-regulated) of totally 9592 genes microarray were consistently expressed in one-third patients<sup>[14]</sup>. In an effort to use gene expression profiles to find the molecular marker of rectal cancer, we constructed cDNA microarray with 373 known genes and 73 expressed sequence tags (ESTs) that are related to the pathogenesis of tumor.

## MATERIALS AND METHODS

Fabrication of tumor associated genes cDNA microarray. Totally 447 cDNA clones were obtained from the Research Genetics (Invitrogen, life Technologies, USA). *E. coli* with cDNA clones were cultured with LB supplemented with ampicillin (50 mg/L) or chloramphenicol (170 mg/L). Clone plasmids were extracted with Edge BioSystems plasmid extraction kit. Clone inserts were PCR amplified from the plasmids with M13 vector specific universal primer (M13F: 5'-GGT GTA AAA CGA CGG CCA GTG-3'; M13R: 5'-CAC ACA GGA AAC AGC TAT G-3') in 96-well PCR microtiter. The PCR products were purified according to protocols published previously, and resuspended in Arrayit Spot solution [DNA precipitations. [http://cmgm.stanford.edu/pbrown/protocols/2\\_DNA.html](http://cmgm.stanford.edu/pbrown/protocols/2_DNA.html)<sup>[15]</sup>. The re-suspended PCR products were printed in duplicate on silanated glass slides (Cel associated) with Cartisan Spot machines and UV-cross-linked at 3500 mJ using Stratagene cross-linker. Printed slides were post-processed using an online method<sup>[16]</sup>.

### Tissue samples

Rectal cancer tissues and their corresponding normal rectal tissues were obtained with informed consent from 21 patients who underwent surgical resection of their tumor in Shandong Tumor Hospital. The tissues were stored at -80°C. Tissues were homogenized with Trizol (Life Technologies) in homogenizer of IKA. Total RNA was extracted according to the manufacturer's protocols. The  $A_{260/280}$  of total RNA was between 1.8-2.0.

### Probe preparation and hybridization and data analysis

Twenty microgram of total RNA from matched tumor/normal sample was reverse transcribed into cDNA using Superscript II (Invitrogen, Carlsbad CA) with random hexamers (Invitrogen, Carlsbad CA). Probe preparation was done based on online protocols and as described by Yang<sup>[17]</sup> and slightly modified by our laboratory<sup>[18]</sup>. First

strand cDNA synthesis was primed with 6 µg random hexamers (Life Technologies) by heating at 70°C for 10 min, snap-cooling on ice for 30 s and incubated at room temperature for an additional 5-10 min. Reverse transcription was performed in the presence of 500 µmol/L each of dATP, dCTP and dGTP, 200 µmol/L aminoalyl-dUTP (Sigma), 300 µmol/L dTTP, 1 × first strand buffer, 10 µmol/L dithiothreitol, and 400 U superscript II (Life Technologies, Carlsbad, CA) in 30 µL reaction at 42°C overnight. Reactions were quenched with 0.5 mol/L EDTA and RNA template was hydrolyzed by addition of 10 µL of 1 mol/L NaOH followed by heating at 70°C for 10 min. Reactions were neutralized with 10 µL 1 mol/L HCl and cDNA was purified with Amicon Microcon YM100 according to the manufacturer's protocol. cDNA was lyophilized in speed vacum Centrifuger (Eppendorf 5301) and resuspended in 4.5 µL of 0.1 mol/L sodium carbonate (pH 9.0) buffer. NHS ester (4.5 µL) Cy3 or Cy5 dye (Amersham Pharmacia, GE Healthcare) in DMSO [dye from one tube (1 mg) was dissolved in 73 µL of DMSO] was added and reactions were incubated at room temperature in the dark for 1 h. Coupling reactions were quenched by addition of 41 µL of 0.1 mol/L sodium acetate, pH 5.2, and unincorporated dye was removed using QiaQuick PCR purification kits according to the manufacturer's instruction.

### Hybridization and image processing

Each slide was printed with duplicate microarrays. Slides were prehybridized in 1% BSA, 5 × SSC, 0.1% SDS for 45 min, washed by dipping in double distilled deionized H<sub>2</sub>O and 2-propanol twice and air dried and used in 1 h. Fluorescent cDNA probes were lyophilized to dryness and resuspended in 10 µL hybridization buffer (formamide 5 µL, 20 × SSC 2.5 µL, RGDDH 201 µL, 2% SDS 0.5 µL and 1 µL human cot-1 DNA). Combined Cy dye labeled probes were denatured at 100°C water bath for 2 min and cooled at room temperature for 5 min. Room temperature probes were applied to the pre-hybridized microarray and covered with hybridized coverslip (Sigma) and placed in the hybridization chamber (Corning). Hybridizations were carried out at 42°C water bath for 20-22 h followed by washing in 2 × SSC and 0.1% SDS for 3 min, 1 × SSC for 2 min and 0.2 × SSC for 1 min and 0.05 × SSC for 10 s, and dried by spinning in plate centrifuge at 800 rotation/min for 4 min. Arrays were scanned using a Scanarray 4000 dual color confocal laser scanner (Packard Bioscience). Data were saved as paired TIFF images. Paired images were analyzed with Quantarray 3.0 provided by the Scanner. After normalized to the total, genes of which the background subtracted intensity did not exceed 2 SD above the mean blank were excluded. The data were then sorted to obtain genes differentially expressed by  $\geq 2$  fold or  $\leq 0.5$  in at least 5 of the patients.

### Semi-quantitative RT-PCR

Some of the differentially expressed genes were selected for validation of the microarray results with semi-quantitative RT-PCR. The sequences of the primers were designed with online primer design software (Primer 3 old

**Figure 1** Histopathological examination of the tumor tissues of rectal cancer. **A:** Normal rectal mucosa tissue; **B:** Adenocarcinoma of rectal tissues; **C, D** and **E:** images of normal tissue, tumor tissues and overlay image of the tumor to normal of patient No. 19 respectively. The density of the spot reflects the fluorescent intensity of the genes. In the overlay images, the yellow spots represent the expression of the genes in tumor tissues and normal tissues were not significant. The red spots represent the up-regulated genes in rectal cancer tissues. The green spots represent the down-regulated genes in rectal cancer tissues.

Version [http://www.genome.wi.mit.edu/cgi-bin/primer/primer3.cgi#PRIMER\\_self\\_any](http://www.genome.wi.mit.edu/cgi-bin/primer/primer3.cgi#PRIMER_self_any)<sup>[19]</sup>. The sequences of primers used for RT-PCR are as follows: MTA1 forward, 5'-AGCTACGAGCAGCACAACGGGGT-3', reverse, 5'-CACGCTTGTTTCCGAGGAT-3';  $\beta$ -actin forward, 5'-GTGGGGCGCCCCAGGCACCA-3', reverse, 5'-CTCCTTAATGTCACGCACGATTTC-3'<sup>[12]</sup>. RT-PCRs were performed with TAKARA version 2.1 RT-PCR kit using random primers in 25  $\mu$ L volume. The PCR reaction was performed at 94°C for 2 min, followed by 30 cycles at 94°C for 30 s, 56°C for 30 s and 72°C for 30 s and a final extension at 72°C for 5 min.  $\beta$ -actin was used as internal control. The products were electrophoresed in 1% agarose (Spanish).

### Immunohistochemistry analysis of the BCL-2 protein expression in all patients

All the samples of rectal cancer and paired normal tissues were subject to immunohistochemistry examination for the expression of BCL-2 to validate the results of microarray. The primary antibody of BCL-2 was a product of Santa Cruz (1:100 dilution). The expressions of BCL-2 in tumor and normal tissues were read by two pathologists blindly. The image was captured with NIKON H600L microscope with digital camera.

### Cluster analysis and principal component analysis

The normalized ratios of all pairs of samples of rectal cancer were put into an Excel-sheet. And every ratio was log2 transformed and saved as a tab-delimited Txt. file that was ready to be analyzed with Version 5.0 kindly provided online free of charge by Professor Leif E Peterson (<http://mbcr.bcm.tmc.edu/genepi>)<sup>[20]</sup>.

## RESULTS

Totally 21 pairs of rectal samples were analyzed. Their pathological and clinical characteristics are shown in Table 1. The

**Table 1** Clinical data of the rectal cancer patients

Patient No.	Age (yr)	Sex	TNM	Clinical stage
1	31	Male	T4N2M0	III
2	51	Female	T3N1M0	III

tissue samples were all confirmed to be rectal cancer and normal paired tissues (Figure 1A and B). The differential expression genes were identified by a tumor associated genes microarray fabricated in our laboratory. The representative scan images are shown in Figure 1C, D and E which represented the image of normal tissue, rectal cancer and the overlay of the image respectively. In the overlay images of microarray, red color spots represented genes that were up-regulated in rectal cancer tissues, green color spots represented down-regulated genes and yellow color spots represented the expression of genes in cancer

The number in the brackets represents IMAGE clone number.

tissue, which were between 0.5-2.0. If the ratio of the duplicate spots was the same, we defined it the significantly differentially expressed gene. The expression ratios of tumor associated genes in tumor and paired normal rectal tissues were analyzed with QuantaArray 3.0 and normalized to the total. The 2-fold up- or down-regulated genes were defined as differential expression genes.

The results showed that 23 genes were up-regulated in at least 5 samples (Table 2) and 15 genes were down regulated at least in 5 samples (Table 3). The up-regulated genes included growth factors, growth factor receptor, nuclear transcription factor, oncogenes, adhesion molecules, and some metabolic enzymes.

To validate the results of microarray examination, the expression of MTA1 mRNA was measured with semi-quantitative RT-PCR using  $\beta$ -actin as internal control.

The numbers in the brackets represent IMAGE clone number.

The results showed that the MTA1 expression was down-regulated (Figure 2). The up-regulation of BCL-2 was also validated by immunohistochemistry and significant expression of BCL-2 was shown in tumor tissues and less expression in normal rectal mucosa (Figure 3A-D).

For the cluster analysis, the Claufavor version 6.0 supplied kindly by Professor Leif Peterson was used to classify the patients or genes by gene expression profiles. As a result, the patients were classified into two groups, with patients No 22, 13, 12, 1, 11, 21, 19, 2, 6, 16, 15, 3 into one group which were all above grade II except patient No 15 and the other patients into another group. The top 100 genes that were related with rectal cancer are shown in Figure 4A and B. Principal component analysis showed that all the genes were belonged to 7 factors, in which 17 genes were positively correlated with factor 1 ( $r > 0.45$ ). They are as follows: apoptosis associated protein, xeroderma pigmentosum, complementation group A (XPA), early endosome antigen 1162 kDa (EEA), lactate dehydrogenase A, spectrin, alpha non-erythrocytic 1 (alpha-fodrin), small nuclear ribonucleoprotein associated protein n (human), phorbol-12-myristate-13-acetate-induced protein 1 (PMAIP1), RAS p21 protein activator (GTPase activating protein) 1 (RASA1), cathepsin D (lysosomal aspartyl protease) (CTSD), v-ski avian sarcoma viral oncogene homolog (SKI), Hs.271616, ESTs, small nuclear ribonucleoprotein associated proteins b and b' (human); contains mer22.

**Figure 2** Semi-quantitative RT-PCR of MTA1 mRNA. **A:** Electrophoresis image of MTA1 expression, lanes 1-8 represent the mRNA expression of MTA1 in 4 pairs of rectal cancer patients, respectively. Lanes 1, 3, 5, 7 were normal tissues and 2, 3, 6, 8 were tumor tissues. **B:** The semi-quantitative analysis results with spot intensity software. The ratios of MTA1 in tumor tissues were lower than that of paired normal tissues.

**Figure 3** Validation of the expression of BCL-2 with immunohistochemistry method. **A:** The normal rectal mucosa. There was no expression of BCL-2 in all the cells; **B:** The expression of BCL-2 in well differentiated rectal cancer. The tumor cells were stained yellow-brown by DAB; **C:** The expression of BCL-2 in another intermediately differentiated rectal cancer. The expression of BCL-2 was also significant in tumor cells; **D:** The expression of BCL-2 in poorly differentiated rectal tissues.

t1 mer22 repetitive element, CD83 antigen (activated B lymphocytes, immunoglobulin superfamily) (CD83), bone marrow stromal cell antigen 1 (BST1), Wnt inhibitory factor-1 (WIF-1), histone deacetylase 1 (HDAC1), microvascular endothelial differentiation gene 1 (MDG1).

Nine genes were negatively correlated with factor 3 ( $r < -0.45$ ) (Figure 4B); they are as follows: apoptosis associated protein, phospholipase C, delta 1 (PLCD1), small nuclear ribonucleoprotein associated protein n (human), RAS p21 protein activator (GTPase activating protein) 1 (RASA1), cathepsin D (lysosomal aspartyl protease) (CTSD), met proto-oncogene (hepatocyte growth factor receptor) (MET), 65 KDa yes-associated protein; contains Alu repetitive element; contains element MER31 repetitive element, KIAA0712 gene product, ESTs (Weakly similar to homolog of the *Aspergillus nidulans* sudD gene product). These results showed that microarray expression profiles may be used for the classification of rectal cancer.

## DISCUSSION

Differential gene expression can be detected in several ways, including differential screening of cDNA libraries<sup>[21]</sup>, subtraction hybridization<sup>[22]</sup> differential display of RNA<sup>[23]</sup>, serial analysis of gene expression (SAGE)<sup>[24]</sup> and cDNA microarray<sup>[25]</sup>. Among these cDNA microarray is the most commonly used technique now for surveying many samples with thousands of genes<sup>[26]</sup>. By using cDNA microarray methods and laser capture microdissection, 235 differential expression genes were identified from colorectal cancers<sup>[14]</sup>. A colonchip has been constructed for the identification of genes that are related to colorectal cancer tumorigenesis, 59 genes showing two-fold increase of altered expression with 23 genes commonly up-regulated and 36 genes commonly down-regulated in colorectal cancer<sup>[27]</sup>. All these studies were about colorectal carcinoma, while few were concerned with rectal cancer. Moreover, rectal cancer has the tendency to occur in young

**Figure 4** Hierarchical cluster analysis and principal component analysis results. **A:** Hierarchical cluster analysis of patients and genes. The patients could be classified into two groups: one group of clinicopathological stage above grade II and one group below grade II. **B:** Principal component analysis of the genes related to rectal cancer.

age. To identify the molecular markers of rectal cancer we constructed a tumor associated genes cDNA microarray for the evaluation of the predisposition to metastasis with gene expression profiles. All the tumor associated genes were selected from literatures that are related with the growth, invasion and metastasis process of tumor and some ESTs. We used this cDNA microarray to detect the differential expression genes that play important roles in the pathogenesis of rectal cancer. We found that 23 genes were up-regulated in rectal cancers compared with their paired normal tissues. The most commonly expressed

gene in rectal cancers was BCL-2. It was validated by immunohistochemistry. We also found that oncogene vav-2 was up-regulated in 5 of the 21 patients. Vav-2 acts as a guanosine nucleotide exchange factor (GEF) for RhoG and RhoA-like GTPases in a phosphotyrosine-dependent manner. Vav-2 oncogenic activation correlates with the acquisition of phosphorylation-independent exchange activity. *In vivo*, wild-type Vav-2 is activated oncogenically by tyrosine kinases, an effect enhanced further by co-expression of RhoA. Likewise, the Vav-2 oncoprotein synergizes with RhoA and RhoB proteins in cellular

transformation. Transient transfection assays in NIH-3T3 cells show that phosphorylated wild-type Vav-2 and the Vav-2 oncoprotein induce cytoskeletal changes resembling those observed by the activation of the RhoG pathway. In contrast, the constitutive expression of the Vav-2 oncoprotein in rodent fibroblasts leads to major alterations in cell morphology and to highly enlarged cells in which karyokinesis and cytokinesis frequently are uncoupled<sup>[28]</sup>.

There were 15 down-regulated genes including PIGF gene products, MTA1, WIF-1 ras-guanine releasing protein and all pre-mRNA cleavage factor Im. There was a controversial report that MTA1 are down-regulated in rectal cancer and it has been validated by RT-PCR. Toh *et al*<sup>[29]</sup> reported a relative over-expression of MTA1 mRNA (tumor/normal ratio  $\geq 2$ ) was observed in 14 of 36 (38.9%) colorectal carcinomas. Tumors over-expressing MTA1 mRNA exhibited a significantly deeper wall invasion and a higher rate of metastasis to lymph nodes, and tended to be at an advanced Dukes' stage with frequent lymphatic involvement<sup>[29]</sup>.

In addition, Nicolson has reported the over-expression of MTA1 in several cell lines (the breast, ovarian, lung, gastric and colorectal cancer but not melanoma or sarcoma) and cancerous tissues (breast, esophageal, colorectal, gastric and pancreatic cancer)<sup>[30]</sup>. Giannini *et al*<sup>[31]</sup> have reported that MTA1 increased in tumor tissues than in normal tissues by real-time PCR. This difference may be attributed to the different function MTA1 exerts in different tumor stage. Further studies are needed at protein levels.

To investigate the possibility of classification of tumor with gene expression profiles, hierarchical cluster analysis was done and the results showed that the patients could be divided into two groups: clinicopathological grade higher than grade II and the other below grade II.

Many studies have done to uncover mechanisms underlying progression of colorectal carcinogenesis and to identify genes associated with the liver metastasis. Li *et al*<sup>[32]</sup> analyzed expression profiles of 14 primary colorectal cancers with liver metastases, and compared them with profiles of 11 non-metastatic carcinomas and those of 9 adenomas of the colon. A hierarchical cluster analysis using data from a cDNA microarray containing 23040 genes indicated that the cancers with metastasis had different expression profiles from those without metastasis although a number of genes were commonly up-regulated in primary cancers of both categories. They found that 54 genes were frequently up-regulated and 375 genes were frequently down-regulated in primary tumors with metastases to liver, but not in tumors without metastasis. Subsequent quantitative PCR experiments confirmed that PRDX4, CKS2, MAGED2, and an EST (GenBank accession number BF696304) were expressed at significantly higher levels in tumors with metastasis<sup>[32]</sup>. Koehler has studied the expression profiles of 25 colorectal carcinomas (CRCs, pT1-4), corresponding normal colonic mucosa, and 14 liver metastases using cDNA arrays containing 1176 cancer-related genes (Clontech). They found no specific expression signature in matching metastases, but a set of 23 classifier genes with statistically significant expression patterns in high- and

low-stage tumors was identified<sup>[33]</sup>.

Komori *et al*<sup>[34]</sup> constructed the gene expression profiles of 50 colorectal cancers (CRCs) and 12 normal colorectal epithelia using a cDNA microarray specially constructed for CRC. Hierarchical clustering analysis and principal component analysis could clearly distinguish the gene profiles of cancer tissues from those of normal tissues. They identified 22 up-regulated genes and 32 down-regulated genes in CRC. Many of these genes have been previously identified in association with human carcinogenesis, being 68% and 78%, respectively<sup>[34]</sup>.

Moreover, D'Arrigo *et al*<sup>[35]</sup> compared the transcriptional profiles of 10 radically resected primary CRCs from patients who did not develop distant metastases within a 5-year follow-up period with those of 10 primary/metastatic tumor pairs from patients with synchronous liver metastases. Arrays of 7864 human cDNAs were utilized using laser-microdissected bioptic tissues. Of 37 gene expression differences found between the 2 groups of primary tumors, 29 were also different between non-metastasizing tumors from metastases. The gene encoding mannosyl (alpha-1, 3-)-glycoprotein beta-1, 4-N-acetylglucosaminyl-transferase (GnT-IV) became significantly up-regulated in primary/metastatic tumor pairs ( $P < 0.001$ )<sup>[35]</sup>. All these results were obtained from colorectal cancer. However, colon cancer and rectal cancer may have different molecular markers. Our methods have similar ability in classifying tumor with gene expression profiles.

In conclusion, we have screened 23 up-regulated genes and 15 down-regulated genes from 21 rectal cancers. Hierarchical cluster analysis divided the patients into one group with clinicopathological stage above II, and one group below stage II. These genes may be the molecular markers of rectal cancer. In addition, we have also found gene expression profiles in different stage of rectal cancers and to further screen the molecular markers in each stage of the cancer larger samples are needed.

## ACKNOWLEDGMENTS

We thank Professor Leaf Peterson at Baylor College of Medicine for his free CLUSFAVOR 5.0 software and his instruction for the study. We also thank Dr Feng-Wei Wang in Medical College of Wisconsin for the language correction.
