<sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  vs DM group.

of food<sup>[20,21]</sup>, and also have various potential applications in agricultural industry<sup>[5]</sup>. Chemical and enzymatic methods are widely used to produce COS and chemical hydrolysis is more commonly used. However, chemical hydrolysis has some drawbacks to be commercialized, due to the production of some toxic compounds, higher risk associated with environmental pollution, and lower production yields. COS prepared by acid hydrolytic methods cannot serve as bioactive materials in general due to the possible contamination of toxic chemical

compounds. Therefore, lack of proper technology for large-scale manufacture of COS with desired molecular weights has made its use difficult in human beings in the past years. Enzymatic processes which are generally carried out in batch reactors are preferred to chemical methods. This is due to minimized adverse chemical modifications of products during enzymatic hydrolysis and promotion of their biological activities. The properties of COS, such as DP, DA, charge distribution and nature of chemical modification in the molecules strongly influence its

observed biological activities. Therefore, molecular weight is considered a principal characteristic of COS that highly correlates to their biological activities. We have successfully obtained highly deacetylated (90%) chitooligosaccharides with a molecular weight of 1200 u by enzymatic hydrolysis and investigated its effect on the proliferation of pancreatic islet cells and release of insulin, lowering 2h plasma glucose and normalizing oral glucose tolerance *in vivo* and *in vitro*.

Type 2 diabetes characterized by peripheral insulin resistance followed by failure of compensation for pancreatic  $\beta$  cells and ultimately frank hyperglycemia<sup>[22]</sup>, is traditionally considered discrete pathophysiological lesions. Proliferation of pancreatic  $\beta$  cells is slow and has a limited potential for regeneration (< 1% of the cells enter mitosis over 24 h in the adult state). Pancreatic  $\beta$  cells maintain the blood glucose concentration within a narrow range by modulating insulin secreting rate in response to the glucose levels in blood. Proper insulin secretion requires the coordinated functioning of numerous  $\beta$  cells that form pancreatic islets. This coordination depends on a network of communication mechanisms whereby  $\beta$  cells interact with extracellular signals and adjacent cells *via* connexin channels. The structure and function of primary culture islet cells and  $\beta$  cell lines were observed under inverted phase contrast microscope, and the viability of pancreatic islet cells and  $\beta$  cell lines was determined by MTT colorimetric assay indirectly in our study. In order to ensure adequate access of COS to pancreatic islet cell surfaces, we performed COS-stimulated insulin release experiments using monolayer cultures of rat islets. The results indicated that all concentrations of COS could markedly increase the viability of pancreatic islet cells. COS at the concentration of 100 mg/L effectively accelerated the proliferation of pancreatic islet cells and had direct effects on pancreatic  $\beta$  cells and release of insulin. Exposure of primary culture pancreatic cells to COS (100 mg/L) could continuously increase the secretion of insulin from 6 to 14 d, as compared to the normal control group.

To study the specific role of COS in endocrine pancreatic function, we performed *in vivo* experiments of islet function in STZ-DM mice and measured the 2hPG and OGTT. Fasting plasma glucose and random plasma glucose used to be measured as the standard about the effect of lowering the plasma glucose. However neither fasting plasma glucose nor random plasma glucose can represent the actual glucose tolerance and insulin action<sup>[23-25]</sup>. The gold standards for assessment of insulin action and glucose homeostasis are the euglycemic, hyperinsulinemic and hyperglycemic clamp studies<sup>[26-28]</sup>. Clinically, single-value glucose determinations are probably the most commonly used marker of glucose homeostasis. Assessment of glucose tolerance in a clinical setting has traditionally been conducted using the glucose tolerance test<sup>[29,30]</sup>. Since 2 h plasma glucose is far more sensitive than fasting plasma glucose, we chose 2 h plasma glucose and oral glucose tolerance test as the standard to evaluate the effect of chitooligosaccharides in STZ-induced diabetic rats.

Our findings suggest that all concentrations of chitooligosaccharides can decrease 2hPG in 60 d. The best

effect was observed in the medium dosage (500 mg/kg) treatment group, with the plasma glucose level decreased to 16.14 mmol/L compared to the DM group ( $P < 0.01$ ). The medium dosage of chitooligosaccharides also had the best effect on glucose tolerance, accounting for 68.69% of the area under the DM group curve. The mechanism of chitooligosaccharides in decreasing the plasma glucose is perhaps due to the following reasons. Chitooligosaccharide is an alkaline, which can increase the pH values in the body fluid and the sensitivity of insulin. Chitooligosaccharides can regulate the function of the endocrine system, and reduce the secretion of insulin to normal, thus maintaining the normal metabolism of plasma glucose. Chitooligosaccharides can promote the proliferation of  $\beta$  cells and recovery of the function of damaged  $\beta$  cells.

Insulin is the primary hormone that regulates glucose uptake in mammals. In addition, a recent study demonstrated that insulin resistance itself at the level of  $\beta$  cells may contribute to the failure of pancreatic compensation, suggesting a theory for the pathogenesis of type 2 diabetes<sup>[31]</sup>. Indeed, mice with STZ-induced damage in  $\beta$  cells lose their ability to respond adequately to glucose stimulation and have progressive glucose intolerance. In the present study, we demonstrated that patients treated with COS had a normal  $\beta$  cell hyperplastic response to insulin resistance, with their 2hPG and urine glucose decreased, and the disorders of glucose tolerance normalized, indicating that COS play an important role in maintenance of glucose homeostasis *in vivo*.

In conclusion, COS possess various biological activities and can be used in the treatment of diabetes mellitus. COS can increase insulin secretion of pancreatic cells and improve the overgrowth of  $\beta$  cells and isolated pancreatic islet cells, decrease the 2hPG, and normalize the disorders of glucose tolerance in STZ-induced diabetic rats *in vivo*. Further study should be directed towards understanding their molecular mechanisms.

## COMMENTS

### Background

Chitin and chitosan can be isolated from different sources, crab and shrimp shell wastes are currently utilized as the major industrial source of biomass for the large-scale production of chitooligosaccharide (COS). Several methods have been recently used to prepare COS, and enzymatic preparation methods capture a great interest due to their safety and non-toxicity. COS possesses various biological activities and has been shown to be particularly useful in many fields. However, little attention has been paid to its activity in diabetes mellitus and related mode of action.

### Research frontiers

Type 2 diabetes is characterized by peripheral insulin resistance followed by failure of compensation for pancreatic  $\beta$  cells and ultimately hyperglycemia. Type 2 diabetes is traditionally considered discrete pathophysiological lesions. The proliferation of pancreatic  $\beta$  cells is slow with a limited potential for regeneration (< 1% of the cells enter mitosis over 24 h in the adult state). Pancreatic  $\beta$  cells maintain the blood glucose concentration within a narrow range by modulating insulin secreting rate in response to the glucose levels in blood. Proper insulin

secretion requires the coordinated functioning of numerous  $\beta$  cells that form pancreatic islets. This coordination depends on a network of communication mechanisms whereby  $\beta$  cells interact with extracellular signals and adjacent cells via connexin channels. Our study indicated that COS could increase insulin secretion of pancreatic cells and improve the overgrowth of  $\beta$  cells and isolated pancreatic islet cells, and decrease 2hPG, normalize the disorders of glucose tolerance of STZ-induced diabetic rats *in vivo*.

### Innovations and breakthroughs

Soluble chitooligosaccharides with lower molecular weight were prepared by enzymatic hydrolysis of chitosan with *t* chitosanase. Enzymatic processes are generally carried out in batch reactors and are preferred to chemical methods. Our study indicated that COS could increase insulin secretion of pancreatic cells and improve the overgrowth of  $\beta$  cells and isolated pancreatic islet cells, decrease the 2hPG, and normalize the disorders of glucose tolerance of STZ-induced diabetic rats *in vivo*.

### Applications

COS possesses various biological activities and can be utilized in a number of industries. Unlike high molecular weight chitosan, COS which is readily soluble in water due to its shorter chain and free amino groups in D-glucosamine units and easily absorbed through the intestine, can quickly get into the blood flow and has systemic biological effects in the organism. However, lack of proper technology for large-scale manufacture of COS with desired molecular weights has made its use difficult in human beings in the past years. Enzymatic processes which are generally carried out in batch reactors are preferred to chemical methods. This is due to minimized adverse chemical modifications of products during enzymatic hydrolysis and its biological activities. We have successfully obtained highly deacetylated (90%) chitooligosaccharide with a molecular weight of 1200 u by enzymatic hydrolysis and investigated its effect on the proliferation of pancreatic islet cells and release of insulin, lowering the 2 h plasma glucose and normalizing the oral glucose tolerance *in vivo* and *in vitro*. Our study indicate that COS could increase insulin secretion of pancreatic cells and improve the overgrowth of  $\beta$  cells and isolated pancreatic islet cells, and decrease the 2hPG, normalize the disorders of glucose tolerance in STZ-induced diabetic rats *in vivo*.

### Terminology

Chitin, chitosan and chitooligosaccharides: Chitin is a natural polymer, the second most abundant organic resource on the earth next to cellulose. Chitosan is a polycationic copolymer consisting of  $\beta$ -1, 4-linked 2-acetamido-D-glucose and  $\beta$ -1, 4-linked 2-amino-D-glucose units. Both chitin and chitosan are copolymers of  $\beta$  (1-4) linked N-acetyl- $\beta$ -glucosamine and glucosamine units. The proportion of N-acetyl-glucosamine units in total number of units determines the degree of deacetylation. The degree of deacetylation has an inverse relationship with the number of N-acetyl-glucosamine units, thus deacetylation of chitosan is achieved by removing Nacetyl group. In chitosan, the degree of deacetylation is higher than 50%. Chitooligosaccharide obtained by hydrolysis or degradation of chitosan, is not only water-soluble but also more effective than chitosan. NIT-1 cell line: NIT-1 cell line, a widely used  $\beta$  cell line in insulin secretion studies, is established from non-obese diabetic (NOD) mice transgenic for the SV40 T antigen under control of the insulin promoter; Streptozotocin (STZ): 2-deoxy-2-(3-methyl-3-nitrosourea)-1-D-glucopyranose is actively transported into pancreatic  $\beta$  cells via the Glut-2 glucose transporter. It reacts at many sites in DNA but in particular at the ring nitrogen and exocyclic oxygen atoms of the DNA bases, predominantly producing 7-methylguanine, 3-methyladenine (3-meA), and O6-methylguanine adducts.

### Peer review

This is a good descriptive study in which authors analyzed the antidiabetic effects of chitooligosaccharide (COS) on proliferation of pancreatic islet cells in streptozotocin-induced diabetic rats. The results are interesting and suggest that COS is a potential therapeutic substance that could be used in the treatment of diabetes mellitus. The authors also studies the interesting questions about the molecular mechanism involved in COS biological activity.

a mean increase  $\geq 1$  CSBM/wk over wk 1-4 (47.7% vs 35.0%, tegaserod vs placebo, respectively,  $P = 0.0018$ ) and for the absolute number of  $\geq 3$  CSBMs/wk over wk 1-4 (25.0% vs 14.5%, tegaserod vs placebo, respectively,  $P = 0.0021$ ). Improvements in other symptoms of CC were also seen in the tegaserod group, including improved stool form and reduced straining. In addition, more patients in the tegaserod group reported satisfactory relief from their constipation symptoms. The frequency and severity of AEs was comparable between tegaserod and placebo groups, with the exception of a greater incidence of diarrhea in patients receiving tegaserod (3.6%) compared with placebo (1.7%).

**CONCLUSION:** Tegaserod treatment improved multiple symptoms of CC and was associated with a favorable safety profile.

### Abstract

**AIM:** To evaluate the efficacy and safety of tegaserod, 6 mg twice daily (b.i.d.), in men and women with chronic constipation (CC) from China.

**METHODS:** This was a multicenter, double-blind, placebo-controlled study. Following a 2-wk treatment-free baseline period, patients were randomized to receive either tegaserod (6 mg b.i.d.) or placebo (b.i.d.) for 4 wk. An analysis of covariance with repeated measures was used to determine the overall effect of treatment for the primary efficacy variable; the change from baseline in the number of complete spontaneous bowel movements (CSBMs) during the 4-wk treatment period. Secondary efficacy endpoints included other measures of response in terms of CSBMs, and patients' daily and weekly assessment of bowel habits. Safety was also assessed, based on the incidence and severity of adverse events (AEs).

**RESULTS:** A total of 607 patients were randomized to receive either tegaserod ( $n = 304$ ) or placebo ( $n = 303$ ). Tegaserod treatment resulted in a rapid and significant increase from baseline in the adjusted mean number of CSBMs per week over wk 1-4 compared with placebo (1.39 vs 0.91,  $P = 0.0002$ ). A statistically significant difference in favor of tegaserod was also observed for

**Key words:** Chronic constipation; tegaserod; China; Complete spontaneous bowel movement; Placebo-controlled; Stool

### INTRODUCTION

Chronic constipation/chronic idiopathic constipation (CC) is a gastrointestinal (GI) motility and sensory disorder that is commonly reported in many regions of the world, including Asia<sup>[1]</sup>, North America<sup>[2]</sup>, and Europe<sup>[3]</sup>. An epidemiological study conducted in Beijing concluded that 6.1% of the adult population were suffering from the symptoms of CC<sup>[4]</sup>. This compares with a survey of 3282 people in Hong Kong, of whom 14% were deemed to be suffering from CC<sup>[1]</sup>. The disorder is more common in women and elderly people<sup>[5]</sup>. The symptoms of CC impact on patients' quality of life (QoL) and result in frequent visits to physicians, particularly by older patients<sup>[1,6]</sup>. In

Hong Kong, approximately 25% ( $n = 820$ ) of those surveyed were reported to visit a physician as a result of their symptoms<sup>[1]</sup>.

The diagnosis of CC has primarily centered on the infrequency of the patients' bowel movements (BMs). However, CC is also associated with other symptoms that include straining, hard stools, feelings of incomplete evacuation, abdominal bloating, and abdominal discomfort/pain. While the pathophysiology of CC is still unclear, a proportion of patients with CC are assumed to have impaired GI motility<sup>[7]</sup>. This prolongs the length of time that stools remain in the bowel, allowing increased absorption of water from the stools which become hard and difficult to pass. Rome II criteria refined the diagnosis of CC by providing a consensus definition that is frequently used in clinical research, and can serve as a useful guide for physicians<sup>[8]</sup>. The Rome II criteria combine symptoms of straining, stool form and feelings of incomplete evacuation with measures of bowel frequency (less than three BMs per week).

A systematic review concluded that there were too few well-designed, randomized, placebo-controlled trials to support the efficacy of many of the available treatments for CC such as bulking laxatives (e.g., psyllium), osmotic laxatives [lactulose or polyethylene glycol (PEG)], and stimulant laxatives (senna or bisacodyl)<sup>[2]</sup>. Furthermore, other symptoms can be aggravated by laxative treatment (e.g., bloating)<sup>[9]</sup>. A further review found good evidence for the efficacy of PEG and tegaserod (Grade A recommendation) and moderate evidence to support the efficacy of lactulose and psyllium (Grade B recommendation)<sup>[10]</sup>. Other treatments for CC include the modification of patients' eating habits (increasing the consumption of dietary fiber/bulking agents), biofeedback training (where patients are taught relaxation and defecation techniques), and in severe cases, surgery. Evidence for the efficacy of these agents, however, is limited<sup>[7,11]</sup>.

Targeting the pathophysiological basis of CC by stimulating intestinal motility and secretion may be a more appropriate approach for the treatment of the disorder, rather than using conventional treatments. Tegaserod is a selective agonist at the serotonin receptor, 5-HT<sub>4</sub>, and has been shown to augment the release of neurotransmitters from the enteric nerves, hence stimulating intestinal peristalsis and secretion<sup>[12,13]</sup>. Two pivotal, randomized, placebo-controlled trials have demonstrated that tegaserod [2 mg or 6 mg twice daily (b.i.d.)] effectively treats the multiple symptoms of CC<sup>[14,15]</sup>. Tegaserod also effectively relieves the multiple symptoms of patients with irritable bowel syndrome (IBS) who suffer from constipation<sup>[16-18]</sup>. The majority of patients in the pivotal CC studies were Caucasian. Given that CC is a common disorder in China, the aim of the current study was to evaluate the efficacy and safety of tegaserod in men and women with CC from China.

## MATERIALS AND METHODS

### Study design

This was a randomized, multicenter, placebo-controlled,

double-blind, parallel-group study, designed to evaluate the efficacy and safety of tegaserod in men and women with CC in China.

After completing an initial screening phase of up to 28 d, patients entered a 2-wk baseline period without study medication. At the end of the baseline period, eligible patients were randomized to receive either tegaserod 6 mg b.i.d. or placebo for 4 wk using a randomization list generated by Novartis Drug Supply Management, using Almedica Drug Label System, version 5.3 a, Almedica Technology Group Inc. All Novartis staff, other than the Drug Supply Management and the Biostatistics Quality Assurance Group, remained blind to the allocation of treatment until database lock. Randomization was performed in blocks using a 1:1 ratio. The randomization list was reviewed and locked by the Biostatistics Quality Assurance group. The identity of the treatments was concealed by using study tablets that were identical in appearance. The study was conducted in accordance with the Declaration of Helsinki and was reviewed by the Independent Ethics Committee or Institutional Review Board for each center.

### Patient selection

Men and women 18 years of age or older with at least a 6-mo history of CC were eligible to participate in the study. CC was defined, according to a modification of Rome II criteria, as less than three complete spontaneous bowel movements (CSBMs) per week accompanied by one or more of the following symptoms on more than 25% of occasions: very hard and/or hard stools (type 1 and/or 2 on the Bristol Stool Form Scale<sup>[19]</sup>), sensation of incomplete evacuation following at least 25% of BMs, and straining on at least 25% of days. All CC-related symptoms were confirmed by patient electronic diary (eDiary) data recorded during the baseline period.

Patients were excluded from entering the study if they had inflammatory bowel disease or other structural bowel disease, CC resulting from bowel surgery (with mechanical outlet obstruction, congenital anorectal malformation or clinically significant rectocele), abdominal pain/discomfort as the most bothersome symptom in the past 6 mo, past or current history or diagnosis of IBS, significant disorders or diseases that may interfere with completion of the study, or if they failed to complete the daily or weekly eDiary assessments during baseline. Patients who planned to use concomitant medications affecting bowel habits (including natural/homeopathic products) 1 wk prior to entry into baseline and during the study were also excluded, as were patients who used laxatives on more than two separate occasions during baseline. However, laxative use (bisacodyl, 15 mg/d) as a rescue medication was allowed for patients who did not experience a BM for at least 72 h.

Patients were excluded from the treatment phase if CC was not confirmed by the baseline eDiary data, if loose or watery stools were reported for 3 or more days during the baseline period, or for lack of compliance with the study protocol.

### Assessments

The primary efficacy variable was the change from

baseline in the number of CSBMs per week during the 4-wk treatment period. Secondary efficacy variables included two response rates in terms of CSBMs: patients with a mean increase of one or more CSBM relative to baseline, and patients with an absolute number of three or more CSBMs per week during the 4-wk treatment period. Additional secondary efficacy variables included assessment of patients' bowel habits [i.e., stool form, frequency, and straining (which was recorded daily regardless of BM)], and patients' satisfaction with bowel habits, bothersomeness of constipation, distension/bloating, and abdominal discomfort/pain. Following each BM, patients were asked to record the time of the BM, whether the BM was accompanied by a feeling of complete evacuation (yes/no), and stool form (using the Bristol Stool Form Scale<sup>[19]</sup>). Patients evaluated their satisfaction with bowel habit on a 5-point scale ranging from 'not at all satisfied' to 'a very great deal satisfied', and bothersomeness of constipation, abdominal distension/bloating and abdominal discomfort/pain on a 5-point scale, which ranged from 'not at all bothersome' to 'a very great deal bothersome'. During the treatment phase of the study, patients also recorded whether they experienced satisfactory relief of constipation symptoms (yes/no) on a weekly basis.

The safety of tegaserod 6 mg b.i.d. *vs* placebo was evaluated by recording the frequency and severity of all adverse events (AEs) and serious adverse events (SAEs), by monitoring hematology, blood chemistry, urine and vital signs, and by performing electrocardiogram (ECG) evaluations. Other outcomes assessed but not presented in this paper included: patients' assessment of constipation on quality of life (PAC-QoL questionnaire) and patients' perception of study medication (PPSM questionnaire).

### Statistical analysis

Planned enrollment was for 600 ( $n = 300$  per arm) randomized patients with CC recruited from 15 centers across China. An assumption was made that the population distribution would be similar to that observed in the two pivotal CC trials<sup>[14,15]</sup>. Based on this assumption, the study was powered to detect a difference (tegaserod-placebo) in a change from baseline of 0.6 CSBMs/wk at a two-sided significance level of 5%. All statistical analyses were carried out with SAS<sup>®</sup> software (version 8.2).

As stated earlier, the primary efficacy variable was the change from baseline in the number of CSBMs per week during the 4-wk treatment period. Secondary efficacy variables included two response rates in terms of CSBMs: patients with a mean increase of one or more CSBMs relative to baseline, and patients with an absolute number of three or more CSBMs per week during the 4-wk treatment period. Additional secondary efficacy variables included assessment of patients' bowel habits [i.e., stool form, frequency, and straining (which was recorded daily regardless of BM)], and patients' satisfaction with bowel habits, bothersomeness of constipation, distension/bloating, abdominal discomfort/pain, and satisfaction with symptom relief (recorded weekly).

All efficacy analyses were performed on the intent-to-treat (ITT) population. Safety analyses included all patients

Figure 1 Participant flow.

who received at least one dose of study medication. An analysis of covariance (ANCOVA) model with repeated measures was used to analyze the overall effect of treatment for the primary efficacy variable (change from baseline in number of CSBM per week). The model included terms for treatment, week, study center, and baseline data as well as baseline data by week, and treatment by week interactions. To be defined as 'complete', BMs had to be associated with a sensation of complete evacuation. The BM was defined as spontaneous if no laxatives were taken during the 24 h prior to the BM.

Statistical analyses of the secondary efficacy variables [response rate relative to baseline (one or more CSBM per week) and response rate in terms of the absolute number of CSBMs (three or more CSBMs per week)] were carried out using a logistic regression model, with treatment and study center as factors, and the number of CSBMs per week at baseline as covariate.

Based on the daily eDiary assessments, the change from baseline was determined for the following variables: 1) the number of SBMs per week, 2) the number of days per week with no stools, hard or very hard stools, 3) the weekly mean straining score, and 4) the number of days with (too much) straining. The same ANCOVA model that was used for the primary endpoint was repeated for these variables. The number of patients with or without satisfactory relief [determined using a weekly eDiary assessment (patients were asked to consider whether they had satisfactory relief from their symptoms of CC in the past week)] were analyzed using Cochran Mantel Haenszel (CMH) tests, with center as a stratification factor.

## RESULTS

### Baseline

A total of 747 patients were screened for participation in this study, and 607 patients (81.3%) were randomized from a total of 15 centers to receive treatment with tegaserod 6 mg b.i.d. ( $n = 304$ ) or placebo ( $n = 303$ ) (Figure 1). The main reasons for screening failure were unacceptable laboratory values (5.0%), withdrawal of consent (4.3%)

**Table 1** Patient demographic and baseline characteristics (ITT population)

Demographic variable	Tegaserod 6 mg b.i.d. ( <i>n</i> = 304)	Placebo ( <i>n</i> = 303)
Age (yr)		
Median	34.5	35
Range	18-80	18-78
Age group, years ( <i>n</i> , %)		
< 35	152 (50.0)	151 (49.8)
35-64	132 (43.4)	135 (44.6)
≥ 65	20 (6.6)	17 (5.6)
Sex ( <i>n</i> , %)		
Male	70 (23.0)	61 (20.1)
Female	234 (77.0)	242 (79.9)
Race ( <i>n</i> , %)		
Oriental	303 (99.7)	303 (100.0)
Other	1 (0.3)	0
Mean duration of constipation symptoms, months (SD)	100.3 (90.7)	94.9 (93.1)

and 'other' (4.3%). Most patients completed the double-blind treatment period (97.7% in the tegaserod group and 98.0% in the placebo group). One patient randomized to receive tegaserod did not receive study medication and was therefore excluded from the safety population.

Demographic and baseline variables were comparable between the tegaserod and placebo groups and most patients were Oriental [99.7% (tegaserod) *vs* 100.0% (placebo)] (Table 1).

Prior to randomization, the duration of patients' constipation symptoms was approximately 8 years in the tegaserod and placebo groups (Table 1). The mean number of CSBMs per week during the 2-wk baseline period was 0.36 in the tegaserod group and 0.31 in the placebo group. The most bothersome symptoms reported by patients subsequently randomized to tegaserod or placebo was straining (53.0% *vs* 56.1%), followed by feeling of incomplete evacuation (15.1% *vs* 15.2%), hard stools (13.5% *vs* 13.9%) and infrequent defecation (14.5% *vs* 11.9%). Laxative use in both treatment groups was comparable during the baseline period (35.5% and 36.0% of patients, randomized to tegaserod and placebo, respectively).

### Primary efficacy variable

An increase from baseline in the overall number of CSBMs per week during the 4-wk treatment period was observed in patients receiving tegaserod (adjusted mean 1.39) and placebo (adjusted mean 0.91) (treatment difference; 0.48, 95% confidence interval; 0.23-0.73), yielding a statistically significant difference in favor of tegaserod ( $P = 0.0002$ , Figure 2 and Table 2). Tegaserod treatment significantly increased the number of CSBMs per week from baseline during each week of treatment, compared with placebo ( $P < 0.05$ ) (Figure 3 and Table 2). Subgroup analysis revealed that men treated with tegaserod showed a greater increase from baseline in the overall number of CSBMs per week (wk 1-4) compared with women treated with tegaserod (the mean increase in the number of CSBMs per week was 1.67 in men and 1.29 in women).

**Figure 2** Change from baseline in the number of CSBMs per week (wk 1-4) by treatment (ITT population). Footnote: <sup>b</sup> $P = 0.0002$  vs placebo; Mean number of CSBMs per week at baseline: tegaserod 0.36; placebo 0.31.**Table 2** Treatment differences in change from baseline in number of CSBMs/wk for wk 1-4 (ITT population)

CSBM: complete spontaneous bowel movement; SD: standard deviation; CI: confidence interval. Change from baseline (cfb) = post-baseline-baseline. A positive cfb indicates an increase in the number of CSBMs/wk. <sup>1</sup>Adjusted mean cfb. Calculated from least square mean estimate of repeated measures analysis. <sup>2</sup>Treatment difference ( $> 0$  favors tegaserod). <sup>3</sup>Repeated measures model: cfb in number of CSBMs/wk = treatment (patient) + week + center + baseline + baseline \* week + treatment \* week.

### Secondary efficacy variables

Analysis of response, defined as a mean increase of one or more CSBMs per week relative to baseline during the 4-wk treatment period, showed that treatment with tegaserod was significantly more effective than treatment with placebo [overall, tegaserod (47.7%) *vs* placebo (35.0%),  $P = 0.0018$ ). While overall response was statistically significant for all 4 wk combined, statistical significance for individual weeks was reached at wk 2, 3 and 4 of treatment (Figure 4A).

Overall, treatment with tegaserod was superior to

**Figure 3** Change from baseline in the number of CSBMs per week by study week and treatment (ITT population). Footnote: <sup>a</sup> $P < 0.05$  vs placebo; Mean number of CSBMs per week at baseline: tegaserod 0.36; placebo 0.31.

**Figure 5** Change from baseline in number of SBMs per week by study week and treatment (ITT population). <sup>a</sup> $P < 0.05$  vs placebo; Mean number of SBMs per week at baseline: tegaserod 2.33; placebo 2.26.

treatment with placebo in terms of the absolute response rate (three or more CSBMs per week) [tegaserod (25.0%) *vs* placebo (14.5%),  $P = 0.0021$ ]. This difference was statistically significant at each week of treatment (Figure 4B).

### Assessment of constipation symptoms

Improvements in constipation symptoms were observed in patients receiving tegaserod over wk 1-4. Tegaserod significantly increased the number of SBMs per week compared with placebo (adjusted mean 1.57 *vs* 0.89,  $P < 0.0001$ ), and this was statistically significant for each of the 4 wk of treatment ( $P < 0.05$ ) (Figure 5). Compared with placebo, treatment with tegaserod also decreased the overall number of days per week (wk 1-4) with no stools, hard or very hard stools (adjusted mean -1.94 *vs* -1.19,  $P < 0.0001$ ) and this was statistically significant for each of the 4 wk of treatment ( $P < 0.05$ ) (Figure 6). Treatment with tegaserod also resulted in a decrease in the weekly mean straining score (adjusted mean -0.41 *vs* -0.33,  $P = 0.0282$ ) and a decrease in the number of days per week with straining (adjusted mean -1.65 *vs* -1.24,  $P = 0.0085$ ).

Significantly more patients receiving tegaserod than

**Figure 4 A:** Response rate relative to baseline (increase of  $\geq 1$  CSBM per week) by week (ITT population); **B:** Absolute response rate (increase of  $\geq 3$  CSBM per week) (ITT population). <sup>a</sup> $P < 0.05$  vs placebo; Mean number of CSBMs per week at baseline: tegaserod 0.36; placebo 0.31.

**Figure 6** Change from baseline in number of days per week with no stool, hard, or very hard stools by treatment (ITT population). <sup>a</sup> $P < 0.05$  vs placebo; An improvement was defined as a decrease in the number of days with no stool, hard, or very hard stools (Bristol stool score of 1 or 2<sup>[19]</sup>) relative to baseline.

placebo responded positively to the question of whether they had 'satisfactory relief from their constipation symptoms over the past week of treatment' at all 4 wk of treatment (wk 1: 52.5% *vs* 35.0%; wk 2: 54.9% *vs* 40.5%; wk 3: 56.5% *vs* 41.3%; wk 4: 57.8% *vs* 44.2%; all  $P < 0.05$ ) and at end of treatment (57.8% *vs* 43.9,  $P < 0.05$ ) (Figure 7).

Trends in favor of tegaserod were observed for

**Figure 7** Satisfactory relief of constipation symptoms by week and treatment period (ITT population). <sup>a</sup> $P < 0.05$  vs placebo.

the following secondary variables: bothersomeness of constipation, distension/bloating and abdominal discomfort/pain. Statistical significance was observed in wk 3 (bothersomeness of distension/bloating and abdominal pain/discomfort) and in wk 1-3 (bothersomeness of constipation). The number of patients using laxatives during the double-blind treatment period was higher in the placebo group (31.4%) compared with the tegaserod group (27.0%), although this difference was not statistically significant.

### Safety assessments

The AEs reported in this study were mostly mild and transient. The overall frequency of AEs was similar in both the tegaserod and placebo groups (9.9% *vs* 11.2%) (Table 3). Diarrhea was the most common AE, reported by 3.6% of patients in the tegaserod group and 1.7% of patients in the placebo group. The study investigators considered the majority of cases of diarrhea to be mild (no cases were reported to be severe), and transient [median duration of first episode of diarrhea: 2 d (tegaserod group) *vs* 3 d (placebo group)]. All cases of abdominal pain were reported to be mild or moderate in severity and were reported with equal frequency in both groups (1.7% in each group).

The number of discontinuations due to AEs was the same in both treatment groups (0.7% each) (AEs resulting in discontinuation included diarrhea, dizziness, hypertension, rash, tinnitus, venous thrombosis in the limb, and vertigo). Other reasons for discontinuation included unsatisfactory therapeutic effect (0.3% in each group), patients no longer requiring study drug due to symptom improvement (0.3% in the tegaserod group and 0.0% in the placebo group), withdrawal of consent (0.3% in the tegaserod group and 0.7% in the placebo group) and patients lost to follow-up (0.7% in the tegaserod group and 0.3% in the placebo group). Five SAEs were reported, none of which were considered to be related to the study drug [one case of ureteric cancer in the tegaserod group (0.3%) and one case each of ankle fracture, pregnancy, hemorrhoid surgery, and venous thrombosis in the limb in the placebo group (1.3% in total)]. No cases of ischemic colitis were reported during this study, and no deaths

**Table 3** Incidence of most frequent AEs, regardless of relationship to study drug (safety population)

Adverse event	Tegaserod 6 mg b.i.d. (n = 303) (%)	Placebo (n = 303) (%)
Diarrhea	11 (3.6)	5 (1.7)
Abdominal pain	5 (1.7)	5 (1.7)
Nasopharyngitis	1 (0.3)	7 (2.3)
Transaminases increased	3 (1.0)	1 (0.3)
Nausea	1 (0.3)	3 (1.0)

occurred. Laboratory and ECG evaluations, and vital signs were comparable between treatment groups.

### DISCUSSION

This is the first randomized, double-blind, placebo-controlled trial designed to evaluate the efficacy and safety of tegaserod in an adult population of men and women from China, who met the Rome II diagnostic criteria for CC. The recent Rome III criteria, published after this study was conducted, have further refined diagnostic criteria for CC<sup>[20]</sup>.

The key efficacy analyses demonstrated that tegaserod improves multiple symptoms of CC. The results revealed that treatment with tegaserod was associated with a rapid and significant increase from baseline in the number of CSBMs at wk 1, which was sustained over each of the 4 wk of treatment. Secondary efficacy analyses also showed statistically significant improvements for tegaserod over placebo with regard to evaluation of bowel habits and satisfaction with constipation relief.

The responder rate for mean increase of one or more CSBM per week during the 4-wk treatment period [tegaserod (47.7%) *vs* placebo (35.0%)] was similar to the results obtained with Caucasian patients<sup>[14,15]</sup> suggesting that patients from China with CC respond in a similar fashion to those from Western countries.

Subgroup analysis confirmed that tegaserod relieved the multiple symptoms of CC in both men and women. This observation has clinical relevance, as fewer data are available in men, and further confirms the results from other pivotal studies<sup>[14,15]</sup>.

Treatment with tegaserod was associated with a safety profile similar to that seen with placebo, although slightly more patients receiving tegaserod than placebo reported mild and transient diarrhea. Diarrhea is a predictable pharmacological event, and is likely due to tegaserod's promotile effect that stimulates peristalsis, reduces stool hardness and accelerates orocecal transit, promoting stool expulsion<sup>[12,13]</sup>. The increased incidence of diarrhea following treatment with tegaserod was similar to that reported in all other clinical studies of patients with CC from different ethnic groups<sup>[14,15,17,18]</sup>.

The primary efficacy variable used in this study was the change from baseline in the number of CSBMs per week.

The assessment of SBMs discounts laxative-induced BMs, while further characterizing SBMs as 'complete' ensures that measurements are not simply based on an increase in the number of small hard pellets that are passed, which would leave symptoms unimproved for the patient. Hence, the definition of CSBM used in this study provides a subjective measure of BMs that are associated with a sense of complete evacuation, while in addition, providing an objective measure of the number of BMs. This assessment of CSBMs is considered to be able to detect changes that are meaningful to the patient.

Medications, such as laxatives, which are traditionally used to treat CC, may improve the frequency of BMs, but they do not treat the underlying causes of CC and have no proven effect on the multiple symptoms including straining, incomplete evacuation, abdominal bloating and abdominal discomfort/pain<sup>[9,21]</sup>. Therefore, in order to control their symptoms, patients often rely on multiple treatments, which are often ineffective. These include the increased intake of fiber, modifications in lifestyle and diet, and the use of prescription/non-prescription laxatives. This has led to high patient dissatisfaction and frustration with current treatments for CC<sup>[1]</sup>, and hence there is a need for simple, safe, and effective first-line therapies to treat the multiple symptoms of patients with this disorder.

In conclusion, this was the first rigorously designed study to evaluate the efficacy and safety of tegaserod in an adult population of men and women from China with CC. The results of key efficacy analyses demonstrated that compared with placebo, tegaserod 6 mg b.i.d. increased the frequency of CSBMs, improved multiple symptoms of constipation, and was associated with a safety profile that is similar to that of placebo. Therefore, tegaserod offers an effective treatment option for patients from China with CC.

The study design, collection, analysis and interpretation of the data was sponsored by Novartis Pharma AG. The authors would like to acknowledge the editorial support and contribution of Nicci Crofts of ACUMED<sup>®</sup> to this manuscript. ACUMED's contribution was funded by Novartis Pharma AG.

## COMMENTS

### Background

Chronic constipation/idiopathic constipation (CC) affects 11% to 14% of the Chinese population; however, currently prescribed first-line therapies for CC are suboptimal. Tegaserod is a selective partial agonist at the serotonin receptor, 5-HT<sub>4</sub>, which is a well tolerated and effective treatment for the multiple symptoms of CC in Caucasian patients. However, its efficacy in patients from Asia-Pacific countries is unknown.

### Research frontiers

There has been increasing interest in the use of serotonergic agents, such as tegaserod, for the treatment of gastrointestinal motility disorders. This study is the first randomized, double-blind, placebo-controlled trial designed to evaluate the efficacy and safety of tegaserod in men and women from China with CC.

### Innovations and breakthroughs

The placebo-controlled trials demonstrating the promotile action of tegaserod on

the gut (Degen *et al*, 2000 and Prather *et al*, 2000) led to the design of phase III trials of tegaserod in patients with irritable bowel syndrome whose predominant symptom was constipation (IBS-C) and patients with CC. These studies demonstrated that treatment with tegaserod relieved multiple symptoms of these burdensome conditions (Johanson *et al*, 2004; Kamm *et al*, 2005; Müller-Lissner *et al*, 2001; Novick *et al*, 2002; Tack *et al*, 2005). As these studies were performed predominantly in patients from Western countries, this study aimed to evaluate the efficacy of tegaserod for the treatment of CC in patients from China.

## Applications

The results of this study demonstrated that compared with placebo, tegaserod 6 mg b.i.d. increased the frequency of CSBMs, improved multiple symptoms of constipation, and was well tolerated in both men and women with CC from China.

## Terminology

Complete spontaneous bowel movement (CSBM): The term 'CSBM' refers to the spontaneous occurrence of a bowel movement associated with a feeling of complete evacuation. Assessing bowel movements as 'spontaneous' discounts laxative-induced bowel movements, but further characterizing spontaneous bowel movements as 'complete' (CSBMs) ensures that measurements are not simply based on an increase in the number of small hard pellets that are passed, which would leave symptoms unimproved for the patient. The definition of CSBM used in this study therefore provides a subjective measure of bowel movements that are associated with a sense of complete evacuation, while in addition, providing an objective measure of the number of bowel movements. Tegaserod: A selective partial agonist of the 5-HT<sub>4</sub> receptor.

## Peer review

This is an excellently designed, performed and presented study examining the efficacy of tegaserod in Chinese patients with chronic idiopathic constipation.

### Abstract

**AIM:** To demonstrate that age does not influence the choice of treatment for gastroesophageal reflux disease (GERD). We hypothesized that the outcome of total fundoplication in patients > 65 years is similar to that of patients aged ≤ 65 years.

**METHODS:** Four hundred and twenty consecutive patients underwent total laparoscopic fundoplication for GERD. Three hundred and fifty-five patients were younger than 65 years (group Y), and 65 patients were 65 years or older (group E). The following elements were considered: presence, duration, and severity of GERD symptoms; presence of a hiatal hernia; manometric evaluation, 24 h pH-monitoring data, duration of operation; incidence of complications; and length of hospital stay.

**RESULTS:** Elderly patients more often had atypical symptoms of GERD and at manometric evaluation had a higher rate of impaired esophageal peristalsis in comparison with younger patients. A mild intensity of heartburn often leads physicians to underestimate the severity of erosive esophagitis. The duration of the operation was similar between the two groups. The incidence of intra-operative and postoperative complications was low and the difference was not statistically significant between the two groups. An excellent outcome was observed in 92.9% young patients and 91.9% elderly patients.

**CONCLUSION:** Laparoscopic antireflux surgery is a safe and effective treatment for GERD even in elderly patients, warranting low morbidity and mortality rates and a significant improvement of symptoms comparable to younger patients.

**Key words:** Gastroesophageal reflux disease; Esophagitis;

### INTRODUCTION

The population of elderly is rapidly growing globally, e.g. in the USA nearly 20 million of people will be more than 85 years old in the next fifty years<sup>[1]</sup>. Digestive diseases are common causes of morbidity and mortality in the elderly<sup>[2]</sup>. Among them gastroesophageal reflux disease (GERD) is usually more severe than in younger patients, which is frequently under-diagnosed and less treated<sup>[2]</sup>. This results in an increase of esophageal mucosal injuries and subsequent complications. Therefore, a more aggressive treatment has been advocated in these patients<sup>[3]</sup>. However, a higher morbidity and mortality of open surgery in the elderly, limited the number of these patients referred for surgical treatment. Moreover, their shorter life expectancy made surgery to be deemed a cost-ineffective strategy.

The advent of laparoscopic fundoplication has greatly reduced the morbidity of antireflux surgery and by now, it should be considered the surgical treatment of choice for GERD<sup>[4]</sup>. The aim of the current study is to review the outcome of young and elderly patients undergoing laparoscopic antireflux surgery for the treatment of GERD.

### MATERIALS AND METHODS

From September 1992 to December 2005, 420 consecutive patients, 171 male and 249 female, mean age 42.8 years (range 12-80) with GERD underwent laparoscopic Nissen-Rossetti fundoplication. The preoperative and postoperative data were prospectively collected. Demographic data were obtained at the time of first visit. Sixty-five patients older than 65 years of age were defined as the elderly group (EG) whereas the remaining 355 younger than 65

years of age were defined as the young group (YG). Ethics board approval for collecting and using these data was obtained.

### Preoperative evaluation

Preoperatively all patients underwent Upper Gastrointestinal Endoscopy (UE), X-ray of barium swallow, esophageal manometry and 24-h pH monitoring. They were off peptic medications for thirty days. The medical evaluation included a structured questionnaire based on modified DeMeester symptom scoring system (Table 1). Measurement of hiatal hernia size was performed at the end of endoscopic examination after deflation of the stomach or by X-ray of barium swallow with video-fluoroscopy. The hernia size was measured as the distance between the centre of the diaphragmatic hiatus and the superior aspect of gastric folds. A hiatal hernia was deemed to be present if either gastric folds or a hernia pouch was present above the diaphragm between swallows. Esophagitis severity was assessed by means of Savary-Miller grading system. The location of Barrett's esophagus was noted; and the esophageal strictures, paraesophageal hernias and reinterventions were excluded from the study. Stationary esophageal manometry was carried out using 8-channel perfusion catheters, 4 disposed radially and oriented at 90° to each other and 4 positioned longitudinally at intervals of 5 cm. The catheter was perfused with distilled water using a low-compliance capillary pump at a constant infusion rate of 0.8 mL/min at 1.2 kg/cm<sup>2</sup>. A system of pressure transducers transmitted data to an acquisition device (ACQ1<sup>TM</sup>-Menfis bioMedica-Bologna, Italy) and from there to a personal computer. A specific software package (Dyno 2000<sup>TM</sup>-Menfis bioMedica-Bologna, Italy) was used for data acquisition and processing. The following variables were assessed: (1) pressure of the lower esophageal sphincter; (2) relaxation of the lower esophageal sphincter (LES) in response to swallowing; (3) amplitude and propagation of peristalsis (esophageal peristalsis was considered impaired when < 30 mmHg). The LES was studied by both the stationary and the rapid pull-through methods. Esophagogastric pH monitoring was carried out using two glass probes which were connected to a portable, solid-state recorder (Digitrapper Proxima<sup>TM</sup>-Synetics Medical, Sweden): the electrodes were placed, respectively, 5 cm above the proximal margin and 5 cm below the distal margin of the LES, identified by means of stationary manometry. For statistical analysis, results were expressed as a mean value ± SD; correlations among the various parameters were analysed using Fischer's exact test. The Wilcoxon signed rank test was used to compare the preoperative and postoperative modified DeMeester symptom score. American Society of Anaesthesiologists (ASA) grade was recorded at the time of surgery.

### Postoperative evaluation

On an outpatient basis, the patients came to our department each six months for the first postoperative year and, after, each year and were invited to fulfil a standardized questionnaire dealing with presence of typical or atypical symptoms and based on the modified DeMeester score (Table 1). Satisfaction of the procedure and the will of un-

**Table 1** Modified DeMeester scoring system

Symptoms	Score	Description

Chest pain	18/65 (27.7)	51/355 (14.4)	< 0.05
Respiratory complication (chronic cough, sleep apnoea, asthma, laryngitis)	27/65 (41.5)	19/355 (5.4)	< 0.05

dergoing the same operation after knowing its effects were defined as excellent outcome

Instrumental follow-up after surgery included: X-ray of barium swallow (performed at 1 year after surgery), esophageal manometry (performed at 6 mo, 1 year, and 2 years after surgery) and 24 h pH monitoring (performed at 1 year after surgery).

Statistical analysis was carried out using SPSS for Windows (version 12.0, SPSS Inc. Chicago, IL). Results were expressed as mean ± SD unless otherwise indicated. Student's *t* test, the Chi-square test, the Fischer's exact test and the Wilcoxon signed rank test were used as appropriate. *P* value < 0.05 was considered statistically significant.

## RESULTS

### Preoperative data

Demographics data and ASA score of the two groups are listed in Table 2. In the YG, the mean duration of preoperative symptoms was 4.6 ± 2.3 years (range 1-11) whereas in the EG it was 8.3 ± 2.5 years (range 5-22). Tables 3 and 4 depict the incidence and severity of typical and atypical

**Table 4** Severity of preoperative symptoms in EG and YG (mean  $\pm$  SD)

(%) time pH < 4 (upright)	9 $\pm$ 4	5 $\pm$ 2	< 0.05	15 $\pm$ 5	5 $\pm$ 3	< 0.05	25 $\pm$ 2	22 $\pm$ 7	> 0.05

symptoms in both groups. At manometric evaluation, no statistically significant differences in the mean LES pressure were found when the two groups were compared ( $P = \text{NS}$ ) but the EG had a higher rate of impaired esophageal peristalsis (defined as peristaltic waves with a pressure value lower than 30 mmHg) in comparison with their younger counterparts ( $P < 0.05$ ) (Table 5). Incidence of Hiatal Hernia (HH) was 89.2% (58/65) in elderly patients and 71.3% (253/355) in young patients ( $P < 0.05$ ).

Table 6 shows the prevalence of HH and esophagitis and pH metric values either in Non-erosive reflux disease (NERD) and in Erosive reflux disease (ERD) patients. In the EG, 45/65 (69.2%) patients presented with esophagitis (ERD group): 11 of 45 (24.4%) had a grade I esophagitis while 34 out of 45 (75.6%) had a grade II-III esophagitis. In the YG, 125/355 (35.2%) patients presented with esophagitis (ERD group): 76 out of 125 (60.8%) had a grade I esophagitis while 49 of 125 (39.2%) had a grade II-III esophagitis.

Therefore, in the EG, a significant higher grade of esophagitis has been found along with a higher incidence of Barrett esophagus (Table 6).

A pathologic DeMeester score was found at pH-monitoring in all patients of both subgroups: in the YG, it was  $12.4 \pm 1.2$  and  $14.3 \pm 1.2$ , whereas in the EG it was  $13.1 \pm 11.2$  and  $17.5 \pm 1.4$  respectively for NERD and ERD subgroups. The mean percentage of total time < 4 at 24-h pH monitoring in NERD and ERD subgroups, is shown in Table 6.

### Perioperative results

All the interventions were completed *via* laparoscopic ap-

**Table 7** Perioperative results in EG and YG

proach. Mean operative time was  $45 \pm 14$  min in YG and  $61 \pm 15$  min in EG. No mortality was observed in both groups. A major complication occurred in 4/420 patients (1.0%), all among the YG. Mean postoperative hospital stay was  $2.4 \pm 0.9$  d in YG (range 1-5) and  $3.8 \pm 1.0$  d in EG (range 1-7) ( $P < 0.05$ ). Normal activity resumed in  $8.3 \pm 3.4$  d in YG and  $12.5 \pm 9.0$  d in EG ( $P < 0.05$ ) (Table 7).

### Postoperative results

We followed up clinically 408 (97.1%) of 420 patients, 62 (95.3%) patients in the EG and 338 (95.2%) patients in YG. Two patients in the EG died four years after surgery for no surgery correlated event. In the YG, the mean follow-up was  $83.2 \pm 7$  mo (range 6-141) whereas in EG it was  $60 \pm 8$  mo (range 6-95).

An excellent outcome was observed in 314/338 (92.9%) younger patients and in 57/62 (91.9%) elderly patients ( $P > 0.05$ ). Both groups showed significant improvement

in clinical symptom score (Table 8). At 6 mo, persisting postoperative dysphagia (DeMeester score 2-3) leading to > 15% of weight loss was observed in 11 (3.3%) of 338 patients in YG, 2 patients in the group with preoperative impaired peristalsis and 9 in the group with normal esophageal motility (Table 9). In EG, persisting postoperative dysphagia was relieved in 2 (3.2%) of 62 patients, both in group with normal preoperative esophageal peristalsis (Table 9).

No statistically significant difference was observed between patients with normal and impaired peristalsis. Five patients in YG and both 2 patients in EG were treated with endoscopic dilatation, whereas 6 patients in YG underwent a laparoscopic redo-funduplication with partial resolution of dysphagia. Recurrent heartburn was observed and confirmed with 24 h pH monitoring follow-up in 14/408 patients (3.4%), which was due to a disrupted wrap, an herniated wrap, and a slipped Nissen detected at X-ray barium in 7, 4, and 3 cases, respectively.

Ten patients reassumed their peptic medications; the remaining 4 patients, all in YG, underwent redofunduplication with partial resolution of symptoms. Respiratory symptoms showed a significant improvement in both groups (Table 9). Other data regarding hyper-flatulence, early satiety and bloating are depicted in Table 9.

Esophageal manometric follow-up (performed at 6, 12, and 24 mo after surgery) was made in 331 (81.1%) of 408 patients at 6 mo (48/62, 77.4% in EG and 283/338, 83.7% in YG), 275/408 (67.4%) at 12 mo (38/62, 61.3% in EG and 237/338, 70.1% in YG), and 266/408 (65.2%) at 24 mo (36/62, 58.1% in EG and 230/338, 68.0% in YG). Stationary esophageal manometry showed a significant

improvement in the mean new high pressure zone (N-HPZ) value in comparison with preoperative values in the two groups ( $P < 0.05$ ) (Table 10 and Figure 1); Manometric evaluation at 24 mo after surgery showed an increase of mean peristalsis waves in 28/36 (77.8%) patients of the EG and 100/230 (43.5%) patients of the YG.

Twenty-four hour pH monitoring at 1 year after surgery was performed in 205/408 (50.2%) patients. There was a significant postoperative decrease in DeMeester score and percentage of time pH < 4 during 24 h (Table 11).

## DISCUSSION

Gastroesophageal reflux disease (GERD) is a common disorder in the western population; periodically symptoms

**Table 11** De Meester score and percentage of reflux time during 24 h in EG and YG, preoperative and 1 yr after surgery

	Preoperative	1 yr after surgery
DeMeester score		
EG	15.1 ± 1.1	1.2 ± 0.7
YG	13.4 ± 1.5	1.1 ± 0.2
(%) time pH < 4		
EG	9.1 ± 0.6	1.4 ± 0.3
YG	8.2 ± 0.7	0.9 ± 0.8

occur in approximately 20% of adults in USA<sup>[5]</sup>. Its cost has been estimated to be \$24.1 billion annually<sup>[2]</sup>.

By 2020 more than 16% of population in USA are expected to be more than 65 years old while nearly 20 million ought to be more than 85 years old<sup>[6]</sup>. In the elderly, the prevalence of GERD is nearly the same among the general population, but complicated GERD appears to be more common than in young people<sup>[6]</sup>.

Several authors have reported a higher incidence of esophagitis as well as Barrett esophagus in older patients<sup>[7-11]</sup>. Collen<sup>[7]</sup> found that esophagitis and Barrett esophagus were almost twice in patients aged 60 years than in young people (81% *vs* 47%,  $P < 0.002$ ). Zhu<sup>[8]</sup> observed that the percentage of time with pH < 4 was 32.5% in older patients with GERD *vs* 12.9% in younger ones ( $P < 0.05$ ). Furthermore, among elderly patients with esophagitis, nearly 21% had grade III-IV disease compared with only 3.4% of younger patients ( $P = 0.002$ ). Cameron<sup>[9]</sup> demonstrated that the prevalence of Barrett's esophagus increased with age to reach a plateau by the seventh decade. Fass<sup>[11]</sup> reported that the mean incidence rate of erosive esophagitis was 74% in the elderly and 64% in the younger patients and the frequency of symptoms was lower in the elderly group. David<sup>[12]</sup> demonstrated that the prevalence of severe esophagitis increased with age: only 12% in GERD patients < 21 years old in comparison with 37% in patients > 70 years old had severe esophagitis.

Also in our study, the elderly group (EG) had a higher rate of erosive esophagitis (69.2% *vs* 35.2%) and a lower rate of Grade I esophagitis (22.2% *vs* 60.8%). Moreover, incidence of Barrett's esophagus as well as mean percentage of total time < 4 at pH-monitoring were significantly higher in the EG (Table 7). The frequency of reflux episodes has been reported to be similar either in the elderly or in young people whereas the duration of individual reflux episodes seems to be longer in the elderly<sup>[13]</sup>. However, it is not clear which factors lead to a more severe GERD in the elderly.

The etiopathogenesis of GERD seems to be multifactorial. The alteration may include a defective antireflux barrier, abnormal esophageal-clearance, altered esophageal mucosal resistance, and delayed gastric emptying<sup>[14]</sup>.

Hiatal hernia (HH) as a structural defect of the antireflux barrier is a determining factor of GERD, by impairing both the diaphragmatic component and the clearance of acid refluxate from the distal esophagus<sup>[15]</sup>. HH has been identified in 60% of patients > 60 years old<sup>[16]</sup>.

Furthermore, several studies found a higher frequency of esophagitis in patients with HH compared with patients without HH, and the severity was proportional to the size of HH. In our study, we noted a significant higher rate of HH in the EG (Table 6). Previous studies excluded any adverse effect of aging on the lower esophageal sphincter (LES) of healthy subjects<sup>[17,18]</sup>. Similarly, we did not find any significant difference in LES pressure between the EG and the YG. However, an impaired esophageal peristalsis (waves pressure < 30 mmHg) has been found in 66.7% of the EG and 33.4% of the YG (Table 5). It is not clear whether impaired peristalsis is a cause of or affects a more severe GERD, since we noted an increased amplitude of peristaltic waves both in the EG and in the YG at the postoperative manometric follow-up evaluation (Figure 1).

Changes in motility seen in older patients is related to long-term esophageal acid exposure rather than to effects of aging on esophageal smooth muscle and on collagen production that is increased in chronic inflammation<sup>[18,19]</sup>. In our study, the mean duration of preoperative symptoms was significantly longer in the EG. Probably a vicious circle begins in these subjects between cardia incontinence, increasing reflux and impaired peristalsis determining a reduction of esophageal clearing<sup>[20]</sup>. The realization of antireflux procedure seems to break this circle. Some authors described the increased amplitude of peristalsis in patients undergoing total fundoplication<sup>[21,22]</sup>.

Besides, Sonnemberg showed an age dependent fall in salivary bicarbonate production while physiologic levels of gastric acid secretion remained stable in advanced age. These factors may increase esophageal acid exposure because of delayed acid clearance<sup>[23]</sup>. We found elderly patients having less frequency and severity of symptoms like heartburn and acid regurgitation than younger patients<sup>[24]</sup> (Tables 3 and 4). Raiha<sup>[24]</sup> hypothesized that typical symptoms should not be considered as expression of acid reflux in older patients. However, it is not clear which factors reduce frequency and severity of these symptoms although these patients have a higher rate of acid exposure and develop a more severe esophagitis.

Several studies have shown that altered esophageal pain perception to acid in the elderly is the result of an ageing process that may be responsible for an increased severity of GERD<sup>[11]</sup>. On the other hand, frequency and severity of atypical symptoms have been reported to be higher in elderly people with GERD<sup>[24]</sup>. Also in our study, we found a statistically significant higher rate of atypical symptoms such as dysphagia for solids, chest pain and respiratory symptoms in the EG (Tables 3 and 4).

Therefore, a mild intensity of heartburn often leads physicians to underestimate the severity of erosive esophagitis and its complications.

Surgical correction of GERD has been shown to be a cost-effective treatment by reducing long-term complications such as Barrett esophagus and stricture and by eliminating the need of a life-long medical therapy especially for young patients. However, a high morbidity and mortality rate of open surgery performed in the elderly, limited the number of these patients referred to surgical units<sup>[25]</sup>. Since a laparoscopic Nissen fundoplication

has been reported for the first time, a growing number of antireflux procedures have been performed in the USA<sup>[26]</sup>. Several studies showed laparoscopic surgery to be a safe and effective treatment for GERD being able to improve quality of life and warranting an early return to daily activities<sup>[27]</sup>.

In elderly population with GERD, laparoscopic surgery has proven to be effective with low morbidity and mortality rates. Richter<sup>[2]</sup> observed that Laparoscopic Nissen Fundoplication did not increase the mortality, morbidity and hospital stay in the elderly patients compared to younger surgical patients. Kalmoz<sup>[28]</sup> showed that age should not be considered a contraindication to laparoscopic surgical treatment of GERD as 97% of elderly patients would choose surgical treatment again if necessary. Bammer<sup>[29]</sup> reported that laparoscopic surgery is a good option for the treatment of severe GERD in octo- and nonagenarians, with an excellent follow-up in 93% of elderly patients. Except for preoperative disease severity, we did not find any significant difference in perioperative and postoperative results as well as in subjective and objective outcome between the two groups. The only observed differences in the operative time and blood loss seem to be related to the high ASA scores and the higher incidence and size of hiatal hernia in the EG.

Statistically significant improvement in heartburn, acid regurgitation, chest pain and respiratory complications of GERD was observed in both EG and YG (Table 9). An excellent outcome was observed in 314/338 (92.9%) younger patients and in 57/62 (91.9%) elderly patients.

A poor outcome was observed in 27 patients, 23/338 (7.1%) in YG and 4/62 (6.5%) in EG; persisting dysphagia occurred in 11/338 (3.3%) in YG and 2/62 (3.2%) in EG; and 12/338 (3.6%) in YG and 2/62 (3.2%) in EG had recurrent of heartburn. Differences between the two groups were not statistically significant also regarding the incidence of other side effects (flatulence, early satiety, etc) (Table 10). Outcome was not dependent on the presence of disordered esophageal motility.

There have been debates in literature regarding the realization of partial fundoplication in patients with defective esophageal peristalsis, and it seemed reasonable therefore, to choose this kind of wrap in elderly patients. Many authors supported the realization of a partial fundoplication in patients with impaired esophageal peristalsis to lower the incidence of persistent postoperative dysphagia<sup>[30-32]</sup>; moreover, partial wrap was considered as effective as total wrap to control gastroesophageal reflux, and short-term follow-up seemed to validate the choice of partial fundoplication<sup>[33,34]</sup>. Later on, partial antireflux procedure showed its inadequacy to assure a good protection from reflux at a long-term follow-up<sup>[35-37]</sup>. Livingston<sup>[38]</sup> reported a 1.4% recurrence rate of reflux in patients with total fundoplication versus 6.7% in those with partial fundoplication. At a long-term follow-up, Fernando<sup>[39]</sup> observed that 38% of Toupet patients used PPI versus 20% with Nissen. Jobe<sup>[40]</sup>, in a ten years follow-up, noted a recurrence rate for reflux until 51% in patients treated with partial fundoplication (Toupet and Dor). Moreover, total fundoplication seems not to determinate a higher incidence of postoperative

dysphagia compared with the partial wraps, even in patients with impaired peristalsis<sup>[41,42]</sup>. Patti<sup>[43]</sup> analysed the long-term results of patients treated with partial versus total antireflux procedures: efficacy was higher for total fundoplication (recurrence of reflux in 4% of patients with total fundoplication versus 19% in patients with partial fundoplication), while the incidence of postoperative dysphagia was similar in both groups, even in patients with impaired esophageal peristalsis (8% Toupet versus 9% Nissen). Pessaux<sup>[44]</sup>, at a three-month follow-up, noted a dysphagia rate of 4.2% in patients treated with Nissen fundoplication versus 5.9% with Nissen-Rossetti wrap and 6.9% in those treated with Toupet. In a prospective randomized trial, Bessel<sup>[45]</sup> concluded that calibrating the antireflux wrap according to esophageal motility was not necessary, because the postoperative persistent dysphagia rate was similar between patients with total or partial wrap. Velanovich<sup>[46]</sup> did not find any statistically significant difference in postoperative dysphagia rate related to esophageal motility disorders (MD) (15.8% MD+ versus 16.4% MD-) in a group of patients undergoing total fundoplication.

Besides, total wrap seems to bring about an improvement of esophageal peristalsis. Heider<sup>[47]</sup> observed an increase of 47% of mean peristaltic waves in distal esophagus compared with preoperative time ( $P < 0.01$ ), with the normalization of the esophageal motility in 74% of patients. Diaz de Liano<sup>[48]</sup>, at 1 year follow-up, noted an augment of esophageal peristalsis in 43% of patients with impaired peristalsis undergoing total fundoplication. Scheffer<sup>[49]</sup> showed an increase of mean amplitude of peristalsis from a preoperative value of 57 mmHg to 86 mmHg at 3 mo follow-up and 92 mmHg at 2 years after surgery in a group of 34 patients. Oleynikov<sup>[50]</sup> in a trial comparing total and partial fundoplication noticed that in patients undergoing partial wrap, the mean amplitude of peristaltic waves increased from 27.8 mmHg before surgery to 35.6 mmHg postoperatively ( $P > 0.05$ ), while in patients treated with total fundoplication, these values were respectively 28.2 mmHg versus 49.0 mmHg ( $P < 0.05$ ). These evidences strongly support the choice of performing a total fundoplication also in elderly patients, which is often affected by severe impairment of esophageal peristalsis.

Our choice since 1972, has always been favorable to the total fundoplication, without section of short gastric vessel. We usually perform intraoperative endoscopy and manometry in order to calibrate antireflux wrap<sup>[51]</sup>. Usually, we calibrate the n-HPZ at values ranging from 20 to 45 mmHg ('hypercalibrated Nissen'), building the wrap around the gastroscope (with a diameter of 9 mm). This hypercalibration, in contrast with the 'floppy Nissen' of Donahue and DeMeester<sup>[52]</sup>, resulted from the retrospective evaluation of a former series in which we used to calibrate the fundoplication to pressure values similar to those of a normal sphincter ('normocalibrated Nissen': 10-20 mmHg). This experience was followed by a high rate of gastroesophageal reflux recurrence (28.5%) in the first 12 mo after surgery<sup>[51]</sup>, demonstrating that high pressure zone (HPZ) values of the Nissen-Rossetti wrap decrease after surgery with time (Figure 1). It is effective to

protect from GERD while avoiding a persistent dysphagia because a routine intraoperative manometric control of the wrap is always performed at the end of the procedure. Our preference for total calibrated wrap led us to consider it also in the treatment of patients affected with severe motility disorders such as achalasia and epiphrenic diverticula with excellent results<sup>[52,53]</sup>.

In conclusion, laparoscopic antireflux surgery, is a safe and effective treatment for GERD even in elderly patients warranting low morbidity and mortality rates and a significant improvement of symptoms comparable to younger patients. Preoperative defective esophageal peristalsis is not a contraindication to total laparoscopic fundoplication.

### Abstract

**AIM:** To evaluate the effectiveness of mastic administration on the clinical course and plasma inflammatory mediators of patients with active Crohn's disease (CD).

**METHODS:** This pilot study was conducted in patients with established mild to moderately active CD, attending the outpatient clinics of the hospital, and in healthy controls. Ten patients and 8 controls were recruited for a 4-wk treatment with mastic caps (6 caps/d, 0.37 g/cap). All patients successfully completed the protocol. CD Activity Index (CDAI), Nutritional Risk Index (NRI), C-reactive protein (CRP), interleukin-6 (IL-6), tumor necrosis factor-alpha (TNF- $\alpha$ ), monocyte chemotactic protein-1 (MCP-1), and total antioxidant potential (TAP) were evaluated in the plasma at baseline and at the end of the treatment period. Results were expressed as mean values  $\pm$  SE and  $P < 0.05$  was considered to indicate statistical significance.

**RESULTS:** Patients exhibited significant reduction of CDAI ( $222.9 \pm 18.7$  vs  $136.3 \pm 12.3$ ,  $P = 0.05$ ) as compared to pretreatment values. Plasma IL-6 was significantly decreased ( $21.2 \pm 9.3$  pg/mL vs  $7.2 \pm 2.8$  pg/mL,  $P = 0.027$ ), and so did CRP ( $40.3 \pm 13.1$  mg/mL vs  $19.7 \pm 5.5$ ,  $P = 0.028$ ). TAP was significantly increased ( $0.15 \pm 0.09$  vs  $0.57 \pm 0.15$  mmol/L uric acid,  $P = 0.036$ ). No patient or control exhibited any kind of side effects.

**CONCLUSION:** The results suggest that mastic significantly decreased the activity index and the plasma levels of IL-6 and CRP in patients with mildly to moderately active CD. Further double-blind, placebo-controlled studies in a larger number of patients are required to clarify the role of this natural product in the treatment of patients with CD.

### INTRODUCTION

Crohn's disease (CD) is a chronic inflammatory disease of unknown etiology that may affect any level of the gastrointestinal tract<sup>[1-3]</sup>. It is well established that immunological mechanisms are involved in the pathogenesis of the disease. Inflammatory cytokines, such as interleukin-6 (IL-6) and tumor necrosis factor-alpha (TNF- $\alpha$ ), have a pivotal role in induction and amplification of the inflammatory cascade. Particularly, IL-6 stimulates T-cell and B-cell proliferation and differentiation<sup>[4]</sup>, while it mediates the hepatic expression of acute phase proteins<sup>[5]</sup>. Increased concentration of TNF- $\alpha$  and monocyte chemoattractant protein-1 (MCP-1) have been reported in patients with CD<sup>[6]</sup>. Additionally, during chronic inflammation, when sustained production of reactive oxygen and nitrogen species occurs, antioxidant defenses may weaken, resulting in a situation termed oxidative stress<sup>[7]</sup>. Thus, in patients with CD, elevated oxidized low-density lipoprotein levels have been reported compared to healthy controls<sup>[6]</sup>.

Despite the large number of therapeutic agents available today, none can be considered as completely satisfactory either due to resistant cases or because of significant side effects. To our knowledge, there are only scattered reports of natural compounds that potentially reverse relapse in CD. Trebble and co-workers<sup>[8]</sup> demonstrated an anti-inflammatory activity of fish oil and antioxidant supplementation evaluated in mononuclear cells of CD patients, while Lavy *et al*<sup>[9]</sup> demonstrated the effectiveness of the antioxidant  $\beta$ -carotene in a rat model as a prophylactic dietary measure in reducing the effects of acid induced enteritis, thus raising the possibility that patients with CD may benefit from the consumption of natural  $\beta$ -carotene. Also the flavonoid rutin, a well-established antioxidant compound, has been suggested as a therapeutic agent in CD. Rutin has been shown to attenuate pro-inflammatory cytokine production in both colonic

mucosa and peritoneal macrophages of experimental animals<sup>[10]</sup>. Treatment with food phytochemicals has been shown to be safe, sustainable and practical and changes of dietary habits have been advocated in the therapy of CD<sup>[11]</sup>.

*Pistacia lentiscus* var. Chia (Anacardiaceae), well known as Chios mastic gum, is an evergreen shrub widely distributed in the Mediterranean region. Many ancient Greek authors, including Dioscurides and Theophrastus, mentioned Chios mastic for its healing properties in intestines, stomach and liver. Mastic has also been reported to possess antioxidant<sup>[12]</sup> and antibacterial<sup>[13]</sup> activity. With reference to gastrointestinal disorders, the effectiveness of the resin against peptic ulcers is evident<sup>[14]</sup> in most studies, while only in two reports there is no effect on *H. pylori* eradication *in vivo*<sup>[15,16]</sup>. Furthermore, regarding gastric mucosa, the plant has been shown to be hepatoprotective in tetrachloride-intoxicated rats<sup>[17]</sup> and to suppress the extent of iron-induced lipid peroxidation in rat liver homogenates<sup>[18]</sup>, without any toxic effect. A major constituent of mastic, namely oleanolic acid, is among the best-known triterpenes with biological properties against chemically induced liver injury in laboratory animals, exerting anti-inflammatory and antitumor-promotion effects<sup>[19]</sup>. This background information led us to examine the effects of supplementation with mastic in patients with active CD. This study is the first ever reported to evaluate mastic for possible clinical effectiveness in patients with CD.

## MATERIALS AND METHODS

### Study population

Ten consecutive patients with established CD and eight healthy controls were recruited to participate in the trial. All patients were attending the outpatient clinic of the Department of Gastroenterology, Saint Panteleimon General State Hospital in Nicea, Athens. Clinical evidence of mild to moderate Crohn's disease exacerbation was defined by a score of CD Activity Index (CDAI) higher than 150. Patients with clinical evidence of recurrence and CDAI higher than 400 were excluded from the study. Patients receiving mesalazine or antibiotics during the time of relapse were asked to continue treatment. None was receiving elemental diet or parenteral nutrition or antioxidant/mineral supplements and none was under treatment with immunosuppressives, immunomodulators and/or corticosteroids. Eight healthy volunteers with normal serum concentrations of C-reactive protein (CRP) (< 5 mg/L) and albumin (> 40 g/L) served as controls. Assessed by Medical History questionnaires, controls included in the study were healthy persons without chronic inflammatory disorder. Exclusion criteria for control recruitment were a body mass index (BMI) higher than 30 and anti-inflammatory drug treatment or antioxidant vitamin/mineral supplementation prior to trial. All volunteers gave a written consent after having received thorough information about the aims and procedure of the study. The Ethical Committees of both Harokopio University and Saint Panteleimon General State Hospital approved the protocol. Table 1 shows some demographic

**Table 1** Demographic characteristics and medications of patients with CD and controls

Characteristic	Patients	Controls

Fistulizing disease	3	-

characteristics of patients and controls.

### Preparation of mastic caps

A UV source device (Jost/Ba-ro, Type FDLT 250/-80 × 2500) was used for sterilization of the Chios Mastic resin. Then, the sterilized mastic granules were milled to fine powder (particle size < 400 µm) by using a Hosokawa Alpine Mill (Fine Impact Mill 100 UP2). The encapsulation of powder was performed using the Profill Capsule filling System (Torpac Inc.). Capsule cells (capsugel, V caps, size 0) were made of Hpromellose (hydroxypropyl methylcellulose) and each contained 0.37 (± 0.02) g of mastic powder.

### Intervention trial protocol

Dissolution time was measured according to standard methods<sup>[20]</sup> and was found to last approximately 7 min. Patients and healthy controls were subjected to a 4-wk supplementation with mastic caps (6 caps/d, 2.2 g in total) over a period from June 2005 to January 2006. Dietary assessment was accomplished applying Food Frequency Questionnaire (FFQ) and 24 h recalls. Dietary instructions were given to both healthy controls and patients as to maintain consumption of food rich in anti-inflammatory and antioxidant ingredients as poor as initially assessed by FFQ and 24 h recall interviews. Assessment of compliance during the trial was tested applying 24 h recalls twice a week. Mastic, either in the form of gum or as a sweet or bread ingredient, and fish oil, either crude or in the form of supplement, was not allowed in either group. The daily energy intake was evaluated by means of 24 h recalls. Blood samples were obtained for plasma isolation and subjected to CRP and albumin measurements prior and after the trial. At the same time points, plasma cytokine and antioxidant potential measurements were performed. Body weight was measured using electronic scales initially and at the end of the trial.

### Disease activity index evaluation

The Crohn's Disease activity was evaluated by means

of the CDAI<sup>[21]</sup>. The CDAI incorporates eight related variables: the number of liquid or very soft stools per day, the severity of abdominal pain or cramping, general well being, the presence or absence of extraintestinal manifestations of CD, the presence or absence of an abdominal mass, the use of antidiarrheal drugs, hematocrit, and body weight. Scores range from 0 to 600 with higher scores indicating more severe disease activity. A score of 151 to 200 corresponds with mild disease activity; moderate disease has a score of 201 to 400, and scores of 401 or greater represent severe disease activity.

### Biochemical measurements

CRP concentrations were analyzed immunoturbidimetrically on a Beckman Synchron CX5 fully automated chemistry analyzer. Albumin was measured by means of the bromocresol green method on the same analyzer.

### Cytokine assays

Plasma cytokines from patients with CD and controls were assessed by quantitative enzyme-linked immunosorbent assays (ELISA) (R & D Systems Abingdon, UK) according to the manufacturer's instructions. Sensitivity limits of TNF- $\alpha$ , IL-6, and MCP-1 ELISAs are, respectively, 1.6 pg/mL, 0.70 pg/mL and 5.0 pg/mL. Plasma cytokines from patients with CD and controls were assessed in duplicate.

### Plasma total antioxidant potential assay

Total antioxidant potential (TAP) in plasma was assessed by a colorimetric, quantitative assay for TAP in aqueous samples (OxisResearch Portland, USA) according to the manufacturer's instructions. The results of the assay were expressed as mmol/L of uric acid equivalents. The sensitivity of the assay is 30  $\mu$ mol/L uric acid equivalents.

### Statistical analysis

Results were expressed as mean  $\pm$  SE. The Mann-Whitney Test was used for comparing differences between patients and controls prior the intervention. Differences reported primarily and at the end of the study within individual groups, were tested for significance by the Wilcoxon signed ranks test. Calculated  $P < 0.05$  was considered to indicate statistical significance.

## RESULTS

### Alterations of CDAI and induction of remission

The CDAI score was assessed at baseline and after the 4 wk treatment with mastic. All patients receiving mastic showed a reduction of the CDAI as compared to pretreatment values. The reduction of the mean CDAI value was statistically significant (from  $222.9 \pm 18.7$  to  $136.3 \pm 12.3$ ,  $P = 0.05$ ) (Figure 1). The two main elements of CDAI showing the most striking improvement were the number of liquid stools per day and the score of general well being.

### Nutritional risk index

One of the clinically useful measures of nutritional status in CD is the Nutritional Risk Index (NRI), which is

**Figure 1** Crohn's disease activity index (CDAI) was decreased in patients with active Crohn's disease ( $n = 10$ ) after 4-wk treatment with mastic caps ( $^aP < 0.05$ ). Horizontal bars represent the mean value ( $\pm$  SE).

calculated based on serum albumin levels and body weight using the following equation:  $NRI = [1.519 \times \text{albumin (g/L)}] + [0.417 \times (\text{current weight/usual weight}) \times 100]$ . A  $NRI > 100$  denotes absence of nutritional risk.  $NRI$  values between 97.5 and 99.9 correspond to a mild nutritional risk,  $NRI$  values from 83.5 to 97.5 to moderate nutritional risk, and  $NRI$  values lower than 83.5 to severe nutritional risk.

The patients' "usual weight" was the body weight at the time of remission, as reported in medical records at the hospital and confirmed by each single patient.  $NRI$  of healthy controls was normal at the start of the study and remained unchanged after the mastic supplementation (data not shown). The mean  $NRI$  value of CD patients increased from  $87.5 \pm 3.7$  before treatment to  $91.5 \pm 3.2$  at the end of treatment ( $P = 0.059$ ). This increase was evident at the end of the second week of mastic supplementation and remained constant thereafter until the end of the trial.

### CRP

Prior to mastic treatment, CRP levels were significantly higher in CD patients ( $40.3 \pm 13.1$  mg/mL) than in healthy controls ( $2.4 \pm 0.7$  mg/L) ( $P = 0.002$ ). Treatment with mastic caps of healthy controls resulted in no modifications in CRP values ( $2.3 \pm 0.6$  mg/L), which remained at concentrations  $\leq 5.0$  mg/mL in all individuals. In CD patients, mean CRP levels were significantly decreased after treatment (from  $40.3 \pm 13.1$  mg/mL to  $19.7 \pm 5.5$ ,  $P = 0.028$ ) (Figure 2).

### IL-6 plasma concentration

IL-6 was below detection in healthy controls prior to therapy, while in patients it was significantly elevated compared to controls ( $P = 0.034$ ). As with CRP, IL-6 in controls remained unaltered, while in patients it decreased significantly (from  $21.2 \pm 9.3$  pg/mL to  $7.2 \pm 2.8$  pg/mL,  $P = 0.027$ ) (Figure 3).

### TNF- $\alpha$ plasma concentration

Patients with active CD had TNF- $\alpha$  plasma concentrations 10-fold higher compared to controls before therapy ( $27.1 \pm 9.7$  pg/mL *vs*  $2.6 \pm 1.5$  pg/mL,  $P = 0.009$ ). After

**Figure 2** C-reactive protein (CRP) concentrations in patients with active Crohn's disease ( $n = 10$ ) before and after 4-wk treatment with mastic caps ( $^aP < 0.05$ ). Horizontal bars represent the mean value ( $\pm$  SE).

treatment, plasma TNF- $\alpha$  decreased in patients, although this decrease did not reach statistical significance ( $27.1 \pm 9.7$  pg/mL to  $16.4 \pm 4.7$  pg/mL,  $P = 0.114$ ).

#### MCP-1 plasma concentration

In the case of MCP-1, patients with active CD had MCP-1 plasma concentrations 2.5-fold higher compared to controls ( $140.7 \pm 43.9$  pg/mL *vs*  $57.5 \pm 11.8$  pg/mL,  $P = 0.368$ ). Although not statistically significant, a decrease was observed in MCP-1 in CD patients at the end of the trial ( $76.6 \pm 20.9$  pg/mL,  $P = 0.074$ ).

#### Plasma TAP

TAP was significantly different between the two groups before mastic treatment (healthy controls,  $0.4 \pm 0.06$  *vs* CD patients,  $0.15 \pm 0.09$  mmol/L uric acid,  $P = 0.003$ ). As shown in Figure 4, TAP was significantly increased in individual groups after mastic treatment (controls,  $0.4 \pm 0.06$  *vs*  $0.5 \pm 0.05$  mmol/L uric acid,  $P = 0.025$ ; CD patients,  $0.15 \pm 0.09$  *vs*  $0.57 \pm 0.15$  mmol/L uric acid,  $P = 0.036$ ).

#### Side-effects

No patient exhibited any side effects. However, during the third day of treatment, one female patient with CD of the small and large bowel reported an abrupt onset of constipation. She was advised to reduce the dose for two days. After that, she continued treatment without further complaints. No other untoward effect was reported.

## DISCUSSION

Chios mastic has been previously shown to exert various biological properties *in vitro*<sup>[12]</sup>, in experimental animal models<sup>[18]</sup> and in humans<sup>[14]</sup>. In the current study, we demonstrated that mastic was effective in the regulation of inflammation, evaluated by CRP, IL-6, TNF- $\alpha$  and MCP-1 in plasma, as well as in the regulation of oxidative stress, evaluated by TAP. In more details, mastic treatment significantly decreased the CDAI, which probably occurred through decrease of the pro-inflammatory IL-6, inducing remission in seven out of ten patients. Another important

**Figure 3** Plasma concentrations of interleukin-6 (IL-6) were suppressed in patients with active Crohn's disease ( $n = 10$ ) after 4-wk treatment with mastic caps ( $^aP < 0.05$ ). Horizontal bars represent the mean value ( $\pm$  SE).

**Figure 4** Plasma total antioxidant potential (TAP) was upregulated in patients with active Crohn's disease ( $n = 10$ ) after 4-wk treatment with mastic caps ( $^aP < 0.05$ ), indicating absorption of antioxidants and an improved *in vivo* antioxidant status. Horizontal bars represent the mean value ( $\pm$  SE).

observation was that mastic resulted in improvement of the nutritional status, as shown by NRI.

Nutritional support in patients with CD has a primary role in inducing remission and malnutrition is very common in CD. While several factors, such as malabsorption and increased resting energy expenditure in underweight patients, may contribute to malnutrition<sup>[22]</sup>, decreased oral intake is the primary cause. The methods used to support patients with CD are enteral and parenteral nutrition, in terms of protein-calorie intake. NRI is one of the most useful measures of nutritional status and points out severely malnourished patients when less than 83.5<sup>[23]</sup>. Hereby we show that NRI in patients supplemented with mastic was increased, however not significantly, perhaps due to the limited number of subjects. Particularly, NRI was increased in nine out of ten patients supplemented with mastic, two of whom experienced no nutritional risk (data not shown). The main element of NRI showing improvement was body weight gain. Based upon the fact that daily energy intake was unchanged during the trial (data not shown), increase in body weight and in NRI is due to the fact that mastic treatment resulted in decrease of liquid stools and therefore improvement in nutrient absorption.

The observed decrease in NRI in one of the patients was due to body weight loss, despite the fact that the number of liquid stools decreased. The daily energy intake of this young patient was gradually reduced and, according to her statement long after the end of the protocol, she was on a diet for weight loss.

The importance of IL-6 in patients with CD has been well documented. In patients with active CD, mRNA for IL-6 is overexpressed in the inflamed mucosa<sup>[24]</sup> and IL-6 is thought to play a crucial role in the pathogenesis of CD. Elevated IL-6 in plasma of patients with CD has been previously described<sup>[25]</sup>. Accordingly, we report that in patients with CD plasma concentration of IL-6 was significantly higher versus the control group. Significant decrease in IL-6 with mastic treatment was observed in patients following a decrease in plasma CRP (Figure 2). Because IL-6 is the main cytokine factor responsible for hepatic induction of acute phase proteins in CD, respective decrement in CRP is reasonable. In view of the fact that (1) oleoresins consist of triterpenes<sup>[26]</sup> with established anti-inflammatory and antioxidant effects<sup>[19,27]</sup> and (2) mastic contains antioxidant phenolic compounds<sup>[28]</sup>, it is more likely that the plasma IL-6 decrease observed in CD patients was due to these compounds.

TNF- $\alpha$  showed an insignificant ( $P = 0.114$ ) 1.6-fold decrease in CD patients. On the other hand, the difference in TNF- $\alpha$  concentrations between patients and controls at baseline was significant. The data reported about TNF- $\alpha$  in CD are somewhat contradictory. Whereas some groups were able to demonstrate increased concentrations of TNF- $\alpha$  in CD compared to healthy controls<sup>[29]</sup>, others were not<sup>[30]</sup>. Because TNF- $\alpha$  induces MCP-1 secretion via the activation of nuclear factor-kappa B<sup>[31]</sup>, it is likely that the slight decrease in MCP-1 was due to the lower activation of the nuclear factor-kappa B pathway secondary to the decrease in TNF- $\alpha$ .

Oxidative stress has been proven to upregulate IL-6 gene expression<sup>[32]</sup>. We show that mastic treatment resulted in increase of plasma TAP in CD patients (Figure 4) as well as in controls. Plasma is a heterogeneous solution of diverse antioxidants and an increase in the antioxidant capacity indicates absorption of antioxidants and an improved *in vivo* antioxidant status<sup>[33]</sup>. Whether the antioxidant triterpenes and phenolics contained in mastic<sup>[12]</sup> are absorbed or act on the exposed gastrointestinal mucosa, remains uncertain. Generally, our knowledge on the absorption and bioavailability of polyphenols is still limited, and the few studies in humans show that some are well absorbed and others hardly absorbed<sup>[34]</sup>. The unabsorbed may remain in the lumen and become available for fermentation in the colon. A substantial proportion of the gastrointestinal mucosa is therefore exposed to these compounds, or to their bacterial and systemic metabolites<sup>[35]</sup>. However, phenolic compounds do not seem to be absorbed as well as vitamins C and E, and hence their concentrations can be much higher in the lumen of the gastrointestinal tract than are ever achieved in plasma or other body tissues, making the action in the gastrointestinal tract more likely. Even less are the data on the absorption of triterpenes. Glycyrrhetic acid, the triterpene derivative of glycyrrhizin, has been shown to be bioactive in experimental gastric lesion

models<sup>[36]</sup> and has also been detected in the serum of experimental animals<sup>[37]</sup>.

In conclusion, subjecting CD patients with mild to moderate activity to mastic treatment seems to improve the clinical features of the disease and to regulate inflammation and antioxidant status. The use of natural products as primary treatment in CD should attract wider support and research, with increasing awareness of the harm of the long-term use of corticosteroids. Whether it is time for gastroenterologists to embrace the concept that natural products, such as mastic, may be beneficial to CD needs further research in larger cohorts.

## ACKNOWLEDGMENTS

We wish to thank the Chios Mastic Growers Association, especially Dr. Christos Kartalis, for the production and kind donation of Chios mastic caps, exclusively for the needs of the trial.

## Abstract

**AIM:** To investigate active cytomegalovirus (CMV) infection following the cyclosporine A (CyA) treatment of steroid-refractory ulcerative colitis (UC).

**METHODS:** Twenty-three patients with severe UC not responding to steroid therapy (male 14, and female 9) enrolled at Nagoya University Hospital from 1999 to 2005. They received continuous intravenous infusion of CyA (average 4 mg/kg per day) for 1 mo. Serum and colonic biopsy samples were collected before CyA treatment and 4 d, 10 d, 20 d, and 30 d after treatment. Patients were evaluated for CMV by using serology (IgM antibody by ELISA), quantitative real-time PCR for CMV DNA, and histopathological assessment of hematoxylin and eosin (HE)-stained colonic biopsies. CMV infection was indicated by positive results in any test.

**RESULTS:** No patients had active CMV infection before CyA treatment. Eighteen of 23 UC patients treated with CyA were infected with active CMV (IgM antibody in 16/23 patients, 69.6%; CMV DNA in 18/23 patients, 78.2%; and inclusion bodies in 4/23 patients, 17.3%). There was no difference in the active CMV-infection rate between males and females. Active CMV infection was observed after approximately 8 d of CyA treatment, leading to an exacerbation of colitis. Fifteen of these 18 patients with active CMV infection (83.3%) required surgical treatment because of severe deteriorating colitis. Treatment with ganciclovir rendered surgery avoidable in three patients.

**CONCLUSION:** Our results suggest that active CMV

## INTRODUCTION

Cytomegalovirus (CMV) infection is one of the most common infectious complications after immunosuppressive therapy. It occurs mainly as a secondary infection in CMV-seropositive patients. CMV infection is a common viral infection in humans, occurring in 40%-100% of adults<sup>[1]</sup>. CMV infections are generally asymptomatic or are manifested as a mild mononucleosis-like syndrome<sup>[2]</sup>. Significant CMV disease may occur in various organs such as the retina, lung, and gastrointestinal tract, and the target organ is related to the etiology of immunosuppression<sup>[1]</sup>. Gastrointestinal (GI) CMV infection is rare in immunocompetent individuals. Clinically significant GI CMV infection generally occurs in immunocompromised patients<sup>[3]</sup>. In the gastrointestinal tract, CMV disease can occur in all locations, from the mouth to the rectum, and generally involves the formation of ulcers in the mucosa, often accompanied by hemorrhage<sup>[1]</sup>.

Ulcerative colitis (UC) is common all over the world and is generally more frequent than Crohn's disease (CD)<sup>[4]</sup>. UC is thought to result from the inappropriate and progressive activation of the mucosal immune system driven by the presence of normal luminal flora. The aberrant response is most likely facilitated by defects in both the barrier function of the intestinal epithelium and the mucosal immune system<sup>[4]</sup>.

Cyclosporine A (CyA) selectively inhibits immune

responses mediated by T lymphocytes by modulating the interaction of calcineurin-calmodulin<sup>[5]</sup>. This recognition has led to its use in patients with severe UC, with variable results. In an uncontrolled study, approximately 60%-80% of patients suffering from severe corticosteroid-refractory ulcerative colitis responded to cyclosporine therapy<sup>[6,7]</sup>. Since an intravenous infusion of CyA has clinical benefits in patients with steroid-resistant UC, it has been generally accepted that CyA selectively blocks the activation of helper and cytotoxic T cells and acts by inhibiting the nuclear factor of activated T cells and cytokine gene expression<sup>[8]</sup>.

In Japan, patients with severe, corticosteroid-refractory or corticosteroid-dependent UC are frequently treated with strong immunosuppressive agents, including CyA. Therefore, patients with inflammatory bowel disease (IBD) are expected to be at an increased risk of infection with CMV. Despite the frequent use of immunosuppressive drugs in patients with UC, data on the frequency of CMV infection and its clinical significance in patients with UC are limited. The aim of this study was to describe our experience with active CMV infection following treatment with CyA for UC.

## MATERIALS AND METHODS

### Patients

Twenty-three patients with severe UC enrolled at Nagoya University Hospital from 1999 to 2005. They did not respond to a minimum of 7 d of intravenous systemic steroid therapy (prednisolone, more than 30 mg/d). The diagnosis of UC was based on clinical, endoscopic, radiological, and histological parameters. The study was approved by the Ethical Committee of the Graduate School of Medicine, Nagoya University, and all samples were obtained with informed consent in accordance with the Helsinki Declaration.

### CyA treatment

Twenty-three patients received a continuous intravenous infusion of CyA in the form of Sandimmun solution (Novartis Pharma KK, Tokyo, Japan) at an average daily dose of 4 mg/kg for 1 mo. The CyA dose was adjusted to maintain a whole-blood CyA concentration of less than 500 pg/L. Complete blood cell counts, C-reactive protein (CRP), liver function tests (aspartate aminotransferase and alanine aminotransferase), renal function tests (creatinine and blood urea nitrogen), and clinical evaluation were performed before CyA treatment and then 4 d, 10 d, 20 d, and 30 d after treatment.

### Collection of specimens and blood serum samples

Serum samples and colonic biopsy specimens were obtained from all patients before CyA treatment and then 4 d, 10 d, 20 d, and 30 d after treatment. Multiple biopsy samples were obtained from the inflamed area during colonoscopy for histopathological examination of inflammatory activity and CMV inclusion bodies; these samples were fixed in buffered neutral formalin. EDTA-treated venous blood (5 mL) was obtained from each

patient under aseptic conditions for serological studies. The plasma was separated by centrifugation.

### Histopathology

The colonic biopsy samples were paraffinized, sectioned, and stained with hematoxylin and eosin (HE). These sections were microscopically evaluated for the presence of characteristic cytomegalic cells and "owl's eye" nuclear inclusion bodies. Histologically, the activity of IBD was classified according to a standard system described previously<sup>[9]</sup>.

### Sample preparation

For the PCR assays, DNA was extracted from 200  $\mu$ L of plasma by using the QIAamp Blood Kit (QIAGEN Ltd, Tokyo, Japan), eluted in 100  $\mu$ L of distilled water, and stored at -30°C until analysis.

### Serological tests

The presence of anti-CMV IgM antibodies in all sera were tested by using the CMV IgM ELISA kit (Genesis Diagnosis Ltd, UK), a commercially available kit, by using the positive and negative controls provided with the kit. Virus-specific IgM antibodies were measured in the plasma regardless of the PCR results.

### Real-time semi-quantitative PCR assay

The PCR primers used were from the immediate early (IE) gene<sup>[10]</sup>. The upstream primer was 5'-GACTAGTGTGTGATGATGCTGGCCAAG-3', and the downstream primer was 5'-GCTACAATAGCCTCTTCCTCATCTG-3'. A fluorogenic probe (5'-carboxyfluorescein-AGCCTGAGGTTATCAGTGTAATGAAGCGCC-3') was located between the PCR primers<sup>[11]</sup>. PCR was carried out by using a TaqMan PCR kit (PE Applied Biosystems, Foster City, CA), as described previously<sup>[11]</sup>. Briefly, 10  $\mu$ L of the DNA extraction solution from the samples was added to a PCR mixture containing 10 mmol/L of Tris (pH 8.3); 50 mmol/L of KCl; 10 mmol/L of EDTA; 5 mmol/L of MgCl<sub>2</sub>; 100 mmol/L of dATP, dCTP, dGTP, and dTTP; 0.2 mmol/L of each primer; 0.1 mmol/L of fluorogenic probe; and 1.25 U of AmpliTaq Gold (PE Applied Biosystems). After activation of the AmpliTaq Gold for 10 min at 95°C, 50 cycles each of 15 s at 95°C and 1 min at 62°C were carried out in a Model 7700 Sequence Detector (PE Applied Biosystems). Real-time fluorescent measurements were taken and a threshold cycle (C<sub>t</sub>) value for each sample was calculated by determining the point at which the fluorescence exceeded a threshold limit (10  $\times$  SD of the base line). For a positive control, a plasmid that contained the IE gene was constructed using the pGEM-T vector (Promega, Madison, WI) and was termed pGEM-IE. A standard graph was constructed using the C<sub>t</sub> values obtained from the serially diluted pGEM-IE. The C<sub>t</sub> values from the clinical samples were plotted on the standard curve, and the copy number was calculated automatically by using Sequence Detector v1.6 (PE Applied Biosystems), a software package for data analysis. Samples were defined as negative when the C<sub>t</sub> value exceeded 50 cycles<sup>[12]</sup>. The DNA copy numbers in

the plasma were expressed per milliliters. The minimum detection level was 100 copies/mL of plasma.

### Criteria for diagnosis of CMV infection

Positive results in any tests (IgM antibody, CMV DNA, or inclusion bodies in HE stained sections) were considered as evidence of CMV infection.

### Statistical analysis

The results were expressed as mean  $\pm$  SD. The *P* values below 0.05 were considered significant. The accuracy of each test was calculated considering a positive result in any test for CMV as evidence of infection.

## RESULTS

Twenty-three patients were treated with intravenous CyA and they evidenced no severe side effects of the drug, such as renal failure or liver failure. The patient characteristics are listed in Table 1. All patients had received corticosteroids before the initiation of treatment with CyA. The degree of the severity of UC in all patients was pan colitis. Prior to treatment with CyA, active CMV infection was not observed in any of the patients. Eighteen of the 23 UC patients treated with CyA were infected with CMV (IgM antibodies in 16/23 patients, 69.6%; CMV DNA in 18/23 patients, 78.2%; and inclusion bodies in 4/23 patients, 17.3%). The rate of CMV detection by real-time PCR was significantly higher than other methods (*P* < 0.05). There was no difference in the CMV infection rate between males and females (males, 11/14; 78.57% and females, 7/9; 77.7%) (Table 2). With the exception of four of the tissue sections, all the sections from our UC patients who were treated with CyA were negative for CMV as demonstrated by histochemistry. After CyA treatment, none of the CMV-positive patients had pneumonia,

Figure 1 Comparison of initial CMV detection by day among the three methods (Real-time PCR, CMV IgM, and HE stain).

hepatitis, retinitis, nephritis, or pancreatitis. Their only clinical symptoms were those of gastrointestinal disorder caused by colitis.

The median time of onset of the CMV infection after CyA treatment was 8.5 d (range: 4-20 d).

Real-time PCR detection is the most rapid of the three methods used (CMV IgM, HE biopsy, and real-time PCR results) (Figure 1). In particular, the HE biopsy method is slower and less sensitive than the other methods.

All patients showed an improvement in their symptoms after the initiation of the CyA treatment. Four CMV-negative patients treated with CyA showed a drastic improvement in their symptoms, and one CMV-negative patient who received CyA showed slight improvement. The degree of hematochezia progressively decreased after CyA treatment. CMV-negative patients continued to show an improvement in their symptoms during CyA treatment; further, even though CyA treatment was terminated, no deterioration in the degree of bowel symptoms was observed. On the other hand, all CMV-infected patients demonstrated an aggravation of the symptoms of colitis, i.e., an increase in the body temperature and the degree of hematochezia; after CMV infection (*P* < 0.05) (Figure 2). Further, the inflammatory values, i.e., the white blood cell (WBC) count and the CRP values worsened after CMV infection (*P* < 0.05) (Figure 3). However, an assessment of liver and renal functions after infection did not reveal any deterioration (Figure 4). After 10 d of CyA administration, CMV DNA was detected in 16 of the 18 UC patients, however, the clinical symptoms were improving. On the other hand, after 20 d, the clinical symptoms worsened in the CMV infected patients and CMV IgM and the histopathology results were positive. The values of the CMV IgM titer and the number of CMV DNA copies both increased after infection (Figure 5). The increased CMV load was followed by an increase in the severity of colitis.

Fifteen of these 18 patients with CMV infection (83.3%) required surgical treatment because of uncontrolled, severe deteriorating colitis. Perforation of the colon was observed in one of the patients after CMV infection; he underwent an emergency total colectomy. Nevertheless, in our study,

Panel B showed the change in CRP value. The mean values of each group were plotted. Symbols: ◆, CMV positive; ■, CMV negative. <sup>a</sup>*P* < 0.05.

**Figure 5** Change in mean CMV IgM value and CMV viral DNA load after CMV infection. Panel A showed the change in mean CMV IgM value after infection. Panel B showed the change in mean CMV viral load after infection.

there were no deaths among the UC patients after CMV infection.

Only three patients (males 2, and female 1) showed an improvement in the severity of colitis and did not require

a colectomy since they were treated with ganciclovir following the identification of the CMV infection. The CMV IgM values did not decrease after ganciclovir treatment. However, in these three patients, the CMV DNA copy number decreased and did not show any further increase. Further, CMV infection was detected in one of the patients by an HE histopathological study. After ganciclovir administration, the owl's eye sign in the colon tissue was not observed. Thus, the three patients who were treated with ganciclovir were not reinfected with CMV although CyA treatment was continued.

## DISCUSSION

We clarified a possible relationship between CMV infection and UC treated with CyA. We showed a significant deterioration in the clinical symptoms and the inflammatory response after active CMV infection. However, no impairment in hepatic or renal function was observed since we could not detect either CMV hepatitis or acute renal failure. Our results suggest that CMV infection in patients with severe UC treated with CyA is associated with a poor outcome because of severe deterioration in UC.

In general, a primary CMV infection, which is usually acquired early in life, is overcome by the humoral and cellular immunological response. Thereafter, the virus remains latent, particularly in endothelial cells and monocytes. Reactivation occurs during the use of immunosuppressive drugs. The viral load is the highest during active infection and the lowest during the latency stage in immunocompetent persons. We observed that CyA treatment may cause the reactivation of CMV and a subsequent deterioration in colitis. During a CMV infection, an increase in intestinal permeability has been shown to occur in kidney transplant recipients<sup>[14]</sup>. This defect in the barrier function may facilitate the exposure of the mucosal immune system to antigens from the luminal flora. CMV may also spread from the mucosa to the bloodstream because of such a defect in the barrier function, leading to CMV viremia in the bloodstream.

Steroid-resistant UC is defined as persistent active disease despite high-dose systemic corticosteroid therapy. A history of steroid resistance increases the possibility of complications such as CMV infection. CMV infections were detected in 4.6% to 13% of the patients diagnosed with UC<sup>[15,16]</sup>. Up to 33% of the patients with severe steroid-refractory UC were found to harbor the CMV virus. CMV was detected in 25% of the patients with steroid-refractory UC as compared to only 2.5% of patients with medically non-refractory UC. All the cases of UC with CMV infection in other investigations were clinically severe and steroid-resistant, and approximately 70% of the cases suffered from an acute exacerbation of symptoms and required immediate emergency surgeries. These results may suggest that CMV is not a coincidental occurrence but an exacerbating factor<sup>[17]</sup>.

Although it is important to prevent the development of CMV disease<sup>[18]</sup>, the availability of rapid, sensitive, and reliable methods for the early diagnosis of CMV infection

is desirable<sup>[15]</sup>. As mentioned above, CMV disease can take many forms, depending upon the type of patient group under consideration. A consensus is available from the international CMV workshop for the definition of CMV disease<sup>[19]</sup>. The guidelines are purposefully rigorous and have aided the interpretation of clinical trial data and population based studies. However, they are likely to lead to an under appreciation of the contribution of CMV to patient morbidity. This is particularly true in the case of the histopathological diagnoses of CMV. Gastrointestinal symptoms along with histopathologically detected CMV are widely acceptable diagnostic criteria for CMV infections. In particular, the histopathological study of colon tissue is considered acceptable for CMV detection. Many CMV inclusion bodies were found in the surgical specimens of the UC cases in which CMV infection was detected, whereas CMV infection had not been detected by biopsy prior to surgery. CMV infection was observed in only 1 of the 55 cases investigated by endoscopic biopsy; however, it was detected in 8 of the 39 surgical cases<sup>[17]</sup>. Thus, it was rather difficult to detect CMV infection by biopsy, possibly because of sampling limitations. The characteristic inclusion bodies are not readily visible in routinely performed HE staining and CMV-infected cells are not always cytomegalic; therefore, the histopathological examination of the colonic biopsies had the lowest sensitivity. It has been suggested that CMV inclusion bodies are found more frequently in the right colon than in the left<sup>[16]</sup>; hence, multiple biopsies were taken from the colon, particularly from the inflamed and ulcerated areas, considering the fact that CMV exhibits tropism for the inflamed sites<sup>[20]</sup>. Therefore, it is likely that the false-negative results in the present study were related to sampling errors. Although our study did not confirm this, an immunohistochemical study of biopsy specimens may be more useful in diagnosis; however, immunohistochemistry is not a convenient tool for routine diagnosis.

The investigation of plasma CMV DNA is a simple, noninvasive, and nontraumatic method for evaluating and monitoring the CMV infection in patients. Procedures such as endoscopy and biopsies are traumatic and uncomfortable for a UC patient. The CMV-associated disease is generally the result of the reactivation of latent viruses rather than reinfection with the virus, and the measurement of CMV antibodies is often of no diagnostic use.

The real-time PCR assay was found to be as useful as the pp65 antigenemia assay because they were highly correlated<sup>[12]</sup>. Unlike the conventional qualitative PCR assay, which is not beneficial for determining the termination of antiviral therapy<sup>[21]</sup>, this assay showed that the copy numbers of CMV DNA decreased and disappeared in response to anti-CMV therapy. Additionally, with this PCR method there is almost no room for bias due to subjective assessments by technicians. One investigator reported that real-time PCR is more sensitive (92%) than the pp65 test (88%) with regard to positive findings. Further, the correlations between real-time PCR and the pp65 antigenemia assay were statistically

significant<sup>[22]</sup>. The advantage of quantitative techniques is that by defining a “threshold value” of CMV load, they may allow a distinction between the commonly occurring, clinically irrelevant CMV infection and the levels of active CMV replication that are likely to lead to clinical disease<sup>[23]</sup>.

However, there is still disagreement with regard to the optimal type of sample material, for example, leukocyte fractions versus plasma versus whole blood, and to the desirable sensitivity, which depends on the initial sample volume.

We used a quantitative CMV PCR assay that was able to quantify CMV DNA in plasma over the 100 copies/mL. The assay is fully controlled for maximal efficiency in at all steps. This is achieved by employing the widely used principle of an “internal control” and taking it one step further as a control for extraction efficacy.

Although the quantitative results obtained with different assays are difficult to compare because of the absence of an international standard, the results obtained with quantitative PCR correlate well with those of a number of other assays, and its sensitivity is generally higher<sup>[24]</sup>. The high sensitivity of the quantitative PCR assay is partly due to the use of a relatively large sample volume and the concentration of the DNA contained therein. Using plasma appears to avoid the loss of sensitivity as reported previously as compared to using whole blood or leukocytes<sup>[25]</sup>. Using plasma may also avoid the possibility of amplifying “latent” CMV from leukocytes. The exclusion of CMV DNA of intracellular origin may increase the clinical relevance of latent CMV detection; this in turn may decrease the predictive value of the test for active CMV infection<sup>[26]</sup>. Plasma is also easier to handle than cellular fractions such as leukocyte preparations and is better standardized, particularly in leukopenic patients. In HIV-positive individuals, the CMV load in whole blood and plasma has also been shown to be an important indicator of pathogenesis<sup>[27]</sup>. The presence of CMV DNA in the blood of HIV-positive patients identifies a group of patients who are almost 20 times more likely to progress to CMV disease than those who remain negative for CMV DNA in their blood<sup>[28]</sup>. In addition, an increasing CMV load in the blood was associated with an increased risk of disease progression<sup>[28]</sup>. CMV load was correlated with tissue samples obtained at the postmortem examinations of the HIV patients with histological evidence of CMV inclusions, and it was found that a viral load of  $> 5\,000\,000$  genomes/ $\mu\text{g}$  DNA is required before CMV inclusions are observed<sup>[29]</sup>. It should be noted that some of these manifestations do not satisfy the criteria outlined for the diagnosis of CMV disease. Thus, it appears likely that cases of CMV colitis may also be dismissed because they do not meet the definition of CMV infection, despite the presence of clinical symptoms and CMV DNA in the blood. It is important to appreciate that with the advent of more sensitive molecular-based assays, a reappraisal of many of these definitions may be required.

In conclusion, a CMV infection in patients with steroid-resistant UC should be ruled out prior to initiating aggressive immunosuppressive therapy such as CyA for steroid-resistant UC. Further, ganciclovir as an anti-viral

agent is useful for the treatment of CMV-associated UC after immunosuppressive therapy.

## COMMENTS

### Background

Cytomegalovirus (CMV) infection is one of the most common infectious complications after immunosuppressive therapy. Ulcerative colitis (UC) is thought to result from the inappropriate and progressive activation of the mucosal immune system driven by the presence of normal luminal flora. Cyclosporine A (CyA) selectively inhibits immune responses mediated by T lymphocytes by modulating the interaction of calcineurin-calmodulin. This recognition has led to its use in patients with severe UC. In Japan, patients with severe UC are frequently treated with CyA and are expected to be at an increased risk of infection with CMV. Despite the frequent use of immunosuppressive drugs in patients with UC, data on the frequency of CMV infection and its clinical significance in patients with UC are limited.

### Research frontiers

The aim of this study was to describe our experience with active CMV infection following treatment with CyA for UC in Japan.

### Innovations and breakthroughs

Twenty-three patients with severe UC not responding to steroid therapy at Nagoya University Hospital received continuous intravenous infusion of CyA (average 4 mg/kg per day) for 1 mo. Serum and colonic biopsy samples were collected from all patients before CyA treatment and 4 d, 10 d, 20 d, and 30 d after treatment and were evaluated for CMV by using serology (IgM antibody by ELISA), quantitative real-time PCR for CMV DNA, and histopathological assessment of hematoxylin and eosin-stained colonic biopsies.

### Applications

No patients had active CMV infection before CyA treatment. Eighteen of 23 UC patients treated with CyA were infected with active CMV (IgM antibody in 16/23 patients, 69.6%; CMV DNA in 18/23 patients, 78.2%; and inclusion bodies in 4/23 patients, 17.3%). Fifteen of these 18 patients with active CMV infection (83.3%) required surgical treatment because of severe deteriorating colitis. Treatment with ganciclovir rendered surgery avoidable in three patients. Active CMV infection in severe UC patients treated with CyA is associated with poor outcome. Further, ganciclovir is useful for treatment of CMV-associated UC after immunosuppressive therapy.

### Terminology

CMV infection is one of the most common infectious complications in immune-compromised patients. UC is chronic inflammation colitis thought to result from the inappropriate and progressive activation of the mucosal immune system driven by the presence of normal luminal flora. CyA is a drug to inhibit immune responses selectively mediated by T lymphocytes by modulating the interaction of calcineurin-calmodulin.

### Peer review

Severe ulcerative colitis is a potentially life-threatening condition. Traditional treatment for such patients is high-dose intravenous corticosteroids but up to 40% of patients become refractory to this treatment. In these patients CyA therapy has been shown to have an initial positive clinical response in many patients. However, i.v. cyclosporine is recommended only as short term “bridging” therapy to induce remission followed by azathioprine or 6-mercaptopurine maintenance therapy. In the present study Minami and coworkers investigated the frequency of the development of a CMV infection during a continuous intravenous cyclosporine treatment in ulcerative colitis and the clinical outcome in CMV infected vs. non infected patients. The study is of interest.

## Abstract

**AIM:** To assess the outcome of patients, who underwent transarterial chemoembolization (TACE) for hepatocellular carcinoma (HCC) and subsequently liver transplantation (OLT) irrespective of tumor size when no tumor progression was observed.

**METHODS:** Records, imaging studies and pathology of 84 patients with HCC were reviewed. Ten patients were not treated at all, 67 patients had TACE and 35 of them were listed for OLT. Tumor progression was monitored by ultrasound and AFP level every 6 wk. Fifteen patients showed signs of tumor progression without transplantation. The remaining 20 patients underwent OLT. Further records of 7 patients with HCC seen in histological examination after OLT were included.

**RESULTS:** The patients after TACE without tumor progression underwent transplantation and had a median survival of 92.3 mo. Patients, who did not qualify for liver transplantation or had signs of tumor progression had a median survival of 8.4 mo. The patients without treatment had a median survival of 3.8 mo. Independent of International Union Against Cancer (UICC) stages, the patients without tumor progression and subsequent OLT had longer median survival. No significant difference was seen in the OLT treated patients if they did not fulfill the Milan criteria.

**CONCLUSION:** Selection of patients for OLT based on tumor progression results in good survival. The evaluation of HCC patients should not only be based on tumor size and number of foci but also on tumor progression and growth behavior under therapy.

## INTRODUCTION

Hepatocellular carcinoma (HCC) is the third leading cause of cancer related mortality and the fifth most common cancer<sup>[1]</sup> worldwide. Nearly 500 000 cases are diagnosed each year in the United States and the incidence increased from 1.4 cases per 100 000 between 1976 and 1980 to 2.4 cases per 100 000 from 1990 to 1995. Furthermore, the associated mortality rate and hospitalization showed an increase of 41% and 46%, which demands a significant challenge in the management of HCC patients<sup>[2]</sup>.

The stage of disease divides HCC therapy into curative versus palliative approaches. Curative treatments are reserved for patients without portal vein invasion or distant metastases and include percutaneous ablation, surgical resection and liver transplantation<sup>[3-5]</sup>. Palliative attempts include liver-directed therapies, rarely systemic chemotherapy, and are offered when local extra-hepatic spread or distant metastases are present. Palliative therapy via transarterial chemoembolization (TACE) may be offered for unresectable HCC. TACE involves the injection of chemotherapeutic agents into the hepatic artery<sup>[6,7]</sup>. Multiple large randomized and controlled trials have failed to demonstrate a beneficial effect in survival of patients treated with TACE, but meta-analysis of these trials show a slight beneficial effect in survival in comparison with conservative treatment<sup>[8]</sup>.

For localized HCC in curative situations, which is defined by the absence of macro-vascular invasion and metastatic disease with well-preserved hepatic function, the initial treatment of choice is hepatic resection. In case of cirrhosis, optimal candidates for surgical resection show a single lesion less than 5 cm in size, with no complications of end-stage liver disease and no significant portal hypertension (portal pressure gradient less than 10 mmHg). Nevertheless, after 5 years there are significant

recurrence rates (70%) in HCC patients after surgical resection, and the 5-year survival rate is 30%. Taken together only about 5% of patients are ideal candidates for hepatic resection<sup>[9-11]</sup>. Therefore liver transplantation (OLT) is the only curative approach that addresses the HCC lesion as well as the underlying liver cirrhosis<sup>[12-15]</sup>.

Initial reports of liver transplantation in patients with HCC showed poor outcomes with a recurrence rate up to 50% and a 5-year survival of less than 40%. In these reports many patients underwent OLT in the setting of advanced HCC. As a consequence the Milan criteria have been put forward to provide guidelines that help select HCC patients for curative OLT. The goal of this effort was to achieve comparable survival rates in liver transplanted patients with HCC and patients without concomitant neoplasias<sup>[12]</sup>.

Patients fulfilling the criteria (single nodule < 5 cm or up to three nodules each < 3 cm) have a favorable prognosis with 3-year survival rates of 75% up to 85% and a recurrence rate of less than 15%. However, a retrospective cohort analysis showed comparable survival rates in patients who had solitary nodules less than 6.5 cm or 3 nodules with a combined diameter of less than 8 cm<sup>[13]</sup>, demonstrating that OLT is a potentially curative approach for patients with HCC extending the Milan criteria.

However, the general scarcity of donor livers hampers timely liver transplantation. In the interim specific therapy such as TACE can be initiated to stabilize the patient's health condition. Because the Milan criteria do not take into account tumor progression following non-surgical intervention strategies, patients treated with TACE cannot be necessarily evaluated on the basis of these criteria. We therefore selected patients for liver transplantation based on the lack of tumor progression during the waiting time and determined the clinical outcome in patients who were treated with TACE and subsequently underwent liver transplantation.

## MATERIALS AND METHODS

### Study design and characteristics of patients

From January 1995 to March 2002, 77 patients with HCC were seen at the Department of Surgery, University of Goettingen. The diagnosis of HCC was confirmed in all patients either by biopsy of the tumor or by a serum alpha-fetoprotein (AFP) measurement. In addition, in 7 patients who underwent OLT, HCC was diagnosed in the histological examination of the explanted organ.

Patient demographics showed a male: female ratio of 70:14 and a mean age of  $59 \pm 11.4$  years (range 31-84). The main underlying disease of HCC was liver cirrhosis ( $n = 63$ , 75%), which could be assigned to the diagnoses of alcohol ( $n = 23$ ), hepatitis C ( $n = 22$ ) and hepatitis B ( $n = 18$ ) (Table 1).

Age, gender, Child-Pugh score and tumor stage of all patients are shown in Tables 2 and 3. At the time of HCC diagnosis, 10 (12%) patients had no evidence of impaired liver function, 28 (33%) patients presented with class A, 29 (35%) with class B, and 17 (20%) with class C impaired liver function according to the Child-Pugh classification.

Table 1 Diagnostic chart of patients with HCC

Diagnoses	<i>n</i>	Age (yr, mean $\pm$ SD)
No liver disease	10	61 $\pm$ 12.2
Fibrosis	3	66.7 $\pm$ 0.6
Alcohol induced cirrhosis	23	60 $\pm$ 8.3
Hepatitis (C) cirrhosis	22	55.9 $\pm$ 9.9
Hepatitis (B) cirrhosis	18	55 $\pm$ 14.1
Others <sup>1</sup>	8	56 $\pm$ 16.9
Total	84	59 $\pm$ 11.4

<sup>1</sup> Haemochromatosis 2, Caroli-syndrome 1, primary biliary cirrhosis 1, primary sclerosing cholangitis 1, hepatitis C 1, acute liver failure 1, cryptogenic cirrhosis 1. The majority of patients had liver cirrhosis secondary to viral hepatitis and alcohol-related liver disease.

Table 2 Cirrhosis scoring of study patients according to Child-Pugh Score

Child-Pugh Score	<i>n</i>	Age (yr, mean $\pm$ SD)	Gender	
			Male	Female
A	28	56 $\pm$ 13.2	26	2
B	29	57 $\pm$ 9.7	25	4
C	17	56 $\pm$ 9.1	15	2
Total	74	56.3 $\pm$ 11.3	66	8

HCC was classified at hospital admission.

Table 3 Staging of the patients according to UICC

UICC stage	<i>n</i>	No cirrhosis	Cirrhosis	Age (yr, mean $\pm$ SD)
I	5	1	4	52 $\pm$ 11.7
II	13	1	12	60 $\pm$ 13.5
III	11	3	8	60.8 $\pm$ 8.0
IV	55	5	50	58 $\pm$ 11.6
Total	84	10	74	59 $\pm$ 11.4

Table 4 Treatment modalities of patients with HCC

Treatment	<i>n</i>	No cirrhosis	Cirrhosis
No treatment	10	3	7
TACE, not listed for OLT	32	6	41
TACE, died waiting for OLT	15		
TACE and liver transplantation	20	0	20
Liver transplantation	7	1	6
Total	84	10	74

The tumor staging according to the UICC criteria of patients used in this study is shown in Table 3.

Ten (12%) out of 84 patients were not treated because they died before the treatment was started ( $n = 4$ ), they refused treatment ( $n = 1$ ) or TACE could not be done due to their cardio-pulmonary risk ( $n = 5$ ). The remaining 74 patients were treated as seen in Table 4. In 7 transplanted patients, the HCC was diagnosed after liver transplantation and therefore they were not treated before OLT. In the other 67 patients TACE was done and 35 of them were listed for OLT. The reasons for not listing a patient for

liver transplantation were no additional liver cirrhosis ( $n = 10$ ), age older than 65 ( $n = 11$ ) and persistent alcohol disease ( $n = 11$ ). From the initial 35 patients who were listed for OLT, 15 showed tumor progression after TACE and were therefore subsequently removed from the transplantation list. These patients showed a median time of tumor progression of 3.1 mo. The remaining 20 patients underwent OLT with a median time on waiting list of 7.6 mo.

Chest X-ray, computed tomography (CT) and staging by the TNM scoring system of the UICC was performed in all the patients. Tumors that were first identified by histopathology of the explanted liver were classified as incidental tumors.

### Selection criteria for OLT

Patients were selected for OLT based on the guidelines of Transplantations Gesellschaft (DTG). In addition, patients with extrahepatic tumor manifestation did not qualify for OLT. Tumor size or number of tumors were not taken into account for listing the patient. The patients received TACE and were restaged every 6 wk during waiting time. Evidence of tumor progression resulted in removal of the patients from the waiting list.

### Transarterial chemoembolization protocol

Patients were listed for OLT and immediately obtain TACE. TACE was performed in cases of advanced HCC stage or when tumors progressed during the staging work-up every 6 wk. Patients in advanced tumor stage (downstaging group) were listed when they responded to the first TACE treatment cycle. Sixty-seven patients were subjected to selective TACE before transplantation. The chemoembolization solution contained 50 mg epirubicin, 10 mL lipiodol and 3 mL water-soluble contrast material. Embolization was performed until blood flow to the tumor stopped.

The following day CT scanning was performed to determine the lipiodol uptake by the tumor tissue. Each TACE cycle was repeated every 6 wk and ultrasound, CT scan and AFP levels were assessed. Response to TACE is defined as constant size of the tumor and/stable AFP levels. Patients showing a positive response to TACE remained on the waiting list and were monitored by a CT scan (every 3 mo) and determination of AFP level (monthly). Patients with tumor progression under TACE treatment were discharged from the waiting list (non-responder).

### Post-transplantation management and follow-up

Immunosuppressive therapy following OLT consisted of a drug regimen of Prograf in combination with corticosteroids. Corticosteroids were gradually tapered and discontinued within 3 mo. Prograf was continued for one year after OLT unless side-effects were seen. The frequency of the outpatient visits thereafter varied according to the patient conditions and types of complications. No anti-cancer treatment was given after transplantation. All patients were followed up weekly in the outpatient clinic for the first month after discharged from the hospital. Screening for tumor recurrence was

**Figure 1** Survival probabilities for the first 5 yr after treatment. Overall HCC patient survival who had received TACE and OLT, only TACE and patients who received no treatment.

assessed by determination of  $\alpha$ -fetoprotein (AFP) and ultrasonography every 3 mo. A routine CT scan of the abdomen and chest was performed every year, and additional imaging techniques (bone scan, magnetic resonance imaging) were done if HCC recurrence was suspected. The medical records and pathologic reports were analyzed retrospectively.

### Statistical analysis

We analyzed the statistical significance on recurrence and survival of tumor-related risk factors, tumor size, number of nodules, and Milan criteria. We used the Kaplan-Meier method to measure survival and the log-rank test to analyze statistical differences. Results are expressed as mean  $\pm$  SD. One-way ANOVA was used for comparisons between the groups when one measurement per experiment was available. Non-normally distributed data was calculated after rank transformation. Data were calculated by univariate ANOVA. Tukey's-HSD test was used for post hoc comparisons.  $P < 0.05$  was considered significant in difference. Survival was estimated using Kaplan-Meier/log-rank analysis. All calculations were performed using SPSS 10.0<sup>®</sup>, standard version.

## RESULTS

### Tumor progression after TACE

Chemoembolization was well tolerated in the majority of patients. The most common complaints after TACE were pain, transient fever, and nausea. No patient developed major complications, which required surgical intervention. After TACE, 20 (29.2%) showed response and 47 (70.1%) showed tumor progression.

### Tumor progression defines a group with good survival after OLT

As expected, the patients without treatment had the worst outcome with a median survival of 3.8 mo as seen in Figure 1. The Patients who were treated with TACE but did not qualify for liver transplantation due missing signs of liver cirrhosis ( $n = 10$ ), age older than 65 ( $n = 11$ ), persistent alcohol disease ( $n = 11$ ) or tumor progression ( $n = 15$ ) had a median survival of 8.4 mo (Figure 1). The

**Figure 2** Kaplan-Meier patient survival curves showing survival dependent on UICC stage.

**Figure 4** Kaplan-Meier patient survival curves. OLT improved survival UICC stage III.

**Figure 3** Kaplan-Meier patient survival curves demonstrating that OLT improved survival UICC stage I and II.

**Figure 5** Kaplan-Meier patient survival curves. OLT improved survival UICC stage IV.

patients who showed no signs of tumor progression during waiting time had an average of 3 sessions of TACE (range, 1 to 10) before OLT. The TACE treated and liver transplanted patients ( $n = 20$ ) had a significant better outcome compared with TACE treated patients with a median survival of 92.3 mo (Figure 1). The time of median survival in the transplanted group is comparable to OLT patients with non-malignant diseases (median survival of 101.6 mo) and confirms the selection criteria for OLT are suitable to select HCC patients for liver transplantation.

### Survival dependent on UICC stage

Survival analysis revealed that the patient overall survival was dependent on the UICC stage. Patients with UICC stage I ( $n = 5$ ) had an overall survival of 100%, stage II ( $n = 13$ ) 64%, stage III ( $n = 11$ ) 45% and stage IV only 8% ( $n = 55$ ) (Figure 2).

### Lack of tumor progression and subsequent OLT improves survival irrespective of UICC stage

Patients, who fulfilled the selection criteria for liver transplantation and had no signs of tumor progression, underwent subsequently OLT. Independent of UICC stage, the patients with TACE and OLT had a better survival (Figures 3, 4 and 5). None of the patients with

UICC stage I on the waiting list showed signs of tumor progression. In UICC stage II and III, 4 patients had signs of tumor progression during waiting time. Seven of the UICC stage IV patients displayed signs of tumor progression. Independent of the UICC stage the patients without tumor progression and subsequent OLT had a significant better median survival. Patients who did not fulfill the criteria for liver transplantation or showed signs of tumor progression in UICC stage III had a median survival of 14.2 mo compared to 39.5 mo in the liver transplanted group (Figure 4). In UICC stage IV patients the median survival was 8.6 versus 15.6 mo, respectively. The patients who were not treated at all had the worst survival with a median survival time of 3.8 mo (Figure 5). Taken together, independent of the UICC stage, the survival was significantly better in patients who qualified for liver transplantation and without any evidence of tumor progression while waiting for OLT ( $P > 0.05$ ).

### Patients without tumor progression have a comparable outcome irrespective of the Milan criteria

Patients, who fulfilled the Milan criteria, are considered to have an excellent outcome. Interestingly, in our study there was no significant difference ( $P = 0.19$ ) in survival

**Figure 6** Survival probabilities for the first 5 years after liver transplantation according to the Milan criteria (A) and tumor size (B).

of patients, who fulfilled the Milan criteria compared to the more advanced patients (Figure 6A). However, the patients with tumors less than 5cm had a significantly better median survival ( $P = 0.03$ ) compared to patients with tumors larger than 5 cm (Figure 6B).

## DISCUSSION

Liver transplantation is the only approach that addresses the multifocal hepatocellular carcinoma and also treats the underlying cirrhosis but the limited availability of donor organs and the subsequent immunosuppression urge criteria of patient selection. Our data suggest that patients, who do not show signs of tumor progression after TACE treatment benefit from OLT irrespective of UICC stage. Without tumor progression, even patients outside of the Milan criteria do have a good outcome. Therefore we suggest that patient selection for OLT should be based on tumor size and additionally on assessment of tumor progression.

The current UNOS policy for organ allocation among patients with HCC favors those with tumors confined within the limits of diameter and number of nodules defined by the Milan criteria<sup>[12]</sup>. These were derived from a prospective study showing significantly better recurrence-free survival for 35 patients meeting the proposed criteria than for 13 patients with HCC exceeding criteria because of preoperative tumor stage underestimation based on pathologic analysis of the liver explants (92% *vs* 59% at 4 years). Other study groups proposed to “expand” the limits concerning OLT for HCC<sup>[16]</sup>, because studies using the extended UCSF criteria (solitary tumor < 6.5 cm,

three or fewer nodules with the largest lesion < 4.5 cm, total tumor diameter < 8 cm or without gross vascular invasion) do not worsen the outcome of patients after OLT<sup>[13]</sup>. Therefore, concerns arise whether the Milan criteria may be too restrictive, thus excluding patients who would otherwise benefit from OLT. The decision for OLT is based on tumor size and number of tumor within the liver but not on growth behavior of the tumor or response of the tumor after bridging therapy. In our present study, 12 patients were found to have tumor characteristics exceeding the Milan criteria and underwent OLT. These patients were selected on the tumor progression after TACE and the difference in survival among those patients compared to patients meeting the Milan criteria did not reach statistical significance ( $P = 0.19$ ). Thus patients without tumor progression not fulfilling the Milan criteria might benefit from OLT.

Vitale *et al*<sup>[17]</sup> described a very low occurrence of drop-outs from waiting list, though they had a quite long median waiting time of 11 mo<sup>[18]</sup>. In their study they used the following criteria to exclude patients from OLT: short-listing, general contraindication to transplant, extrahepatic spread, vascular invasion or poorly differentiated HCC (G3) at pre-OLT percutaneous biopsy. Size and number were not considered absolute selection criteria. They suggest that adoption of different selection criteria accounting more for tumor biology (grading) rather than tumor size and number and a use of a pre-OLT multimodal strategy probably may guarantee a lower number of drop-outs. Our results demonstrate that patients who show no further tumor progression under TACE treatment significantly ( $P < 0.05$ ) benefit from OLT. It seems to be an easier biological grading method than the routine percutaneous biopsy for liver lesions because of the given potential risk of tumor seeding along the biopsy tract.

Furthermore, current imaging techniques have a high incidence of false-negative and false-positive results when evaluating HCC in cirrhosis. Only in 14.3% of OLT patients, tumor diameter was correctly identified by pretransplant radiological examinations shown by Sotiropoulos *et al*<sup>[19,20]</sup>. Sensitivity of radiological imaging was especially poor for tumors between 1 and 2 cm and less than 1 cm (21% and 0%, respectively), indicating that detection of small HCCs, especially in end-stage cirrhotic livers, remains problematic. A critical appraisal of patient characteristics together with great caution when interpreting imaging studies is recommended to determine candidacy for transplantation. Otherwise many patients are not given the opportunity to undergo OLT.

TACE involves the injection into the hepatic artery of chemotherapeutic agents such as doxorubicin, mitomycin, or cisplatin with lipiodol, to promote intra-tumor retention of the medications. TACE has the advantage of treating larger tumor-areas, being repeatable and perhaps downstaging patients. Disadvantages of TACE include significant toxicity and acute liver failure, especially when treating large areas<sup>[17]</sup>. Even if downstaging by TACE has been reported, TACE has not been shown to improve survival or recurrence of HCC after transplantation. Even in patients who were not transplanted, multiple large randomized controlled trials have failed to demonstrate

a survival benefit. Only a small survival benefit in comparison with conservative treatment was seen in meta-analysis of these trials. In addition, none of the current studies have examined the ability of TACE to sustain patients on the transplantation waiting list. Our data demonstrate that the patients, who have no tumor progression after TACE benefit substantially from OLT. Whether these patients would progress without TACE remains speculative<sup>[19,21-26]</sup>.

In contrast to other malignant diseases, assessment of HCC patients on the waiting list should not only account for the current stage, it although should evaluate the tumor progression. Multiple genetic lesions within the HCC cells, which modulate growth, cell cycle, apoptosis and invasion, define tumor progression<sup>[27-31]</sup>. These genetic lesions are not defined in number and location and therefore prospective evaluation based on molecular pattern is not possible. On the other hand it is practicable to assess tumor growth by size and AFP levels.

Therefore, we conclude that the growth behavior of the tumor (defined as progression under anti-cancer therapy) could provide simple but helpful information about the recurrence rate and the outcome of HCC patients after OLT. We propose that growth behavior (P0 for no progression and P1 for progression) should be added to staging systems for classification of HCC to select patients for OLT<sup>[32-34]</sup>.

## Abstract

**AIM:** To study the endoscopic, pathological and immunohistochemical features of esophageal mesenchymal tumors.

**METHODS:** Twenty-nine patients diagnosed as esophageal mesenchymal tumors by electronic endoscopy and endoscopic ultrasound (EUS) were observed under light microscopes, and all tissues were stained by the immunohistochemical method. The expression of CD117, CD34, SMA and desmin were measured by staining intensity of cells and positive cell ratios.

**RESULTS:** Endoscopically, esophageal gastrointestinal stromal tumors (GISTs) and leiomyomas (LMs) had similar appearances, showing submucosal protuberant lesions. They all showed low echo images originated from the muscularis propria or muscularis mucosa on EUS. Endoscopy and EUS could not exactly differentiate esophageal GISTs from LMs. Microscopically, there were two kinds of cells: spindle cell type and epithelioid cell type in esophageal GISTs. Leiomyomas and leiomyosarcomas were only of spindle cell type. One malignancy was found in five cases of esophageal GISTs, and one malignancy in 24 cases of leiomyomas and leiomyosarcomas. Using Fisher's exact method, the differences of malignant lesion proportion were not significant between esophageal LMs and GISTs, 1/5 vs 1/24 ( $P > 0.05$ ). All cases of esophageal GISTs were positive for CD117, and 3 cases were also positive for CD34. The 24 cases of leiomyomas and leiomyosarcomas were all negative for CD117 and CD34. The differences of positive rates of CD117 and CD34 were significant

between esophageal GISTs and LMs, 5/5 vs 0/24, 3/5 vs 0/24 ( $P < 0.005$ ). All leiomyomas and leiomyosarcomas were positive for SMA, and desmin. Among 5 cases of esophageal GISTs, 2 cases were SMA positive, and 1 case was desmin positive. The differences in positive rates and expression intensity of SMA and desmin were significant between esophageal LMs and GISTs, 2/5, 24/24 vs 1/5 ( $P < 0.005$ ).

**CONCLUSION:** The most common esophageal mesenchymal tumors are leiomyomas, and esophageal GISTs are less common. Most of esophageal LMs and GISTs are benign. Endoscopy and EUS are the effective methods to diagnose esophageal mesenchymal tumors and they can provide useful information for the treatment of these tumors. However, they cannot exactly differentiate esophageal GISTs from LMs. Pathological, especially immunohistochemical features are useful to differentiate GISTs from leiomyomas.

## INTRODUCTION

Traditionally, the gastrointestinal mesenchymal tumors (GIMTs) have been almost uniformly classified as gastrointestinal leiomyomas (LMs). However, recent evidence indicates that most mesenchymal tumors of the gastrointestinal tract are gastrointestinal stromal tumors (GISTs)<sup>[1]</sup>. It is difficult to differentiate esophageal GISTs from LMs because of their similar appearance. GISTs frequently have malignant potential, therefore, it is important to differentiate GISTs from LMs. GISTs arising in the gastrointestinal tract have been known quite well. Whether there are the same stromal tumors in the esophagus, and whether stromal tumors are the most

frequent mesenchymal tumors of the esophagus, are big concern of clinical doctors<sup>[2,3]</sup>.

## MATERIALS AND METHODS

### Specimen collection

All the patients were in- and outpatients from the First Affiliated Hospital of Nanchang University during June 2004 to November 2005 and they all met with the following two criteria: (1) Endoscopically, the tumors showed submucosal protuberant lesions, and they showed low echo images originated from the muscularis propria or muscularis mucosa on EUS. (2) Microscopically, they were diagnosed as esophageal mesenchymal tumors. All tissue specimens were obtained by the following 3 methods: biopsy, endoscopic mucosal resection (EMR) or surgical operation.

### Methods

All tissue specimens were fixed in 10% formalin and processed routinely for paraffin embedding. Sections of 4-mm thick were stained with hematoxylin and eosin, and observed by light microscopy. Then all cases were stained for CD117, CD34, SMA, and desmin. All antibodies were purchased from Beijing Zhongshan Corporation. The detailed procedures were carried out according to instructions of the kits.

### Criteria for histopathology

First, esophageal mesenchymal tumors: According to the criteria of 2005 WHO Oncopathology and Genetics<sup>[4]</sup>, if spindle cells and epithelioid cells were shown microscopically, esophageal mesenchymal tumors can be diagnosed. Second, criteria for assessing malignancy of gastrointestinal stromal tumors: according to the criteria of 2005 WHO Oncopathology and Genetics and the advice of Singer and Miettinen<sup>[4-6]</sup>, GISTs were diagnosed as malignant when the following criteria were met: tumor size  $\geq 5$  cm, nuclear mitotic figure  $> 5/50$  HPF. GISTs were diagnosed as benign: tumor size  $< 5$  cm, nuclear mitotic figure  $< 5/50$  HPF. GISTs were diagnosed as potentially malignant: tumor size  $\geq 5$  cm, nuclear mitotic figure  $< 5/50$  HPF or tumor size  $< 5$  cm, nuclear mitotic figure  $> 5/50$  HPF. At the same time, tumor hemorrhage/necrosis, peripheral invasive growth, lymph node metastasis and metastasis to another organ are all considered also. Third, criteria for leiomyosarcomas: according to the criteria of 2005 WHO Oncopathology and Genetics and internal reports<sup>[4,7,8]</sup>, tumor size  $\geq 5$  cm, nuclear mitotic figure  $> 5/50$  HPF, tumor hemorrhage/necrosis, peripheral invasive growth and metastasis.

### Assessment for immunohistochemical results

Positive results were indicated if the cytoplasm was stained brown, and cell membrane was stained positive for CD34 and CD117. The categories were (+): more than 10% of cells stained; (-): less than 10% of cells stained. Positive control: CD117, an indicator of the known GISTs; CD34, an indicator of vascular endothelial cells in tumors; SMA, an indicator of normal smooth muscles in vascular walls or

**Table 1** Clinical findings of 29 cases of esophageal mesenchymal tumors

Tumor type	n	Dysphagia	Heart burn/ retrosternal pain	Hemorrhage	Stomachache	Asymptomatic
LMs	24	4	7	1	2	10
GISTs	5	1	1	1	0	2
Total	29	5	8	2	2	12

Tested by Fisher's exact method, the differences of symptoms are not significant between esophageal LMs and GISTs ( $P > 0.05$ ).

**Figure 1** Endoscopic image of esophageal stromal tumors.

esophageal walls; Desmin, an indicator of normal smooth muscles in esophageal walls. Negative control: the primary antibody was replaced by PBS for negative control.

### Statistical analysis

Data was tested using Fisher's exact method. A  $P$  value less than 0.05 was considered statistically significant.

## RESULTS

### Clinical data

Among 29 cases of esophageal mesenchymal tumors diagnosed by endoscopy, pathology and immunohistochemistry, 5 cases were esophageal GISTs, 23 cases were leiomyomas and 1 case was leiomyosarcoma. In the group of esophageal GISTs, 3 cases were male, and 2 cases were female. Their age ranged from 44-63 years (mean  $52 \pm 7.8$  years). In the group of leiomyomas and leiomyosarcomas, 13 cases were male, and 11 cases were female. Their age was between 24-68 years (mean  $55 \pm 10.2$  years). The symptoms of esophageal mesenchymal tumors are summarized in Table 1.

### Endoscopic and EUS characteristics

Endoscopically, GISTs showed submucosal protuberant lesions such as hemisphere, nodosity, strip or irregular shape, and had smooth surface, wide bases and the same color as its adjacent mucosa (Figures 1 and 2). The malignant lesions showed ulceration or hemorrhage, and had no clear boundaries with the normal tissue. Benign tumors varied from 0.5-3 cm in size. One malignant tumor

**Figure 2** Endoscopic image of leiomyomas.

**Figure 3** EUS image of esophageal stromal tumors: originated from muscularis propria.

**Figure 4** EUS image of leiomyomas: originated from muscularis mucosa.

**Figure 5** Malignant esophageal stromal tumor: tumor cells were intensely stained, but there was no visible mitosis. (HE × 200).

**Figure 6** Esophageal leiomyoma: cells were all spindle, with abundant eosinophilic cytoplasm (HE × 200).

was especially large, extending to the cardia and body of the stomach. LMs showed submucosal protuberant lesions such as polyps, hemisphere, pillar, dumb bell, with smooth surfaces. Tumors varied between 0.5-3 cm in size, and had clear borders. One leiomyosarcoma showed irregular nodosity. Its size was 3 cm × 4 cm with anabrotic surfaces.

On EUS, GISTs showed round, spindle-shaped or irregular low echo images originated from the muscularis propria or muscularis mucosa, from which internal echoes were homogeneous or heterogeneous. Two cases were originated from the muscularis mucosa and 3 cases from the muscularis propria (Figures 3 and 4). LMs also showed low echo images originated from the muscularis propria or muscularis mucosa and their internal echoes were homogeneous or heterogeneous. Eleven cases were originated from the muscularis mucosa and 12 cases were originated from the muscularis propria. Endoscopy and EUS could not differentiate esophageal GISTs from LMs because of their similar appearances.

### Pathological characteristics

Among 5 cases of GISTs, 4 cases were of spindle cell type, and one case was of epithelioid cell type. There was no mixture of cell types. The cells of GISTs were more intense than leiomyomas, and had a less eosinophilic cytoplasm. The spindle cells were arranged in braid, sarciniform, or cord-like and their nuclei were rod-like.

The epithelioid cells were round, orbicular-ovate or polygon and their nuclei were conspicuous. According to the above mentioned criteria, there was 1 case of malignancy at the inferior segment of the esophagus, which size was uncertain, with hemorrhage and necrosis on its surface. Microscopically, the tumor cells were intense, but there was no visible mitosis (Figure 5).

Twenty three cases of LMs were composed of well-differentiated smooth muscle cells of spindle cell type and the cells were arranged as braid, sarciniform. The tumors were moderately cellular with abundant eosinophilic cytoplasm (Figure 6). According to the criteria, there was one leiomyosarcoma, which size was 3 cm × 4 cm, with ulceration and bleeding on its surface and without clear borders. Microscopically, there were abundant spindle cells with a few mitosis.

Among 29 cases of esophageal mesenchymal tumors, one case with malignancy (20%) was found in 5 cases of esophageal GISTs, and one case with malignancy (4.2%) was found in 24 cases of leiomyomas and leiomyosarcomas. Using Fisher's exact method, the differences of malignant lesions proportion were not significant between esophageal LMs and GISTs, 1/5 *vs* 1/24 ( $P > 0.05$ ).

### Immunohistochemical results

were all stained positive for CD117, CD34, SMA and desmin. The results are summarized in Table 2, Table 3, Table 4 and Table 5, Figures 7 and 8.

## DISCUSSION

Gastrointestinal mesenchymal tumors have long

been classified as LMs, including leiomyoma and leiomyosarcoma. In 1983 Mazur and Clark introduced the term of gastrointestinal stromal tumors (GISTs). GISTs are a kind of potentially malignant tumor. Most scholars believe that the stomach is the predilective site of GISTs, next are the intestines, the colon and the rectum. And GISTs seldom occur in the esophagus<sup>[9,10]</sup>.

Gouveia<sup>[11]</sup> reported that esophageal GISTs, though less in number, were also made up of fusiform cells, and their mitotic index was low. CD117 and CD34 were expressed, and the malignant degree was low. Among 57 cases of esophageal mesenchymal tumors, studied by Madalie<sup>[12]</sup>, 14 cases of esophageal GISTs were found, and only 2 cases were malignant. Wang<sup>[13]</sup> reported that 9 cases of GISTs were found among 44 cases of esophageal mesenchymal tumors, and 3 cases were malignant. In our study, among 29 cases of esophageal mesenchymal tumors, 5 cases were demonstrated to be GISTs by endoscopy, pathology, and immunochemistry, and the other 24 cases were LMs. This result further proved that esophageal GISTs exist in the gastrointestinal tract, though they are fewer in number than esophageal LMs, accounting for only 20%<sup>[12-14]</sup>.

Esophageal mesenchymal tumors mostly occur in people of middle and old age, especially over 50 years old, occasionally in children. In the current study, all the 5 cases were over 40 years old, and 3 of them were over 50 years old (the youngest one was 40 years old). The mean age was 52 years. Esophageal leiomyomas may occur at any age. In our group, age of patients with LMs was from 20 to 70 years, and males were slightly more than females. The clinical manifestations of esophageal mesenchymal tumors are closely correlated with the size, nature, and growth pattern of the tumor. In the earlier period, clinical symptoms are nonspecific. When the tumor volume becomes bigger grossly and grows intracavitarily, symptoms such as dysphagia, heart burn, and retrosternal pain may become obvious. Some patients may have upper gastrointestinal hemorrhage.

The appearance of esophageal GISTs and leiomyomas are similar under the endoscope. They are generally globular, hemispheroid, polypoid, with tubercular eminences. The surface of benign GIMTs is smooth, while there is ulceration or hemorrhage on the surface of malignant GIMTs. EUS can not only examine the wall of the esophagus, but can also estimate the topography of the extent, location of lesions, and their relation to the surrounding organs<sup>[15,16]</sup>. EUS can discriminate GIMTs from other protrusion lesions of the esophagus. Usually esophageal mesenchymal tumors show a low echo image. Though EUS can help doctors to make therapeutic decisions by surgery or by endoscopy, it cannot help doctors to judge the type of the GIMTs.

Esophageal GISTs originate from between the walls of the esophagus. They are a kind of proliferation of spindle cells or epithelioid cells. No matter where the tumor is originated, the cells of GISTs are more abundant than that of leiomyomas and have less eosinophilic cytoplasm. The tumor cells are interlaced, dispersed, or paliformly arranged. In our study, cell nests made up of spindle cells were found in three cases of esophageal GISTs. These cell nests can only be found in GISTs, but not in LMs. This result is coincident with that of Franquemont<sup>[17]</sup>.

There is no definite criterium for differentiation between benign and malignant esophageal mesenchymal tumors. We determined the nature of tumors according to their infiltration, metastasis, volume, and nuclear mitotic figure. In the present study, one case of interstitialoma occurred at the inferior segment of the esophagus. Its

diameter was more than 5 cm. There was ulceration and hemorrhage on the surface, but no obvious mitosis. This tumor can still be judged as malignant. Kimiyoshi<sup>[18]</sup> suggested a criterium for differentiation between benign and malignant GISTs: hemorrhage or necrosis, the diameter of the tumor > 5 cm, Ki-67 labeling index (LI) > 3%. If the tumor has any one of the items above, it is malignant. If none of the items above can be found, then it is benign. Kimiyoshi also found that cellularity, nuclear atypia, and mitosis were not related to the nature of the tumor. This is different from the traditional diagnostic criteria. And further studies are needed. Leiomyosarcomas are not common, and its diagnostic criteria are not well studied. According to the criteria of WHO, there was only 1 case of leiomyosarcoma in the present study. The tumor occurred at the inferior segment of the esophagus. Intensive fusiform cells could be seen under the microscope. Mitosis could be seen accidentally. The diagnosis was low potential malignant leiomyosarcoma. The incidence of esophageal leiomyosarcoma is low.

In our study, the difference between the ratio of malignant GISTs (1/5) and that of leiomyosarcoma (1/24) was insignificant. It showed that the biological behaviour of GISTs was related to the site of the tumor. Esophageal GISTs are not as malignant as those in the gastrointestinal tract. It was also noted that 1 case of esophageal leiomyosarcoma and 1 case of esophageal interstitialoma both occurred in the inferior segment of the esophagus adjacent to the cardia. Whether the predilection site for malignant lobus intermedius tumor is the inferior segment of the esophagus is still to be studied.

In 1998, Kindblom *et al*<sup>[19]</sup> found that GISTs expressed CD117, which provided an effective means to study GISTs. CD117 is sensitive and specific. Studies reported that the sensitivity was 90%-100%<sup>[20,21]</sup>. In this study, all 5 cases of esophageal interstitialoma expressed CD117, while no case of leiomyoma expressed CD117. Both the sensitivity and specificity were 100%. This result is coincident with most overseas studies. However, not all GISTs expressed CD117. Debiec-Rychter found that in some of the malignant or recurrent cases of GISTs, CD117 was not expressed<sup>[22]</sup>. CD34 is a sensitive immunochemistry marker of GISTs. CD34 was expressed in 60%-70% cases of GISTs<sup>[23,24]</sup>, but barely expressed in leiomyomas and myoschwannomas<sup>[25,26]</sup>. In our group the sensitivity of CD34 was 60%, and the specificity was 100%. Smooth muscle actin (SMA) is widespread and strong positive in smooth muscles, and also positive in GISTs. This shows that some GIST cells could differentiate into smooth muscles. Desmin is a key index for diagnosis and differential diagnosis of GIMTs, which is strongly expressed in smooth muscles, while barely expressed in GISTs. In this group, desmin was positive in all 24 cases of leiomyoma (leiomyosarcoma); only positive in 1 GIST. This is consistent with previous reports<sup>[27,28]</sup>.

Our study provided evidence that all esophageal mesenchymal tumors had the same immunohistochemical features, and combined detection of CD117, CD34, SMA and desmin can help differentiate esophageal GISTs from LMs.

In summary, the present study demonstrates that

the traditional classification is not precise by combined analysis of the clinical, endoscopic, pathological and immunohistochemical features of esophageal mesenchymal tumors. Clinical findings, endoscopy and EUS can be helpful for diagnosis of esophageal mesenchymal tumors, but cannot determine the nature of tumors. Pathology and immunohistochemistry play an important role in their diagnosis and differential diagnosis.

and cold stress, which might be the pathogenesis of altitude GIB. Those who consumed large amount of alcohol, aspirin or dexamethasone were at a higher risk of developing GIB. Persons who previously suffered from peptic ulcer or high-altitude polycythemia were also at risk of developing GIB. Early diagnosis, evacuation, and treatment led to early recovery.

**CONCLUSION:** GIB is a potentially life threatening disease, if it is not treated promptly and effectively. Early diagnosis, treatment and evacuation lead to an early recovery. Death due to altitude GIB can be avoided if early symptoms and signs are recognized.

### Abstract

**AIM:** To investigate the gastrointestinal bleeding (GIB) in people from lowland to high altitude and in workers on Mountain Tanggula and its causes as well as treatment and prophylaxis.

**METHODS:** From 2001 to October 2003, we studied GIB in 13502 workers constructing the railroad on Mountain Tanggula which is 4905 m above the sea level. The incidence of GIB in workers at different altitudes was recorded. Endoscopy was performed when the workers evacuated to Golmud (2808 m) and Xining (2261 m). The available data on altitude GIB were analyzed.

**RESULTS:** The overall incidence of GIB was 0.49% in 13502 workers. The incidence increased with increasing altitude. The onset of symptoms in most patients was within three weeks after arrival at high altitude. Bleeding manifested as hematemesis, melaena or hematochezia, and might be occult. Endoscopic examination showed that the causes of altitude GIB included hemorrhage gastritis, gastric ulcer, duodenal ulcer, and gastric erosion. Experimental studies suggested that acute gastric mucosal lesion (AGML) could be induced by hypoxic

### INTRODUCTION

Although cardiac, respiratory and neurological symptoms are more common among mountaineers and persons from lowland going to the high altitude, little work has been done on the effect of hypoxia on digestive system in either patients with altitude illness or in healthy individuals at high altitude. In fact, symptoms of the digestive system such as anorexia, epigastric discomfort, epigastralgia, heart burn, dyspepsia, nausea, vomiting, diarrhea, haematemesis, piles and peptic ulcers are frequently found in mountaineers and altitude sojourners<sup>[1,2]</sup>. Moreover, epidemiological and clinical studies suggest that gastrointestinal bleeding (GIB) is not uncommon at high altitude, and is often life-threatening<sup>[3,4]</sup>. There are two diagnostic criteria for acute mountain sickness (AMS), one is the ESQ III<sup>[5]</sup> and the other is the Lake Louise consensus scoring system<sup>[6]</sup>. Gastrointestinal symptoms include nausea/vomiting, loss of appetite, stomach/abdominal pain, constipation,

however, the GIB is not included in the diagnostic criteria. Furthermore, data on GIB are available from Japanese, Chinese, and Peruvians, but rarely reported in western people<sup>[7]</sup>.

Altitude problems are of great importance for the railroad construction workers at high altitude. The construction of railroad on Mountain Tanggula offered a unique opportunity for investigation and study of AMS, high altitude pulmonary edema (HAPE), and high altitude cerebral edema (HACE), as well as high altitude GIB. This paper describes the incidence, clinical features, and risk factors for GIB in the railroad construction workers on Mountain Tanggula.

## MATERIALS AND METHODS

### Areas and subjects

Between June 29, 2001 and October 31, 2003, altitude gastrointestinal problems including altitude GIB were studied at two hospitals near the construction site. One hospital is located on the Fenghoushan at an altitude of 4779 m and the other hospital is situated in the Kekexili area at an altitude of 4505 m. These two hospitals received patients from the construction sites, working at altitudes between 3486 m and 4905 m. A total of 8014 workers worked at Fenghoushan and 5488 in Kekexili over the past three years. The weather conditions in the two surveying regions and the evacuated areas in Golmud and Xining are summarized in Table 1.

The weather and climatologic data were provided by the Tanggula Meteorological Observatory Station and the Qinghai Weather Bureau. Workers were not only exposed to a hypoxic environment, but also to severe cold. The temperature in winter ranged between -27°C and -36°C, with an annual average temperature of -3°C to -7°C.

A questionnaire was delivered to the persons to be investigated, including age, gender, ethnicity, occupation, place of birth, length of time at low altitude, length of time after ascending to high altitude, history of smoking and consumption of alcoholic beverages, current and past medical history, and family history.

All subjects underwent a careful medical evaluation before and after ascending to high altitude. Physical examination, routine blood tests, chest roentgenograms, electrocardiograms, *etc* were performed. The protocol was approved by the Qinghai High Altitude Medical Research Institute Committee on Human Research. Informed consent was obtained verbally for each subject.

### Diagnosis

The diagnosis of AMS was made using the Lake Louise scoring system (LLSS) in which two or more of symptoms monitored were defined as AMS<sup>[6]</sup>. The clinical diagnosis of GIB was based on the following criteria: (1) occurrence in unacclimatized individuals who were rapidly exposed to altitudes exceeding 3000 m; (2) onset of typical symptoms including epigastric discomfort, epigastric pain, haematemesis, melaena, or hematochezia; (3) significant decrease in hemoglobin concentration (Hb) or hematocrit value (Hct); (4) endoscopic diagnosis of GIB after descending to the Golmud (2808 m) or Xining (2261 m);

**Table 1** Weather conditions in the two surveying regions and the two evacuated areas-Golmud and Xining

Area	Fenghoushan	Kekexili	Golmud	Xining
Altitude (m)	4905	4505	2808	2261
PB (mmHg)	417	440	538	585
Average annual temperature (°C)	-7.0	-2.6	3.6	6.7
Annual precipitation (mm)	317	291	42	371
Annual sunshine time (h)	2712	2764	3101	2793
Relative humidity (%)	57	58	34	57

**Figure 1** Frequency distribution of altitudes in patients with gastrointestinal bleeding diagnosed at two hospitals on Mountain Tanggula. The incidence of GIB increases with increasing altitude.

(5) disappearance of symptoms and signs after treatment with blood transfusion and oxygen. Outcome was assessed according to the clinical and laboratory results.

### Statistical analysis

Statistical analysis was made by the IBM 3990 system. The incidence (cumulative case rate over a defined period in a defined population) of GIB in these populations was calculated. The frequency of risk factors for GIB was examined, using two by two tables, odds ratios, and chi square test. Comparison of mean numerical values was made by *t* test. *P* < 0.05 was considered statistically significant.

## RESULTS

### Overall incidence

We selected two typical areas where the local hospitals are located to investigate the altitude illness. From 2001 to 2003, GIB was found in 66 cases of 13 502 workers on Mountain Tanggula during the period with an incidence of 0.49%.

### Predisposing factors

The incidence of GIB was also found to be dependent upon many variables, including altitude, length of stay at high altitude, age, sex, labouring conditions, and ethnicity.

**Altitude:** The incidence of GIB at various altitudes is shown in Figure 1. Occurrence of GIB was rarely found below 3500 m. The highest frequency of GIB

**Figure 2** Time lag between ascent and onset of illness.

was observed between 4500 m and 5000 m, its incidence increased gradually with altitudes being 0.2% at 3500 m and 1.1% at 4905 m ( $P < 0.01$ ).

**Onset time of symptoms:** Symptoms suggestive of GIB occurred in 17 out of 66 cases (25.8%) within 5-10 d after arrival at high altitude, in 24 cases (36.3%) within 11-15 d, 14 cases (21.2%) within 16-20 d, the remaining 11 cases (16.7%) within 21-122 d (16.7%) (Figure 2). The onset time of most symptoms was within three weeks after arrival at high altitude.

**Age and gender:** Many of the patients were young or middle-age adults, and the oldest was 46 years of age. The mean age of all cases was  $34 \pm 7.8$  years.

GIB occurred frequently in men. Since the total number of females was small (21 persons), and could be neglected.

**Occupation:** The incidence of GIB in workers and carders was 0.51% and 0.46%, respectively. There was no significant difference between the two groups ( $P > 0.05$ ).

**Ethnicity:** Interestingly, all the GIB patients were Han Chinese lowlanders. Over one-third of the workers were native highlanders (most of them were Tibetans who permanently lived at altitudes from 2500 m to 3200 m) and no GIB was found in them.

### Endoscopic findings

All patients with altitude GIB were evacuated to the hospitals in Golmud or Xining. Among them, 28 had an endoscopic examination either at admission or within 24 h after admission and others were not able or refused to undergo an endoscopic examination. Endoscopic examination showed gastric ulcer in 11 cases, duodenal ulcer in 4, combined ulcers in 4, hemorrhage erosion in 5, bleeding gastritis in 4 and chronic atrophic gastritis in 1, respectively.

### Risk factors

GIB was obviously related to drinking alcohol and use of aspirin and/or dexamethasone in 3 patients. Case one was a 37-year old railroad worker from lowland to a construction site at 4505 m. During the ascent, he was given 8 mg dexamethasone followed by 4 mg every eight

hours for AMS prophylaxis. In the morning after arrival at 4505 m, he complained of severe headache. He was given 0.5 g of aspirin and dexamethasone, which did not relieve his headache. He drank approximately 300 mL of liquor (50% alcohol). After eight hours he suddenly became incapacitated with symptoms of upset stomach, abdominal pain, and severe fatigue. At about 6.0 AM on the third day, he had melaena and tarry black stool, thus aspirin and dexamethasone were immediately stopped. Within a few hours his condition became progressively worsened, and he was promptly evacuated to the Golmud Hospital (2808 m). At admission, his BP was 90/50 mmHg and Hb level was below 65 g/L. Gastro-fiberscopic examination was performed within six hours after admission and revealed diffuse gastric bleeding and erosion, and linear gastric ulcer combined with duodenal ulcer. Supplementary oxygen was given and an intravenous drip was put up. After 600 mL whole blood transfusion over about five hours, and administration of H<sub>2</sub> blocker (ranitidine), his BP gradually increased (110/80 mmHg), and melaena was stopped. He slowly improved over two weeks, his Hb increased to 105 g/L. He was discharged 21 d after admission and returned to his lowland home.

In addition to this case, we encountered 2 similar cases at the Kekexili construction site. Case two was a healthy young man who took aspirin and dexamethasone to prevent AMS and drank alcohol in the evening, he had brisk melaena in the next morning. Case three was a middle age worker, with a previous history of gastric peptic ulcer. He took aspirin for headache, after drinking 100 mL of hard liquor, he developed acute melaena.

Polycythemia (Hb  $> 210$  g/L) was found in 5 patients with GIB having lived at altitude above 4000 m for more than 45 d.

Moreover six patients with GIB had a previous history of potential peptic ulcer and 5 had chronic gastritis.

### Outcomes

Once the diagnosis was confirmed, the patients were either evacuated to the Golmud Hospital (2808 m), or treated as outpatients or sent to Xining (2261 m). Their conditions gradually improved after effective treatments.

## DISCUSSION

### Nomenclature and relation between AMS and altitude GIB

High-altitude GIB is a distinct clinical entity. However, the different terms of this syndrome have been used by different authors. The term "hypoxic gastric bleeding" is used loosely in some Peruvian scientists<sup>[8]</sup>, "altitude digestive hemorrhage" is also used for this illness<sup>[9]</sup>. Since hemorrhage could occur in buccal mucosa, digestive mucosa, finger nails, as well as in gastrointestinal tract, urinary tract, retina and gums<sup>[10,11]</sup>, it is named as "high altitude hemorrhage syndrome". GIB is one of the clinical manifestations of this syndrome<sup>[11]</sup>. However, GIB is almost an independent digestive mucosal lesion, causing gastrointestinal bleeding at high altitude. We hold that the term "high altitude gastrointestinal bleeding" (altitude GIB) is more suitable for this condition.

We also noted that approximately 58% of GIB patients are accompanied with AMS, and about 42% have altitude GIB alone. However, GIB has not been found to be associated with HAPE or HACE. Thus whether altitude GIB is a gastrointestinal type of AMS should be further studied.

### **Incidence of altitude GIB**

The incidence of altitude GIB among workers constructing Qinghai-Tibetan highway on Mountain Tanggula from 1978 to 1984 was 1.1%<sup>[4]</sup>. The incidence of altitude GIB in workers constructing the Qinghai-Tibetan railroad at the same mountainous areas was 0.49% in 2001-2003, which is much lower than the reported incidence in mountaineers on Everest. During 1988 the China-Japan-Nepal Friendship Expedition to Mountain Qomolungma (Everest), a total of 52 Japanese mountaineers climbed from Tibetan (north) side (5154 m) to the summit (7790 m), five on the north side suffered from upper alimentary bleeding with an incidence of 9.6%<sup>[12]</sup>, suggesting that the incidence of GIB increases with the increase of altitude.

Liu<sup>[13]</sup> reported that the occurrence of GIB in soldiers stationed between 3700 m and 5380 m for one year is 0.8% of the total patients and 1.5% of AMS cases at a Chinese Army Hospital located at the foot of Mountain Karakoram (3550 m) during the same period. However, endoscopy examination showed that the incidence of acute gastric mucosal lesion (AGML) in mountaineers is as high as 16%-49%<sup>[14-16]</sup>, suggesting that some subclinical GIB exists.

### **Clinical features of altitude GIB**

Of the 66 cases, 17 had altitude GIB within 10 d after arrival at above 3500 m. Most patients (55) had altitude GIB within 20 d, and 11 had altitude GIB after 21 d. These observations were incomparable with the onset of HAPE or HACE. In general, the mean time of HAPE or HACE occurrence after arrival at above 3500 m was three days with a range of 1-5 d.

The victims of GIB include both mountaineers and native highlanders<sup>[8,17]</sup>. Macedo<sup>[8]</sup> reported that two adult male native Quechua Indians presented a sudden and severe gastric bleeding of unknown etiology in the Andes. However, in our GIB patients, there were no Tibetan natives. It is possible that these individuals have greater genetic resistance to hypoxia at high altitude.

At high altitude, GIB may be manifested as haematemesis (vomiting of blood, either bright red or brown in color), melaena (tarry black, sticky stool) or hematochezia (fresh red blood per rectum, ruling out the diagnosis of piles). However, hemorrhage was manifested as melaena in almost all 64 patients except for two with haematemesis. Bleeding, however, might be occult, with normal appearance of stools. Occult blood in stools was detected in 10 mountaineers by Naito *et al*<sup>[18]</sup> using "OC-Hemodia Kit" which can detect only human hemoglobin without cross-reaction in any other animals during their Iwate Karakoram expedition in 1989, a total of 8 persons presented a positive reaction, suggesting that silent bleeding from gastrointestinal mucosa commonly exists in

mountaineers.

GIB gives rise to symptoms and signs depending upon the rate and extent of bleeding. In our experiences, acute moderate bleeding (blood loss greater than 500 to 1000 mL) results in drowsiness, dizziness, oliguria, sweating and pallor. BP changes occur first in the form of orthostatic hypotension. Pulse rate seems to be a far less accurate parameter, particularly at high altitude, as tachycardia is common amongst such mountaineers. Acute massive bleeding is characterized by loss of greater than 1500 mL or 25% of the circulating blood volume within a period of minutes to hours, decreased systolic and diastolic BP, increased pulse rate, decreased hemoglobin concentration or Hct values. It is a critical indicator for the desperate situation. Therefore any patient experiencing melaena with or without hematemesis or associated symptoms or hypotension, should be evacuated promptly and hospitalized immediately for further evaluation and treatment<sup>[4]</sup>.

### **Endoscopic findings and causes of altitude GIB**

Endoscopy is highly advisable. Sugie *et al*<sup>[19]</sup> found gastro-duodenal mucosa lesions in 13 out of 22 mountaineers at Mountain Xixapangma (5020 m). The results of arterial blood gas analysis reported by Sugie *et al*<sup>[20]</sup> are as follows: PaO<sub>2</sub> = 43 mmHg, PaCO<sub>2</sub> = 23.5 mmHg, pH = 7.51, BE = 1.0. Zhao and Li<sup>[15,16]</sup> reported that the incidence of gastro-duodenal mucosal lesions is 49% in 51 young healthy male subjects at the altitude between 3658 m and 4200 m. Occasionally, upper digestive hemorrhage may occur in gastric cancer patients at altitude<sup>[21,22]</sup>.

Saito<sup>[12]</sup> reported a male mountaineer on Mt. Everest expedition who developed massive GIB and serious anemia at the altitude of 7028 m. Endoscopy after his arrival at sea level, showed no abnormality<sup>[23]</sup>. Zhou<sup>[24]</sup> reported a case of a healthy lowland Han subject who developed GIB during a sojourn at Lhasa (3658 m) and died of recurrent massive GIB. Postmortem revealed diffuse superficial erosion in the stomach but no peptic ulcers.

### **Mechanism of altitude GIB**

The mechanism of altitude GIB remains unclear. Pathological studies in patients died of altitude GIB revealed significant dilatation of arterioles and venules, formation of extensive blood capillaries in gastric mucosa<sup>[25]</sup> and hemorrhage into the gastric mucosa<sup>[26]</sup>. Different kinds of stress can cause AGML. It was reported that cold or hypoxic stress can induce AGML in rats<sup>[27,28]</sup>. However, on high mountains, cold stress usually accompanies the effects of hypoxic stress in mountaineers, suggesting that hypoxemia is probably the main factor for AGML in mountaineers who are healthy at sea level<sup>[19]</sup>. Kamiyama *et al*<sup>[29]</sup> have attributed the potential difference (PD) to the indicator of gastric integrity or gastric mucosa defensive mechanism that may play an important role in the pathogenesis of hypoxia-induced AGML. The PD is closely related to the transport of electrolytes by gastric mucosa cells depending on aerobic metabolism. Hypoxemia may cause changes

in tissue levels of oxygen resulting in decrease of PD. Strenuous exertion and hard work increase hypoxia stress and induce injury of gastric mucosa capillaries<sup>[14,17]</sup>. Naito *et al*<sup>[30]</sup> noted that peroxidation of phosphatidylcholine in gastric mucosa is another possible mechanism underlying AGML at high altitude. It was reported that ulcer index (UI) and phosphatidylcholine hydroperoxide (PCOOH) are higher in hypoxia group than in control group, though thiobarbituric acid (TBA) substance does not differ between the two groups, suggesting that lipid peroxidation in gastric mucosa may play a role in the pathogenesis of hypoxia-induced AGML. Acute diffuse lesions induced by stresses are pathologically and clinically distinct from gastro-duodenal mucosa lesions and present as an upper alimentary bleeding.

### **Fisk factors for altitude GIB**

**Alcohol:** It is historically believed that alcohol could relieve and protect against AMS<sup>[4]</sup>. More recently, Houston<sup>[31]</sup> has recommended less alcohol use on mountains. It appears that alcohol may also be a risk factor for GIB at altitude. Ravenhill<sup>[32]</sup> has observed that alcohol increases the severity of symptoms of AMS. Those who drink a little alcohol under a simulated hypoxic condition (7620 m), may impair their mental and physical function<sup>[33]</sup>. Steele<sup>[34]</sup> has described three Sherpas who had severe epigastric pain, nausea and vomiting after heavy drinking on Mountain Everest. Zhou<sup>[24]</sup> reported three young men in Lhasa who developed massive gastric hemorrhage due to acute hemorrhagic gastritis after a hard drinking. High altitude native populations, such as Quechua Indians, like to drink inferior rough alcohol, which may be the aetiology of the increased prevalence of gastric ulceration<sup>[26]</sup>. From 1978 to 1984 when the Qinghai-Tibetan Highway was under construction, the incidence of GIB was higher (1.93%) in workers who drank more of it than in those (0.95%) who drank it less<sup>[4]</sup>, suggesting that drinking alcohol increases the risk of developing GIB at altitude and alcohol should be avoided.

**Aspirin or other NSAID agents:** Aspirin has been shown to be effective in treating headache due to AMS<sup>[35]</sup>. Aspirin alone is not very effective in preventing headache due to AMS, whereas aspirin in combination with dexamethasone can achieve rather good results<sup>[36]</sup>. There is strong but not conclusive evidence that major bleeding episodes could result from acute, diffuse hemorrhagic lesions in the upper GI tract after ingestion of aspirin. Thus, relief of headache due to AMS is a difficult matter because aspirin and other non-steroidal anti-inflammatory drugs (NSAID) lead to GIB<sup>[17,37]</sup>. It was reported that drugs such as paracetamol (acetaminophen) or ibuprofen, have a strong anti-inflammatory action on headache or other pains and do not cause gastrointestinal bleeding<sup>[38]</sup>.

**Dexamethasone:** Dexamethasone has been used in the prevention and treatment of AMS<sup>[39,40]</sup> because administration of it for a short time does not result in any problems at high altitude<sup>[31]</sup>. However, dexamethasone is one of the drugs that are strongly suspected of being ulcerogenic, especially in patients with a prior history of peptic ulcer disease, and may increase the risk of GIB at

altitude. Concomitant use of dexamethasone, aspirin and alcohol has an additive or synergistic effect on the upper GI tract mucosa, and could lead to rapid and serious GIB as in our cases.

**High altitude polycythemia:** Polycythemia is a common feature seen in altitude residents and patients with hypoxemia<sup>[15,16,24]</sup>. Digestive symptoms such as epigastric pain, dyspepsia, anorexia, vomiting, and diarrhea can be frequently eliminated in 89%-100% of patients with high altitude polycythemia (HAPC)<sup>[24]</sup>. GIB is a common complication of HAPC. In our series five patients with GIB had HAPC. Zhou<sup>[24]</sup> reported polycythemia in 21 young male Chinese soldiers (mean age 26.6 years) stationed in Lhasa (3658 m) who had no previous history of peptic ulcer. GIB occurred following development of HAPC. They found that exposure to cold, strenuous exertion, and drinking alcohol are the main predisposing causes.

Zhao and Li<sup>[15,16]</sup> have reported their endoscopic examinations in 98 patients with HAPC (Hb > 210 g/L) in Lhasa, showing superficial gastritis in 29, gastric ulcer in 26, duodenal ulcer in 12, complex ulcers in 5, and atrophic gastritis in 3. Chu and Sun<sup>[41]</sup> examined 5 patients with HAPC (mean Hb = 225 g/L) in Madou (4300 m), diffuse bleeding and erosion as well as ulcerous necrosis were observed in their stomach, and electromicroscopic examination showed the ultrastructural characteristics of their gastric mucosal biopsies, such as irregularly arranged thick microvilli, microfilament enlargement of secretory canaliculus, and high density of enlarged mitochondria in parietal cells, increased zymogen granules and rough endoplasmic reticulum in principal cells, proliferation of vascular endothelial cells, microvilli-like appearance of their surface and basement membrane thickening. Such gastric mucosal lesions may be associated with gastric mucosal ischemia caused by microvascular thrombosis due to excessive polycythemia.

**Peptic ulcerations at high altitude:** Clinical observations on the Himalayas and Andes suggest that peptic ulcer occurs more frequently at high altitude than at sea level<sup>[21,24,42]</sup>. At high altitude, the ulceration rate is higher in gastric ulcer than in duodenal ulcer<sup>[43,44]</sup>. Berrio *et al*<sup>[42]</sup> reported that 100 cases of GIB have been diagnosed by endoscopic examinations in General Hospital at La Oroya (3800 m), gastric ulcer accounting for 33%, duodenal ulcer accounting for 23%, gastric erosion accounting for 23%, neoplasias accounting for 2%, respectively. The prevalence of gastric ulcer increases with increasing altitude, while the prevalence of duodenal ulcer does not<sup>[42]</sup>. Upper digestive hemorrhage is a common complication of peptic ulceration at high altitude<sup>[42,45]</sup>, the hemorrhagic rate is 20%-66%<sup>[9,45]</sup>.

It is well known that the incidence of gastric ulcers and bleeding is increasing in high altitude residents chronically exposed to a hypoxic environment<sup>[42,45-47]</sup>. In addition, hypoxic and cold stress-induced gastric mucosal lesion may explain in part, the high incidence of gastric ulcers in altitude populations.

In the present 66 cases of GIB, 4 had a previous history of peptic ulcer. Among them, GIB occurred

rapidly in 1 patient after using aspirin, suggesting that persons with known peptic ulceration should not go to high altitude mountains unless their symptoms have been well controlled before they go to high altitude mountains as complications in the field can be fatal<sup>[37]</sup>.

### Course and prognosis of altitude GIB

Altitude GIB can be life threatening and acute massive bleeding due to secondary effects of shock-increasing anoxia, cellular dysfunction and acidosis at high mountains may lead to death<sup>[4]</sup>. We have reported that the mortality of altitude GIB is as high as 6.8% in Qinghai-Tibetan Highway construction workers on Mountain Tanggula<sup>[4]</sup>.

The emergency measures taken for acute altitude GIB include early evacuation or just descent with oxygen inhalation and saline-infusion or blood transfusion. Drugs, such as H<sub>2</sub> blockers or proton pump inhibitors have been shown to be more effective in ameliorating GIB<sup>[4]</sup>. Mountaineers and highlanders should know well about the symptomatic self care (SSC) for altitude GIB<sup>[48]</sup>, that is when symptoms such as epigastric pain or dyspepsia are present, a H<sub>2</sub>-receptor antagonist is effective for ulcers and GIB and the current therapy for altitude GIB.

In conclusion, early diagnosis, treatment and evacuation lead to an early recovery. Death due to altitude GIB can be avoided if early symptoms and signs are recognized.

### Abstract

**AIM:** To examine the clinical characteristics of a subgroup of patients with hepatocellular carcinoma (HCC) and compare them to those with known risk factors.

**METHODS:** We used the HCC database of 306 patients seen at our institution from January 1, 1995 to December 31, 2001. Of the 306 patients, 63 (20%, group 1) had no known risk factors (hepatitis C virus, hepatitis B virus, alcohol, hemochromatosis or cirrhosis from any cause) and 243 (group 2) had one or more risk factors.

**RESULTS:** The median age was similar in both groups, but there were disproportionate numbers of younger (< 30 years old), older (> 80 years) patients, women (33% vs 18%), and Caucasians (81% vs 52%) in group 1 as compared to group 2. There were fewer Asians (2% vs 11%) and African Americans (13% vs 27%) in group 1. Abdominal pain (70% vs 37%) was more common while gastrointestinal bleeding (0% vs 11%) and ascites (4% vs 17%) were less common in group 1 compared to group 2. Group 1 had larger tumor burden (median size 9.4 cm vs 5.7 cm) at the time of presentation, but there were no differences in the site (right, left or bilateral lesions), or number of tumors between the two groups.

**CONCLUSION:** HCC patients without identifiable risk factors have different characteristics and clinical presentation compared to those with known risk factors.

### INTRODUCTION

Hepatocellular carcinoma (HCC) is a common cancer in the world with more than 500 000 new cases reported per year<sup>[1,2]</sup>. The disease is unevenly distributed worldwide with a higher incidence in South-East Asia and Sub-Saharan Africa than in other regions of the world<sup>[1,2]</sup>. Although it is less common in the United States and Western Europe, there are data to suggest that the incidence may be increasing secondary to hepatitis C virus (HCV)<sup>[1-3]</sup>. The common risk factors that predispose to HCC include hepatitis B virus (HBV), hepatitis C virus (HCV), aflatoxin, and cirrhosis in general<sup>[6-9]</sup>. In addition, hemochromatosis, alcoholism, and non-alcoholic fatty liver disease (NAFLD cirrhosis) increase the risk of developing HCC<sup>[10]</sup>. In the United States, alcoholism and hepatitis C are the leading predisposing causes of HCC<sup>[11]</sup>. However, a significant proportion of patients develop HCC despite the absence of any known risk factors including cirrhosis. There is only limited information on the differences in the characteristics and outcomes of patients with or without risk factors who develop liver cancer in the USA.

The purpose of this study was to define the clinical characteristics and presentation of patients without identifiable risk factors and compare them to those with known risk factors.

### MATERIALS AND METHODS

For the purpose of this study, we studied patients who

presented to the Johns Hopkins Hospital with HCC from January 1, 1995 to December 31, 2001. A retrospective database was created with the approval of the Institutional Review Board. Patients with HCC were identified for inclusion in the database by searching the medical records using an ICD-9 code for liver cancer (155.0) and the Database of Pathology Departments using the term “hepatocellular carcinoma”. The information was collected on all patients using the hospital’s electronic patient record.

To be included in the study, a patient was 18 years or older, visited Johns Hopkins Hospital during the designated period, and had a confirmatory diagnosis of HCC. HCC was diagnosed based on histological confirmation or an elevated alpha fetoprotein (AFP) > 400 IU/mL with a liver image showing characteristic features of HCC. In the absence of elevated AFP or histological confirmation, characteristic liver image along with a clinical history compatible with HCC was necessary<sup>[12]</sup>. A compatible clinical history included known cirrhosis, HBV or HCV infection, hemochromatosis or history of alcoholism.

The risk factors for HCC were defined as HBV, HCV, cirrhosis from any cause (based on imaging and/or liver histology), aflatoxin, alcoholism, hemochromatosis, pre-malignant liver tumors and rare metabolic syndromes that are known to predispose to HCC. Patients without any known identifiable risk factors were included in group 1 and compared to those patients with one or more risk factors (group 2).

Statistical analysis was performed with SPSS version 10.0. Statistical tests included chi-square and Student-*t* tests. *P* < 0.05 was considered statistically significant.

## RESULTS

Three hundred and six patients were seen with HCC at our

institution from January 1, 1995 to December 31, 2001. Of the 306 patients, 63 (20%, group 1) had no known risk factors (HCV, HBV, alcohol, hemochromatosis or cirrhosis from any cause) and 243 (group 2) had one or more risk factors.

Of the 243 patients (group 2) with a known risk factor for HCC, hepatitis B was documented in 49 (20%), hepatitis C was present in 110 (45%) and 115 (47%) acknowledged moderate or abusive alcohol use. Rare disorders such as Wilson’s disease, porphyria cutaneous tarda, autoimmune hepatitis, schistosomiasis, and sclerosing cholangitis were noted in one patient each. Cirrhosis was documented by histology in 164 (67%).

Demographic data of both groups are shown in Table 1. There was a male predominance in both groups but there was a higher proportion of females in group 1 (2:1 *vs* 9:2) compared to group 2. The median age was greater in group 1 with a disproportionate distribution of patients at the extremes of age.

Presenting signs and symptoms are shown in Table 2, with complete data available in 263 of the 306 patients. The most common presenting symptom in each group was abdominal pain, but it was more common in group 1. Other statistically significant differences noted were the frequency of gastrointestinal bleeding and the presence of ascites. Weight loss was comparable in both groups. As expected, HCC was not diagnosed during routine screening or surveillance in any patient of group 1 but in 46 (21%) of group 2 (*P* < 0.001).

Diagnostic imaging data revealed differences between groups 1 and 2 (Table 3). We excluded studies that were not done at our institution since films were not available for confirmation. Imaging studies showed a larger tumor diameter (median 9.3 cm, range 4–25 cm *vs* 5.7 cm, range 0.7–20 cm) in group 1 than 2. Approximately half of the patients (52% and 48%) in both groups had a solitary tumor, and the majority of tumors were located in the right liver (67% and 60%). A higher proportion of patients in group 2 had bilateral tumors (7% *vs* 24%, *P* = NS). Portal vein involvement was similar in both groups.

Histological examination demonstrated fibrolamellar

Table 3 Tumor imaging characteristics

	Group 1	Group 2

Median (cm)	9.3	5.7
Minimum (cm)	4	0.7
Maximum (cm)	25	20
	n (%)	n (%)
< 2 (cm)	0 (0)	15 (9)
2.01-5.0	2 (8)	59 (37)
5.01-10.0	13(54)	68 (43)
> 10.0	9 (38)	7 (11)
Focality	n = 25	n = 149
Unifocal	13 (52)	72 (48)
Multifocal	12 (48)	77 (52)
Hemiliver	n = 30	n = 162
Right	20 (67)	97 (60)
Left	5 (17)	27 (17)
Bilateral	5 (7)	38 (24)

Please note that size could not be determined in 6 patients in group 1 and 3 in group 2. Similarly 'focality' could not be determined in 5 patients in group 1 and 13 in group 2.

variant HCC in 6/63 patients of group 1 and 0/243 patients of group 2.

## DISCUSSION

In this study, we described the characteristics of patients who presented to a tertiary care center in the United States without known risk factors for HCC and compared them to those with one or more identifiable risk factors. The patients in group 1 without identifiable risk factors had a relatively higher proportion of women and Caucasians. The age distribution of this group was asymmetrical, with a disproportionate number of patients less than 30 years old and older than 80 years. The increased frequency of younger HCC patients in this group could be explained by the fibrolamellar variant of HCC that is known to affect younger patients without risk factors. This tumor was exclusively seen in group 1, 4 out of the 6 patients less than 30 years old had fibrolamellar variant. While fibrolamellar variant could explain the disproportionate number of younger patients in group 1, another explanation must be found for the increased number of patients over the age of 80 years in this group. It is certainly possible that these patients may have had occult viral hepatitis or alcohol use, and examination of liver tissue or peripheral blood monocytes may have detected occult HBV and HCV infections in some of them. The retrospective nature of this study also did not permit us to determine whether these patients had adequate tests to rule out viral hepatitis. Another demographic difference between the two groups of patients was the ratio of males to females. Group 1 had a relatively higher proportion of female patients, and it is possible that some of these patients may have progressed from adenoma.

The clinical presentation was also different in both groups. Group 2 was more likely to present without any symptoms (40% *vs* 17%) and this could be partly explained by the fact that many of these patients (19%) were

diagnosed with HCC during surveillance or screening. Abdominal pain was the most common symptom in both groups, but it was more common in group 1 and this could be explained by the larger tumor burden. Despite the smaller (40% smaller) tumor size in group 2, portal vein involvement and metastases were similar in both groups, suggesting that there may be differences in tumor biology.

Our study suggested that there were differences in patient characteristics, symptoms, and tumor size in patients who presented with and without known risk factors for HCC. Absence of cirrhosis and tumor size may explain the differences in symptoms, and there is a suggestion that tumor biology may be different in these groups. The higher proportions of women and older patients without risk factors remain poorly explained. It is important to note that our study had all the inherent weaknesses of a retrospective study. It is more than likely that a more detailed diagnostic work-up may have revealed more risk factors in both groups. In addition, we could not independently confirm the laboratory test results in many patients. The prospective and complete collection of data on risk factors and tumor characteristics of patients diagnosed with HCC will further distinguish the differences between patients who present with and without risk factors.

Most patients with HCC have known risk factors such as HCV, HBV, or cirrhosis. Genetic changes that lead to HCC are complex and poorly understood, and most studies have focused on the genetic changes in the 'high risk' population<sup>[13,14]</sup>. Genetic changes that lead to HCC take place over 30-50 years, and this may partly explain the difficulty to define the sequential molecular changes that lead to HCC. There is increasing circumstantial evidence that the development of HCC, like most other cancers, is a multi-step process including inactivation or loss of tumor suppressor genes, activation or over expression of multiple oncogenes and heterozygosity of multiple chromosomes<sup>[13-18]</sup>. There is experimental evidence that p53, Rb1 and Wnt pathways are important molecular pathways involved in the development of HCC. The early genetic changes may vary depending on the etiology of liver disease and geographic location. Even in the same patient, there may be considerable genetic heterogeneity among different tumor nodules, suggesting that we may not find a common unifying pathway in the pathogenesis of HCC. However, accumulating evidence indicates that hepatocytes with multiple genetic changes may expand in a clonal fashion leading to dysplastic nodules and liver cancer. The molecular mechanisms of liver cancer in patients without known risk factors are difficult to explain. It is possible that many of these patients have been exposed to known or unknown carcinogens. Prospective studies should be designed to identify hitherto unidentified factors including the role of obesity or non-alcoholic fatty liver disease, occult HBV or HCV infections and genetic predisposition.

### Abstract

**AIM:** To investigate the association between serum insulin-like growth factor 1 (IGF-1), osteocalcin, and parathyroid hormone (PTH) levels with the etiology and clinical condition of patients with chronic liver disease.

**METHODS:** Eighty children with hepatocellular damage were divided into 3 groups according to the etiology of disease infection: bilharziasis (9 patients), hepatitis B virus (HBV, 12 patients) and hepatitis C virus (HCV, 29 patients). The Child score index was found as A in 24 patients, B in 22 patients, C in 4 patients. Thirty healthy children served as control group. HBsAg, HbAbIgM, HbAbIgG, and anti-HCV were detected using ELISA technique. HCV-RNA was measured by reverse transcription polymerase chain reaction (RT-PCR). Anti-bilharzial antibodies were detected by indirect haem-agglutination test. Liver function tests were performed using autoanalyser. Serum IGF-1, osteocalcin and PTH levels were measured by ELISA technique. Abdominal ultrasonography was also conducted.

**RESULTS:** Serum IGF-1 level was significantly lower in all patient groups with liver diseases, while serum osteocalcin and PTH levels were significantly elevated in patients with HBV and HCV infections compared with the control group. Serum osteocalcin and PTH concentrations were measured with the severity of liver disease from Child A to C. Child A patients unexpectedly showed significantly reduced IGF-1 levels in comparison to patients staged as Child B or C. Serum osteocalcin level was negatively correlated with albumin ( $14.7 \pm 0.54$  vs  $3.6 \pm 0.10$ ,  $P < 0.05$ ), while that for PTH was positively

correlated with total protein ( $70.1 \pm 2.17$  vs  $6.7 \pm 0.10$ ,  $P < 0.05$ ) in patients with HCV infection.

**CONCLUSION:** Low serum IGF-1 level seems to play a critical role in the bone loss in patients with chronic liver disease. Elevated biochemical markers of bone remodeling suggest high-turnover in patients with viral infection and reflect severity of the clinical stage.

### INTRODUCTION

Bone tissues are metabolically active and undergo continuous remodeling throughout their life. Skeletal remodeling is achieved by two counteracting processes: bone formation which is accomplished through osteoblasts and bone resorption that is attributed to osteoclast activity<sup>[1]</sup>. Bone manifestations are well-known as extrahepatic complications of chronic liver disease<sup>[2]</sup>. Patients with chronic liver disease are at increased risk of developing hepatic osteodystrophy manifested as osteomalacia or osteoporosis<sup>[3]</sup>. Osteoporosis can be described as a disturbance in the bone remodeling process. Bone loss is a result of an imbalance of the bone remodeling process, where bone resorption exceeds bone formation<sup>[4]</sup>.

The prevalence of osteoporosis in patients with chronic liver diseases ranges from 10% to 60%<sup>[5,6]</sup>. In general, secondary factors such as malabsorption and nutritional deficiencies may cause bone changes in chronic liver disease<sup>[7]</sup>. Insulin like growth factor (IGF) family is considered as important anabolic hormones, which play a role in anabolic metabolism and stimulating DNA synthesis, cell proliferation and meiotic division throughout life<sup>[8]</sup>. Since most circulating IGFs are synthesized by hepatocytes, lower levels of these parameters could be found in patients with liver diseases<sup>[8]</sup>.

Regulation of bone metabolism is achieved by various factors such as mechanical motion, minerals, and hormones, all influencing bone turnover<sup>[4]</sup>. Osteocalcin is a protein produced by osteoblasts. Its level is reduced in the presence of osteodystrophy and can be recommended as a very sensitive and specific marker for bone formation/turnover<sup>[9]</sup>.

Parathyroid hormone has a dual effect on bone cells. It can stimulate osteoblast activity and lead to substantial increase in bone density. In contrast, when secreted continuously at relatively high rates, as in hyperparathyroidism patients it can stimulate osteoclast-mediated bone resorption and suppress osteoblast activity<sup>[11]</sup>. The anabolic effect of parathyroid hormone (PTH) on osteoblasts is probably both direct and indirect via growth factors such as insulin like growth factor-1 (IGF-1) and transforming growth factor- $\beta$  (TGF- $\beta$ )<sup>[11]</sup>.

However, the role of hepatocellular dysfunction in hepatic osteodystrophy is not clear. Therefore, this study aimed to clarify the influence of hepatocellular dysfunction on bone loss, and to outline the clinical benefits of controlling serum IGF-1, osteocalcin and parathyroid hormone levels in children with chronic liver diseases.

## MATERIALS AND METHODS

Eighty children were enrolled in this study, from Liver Institute, Menoufia University Inpatient and Outpatient Clinic and divided into: (1) Bilharziasis group: 9 patients (males whose age ranged from 6 to 15 years). (2) HBV group: 12 patients (10 males and 2 females whose age ranged from 3 to 15 years). (3) HCV group: 29 patients (22 males and 7 females whose age ranged from 2 to 16 years). (4) Control group: 30 apparently healthy children (22 males and 8 females whose age ranged from 3 to 15 years) with no history or clinical evidence of liver disease or any other diseases. (5) History was obtained from all individuals and clinical examination was carried out.

### Specimen collection

Under complete aseptic condition, 5 mL of blood was taken from all the patients and controls. Each blood sample was divided into two portions: a small portion (1.8 mL) was taken on 3.8% Na-citrate as anticoagulant (0.02 mL) to obtain plasma and a larger portion of blood sample was allowed to clot. Sera were separated and stored at -80°C till being tested, while the plasma sample was used immediately to measure prothrombin time and concentration.

### Serological test

Hepatitis surface antigen (HBsAg), hepatitis B core antibody IgM (HBcAb IgM) and hepatitis B core antibody IgG (HBcAb IgG) were measured by ELISA technique using kits from Dia-Sorin Biomedica Co., according to the methods of Boniolo *et al*<sup>[10]</sup>, Tedder and Wilson<sup>[11]</sup> and Hoofangle *et al*<sup>[12]</sup> respectively.

Anti-HCV was detected by third generation of ELISA using kit from the Biochem ImmunoSystem Inc<sup>[13]</sup>, HCV-RNA extraction was carried out by reverse transcription polymerase chain reaction (RT-PCR) according to the

**Table 1** Serum IGF-1, osteocalcin and PTH levels in patient groups and control group (mean  $\pm$  SE)

IGF-1 (ng/mL)	277.1 $\pm$ 12.2	94.0 $\pm$ 4.30 <sup>b</sup>	105.1 $\pm$ 10.3 <sup>b</sup>	230.0 $\pm$ 10.5 <sup>b</sup>
Osteocalcin (ng/mL)	5.7 $\pm$ 0.3	6.8 $\pm$ 0.66	16.5 $\pm$ 0.76 <sup>b</sup>	14.7 $\pm$ 0.54 <sup>b</sup>
PTH (ng/mL)	61.6 $\pm$ 2.7	63.3 $\pm$ 3.03	83.4 $\pm$ 4.30 <sup>b</sup>	70.1 $\pm$ 2.17 <sup>a</sup>

<sup>a</sup>P < 0.05, <sup>b</sup>P < 0.01 vs control group.

method described by Ravaggi *et al*<sup>[14]</sup>. Anti-bilharzial antibodies were detected by indirect haem-agglutination test (IHA) according to the method of Hoshino *et al*<sup>[15]</sup>, using kits of Fumozze-France.

### Liver function tests

Serum AST, ALT, alkaline phosphatase (ALP), GGT, total and direct bilirubin, total protein, and albumin levels were measured using EKTOCHEM 750XRC analyzer. Prothrombin time and concentration were also estimated in plasma according to the method of Poller<sup>[16]</sup>.

### Biochemical markers of bone turnover

Serum insulin like growth factor-1 (IGF-1), osteocalcin and PTH levels were measured by ELISA technique using kits of BioSource-Belgium<sup>[17-19]</sup>.

### Abdominal ultrasonography

To assess the size and echopattern of the liver, the size of the spleen and the presence of ascitis or any other abnormalities in the abdomen were detected using RT-X200 Prob 3.5 MHZ convex of General Electric Company -USA.

### Statistical analysis

The obtained data are presented as mean  $\pm$  SE. The difference between two groups was calculated using unpaired *t*-test, while the difference between more than two groups was calculated using one way analysis of variance ANOVA according to Snedecor and Cochran<sup>[20]</sup>. Least significant difference (LSD) test was used to compare the means of Child classification according to Walter and Duncan<sup>[21]</sup> at probability 0.05.

## RESULTS

Patients with chronic liver diseases were divided into three groups according to the etiology: group 1 (9 patients with bilharziasis whose mean age was 10.8  $\pm$  1 years), group 2 (12 patients with HBV whose mean age was 11.5  $\pm$  0.6 years, and group 3 (29 patients with HCV infection whose mean age was 11.8  $\pm$  1.5 years). Thirty children whose mean age was 10.5  $\pm$  0.5 years and were sex matched with normal liver served as control group.

Table 1 depicts the results of serum IGF-1, osteocalcin and PTH levels in patients with either bilharziasis or HBV and HCV infections as well as in controls. The results revealed that patients with bilharziasis and those with either HBV or HCV infections showed a significant

**Table 2** Liver function tests in different patient groups and control group (mean  $\pm$  SE)

	Control (n = 30)	Bilharziasis (n = 9)	HBV (n = 12)	HCV (n = 29)

<sup>a</sup>*P* < 0.05 *vs* control group.

decrease (*P* < 0.01) in serum IGF-1 level compared to the controls. The most significant decrease in serum IGF-1 was recorded in patients with bilharziasis followed by HBV-infected and HCV-infected patients. Serum osteocalcin level showed a significant increase (*P* < 0.01) in patients with HBV and HCV infection compared to the controls. The most significant increase in serum osteocalcin level was observed in HBV-infected patients. Patients suffering from bilharziasis had no significant (*P* > 0.05) change in serum osteocalcin level compared to the controls. Serum PTH level was significantly increased in HBV-infected patients (*P* < 0.01) and in those with HCV infection (*P* < 0.05) compared to the controls. No significant change in serum PTH level was detected in patients with bilharziasis compared to the controls (Table 1).

Liver function tests in patients with bilharziasis or HBV and HCV infection as well as in the control are presented in Table 2. Serum ALT and AST activities showed a significant (*P* < 0.05) increase in all patient groups compared to the control group. The most significant increase in serum ALT and AST activities was recorded in the patients suffering from HCV infection. The activities of ALP, GGT and total bilirubin in serum revealed a significant increase (*P* < 0.05) in patients with HBV and HCV infection compared to the control, while no significant change (*P* > 0.05) was recorded in patients with bilharziasis as compared to the control group. Serum total protein level showed significant decrease (*P* < 0.05) in patients with HCV infection, whereas patients with either bilharziasis or HBV had no significant (*P* > 0.05) change as compared to the control (Table 2). Serum albumin level revealed a significant (*P* < 0.05) decrease in patients suffering from either HBV or HCV infection compared to the control. No significant change in serum albumin level was observed in patients with bilharziasis compared to the control. Patients suffering from either bilharziasis or HBV and HCV infection had a significant (*P* < 0.05) decrease in

PTH (ng/mL)	71.1 $\pm$ 14.0	72.3 $\pm$ 13.8	0.786	73.1 $\pm$ 13.8	67.2 $\pm$ 13.1	0.249

<sup>a</sup>*P* < 0.05 *vs* males.

prothrombin concentration compared to the control. The most significant decrease in prothrombin concentration was detected in HCV-infected patients (Table 2).

Alterations in serum IGF-1, osteocalcin and PTH level according to the severity of the disease from Child class A to C are depicted in Table 3. Significant (*P* < 0.05) change was detected in the three serum markers (IGF-1, osteocalcin and PTH) in each grade of the disease. The mean values of the three serum markers were markedly increased with the severity of the disease and the highest value was recorded in Child class C of the disease using LSD at probability 0.05.

Noteworthy, our results revealed that serum IGF-1, osteocalcin and PTH levels were not age or sex dependent except for osteocalcin level which was higher in females (Table 4).

On correlating the three bone markers with each other and liver function indices using Pearson correlation, there was only significant negative correlation between serum osteocalcin and albumin (*r* = -0.409, *P* = 0.027) and significant positive correlation between PTH and total protein (*r* = 0.451, *P* = 0.014) in patients with HCV infection (Figure 1A and B), while no significant correlation was recorded between IGF-1, PTH or osteocalcin in our patients.

## DISCUSSION

Patients with chronic liver disease are prone to develop hepatic osteodystrophy. In the majority of cases it is

**Figure 1** Correlation coefficient between serum osteocalcin and albumin levels (A) & between serum PTH and total protein levels (B) in patients with HCV infection.

characterized by development of osteoporosis and/or osteomalacia with possible persistence of minor or major disability<sup>[3]</sup>. Osteoporosis reflects loss of bone (both matrix and its mineral) and osteomalacia is due to defective mineralization of osteoid<sup>[22]</sup>. Osteoporosis is a frequent complication of end-stage liver disease irrespective of its etiology. The prevalence varies between 9% and 60%, the highest being observed in cholestatic disorders and alcoholic liver disease<sup>[23]</sup>.

The present study aimed at elucidating the influence of bilharziasis, hepatitis B or C infections on the development of osteoporosis in children. Serum levels of IGF-1, osteocalcin and PTH were measured and correlated with the routine liver functions as well as the child-pough score. The results of the present work showed that serum IGF-1 level was significantly decreased in all children infected with bilharziasis, HBV and HCV, while unexpectedly it showed significant increase with the severity of liver diseases from A to B or C classification but its level was still lower than that in the control.

These results are greatly supported by the finding of Hassan *et al*<sup>[24]</sup> who showed a significant reduction in the level of IGF-1 in children with schistosomiasis with or without hepatic fibrosis. Also, our results are in agreement with the findings of Orsini *et al*<sup>[25]</sup> who found similar results in hepatosplenic schistosomiasis patients and the results of Mazziotti *et al*<sup>[26]</sup> in patients with hepatocellular carcinoma (HCC) and hepatitis C virus-related cirrhosis. The

reduction in IGF-1 level also can precede the diagnosis of HCC<sup>[26]</sup>. Similarly, decreased serum IGF-1 level has been recorded both in patients with viral cirrhosis<sup>[9,27]</sup> and in patients with hepatitis B infection without cirrhosis<sup>[28]</sup>.

In schistosomiasis patients with hepatic fibrosis, the depressed circulation of IGF-1, free T4 and growth hormone may be responsible for stunted stature<sup>[24]</sup>. Moreover, low serum IGF-1 level in hepatosplenic schistosomiasis patients has been found to be related to the clinical form of hepatosplenic schistosomiasis<sup>[25]</sup>. The level of IGF-1 is elevated in patients with schistosomiasis with or without liver fibrosis and relates to its clinical form<sup>[25]</sup>, suggesting that the severity of liver dysfunction can affect the level of IGF-1. As liver function of patients with bilharziasis is usually better than those with cirrhosis due to HBV and HCV infection and usually scored as child A, this may partly explain the relatively unexpected low level of IGF-1 in our patients with less severe liver affection (child A group).

The present study recorded a significant increase in serum osteocalcin level in patients with viral hepatitis infection only. Also a negative correlation was obtained with the level of serum albumin in patients with HCV infection. Moreover, serum osteocalcin level was significantly increased in child B and C patients than in child A patients.

It has been reported that serum osteocalcin level is higher in cirrhotic patients than in control, suggesting that cirrhotic patients have high bone turnover. In addition, osteodystrophy associated with hepatic cirrhosis is due to a defect in alpha-hydroxylation (1, 25(OH)<sub>2</sub>D) by the kidney due to the decrease in its primary substrate, the liver 25(OH)<sub>2</sub>D. This could be attributed to the reduced availability of vitamin D, inadequate conversion of vitamin D to 25(OH)<sub>2</sub>D, accelerated metabolism of 25(OH)<sub>2</sub>D, and urinary loss of 25(OH)<sub>2</sub>D with its transport protein<sup>[29]</sup>. However, some studies reported that serum osteocalcin level is low in cirrhotic patients and osteopenia in these patients is not due to a decrease in bone formation<sup>[30,31]</sup>, but may be a consequence of hepatic osteodystrophy due to low plasma vitamin D and calcium levels<sup>[31]</sup>.

Concerning the changes in serum PTH level, the present study recorded significant increase in patients with Hepatitis B and C infections. As regard a positive correlation was obtained with serum total protein level among the group of HCV infection. Moreover, serum PTH was significantly increased in class B and C patients than patients of class A.

In hepatocellular dysfunction some previous studies reported that serum PTH level is high in patients with primary biliary cirrhosis<sup>[32]</sup>, liver cirrhosis<sup>[33]</sup>, HBV infection<sup>[34]</sup>, as well as in dogs with schistosomiasis<sup>[35]</sup> and in children with cholestatic and non-cholestatic liver disease<sup>[36]</sup>. On the other hand, other studies reported that PTH is unchanged in patients with chronic viral liver disease<sup>[37]</sup> and post hepatic cirrhosis<sup>[38]</sup>. Kirch and co-workers<sup>[33]</sup> have found a significant correlation between PTH and the parameters of liver functions such as prothrombin, albumin and bilirubin, suggesting that the increasing PTH level is related to liver dysfunction. This may explain why the elevation of PTH level is due

to the impaired liver function rather than secondary hyperparathyroidism<sup>[33]</sup>. Moreover, elevated PTH-related protein was observed with hyperglobulinemia and hypoalbuminemia in dogs with schistosomiasis<sup>[35]</sup>, and this may explain the obtained positive correlation between PTH and serum total protein levels in patients with HCV infection due to hyperglobulinemia observed in our study.

Hepatic osteodystrophy (HOD) begins at the stage of chronic non-cirrhotic liver injury and bone loss is connected with liver damage, suggesting that the principal pathogenesis of HOD is attributed to intestinal Ca-malabsorption as a result of low serum albumin and villous atrophy<sup>[39]</sup>. Lower ionized calcium resulting from deficient intestinal absorption due to low 25(OH)<sub>2</sub>D, leads to increase in PTH level<sup>[36]</sup>.

The significant rise in serum osteocalcin level in our female patients indicated that their bone turnover was accelerated. This result is in agreement with Steinberg *et al*<sup>[40]</sup> who found that female sex is a risk factor for bone turnover and low bone density.

In conclusion, serum IGF-1, osteocalcin and PTH appear to be markers of bone metabolism in children with hepatocellular damage. Low level of IGF-1 seems to play a role in the bone mass loss in patients with chronic liver disease. Elevated biochemical markers of bone remodeling suggest high bone turnover in children with viral infections. Fortification of diet by ergocalciferol is essential in patients with chronic liver disease and regular bone density measurements are necessary in these patients.

### Abstract

**AIM:** To investigate potential roles of per rectal portal scintigraphy in diagnosis of esophageal varices and predicting the risk of bleeding.

**METHODS:** Fifteen normal subjects and fifty cirrhotic patients with endoscopically confirmed esophageal varices were included. Patients were categorized into bleeder and non-bleeder groups according to history of variceal bleeding. All had completed per rectal portal scintigraphy using  $^{99m}\text{Tc}$ Technetium pertechnetate. The shunt index was calculated from the ratio of  $^{99m}\text{Tc}$ Technetium pertechnetate in the heart and the liver. Data were analyzed using Student's *t*-test and receiver operating characteristics.

**RESULTS:** Cirrhotic patients showed a higher shunt index than normal subjects ( $63.80 \pm 25.21$  vs  $13.54 \pm 6.46$ ,  $P < 0.01$ ). Patients with variceal bleeding showed a higher shunt index than those without bleeding ( $78.45 \pm 9.40$  vs  $49.35 \pm 27.72$ ,  $P < 0.01$ ). A shunt index of over 20% indicated the presence of varices and that of over 60% indicated the risk of variceal bleeding.

**CONCLUSION:** In cirrhotic patients, per rectal portal scintigraphy is a clinically useful test for identifying esophageal varices and risk of variceal bleeding.

Chitapanarux T, Praisontarangkul O, Thongsawat S, Pisespongsa P, Leerapun A. Per rectal portal scintigraphy as a useful tool for predicting esophageal variceal bleeding in cirrhotic patients. *World J Gastroenterol* 2007; 13(5): 791-795

### INTRODUCTION

Esophageal variceal bleeding is a serious and potentially life-threatening complication of liver cirrhosis<sup>[1-4]</sup>. No simple noninvasive method which accurately predicts esophageal variceal bleeding is available so far and endoscopists have had to perform endoscopy every 3 to 6 mo to evaluate patients with previously bleeding esophageal varices<sup>[5,6]</sup>. However, this approach is costly and not all patients with liver cirrhosis and esophageal varices are good candidates for such procedures<sup>[7]</sup>.

Per rectal portal scintigraphy is a noninvasive method for evaluation of portosystemic shunting using portal shunt index (SI) calculated from radioactivity curves of the liver and the heart. In humans, such an SI shows a good correlation with portal pressure measured by percutaneous transhepatic portography or intraoperative method<sup>[8]</sup>. Portal scintigraphy is also clinically useful, especially in establishing prognosis of cirrhotic patients with varying shunt indices<sup>[9]</sup>. Evaluating portal pressure using per rectal portal scintigraphy may be easily performed and might provide information on risk of variceal bleeding.

The aim of this study was to determine the benefit of per rectal portal scintigraphy for evaluation of non-bleeding esophageal varices, bleeding esophageal varices and normal control subjects. We also compared different portal shunt indices, Child-Pugh grades and endoscopic appearances in various groups and examined the correlation between the portal SI and risk of variceal bleeding.

### MATERIALS AND METHODS

#### Normal subjects and patients

**Normal subjects:** Normal adult volunteers of both sexes, with a minimum age of 18 years, were recruited. An attempt was made to obtain subjects in well distributed age groups, and equal in number for both sexes. All of the subjects were in good health, with no history of the liver and vascular diseases, or use of medication, alcohol or any substances that might affect the liver. The liver function test was normal, and tests for viral hepatitis (B, C) were negative or revealed immunized status. Hepatic ultrasonography was also performed to rule out structural liver disease or hepatocellular carcinoma.

**Patients:** Cirrhotic patients of either alcoholic or viral in etiology who had signs of portal hypertension, and a history or physical signs suggesting esophageal varices, or even esophageal variceal bleeding, were asked to participate in this study. Only patients with endoscopically confirmed esophageal varices were included. The esophageal varices were graded according to criteria developed by the Japanese Research Society for Portal Hypertension<sup>[10]</sup>. Thorough medical examination and interview for the history of gastrointestinal bleeding were performed. Only cirrhotic patients with esophageal varices were included in this study. The initial laboratory tests performed in this study included complete blood count, liver function test, viral hepatitis (B, C) profile, and renal function test. All patients were graded according to Child-Pugh classification. The etiology of bleeding was considered to be variceal if either actively bleeding varices were observed by endoscopy or if varices were endoscopically found without other sources of bleeding.

Informed consent were obtained from all patients and the protocol was in conformity with the ethical guidelines of the Declaration of Helsinki and the Clinical Research Committee at Chiang Mai University Hospital.

#### Measurement of the portal shunt index

The procedure used for per rectal portal scintigraphy was the same for both normal subjects and cirrhotic patients<sup>[9]</sup>. After fasting overnight for at least 6 h, the rectum was emptied by administration of laxatives (unison enema 100 mL). A polyethylene device (Terumo® feeding tube Fr.8) was inserted deep into the rectum with the tip of the tube being placed in the upper rectum, 20 cm above the anal verge, to avoid absorption into the systemic circulation via the inferior rectal vein in the lower rectum. To generate time-activity curves, a gammascinti camera with a large field of view (Apex SP4, El-Scint Co., Israel), equipped with a low-energy, multipurpose, parallel-hole collimator was used. The collimator was positioned over the patient's abdomen so that the field of view would always include the heart, the liver, and the spleen. Ten millicuries (2 mL) of <sup>99m</sup>Tc pertechnetate, followed by 15 mL of air, was infused into the rectum through the tube. The sequential images were generated from counts in their areas of interest (AOI). For color display, the summed images were reconstructed by grouping of 20 s per image from the original 60 images. <sup>99m</sup>Tc pertechnetate is commonly used in diagnostic scanning and imaging both in clinics and research. The procedure is safe and readily applicable because of the amount and short half life of radioactive substance used. Portal pressure increases shortly after an episode of variceal bleeding<sup>[11]</sup> and is stable over 72 h after bleeding<sup>[12]</sup>. Therefore, per rectal portal scintigraphy in patients of the bleeding group was performed 72 h after bleeding when the portal pressure returned to baseline level in order to determine the risk of that episode of bleeding.

#### Calculation of the portal shunt index

To calculate the amount of blood that entered the portal system and went to the liver and the heart, we used the

portal SI<sup>[8]</sup>. This index was derived from the ratio of <sup>99m</sup>Tc pertechnetate in the heart and the liver at the exact time as shown in the following equation.

$$SI = \frac{\sum_0^{(n+25)/5} x_i(H)}{\sum_0^{(n+25)/5} x_i(L) + \sum_0^{(n+25)/5} x_i(H)} \times 100\%$$

$n$  = time at which radionuclides appeared in the area of the liver (s).

$n'$  = time at which radionuclides appeared in the area of the heart (s).

$X_i(L)$  = the count per 5 s over the AOI of the liver.

$X_i(H)$  = the count per 5 s over the AOI of the heart.

In normal portal circulation, the transit time of blood circulation from the liver to the heart via hepatic veins and inferior vena cava was 18-26 s, and the scinti images were acquired in 5 s per image. The SI was calculated at the time of  $n + 25$  s. The results were shown as the pattern of time-activity curves and summed-images.

#### Statistical analysis

Results were expressed as mean  $\pm$  SD. The significance of difference between mean values was evaluated by Student's  $t$ -test. Differences with probability values of less than 0.05 were considered to be significant. The selection of an appropriate cutoff point of portosystemic shunt for the presence of esophageal varices and the risk of variceal bleeding was analyzed by the receiver operating characteristic (ROC)<sup>[13]</sup>.

## RESULTS

The normal control group consisted of eight male and seven female subjects (aged 28-59 years, mean 44.3 years). Fifty cirrhotic patients (45 males and 5 females), of various etiologies, aged between 30 and 70 years (mean 46.9 years) were recruited in this study. The baseline characteristics of all study patients are shown in Table 1. The patients were categorized into two groups according to their history of variceal bleeding, namely a non-bleeding group including 25 patients and a bleeding group with 25 patients. Bleeding was the first episode in all 25 patients in the bleeding group. All patients had received neither endoscopic variceal surveillance nor prophylactic treatment to prevent variceal bleeding. The two groups of patients showed similar baseline characteristics with the exception of alanine aminotransferase, total bilirubin, and prothrombin time. The severity of liver disease in the bleeding group was higher than that of the non-bleeding group. In the non-bleeding group, etiologies of liver disease were alcoholic in 9, hepatitis viral B in 6, hepatitis viral C in 5, and alcoholic and virus in 5 cases. In the bleeding group, etiologies of liver disease were alcoholic in 20, hepatitis virus B in 3, and alcoholic and virus in 2 cases. The mean SI in normal subjects was  $13.54\% \pm 6.46\%$ . For the cirrhotic patients, the mean SI was  $63.80\% \pm 25.21\%$ . Normal subjects were found to have significantly lower average SI than cirrhotic patients with esophageal varices ( $P < 0.01$ ). If cirrhotic

Table 1 Baseline characteristics of the study patients

	Control (n = 15)	Non bleeder (n = 25)	Bleeder (n = 25)
Age (yr)	44.27 ± 8.48	49.32 ± 10.25	44.25 ± 8.86
Sex (M/F)	8/7	20/5	25/0
Presence of ascites (%)	0	10 (40)	7 (28)
Hepatic encephalopathy (%)	0	0	3 (12)
Serum albumin (g/dL)	4.55 ± 0.26	3.16 ± 0.54	2.76 ± 0.83
Alanine aminotransferase (U/L)	18.93 ± 4.03	51.88 ± 45.9	77.12 ± 61.41 <sup>b</sup>
Serum bilirubin (mg/dL)	0.65 ± 0.19	2.49 ± 1.16	5.27 ± 6.55 <sup>b</sup>
Prothrombin time (s)	-	2.67 ± 1.02	3.27 ± 2.43 <sup>b</sup>
Etiology of cirrhosis			
Alcohol	-	9	20

Hepatitis C virus	-	5	0
Alcohol and virus	-	5	2
Child-Pugh A	-	13	8
B	-	9	9
C	-	3	8

<sup>b</sup> $P < 0.01$  vs bleeder and non bleeder group.

**Figure 1** Comparison of portal shunt index in normal subjects and cirrhotic patients, with and without variceal bleeding. Data shown as mean (horizontal bar) ± SD (vertical bar).

patients were grouped as non-bleeding and bleeding, the mean SIs were  $49.35\% \pm 27.72\%$  and  $78.45\% \pm 9.40\%$ , respectively. The average SI in bleeding group was significantly higher than in non-bleeding group ( $P < 0.01$ ), as shown in Figure 1.

Analysis was done to discover any difference in SIs when the patients were sub-grouped according to etiologies (i.e. alcoholic, viral, or both), presence of ascites, endoscopic appearances and Child-Pugh grade. Details are shown in Table 2. The mean SI was  $78.87\% \pm 22.05\%$  in cirrhosis from alcohol,  $56.67\% \pm 24.08\%$  in cirrhosis from virus, and  $41.23\% \pm 23.47\%$  in cirrhosis from alcohol plus viruses. The average SI in the etiology group of alcohol significantly differed from that of virus, and also that of alcohol plus virus ( $P < 0.05$ ). The mean SI was  $62.87\% \pm 28.62\%$  in cirrhotic patients without ascites and  $65.92\% \pm 23.64\%$  in cirrhotic patients with ascites. The difference between both groups was not significant ( $P = 0.35$ ). We

used Child-Pugh classification to estimate the severity of liver disease in both bleeding and non-bleeding groups as a whole. The mean SI was  $52.60\% \pm 25.31\%$  in Child-Pugh grade A,  $69.29\% \pm 22.34\%$  in Child-Pugh grade B, and  $76.64\% \pm 22.01\%$  in Child-Pugh grade C. The SI in Child-Pugh grade A differed significantly ( $P < 0.05$ ) from those in Child-Pugh grades B and C. Although the SI in Child-Pugh grade B seemed to be lower than that in Child-Pugh grade C, the difference was not statistically significant ( $P = 0.20$ ).

#### Portal shunt index and endoscopic appearances of esophageal varices

The esophageal varices were endoscopically graded according to the Japanese Research Society for Portal Hypertension by color, forms, location, diameters, and the red color sign (RCS). Variceal forms were classified into three types: straight ( $F_1$ ), enlarged tortuous ( $F_2$ ), and largest sized ( $F_3$ ). The mean SI was  $57.03\% \pm 27.63\%$  in  $F_1$  group,  $67.47\% \pm 24.99\%$  in  $F_2$  group, and  $72.65\% \pm 8.77\%$  in  $F_3$  group (Table 2). Mean SI in  $F_3$  group was higher than in  $F_2$  and  $F_1$  groups. The difference between the groups was statistically significant ( $P < 0.05$ ). Mean SI in RCS-negative group was  $52.94\% \pm 26.31\%$  and in RCS-positive group was  $68.16\% \pm 23.78\%$ . The difference between both groups was not significant ( $P = 0.054$ ).

#### Portal shunt index and risk of esophageal variceal bleeding

The receiver operating characteristic (ROC) showed the cutoff point of portal SI between normal subjects and cirrhotic patients at 20% with a 90.0% sensitivity and 53.3% specificity. The cutoff point of portal SI between the cirrhotic patients with and without variceal bleeding was 60% with a 96.0% sensitivity and 72.0% specificity (Figure 2). Basically, the cirrhotic patients with esophageal varices who had a portal SI of more than 60% might have high risk of variceal bleeding, and the patients who had a portal SI more than 20% were likely to develop esophageal varices.

**Table 2** Portal shunt index in cirrhotic patients according to the etiologies of cirrhosis, presence of ascites, Child-Pugh grade and endoscopic appearances

		<i>n</i>	Portal shunt index (%)
Etiology of cirrhosis			
Alcohol		29	78.87 ± 22.05
Virus <sup>1</sup>		14	56.67 ± 24.08
Alcohol with virus <sup>1</sup>		7	41.23 ± 23.47
Ascites	Absence	33	62.87 ± 28.62
	Presence	17	65.92 ± 23.64
Severity of liver diseases	Child A	21	52.60 ± 25.31
	Child B	18	69.29 ± 22.34
	Child C	11	76.64 ± 22.01
Endoscopic appearances	F <sub>1</sub>	14	50.03 ± 27.63
	F <sub>2</sub>	20	67.47 ± 24.99
	F <sub>3</sub>	16	72.65 ± 8.77
	RCS-positive	27	68.16 ± 23.78
	RCS-negative	23	52.04 ± 26.31

<sup>1</sup>Including hepatitis B virus and hepatitis C virus.

## DISCUSSION

In this study, we used per rectal portal scintigraphy to detect and investigate portosystemic shunting in order to determine the difference among the bleeding, the non-bleeding cirrhotic and the normal control groups. We found that the SI was higher in the bleeders compared with other groups. The SI correlated with the severity of liver disease and the size of esophageal varices. Bleeding from the varices was a major complication of portal hypertension that may vary according to the severity of portal hypertension. The cumulative survival rate of patients with esophageal varices was significantly lower than that of patients without varices<sup>[14]</sup>. The cumulative survival rate of patients with portosystemic shunting seen by scintillation splenoportography was also significantly lower than that of patients without such a shunt<sup>[15]</sup>. Many factors could potentially be used to predict variceal bleeding in cirrhotic patients with esophageal varices. These predictors include the following: (1) local factors such as variceal size, vessel radius, or red color sign; (2) hemodynamic factors: portal pressure > 12 mmHg, blood volume, and collateral blood flow; and (3) severity of liver disease<sup>[10]</sup>. In general, the direct measurement of portal pressure is performed invasively and not readily available in many clinical settings. In those circumstances, indirect measurement of portal pressure, such as portosystemic shunt evaluation may be used instead. Recently, various methods of measuring portosystemic shunt have been developed, and the relationships between the risk of variceal bleeding and the extent of portosystemic shunt have been studied.

Per rectal portal approach in the measurement of portal circulation using various radionuclides has been described as a relatively non-invasive method by many researchers<sup>[9,16-19]</sup>. In our present study, we chose to perform non-invasive per rectal portal scintigraphy using <sup>99m</sup>Tc-Technetium pertechnetate because this radionuclide is well absorbed by the rectum, has a short half life and

**Figure 2** ROC curves of the portal shunt indices. **A:** Between normal subjects and cirrhotic patients with esophageal varices; **B:** Between cirrhotic patients with and without variceal bleeding (bleeder vs non-bleeder). + Indicates a cutoff point with maximum discrimination.

large doses could be used<sup>[20]</sup>; it also generates images useful for diagnosis and is economical. The SI from per rectal scintigraphy also correlated well with the degree of portal pressure<sup>[9]</sup>. In this study, the mean SI in cirrhotic patients with esophageal varices was significantly higher than that in normal subjects. The cutoff level of SI indicating development of esophageal varices derived from the ROC was 20%. All six cirrhotic patients with esophageal varices whose SIs were less than 20% belonged to Child-Pugh grade A and had less severe variceal forms without red color signs than patients with esophageal varices and an SI more than 20%. None of these six patients with small varices bled.

We also studied the association between Child-Pugh class, etiology of cirrhosis and portal scintigraphy in cirrhotic patients with esophageal varices. The mean SI

in Child-Pugh grade C was higher than that of Child-Pugh grade B and grade A, with a significant difference between grade C and A. The SI tended to be higher in patients with more severe liver disease. Because the Child-Pugh classification correlated well with the severity of liver disease, serial measurement of portal circulation by SI might be helpful in investigating the progress of cirrhosis. The SI in alcoholic cirrhosis was significantly higher than other etiologies because of more severe liver disease in alcoholic group. The SI in patients with alcohol and virus cirrhosis was lower compared with cirrhosis induced by alcohol or virus alone. This might possibly result from the small number of patients in alcohol with virus group. The SIs in cirrhotic patients with and without ascites were not significantly different. In comparison of the SI in different variceal forms, there were significant differences among the size of varices. Higher SIs were found in patients with higher variceal forms. There was a good relationship between SI and the size of esophageal varices.

The SI values in the present study were significantly different in cirrhotic patients with and without variceal bleeding. It was presumed that an increasing flow of blood through the collateral of inferior mesenteric veins measured by portal scintigraphy reflected the increasing pressure in the portal system, the development and the size of esophageal varices. This increasing pressure was at a certain level, adequately high for the varices to rupture. So the higher the SI, the higher was the risk of bleeding. In this study, the SI was clearly demonstrated to be a useful predictor of the risk of bleeding. By ROC, an SI of more than 60% correlated with esophageal variceal bleeding. We presumed that if cirrhotic patients had an SI of more than 20%, they would have adequate portal pressure to develop the esophageal varices, and if the SI was more than 60% they carried the risk of variceal bleeding. However, further prospective, longitudinal studies are needed to confirm these results.

In conclusion, this study suggests that portosystemic shunt, represented by the SI and evaluated by per rectal portal scintigraphy, is higher in cirrhotic patients with esophageal varices. The magnitude of blood shunting through these tributaries correlates well with the etiology and severity of cirrhosis and the risk of variceal bleeding. An SI of more than 60% in cirrhotic patients with esophageal varices reflects a high risk of variceal bleeding.

### Abstract

**AIM:** To unravel the possible association of malondialdehyde (MDA) and fructosamine in anemic *H pylori* infected patients and to observe the alteration in MDA and fructosamine levels in these patients after treatment for one month.

**METHODS:** Fructosamine, MDA and glucose were estimated in 22 anemic *H pylori* infected patients and 16 healthy controls. Hematological parameters were also evaluated in both the groups using Sysmex-K-100 automated cell counter. The *H pylori* infected patients were randomly divided into two groups. *H pylori* infected patients in Group I received both iron supplementation and anti-*H pylori* therapy, while patients in Group II received only iron supplementation. All the biochemical and hematological parameters were estimated after one month of treatment.

**RESULTS:** In anemic *H pylori* infected patients, while MDA ( $5.41 \pm 2.16$  vs  $2.26 \pm 0.50$ ;  $P < 0.05$ ) and fructosamine ( $2.64 \pm 0.93$  vs  $1.60 \pm 0.35$ ;  $P < 0.05$ ) were significantly increased, iron ( $32.72 \pm 14.93$  vs  $110.25 \pm 26.58$ ;  $P < 0.05$ ), hemoglobin ( $6.9 \pm 2.6$  vs  $12.66 \pm 0.74$ ;  $P < 0.05$ ) and ferritin ( $28.82 \pm 16.27$  vs  $140.43 \pm 30.72$ ;  $P < 0.05$ ) levels were significantly decreased compared with the controls. With partial correlation analysis, fructosamine was found to have a significant positive correlation with MDA. In Group I, while MDA level decreased significantly ( $3.11 \pm 1.73$  vs  $5.50 \pm 2.46$ ;  $P < 0.05$ ), there was a significant increase in iron ( $84.09 \pm 29.51$  vs  $36.09 \pm 17.81$ ;  $P < 0.05$ ), hemoglobin ( $10.40 \pm 1.11$  vs  $7.42 \pm 1.90$ ;  $P < 0.05$ ) and ferritin ( $116.91 \pm 63.34$  vs  $30.46 \pm 17.81$ ;  $P < 0.05$ ) levels after one month. There was no significant change

in the levels of fructosamine in group I after treatment. Similarly, no significant alterations were noted in the levels of MDA, fructosamine, hemoglobin or ferritin in Group II patients after one month of treatment.

**CONCLUSION:** An increased level of fructosamine and MDA was found in anemic *H pylori* infected patients. Present data supports the premise that lipid peroxides *per se* do play a role in the glycation of plasma proteins. Furthermore, the findings from this study indicate that treatment for both anemia and *H pylori* infections is required for lowering the levels of lipid peroxides in these patients.

### INTRODUCTION

*H pylori*, a gram negative bacillus is the most common pathogenic bacteria in the world<sup>[1]</sup>. Even though approximately half of the population in the world has *H pylori* infection, the prevalence and severity vary greatly among countries and population groups within the same countries. The overall prevalence of *H pylori* is strongly correlated with socio-economic conditions<sup>[1]</sup>. The prevalence among middle aged adults is over 80% in many developing countries as compared with 20%-50% in industrialized countries<sup>[2]</sup>.

Accumulating evidences suggest an association between gastric *H pylori* infection and low iron stores and anemia<sup>[3-6]</sup>. Epidemiological studies have demonstrated a close relationship between serum ferritin and presence of anti-*H pylori* IgG<sup>[3,4]</sup>. A fall in serum ferritin reflects declining body iron stores and is an accepted marker of iron deficiency. It has also been found that eradication of *H pylori* infection in iron-deficient anemic patients was found to reverse the iron deficiency status in both children and adults<sup>[5,6]</sup>.

Spontaneous nonenzymatic modifications of protein are commonly reported in tissues with slow turnover and they are considered by several authors as a possible common mechanism involved in the progression of many pathological conditions<sup>[6]</sup>. Among the nonenzymatic processes, oxidative stress and glycation have aroused a particular interest in recent years<sup>[7,8]</sup>.

Glycation is a non-enzymatic condensation reaction between reducing sugars and free amino groups at NH<sub>2</sub>-terminus or susceptible  $\epsilon$ -amino groups of lysine residues of proteins. The reaction is initiated by the reversible formation of a schiff base, which undergoes a rearrangement to form a relatively stable Amadori product<sup>[9]</sup>. The pathological consequences of these alterations very much depend on the nature of proteins involved as well as on their function and concentration in a particular organ<sup>[9]</sup>. The rate of formation of glycated protein is considered to depend on the ambient concentration of glucose and half life of the protein<sup>[9]</sup>. However, there is convincing evidence that concentrations of nonenzymatically glycated protein are increased in many non-diabetic pathological states<sup>[10-13]</sup>. Elevated concentrations of glycated hemoglobin have been found in myocardial infarction, chronic renal failure, and nephrotic syndrome patients with normal blood glucose concentrations<sup>[10-12]</sup>. Similarly high concentrations of fructosamine are reported in non-diabetic chronic renal failure and rheumatic arthritis patients<sup>[12,13]</sup>. Increased levels of glycated hemoglobin (HbA<sub>1c</sub>) have also been documented in iron deficiency anemic patients without any history of diabetes<sup>[14-16]</sup>.

We have recently demonstrated that lipid peroxides *per se* can enhance the process of protein glycation<sup>[17]</sup>. This result was in agreement with the findings of Jain *et al*<sup>[18]</sup>. We have also demonstrated that the process of lipid peroxidation and glycation are closely associated in patients with chronic renal failure, hyperthyroid, asthma, nephrotic syndrome and patients with rheumatoid arthritis<sup>[19-24]</sup>.

Even though there are substantial reports demonstrating the presence of excess lipid peroxides in patients with *H pylori* infection, there is a dearth of information regarding the levels of glycated proteins in these patients with anemia. Given the importance of glycated protein in causing pathological complication in various diseases, it was deemed pertinent to investigate the levels of glycated plasma protein and the possible association with the levels of lipid peroxides in *H pylori* infected patients who were anemic. Furthermore, we explored the effect of treatment on the levels of these parameters. This study is the first to describe an association between lipid peroxides and glycated protein in anemic *H pylori* infected patients.

## MATERIALS AND METHODS

Blood sample (3 mL) was obtained from 22 anemic patients with *H pylori* infection and 16 age matched healthy subjects. Anemic patients were recruited from the outpatient department of our institute, JIPMER, Pondicherry, India. Only patients of 13 years of age or older were enrolled for this study. Anemic patients were selected based on the hemoglobin levels (Hb < 11 g/dL)

and peripheral blood smear suggesting iron deficiency anemia. Selected patients underwent detailed physical examination and laboratory evaluation.

One milliliter of the whole blood in EDTA was used for the analysis of hemoglobin and red cell indices using Sysmex-K-100 automated cell counter (Sysmex Singapore Pvt. Ltd, Singapore). The rest of the sample was centrifuged at 3000 r/min for 10 min. The plasma was separated and analyzed for lipid peroxides, fructosamine, iron, ferritin and glucose. Plasma ferritin level was determined by ELISA using human ferritin enzyme immunoassay test kit (IBL Immunobiological Laboratories, Hamburg, Germany). Fructosamine was measured by p-indonitrotetrazolium violet kinetic method using the Raichem Kits (Haemagen Diagnostics, San Diego, CA) adapted to 550 Express Plus Analyzer (Ciba Corning Diag, Oberlin, OH). The concentration of lipid peroxides in plasma was measured by thiobarbituric acid method<sup>[25]</sup>. Plasma iron and glucose were measured by fully automated ferrozine and glucose oxidase methods respectively in Ciba Corning 550 Express Plus. All patients who were found to have iron deficiency by the above parameters underwent stool examination on three consecutive days for the presence of hookworm ova on microscopy and for occult blood by benzidine test.

After informed consent, upper gastrointestinal endoscopy was done and multiple biopsy specimens were obtained from the antral mucosa for rapid urease test and histology. Tissue sections were stained for *H pylori* with Geimsa. *H pylori* infection was defined as a visible organism seen under microscopy and a positive rapid urease test. Patients with histories of consumption of nonsteroidal anti-inflammatory drugs (NSAIDs), anticoagulants or corticosteroids, those with hematological disorders or stool samples positive for occult blood or hookworm ova, and those with duodenal or gastric ulcers or carcinoma stomach at endoscopy were excluded from the study.

Patients positive for *H pylori* infection by rapid urease test and on histology were randomly assigned to two groups (Group I and II) by creating block sizes of six or eight and linking to five-digit random numbers (Rand Corporation; New York: The Free Press, 1955). Patients in Group I received oral ferrous sulfate tablets 200 mg thrice a day for 1 mo, and a 14-d course of anti-*H pylori* therapy consisting of clarithromycin 250 mg bid, lansoprazole 30 mg bid and tinidazole 500 mg bid. Those in Group II received only oral ferrous sulfate tablets as above. All the above-mentioned biochemical and hematological parameters were assayed after 1 mo therapy. This study was approved by the ethics committee of JIPMER. Informed consent was obtained from all subjects.

## Statistical analysis

Student's *t* test was used to estimate the differences between the groups. Correlation was assessed by the partial correlation analysis. All results are presented as mean  $\pm$  SD. *P* < 0.05 was considered statistically significant.

## RESULTS

All the parameters tested in both the *H pylori* infected

**Table 1** Comparison of biochemical and hematological parameters in *H pylori* infected anemic patients and controls

Parameters	Control group (n = 16)	Test group (n = 22)
Hemoglobin (g/dL)	12.66 ± 0.74	6.9 ± 2.6 <sup>a</sup>
Iron (μg/dL)	110.25 ± 26.58	32.72 ± 14.93 <sup>a</sup>
Ferritin (ng/mL)	140.43 ± 30.72	28.82 ± 16.27 <sup>a</sup>
Fructosamine (nmol/L)	1.60 ± 0.35	2.64 ± 0.93 <sup>a</sup>
MDA (mmol/L)	2.26 ± 0.50	5.41 ± 2.16 <sup>a</sup>
Glucose (mg/dL)	81.19 ± 9.74	83.50 ± 8.27

<sup>a</sup>P < 0.05 vs control group.

group and healthy controls are given in Tables 1 and 2. Fructosamine levels were significantly higher in *H pylori* infected patients compared to controls. Levels of lipid peroxides were significantly increased in the test group than the healthy age-matched controls. In the test group, a significant correlation ( $r = 0.50$ ,  $P = 0.02$ ) was observed between fructosamine and MDA using partial correlation analysis controlling for blood glucose level. As previously reported, hemoglobin, serum iron and ferritin levels were significantly reduced in *H pylori* infected patients when compared with controls.

### Response to therapy

Patients in group I had a greater increase in mean hemoglobin level (2.98 g/dL) after one mo than those in Group II (1.07 g/dL). The increases in mean serum iron (48 μg/dL vs 15.91 μg/dL) and ferritin levels (86.45 ng/mL vs 25.28 ng/mL) after one mo of treatment were also more marked in Group I than in Group II. There was also a significantly decreased MDA levels in Group I when compared with Group II after one mo of treatment. However, there was no significant alteration in fructosamine levels in both the groups after one mo of treatment.

## DISCUSSION

Free radicals and other reactive oxygen species (ROS) are generated by all aerobic cells and are known to participate in a great variety of deleterious reactions<sup>[26]</sup>. The oxidative damage caused by free radicals is believed to play a pivotal role in the pathogenesis of *H pylori* infection<sup>[27-29]</sup>. Lipid peroxidation is one of the reactions set into motion as a consequence of the formation of these radicals in cells and tissues<sup>[26]</sup>. The initiation of lipid peroxidation has been considered the proximal cause of cell membrane destruction and cell damage<sup>[26]</sup>. Increased amounts of malondialdehyde (MDA) have been found in patients infected with *H pylori*<sup>[30-32]</sup>. Our results also indicate an increased lipid peroxidation in *H pylori* infected patients.

Lipid peroxidation can damage proteins, lipids, carbohydrates and nucleic acids. Plasma membranes are the critical targets of lipid peroxides<sup>[26]</sup>. Apart from participating in these deleterious reactions, lipid peroxides *in vitro* have been found to enhance the glycation of proteins<sup>[18]</sup>. We have also recently reported that MDA can

**Table 2** Changes in hematological and biochemical parameters of groups after treatment

Parameters	Group I ( <i>H pylori</i> treatment + oral iron therapy) (n = 11)	Group II (Oral iron therapy) (n = 11)

<sup>a</sup>P < 0.05 vs the baseline value before treatment.

enhance the glycation of hemoglobin *per se*<sup>[17]</sup>.

We have found that lipid peroxides are closely associated with glycated hemoglobin in hyperthyroid, chronic renal failure and asthma patients<sup>[20-22]</sup>. We observed a significant association between MDA and fructosamine in non-diabetic asthma, nephrotic syndrome, rheumatoid arthritis and chronic renal failure patients<sup>[19,22-24]</sup>.

In the present study, the levels of fructosamine were increased significantly in anemic patients infected with *H pylori* when compared with healthy controls. Among the various methods proposed for the measurement of glycated serum proteins, fructosamine is the method of choice for the clinicians<sup>[9]</sup>. As albumin is the most abundant protein in serum and contains multiple lysine residues, measurement of fructosamine is mainly the determination of glycated albumin<sup>[9]</sup>.

In anemic patients, the concentrations of HbA<sub>1c</sub> have been reported to be increased<sup>[14-16]</sup>. Several hypotheses have been formulated to explain the increase in glycated hemoglobin concentrations in these patients. It has been proposed that in iron deficiency the quaternary structure of the hemoglobin molecule may be altered, thus glycation of the β-globin chains occur more readily<sup>[14]</sup>. According to some investigators, the increase in glycated hemoglobin in non-diabetic anemic patients is mainly attributed to the decrease in hemoglobin levels in these patients<sup>[16]</sup>.

To our knowledge, no study to date has attempted to clarify whether there is any increase in glycated protein levels in anemic, *H pylori* infected patients and whether this increase is the consequence of an increased lipid peroxidation among these patients.

To verify this hypothesis, we tested a well-defined group of anemic, *H pylori* infected patients before and after one month of treatment. In our study, the increased MDA was found to be significantly associated with increased fructosamine concentrations ( $r = 0.50$ ,  $P = 0.02$ ) before treatment, even when the proposed effect of

glucose on the concentrations of fructosamine was refuted by partial correlation analysis. The mechanism by which MDA enhances the glycation process has not been clearly elucidated. MDA is thought to enhance the process of protein glycation by acting as an anchor between sugar and hemoglobin moieties<sup>[18]</sup>. It has also been suggested that oxidative stress can facilitate the autoxidation of glucose to dicarbonyl intermediates, an early step in the Maillard reaction<sup>[33]</sup>.

There was a significant decrease in MDA levels in *H pylori* infected patients after one month of treatment with both ferrous sulfate and anti-*H pylori* therapy. Previous reports have indicated that the levels of lipid peroxides decrease significantly after treatment for *H pylori* infection<sup>[30,32]</sup>. Similarly, in iron deficiency anemia it has been found that supplementation with iron reduces the levels of glycated hemoglobin<sup>[14]</sup>. There was no significant decrease in MDA levels in the test group treated with only oral iron. In both the test groups, there was no significant reduction in fructosamine levels after one month of treatment. There also existed no significant association in the anemic *H pylori* infected group between fructosamine and MDA after one month of treatment. One reason for these observed results can be attributed to the half-life of glycated proteins.

Recent studies have uncovered a myriad of pathological events induced by glycated albumin. These include increasing the expression of extracellular matrix protein, activation of protein kinase C, and stimulating the expression of transforming growth factor  $\beta_1$  and its primary signaling receptor, the TGF- $\beta$  type II receptor. Apart from these alterations, glycated albumin has been found to alter the levels of NF- $\kappa$ B. These data support the hypothesis that glycated albumin is a sufficient stimulus to set into motion pathogenic signaling pathways. Several investigators have also reported that *H pylori* can activate NF- $\kappa$ B in human gastric mucosa *in vivo* and cultured gastric epithelial cells *in vitro*, thus the pathogenesis may be mediated through NF- $\kappa$ B<sup>[34-36]</sup>. Studies have shown that these alterations in molecular pathways play an essential role in the *H pylori* induced inflammation and associated complications.

In conclusion, this study gives a snapshot of an increased glycated serum protein and lipid peroxide levels in *H pylori* infected patients who were anemic as well. These data from the present study also supports the notion that alteration in the levels of MDA in anemic *H pylori* infected patients may be the basis for enhanced levels of fructosamine. Furthermore, the findings from our study indicate that treatment for both anemia and *H pylori* are required for reducing the levels of lipid peroxides in these patients.

It would be interesting to investigate the levels of fructosamine in non-anemic *H pylori* infected patients and it is worthwhile to investigate if additional supplementation of antioxidants would potentiate any further attenuation of protein glycation in *H pylori* infected patients when compared with the regular therapy. A longer follow-up investigation after treatment would shed more light into the above-mentioned alterations in anemic *H pylori* infected subjects.

### Abstract

Fistula between digestive tract and airway is one of the complications after esophagectomy with lymph node dissection. A case of esophagotracheal fistula secondary to esophagitis 9 years after esophagectomy and gastric pull-up for treatment of esophageal carcinoma is described. It was successfully treated with transposition of a pedicled pectoralis major muscle flap.

### INTRODUCTION

The denervated stomach as an esophageal substitute recovers intraluminal acidity with time. Increased risk for acid reflux after incurs prolonged esophageal exposure to gastric acid which may lead to esophageal mucosal injury. A patient with esophagotracheal fistula caused by reflux esophagitis 9 years after esophagectomy with postoperative radiation therapy was treated with transposition of a pedicled pectoralis major muscle flap. This complication caused by esophagitis has been described.

### CASE REPORT

A 59-year old man presented with a sudden onset of

dyspnea and increasing cough productive of gastric contents and saliva. Significant past medical history included an esophagectomy with a reconstruction of gastric tube pulled up through the posterior mediastinum 9 years earlier for esophageal squamous cell carcinoma (pT1, pN0, pM0, pStage I), followed by irradiation (58 Gy) due to positive for malignancy of proximal surgical margin of the esophagus with histological examination. After the operation he had relapses of gastric ulcer and reflux esophagitis. There was no evidence of cancer recurrence over the follow-up period.

He was symptom-free except for cough after swallowing and regurgitation. None of abnormal shadows was detected in chest radiographs. Upper gastrointestinal endoscopy showed a fistula with a diameter of 5 mm on the anterior wall of the esophagus, 20 mm proximal to the esophagogastric anastomosis (Figure 1A), and a gastric ulcer just below the anastomosis (Figure 1B). No malignant feature was detected around the fistula and pathological examination of biopsy specimens from the gastric ulcer showed chronic inflammation. Bronchoscopic examination demonstrated the fistula in the membranous portion of the trachea, 90 mm distal to the vocal cord and 50 mm proximal to the bifurcation (Figure 2). Computed tomography confirmed the fistula located on a level with the upper wedge of sternum and no image of cancer recurrence (Figure 3). Twenty-four pH monitoring in the cervical esophagus was failed because of his rejection.

The patient received proton pump inhibitors before operation with a slight improvement in his clinical symptoms, but no apparent improvement in the bronchoscopic examination. Surgery was performed 20 d after administration. A cuff of spiral endotracheal tube (8 mm in diameter) was situated below the fistula in the trachea. With the patient in the supine position, a U-shaped skin incision in the anterior cervix and median sternotomy to the 3rd rib were made. Previous radiation therapy made the procedure difficult. After lysis of adhesions, cervical esophagus and the upper portion of gastric tube were freed. Then, the common wall between esophagus and trachea was carefully dissected free in a cranial to caudal direction until the fistula was identified. No malignant changes were found macroscopically. The wall of the fistula was cut sharply, taking care to avoid tearing of the membranous portion of trachea widely. The fistula orifice in the esophageal wall was closed primarily in layers and the orifice in the trachea was also sutured primarily. The

**Figure 1** Upper gastrointestinal endoscopy showing a fistula in the esophagus, 20 mm proximal to the anastomosis (A), and a gastric ulcer just below the anastomosis (B).

**Figure 2** Bronchoscopic examination showing a fistula in the membranous portion of the trachea, 90 mm distal to the vocal cord.

**Figure 3** Computed tomography showing an esophagotracheal fistula located on a level with the upper wedge of sternum.

medial wedge of the left clavicle, 1st and 2nd ribs, and the left half of the sternum to the 2nd rib were excised. The left pectoralis major muscle flap was inserted and fixed between the trachea and the gastric tube. His endotracheal tube was extubated immediately after the operation. The patient's postoperative course was uneventful. On the 16th postoperative day, feeding was started when no leak was found after a gastrograffin swallow revealed no leak. The patient was discharged on the 28th postoperative day. He had no evidence of esophagitis, gastric ulcer and fistula 9 mo after the operation.

## DISCUSSION

Fistulae between digestive tract and airway are recognized as complications after esophagectomy. The digestive tracts include residual esophagus, esophagogastric anastomosis and gastric tube. Leakage from esophagogastric anastomosis can lead to localized mediastinitis and represents a possible cause of tracheoesophagogastric fistula. Gastric tube-to-airway fistula develops due to peptic ulcer, ischemia of gastric tube or airway, radiation or abscess in the mediastinum. Fistula between cervical esophagus and trachea is the rarest case in these three types of fistulae. This fistula caused by gastroesophageal reflux after esophagectomy has not been reported previously.

Peptic ulcers of pulled-up gastric tubes often cause hemorrhage, perforation and penetration<sup>[1]</sup>. Gutschow *et al*<sup>[2]</sup> reported that the denervated stomach as an esophageal substitute recovers a normal intraluminal acidity with time, so that more than 3 years after surgery the 24-hour pH profile in the gastric cavity of almost all patients is similar to that in healthy subjects. Shibuya<sup>[3]</sup> showed that severe esophagitis is found in 75.6% of remnant esophagus after esophagectomy for esophageal cancer. Gutschow *et al*<sup>[2]</sup> showed that 38.5% of patients have reflux esophagitis in the remnant esophagus for 3 years or more after esophagectomy. In our patient, endoscopic examination more than 4 years after esophagectomy revealed often severe esophagitis and gastric ulcer. Although he was treated with a proton pump inhibitor every time, he discontinued himself taking drugs because of symptom-free. Therefore, it is strongly suggested that repetition of severe esophagitis and postoperative radiation therapy influenced formation of his fistula. In this patient, *H pylori*-IgG was positive. Although evaluation of his gastric emptying was not made, he often had reflux-symptom after esophagectomy.

Myocutaneous or muscle flap, because of their rich blood supply, can be used to fill the dead space after fistulectomy and add vital tissue to prevent recurrent fistulization<sup>[1,4-6]</sup>. In the part of cervical area, sternocleidomastoid muscle and pectoralis major have been used. If the esophagus and/or gastric tube cannot be preserved, continuity of the gastrointestinal tract may be reconstructed with, for example, colonic or small bowel interposition<sup>[7]</sup>.

No significant relationship has been found between reflux symptoms, such as heart burn and regurgitation, and endoscopic findings after esophagectomy in the previous reports<sup>[3,8]</sup>. Patients with denervated stomach may be free from symptoms of gastric ulcer. Therefore, endoscopic examination is necessary at least once a year for early detection of ulceration and esophagitis. Fistulae between digestive tract and airway are grave complications of esophagectomy because they frequently result in respiratory failure and life-threatening conditions. If gastric ulcer or esophagitis is detected in endoscopic examination after esophagectomy, this therapy should be

started immediately regardless of the interval between the examination and esophagectomy.

## Abstract

Percutaneous radiofrequency thermal ablation (RFA) is an effective and safe therapeutic modality in the management of liver malignancies, performed with ultrasound guidance. Potential complications of RFA include liver abscess, ascites, pleural effusion, skin burn, hypoxemia, pneumothorax, subcapsular hematoma, hemoperitoneum, liver failure, tumour seeding, biliary lesions. Here we describe for the first time a case of biliary gastric fistula occurred in a 66-year old man with a Child's class A alcoholic liver cirrhosis as a complication of RFA of a large hepatocellular carcinoma lesion in the III segment. In the light of this case, RFA with injection of saline between the liver and adjacent gastrointestinal tract, as well as laparoscopic RFA, ethanol injection (PEI), or other techniques such as chemoembolization, appear to be more indicated than percutaneous RFA for large lesions close to the gastrointestinal tract.

## INTRODUCTION

Percutaneous radiofrequency thermal ablation (RFA) is an emerging therapeutic modality in the management of liver malignancies<sup>[1]</sup>, particularly in patients who cannot

undergo surgery<sup>[2]</sup>. The increasing attractiveness of this technique is due to its effectiveness, safety and low morbidity rate<sup>[1,2]</sup>. Compared with ethanol injection (PEI), the first percutaneous therapy to be introduced, RFA is characterized by the need of a reduced number of treatment sessions. Both therapies are generally performed with ultrasound (US) guidance which allows considerable ease of application, due to their low costs and no X-ray exposure. Nevertheless, a number of potential complications of RFA have been described, occurring with a rate of almost 9%<sup>[3]</sup>, including liver abscess, ascites, pleural effusion, skin burn, hypoxemia, pneumothorax, subcapsular hematoma, hemoperitoneum, liver failure, and tumour seeding. In addition, biliary lesions have been described in 1% of a large number of patients included in a review of the literature in this field<sup>[3]</sup>, and two case reports describing enterobiliary<sup>[4]</sup> and biliary pleural<sup>[5]</sup> fistulae have been published so far.

## CASE REPORT

Here we describe a case of biliary gastric fistula occurred in a 66-year old man with a Child's class A alcoholic liver cirrhosis as a complication of RFA of a large (4.0 cm × 4.5 cm) hepatocellular carcinoma (HCC) lesion in the III segment. Written informed consent was obtained from the patient before treatment. The ablation was performed under US-guidance [Eidos (EUB-525), Esaote, Genova, Italy] using a 3.5 MHz sector probe, with a lateral guide for electrode placement. The treatment was made under general anesthesia using a 20-cm long, 18-gauge electrode to apply the RF current (MIRAS RC, Invatec Italia, Brescia, Italy). The procedure lasted 30 min without apparent complications. In the night following the intervention, the patient experienced transient retching, responsive to metoclopramide administration, and moderate abdominal pain. An enhanced computed axial tomography (CT) scan of the abdomen, performed 22 d after the procedure, showed the presence of aerobilia within the left portion of the liver attributed to a biliary gastric fistula (Figure 1A). A subsequent conventional contrast-enhanced study of the first gastrointestinal tract, showed a fistulous tract starting from the lesser curvature of the stomach with concomitant spasm of the greater curvature, causing a communication with the left portion of the liver (Figure 1B).

## DISCUSSION

Biliary gastric fistulae can be diagnosed on the basis of both direct and indirect radiological signs. The diagnosis

**Figure 1** Enhanced CT abdominal scan performed after the percutaneous procedure showing air inclusions in the bile ducts within the left portion of the liver (A), radiograph of the first gastrointestinal tract showing a biliary gastric fistula starting from the lesser curvature of the stomach with concomitant spasm of the greater curvature (B), and enhanced CT scan of the abdomen performed before percutaneous thermal ablation of the HCC lesion in the III liver segment showing a left portion of the liver without aerobilia (C).

with indirect radiological criteria was made by enhanced CT. The presence of aerobilia confined to the left por-

tion of the liver (Figure 1A), in the absence of surgery for biliary-digestive by-pass procedures and the fact that the thermoablative treatment was performed after a previous CT in which the fistula was not present (Figure 1C), led to the hypothesis of a iatrogenic alteration. This was confirmed by a conventional contrast-enhanced study of the first gastrointestinal tract, showing a fistulous tract starting from the lesser curvature of the stomach with concomitant spasm of the greater curvature, causing a communication with the left portion of the liver (Figure 1B).

Perforation of the gastrointestinal tract, a possible major complication of RFA of hepatic nodules, can be difficult to recognize as its clinical manifestations can be attributed to the normal course of the so called "post-ablation syndrome". Indeed, mild to moderate abdominal pain is not uncommon after RFA of large lesions, particularly when they abut the Glisson's capsule containing nerve endings.

We describe here for the first time in the literature a case of biliary gastric fistula as a possible complication of thermal ablation of HCC lesions. A recent study has shown the efficacy and safety of percutaneous RFA of HCC abutting the gastrointestinal tract<sup>[6]</sup>. Nevertheless, in the light of this case and previous descriptions of entero-biliary fistulae occurred following the same therapeutic modality, RFA with injection of saline between the liver and adjacent gastrointestinal tract, as well as laparoscopic RFA, PEI, or other techniques such as chemoembolization, appear to be more indicated than percutaneous RFA for large lesions close to the gastrointestinal tract.

## Abstract

Hydatid disease is an endemic disease in certain areas of the world. It is located mostly in the liver. Spontaneous rupture of the hydatid cyst into the peritoneum is a rare condition, which is accompanied by serious morbidity and mortality generally. We present herein a case with a spontaneous rupture of a hepatic hidatid disease into the peritoneum without any serious symptoms. A 15-year-old boy was admitted to the emergency room with a mild abdominal pain lasting for a day. Physical examination revealed only mild abdominal tenderness. There was no history of trauma or complaints related to hydatid diseases. Ultrasonography showed a large amount of free fluid and a cystic lesion with irregular borders in the liver. He was operated on. Postoperative albendazol therapy was given for 2 mo. No recurrence or secondary hydatidosis was seen on CT investigation in the 3<sup>rd</sup>, 6<sup>th</sup> and 12<sup>th</sup> mo following surgery.

## INTRODUCTION

Hydatid disease is a parasitic infestation caused by *Echinococcus granulosus*<sup>[1-3]</sup>. Hydatid disease is an endemic problem in Turkey as well as in sheep-bearing regions of the world<sup>[1,2,4]</sup>.

Although hepatic hydatid disease may be asymptomatic for many years, it can become symptomatic due to

expansion, rupture or pyogenic infection<sup>[2,3,5]</sup>. Hydatid cyst rupture may cause mild to fatal complications<sup>[2,5]</sup>. Rupture of the hepatic hydatid disease generally occurs into the biliary tree. Rupture of the cyst in the peritoneal cavity is rare and generally followed by anaphylactic reactions.

In this study, we present a case of a spontaneous rupture of a hepatic hydatid cyst into the peritoneum, in which the patient was admitted to the emergency room for mild abdominal pain without any other symptom. Spontaneous rupture of the hepatic hydatid cyst into peritoneum without any serious symptom is unusual.

## CASE REPORT

A 15-year-old boy perceived sudden abdominal pain in the epigastrium and right upper quadrant a day ago. After a short duration his pain was ameliorated spontaneously. The following day he perceived mild pain in the right lower quadrant. He had no pruritis, erythema or any other symptom except the abdominal pain. No history of blunt trauma was found.

Physical examination revealed a blood pressure of 100/70 mmHg, and a pulse rate of 78 beats/min. The patient was afebrile. Abdominal palpation revealed mild tenderness. He was comfortable on his movements. There was no history of nausea, vomiting or loss of appetite. Laboratory investigations were normal except mild leukocytosis (WBC: 11 000/mm<sup>3</sup>).

Abdominal ultrasonography showed a large amount of free fluid and a cystic lesion measuring 10 cm × 12 cm with irregular borders in the right lobe of the liver. The anterior border of the cyst was incomplete. Floating membrane image was seen. The biliary ducts were normal in calibration.

The abdomen was exposed through a right paramedian incision. Approximately 3500 mL clear fluid was aspirated from the intraperitoneal space. There was a hydatid cyst in the right lobe of the liver. The cyst was 13 cm in size and had a ruptured area of 5 cm × 7 cm anteriorly (Figure 1). There were firm adhesions between the liver and right diaphragm. There was no daughter vesicle in the abdominal cavity. The germinative membrane was taken out completely (Figure 2). No biliary leakage was seen. We could not find any other pathological evidence on exploration. The cyst pouch was irrigated with hypertonic saline (20%) and then followed by isotonic saline. The peritoneal cavity was irrigated with isotonic saline. Introflexion procedure was performed. Latex drains were

**Figure 1** Ruptured hydatid cyst in the liver.

**Figure 2** Germinative membrane extracted totally.

placed into the sub-hepatic and recto-vesicle areas.

The patient was discharged from the hospital on the 9<sup>th</sup> postoperative day without any complication. Postoperative albendazole therapy (10 mg/kg) was prescribed for 2 mo under the liver enzyme and blood count monitoring. The patient was controlled as an outpatient. Postoperative follow up was uneventful for 13 mo. No recurrence or secondary hydatidosis was seen on CT investigation in the 3<sup>rd</sup>, 6<sup>th</sup> and 12<sup>th</sup> mo following surgery.

## DISCUSSION

The hydatid cyst is typically filled with clear fluid (hydatid fluid). The cyst consists of an internal cellular layer (germinal layer) and an outer, acellular layer (laminated layer). As the cyst expands gradually, a granulomatous host reaction followed by a fibrous reaction forms a connective tissue layer, which is called a pericyst<sup>[1]</sup>.

Hydatid disease is a serious health problem in endemic areas as well as in Turkey<sup>[6,7]</sup>. The diagnosis and appropriate surgical therapy is usually delayed because most of the hydatid cysts remain asymptomatic until it is getting complicated<sup>[1-3,7,8]</sup>.

Precautions for the hydatid disease are mostly insufficient. Treatment of dogs with antihelminthic is the main procedure to control the parasite (*Echinococcus* spp.)<sup>[9]</sup>. In rural areas of Turkey this treatment is not applied routinely. In the rural area, sheep are home-

slaughtered routinely. Dogs can access to the infected viscera. This is true in almost all of the developing or underdeveloped countries in the world<sup>[9]</sup>.

Initially almost all of the hydatid cysts are asymptomatic. Later in time some symptoms depending on the involved organ, localisation of the cyst and pressure effect of the cyst on the surrounding tissues and structures develop<sup>[1,7,10]</sup>. Abdominal pain is the most commonly encountered symptom. The second one is the symptoms arising from the pressure effect of the cyst<sup>[7,8,11]</sup>. It is known that rupture of the cyst ameliorates the abdominal pain and the patient feels comfortable to some degree<sup>[2]</sup>. Later in time rupture of the hydatid cyst produces symptoms and signs of allergy or peritoneal irritation almost all the time<sup>[10]</sup>. No history of previous abdominal pain or any other symptom relating to the hydatid cyst was present in the case presented here.

Diagnosis of the hydatid cyst is mainly based on ultrasonography and computed tomography (CT)<sup>[1-3,7,8,10,11]</sup>. CT is especially valuable for the 3-dimensional localisation of the cyst preoperatively<sup>[8,11]</sup>. MRI, magnetic resonance cholangio pancreatography (MRCP), scintigraphy scans and laparoscopy may be useful for diagnosis of the rare, undiagnosed cases and for its complications. As we made the diagnosis of a ruptured hepatic hydatid cyst by US examination, the other investigational techniques were not used for preoperative evaluation.

Surgery is the preferred treatment for the cure of the hydatid disease<sup>[3,6,8]</sup>. Surgical procedures may differ from percutaneous aspiration instillation and reaspiration to complete excision of the cyst<sup>[1,6,7]</sup>. We performed introfleksion procedure on the patient. Rupture of the cyst is usually related to increased intracystic pressure. This may be related to trauma, or over enlargement of the cyst<sup>[2,10]</sup>. Perforation of the hydatid cyst may cause dissemination of the parasite and increased morbidity and mortality rate<sup>[1,2,9]</sup>. As cyst size increases, risk of rupture increases<sup>[5]</sup>. Cyst size measured 13 cm preoperatively in our case. Intraperitoneal rupture of the hydatid cyst can cause abdominal pain, allergy and anaphylaxis<sup>[1,2,5]</sup>. Mild abdominal tenderness was present in our patient on admission. The patient had no history of trauma or any event that increases intra-abdominal pressure such as coughing or constipation.

Medical treatment with albendazole is described elsewhere<sup>[1,6,7,10,11]</sup>. The patient was treated with albendazole 10 mg/kg for 2 mo under liver enzyme and blood count monitoring. Postoperative follow up was uneventful.

Intra-peritoneal hydatidosis is a major problem for the patients who have hydatid cyst rupture. The patient presented here had no recurrence or secondary hydatidosis.

In endemic regions, it is useful to consider hydatid cyst disease for patients with abdominal pain admitted to the emergency room. Rupture of the hydatid cyst may be fatal.

## Abstract

We report an extremely rare case where a mesenchymal differentiation, especially embryonal sarcoma, was demonstrated in cholangiocarcinoma. At autopsy, a yellowish-white tumor (15 cm x 12 cm) was found in the right hepatic lobe, and there were several daughter nodules in both hepatic lobes. Histologically, most of the main tumor and all of the daughter nodules examined showed sarcomatous changes (spindle cells, pleomorphic cells and hyalization). Histologic examination of a part of the main tumor disclosed a focus of adenocarcinoma within the tumor. The frequent transitions between the adenocarcinomatous areas and the sarcomatous areas suggested that sarcomatous transformation occurred in the cholangiocarcinoma and then spread rapidly. Immunohistochemically, the adenocarcinomatous elements were positive for cytokeratin, carcinoembryonic antigen (CEA) and epithelial membrane antigen, and negative in the sarcomatous cells. Vimentin was positive only in the sarcomatous elements. The findings of the present case support the view that carcinosarcomas represent carcinomas that develop sarcomatous elements via metaplasia of the epithelial element.

**Key words:** Cholangiocarcinoma; Carcinosarcoma; Mesenchymal differentiation

Sumiyoshi S, Kikuyama M, Matsubayashi Y, Kageyama F, Ide Y, Kobayashi Y, Nakamura H. Carcinosarcoma of the liver with mesenchymal differentiation. *World J Gastroenterol* 2007; 13(5): 809-812

## INTRODUCTION

Cholangiocarcinoma is usually a moderately to well differentiated adenocarcinoma with considerable demoplastic reactions. Nakajima *et al*<sup>[1]</sup> reported that 92 of 102 cases of cholangiocarcinoma were mucin-producing adenocarcinomas, and the remaining were adenosquamous (3 cases), squamous (3 cases), mucinous (1 case), or anaplastic carcinoma (3 cases). Only brief descriptions of sarcomatous changes and sarcomatous variants of cholangiocarcinoma can be found in a few studies or reviews dealing with a large series of cholangiocarcinoma cases<sup>[1,2]</sup>. However, detailed clinicopathological studies of sarcomatous changes in cholangiocarcinoma have not been reported in English and Japanese literature to the best of our knowledge.

Because we recently encountered an autopsy case of cholangiocarcinoma showing sarcomatous changes, we report this case to emphasize the autopsy findings, as well as the histogenesis of sarcomatous changes in cholangiocarcinoma.

## CASE REPORT

A 74-year old Japanese woman was admitted to our hospital complaining of pain in the right hypochondrium and underwent a cholecystectomy. The main laboratory data were as follows: red blood cells  $378 \times 10^4/\text{mm}^3$ , white blood cells  $5200/\text{mm}^3$ , serum total protein 8.0 g/dL, total bilirubin 0.8 mg/dL, serum glutamic-oxaloacetic transaminase 46 IU/L, serum glutamic-pyruvic transaminase 58 IU/L, lactic acid dehydrogenase 416 IU/L, alkaline phosphatase 476 IU/L,  $\gamma$ -glutamyl transpeptidase 119 IU/L, and C-reactive protein 2.9 mg/dL. Carcinoembryonic antigen (CEA) was 51.5 ng/mL, but serum  $\alpha$ -fetoprotein (AFP), a protein induced by vitamin K absence or antagonists (PIVKA-II) and carbohydrate antigen 19-9 (CA19-9) were within the normal range. Hepatitis B core (HBc) antibody, hepatitis C antibody (HCV-Ab), and human immunodeficiency virus (HIV) were all negative. A computed tomography scan of the abdomen revealed a low-density mass with renal invasion in all segments of the right hepatic lobe, without lymph node swelling or dilatation of the intrahepatic bile ducts. Magnetic resonance imaging revealed hypointensity on the T1-weighted images and heterogeneous hyperintensity on the T2-weighted images (Figures 1A and B). Angiography showed a malignant blush in the right lobe (not shown). A sonographically guided hepatic tumor biopsy showed the

**Figure 1** Magnetic resonance imaging showing hypointense areas in the right lobe of the liver on a T1-weighted image (A) and an inhomogeneously hyperintense mass on a T2-weighted image (B).

**Figure 2** Needle biopsy showing a sarcomatous area consisting of interlacing bundles of atypical spindle cells [hematoxylin-eosin stain; magnification x 200 (A), x 100 (B)] and immunohistochemical staining showing positive  $\alpha$ -SMA (C).

**Figure 3** Gross appearance of hepatic tumor.

proliferation of spindle cells. An immunohistochemical study showed that  $\alpha$ -smooth muscle actin (SMA) was positive, and keratin, vimentin, desmin, CEA, and S-100 protein were negative, thus leiomyosarcoma was suspected (Figure 2). Her general condition gradually worsened and she died of hepatic failure and disseminated intravascular coagulation (DIC) after two months.

### Autopsy findings

The gross findings were a yellowish-white tumor (15 cm  $\times$  12 cm) with blurred borders in the right hepatic lobe (Figure 3) where the right branch of the portal vein and right kidney were occluded.

Microscopically, the majority of the main tumor and all daughter nodules examined showed a sarcomatous appearance. Elongated cells were arranged in bundles, occasionally interlacing. These histologic features were similar to those of fibrosarcoma or leiomyosarcoma.

That is, these areas were composed of nonadhesive spindle-shaped or fusiform cells, and to a lesser degree, pleomorphic giant or multinuclear cells, the majority of the latter showing bizarre nuclei and prominent nucleoli (Figure 4). These sarcomatous areas looked like malignant leiomyosarcoma. There were many foci of coagulative necrosis within these sarcomatous areas. In addition, there was a well-differentiated tubular adenocarcinoma within the tumor (Figure 5). There were direct transitions between adenocarcinomatous elements and sarcomatous elements. However, the transitions were unclear. A hydropsy-like part was recognized at the side edge of the tumor, and tumor cells floating in mucinous cytoplasm were evidence of undifferentiated (embryonal) sarcoma (Figure 6).

These two elements on the representative section of tumor were mapped (Figure 3), showing adenocarcinomatous elements within the tumor and a considerable amount of sarcomatous elements surrounding this carcinoma. There were no histologic elements suggestive of hepatocellular carcinoma.

The nontumorous hepatic tissue showed nonspecific reactive changes with mild fibrous enlargement of the portal tracts, but not liver cirrhosis. There were no regenerative nodules throughout the liver, and HBsAg was not detected in the liver by orcein stain.

Primary antisera to keratin, vimentin, desmin, AFP, CEA, and S-100 protein were obtained from DAKO Corporation. Keratin was weakly positive in the adenocarcinoma cells. There was positive staining for CEA at the part of tubular adenocarcinoma. Vimentin was expressed only in the sarcomatous cells. There were no positive reactions for AFP, desmin, S-100 protein, or CA19-9 in the tumor cells.

It was diagnosed as cholangiocarcinoma and carcino-

**Figure 4** Spindle cells (A), pleomorphic areas (B), or hyalination (C) in leiomyosarcoma (hematoxylin-eosin stain; magnification x 160).

**Figure 5** Cholangiocarcinoma focus (A) (hematoxylin-eosin stain; magnification x160), component surrounded by fibrosis (B) (hematoxylin-eosin stain; magnification x100), intimately mixed carcinomatous and sarcomatous components (C) (hematoxylin-eosin stain; magnification x 160).

**Figure 6** Sarcomatous portion of the tumor consisting of undifferentiated (embryonal) sarcoma [hematoxylin-eosin stain; magnification x 25 (A, B), x 160 (C)].

sarcoma with mesenchymal differentiation that specialized and coexisted in a lobe corollary tumor.

## DISCUSSION

Sarcomatous transformation of primary cancer of the liver in adults is most common in hepatocellular carcinoma (HCC), especially after anticancer chemotherapy or transarterial embolization therapy<sup>[3]</sup>. In our patient, there were no lesions resembling HCC, and AFP was negative in the tumor, so that the derivation of sarcomatous cells from HCC was excluded.

Histologic mapping of a whole section of the main tumor showed adenocarcinomatous and sarcomatous elements within the main tumor. Considering the mapping,

the sarcomatous elements would be interpreted as the result of the metaplastic transformation of pre-existing adenocarcinoma cells<sup>[4]</sup>.

In our case, direct transitions between sarcoma and adenocarcinoma in the main tumor suggested that the sarcomatous changes might have developed secondarily from pre-existing cholangiocarcinoma. Most of the daughter nodules showed such sarcomatous changes, suggesting that sarcomatous elements grow and spread more rapidly than the adenocarcinomatous elements.

Thompson *et al.*<sup>[5]</sup> stated that the carcinomatous and sarcomatous components may be monoclonal in origin and derived from single stem cells. Genetic analysis is one possible solution to this problem, as reported in esophageal carcinosarcoma<sup>[6]</sup>.

What is more, various other hypotheses have been proposed to explain the biphasic appearance of sarcomatoid carcinomas<sup>[7,8]</sup>. Briefly, the explanations include the collision theory of independent neoplastic growth from multipotent stem cell origins, epithelial to mesenchymal conversion by epithelial-stromal interaction, and a combination of the two. The salient features in our case were the presence of dysplasia and adenocarcinoma *in situ*, morphological “transition” between carcinomatous and sarcomatous tissues in relation to expansion of invasion, and the detection of sarcomatous characteristics by immunohistochemistry in the epithelial component, which strongly support the histogenesis of epithelial to mesenchymal conversion. Gentile *et al*<sup>[9]</sup> reported that the presence of productive retroviral infection in the sarcomatous cells is related with tumor progression from the carcinomatous to the sarcomatous phase. The examination I performed confirmed that it was negative for viruses, but it was related with an unknown virus. However, why sarcomatous changes develop is a mystery.

In summary, sarcomatoid carcinoma derived from cholangiocarcinoma is an extremely rare tumor composed of mixed malignant epithelial and mesenchymal cells, with only 12 cases<sup>[10-12]</sup> reported to date who died of liver failure due to extensive metastatic growth of sarcomatoid carcinoma despite postoperative chemotherapy. The histologic features, stage, and outcome of the reported cases indicate that this neoplasm generally pursues a highly aggressive and malignant biological course with rapid growth and wide local infiltration, leading to a poor prognosis. Radical surgery with adjuvant chemotherapy, and close follow-up are necessary for the management of this disease.

### Abstract

Metastatic melanoma to the common bile duct is very rare with only 18 cases reported so far. We report a 46 year old women who, 18 mo after excision of a skin melanoma, developed a painless progressive obstructive jaundice. At operation a melanoma within the distal third of the common bile duct was found. There were no other secondaries within the abdomen. The common bile duct, including the tumor, was resected and anastomosed with Roux-en-Y jejunal limb. The patient survived 31 mo without any sign of local recurrence and was submitted to three other operations for axillar and brain secondaries, from which she finally died. Radical resection of metastatic melanoma to the common bile duct may result in lifelong relief of obstructive jaundice. It is safe and relatively easy to perform. In other cases, a less aggressive approach, stenting or bypass procedures, should be adopted.

### INTRODUCTION

The great majority of malignant melanomas arise from the skin, squamous mucose membranes, retina, and

leptomeninges. They can metastasize to almost every organ of the body. The intraabdominal viscera are involved in diffuse metastatic disease in approximately 60% of patients<sup>[1-3]</sup>. DasGupta and Brasfield in 1964 reported a 15% involvement of the gallbladder and 6% involvement of the remainder of the biliary tree<sup>[2]</sup>.

### CASE REPORT

A 46-year-old woman was admitted to our hospital with painless progressive obstructive jaundice. Previously she had been submitted to excision of a skin melanoma on the back in a local hospital. Our laboratory data showed an elevated bilirubin (235.9  $\mu\text{mol/L}$ , direct bilirubin 138.4  $\mu\text{mol/L}$ ), alkaline phosphatase (1540 U/L), gamma GT (638 U/L), SGOT (525 U/L), SGPT (870 U/L), and ESR (76/1 h). Ultrasonography showed a dilated gallbladder and common bile duct and suspected stone within the distal third of the common bile duct. In December 1996, a cholecystectomy was performed. An operative cholangiography through the cystic duct showed a tumorous mass within the distal common bile duct causing almost complete obstruction (Figure 1). The duodenum was mobilized, the common bile duct was opened and a piece of dark soft tumour tissue was removed. Frozen section biopsy showed a malignant melanoma. The common bile duct was then carefully dissected and transected 1 cm away from the lower edge of the tumor. The duct was proximally resected close to the convergence of the hepatic ducts. The distal end of the common bile duct was oversewn and the proximal end was anastomosed with Roux-en-Y jejunal limb. A careful search showed no other secondaries within the abdomen.

The recovery was uneventful. Histopathology revealed ill-defined epithelioid tumor cell aggregates infiltrating bile ducts and the surrounding fibro-adipose structures. There was strong brown granular intracytoplasmic pigmentation in some parts of the infiltrate (Figures 2 and 3). Fontana-Masson histochemical staining confirmed melanin pigment and positive strong anti-S100 protein and anti-HMB45 immunoreactivity with weak positivity to anti-melan A antibodies proved the diagnosis of a metastatic melanoma. The patient survived 31 mo without any signs of local recurrence. She had to be submitted to another three surgeries for the axillar and brain secondaries, which were a final cause of her death.

**Figure 1** Showing filling defect within the distal common bile duct causing almost complete obstruction.

**Figure 2** A pigmented malignant tumour evidently infiltrates extrahepatic bile duct. Later histochemical and immunohistochemical analyses showed melanoma cells (HE,  $\times 13$ ).

**Figure 3** Higher magnification of the same tumour field showed insular and trabecular-to-solid histological organization of melanoma cells. Most of the cells were hyperpigmented with massive intracytoplasmic melanosome granules (HE,  $\times 64$ ).

## DISCUSSION

The first case of a metastatic melanoma to the bile duct was described by Spiegelberg in 1895, and the second by Duval in 1908<sup>[4]</sup>. A search throughout Medline showed 18 metastatic melanomas to the common bile duct reported so far<sup>[4-19]</sup>. Within this period, about 20 cases of primary malignant melanomas of the common bile duct have been described. However, in spite of confirmatory immunohistochemical stains, electron microscopic studies, the presence of junctional activity adjacent to the tumour, and tests to rule out other possible remote or concurrent primary sites, absolute exclusion of a metastatic melanoma from an unknown occult site or regressed site is not entirely possible<sup>[20]</sup>. The melanoma secondaries usually arise from the primary skin lesion but occasionally they may arise from primary or metastatic melanoma of the gallbladder<sup>[7,12,16]</sup>.

Patients with metastatic melanoma to the common bile duct usually present with progressive painless obstructive jaundice<sup>[4,19]</sup>. Rarely the patients have hemobilia<sup>[10]</sup>, pain<sup>[5,8]</sup>, or cholangitis<sup>[19]</sup>. Laboratory data show a cholestatic jaundice. On ultrasonography this tumour is echogenic with little or no acoustic shadowing<sup>[9]</sup>. The

exact preoperative diagnosis of the tumour is established, almost exclusively when localised at the Vater's papilla so that a biopsy can be taken<sup>[18]</sup>, or on the basis of histologic examination of a small fragment of the tissue retrieved from the bile duct with a Dormia basket after papilotomy<sup>[19]</sup>.

The current literature has few recommendations with regard to appropriate treatment of the melanoma metastases to the bile ducts<sup>[14,19]</sup>. It seems reasonable to perform radical surgical resection in patients with potentially curable disease and isolated deposits in the bile duct<sup>[14,19]</sup>. We believe it is particularly indicated if resection is not too dangerous and if it is relatively easy to perform, as in the present case. A resection may be necessary in cases of serious hemobilia<sup>[10]</sup>. If there is a concurrent metastatic disease elsewhere, it is prudent to adopt a less aggressive approach in order to relieve obstructive jaundice, such as the bypass procedures<sup>[14]</sup>, or stenting<sup>[18,19]</sup>.

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297 mm × 210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, acknowledgements, References, Tables, Figures and Figure Legends. Neither the editors nor the Publisher is responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part without the written permission of both the authors and the Publisher. We reserve the right to put onto our website and copy-edit accepted manuscripts. Authors should also follow the guidelines for the care and use of laboratory animals of their institution or national animal welfare committee.

Authors should retain one copy of the text, tables, photographs and illustrations, as rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for the loss or damage to photographs and illustrations in mailing process.

#### Online submission

Online submission is strongly advised. Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/index.jsp>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. Authors encountering problems with the Online Submission System may send an email you describing the problem to [wjg@wjgnet.com](mailto:wjg@wjgnet.com) for assistance. If you submit your manuscript online, do not make a postal contribution. A repeated online submission for the same manuscript is strictly prohibited.

#### Postal submission

Send 3 duplicate hard copies of the full-text manuscript typed double-spaced on A4 (297 mm × 210 mm) white paper together with any original photographs or illustrations and a 3.5 inch computer diskette or CD-ROM containing an electronic copy of the manuscript including all the figures, graphs and tables in native Microsoft Word format or \*.rtf format to:

#### Editorial Office

##### *World Journal of Gastroenterology*

Editorial Department: Apartment 1066, Yishou Garden,  
58 North Langxinzhuang Road,  
PO Box 2345, Beijing 100023, China  
E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)  
<http://www.wjgnet.com>  
Telephone: +86-10-85381892  
Fax: +86-10-85381893

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using a word-processing software. All submissions must be typed in 1.5

line spacing and in word size 12 with ample margins. The letter font is Tahoma. For authors from China, one copy of the Chinese translation of the manuscript is also required (excluding references). Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was accomplished, disclosure of any financial support for the research, and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (removing all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s) and full family name.

#### Abstract

An informative, structured abstract of no more than 250 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipments, and the experimental procedures should be included. RESULTS: The observatory and experimental results, including data, effects, outcome, etc. should be included. Authors should present *P* value where necessary, and the significant data should accompany. CONCLUSION: Accurate view and the value of the results should be included.

The format of structured abstracts is at: <http://www.wjgnet.com/wjg/help/11.doc>

#### Key words

Please list 5-10 key words that could reflect content of the study mainly from *Index Medicus*.

#### Text

For most article types, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include in appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both.

#### Illustrations

Figures should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. No detailed legend should be involved under the figures. This part should be added into the text where the figures are applicable. Digital images: black and white photographs should be scanned and saved in TIFF format at a resolution of 300 dpi; color images should be saved as CMYK (print files) but not as RGB (screen-viewing files). Place each photograph in a separate file. Print images: supply images of size no smaller than 126 mm × 85 mm printed on smooth surface paper; label the image by writing the Figure number and orientation using an arrow. Photomicrographs: indicate the original magnification and stain in the legend. Digital Drawings: supply files in EPS if created by freehand and illustrator, or TIFF from photoshops. EPS files must be accompanied by a version in native file format for editing purposes. Existing line drawings should be scanned at a resolution of 1200 dpi and as close as possible to the size where they will appear when printed. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes of atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...

#### Tables

Three-line tables should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each table. No detailed legend should be included under the tables. This part should be added into the text where the tables are applicable. The information should complement but not duplicate that contained in the text. Use one horizontal line under the title, a second under the column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

#### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup>*P*<0.05, <sup>b</sup>*P*<0.01 should be noted (*P*>0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P*<0.05 and <sup>d</sup>*P*<0.01 are used. Third series of *P* values can be expressed as <sup>e</sup>*P*<0.05 and <sup>f</sup>*P*<0.01. Other notes in tables or under

illustrations should be expressed as  $^1F$ ,  $^2F$ ,  $^3F$ ; or some other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, etc. in a certain sequence.

### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions are included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should code the references according the citation order in text in Arabic numerals, put references codes in square brackets, superscript it at the end of citation content or the author name of the citation. For those citation content as the narrate part, the coding number and square brackets should be typeset normally. For example, Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>. If references are directly cited in the text, they would be put together with the text, for example, from references [19,22-24], we know that...

When the authors code the references, please ensure that the order in text is the same as in reference part and also insure the spelling accuracy of the first author's name. Do not code the same citation twice.

### PMID requirement

PMID roots in the abstract serial number indexed by PubMed (<http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed>). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information of the journal citations is very important. Through reference testing system, the authors and editor could check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in ASP file so that the readers can read the abstract of the citations online immediately.

### Style for journal references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). Title of the cited article and italicized journal title (Journal title should be in its abbreviation form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634]

Note: The author should test the references through reference testing system (<http://www.wjgnet.com/cgi-bin/index.pl>)

### Style for book references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

**Patent** (list all authors)

- 16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

### Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those that are linked with a hyphen and the difference between the two numbers at two sides of the hyphen is more than 5. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered as inappropriate references. Authors should not cite their own unrelated published articles.

### Statistical data

Present as mean  $\pm$  SD or mean  $\pm$  SE.

### Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\gamma$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

### Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p*(B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5  $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub> not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format about how to accurately write common units and quantum is at: <http://www.wjgnet.com/wjg/help/15.doc>

**Abbreviations**

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further mention.

**Italics**

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kbo I*, *Kpn I*, etc.

Biology: *H pylori*, *E coli*, etc.

**SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED**

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. Author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, the final check list for authors, and responses to reviewers by a courier (such as EMS) (submission of revised manuscript by e-mail or on the *WJG* Editorial Office Online System is NOT available at present).

**Language evaluation**

The language of a manuscript will be graded before sending for revision.

(1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing; (4) Grade D: rejected. The revised articles should be in grade B or grade A.

**Copyright assignment form**

Please download CAF from <http://www.wjgnet.com/wjg/help/9.doc>.

We certify that the material contained in this manuscript:

**Ms:**

**Title:**

is original, except when appropriately referenced to other sources, and that written permission has been granted by any existing copyright holders. We agree to transfer to *WJG* all rights of our manuscript, including: (1) all copyright ownership in all print and electronic formats; (2) the right to grant permission to republish or reprint the stated material in whole or in part, with or without a fee; (3) the right to print copies for free distribution or sale; (4) the right to republish the stated material in a collection of articles or in any other format. We also agree that our article be put on the Internet.

**Criteria for authorship:** The *WJG* requests and publishes information about contributions of each author named to the submitted study. Authorship credit should be based on (1) direct participation in the study, including substantial contributions to conception and design of study, or acquisition of data, or analysis and interpretation of data; (2) manuscript writing, including drafting the article, or revising it critically for important intellectual content; (3) supportive work, including statistical analysis of data, or acquisition of funding, or administration, technology and materials support, or supervision, or supportive contributions. Authors should meet at least one of the three conditions. The *WJG* does not publish co-first authors and co-corresponding authors.

We hereby assign copyright transfer to *WJG* if this paper is accepted.

Author Name in full (Full names should be provided, with first name first, followed by middle names and family name at the last, eg, Eamonn MM Quigley). Handwritten names are not accepted.

Author Name in abbreviation (Family name is put first in full, followed by middle names and first name in abbreviation with first letter in capital, eg, Quigley EMM). Handwritten names are not accepted.

**Final check list for authors**

The format is at: <http://www.wjgnet.com/wjg/help/13.doc>

**Responses to reviewers**

Please revise your article according to the comments/suggestions of reviewers. The format for responses to the reviewers' comments is at: <http://www.wjgnet.com/wjg/help/10.doc>

## Abstract

Colorectal cancer (CRC) is a common malignant disease and the severe nature of cases in men and women who develop colorectal cancer makes this an important socio-economic health issue. Major challenges such as understanding and modeling colorectal cancer pathways rely on our understanding of simple models such as outlined in this paper. We discuss that the development of novel standardized approaches of multidimensional (correlative) biomolecular microscopy methods facilitates the collection of (sub) cellular tissue information in the early onset of colorectal liver metastasis and that this approach will be crucial in designing new effective strategies for CRC treatment. The application of X-ray micro-computed tomography and its potential in correlative imaging of the liver vasculature will be discussed.

## INTRODUCTION

Colorectal cancer (CRC) is a common malignant disease, with the majority of deaths attributable to hepatic metastasis. In the Western world, it is the second cause of cancer death in women after breast cancer, and the third cause of cancer death in men after lung and prostate cancer, being responsible for about 492 000 deaths p.a. worldwide and 4500 deaths p.a. in Australia<sup>[1]</sup>. In addition, the statistical data reveal that the risk of developing CRC disproportionately strikes individuals in the age group 65 years and older, illustrating its health longevity impact on the ageing population. At the first diagnosis of CRC, 20% of the patients already have liver metastasis and 30% of the patients will develop metastasis afterwards. 80% of the patients who die of CRC have metastases in the liver and prognosis is generally poor<sup>[2]</sup>.

It is obvious that once the tumour cells have immigrated to the liver, they cross the hepatic sinusoidal endothelial barrier and by the time liver metastases form, most steps in the metastatic cascade have been completed. Consequently, exploring the preceding stages of CRC metastasis, proliferation and new blood vessel formation as well as mechanisms to disturb cell survival are to date of main interest as they are largely unexplored. As discussed in the following sections, the availability of new reconstructing and modeling techniques provide liver cancer biologists with an invaluable tool to bridge the gap between bench science and the development of potential novel liver CRC (immuno) therapeutic strategies.

## COLORECTAL CANCER AND THE HEPATIC SINUSOIDAL IMMUNE SYSTEM

When the tumour cells invade the vascular bed and metastasise to the liver, they encounter the liver specific immune defence mechanisms. This hepatic sinusoidal immune system involves the hepatic-specific natural killer cells (NK) (pit cells)<sup>[3]</sup>, Kupffer cells (KC) (liver-associated macrophages)<sup>[4]</sup> and hepatic endothelial cells (HEC)<sup>[5]</sup>, and is proven to play an important role in protecting the liver from invading colon carcinoma cells<sup>[6]</sup>. The conventional paradigm of CRC liver metastasis is based on a multi-step process characterized by a series of structural, cellular and molecular events, which give the tumour cells the ability to proceed through the many phases of liver metastasis. Based on literature survey the following common sequence of key-events within the liver sinusoids are involved in the

**Figure 1** Schematic representation of the local hepatic sinusoidal immune defence system in the different steps of CRC liver metastasis (Steps I to III) as outlined in detail in the "Phagocytosis, Apoptosis, Endothelial Retraction and Tumour Survival"-section. The subsequent steps in the metastatic cascade as denoted by question marks illustrate that considerable work remains, especially once CRC cells traverse the sinusoidal endothelial lining and invade the liver tissue.

process of CRC liver metastasis: Tumour cells approach the liver tissue through finer branches of the portal vein, where they will be trapped in either the finest branch of the portal veins, or the portal hepatic sinusoids. These sinusoids are narrow and tortuous. The diameter of sinusoids is much smaller than the diameter of CRC cells. NK and KC are mobile cells and can be seen moving along the hepatic sinusoid in *in vivo* microscopy experiments (our unpublished data). At this stage, the NK and KC are seen to be associated with the majority of the tumour cells, resulting in cytolysis and subsequent phagocytosis of the majority of the cancer cells<sup>[7-9]</sup>. Subsequently, specific adhesion of tumour cells within the hepatic microcirculation and active extravasation of the surviving cancer cells through the damaged hepatic endothelium takes place<sup>[10]</sup>. Both are believed to be essential events for cancer metastasis in the liver<sup>[11]</sup>, although others postulate that tumour cells develop exclusively intravascularly during the early stages<sup>[12]</sup>. However, it has been demonstrated that endothelial damage and gap formation occurs in both scenarios, enabling large cellular surface interactions between the tumour cells and the hepatocytes<sup>[9-11]</sup>.

In a later stage, matrix proteins derived from the stellate cells (SC) (liver-associated fibroblasts) are believed to provide a substrate for migration of tumour cells and infiltrating immuno-competent cells, whereas later on tight structures of matrix proteins surrounding tumour nodules provide a barrier for establishment of direct KC- and NK-cell-to-tumour-cell-contact and/or targeted therapies<sup>[9,13]</sup>. This is supported by the observation that large numbers of KC and NK cells were not activated at later phases in the metastasis process<sup>[14]</sup>. Finally, CRC cells spread throughout the liver, followed by the abdominal and peritoneal cavity<sup>[9,15]</sup>.

## PHAGOCYTOSIS, APOPTOSIS, ENDOTHELIAL RETRACTION AND TUMOUR SURVIVAL

Our previous microscopy and fine structural immunochemistry studies significantly contributed to the above model and as depicted in figure 1 we were able to demonstrate that KC, NK and HECs all work together in concert as one immune-surveillance guardian in the defence against CRC liver metastasis (Figure 1)<sup>[6]</sup>. Furthermore, it was shown that phagocytosis and apoptosis are key processes in three central steps in the complex CRC liver metastatic cascade, briefly: (Step I) When CC531s colon carcinoma cells encounter the liver sinusoid about 90% of the tumour cells are eliminated by a synergistic action between KC and NK cells<sup>[9]</sup>; (Step II) We have proven that HECs express FasL and that about 5% of the colorectal CC531s cell population express functional Fas under influence of IFN $\gamma$  and NO released in the sinusoid by NK and HECs, respectively. In this situation, the IFN $\gamma$ -activated pathway supports the immune system by inducing apoptosis in CC531s cells<sup>[16]</sup>; (Step III) Conversely, Fas expressing HEC undergo apoptosis by FasL expressing CC531s cells. As a result, about 5% of the CC531s cells are able to escape the local immune system and provide themselves a gateway towards the liver tissue as the HECs retracts. Next the CC531s cells have free access to the Fas expressing hepatocytes (Hep) which undergo in turn apoptosis by the FasL bearing CC531s cells and as a result invade the liver tissue<sup>[17]</sup>. Reconstruction data obtained *via* the aid of confocal laser scanning microscopy indicated that surviving cancer cells are primarily confined to the Space of Disse and to the Glisson capsule, suggesting that metastasis would initiate from this extracellular matrix-rich region.

**Figure 2** Transmission electron microscopy photomicrograph at low magnification (6700 x) of rat liver one week after i.v. injection of one million CC531s colon cancer cells. Tumour cells (Tc) can be recognized by a ribosome-rich, bulky cytoplasm containing few organelles. Tumour cell nuclei are large and contain mostly euchromatin. In this picture, tumour cells have already taken position in the liver parenchyma and compress or deform the parenchymal cells (Pc1 and Pc2). In this stage, tumour cells are so numerous that defending cells, such as Kupffer cells (Kc) and monocytes (M) in the hepatic sinusoids (sin) and B lymphocytes (B) seem to be no longer involved as in earlier stages. At this stage of tumour cell settlement, rebuilding of the hepatic tissue sets in and soon small visible white spots of metastasis will be seen on the surface of the liver.

Overall, based on our combined light-, laser- and electron microscopic *in vivo* and *in situ* studies, we believe that the majority of tumour cells entering the liver will be destroyed in this first confrontation with hepatic sinusoidal cells. The trouble is supposed to be the fact that only a very few tumour cells need to escape from the hepatic sinusoids and after settling in the liver parenchymal tissue, as depicted in the photograph (Figure 2), they form metastases and start spreading new tumour cells in the hepatic tissue (i.e., secondary metastasis). It is also supposed that after leaving the hepatic sinusoids, the tumour cells are not chased by the local hepatic sinusoidal immune cells, and that the liver tissue has to rely from that moment onwards on other cellular- and immune defence systems, such as those offered by cytotoxic T cells, monocyte-derived macrophages and others.

## RECONSTRUCTING AND MODELING COLORECTAL HEPATIC METASTASIS WITH CORRELATIVE THREE-DIMENSIONAL IMAGING TECHNIQUES

In the past, mainly two-dimensional structural tissue information has been generated about the metastasis pathways of CRC tumour formation in the liver. Attempts to target specific CRC pathways for therapeutic intervention, such as apoptosis by cell-death mediated drug delivery and/or new blood vessel outgrowth by specific

anti-angiogenic drug release, partly failed because of our limited structural and molecular understanding about the tumour's complex cell- and tissue microenvironment using two-dimensional imaging. New concepts and progress in cell biology have been discovered thanks to improved correlative microscopy techniques that continue to rely predominantly on advances in new, three-dimensional (3D) reconstructing and modeling techniques<sup>[18,19]</sup>. Ideally, 3D correlative microscopy can be defined as an imaging platform aiming to cross-correlate information with multiple microscopy techniques on the same tissue(s) and/or cell(s). There is growing evidence from the literature that this approach facilitates the understanding of cellular and/or rare events by providing the possibility to collect new qualitative and quantitative information in a large sample volume<sup>[20,21]</sup>. In the past our group successfully applied different biomolecular microscopy methods on our CC531s CRC model. The data conferred under the above section were obtained by combining confocal laser scanning<sup>[9,22]</sup>, live cell<sup>[23]</sup>, atomic force<sup>[24]</sup>, scanning electron<sup>[10,17]</sup> and transmission electron<sup>[16,25]</sup> microscopy data. In line, we started up correlative confocal laser scanning microscopy<sup>[9,18]</sup> and X-ray micro-computed tomography (CT)<sup>[26]</sup> studies as defined above to quantitatively collect the spatial and temporal cell- and tissue architecture at different resolution levels of CRC hepatic metastasis (*vide infra*).

In a recent study<sup>[27]</sup>, we applied the impregnation method in which en bloc staining of perfused-fixed hepatic tissue with osmium tetroxide and uranyl acetate was shown

**Figure 3** X-ray micro-computed tomography (CT) image set of hepatic tissue. For detailed recording and subsequent image processing settings we refer to Ananda *et al* (27). **A:** Low -magnification data showing an overview of a glutaraldehyde perfused-fixed and subsequently osmium tetroxide/uranyl acetate *en bloc* stained liver lobule (arrow) versus the unstained sample mounting support (arrowhead). Note, inset shows the corresponding Z-info at an ad random height of the main image; **B:** X-ray micro CT 3D reconstruction image showing the portal venous blood vessels (arrow) and hepatic tissue (arrowhead); **C:** X-ray micro CT reconstruction after density histogram image filtering, showing the intricate pattern of hepatic sinusoids (arrow) in 3D context. Note the absence of liver tissue information under this image processing condition (compare with B for the difference); **D:** Conversely, using different opacity thresholds resulted in the visualization of the hepatic cords, i.e. parenchymal tissue, (arrow). (Courtesy to Ms. S. Ananda and Ms. V. Marsden). Scale Bars (B-D), 500  $\mu\text{m}$ .

to be successful to reconstruct and model a large sample volume of the macro- and microvasculature of hepatic tissue with X-ray micro-computed tomography (Figure 3). Furthermore, we demonstrated that correlative laser light optical imaging provided a limit of confidence for X-ray micro CT imaging of the hepatic vasculature as the large blood vessels such as the hepatic portal veins, and the smaller blood vessels i.e., the hepatic sinusoidal vascular bed could be visualized<sup>[27]</sup>. When applying the established contrasting method to the CC531s CRC metastasis model<sup>[19]</sup> it was observed that the dense array of blood vessels was interrupted in the liver tissue samples bearing the CRC cells when compared to the controls<sup>[27]</sup>. This is in line with the earlier observations made by Machara<sup>[28]</sup> who showed tumour-induced reorganization of the auricular vascular bed after barium sulphate contrasting. Based on these data we forth casting the ability to correlate information in large tissue volumes from the X-ray micro CT models with reconstruction data obtained from confocal laser scanning microscopy on the same sample and region of interest by using fluorescent- and X-ray dense fiducial markers. This will definitely bridge the resolution gap from the micrometre to nanometre scale in studying cancer-mediated events, respectively.

In conclusion. Advanced multidimensional correlative microscopy methods and modeling techniques will

feature heavily in the future quest to understand and to quantitatively define the spatial and temporal mechanisms regulating the pathways of CRC liver metastasis. There will be no doubt that elucidating the subcellular and molecular events of tumour-mediated cell-death processes (apoptosis) and collecting simultaneously additional structural and functional data in tumour-induced new blood vessel formation (angiogenesis) will be of main interest in future combined imaging studies as this approach will most probably result in an accurate correlative representation of the liver architecture and the tumour's microvasculature. One may hope that the combination of correlative insights gathered will be a breakthrough in the study of liver tumours and this will facilitate novel targeted cancer therapies in the long-term.

## ACKNOWLEDGMENTS

The authors acknowledge the facilities as well as technical and administrative assistance from staff in the NANO Major National Research Facility at the "Australian Key Centre for Microscopy and Microanalysis" of The University of Sydney. T.M. and F.B. also acknowledge the support of the "Japan Association for the Advancement of Medical Equipment" (H17-nano-013 No. 141/Japanese Government-Ministry of Welfare and Labour). The authors are grateful to Ms. A Simpson, Ms. E Kable, Ms. E Korkmaz & Dr. L Cole, for excellent technical assistance, to Dr K Vekemans for providing hepatic tissue (Figure 3A), and to Mr. G Cohn, Mr. A Restov & Dr. A Jones for supporting Ms. S Ananda and Ms. V Marsden in soft X-ray imaging.

## COMMENTS

### Background

Major challenges such as understanding and modeling colorectal liver metastases pathways rely on the understanding of simple models derived from large biomolecular image data sets.

### Research frontiers

This paper elegantly demonstrated that the development of novel standardized approaches of multidimensional (correlative) biomolecular microscopy methods facilitated the collection of (sub) cellular tissue information in the early onset of colorectal liver metastasis and that this approach is crucial in designing new effective strategies for colorectal cancer treatment.

### Innovations and breakthroughs

Advanced multidimensional correlative microscopy methods and modeling techniques will feature heavily in the future quest to understand and to quantitatively define the spatial and temporal mechanisms regulating the pathways of colorectal cancer liver metastasis.

### Applications

There is no doubt that the "correlative insights"-approach, as discussed in depth in this "invitation expert review"-paper, will be a breakthrough in the study of liver tumours and will facilitate the design of novel targeted cancer therapies.

### Terminology

Colorectal cancer is a common malignancy that frequently metastasizes to the liver. Identifying the mechanisms regulating the nanobiology of colorectal liver metastasis, as well as gaining a better understanding of the interaction between the metastatic tumour cell and the different types of liver cells, including the liver

vasculature, is a first when new therapeutic approaches wanted to be designed.

### Peer review

How and why colorectal cancer cells metastasize to the liver has always been a subject of continuing interest. The authors describe this concept nicely, supported by excellent pictures.

### Abstract

Liver resections are demanding operations which can have life threatening complications although they are performed by experienced liver surgeons. Recently new technologies are applied in the field of liver surgery, having one goal: safer and easier liver operations. The aim of this article is to address the issue of bloodless liver resection using radiofrequency energy. Radionics, Cool-tip™ System and Tissue Link are some of the devices which are using radiofrequency energy. All information included in this article, refers to these devices in which we have personal experience in our unit of liver surgery. These devices take advantage of its unique combination of radiofrequency current and internal electrode cooling to perform sealing of the small vessels and biliary radicals. Dissection is also feasible with the cool-tip probe. For the purposes of this study patient sex, age, type of disease and type of surgical procedure in association with the duration of parenchymal transection, blood loss, length of hospital stay, morbidity and mortality were analyzed. Cool-tip RF device may provide a unique, simple and rather safe method of bloodless liver resections if used properly. It is indicated mostly in cirrhotic patients with challenging hepatectomies (segment VIII, central resections). The total operative time is eliminated and the average blood loss is significantly decreased. It is important to note that this technique should not be applied near the hilum or the vena cava to avoid damage of these structures.

<http://www.wjgnet.com/1007-9327/13/826.asp>

### INTRODUCTION

Bleeding after liver resection remains a significant factor affecting prognosis. The concept of introducing new bloodless techniques to facilitate surgical resection of liver tumors have stimulated hepatobiliary surgeons. This has taken the form of vascular occlusion of the inflow (Pringle), the outflow or both (total vascular exclusion). Ischemic preconditioning or hemi-hepatic inflow vascular occlusion are alternative methods better tolerated in patients with cirrhosis. Although vascular occlusion techniques have been proven effective to control intraoperative bleeding, the pathophysiologic effects are still poorly analyzed and difficult to predict for patients with decreased hepatic reserve<sup>[1-5]</sup>.

### PATHOPHYSIOLOGIC EFFECTS OF VASCULAR OCCLUSION

The Pringle maneuver places the surgical candidate at a high risk for liver damage due to ischemia and subsequent postoperative liver failure<sup>[4,5]</sup>. The spectrum of mechanism leading to ischemia-reperfusion (I-R) injury is large and involves metabolic and mitochondrial changes as adenosine triphosphate depletion, Kupffer cell activation, release of reactive oxygen species, cytokine secretion and microcirculatory disturbances. Granulocytes have been strongly suggested to play a key role in the amplification of I-R injury ending in apoptosis, necrosis and organ failure<sup>[6,7]</sup>. A recent paper by Kukita showed that the Pringle maneuver in hepatectomy caused remnant liver injury in a pig model by expression of iNOS, a marker related to I-R injury<sup>[8]</sup>.

### THE USE OF RADIOFREQUENCY DEVICES IN LIVER RESECTION

Recent efforts have aimed to perform bloodless liver resections in the setting of parenchymal transection with new sophisticated devices<sup>[9-14]</sup> avoiding inflow occlusion. The Cool-tip radiofrequency device (Radionics, Tyco Healthcare) and the Tissue Link equivalent both use radiofrequency energy transmitted through the electrode to the adjacent liver parenchyma causing ion vibration with heat production. In fact the devices are able to achieve both necrosis of the liver tissue and sealing of blood vessels up to 3 mm in diameter by collagen fusion<sup>[9]</sup>. The saline circuit at the tip of the RF needle offers better ion agitation thus preventing charring with eschar formation.

## DISCUSSION

The unique function to enhance heat conduction with a better tumoricidal effect makes these devices an advantageous tool for liver transactions. These findings lend important functional support to the concept of bloodless liver resection in cirrhotic patients and demanding segmentectomies (segment VIII, central hepatectomy etc). There is also a theoretical advantage of further liver necrosis beyond the demarcation line with increase of the surgical margin as proved by enzymatic analysis in frozen liver specimens<sup>[13]</sup>. However, the effect of this amount of necrotic tissue on cirrhotic patients with limited liver remnant reserve is not clear.

From our own experience, in more than 30 liver resections in fibrotic or even cirrhotic livers with both devices, the negative effect is minimal. We noted one case of hyperbilirubinemia postoperatively in a thrombocytopenic patient with hepatitis C related cirrhosis after a segment V-VI resection for a 5 cm single hepatocellular carcinoma (HCC). However the enzymes declined sharply the following days. In challenging segmentectomies the adjacent liver damage is not avoided but overall it is not harmful. The high postoperative aspartate aminotransferase (AST) levels reflect the coagulation-necrosis pattern at the raw surface of the remnant liver parenchyma and the maximum AST value is well correlated with the transection area<sup>[13]</sup>. It is worth noting that parenchymal degeneration is limited to the transection surface, which differs from the whole-liver ischemic damage caused by the Pringle maneuver. In addition coagulation induced by RF might be less prone to infection as we noted in our series, in opposition to ischemic necrosis due to inflow occlusion.

There is growing evidence that radio frequency (RF) is implicate in the enzymatic mechanism of cell division causing cell apoptosis<sup>[13]</sup>. In this regard, as already reported, an exciting possibility of tissue ablation beyond the histologic margins exists but needs further studies to establish its clinical effectiveness.

Complications relating to biliary tree following RF ablation are described in the literature<sup>[12]</sup>. Such complications remain to be the main problem with major resections using RF and regardless of the ultimate advantageous function of a bloodless RF device the liver surgical principles of hilar dissection should not be overlooked. There is a sense that, although the technique simplifies parenchymal transection, it cannot alter the conventional thought that such devices must only be used by experienced hepatobiliary surgeons. At the beginning of the learning curve with these new techniques we experienced two bile leaks suggesting that the dissecting sealer provides secure sealing of small bile ducts.

Even major anatomic liver resections can usually be performed without inflow occlusion and with infrequent need for blood transfusion. The results compare favorably with reports in which inflow occlusion was used routinely<sup>[2]</sup>. Most of the blood loss during major resections occurred from small branches or side holes of the middle hepatic vein. Unfortunately this anatomic structure appeared to be more difficult to visualize with the RF devices compared with CUSA or the traditional Kelly crashing technique and is correlated with similar findings pointed out by Poon<sup>[11]</sup>.

However the likelihood of vessel identification is strongly affected by operator experience. Although Poon *et al*<sup>[11]</sup> suggest selective use of Tissue Link for wedge resections and segmentectomies our experience with application of both Radionics and Tissue Link in major liver resections is promising regarding blood loss and transection time. Even though the transection time appears to be longer with our approach due to the lower transection speed of the device we demonstrate better control of capillary bleeding with subsequent less total operative time. An additional advantage of the RF devices is their potential effectiveness in the laparoscopic era of liver resection although it is still premature.

## OUR EXPERIENCE

In our series a total of 36 patients underwent liver resections using the Radiofrequency Cool-Tip device (Radionics, Tyco Healthcare) in the Liver Unit of Agia Olga Hospital.

### Patients and methods

Twelve patients had HCC, 20 had liver metastasis from colon cancer (CRM), 1 cystic ovarian metastasis (OM) of segment III, 1 focal nodular hyperplasia (FNH), 1 liver metastasis from renal tumor (RM) and 1 intrahepatic cholangiocarcinoma (ICC). Sixteen major and twenty minor hepatectomies have been performed using this new device. A redo hepatectomy of segment VI combined with wedge lung resection for an upper lobe metastatic lesion and a laparoscopic segment III resection were included, both for CRM. Eight of our CRM patients had significant steatosis (> 30%) due to preoperative chemotherapy. All cases of HCC had underlying Child A cirrhosis with normal platelet counts except for a hepatitis B, C and Delta carrier with a low platelet count (PLT 84 000/mL) due to mild portal hypertension and pegylated interferon treatment.

### Technique

The RF device was set at 95 watts on the 480 kHz electrosurgical generator. RF should last 30-60 s to obtain a zone of tissue necrosis with a radius of 1 cm and 3 cm in depth. Once RF ablation has been completed (proven by increase tissue impedance) a common scalpel was used to divide the tissue. The probes were moved along the transection line to accomplish both dissection and liver coagulation. Small vessels < 5 mm and biliary radicles are sealed by collagen fusion although major intrasegmentary vessels (middle hepatic vein branch to segment VIII) require clips or sutures.

### Results

The median transection time was 44 min (range 26 to 81 min). The operative time for parenchymal transection was primarily affected due to two independent factors: (a) the raw liver surface (major hepatectomies defined as more than 3 segments resected were prolonged with median transection time 62 min and range 47 to 81 min compared to minor liver resections; median 30 min) and (b) the underlying liver disease. Radionics required more time to

perform resections in cirrhotic livers (median 45 min; range 30 to 70 min) compared to the non-cirrhotic control<sup>[5]</sup> (median 30 min; range 25 to 50 min). Intraoperative blood loss was 100 mL (range 30 to 300 mL). Stitches were not placed except in the group of patients who underwent major hepatectomies or challenging segmental resections.

All patients had a postoperative increase of liver enzymes which normalized within 7 d. Serial monitoring of liver function in the first 7 postoperative days revealed peak serum aspartate aminotransferase (median 504.5 U/L, range 101 to 856 U/L) on d 1 or 3 with a rapid decline thereafter by d 7. Median peak postoperative serum bilirubin level was 1, 17 mg/dL (range 0.45 to 3.48 mg/dL).

Resected specimens were carefully examined for depth of tissue coagulation along the transection margin. Depth of tissue coagulation was 3 to 5 mm while providing an additional tumor negative margin at the resection border.

The in hospital mortality rate was zero. Procedure related complications included two bile leaks managed conservatively after major hepatectomies at the beginning of our learning curve. It is obvious that sealing of biliary radicles requires more time than vessels and therefore meticulous ablation is mandatory. No liver failure was reported in our series even in the cirrhotic group of patients. No reoperation was documented for rebleeding. The length of hospital stay ranged from 3 to 12 d with a mean value of 7 d.

We concluded that RF assisted liver resections can achieve low morbidity with minimal blood loss particularly in cirrhotic livers or challenging segmentectomies avoiding the sequela associated with the inflow occlusion techniques.

## OTHER DEVICES USED IN LIVER RESECTION

A different approach for liver transection was introduced by Habbib and associates<sup>[10]</sup> with sequential RF needle insertion around the tumor until a necrotic rim is achieved. The transection of the parenchyma follows in a bloodless field. However the technique is applied much easier in the periphery of the liver compare to the hilum. Furthermore multiple insertions of the needle close to the tumor margin require superior Ultrasound (US) skills especially in demanding segmentectomies or central resections. Practically, once the ablation process starts, the sensitivity of the US to credibly detect tumor stereo tactic structure and ablation interface in real time decreases significantly.

Another interesting device introduced recently is the high frequency supported jet cutting device (HF jet) which allows rapid resections with minimal blood loss and no electrolyte disturbances. However, it is still undergoing experimental studies and it is difficult to translate experimental success to the clinical arena yet.

## CONCLUSION

Although Bloodless cutting devices are promising there are several issues worth noting: (1) The techniques are still in progress and no randomization exists to compare the bloodless liver resection with the traditional approaches. (2) The bile leak rate is not reported thoroughly due to the fact that some groups use the bloodless devices

combined with clips or staples and rely on intraoperative cholangiograms to early diagnose and treat. (3) Although the device provides excellent coagulation and is strongly recommended for cirrhotic patients, limited experience exists in patients with advanced cirrhosis, portal hypertension and low platelet count. (4) Sufficient data is not available with regard to liver resection in jaundiced patients with hilar cholangiocarcinoma wherein CUSA or water-jet seems to be more efficient. However, the RF devices are effective tools in a selective group of liver surgical patients. A randomized prospective trial comparing hepatectomies under intermittent Pringle maneuver or without clamping using modern equipment would be appropriate.

Although limited data regarding efficacy of the most popular transaction devices (CUSA, Hydro-Jet) including dissecting RF sealer is available the cost-effectiveness of expensive devices is not thoroughly analyzed. Two randomized controlled trials comparing clamp crushing technique versus CUSA and CUSA versus Hydrojet using inflow occlusion are published 15, 16. Both had critical limitations which included normal and cirrhotic livers. In the most recent prospective randomized study by Clavien and associates, 17 conclude that clamp crushing technique is the most efficient device in terms of resections time, blood loss and blood transfusion frequency compared with CUSA, Hydrojet and dissecting RF sealer. Pringle was applied routinely in the group of clamp crushing transection but not in the equivalent groups of bloodless liver resection. Even though Kelly crashing was proved the most cost-efficient, no marginal livers (cirrhotic, cholestatic) were included in the study.

## Abstract

Currently approved treatments for hepatitis B virus (HBV) infection include the immunomodulatory agent, IFN- $\alpha$ , and nucleos(t)ide analogues. Their efficacy is limited by their side effects, as well as the induction of viral mutations that render them less potent. It is thus necessary to develop drugs that target additional viral antigens. Chemicals and biomaterials by unique methods of preventing HBV replication are currently being developed, including novel nucleosides and newly synthesized compounds such as capsid assembling and mRNA transcription inhibitors. Molecular therapies that target different stages of the HBV life cycle will aid current methods to manage chronic hepatitis B (CHB) infection. The use of immunomodulators and gene therapy are also under consideration. This report summarizes the most recent treatment possibilities for CHB infection. Emerging therapies and their potential mechanisms, efficacy, and pitfalls are discussed.

## INTRODUCTION

The hepatitis B virus (HBV) is a major world health problem, leading to 1.2 million deaths per year according to the World Health Organization (WHO)<sup>[1]</sup>. HBV

infection can result in acute, fulminant, or chronic disease, liver cirrhosis, and the development of hepatocellular carcinomas (HCC). There is a vaccine, but no 100% effective antiviral treatment available for patients with chronic hepatitis B (CHB). The response rate to IFN therapy, as measured by the loss of hepatitis B e antigen (HBeAg), is less than 40%<sup>[2]</sup>. This treatment is even less effective in Asian patients (primarily Chinese), particularly for those with below normal alanine transaminase (ALT) levels<sup>[3]</sup>. IFN therapy is also associated with many disabling side effects and is therefore only suitable for some patients.

Since HBV DNA replication occurs via reverse transcription<sup>[4]</sup>, the use of reverse transcriptase inhibitors is an attractive target for anti-HBV therapy. Nucleoside analogues are chemically synthesized drugs that mimic natural nucleosides. In China, three nucleoside/nucleotide drugs are used to manage chronic HBV infection: lamivudine (3TC), adefovir dipivoxil (ADV), and entecavir (ETV). Although all three are potent viral suppressors, none is able to permanently eradicate HBV<sup>[5]</sup>. As a result, the durability of the antiviral response is suboptimal once treatment is halted. In some patients, HBV DNA levels and ALT concentrations increase and result in a potentially life-threatening recurrence of disease<sup>[6,7]</sup>. Patients can only be safely withdrawn from nucleos(t)ide therapy if HBeAg seroconverts to anti-HBe or HBV DNA diminishes to undetectable levels<sup>[8,9]</sup>. To prevent disease recurrence, long-term polymerase inhibitor maintenance therapy is often required<sup>[10]</sup>. In addition, prolonged use of nucleoside/nucleotide is associated with the emergence of drug-resistant mutants<sup>[11,12]</sup>, and clinically characterized by increasing serum HBV DNA and ALT levels<sup>[10,13]</sup>. Each drug has a different profile of resistant mutations<sup>[14]</sup>, so it is essential that each is appropriately managed. These findings underscore a requirement for new and better-tolerated therapies for hepatitis B virus infection.

In this report, we review different strategies for drug design, and evaluate their effectiveness *in vitro*, in models of HBV replication *in vivo*, and in clinical trials.

## NUCLEOSIDE ANALOGUES

Orally applied nucleoside and nucleotide analogs have been important therapies against HBV infection throughout the last decade. The nucleoside analogs, lamivudine and entecavir, and the nucleotide analog, adefovir dipivoxil, are approved for use in humans. Many similar compounds are being tested in preclinical or clinical settings (Table 1).

Table 1 Anti-HBV nucleoside/nucleotide analogues under development

Phase	Drugs	Company
Phase III	Emtricitabine (FTC)	Gilead (California, USA)
	Tenofovir DF	Gilead (California, USA)
	Telbivudine (L-dT)	Idenix (Massachusetts, USA)
Phase II	Clevudine (L-FMAU)	Gilead/Triangle (California, USA)
	Elvucitabine ( $\beta$ -L-Fd4C)	Achillion (Connecticut, USA)
	Valtorcitabine (val-L-dC)	Idenix (Massachusetts, USA)
	Amdoxovir (DAPD)	Triangle (California, USA)
	Racivir [(+/-)-FTC]	Pharmasset (New Jersey, USA)
	LB80380	LG Life Sciences (Seoul, Korea)
Phase I	Alamifovir (purine nucleoside analogue)	Lilly/Mitsubishi (Indiana, USA/Osaka, Japan)
	MIV 210 (FLG prodrug)	Medivir/GSK (Huddinge, Sweden/Brentford, UK)
	Hepavir B (PMEA prodrug)	Ribapharm (California, USA)
Pre-clinical	$\beta$ -L-FddC	Biochem/GSK (Sante-Foy, Canada/Brentford, UK)
	6- [2- (phosphonomethoxy) alkoxy]-2, 4-diaminopyrimidines	Rega Institute for Medical Research, K.U.Leuven (Leuven, Belgium)
	2-benzenesulfonylalkyl-5-substituted-sulfanyl-[1, 3, 4]-oxadiazoles	National University of Singapore (Singapore)

### EMTRICITABINE (FTC)

Emtricitabine is a nucleoside analogue used for treatment against human immunodeficiency virus (HIV) and also has clinical activity against HBV. It has a similar structure to lamivudine, differing only in a fluorine at its 5 prime end. In a randomized double-blind study, patients received 200 mg of emtricitabine ( $n = 167$ ) or a placebo ( $n = 81$ ) once daily for 48 wk and underwent a pretreatment and end-of-treatment liver biopsy. Following treatment, 62% of patients who had received emtricitabine had improved liver histology, while only 25% of the placebo patients showed improvement ( $P < 0.001$ ). Significant improvement was also demonstrated between subgroups that were positive ( $P < 0.001$ ) and negative ( $P = 0.002$ ) for hepatitis B e (HBe) antigen. Serum HBV DNA levels were below 400 copies/mL in 54% ( $n = 167$ ) of the emtricitabine group and only 2% ( $n = 81$ ) of the placebo group ( $P < 0.001$ ), while alanine aminotransferase levels were normal in 65% (109/167) of the emtricitabine group and 25% (20/81) of the control group ( $P < 0.001$ ). At wk 48, 20 of 159 patients (13%) from the emtricitabine group in whom HBV DNA was detected at the end of treatment, had virus with resistance mutations (95% confidence interval, 8%-18%). The rate of seroconversion to anti-HBe (12%) and loss of HBe antigen were not different between arms, and the safety profiles of emtricitabine and placebo were similar during treatment. Forty-eight weeks of emtricitabine treatment resulted in significant histologic, virologic, and biochemical improvement in chronic HBV infected patients, regardless of whether HBe antigen was detectable<sup>[15]</sup>.

Phase III clinical trials are underway to determine the long-term safety and efficacy of emtricitabine, however its role as a monotherapy may be limited by its structural similarity to lamivudine and the corresponding risk of drug resistance.

### TENOFOVIR (VIREAD, PMPA)

Tenofovir was FDA approved in 2001 for use in HIV infected adults in combination with other antiretroviral agents. Lamivudine-associated and ADEFOVIR-resistant

mutations were not detected when tenofovir was used in a clinical trial. Thus, tenofovir may be a highly effective rescue drug in HBV-infected patients who show altered responsiveness to lamivudine and ADEFOVIR<sup>[16]</sup>. An additional double-blind, placebo-controlled trial showed that tenofovir may be a useful component of antiretroviral therapy for HIV/HBV co-infected patients. Importantly, tenofovir is equivalent to adefovir in its ability to reduce HBV DNA levels, and may, in fact, be superior<sup>[17]</sup>. If HBV treatment can be deferred until combination antiretroviral therapy for HIV infection is needed, the combination of tenofovir plus lamivudine or emtricitabine will be the potent HBV therapy and a solid backbone for HIV combination antiretroviral therapy, and a potent treatment for HBV and it likely decreases the emergence of HBV resistance. It will decrease the chance that HBV resistance will emerge as well<sup>[18]</sup>.

### CLEVUDINE (L-FMAU)

Clevudine is a nucleoside analog with an unnatural beta-L configuration, and *in vitro* studies suggest that it is effective against lamivudine-resistant HBV mutants. In the Woodchuck model, a daily clevudine dose of 10 mg/kg resulted in a 100 million copies' decrease in viral load. Interestingly, a delayed rebound in viral load was observed after drug cessation in a dose-dependent manner. No evidence of clevudine toxicity was observed in treated animals, however, further studies are being conducted to assess its long-term efficacy and safety<sup>[19]</sup>. Clinical trials show that clevudine is one of the most potent analogs available for treating HBV, and that its antiviral effects can last up to 6 mo after treatment, as illustrated by sustained normalization of ALT levels<sup>[18]</sup>. The mechanism by which clevudine elicits its anti-hepadna virus activity is distinct from other nucleoside analogs. It acts as a competitive inhibitor by binding to the catalytic site of HBV polymerase and inhibiting the priming of HBV DNA chain elongation. Nucleoside inhibitors, in general, interfere with viral polymerase activity through competitive inhibition and incorporation into the viral DNA strands<sup>[20]</sup>.

## TELBIVUDINE (LdT)

Telbivudine is a novel nucleoside analog that is being developed for the oral treatment of chronic HBV. It is a highly specific and selective inhibitor of replication *in vitro*, and specifically targets the HBV DNA polymerase. Unlike other nucleoside antivirals, telbivudine does not act against other viruses or induce mitochondrial toxicity by targeting mammalian DNA polymerases. Telbivudine preferentially inhibits HBV second-strand (DNA-dependent) DNA synthesis, in contrast to LdC and lamivudine, which are first-strand (RNA-dependent) DNA synthesis inhibitors<sup>[21]</sup>.

Telbivudine has a significantly higher rate of response than the standard HBV treatment, lamivudine, as well as superior viral suppression capability. It is generally well tolerated, with a low adverse effect profile, and no toxicity at its effective treatment dose.

Preclinical and clinical studies show that telbivudine has good pharmacokinetic properties that support once-daily dosing, and are not affected by gender, food intake, or liver health. Patients with moderate to severe renal impairment do require dose adjustment, however, which is also necessary for other drugs of this class.

Phase II b clinical trial results illustrate that patients with chronic HBV who are treated with telbivudine have significantly greater virologic and biochemical responses than those treated with lamivudine. Combination therapies revealed similar results to those obtained using telbivudine alone. These data support the ongoing phase III evaluation of telbivudine as a treatment for patients with chronic HBV<sup>[22]</sup>.

## OTHER NUCLEOSIDE ANALOGS

Additional nucleoside analogs that have favorable toxicity profiles and a promise of increased effectiveness against HBV are in various stages of clinical development. The phase III trials of emtricitabine, clevudine, tenofovir, and telbivudine will help define the efficacy and safety profiles of these drugs, while the profiles of newer and more potent drugs like LB80380 remain to be confirmed. It is important to recognize, however, that many of these compounds share cross-resistance profiles with existing nucleoside analogues such as lamivudine, adefovir, and entecavir<sup>[23,24]</sup>. As a result, these drugs may not offer much advantage over current treatment regimens. Current research efforts are focusing on the development of drugs that offer low rates of resistance or little cross-resistance with other nucleoside analogues.

## NOVEL MOLECULAR TARGETS OF HBV THERAPY

Because HBV pol carries out the enzymatic functions of reverse transcription and DNA synthesis, it is the primary target of HBV antiviral development<sup>[25]</sup>. Nucleoside and nucleotide analogues are the primary class of antiviral agents used for this purpose. In recent years, several compounds that specifically attack molecular targets other than HBV pol have been identified, including inhibitors of HBV encapsidation and HBcAg translation. Encapsidation

occurs when the viral RNA, pol, and core are assembled into the nucleocapsid prior to viral replication<sup>[26]</sup>.

## HETEROARYLDIHYDROPYRIMIDINE (HAP)

The heteroaryldihydropyrimidines (HAPs), including BAY41-4109, BAY38-7690, and BAY39-5493, are a new class of antivirals that inhibit production of HBV virions. HAPs show more favorable (50% and 90%) inhibitory concentrations (IC<sub>50</sub> and IC<sub>90</sub>) than lamivudine in a cell-based HBV replication assay. They act as allosteric effectors, binding the HBV core protein and resulting in its degradation, which subsequently inhibits nucleocapsid formation<sup>[27]</sup>. HAPs inhibit HBV replication in a transgenic mouse model with an efficacy similar to that of lamivudine<sup>[28]</sup>. Since these drugs destabilize preformed capsids, they may be used to treat blood products in order to lower the HBV transmission rates. Thus, HAPs may become a valuable addition to anti-HBV therapy. None of them has yet been tested in humans, but the clinical trial results of Bay 41-4109 are expected.

## PHENYLPROPENAMIDES

The phenylpropenamides represent another group of compounds that inhibit encapsidation<sup>[29]</sup>. The phenylpropenamide derivatives, AT-61 and AT-130, are synthesized and shown to inhibit HBV replication. These agents inhibit encapsidation by directly preventing nucleocapsid formation, a mechanism distinct from that used by HAPs. In a cell-based replication system, the phenylpropenamides are not as potent as lamivudine in inhibiting HBV replication (the IC<sub>50</sub> is approximately 10 times higher), but are active against the lamivudine-resistant YMDD mutant<sup>[29,30]</sup>. These drugs are specific for HBV and have no activity against related viruses such as woodchuck hepatitis virus (WHV) and DHB. Although this class of compounds has a favorable toxicity profile, clinical trials are still required.

## HELIOXANTHIN ANALOGUES

Helioxanthin was originally isolated from the shrub, *Taiwania ctyptomerioides*, and its derivative, 5-4-2, was synthesized in the laboratory. Helioxanthin and 5-4-2 belong to a class of small molecules that inhibit the HBV DNA as well as the HBV RNA and viral protein expression. Their structures are different from other anti-HBV compounds, suggesting that they may have a unique mode of action. Cheng YC *et al*<sup>[31]</sup> found that helioxanthin and 5-4-2 inhibited HBV mRNA levels in HepG2 2.2.15, as well as the HBV transcripts, 3.5 kb and 2.4/2.1 kb. The HBV core protein also decreased after treatment. Anti-HBV activity was evaluated *in vitro* using the HBV stably transfected hepatoma cell lines, W10 (adr, wt) and DM2 (adr, rtL180M/rtM204V, lamivudine-resistant), and helioxanthin and 5-4-2 inhibited both wild type and mutated HBV. Since the core protein activates the pregenomic/pre C promoters, it is possible that the decrease in 3.5 kb transcript results from a lack of transactivation by the core protein. Helioxanthin and 5-4-2 profoundly inhibited

pregenomic/preC and preS/S promoter activity using a gene reporter system, suggesting that they target multiple steps of the viral life cycle. The detailed mechanism of action by this class of compounds is being explored, and clinical trials are still required.

## GLUCOSIDASE AND PEPTIDE INHIBITORS OF CAPSID ASSEMBLY

The heavy glycosylation of HBV envelope proteins is important for viral assembly. As a result, specific glucosidase inhibitors have been developed to inhibit the assembly process. N-nonyl-deoxynojirimycin (N-nonyl-DNJ) is an inhibitor of N-linked glycan processing and the endoplasmic reticulum (ER) glucosidase. Researchers show the N-nonyl-DNJ has antiviral activity in the woodchuck model of HBV infection<sup>[32]</sup>. Another glucosidase inhibitor, N-nonyl-deoxygalactojirimycin (N-nonyl-DGJ), exerts its antiviral activity prior to viral envelopment, thus may prevent proper encapsidation of the HBV pregenomic RNA. These agents show promise in inhibiting viral replication using the WHV model, but toxicity may limit their clinical efficacy. Using a molecular approach to screen a phage display library, Dyson *et al.*<sup>[34]</sup> identified peptide aptamers that specifically interfere with the interaction between core particles and envelop proteins during assembly<sup>[33]</sup>. These peptides bind specifically to the tip of the core protein shell that comprises conserved amino acid residues within the nucleocapsid. This is important because of the risk of drug resistance. One candidate peptide inhibited HBV replication in a cell-based assay and exhibited no toxicity.

These promising approaches underscore the importance of identifying other molecular targets that may be used in combination therapies.

## IMMUNOMODULATORY AGENTS

A variety of immunomodulatory therapies have been developed over the last few decades to manage CHB. These therapies are designed to eliminate the virus by activating either nonspecific host immune responses or HBV-specific CD4<sup>+</sup> T helper and CD8<sup>+</sup> cytotoxic lymphocytes<sup>[35]</sup>. The nonspecific modalities include the use of TLRs, thymosin, IFN- $\alpha$ , and IFN- $\gamma$ , and the specific modalities include dendritic cell and cytotoxic T-lymphocyte (CTL)-based therapies. In recent years, the APOBEC family has shown promise as an anti-HBV drug.

## APOBEC3G

To replicate efficiently, viruses must overcome innate defense mechanisms. Human APOBEC3G is a cytidine deaminase that represents one such barrier by conferring broad intracellular antiretroviral protection. This enzyme is packaged in virions and acts during reverse transcription to deaminate deoxycytidine residues to deoxyuridine (dU) within the growing minus-strand of viral DNA. These dU-rich reverse transcripts are either degraded or result in proviruses that are largely nonfunctional due to a G-to-A hypermutation. Most lentiviruses escape APOBEC3G

inhibition by expressing a protein, Vif, which prevents deaminase incorporation into the virion and triggers its proteasomal degradation. However, APOBEC3G is capable of blocking a wide spectrum of distantly related retroviruses. Turelli *et al.*<sup>[36]</sup> show APOBEC3G-mediated inhibition of HBV and DHBV DNA production in human HuH-7 hepatoma cells and avian hepatoma cells. Thus, the viral and cellular interaction partners required for anti-hepadnaviral APOBEC3G action are conserved among these species. Rosler C *et al.*<sup>[37]</sup> found that core-associated HBV RNA is not reduced in the presence of A3G, and that wild-type levels of pgRNA associate with HBV core protein in the presence or absence of A3G. Yang DL *et al.*<sup>[38]</sup> showed a dose dependent decrease in the levels of intracellular core-associated HBV DNA, however, as well as a decrease in the extracellular production of HBsAg and HBeAg following APOBEC3G treatment. The levels of intracellular core-associated viral RNA also decreased, but the expression of HBcAg in transfected cells remained the same. Consistent with these *in vitro* results, levels of HBsAg in the sera of mice decreased dramatically. A larger 1.5-log<sub>10</sub> decrease in serum HBV DNA and liver HBV RNA levels were observed in APOBEC3G-treated versus control groups. These findings suggest that APOBEC3G suppresses HBV replication and antigen expression both *in vivo* and *in vitro*, and is a promising advance in HBV therapy.

## THERAPEUTIC VACCINATION

HBV persistence is thought to result from poor HBV-specific T cell responses<sup>[39]</sup>. This has resulted in efforts to stimulate HBV-specific T cells using therapeutic vaccines<sup>[40]</sup>. Mancini-Bourgine *et al.*<sup>[41]</sup> conducted a phase I study to evaluate the effectiveness of an HBV DNA vaccine that encodes HBV envelope proteins in ten chronic HBV carriers who did not respond to current antiviral therapies. Patients received four 1 mg intramuscular injections of the vaccine and an increased frequency of HBV specific T cell responses was observed. HBV DNA levels declined in five patients, and one patient successfully cleared the infection.

Yuan *et al.*<sup>[42]</sup> constructed a hepatitis B immunogenic complex therapeutic vaccine from a combination of yeast-derived recombinant HBsAg and human anti-HBs immunoglobulin (YIC). Its safety profile and the immune responses it elicited were examined in a phase I clinical trial. IFN- $\gamma$  levels were higher in all eight subjects studied ( $P = 0.015$ ) and IL-2 levels increased in seven of the eight subjects ( $P = 0.002$ ). These results show that the hepatitis B immunogenic complex therapeutic vaccine (YIC) can induce a potent anti-HBs response.

Wu *et al.*<sup>[43]</sup> also developed an innovative minovirus vaccine to induce hepatitis B virus specific cytotoxic T-lymphocyte responses. They proved that their mimovirus could induce an HBsAg28-39-specific CTL response *in vivo*. This type of vaccine is now under the phase II clinical trial in China.

The promise of these approaches requires further examinations in a large randomized study.

## DENDRITIC CELL VACCINATION

Dendritic cells (DCs) function as antigen-presenting cells. Peripheral DCs phagocytose microbes and viruses, and migrate to the regional lymph nodes where they mature and present foreign protein peptides to naive T cells<sup>[44]</sup>. These T cells then become activated, and acquire direct antiviral function as well as the ability to produce a variety of cytokines, including IFN, IL-2, IL-12, and IL-18. Many viruses, including HBV, are able to escape immune surveillance and persist in the host without evoking an immune response. Zheng *et al*<sup>[45]</sup> studied the functional defects of DCs in patients with CHB and showed that human leukocyte antigen (HLA) class II and B7 expression are not upregulated on these cells, leading to inadequate IL-12 levels to fight against infection. Although DC vaccination shows promise, it is still in the preclinical phase. With advances in technology, DC-based therapy may be an important method of managing CHB<sup>[46]</sup>.

## TLR LIGANDS

TLRs play an important role in innate immune recognition and regulation<sup>[47]</sup>. They belong to a family of evolutionarily conserved receptors that recognize structural patterns on different pathogens<sup>[48]</sup>. After finding a particular virus or microbe, TLRs activate phagocytes and DCs to mount an immune response<sup>[49]</sup>. In an HBV transgenic mouse model, Isogawa *et al*<sup>[50]</sup> showed that a single injection of a TLR ligand can inhibit HBV replication in hepatocytes by inducing the production of antiviral cytokines. These data support the further development of this approach.

## CTL-BASED THERAPY

CTL-based immunotherapy is based on the concept that HBV-specific CTLs control infection by suppressing HBV replication in infected humans<sup>[51]</sup>. Vitiello *et al*<sup>[52]</sup> developed a lipopeptide-based vaccine containing one CTL epitope from the HBV core region. This vaccine induced an HBV-specific CTL response in healthy volunteers in a phase I clinical trial that was comparable to CTL responses observed during acute HBV infection. In a phase II trial in patients with chronic HBV, however, CTL-based therapy was much less effective for suppressing HBV DNA<sup>[53]</sup>. This therapeutic approach may still be clinically useful if it is designed to recognize multiple CTL epitopes.

## CYTOKINES

Cytokines play a major role in controlling viral infections<sup>[54]</sup>. In a transgenic mouse model, type 1 IFNs ( $\alpha$  and  $\beta$ ) were shown to inhibit HBV viral replication<sup>[55,56]</sup>. IFN- $\gamma$  also prevents HBV replication by activating natural killer T (NKT) cells and T cells<sup>[57]</sup>, however, clinical trials with IFN- $\gamma$  did not show much benefit in patients with CHB<sup>[58]</sup>. Robek *et al*<sup>[59]</sup> reported that IFN- $\lambda$  inhibits HBV replication and induces IFN-stimulated gene expression using a mechanism distinct from that used by IFN- $\alpha$ ,  $\beta$ , or  $\gamma$ . Thus, IFN- $\lambda$  may be useful as a therapeutic agent in

the management of CHB.

Because of its ability to induce T cell proliferation, IL-2 is hypothesized to be an important immunostimulatory molecule, especially during chronic viral diseases<sup>[54]</sup>. IL-2 downregulates HBV gene expression in a transgenic mouse model and in patients with HIV, intermittent rIL-2 therapy prolongs CD4 T cell survival<sup>[60]</sup>. As a result, rIL-2 may be used as an adjunct therapy to prime other forms of immunomodulation such as therapeutic vaccination<sup>[61]</sup>.

Cavanaugh *et al*<sup>[62]</sup> demonstrated the antiviral efficacy of IL-12 in an HBV transgenic mouse model, however the overall reduction in viral titers was modest compared to other anti-HBV treatments<sup>[63]</sup>. Kimura *et al*<sup>[64]</sup> showed that IL-18 also inhibits HBV replication in a transgenic mouse model, but its efficacy in humans remains to be tested.

While many of these cytokines may not be potent as single agents they may help understand the mechanisms used by various immunomodulatory strategies to control HBV infection<sup>[61]</sup>.

## ADOPTED CELL THERAPY

Sun *et al* isolated peripheral blood mononuclear cells from patients and activated them by anti-CD3 monoclonal antibody, interleukin-2 and interferon- $\gamma$  *in vitro* for 10 d to produce multifactors activated immune cells (MAICs). When the cells have expanded and activated effectively 10 d later, these patients were transfused with these cells. Significant HBV inhibition was observed in 8 out of 14 until 1 year after transfusion. These findings strongly suggest that MAICs transfusion can effectively inhibit the replication of hepatitis B virus.

## GENE THERAPY

Researchers are developing novel nucleic acid-based interventions against HBV. These tools for manipulating gene expression are an attractive means of targeting HBV at different stages of its life cycle, with the ultimate goal of completely eradicating the virus<sup>[66]</sup>. Although this approach is not realistic for clinical use at this time, tremendous advances in this field have been made over the past few years. There are three gene therapy approaches: the use of antisense oligodeoxyribonucleic acids (ODNs), ribozymes, and short interfering RNAs (siRNAs). Some researches have shown significant results using these treatments, but the mode of delivering nucleic acid-based therapies remains a problem. Since HBV primarily replicates in hepatocytes, it is important that these compounds target the liver in order to reduce the required dose and minimize nonspecific effects<sup>[67]</sup>. Safety is also a potential concern with this therapeutic approach<sup>[68]</sup>, as is the issue of host enzymes biodegrading these compounds and rendering them ineffective. Nonspecific activation of the immune system is further noted as a risk of administering nucleic acid-based compounds<sup>[69]</sup>. Advances in delivery strategies and an improved understanding of the mechanisms of these technologies should lead to safer and more efficacious nucleic acid-based therapeutic approaches.

## CONCLUSIONS

Treatment of chronic HBV requires inhibiting hepatitis B virus replication or eliminating the virus from cells. The major problem with current treatments is the emergence of drug resistant variants over time. Novel therapies that target unique molecules or require shorter treatment time are still in demand. Several new anti-HBV nucleoside analogues are in different stages of clinical trials, and in the next decade we should see an increase in the use of agents designed to target specific molecules. The greatest challenge in the future of HBV treatment is the achievement of a safe, cost-effective, and durable regimen that takes advantage of novel therapeutic modalities.

### Abstract

**AIM:** To investigate whether serum levels of two soluble forms of extracellular cytokeratin 18 (M30-antigen and M65-antigen) may differentiate nonalcoholic steatohepatitis (NASH) from simple steatosis in patients with nonalcoholic fatty liver disease (NAFLD).

**METHODS:** A total of 83 patients with suspected NAFLD and 49 healthy volunteers were investigated. Patients with suspected NAFLD were classified according to their liver histology into four groups: definitive NASH ( $n = 45$ ), borderline NASH ( $n = 24$ ), simple fatty liver ( $n = 9$ ), and normal tissue ( $n = 5$ ). Serum levels of caspase-3 generated cytokeratin-18 fragments (M30-antigen) and total cytokeratin-18 (M65-antigen) were determined by ELISA.

**RESULTS:** Levels of M30-antigen and M65-antigen were significantly higher in patients with definitive NASH compared to the other groups. An abnormal value ( $> 121.60$  IU/L) of M30-antigen yielded a 60.0% sensitivity and a 97.4% specificity for the diagnosis of NASH. Sensitivity and specificity of an abnormal M65-antigen level ( $> 243.82$  IU/L) for the diagnosis of NASH were 68.9% and 81.6%, respectively. Among patients with NAFLD, M30-antigen and M65-antigen levels distinguished between advanced fibrosis and early-stage fibrosis with a sensitivity of 64.7% and 70.6%, and a specificity of 77.3% and 71.2%, respectively.

**CONCLUSION:** Serum levels of M30-antigen and M65-

### INTRODUCTION

Nonalcoholic fatty liver disease (NAFLD) is a common condition comprising a wide spectrum of liver damage associated with metabolic disorders, including central obesity, dyslipidemia, hypertension, and hyperglycemia. The spectrum of disease is variable, ranging from simple steatosis with benign prognosis, to nonalcoholic steatohepatitis (NASH), advanced fibrosis and cirrhosis, conferring increase in morbidity and mortality<sup>[1,2]</sup>.

NASH could be present in one third of NAFLD cases and appears to have a higher likelihood of progression to cirrhosis. Furthermore, an increased risk of hepatocellular carcinoma and end-stage liver disease has been reported among patients with NASH<sup>[3,4]</sup>. It follows that early recognition of subjects with NASH is crucial to prevent the development of severer forms of liver disease and improve the clinical outcome. Differentiation of simple steatosis from NASH requires histopathologic evaluation<sup>[5]</sup>. In this regard, liver biopsy remains the most sensitive and specific means of providing important diagnostic and prognostic information<sup>[6,7]</sup>. Nonetheless, given that liver biopsy is an expensive procedure, with occasional complications and poor patient acceptance<sup>[8-11]</sup>, the search for surrogate markers to replace liver biopsy is highly recommended.

A growing body of evidence has recently suggested that dysregulation of hepatocyte apoptosis could play an important role in the progression of NAFLD to

NASH<sup>[12-14]</sup>. During apoptosis, a number of intracellular proteins are cleaved by caspases. A neoepitope in cytokeratin 18 (CK18), termed M30-antigen, becomes available at an early caspase cleavage event during apoptosis and is not detectable in vital or necrotic cells<sup>[15-18]</sup>. A monoclonal antibody, M30, specifically recognizes a fragment of CK18 cleaved at Asp396 (M30-antigen)<sup>[19]</sup>. By contrast, the cytosolic pool of uncleaved CK18 (also termed M65-antigen) is released from cells during necrosis<sup>[19]</sup>. These findings implicate that assessments of different forms of CK18 in patient sera (M30-antigen for apoptosis and M65-antigen for necrosis) could be used to examine different cell death modes *in vivo*. Two robust immunoassays are currently available to measure the levels of M30-antigen and M65-antigen<sup>[20-22]</sup>.

In this study, we have measured different forms of CK18 (M30-antigen and M65-antigen) in serum from NAFLD patients as an approach for differentiating simple steatosis from NASH. Specifically, we wanted to establish a reliable diagnostic model by using these non-invasive biomarkers.

## MATERIALS AND METHODS

### Study participants

Between November 2005 and October 2006, we enrolled a total of 83 patients (38 females and 45 males, age range: 25-76 years) with suspected NAFLD. By the ATP III Expert Panel of the U.S. National Cholesterol Education Program criteria<sup>[23]</sup>, approximately one third of participants had the metabolic syndrome. Patients with viral hepatitis, hemochromatosis, Wilson's disease, autoimmune hepatitis, primary biliary cirrhosis, sclerosing cholangitis, biliary obstruction, alpha-1 antitrypsin deficiency, or malignancies were excluded from the present study. None of the subjects was using any medications, including estrogens, amiodarone, steroids, tamoxifen, or herbal supplements. Furthermore we excluded patients with daily alcohol intake exceeding 20 g/d or previous abdominal surgery. For control purposes, 49 healthy age- and gender-matched volunteers were recruited. All controls were judged to be in good health, with normal results on liver function tests and confirmed as having normal liver by ultrasound. Subjects with a consumption of alcohol > 20 g/d or who were taking any medication were not included in the control group.

A written informed consent was obtained from all participants. The study protocol was reviewed and approved by the Ethics Committee of the Uludag University Medical School.

### Clinical assessment

All subjects underwent physical examination, anthropometric measurements and biochemical screening. Liver ultrasound (US) scanning was performed to assess the degree of steatosis. All US procedures were performed by the same operator. Liver steatosis was assessed semiquantitatively on a scale of 0 to 3: 0, absent; 1, mild; 2, moderate; and 3, severe. Computed tomography (CT) evaluation of liver parenchyma was performed in all

NAFLD patients. An experienced pathologist examined liver histology according to the NIDDK NASH Clinical Research Network scoring system<sup>[24]</sup>. Patients with suspected NAFLD were classified according to their liver histology into four groups: definitive NASH ( $n = 45$ ), borderline NASH ( $n = 24$ ), simple fatty liver ( $n = 9$ ), and normal tissue ( $n = 5$ ). In a secondary analysis, patients with borderline NASH, simple fatty liver, and normal tissue were grouped together and analyzed as a single group which is named as no-NASH.

### Histological analysis

Ultrasonography-guided liver biopsies were performed under conscious sedation using a 16-gauge Klatskin needle. The length of histological specimens was not smaller than 2.5 cm. All biopsy specimens were placed in formalin solution for fixation and embedded in paraffin blocks. Serial sections (sectioned at 4  $\mu$ m intervals) were stained with hematoxylin-eosin, Masson's trichrome. An experienced pathologist blinded to clinical data scored the liver biopsies according to the NIDDK NASH Clinical Research Network scoring system<sup>[24]</sup>. Steatosis was scored from 0 to 3 with a four grades scoring system from S0 to S3: S0: no steatosis or less than 5%, S1: 5%-33%, S2: 33%-66%, S3: > 66%. Lobular inflammation was graded as follows: stage 0, no foci; stage 1: < 2 foci per 200  $\times$  field; stage 2: 2-4 foci per 200  $\times$  field; stage 3: > 4 foci per 200  $\times$  field. Fibrosis was staged as follows: stage 0: no fibrosis; stage 1: perisinusoidal or periportal fibrosis with 3 different patterns: 1A: mild, zone 3, perisinusoidal; 1B: moderate, zone 3, perisinusoidal fibrosis, and 1C portal/periportal fibrosis; stage 2: perisinusoidal and portal/periportal fibrosis; stage 3: bridging fibrosis; stage 4: cirrhosis. The histological NASH score was defined as the unweighted sum of the scores for steatosis (0-3), lobular inflammation (0-3), and ballooning (0-2); thus ranging from 0 to 8. Cases with scores of 0 to 2 were considered as having simple steatosis; on the other hand, cases with scores of 5 or greater were diagnosed as definitive NASH<sup>[24]</sup>. Cases with activity scores of 3 and 4 were considered as borderline (probable) NASH.

### ELISA assays

Blood samples were centrifuged at 2500 g for 10 min, and serum aliquots were stored at -80°C until immediately before analysis. All samples were analyzed in duplicate and in a blinded fashion. Serum levels of M30-antigen and M65-antigen were determined by commercially available immunoassays (M30-Apoptosense ELISA kit and M65 ELISA kit, Peviva AB, Bromma, Sweden) according to the manufacturer's instructions. The M65-ELISA assay measures native soluble CK18 (M65-antigen), whereas the M30-Apoptosense ELISA kit measures the levels of the CK18-Asp396 neo-epitope (M30-antigen). Briefly, samples were placed into wells coated with a mouse monoclonal antibody as a catcher. After washing, a horseradish peroxidase conjugated antibody (M30 or M65) was used for detection. Reference concentrations of M30-antigen or M65-antigen were used to prepare assay calibration. The absorbance was determined with an ELISA reader at 450 nm.

Table 1 General and biochemical characteristics of patients with suspected NAFLD

Characteristic	Entire cohort ( <i>n</i> = 83)	Definitive NASH ( <i>n</i> = 45)	Borderline NASH ( <i>n</i> = 24)	Simple steatosis ( <i>n</i> = 9)	Normal tissue ( <i>n</i> = 5)
Male gender	54.2%	62.2%	50.0%	44.4%	20.0%
Age (yr)	48.9 ± 9.1	47.8 ± 8.8	48.7 ± 6.2	53.1 ± 10.1	52.4 ± 19.2
Body mass index (kg/m <sup>2</sup> )	30.3 ± 4.8	30.2 ± 4.1	31.1 ± 6.5	29.5 ± 3.7	28.0 ± 3.0
Waist circumference (cm)	99 ± 9	101 ± 8	100 ± 9	94 ± 10	93 ± 11
Waist/hip ratio	0.93 (0.01-1.08)	0.95 (0.09-1.08)	0.93 (0.09-1.02)	0.8 (0.74-1.05)	0.86 (0.01-0.87)

<sup>1</sup>Data expressed as median (minimum-maximum); HOMA: homeostasis model assessment; HDL: high-density lipoprotein; Lp(a): lipoprotein(a); AST: aspartate aminotransferase; ALT: alanine aminotransferase; ALP: alkaline phosphatase; GGT: gamma glutamyl transpeptidase; LDH: lactate dehydrogenase; HbA1c: glycated hemoglobin; ANA: antinuclear antibodies; AMA: antimitochondrial antibodies; ASMA: anti-smooth muscle antibody; LKM-1, liver-kidney microsomal antigen.

### Statistical analysis

Variables are presented as counts and percentages or means ± SD, unless otherwise indicated. Pearson's  $\chi^2$  test was used for comparison of categorical variables. Between group mean differences were tested by the Mann-Whitney *U* test or the Kruskal-Wallis test, as appropriate. The sensitivity, specificity, positive predictive value, and negative predictive value of the serum biomarkers in predicting definitive NASH were calculated using receiver operating characteristic (ROC) analyses. Diagnostic properties were expressed as percentages, with 95% confidence intervals (95% CIs). Cut-off values for serum biomarkers were determined using the MedCalc demo statistical software (Mariakerke, Belgium). Univariate (simple) and multivariate (forward stepwise) regression models were used to assess the independent predictors of definitive NASH in patients with suspected NAFLD. A *P* < 0.05 was retained for statistical significance. All computations were made using SPSS 10.0 (SPSS Inc., Chicago, IL, USA).

## RESULTS

### Patients Characteristics

The control (*n* = 49) and NAFLD (*n* = 83) groups were

well balanced for age and gender (data not shown). Table 1 shows the clinical and biochemical characteristics of the NAFLD patients stratified by their liver histology into four groups: definitive NASH (*n* = 45), borderline NASH (*n* = 24), simple fatty liver (*n* = 9), and normal tissue (*n* = 5).

There was a statistically significant difference in microalbuminuria (*P* < 0.05), ALT levels (*P* < 0.05) and AST/ALT ratio (*P* < 0.05) between the four groups. By contrast, there were no statistically significant differences between the groups in age, gender, BMI, waist circumference, history of hypertension, hyperlipidemia, diabetes, or prevalence of the metabolic syndrome. Values of alkaline phosphatase, gamma-glutamyl transferase, lactic acid dehydrogenase, ferritin, and homeostasis model assessment-estimated insulin resistance (HOMA) were not significantly different across the four patient groups. 27% of patients with suspected NAFLD had positive serological testing for autoantibodies.

### Histopathology

The histological features of patients with suspected NAFLD are presented in Table 2. Of 83 subjects, 5 had normal biopsies with < 5% steatosis. Nine subjects had steatosis alone. In the present study, 24 patients with suspected NAFLD had histological borderline NASH.

Table 2 Histological findings in 83 patients with suspected NAFLD

Variable	Definition	Score	Entire cohort ( <i>n</i> = 83) (%)	Definitive NASH ( <i>n</i> = 45) (%)	Borderline NASH ( <i>n</i> = 24) (%)	Simple steatosis ( <i>n</i> = 9) (%)	Normal tissue ( <i>n</i> = 5) (%)
Steatosis	< 5%	0	8.40	0	8.30	0	100
	5%-33%	1	39.80	13.30	75.00	100	0
	> 33%-66%	2	30.10	46.70	16.70	0	0
	> 66%	3	21.70	40.00	0	0	0
Lobular inflammation (foci per 200 × field)	No foci	0	15.70	0	0	88.90	100
	< 2 foci	1	26.50	8.90	70.80	11.10	0
	2-4 foci	2	43.40	64.40	29.20	0	0
	> 4 foci	3	14.50	26.70	0	0	0
Ballooning	None	0	12	0	0	55.60	100
	Few balloon cells	1	24.10	6.70	70.90	44.40	0
	Many cells/prominent ballooning	2	63.90	93.30	29.10	0	0
Fibrosis stage	None	0	54.20	33.30	66.70	100	100
	Mild, zone 3, perisinusoidal	1A	8.40	11.10	8.30	0	0
	Moderate, zone 3, perisinusoidal	1B	3.60	6.70	0	0	0
	Portal/periportal	1C	13.30	15.60	16.60	0	0
	Perisinusoidal and portal/periportal	2	13.30	22.20	4.20	0	0
	Bridging fibrosis	3	7.20	11.10	4.20	0	0
	Cirrhosis	4	0	0	0	0	0

Table 3 Imaging findings in 83 patients with suspected NAFLD

Steatosis		Entire cohort ( <i>n</i> = 83)	Definitive NASH ( <i>n</i> = 45)	Borderline NASH ( <i>n</i> = 24)	Simple steatosis ( <i>n</i> = 9)	Normal tissue ( <i>n</i> = 5)
Sonographic grade of hepatosteatosis	Mild	44.00%	27.50%	50.00%	77.80%	100.00%
	Moderate	40.00%	55%	31.80%	11.10%	0%
	Severe	16.00%	17.50%	18.20%	11.10%	0%
Liver attenuation on CT (HU)		43.8 ± 14.6	36.9 ± 11.9	49.5 ± 15.1	55.2 ± 6.2	64.1 ± 3.3

Criteria for definitive NASH, as proposed by the NASH Clinical Research Network<sup>[24]</sup>, were fulfilled by 45 patients. Among patients with definitive NASH, liver biopsy showed that steatosis was mild in 13.3%, moderate in 46.7%, and severe in 40.0%. Lobular inflammation and ballooning were present in all biopsy specimens from definitive NASH patients in varying amounts. 77% of definitive NASH patients exhibited fibrosis. No liver biopsy demonstrated cirrhosis.

### Imaging

Ultrasound and CT findings are summarized in Table 3. Among the 83 subjects with suspected NAFLD, ultrasonographic examination revealed mild steatosis in 44%, moderate steatosis in 40% and severe steatosis in 16% of cases. By CT scans, the mean (SD) absolute liver density value of the entire study cohort was 43.8 ± 14.6 Hounsfield units (HU).

### Serum biomarkers

As shown in Table 4, the serum levels of M-30 antigen were markedly higher in the definitive NASH group than in the control ( $P < 0.001$ ), simple fatty liver ( $P < 0.01$ ) and borderline NASH ( $P < 0.001$ ) groups. Serum levels of M-30 antigen did not differ between patients with

definitive NASH and subjects with normal biopsy.

Serum concentrations of M-65 antigen were higher in the patients with definitive NASH than in those with borderline NASH ( $P < 0.001$ ), simple fatty liver ( $P < 0.01$ ), normal tissue ( $P < 0.05$ ), or in healthy individuals ( $P < 0.001$ ). Serum levels of both biomarkers did not differ between the possible NASH, simple steatosis, and normal biopsy groups compared with the control group.

Subjects with possible NASH, simple fatty liver, or normal tissue were then grouped together (no-NASH group,  $n = 38$ ) for a secondary analysis. The results of this analysis showed that the serum levels of both biomarkers were markedly higher in the definitive NASH group than in the no-NASH group ( $P < 0.001$  for both biomarkers).

### Diagnostic value of serum biomarkers for the prediction of definitive NASH

Table 5 lists the sensitivity, specificity, positive predictive value, and negative predictive value of the M30-antigen and the M65-antigen in predicting definitive NASH. In addition, the area under the ROC curve (ROC AUC) for both biomarkers was determined. The ROC AUC provides a measure of the overall discriminative ability of a test. In general, ROC AUC  $\geq 7$  indicates acceptable discrimination, ROC AUC  $\geq 8$  excellent discrimination

Table 4 Concentrations of serum M30-antigen and M65-antigen in the study groups

Biomarker	Definitive NASH (n = 45)	Borderline NASH (n = 24)	Simple steatosis (n = 9)	Normal tissue (n = 5)	Healthy volunteers (n = 49)	No-NASH (n = 38)	<sup>1</sup> P
M30-antigen (IU/L)	200.4 ± 183.1	69.8 ± 37.1	60.1 ± 36.8	81.0 ± 17.5	43.3 ± 45.9	69.0 ± 34.9	< 0.001
<sup>2</sup> P	Reference category	< 0.001	< 0.01	NS	< 0.001	< 0.001	
M65-antigen (IU/L)	362.8 ± 178.7	210.6 ± 59.6	215.3 ± 78.2	207.0 ± 47.4	150.9 ± 44.1	211.2 ± 61.5	< 0.001
<sup>2</sup> P	Reference category	< 0.001	< 0.01	< 0.05	< 0.001	< 0.001	

<sup>1</sup>P value calculated using Kruskal-Wallis test. <sup>2</sup>Comparisons between definitive NASH patients and other patient groups were performed by Mann-Whitney U Test.

Table 5 Diagnostic performance of serum M30-antigen and M65-antigen levels for the diagnosis of definitive NASH

Patient category	Serum biomarker	Cut-off value <sup>1</sup> (IU/L)	Sensitivity (95% CI)	Specificity (95% CI)	Positive predictive value (%)	Negative predictive value (%)	Negative likelihood ratio	Area under the ROC curve (95% CI)
Borderline NASH	M30-antigen	121.6	60 (44.3-74.3)	95.8 (78.8-99.3)	96.40	56.10	0.42	0.783 (0.668-0.783)
	M65-antigen	241.34	68.9 (53.3-81.8)	83.3 (62.6-95.2)	88.60	58.80	0.37	0.809 (0.697-0.894)

<sup>1</sup>Cut-off value corresponding to the highest accuracy value (minimal false negative and false positive results).

and ROC AUC  $\geq 9$  outstanding discrimination (very unusual). As shown in Table 5, both biomarkers revealed good discriminative ability for predicting definitive NASH. Notably, M30-antigen and M65-antigen gave similar diagnostic abilities.

#### Relationship between liver fibrosis and serum biomarkers

Table 6 shows the sensitivity, specificity, positive predictive value, and negative predictive value of M30-antigen and M65-antigen in differentiating early liver fibrosis from advanced fibrosis. Serum levels of both M30-antigen ( $P < 0.01$ ) and M65-antigen ( $P < 0.01$ ) were higher in patients with advanced fibrosis compared to those with early fibrosis. Both biomarkers appeared to have similar diagnostic ability.

#### Relationship between transaminases and serum biomarkers

We found a weak, albeit significant, positive correlation between M30-antigen levels with both AST ( $r = 0.441$ ,  $P < 0.001$ ) and ALT values ( $r = 0.425$ ,  $P < 0.001$ ). Similarly, concentrations of M65-antigen were positively related to both AST ( $r = 0.490$ ,  $P < 0.001$ ) and ALT ( $r = 0.473$ ,  $P < 0.001$ ).

#### Multivariate analysis

To assess the independent contribution of M30-antigen, M60-antigen as well as CT findings in identifying subjects with definitive NASH, simple and multiple linear regression analyses were performed (Table 7). Simple regression analysis showed that AST/ALT ratio, microalbuminuria, waist/hip ratio, CT density as well as levels of M30-antigen and M-65 antigen were all significantly associated

with the presence of definitive NASH (data not shown). Variables associated with definitive NASH on univariate analysis were then entered into a multivariate model. The model showed that the addition of M-30 antigen to computed tomography yielded a 86.1% sensitivity and a 83.3% specificity for NASH. Similarly, the addition of M-60 antigen to computed tomography yielded a 83.3% sensitivity and a 83.3% specificity for NASH.

## DISCUSSION

The results of our study show that different forms of CK18 in patient sera (M30-antigen and M65-antigen) may be of clinical usefulness in discriminating NASH from simple fatty liver or NAFLD patients with severe fibrosis from subjects with early fibrosis.

NAFLD is increasingly recognized as one of the most common causes of liver disease worldwide<sup>[25,26]</sup>. In this regard, in view of the epidemic of the metabolic syndrome, the prevalence of NAFLD is expected to continue to increase in future years<sup>[25]</sup>. A liver biopsy remains the gold standard for the evaluation of liver histology and is therefore a key test used to establish the diagnosis of NAFLD<sup>[1]</sup>. Unfortunately, it is an invasive procedure associated with discomfort and some risk<sup>[8,9]</sup>. It is therefore not suitable for the evaluation of all individuals with suspected NAFLD. The limitations of a liver biopsy have led to considerable interest and attempts to diagnose this condition with laboratory tests and imaging modalities.

Although simple fatty liver has been considered a benign disease, NASH appears to be a common cause of cryptogenic cirrhosis and may even result in hepatocellular carcinoma<sup>[26-28]</sup>. To date, the pathophysiological pathways

	M30-antigen	0.002	1.029	1.011-1.048					
Combination	CT	0.003	0.916	0.865-0.971	83.30	83.30	85.70	86.60	83.30
	M65-antigen	0.003	1.015	1.005-1.025					

involved in liver damage and in the progression of pure fatty liver to NASH remain largely unknown. Currently, the most accepted theory to explain the pathogenesis of NAFLD is the so-called “two-hit” hypothesis<sup>[29]</sup>. According to this model, the development of hepatic steatosis constitutes the first hit, and cellular events leading to hepatic inflammation constitute the second hit.

Experimental and clinical data have suggested a role for hepatocyte apoptosis in liver inflammation and tissue damage, regeneration of parenchyma, and fibrosis<sup>[30-33]</sup>. In this regard, a reduction in hepatocyte apoptosis has been shown to result in decreased liver fibrosis in animal models of cholestasis<sup>[32]</sup>. Of interest is also the observation that fibrosis has been suggested to rely on induction of hepatic stellate cells apoptosis<sup>[32]</sup>. In the clinical setting, Bantel *et al*<sup>[34]</sup> have previously shown that sera from patients with HCV infection had a markedly higher caspase activation than controls. In addition, measurements of caspase activity in serum were found to be related to the extent of steatosis or presence of fibrosis.

Recently, there has been a growing interest in measuring different CK18 forms in peripheral blood as a means to examine different cell death modes. Intriguingly, a recent report by Wieckowska *et al*<sup>[35]</sup> has shown that measurement of serum M30-antigen levels may allow discrimination of definitive NASH patients from simple fatty liver with high sensitivity and specificity. However, the sample size in this study was small, and no attempt was made to study the concentrations of M-30 antigen in patients with possible NASH.

Our present results confirm and expand previous findings<sup>[35]</sup> on the potential clinical usefulness of different forms of CK18 (M30-antigen and M65-antigen) as biochemical assays to accurately distinguish definitive NASH from simple fatty liver. Notably, we are also able to investigate a group of patients with possible NASH and to establish reliable cutoffs for the differential diagnosis of possible NASH from definitive NASH. Appropriate cut-off values for serum M-30 antigen and M-65 antigen

were 121.60 IU/L (sensitivity, 60.0%; specificity, 95.8%; positive predictive value, 96.4%; negative predictive value, 56.1%) and 241.34 IU/L (sensitivity, 68.9%; specificity, 83.3%; positive predictive value, 88.6%; negative predictive value, 58.8%), respectively. Altogether, these biochemical findings seem to indicate that possible NASH more closely resembles the clinical and pathophysiological features of simple fatty liver than those of definitive NASH.

Importantly, it remains a clinically crucial issue to distinguish definitive NASH from more benign forms of NAFLD<sup>[1]</sup>. The appropriate cut-off values for serum M-30 antigen and M-65 antigen that distinguish between NASH and no-NASH (borderline NASH, simple fatty liver, normal tissue) were 121.60 IU/L (sensitivity, 60.0%; specificity, 97.4%; positive predictive value, 96.4%; negative predictive value, 67.3%) and 243.82 IU/L (sensitivity, 68.9%; specificity, 81.6%; positive predictive value, 81.6%; negative predictive value, 68.9%), respectively. Of great interest, multivariate regression analysis showed that the combination of M-30 antigen and CT increased the sensitivity and specificity for definitive NASH to 86.1% and 83.3%, respectively. Similarly, the combination of M-65 antigen and CT increased the sensitivity and specificity for NASH to 83.3% and 83.3%, respectively. Altogether, our data suggest that measurement of different forms of CK18 in combination with CT has greater diagnostic utility for the identification of patients with definitive NASH than the use of either test alone.

A weak, albeit significant, correlation between serum forms of CK18 (both M30-antigen and M65-antigen) and levels of hepatic transaminases was found. Although it has been suggested that aminotransferases are released during necrosis at a higher rate than in apoptosis<sup>[36]</sup>, we found that hepatic transaminases were significantly correlated with levels of both M-30 antigen (a marker of apoptosis) and M-65 antigen (a marker of necrosis). To quantify the rates of apoptosis and necrosis in patients with definitive NASH, we also determined the M30:M65 ratio<sup>[22]</sup> as a means to investigate mode of cell death of hepatocytes

(data not shown). Of note, differently from other forms of NAFLD, the mode of such cellular death was apoptosis dominant in definitive NASH individuals compared to other NAFLD patient groups.

In summary, the results of the present study suggest that noninvasive monitoring of different forms of CK18 (M30-antigen and M65-antigen) in sera of patients with suspected NAFLD may represent a reliable tool to differentiate definitive NASH from simple fatty liver. Additionally, these biomarkers may be useful for identifying NAFLD patients with more severe liver fibrosis. Further validation studies in larger groups of patients are needed to confirm our findings.

## COMMENTS

### Background

Liver biopsy remains the gold standard for assessing histologic lesions of non-alcoholic fatty liver disease (NAFLD). Unfortunately, it is an invasive procedure associated with discomfort and some risk. The limitations of a liver biopsy have led to considerable interest and attempts to diagnose this condition with laboratory tests and imaging modalities.

### Research frontiers

As liver biopsy is impossible to perform as a diagnostic mass-screening tool, great effort is currently being spent in the validation of simple non-invasive markers of liver injury in patients with NAFLD. Specifically, the early identification of patients with nonalcoholic steatohepatitis (NASH) is of clinical importance because of the prognostic implications.

### Innovations and breakthroughs

We demonstrated that noninvasive monitoring of different forms of cytokeratin-18 (M30-antigen and M65-antigen) in sera of patients with suspected NAFLD may represent a reliable tool to differentiate definitive NASH from simple fatty liver. Additionally, these biomarkers may be useful for identifying NAFLD patients with severer liver fibrosis.

### Applications

In patients with non-alcoholic fatty liver disease, measurement of different forms of cytokeratin-18 in patient sera, a simple and non-invasive biomarker reliably predicts the presence or absence of NASH.

### Terminology

Cytokeratin-18: a cytoskeletal protein found primarily in epithelial cells; M30-antigen: a fragment of cytokeratin-18 cleaved at Asp396 by caspases (a marker of apoptosis); M65-antigen: full-length soluble cytokeratin-18 (a marker of necrosis).

### Peer review

This manuscript is pertinent, timely, with a fairly rigorous statistical approach to an important clinical question: what would be the best biological markers in human NAFLD.

## Abstract

**AIM:** To assess the adhesion and invasion abilities of different mouse adapted *H pylori* strains in different cell lines *in vitro* and investigate their effects on the virulence factors cagA and vacA.

**METHODS:** The adherence and invasion abilities of different *H pylori* strains in different epithelial cell lines were examined by the gentamycin protection assay. The null mutants of cagA and vacA were processed by direct PCR mutation method. The morphologic changes of different cell lines after *H pylori* attachment were examined by microscopy.

**RESULTS:** The densities of adherence to and invasion into cells *in vitro* were different from those in the mouse infection experiments. 88-3887 strain could invade and adhere to cells stronger than SS1 and X47. All tested strains had better adhering and invasive abilities in SCG-7901 cell. CagA and vacA minus mutants had the same invasion and adherent abilities as their wild types. In all strains and cell lines tested, only AGS cell had the significant hummingbird phenotype after inoculation with the 88-3887 wild-type.

**CONCLUSION:** Both the host cells and the bacteria play important parts in the invasion and adhesion abilities of *H pylori*. CagA and VacA are not related to the ability of invasion and adhesion of *H pylori* in different cell lines *in vitro*.

## INTRODUCTION

Infection with the human gastric pathogen *H pylori* can develop into chronic gastritis, peptic ulcer and gastric cancer<sup>[1-4]</sup>. Adhesion to the gastric epithelium and the host responses take the crucial role in the pathogenesis of *H pylori* infections.

Adherence is considered to be associated with both colonization and virulence properties of *H pylori*. A mouse infection model has been used to investigate the pathogenesis of *H pylori*<sup>[5-8]</sup>. Results from Dr. Berg, DE and colleagues suggested that different *H pylori* strains had gradient colonization abilities in various mouse cell lines *in vivo* (unpublished data). Studies at cellular levels showed *H pylori* induced the secretion of pro-inflammatory cytokines, cell proliferation, and apoptosis of epithelial cells and the cell lines were used as models for the investigation of the interaction between the bacteria and hosts *in vitro*<sup>[9-12]</sup>. There were proofs that *H pylori* were not present in the gastric epithelial cells but in the mucus layer overlying the gastric tissue<sup>[1,13]</sup>. However, there were also a number of biopsy studies<sup>[14-16]</sup> and cell culture infection models<sup>[17-21]</sup> that provided increasing evidence for the intracellular survival of *H pylori*. Internalization into the host cell should be considered a major strategy to evade the host immune response of the bacteria. Amieva *et al*<sup>[22]</sup> proved that the intercellular *H pylori* may be released to repopulate the extracellular environment again. It is well accepted that *H pylori* infection is hard to be eradicated in some cases, and triple drug therapy often fails to eliminate *H pylori* in infected patients<sup>[23-25]</sup>.

In this study, the adherence and invasion abilities of 3 mouse-adapted *H pylori* strains, which colonized the mice at different densities in different epithelial cells lines, were assessed by gentamycin adherence and invasiveness assay. Moreover, to investigate whether the virulence factors cagA and vacA could affect these abilities, mutants in these genes were established to examine their capacities to adhere to epithelial cells and compared to their wild-type counterparts.

## MATERIALS AND METHODS

### Bacteria and culture condition

The backgrounds of 3 mouse passed *H pylori* strains are shown in Table 1. All these mouse passed strains were

kindly offered by Dr. Berg DE, (Washington University, School of Medicine, St. Louis, MO 63110). The mouse inoculation experiments were done with C57BL/6J IL-12 KO mouse by Dr Berg DE's lab and the results from all these 4 strains were obtained. 88-3887 is a mouse adapted strain parentally from *H pylori* 26695. So far, there has been no reported data on the mouse colonization capacity of 88-3887 *cagA::cam* and SS1 *vacA::cam*.

Wild type *H pylori* strains of SS1, X47 and 88-3887 were grown in an *H pylori* selective medium (Columbia Agar Base supplemented with 5% sheep blood and 0.25 mg/mL vancomycin, 0.2 mg/mL amphotericin B, 0.2 mg/mL polymyxin B and 0.3 mg/mL trimethoprim) and incubated at 37°C in a microaerobic atmosphere containing 5% O<sub>2</sub>, 10% CO<sub>2</sub> and 85% N<sub>2</sub>. *CagA* and *vacA* null mutants (88-3887 *cagA::cam*, SS1 *vacA::cam*) were grown in an *H pylori* selective medium with 20 µg/mL chloramphenicol and cultured under the same condition as wild type strains.

### Generation of *H pylori* allelic replacement mutants

The null mutants for *cagA::cam* and *vacA::cam* were generated by direct PCR method as described previously<sup>[26,27]</sup>. Chloramphenicol resistance cassette (*cat*) was amplified using primers C1 and C2 designated from the pBlueScript II SK plasmid. The alleles in which *cagA* and *vacA* were replaced by *cat* were generated by the PCR method. The PCR products containing those Δ*cagA* (*cagA::cam*) and Δ*vacA* (*vacA::cam*) alleles were used to transform the wild-type *H pylori* strains 88-3887 and SS1 with selection for *Camr* (20 µg/mL). The primers for 88-3887 Δ*cagA* (88-3887 Δ*cagA::cam*) were *cagA*-P1, *cagA*-P2, *cagA*-P3 and *cagA*-P4. Primers for SS1 Δ*vacA* (SS1 Δ*vacA::cam*) mutant were *vacA*-P1, *vacA*-P2, *vacA*-P3 and *vacA*-P4. The sequences of the primers are listed in Table 2. All mutations were confirmed by specific PCR using *cat*, *vacA* and *cagA* genes.

### Preparation of cell line cultures

AGS cells (ATCC CRL 1739, human gastric adenocarcinoma epithelial cell line), SGC-7901 cells (human gastric cancer cell line from laboratory collection), MDCK cells (ATCC CCL-34, Marbin-Darby canine kidney epithelial cell line) were seeded to generate  $2 \times 10^5$  cells in RPMI 1640 medium supplemented with 10% FCS (Gibco BRL, Eggenstein, Germany) per well in 24-well tissue culture plates. The plates were incubated at 37°C in 5% CO<sub>2</sub> for 24 h. The culture medium was replaced with fresh RPMI1640 medium without FCS for 2 h before the inoculation of bacteria.

### Adherence and invasiveness assay

The 24 h cultured bacteria were harvested from plates with phosphate-buffered saline (PBS) and washed by centrifugation at 5000 r/min for 5 min at 4°C 3 times. The pellets were suspended in PBS to 1 OD<sub>600</sub> (approximately 108 CFU/mL), and 0.1 mL of this suspension was inoculated into each duplicate host cell wells to achieve a multiplicity of infection (MOI) of 100. As a control, 0.1 mL of PBS was added to each host cell lines. Infection was carried out at 37°C in 5% CO<sub>2</sub> for 5 h. After 5 h infection,

the monolayer was then washed 3 times with 1 mL RPMI1640 with 10% FCS medium and reincubated under the same conditions for another 2 h. Cell culture medium containing 25 mg/mL of gentamicin was added to each of the wells for the enumeration of intracellular bacteria (In preliminary experiments, 25 mg/mL of gentamicin could kill all *H pylori* isolates after a 2 h exposure and 0.1% saponin had no influence on *H pylori* culture compared with PBS). Following incubation, all monolayers (with or without gentamicin) were washed 5 times with RPMI 1640 and lysed with 0.1% saponin (Sigma cat#S-7900) in PBS. The suspensions were serially diluted. Both the intracellular bacteria and the total cell-associated bacteria were estimated by counting the number of CFU on *H pylori* selective plates. Results are expressed as the average from 3 independent experiments. Wild type *H pylori* strains and their mutants were inoculated into different cell lines respectively and mixed simultaneously. For the mix infection, the bacteria were counted on the normal selective medium and the selective medium with 20 µg/mL chloramphenicol separately.

### Image capture

After the co-culture of bacteria and different cells for 5 h, the monolayer cells were washed by PBS and the images were obtained under the microscope (Olympus BX 51).

## RESULTS

### Invasion and adherence abilities of *H pylori* strains in different cell lines

SS1, X47 strains had higher capacities to colonize the mice than 88-3887 but the intensities of their invasion and adherence in the cell lines were quite different. 88-3887

**Figure 1** Levels of adherence and invasion of *H pylori* in different cell lines. Bacteria were added to AGS cell monolayer at an MOI of 100 for 5 h at 37°C in a humidified atmosphere with 5% CO<sub>2</sub>. Data were obtained by adherence and invasiveness assays in three independent experiments and are expressed as CFU per well of AGS cells. The left side 3 refrangible lines indicate the ability of the adherence in 3 different cell lines. The right sides indicate the invasiveness ability in the 3 cell lines. Values represent the mean CFU of viable bacteria recovered per well of a 24-well tissue culture tray.

**Figure 2** Images showing morphologic changes induced by *H pylori* attachment. After co-culture of the bacteria with different cells for 5 h, the monolayer AGS cells were washed with PBS and the images were captured by microscopic Olympus BX51. **A:** AGS cell; **B:** The hummingbird/scattering appearance of AGS after being attached with 88-3887 wild-type, 5 h; **C:** AGS with *H pylori* 88-3887 cagA minus mutant (88-3887 cagA::cam), 5 h.

could invade and adhere to the cells better than SS1 and X47. The intensity of SS1 was lowest among the three tested strains. Each of the three *H pylori* strains had the highest adherent and invasive ability in the SCG-7901 cell. 88-3887  $\Delta$ cagA::cam and SS1  $\Delta$ vacA::cam had the same invasiveness and adherence ability as their wild type counterparts, respectively. The effects of different bacteria in different cell lines are shown in Figure 1.

### Morphologic changes of different cell lines after inoculation with *H pylori*

Cell morphology was examined under the microscope after 5 h co-culture. Fifty percent AGS cells became elongated like the hummingbird phenotype after attachment with 88-3887 wild type strain, while there were no such hummingbird like changes in AGS cell after inoculation with 88-3887  $\Delta$ cagA::cam. There were no significant hummingbird like phenotype in AGS after attachment with X47, SS1 and SS1vacA::cam strains. MDCK cells were scattered and slightly elongated after inoculation with 88-3887, 88-3887  $\Delta$ cagA::cam, SS1 and SS1  $\Delta$ vacA::

cam strains. After inoculation with X47 wild type strains, MDCK cells changed to round shape. The attachment of the 5 tested *H pylori* strains caused the SCG-7901 cells to become scattered, and there was no significant difference in phenotypic changes between different strains. The morphologic images are shown in Figure 2.

## DISCUSSION

*H pylori* is one of the most prevalent and persistent infectious agents in humans<sup>[28-30]</sup>. Adhesion is considered to be a major process for *H pylori* to colonize the host tissue and cause diseases. Intimate attachment to the host cells could facilitate the bacterium's colonization, efficient delivery of effector proteins such as cagA and vacA from the bacteria to the host cell and gain of nutrients from the environment. Bacteria with better adherence properties would colonize the host at higher densities and cause severe damage of the host<sup>[31,32]</sup>. Although *H pylori* have generally been considered as an extracellular pathogen, a number of *in vitro* infection experiments and biopsy

examinations have shown that it is capable of occasionally entering mammalian cells<sup>[33]</sup>. This penetration action may be one of the mechanisms for survival of the bacteria. In the present study, all tested *H pylori* strains adhered to SCG-7901, AGS and MDCK cells in a gradient way and the densities were  $10^{7-8}$ ,  $10^{3-5}$  and  $10^{2-4}$  CFU/mL, respectively. The intensities of the adhering ability in different cells in vitro were quite different from those in the mouse infection models *in vivo* and the *H pylori* adherence capacities in human cells were stronger than that in the canine kidney epithelial cells. According to this study, the invasive capacity was always consistent with the adhesion ability in all the tested cell lines, the higher the adhesion capacity, the better the invasion ability. Our results are consistent with previous evidence of the invasion ability in mammalian cells of *H pylori*<sup>[22,34]</sup> and it may imply the varied attachment mechanisms among different host species during *H pylori* infection. It also supports the view that both the host and bacterial factors mediate the adhesion and invasion of *H pylori*.

In the present study, the gentamicin protection assay was relatively simple, reproducible and measureable. Bacteria were determined after recovery from an additional 2 h incubation with gentamicin in the medium. The internalized bacteria were protected since the gentamicin could not penetrate the mammalian cell membranes. All the calculated data were repeated 3 times and each host cell had duplicate wells for each *H pylori* strain for validation.

CagA is present in some *H pylori* strains with enhanced virulence, and has been identified as an important risk factor for development of severe gastric diseases. *H pylori* strains are divided into two groups named type I and type II strains, based on whether they express cagA or not<sup>[35,36]</sup>. It was previously described that cagA was an effector protein of *H pylori* that was translocated *via* a type IV secretion system into gastric epithelial cells, interacted with different components in the host cell signal transduction pathways and the actin binding proteins, which ultimately affect the cytoskeletal organization<sup>[37-40]</sup>. This study shows no correlation between the presence of cagA with the ability of adhesion and invasion of *H pylori*. The only hummingbird response of AGS cell was induced by 88-3887 wild type strain but not the cagA minus mutant. This result is consistent with the previous conclusion that cagA plays a crucial role in the host cytoskeleton change. However, neither SS1 (cagA+) nor X47 (cagA-) could induce the same morphologic changes in the tested cells. Apart from AGS with the 88-3887 wild type, the other tested host cells attached with *H pylori* presented the under stress phenotypic changes such as cell scattering, elongation, and roundness in shape. These induced changes were not necessarily associated with cagA or vacA. It has been discovered that translocated cagA forms a physical complex with tyrosine phosphatase SHP-2, which plays an important role in the signal transduction pathway of the cell skeleton. According to the sequences constituting the SHP-2 binding site, cagA proteins can be sub-classified into East Asian and Western types, which have different binding and transforming activities<sup>[41,42]</sup>; while SS1 and 88-3887 all belong to the Western type. However, this could not explain why SS1

did not induce the same phenotypic change in AGS as 88-3887. SS1 also harbors cagA and could achieve high level mouse colonization. But this is controversial to the fact that the cag PAI in this strain is incomplete, as it lacks one open reading frame in the so-called 'left half' of the island<sup>[43,44]</sup>. On the other hand, we had no evidence to support that the gene defect SS1 strain caused different effects on AGS phenotypic changes from that of 88-3887 strain. Dana *et al*<sup>[45]</sup> reported that mouse adapted strains had a reduced capacity to induce inflammatory responses in AGS cells and suggests that such bacteria are more easily to colonize mice. The present results may indicate that the effector function of cagA in the host cell cytoskeletal rearrangement is pivotal and bacterium and host dependent. In different hosts, different *H pylori* strains invade *via* alternate receptor mechanisms, and various signal transduction pathways. The high degree genetic diversities of *H pylori* may be generated depending on the geographic origin or the ethnic origin of the host.

VacA cytotoxin is also considered to be an important virulence factor in *H pylori*, since it induces large cytoplasmic vacuoles in cultured mammalian cells. VacA is present in all *H pylori* strains and has been shown to be related to the colonization and intracellular survival of the bacteria<sup>[46,47]</sup>. This study shows that vacA has no effect on the adhesion and invasion abilities of *H pylori*. Our results are conflict with Terebiznik's data but consistent with Amieva *et al*<sup>[22]</sup>'s observation that the internalization of *H pylori* did not require vacA or cagA<sup>[48]</sup>. The phenotypic changes of the host cells attached with SS1 vacA minus mutant were the same as the wild type *H pylori* strains.

In summary, this study assesses the adherence and invasiveness abilities of different mouse adapted *H pylori* strains in different mammalian cell lines. The results imply that both the host-genetic and the microbial factors are involved in the development of the pathogenic infection outcome. VacA and cagA constitute important virulence factors of *H pylori* and both are delivered into the host cells depending on the intimate contact between bacteria and the gastric epithelial cells. This study suggests that neither vacA nor cagA is associated with the adhesion and invasion abilities of *H pylori* in different mammalian cell models. The phenotypic changes induced by *H pylori* are also host and bacterium dependent.

## ACKNOWLEDGMENTS

We are grateful to Dr. Douglas E Berg for his kind donation of the pBlueScript II SK plasmid and the entire mouse adapted *H pylori* strains.

## Abstract

**AIM:** To determine if proteasome inhibition induces apoptosis in human cholangiocarcinoma cells, and if so, to elucidate the cellular mechanisms.

**METHODS:** Studies were performed in the human KMCH, KMBC, and Mz-ChA-1 cholangiocarcinoma, and normal rat cell lines. MG132, a peptide aldehyde, which inhibits the chymotrypsin-like activity of the proteasome was employed for this study. Apoptosis was assessed morphologically by 4'-6-Diamidino-2-phenylindole (DAPI) nuclear staining and fluorescence microscopy. Mitochondrial membrane potential was examined using a fluorescent unquenching assay. Ultrastructural changes during cell death were examined using transmission electron microscopy (TEM). Caspase 3/7 activity was assessed using an enzymatic-based fluorescent assay. Cytosolic-free calcium concentrations were measured using Fura-2 and digitized fluorescent microscopy.

**RESULTS:** MG132, a proteasome inhibitor, induced apoptosis in all the cholangiocarcinoma cell lines examined. In contrast, minimal cytotoxicity was observed in normal rat cholangiocytes. Apoptosis was time- and -concentration-dependent. There was no change in the mitochondrial membrane potential between treated and untreated cells. Ultrastructural examination by transmission electron microscopy displayed the classic features of apoptosis, but in addition, there was also dramatic vacuolization of the endoplasmic reticulum (ER). Unexpectedly, no increase in caspase 3/7 activity was observed in MG132 treated cells, nor did the pancaspase inhibitor, Q-VD-OPh prevent cell death. The protein synthesis inhibitor, cycloheximide, blocked apoptosis induced by proteasome inhibitor indicating that ER dysfunction was dependent upon the formation of new proteins.

**CONCLUSION:** Proteasome inhibition induces ER

dysfunction and caspase-independent cell death selectively in human cholangiocarcinoma cells. Proteasome inhibitors warrant evaluation as anticancer agents for the treatment of human cholangiocarcinoma.

## INTRODUCTION

Cholangiocarcinoma is a malignant disease arising from the epithelial cells, termed cholangiocytes, lining the intra and extrahepatic bile duct. Unfortunately, the incidence of disease is increasing in many Western countries<sup>[1,2]</sup>. Surgery and liver transplantation are the only curative treatment options; however, disease recurrence is common even after ostensibly curative surgical procedures<sup>[3,4]</sup>. Non-surgical therapy is palliative and there is no proven medical therapy for this neoplasm. Thus, cholangiocarcinoma is a devastating disease which frequently causes death. Additional therapies are needed for the treatment of this cancer. Cholangiocarcinoma has many phenotypic similarities with the hematologic malignancy multiple myeloma. For example, both neoplasms are IL-6 dependent, evade apoptosis by overexpression of the Bcl-2 family protein Mcl-1, and are associated with genetic silencing of the tumor suppressor gene *p16*<sup>[5,6]</sup>. Recently, targeted inhibition of the proteasome has been shown to be effective anticancer therapy for multiple myeloma<sup>[7]</sup>. In contrast, the effect of proteasome inhibition as therapy for cholangiocarcinoma is unknown.

Proteasomes are complex macromolecular structures which enzymatically degrade ubiquitinated proteins<sup>[8]</sup>. The barrel shaped 20S proteasome is a very large ATP dependent proteolytic complex which has 4 rings that enclose a central hollow where proteolysis takes place<sup>[9]</sup>. Its 2 central  $\beta$ -rings contain multiple chymotrypsin-like, two trypsin-like and two caspase-like activities. The outer 2 alpha rings encircle a small opening through

which polypeptide substrates enter. These alpha rings are essential for assembly of the whole particle. The ubiquitin-proteasome pathway plays an important role in signal transduction, transcriptional regulation and response to stress<sup>[10,11]</sup>. Inhibition of this pathway can trigger cell cycle arrest at G1-S and G2-M phases of the cell cycle and apoptotic pathways<sup>[12]</sup>. Although proteasome inhibition may be predicted to have nonspecific cytotoxicity, malignant cells are much more sensitive to the proapoptotic effects of proteasome inhibition than normal cells<sup>[13]</sup>. The potential explanation for this selectivity appears to be due to the fact that cancer cells have more defective proteins accumulating at much higher rates than normal cells. This increases their dependency on optimal proteasome function to dispose of these proteins. Proteasome failure leads to the accumulation of these proteins which are toxic to the cell.

In cancer cells, the accumulation of proteins, due to proteasome inhibition induces cell death by multiple mechanisms. Loss of proteasome function can lead to accumulation of pro-apoptotic mediators which trigger the cellular apoptotic machinery<sup>[14,15]</sup>. For example proteasome inhibition leads to cellular accumulation of the proapoptotic BH3 domain only protein of the Bcl-2 family, Bim<sup>[15]</sup>. Bim dependent cell death is associated with mitochondrial dysfunction and activation of intracellular caspases, cysteine proteases which trigger canonical apoptotic programs<sup>[15]</sup>. By preventing activation of the pro-survival transcription factor, NF- $\kappa$ B, proteasome inhibition can also trigger apoptosis<sup>[16]</sup>. More recently, proteasome inhibitors have also been associated with cell death by inducing endoplasmic reticulum (ER) dysfunction<sup>[17]</sup>. Thus, the mechanisms of cell death by proteasome inhibition are complex and likely cell type specific.

The overall objective of this study was to determine if proteasome inhibition induces apoptosis in cholangiocarcinoma cell lines. The results demonstrate that proteasome inhibition induces caspase-independent cell death of human cholangiocarcinoma cell lines. This cell death pathway is associated with structural abnormalities of the ER. Proteasome inhibition appears to induce ER dysfunction and cell death in human cholangiocarcinoma cells.

## MATERIALS AND METHODS

### Reagents

MG132 was from Calbiochem (San Diego CA). Bortezomib was obtained from the Mayo Clinic Formulary (Rochester, MN). DMEM (Life Technologies, Gaithersburg, MD), fetal bovine serum (Summit Biotechnology, Fort Collins, CO), Penicillin-streptomycin (Bio-Whittaker, Walkersville, MD), gentamycin (GIBCO BRL, Life Technologies, Grand Island, NY), and O-VDOPh (Enzyme Systems, Livermore, CA), ECL (Amersham, Arlington Heights, IL), BAPTA, AM (Invitrogen, Eugene, OR) staurosporine (Sigma Chemicals Co, St Louis, MO) and cycloheximide (Sigma Chemicals Co, St Louis, MO) were purchased as indicated.

### Cell lines

The human cholangiocarcinoma cell lines KMCH-1,

KMBC, Mz-ChA-1, and normal rat cholangiocyte cell line were cultured in Dulbecco's modified Eagle medium supplemented with 10% fetal bovine serum, penicillin G (100 000 U/L), streptomycin (100 mg/L) and gentamycin (100 mg/dL) as described previously<sup>[18-20]</sup>. The normal rat cholangiocyte cell line was a generous gift from Nicholas F. LaRusso, Mayo Clinic, Rochester, MN<sup>[21]</sup>. Cells were maintained in a humidified incubator under an atmosphere containing 10% CO<sub>2</sub> at 37°C.

### Quantitation of apoptosis

Morphologic features of apoptosis were quantified by assessing the characteristic nuclear changes of apoptosis (i.e., chromatin condensation and nuclear fragmentation) using the nuclear binding dye 4',6-diamino-2-phenylindole dihydrochloride (Sigma chemicals, St. Louis, MO) and fluorescent microscopy<sup>[22]</sup>.

### Caspase 3/7 assay

Cells were cultured in 96 well plates (Corning, NY, NY). Cellular caspase activation was assessed using the Apo-One™ homogeneous caspase-3/7 Assay according to the supplier's instructions (the Apo-ONE™ Homogenous Caspase 3/7 activity kit-Promega Corporation, Madison WI, USA). The Apo-One™ Reagent was added directly to the cells in a 1:1 (Apo-One™ Reagent: cell culture medium) ratio of reagent to sample. After gently mixing by shaking at 300-500 r/min on a plate shaker for 30 s, the fluorescence of each well was measured at an excitation wave length of 485 and an emission wavelength of 530 nm using a fluorescent plate reader<sup>[23]</sup>.

### Transmission electron microscopy

Cultured KMCH cells were fixed using Trump's fixative as previously described<sup>[24]</sup>. Briefly, the media was aspirated and replaced with equal volume of Trump's fixative (1% glutaraldehyde and 4% formaldehyde in 0.1 mol/L phosphate buffer, pH 7.2). Specimens were post-fixed with 1% osmium tetroxide in 0.1 M cacodylate buffer and embedded in Spurr's resin. Thin sections (70 nm) were cut and placed on copper grids and double stained with uranyl acetate and lead citrate. The tissue was examined and photographed with a transmission electron microscope (1200 EXII; JEOL, Peabody, MA) operating at 60 kV. Electron micrographs of cholangiocarcinoma cells each were examined by two masked observers.

### Measurement of cytosolic free calcium (Ca<sup>2+</sup>)

Ca<sup>2+</sup> was measured in cultured KMCH cells loaded with fura-2 using multiparameter digitized videomicroscopy as previously described by us<sup>[25]</sup>. The microscope was a Zeiss IM-35 inverted fluorescence microscope (Thornwood, NY) equipped with phase contrast optics. A low light intensified video camera (Model 66, MTT-Dage, Michigan City, IN) collected fluorescent images which were digitized with a QVG/AFA-123 video acquisition and display board set (Imaging technologies, Woburn, MA) operating in a MicroPDP 11/23 computer (Digital Equipment Corporation, Maynard, MA). Ca<sup>2+</sup> was quantified by ratio imaging of fura-2

fluorescence excited at 340 and 380 nm. Fluorescence was taken through a 395 nm dichroic reflector and a 470-550 emission filter. By using a  $K_d$  of 224 nmol/L for the fura-2- $\text{Ca}^{2+}$  complex, the mean values of pixel ratios for each cell were converted to  $\text{Ca}^{2+}$  as described previously by Gyrinkiewicz *et al.*<sup>[26]</sup>.  $R_{\text{min}}$ ,  $R_{\text{max}}$  and  $\text{sfb2/sb2}$  values were calculated from measurements with fura-2 free acid solutions in capillary tubes (Vitro Dynamics, Inc., Rockaway, NJ) set on the microscope stage<sup>[27]</sup>. To test whether the involvement of  $\text{Ca}^{2+}$  homeostasis could be the key to the specific vulnerability of cholangiocarcinoma cells to proteasome inhibition, we co-treated KMCH cell cultures with an intracellular  $\text{Ca}^{2+}$  chelator, BAPTA-AM (5  $\mu\text{mol/L}$ ) with MG132 for 24 h.

### Quantification of mitochondrial membrane potential

The mitochondrial membrane potential in KMCH cells was measured by using a fluorescence unquenching assay as previously described in detail by us<sup>[28]</sup>. This assay is based on the concept of resonance energy transfer between the mitochondrial membrane potential-sensitive dyes tetramethylrhodamine ethyl ester and mitotracker green. Cellular fluorescence was depicted using the multiparameter digitized fluorescence microscopy system described above and quantified by a software program (Universal Imaging Co) as previously described elsewhere in detail<sup>[29]</sup>.

### Immunocytochemistry for cellular NF- $\kappa$ B localization

Cells, cultured on collagen-coated glass cover slips, were fixed with 4% paraformaldehyde. Cells were then permeabilized with 0.5% Triton-X in PBS and blocked with PBS containing 1% bovine serum albumin. To ascertain the cellular localization, cytoplasmic *vs* nuclear, for the p65 subunit of NF- $\kappa$ B, cells were next incubated with a polyclonal rabbit anti-p65 immunoglobulin G (sc-372, Santa Cruz Biotechnology, Santa Cruz, CA) in blocking buffer (1:1500) at 4°C overnight. After washing, Cy3-conjugated goat anti-rabbit Ig (Jackson Immuno Research Labs, West Grove, PA) in blocking buffer (1:1000) was added for one hour at room temperature. Cells were then imaged by confocal microscopy (Zeiss LSM 510, Carl Zeiss, Inc., Thornwood, NJ), as described previously in detail<sup>[30]</sup>.

### Statistical analysis

All data represent at least three independent experiments and are expressed as the mean  $\pm$  SE unless otherwise indicated. All of the data were expressed as means from three individual experiments. Differences between groups were determined by using the Student's *t*-test for unpaired observations.

## RESULTS

### Proteasome inhibition induces apoptosis selectively in human cholangiocarcinoma cells

MG132 was employed to inhibit proteasome proteolytic activity. Proteasome inhibition by MG132 induced apoptosis in all three human cholangiocarcinoma cells. Apoptosis was time-dependent and was maximal (65%  $\pm$  2%) at a

**Figure 1** Morphologic assessment of MG132 induced death in KMCH, KMBC and Mz-ChA-1 cholangiocarcinoma and normal rat cholangiocytes (NRC) cell lines. **A:** MG132 induces apoptosis in all cholangiocarcinoma cell lines was maximal (> 90%) with a MG132 concentration of 10 ( $\mu\text{mol/L}$ ); **B:** MG132 (1  $\mu\text{mol/L}$ ) induced apoptosis in the human KMCH cholangiocarcinoma cell line, but not in the nontransformed NRC cells; **C:** Apoptosis had the classic nuclear appearance as assessed by DAPI staining and fluorescence microscopy.

MG132 concentration of 1  $\mu\text{mol/L}$  at 24 h. Apoptosis was also concentration-dependent as maximal apoptosis (90%) was observed at 24 h in KMCH cells treated with 10  $\mu\text{mol/L}$  MG132 (Figure 1A, B, and C). In contrast, minimal cytotoxicity was observed in normal rat cholangiocytes treated with 10  $\mu\text{mol/L}$  MG132 (Figure 1B and C). As assessed by nuclear morphology, dead cells had the classic features of apoptosis (Figure 1C). We selected the KMCH cells for further mechanistic studies as this cell has been frequently employed for studies of human cholangiocarcinoma<sup>[31]</sup>.

### Proteasome inhibition induces caspase-independent cell death

In many models, but not all, apoptosis is caspase-dependent. To determine if MG132 mediated apoptosis is caspase-

**Figure 2** Caspase 3/7 activity and apoptosis in MG132 and staurosporine (SP) treated KMCH cells **A:** Cells were treated with MG132 1  $\mu\text{mol/L}$  and SP 5  $\mu\text{mol/L}$  for 16 h. Caspase 3/7 activity was increased SP cells ( $P < 0.05$ ). In contrast, caspase activity was not different for MG132 treated cells vs controls. **B:** Cell death was assessed by morphologic criteria using DAPI and fluorescence microscopy. Cells were treated with SP or MG132 for 24 h in the absence or presence of the pancaspase inhibitor, QVD at 5  $\mu\text{mol/L}$ . Note QVD blocked staurosporine, but not MG132, induced apoptosis. Data represent the mean  $\pm$  SE of three separate studies.

**Figure 3** Immunofluorescence for cell localization of the p65 NF- $\kappa$ B subunit. Cellular compartmentation of the p65 NF- $\kappa$ B subunit was examined in KMCH cells by confocal laser scanning microscopy. The p65 NF- $\kappa$ B subunit was completely cytoplasmic in untreated KMCH cholangiocarcinoma cells; its localization also remained cytoplasmic following exposure to MG132 (1  $\mu\text{mol/L}$ ) for 24 h.

dependent in KMCH cells, we initially measured caspase activity (Figure 2A). Unexpectedly, an increase in caspase 3/7 activity was not observed in MG132 treated cells, although a 5-fold increase was readily observed in staurosporine treated cells, an agent which induces caspase-dependent cell death<sup>[32]</sup>. Consistent with this observation, MG132 mediated apoptosis was also not inhibited by the pancaspase inhibitor QVD-OPh<sup>[33]</sup>. In contrast, QVD-(0Ph) readily inhibited staurosporine mediated apoptosis (Figure 2B). Thus, in human cholangiocarcinoma cells, proteasome inhibition is associated with caspase- independent cell death.

### **NF- $\kappa$ B is not constitutively activated in cholangiocarcinoma cells**

Several effects of proteasome inhibitors including apoptosis seem to be mediated through inhibition of NF- $\kappa$ B by blocking the degradation of I- $\kappa$ B<sup>[34]</sup>. Since this transcription factor is constitutively activated in many malignant cells, we examined NF- $\kappa$ B activation in cholangiocarcinoma by immunocytochemistry<sup>[35,36]</sup>. NF- $\kappa$ B nuclear immunoreactivity was not identified in cholangiocarcinoma cells (Figure 3). Thus, NF- $\kappa$ B is not constitutively activated in this cell type. Therefore, proteasome inhibition cannot induce apoptosis by blocking this pathway in this cell type.

### **Proteasome inhibition induces an ER stress pathway of apoptosis**

To further examine the mechanisms of cell by MG132 in

these cells, ultrastructural studies of the MG132 treated cells were performed. Both in MG132 and bortezomib treated cells, prominent ER vacuolization was observed. This observation was extremely pronounced and readily apparent in all apoptotic cells (Figure 4A). Thus, proteasome inhibition is associated with morphologic evidence for ER dysfunction. The specificity of proteasome inhibition in this cell type was verified by examining mitochondrial function. The mitochondrial membrane potential is a sensitive indicator of mitochondrial function. In contrast to the ER structure and function alterations, proteasome inhibition by MG132 did not perturb the mitochondrial membrane potential. Indeed, integrated mitochondrial membrane fluorescence (average fluorescent intensity  $\times$  pixels above background) was observed to be  $168736 \pm 17699$  and  $143269 \pm 8859$  in untreated and treated cells following 24 h of incubation, respectively ( $P = \text{NS}$ ). Thus, proteasome inhibition by MG132 induces significant ER structural alterations in the absence of mitochondrial dysfunction.

Because the ER stress pathway of cell death can be associated with sustained increases in cytosolic-free  $\text{Ca}^{++}$ , we next measured cytosolic-free  $\text{Ca}^{++}$  in MG132 treated KMCH cells. Sustained, but very modest, increases in cytosolic-free  $\text{Ca}^{++}$  were observed after treatment with MG132 and bortezomib. Cytosolic-free  $\text{Ca}^{++}$  concentrations increased only 2 fold ( $129 \pm 3$  nmol/L to  $244 \pm 33$  nmol/L with 1  $\mu\text{mol/L}$  MG132 and  $292 \pm 54$  nmol/L with 1  $\mu\text{mol/L}$  bortezomib,  $P < 0.05$ ). (Figure

**Figure 4** **A:** Morphologic features of apoptosis induced by proteasome inhibitors, MG132 and bortezomib in KMCH cells. On the left up panel, transmission electron microscopic appearance of untreated cholangiocarcinoma cell is depicted (bar = 0.5 μm). In the right up panel, exposure to MG132 (1 μmol/L) for 24 h results in a distinctly dilated ER (arrowhead) (bar = 2 μm). On the bottom-left panel, similar results are observed with MG 132 (0.5 μmol/L) for 24 h (arrowhead) (bar = 2 μm). Note apoptotic morphology also characterized by condensation of heterochromatin; On the bottom-right panel, high magnification image of cytoplasm shows dilated ER (arrowhead) (bar = 2 μm); **B:** Ca<sup>2+</sup> increases following treatment with proteasome inhibitors in KMCH cells. The time course of Ca<sup>2+</sup> changes is demonstrated. At 24 h, Ca<sup>2+</sup> levels were significantly increased in MG132 1 μmol/L and Bortezomib 1 μmol/L treated cells than untreated KMCH cells ( $P < 0.05$ ); **C:** Intracellular Ca<sup>2+</sup> chelation with BAPTA does not prevent apoptosis by MG132.

4B). Co-treatment of BAPTA-AM, a potent calcium-chelator, with MG132 did not reduce MG132 induced apoptosis (Figure 4C). Taken together, proteasome inhibition induces ER dysfunction and apoptosis in human cholangiocarcinoma cells. This ER dysfunction is characterized by morphologic changes in the ER and modest elevations in cytosolic-free calcium. However, the latter is unlikely to be the mediator of cell death.

**Figure 5** The translational inhibitor cycloheximide inhibits MG132 induced cell death in KMCH cells. The translational inhibitor, cycloheximide (CHM) 50 μmol/L, completely inhibited MG132 1 μmol/L induced apoptosis in KMCH cells co-treated with both agents for 24 h. Cell death was assessed by morphologic criteria using DAPI and fluorescence microscopy. Data represent the mean ± SE of three separate studies.

### Cycloheximide inhibits MG132 induced apoptosis

Proteasome inhibitors allow cellular protein synthesis to continue while they block degradation of damaged or unfolded proteins. Accumulation of unfolded proteins in the ER can trigger ER dysfunction and cell death. To ascertain if this is the mechanism of proteasome inhibitor mediated cell death in cholangiocarcinoma cells, the cells were co-incubated with MG132 plus cycloheximide, a protein synthesis inhibitor<sup>[37]</sup>. Cycloheximide remarkably blocked MG132 induced apoptosis (7.5 vs 64.5%,  $P < 0.05$ ) (Figure 5). This observation suggests active protein synthesis is necessary for the cytotoxicity of proteasome inhibition in human cholangiocarcinomas.

## DISCUSSION

The principal findings of this study relate to the mechanism of cell death in human cholangiocarcinoma cells by proteasome inhibition. The results demonstrated that (1) proteasome inhibition induces apoptosis in cholangiocarcinoma cells; (2) the cell death is caspase-independent; and (3) is associated with morphologic changes of the ER; and (4) the cell death is dependent upon protein synthesis. The results support the further exploration of proteasome inhibition as a therapeutic strategy for human cholangiocarcinoma. The proteasome inhibitor MG132 induced time- and concentration-dependent cell death in all cholangiocarcinoma cell lines examined. These data suggest proteasome inhibitors are potential anti-cancer drugs for this neoplasm. This class of agents is currently employed for the treatment of multiple myeloma. Although, the efficacy of proteasome inhibitors for the treatment of solid tumors has been disappointing, this may not be necessarily true for cholangiocarcinoma. Despite the fact that cholangiocarcinoma is an epithelial cell tumor, it has many phenotypic features similar to multiple myeloma including interleukin 6 dependent survival signaling pathways<sup>[38]</sup>. From this prospective, proteasome inhibitors may be anti-cancer drugs for cholangiocarcinoma as well.

Proteasome inhibitors have been reported to trigger caspase-dependent apoptosis by caspase-3 and 8 activation in multiple myeloma and chronic lymphocytic leukemia cells<sup>[16,39]</sup>. The caspase dependent apoptosis can be induced by preventing proteasome degradation of Bim, a potent proapoptotic member of the Bcl-2 family of proteins. Bim accumulation then triggers the mitochondrial pathway of

apoptosis. Nevertheless, MG132 induced apoptosis was found to be caspase independent in cholangiocarcinoma cell lines as an increase of caspase-3/7 activity was not observed in our studies. Likewise, there was no inhibition of apoptosis by a pancaspase inhibitor. Consistent with the lack of caspase activity, the mitochondrial membrane potential was also unperturbed in treated cells. This observation suggests proteasome inhibition triggers an alternative cell death pathway in these cells. Proteasome inhibitors have several anti-tumoral mechanisms. One of them is by inactivation of the transcription factor, NF- $\kappa$ B. Indeed, inhibition of NF- $\kappa$ B is a prominent mechanism by which proteasome inhibition induces apoptosis. In response to cellular stress; I- $\kappa$ B is degraded by proteasomes and NF- $\kappa$ B released activating transcription of genes for several factors including apoptosis inhibitors<sup>[16]</sup>. However, our current study demonstrated that NF- $\kappa$ B is not constitutively active in KMCH, KMBC and Mz-ChA-1 cholangiocarcinoma cell lines and, therefore, proteasome inhibitors can not induce cell death in these cells by blocking NF- $\kappa$ B activation.

The ER can be involved as a primary target organelle in apoptosis. Secretory proteins or proteins for plasma membrane are modified and acquire their correct folding conformation in the ER. Proteins that are unable to fold properly in the ER are degraded by the proteasome. It is proposed that proteasome inhibition can cause the accumulation of misfolded proteins, resulting in excessive ER stress<sup>[17]</sup>. Transformed cells are particularly sensitive to the ER cell death pathway<sup>[40]</sup>. Indeed, our ultrastructural studies demonstrated marked alterations of ER morphology by proteasome inhibition. Similar morphologic findings have also been reported in glioma cells undergoing apoptosis after treatment with proteasome inhibitor, bortezomib<sup>[41]</sup>. The protein synthesis inhibitor cycloheximide did reduce cell death by the proteasome inhibitor MG132. This observation suggests that accumulation of misfolded or unfolded proteins following protein inhibition likely contributes to the ER morphologic changes and cell death observed in the current study. The ability of MG132 to induce cell death in the cells by a selective mechanism is of therapeutic interest. Drugs such as bortezomib warrant further attention as therapeutic agents in the treatment of cholangiocarcinoma.

### Abstract

**AIM:** To evaluate the ability of the time-signal intensity curve (TIC) of the pancreas obtained from dynamic contrast-enhanced magnetic resonance imaging (MRI) for differentiation of focal pancreatic masses, especially pancreatic carcinoma coexisting with chronic pancreatitis and tumor-forming pancreatitis.

**METHODS:** Forty-eight consecutive patients who underwent surgery for a focal pancreatic mass, including pancreatic ductal carcinoma ( $n = 33$ ), tumor-forming pancreatitis ( $n = 8$ ), and islet cell tumor ( $n = 7$ ), were reviewed. Five pancreatic carcinomas coexisted with longstanding chronic pancreatitis. The pancreatic TICs were obtained from the pancreatic mass and the pancreatic parenchyma both proximal and distal to the mass lesion in each patient, prior to surgery, and were classified into 4 types according to the time to a peak: 25 s and 1, 2, and 3 min after the bolus injection of contrast material, namely, type- I, II, III, and IV, respectively, and were then compared to the corresponding histological pancreatic conditions.

**RESULTS:** Pancreatic carcinomas demonstrated type-III ( $n = 13$ ) or IV ( $n = 20$ ) TIC. Tumor-forming pancreatitis showed type- II ( $n = 5$ ) or III ( $n = 3$ ) TIC. All islet cell tumors revealed type- I. The type-IV TIC was only recognized in pancreatic carcinoma, and the TIC of carcinoma always depicted the slowest rise to a peak among the 3 pancreatic TICs measured in each patient, even in patients with chronic pancreatitis.

**CONCLUSION:** Pancreatic TIC from dynamic MRI provides reliable information for distinguishing pancreatic carcinoma from other pancreatic masses, and may enable us to avoid unnecessary pancreatic surgery and delays in making a correct diagnosis of pancreatic carcinoma, especially, in patients with longstanding chronic pancreatitis.

### INTRODUCTION

The differential diagnosis between carcinoma and benign lesion in the pancreas is extremely important because surgical resection offers the only chance of a cure in patients with pancreatic carcinoma or, conversely, may result in unnecessary risk of morbidity and mortality for benign lesions. Recent advances in imaging techniques have enabled us to precisely detect pancreatic carcinoma, however, it still remains difficult to distinguish chronic pancreatitis from this dismal pancreatic malignancy because chronic pancreatitis occasionally presents as a focal pancreatic swelling or mass with similar clinical and radiologic features to pancreatic carcinoma<sup>[1-3]</sup>. To complicate this issue even further, chronic pancreatitis may develop into pancreatic carcinoma<sup>[4-7]</sup>, and also pancreatic carcinoma may develop obstructive chronic pancreatitis secondary to pancreatic ductal obstruction<sup>[2,8,9]</sup>.

Both pancreatic carcinoma and chronic pancreatitis

possess a large degree of fibrosis<sup>[10-13]</sup>, which is associated with a gradual progressive enhancement on contrast-enhanced computed tomography (CT) and dynamic magnetic resonance imaging (MRI)<sup>[2,3,14,15]</sup>, making the distinction of these entities difficult. We recently demonstrated a time-signal intensity curve (TIC) of the pancreas obtained from dynamic contrast-enhanced MRI to be a reliable and non-invasive monitoring technique for a precise evaluation of pancreatic fibrosis<sup>[16]</sup>. In this study, we investigated the ability of the pancreatic TIC from dynamic MRI to differentiate pancreatic carcinoma from other focal pancreatic masses, especially in patients with chronic pancreatitis.

## MATERIALS AND METHODS

We evaluated 48 consecutive patients who underwent surgery for focal pancreatic masses due to focal solid tumors or focal enlargement of the pancreas, between March 1999 and May 2006. The pancreatic masses with cystic components, such as cystadenocarcinoma, intraductal papillary-mucinous neoplasm, solid-pseudopapillary tumor, or pseudocyst, were excluded. The patients ranged in age from 45 to 82 years, with a mean of 65 years. There were 30 men and 18 women. From the clinical and radiologic findings, 34 patients were suspected of having pancreatic carcinoma, 7 of having focal chronic pancreatitis (so-called tumor-forming pancreatitis), and 7 of having islet cell tumor. The surgical interventions consisted of a pancreaticoduodenectomy (PD,  $n = 13$ ), a pylorus-preserving pancreaticoduodenectomy (PPPD,  $n = 18$ ), a duodenum-preserving pancreatic head resection (DPPHR,  $n = 1$ ), a middle pancreatectomy (MP,  $n = 2$ ), a distal pancreatectomy (DP,  $n = 13$ ), and a hepaticojejunostomy together with biopsies of the pancreas ( $n = 1$ ). The postoperative histological evaluations of the surgical specimens revealed the pancreatic masses to be pancreatic ductal carcinoma in 33, tumor-forming pancreatitis in 8, and an islet cell tumor in 7.

All 48 patients received dynamic contrast-enhanced MRI of the pancreas prior to surgery. The pancreatic MRI was conducted by using the 1.5-T superconducting system (SIGNA Horizon LXTM; GE Medical Systems, Milwaukee, WI). We used a fat-suppressed three-dimensional fast spoiled gradient re-called echo sequence with the following imaging parameters: TR/TE, 6.0-6.1/1.3-1.4 msec; flip angle, 20°; section thickness, 6-8 mm; no intersection gap; matrix, 256 × 160; 1 excitation; field of view, 32-36 cm. The dynamic series comprised 5 individual dynamic images, obtained before and 25 s and 1, 2 and 3 min after the rapid bolus injection of 0.1 mmol of meglumine gadopentetate (Magnevist®; Schering, Berlin, Germany)/kg of body weight. The contrast medium was administered intravenously at approximately 3 mL/s followed by flushing with 20 mL saline solution. The original MRI data were then loaded onto a workstation, and the regions of interest (ROI) were placed at 3 different parts of the pancreas in each patient, i.e., the pancreatic mass and the non-tumorous pancreatic parenchyma both proximal (head-sided) and distal (tail-sided) to the mass

**Figure 1** Patterns of the time-signal intensity curve (TIC) from dynamic contrast-enhanced magnetic resonance imaging of the pancreas.

lesion. The ROI ranged in size from 0.2 to 1 cm<sup>2</sup>. The pancreatic TIC was then generated as a percentage increase in the signal intensity (SI), according to the following enhancement formula: (SIpost-SIpre)/SIpre × 100, where SIpre and SIpost represent the pre- and post-contrast SIs, respectively.<sup>16</sup> The patterns of pancreatic TIC were classified into 4 types (Figure 1): type-I, characterized by a rapid rise to a peak (25 s after injection of contrast material) followed by a rapid decline; type-II, with a slow rise to a peak (1 min after administration of contrast material) followed by a slow decline; and type-III or IV, with an even slower rise to a peak (2 or 3 min after the administration of contrast material) followed by a slow decline or plateau.

A retrospective review of the preoperative pancreatic MRI study and pancreatic histology was performed, and the patterns of TIC from dynamic MRI measured at the 3 parts of the pancreas were then compared with the corresponding histological pancreatic sections in each patient.

## RESULTS

The clinicopathological characteristics and the results of a pancreatic MRI study of 33 patients with pancreatic ductal carcinoma are described in Table 1.

Pancreatic carcinomas developed in a normal pancreas in 28 patients, whose preoperative diagnosis based on the clinical and radiologic findings was identical to the histological diagnosis. Pancreatic carcinomas demonstrated type-III ( $n = 12$ ) or type-IV ( $n = 16$ ) TIC. In contrast, the pancreatic parenchyma proximal to the tumor showed type-I TIC, while the distal pancreas revealed type-I ( $n = 5$ ) or type-II ( $n = 23$ ) TIC (Figure 2). A histological study of the distal pancreas showing type-II TIC revealed obstructive chronic pancreatitis with mild to severe fibrosis.

Five patients had pancreatic carcinoma in the background of longstanding chronic pancreatitis. Two

of them underwent surgery under a diagnosis of tumor-forming pancreatitis and were confirmed to be pancreatic carcinoma during the operation: one patient underwent a pancreaticoduodenectomy, while the other received a palliative operation because of the far advanced stage of the disease. The TIC profiles of 5 carcinomas coexisting with chronic pancreatitis showed type-III ( $n = 1$ ) or type-IV ( $n = 4$ ) TIC. Although the proximal and distal pancreas demonstrated type-II or type-III pancreatic TIC, pancreatic carcinoma displayed a distinctive TIC profile in every patient, depicting the slowest rise to a peak among the 3 pancreatic TICs measured in each individual pancreas

(Figure 3).

In 8 patients with tumor-forming pancreatitis, 6 lesions were associated with longstanding chronic pancreatitis and 2 lesions were recognized in a normal pancreas (Table 2). Preoperative diagnosis of these patients was tumor-forming pancreatitis, but in 2 patients, who underwent a pylorus-preserving pancreaticoduodenectomy together with lymphadenectomy, the possibility of carcinoma of the head of the pancreas could not be ruled out and the definitive diagnosis of chronic pancreatitis was confirmed after surgery. The focal pancreatic masses due to tumor-forming pancreatitis demonstrated the TIC of type-II ( $n =$

**Figure 4** Tumor-forming pancreatitis in a 70-year-old man with a long history of alcohol abuse. The patient underwent a pylorus-preserving pancreaticoduodenectomy together with lymphadenectomy for a suspected pancreas head carcinoma associated with obstructive jaundice and was confirmed to be chronic pancreatitis after surgery. **A, B:** Dynamic contrast-enhanced MRI images of the pancreas. The ROIs are placed at the pancreatic mass (No.2 ROI) and the pancreatic parenchyma both proximal (nNo.1 ROI) and distal (No.3 ROI) to the mass lesion; **C:** Both of the pancreatic TICs obtained from the No.1 and no.2 ROIs as in Figure 4A demonstrate type- II; **D:** Pancreatic TIC obtained from the No.3 ROI as in Figure 4B also shows type- II.

TIC: time-signal intensity curve; Ph: pancreatic head, Pb: pancreatic body; PPPD: pylorus-preserving pancreaticoduodenectomy; DPPHR: duodenum-preserving pancreatic head resection; MP: middle pancreatectomy; DP: distal pancreatectomy; NFICT: non-functioning islet cell tumor.

5) or type-III ( $n = 3$ ). Meanwhile, the TICs of the proximal and distal pancreas varied in type from type- I to type-III. In comparing 3 pancreatic TICs measured for each patient, the TIC profile of the focal mass was identical to TICs of both the proximal and distal pancreas in 3 patients (Figure 4), or equal to at least one of these TICs in 5 patients.

In 7 patients with islet cell tumors, a correct diagnosis was made preoperatively on the basis of their characteristic clinical and radiologic features. The tumors demonstrated type- I TIC, and the TICs of the proximal and distal pancreas also showed type- I (Table 3). The histological study revealed the non-tumorous pancreatic parenchyma to be normal in these cases.

Overall, pancreatic ductal carcinomas demonstrated type-III ( $n = 13$ ) or IV ( $n = 20$ ) TIC, and the type-IV TIC was only recognized in pancreatic carcinoma among the 48 series of focal pancreatic mass. Moreover, the TIC profile of carcinoma always depicted the slowest rise to a peak

among the 3 pancreatic TICs measured in each patient. Tumor-forming pancreatitis showed type- II ( $n = 5$ ) or III ( $n = 3$ ) TIC, and the TICs of the focal mass due to chronic pancreatitis were identical to at least one of the TICs in the proximal and distal pancreas in each patient. All islet cell tumors revealed type- I TIC.

## DISCUSSION

The differentiation between pancreatic carcinoma coexisting with chronic pancreatitis and focal mass due to chronic pancreatitis continues to be a challenge. Although various diagnostic modalities have been proposed to help differentiate these 2 pancreatic entities<sup>[17-22]</sup>, the accuracy of each method varies and no single non-invasive method for making a correct diagnosis has yet been suggested. The presence of a focal pancreatic mass is generally indicative of a neoplasm, and thus the patients are often subjected to

major pancreatic surgery such as pancreaticoduodenectomy for presumed pancreatic malignancy that proves later to be benign in 5% to 11% of all cases<sup>[23-26]</sup>. In our series, 2 of 8 patients with tumor-forming pancreatitis underwent a pancreas head resection along with lymphadenectomy, because pancreatic carcinoma could not be ruled out. Conversely, 2 patients with preoperative diagnosis of tumor-forming pancreatitis were revealed to have pancreatic malignancy during operation. An accurate preoperative differential diagnosis is needed to avoid such unnecessary surgery and delays in making a correct diagnosis of pancreatic carcinoma.

The present study on the differentiation of focal pancreatic masses with dynamic contrast-enhanced MRI demonstrated that pancreatic ductal carcinomas exhibit a characteristic TIC profile which is different from other focal masses of the pancreas. The type-IV TIC was a unique profile indicative of pancreatic carcinoma since no other focal pancreatic masses displayed type-IV TIC. A representative TIC profile pattern of the pancreas with carcinoma was comprised of type- I TIC in the proximal pancreas, type-IV TIC in the mass lesion, and type- II TIC in the distal pancreas. Our previous study demonstrated the fibrosis ratios of pancreas with type- I , II , or III TICs as to be 3.5% (range, 1.5-10.1), 15.9% (range, 7.5-25.2), and 22.6% (range, 17.8-27.3), respectively<sup>[16]</sup>. In the present study, the type- II TIC of the distal pancreas in patients with pancreatic carcinoma also reflected the increase in fibrosis in the distal pancreas due to obstructive chronic pancreatitis. Similar findings of delayed enhancement of the pancreas distal to pancreatic carcinoma have been noted on both dual-phase CT examinations<sup>[2]</sup> and a dynamic MRI study<sup>[8]</sup>.

On the other hand, there was an overlap in the TIC profile between pancreatic carcinoma and tumor-forming pancreatitis in this study, i.e., type-III TIC. The type-III TIC accounted for 39% (13/33) of pancreatic carcinoma and 38% (3/8) of tumor-forming pancreatitis. However, the series of pancreatic TICs measured in 3 parts of the individual pancreas provided helpful information for distinguishing these 2 pancreatic pathologies. The TIC profile of a mass due to carcinoma always depicted the slowest rise to a peak among the 3 pancreatic TICs, even in carcinomas occurring in patients known to have longstanding chronic pancreatitis, while the TIC profile of the focal mass due to chronic pancreatitis was identical to at least one of the proximal and distal pancreatic TICs in individual patients. Chronic pancreatitis has a risk for pancreatic carcinoma with an incidence of 2% after 10 years and 5.9% after 20 years of documented chronic pancreatitis<sup>[4]</sup>, and the diagnosis of pancreatic carcinoma in this setting may therefore be difficult or even impossible<sup>[1,24,25,27,28]</sup>. Thus far, at the time of detection, the majority of patients with pancreatic carcinoma associated with chronic pancreatitis tend to be surgically unresectable. However, our findings suggest that the pancreatic TIC from dynamic MRI is a potential diagnostic tool for detecting pancreatic carcinoma in patients with longstanding chronic pancreatitis, which enable us to distinguish pancreatic

carcinoma from tumor-forming pancreatitis.

The major morphologic change of chronic pancreatitis is the progressive destruction of the exocrine parenchyma with replacement by dense fibrous tissue<sup>[1-3]</sup>. However, pancreatic carcinomas also possess an abundant degree of fibrosis<sup>[10,12]</sup> since pancreatic carcinoma cells induce fibrosis by the stimulation of pancreatic stellate cells<sup>[29,30]</sup>. Fibrosis diminishes the amount of aqueous protein in the pancreatic acini and the capillary network of the pancreas that may underlie both the loss of signal intensity in the pancreas on fat-suppressed T1-weighted images and the diminished enhancement on dynamic contrast-enhanced images<sup>[31,32]</sup>. Experimental and clinical studies have demonstrated alcoholic or occlusive chronic pancreatitis and pancreatic carcinoma to be associated with tissue fibrosis, a reduced blood vessel density<sup>[33,34]</sup>, and a decreased pancreatic blood flow<sup>[35-38]</sup>. In contrast, pancreatic islet cell tumors are hypervascular neoplasms<sup>[39]</sup> and it is therefore reasonable that all pancreatic islet cell tumors showed type- I TIC in this study. The number of blood vessels, the amount of aqueous protein, and the degree of fibrosis in the pancreas, along with the difference in the mass-to-pancreatic parenchymal contrast, may together play a role in the MRI contrast-enhancement of pancreatic masses. However, there is a considerable discrepancy in the reported results of the blood vessel count and the degree of fibrosis in pancreatic carcinoma, tumor-forming pancreatitis, tumor-associated chronic pancreatitis, and the normal pancreas<sup>[10,33,34,40-44]</sup>. To clarify the precise pancreatic pathology based on the pancreatic TIC from dynamic MRI, a qualitative assessment of the changes in pancreatic microcirculation during neovascularization and the obliteration of the small vessels by fibrosis or cancer cells is thus called for.

In conclusion, pancreatic TIC from dynamic MRI was found to provide reliable information for differentiating pancreatic carcinoma from a focal mass due to chronic pancreatitis and for also detecting pancreatic carcinoma associated with longstanding chronic pancreatitis. This imaging technique may therefore make it possible to eliminate the number of exploratory laparotomies as well as unnecessary major pancreatic surgery and delays in making a correct diagnosis of pancreatic carcinoma, especially in patients associated with chronic pancreatitis.

## Abstract

**AIM:** To transplant undifferentiated embryonic stem (ES) cells into the spleens of carbon tetrachloride (CCl<sub>4</sub>)-treated mice to determine their ability to differentiate into hepatocytes in the liver.

**METHODS:** CCl<sub>4</sub>, 0.5 mL/kg body weight, was injected into the peritoneum of C57BL/6 mice twice a week for 5 wk. In group 1 ( $n = 12$ ),  $1 \times 10^5$  undifferentiated ES cells (0.1 mL of  $1 \times 10^6$ /mL solution), genetically labeled with GFP, were transplanted into the spleens 1 d after the second injection. Group 2 mice ( $n = 12$ ) were injected with 0.2 mL of saline twice a week, instead of CCl<sub>4</sub>, and the same amount of ES cells was transplanted into the spleens. Group 3 mice ( $n = 6$ ) were treated with CCl<sub>4</sub> and injected with 0.1 mL of saline into the spleen, instead of ES cells. Histochemical analyses of the livers were performed on post-transplantation d (PD) 10, 20, and 30.

**RESULTS:** Considerable numbers of GFP-immunopositive cells were found in the periportal regions in group 1 mice (CCl<sub>4</sub>-treated) on PD 10, however, not in those untreated with CCl<sub>4</sub> (group 2). The GFP-positive cells were also immunopositive for albumin (ALB), alpha-1 antitrypsin, cytokeratin 18, and hepatocyte nuclear factor 4 alpha on PD 20. Interestingly, most of the GFP-positive cells were immunopositive for DLK, a hepatoblast marker, on PD 10. Although very few ES-derived cells were demonstrated immunohistologically in the livers of group 1 mice on PD 30, improvements in liver fibrosis were observed. Unexpectedly, liver tumor formation was not observed in any of the mice that received ES cell transplantation

## INTRODUCTION

Embryonic stem (ES) cells are self-renewing and multipotent cells derived from the inner cell masses of preimplantation blastocysts<sup>[1,2]</sup>, and have many characteristics of an optimal cell source for cell-replacement therapy. Theoretically, ES cells are able to be produced limitlessly, and various kinds of cell-types have been generated *in vitro* and *in vivo*. Thus, ES cells are considered to have potential to become an optimal cell source for cell-replacement therapy.

We previously showed that mouse ES cells have an ability to differentiate into hepatocyte-like cells *in vitro* using an attached culture of embryoid bodies (EBs)<sup>[3]</sup> and demonstrated that introduction of transcription factor gene hepatocyte nuclear factor 3 beta, which plays an important role in liver development, led to an efficient induction of ES cells into hepatocyte-like cells<sup>[4,5]</sup>. The *in vitro* capability of ES cells to differentiate into hepatocyte-like cells has also been proven by other investigators<sup>[6-21]</sup>. In general, the methods used in those studies can be divided into spontaneous and directed differentiation. For spontaneous differentiation, the formation of embryoid bodies (EBs) has been mostly utilized<sup>[6-11]</sup>. With directed differentiation, different processes of enrichment of a specific differentiated cell type that use elements to promote the differentiation of ES cells into an endodermal lineage, such as the addition of growth factors (GFs) and

hormones<sup>[12-20]</sup>, and the constitutive expression of hepatic transcription factors<sup>[21]</sup>, have been utilized.

In contrast to a number of reports of hepatic differentiation of ES cells *in vitro*, the behavior of transplanted ES cells in the liver has not been reported, except for the formation of teratomas<sup>[9,22]</sup>. According to the results of a study that utilized intravenous transplantation of a relatively large number of undifferentiated ES cells ( $2 \times 10^6$ /mouse)<sup>[9]</sup>, tumor formation was observed in the livers of all carbon tetrachloride (CCl<sub>4</sub>)-treated mice, but not in mice with normal livers. Although the tumors formed in the livers contained ES-derived mature hepatocytes, few cells seemed to have been integrated into the ordinary structure of the residual normal livers. Recently, bone marrow stem cells (BMSCs) were demonstrated to differentiate into hepatocytes and integrate into the liver after intravenous transplantation in CCl<sub>4</sub>-treated mice, even without *in vitro* induction directed toward an endoderm or hepatocyte lineage<sup>[23]</sup>. Those results suggested that the livers in CCl<sub>4</sub>-mice provide a microenvironment necessary for the lodging of BMSCs or ES cells, and their subsequent differentiation into hepatocytes.

In the present study, we investigated whether ES cells are able to differentiate into hepatocytes *in vivo*. For this purpose, we transplanted a reduced number of undifferentiated ES cells ( $1 \times 10^5$ /mouse) into the spleens of CCl<sub>4</sub>-treated experimental and CCl<sub>4</sub>-untreated control mice, expecting that tumors would develop in the livers. We found that the native ES cells migrated to the liver and developed into hepatocyte-like cells in CCl<sub>4</sub>-treated mice, but not in the CCl<sub>4</sub>-untreated control mice. Further, localization of migrated ES cells in the CCl<sub>4</sub>-mice livers was found in the periportal regions on post-transplantation day (PD) 10 and the cells were immunopositive for albumin (ALB), alpha-1 antitrypsin ( $\alpha$ 1AT), and cytokeratin 18 (CK18) on PD 20. Hepatocyte nuclear factor 4 alpha (HNF4 $\alpha$ ), an important transcription factor for mature hepatocytes, was also detected immunohistochemically. Interestingly, most of the GFP-positive cells showed immuno-positivity to DLK, a hepatoblast marker, on PD 10. Although there were very few ES-derived cells demonstrated immunohistologically in the livers on PD 30, improvements in liver fibrosis were observed. Unexpectedly, formation of liver tumors was not observed in any of the mice that received transplanted cells during the experimental period.

Our results suggest that undifferentiated ES cells can develop into hepatocyte-like cells with appropriate integration into tissue without invariably leading to uncontrolled cell growth. In the future era of cell growth control, undifferentiated ES cells may be directly used for therapeutic transplantation as well as terminally differentiated derivatives.

## MATERIALS AND METHODS

### Murine ES cell line

We utilized G4-2 cells from a mouse ES cell line (129/SvJ mouse ES cells, a kind gift from Dr. Hitoshi Niwa, RIKEN

Center for Developmental Biology, Kobe, Japan). The G4-2 cells were derived from EB3 ES cells<sup>[24,25]</sup> and carried an enhanced green fluorescent protein (EGFP) gene under the control of the CAG expression unit. EB3 ES cells are a subline derived from E14tg2a ES cells<sup>[26]</sup> and carry the blasticidin S-resistant selection marker gene driven by the Oct-3/4 promoter (active under undifferentiated status). For the present study, undifferentiated G4-2 cells were maintained on gelatin-coated dishes without feeder cells in Dulbecco's modified Eagle's medium (DMEM; Sigma; St. Louis, MO) supplemented with 10% fetal bovine serum (FBS; GIBCO/BRL; Grand Island, NY), 0.1 mmol/L 2-mercaptoethanol (Sigma), 10 mmol/L nonessential amino acids (GIBCO/BRL), 1 mmol/L sodium pyruvate (Sigma), and 1400 U/mL of leukemia inhibitory factor (LIF; GIBCO/BRL). For some of the experiments, G4-2 cells were cultured in medium containing 10  $\mu$ g/mL of blasticidin S to eliminate differentiated cells.

### Preparation of graft cells

Culture dishes (9 cm in diameter), used to maintain the undifferentiated ES colonies, were washed with 8 mL of ice-cold phosphate-buffered saline (PBS, pH 7.4) 3 times and then treated with 1.0 mL of 0.025% trypsin/PBS for 2 min at 37°C. Five milliliters of ES maintenance medium containing 10% FBS was added to the culture dish to stop trypsin activity. Single cell solutions were easily obtained by repeated pipetting. Cells were washed with ice-cold PBS 3 times and finally prepared for transplantation in a PBS solution at a cell concentration of  $1 \times 10^6$ /mL.

### CCl<sub>4</sub> treatment

To induce liver damage, CCl<sub>4</sub> at 0.5 mL/kg of body weight was injected into the peritoneum twice a week for 5 wk.

### Grouping of experimental animals

Female C57BL/6 mice were purchased from Japan SLC (Shizuoka, Japan) at 6 wk of age and used as experimental animals. All procedures including the surgical steps were performed in accordance with the Guidelines of Nara Medical University for experiments involving animals and recombinant DNA. The mice were divided into 3 groups. Group 1 ( $n = 12$ ) received CCl<sub>4</sub> treatment and transplantation of graft cells. One day after the second injection of CCl<sub>4</sub>,  $1 \times 10^5$  GFP-positive undifferentiated ES cells (0.1 mL of  $1 \times 10^6$ /mL solution) were transplanted into the spleen. Briefly, a 1-cm incision was made on the left flank and the spleen was extracted through the incision. Then, 0.1 mL of the graft cell solution ( $1 \times 10^6$  cells/mL) was slowly infused into the inferior pole of the spleen using a 31-gauge needle and a Hamilton syringe. Once the infusion was complete, the syringe was left in place for 1 min. Group 2 mice ( $n = 12$ ) were injected in the same manner with 0.2 mL of saline twice a week, instead of CCl<sub>4</sub>, and transplanted with the same amount of ES cells into the spleen as Group 1. Group 3 mice ( $n = 6$ ) were treated with CCl<sub>4</sub> and injected with 0.1 mL of saline into the spleen in the same manner, instead of ES cells. Grouping and an outline of the experiments are shown in Figure 1.

### Tissue preparation

The livers were thoroughly perfused *via* the heart with 4% paraformaldehyde to wash out contaminating blood cells. For fixation, the perfused livers were incubated with 4% paraformaldehyde overnight, then soaked in 30% sucrose for 3 d. Tissues were frozen on dry ice and then sectioned into 5- $\mu$ m slices using a cryostat in preparation for dyeing.

### Immunohistochemistry and double immunofluorescence for GFP

Immunohistochemical analysis was performed in accordance with previously reported methods<sup>[27]</sup>. Frozen tissue sections were desiccated completely at room temperature using a dryer, washed with phosphate-buffered saline (PBS) 3 times for 5 min each, and soaked in PBS containing 5% bovine serum albumin (BSA) once for 5 min. Sections were incubated overnight with anti-GFP (1:1000, Molecular Probe Inc, OR, USA and Nacalai Tesque Inc, Kyoto, Japan), anti-ALB (1:100, Biogenesis Ltd, England, UK), anti- $\alpha$ 1AT (1:100, Zymed Laboratories Inc, CA, USA), anti-CK18 (1:100, Chemicon International Inc, CA, USA), anti-CK19 (1:100, Abcam Ltd, Cambridge, UK), anti-HNF4 $\alpha$  (1:50, Santa Cruz Biotechnology Inc, CA, USA), and anti-DLK<sup>[28]</sup> (1:100) antibodies. Tissue sections were then washed with PBS 3 times for 5 min each and incubated with biotin-conjugated anti-rat (anti-rabbit or anti-mouse) IgG (1:200, Vector Laboratories Inc, CA, USA) secondary antibodies for 1 h at 37°C, then washed 3 times for 5 min each with diluted water. Next, for the purpose of intrinsic peroxidase elimination, the tissue sections were immersed in 3% hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) for 30 min, then washed 3 times for 5 min each with PBS. The sections were incubated with Vectastain ABC<sup>R</sup> reagent (Vector Laboratories Inc, CA, USA) for 2 h at 37°C, then washed 3 times for 5 min with diluted water and treated with 0.02 mol/L Tris-HCl buffer (pH 7.5) containing 4% diaminobenzidine tetrahydrochloride (Vector Laboratories Inc, CA, USA) in the presence of 0.0004% H<sub>2</sub>O<sub>2</sub> for 2 min at room temperature. Stained sections were rinsed with diluted water, and immersed in ethanol and xylene for complete dehydration. Finally, the sections were enclosed with Entellan-new<sup>R</sup>.

For fluorescent immunohistochemistry, tissue sections were incubated with Alexa Fluor<sup>R</sup> 488 and 546 goat anti-rat (anti-rabbit or anti-mouse) IgG (H + L) conjugate (Molecular Probe Inc, OR, USA) secondary antibodies for 1 h, then washed 3 times for 5 min each with PBS. Sections were mounted on glass slides from an Anti-fade Kit (Molecular Probe Inc, OR, USA). Positive cells in the liver were observed using a Provis microscope (Olympus, Tokyo) equipped with a charge coupled device (CCD) camera. A total of 10 different areas in each liver section were analyzed independently for each mouse.

## RESULTS

### Migration of ES cells into CCl<sub>4</sub>-treated mouse livers

GFP-immuno-positivity was examined in the liver specimens 10 d after intrasplenic transplantation (PD 10 of  $1 \times 10^5$  GFP-positive ES cells (groups 1 and 2) or

**Figure 1** Grouping of experimental animals. Female C57BL/6 mice were divided into 3 groups. Intraperitoneal injection of CCl<sub>4</sub> at 0.5 mL/kg body weight was performed twice a week in group 1 mice ( $n = 12$ ) and group 3 mice ( $n = 6$ ), while 0.2 mL of saline was injected instead of CCl<sub>4</sub> in group 2 mice ( $n = 12$ ). One day after the second intraperitoneal injection of CCl<sub>4</sub> or saline,  $1 \times 10^5$  GFP-positive undifferentiated ES cells (0.1 mL of  $1 \times 10^6$ /mL solution) were transplanted into the spleens in groups 1 and 2, whereas no cell transplantation was performed with group 3.

intrasplenic injection of saline (group 3) (Figure 2). A distinct distribution of immunoreactivity against GFP was observed in the liver sections of group 1 mice, which were treated with CCl<sub>4</sub> and grafted with ES cells (Figure 2A). Further, GFP-positive cells were present in the periportal regions of the hepatic lobules. However, no GFP-positive cells were detected in liver sections from group 2 mice (not treated with CCl<sub>4</sub>, grafted with ES cells) (Figure 2B), or in those from group 3 mice (treated with CCl<sub>4</sub>, not grafted with ES cells) (Figure 2C).

GFP-immuno-positivity was also examined in the liver specimens on PD 20 and 30 (Figure 3). Immunoreactivity to GFP was detected in the liver sections from group 1 mice on PD 20 (Figure 3B), though the intensity was weaker than that on PD 10. On PD 30, scant or no GFP-immuno-positivity was detected in group 1 mice (Figure 3C). We also counted the number of GFP-positive cells in 10 microscopic fields, focusing on the periportal area. The average numbers of GFP-positive cells around the portal vein on PD 10, 20, and 30 were  $65 \pm 18$ ,  $26 \pm 15$ , and  $4.0 \pm 2.0$  respectively, in each microscopic field at  $400 \times$  magnification (Figure 3D).

### Expression of hepatocyte-related markers in GFP-positive cells

Nearly all of the GFP-positive cells had disappeared from the livers of the transplanted mice by PD 30, however, considerable numbers of GFP-positive cells were present in the hepatic lobules for a limited period in those in group 1. Next, we utilized immunohistochemistry to examine the expressions of ALB,  $\alpha$ 1AT, and CK18 on PD 20 (Figure 4A). ALB immuno-positivity was observed homogeneously throughout the hepatic lobules without discrimination between the periportal regions and the other parts. Immuno-positivity for  $\alpha$ 1AT and CK18 was also observed throughout the lobules, though some cells located in the

**Figure 2** Migration of ES cells into CCl<sub>4</sub>-treated mouse livers. GFP-immuno-positivity was examined in the liver specimens on PD 10. **A:** Immunoreactivity against GFP was clearly observed in the liver sections of Group 1 mice and GFP was predominantly distributed in the portal regions; **B, C:** No GFP-positive cells were detected in liver sections of group 2 (**B**) and group 3 mice (**C**).

**Figure 3** Disappearing GFP-immuno-positivity. GFP-immuno-positivity on PD 10, 20, and 30 was examined using liver specimens from group 1 mice. **A:** GFP-immunoreactivity was clearly observed in the periportal regions on PD 10; **B:** GFP-immunoreactivity was still detected on PD 20, though the intensity was weaker than on PD 10. Cells presenting GFP-immunoreactivity were more inwardly distributed in the hepatic lobules, as compared to PD 10; **C:** Scant or no GFP-immuno-positivity was detected on PD 30; **D:** The average numbers of GFP-positive cells around the portal vein were determined after examining 10 microscopic fields in the periportal area at 400 x magnification.

periportal area showed a higher level of intensity. Double immunofluorescent studies on PD 20 demonstrated that most of the GFP-immuno-positive cells expressed ALB,  $\alpha$ 1AT, and CK18 (Figure 4B). Further, the expression of HNF4 $\alpha$ , a transcription factor necessary for complete differentiation of hepatocytes *in vivo*<sup>[29]</sup>, was confirmed in GFP-immuno-positive cells (Figure 4C). In contrast to the expression of hepatocyte-related markers on GFP-positive cells, there were no CK19-positive ES-derived cells (Figure 4D).

#### Expression of hepatoblast marker on GFP-positive cells

Next, we used an antibody against DLK for an immunohistochemical examination of the involvement of recapitulating developmental processes. DLK is a molecule identified as a possible hepatoblast marker and known to be strongly expressed on hepatoblasts in mouse embryonic livers until embryonic d 16.5, after which it becomes downregulated and disappears by birth<sup>[28]</sup>. Immunoreactivity against DLK was clearly observed in

the periportal regions on PD 10 (Figure 5A, left), though few DLK-immuno-positive cells were present in the hepatic lobules on PD 20 (Figure 5A, right). A double immunofluorescent study on PD 10 showed that the DLK-immuno-positive cells were also GFP-immuno-positive (Figure 5C).

#### Decreased fibrosis after ES transplantation

Liver fibrosis was histologically evaluated using picro-Sirius red staining. Representative liver sections stained with Sirius red are shown in Figure 6. The five-week treatment with CCl<sub>4</sub> induced liver fibrosis in group C mice, whereas decreased fibrosis was observed in group 1, which received ES cells (Figure 6B).

#### Tumor formation

All of the livers in the experimental animals were removed and the lobes sliced into 2-mm widths, with specimens from the middle lobes used for microscopic analysis. No tumor formation was observed macroscopically or

**Figure 4** Expression of hepatocyte-related markers on GFP-positive cells. **A:** Prior to conducting immunofluorescent studies, the expression of GFP, ALB,  $\alpha$ 1AT, and CK18 on PD 20 was examined using a conventional method; **B, C:** Double immunofluorescent studies on PD 20 demonstrated that most of the GFP-immuno-positive cells expressed ALB,  $\alpha$ 1AT, and CK18; **C:** Expression of HNF4 $\alpha$  was confirmed in the GFP-immuno-positive cells; **D:** There were no CK19-positive ES-derived cells.

microscopically in any of the livers. All of the spleens were also examined macroscopically and microscopically, and no tumors were found. Further, no tumor development in any organs other than the liver and spleen was observed for up to 30 d after transplantation.

## DISCUSSION

In the present study, we demonstrated that ES cells migrated to the liver and differentiated into hepatocyte-like cells after intrasplenic transplantation. It is reasonable to speculate that generation of a favorable microenvironment is required in the recipient liver for undifferentiated

ES cells to differentiate into hepatocytes. We adopted a method of repeated CCl<sub>4</sub> administration to induce undifferentiated ES cells into hepatocyte-like cells. It has been reported that BMSCs intravenously transplanted into mice that received repeated CCl<sub>4</sub> treatments migrated to the liver and differentiated into hepatocytes<sup>[23]</sup>, suggesting that a favorable condition was generated in the CCl<sub>4</sub>-treated livers to trap exogenously administered BMSCs and allow them differentiate into hepatocyte-like cells. Although the mechanisms by which a CCl<sub>4</sub>-treated liver favors hepatic differentiation of BMSCs remain to be elucidated, we considered that CCl<sub>4</sub> treatment provides a suitable condition for ES cells to differentiate into

**Figure 5** Expression of hepatoblast marker DLK on GFP-positive cells. **A:** DLK-immuno-positivity was examined on PD 10 (left) and PD 20 (right). A number of cells showed immunoreactivity against DLK on PD 10, whereas there were few on PD 20; **B:** Most of GFP-immunopositive cells on PD 10 were positive for DLK.S.

**Figure 6** Decreased fibrosis after ES transplantation. Liver fibrosis was histologically evaluated on PD 30 using picro-Sirius red staining. Representative liver histology results for group 3 (**A**) and group 1 (**B**) mice. Decreased fibrosis was observed in group 1 mice, as compared to those in group 3.

hepatocyte-like cells in a manner similar to that for BMSCs. In addition to the differentiation of BMSCs into hepatocyte-like cells *in vivo*, that of hematopoietic stem cells (HSCs) into hepatocyte-like cells has been reported using a coculture with hepatocytes from CCl<sub>4</sub>-treated livers<sup>[30]</sup>. Based on those reports, we transplanted ES cells into CCl<sub>4</sub>-treated livers of mice with the expectation that they would differentiate into hepatocyte-like cells.

We found that ES cells migrated into the livers of the CCl<sub>4</sub>-treated mice, whereas no such migration was observed in CCl<sub>4</sub>-untreated mice. The migrated ES cells, shown by GFP-immuno-positivity, were distributed in the periportal regions on PD 10 and 20, and disappeared by PD 30. GFP-immuno-positive ES-derived cells in the livers on PD 20 were also immuno-positive for the hepatocyte-related markers ALB,  $\alpha$ 1AT, and CK18, suggesting their successful differentiation into hepatocyte-like cells. Further, the expression of HNF4 $\alpha$ , an important transcription factor for hepatocyte maturation, was also observed in the ES-derived cells in our immunohistochemical examination. These results suggest that a CCl<sub>4</sub>-treated liver has the

ability to support homing and hepatic differentiation of undifferentiated ES cells.

It is difficult to fully elucidate the mechanisms involved with generation of ES-derived hepatocyte-like cells in the liver. However, we considered that recapitulation of the developmental process in the liver may have a role. In the present study, we tested for immunopositive reactions to DLK, which is a molecule that has been identified as a possible hepatoblast marker and shown to be strongly expressed on hepatoblasts in mouse embryonic livers until embryonic d 16.5, after which it was downregulated and disappeared by birth<sup>[28]</sup>. DLK-positive cells were detected and found to have a similar distribution as GFP-positive cells in the CCl<sub>4</sub>-treated livers, as they were markedly present in the periportal regions on PD 10 and few in number on PD 20. Most of the GFP-positive cells were also immuno-positive for DLK on PD 10. These results strongly suggest that mechanisms similar to those related to hepatocyte development are involved in generating ES-derived hepatocyte-like cells. Apart from the involvement of recapitulated liver development, it is known that oval

cells are activated to proliferate following extensive and chronic liver damage with inhibited proliferation of hepatocytes<sup>[31,32]</sup>. Those cells are considered to represent a type of hepatic stem cells derived from the canal of Hering<sup>[33-35]</sup>. Although we did not examine for the presence of oval cells in the present study, some GFP-positive grafted cells may also express markers for those cells, as shown in the case of BMC transplantation to CCl<sub>4</sub>-treated mice.

Because of the risk of tumor formation, we transplanted small numbers of undifferentiated ES cells in the present study. Using a rat model of Parkinson's disease, it was initially reported that transplantation of small numbers of mouse ES cells increases the influence of the host tissue and allows for default differentiation<sup>[36]</sup>. Therefore, we used 10<sup>5</sup> cells for intrasplenic transplantation, which was 20-fold fewer than the number of transplanted ES cells in a previous report<sup>[9]</sup>, in which teratoma formation in the liver was documented. Nevertheless, we expected teratoma development, because ES cells in an undifferentiated state were utilized as graft cells. However, no tumors developed in the livers or spleens in the mice that received transplants up to the end of the 30-d experimental period. This observation might be explained by the disappearance of GFP-immunopositive cells from the liver by PD 30. PCR analysis of liver tissue specimens collected on PD 30 using a GFP-specific primer set failed to reveal PCR products (data not shown), suggesting the absence of transplanted ES cells or ES-derived cells in the liver. A previous study<sup>[23]</sup> reported that transplanted BMSC cells were retained in the liver under conditions of persistent CCl<sub>4</sub> treatment. We consider that one of the reasons for the elimination of grafted ES cells seen in our study was because of the allogeneic transplantation method utilized, as the grafted ES cells were derived from 129SVJ mice and the donor mice were C57BL/6, even though 129SVJ and C57BL/6 are classified as the same haplotype, H-2<sup>b</sup>. It is conceivable that an immunological barrier may eliminate non-self-grafted cells, leading to the absence of ES-derived cells and no occurrence of tumor formation.

Interestingly, a reduction of liver fibrosis was observed on PD 30 in CCl<sub>4</sub>-treated mice that underwent ES-cell transplantation, despite the absence of grafted cells in the liver. It has been reported that transplantation of BMSCs<sup>[37]</sup> and BM-derived mesenchymal stem cells<sup>[38]</sup> had a protective effect against fibrosis in livers chronically damaged by administration of CCl<sub>4</sub>. However, no results of the effects of ES cells on hepatic fibrosis are known to have been reported. Thus, there may be some common mechanisms underlying the improvement of hepatic fibrosis following the transplantation of cells with stem cell characteristics, as has been reported in the case of BMSCs.

Recently, it was reported that mouse undifferentiated ES cells fused with mouse bone marrow cells and neural stem cells *in vitro*<sup>[39,40]</sup>. Further, hybrid hepatocytes were produced by cell fusion between embryoid body-derived cynomolgus monkey ES cells and hepatocytes from uPA/SCID mice<sup>[41]</sup>. In the present study, we did not investigate

whether generation of GFP-immunopositive hepatocyte-like cells in the liver was due simply to the differentiation of the transplanted ES cells, or to cell fusion between ES cells and hepatocytes. In the near future, we intend to perform FISH analyses using a set of mouse chromosome X- and Y-specific probes.

In conclusion, we found that undifferentiated ES cells grafted into the spleen migrated to the liver and developed into hepatocyte-like cells without apparent tumor formation in CCl<sub>4</sub>-treated mice. Although a prolonged presence of grafted cells in the liver was not observed, a beneficial effect of inhibiting fibrosis was obtained by the present single transplantation method. In the coming era of control of cell growth, undifferentiated ES cells may be directly used for therapeutic transplantation as well as terminally differentiated derivatives.

### Abstract

**AIM:** To investigate the effects of electrical stimulation of hypothalamic paraventricular nuclei (PVN) on gastric mucosal cellular apoptosis and proliferation induced by gastric ischemia/reperfusion (I/R) injury.

**METHODS:** For different experimental purposes, stimulating electrode plantation or electrolytic destruction of the PVN was applied, then the animals' GI/R injury model was established by clamping the celiac artery for 30 min and allowing reperfusion of the artery for 30 min, 1 h, 3 h or 6 h respectively. Then histological, immunohistochemistry methods were used to assess the gastric mucosal damage index, the gastric mucosal cellular apoptosis and proliferation at different times.

**RESULTS:** The electrical stimulation of PVN significantly attenuated the GI/R injury at 30 min, 1 h and 3 h after reperfusion. The electrical stimulation of PVN decreased gastric mucosal apoptosis and increased gastric mucosal proliferation. The electrolytic destruction of the PVN could eliminate the protective effects of electrical stimulation of PVN on GI/R injury. These results indicated that the PVN participated in the regulation of GI/R injury as a specific area in the brain, exerting protective effects against the GI/R injury, and the protection was associated with the inhibition of cellular apoptosis and

### INTRODUCTION

Since the 1980s, ischemia-reperfusion (I/R) injury of organs has been frequently encountered as a complex phenomenon in medicine and biology. Researches have been focused on I/R injury of organs such as the heart, brain, lungs, and the kidneys. In recent years, there has been an increase in the available information concerning the acute gastric mucosal injury induced by I/R, or gastric I/R injury<sup>[1-4]</sup>. The investigative key points have focused on the effects of individual factors on gastric mucosal injury induced by gastric I/R, including increase of oxygen free radicals and endothelin level, microvascular dysfunction, polymorphonuclear leukocyte infiltration, nitric oxide release, gastric acid secretion, prostaglandin decrease and so on<sup>[5-15]</sup>. Some researchers have questioned the best methods to protect the gastric mucosa against gastric I/R injury, such as the endothelin converting enzyme inhibitor phosphoramidon<sup>[16]</sup>, the anti-reactive oxygen species drug, tetrahydrabiopitin<sup>[9]</sup> and the adhesion molecules of anti-leukocytes<sup>[17]</sup>. However, little is known about the systemic regulation of gastric I/R injury, particularly the role of related central nuclei.

It has been known that the gastric mucosal tissue integrity depends upon the interplay between cell renewal

and death of damaged or aged cells. The gastric mucosa has a high renewal rate, and all gastric mucosal surface epithelial cells are replaced within 3-5 d as the exfoliated surface mucosal cells are replaced by cells migrating from the glandular foveolar and neck area<sup>[18]</sup>. The mucosa is maintained by the balance between proliferation and apoptosis of gastric mucosal cells. To study the imbalance between proliferation and apoptosis is of great significance in understanding the causes of gastric lesions.

Recently, literature reviews revealed that I/R could induce tissue injury and cellular apoptosis in many important organs<sup>[19-25]</sup>. Apoptosis of gastric mucosal cells has also been studied under varied conditions in rats, including ethanol, non-steroidal anti-inflammatory drugs, retinoic acids, *H pylori* infection<sup>[26-30]</sup>. Some reports of gastric mucosal cellular apoptosis induced by gastric I/R are contradictory. Fukuyama *et al*<sup>[31]</sup>, for example, reported that apoptosis is not induced in the gastric mucosa after gastric I/R. Wada *et al*<sup>[32]</sup> demonstrated that gastric I/R induces significant apoptosis in the gastric mucosa. However, the central regulation of gastric mucosal cellular apoptosis and proliferation induced by gastric I/R in rats has not yet been fully elucidated.

In his early study<sup>[33]</sup>, Salim pointed out that hypothalamus, especially the paraventricular nuclei (PVN), is extraordinarily complex in its structure and function. It participates in the regulation of various activities of the stomach, including secretion, electrical activation and gastric motor. Our previous study<sup>[34]</sup> showed that PVN and its associated nuclei could regulate the development of restraint and cold-water immersion stress-induced ulcer in stomach and that PVN is involved in the regulation of gastric I/R injury as one of the specific CNS areas attenuating gastric I/R injury<sup>[35]</sup>. The cellular mechanisms responsible for the attenuation of GI/R injury by electrical stimulation of PVN are still unknown.

The aim of our study is to investigate the molecular mechanisms of stimulating PVN in protecting against gastric I/R injury, to observe the characteristics of gastric mucosal cellular apoptosis and proliferation induced by gastric I/R at various times. It is believed that any progress in this field will help better understand the pathology of gastric I/R injury at cellular level.

## MATERIALS AND METHODS

### Reagents

M30 CytoDEATH monoclonal antibody was obtained from Roche (Basel, Switzerland). Mouse anti-rat proliferative nucleolus monoclonal antibody (proliferative cell nuclear antigen, PCNA), PowerVision<sup>TM</sup> two-step immunohistochemistry detection kit, and 3,3'-diaminobenzidine (DAB; Maixin-Bio Co., China) substrate solution were obtained from Zhongshan Biotech Co. (Beijing, China).

### Animals

Groups of six adult male Sprague-Dawley rats, weighing 180-220g, were supplied by the Experimental Animal Center of Xuzhou Medical College (usage certificate of experimental animals, No: SYXK (su) 2002-0038). All

experiments were carried out in accordance with the National Institute of Health Guide for the Care and Use of Laboratory Animals. The animals were housed under controlled temperature (22-24°C) and photoperiod (12 h light: 12 h dark) in wire-mesh-floor cages to prevent ingestion of hair and feces. The animals were fasted for 24 h before the experiment with free access to tap water. The animals were allocated to different groups to serve as gastric I/R injury models for different purposes in the experiments.

### Electrical stimulation of PVN

Three days before the experiment, the rats were anesthetized with sodium pentobarbital (40 mg/kg i.p.) and mounted onto a stereotaxic apparatus. The scalp was incised, and a 0.5 mm hole was drilled in the cranium dorsal to the target site. The coordinates of PVN for the placement of electrodes were taken from the atlas of Paxinos and Watson<sup>[36]</sup> as follows: AP 1.5 mm, LR 0.4 mm, H 7.7-7.8 mm, and the incisor bar was positioned 3.3 mm below the center of the aural bars.

The concentric bipolar stimulating electrode consisted of an insulated outer barrel formed from the needle of a medical syringe (0.4 mm in diameter) and an inner Ni-Cr wire, insulated except for the tip, which protrudes about 0.2 mm from the barrel. The stimulating electrode was inserted into PVN and fixed to the cranium with dental cement.

During the experiment, the rat was also anesthetized with sodium pentobarbital (40 mg/kg i.p.). PVN was stimulated before the induction of gastric I/R injury. The electrical stimulating parameters have been described previously<sup>[35]</sup>. Stimulation was performed 5 times with uniphasic, constant current square wave pulses (pulse width 0.2 ms, intensity 0.4 mA, frequency 50 Hz, duration 1 min), at 5 min intervals. In the sham PVN stimulation group, only the electrode was inserted, and no current was passed.

### Electrical destruction of PVN

Three days before the experiment, the rat was anesthetized with sodium pentobarbital (40 mg/kg i.p.) and mounted onto a stereotaxic apparatus. The coordinates of PVN for the placement of destructing electrodes was similar to that of the stimulating electrodes. The destructing electrodes was in bilateral PVN. The destructing electrode were placed a single stainless steel wire, 0.3 mm in diameter, with a naked tip about 0.3 mm, and void of insulation. Bilateral lesions were then made by passing a positive DC of 1 mA for 10 s. The lesion electrode was immediately removed after destruction. Sham operations were performed with the same surgical procedures, and no current was passed.

### Preparation of gastric I/R model

The animal, were kept fasting for 24 h with free access to water before experiment. All experiments were carried out under anesthesia with sodium pentobarbital (40 mg/kg i.p.), the supplemental dose of the anesthetic was given i.p. to maintain animal anesthesia throughout the experiment. Gastric I/R injury was induced according to the method of

Wada *et al*<sup>[37]</sup>. Briefly, the abdominal cavity was cut open, and the celiac artery and its adjacent tissues were carefully isolated. The celiac artery was first clamped with a small vascular clamp for 30 min to induce ischemia, and was then released to allow reperfusion for 30 min, 1 h, 3 h or 6 h respectively. Sham-operated animals underwent all of the surgical procedures except for the arterial clamping. At the end of each experiment, the rats with gastric I/R injury or sham-operated groups were killed by exsanguination via the abdominal aorta under anesthesia<sup>[38]</sup>, while the rats with embedded electrode in PVN were killed by decapitation under deep anesthesia. The stomach was removed rapidly, opened along the great curvature, rinsed with ice-cold phosphate buffered saline (PBS, 0.1 mol/L), and spread onto a cold plate. The gastric mucosa was carefully examined grossly and microscopically.

### Assessment of gastric mucosal injury index

Quantitative histological assessment of mucosal injury was performed with the method described by Guth *et al*<sup>[39]</sup> with slight modifications. The index is based on a cumulative-length scale. In which an individual lesion limited within the mucosal epithelium (including the pinpoint erosions, ulcers and hemorrhagic spots) is scored by giving points for its length. The score is 1 for a lesion  $\leq 1$  mm, 2 for a lesion  $> 1$  mm and  $\leq 2$  mm, for a lesion  $> 2$  mm  $\leq 3$  mm, and so on. For a lesion with a width  $> 1$  mm, the lesion score is doubled. The sum of the scores represents the GMDI. To avoid the researcher's bias, the GMDI was determined by a researcher who was unfamiliar with the details of the experiment.

### Immunohistochemical staining

Immunohistochemistry was performed with the streptavidin-peroxidase (SP) method<sup>[40]</sup>. The primary antibodies used were polyclonal antibody against proliferating cell nuclear antigen (PCNA), monoclonal antibody against M30 CytoDEATH. The gastric tissue samples were fixed in Bouin's fixative for paraffin tissue slices. Five- $\mu$ m thick sections were, deparaffinized, rehydrated, and boiled. The dewaxed sections were heated in a microwave oven (700 W) for 12 min to retrieve the antigens, and cooled to room temperature. The endogenous peroxide was blocked with 3% hydrogen peroxide ( $\text{H}_2\text{O}_2$ ) for 15 min in methanol. The sections were washed with PBS (0.01 mol/L), blocked with 10% goat serum for 15 min to reduce the non-specific antibody binding, and then incubated with the primary antibody (M30CytoDEATH 1:10, PCNA 1:50) at 4°C overnight. The sections were washed twice for 5 min with PBS, incubated with the secondary anti-mouse immunoglobulin (Santa Cruz Inc., USA) conjugated with biotin at room temperature for 30 min, washed again with PBS (0.01 mol/L), and incubated with SP complex for 15 min. The reaction products of peroxidase were visualized by incubation with 0.05 mol/L Tris-HCl buffer (pH 7.6) containing 20 mg 3,3'-diaminobenzidine (DAB, Maixin-Bio Co. China) and 100  $\mu$ L 5%  $\text{H}_2\text{O}_2$  per 100 mL. The brown color signifying the presence of the antigen bound to the antibodies was detected by light microscopy. Finally, the sections were counterstained for nuclei with

hematoxylin. The sections obtained from the control group were stained according to the same method except that PBS was substituted for the specific primary antibody. M30 CytoDEATH staining was quantified by calculating the average ratio of positive cells in 10 vision fields under a 400  $\times$  microscope. PCNA staining was quantified by calculating the average ratio of positive cells in 10 vision fields under a 100  $\times$  microscope.

### Histological verification of stimulated or destructed PVN sites

At the end of each experiment, the PVN site was marked by passing a positive direct current of 1 mA for 10 s. The experimental rats were killed by decapitation under deep anesthesia, and the brains were removed and fixed in 10% formalin for 7 d. Frozen coronal serial sections (45  $\mu$ m) were cut through the hypothalamus and mounted and stained with 1% neutral red to verify the sites of electrical stimulation under a light microscope. The data from rats whose target sites failed to meet the histological criteria were deleted from the statistical analysis.

### Statistical analysis

All results are expressed as mean  $\pm$  SE. Data were compared by an analysis of variance (ANOVA) followed by Student-Newman-keuls (SNK) test. All calculations were performed with SPSS 10.0 for Windows,  $P < 0.05$  was considered statistically significant.

## RESULTS

### Histological verification of stimulated PVN sites

By referring to Paxinos and Watson's Stereotaxic Atlas<sup>[36]</sup>, histological verification was performed at all sites of electrical stimulation (Figure 1)

### Effects of electrical stimulation and electrolytic destruction of PVN on gastric I/R injury in rats

Our previous experiments confirmed that the GMDI of the gastric I/R injury only group is similar to that of sham electrically stimulated PVN plus gastric I/R injury group (sham PVN + gastric I/R injury) at the different time points during reperfusion. Thus, we compared the differences between GI/R only and PVN + gastric I/R injury groups in subsequent experiments.

As shown in Figure 2, gastric mucosal injury was not found (the GMDI being zero) in the sham-operated group. The stimulated PVN + normal stomach group or the destructed PVN + normal stomach group was similar to that of normal rat group. In the gastric I/R injury group, the GMDI was  $94.67 \pm 25.57$  at 1 h after reperfusion. The GMDI was significantly lower in the electrical stimulation of PVN + gastric I/R injury group than in the gastric I/R injury only group at 1 h after reperfusion ( $94.67 \pm 25.57$  vs  $54.83 \pm 12.64$ ,  $P < 0.05$ ). The GMDI was not significantly different in the bilateral PVN destruction + gastric I/R injury group compared with that in the gastric I/R injury only group or sham stimulating PVN plus gastric I/R injury group ( $106.94 \pm 20.91$  vs  $94.67 \pm 25.57$ ,  $P > 0.05$ ), but was markedly higher than that gastric I/R injury the electrical stimulation of PVN + GI/R group ( $106.94$

**Figure 1** Sites of the stimulating electrode tip in PVN. **A:** Standard atlas sections of the rat brain showing the distributions of stimulating sites of the experimental animals; **B:** Photomicrographs of stimulating sites in the rat brain. The section stained with neutral red, showing the position of stimulating electrode tip by passing a positive DC of 1 mA for 10 s, which indicates a placement within the PVN.

$\pm 20.91$  vs  $54.83 \pm 12.64$ ,  $P < 0.05$ ).

As shown in Figure 3, in the gastric I/R injury group, the gastric mucosal lesions appeared 30 min after reperfusion, the GMDI reached maximum at 1 h after reperfusion ( $94.67 \pm 25.57$ ), but then declined. In the group of PVN + gastric I/R, the GMDI was significantly lower than that the gastric I/R group at 30 min, 1 h and 3 h after reperfusion ( $P < 0.01$ ). At 6 h after reperfusion, there was no significant difference ( $P > 0.05$ ) between the GI/R group and the stimulating PVN + gastric I/R group.

#### Effect of electrical stimulation of PVN on apoptosis of gastric mucosal cells induced by GI/R in rats

As shown in Figure 4, the M30 CytoDEATH positive apoptotic cells (i.e. apoptotic cells) were distributed predominantly in the upper part of the gastric glands and epithelial cells, where the cytoplasm was stained brown. In the normal gastric mucosa (Figure 4A and B), the few apoptotic cells were apparent. In the GI/R injury group, the percentage of apoptotic cells increased rapidly at the onset of reperfusion, and peaked at 1 h after reperfusion (6.32 times higher than that in the normal gastric mucosa,  $P < 0.01$ ) (Figure 4C). Electrical stimulation of PVN markedly decreased the percentage of M30 CytoDEATH positive cells at 1 h after reperfusion (Figure 4D), which declined to the basal level at 6 h after reperfusion (Figure

**Figure 2** Effect of electrical stimulation and bilateral electrolytic destruction of PVN on gastric mucosal damage induced by I/R at 1 h after reperfusion in rats. Intact: normal rat; sham: sham-operation (electrode was inserted, with no current passing and no artery clamped); ES + N: intact stomach after electrical stimulation of the PVN. EL + N: intact stomach after bilateral electrolytic destruction of the PVN; GI/R injury: gastric ischemia-reperfusion injury; Sham+GI/R injury: sham electrical stimulation of the PVN plus GI/R injury; ES: electrical stimulation of the PVN plus GI/R injury; EL: bilateral electrolytic destruction of the PVN plus GI/R injury. Values of GMDI are mean  $\pm$  SE ( $n = 6$ ). <sup>b</sup> $P < 0.01$  vs intact, <sup>d</sup> $P < 0.01$  ES vs ES + N, <sup>a</sup> $P < 0.01$  EL vs EL + N, <sup>e</sup> $P < 0.05$ , ES vs GI-R, <sup>c</sup> $P < 0.05$ , EL vs ES.

Sham: sham-operation (electrode was inserted, with no current passing and no artery clamped); GI/R: gastric ischemia/reperfusion was maintained for 30 min, 1 h, 3 h and 6 h after 30 min of ischemia, respectively; PVN + GI/R: electrical stimulation of the PVN plus GI/R. Values: Each column represents mean  $\pm$  SE ( $n = 6$ ). <sup>b</sup> $P < 0.01$  vs sham; <sup>a</sup> $P < 0.05$ , <sup>d</sup> $P < 0.01$ , PVN + GI/R vs GI/R at different times.

4E and F). Figure 4G indicates the negative control group.

As shown in Figure 5, the electrical stimulation of PVN significantly decreased the percentage of M30 CytoDEATH positive cells throughout the 6 h reperfusion ( $P < 0.05$  or  $P < 0.01$ ).

#### Effect of electrical stimulation of PVN on proliferation of gastric mucosal cells induced by GI/R in rats

As shown in Figure 6, the proliferating-positive cells were found in the normal gastric mucosa, which were distributed predominantly in the glandular neck area of the gastric mucosa (Figure 6A and B). The percentage of proliferating cells decreased rapidly at 1 h after reperfusion

**Figure 4** Histological exhibition of electrical stimulation of PVN on gastric mucosal apoptosis induced by I/R at different times in rats. The apoptotic-positive cells were probed with anti-M30 CytoDEATH antibody and counter-stained with hematoxylin in rat gastric mucosa ( $\times 400$ ). A: normal gastric mucosa; B: sham operation; C: GI/R at 1 h after reperfusion; D: PVN + GI/R at 1 h after reperfusion; E: GI/R at 6 h after reperfusion; F: PVN+GI/R at 6 h after reperfusion; G: negative control group.

**Figure 5** Effect of electrical stimulation of PVN on gastric mucosal cellular apoptosis induced by I/R at different time points in rats. Sham: sham-operation; GI/R: reperfusion was maintained for 30 min, 1 h, 3 h and 6 h after 30 min of ischemia, respectively; PVN + GI/R: electrical stimulation of PVN plus GI/R. The percentage of apoptotic cells was taken by counting the cells in 10 microscopic fields ( $\times 400$ ). Each column represents mean  $\pm$  SE ( $n = 6$ ).  $^aP < 0.05$ ,  $^bP < 0.01$ , GI/R vs sham-operation;  $^cP < 0.05$ ,  $^dP < 0.01$ , PVN + GI/R vs GI/R at each time point.

(Figure 6C). The percentage of proliferating positive cells were significantly higher in the stimulating PVN + gastric I/R injury group than in the gastric I/R injury group (Figure 6D). The proliferating-positive cells accumulated in both the gastric I/R injury only group and the stimulating PVN + gastric I/R injury group at 6 h after reperfusion, and the crowding was not significantly different at this time (Figure 6E and F). Figure 6G negative control group.

Figure 7 also shows that the electrical stimulation of PVN significantly increased the percentage of proliferating-positive cells at 30 min (1.47 times), 1 h (1.89

**Figure 6** Histological exhibition of electrical stimulation of PVN on gastric mucosal cellular proliferation induced by I/R at different times in rats. Proliferating-positive cells were probed with anti-mouse anti-proliferating cell nuclear antigen (PCNA) antibody and counter stained with hematoxylin in gastric mucosa ( $\times 100$ ). A: normal control gastric mucosa; B: gastric mucosa after sham operation; C: GI/R, 1 h after reperfusion; D: PVN + GI/R, 1 h after reperfusion; E: GI/R, 6 h after reperfusion; F: PVN + GI-R, 6 h after reperfusion; G: negative control group.

**Figure 7** Effect of electrical stimulation of PVN on gastric mucosal proliferation induced by I/R at different times in rats. Sham: sham-operation; GI/R: reperfusion was maintained for 30 min, 1 h, 3 h and 6 h after 30 min of ischemia, respectively; PVN+GI/R: electrical stimulation of PVN plus GI/R. The percentage of proliferating cells was taken by using cell count in 10 microscopic fields ( $\times 100$ ). Each column represents an average value expressed in mean  $\pm$  SE ( $n = 6$ ).  $^bP < 0.01$ , GI/R vs sham operation;  $^aP < 0.05$  and  $^dP < 0.01$ , PVN + GI/R vs GI/R.

times) and 3 h (1.43 times) after reperfusion compared with the respective values in the gastric I/R injury group.

## DISCUSSION

In our present study, the gross gastric mucosa damage index was determined to evaluate the extent of gastric I/R injury. Immunohistochemistry was also used to assess the processes of gastric mucosal cellular apoptosis and proliferation in gastric I/R injury by detecting the apoptotic cells with the M30 CytoDEATH monoclonal antibody (which binds to a caspase-cleaved formalin-

resistant epitope of the cytokeratin 18 cytoskeletal protein in the cytoplasm of apoptotic cells) and by labelling the proliferating cells with multi-clonal antibodies to PCNA (an assistant factor of DNA polymerase)<sup>[41,42]</sup>. We assessed these variables at different times from 30 min to 6 h after reperfusion. We reasoned that our histological analysis the process would help us better understand the cellular mechanisms responsible for the reperfusion injury.

In our analysis of the GMDI data, which was obtained with gastric I/R injury model of anesthetized (sodium pentobarbital, 40 mg·kg<sup>-1</sup>·i.p.) rats, it was noticed that the gastric mucosal damage was localized within the mucosal epithelium, the lesions started to occur at 30 min after reperfusion, reached their peak at 1 h and then subsided. We dynamically observed the changes of apoptosis and proliferation of gastric mucosal cells at different times from 30 min to 6 h after gastric I/R injury. Histological study of the normal gastric mucosa revealed a few apoptotic cells in the superficial layer of gastric mucosa and proliferating cells only in the gastric glandular neck area. These patterns contrast with previous reports<sup>[43,44]</sup>, supporting the notion that cell renewal and apoptosis are two essential processes maintaining the homeostasis of normal gastric mucosa. The pattern of simultaneous change in gastric mucosal cellular apoptosis during reperfusion is similar to that of gastric I/R injury; i.e., the level of apoptosis also reached its peak at 1 h after reperfusion when the gastric mucosal injury was most serious, and then declined. In contrast, the level of gastric mucosal cellular proliferation induced by ischemia/reperfusion also reached its minimum at 1 h after reperfusion, but the level of proliferation reached its maximum at 6 h after reperfusion, indicating that the proliferating process of gastric mucosal cells is slower than the apoptosis process. It is widely accepted that the gastric mucosal integrity depends on the balance between apoptosis and proliferation, which explains the equilibrium between cell renewal and death of damaged or aged cells, and that ischemia/reperfusion may induce mucosal injury by altering this balance.

In our present study, techniques of electrical stimulation and electrolytic destruction were adopted and the role of electrical stimulation of PVN in gastric mucosal injury, cellular apoptosis, and proliferation induced by gastric I/R injury were observed. It was found that PVN stimulation protected against gastric I/R injury. In the electrical stimulation of PVN plus gastric I/R group, the GMDI was significantly lower than that in the gastric I/R injury only group at 30 min, 1 h and 3 h after reperfusion. After bilateral PVN destruction, the GMDI was not significantly different from that in the gastric I/R only group, but it was significantly higher than that in electrical stimulation of PVN plus gastric I/R group ( $P < 0.05$ ). Furthermore, our results also revealed that the electrical stimulation of PVN markedly decreased the expression of apoptotic-positive cells, and increased the expression of proliferating positive cells at 0.5, 1, 3 h after reperfusion, respectively. These results indicate that PVN participates in the regulation of gastric mucosal cellular apoptosis and proliferation after gastric I/R in rats. Inhibiting gastric mucosal cellular apoptosis and promoting gastric mucosal cellular proliferation might

mediate the dramatic protective effect of PVN on gastric mucosal injury. Our data also support the notion that PVN is a specific center in the brain that maintains the integrity of gastric mucosa and modifies the equilibrium between gastric mucosal apoptosis and proliferation.

Our previous experimental results have testified that the protective effect against gastric I/R injury is related to the excitation of PVN neurons. We focused on the microinjection of L-glutamic acid (a neuronal stimulant) into PVN, and found that the chemical stimulation produces a similar effect to that of 0.4 mA electrical stimulation of PVN<sup>[35]</sup>, and the histological evidence from present study illustrates that the destroyed locus is only restricted within PVN. These results imply that the protection against gastric I/R injury resulted from the excitation of PVN neurons rather than from the excitation of nerve fibers passing PVN or spreading the stimulating current. Therefore, PVN is closely related to the gastric mucosal cellular apoptosis and proliferation induced by gastric I/R, suggesting that PVN is one of the specific brain areas in regulating the gastric I/R injury.

The research on the neuro-endocrine mechanism of the protection of stimulating PVN on gastric I/R injury has been limited except for our previous reports. Our previous study indicates that PVN stimulation, electrical or chemical, activates its neurons to affect the activity of nucleus tractus solitarius (NTS)-dorsal vagal complex (DVC) through its descending fibers and then accomplish the protection against gastric I/R injury by the mediating vagus and sympathetic nerves<sup>[45]</sup>. Our another study also discovered that electrical stimulation of PVN significantly increases the stress gastric ulceration, while electrolytic lesion of PVN decreases it. PVN is an important brain site in regulating the development of stress-induced gastric ulcers, and is involved in classical neurotransmitters of ACh, NE and 5-HT, with the parasympathetic, sympathetic nervous systems and the three endocrine glands (thyroid, adrenal and gonad) taking part in the effect<sup>[34]</sup>. Nevertheless, when compared with our previous study on stress-induced gastric ulcer, in our present study the stimulating PVN attenuated gastric mucosal damage induced by gastric I/R, instead of aggravating it, as mentioned above, the contradictory results cannot be satisfactorily explained. It might be wise to regard the PVN as an extremely complicated regulatory mechanism integrating various stress information. Hence the mechanism of the protective effect of PVN against gastric I/R injury may not be a simple one. Recently, Tarnawski reviewed cellular and molecular mechanisms of gastrointestinal ulcer healing, and pointed out that the healing processes are controlled by many cytokines, growth factors (EGF, PDGF, KGF, HGF, TGF $\beta$ , VEGF, angiopoietins) and transcription factors activated by tissue injury in spatially and temporally coordinated manners<sup>[46]</sup>. It will be of interest to further examine this hypothesis in our experimental system.

In future, our further investigation will involve gathering more information and understand the mechanisms of PVN protecting against gastric reperfusion injury. At present, some efforts are being made in our laboratory to assess the effect of molecular mechanisms

and signaling pathways of the protective effect of PVN.

## COMMENTS

### Background

Little is known about the systemic regulation of gastric I/R injury, particularly the role of related central nuclei. The present study found that the paraventricular nuclei (PVN) exerts protective effects against gastric I/R injury as a specific area in the brain, and the protection is associated with the inhibition of cellular apoptosis and promotion of gastric mucosal proliferation.

### Research frontiers

The present study discussed the cellular mechanisms responsible for the gastric I/R injury and the possible cellular mechanisms of the attenuation of gastric I/R injury by electrical stimulation of PVN.

### Innovations and breakthroughs

Our previous study showed that PVN is involved in the regulation of gastric I/R injury as one of the specific CNS areas attenuating gastric I/R injury. The cellular mechanisms responsible for the attenuation of gastric I/R injury by electrical stimulation of PVN are still unknown. It was the first time in this study to investigate the molecular mechanisms of stimulating PVN in protecting against gastric I/R injury, to observe the characteristics of gastric mucosal cellular apoptosis and proliferation induced by gastric I/R at various times.

### Applications

The present study would help better understand the pathology of gastric I/R injury at cellular level and the regulation role of PVN in gastric function.

### Terminology

M30 CytoDEATH is a caspase-cleaved formalin-resistant epitope of cytokeratin 18 cytoskeletal protein in the cytoplasm of apoptotic cells. PCNA is a proliferating cell nuclear antigen as an assistant factor of DNA polymerase.

### Peer review

This is an interesting manuscript that links central neural mechanisms with protection of gastric mucosa following gastric I/R injury and found that stimulating PVN significantly inhibits gastric mucosal cellular apoptosis and promotes gastric mucosal cellular proliferation, which is probably one of the protective mechanisms of electrical stimulation of PVN against gastric I/R injury. It was suggested that more methods should be performed to clarify the change patterns of gastric mucosal cellular apoptosis and proliferation.

Xia SH, Fang DC, Hu CX, Bi HY, Yang YZ, Di Y. Effect of BN52021 on NF- $\kappa$ Bp65 expression in pancreatic tissues of rats with severe acute pancreatitis. *World J Gastroenterol* 2007; 13(6): 882-888

<http://www.wjgnet.com/1007-9327/13/882.asp>

### Abstract

**AIM:** To investigate dynamic changes and significance of expression of NF- $\kappa$ Bp65 in pancreatic tissues of rats with severe acute pancreatitis (SAP), as well as BN52021 effects.

**METHODS:** Wistar male rats were randomly divided into negative control group (NC group,  $n = 60$ ), SAP-model group (SAP group,  $n = 60$ ), and BN52021-treated group (BN group,  $n = 60$ ), and each of the above groups was respectively divided into 6 subgroups at different time points after operation (1 h, 2 h, 3 h, 6 h, 12 h, and 24 h) ( $n = 10$ ). By RT-PCR and Western blot, NF- $\kappa$ Bp65 mRNA and its protein expression in pancreatic tissues of rats were detected respectively.

**RESULTS:** The expression of NF- $\kappa$ Bp65 mRNA dynamically changed in both SAP groups and BN groups. The mRNA level was higher in SAP groups than NC groups at 2 h, 3 h, 12 h, and 24 h after operation ( $P < 0.05$ ), higher in BN groups than NC groups at all time points ( $P < 0.05$ ), and higher in BN groups than SAP group at 1 h ( $P < 0.05$ ). The NF- $\kappa$ Bp65 protein level was higher in SAP groups than NC groups at 1 h, 3 h, and 6 h ( $P < 0.01$ ), and 2 h, 12 h, and 24 h ( $P < 0.05$ ), higher in BN groups than NC groups at all time points ( $P < 0.05$ ), and lower in BN groups than SAP groups at 1 h, 3 h, and 6 h ( $P < 0.05$ ).

**CONCLUSION:** The expression of NF- $\kappa$ Bp65 in pancreatic tissues is dynamically changed and the changes play an important role in pathogenesis of SAP. BN52021 exerts therapeutic effects through reducing the expression level of NF- $\kappa$ Bp65 protein in the early stage of SAP.

### INTRODUCTION

Up to now, the precise pathogenesis of Severe acute pancreatitis (SAP) with a high mortality has not been completely elucidated although the theories of self-digestion, leukocyte over-activation, microcirculatory disorder, bacterial shifting and secondary infection, i.e. the second attack, immune functional change, cell apoptosis and oxygen free radicals etc. have explained the pathogenesis of SAP from different angles<sup>[1,2]</sup>.

NF- $\kappa$ Bp65 is a type of protein that can bind many kinds of cytokines and adhesion molecules at the  $\kappa$ B site of their gene promoters to enhance transcription of the genes. It plays an important role in cellular signal transduction in different theories of SAP pathogenesis<sup>[3]</sup>. For example, the activation of NF- $\kappa$ Bp65 is the decisive factor in many pathological states and it especially has a close relationship with the occurrence and pathophysiological process of severe infections<sup>[4]</sup>. In SAP pathogenesis, the clinical course of SAP is dependent on the over-activated inflammatory cells and inflammatory factors expressed, in which platelet activating factor (PAF) is a crucial transmitter for systematic inflammatory reaction of SAP. PAF was found to have the ability to activate NF- $\kappa$ B in 1994<sup>[5]</sup>, and the studies since then have shown that PAF receptor (PAF-R) is a target gene of NF- $\kappa$ B<sup>[6]</sup>. All these findings have attracted researchers to further study the relationship between PAF and NF- $\kappa$ B.

BN52021 (ginkgolide B) is a specific antagonist to PAF-R. In recent years, studies at home and abroad have showed that it has significant physiological activities, such as platelet aggregation inhibition, anti-inflammation, and anti-shock, etc. BN52021 has significant effects in treatment of animals with SAP<sup>[7,8]</sup>. But the exact pathogenesis of BN52021 on SAP is unknown. This study was aimed at dynamically investigating the changes and significance of the expression of NF- $\kappa$ Bp65 mRNA and its protein in pancreatic tissues and effects of BN52021 in rats with SAP.

## MATERIALS AND METHODS

### Main reagents and apparatus

BN52021 and sodium taurocholate were purchased from Sigma (USA), amylase kit was from Beijing Kemei Reagent Co. (Beijing, China), trizol and diethyl pyrocarbonate (DEPC) were from Invitrogen Company (USA), RT kit was from IBM Fermentas Company (Lithuania), dNTPs and the RNA enzyme inhibitor were from TaKaRa Company (Japan), DNA Tag enzyme was from Promega (USA), Primary antibody of NF-κBp65 rabbit-anti-rat serum and the enhanced chemiluminescence (ECL) system were from Santa Cruz Biotechnology (USA), secondary antibody of sheep-antirabbit was from Beijing Dingguo Biotechnology Co., Ltd. (Beijing, China), polyvinylidene fluoride (PVDF film) was from Millipore Corp. (USA), prestained marker was from Beijing Tianwei Time Biotechnology Co., Ltd. (Beijing, China), β-actin was from Beijing Zhongshan Biotechnology Co., Ltd. (Beijing, China), DYY-12 electrophoresis system and electric trans-blot SD were from Beijing Liuyi Instrument Factory (Beijing, China), type-2720 PCR apparatus was from ABI Company (USA), and gel scanning & imaging system and vertical electrophoresis system were from Bio-Rad (USA).

### Animal grouping and model preparation

One hundred and eighty Wistar male rats (weighing 0.20-0.23 kg, 6-8 wk old, Grade II, Certificate SCXK 2002-001) were provided by Laboratory Animal Center of PLA Academy of Military Medical Sciences, China. All rats were maintained in an environment of controlled temperature (22°C-25°C), humidity (55%-58%), and lighting (12 h light/12 h dark), with free access to tap water and regular chow diet. They were randomly divided into the negative controlled group (NC group,  $n = 60$ ), SAP-modeled group (SAP group,  $n = 60$ ), and BN52021-treated group (BN group,  $n = 60$ ), and each of the above groups was respectively divided into 6 subgroups at different time points after operation (1 h, 2 h, 3 h, 6 h, 12 h, and 24 h) ( $n = 10$ ). SAP models were prepared according to the method by Aho *et al.*<sup>[9]</sup>. Wistar male rats were weighed, marked and fasted for 24 h before the operation, with free access to water. Anaesthesia was conducted by abdominal cavity injection of 0.4% sodium pentobarbital (40 mg/kg). Rats were fixed in dorsal decubitus. The skin was prepared and sterilized. And a 2-cm incision was made along the middle line of the upper belly and the abdominal cavity was entered. The duodenum and pancreaticobiliary duct were searched, the hepatic end of the pancreaticobiliary duct was clipped with a non-invasive vascular clip, pancreaticobiliary duct retrograde centesis was conducted with an obtuse (pointless) needle through duodenum seromuscular layer, and then 5% sodium taurocholate (0.1 mL/100 g) was injected in the retrograde direction of pancreaticobiliary duct with a micro-syringe, at an injection rate of 0.20 mL/min. After the injection of the drug, the part of pancreaticobiliary duct entering the duodenum was clipped with a non-invasive vascular clip for 10 min, and then the vascular clip was removed. After making sure that there was no active bleeding in the abdominal cavity, the abdomen was closed in two layers, and the wound was covered with sterile gauze. For the rats in NC group, the

Table 1 Scoring standard of pathological change for pancreatic tissue of rats with SAP

Pathological grading	Pathological change	Scores
Edema	Inter-lobule local edema, widened pleura	1
	Inter-lobule diffuse edema, widened intra-lobule clearance	2
	Increased intra-lobule clearance, alveolus swollen, and separated	3
Inflammatory	White cells < 20/visual field under high-power microscope	1
Cell infiltration	White cells 20-50/visual field under high-power microscope	2
	White cells > 30/visual field under high-power microscope, or micro-abscess occurs	3
Hemorrhage	Parenchymal hemorrhage < 20%	1
	Parenchymal hemorrhage 20%-50%	2
	Parenchymal hemorrhage > 50%	3
Necrosis	Necrosis area < 20%	1
	Necrosis area 20%-50%	2
	Necrosis area > 50%	3

duodenum was merely stirred and pancreas was touched several times after opening the abdomen, and then the abdomen was closed. For the BN group, BN52021 (5 mg/kg; dissolved with Me<sub>2</sub>SO) was injected intravenously within 15 min after the operation; and for the groups of NC and SAP, the same volume of physiological saline (0.9% NaCl) was injected through femoral vein.

### Sample collection and storage

The rats in each group received anaesthesia at respective time points after the operation (1 h, 2 h, 3 h, 6 h, 12 h, and 24 h), and venous blood was collected from the right atrium. After a 10 min water bath at 37°C, and then a centrifugation for 10 min at 3000 g/min, the supernatant of the blood was respectively placed into sterilized EP tubes, and stored in a refrigerator at -20°C for determination of serum amylase. Meanwhile, two portions of pancreatic tissues of each group were treated differently; one portion was placed in liquid nitrogen overnight, and then frozen in a refrigerator at -80°C for further use, and another portion was fixed with 40 g/L neutral buffer formaldehyde, embedded with paraffin wax, cut into slices, and then HE stained for pathological observation and scoring.

### Determination of serum amylase

Determination of serum amylase was conducted using a fully automatic biochemical apparatus and an amylase kit.

### Pathological observation and scoring of pancreas

Pathological observation and scoring for pancreatic tissue samples (Table 1)<sup>[10]</sup>: 10 visual fields under a high-power microscope (HE stain, × 400) were randomly selected, and pathological changes of each item in the table were graded and scored, with a score of 0 for pathological changes of items not included in Table 1.

### Primers

NF-κBp65 primer was prepared according to the previous

method as reported<sup>[11]</sup>. The NF- $\kappa$ Bp65 and  $\beta$ -actin primers were synthesized by Shanghai Yingjun Biotechnology Co. Ltd. (Table 2).

#### Determination of NF- $\kappa$ Bp65 mRNA expression by RT-PCR

First, the total RNA of pancreatic tissues was extracted with Trizol Reagent for each group. Then, the integrity of the total RNA was examined by agarose electrophoresis, its concentration and purity were determined by a UV spectrophotometer, and the total RNA concentration of the sample was calculated. According to instructions of the RT reagent kit, 1  $\mu$ g of the total RNA was used, and OligdT18 was used as a primer to produce 20  $\mu$ L of the reaction system. PCR reaction was conducted by using 4  $\mu$ L cDNA-RT product, 3  $\mu$ L 10  $\times$  PCR buffer, 3  $\mu$ L dNTPs of 200  $\mu$ mol/L, 3  $\mu$ L upstream primer of 10 pmol/ $\mu$ L, 3  $\mu$ L downstream primer of 10 pmol/ $\mu$ L, 1  $\mu$ L Taq enzyme, and 13  $\mu$ L deionized double-distilled water. Thermal cycle conditions were as follows: Pre-degeneration for 4 min at 94°C, 45 s at 94°C, 1 min at 72°C; after 35 cycles, an extension was conducted for another 5 min at 72°C. For each PCR reaction, a negative control with the same volume of deionized double-distilled water instead of cDNA was used, and meanwhile, amplification was conducted to control DNA contamination. The housekeeping gene was amplified, i.e.  $\beta$ -actin, as internal reference for gene quantitative expression. The sequence of PCR product was determined by Shanghai Yingjun Biotechnology Co., Ltd., and the results were in accordance with the corresponding mRNA. To 5  $\mu$ L of RT-PCR product, 1  $\mu$ L of supernatant buffer (containing 0.2 mg/mL ethidium bromide) was added, electrophoresis was conducted on gels containing 1.5% agarose at 80 V for 45 min, and photographed with Quantity One Gel Imaging System. A semiquantitative analysis of the experimental results was conducted.

#### Determination of NF- $\kappa$ Bp65 protein expression by Western blot

The prepared total protein was added to gel-added buffer at a ratio of 1:2 and then heated in water at 100°C for 5 min. For its vertical plating electrophoresis, the added volume was 15  $\mu$ L. Each sample was palced on 2 parallel glue plates, one of which was used for staining and the other for membrane transferring. The voltage and time of electrophoresis were 80 v, 10 min and 120 v, 60 min for concentrating glue and isolating glue, respectively. The gels and membranes were placed among 6 sheets of filter paper and then between 2 foamy pads and put into electrical transfer tank containing buffer. After precooling for 10 min in icy water, the gel and membrane were galvanized for trans-printing for 4 h at a current of 1 mA/cm<sup>2</sup>. The trans-printed gel was stained to determine whether the trans-printing was complete. The trans-printed product was put into a solution containing 0.5% bovine serum albumin, slightly shaken and enclosed for 1 h. NF- $\kappa$ Bp65 antibody (diluted in 1:400) was added and placed at 4°C overnight. After the labeled PVDF membrane was washed with 0.05% Tween-20 buffer (TBST) for 5 min three times, it was incubated with IgG labeled with HRP (diluted

Table 2 PCR primer series, position and segment length of NF- $\kappa$ Bp65 and  $\beta$ -actin.

Gene	Primer series (5'-3')	Gene No.	Position	Length
NF- $\kappa$ Bp65	GAAGAAGCGAGACCTGGAG TCCGGAACACAATGGCCAC	NM_199267	424-442 821-803	398 bp
$\beta$ -actin	TCCTAGCACCATGAA GATC AAACGCAGCTCAGTAACAG	NM_031144	1044-1062 1233-1215	190 bp

in 1:200) at 4°C overnight. The membrane was washed with 0.05% TBST again for 5 min three times. The liquid of ECL A and that of ECL B were mixed at an equal volume (0.125 mL liquid/cm<sup>2</sup> membrane). The PVDF membrane was immersed in the mixed liquid for 1 min. Then the membrane was put on the freshness-retaining membrane. The trans-printing membrane was fixed in the developing tray and pictured using medical film for 30 s to 1 min, developed for 1-3 min and fixed for 1 min. Finally, the membrane was cleaned with water and dried up. The PVDF membrane was put into the desorption liquid, shaken at 50°C for 30 min, enclosed, added with  $\beta$ -actin antibody (diluted in 1:200) and placed at 4°C overnight. Then the above-mentioned process was repeated again for imaging. The results were photographed, saved in a computer, analysis was conducted by using Image-Pro Plus 4.5 image-analyzing software, and the integrated optical density (IOD) was calculated. The optical density ratio of target protein and  $\beta$ -actin in the same membrane was taken as the value of the final experimental results.

#### Statistical analysis

The above experiments were repeated 3 times, the average values were calculated as the final data, and expressed as mean  $\pm$  SEM. Data were processed with SPSS11.5 statistical software, normal test was conducted using *t* test and single-factor analysis of variance. Results were considered statistically significant when  $P < 0.05$  or  $P < 0.01$ .

## RESULTS

#### Serum amylase

It showed that the serum amylase in the SAP groups and the BN groups significantly increased at each time point than those in the NC groups ( $P < 0.05$ ); however, the values in the BN groups significantly decreased at 3 h, 6 h, and 24 h than those in the SAP groups ( $P < 0.05$ ) (Table 3).

#### Pathological observation and scoring

The pathological results showed that there was no obvious abnormality in abdominal cavity at all time points, and the pancreatic structure was almost normal in NC groups; in the SAP groups, hemorrhagic ascites occurred, necrosis foci were present in the pancreas, a number of saponifying spots occurred in the mesentery and greater omentum, and inflammatory cells infiltrated in pancreatic stroma and glandular lobule, and diffuse bleeding and piecemeal necrosis occurred and over time, the pathological changes were exacerbated; in the BN groups, the pathological changes were less serious than those in the SAP groups. It

**Figure 1** Pathological change of pancreatic tissues at 6 h after operation in each group. **A** and **B**: In NC group, the pancreatic structure was almost normal; **C** and **D**: In SAP group, inflammatory cells infiltrated, diffuse bleeding and piecemeal necrosis were occurred; **E** and **F**: In BN group, the pathological changes were less serious than those in SAP group.

**Table 3** Level of serum amylase at each time point in each group after operation (U/L)  $n = 10$ , mean  $\pm$  SD

Groups	Time points					
	1 h	2 h	3 h	6 h	12 h	24 h
NC	1835.6 $\pm 613.2$	1491.5 $\pm 507.0$	1530.4 $\pm 247.0$	1400.2 $\pm 447.5$	2153.2 $\pm 236.3$	337 $\pm 43.7$
SAP	2560.5 $\pm 121.5^a$	2810.5 $\pm 147.2^a$	4799.3 $\pm 107.0^a$	4919.7 $\pm 139.6^a$	3486.3 $\pm 181.8^a$	2283 $\pm 127.0^a$
BN	2214.5 $\pm 109.1^b$	3331.7 $\pm 196.4^b$	4185 $\pm 147.8^{bc}$	3784.7 $\pm 124.1^{bc}$	3454 $\pm 264.1^b$	1360.4 $\pm 161.4^{bc}$

<sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.05$  vs NC group; <sup>c</sup> $P < 0.05$  vs SAP group.

was shown that the scores in the SAP groups and the BN groups significantly increased at all time points than those in the NC groups ( $P < 0.05$ ); however, the scores in the BN groups markedly decreased at 3 h, 6 h, and 24 h than those in the SAP groups ( $P < 0.05$ ) (Figure 1, Table 4).

#### NF-κBp65 mRNA expression in the pancreatic tissues and effects of BN52021 on it

The expression of NF-κBp65 mRNA was dynamically changed in both SAP groups and BN groups in a dual-peak manner. The two peaks of the expression appeared at 1 h and 24 h in the SAP groups and at 1 h and 12 h in the BN groups and then the expression reached its lowest level at 6 h. The mRNA level was higher in SAP groups than NC groups at 2 h, 3 h, 12 h, and 24 h after operation ( $P < 0.05$ ), higher in BN groups than NC groups at all time points ( $P < 0.05$ ), and higher in BN group than SAP group at 1 h ( $P < 0.05$ ) (Figure 2, Table 5).

**Table 4** Scores of pancreatic tissues at each time point in each group after operation  $n = 10$ , mean  $\pm$  SD

Groups	Time points

<sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.05$  vs NC group; <sup>c</sup> $P < 0.05$  vs SAP group.

#### NF-κBp65 protein expression in the pancreatic tissue and effects of BN52021 on it

The NF-κBp65 protein level was markedly higher in SAP groups than NC groups at 1 h, 3 h, and 6 h ( $P < 0.01$ ), and 2 h, 12 h, and 24 h ( $P < 0.05$ ), also higher in BN groups than NC groups at all time points ( $P < 0.05$ ), but lower in BN group than SAP groups at 1 h, 3 h, and 6 h ( $P < 0.05$ ) (Figure 3, Table 6).

## DISCUSSION

Studies in recent years confirmed that cytokines and adhesion molecules play an important role in pathogenesis of SAP. NF-κBp65, which is a type of protein that can bind many kinds of cytokines and adhesion molecules at the κB site of their gene promoters to enhance transcription of the genes, plays an important role in the occurrence and development of SAP<sup>[4,11]</sup>. Meanwhile, it is one member of the family of transcription-regulating protein and a homologous or heterogenous dimer that contains 5 subunits of p50, p52, p65, cRel and RelB.

Under normal condition, it binds to its inhibiting protein single IκB (including IκBα, IκBβ and IκBε) and has no activity. Upon stimulation of cells by such activating signals as endotoxin or TNF-α, it separates from IκB and enters the cellular nucleus and binds with specific κB sequence of

DNA to enhance transcription of genes of inflammatory media and cytokines. In 1997, Dunn *et al*, for the first time, found that activation of NF-κBp65 is an important early event in the occurrence of acute pancreatitis (AP) through establishing bile-originated AP by ligation of pancreatic duct. Blinman *et al* showed that the activity of NF-κBp65 is significantly enhanced and the expression of IL-6 and KC increases in the pancreatic tissues in the early stage of edematous pancreatitis in rats induced by litorin. Therefore, they believe that the activation of NF-κBp65 plays an important role in pathogenesis of AP; IL-1, IL-6, IL-8, IL-10 and TNF are associated with AP. Since the production of these inflammatory cytokines is regulated by NF-κBp65 and activator protein 1, it is believed that NF-κBp65 plays the major role in the inflammatory media regulating network<sup>[12,13]</sup>.

In this study, we found that the expression of NF-κBp65 mRNA and protein were significantly higher in SAP groups than in NC groups at all time points. Moreover, the expression markedly increased in the early stage, dynamically changed in dual-peak and time-dependent

manners. These findings confirm that NF- $\kappa$ Bp65 plays an important role in the occurrence and development of SAP. The mechanisms include: SAP causes severe endotoxemia, and LPS and endotoxin component bind with their respective binding protein and CD14 molecule on cell membrane to form an LPS-LBP-CD14 complex to activate the signal transduction of Toll-like receptor 4, and the signal transduction further activates gene transcription of cytokines (such as IL-1, IL-6 and IL-8)<sup>[14]</sup>. In SAP, the pancreatic elastase is activated to activate NF- $\kappa$ Bp65 to exert its inflammation-inducing effects through the TLR4/NF- $\kappa$ B pathway. Consequently, damage of pancreatic self-digestion function and injuries of other organs outside of pancreas occur<sup>[15]</sup>. In SAP, PLA2 is activated to activate expression of NF- $\kappa$ Bp65 of target cells in tissues<sup>[16]</sup>. NF- $\kappa$ Bp65 is firstly activated in the pancreatic tissue to release cytokines. The cytokines start the “waterfall reaction” of inflammatory media through the “triggering role”. The inflammatory media such as PAF are released into the blood. Though the activation of NF- $\kappa$ B in the pancreatic tissues can be partly inhibited by intra- and extracellular pathways of negative feedback of NF- $\kappa$ Bp65, the inflammatory media can again activate NF- $\kappa$ Bp65 in other organs outside of pancreas (neutrophils, Kuffer cells, liver, lung and intestines, etc.) to produce more inflammatory media. As a result, they participate in the development of SAP and aggravate the injuries of pancreas and other organs or even cause SIRS, ARDS and MOF<sup>[4]</sup>.

BN52021, one of the effective components of Chinese medicine ginkgo biloba leaf and a strong antagonist against the inflammatory medium of PAF, can not only block the signal transduction of PAF but also decrease blood concentration of PAF to exert its biological effect<sup>[17]</sup>. This study showed that BN52021 could decrease serum amylase level and alleviate pathological changes in SAP, which is consistent with that reported by other researchers<sup>[18,19]</sup>. The expression of NF- $\kappa$ Bp65 mRNA was significantly higher in SAP and BN groups than in NC group at all time points after operation. However, it was markedly higher in BN groups than in SAP group at 1 h after the operation. The reason for the latter might be that the MeSO used for dissolution of BN52021 can aggravate inflammatory reaction in the early stage of SAP, resulting in enhancement of NF- $\kappa$ Bp65 mRNA expression, however, the mechanism needs to be further elucidated. Our results suggest that BN52021 does not significantly affect the expression of NF- $\kappa$ Bp65 mRNA. The expression of NF- $\kappa$ Bp65 protein was significantly lower in BN groups than in SAP groups at 1, 3 and 6 h after operation. However, it was still markedly higher in BN groups than in NC groups at all time points after operation. These findings suggest that BN52021 can inhibit the expression of NF- $\kappa$ Bp65 protein in the early stage, to some extent, which might be one mechanism of its therapeutic effects on SAP. However, there was difference in the effect of BN52021 on NF- $\kappa$ Bp65 mRNA expression and its protein expression. We believe that BN52021 causes downstream changes in signal transduction, leading to the difference, the mechanism of which also needs to be further studied.

In summary, the increase of NF- $\kappa$ Bp65 expression

plays an important role in pathogenesis of SAP. BN52021 can decrease serum level of amylase and alleviate pathological changes in SAP. Meanwhile, it can decrease expression of NF- $\kappa$ Bp65 protein in pancreatic tissues in the early stage of SAP to exert its therapeutic effects.

## COMMENTS

### Background

BN52021 (ginkgolide B) is a specific antagonist to platelet activating factor receptor (PAF-R). In recent years, studies at home and abroad have shown that it has significant physiological activities, such as platelet aggregation inhibition, anti-inflammation, and anti-shock. BN52021 has significant effects in treatment of animals with severe acute pancreatitis (SAP). But the exact pathogenesis of BN52021 on SAP is unknown. This study was aimed to dynamically investigate the changes and significance of the expression of NF- $\kappa$ Bp65 mRNA and its protein in pancreatic tissues and effects of BN52021 in rats with SAP.

### Research frontiers

To explore molecule mechanism of BN52021 on severe acute pancreatitis.

### Innovations and breakthroughs

BN52021 has remarkable curative effects in acute pancreatitis. But the mechanism of BN52021 hasn't been researched extensively. The study explored the significance of NF- $\kappa$ Bp65 in platelet activating factor receptor signal transduction.

### Applications

The results may provide theoretic and experimental evidence for study, and application of BN52021, and new approaches for therapy of severe acute pancreatitis.

### Terminology

NF- $\kappa$ Bp65 is a type of protein that can bind many kinds of cytokines and adhesion molecules at the  $\kappa$ B site of their gene promoters to enhance transcription of the genes. It plays an important role in cellular signal transduction in different theories of pathogenesis of severe acute pancreatitis. BN52021, namely code of ginkgolide B, one of the effective components of Chinese medicine ginkgo biloba leaf and a strong antagonist against the inflammatory medium of platelet activating factor (PAF), can not only block the signal transduction of PAF but also decrease blood content of PAF to exert its biological effect. It has significant physiological activities, such as platelet aggregation inhibition, anti-inflammation, and anti-shock.

### Peer review

The results show that the expression of NF- $\kappa$ Bp65 in pancreatic tissues dynamically changed and the changes played an important role in pathogenesis of severe acute pancreatitis (SAP). BN52021 exerted some kind of therapeutic effect through reducing the expression level of NF- $\kappa$ Bp65 proteins in the early stage of SAP.

### Abstract

**AIM:** To determine serum  $\gamma$ -glutamyltransferase (GGT), alanine aminotransferase (ALT), and aspartate aminotransferase (AST) activity, and to assess their correlation with demographic and clinical findings in healthy blood donors.

**METHODS:** This cross-sectional study was performed in 934 male blood donors, aged 18 to 68 years, who consecutively attended Tehran blood transfusion service in 2006. All participants were seronegative for HBV or HCV infections, non alcohol users, and all underwent a standard interview and anthropometric tests. Clinical and biochemical parameters including AST, ALT, and GGT activities were determined. Patients taking drugs known to cause hepatic fat deposition were excluded. For AST, ALT, and GGT variables, we used 33.33 and 66.66 percentiles, so that each of them was divided into three tertiles.

**RESULTS:** Mean AST, ALT, and GGT activities were  $25.26 \pm 12.58$  U/L (normal range 5-35 U/L),  $33.13 \pm 22.98$  (normal range 5-35 U/L), and  $25.11 \pm 18.32$  (normal range 6-37 U/L), respectively. By univariate analyses, there were significant associations between increasing AST, ALT, or GGT tertiles and age, body weight, body mass index, and waist and hip circumferences ( $P < 0.05$ ). By multiple linear regression analyses, ALT was found to be positively correlated with dyslipidemia ( $B = 6.988$ ,  $P = 0.038$ ), whereas ALT and AST were negatively correlated with age. AST, ALT, and GGT levels had positive correlation with family history of liver disease ( $B = 15.763$ ,  $P < 0.001$ ), ( $B = 32.345$ ,  $P < 0.001$ ), ( $B =$

$24.415$ ,  $P < 0.001$ ), respectively.

**CONCLUSION:** Although we did not determine the cutoffs of the upper normal limits for AST, ALT, and GGT levels, we would suggest screening asymptomatic patients with dyslipidemia and also subjects with a family history of liver disease.

### INTRODUCTION

The level of aspartate aminotransferase (AST), alanine aminotransferase (ALT),  $\gamma$ -glutamyltransferase (GGT) elevation that is considered abnormal varies widely and has recently been brought into question<sup>[1]</sup>. There is also debate as to whether or not different cutoffs are indicated for normal ranges of liver enzymes. Several studies have shown that variation in serum AST ALT or GGT in the population is associated with risk of development of cardiovascular disease, type 2 diabetes, stroke, or hypertension<sup>[2,3]</sup>. Nonalcoholic fatty liver disease (NAFLD) is a common explanation for abnormal liver-test results in blood donors, and it is the cause of asymptomatic elevation of aminotransferase levels in up to 90 percent of cases once other causes of liver disease are excluded<sup>[4]</sup>. Associations between abnormal values and also the prevalence and the risk factors for fatty liver have not undergone a formal evaluation in a representative sample of the general population. NAFLD is emerging as a component of the metabolic syndrome, although it is not known whether markers of NAFLD, including elevated concentrations of AST, and ALT, predict the development

of metabolic syndrome. The third report of the National Cholesterol Education Program expert panel on Detection, Evaluation, and Treatment of High Blood Cholesterol in Adults (ATP III) defines metabolic syndrome as involving three or more of the following criteria<sup>[5]</sup>:

- Central/abdominal obesity as measured by waist circumference: for men > 40 inches (102 cm) and for women > 35 inches (88 cm).
- Fasting plasma triglycerides  $\geq$  150 mg/dL (1.69 mmol/L)
- HDL cholesterol for men < 40 mg/dL (1.04 mmol/L), and for women < 50 mg/dL (1.29 mmol/L)
- Blood pressure  $\geq$  130/85 mmHg
- Fasting plasma glucose  $\geq$  110 mg/dL (6.1 mmol/L)

Also frequently seen with metabolic syndrome but not included in the ATP III criteria are prothrombotic and proinflammatory tendencies. All of the factors associated with metabolic syndrome are interrelated. Obesity and lack of exercise tend to lead to insulin resistance. Insulin resistance has a negative effect on lipid production, increasing VLDL (very low-density lipoprotein), LDL and triglyceride levels in the bloodstream and decreasing HDL (high-density lipoprotein). This can lead to fatty plaque deposits in the arteries enhancing the risks for cardiovascular disease, blood clots, and strokes. Excess insulin increases renal sodium retention, which increases blood pressure and can lead to hypertension.

Our aim was to determine serum  $\gamma$ -glutamyltransferase, alanine aminotransferase, and aspartate aminotransferase activity and to investigate their relationship with several components of the metabolic syndrome in 934 healthy male blood donors in Tehran blood transfusion center from 15 February to 22 March 2006.

## MATERIALS AND METHODS

### *Clinical and laboratory assessment*

Nine hundred thirty four apparently healthy Iranian men, who attended to Tehran blood transfusion center for blood donation during a 37-d period from 15 February to 22 March 2006, were consecutively enrolled in the cross-sectional study. A standard interview, anthropometrics, and biochemical analyses were conducted for each participant. Samples from all donations were tested according to the recognized screening test algorithms for hepatitis B surface antigen, anti-HCV, anti-HIV1/2, syphilis, and for AST, ALT and GGT levels. Samples repeatedly reactive or indeterminate for HBsAg were further analyzed with a second independent HBsAg enzyme immunoassay (EIA), and if further reactive, were tested by a neutralization assay. Samples repeatedly reactive or indeterminate for anti-HCV were confirmed with an additional independent anti-HCV EIA and with a HCV-RIBA assay. Samples repeatedly reactive or indeterminate for HIV were confirmed with a second independent anti-HIV1/2 test, a p24 Ag assay and a HIV western blot. Samples reactive to venereal disease research laboratory (VDRL) were tested by fluorescent Treponemal antibody absorbed (FTA-ABS) as confirmatory test for syphilis infection.

The following conditions were excluded: seropositivity for hepatitis B surface antigen, and or antibody to hepatitis C virus, approved by confirmatory tests of hepatitis B and

C viruses, alcohol consumption, use of drugs which may produce fatty liver as asparaginase, tetracycline, warfarin, amiodarone, tamoxifen, estrogens, bleomycin, diltiazem, nifedipine, methotrexate, corticosteroids, and salicylates. Cigarette smoking was not considered a criterion for exclusion. As number of female blood donors were limited (56 subjects), their data were not included. Personal and family history of hypertension, ischemic heart disease, stroke, dyslipidemia, diabetes mellitus, chronic liver disease according to diagnosis of physician, cigarette smoking, medication history, demographic findings such as body weight, height, body mass index, waist and hip circumferences, waist to hip ratio, and blood pressure were recorded. All anthropometric measurements were made by the same physician. Former and present smokers were defined as ever smokers. Established diagnosis of diabetes was considered if random blood sugar > 200 mg/dL ( $\geq$  11.1 mmol/L) plus symptoms of diabetes or the patient was a known case of diabetes by a physician. Dyslipidemia was diagnosed in the case of documented use of anti-lipemic medication, or the fasting levels of total cholesterol above 200 mg/dL or triglycerides above 170 mg/dL. The diagnosis of hypertension was based on the following criteria: systolic blood pressure  $\geq$  140 mmHg and or diastolic blood pressure  $\geq$  90 mmHg measured within 30 min in the sitting position using a brachial sphygmomanometer or ongoing use of antihypertensive treatment. Personal history of ischemic heart disease, stroke, family history of diabetes, family history of chronic liver disease in first relatives were recorded if the diagnoses were approved by a physician.

Venous blood was drawn from antecubital vein. AST, ALT and GGT levels were detected by auto-analyzer. AST, ALT and GGT in serum were determined by ELISA method. Furthermore, to eliminate effect of freeze-thawing of samples that may lower enzyme activity values, ALT, AST, and GGT testing was conducted on samples which were immediately carried to the laboratory. We did not exclude people with known diabetes that is likely to be affected more commonly with fatty liver disease, to avoid bias in conclusions. The study proposal and the protocol were approved by the ethics committee of Baqiyatallah University of Medical Sciences, and a written informed consent was obtained from each participant.

### *Statistical analysis*

Analysis was performed using SPSS software version 13.0. For numerical variables we used mean value, standard deviation, median, 5<sup>th</sup> and 95<sup>th</sup> percentiles, maximum and minimum. For categorical variables we used number and percent. Since AST, ALT, and GGT values were not gaussian distributed, the levels of these variables were logarithm neperian (Ln) transformed. For measurement of their mean, we changed the amounts to normal Log and then we used exponential of mean and used that as mean of variables.

We used 33.33 and 66.66 percentiles and each variable was divided into three groups. For associations of them with numerical variables variance analyses, and for analyzing statistical difference among categorical variables in relation to AST, ALT, and GGT levels, chi-square tests

were performed. If it was a difference between groups, in analysis variance, we used LSD test for showing the group that had significant difference. All reported *P* values are two tailed, and those < 0.05 were considered statistically significant. Multiple linear regression analyses were conducted to assess variables that are associated with increased AST, ALT, or GGT levels, and all the variables entered the model and then those that had a *P* value less than 0.1 were maintained in the equation.

## RESULTS

The mean age of 934 participants was 40.83  $\pm$  10.96 (range of 18.00 to 68.00) years. The mean body mass index, waist circumference, and waist to hip ratio (WHR) were 27.09  $\pm$  3.98, 95.62  $\pm$  9.41 centimeter, and 0.93  $\pm$  0.04, respectively. Mean AST, ALT, and GGT activities were 25.26  $\pm$  12.58 U/L (normal range 5-35 U/L), 33.13  $\pm$  22.98 U/L (normal range 5-35 U/L), and 25.11  $\pm$  18.32 U/L (normal range 6-37 U/L), respectively. Mean (Transformation Ln) of AST, ALT, and GGT were 23.76, 28.45, and 20.52, respectively. Considering 5<sup>th</sup> and 95<sup>th</sup> percentiles of AST (16, 42), ALT (13, 70), or GGT (8, 58) U/L, the 95<sup>th</sup> percentiles values were high in the population studied. Subjects were divided into three groups according to liver enzyme

tertiles. In AST tertiles, AST level was < 21, 21-25 U/L, and AST > 25 U/L in groups 1, 2, and 3, respectively. In ALT tertiles, ALT level was < 22, 22-34, and > 34 U/L in groups 1, 2, and 3, respectively. In GGT tertiles, GGT level was < 15 U/L, 15-25 U/L, and > 25 U/L in groups 1, 2, and 3, respectively.

Comparative demographic, clinical and biochemical characteristics of our study population in AST, ALT, and GGT tertile groups by univariate analyses are shown in Tables 1, 2, and 3. Univariate analyses show significant associations between increasing AST, ALT, or GGT tertiles and age, body weight, body mass index, central adiposity, waist and hip circumferences (*P* < 0.05). Moreover, evidence that increasing ALT, AST, and GGT tertiles are associated with demographic parameters of the metabolic syndrome (body weight, body mass index, waist circumference and hip circumference), support the conclusion that most of the abnormalities are probably due to NAFLD. The mean body mass index in our study population of 27.09  $\pm$  3.98 could implicate a potentially important public health attention.

Table 4 shows correlation of our study characteristics with AST, ALT, or GGT levels in multiple linear regression.

In multiple linear regression analysis, AST was found

Table 3 GGT tertiles according to characteristics of the study population

Variable	GGT			P
	< 15	15-25	> 25	
Age (mean ± SD), yr	38.8 ± 11.4	42.4 ± 11.2	41.3 ± 10.1	0.000 (group 1 vs group 2, 3)
Body weight (mean ± SD), kg	79.1 ± 11.2	83.8 ± 12.6	85.7 ± 13.9	0.000 (group 1 vs group 2, 3)
Height (mean ± SD), cm	174.6 ± 6.5	174.9 ± 7.0	175.1 ± 6.6	0.675
Body mass index (BMI) (mean ± SD)	25.9 ± 3.3	27.6 ± 4.3	27.9 ± 4.0	0.000 (group 1 vs group 2, 3)
Waist circumference (mean ± SD), cm	92.9 ± 9.1	96.5 ± 9.5	97.8 ± 8.9	0.000 (group 1 vs group 2, 3)
Hip circumference (mean ± SD), cm	99.2 ± 8.9	102.8 ± 9.0	103.7 ± 8.5	0.001 (group 1 vs group 2, 3)
Waist to hip ratio (WHR) (mean ± SD)	0.94 ± 0.04	0.94 ± 0.04	0.94 ± 0.05	0.103
Diabetes mellitus (% positive)	0.6	2.0	2.3	0.217
Family history of diabetes (% positive)	19.1	22.1	19.5	0.608
Family history of liver disease (% positive)	0.0	1.0	2.3	0.023
Hypertension (% positive)	2.2	2.7	3.6	0.582
Dyslipidemia (% positive)	5.1	7.1	7.2	0.486
Smoking habit (% positive)	19.49	23.29	22.7	0.471

to be inversely related with age and smoking habit ( $B = -0.125$ ,  $P = 0.002$ ;  $B = -1.874$ ,  $P = 0.076$ , respectively).

ALT was negatively correlated with age ( $B = -0.317$ ,  $P = 0.000$ ), and positively with a personal history of dyslipidemia ( $B = 6.988$ ,  $P = 0.038$ ). For AST, ALT, and GGT levels positive associations were found with a family history of liver disease ( $B = 15.763$ ,  $P < 0.001$ ;  $B = 32.345$ ,  $P < 0.001$ ; and  $B = 24.415$ ,  $P < 0.001$ , respectively).

## DISCUSSION

In the general population, the estimated NAFLD prevalence ranges from 3% to 24%, with most estimates in the 6% to 14% range. NAFLD appears to be most strongly associated with obesity. It appears to be more common in men, and it increases with increasing age and after menopause. More advanced stages of NAFLD are associated with older age and higher body mass index<sup>[6]</sup>. In Ruhl *et al*<sup>[7]</sup> study, elevated ALT was associated with younger age corresponding to our study in which increasing ALT and AST tertiles were inversely related to age.

NAFLD is the major cause of elevation of ALT and it is in fact considered the hepatic manifestation of metabolic syndrome<sup>[8]</sup>. In a study of 10 368 adults aged 20 years and over, participating in the Tehran Lipid and Glucose Study<sup>[9]</sup>, the age-standardized prevalence of the metabolic syndrome was 33.7%.

Several studies have shown that variation in serum GGT in the population is associated with risk of death or development of cardiovascular disease, type 2 diabetes, stroke, or hypertension. Whitfield JB *et al*<sup>[2]</sup> estimated the relative importance of genetic and environmental sources of variation in GGT. There were highly significant correlations between GGT and body mass index, serum lipids, lipoproteins, glucose, insulin, and blood pressure. These correlations were more attributable to genes that affect both GGT and known cardiovascular risk factors than to environmental factors.

Nakanishi N *et al*<sup>[3]</sup> investigated the association between serum GGT and risk of metabolic syndrome and type 2 diabetes mellitus. The results of the article indicate that serum GGT may be an important predictor for developing

Table 4 Correlation of the study population characteristics with AST, ALT, and GGT levels

Dependent variable	Independent variable	Coefficients		P
		B	Std. Error	
AST	Age	-0.125	0.039	0.002
	Family history of liver disease	15.763	4.029	0.000
	Smoking habit	-1.874	1.056	0.076
ALT	Age	-0.317	0.071	0.000
	Family history of liver disease	32.345	7.258	0.000
	Dyslipidemia	6.988	3.363	0.038
GGT	Family history of liver disease	24.415	5.791	0.000

metabolic syndrome and type 2 diabetes mellitus. Kim HC, *et al*<sup>[10]</sup> showed that the serum ALT and GGT levels were significantly associated with metabolic syndrome in men but not in women.

In the present study, correlation between family history of liver disease and increased liver enzymes may be attributable to genes that affect AST, ALT, and GGT and also known metabolic syndrome risk factors and environmental factors. Although we did not exclude other etiologies of hepatitis in families of blood donors, the association of family history of hepatitis with increasing AST, ALT, or GGT levels may show a genetic predisposition. As fatty liver is the most common cause of liver function test abnormality, further investigation is needed for genetic and dietary habits as predisposing factors for liver abnormality. Interaction of genetic and environmental factors might be the trigger of inflammatory cascades leading to metabolic syndrome. Rising liver enzymes activity may be the hepatic manifestation of ongoing inflammation and metabolic syndrome. The liver plays an important role in maintaining normal glucose concentration. It is also a major site of insulin clearance<sup>[11]</sup>. Type 2 diabetes mellitus is a public health problem of epidemic dimension and its prevalence is on the rise. Many risk factors, including the metabolic syndrome, have been implicated in its development<sup>[12]</sup>.

There are controversies about normal ranges of liver enzymes in the general population. Furthermore, the level of elevation that is considered abnormal varies widely and has recently been brought into question. There is also a

debate as to whether or not different cutoffs are indicated for normal ranges of liver enzymes in men and women. Given all the controversy, it is clear that more acceptable and accurate means of noninvasive diagnostic approach to NAFLD as the most common cause of liver function test abnormality is needed. In addition, the use of higher cutoff values for normal ALT, AST, or GGT would lower the estimated prevalence of occult liver disease in the population.

Mohammadnejad M *et al*<sup>[13]</sup> showed that serum ALT activity was independently associated with body mass index and male gender, but not with age. The upper normal limit for non-overweight women (BMI of less than 25) was 34 U/L, and for non-overweight men 40 U/L. This article suggested that the normal range of ALT should be defined for male and female separately. Using this level of upper limit value for ALT activity, the authors of this paper may lose some men with NAFLD who need screenings. Our study corresponds with their data with respect to the association of liver enzymes and body mass index but we also noted liver enzyme correlation with age, body weight, and waist and hip circumferences.

Ruhl and Everhart<sup>[7]</sup> reviewed data from the third US National Health and Nutrition Examination Survey (1988-1994) in which adult participants underwent anthropometric measurements. Abnormal ALT was defined as ALT > 43 U/L for men or women. Serum ALT levels as a surrogate marker for NAFLD were elevated in 2.8% of the study population. Moreover, using recently suggested lower normal values for ALT (> 30 U/L for men and > 19 U/L for women), they found elevated levels in 12.4% of men and 13.9% of women. Clark JM and Diehl AM<sup>[1]</sup> in their editorial comment on Ruhl C *et al*<sup>[7]</sup> acknowledged that occult liver disease may be more common than previously suspected. They agreed that the association of ALT abnormalities with the metabolic syndrome supports the conclusion that the ALT elevations are due to NAFLD. The conditions associated with fatty liver disease presenting with normal liver enzymes and the mechanism involved in its development remain to be fully elucidated.

The hypothesis that fatty liver with normal liver enzymes occurs more frequently in arterial hypertensive patients was tested by Donati G *et al*<sup>[14]</sup> and they found that the condition is associated with insulin resistance. Essential hypertension is considered an insulin resistant state<sup>[15]</sup>, and approximately 50% of patients with arterial hypertension are reported to be insulin resistant with hyperinsulinemia<sup>[16]</sup>, a value much higher than that is found in the general population.

Our study population was consisted of healthy blood donors who are a better sample to indicate the burden of occult liver disease and NAFLD in the general population compared to the sampling from gastroenterology clinics or referred patients with metabolic syndrome. History of personal hypertension had no statistically significant association with increasing liver enzyme levels. It is noteworthy that hypertensive patients are not good candidates for blood donation and, because most of them have already been excluded from our study, interpretation of our findings in this regard is limited.

Our study has some limitations. The vast majority of our participants were male; and the volunteer blood donors are healthier than general population. In this study, all the biochemical and clinical variables predicting the presence of metabolic syndrome were not examined. We did not consider the racial, ethnicity, genetic and environmental sources of variation in AST, ALT, and GGT; amount of regular physical activity, eating habits, and biochemical characteristics of metabolic syndrome. We did not determine cutoffs of liver enzymes for estimation of non-alcoholic fatty liver disease, although NAFLD is reported even in normal range of liver enzymes. A better understanding of the factors that modulate liver disease progression is critical, so that we can target selected patients for more aggressive monitoring, lifestyle interventions, and pharmacotherapy.

In conclusion, variation within the normal ranges of AST, ALT, and GGT in healthy subjects is associated with some components of metabolic syndrome. In adult healthy men, those in the highest AST, ALT, and GGT levels, present with family history of liver disease; and those in the highest ALT levels, present with dyslipidemia. It is reasonable to recommend screening those with dyslipidemia that is also a risk factor for atherosclerosis and premature cardiovascular disease. Moreover, screening subjects with evidence of abdominal obesity and family history of liver disease is necessary.

The follow-up of these individuals would determine if certain amounts of AST, ALT, and GGT values might be considered as early predictors of subsequent fatty liver and the metabolic syndrome. In this way, the health-related outcomes of AST, ALT, and GGT values and the needed optimal frequency of their visiting would be determined. The health benefits of screening for fatty liver and other components of metabolic syndrome seems as necessary as performing tests for evidence of viral hepatitis B and C infections.

## Abstract

**AIM:** To assess whether radiation dose and duration of treatment influence local control and survival of patients with locally advanced anal cancer treated with definitive chemoradiation.

**METHODS:** Twenty-eight consecutive patients who were treated with definitive radiation therapy for bulky anal cancers (> 5 cm in size) were reviewed. Nineteen patients had T3 lesions, 8 patients had T4 lesions, and 15 patients had lymph node involvement. The median tumor size was 7.5 cm. All but one patient received concurrent chemoradiation. The median radiation dose was 54 Gy. The median duration of treatment was 58 d.

**RESULTS:** With a median follow-up of 2.5 years in all patients and 7.8 years in living patients, the 2-year local recurrence-free probability was 57% and overall survival rate was 67%. Neither radiation dose nor duration of treatment alone was predictive of either time to local failure or overall survival. However, longer treatment breaks can potentially mask an advantage over higher radiation doses. Therefore, we examined those patients who received  $\geq 54$  Gy within 60 d, comparing them to the rest of the patients. Of patients who received  $\geq 54$  Gy within 60 d, local progression-free probability was 89% versus 42% for the rest of the group ( $P = 0.01$ ).

**CONCLUSION:** Local failure is a significant problem in locally advanced carcinomas of the anal canal. Higher radiation doses with limited treatment breaks may offer an increase in local control and survival.

## INTRODUCTION

Combined chemoradiation has been established as the standard treatment for epidermoid anal cancer by randomized trials that have demonstrated improvements in local control and disease free survival compared to radiation alone<sup>[1,2]</sup>. Administered with radiation, the combination of 5-fluorouracil (5-FU) and mitomycin C is the regimen of choice, providing superior disease-free survival compared to 5-FU alone<sup>[3]</sup>. However, for locally advanced anal cancer, especially lesions greater than 5 cm, local control rates of only 50% have been achieved<sup>[4,5]</sup>. Higher radiation dose has been shown to improve outcome in some studies<sup>[6-9]</sup>. A phase II radiation dose escalation trial for anal cancer performed by the Radiation Therapy Oncology Group (RTOG) showed increased colostomy rates with increased doses compared to patients treated with a lower dose in a previous RTOG trial<sup>[10]</sup>. The worse outcome may in part be attributed to a mandatory 2 wk break in this trial. It is unclear if increasing the radiation dose in patients with locally advanced anal cancer receiving combined modality therapy will improve the results compared with doses of 45-50 Gy<sup>[10]</sup>.

In order to assess whether higher radiation doses improve clinical outcome for patients with locally advanced anal cancer, we retrospectively reviewed treatment outcomes of patients with bulky (> 5 cm) epidermoid anal cancer. Radiation dose, treatment time, as well as patient, tumor and treatment related factors were evaluated for prognosis.

## MATERIALS AND METHODS

### Subjects

This work has been approved by the Institutional Review

Board of the University of California, San Francisco. Between 1982 and 2000, 28 consecutively treated patients underwent definitive radiation therapy for documented bulky anal cancers (disease greater than 5 cm in primary tumor or lymph nodes). Patients who had local excision prior to radiotherapy were excluded. Of 28 patients, 27 had bulky disease at primary sites and one had bulky lymph node disease. One patient was treated for bulky recurrent disease after abdominoperineal resection.

### Treatment

One patient declined treatment with chemotherapy and was treated with radiation alone, while the other 27 patients received concurrent chemoradiation. Chemotherapy consisted of 5-FU and mitomycin C in 23 patients, 5-FU and cisplatin in one patient and 5-FU alone in three patients. 5-FU was given at 1000 mg/m<sup>2</sup> over 4 d. Generally mitomycin C was given at 10 mg/m<sup>2</sup>. Cisplatin was given at 75 mg/m<sup>2</sup> every 4 wk. One patient was treated with induction 5-FU and cisplatin with progressive disease, followed by 5-FU and mitomycin C concurrently with radiation. All patients received 2 cycles of chemotherapy generally at an interval of 4 wk concurrently with radiation, except for one patient who died of fulminant hepatitis after receiving only one cycle of chemotherapy. Two patients received 5-FU alone during the second cycle after severe hematologic toxicity associated with the first cycle of chemotherapy with 5-FU and mitomycin.

Radiation was administered utilizing 6 or 18 MV photons. Treatment fields were AP/PA to the whole pelvis and bilateral inguinal regions, followed by a lateral field boost plus/minus electron field boost to cover the inguinal regions. The first field reduction was at 30.6 Gy to the true pelvis, followed by subsequent field reductions at 36 Gy and 45 Gy. For patients who had a CD4 count < 200, the initial field was the true pelvis to minimize toxicity. Before 1985, radiation doses of 40-50 Gy were planned, while after 1985, target radiation doses were increased to 54-60 Gy. Five patients did not receive the planned doses of radiation, secondary to toxicity in 3 patients, receiving 36 Gy, 50.4 Gy and 51.4 Gy, respectively, and noncompliant in 2 patients, receiving 50.4 Gy and 45 Gy, respectively. The radiation doses ranged from 31 to 65 Gy, with a median of 54 Gy. The dose per fraction ranged from 1.6 to 2.0 Gy once daily. The lower dose per fraction of 1.6 to 2.0 Gy was used in the early 80's when radiation was first used concurrently with chemotherapy.

### Follow-up

All the patients were evaluated at least once a week during radiotherapy. The patients were then evaluated every 1-2 mo for the first 6 mo, followed by every 3 mo for the next 6-12 mo, every 4-6 mo from 18 mo through 3 years, and annually thereafter. At each follow-up visit, a physical examination, including digital rectal examination, and palpation of the inguinal regions was performed. Acute and late effects on normal tissues were graded according to the CTCAE v3 scoring criteria.

Table 1 Distribution of patients by the 2002 American Joint Committee on Cancer Staging Classification<sup>1</sup>

Stage	N0	N1	N2	N3	Total
T3	6	3	6	4	19
T4	6	0	1	1	8
Total	12	3	7	5	27

<sup>1</sup>One patient who had recurrent disease with an initial stage of T2N0 was not included in this table.

Figure 1 Kaplan-Meier estimate of the probability of local freedom from progression.

### Statistical analysis

This is a retrospective analysis of treatment outcomes for bulky anal carcinoma treated at UCSF. Descriptive statistics (mean, median, and proportions) were calculated to characterize the patient, disease, and treatment features. Estimates of survival rates and recurrence-free probabilities were calculated using the Kaplan-Meier product limit method. Durations were calculated from the date of diagnosis. Univariate analyses were performed to evaluate factors that may be predictors of outcome. The log rank test was used to compare distributions of subsets.

## RESULTS

### Patient characteristics

The cohort included 10 women and 18 men with a median age of 63 years (range 30-79 years). Eight patients had cloacogenic carcinoma and 20 patients had squamous cell carcinoma. Table 1 shows the T- and N-stage distributions of the patients according to the 2002 AJCC staging classification. Nineteen patients had T3 lesions, 8 patients had T4 lesions, 1 had recurrent disease and 15 patients had pathologically involved lymph nodes. The median tumor size was 7.5 (range 5.5-12) cm. Four patients were human immunodeficiency virus (HIV) positive with CD4 counts of 63 180 238 and 347, respectively.

### Treatment outcome

With a median follow-up of 2.5 (range 0.2-17.3) years for

**Figure 2** Kaplan-Meier estimate of the probability of overall survival.

all patients and 7.8 (range 1.1-17.3) years for living patients, the 2-year and 5-year local recurrence-free probabilities and 95% confidence intervals (CI) were 57% (95% CI: 37%-73%) and 52% (95% CI: 32%-69%), respectively (Figure 1). The 2- and 5-year overall survival estimates were 67% (95% CI: 46%-81%) and 54% (33%-71%), respectively (Figure 2). The 2- and 5-year colostomy-free survival estimates were 42% (95% CI: 24%-60%) and 33% (95% CI: 16%-51%), respectively. Sixteen patients had persistent abnormalities at the completion of radiotherapy. In 12 of the 16 patients, biopsies of the persistent abnormalities revealed pathological documentation of residue disease in 5 patients. The single patient with a bulky lymph node experienced a lymph node failure, with a concurrent distant failure 25 mo after diagnosis. In the 4 patients who were HIV positive, 2 experienced local failures, 1 experienced a regional failure, and one died of fulminant hepatitis during treatment after receiving only 36 Gy, presumably secondary to chemotherapy. In patients treated with 5-FU alone with concurrent radiation, 2 out of 3 experienced local failures. The patient who did not receive any chemotherapy also had a local recurrence.

### Toxicity

Acute side effects of radiation therapy and chemotherapy were moderate to severe. Twenty patients had acute grade 3 or 4 toxicities including 15 patients with grade 3 dermatological toxicities, 1 patient with grade 3 gastrointestinal toxicity, and 5 patients with grade 3 and 4 with grade 4 hematologic toxicities. The worst acute toxicity was dermatological in 10 patients, hematologic in 5 patients, both dermatological and hematologic in 4 patients, and gastrointestinal in 1 patient. In patients who received  $\geq 54$  Gy, 15 out of 17 patients experienced grade 3 or 4 toxicity, compared to 5 out of 11 patients who received less than 54 Gy. In the 4 patients who were HIV positive, one did not have any grade 3 or 4 acute toxicity, one had grade 3 dermatological toxicity, 1 had grade 3 dermatological and hematologic toxicities, 1 had grade 3 dermatological toxicity and grade 4 hematologic toxicity and died of fulminant hepatitis after receiving 30 Gy of radiation.

**Figure 3** Kaplan-Meier estimate of the probability of local freedom from progression in comparison of patients with T3 versus T4 disease.

The median duration of treatment was 58 (range 31-112) d. In patients who received  $\geq 54$  Gy, the median duration of treatment was 60 d compared to 44 d in those who received  $< 54$  Gy. Twenty-two patients had treatment breaks longer than 3 d. Ten patients had only one treatment break and 12 had more than 1 treatment break. The median length of total treatment breaks was 11 (range 0-53) d. Twelve patients had treatment breaks totaling longer than 14 d. The median dose at the first treatment break was 30.6 (range 3.6-52.2) Gy. Three patients had treatment breaks due to non-compliance, and the rest of patients due to toxicity. For patients who received  $\geq 54$  Gy, 16 out of 17 patients had a break longer than 3 d, compared to 6 out of 11 patients who received  $< 54$  Gy.

### Disease control

Univariate analyses revealed that male gender and HIV infection were each associated with worse overall survival ( $P = 0.02$  and  $P = 0.01$ , respectively). Excluding HIV positive patients, male gender demonstrated a trend towards worse survival ( $P = 0.08$ ). There was no significant difference in local control (Figure 3) or survival when comparing patients with T3 and T4 disease. Nodal stage, tumor size and type of chemotherapy were not predictive of either time to failure or overall survival. Neither radiation dose nor duration of treatment alone was statistically associated with either time to failure or overall survival.

### Time and dose consideration

Even though radiation dose or duration of treatment alone was not statistically correlated with either time to failure or overall survival, these two factors were interrelated. Patients who received  $\geq 54$  Gy were more likely to experience treatment breaks resulting in longer treatment duration, potentially masking an advantage over higher radiation doses. Therefore, we examined those patients who received  $\geq 54$  Gy within 60 d, and compared them to the rest of the group (Figure 4). Patients who received  $\geq 54$  Gy within 60 d had significantly improved local progression-free and overall survival rates compared to

**Table 2** Subgroup analysis of local control based on total radiation dose and overall treatment time

Fraction of patients controlled locally	High dose (> 54 Gy)	Low dose (< 54 Gy)
Short duration ( $\leq 60$ d)	8/9 <sup>b</sup>	4/9
Long duration (> 60 d)	2/8	1/2

<sup>b</sup> $P = 0.01$  vs the rest of the subgroups.

those whose treatments spanned longer than 60 d or who received less than 54 Gy (2-year local progression-free and overall survival probabilities of 89% (95% CI: 43%-98%) and 100% for treatments within 60 d compared to 42% (95% CI: 20%-62%) and 53% (95% CI: 29%-72%) for the rest of the group ( $P = 0.01$  and  $P = 0.02$ , respectively). Of patients who received  $\geq 54$  Gy, 8 out of 9 patients were locally controlled if the treatment was completed within 60 d. However, for those patients who received  $\geq 54$  Gy with treatment durations longer than 60 d, only 2 out of 8 were locally controlled. For those patients who received less than 54 Gy, only 5 out of 11 were locally controlled (Table 2). The mean total dose in patients who received less than 54 Gy was 46 Gy.

## DISCUSSION

In the current study, neither total radiation dose nor treatment time alone was prognostic for local control or survival. The two factors were interrelated in that it took a longer treatment time to deliver an overall higher radiation dose: 35 d for 45 Gy and 45 d for 60 Gy. In addition, higher radiation doses resulted in higher toxicity rates and therefore a higher likelihood of treatment breaks. In this study, patients who received  $\geq 54$  Gy within 60 d had significantly improved local progression-free (Figure 4) and overall survival compared to those whose treatment spanned longer than 60 d or who received less than 54 Gy. This confirms a dose response in the treatment of locally advanced anal cancer with chemoradiation, although prolonged treatment breaks negate the advantage of higher dose.

Total radiation dose has been shown to impact outcome in anal carcinoma treated with combined chemoradiation<sup>[6-9]</sup>. Constantinou *et al*<sup>[6]</sup> found that radiation doses of  $\geq 54$  Gy were associated with significantly improved survival (84% vs 47%) and local control (77% vs 61%) in anal cancer patients treated with chemoradiation. About 30% of patients in their study had T3 or T4 lesions. In a group of patients treated with chemoradiation using continuous infusion of 5-FU, local control increased from 50% in those receiving < 45 Gy, to 73% in those receiving 50-54 Gy and 83% in those receiving > 60 Gy<sup>[9]</sup>. Nigh *et al*<sup>[8]</sup> reported a dose response with improved local control at higher doses: 64% at < 45 Gy, 77% at 45-55 Gy and 92% at > 55 Gy. At MD Anderson, local control was 50% for all stages receiving 45-49 Gy and 90% for those patients receiving greater than or equal to 55 Gy<sup>[7]</sup>.

Overall treatment time has similarly been shown to impact outcome in treatment of anal cancer<sup>[10-15]</sup>. In the

**Figure 4** Kaplan-Meier estimate of the probability of local freedom from progression comparing patients who received > 54 Gy within 60 d vs the rest of the patients.

second phase of the dose escalation study RTOG 9208 without the mandatory break, the 1-year colostomy rate decreased from 23% to 11%<sup>[10,14]</sup>. In an European Organization for Research and Treatment of Cancer (EORTC) trial with a similar design to RTOG 9208 including a 2 wk break at 36 Gy (but slightly different chemotherapy with 5-FU given continuously during radiation), the 3-year local control and colostomy-free interval were 88% and 81% respectively, which compared favorably to the earlier EORTC randomized trial with a 6 wk break and mitomycin C given only on the first day of radiation<sup>[12]</sup>. Built in breaks > 37.5 d correlate with poorer loco-regional control in patients treated with a median of 40 Gy to the pelvis and a 20 Gy boost with either external beam radiation or brachytherapy<sup>[15]</sup>. Ceresoli *et al*<sup>[13]</sup> found that overall treatment times longer than 70 d were related to a worse disease-free survival in a group of patients treated with a median radiation dose of 56 Gy. Overall treatment times > 75 d were associated with poorer local control (69% vs 85%) in a study by Allal<sup>[11]</sup>.

Increased toxicities have been observed in patients treated with higher radiation doses. In the second phase of the dose escalation study RTOG 9208 without the mandatory break, 50% of patients required treatment interruptions lasting at least 7 d. In our study, 71% of patients had treatment breaks longer than 3 d. Fourteen patients had grade 3 or greater dermatological toxicities requiring treatment breaks. One way to decrease toxicities is to use conformal radiation therapy. Indeed, one study showed that conformal radiotherapy enhanced tolerance to treatment, shortened treatment time to 6 wk and significantly decreased acute toxicities<sup>[16]</sup>. In another study, intensity-modulated radiotherapy (IMRT) improved conformality and reduced normal structure dose without compromising local control in the treatment of anal cancer<sup>[17]</sup>. We have investigated the potential to improve coverage of tumor volumes while maximizing sparing of normal tissues such as the skin and bowel using IMRT and have adopted IMRT as the preferred treatment technique for locally advanced anal cancer. Grade 3 or greater

hematologic toxicity was observed in 9 patients. Cisplatin-based combined modality therapy may generate less acute toxicity and a wider therapeutic index. In a retrospective analysis of patients treated with 55 Gy of radiation and continuous infusion of cisplatin and 5-FU, local control and survival were comparable to the best results reported with mitomycin C and 5-FU, with greater than 90% of patients completing treatment without significant treatment interruptions<sup>[18]</sup>.

Hoffman *et al*<sup>[19]</sup> previously reported our institutional experience of treating HIV positive anal cancer patients with chemoradiation. Excellent disease control with acceptable morbidity was achieved in patients with a CD4 count of greater than or equal to 200<sup>[19]</sup>. There were 4 HIV positive patients with locally advanced disease in the group reported herein. Their disease control and survival were poor and toxicities were significant, although the small number of patients precluded firm conclusions regarding the role played by their HIV status.

The ideal chemotherapy regimen has yet to be established. An Eastern Oncology Group trial tested concurrent cisplatin, 5-FU, and 59.4 Gy of radiation with a 2-wk break after 36 Gy, which resulted in a complete response rate of 68%<sup>[20]</sup>. Adjuvant chemotherapy after combined chemoradiation is being tested in the ACT II randomized trial from the United Kingdom<sup>[21]</sup>. The recently closed randomized trial RTOG 9811 compares concurrent chemoradiation with 5-FU and mitomycin C versus induction chemotherapy and concurrent chemoradiation with 5-FU and cisplatin. In addition, for T3, T4, node positive and any lesions with residual disease after 45 Gy, a boost of 10-14 Gy is included to achieve total doses of 55-59 Gy. The result from this trial may answer some of the questions pertaining to the best treatment regimen for anal cancer.

In conclusion, local failure is a significant problem in locally advanced carcinomas of the anal canal. Although the number of patients in this study was relatively small, we believe that higher radiation doses with limited treatment breaks may offer an increase in local control and survival.

## COMMENTS

### Background

There is controversy in the field regarding whether higher radiation doses improve outcome in anal cancer. Local control rate for locally advanced anal cancer is around 50%, which clearly needs to be improved. This paper tries to address the interrelation of time and dose and generates the hypothesis of higher radiation doses with shorter treatment duration improve outcome in locally advanced anal cancer.

### Research frontiers

The current focus of research is in the delivery of intensity modulated radiation therapy to treat anal cancer. The highly conformal dose distribution allows more sparing of normal tissues and high dose to the tumor, therefore, fewer toxicities and treatment breaks and hopefully improved tumor control.

### Innovations and breakthroughs

Constantinou *et al* found that radiation doses of  $\geq 54$  Gy were associated with significantly improved survival (84% vs 47%) and local control (77% vs 61%) in anal cancer patients treated with chemoradiation. Other studies addressed treatment time to some extent. This is the only study looking at radiation doses

and treatment time in locally advanced anal cancer.

## Applications

To achieve improved local control in locally advanced anal cancer patients, radiation doses of at least 54 Gy should be given concurrently with chemotherapy. Treatment breaks should be minimized to realize the effect of the higher doses of radiation. Modern techniques such as intensity-modulated radiotherapy may be a means to deliver higher doses of radiation while minimizing toxicities and treatment breaks.

## Terminology

Total radiation dose is the final dose that is delivered to the gross tumor. Overall treatment time is the entire duration of radiation from beginning to end including any mandatory or elective treatment breaks. Intensity-modulated radiotherapy is a technique which delivers radiation in multiple fields of varying radiation intensity so that the dose distribution can be highly conformal around the target and minimizing doses to nearby critical tissues.

## Peer review

The paper addresses one of the controversies in the field, that is, whether higher radiation dose improves outcome in locally advanced anal cancer. The data suggests higher radiation dose with shorter treatment duration improves outcome in this group of patients.

## Abstract

**AIM:** To investigate retrospectively the long-term effect of endoscopic sphincterotomy (ES) including exocrine pancreatic function in patients with stenosis of ampulla of Vater.

**METHODS:** After diagnostic endoscopic retrograde cholangiopancreatography (ERCP) and ES because of stenosis of the ampulla of Vater (SOD Type I), follow-up examinations were performed in 60 patients (mean follow-up time 37.7 mo). Patients were asked about clinical signs and symptoms at present and before intervention using a standard questionnaire. Before and after ES exocrine pancreatic function was assessed by determination of immunoreactive fecal elastase 1. Serum enzymes indicating cholestasis as well as serum lipase and amylase were measured.

**RESULTS:** Eighty percent of patients reported an improvement in their general condition after ES. The fecal elastase 1 concentrations (FEC) in all patients increased significantly after ES. This effect was even more marked in patients with pathologically low concentrations ( $< 200 \mu\text{g/g}$ ) of fecal elastase prior to ES. The levels of serum lipase and amylase as well as serum alkaline phosphatase (AP) and gamma-glutamyltranspeptidase (GGT) decreased significantly after ES.

**CONCLUSION:** The results of this study demonstrate that patients with stenosis of the ampulla of Vater can be successfully treated with endoscopic sphincterotomy. The positive effect is not only indicated by sustained improvement of clinical symptoms and cholestasis but also by improvement of exocrine pancreatic function.

## INTRODUCTION

Endoscopic sphincterotomy (ES) has been introduced as a treatment for sphincter of Oddi dysfunction (SOD)<sup>[1,2]</sup>. At least in SOD type I, which is caused by structural changes of the papilla in the majority of patients, ES is the treatment of choice<sup>[3,4]</sup>. In most of the recent papers the focus of clinical interest has been put on aspects of cholestasis.

Gallstones, bile duct microlithiasis and sludge may repeatedly induce ductal lesions leading to obstruction and stenosis of the papilla of Vater<sup>[5-7]</sup>. In addition to the resulting problems concerning the bile duct system, chronic obstruction of the papilla of Vater may also contribute to lesions of the pancreas. This might also play a role in the pathogenesis of chronic pancreatitis. Segmental or diffuse dilation of the main pancreatic duct as part of the spectrum of chronic pancreatitis has given rise to the concept of obstruction and pancreatic ductal hypertension as an important pathogenetic mechanism of chronic pancreatitis<sup>[8,9]</sup>. Data from an autopsy study also showed that the incidence of chronic pancreatitis is higher in patients with gallstones which emphasises the role of gallstones, sludge and papillary stenosis in the pathogenesis of chronic pancreatitis<sup>[10]</sup>.

The former gold standard imaging technique, endoscopic retrograde cholangiopancreatography (ERCP), is based on ductal abnormalities. Pancreatographic changes correlate with exocrine dysfunction<sup>[11]</sup>. As an indirect pancreatic function test measurement of fecal elastase-1 concentrations (FEC) shows a 93%-100% sensitivity for moderate and 96%-100% sensitivity for severe exocrine pancreatic insufficiency as well as a specificity of 93%-98%<sup>[12,13]</sup>.

The aim of this study was to investigate the long-term effects of ES not only regarding clinical symptoms

and parameters of cholestasis, but also with a focus on exocrine pancreatic function.

## MATERIALS AND METHODS

### Patients

Nineteen male and 41 female patients aged between 21 and 80 years (mean age  $57.4 \pm 15.2$  years) were investigated retrospectively. The follow-up period averaged  $37.7 \pm 7.0$  mo (ranging from 28-51 mo). The mean body mass index was  $24.4 \pm 4.0$  kg/m<sup>2</sup> (ranging from 18.4-35.5 kg/m<sup>2</sup>).

All patients, who initially presented with signs of either cholestasis or pancreatic inflammation and abdominal complaints, underwent ERCP and endoscopic sphincterotomy (ES) in our department after giving their informed consent. The period between the first ES and follow-up averaged 37.7 mo. Follow-up consisted of assessing clinical and laboratory data of the patients before and after ES by using the patients' records and personal interviewing based on a standardized questionnaire. Patients with malignancy of the pancreas and/or the bile duct system were not included.

### ERCP and ES

All patients underwent ERCP and ES in our department. All procedures were performed by one experienced investigator using standard techniques. Radiological changes of the pancreatic duct system were evaluated according to the Cambridge classification<sup>[14]</sup>. In all patients ES was performed because of SOD type 1 [clinical symptoms, laboratory findings and findings in imaging techniques (ultrasound or ERCP)]. For ES a single use precurved sphincterotome (Wilson-Cook Medical Inc., NC, USA) and a single use guidewire 0.18 inch (Medwork, Neuss, Germany) were used. ES was performed as sphincterotomy of the pancreatic and/or biliary segment of the sphincter of Oddi. Some patients underwent ES more than once because of recurrent symptoms and/or signs of cholestasis and/or pancreatic inflammation. In some cases a precut of the papilla was necessary.

### Questionnaire

The questionnaire included the following items: age, sex, and body mass index (BMI). The intensity of clinical symptoms such as nausea, emesis, and quantity of abdominal pain were assessed using the visual analogue scale (0 = not present, 10 = maximum complaint).

### Laboratory methods

Blood samples were taken routinely prior to and after ES and checked for the following parameters: serum lipase (normal range 20-160 U/L), serum alpha-amylase (< 53 U/L), serum aspartate aminotransferase (AST/SGOT; male 5-20, female 5-17 U/L), serum alanine aminotransferase (ALT/SGPT; male 5-23, female 5-17 U/L), alkaline phosphatase (AP; male adult 60-170 U/L, female adult 40-160 U/L), gamma-glutamyltranspeptidase (GGT; male 6-28 U/L, female 4-18 U/L), and bilirubin (< 1.0 mg/dL). Fecal elastase-1 was determined by ELISA using two monoclonal antibodies specific for human

Table 1 ERCP findings in 60 patients

	Patients <i>n</i> (%)

elastase-1, which bind to different epitopes of the enzyme (elastase-1 stool kit; Schebo-Biotech, Giessen, Germany). Results were expressed in µg/g stool. Values < 200 µg/g were considered to represent exocrine insufficiency, values > 200 µg/g were regarded as normal.

### Statistical analysis

Results are expressed as mean  $\pm$  SD and range of values if not otherwise indicated. Statistics were carried out by the Statistical Package for Social Sciences (SPSS) for Windows, version 11.01. Wilcoxon-test was performed to test for significant differences between pre-treatment and post-treatment values.  $P < 0.05$  was considered statistically significant.

## RESULTS

Table 1 shows findings in ERCP, Table 2 indicates the amount as well as the kind of ES (biliary/pancreatic sphincterotomy). Fifty patients (83%) showed either impaired exocrine pancreatic function (fecal elastase-1 < 200 µg/g) or were classified as Cambridge I-III based on radiological changes of the pancreas irrespective of the initial indication for ERCP.

### Clinical symptoms

After ES, 80% of the patients reported a general relief of

**Figure 1** Clinical symptoms prior to and after endoscopic sphincterotomy due to the visual analogue scale (0 = not present, 10 = maximum complaint),  $n = 55$ .

symptoms, 6.7% reported the same general condition by their own assessment, whereas only 5.0% reported a worse condition. No data were given in 8.3% of all patients. There was a significant reduction of clinical symptoms such as nausea, emesis and abdominal pain after ES (Figure 1).

### Laboratory findings

Serum enzymes indicating cholestasis such as Gamma-glutamyltranspeptidase, alkaline phosphatase and bilirubin showed a significant reduction after ES. Serum alpha-amylase and serum lipase also significantly decreased to normal levels after ES (data given in Table 3).

### Exocrine pancreatic function

In all the 60 patients, fecal elastase-1 increased significantly from a mean of  $264.38 \pm 184.01$   $\mu\text{g/g}$  (range 10-741  $\mu\text{g/g}$ ) prior to ES to  $337.05 \pm 185.35$   $\mu\text{g/g}$  (range 10-816  $\mu\text{g/g}$ ) after ES ( $P < 0.05$ ) (Figure 2). In patients with very low levels of fecal elastase-1 ( $< 200$   $\mu\text{g/g}$ ) prior to ES, fecal elastase-1 rose significantly from a mean of  $82.46 \pm 60.22$   $\mu\text{g/g}$  (range 15-187  $\mu\text{g/g}$ ) to  $253.42 \pm 200.18$   $\mu\text{g/g}$  (range 10-705  $\mu\text{g/g}$ ) after ES ( $P = 0.001$ ). In seven patients with fecal elastase-1 levels between 200 and 300  $\mu\text{g/g}$  prior to ES, fecal elastase-1 increased significantly from a mean of  $262 \pm 36.47$   $\mu\text{g/g}$  (range 212-297  $\mu\text{g/g}$ ) prior to ES to  $442.29$   $\mu\text{g/g}$  (range 360-610  $\mu\text{g/g}$ ) after ES ( $P = 0.018$ ).

## DISCUSSION

In sphincter of Oddi dysfunction (SOD), especially in type 1 displaying structural changes of the papilla in most cases, endoscopic sphincterotomy (ES) has been introduced as a definitive treatment<sup>[3]</sup>. Most of the available research efforts focus on the beneficial effects of ES concerning clinical symptoms and parameters of cholestasis. In the present study all patients with cholestatic problems prior to ES showed an improvement after treatment. In 94% of our patients biliary sphincterotomy could effectively improve cholestasis as indicated by the normalized GGT and AP. Obviously these positive effects, lasting a mean of three years so far, are results from optimized biliary drainage without stenting. This is remarkable because pancreatobiliary drainage by endoscopic placement of an

ES: Endoscopic sphincterotomy.

endoprosthesis (needing exchange of stents at intervals of 2 to 4 mo) is accompanied with complications and shows poor long-term results<sup>[15,16]</sup>.

Since papillary stenosis has been suggested to play a possible role as a pathogenetic factor in pancreatitis<sup>[6,17,18]</sup>, the present study included patients with pancreatitis type symptoms and focused on changes in exocrine pancreatic function. Therapeutical approaches in patients with chronic pancreatitis aim to alleviate pain, prevent attacks of pancreatitis, reduce the effects of pancreatic insufficiency and manage complications no matter what the etiology of chronic pancreatitis might be. Medical management may include oral analgesics, enzymatic replacement, diet, and abstinence from alcohol. If obstruction of the pancreatic duct is present, invasive options must be considered. Endoscopic therapeutic techniques such as insertion of endoprosthesis, balloon or catheter dilation or sphincterotomy are applied increasingly<sup>[19]</sup>. The facilitation of pancreatic ductal drainage should lead to a reduction of ductal pressure which is the rationale for the endoscopic intervention. The exact role of increased pressure in the pancreatic ductal system in the pathogenesis of chronic pancreatitis is not known, although elevated pressures have been documented in different animal models and human beings<sup>[20-22]</sup>. It was reported that patients with chronic pancreatitis and pain have higher main pancreatic duct pressures than controls and experience pain relief after surgical decompression<sup>[23]</sup>. Cholelithiasis, bile duct microlithiasis and biliary sludge might induce

papillitis or papillary stenosis followed by recurrent or permanent elevation of pancreatic ductal pressure with the consequence of chronic pancreatitis. This role of cholelithiasis and sludge in the pathogenesis of chronic pancreatitis still remains a controversy. However, several reports indicate that in patients who are thought to have 'idiopathic' pancreatitis, bile duct microlithiasis, sludge and bile crystals may account for the pancreatitis<sup>[24-28]</sup>. There are individual reports on patients with sphincter of Oddi dysfunction or stenosis and recurrent episodes of pancreatitis which have been treated successfully with sphincterotomy.

In this study the long term effect of ES on pancreatic function and clinical symptoms of 60 patients with stenosis of ampulla of Vater was investigated. Regarding the clinical symptoms such as abdominal pain, nausea and emesis, most of our patients (80%) experienced a long-term improvement after ES. In the majority of patients we could also observe an improvement of exocrine pancreatic function as measured by FEC. It must be stressed that the follow-up study was performed at least 28 mo (maximum 51 mo) after endoscopic treatment. Other studies have reported similar immediate symptomatic improvements in patients who underwent dilation of the pancreatic duct followed by placement of an endoprosthesis, but the long-term results are not very promising as symptomatic stent occlusion often occurs<sup>[15,29]</sup>. As reported elsewhere<sup>[30]</sup>, in some of our patients several sphincterotomies (up to six) had to be performed, if symptoms and pathological laboratory findings persisted. It appears possible, that recurrent cholestasis or clinical symptoms can be caused by papillary restenosis which is a known complication of sphincterotomy, usually occurring years after intervention<sup>[31]</sup>. We think that the patients' long-term clinical improvement concerning pancreatic pathology is due to a decrease of pancreatic ductal pressure after overcoming the underlying pathogenetic factor of papillary stenosis. Few of our patients (11.7%) reported no improvement or even aggravation in their clinical condition after ES. Most of these cases were classified as chronic pancreatitis III according to the Cambridge-Classification. They showed persisting impaired exocrine pancreatic function after ES indicated by persisting reduced FEC. This sub-group of patients had proven advanced structural and functional abnormalities, which were probably progressive and irreversible. Since pain is often a cardinal symptom of chronic pancreatitis, many studies focus on it beside other clinical symptoms when judging the effect of treatment. This is the first time that the effect of endoscopic sphincterotomy on exocrine pancreatic function based on fecal elastase-1 was investigated. In summary, all patients showed a significant increase in fecal elastase-1 levels after ES, which was even more marked in patients with pathologically low concentrations of fecal elastase-1 prior to ES, indicating that endoscopic sphincterotomy has positive effects on exocrine pancreatic function. A similar effect was found in patients with low, but still normal fecal elastase-1 levels (200-300 µg/g) prior to ES. The results are due to effective treatment of the underlying ethiological factor which leads to normalized ductal pressure of the pancreas and regeneration of pancreatic parenchyma. In

contrast to the common belief of irreversibel structural and functional impairment of the pancreas in chronic pancreatitis, the findings of the present study confirm that there is at least a subset of patients with chronic pancreatitis in which a recovery of functional capacity is possible<sup>[32]</sup>.

In conclusion, patients with stenosis of the ampulla of Vater can be successfully treated with endoscopic sphincterotomy. The positive effect is indicated not only by sustained improvement of biliary type clinical symptoms and laboratory markers of cholestasis, but also by improvement of exocrine pancreatic function and pancreatitis type clinical symptoms. Without question there is a need for prospective, randomized, controlled trials which investigate endoscopic sphincterotomy versus pancreatobiliary stenting and conservative medical therapy in chronic pancreatitis.

## COMMENTS

### Background

Endoscopic sphincterotomy has been introduced as a treatment for sphincter of Oddi dysfunction. In most recent papers the focus of clinical interest has been put on aspects of cholestasis. In addition to the resulting problems concerning the bile duct system, chronic obstruction of the papilla of Vater may also contribute to lesions of the pancreas, and may also play a role in the pathogenesis of chronic pancreatitis. The aim of this study was to investigate the long-term effects of ES not only on clinical symptoms and parameters of cholestasis, but also on exocrine pancreatic function.

### Innovations and breakthroughs

The study showed that patients with stenosis of the ampulla of Vater could be successfully treated with endoscopic sphincterotomy. The positive effect was indicated not only by sustained improvement of biliary type clinical symptoms and laboratory markers of cholestasis, but also by improvement of exocrine pancreatic function and pancreatitis type clinical symptoms. The improvement in exocrine pancreatic function and pancreatic regeneration after endoscopic sphincterotomy is remarkable.

### Applications

There is a definite need for prospective, randomized, controlled trials which investigate endoscopic sphincterotomy versus pancreatobiliary stenting and conservative medical therapy in chronic pancreatitis.

### Terminology

Sphincter of Oddi dysfunction (SOD): Sphincter of Oddi dysfunction refers to structural or functional disorders involving the sphincter of Oddi that may result in impedance of bile and pancreatic juice flow. Geenen *et al* have divided SOD patients into three types. Type I patients exhibit all three criteria (biliary pain, abnormal liver serology and bile duct dilation). Type II patients have typical biliary pain and either abnormal liver serology or dilation of the bile duct, but not both. In type III patients, the extrahepatic bile duct is not dilated, and abnormal liver serology is not found, whereas pain is present.

### Peer review

The authors retrospectively audited a series of 60 patients with stenosis of the ampulla Vater (SOD) who had undergone endoscopic sphincterotomy (ES) and their 3-year follow-up concerning symptom improvement & pancreatic exocrine function. I agree with the acceptance of this manuscript for publication in the WJG.

## Abstract

**AIM:** to compare the feasibility and patients' tolerance of esophagogastroduodenoscopy (EGD) using a thin endoscope with those of conventional oral EGD and to determine the optimal route of introduction of small-caliber endoscopes.

**METHODS:** One hundred and sixty outpatients referred for diagnostic EGD were randomly allocated to 3 groups: conventional (C)-EGD (9.8 mm in diameter), transnasal (TN)-EGD and transoral (TO)-EGD (5.9 mm in diameter). Pre-EGD anxiety was measured using a 100-mm visual analogue scale (VAS). After EGD, patients and endoscopists completed a questionnaire on the pain, nausea, choking, overall discomfort, and quality of the examination either using VAS or answering some questions. The duration of EGD was timed. Blood oxygen saturation (SaO<sub>2</sub>) and heart rate (HR) were monitored during EGD.

**RESULTS:** Twenty-one patients refused to participate in the study. The 3 groups were well-matched for age, gender, experience with EGD, and anxiety. EGD was completed in 91.1% (41/45), 97.5% (40/41), and 96.2% (51/53) of cases in TN-EGD, TO-EGD, and C-EGD groups, respectively. TN-EGD lasted longer ( $3.11 \pm 1.60$  min) than TO-EGD ( $2.25 \pm 1.45$  min) and C-EGD ( $2.49 \pm 1.64$  min) ( $P < 0.05$ ). The overall tolerance was higher ( $P < 0.05$ ) and the overall discomfort was lower ( $P < 0.05$ ) in TN-EGD group than in C-EGD group. EGD was tolerated "better than expected" in 73.2% of patients in TN-EGD group and 55% and 39.2% of patients in TO-EGD and C-EGD groups, respectively ( $P < 0.05$ ). Endoscopy was tolerated "worst than expected" in 4.9% of patients in TN-EGD group and 17.5% and 23.5% of patients in TO-EGD and C-EGD groups, respectively ( $P < 0.05$ ). TN-EGD

caused mild epistaxis in one case. The ability to insufflate air, wash the lens, and suction of the thin endoscope were lower than those of conventional instrument ( $P < 0.001$ ). All biopsies performed were adequate for histological assessment.

**CONCLUSION:** Diagnostic TN-EGD is better tolerated than C-EGD. Narrow-diameter endoscope has a level of diagnostic accuracy comparable to that of conventional gastroscope, even though some technical characteristics of these instruments should be improved. Transnasal EGD with narrow-diameter endoscope should be proposed to all patients undergoing diagnostic EGD.

## INTRODUCTION

Esophagogastroduodenoscopy (EGD) is a safe and quick procedure, and can be carried out without sedation<sup>[1]</sup>. However, it can evoke anxiety, feelings of vulnerability, embarrassment, and discomfort<sup>[2]</sup>. The fears and concerns associated with the endoscopic procedure decrease patient's compliance, making EGD execution more difficult<sup>[2-4]</sup>, and in many countries EGD is performed using conscious sedation<sup>[5]</sup>. Although usually safe, sedation is not free from adverse effects<sup>[6-8]</sup>, and produces a 30%-50% increase of the EGD costs, either direct (medications, additional time required to sedate and recover the patients, additional personnel needed to monitor the patients) or indirect (time lost from work by both the patient and patient's escort)<sup>[9,10]</sup>.

Narrow-diameter endoscopes (< 6 mm) were developed in the early 1990s with the aim of reducing patient discomfort and avoiding the cost and risks of conscious sedation. These endoscopes can also be

introduced through the nose, as reported by Shaker in 1994<sup>[11]</sup>. Either this study or a cancer screening program in Japan<sup>[12]</sup> showed that the transnasal unsedated procedure is safe and well tolerated, and allows adequate visualization of the upper gastrointestinal tract. However, the use of these endoscopes is still limited to a small subset of patients<sup>[10]</sup>, even though they have been reported to be suitable not only for diagnostic purposes, but also for interventional procedures, such as PEG and placement of nasoenteric feeding tubes<sup>[13-16]</sup>.

In this randomized trial, we compared the unsedated small-caliber endoscopy using the transnasal and transoral routes with unsedated conventional endoscopy. Our primary aims were to compare the patients' tolerance to small-caliber and conventional endoscopes, to determine the optimal route of introduction of small-caliber endoscopes, and to evaluate the differences in the general handling of small-caliber and conventional instruments. Secondary objectives were to evaluate duration and safety of the procedure.

## MATERIALS AND METHODS

### Study population

One hundred and sixty consecutive outpatients, undergoing elective diagnostic EGD and fulfilling the eligibility criteria, were randomly assigned to three groups by a computer-generated randomization list and asked to participate in the study. Inclusion criteria were age between 18 and 70 years, and capability (evaluated by the endoscopist) of fully understanding and filling up the questionnaire of the study. Exclusion criteria were history of gastrectomy, esophagectomy, or other upper-gastrointestinal (GI) tract surgery, history of sinus or nasal septum surgery, planned endoscopic therapy, coagulopathy or anticoagulant therapy, psychiatric diseases or long-term psychiatric drug addiction, presence of neoplastic or other serious concomitant diseases, pregnancy.

In the control group (C-EGD), unsedated EGD was performed with pharyngeal topical anesthesia, using a Fujinon EG-250WR5 videoendoscope (outer diameter of the insertion tube is 9.8 mm). In the transnasal-EGD (TN-EGD) and transoral-EGD (TO-EGD) groups, unsedated EGD was performed with pharyngeal or nasal topical anesthesia alone, using a Fujinon EG-270N5 videoendoscope (outer diameter of the insertion tube is 5.9 mm), which was introduced through the nose or the mouth. The patients underwent EGD in the left lateral position, and all procedures were carried out by three endoscopists well trained in unsedated narrow-diameter transnasal and transoral endoscopy.

The study protocol was approved by the Ethical Committee of our hospital, and all patients enrolled gave their written informed consent to participate in the study.

### Outcome measurements

Pre-EGD assessment: Age, gender, prior experience of endoscopic examination, blood oxygen saturation (SaO<sub>2</sub>), and heart rate (HR) were recorded. Since anxiety was hypothesized to be a potential factor of discomfort,

all patients were asked to rate their pre-EGD anxiety level using a 100-mm visual analogue scale (VAS), with 100 being the highest level. The patients were asked also to specify what they dreaded more about endoscopic examination among the following six items: fear of pain, fear of vomiting, fear of stifling, fear of complications, fear of endoscopic findings, and others.

Monitored parameters: SaO<sub>2</sub> and HR were continuously monitored during EGD. An abnormal vital sign was defined as HR > 130 bpm or decrease in SaO<sub>2</sub> below 90% for over one minute. The duration of EGD was timed in all patients. A procedure was considered complete if gastric retroflexion was accomplished, the second portion of the duodenum was reached, and all indicated biopsies were obtained. If the transnasal route failed, a switch was made to the oral route using the same instrument, and EGD was considered unsuccessful according to the study design. The occurrence of complications was recorded after each procedure.

Post-EGD assessment: Data were collected from both the patient and the endoscopist. The sensation of pain and overall discomfort were quantified on a 100-mm VAS (0 = non existent, 100 = unbearable), and the overall tolerance to EGD was assessed as very poor, poor, fair, good, excellent. Patients scored their sensation of nausea and choking on a 100-mm VAS, and indicated also their tolerance by answering the questions of "how did you tolerate EGD, and what you were expecting?" and choosing one of the following 3 items: worse than expected, as expected, better than expected.

Endoscopists scored the level of difficulty in introduction of the gastroscope on a 100-mm VAS. Endoscopists' satisfaction was assessed with 100-mm VAS for the performances of the endoscopes, with regard to the adequacy of the view, the air insufflation/washing of the lens, and suction.

### Statistical analysis

Statistical analysis was performed by using Statgraphics V4 (STSC Inc.; Rockville, MD, USA) and SPSS V8 (SPSS Inc.; Chicago, IL, USA) statistical software packages. Gender and previous experience of endoscopic examination were analyzed by the chi square test. Age and pre-endoscopic anxiety levels were analyzed using the Kruskal-Wallis non parametric test. Kruskal-Wallis test was also used to analyze the duration of EGD, difficulty in introduction of the gastroscope, nausea, choking, and performances of the endoscope. ANOVA-RM was used to compare physicians' and patients' opinions about intubation pain, overall discomfort, and overall tolerance.

The statistical power of the sample size was also evaluated, and levels over 90% were found in the most part of the tests applied.  $P < 0.05$  was considered statistically significant.

## RESULTS

Twenty-one out of 160 patients who were considered eligible and randomized into TN-EGD group ( $n = 9$ ), TO-EGD group ( $n = 11$ ), and C-EGD group ( $n = 1$ ), refused

Table 1 Demographic and clinical data of the patients

	TN-EGD	TO-EGD	C-EGD	P
Patients (n)	45	41	53

to participate in the study. One hundred and thirty-nine patients (61 males and 78 females) entered the study. The three groups were well-matched for age, gender, previous experience of endoscopic examination, blood oxygen saturation, heart rate, and baseline anxiety score (Table 1). In all groups the most common cause of fear before EGD was fear of stifling (44 cases on the whole). Seven out of 139 patients (5.0%) did not complete EGD and were excluded from any subsequent analysis. EGD was successfully completed in 91.1% (41/45) of patients in TN-EGD group, 97.5% (40/41) in TO-EGD group, and 96.2% (51/53) in C-EGD group, respectively. TN-EGD failed in 4 cases (8.9%) due to difficult insertion of the endoscope through the nose or intolerance. These patients were excluded from any subsequent analysis.

The duration of the procedure was significantly longer in TN-EGD group than in TO-EGD and C-EGD groups ( $3.11 \pm 1.6$  min *vs*  $2.25 \pm 1.45$  min and  $2.49 \pm 1.64$  min, respectively;  $P < 0.05$ ). Such a difference was not due to a higher frequency of biopsy sampling that was similar in the three groups (Table 1).

No complication occurred in C-EGD and TO-EGD groups. One patient (2.4%) in TN-EGD group had mild and self-limiting epistaxis. Occurrence of abnormal vital signs (blood oxygen desaturation and tachycardia) was less frequent in TN-EGD group than in the other two groups, but the difference was not statistically significant (Table 1).

Endoscopists' assessment showed no difference in the intubation difficulty among the three groups (Table 2).

Likewise, on the basis of patients' evaluation, no difference was found in choking or nausea/vomiting among the three groups.

ANOVA-RM analysis of the factor "method" (TN-EGD *vs* TO-EGD *vs* C-EGD) independently of the observer (patient or endoscopist), showed that the overall tolerance was significantly higher in TN-EGD and TO-EGD groups than in C-EGD group ( $P < 0.001$  and  $P < 0.01$ , respectively). TN-EGD and TO-EGD groups did not differ from each other. Conversely, no difference was observed in intubation pain and overall discomfort (Table 2). ANOVA-RM analysis of the factor "observer" (patient *vs* endoscopist) independently of the method, showed that endoscopist underestimated the levels of intubation pain ( $P < 0.01$ ) and overall discomfort ( $P < 0.001$ ), and overrated the overall tolerance ( $P < 0.001$ ) in comparison with the patient. Contemporaneous analysis of both factors "observer" and "method", a significant difference was observed in overall discomfort and overall tolerance between TN-EGD and C-EGD ( $P < 0.05$ ) (Figures 1A and B). All these results had a power greater than 90%, even though some differences were observed according to the factor considered (method, observer, and their combination).

Seventy-three point two percent of patients in TN-EGD group, 55% in TO-EGD group, and 39.2% in C-EGD group tolerated EGD better than expected (Table 3). EGD was tolerated worst than expected by 4.9%, 17.5%, and 23.5% of patients, respectively. Frequency

**Figure 1** Overall discomfort (A) and overall tolerance (B) at EGD for patients and endoscopists in the three groups of patients. Statistical difference can be observed comparing TN-EGD vs C-EGD.

**Table 3** Answers to the questions of “how did you tolerate EGD and what you were expecting of?”

	TN-EGD (n = 41)	TO-EGD (n = 40)	C-EGD (n = 51)
Worse than expected, n (%)	2 (4.9)	7 (17.5)	12 (23.5)
As expected, n (%)	9 (21.9)	11 (27.5)	19 (37.3)
Better than expected, n (%)	30 (73.2)	22 (55.0)	20 (39.2)

analysis showed a statistically significant trend ( $P < 0.05$ ) due to the difference between TN-EGD and C-EGD ( $P < 0.01$ ).

On the basis of the endoscopists' rating scores, the ability to insufflate air/wash the lens, and suction of ultrathin endoscope were lower than those of conventional endoscope ( $P < 0.001$ ) (Table 4). No difference was observed in image quality, and the second portion of the duodenum was reached in all cases with both instruments. In no case the examination was not completed because of the higher flexibility of ultrathin endoscope.

Biopsies were taken at the operator's discretion in 59 cases (19 in TN-EGD group, 16 in TO-EGD group, and 24 in C-EGD group). All biopsies were adequate (Table 3), EGD needed to be repeated in no case because of inadequate histopathologic results.

## DISCUSSION

Narrow-diameter endoscopes have been put on the market about ten years before, but their use in clinical practice is still limited to a small subset of patients, either in the United States<sup>[10]</sup> or in countries such as Italy, where EGD is performed without routine conscious sedation. It is still debated whether the best way of introduction of these instruments is the transnasal or the peroral route, as until now few comparisons have been published in literature. Some randomized trials suggested that the peroral route may be easier to perform and slightly preferred by both patients and endoscopists<sup>[17-20]</sup>. Conversely, in our series TN-EGD caused less discomfort and was better tolerated. Indeed, univariate analysis seemed to suggest that both TN-EGD and TO-EGD were better tolerated than C-EGD, but multivariate analysis revealed that

**Table 4** Results of the endoscopists' evaluation of the performances of endoscopes

	TN-EGD (n = 41)	TO-EGD (n = 40)	C-EGD (n = 51)	P
Endoscopists' score (mean $\pm$ SD)				
Image quality	87.85 $\pm$ 14.34	89.57 $\pm$ 11.00	91.98 $\pm$ 11.85	NS
Suction	81.90 $\pm$ 9.98	84.82 $\pm$ 11.82	94.37 $\pm$ 7.49	< 0.001
Air insufflation/washing of the lens	83.90 $\pm$ 13.70	85.80 $\pm$ 13.34	94.76 $\pm$ 6.49	< 0.001
Reaching of the second portion of the duodenum, n (%)	41 (100)	40 (100)	51 (100)	NS
Adequate biopsy sampling, n (%)	19/19 (100)	16/16 (100)	24/24 (100)	NS

only TN-EGD showed significantly lower discomfort and higher tolerance than C-EGD. Moreover, TN-EGD patients answered the questions of “how did you tolerate EGD and what you were expecting of?” more positively than the other patients. Our results partially agree with those of Preiss *et al.*<sup>[21]</sup> who observed that patients' acceptance of the EGD is significantly better with the ultrathin endoscope introduced through the nose (but not through the mouth) than with the standard endoscope, as choking was lower. More recently, Thota *et al.*<sup>[22]</sup> reported that the transnasal route is better tolerated than the transoral route, but a 4-mm videoendoscope was used in their study. Conversely, in a randomized trial comparing ultrathin endoscopy through both the transnasal and oral routes with standard EGD, Birkner *et al.*<sup>[23]</sup> observed that patients' opinion about the overall assessment is significantly better in the standard oral EGD. However, this result may be biased by the presence of higher anxiety levels in ultrathin endoscope groups than in control group. Indeed, anxiety is well known to decrease patient compliance, making EGD execution more difficult<sup>[3,24]</sup>. Such a bias could also explain the surprising observation that patients who underwent peroral EGD with a 6-mm endoscope complained of greater gagging than those who underwent peroral EGD with a 9.8-mm endoscope. Indeed, a lot of trials reported that patient discomfort is lower when small-caliber endoscopes are used<sup>[17,25]</sup> or no difference is found in tolerance related to endoscope

size<sup>[26]</sup>. To our knowledge no other study has reported that increasing diameters of the instrument can improve the feasibility and tolerance of unsedated upper endoscopy. Unlike the trial of Birkner<sup>[23]</sup>, our three groups were well-matched for parameters such as gender, age, previous experience of EGD, and anxiety, which can influence the tolerance to endoscopy<sup>[24,27]</sup>. In our study, transnasal EGD failed in only 4 out of 45 patients (8.9%) because of inability to insert the endoscope through the nose. Once the nasal tract was passed, it was possible to complete all the EGD procedures, including exploration of the second part of the duodenum. Our failure rate is similar to that reported by other authors who used endoscopes with outer diameter of 5.9 mm<sup>[21]</sup>. Today, endoscopes with a smaller diameter have become available, so it is likely that failure rate will decrease and patients' acceptance will improve in the near future, as the larger-endoscope diameter is considered a predictive factor for procedure failure<sup>[19,22]</sup>.

All biopsy samples taken in our patients were of good quality, and EGD never needed to be repeated because of inadequate histopathologic results. This confirms that biopsy sampling can successfully be done using small diameter endoscopes<sup>[17,26,28]</sup>.

According to other trials<sup>[21,29]</sup>, in our study the percentage of abnormal vital signs was similar in the three groups of patients. However, it has recently been reported that TN-EGD is associated with fewer adverse effects on cardiopulmonary function than TO-EGD<sup>[30]</sup>.

Our study confirmed that the performances of the narrow endoscope were acceptable. Unlike some prior reports<sup>[23,26]</sup>, our experience indicates that image quality and handling of ultrathin and standard endoscopes are similar. Compared to the older color wheel technology, the new ultrathin technology using a color chip similar to that used in standard endoscopes is therefore not susceptible to image distortion. Conversely, the ability to insufflate air, wash the lens, and suction of ultrathin endoscope were lower than those of conventional endoscope. These limits do not compromise diagnostic EGD, but might hamper operative endoscopy, even though some studies suggested that ultrathin endoscopes can work well also in some interventional procedures<sup>[13-16]</sup>.

The average duration of TN-EGD is significantly longer than that of TO-EGD, either in our study or in many other prior reports<sup>[17,23,31,32]</sup>, probably because gastroenterologists are commonly not familiar with the introduction of endoscopes through the nose. Conversely, some authors have not found any difference in duration of EGD between oral and nasal route<sup>[21]</sup> and a prospective study reported that the duration of transnasal technique is even shorter than peroral technique<sup>[33]</sup>. However, in this latter study, the time spent to perform transoral EGD was unusually long (11 min).

In conclusion, small-caliber peroral or transnasal EGD has good technical performances, and is safe, generally well accepted and preferred by the patients to conventional EGD. In our opinion, unsedated EGD with narrow-diameter endoscopes should be proposed to all patients undergoing diagnostic EGD. As transnasal EGD seems better tolerated than peroral endoscopy, endoscopists should acquire more familiarity with this

route of introduction. The growing skill of endoscopists, as well as further technical improvements in the ultrathin endoscopes, will probably lead to the increasing use of transnasal gastroscopy in the near future.

### Abstract

**AIM:** To investigate the efficacy of a high-potency probiotic preparation on prevention of radiation-induced diarrhea in cancer patients.

**METHODS:** This was a double-blind, placebo-controlled trial. Four hundred and ninety patients who underwent adjuvant postoperative radiation therapy after surgery for sigmoid, rectal, or cervical cancer were assigned to either the high-potency probiotic preparation VSL#3 (one sachet *t.i.d.*) or placebo starting from the first day of radiation therapy. Efficacy endpoints were incidence and severity of radiation-induced diarrhea, daily number of bowel movements, and the time from the start of the study to the use of loperamide as rescue medication.

**RESULTS:** More placebo patients had radiation-induced diarrhea than VSL#3 patients (124 of 239 patients, 51.8%, and 77 of 243 patients, 31.6%;  $P < 0.001$ ) and more patients given placebo suffered grade 3 or 4 diarrhea compared with VSL#3 recipients (55.4% and 1.4%,  $P < 0.001$ ). Daily bowel movements were  $14.7 \pm 6$  and  $5.1 \pm 3$  among placebo and VSL#3 recipients ( $P < 0.05$ ), and the mean time to the use of loperamide was  $86 \pm 6$  h for placebo patients and  $122 \pm 8$  h for VSL#3 patients ( $P < 0.001$ ).

**CONCLUSION:** Probiotic lactic acid-producing bacteria are an easy, safe, and feasible approach to protect cancer patients against the risk of radiation-induced diarrhea.

### INTRODUCTION

Almost all regimens of radiation therapy may disturb the colonization resistance of the indigenous gut flora. This is the main mechanism underlying the pathophysiology of acute radiation-induced enteritis and colitis, which are a common and potentially severe complication among cancer patients treated with radiation therapy. Attempts to treat this complication with antibiotics, sucralfate, anti-inflammatory drugs such as mesalazine and balsalazide, glutamine, octreotide, proteolytic enzymes, and hyperbaric oxygen have so far provided inconclusive clinical results with failure of treatment occurring in a substantial proportion of patients<sup>[1-9]</sup>. Furthermore, prophylactic use of sucralfate does not reduce the burden of radiation-induced bowel toxicity but rather, is associated with more severe gastrointestinal symptoms including bleeding and fecal incontinence<sup>[10,11]</sup>. In the light of these contradictory findings, we urgently need innovative approaches that target other steps in the pathophysiology of radiation-induced diarrhea.

The term probiotic refers to a product or preparation containing viable and defined microorganisms in a number thought to be sufficient to alter by implantation or colonization the host's microflora and thereby exert beneficial effects<sup>[12,13]</sup>. Experimental studies in animal models and clinical trials of patients with inflammatory bowel disease (IBD) have consistently shown that use of probiotic organisms may effectively down-modulate the severity of intestinal inflammation through altering the composition and the metabolic and functional properties of gut indigenous flora<sup>[12,13]</sup>. Experience with probiotic organisms for the prevention of enteritis and colitis in cancer patients receiving radiation therapy is limited, however we have recently shown in a small pilot trial of feasibility and safety that both the incidence and severity of radiation-induced diarrhea were appreciably reduced with pre-emptive treatment with VSL#3, a new high potency preparation of probiotic lactobacilli, during adjuvant radiotherapy after surgery for abdominal and pelvic cancer<sup>[14]</sup>. The present study was undertaken to assess and compare the benefits of probiotic therapy with VSL#3 on clinically relevant endpoints in a greater sample of 490 patients, including 190 subjects we enrolled in our earlier trial.

## MATERIALS AND METHODS

Four hundred ninety consecutive patients attending the outpatient clinics of the Cancer X-Ray Unit of the University of Messina, Italy, from May 1999 to December 2005, who had received adjuvant postoperative radiation therapy after surgery for sigmoid, rectal, or cervical cancers were randomly assigned to either treatment with VSL#3 (VSL Pharmaceuticals, Fort Lauderdale, MD), one sachet *t.i.d.*, or a VSL#3-identical appearing placebo starting from the first day of radiation therapy until the end of the scheduled cycles of radiation therapy. The design of the study was approved by the Ethics Committee of our hospital, and all patients gave written informed consent to participate. The study was double-blind, parallel-group, and placebo-controlled and was performed in accordance with the Declaration of Helsinki and standards of good clinical practice.

Each sachet of VSL#3 contained 450 billions/g of viable lyophilized bacteria, including four strains of lactobacilli (*L. casei*, *L. plantarum*, *L. acidophilus*, and *L. delbrueckii subsp. bulgaricus*), three strains of bifidobacteria (*B. longum*, *B. breve*, and *B. infantis*), and one strain of *Streptococcus salivarius subsp. thermophilus*. Patients were eligible for inclusion if they had no contraindication for probiotic or antibiotic therapy or radiation therapy. We excluded by randomization patients with a Karnofsky performance score  $\leq 70$ , a life expectancy  $\leq 1$  year, persistent vomiting or diarrhea, fistulizing disease, known Crohn's disease or ulcerative colitis, intra-abdominal abscesses or fever (more than 37.5°C) at the time of enrolment, or clinical, microbiological, or imaging evidence of sepsis syndrome, and requirement for continuous antibiotic treatment or use of antibiotics in the last 2 wk before initiation of VSL#3 therapy.

At base-line, patients provided a medical history and had a physical examination (consisting of vital signs, 12-lead electrocardiogram, neurological examination, and laboratory testing). The study subjects were followed up weekly during the scheduled cycle of radiation therapy and then 1 mo after completion of radiation therapy. At each visit, clinical symptoms, concomitant medications, and any adverse events were reviewed, and a physical examination and laboratory studies were performed. Efficacy endpoints were incidence and severity of radiation-induced diarrhea, number of patients who discontinued radiotherapy because of diarrhea, daily number of bowel movements, and the time from the start of the study to the use of loperamide as rescue medication for diarrhea. The randomization was balanced between treatment groups in terms of sex, age, nodal involvement, tumor grade and size, local invasion at operation, invasion of contiguous structures at histology, and postoperative complications. The total X-ray dose the patients were given was between 60 and 70 Gy. We measured the severity of gastrointestinal toxicity according to World Health Organization grading, with grade 0 indicating no toxicity, grade 1 indicating self-limited toxicity lasting less than 2 d, grade 2 indicating self-limited symptoms lasting more than 2 d, grade 3 referring to symptoms requiring treatment, and grade 4 indicating severe toxicity with dehydration and/or hemorrhage.

## Statistical analysis

Statistical analysis of results was performed using Kaplan-Meier estimates.  $P < 0.05$  was taken as significant.

## RESULTS

Two hundred thirty nine out of 245 patients in the placebo group (97.5%) completed the study as 6 patients were withdrawn after a few sessions of radiation therapy due to the occurrence of severe diarrhea resistant to loperamide and the usual standard of care; these patients were excluded from the analysis of results. Two hundred forty three among the 245 patients in the VSL#3 group (99.1%) completed the study, one patient withdrew his consent after the first session of radiation therapy, and one patient died of myocardial infarction after three sessions of radiation therapy; both patients were excluded from analysis of the results.

More patients in the placebo group had radiation-induced enteritis and colitis compared with the VSL#3 group (124 of 239, 51.8%, versus 77 of 243 patients, 31.6%;  $P < 0.001$ ). Furthermore, patients given the placebo suffered more severe toxicity compared with VSL#3 recipients as grade 3 or 4 diarrhea was documented in 69 of 124 (55.4%) placebo-treated patients and 8 of 77 (1.4%) VSL#3-treated patients ( $P < 0.001$ ), whereas 50 of 124 placebo-treated patients had grade 1 or 2 diarrhea compared with 34 of 77 VSL#3 recipients (NS). Even though the difference did not reach statistical significance, there was clearly a trend in favor of the treatment with VSL#3 compared with the placebo.

The mean daily number of bowel movements for patients with radiation-induced diarrhea was  $14.7 \pm 6$  and  $5.1 \pm 3$  among placebo and VSL#3 recipients, respectively ( $P < 0.05$ ), and the mean time to the use of loperamide as rescue medication for diarrhea was  $86 \pm 6$  h for patients receiving placebo versus  $122 \pm 8$  h for patients receiving VSL#3 ( $P < 0.001$ ).

No tumor- or treatment-related deaths or deaths from other causes were recorded in either group during the period of radiation therapy, and no case of bacteremia, sepsis, or septic shock due to the probiotic lactobacilli was reported among the VSL#3 recipients during the treatment period with the probiotic preparation or during the six months beyond active treatment. Likewise, no case of bacteremia, sepsis, or septic shock due to organisms other than the probiotic lactobacilli was recognized during the period of active treatment. We did not recognize any other toxicity reasonably attributable to VSL#3.

## DISCUSSION

We have clearly demonstrated in a large sample of patients the benefits of probiotic therapy with VSL#3 for the prevention and/or reduction of both the incidence and severity of enteritis and colitis associated with adjuvant radiation treatment after surgery for abdominal and pelvic cancer. Significantly fewer patients treated with VSL#3 had grade 3 or 4 diarrhea during the period of radiation treatment compared with patients given placebo, in

addition to the usual standard of care. We also observed a trend in favor of VSL#3 in terms of reduced incidence in grade 1 or 2 intestinal toxicity, even though the difference between the two groups did not reach statistical significance.

The findings of this study have reiterated those of our early pilot trial<sup>[14]</sup> and strongly support our working hypothesis that using probiotic lactobacilli may be an easy, cheap, safe, and feasible approach to effectively protect patients against the risk of radiation-induced diarrhea, which is a severe and potentially lethal complication of radiation therapy for abdominal and pelvic cancer. However, apart from our two studies with VSL#3, experience with probiotic organisms in this setting is limited. Our Medline search yielded indeed only one other study with probiotics, i.e. the double-blind and randomized trial by Urbancsek and colleagues who reported favorable results with *Lactobacillus GG* treatment<sup>[15]</sup>. In contrast, we used VSL#3, which is a high-potency preparation with unique characteristics compared with traditional probiotics, in particular, because of the enormously high bacterial concentration and the presence of a consortium of different bacterial species with potential synergistic relations between different strains that may greatly enhance the suppression of potential pathogens<sup>[12]</sup>. Whether treatment with VSL#3 could be more effective than using *Lactobacillus GG* or other probiotic organisms is unknown for several reasons, including the lack of a well-designed head-to-head comparison between the different probiotic preparations. However, the composite mixture of VSL#3 with a large number of probiotic strains possessing very different and specialized metabolic and immunoregulatory activities is a unique feature of this preparation, and may explain its wide spectrum of biological activities. One additional important point is that results of experimental studies and double-blind placebo-controlled clinical trials have consistently validated VSL#3 as a therapeutic tool to down-modulate intestinal inflammation in several animal and human models of IBD<sup>[13]</sup>. In contrast, clinical trials of *Lactobacillus GG* treatment for IBD patients have provided conflicting results and the true clinical efficacy of this probiotic strain is still substantially unclear<sup>[16-18]</sup>.

Clinical and experimental studies of VSL#3 in patients with ulcerative colitis and animal models of IBD have provided insights into the mechanisms underlying the efficacy of probiotic lactobacilli of VSL#3 to protect patients against radiation-induced diarrhea. VSL#3 lactobacilli lower the production of proinflammatory cytokines and several other effectors of inflammation and tissue injury, such as nitric oxide and metalloproteinases, interfere with the pro-inflammatory signal transduced by toll-like receptors, exert a significant protection upon the integrity of the intestinal epithelial barrier, and down-modulate the process of apoptosis. This latter mechanism is of utmost importance because the triggering of an unregulated process of apoptosis is regarded as the main factor ultimately responsible for the radiation-induced injury of the intestinal epithelium<sup>[19]</sup>. Furthermore, probiotic bacteria up-regulate the innate immune response in the gut and are thus part of a protective mechanism against invasive organisms, which is important when ileal

and colonic protection against invading organisms is severely impaired as a result of exposure to radiation. All these mechanisms are likely to synergistically contribute to the down-modulation of gut inflammation and host protection against intestinal colonization by invasive pathogens and their subsequent translocation into portal circulation also in patients irradiated for therapeutic purposes.

Treatment with VSL#3 proved in our study to be remarkably safe and we did not recognize any toxicity reasonably attributable to VSL#3 over the time-span of probiotic treatment. Furthermore, we observed no case of bacteremia, sepsis, or septic shock due to the probiotic lactobacilli of VSL#3, which is in agreement with results of other clinical trials of VSL#3 in IBD patients. Previous clinical experience with this probiotic preparation has indeed demonstrated the remarkable safety of VSL#3 bacteriotherapy even with dosages significantly greater than those used in this trial. This does strongly reinforce the view that probiotic treatment with VSL#3 should be regarded as remarkably safe even in the setting of intestinal inflammation associated with severely altered barrier function as it may occur in patients with radiation-induced enteritis and colitis.

## Abstract

**AIM:** To ascertain clinical outcome and complications of self-expandable metal stents for endoscopic palliation of patients with malignant obstruction of the gastrointestinal (GI) tract.

**METHODS:** A retrospective review was performed throughout August 2000 to June 2005 of 53 patients with gastric outlet obstruction caused by stomach cancer. All patients had symptomatic obstruction including nausea, vomiting, and decreased oral intake. All received self-expandable metallic stents.

**RESULTS:** Stent implantation was successful in all 53 (100%) patients. Relief of obstructive symptoms was achieved in 43 (81.1%) patients. No immediate stent-related complications were noted. Seventeen patients had recurrent obstruction (tumor ingrowth in 14 patients, tumor overgrowth in 1 patient, and partial distal stent migration in 2 patients). The mean survival was 145 d. Median stent patency time was 187 d.

**CONCLUSION:** Endoscopic placement of self-expandable metallic stents is a safe and effective treatment for the palliation of patients with inoperable malignant gastric outlet obstruction caused by stomach cancer.

**Key words:** Self-expandable metallic stents; Malignant gastric outlet obstruction; Stomach cancer

Kim TO, Kang DH, Kim GH, Heo J, Song GA, Cho M, Kim DH, Sim MS. Self-expandable metallic stents for palliation

## INTRODUCTION

Malignant obstruction of the stomach is a preterminal event that causes nausea, vomiting, dysphagia, and nutritional deficiencies leading to progressive deterioration in a patient's quality of life. It is generally managed by surgical intervention. Because a subgroup of these patients consists of people who are elderly or have advanced, metastatic disease or other medical illness, surgery may be impossible in such patients.

Endoscopic placement of self-expandable metallic stents (SEMS) has been used for palliative treatment of patients with malignant obstruction of the gastrointestinal (GI) tract for over a decade<sup>[1,2]</sup>. Endoscopic stent placement is a safe and feasible treatment option for patients with malignant gastric outlet obstruction. In retrospective comparative studies, patients who underwent an open gastrojejunostomy had delayed oral intake after surgery<sup>[3]</sup>, higher procedure-related morbidity, higher 30-d mortality<sup>[4]</sup>, and a longer length of hospital stay<sup>[4-6]</sup>, and incurred greater hospital charges<sup>[5]</sup> than patients who underwent an endoscopic stent insertion. To date, there has been no study that assesses clinical outcome after SEMS insertion for malignant gastric outlet obstruction caused by stomach cancer only, rather than by pancreatic, biliary, or duodenal cancer. Here we report results from a 5-year, single-center experience with the use of SEMS to palliate patients hospitalized with gastric outlet obstruction because of inoperable gastric cancer.

## MATERIALS AND METHODS

### Patients

Between August 2000 and June 2005, 103 patients with malignant gastroduodenal and jejunal stenosis underwent endoscopic procedures with uncovered SEMS. Obstruction was caused by stomach cancer in 53 (51.3%) patients, by recurrent malignant obstruction after gastric surgery in 20 (19.4%), by pancreatic cancer in 14 (13.6%), by bile

duct cancer in 7 (6.8%), by duodenal cancer in 3 (2.9%), by ampullary cancer in 2 (2.0%), by gallbladder cancer in 2 (2.0%) and unclassified in 2 (2.0%) patients. Only patients with malignant obstruction due to stomach cancer were included in this study. The diagnosis of malignant tumor and gastric outlet obstruction was established by means of endoscopy, duodenography and computed tomography. Fifty three patients (35 men, 18 women; mean age 64.0 years, range 34-85 years) with malignant gastric outlet obstruction who were treated with SEMS were followed at our out-patient department, inpatient department or by phone calls. None of the patients were operative candidates based on the presence of advanced, metastatic disease or medical comorbidity. All patients had symptomatic obstructions such as nausea, vomiting, bloating, and abdominal pain. The degree and site of the stenosis were usually evaluated before endoscopy, using radiographs taken after oral contrast opacification; the gastric outlet area was divided into the antropyloric portion (40 patients), pyloric and duodenal bulb portion (8 patients), body and antropyloric portion (5 patients). Patient demographics are summarized in Table 1.

### Equipments

The stents used in this study were the SEMS (NiTi-S®, Pyloric(TTS), Taewoong, South Korea), 18 mm in diameter and 60, 80, 100, or 120 mm in length. These stents are constructed from a nickel-titanium alloy with or without an outer membrane. The covered stent is coated with polyurethane in the body and the proximal flare portion. The diameters are 18 mm and 26 mm in the body and flare portions, respectively. The stent is tightly mounted on a delivery system with an outer diameter of 10-11 Fr and an overall length of 180 cm. This long and slim delivery system allowed us to insert and deploy the stent through the working channel of the therapeutic endoscope. A 300-cm long, 0.035- or 0.025-inch diameter biliary guidewire (Zebra, Microvasive, USA, or Metro, Wilson Cook, USA) or a 260-cm long, 0.035-inch diameter exchange guidewire (Radiofocus M, Terumo, Tokyo, Japan) was used. The endoscopes used were a 2-channel endoscope with a working channel of 3.7 mm (GIF-2T200, Olympus Co., Japan) or a therapeutic duodenoscope with a working channel of 4.2 mm (TJF 200, Olympus Co., Japan).

### Endoscopic techniques

We placed all stents under endoscopic and fluoroscopic guidance. Stent insertion was performed under conscious sedation using titrated doses of midazolam administered by an experienced endoscopist or a nurse with appropriate monitoring. After identification of the stenosis, a guidewire was passed through it using a standard endoscopic retrograde cholangiopancreatography (ERCP) catheter. The length of the stenosis was determined by the stricture identified with a water-soluble, iodinated contrast medium. The stent chosen extended at least an additional 1-2 cm in length on each side of the stenosis to allow an adequate margin of stent. An undeployed SEMS

**Table 1 Patient demographics**

Total number of patients	53
Mean age, yr (range)	64.0 (34-85)
Male/Female	35/18
Present illness	
Stomach cancer	53 (100%)
Location of obstruction	
Antropyloric	40 (75.5%)
Pylorus and duodenal bulb	8 (15.1%)
Body and antropyloric	5 (9.4%)

delivery system was passed through the working channel of the endoscope over the guidewire so that the ends of the undeployed stent were equidistant from the ends of the stenosis. The stent was deployed from the distal end with frequent repositioning of the proximal position in the desired location because of a tendency for it to move away from the scope. The adequacy of stent placement was assessed at the conclusion of each procedure using a combination of endoscopy and fluoroscopy. An oral contrast opacification was obtained immediately after the procedure. Technical endoscopic success was defined as correct placement of the stent across the stricture with an established patency confirmed fluoroscopically. Uncovered stents were used primarily in all cases. The patients provided informed consent before endoscopic stent insertion.

Oral intake was allowed immediately after the procedure, beginning with liquid followed by a semisolid or soft diet, if possible. When uncovered stents were occluded by tumor ingrowth, a covered stent was reimplanted through the first stent to palliate tumor ingrowth through openings between the mesh. A good clinical outcome was defined as an immediate improvement in the patient's oral intake, thereby obviating the need for other palliative options. Follow-up investigations were performed only if symptoms recurred.

### Statistical analysis

Survival was calculated using the Kaplan-Meier estimator. The date of censoring was the date of death. Cumulative stent patency was also tabulated using Kaplan-Meier plots. Censored data were determined by patients without stent occlusion and still alive, while events were determined by patients with stent occlusion, dislocation, or death.

## RESULTS

### Stent implantation

Stent implantation was successful in all 53 patients, and we used uncovered stents initially to prevent migration. A complementary hydrostatic dilation of the stent was not needed.

### Clinical outcomes and complications

Relief of major clinical symptoms (nausea, abdominal distension, reflux symptoms, vomiting) was achieved in 43

**Table 2** Clinical outcomes after stent insertion in 53 patients with stomach cancer

Technical success, <i>n</i> (%)	53 (100)
Clinical success, <i>n</i> (%)	43 (81.1)
Tolerated diet, %	43 (81.1)
Regular diet, %	9.3 (4/43)
Soft diet	58.1 (25/43)
Liquid diet	32.6 (14/43)
30-d mortality, <i>n</i> (%)	10 (18.9)
Reintervention, <i>n</i> (%)	17 (32.1)
Tumor ingrowth	14 (26.4)
Tumor overgrowth	1 (1.9)
Stent migration	2 (3.8)
Mean follow up period, d	145 (4-718)
Mean survival, d (SD)	145 (± 150.4)
Mean stent patency, d (range)	187 (33-335)

of 53 (81.1%) patients. A total of 4 of 43 (9.3%) patients could eat solid food, 25 patients (58.1%) tolerated a soft diet, and 14 patients (32.6%) continued to take liquids alone. Of the 53, 10 (18.9%) patients had intermittent episodes of vomiting, and their diets were modified as necessary (Table 2).

During the stent-insertion procedure, no major complications such as serious bleeding, bowel perforation, infection, or procedure-related mortality were noted. After the insertion of the stent, only minor complications such as mild abdominal pain occurred. During follow-up, stent-related problems required treatment in 17 patients (32.1%). Distal stent migration occurred partially in 2 patients (3.8%), 36 and 149 d after stent insertion, respectively, with resultant recurrence of obstructive symptoms. A second stent was inserted to overlap the first, which resulted in immediate relief of symptoms. Stent obstruction caused by proximal and distal tumor overgrowth occurred in 1 patient (1.9%) at 331 d after deployment. Tumor ingrowth through the stent mesh was observed in 14 patients (26.4%) at a mean of 78.4 d after the initial procedure. We defined early restenosis as a stent obstruction from tumor ingrowth within 4 wk after first stent implantation, and identified its development in 5 of 43 (11.6%) patients. Occlusion was identified clinically, radiologically, and endoscopically. We reimplanted covered stents in those who had tumor ingrowth or overgrowth.

### Survival and stent patency

The mean follow-up period for the patients was 145 d (range, 4-718 d). The mean survival was 145 d (SD; ± 150.4 d) (Figure 1), and median stent patency time was 187 d (95% CI, 39-335) (Figure 2). The overall 30-d mortality was 10 of 53 patients (18.9%).

## DISCUSSION

Malignant gastric outlet obstruction is a distressing complication of gastric cancer that results in inexorable deterioration of patient quality of life. Although surgical palliation is an available option in such patients, the results of palliative gastric bypass surgery are poor with high rates of morbidity and mortality<sup>[6-8]</sup>. Because of the limitations

**Figure 1** Survival curve of 53 patients with malignant gastric outlet obstruction caused by stomach cancer treated with SEMS.**Figure 2** Survival curve showing the probability of stent patency among 53 patients with malignant gastric outlet obstruction caused by stomach cancer treated with SEMS.

of surgery and because many patients are elderly, frail, and in an advanced stage of disease, various techniques for restoration of bowel function by non-surgical means (eg, balloon dilation and laser photoablation) have been proposed; all have met with limited success<sup>[9,10]</sup>.

Since the endoscopic application of SEMS to malignant gastric outlet obstruction in the early 1990s, the use of SEMS to pass through an obstructing neoplasm with minimal morbidity has become increasingly widespread. SEMS insertion becomes popular for treatment of malignant gastric outlet obstruction because it provides prolonged patency and simple, safe, and effective palliation in these patients.

However, the results of previous studies suggested limitations in stent patency and overall survival; these studies included heterogeneous patient groups with different causes of gastric outlet obstruction or using different types of stents. To explore the effect and complications of pyloric stents in patients with stomach cancer, we excluded patients with gastric outlet obstruction resulting from other types of cancer. To date, this is the first and largest study of endoscopic stenting for malignant gastric outlet obstruction

resulting from stomach cancer only.

The results of the present study are similar or superior to those of prior published studies of enteral stent insertion for malignant gastric outlet obstruction with respect to technical success<sup>[11-15]</sup>. When we had difficulties performing the procedure, we modified the stenting technique, including using a more hydrophilic Terumo guidewire, stiffer guidewire, or a therapeutic duodenoscope; these modifications helped us overcome difficulties and achieve successful stenting. In our study, enteral stent placement allowed 81.1% of patients to resume an oral diet, an outcome similar to that reported in other studies<sup>[11,12,14-16]</sup>. The complications related to stent insertion in the present study are less than those noted in previous studies<sup>[12-14]</sup>.

Restenosis by tumor ingrowth is the most common problem of uncovered stents, and some studies describe the use of covered stents to prevent this complication. Despite their ability to prevent tumor ingrowth, covered stents have been reported to migrate more often (more than 20%) than uncovered stents<sup>[17,18]</sup>. Stent migration could cause bleeding, perforation, or obstruction and require operation. Recently, a new double-layered combination stent (outer uncovered and inner covered dual stent, a Combi pyloric stent) was developed to prevent tumor ingrowth and migration and prolong stent patency in patients with gastric outlet obstruction. More data are needed to confirm the above results. Based on these results, we used uncovered stents initially. Recurrent stenosis of the stent because of progressive tumor ingrowth was a problem because most of the stents used were uncovered. Tumor ingrowth occurred in 14 (26.4%) patients at a mean of 78.4 d in our study. Overall recurrent stenosis rates of 8%-46% at an interval of 2-21 wk (mean, 7.5 wk) have been reported in other studies<sup>[14,15,19-24]</sup>. It is difficult to compare our results with results of other studies because other reports included patients with a variety of cancers. Early restenosis within 4 wk after stenting occurred in 5 (11.6%) patients in the current study. This result is similar to our previous result (14.3% for total gastric outlet obstruction patients and 10% for stomach cancer patients) and lower than our results for patients with recurrent malignant obstruction after gastric surgery (60%, unpublished data). Obstruction by tumor ingrowth usually is managed with placement of additional covered stents through the original stent.

Stent patency is influenced partly by tumor ingrowth and survival, which are also influenced by disease type. Survival is influenced by underlying diseases also. Our results of mean patient survival time and median stent patency time are somewhat longer than previously reported results<sup>[2,5,13-15]</sup>, however, as stated, comparisons are difficult because ours is the sole report addressing gastric outlet obstruction resulting from stomach cancer only. Thus, the reason for these differences is not clear, but the primary illnesses that caused the gastric outlet obstruction can be the most important factor. In most western reports, the most common primary illness related to gastric outlet obstruction is pancreatic cancer, and most gastric outlet obstruction develops in the terminal stage in patients with pancreatic or biliary cancer. While in our report, stomach

cancer was the sole primary disease. When compared with surgical palliation, endoscopic stenting decreases the length of hospital stay and improves survival and oral intake.

All published series on SEMS in the upper gastrointestinal tract are retrospective. The studies all differ in stent types used, and the populations differ with regard to the demographic characteristics and etiologic causes of the upper GI obstruction. There are no exact criteria regarding the selection of an uncovered stent versus a covered stent; studies are retrospective with varying definitions of complications; and a variety of stent types and insertion methods are used. Although our study is also retrospective with several similar limitations, it includes a more homogeneous patient group compared to previous studies.

In conclusion, SEMS placement is a safe and effective treatment for the palliation of patients with inoperable malignant gastric outlet obstruction caused by stomach cancer. Therefore, it should be considered as the primary choice over palliative resection for the palliation of obstruction in such patients.

### Abstract

**AIM:** To evaluate different types of treatment for sigmoid volvulus and clarify the role of endoscopic intervention versus surgery.

**METHODS:** A retrospective review of the clinical presentation and imaging characteristics of 33 sigmoid volvulus patients was presented, as well as their diagnosis and treatment, in combination with a literature review.

**RESULTS:** In 26 patients endoscopic detorsion was achieved after the first attempt and one patient died because of uncontrollable sepsis despite prompt operative treatment. Seven patients had unsuccessful endoscopic derotation and were operated on. On two patients with gangrenous sigmoid, Hartmann's procedure was performed. In five patients with viable colon, a sigmoid resection and primary anastomosis was carried out. Three patients had a lavage "on table" prior to anastomosis, while in the remaining 2 patients a diverting stoma was performed according to the procedure of the first author. Ten patients were operated on during their first hospital stay (3 to 8 d after the deflation). All patients had viable colon; 7 patients had a sigmoid resection and primary anastomosis, 2 patients had sigmoidopexy and one patient underwent a near-total colectomy. Two patients (sigmoidectomy-sigmoidopexy) had recurrences of volvulus 43 and 28 mo after the initial surgery. Among 15 patients who were discharged from the hospital after non-operative deflation, 3 patients were lost to follow-up. Of the

remaining 12 patients, 5 had a recurrence of volvulus at a time in between 23 d and 14 mo. All the five patients had been operated on and in four a gangrenous sigmoid was found. Three patients died during the 30 d postoperative course. The remaining seven patients were admitted to our department for elective surgery. In these patients, 2 subtotal colectomies, 3 sigmoid resections and 2 sigmoidopexies were carried out. One patient with subtotal colectomy died. Taken together of the results, it is evident that after 17 elective operations we had only one death (5.9%), whereas after 15 emergency operations 6 patients died, which means a mortality rate of 40%.

**CONCLUSION:** Although sigmoid volvulus causing intestinal obstruction is frequently successfully encountered by endoscopic decompression, however, the principal therapy of this condition is surgery. Only occasionally in patients with advanced age, lack of bowel symptoms and multiple co-morbidities might surgical repair not be considered.

### INTRODUCTION

Although sigmoid volvulus is uncommon in Western Europe, it nevertheless constitutes the third leading cause of large bowel obstruction in adults<sup>[1]</sup>. The main predisposing factor to sigmoid volvulus is a long, redundant sigmoid colon with an elongated mesentery, which is prone to twisting on itself. Sigmoid volvulus is an abdominal emergency occurring more commonly in the elderly, particularly in individuals with dementia or a psychiatric illness<sup>[1,2]</sup> and has a high mortality rate up to 50% in each episode<sup>[3]</sup>. In elderly patients who have no

signs of peritonitis or bowel gangrene an initial attempt with non-operative reduction is justified. After a successful non-operative reduction, an elective resection of the sigmoid colon is recommended as the risks of elective surgery are less compared with those associated with recurrent volvulus. We report the results of a series of 33 adult patients with a mean follow-up of 4.5 year (range 2-18 year) supporting this assumption.

## MATERIALS AND METHODS

In the period of 1984-2003, 33 patients (18 males and 15 females) ranging in age between 58 and 89 year, were treated for sigmoid volvulus at the 2<sup>nd</sup> Department of Propaedeutic Surgery, Medical School, Athens University, Laiko General Hospital in Greece. The hospital records of these thirty three patients were retrospectively reviewed. All patients were admitted to our department on an emergency basis due to abdominal pain, vomiting and abdominal distention. Among these patients, 7 were institutionalized. Abdominal radiographs and CT scans were indicative of sigmoid volvulus (Figures 1 and 2), showing marked bowel dilatation and fluid levels, while the outline of twisted loop was evident.

## RESULTS

All patients were actively resuscitated by means of nasogastric suction and correction of fluid-electrolyte imbalance, while broad-spectrum antibiotics were started immediately after admission. Subsequently, all patients, without signs of peritonitis, underwent sigmoidoscopy post bowel preparation with edema. In 26 patients detorsion was achieved after the first attempt. However, one patient developed septic peritonitis four days after detorsion and even though he was immediately operated on, he passed away.

Seven patients had unsuccessful endoscopic derotation and were operated on within 48 h after their admission. In two patients with gangrenous sigmoid, Hartmann's procedure was performed, however, one patient died. In five patients with viable colon, sigmoid resection and primary anastomosis were carried out (Figure 3). Three patients had a lavage "on table" prior to anastomosis, while in the remaining 2 patients a diverting stoma according to the technique of the first author (MS) was used (Figure 4).

Ten patients were operated on during their first hospital stay (3 to 8 d after the deflation). All patients had viable colon; 7 patients had a sigmoid resection and primary anastomosis, 2 patients had sigmoidopexy and one patient underwent a near-total colectomy. Two patients (sigmoidectomy-sigmoidopexy) had recurrences of volvulus 43 and 28 mo after the initial surgery. Among 15 patients who were discharged from the hospital after the non-operative deflation, 3 patients were lost to follow-up. Of the remaining 12 patients, 5 had a recurrence of volvulus at a time in between 23 d and 14 mo. All the five patients had been operated on and in four a gangrenous sigmoid was found. Three patients died during the 30 d postoperative course. The remaining seven patients were admitted to our department for elective surgery. In these

**Figure 1** Plain abdominal film showing sigmoid volvulus.

**Figure 2** CT scan showing dilated colon due to its torsion.

**Figure 3** Surgical specimen of sigmoid volvulus showing the distention of the bowel.

patients, 2 subtotal colectomies, 3 sigmoid resections and 2 sigmoidopexies were carried out. One patient with subtotal colectomy died. Taken together of the results, it is evident that after 17 elective operations we had only one death (mortality rate: 5.9%), whereas after 15 emergency operations 6 patients died (mortality rate: 40%). In Figure 5 the course of 33 patients is schematically depicted.

## DISCUSSION

Sigmoid volvulus is the most common cause of strangulation of the colon and is also the cause for 1% to 7% of all intestinal obstructions in Western countries<sup>[4]</sup>. Many patients with sigmoid volvulus have clinical findings

**Figure 4** Schematic representation of the procedure described by Michael Safioleas, i.e. Sigmoidectomy, primary anastomosis and diverting stoma. The technique is introduced in *International Journal of Colorectal Disease* 2006 vol: 21.

indicating a disorder of bowel movement<sup>[5,6]</sup>, such as constipation and abdominal distention long before the development of a sigmoid volvulus. Some researchers have claimed that sigmoid volvulus might be one of the disorders allied with Hirschsprung's disease<sup>[7]</sup>. It is also a fact that patients undergoing sigmoidectomy for sigmoid volvulus frequently suffer from elongation and dilatation of the remaining colon and some even require surgery for revolvulus<sup>[8]</sup>. The disease is rare in children<sup>[9]</sup>; however, if it occurs, it may result in acute intestinal obstruction, unlike in adults where the obstruction may be subacute and progressive<sup>[10]</sup>. In our series 19 patients had a history of undetermined abdominal pain during the period of 3 to 9 mo. Moreover, besides chronic constipation and despite the use of laxatives<sup>[2,11]</sup>, other risk factors that predispose to sigmoid volvulus are considered as follows: (1) a course with high fiber diet, (2) pregnancy, (3) pelvic tumors or cysts, (4) previous abdominal surgery. Concerning the last factor, the presence of a band attaching the sigmoid colon to the abdominal wall can act as an axis for volvulus. Furthermore, it is supposed that the loss of ganglion cells is only a consequence, not a cause, since the exact cause leading to sigmoid volvulus is not clear<sup>[12]</sup>.

All these conditions may produce a large, redundant sigmoid colon, in association with mesocolon, long and narrow at its parietal attachment, resulting in the two ends of the loop being close together, under which condition, the bowel is capable of becoming torted around its central mesenteric axis.

Although sigmoid volvulus has been well studied for many decades, its treatment appears to be still evolving<sup>[3]</sup>; however, over the past two decades, resection and primary anastomosis has emerged as the preferable treatment for this disease<sup>[13]</sup>. Whether endoscopic deflation is feasible to perform prior to surgery is an optimal choice. Unfortunately endoscopic detorsion is not always successful. In Western countries a 30% failure has been reported<sup>[14-16]</sup>.

In our department, since 1995, we have always followed such a strategy. Initially, we attempt an endoscopic deflation and if it is unsuccessful we proceed to an emergency operation; while if detorsion has been achieved the operation is performed after 3 to 8 d by a semi-elective or elective way. In the majority of cases resection of the involved sigmoid colon is carried out, in which case primary anastomosis is the goal, either after "on table" lavage, or applying a diverting stoma<sup>[17]</sup>.

In the presence of megacolon, a near-total colectomy

**Figure 5** Schematic depiction of the course of 33 patients suffering from volvulus of the sigmoid colon and treated in our department.

is required. Furthermore, various procedures have been adopted for sigmoid volvulus in adult patients, such as mesosigmoidoplasty, sigmoidopexy, tube sigmoid colostomy or mesocoloplasty. In patients with sigmoid resection a recurrence is possible in approximately 25% to 35% cases<sup>[5,13,18]</sup>. The mortality rate ranges from 1% to 9% for viable colon<sup>[15,19]</sup>, and 25% for gangrenous volvulus<sup>[15]</sup>. Colonic resection for non-gangrenous sigmoid volvulus has an acceptably low rate of complications, particularly when it is done as a semi-elective procedure, i.e., subsequent to endoscopic detorsion and deflation<sup>[20]</sup>. Finally, recurrent volvulus after resection has been reported at an incidence rate ranging from 24% to 33% of cases<sup>[5,18]</sup>.

In conclusion, even though sigmoid volvulus causing intestinal obstruction is frequently encountered in endoscopic decompression, this condition should be definitely treated by surgery; and only occasionally in patients with advanced age, lack of bowel symptoms, having multiple co-morbidities might surgical repair not be considered.

### Abstract

**AIM:** To validate and compare the cost of microdose  $^{14}\text{C}$  urea breath test (UBT) with histology and rapid urease test for the diagnosis of *H Pylori*.

**METHODS:** Ninety-four consecutive patients with dyspeptic symptoms undergoing gastroscopy were enrolled. Gastric biopsies were taken for histology and rapid urease test. UBT was performed after gastroscopy by microdose  $^{14}\text{C}$  urea capsules. Sensitivity, specificity and accuracy of UBT were calculated and compared with histology and rapid urease test. Cost comparison of these tests was also performed.

**RESULTS:** *H pylori* was diagnosed by histology and rapid urease test in 66 (70%) and 61 (65%) patients, while  $^{14}\text{C}$  UBT detected infection in 63 (67%). Accuracy of UBT was 93% in comparison with histology while its positive and negative predictive values were 97% and 84%, respectively. Comparison of  $^{14}\text{C}$  UBT with rapid urease test gives an accuracy of 96%, with positive and negative predictive values of 95% and 97%, respectively. These results were highly reproducible with a Kappa test ( $P$  value < 0.001). Cost of histology or rapid urease test with gastroscopy was 110 USD or 95 USD respectively while the cost of UBT was 15 USD.

**CONCLUSION:** Microdose  $^{14}\text{C}$  UBT was comparable to histology and rapid urease test.  $^{14}\text{C}$  UBT is an economical, self sufficient and suitable test to diagnose active *H pylori* infection in less developed countries.

### INTRODUCTION

*H Pylori* is a gram negative, microaerophilic human pathogen which is prevalent worldwide. *H Pylori* infection causes gastritis and is associated with development of peptic ulcer disease, gastric carcinoma, lymphoma, micronutrient deficiencies and ischemic heart disease<sup>[1,2]</sup>. The International Agency for Research on Cancer classified *H Pylori* as group 1 carcinogen (a definite cause of cancer in humans)<sup>[3]</sup>.

*H Pylori* can be diagnosed by invasive techniques requiring endoscopy and biopsy such as histology, tissue culture and detection of *H Pylori* by polymerase chain reaction. The non-invasive techniques for the diagnosis of *H Pylori* include serum *H Pylori* antibody titer, urea breath test (UBT) and *H Pylori* stool antigen test. A reliable, non-invasive and economical diagnosis is a best choice for the management of *H Pylori* in both test and treatment.

Among the non-invasive tests, UBT is supposed to be a gold standard test for the diagnosis of *H Pylori* infection. UBT is based on enzymatic hydrolysis of labeled urea in the stomach by urease, an enzyme produced in abundance by *H Pylori*. In the presence of *H Pylori* infection, urea is hydrolyzed to ammonia and carbon dioxide ( $\text{CO}_2$ ). This labeled  $\text{CO}_2$  is exhaled and measured for radioactivity. Bacteria other than *H Pylori* that produce urease in a small amount cannot survive in the gastric mucosa.

There are two types of UBT,  $^{13}\text{C}$  UBT and  $^{14}\text{C}$  UBT. The former is difficult to analyze because it requires sophisticated infrastructure such as a mass spectrometer, technical expertise and therefore costly while  $^{14}\text{C}$  UBT is an easily available technique that uses  $^{14}\text{C}$  urea capsules with a 5, 3 or 1  $\mu\text{Ci}$  dose. The microdose 1  $\mu\text{Ci}$  (Helicap) utilizes a very low dose of radiation<sup>[4,5]</sup>. Considering these facts, in 1997 the Nuclear Regulatory Commission permitted *in vivo* diagnostic use of capsules containing 1  $\mu\text{Ci}$  of  $^{14}\text{C}$  urea without a license<sup>[6]</sup>. The equipment is small, portable and can be placed on a desktop. Microdose  $^{14}\text{C}$  UBT is claimed to be a reliable and economical diagnostic test for *H Pylori* infection, which may be used even in remote areas with limited resources.

This prospective study was done to determine the validity and cost of microdose  $^{14}\text{C}$  UBT in comparison with histology and rapid urease test for the diagnosis of *H Pylori*.

## MATERIALS AND METHODS

All consecutive men and non-pregnant women with dyspeptic symptoms undergoing gastroscopy were considered for enrollment.

Dyspepsia was defined as the presence of one or more of the postprandial fullness, early satiation, or epigastric pain or burning for the last three months with symptom onset at least six months before diagnosis according to the latest Rome III criteria<sup>[7]</sup>.

### Inclusion criteria

Patients of both genders with dyspepsia were 18-70 years in age. Patients with a history of recent intake of proton pump inhibitor and antibiotics were enrolled only if four weeks have passed since last systemic antibacterial or bismuth medication therapy and 1 wk since last use of proton pump inhibitor or H<sub>2</sub>-receptor antagonist.

### Exclusion criteria

Pregnant women, patients who had gastric surgery, patients with a history of *H Pylori* eradication therapy in the past six months and patients with active gastrointestinal bleeding were excluded from the study.

### Ethical clearance

Study protocol was approved by the institutional ethical review committee. Written informed consent was obtained from all patients before enrollment.

### Endoscopy and biopsy sampling

After overnight fast, esophago-gastro-duodenoscopy was performed with Olympus or Pentax videoscope. Six biopsies were taken, three from antrum and other three from the body of stomach from each patient. Two biopsies, one from the antrum and the other from the body were used for rapid urease test and the other four (two from antrum and two from body) for histology.

### Rapid urease test

Rapid urease test kit (Pronto Dry, Medical Instrument Corp., France) was used to detect the presence of *H Pylori* urease<sup>[8]</sup>. Result was read in 30 min and 1 h after sampling. The color change from yellow to pink was considered positive and no color change as a negative result. Results were interpreted by either endoscopist or his assistant who were blinded about the results of UBT and histology.

### Histology

Four biopsy specimens (two from corpus and two from antrum) were processed separately for histological examination according to standard procedure. Hematoxylin and eosin (HE) and Giemsa staining was performed on these samples. Results were interpreted by

a pathologist who was blinded about the results of UBT and rapid urease test. Pathologist commented on the active and chronic *H Pylori* infection based on the presence of *H Pylori* along with neutrophils, eosinophils, lymphocytes, lymphoid follicles, and intestinal metaplasia according to the classification by Genta RM *et al*<sup>[9]</sup>.

### $^{14}\text{C}$ UBT

Patients swallowed 37 kBq (1 uCi) of an encapsulated form of  $^{14}\text{C}$ -urea/citric acid composition (Helicap, Noster System AB Stockholm, Sweden) with water after endoscopy. Breath samples were collected with a special dry cartridge system (Heliprobe Breath Card, Noster System AB Stockholm, Sweden) after 10 min. Patients exhaled gently into the cartridge mouthpiece until the indicator membrane changed in color from orange to yellow. Breath card was inserted into a  $\beta$ -scintillation counter (Heliprobe-analyser, Noster System AB Stockholm, Sweden) and activity was counted for 250 s. This is a portable machine that can be placed on a desktop. Results were expressed both as counts per minute (HCPM) and as grade (0: not infected, CPM < 25; 1: equivocal, CPM 25-50; 2: infected, CPM > 50), which was suggested by the producer according to the counts obtained from the cartridges<sup>[10]</sup>. Grades 0 and 1 were considered negative for the detection of *H Pylori*.

### Statistical analysis

The statistical package for social science SPSS (release 11.5, standard version, copyright © SPSS) was used for data analysis. The descriptive analysis was done for demographic features. Results were presented as mean  $\pm$  SD in number (percentage).

Sensitivity, specificity, positive and negative predictive values of UBT with 95% confidence intervals were calculated against histology and rapid urease test. Kappa test was applied to check the reproducibility of the results. Cost comparison of these diagnostic methods was also performed.

## RESULTS

Ninety-four consecutive patients with dyspeptic symptoms undergoing gastroscopy were enrolled for the validity of microdose  $^{14}\text{C}$  UBT. There were 60 (64%) men and the mean age of study group was  $40.8 \pm 12.8$  years. *H Pylori* infection was diagnosed by histology in 66 (70%) patients and by rapid urease test in 61 (65%) patients. UBT detected active *H Pylori* infection in 63 (67%) patients. Demographic characteristics of the patients and results of these diagnostic tests are summarized in Table 1.

### $^{14}\text{C}$ UBT vs histology

In comparison with histology, UBT has a sensitivity and specificity of 92% (95% CI: 87%-95%) and 93% (95% CI: 79%-99%), respectively. The positive predictive value (PPV) of  $^{14}\text{C}$  UBT was found to be 97% (95% CI: 91%-99%) and negative predictive value (NPV) was 84% (95% CI: 72%-89%) compared with histology. These results show that UBT has an accuracy of 93% as compared with

**Table 1** Patient demographics and results of *H Pylori* detection by various tests ( $n = 94$ ), mean  $\pm$  SD

Parameters	$n$ (%)
Gender	
Male	60 (64)
Female	34 (36)
Age (yr)	40.8 $\pm$ 12.8
Histopathology	
Positive	66 (70)
Negative	28 (30)
UBT	
Positive	63 (67)
Negative	31 (33)
Rapid urease test	
Positive	61 (65)
Negative	33 (35)

histology. Kappa test result was 0.805 with  $P$  value  $< 0.001$ , indicating that these results were reproducible (Table 2).

### $^{14}\text{C}$ UBT vs rapid urease test

In comparison of UBT and rapid urease test, the sensitivity and specificity of UBT were 98% (95% CI: 93%-99%) and 91% (95% CI: 80%-94%). The PPV and NPV were 95% (95% CI: 89%-97%) and 97% (95% CI: 86%-99%), respectively. UBT has an accuracy of 96% in comparison with rapid urease test. Result of Kappa test was 0.881 ( $P \leq 0.001$ ) which showed a good response (Table 2).

Four patients with histological evidence of *H Pylori* infection had negative results with UBT and rapid urease test. The discordant results between histology, UBT and rapid urease test are shown in Table 3.

### Cost analysis

At the time of this study, the cost of gastroscopy was 90 USD while the cost of histology and rapid urease test was 20 USD and 5 USD in our institute. Therefore, the overall cost of *H Pylori* diagnosis by histology was 110 USD and 95 USD by rapid urease test. The cost of UBT was only 15 USD in our institute.

## DISCUSSION

Current guidelines for the management of *H Pylori* infection recommend eradication treatment without performing endoscopy in patients under 45 years of age who have no remarkable symptoms<sup>[11-13]</sup>. The use of non-invasive tests has been advocated in different strategies for management of dyspeptic patients in the primary care based on clinical and economical analyses<sup>[14,15]</sup>.

Invasive diagnostic tests for *H Pylori* diagnosis need gastroscopy that requires sedation and monitoring during the procedure by trained staff and expertise. These diagnostic tests are costly and require an established healthcare infrastructure.

In practical terms, invasive tests for the diagnosis of *H Pylori* are not feasible, especially in less developed countries. An economical, reliable and office based diagnostic test is therefore, more appropriate in settings of

**Table 2** Sensitivity and specificity of  $^{14}\text{C}$  UBT against histopathology and rapid urease test for *H Pylori* diagnosis ( $n = 94$ )

UBT compared to:	Sensitivity (95% CI)	Specificity (95% CI)	PPV (95% CI)	NPV (95% CI)	Accuracy
Histopathology	92% (87-95)	93% (79-99)	97% (91-99)	84% (72-89)	93%
Rapid urease test	98% (93-99)	91% (80-94)	95% (89-97)	97% (86-99)	96%

UBT: urea breath test; PPV: positive predictive value; NPV: negative predictive value; CI: confidence interval.

**Table 3** Discordant results between histopathology,  $^{14}\text{C}$  UBT and rapid urease test for *H Pylori* diagnosis ( $n = 94$ )

Groups	Patients ( $n$ )	Histopathology	UBT	RUT
Group 1	59	+	+	+
	2	+	+	-
	1	+	-	+
	4	+	-	-
Group 2	1	-	+	+
	1	-	+	-
	26	-	-	-

UBT: urea breath test; RUT: rapid urease test; +: positive; -: negative.

under privileged and cost constraint societies.

Other factors that determine choice of diagnostic tests apart from accuracy, in primary care setting include the availability of test, ease to perform, cost, self-sufficiency and acceptance by the patients. Present study has shown that microdose  $^{14}\text{C}$  UBT has all these features.

Our study has demonstrated a high accuracy of microdose  $^{14}\text{C}$  UBT for the detection of *H Pylori* infection comparable to histological diagnosis of *H Pylori*. The results of present study are comparable to other studies, with a sensitivity and specificity of more than 90% for the diagnosis of *H pylori* infection<sup>[16-18]</sup>.

The sensitivity and specificity of  $^{14}\text{C}$  UBT were 98% and 91% while PPV and NVP were 95% and 97% respectively, compared with rapid urease test. The overall accuracy was 96%. These results are similar to another study that found a 93% sensitivity, 96% specificity and 95% accuracy in comparison with rapid urease test<sup>[19]</sup>. Moreover, studies using a combination of histopathology and rapid urease test as a gold standard has also reported a comparable sensitivity and specificity of  $^{14}\text{C}$  UBT above 90%<sup>[20,21]</sup>.

*H Pylori* Stool Antigen (HpSA) test is a promising non-invasive test. This test seems to be equivalent to the UBT in terms of its yield of diagnosing *H Pylori*<sup>[22]</sup>. However, collection of stools may be a disagreeable task for many patients and it is difficult to manage in office based settings. *H Pylori* serum antibody test is another non-invasive test. It has a low sensitivity and specificity and it does not indicate active *H Pylori* infection because antibody titers can remain high for a long period despite adequate treatment<sup>[23]</sup>. It is one of the best tests for estimation of sero-prevalence of *H Pylori*, unfortunately it is not an ideal

test for the diagnosis of active *H Pylori* infection.

It has been shown that UBT becomes false negative during treatment with proton pump inhibitors and H-2 blockers<sup>[24,25]</sup>. However, it has been observed recently that addition of citric acid in the urea capsule may diminish the negative effect of acid inhibitory drugs on the accuracy of <sup>14</sup>C UBT<sup>[26]</sup>. Although we used an acidified <sup>14</sup>C urea capsule (Helicap), we preferred to discontinue anti-acid medications for at least seven days before the test. Controversies exist regarding the best diagnostic test for *H Pylori* among patients with active upper GI bleeding. <sup>13</sup>C UBT was found better than histology and rapid urease test by a few studies in patients with active upper GI bleeding<sup>[27,28]</sup>. However, validity of <sup>14</sup>C UBT in patients with active upper GI bleeding has never been assessed.

Concerns about the radiation hazard can be raised against <sup>14</sup>C UBT. However, it has been found in practice that by using microdose <sup>14</sup>C UBT, only a small amount of isotope was used and the test actually entailed low radiation exposure (3 mSv)<sup>[29,30]</sup>.

Nearly the entire ingested isotope is rapidly excreted in urine or breath within 72 h. Recently safety of microdose <sup>14</sup>C UBT has been established even in young children<sup>[31]</sup>.

In conclusion, microdose <sup>14</sup>C UBT is a highly sensitive and specific non-invasive test comparable to the invasive methods such as histology and rapid urease test used for *H Pylori* diagnosis. This test requires no sophisticated infrastructure. <sup>14</sup>C UBT is self-sufficient and easy to perform with readily available results. In our opinion, this is one of the best options for detection of *H Pylori* infection in office based settings, especially in less developed countries.

## ACKNOWLEDGMENTS

The authors want to thank Mr. Mohammad Islam for his statistical advice and Ms. Rozina Wasaya for her support in endoscopy.

## COMMENTS

### Background

*H pylori* is one of the most prevalent infection organisms, especially in low socio-economic societies. It is associated with intestinal and extra-intestinal manifestations including malignancy. There is a need to establish cost-effective eradication strategies especially in less developed countries.

### Research frontiers

Microdose <sup>14</sup>C Urea Breath Test (UBT) is carried out without the use of sophisticated equipment and specialized trained personnel. There is a need to compare the diagnostic usefulness of <sup>14</sup>C UBT with other diagnostic modalities such as histopathology and rapid urease test for *H pylori* detection. This comparison will help establish the value of <sup>14</sup>C UBT in resource constraint settings.

### Innovations and breakthrough

<sup>14</sup>C UBT is not a commonly used diagnostic method and there are only few studies about the accuracy of <sup>14</sup>C UBT for *H pylori* diagnosis. This study concluded that the sensitivity and specificity of microdose <sup>14</sup>C UBT is comparable to mostly used invasive diagnostic tests, such as histopathology and rapid urease test.

### Application

Microdose <sup>14</sup>C UBT may be utilized for the non-invasive diagnosis of *H pylori* especially in the areas lacking an established health care structure. It can be

used in accordance with the "test and treatment" policy in patients with dyspepsia without remarkable features.

## Terminology

Dyspepsia is defined as the presence of one or more symptoms of the postprandial fullness, early satiation, epigastric pain or burning for the past three months with symptom onset at least six months before the diagnosis according to the latest Rome III criteria. <sup>14</sup>C UBT is available in 5, 3 and 1 uCi dose. The microdose 1 uCi (Helicap) utilizes a very low dose of radiation.

## Peer review

This is an interesting paper which addresses an important issue in the diagnosis of *H pylori* infection. Authors reported that the microdose <sup>14</sup>C UBT is a simple, less expensive and accurate test to diagnose *H pylori* infection. The paper is well written and conclusions are supported by results.

<http://www.wjgnet.com/1007-9327/13/930.asp>

## Abstract

**AIM:** To investigate the efficacy and tolerability of *H pylori* eradication in an omeprazole-based triple therapy with high- and low-dose of clarithromycin and amoxicillin.

**METHODS:** One hundred and sixty *H pylori* positive patients were randomly assigned to two groups based on the following 2 wk investigation; (1) group A or low-dose regimen received omeprazole 20 mg b.i.d, clarithromycin 250 mg b.i.d and amoxicillin 500 mg b.i.d; and (2) group B or high-dose regimen received omeprazole 20 mg b.i.d, clarithromycin 500 mg b.i.d and amoxicillin 1000 mg b.i.d. During the study *H pylori* status was assessed by histology and rapid urease test prior and by <sup>13</sup>C-urea breath test 6 wk after the therapy. Standard questionnaires were administered to determine the compliance to treatment and possible adverse events of therapy. Data were subject to  $\chi^2$  to compare the eradication rates in the two groups. The significant level of 95% ( $P \leq 0.05$ ) was considered statistically different.

**RESULTS:** We found that the per-protocol eradication rate was 88% (68/77) in group A, and 89% (67/75) in group B. The intention-to-treat eradication rate was 85% (68/80) in group A and 83.75% (67/80) in group B. Overall adverse events were 26% in group A and 31% in group B. The adverse events were generally mild in nature and tolerated well in both groups with a compliance of 98% in group A vs 96% in group B.

**CONCLUSION:** The omeprazole-based low dose regimen of clarithromycin and amoxicillin for two weeks in *H pylori* eradication is as effective as high dose regimen in Iranian population.

## INTRODUCTION

*H pylori* is associated with chronic active gastritis, peptic ulcer diseases, gastric adenocarcinoma and mucosa-associated lymphoid tissue lymphoma<sup>[1-3]</sup>. Numerous treatment regimens for *H pylori* eradication with particular attention to duration and dosage have been adopted in various geographic regions of world with contradictory results<sup>[4-6]</sup>. The goal of all these attempts is to obtain a cheap, safe, tolerable and acceptable *H pylori* eradication rate regimen. An *H pylori* regimen should achieve at least an 80% eradication rate<sup>[7,8]</sup>. Classical triple therapy based on H<sub>2</sub>-receptor antagonist or a proton pump inhibitor (PPI) due to high prevalence (75.2%) of *H pylori* resistance to metronidazole in Iran, is not accompanied by acceptable eradication rates<sup>[9,10]</sup>. In a randomized study of two weeks treatment in Iranian duodenal ulcer patients with bismuth triple therapy (bismuth, metronidazole and amoxicillin), the cure rate for *H pylori* was 46.0% by per-protocol (PP) analyses<sup>[11]</sup>. Furazolidone, a cheap antibiotic, has been focus of attention as a substitute for clarithromycin or metronidazole in few clinical trials of bismuth triple and quadruple therapy in Iran<sup>[12,13]</sup>. In a bismuth quadruple therapy with two different doses of furazolidone, intention-to-treat (ITT) and PP eradication rates were 72% with low and 92% with high dose of furazolidone respectively<sup>[13]</sup>. Regardless of this study, in practice its higher doses are accompanied by poor compliance and severe side-effects, and so far no Hp consensus group has recommended its routine use. To keep in mind these facts and overcome the above shortcomings, the first line of therapy as suggested by European, American, and Asian-Pacific guidelines for *H pylori* eradication that combines a PPI with clarithromycin and either amoxicillin

or metronidazole should be considered as first line of *H pylori* treatment in Iranian patients. Based on high resistance of *H pylori* strains to metronidazole in Iran, non-metronidazole containing regimens are recommended for *H pylori* eradication in our country. Since short-term regimens are not effective in *H pylori* eradication in Iranian patients, a 10-14 d therapy is needed<sup>[14]</sup>. As this regimen is costly for routine use in developing countries, dose reduction is an option to decrease its cost. There are limited studies that have evaluated the efficacy of both clarithromycin and amoxicillin in low-dose regimens in *H pylori* eradication with a PPI-based triple therapy<sup>[15-19]</sup>. Therefore, we tried to investigate the efficacy and tolerability of omeprazole-based triple therapy with high and low doses of clarithromycin and amoxicillin in *H pylori* eradication in Iranian population.

## MATERIALS AND METHODS

Between October 2004 and September 2005, 160 consecutive *H pylori*-infected patients, 18-80 years of age, were recruited for this study. The patients were excluded from enrolment if they had taken proton pump inhibitors, bismuth preparations or antibiotics within 4 wk prior to the study; had histories of gastric or duodenal surgery, allergy to medications or endoscopic evidence of gastric malignancy, gastric outlet obstruction, bleeding or if they had clinically significant cardiovascular, hepatic, pulmonary metabolic or psychiatric diseases. The *H pylori* infection was defined as positive when both rapid urease test and histology were positive for *H pylori* documentation. In the biopsy rapid test, two biopsy specimens (one from antrum and one from corpus on the greater curvature) were examined. Four biopsy specimens (two from antrum and two from the mid-corpus on the greater and lesser curvature) underwent histopathological assessment. Eligible patients were randomized to receive the two following regimens: group A or low-dose regimen ( $n = 80$ ) received omeprazole 20 mg b.i.d, clarithromycin 250 mg b.i.d and amoxicillin 500 mg b.i.d, and group B or high-dose regimen ( $n = 80$ ) received omeprazole 20 mg b.i.d, clarithromycin 500 mg b.i.d and amoxicillin 1000 mg b.i.d for two weeks. Eradication was confirmed by <sup>13</sup>C-urea breath test 6 wk after completion of treatment. Results under 5 cut-off were considered negative. Adverse events were prospectively evaluated. They were assessed as mild (discomfort not interfering with daily activity); moderate (discomfort interfering with daily activity); and severe (discomfort resulting in discontinuation of therapy). Compliance was checked by pill count at the end of treatment. Poor compliance was defined as taking less than 70% of pills. Eradication rates were evaluated by ITT and PP analyses. The eradication and adverse event rates in the two treatment groups were compared using  $\chi^2$  test. A  $P$  value less than 0.05 was considered statistically significant. Data were analyzed using the SPSS for Windows (version 11.5; SPSS, Inc, Chicago, Illinois, USA).

## RESULTS

Demographic and outcome data of two eradication

**Table 1** Demographic data and outcomes of two enrolled groups

Data	Group A ( $n = 80$ )	Group B ( $n = 80$ )
Mean age (yr) (mean $\pm$ SD)	52.4 $\pm$ 13	53.1 $\pm$ 12.3
Gender (male/female)	55/25	57/23
Eradication rate		
Intension-to-treat	85% (68/80)	83.75% (67/80)
Per-protocol	88% (68/77)	89% (67/75)
Adverse events		
Mild	20% (15)	22% (17)
Moderate	5% (5)	8% (6)
Severe	1.25% (1)	2.5% (2)
Compliance	98% (78/80)	96% (77/80)

regimen groups are summarized in Table 1. No significant difference was found between the two groups of patients with regard to clinical variables. Five patients (2 in group A and 3 in group B) with poor compliance and 3 (1 in group A and 2 in group B) with incomplete follow-up therapy were excluded from PP analysis for *H pylori* eradication. The per-protocol eradication rate was 88% in group A, and 89% in group B. The ITT eradication rate was 85% in group A and 83.75% in group B. The differences were not statistically significant between the two groups by ITT and PP. All the patients receiving at least one dose of medications were included in adverse event analysis, and 26% of the group A and 31% of group B reported at least one adverse event during the therapy. Diarrhea was the most common adverse event in both groups (5% in group A *vs* 9% in group B). All but 5 (2 in group A and 3 in group B) complied with the eradication therapies and took more than 70% of assigned tablets. Both groups displayed similar compliance rates (98% in group A *vs* 96% in group B).

## DISCUSSION

The results of this study confirm that efficacy of low and high dose regimens of clarithromycin and amoxicillin and comparable omeprazole dose (20 mg b.i.d) are equal in *H pylori* eradication in Iranian population. The treatments were well tolerated and associated with a high compliance rate. Many studies have compared different doses of clarithromycin in *H pylori* eradication, with contradictory results, but those that have evaluated clarithromycin-amoxicillin combination in low-dose regimens for *H pylori* eradication are scarce<sup>[15]</sup>. Hp consensus groups have generally recommended a 500 mg b.i.d dosage of clarithromycin for *H pylori* eradication<sup>[7,8]</sup>. However, some issues with regard to the clarithromycin dosage need to be addressed. MACHI study produced disappointing results for low-dose clarithromycin regimens, with an eradication rate of 79.5% by intension-to-treat analysis compared with 90.6% for the clarithromycin 500 mg b.i.d regimen<sup>[16]</sup>. A meta-analysis also showed that pooled eradication rate of the clarithromycin 500 mg b.i.d regimen was 86.6% by ITT analysis and 89.5% by PP analysis, which were significantly higher than those achieved with the clarithromycin 250 mg b.i.d regimen, 78.2% by ITT and 83.3% by PP analyses<sup>[19]</sup>. However, even in that meta-analysis, subgroup analysis

showed that proton pump inhibitor dosing frequency affected the efficacy of *H. pylori* eradication. On the basis of proton pump inhibitor b.i.d regimens, the *H. pylori* eradication rates by pooled PP analysis were 86.1% and 89.6% in the clarithromycin 250mg b.i.d and 500 mg b.i.d regimens, respectively. In contrast, a recent Japanese study showed that clarithromycin 200 mg b.i.d regimen was as effective as 400 mg b.i.d<sup>[18]</sup>. In addition, a multi-center study performed in France demonstrated a somewhat higher, although not significant, eradication rate with low-dose clarithromycin triple therapy compared with the conventional regimen<sup>[17]</sup>. In a study by Miwa H *et al*<sup>[15]</sup> using different doses of omeprazole-clarithromycin-amoxicillin, in their low-dose group of omeprazole 20 mg, amoxicillin 750 mg and clarithromycin 200 mg all b.i.d, the eradication rates by ITT and PP were 82.5% and 90% respectively. In our study, the eradication rate of low-dose regimen was 85% and 88% by ITT and PP analysis, respectively. Because of the high metronidazole resistance in our country (75.2%)<sup>[10]</sup> and low eradication rate of *H. pylori* with metronidazole containing regimens and shortcomings with other applied *H. pylori* eradication regimens in Iran, the first line of *H. pylori* treatment as suggested by most *H. pylori* consensus groups, the PPI-based therapy with low-dose regimen of clarithromycin-amoxicillin seems to be a good option to overcome its high cost in developing countries. In a study by Malekzadeh *et al*<sup>[14]</sup> using a 7-d conventional therapy with clarithromycin, regardless of low prevalence of *H. pylori* resistance to clarithromycin in their report (1.2%), the eradication rate was unacceptably low (35.5% in ITT). This low eradication rate has been attributed to the high prevalence of cancer in the areas of the study, their conclusion was that patients in this high-prevalence cancer area may have a higher bacterial load in gastric mucosa with different biological behaviors, Cag A strains or host-immune response. It has been estimated that the rate of eradication increased by 9% by extending duration of therapy from 7 to 10 d<sup>[20]</sup>. Based on these reports and our results, efficacy of proton pump triple therapy with conventional and low-dose regimens of clarithromycin and amoxicillin with 7, 10 and 14 d requires more evaluation in different geographic regions of Iran by further multi-center head-to-head comparison studies in our country. In conclusion, two weeks triple therapy with a proton pump inhibitor and low-dose regimen of clarithromycin and amoxicillin is as effective as high-dose regimen, and has acceptable eradication rate and the best cost-benefit ratio in Iranian population.

### Abstract

**AIM:** To observe the growth inhibitory effect of wild-type *Kras2* gene on a colonic adenocarcinoma cell line Caco-2.

**METHODS:** Recombinant plasmid pCI-neo-*Kras2* with wild type *Kras2* open reading frame was constructed. The Caco-2 cells were transfected with either pCI-neo or pCI-neo-*Kras2* using Lipofectamine 2000. The expression of wild type *Kras2* was examined by Northern blot analysis. And the expression of wild type *Kras2* protein was examined by Western blot analysis. The effects of wild-type *Kras2* on cell proliferation were analyzed by monotetrazolium (MTT) assay, meanwhile analyses of cell cycle and spontaneous apoptosis rate were carried out by flow cytometry (FCM).

**RESULTS:** The plasmid of pCI-neo-*Kras2* was successfully established. The growth rate of cells transfected with pCI-neo-*Kras2* was significantly lower than the control cells transfected with the empty pCI-neo vector ( $P < 0.05$ ). Cell cycle analysis revealed arrest of the pCI-neo-*Kras2* transfected cells in G<sub>0</sub>/G<sub>1</sub> phases, decreased DNA synthesis and decreased fractions of cells in S phase. The proliferative index of cells transfected with pCI-neo-*Kras2* was decreased compared with the control cells (49.78% vs 64.21%), while the apoptotic rate of Caco-2 cells with stable *Kras2* expression increased (0.30% vs 0.02%).

**CONCLUSION:** The wild-type *Kras2* gene effectively inhibits the growth of the colonic adenocarcinoma cell line Caco-2.

### INTRODUCTION

A number of molecular studies have shown that colon carcinogenesis results from an accumulation of epigenetic and genetic alterations, including activation of the proto-oncogenes, and inactivation of the mutations of tumor suppressor genes or of DNA repair genes<sup>[1]</sup>. Previously extensive studies have been done on the activation of the *K-ras2* proto-oncogene<sup>[2-4]</sup> and have revealed the association between colon carcinogenesis and the frequency of RAS mutations. Approximately 50% of colorectal tumors contain *K-ras2* gene mutations, leading to activation of the *K-ras2* oncogene, which is an early event in carcinogenesis. A recent study on *Kras2*, however, demonstrated that the wild-type *Kras2* inhibited the growth, colony formation and *in vivo* tumor formation of lung cancer cells<sup>[5]</sup>. In addition, wild-type *Kras2* has also been shown to inhibit colony formation and tumor development by transformed NIH/3T3 cells. These results indicated wild-type *kras2* might exert its tumor suppressor effect in carcinogenesis. In the current study, we attempted to investigate the tumor suppressive effect of wild-type *Kras2* on the proliferation of a colon cancer cell line. We transfected the wild-type *Kras2* gene into Caco-2 cell, a human colon adenocarcinoma cell line, and established a stably transfected cell line by G418 selection. The effects of wild-type *Kras2* on cell growth, cell cycle distribution and apoptosis were analyzed in Caco-2 cells.

### MATERIALS AND METHODS

#### Cell culture

Human colon tumor cell line Caco-2 was purchased from American Type Culture Center (ATCC) (Rockville, MD, USA) and was maintained in MEM-NEAA medium supplemented with 10% FCS and 100 U/mL penicillin-

streptomycin in a humidified atmosphere with 5% CO<sub>2</sub> at 37°C.

### Cloning of wild-type *Kras2* gene and plasmid construction

Appropriate institutional approval for human tissue studies and the informed consent from all subjects were both obtained. The wild-type *Kras2* cDNA fragment was amplified by PCR. Briefly, total RNA from human peripheral blood was extracted by Trizol reagent (Invitrogen) and the Reverse Transcription System kit (Promega) was used to synthesize the cDNA. The primer sets Y1: 5'-ACCCACGCGTATGACTGAATATAAAC-3' and Y2: 5'-AACGTCGACTTACATAATTACACACT-3' (Shanghai Oke Corp.) with *Mlu* I and *Sal* I enzyme sites respectively were used to amplify the wild-type *Kras2* cDNA. The PCR product was harvested from 1% agarose gel, digested by *Mlu* I and *Sal* I enzymes and inserted into the pCI-neo vector at *Mlu* I and *Sal* I cloning sites to construct the pCI-neo-*Kras2* expression vector. All ligation products were transformed into DH5 competent cells. The constructs were confirmed by restriction enzyme mapping and DNA sequencing.

### Cell transfection and stable screening

For transfection experiment, Caco-2 cells were seeded into 100-mm culture dishes and grown until 80% confluence. The empty plasmid pCI-neo and the pCI-neo-*Kras2* were stably transfected using Lipofectamine 2000 reagent (Invitrogen), according to the manufacturer's instruction. Caco-2 cells were selected with 1.2 mg/mL G418 for 2 wk and maintained in normal MEM medium containing 0.6 mg/mL G418 (Amresco USA).

### RNA isolation and Northern blot analysis

A total of  $1.5 \times 10^5$  viable Caco-2 cells transfected with the pCI-neo empty vector or *Kras2* stably expressing cells were plated into one well of six-well plates with 5 mL of culture medium and cultured until 90% cell confluence. Total RNA was isolated in 2 mL of TRIZOL reagent according to the manufacturer's instruction. Twenty micrograms of total RNA were electrophoresed through a 1% agarose gel containing formaldehyde and were transferred to a Hybond N<sup>+</sup> membrane (Amersham). The membrane was hybridized with a [<sup>32</sup>P]-labeled *Kras2* cDNA probe in 5 mL hybridization buffer containing 50% deionized formamide, 0.5 × Denhardt's solution, 0.5% sodium dodecyl sulfate (SDS), and 1 mg of salmon sperm DNA (Sigma). After hybridization overnight at 50°C, the membrane was washed according to the manufacturer's instruction and exposed to BioMax-MS film (Eastman Kodak) for 2 d at -80°C. The autoradiographic bands were performed in quantitative analysis using Image software.

### Monotetrazolium (MTT) assays

The cancer cells with stable expression of wild-type *Kras2* and the control cells were separately seeded at the same time into 96-well culture plates and then routinely cultured for 6 d. MTT was added to the culture wells and the 570 nm wave-length absorption value (*A* value) was assayed at 5 h, 1, 2, 3, 4, 5 and 6 d after seeding of cells. The cell growth curves were protracted using the following

formula,  $GI = Nc - Nt / Nc \times 100\%$ . Nc and Nt represent the *A* value of the control and the experimental group cells. All experiments were performed in triplicate and repeated 3 times.

### Cell cycle analysis

Cell cycle analysis was performed by propidium iodide (PI) staining. Briefly, Caco-2 cells were firstly seeded into 10-cm dishes at  $5 \times 10^5$ . After further cultured for 2 d, the cells were trypsinized and harvested in PBS followed by two washes with PBS. After that the cells were resuspended in PBS at  $1-2 \times 10^6$ /mL and fixed with 70% cool ethanol for at least 1 h. Next, the cells were washed twice and centrifuged at  $1000 \times g$  for 3 min. The pelleted cells were resuspended in 1 mL PBS and added with 50 µL of RNase A stock solution (10 g/mL) and mixed well, and then incubated for 3 h at 4°C. Finally, the cells were pelleted and added with 1 mL of PI staining solution (3.8 mmol/L sodium citrate, 50 µg/mL PI in PBS) and incubated for 1 h at room temperature. After that the cells were analyzed by flow cytometry on an FACSCalibur (Becton Dickinson Immunocytometry Systems, San Jose, CA) exciting at 488-nm, and the DNA-linked red fluorescence (PI) was measured through a 600-nm wavelength filter. This experiment was performed three times.

### Western blot analysis

A total of 50 µg of proteins in whole cell lysates was separated by SDS-polyacrylamide gel electrophoresis and transferred to PVDF membranes (Millipore, Bedford, MA). After blocking with 5% (w/v) nonfat milk, the blots were incubated with the first anti-*Kras2* antibody (F234, sc-30; SantaCruz Biotechnology, Santa Cruz, CA; 1:100 dilution in a blocking solution, 2 h at room temperature) or with the anti-GAPDH antibody (Sigma Chemical, St. Louis, MO; 1:2000 dilution in a blocking solution, 1 h at room temperature). The blots were then washed with PBST and incubated with a secondary antibody (Amersham Biosciences, Buckinghamshire, UK). Positive signal bands were detected using ECL plus (Amersham Biosciences).

### Statistical analysis

The results for MTT assay and cell cycle analysis were presented as the mean ± SD of three replicate culture wells. Analysis was performed using Statview software. All data were evaluated for paired variables to compare between two groups.  $P < 0.05$  was considered to be statistically significant.

## RESULTS

### Identification of the expression vector of *Kras2* gene

The plasmids including pCI-neo and pCI-neo-*Kras2* were digested with *Mlu* I and *Sal* I enzymes and the 576 bp and 5472 bp products were observed. The 576 bp *Kras2* cDNA was inserted into the pCI-neo vector. And the inserted fragment was verified by sequencing.

### Transcription of the *Kras2* gene in Caco-2 cells

To measure the expression level of *Kras2* gene in Caco-2 cells, northern blot analysis was used to detect the *Kras2*

**Figure 1** mRNA expression of wild-type *Kras2* in Caco-2 cell.

**Figure 2** Growth inhibitory effect of wild-type *Kras2* on Caco-2 cell.

mRNA.  $\beta$ -actin mRNA was also detected as an inner control. Consistent with the information provided by ATCC, the *Kras2* transcript was not detected in Caco-2 cells (Figure 1).

### Suppression of Caco-2 cell growth by wild-type *Kras2*

To determine the effect of wild-type *Kras2* on the proliferative capacity of Caco-2 cells, a cell growth curve was generated by MTT assay. As shown in Figure 2, the growth rate of cells transfected with pCI-neo-*Kras2* was significantly lower than the control cells transfected with the empty pCI-neo vector beginning from the third day after cell seeding.

### Effect of wild-type *Kras2* on cell cycle and apoptosis of Caco-2 cells

To detect the effect of wild-type *Kras2* on cell differentiation and apoptosis of Caco-2 cells, cell cycle distribution and the apoptosis rate were analyzed by flow cytometry. The proliferative index of cells transfected with pCI-neo-*Kras2* was decreased, compared with the control cells (49.78% vs 64.21%) (Table 1). As shown in Figure 3, the pCI-neo-*Kras2* transfected cells were arrested in G<sub>0</sub>/G<sub>1</sub> phases, compared with control cells, and the apoptotic rate of Caco-2 cells with stable *Kras2* expression was increased (0.30% vs 0.02%).

### Expression of wild-type *Kras2* gene

To determine whether the expression level of the *Kras2* protein was different between the cells transfected with pCI-neo-*Kras2* and the control cells transfected with the empty pCI-neo vector, we performed Western blot analysis on both cell lines using a monoclonal *Kras2* antibody. The results showed that the Caco2 cell line without pCI-neo-*Kras2* transfection expressed a faint protein product (Figure

**Table 1** Influence of wild-type *Kras2* gene on cell cycle of Caco-2 cells (%)

Cell lines	G <sub>0</sub> /G <sub>1</sub> phase	S phase	G <sub>2</sub> /M phase	Proliferative index
pCI-neo	35.79	40.04	24.17	64.21
PCI-neo-Kras2	50.22	32.88	16.9	49.78

**Figure 3** Effect of the wild-type *Kras2* on cell cycle of Caco-2 cells.

**Figure 4** Expression of the wild-type *Kras2* protein in cell lines.

4, lane A), and pCI-neo-*Kras2* stably transfected cell line (lane B) expressed a 21 kDa product of *Kras2*. GAPDH was used as an internal control for loading volume.

## DISCUSSION

Human colon carcinogenesis and tumor progression are considered to be the result of multigene alterations. Activating point mutations in *ras* gene are widely correlated with human colon carcinogenesis and progression, and have been detected in more human tumor types and at a higher frequency (25%-30% of all human tumors) than other oncogenes<sup>[6-9]</sup>. For example, *ras* mutations are detected in 40%-50% of colon carcinomas<sup>[10,11]</sup>, 80% of pancreatic carcinomas<sup>[12-15]</sup>, and 30%-50% of lung adenocarcinomas<sup>[16-20]</sup>. *Kras2* mutations account for > 90% of the activating *ras* mutations observed in these tumor types. The oncogenic alleles of *ras* genes are generally perceived to be dominant because their transforming ability exists when normal alleles are also expressed<sup>[21]</sup>. However, recent evidence from both *in vivo* and *in vitro* studies suggested that the dominance of the *ras* oncogene might result from overexpression of the mutant *ras* allele or from deletion of the wild-type allele. Previous studies also suggested that the wild-type *Kras2* allele could suppress the oncogenic potential of the mutant

*Kras2* allele<sup>[5]</sup>. Heterozygous *Kras2* deficient mice were highly susceptible to chemically induced lung tumors compared to wild-type littermates. All tumors displayed an activated *Kras2* because of a chemically induced mutation. Experimental evidence demonstrated that wild-type *Kras2* inhibited cell growth, colony formation and tumor development in a murine lung tumor cell line containing an activated *Kras2* allele. In addition, the loss of wild-type *Kras2* was found in 67%-100% of chemically induced mouse lung adenocarcinomas harboring a mutant *Kras2* allele<sup>[5]</sup>. Moreover, results from epidemiological investigations showed that loss of heterozygosity (LOH) of chromosome 12p was detected in nearly 50% of human lung adenocarcinomas and large cell carcinomas, and *Kras2* mutations were detected at codon 12 in about 40% of human lung cancers<sup>[22]</sup>. We also observed that high frequent loss of heterozygosity in this domain occurred in carcinogenesis and progression of colon carcinoma<sup>[23]</sup>. These findings suggest that wild-type *Kras2* is a tumor suppressor and is frequently lost during tumor progression.

Several mutational events common to tumor cells in colorectal cancer have been identified. It is not known whether the accumulation of these mutations occurs in a specific sequence. However, certain stages in the disease development do correlate with the presence of particular mutations<sup>[24]</sup>. In the genetic model of human colon tumorigenesis, activation of *Kras2* mutation has been identified to promote colon carcinogenesis and progression, meanwhile, masking the potential tumor suppressor effect of the wild-type *Kras2*. To elucidate whether the wild-type *Kras2* is a tumor suppressor in more tumor types, we hypothesized that the *K-ras2* plays double roles of both “oncogenic” and “anti-oncogenic” effects. In physiological state, *K-ras2* is a proto-oncogene, which is transformed to an oncogene by activating point mutation, whereas the wild-type *K-ras* can still maintain its tumor-suppressor function. To explore the biological role of the wild-type *K-ras* gene, it is necessary to exclude the interference of activated mutations of *K-ras*. Therefore, it is reasonable to select Caco-2 cells as the cell model in this study<sup>[25]</sup>. To our knowledge, this is the first report on the relationship between the presence of wild-type *Kras2* and the growth and apoptotic properties of human colon cancer cells. Our results demonstrated that the wild-type *Kras2* effectively inhibited the proliferation, and meanwhile promoted apoptosis of colon cancer cells. Ras is a GTP/GDP binding protein, affecting cell growth and proliferation *via* several signaling pathways<sup>[25]</sup>. In this study, wild-type *Kras2* inhibited the growth of Caco-2 human colon cancer cells mainly through cell cycle arrest in G<sub>0</sub>/G<sub>1</sub> phase, decreased DNA synthesis, and decreased fractions of cells in S phase.

Aberrant apoptosis mechanism also exists in colon cancer. Previous studies have demonstrated that the activating mutation of Ras inhibited apoptosis in colon cancer cells<sup>[26]</sup>. Here, we showed that the exogenous expression of wild-type *Kras2* increased the apoptotic rate of Caco-2 cells (0.30% *vs* 0.02%), possibly via a mechanism involving Ras G-proteins and Raf-1 kinase, which needs to be further investigated<sup>[27]</sup>.

Taken together, through exogenous expression of the

wild-type *Kras2* gene in Caco-2 colon cancer cells, we firstly demonstrate that the wild-type *Kras2* gene is a potential tumor suppressor in human colon cancer. Our study also implies that increase of the expression level of wild-type *Kras2* gene might be a gene therapeutic strategy for human colon cancer.

## COMMENTS

### Background

Conventional viewpoints suggest *ras* gene is closely related to carcinogenesis and progression of colon carcinoma. About 30 percent of tumors display mutation of *ras* gene, in which the most frequent one is *Kras2*, and a relatively high frequency of *Kras2* mutation is seen in colon carcinoma, pancreas carcinoma and lung carcinoma. Recent studies raised doubt about the dominant oncogene roles of *Kras2* gene, and showed the frequent loss of wild type *Kras2* in human and mouse lung adenocarcinomas, and that loss of heterozygosity on chromosome 12p12-13 in *Kras2* gene existed in non-small-cell lung cancer. In addition, wild-type *Kras2* has also been shown to inhibit colony formation and tumor development by transformed NIH/3T3 cells. These results indicate that wild-type *kras2* probably has a tumor suppressor effect in carcinogenesis.

### Research frontiers

We investigated the tumor suppressive effect of wild-type *Kras2* on cell proliferation of a colon cancer cell line.

### Innovations and breakthroughs

To our knowledge, this is the first report on the relationship between the presence of wild-type *Kras2* and the growth and apoptosis properties of human colon cancer cells.

### Applications

This study demonstrates that the wild-type *Kras2* gene is a potential tumor suppressor in human colon cancer. Strikingly and of great potential clinical relevance, our results indicate that increase in the expression level of wild-type *Kras2* gene might be a beneficial gene therapeutic strategy for human colon cancer.

### Terminology

*Kras2*, namely v-Ki-ras2 Kirsten rat sarcoma viral oncogene homolog, is on chromosome 12p12-13, and is one of the three members of the *ras* gene: *Hras1*, *Nras* and *K-ras2*. Apoptosis, also called programmed cell death, or “cell suicide”: A form of cell death in which a programmed sequence of events leads to the elimination of cells without releasing harmful substances into the surrounding area. Apoptosis plays a crucial role in biological development and maintaining health by eliminating old cells, and unhealthy cells. Cell cycle, the sequence of stages that a cell passes through between one cell division and the next. A cell cycle can be divided into four main stages: the M phase, when nuclear and cytoplasmic division occurs; the G<sub>1</sub> phase; the S phase, in which DNA replication occurs; and the G<sub>2</sub> phase, a relatively quiescent period.

### Peer review

This is an interesting paper that challenges dogma of role of *Kras2* in CRC. The study with appropriate methods investigating the effect of re-introduction of wild-type *Kras2* in colorectal cancer cell lines on cell growth, proliferation and apoptosis. A major finding of the study was that re-expression of wild-type *Kras2* inhibited cell growth and proliferation along with induction of the apoptosis in the studied cell line. It is worthy of publication in *WJG*.

### Abstract

**AIM:** To construct a recombinant live attenuated *Salmonella typhimurium* DNA vaccine encoding *H pylori* ureB gene and mouse IL-2 gene and to detect its immunogenicity *in vitro* and *in vivo*.

**METHODS:** *H pylori* ureB and mouse IL-2 gene fragments were amplified by polymerase chain reaction (PCR) and cloned into pUCmT vector. DNA sequence of the amplified ureB and IL-2 genes was assayed, then cloned into the eukaryotic expression vector pIRES through enzyme digestion and ligation reactions resulting in pIRES-ureB and pIRES-ureB-IL-2. The recombinant plasmids were used to transform competent *E. coli* DH5 $\alpha$ , and the positive clones were screened by PCR and restriction enzyme digestion. Then, the recombinant pIRES-ureB and pIRES-ureB-IL-2 were used to transform LB5000 and the recombinant plasmids extracted from LB5000 were finally introduced into the final host SL7207. After that, recombinant strains were grown *in vitro* repeatedly. In order to detect the immunogenicity of the vaccine *in vitro*, pIRES-ureB and pIRES-ureB-IL-2 were transfected to COS-7 cells using Lipofectamine<sup>TM</sup>2000, the immunogenicity of expressed UreB and IL-2 proteins was assayed with SDS-PAGE and Western blot. C57BL/6 mice were orally immunized with  $1 \times 10^8$  recombinant attenuated *Salmonella typhimurium* DNA vaccine. Four weeks after vaccination, mice were challenged with  $1 \times 10^7$  CFU of live *H pylori* SS1. Mice were sacrificed and the stomach was isolated for examination of *H pylori* 4 wk post-challenge.

**RESULTS:** The 1700 base pair ureB gene fragment amplified from the genomic DNA was consistent with the sequence of *H pylori* ureB by sequence analysis. The amplified 510 base pair fragment was consistent

with the sequence of mouse IL-2 in gene bank. It was confirmed by PCR and restriction enzyme digestion that *H pylori* ureB and mouse IL-2 genes were inserted into the eukaryotic expression vector pIRES. The experiments *in vitro* showed that stable recombinant live attenuated *Salmonella typhimurium* DNA vaccine carrying ureB and IL-2 genes was successfully constructed and the specific strips of UreB and IL-2 expressed by recombinant plasmids were detected through Western blot. Study *in vivo* showed that the positive rate of rapid urease test of the immunized group including ureB and ureB-IL-2 was 37.5% and 12.5% respectively, and was significantly lower than that (100%) in the control group ( $P < 0.01$ ).

**CONCLUSION:** Recombinant attenuated *Salmonella typhimurium* DNA vaccine expressing UreB protein and IL-2 protein with immunogenicity can be constructed. It can protect mice against *H pylori* infection, which may help the development of a human-use *H pylori* DNA vaccine.

### INTRODUCTION

*H pylori* infection can lead to chronic gastritis, peptic ulcer disease, and is also a risk factor for gastric adenocarcinoma and mucosa-associated lymphoid tissue (MALT) lymphoma<sup>[1-4]</sup>. More than 50% of the human population worldwide are infected with *H pylori*. About 10%-20% of all the patients have severe diseases such as gastric or duodenal ulcer and gastric cancer. The current therapy, based on the use of proton-pump inhibitor and antibiotics<sup>[5-7]</sup>, is efficacious but faces potential problems like patient compliance, increasingly reported antibiotic resistance, and side effects such as abdominal pain, nausea, diarrhea<sup>[8]</sup>. Vaccination of humans against *H pylori*

infection may be an effective and economic approach to its control.

Studies of *H pylori* vaccine have focused on the individual *H pylori* proteins or the whole bacterial cell sonicates as antigens which need mucosal adjuvants like cholera toxin or *E. coli* labile toxin to elicit effective protection<sup>[9-11]</sup>. However, their use in humans is hampered by extremely high toxicity of mucosal adjuvants<sup>[12,13]</sup>. Recently, DNA vaccine without such mucosal adjuvants has been demonstrated to induce both humoral and cellular immunity and is becoming a promising treatment for viral, bacterial and parasitic pathogens<sup>[14,15]</sup>. Protective immunity against HIV, influenza virus, rabies virus, malaria and tuberculosis has been shown in animal models<sup>[16-19]</sup>. DNA vaccine of *H pylori* is seldom reported.

It was reported that coexpression of cytokine genes together with antigen-encoding genes in DNA vaccination vectors can increase both humoral and cellular immune response<sup>[20,21]</sup>. No information is available about the effects of cytokine-derived adjuvant in combination with *H pylori* vaccine.

In the present study we constructed a recombinant live attenuated *Salmonella typhimurium* DNA vaccine carrying *H pylori* ureB gene and mouse IL-2 gene, and identified its immunogenicity in transfected COS-7 cells *in vitro* and its prophylactic immunization *in vivo*.

## MATERIALS AND METHODS

### Bacteria and mammalian cell line and culture conditions

Attenuated *Salmonella typhimurium* LB5000 and SL7207 kindly provided by Professor Bruce Stocker of Stanford University, USA, were cultured in Amp (-) LB medium. *E. coli* DH5 $\alpha$  was grown in LB medium containing 50mg ampicillin per liter. *H pylori* strain CCUG17874 (NCTC11638) kindly provided by the Italian IRIS Research Center was cultured on *H pylori* selective agar plates with 10% defibrillated sheep blood and antibiotics (Merck Company, Germany) at 37°C under microaerophilic conditions with 5% O<sub>2</sub>, 10% CO<sub>2</sub> and 85% N<sub>2</sub>. COS-7 cell line and recombinant plasmid pCIneo-IL-2 were provided by the Department of Immunology, Secondary Military Medical University of China. The mammalian expression vector pIRES was purchased from Clontech, USA.

### PCR amplification of ureB and IL-2 gene fragments

Genomic DNA of *H pylori* was extracted as previously described using CTAB<sup>[22]</sup>. According to the complete DNA sequence of *H pylori* published and multiple clone sites of pIRES, the primers to amplify ureB containing *Nhe* I site in P1 and *Xho* I site in P2 respectively were designed (P1: 5' GCTAGCCACCATGAAAAAGATTAGCAGAAAAAG 3', P2: 5' CTCGAGCTAGAAAATGCTAAAGAGTTG CGCC 3'). The primers to amplify IL-2 containing *Sal* I site in P3 and *Not* I site in P4 were designed (P3: 5' GTC-GACCACCATGTACAGCATGCAGCTCG 3', P4: 5' GCGGCCGCTTATTGAGGGCTTGTTGAGATG 3'). Amplification conditions for ureB were as follows: at 95°C for 5 min, then 35 cycles at 95°C for 30 s, at 55°C for 50 s and at 72°C for 90 s, followed by 10 min at 72°C. Amplifica-

tion conditions for IL-2 were at 95°C for 5 min, then 30 cycles at 95°C for 30 s, at 55°C for 40 s and at 72°C for 1 min, followed by 5 min at 72°C. The amplified products were analyzed on 1.2% agarose gels stained with ethidium bromide.

### Sequencing analysis of ureB and IL-2

The PCR products were separated using a QIAquick gel extraction kit (QIAGEN, CA, USA). Purified ureB and IL-2 fragments were each subcloned into TA cloning vector pUCmT (Takara, Dalian, China) resulting in pUCmT-ureB and pUCmT-IL-2, then the nucleotide sequences of ureB and IL-2 were analyzed using an automatic sequencer.

### Construction of recombinant pIRES-ureB and pIRES-ureB-IL-2

Fragments of *Nhe* I and *Xho* I-digested pUCmT-ureB were inserted into the *Nhe* I/*Xho* I site of eukaryotic expression vector pIRES, through a serial of enzyme digestion and ligation reactions resulting in pIRES-ureB. Fragments of *Sal* I and *Not* I-digested pUCmT-IL-2 were inserted into the *Sal* I/*Not* I site of pIRES-ureB. The recombinant pIRES-ureB and pIRES-ureB-IL-2 were all confirmed by PCR and restriction enzyme digestion.

### In vitro transfection and expression of UreB and IL-2

Recombinant plasmids of pIRES-ureB and pIRES-ureB-IL-2 were transfected into COS-7 cells respectively in order to detect the proteins expressed by pIRES-ureB and pIRES-ureB-IL-2. COS-7 cell line was cultured at 37°C, in Dulbecco's modified Eagle's medium supplemented with 10% FBS (Gibco-BRL, UK), 100 U/mL penicillin and 100  $\mu$ g/mL streptomycin, 15 mmol/L HEPES, 2 mmol/L L-glutamine. The mixture of pIRES-ureB and Lipofectamine<sup>TM</sup>2000 (Invitrogen, USA) or pIRES-ureB-IL-2 and Lipofectamine<sup>TM</sup>2000 were added to the COS-7 cells. Forty-eight hours after transfection, the cells were washed with PBS and protein extraction reagent was added. The lysate was collected and centrifuged at 12000  $\times$  g for 5 min at 4°C.

Supernatant containing proteins was electrophoretically analyzed in a 10% polyacrylamide gel, subsequently electrotransferred onto nitrocellulose membranes. Nonspecific binding sites were blocked with 2% bovine serum albumin (BSA), then rabbit anti-*H pylori* or rabbit anti-IL-2 antibodies and peroxidase-labeled anti-rabbit immunoglobulin G (IgG) were added. The antigens were visualized by chemiluminescence (Bio-Rad, Germany) according to the manufacturer's instructions.

### Construction of recombinant attenuated Salmonella typhimurium carrying H pylori ureB and mouse IL-2 genes

Recombinant pIRES-ureB and pIRES-ureB-IL-2 were used to transform attenuated *Salmonella typhimurium* LB5000 for methylation decoration using calcium chloride, then the recombinant plasmids extracted were transformed into the final host strain SL7207 by electroporation. The attenuated *Salmonella typhimurium* SL7207 carrying ureB gene and SL7207 carrying both ureB and IL-2 genes were

cultured in LB medium to 80 generations. The recombinant plasmids in transformed SL7207 were isolated from every 10 generations and identified by restriction enzymes and PCR.

### Immunization

Prior to immunization, mice were left overnight without solid food and 4 h without water. One hundred  $\mu\text{L}$  of 3% sodium bicarbonate was given orally using a stainless steel catheter tube to neutralize the stomach pH. Immediately after that, mice in the vaccination group were orally given  $5 \times 10^8$  live attenuated salmonella typhimurium DNA vaccine ureB or ureB-IL-2 in a total volume of 200  $\mu\text{L}$ , mice in the control group were given 200  $\mu\text{L}$  PBS. Mice had free access to water and food after immunization.

### Challenge of mice

Four weeks after immunization, all mice were challenged with 200  $\mu\text{L}$  *H pylori* SS1 ( $1 \times 10^7$  CFU). Before challenge, all mice were prepared as described above.

### Assessment of *H pylori* in gastric tissue

Four weeks after challenge, all mice were sacrificed and the stomach was carefully removed from each mouse under aseptic conditions. The stomach was washed 3 times in sterile PBS to remove food residues. A part of the antral region was used for rapid urease test to measure the urease activity.

### Statistical analysis

Differences in *H pylori* strain-induced urease activity in stomach of immunized and non-immunized mice were evaluated using a two-tailed Fisher's exact test.

## RESULTS

### Sequence analysis of ureB and IL-2

Sequence analysis of ureB and IL-2 showed that the sequences of amplified fragments were consistent with those of *H pylori* ureB and mouse IL-2 published in the gene bank respectively.

### Recombinant plasmids confirmed by PCR and restriction enzyme digestion

After pUCmT-ureB and pIRES were digested by both *Nhe* I and *Xho* I, a 1700 bp fragment of ureB was directly cloned into *Nhe* I/*Xho* I site of pIRES, resulting in a recombinant plasmid pIRES-ureB. IL-2 was inserted into the *Sal* I/*Not* I site of pIRES-ureB to get pIRES-ureB-IL-2. Both PCR and restriction enzyme digestion demonstrated that recombinant plasmids contained the ureB and IL-2 genes. PCR and restriction enzyme digestion products were analyzed on agarose gel (Figure 1).

### Immunoreactivity of expressed recombinant proteins

Identification of pIRES-ureB and pIRES-ureB-IL-2 *in vitro* expression was carried out. The lysate of COS-7 cells transfected by pIRES-ureB and pIRES-ureB-IL-2 was analyzed by Western blot (Figure 2A and B). It revealed the band about 66 000 in relative molecular weight

**Figure 1** Agarose gel electrophoresis analysis of recombinant pIRES-ureB-IL-2. Lane 1: pIRES after digestion with *Nhe* I and *Xho* I as a negative control, lane 2: pIRES-ureB-IL-2 after digestion with *Nhe* I and *Xho* I, lane 3: PCR product of ureB, lane 4: pIRES-ureB-IL-2 after digestion with *Sal* I and *Not* I, lane 5: PCR product of IL-2, lane 6: DNA Marker (DL2000 + 15000).

**Figure 2** Western blot analysis of expressed UreB protein products (A) and IL-2 protein products (B). Lane 1: COS-7 cells transfected by pIRES-ureB, lane 2: COS-7 cells transfected by pIRES-ureB-IL-2, lane 3: COS-7 cells transfected by pIRES as a control.

corresponded to UreB protein and 14 000 to IL-2 protein, but the control transfected with pIRES had no specific band.

### Recombinant attenuated Salmonella typhimurium DNA vaccine and its stability in vitro

After transformed by pIRES-ureB-IL-2, recombinant plasmid extracted from LB5000 was used to transform SL7207. Plasmid stability is essential to assure the stable expression of antigens encoded by genes which were cloned into the plasmids. Therefore, SL7207 carrying pIRES-ureB-IL-2 was grown *in vitro* up to 80 generations to examine the plasmid stability. The objective fragments (1.7 kb and 510 bp) could be seen on the map of agarose gel of PCR products and those of restriction enzyme digested recombinant plasmid isolated from transformed SL7207 (Figure 3A and B).

### Rapid urease test results of gastric mucosa

All mice in the control PBS group were infected with *H pylori*. In contrast, 62.5% and 87.5% of mice immunized with ureB and ureB-IL-2 were resistant to *H pylori* ( $P < 0.01$ ). The negative rate of rapid urease test in ureB-IL-2 group was significantly higher than that in ureB group ( $P < 0.05$ , Table 1).

## DISCUSSION

DNA vaccine or genetic vaccine can induce immune response to DNA-encoded proteins after naked DNA is

**Figure 3** Agarose gel electrophoresis analysis of recombinant attenuated *Salmonella typhimurium* DNA vaccine strain with restriction enzyme digestion (A) (lane1: pIRES after digestion with *Nhe* I and *Xho* I, lanes 2-3: recombinant plasmid pIRES-ureB-IL-2 from strains of different generations after digestion with *Nhe* I and *Xho* I, lanes 4-5: pIRES-ureB-IL-2 from strains of different generations after digestion with *Sal* I and *Not* I, lane 6: DNA marker: (DL2000 + 15000) and identification of recombinant attenuated *Salmonella typhimurium* DNA vaccine strain carrying ureB by PCR (B) (lane1: product amplified from pIRES as a negative control, Lane4: Marker (DL2000); Lanes 2-3: ureB amplified from strains of different generations, lane 4: marker-DL2000, lanes 5-6: IL-2 amplified from strains of different generations).

**Table 1** Rapid urease test results of gastric mucosa in different groups

Group	Positive (n)	Negative (n)	Total (n)	Negative rate (%)
PBS	10	0	10	0
ureB	9	15	24	62.5 <sup>b</sup>
ureB-IL-2	3	21	24	87.5 <sup>ab</sup>

<sup>a</sup>*P* < 0.05 vs ureB group; <sup>b</sup>*P* < 0.01 vs PBS group.

injected into a host. DNA vaccines have been widely used in laboratory animals to elicit comprehensive humoral and cellular immune responses. Clinical trials have shown that DNA vaccines are safe and well tolerated<sup>[15,23]</sup>. Moreover, some reports have demonstrated that DNA vaccine could produce long-lasting immunity<sup>[24-25]</sup>. The vaccine itself is a recombinant plasmid with heat stability and does not need to be purified. It can be used to protect against and treat tumors<sup>[26-29]</sup>.

However, this approach has not been fully explored in *H. pylori* vaccine. The available *H. pylori* vaccine is a protein vaccine, including *H. pylori* whole cells or one of the recombinant proteins of *H. pylori* as an antigen of the vaccine in combination with mucosal adjuvants such as cholera toxin or heat-labile toxin of enterotoxigenic *E. coli*<sup>[11,30,31]</sup>. The manufacture of such vaccines is complicated, and some mucosal adjuvants have gastrointestinal toxicity. It was reported that mucosal immunization with *Helicobacter heilmannii* urease B or *H. pylori* urease, given nasally with cholera toxin, could protect BALB/c mice against *H. heilmannii* infection and significantly reduce the preexisting infection<sup>[32]</sup>. However, immunization aggravates

gastric corpus atrophy.

Urease is an enzyme consisting of six UreA subunits and six UreB subunits. Urease negative *H. pylori* strains are unable to colonize the stomach of gnotobiotic piglets, demonstrating its role in the colonization. Urease may intervene directly or indirectly in induction of tissue damage in the stomach. Moreover, it may play an additional role in adhesion and stimulation of inflammatory cells. Urease is a highly conserved protein among gastric *H. pylori* species and a potential antigen for prophylactic and therapeutic vaccines against *H. pylori* infection among different animals<sup>[33-35]</sup>, suggesting that it is an ideal antigen candidate for *H. pylori* vaccine.

It has been shown that live attenuated bacteria carrier including attenuated strains of *Salmonella in vitro* could deliver DNA vaccines to human cells, thus allowing vaccination via mucosal surfaces and specific targeting of professional antigen presenting cells in mucosa-associated lymphoid tissue tumors<sup>[36,37]</sup>.

Several studies have shown that co-administration of cytokine proteins or of cytokine-expressing plasmids can modulate the immune response to DNA vaccination<sup>[40,41]</sup>. Enhancement of antigen-specific antibody response and T cell response has been demonstrated by vaccine co-expressing DNA and immune adjuvants like IL-2 or granulocyte macrophage colony stimulating factor (GM-CSF) gene<sup>[40,41]</sup>.

In this study, we constructed a live recombinant attenuated *Salmonella typhimurium* DNA vaccine strain expressing UreB protein and mouse IL-2 protein. The complete ureB gene fragment and mouse IL-2 gene were amplified and then sequence analysis was performed after they were cloned respectively into the TA cloning vector pUCmT. Purified ureB and IL-2 were cloned into eukaryotic expression vector pIRES. Both the enzyme digestion and PCR confirmed the successful construction of recombinant plasmid pIRES-ureB and pIRES-ureB-IL-2. Recombinant attenuated *Salmonella typhimurium* carrying *H. pylori* ureB gene and mouse IL-2 was successfully constructed after recombinant plasmid was used to transform LB5000 and SL7207. Since the stability of the protective antigen is very important for a vaccine, we assayed the stability of the recombinant plasmid *in vitro*. PCR and restriction enzyme digestion confirmed the presence of pIRES-ureB-IL-2 in all transformed strains of SL7207 up to the 80th generation, demonstrating the stability of the recombinant plasmid in SL7207.

It was also shown *in vitro* in our present study that COS-7 cells transfected by pIRES-ureB-IL-2 could express 66000 UreB and 14000 IL-2, but COS-7 cells transfected by pIRES could not express them. The pIRES-ureB-IL-2 DNA vaccine we constructed could express UreB protein which can react with anti-*H. pylori* protein and IL-2 which can react with anti-mouse IL-2 protein.

We also demonstrated that a single dose of ureB or both ureB and adjuvant IL-2 delivered by the live attenuated *Salmonella typhimurium* SL7207 strain could protect C57BL/6 mice against *H. pylori* colonization in the stomach. No protection was observed in the control group. Compared with ureB group, ureB-IL-2 group

appeared to induce a better protection against *H pylori* infection with a significantly higher negative rate of rapid urease test, suggesting that adjuvant IL-2 may improve the protective immunization level.

In summary, recombinant attenuated *Salmonella typhimurium* DNA vaccine encoding *H pylori* ureB gene and mouse IL-2 gene can express UreB and IL-2 with immunogenicity. DNA vaccine can protect against *H pylori* challenge in animal models. The therapeutic effect of DNA vaccine on *H pylori* infection and its mechanism should be further studied.

## COMMENTS

### Background

Studies of *H pylori* vaccine have focused on the individual *H pylori* proteins or the whole bacterial cell sonicates as antigens which need mucosal adjuvants like cholera toxin or *Escherichia coli* labile toxin to elicit effective protection. However, clinical trials have shown the intestinal toxicity of mucosal adjuvants. Recently, DNA vaccine without such mucosal adjuvants has been demonstrated to induce humoral and cellular immunity and is becoming a promising treatment for viral, bacterial and parasitic pathogens. Protective immunity against HIV, influenza virus, rabies virus, malaria and tuberculosis has been shown in animal models. DNA vaccine against *H pylori* is seldom reported.

### Research frontiers

It was reported that co-expression of cytokine genes and antigen-encoding genes in DNA vaccination vectors can increase humoral and cellular immune response. No information is available about the effects of cytokine-derived adjuvant in combination with *H pylori* vaccine.

### Innovations and breakthroughs

Recombinant attenuated *Salmonella typhimurium* DNA vaccine encoding *H pylori* ureB gene and mouse IL-2 gene can express UreB and IL-2 with immunogenicity. DNA vaccine against *H pylori* and adjuvant IL-2 may improve the protective immunization level.

### Applications

*H pylori* vaccine can prevent *H pylori* infection in human beings.

### Peer review

The manuscript by Dr. Xu *et al* described an interesting study on the construction of a recombinant attenuated *S. typhimurium* DNA vaccine for *Helicobacter pylori* infection. The authors have coexpressed *H pylori* ureB and cytokine IL-2 which can improve the potential immunogenicity and protective efficacies of the vaccine.

## Abstract

**AIM:** To prepare a complex of hyaluronic acid (HA) and phospholipids (PL), and study the improvement effect of PL on the oral absorption of HA.

**METHODS:** The complex of HA-PL (named Haplex) was prepared by film dispersion and sonication method, its physico-chemical properties were identified by infrared spectra and differential scanning calorimetry (DSC). The oral absorption of Haplex was studied. Thirty-two healthy rats were divided into 4 groups randomly: (1) a normal saline (NS) control group; (2) an HA group; (3) a mixture group and (4) a Haplex group. After intragastric administration, the concentration of HA in serum was determined.

**RESULTS:** The physico-chemical properties of Haplex were different from HA or PL or their mixture. After Haplex was administered to rats orally, the serum concentration of HA was increased when compared with the mixture or HA control groups from 4 h to 10 h ( $P < 0.05$ ). The  $\Delta AUC_{0-12\text{ h}}$  of Haplex was also greater than that of the other three groups ( $P < 0.05$ ).

**CONCLUSION:** The method of film dispersion and sonication can prepare HA and PL complex, and PL can enhance the oral absorption of exogenous HA.

## INTRODUCTION

Hyaluronic acid (HA) is an acidic linear mucopolysaccharide, having regularly alternating units of *N*-acetylglucosamine and *D*-glucuronic acid linked by 1, 4- or 1, 3- $\beta$ -glycosidic bonds. HA distributes widely in connective tissues, vitreous body, and joint fluid of vertebrates. Its relative molecular mass ( $M_r$ ) is  $2 \times 10^5$ - $7 \times 10^6$ , it possesses an important function of water keeping<sup>[1]</sup>. As is well known, the unique viscoelastic and lubricating properties of HA along with its biocompatibility and nonimmunogenicity have led to its wide uses in cosmetic, health care, medical, pharmaceutical applications, and so on.

It has been shown that HA can be absorbed by rats after oral administration in our previous experiments. As skin care and healthy food, HA can increase the precursor which synthesizes HA *in vivo*. It can play a systemic role by increasing the concentration of endogenous HA from dermis to epidermis, therefore delaying aging is possible<sup>[2,3]</sup>. However, several limitations exist and influence the gastrointestinal absorption of exogenous HA when it is administered orally, such as high  $M_r$  and poor liposolubility of HA.

Phospholipids (PL) contains glycerol with a phosphate ester and two fatty acid ester side chains. They are the major building blocks of biological membranes and are tissue compatible<sup>[4]</sup>. PL is a series of amphiprotic materials, which can improve the gastrointestinal absorption of drugs. Since the 1980s, drugs especially plants extracts, complex with PL began to be a common trial to increase their oral bioavailability. The results indicate that PL complex play an important role in increasing the drug therapeutic effects, and the technique is easy to practise<sup>[5,6]</sup>. Consequently, in our experiment, PL was used as an absorption enhancer and the complex of HA and PL was prepared, which was named Haplex. The physico-chemical properties of Haplex were identified by infrared spectrum and differential scanning calorimetry. Haplex was administered to rats orally to prove if PL can enhance the oral absorption of HA.

## MATERIALS AND METHODS

### Reagents

HA was obtained from Shandong Freda Biochemical Limited Company, China. Egg lecithin was obtained from Lipoid Company, Germany. HA radioimmunoassay kit (HA RIA Kit) was obtained from Shanghai Naval Medical

Research Institute, China. The other agents were all analytically pure.

### Animals

Wistar rats (female, 260-300 g in weight) were obtained from the Animal Resource Center of Shandong University. Animals were housed at a constant temperature of  $22 \pm 2^\circ\text{C}$ , and fed on standard pellet chow and water *ad libitum*. All experiments were carried out in accordance with the China Animal Welfare Legislation and were approved by Shandong University Ethics Committee of the Care and Use of Laboratory Animals.

### Haplex preparation

The Haplex was prepared by film dispersion and sonication method<sup>[7,8]</sup>. The mixture of HA and PL was obtained by grinding in mortar.

### Infrared spectra

We detected the position changes of main functional groups of Haplex by attenuated total reflectance infrared spectrum. Samples were spread on the KBr crystal glass plate and impacted. The spectral resolution was 8.0 cm, scanning range was 4000-500  $\text{cm}^{-1}$  and the result was the average value of 200 times.

### Differential scanning calorimetry

The thermochemical property changes of Haplex were detected by DSC. Its operational conditions were as follows: flow rate of  $\text{N}_2$  50 mL/min, scanning range of temperature 0-400°C and raising rate 5°C/min.

### Animal screening

Some diseases could increase the concentration of HA in blood; therefore, the healthy animals should be screened before the experiment. The serum concentration range of HA was lower than plasma in rodent animals. The concentration range of HA in the plasma of healthy rats was 46-260 mg/L<sup>[9]</sup>. In this experiment, we found that the serum concentration of HA in most rats was lower than 180 mg/L, so these rats were selected for the following experiments.

### Group and administration

Thirty-two healthy rats were divided into 4 groups with 8 rats in each group. The 4 groups were: a normal saline (NS) control group; an HA group; a mixture group and a Haplex group. All selected rats were fasted (but free drinking) for 12 h before experiment, and were anesthetized by intraperitoneal injection of Pentobarbital before drawing blood. The rats were intragastrically administrated with HA dosage of 60 mg/kg body weight using an intragastric injector. The injector was inserted into the stomach of rats at a depth of 4-6 cm, and the solution was pushed out.

### Blood drawing and detection

The blood was drawn from subclavian vein at 0, 1, 2, 4, 7, 10 and 12 h after administration, and then was centrifuged after the serum separation. The serum was collected and stored in refrigerator at  $-80^\circ\text{C}$ . After that,

the concentration of HA in serum was detected using HA RIA Kit.

### Statistical analysis

The data were presented as mean  $\pm$  SD, and *t* test was performed between groups.  $P < 0.05$  was considered statistically significant.

Because HA was inherent ingredient of serum, the concentration of HA in blank blood should be precluded when we analyze the data. The absorption effect was evaluated by the net increasing value of area under HA concentration-time curve ( $\Delta\text{AUC}_{0-t}$ ). In our experiment, the time of drawing blood was 0-12 h after administration. The value of  $\Delta\text{AUC}_{0-12\text{h}}$  was calculated by trapezoidal rule, and the formula was expressed as follows:

$$\Delta\text{AUC}_{0-12\text{h}} = \text{SUM}\{(t_{i+1}-t_i)[(C_i-C_0) + (C_{i+1}-C_0)]/2\}$$

In this formula,  $t_i$  and  $C_i$  represent the time of drawing blood and the serum concentration of HA at  $t_i$ .  $C_0$  indicates the serum concentration of HA at 0 h after administration.

## RESULTS

### Infrared absorption

The results of IR are shown in Figure 1. As shown in Figure 1, the absorption peak of C=O and C-N of HA in Haplex shifted to superior position, the dissociated carboxy group of HA was also changed. The stretching vibration peak of P=O and P-O-C of PL in Haplex was budged too ( $\nu_{\text{P=O}}$  moved to superior position,  $\nu_{\text{P-O-C}}$  moved to the opposition). These changes indicated that the interactions of HA and PL in Haplex happened between the carboxyl group and amide group of HA and the polar head of PL, which belonged to ionic bond interaction and hydrophobic interaction<sup>[10-12]</sup>.

### Thermochemical properties

The DSC curves (Figure 2) showed that the endothermic phase transition peak and the exothermic oxygenolysis peak of PL in Haplex both disappeared. But the thermochemical property of HA had no obvious difference. The results revealed that as a mucopolysaccharide, HA could protect PL and weaken the sensibility of PL to temperature<sup>[13]</sup>.

In a word, IR and DSC indicated that the physico-chemical properties of Haplex were different from HA, PL and their mixture. The results proved that the complex formed between HA and PL.

### Oral absorption of Haplex in rats

The basic principle of HA RIA Kit was the competitive binding reaction between  $^{125}\text{I}$ -HA in kit, non-marked HA in serum and HA binding protein (HABP). The amount of  $^{125}\text{I}$ -HA-HABP complex was determined<sup>[14]</sup>. The rat serum samples were collected. After setting the standard curve, the concentrations of HA in serum samples were determined.

The drug concentration-time curves are shown in Figure 3. Compared with NS group, an evident absorption peak appeared in 4-12 h after administration in the

**Figure 1** The IR spectra of HA, PL, Haplex, physical mixture of HA and PL. A: HA; B: PL; C: Mixture of HA and PL; D: Haplex.

**Figure 2** DSC curves of HA, PL, Haplex, physical mixture of HA and PL.

**Figure 3** Serum concentration-time curves of HA after single oral dose of Haplex ( $n = 8$ ).

**Table 1** Comparison of  $\Delta AUC_{0-12 h}$  after oral administration

Groups	$\Delta AUC_{0-12 h}$ (ng·h/mL)
Haplex	$777.9 \pm 318.3^a$
Mixture	$451.6 \pm 401.3$
HA	$381.8 \pm 340.8$

<sup>a</sup> $P < 0.05$  vs HA group.

other three groups ( $P < 0.01$ ). From 0 h to 12 h after administration, the serum concentration of HA in Haplex group was higher than in HA group ( $P < 0.05$  in 4-10 h after administration) and the mixture group. However, the serum concentration of HA in mixture group was higher than that in HA group at some certain time points only. The calculation results of  $\Delta AUC_{0-12 h}$  (Table 1) were coincident with Figure 3.

Therefore, the oral absorption experiment demonstrated that: (1) exogenous HA was absorbed into blood after oral administration; (2) after the formation of the complex, PL in Haplex could promote the oral absorption of exogenous HA, increase the HA concentration in serum and prolong the time of HA absorption. However, during the experiment, no

absorption peak appeared in the NS control group. It indicated that oral administration of NS could not increase the HA concentration in serum, and not influence the absorption of HA. And it is thus rational to use NS to dissolve HA and Haplex.

## DISCUSSION

The results of animal experiments indicated that PL could enhance the oral absorption of HA after the formation of Haplex. The mechanism of the enhancement effect might be related to the following elements.

PL is an important component of cell membrane and the exogenous PL has strong affinity to cell surfaces. In the Haplex, HA and PL combined together, PL could facilitate HA binding to the cells. On the other hand, in the presence of excess water, PL could form lipid spheres. The polar head groups are oriented to the water; the fatty acyl chains could form a palisade structure, with their ends abutting in the center of the membrane. Similarly, Haplex might form the structure of liposome when it entered into the gastrointestinal fluid. Therefore, when Haplex got close to the gastrointestinal mucous membrane cells, fusion, pinocytosis and phagocytosis might occur due to liposome's double molecular constitution. These contributions could improve the absorption of HA into gastrointestinal mucous membrane. Moreover, due to the smaller particle diameter of PL in Haplex, it could increase the contact area and the contact time between Haplex and intestine wall. All these effects benefit the absorption of HA<sup>[5,15-17]</sup>.

The synovial fluid of normal joints contains several molecular species, the most important constitute of which is HA. HA plays critical role in the physiology of joint function, including lubrication of the synovial surfaces. In addition, synovial fluids contains phospholipids. The presence of HA and PL complexes could provide excellent protection of the cartilage surface from enzymes and free radicals in the synovial fluid, so it could be used as an oral protectant of joint function<sup>[18]</sup>.

HA is a slow-release carrier due to its bioadhesion and biocompatibility properties<sup>[19]</sup>. After the formation of complex, HA could improve the absorption of PL because of the three dimensions network of HA, and enhance the health care effect of PL.

Haplex could be made in different types of oral praeparatum, including liquid and solid preparation. The nutrition additives and other active components could be added into Haplex if required. The increased effectiveness of active components might attribute to both the bioadhesion property of HA and the absorption facilitation property of PL. Haplex thus may be used in skin care and joint disease prevention.

## COMMENTS

### Background

Hyaluronic acid(HA) is an endogenous glycosaminoglycan, it possesses unique viscoelastic and lubricating properties, and is widely used in cosmetic, health care, medical, pharmaceutical applications, and so on. When exogenous HA is administrated orally, it can increase the concentration of endogenous HA from

dermis to epidermis, thereby, it can play systemic roles to delay aging and prevent joints diseases. Phospholipids(PL) are a series of amphiprotic materials, they can improve the gastrointestinal absorption and reduce side effects of drugs.

### Research frontiers

In this study, the authors prepared the complexes and mixture of HA and PL. The oral absorption of HA both contained in complex and mixture were studied in rats after intragastric administration.

### Innovations and breakthroughs

Because of the high relative molecular mass and poor liposolubility of HA, its gastrointestinal absorption was limited when it is administered orally. In this study, the authors proved that the serum concentration of HA increased when Haplex was administrated orally. So PL could improve the oral absorption of HA after they formed complexes.

### Applications

This study provided an evidence for the development of oral praeparatum containing HA. The complex could be used in the fields of healthy food development and joint function protection.

### Peer review

This is a descriptive study that shows the improvement effect of phospholipids (PL) on the oral absorption of hyaluronic acid (HA) using a complex between both named Haplex. The manuscript is easy to understand and in general terms well written.

### Abstract

**AIM:** To investigate the feasibility of detecting methylated fecal DNA as a screening tool for colorectal carcinoma (CRC) and precancerous lesions.

**METHODS:** Methylated secreted frizzled-related protein gene 2 (*SFRP2*), hyperplastic polyposis protein gene (*HPP1*) and O<sup>6</sup>-methylguanine-DNA methyltransferase gene (*MGMT*) in stools from 52 patients with CRC, 35 patients with benign colorectal diseases and 24 normal individuals were analyzed using methylation-specific PCR.

**RESULTS:** Methylated *SFRP2*, *HPP1* and *MGMT* were detected in 94.2%, 71.2%, 48.1% of CRC patients and 52.4%, 57.1%, 28.6% of adenoma patients, respectively. The overall prevalence of fecal DNA with at least one methylated gene was 96.2% and 81.8% in patients with CRC and precancerous lesions, respectively. In contrast, only one of the 24 normal individuals revealed methylated DNA. These results indicated a 93.7% sensitivity and a 77.1% specificity of the assay for detecting CRC and precancerous lesions.

**CONCLUSION:** Methylation testing of fecal DNA using a panel of epigenetic markers may be a simple and promising non-invasive screening method for CRC and precancerous lesions.

### INTRODUCTION

Colorectal carcinoma (CRC) is one of the leading causes of cancer-related death in the world. Detection of early-stage cancer and precancerous lesions seems to be a key measure to reduce its death rate<sup>[1]</sup>. Most deaths due to CRC are preventable through screening, which involves the search for neoplasms (cancer and precancerous lesions) in asymptomatic individuals. Several CRC screening tests, including fecal occult-blood testing (FOBT), barium enema, colonoscopy and sigmoidoscopy, have been available for years. However, none of these methods has been established as a well-accepted screening tool, because of their low compliance rates or low sensitivity and/or specificity. More optimized screening methods should be established with a high sensitivity and specificity for early-stage cancers and precancerous lesions.

Epigenetic gene silencing is increasingly recognized to play a crucial role in human tumors<sup>[2]</sup>. One of the principal epigenetic mechanisms known to be involved in carcinogenesis is the methylation of cytosine residues in CpG-rich sequences (CpG islands) located within the promoter regions of genes regulating cell proliferation, apoptosis, and DNA repair. DNA methylation within gene promoters results in aberrant gene silencing, which can make an important contribution to the emergence of neoplasias. A number of genes can now be hypermethylated in colorectal tumors<sup>[3]</sup>. Aberrant promoter methylation often occurs very early during CRC carcinogenesis<sup>[4]</sup>. Moreover, it has been shown recently that DNA hypermethylation can be detected in DNA from stools of patients with colorectal tumor, suggesting that fecal DNA methylation analysis might provide a valuable approach to non-invasive screening for early colorectal lesions<sup>[5-8]</sup>. Lenhard *et al*<sup>[9]</sup> reported that a single methylation marker hypermethylated in cancer 1 (*HIC1*) can be used to detect CRC. Methylated *HIC1* has been found in 42% and 31% of fecal samples from patients with CRC and adenoma, respectively. Aberrant methylation of vimentin gene was also reported in fecal DNA from 43 out of 94

CRC patients, with a sensitivity of 46% and a specificity of 90%, respectively<sup>[10]</sup>. These studies suggested that a panel of methylated genes might be required to improve the detection sensitivity for CRC. However, to date, methylation markers have not been assessed thoroughly in stools. Few studies have been performed on methylated fecal DNA in CRC patients in parallel with healthy individuals and patients with benign colorectal diseases, and most of these investigations only analyzed a small number of samples.

In the present study, we analyzed methylation of three genes: secreted frizzled-related protein gene 2 (*SFRP2*), hyperplastic polyposis protein gene (*HPP1*) and O<sup>6</sup>-methylguanine-DNA methyltransferase gene (*MGMT*) in stools from patients with CRC and benign colorectal diseases as well as from normal controls, and evaluated the feasibility of detecting hypermethylation in stools as a non-invasive screening tool for CRC and precancerous lesions.

## MATERIALS AND METHODS

### Materials

Fifty-two CRC patients, 35 patients with benign colorectal diseases (including 21 with adenomas, 8 with hyperplastic polyps and 6 with ulcerative colitis) and 24 patients with endoscopically normal colons, undergoing colonoscopy for routine clinical indications in the 4th Affiliated Hospital of Soochow University, were enrolled in this study (Table 1). In addition, fifteen CRC tissue samples and 8 normal colon samples that were resected at the time of surgery or colonoscopy were obtained from Wuxi Tumor Resource Bank. The study was approved by the ethical committee of our institution.

Stool specimens were collected by patients and sent to laboratory within 2 h after defecation, aliquoted and stored at -80°C until analysis.

### Methods

**DNA isolation:** DNA was isolated from stool samples (200 mg) using the QIAamp DNA Stool Mini Kit (Qiagen). Genomic DNA was purified from colon tissue samples using the QIAamp DNA Mini Kit. The extracted DNA was quantitated by UV spectrum and stored at -20°C.

**Methylation-specific PCR (MSP):** Stool DNA was modified with sodium bisulfite as previously described<sup>[11]</sup>. Blood DNA treated *in vitro* with SssI methyltransferase was used as a positive control for methylated alleles, and placental DNA was used as a negative control for MSP assay.

The bisulfite-modified DNA was subjected to PCR in a blinded manner using primer pairs designed to amplify specifically the methylated or unmethylated alleles of respective genes (Table 2). PCR products were analyzed by 2.5% agarose gel electrophoresis. To verify the reliability of MSP, ten PCR products from methylated amplicon of *SFRP2* were randomly selected and bidirectionally sequenced.

### Statistical analysis

Statistical probabilities were analyzed by 2 × 2 contingency tables using binomial distribution of differences, Fisher's exact test or Pearson's chi-square test. Calculations were performed using SPSS10.0 software. *P* < 0.05 was considered statistically significant.

## RESULTS

Methylated *SFRP2*, *HPP1* and *MGMT* were found in 14, 11 and 8 of 15 CRC tissue samples, respectively. In contrast, none of the 8 samples from normal colonic epithelia revealed any detectable methylated DNA.

MSP was performed on all the 111 stool samples, including 15 fecal samples from CRC patients with matched CRC tissue samples, to analyze *SFRP2*, *HPP1* and *MGMT* (Figure 1). The conversion rate of unmethylated cytosines by bisulfite was measured by sequencing random PCR products from methylated MSP for *SFRP2* (Figure 2).

by several studies<sup>[7,15]</sup>. Müller *et al*<sup>[7]</sup> reported that *SFRP2* is methylated differentially in stools of patients with or without CRC, and *SFRP2* hypermethylation is proposed as a sensitive marker, detecting 77%-90% of CRCs. However, the sample size used in their study was small and the prevalence of methylated *SFRP2* in patients with benign colorectal diseases and in other races or ethnic group was not addressed. In this study, we detected methylated *SFRP2* in fecal samples from Chinese patients with CRC, benign colorectal diseases and in healthy individuals, simultaneously. Our results show that hypermethylated *SFRP2* is detectable in stools of Chinese patients with CRC and precancerous lesions, suggesting that it is a sensitive marker for detecting CRC in healthy controls with 94.2% of sensitivity and 95.2% of specificity, higher than those in a previous report<sup>[8]</sup>. The different results may be due to the assay-related differences or a different patient population. In addition, methylation of this gene was found in one colonoscopically negative case, which may be most likely owing to the *SFRP2* methylation occurring frequently in premalignant aberrant crypt foci (ACF) that is overlooked at colonoscopy<sup>[15]</sup>.

*HPP1* encodes a transmembrane protein containing follistatin and epidermal growth factor-like domains and contains a CpG island in its promoter region that can be aberrantly hypermethylated in CRC and its precursor lesions<sup>[13,14,16-18]</sup>, indicating that *HPP1* gene methylation is an early epigenetic alteration in colorectal carcinogenesis and may be a valuable molecular marker for early diagnosis of CRC. The results of our study indicate that *HPP1* methylation could be frequently detected in most stool samples from patients with CRC (71.2%) and advanced adenoma (57.1%).

*MGMT* is an important DNA repair enzyme that protects cells from the carcinogenic effects of alkylating agents by removing adducts from the O<sup>6</sup> position of guanine, thus preventing G:C to A:T transition. It was reported that *MGMT* gene inactivation caused by promoter methylation plays a key role in a great variety of human tumors<sup>[12]</sup>. Leung *et al*<sup>[6]</sup> showed that 45% hypermethylated *MGMT* are detected in stools of CRC patients in a small-scale feasibility study without healthy subjects as controls. The positive rate of *MGMT* hypermethylation in our study was comparable with their results.

Of the three genes, *SFRP2* is the most informative marker, reaching a sensitivity of 90.5% for CRC and precancerous lesions. In our study, all the 32 samples with methylated *MGMT* revealed methylated *SFRP2*, suggesting that combined detecting of *MGMT* could not increase the detection rate of *SFRP2* for CRC, while a combined test of *SFRP2* and *HPP1* increased the detection rate (93.7%) for CRC and precancerous lesions.

No significant correlation was found between the presence of methylation in fecal DNA and any clinicopathologic characteristics of cancer in our study, indicating that these methylation markers in later stage CRC are as sensitive as in early stage CRC, and may be equivalently sensitive to proximal or distal cancers. However, Ebert *et al*<sup>[16]</sup> reported that *HPP1* methylation is linked to the location of the primary tumor in the colon and is more frequently methylated in colon cancer

**Table 3** Methylation of *SFRP2*, *HPP1* and *MGMT* in stool samples *n* (%)

Diagnosis	No	Gene locus			Total
		<i>SFRP2</i>	<i>HPP1</i>	<i>MGMT</i>	
Cancer	52	49 (94.2)	37 (71.2)	25 (48.1)	50 (96.2)

Normal	24	1 (4.2)	0 (0)	0 (0)	1 (4.2)

compared to rectal cancer. The reasons for the divergent results may include assay-related differences, different patient population and samples.

Adenomas are the precursor of most sporadic CRCs. Hyperplastic polyp-serrated adenoma to carcinoma sequence is characterized by recognizable histological changes. Colorectal lesions, starting with dysplastic ACF, hyperplastic polyp (HP) and benign tubular adenoma have the potential to progress to advanced adenomas, which have a significant potential to transform into CRC<sup>[17]</sup>. Although both ACF and HP are common lesions and the great majority would not transform into clinically significant polyps. HP occurring in the right colon and in the setting of hyperplastic polyposis has the greatest potential to transform into CRC<sup>[17,18]</sup>. It is unclear if these lesions with methylated DNA would develop into cancer. However, DNA methylation is more common in advanced adenomas. All these findings suggest that methylation may reflect the malignant potential of these lesions. UC-associated CRC is different from sporadic carcinoma. The molecular mechanisms underlying the progression of UC to dysplasia and carcinoma have not been fully understood. One of the UC patients with methylated *SFRP2* and *HPP1* in feces was also diagnosed with high-grade dysplasia, indicating that DNA methylation is not only a frequent event in colorectal tumor, but also detectable in fecal samples from patients with HP and UC. Although detection of early stage CRC represents an important screening goal, efforts should be directed toward detection of dysplastic cells present in patients with benign diseases, such as adenoma, HP and UC. Whether hypermethylation of these three genes can identify these non-malignant diseases, including self-limiting HPs, non-dysplastic ACF and UC, is still unclear. Recent studies indicate that methylation patterns can define a subset of HPs with a significant malignant potential<sup>[17,19]</sup>. Thus, patients with methylated fecal DNA may belong to high-risk individuals and need more accurate/specific clinical examinations and follow-up.

Although FOBT is a valuable noninvasive screening method that reduces the risk of CRC-related death, it has a limited sensitivity. Colonoscopy, with a high sensitivity and specificity for detection of CRC and large adenomas, requires a thorough bowel preparation, which causes discomfort and small but non-negligible risk of major complications in patients. In contrast, using aberrant gene methylation as a molecular marker seems to offer a potentially powerful approach to population-based

screening for CRC and precancerous lesions. However, further prospective study is needed to validate the epigenetic markers. In addition, simplified, non-expensive and automatized assays may be important for population-based screening.

## Abstract

**AIM:** To investigate the safety of adult-to-adult living donor liver transplantation (A-A LDLT) in both donors and recipients.

**METHODS:** From January 2002 to July 2006, 50 cases of A-A LDLT were performed at West China Hospital, Sichuan University, consisting of 47 cases using right lobe graft without middle hepatic vein (MHV), and 3 cases using dual grafts (one case using two left lobe, 2 using one right lobe and one left lobe). The most common diagnoses were hepatitis B liver cirrhosis, 30 (60%) cases; and hepatocellular carcinoma, 15 (30%) cases in adult recipients. Among them, 10 cases had the model of end-stage liver disease (MELD) with a score of more than 25. Donor screening consisted of reconstruction of the hepatic blood vessels and biliary system with 3-dimension computed tomography and volumetry of whole liver and right liver volume. Various improved surgical techniques were adopted in the procedures for both donors and recipients.

**RESULTS:** Forty-nine right lobes and 3 left lobes (2 left lobe grafts for 1 recipient, 1 left lobe graft for 1 recipient who had received right lobe graft donated by relative living donor) were obtained from 52 living donors. The 49 right lobe grafts, without MHV, weighed 400 g-850 g (media 550 g), and the ratio of graft volume to recipient standard liver volume (GV/SLV) ranged from 31.74% to 71.68% (mean 45.35%). All donors' remnant liver volume was over 35% of the whole liver volume. There was no donor mortality. With a follow-up of 2-52 mo (media 9 mo), among 50 adult recipients, complications occurred in 13 (26%) cases and 4 (8%) died postoperatively within 3 mo. Their 1-year actual

survival rate was 92%.

**CONCLUSION:** When preoperative CT volumetry shows volume of remnant liver is more than 35%, the ratio of right lobe graft to recipients standard liver volume exceeding 40%, A-A LDLT using right lobe graft without MHV should be a very safe procedure for both donors and recipients, otherwise dual grafts liver transplantation should be considered.

## INTRODUCTION

With the shortage of donation of livers worldwide, the first pediatric living donor liver transplantation (LDLT) was performed by Raia in Brazil in 1989<sup>[1]</sup>. Yamaoka reported the first case of adult to adult LDLT (A-A LDLT) in 1993<sup>[2]</sup>. Fan reported for the first time a case of A-A LDLT using extended right lobe graft in 1997<sup>[3]</sup>. Since then, its application has successfully expanded from pediatric to adult patients. But A-A LDLT has not become effective for patients with end-stage liver disease until 2000. The risk of donors has obviously increased with A-A LDLT. Although liver transplantation was performed for donors because of remnant liver failure<sup>[4,5]</sup>, the mortality of donors was about 0.2%-0.3%<sup>[6]</sup>. If recipient's body weight is much higher than donor's, the graft can not meet the needs of metabolism, thus resulting in small-for-size syndrome<sup>[7]</sup>, or even the death of recipient. So it is a serious problem at present to make both donors and recipients safe, and for recipients to receive an adequate volume of graft for metabolism.

Since July 2001 we have performed the first case of pediatric LDLT in our hospital. A-A LDLT was performed

in January 2002<sup>[8,9]</sup>. Till July 2006, 62 cases of LDLT have been performed, including 50 cases of A-A LDLT. This article aims to discuss about our experience how to make both donors and recipients safe in A-A LDLT and the indications for dual grafts liver transplantation.

## MATERIALS AND METHODS

### *Materials of recipients*

From January 2002 to July 2006, 50 cases of right lobe graft A-A LDLT were performed in our hospital, including 47 right lobe graft without middle hepatic vein (MHV) liver transplantation and 3 dual graft liver transplantation (dual relative donated left lobe grafts 1, relative right lobe graft and relative left lobe graft 1, relative right lobe graft and cadaveric left lobe graft 1<sup>[10]</sup>). Among the 50 recipients there were 43 men, and 7 women, aged 18-63 years (mean age of 39 years). Primary diseases of recipients included liver cirrhosis after hepatitis B, 30 cases (12 of them had acute liver failure); diffuse ischemic intrahepatic biliary stenosis (DI IBS), 2; Budd-Chiari syndrome with liver cirrhosis<sup>[11]</sup>, 1; postoperative liver failure after three right lobe hepatectomy caused by hepatic trauma, 1; hepatocellular carcinoma, 15; and cholangiocarcinoma, 1. There were 15 (30%) cases at risk among the 50 cases, including 7 cases of acute severe hepatitis, 5 fulminant liver failure, 2 DI IBS with liver failure, and 1 liver failure after hepatectomy. All these patients underwent A-A LDLT at emergency. According to Child-Pugh classification, there were 18 cases of grade A, 7 of grade B, and 25 of grade C. By United Network for Organ Sharing classification, there were 10 cases of stage I, 10 of stage II a, 12 of stage II b, and 18 of stage III. The model of end-stage liver disease scores were:  $\leq 18$ , 35 cases; 19-24, 5 cases; 25-30, 1 case; and  $> 30$ , 9 cases. Among 16 malignant cases, no one exceeded 18 scores.

### *Materials of donors*

There were 52 cases, including 16 men and 36 women, with an age range of 9-65 years (mean age 38 years). The relationship between recipients and donors included father 3, mother 8, brother 14, sister 3, spouse 7 (grafts were all donated by wives in this group), children 3, and others 5.

The donors and recipients were blood group identical in 39 cases and compatible in 13 cases. All donors in this group voluntarily donated part of their liver. The ethical aspect of this study was approved by the Ethical Committee of our hospital.

### *Preoperative evaluation for donors*

Physical examination and retrospective analysis of donors' medical records were performed before their operations. The donors and recipients must be blood group identical or compatible. Hepatitis, syphilis, HIV, or Epstein-Barr virus, cytomegalovirus, tuberculosis infection constituted an ineligibility for potential donor. Hepatic blood vessels and biliary system were reconstructed before operation, and the volume of the total liver and right hemiliver were evaluated and calculated with 3-dimension computed tomography (3-D CT). As a potential donor, the right lobe

graft volume should not exceed 65% of the total liver, while if the ratio of right lobe graft volume to recipients' standard liver volume is less than 40%, the recipients should undergo dual graft liver transplantation.

To minimize the risk and complications of donors, we have adopted the following managements: (1) to abandon preoperative endoscopic retrograde cholangiopancreatography (ERCP), instead of cholangiography intraoperatively; (2) to study the tracks and variations of hepatic artery with 3-D CT before operation; (3) to abandon routine hepatic puncture for biopsy before operation unless patients were supposed to have fatty liver<sup>[12]</sup>.

### *Operative approaches in donors*

Using right Mercedes (Chevron with vertical extension) incision from xiphoid process to midaxillary line, we unfolded abdominal cavity with suspended abdominal puller. All donated livers were right lobe grafts without MHV. We identified hepatic incision line (the line from the gallbladder fossa below the inferior vena cava) with intraoperative ultrasonography to confirm the tracks of MHV, aided by observing the color change of right and left lobes when right hepatic artery and right tributaries of portal vein (PV) were clamped. Without clamping hepatic blood vessel, we resected liver with cavitron ultrasonic surgical dissector, using temporarily bipolar electric coagulation hemostasis to deal with the section plane. According to the caliber of conduits, we selected different methods of hemostasis such as titanium clamp or ligation. The crassitude tributaries of MHV could be transitorily clamped for anastomosis via interpositioning a vein graft when grafts were planted. Operation should be performed meticulously when dissociating around hepatic hilar. One should carefully analyze the cholangiographic film intraoperatively in order to know whether there are branches or variations in the right hepatic duct, snip connective tissue and bile duct of hilar plate, meanwhile carefully distinguish minute orifices of hepatic ducts, making markers with thin sutures for anastomosis when planting grafts.

We dissected liver tissue till making total right lobe graft dissociated with heparinizing the whole donor body, in turn clamped and cut off the right hepatic artery, right tributary of PV and right hepatic vein, placed the graft into the container filled with 4°C University of Wisconsin (UW) solution, then removed it to back table for perfusion.

We continuously stitched the orifices of the right tributary of PV with 5-0 sutures, while the orifices of right hepatic duct were stitched at intervals with 6-0 sutures, without interfering with the blood flow in the trunk and left tributary of PV, and the bile flow direction in common hepatic duct.

### *Bench*

We perfused the grafts from PV with 2 liters of 4°C UW solution, rinsed biliary tracts, repaired orifices of hepatic vein, and kept it as large as possible so as to provide sufficient venous outflow. On back table, we anastomosed recipients' great saphenous vein or cadaveric iliac blood vessels to crassitude tributaries of MHV. We measured and

recorded the hepatic vasculatures and the orificia caliber of bile duct and weight of grafts, then calculated the ratio of grafts to recipients' weight (GRWR)<sup>[13]</sup> and the ratio of grafts volume to recipients' standard liver volume (GV/SLV)<sup>[14]</sup>.

### Operative techniques in recipients

Operation was performed following the routine procedures of our hospital<sup>[9,15]</sup>. When resecting recipients' liver, we attentively reserved posterohepatic inferior vena cava (IVC) integrity, dissociated right hepatic vein cling to IVC, reserved the orificia of right hepatic vein (RHV), along with the end axis enlarged IVC downward, making it suitable for donor's RHV and anastomosis<sup>[12]</sup>. It was necessary to make ellipsed incision on suitable parts of IVC when the orificia of crassitude tributaries of right hepatic inferior vein or MHV were jointed with IVC by interpositioning the great saphenous vein or cryopreserved cadaveric blood vessels. We adopted end-to-end anastomosis of grafts' right tributaries of PV to recipient's PV trunk, maintained a suitable length for PV trunk after anastomosis, then opened blood flow in hepatic vein and PV, recovered blood perfusion of grafts and ended nonhepatic phase period. With loupe, we finished hepatic artery anastomosis and adopted end-to-end anastomosis of right hepatic duct to common hepatic duct, or Roux-en-Y choledochojejunostomy. If right hepatic duct had many tributaries and their caliber  $\leq 2$  mm, biliary tracts should be reconstructed under microscope<sup>[16]</sup>.

Splenectomy should be performed at the same time if donors suffered from splenomegaly and hypersplenism (blood platelet  $\leq 30 \times 10^9/L$ ). If PV pressure was  $> 25$  cmH<sub>2</sub>O, splenic artery ligation should be performed for recipients in order to alleviate PV pressure<sup>[17]</sup>.

## RESULTS

### Preoperative CT evaluation of hepatic volume

We have evaluated the volume of remnant liver with CT. According to the volume of the total liver and right lobe grafts with MHV and right lobe grafts without MHV, we calculated the volume of remnant liver with and without MHV after resection. The evaluation results of 50 donors showed that the volume of remnant liver with MHV  $< 30\%$  in 10 cases,  $30\%-35\%$  in 24 cases,  $> 35\%$  in 16 cases, while the volume of remnant liver without MHV  $< 30\%$  in 0 case,  $30\%-35\%$  in 5 cases, and  $> 35\%$  in 45 cases. According to the Fan criteria<sup>[13]</sup>, the volume of remnant liver should exceed  $30\%$ . In this study, there were 10 cases with a volume of remnant liver with MHV of less than  $30\%$ , which would be ineligible for potential donor, thus reducing the donor pool. According to Lee criteria<sup>[14]</sup>, the volume of remnant liver should exceed  $35\%$ , resulting in just 16 cases of donors. The volume of remnant liver without MHV ranged from  $30\%$  to  $35\%$  in 5 cases. Considering the safety of 3 among 5 cases whose volume of remnant liver was less than  $35\%$ ; we adopted dual grafts liver transplantation.

### Clinical results in donors

Among 52 donors, we resected right lobe grafts in 49

cases and left lobe grafts in 3 cases (2 left lobe grafts for 1 recipient, 1 left lobe graft for 1 recipient who had received right lobe graft donated by a relative living donor). Grafts of 49 cases were all without MHV, and the weight ranged from 400 g to 850 g (mean weight 550 g). The ratio of right lobe graft to recipient's standard liver volume was  $31.74\%-71.68\%$  (mean  $45.35\%$ ). The ratio of graft to recipient's body weight was  $0.72\%-1.31\%$  (mean  $0.91\%$ ). Intraoperative total blood loss volume of donors ranged from 250 mL to 735 mL (mean 345 mL), and these blood was all retransfused with autologous blood recovery system. Only 4 cases in this group received allogeneic RBC transfusion of 200 mL to make up the intraoperative blood loss. Operation time varied from 380 min to 620 min (mean 425 min).

Donors had the following complications: transient chyle leakage, recovered after symptomatic treatment; portal venous thrombosis, received second thrombectomy, mending leakage with a patch of great saphenous vein; subphrenic effusion, cured by surgical drainage; and pleural effusion, recovered after repeated thoracic cavity puncture. There was no donor death, and the hospitalized time ranged from 7 to 30 d (mean 11 d). All donors are well and have returned to their daily life and work.

### Clinical results in recipients

GRWR was  $0.72\%-1.17\%$ . There were 12 cases  $> 1.0\%$ , 31 cases  $0.8\%-1.0\%$ , and 7 cases  $< 0.8\%$ . Mean intraoperative blood loss volume was 980 mL. We used autologous blood recovery system for patients with benign diseases. No allogeneic blood transfusion ( $44\%$ ) was made in 22 cases, and the mean operation time was 542 min (range 365-1400 min). Five cases with fulminant liver failure received venous bypass during operation, while the other 45 cases did not.

Among the 50 cases, except for right hepatic vein, we additionally anastomosed right inferior hepatic vein to IVC in 19 cases, and interposed vein grafts on V segmental tributaries (V5) of MHV in 20 cases, and on VIII segmental tributaries (V8) in 13 cases (single tributary in 9 cases and double tributary in 12 cases).

We found PV variations in 9 cases, and right anterior and posterior sectoral PV and left PV all directly arise from the PV trunk. So there were two PV orificas on the section plane of right hemiliver, we connected orificas of right anterior and posterior sectoral PV to form a big one, then anastomosed it to recipients' PV trunk in 7 cases, and anastomosed two orificas to both right and left PV in 2 cases.

We adopted end-to-end anastomosis of right hepatic duct to recipients' common bile duct in 34 cases of bile duct anastomosis. Three cases received T tube drainage, while 31 cases did not. Among 16 cases who underwent choledochojejunostomy, 3 cases had 3 hepatic duct orificas, 11 cases had 2, and 2 cases had 1. Thirty-three orificas were routinely anastomosed with magnifying glasses. There were 11 orificas in 5 cases with calibers less than 2 mm, for which operative microscope was used for the anastomosis.

All cases in this study were followed up for 2-52 mo (mean 9 mo). Four ( $8\%$ ) patients died at 21 d, 27 d, 31 d, and 42 d after operation respectively. The causes

included: small-for-size syndrome 1, multiple organs failure caused by pulmonary infection 2, and renal failure 1. Complications occurred in 13 (26%) cases which included hepatic artery embolization (2), biliary leakage (2), subphrenic abscess (1), anastomotic bleeding in Roux-Y jejunostomy (1), hepatic venous stenosis (1), small-for-size syndrome (1), pulmonary infection (3), and renal failure (2). The one-year survival rate was 92%.

## DISCUSSION

### **Making donors safe**

Based on familial relationship or friendship, a healthy adult voluntarily donates part of liver, who hopes this will be safe for both donors and recipients. For a surgeon, there is great pressure to ensure operations successful for both donors and recipients. The rationality of LDLT has not been acknowledged worldwide until the first pediatric case was performed in 1989<sup>[1]</sup>.

Pediatric LDLT is that an adult donates small part of liver for a child patient. Donor's safety can be ensured and risk is low. In 1993 Yamaoka *et al*<sup>[2]</sup> and in 1997 Fan *et al*<sup>[3]</sup> respectively successfully performed A-A LDLT using right hemiliver. Compared with pediatric LDLT, the risk of A-A LDLT obviously increased when resecting the right hemiliver. So this operation has not been extensively performed in Europe and America, especially as one donor died of gas gangrene of the stomach in America in 2002<sup>[18]</sup>, enthusiasm for A-A LDLT was lessened with one disaster after another. Data in 2006 indicated that there were more than 2000 LDLT cases in America, 1000 in Europe, 2000 in Asia, respectively. The number of donor deaths have reached 14 all over the world with a mortality of about 0.2%-0.3%. So donor's safety has been widely and closely noticed<sup>[19]</sup>.

If we resect too much of a donor's liver, the volume of remnant liver will become too small to meet the needs of the donor's metabolism, leading to dysfunction of liver after operation, liver failure, or even death. On the other hand, if we resect too small part of donor liver, the graft also cannot meet the needs of a donor's metabolism. It is still a challenging subject attempting to tackle this contradiction. At present, it is well acknowledged that the volume of total liver and right hemiliver can be calculated with 3-D CT. Fan thought that it was effective to ensure the safety of donors provided the volume of evaluated remnant liver exceeded 30% of the total liver<sup>[13]</sup>. So he advocated that we should resect the right lobe graft with MHV, while Huang recently thought the volume of evaluated remnant liver exceeded 35% of total liver<sup>[4]</sup>, and suggested that we should resect right lobe graft without MHV.

In this paper we consecutively calculated the volume of donor's liver in 50 A-A LDLT cases. The results show that if we resect the right lobe graft with MHV, the volume of remnant liver was < 30% in 10 cases, 30%-35% in 24 cases, and > 35% in 16 cases. According to the Fan's criteria, 10 cases could not be the candidates for donor, thus dramatically lowering the score of donor liver. Otherwise if we resect right hemiliver without MHV, none case had remnant liver volume < 30%, 5 cases 30%-35%, and the others > 35%. According to Fan's criteria, all donors in

this study can be candidates for donors, donor pool can be enlarged, while donor safety should be addressed with the increased risk. Alternatively, according to Huang's criteria, 5 cases in this group would be ineligible for donors, donor safety could be enhanced while the donor pool was being reduced.

Both to maximize to make donors safe and to prevent reduction of donor pool, we resected 47 right lobe grafts without MHV among 52 cases, the other 3 cases received dual grafts liver transplantation. In this way, we have not only ensured donor safety, but achieved satisfactory results.

### **Making recipients safe**

Being different from total liver transplantation, the recipients only received parts of donor's liver in A-A LDLT. It is still controversial discerning the optimal volume of graft for metabolism. At present, there are two standards worldwide: one is GRWR and the other is GV/SLV. It is generally thought that the former should be more than 0.8%<sup>[13]</sup>, and the latter should be more than 40%<sup>[14]</sup>. In 49 cases of this group, GV/SLV ranged from 31.74% to 71.66% (mean 45.35%), and GRWR from 0.72% to 1.31% (mean 0.91%). Among these cases, GRWR was < 0.8% in 7 cases, and GV/SLV was < 40% in 6 cases, but GV/SLV all exceeded 40% in 3 cases according preoperative CT evaluation, and the other 3 cases whose GV/SLV < 40% underwent dual grafts LDLT. After resection during operation, GV/SLV < 40% was found in 6 cases. This result showed that there are differences between CT evaluation and grafts real weight. Yet clinical study in this group proved that a little error did not influence clinical prognosis. So preoperative CT evaluation has instructive significance for clinical practice.

One case in this group did not receive reconstruction for crassitude tributaries of MHV at its inception in our hospital, causing right anterior lobe of right hemiliver congestion and swelling, and liver dysfunction, small-for-size syndrome and death finally<sup>[12]</sup>. GV/SLV in this case was 52.98%, which was not definitely related to graft size.

Occurrence of small-for-size syndrome was related to not only small size of grafts, circumfluence of hepatic vein or other factors, but also high pressure in PV, or hyperperfusion of PV which lead to injury of epithelioid cell in hepatic sinus of grafts<sup>[20]</sup>. Ito *et al*<sup>[17]</sup> proved that portal hypertension, ligating splenic artery could make PV pressure decrease by 5-10 cmH<sub>2</sub>O, obtaining more satisfying clinical results. Therefore, 5 cases in this group with splenoporectasis and blood platelet < 30 × 10<sup>9</sup>/L were routinely underwent splenectomy, other 6 cases with PV pressure > 25 cmH<sub>2</sub>O underwent ligation of splenic artery, the results were satisfactory.

### **About dual grafts**

It was effective to use dual grafts to solve the problem of too small size of graft and make donors safe. This approach was first reported by Lee *et al*<sup>[21]</sup>. It requires 3 operation groups performing 3 operations simultaneously, and the cost is high; while if we adopt double left lobe grafts for liver transplantation, we have to turn over 180° and place ectopically at the location of right one. Therefore, surgical techniques became demanding,

increasing the risk of complications. Therefore it is not a popular procedure worldwide<sup>[19]</sup>. We adopted one smaller right lobe graft and one left lobe graft, and placed them at primary locations, which have overcome the shortcomings of difficulties for operation<sup>[10]</sup>. Additionally, it was quite strict controlling the indications of right lobe graft LDLT in South Korea that almost 31% A-A LDLT cases underwent dual graft liver transplantation<sup>[4]</sup>. Only 3 of 50 cases received dual grafts liver transplantation in this study, while other 47 cases underwent right lobe graft LDLT. These protocols can not only make both donors and recipients safe, but also obviously reduce medical cost and consumption of medical materials. The clinical results were satisfactory.

In our experience, right lobe grafts without MHV is adopted, volume of remnant liver is more than 35%, preoperative evaluation with CT and the ratio of right lobe graft to recipients standard liver volume exceeding 40%, are all effective indices to make both donors and recipients safe in right hemiliver LDLT, otherwise we should expect to adopt dual grafts liver transplantation.

## Abstract

Advanced gastric cancer usually presents with symptoms due to direct extension into adjacent viscera, distant metastases from lymphatic or hematogenic dissemination and peritoneal seeding. However, portal hypertension as a presentation of metastatic gastric cancer is rare and usually seen in association with other malignancies, e.g. hepatocellular and pancreatic carcinoma. We report a case of signet ring adenocarcinoma of the stomach that presented with esophageal and duodenal varices and bleeding due to portal hypertensive gastropathy. Pagetoid spread of cancer cells likely caused early metastasis and the unusual presentation. We also discussed the pathophysiology of development of portal hypertension in association with malignancies.

## INTRODUCTION

Portal hypertension in the setting of malignancy could arise from different mechanisms: intraluminal obstruction of portal vein (either due to tumor thrombus<sup>[1-3]</sup> or as a result of deep vein thrombosis due to a paraneoplastic

hypercoagulable state, extraluminal compression due to metastatic lymph nodes or tumor tissue, and acquired portal vein aneurysm<sup>[4]</sup>. Hepatocellular carcinoma and pancreatic adenocarcinoma are the commonest tumors reported in literature to present as variceal bleeding<sup>[5-10]</sup>. A case of ovarian cancer presenting similarly has been reported<sup>[11]</sup>. Gastric adenocarcinoma associated with portal venous thrombosis has been retrospectively recognized using imaging studies and post-mortem analysis<sup>[3]</sup> or encountered during the course of treatment of the primary tumor<sup>[12]</sup>. However, initial presentation as portal hypertension is rare and to our knowledge, has not been reported. We report a case of signet ring adenocarcinoma of the gastric cardia that presented as portal hypertension associated with upper gastrointestinal bleeding. The mechanism of portal hypertension was radiographically confirmed as due to a metastatic lymph node compressing the main and left portal veins.

## CASE REPORT

An 80-year old man presented with 14-kg weight loss and melena for three weeks prior to hospital admission. He was pale, had bilateral pleural effusions, moderate ascites and guaiac-positive melanic stool. Past medical history was significant for gastroesophageal reflux disease, systemic arterial hypertension and depression. There was no history of known liver disease or of alcohol consumption.

Laboratory studies confirmed the presence of normocytic anemia (hemoglobin 8.0 gm/dL), normal coagulation parameters, liver and chemistry panels. An esophagogastroduodenoscopy revealed two columns of grade 1 esophageal varices (Figure 1A and B), moderately severe portal hypertensive gastropathy (Figure 1C) and duodenal varices (Figure 1D). On retroflexed view we identified a nodular growth in the cardia of the stomach (Figure 1E, star) infiltrating into the distal esophagus (Figure 1B). Portal hypertensive gastropathy was felt to be the cause of gastrointestinal bleeding.

Histopathological examination of the biopsies obtained from the nodularity in the cardia revealed a poorly-differentiated infiltrative malignancy characterized by moderately-sized cells with abundant vacuolated cytoplasm, occasional signet ring cells (Figure 2A and B), nuclear pleomorphism and the presence of mitotic figures. Immunohistochemical staining for CK7 was positive in the malignant cells (not shown), while CK20 was negative. Mucicarmine stain showed cytoplasmic positivity (Figure

**Figure 1** Esophagogastroduodenoscopy demonstrating grade 1 esophageal varices (A), tumor invasion of distal third of the esophagus (B), moderate portal hypertensive gastropathy (C), duodenal varices (D), retroflexed view of the nodular tumor in the gastric fundus (E).

**Figure 2** Histology and immunohistochemistry of biopsies from gastric: Light microscopy with hematoxylin and eosin staining of tumor tissue at 40X and 100X with oil magnifications demonstrating moderately-sized cells with abundant vacuolated cytoplasm (A) and occasional signet ring cells (B), and mucicarmine stain demonstrating intracytoplasmic positive staining (C).

2C), differentiating these tumor cells from muciphages in the lamina propria.

In the absence of other causes of portal hypertension, we postulated that the endoscopic appearance was best explained by portal venous obstruction. A color Doppler ultrasonography of the hepatic venous system demonstrated reversal of flow in the left portal vein with appropriate direction of flow in the right and main portal veins. The liver and hepatic arteries appeared normal. A computerized tomography of the abdomen after administration of intravenous contrast revealed a soft tissue mass (Figure 3A and B, star) measuring 5 cm in diameter displacing the pancreatic head and neck inferiorly. The superior mesenteric, splenic (Figure 3B, arrow) and main portal veins were all seen passing through this mass with severe attenuation of all three vessels. The presence of ascites and bilateral pleural effusions was confirmed by both studies.

Due to the advanced stage of the tumor carrying a

poor prognosis in this elderly and frail patient, palliative surgery or systemic chemotherapy was considered counterproductive. He was discharged to hospice and subsequently passed away within three months from the time of diagnosis. At autopsy, metastatic disease to the segment VI of the liver was confirmed. A soft tissue mass was found encasing the spleno-portal venous system without vascular invasion or luminal thrombosis, correlating to that seen on CT image ante-mortem. Histopathologic characterization of this mass confirmed it as a lymph node metastasis from primary gastric adenocarcinoma almost replacing the entire normal architecture.

## DISCUSSION

Advanced gastric cancer presenting as portal hypertension is unusual. Hepatocellular carcinoma is associated with

**Figure 3** Contiguous helical CT scan of the abdomen at 5 mm collimation with intravenous contrast captured in arterial phase (A) and portal venous phase (B) at the level of the pancreas. A 5 cm soft tissue mass (star) was seen with severe attenuation of the splenic (B, arrow), main portal and superior mesenteric veins. An area of increased attenuation within the segment VI of the liver was visualized in arterial phase (A, arrow) concerning for metastasis.

tumor invasion of the portal and hepatic veins whereas pancreatic cancer affects the splenic vein with isolated left-sided portal hypertension. Alpha-feto protein producing hepatoid adenocarcinoma of the stomach also tends to invade the veins and metastasize to the liver<sup>[3]</sup>. In our patient serum level of alpha-feto protein was normal and not expressed within tumor cells. Gastric signet ring adenocarcinoma with metastasis to ovaries (Krukenberg tumors)<sup>[13,14]</sup>, bones, meninges<sup>[15]</sup>, colon, gingiva, tonsils, breasts, para-aortic lymph nodes and cervix has been reported in the literature.

Our case report not only adds to the variety of presentations of this type of cancer, but also provides an example of unusual clinical and endoscopic mimicry. The presence of esophageal and duodenal varices and absence of gastric varices suggested main portal trunk and left portal venous obstruction with effective decompression of the splenic venous system. The absence of splenomegaly, presence of an unusually enlarged inferior mesenteric vein (not shown), multiple perigastric collaterals indicated that indeed the left sided portal circulation was decompressed even though there was no obvious spleno-renal shunt. Esophageal varices usually arise due to increased pressure in the left gastric (coronary) vein that drains into the left portal vein, and less often into the main portal vein. Duodenal varices are a rare occurrence and the incidence is estimated to be 0.4% in the setting of portal hypertension<sup>[16]</sup>. The afferent vessel is usually the superior

or inferior pancreaticoduodenal vein originating in the portal vein trunk or superior mesenteric vein. In our case, superior mesenteric as well as main portal veins were attenuated by encompassing metastatic mass, explaining the occurrence of esophageal and duodenal varices.

Signet ring adenocarcinoma is a rare, distinct type of gastric cancer. A retrospective analysis of this type of tumor has revealed an equal incidence in both genders: a younger age and larger tumor at presentation<sup>[17]</sup>. The histological type is commonly scirrhous and infiltrative. As in other gastric cancers, patients with early signet ring cell carcinoma have a good prognosis. However, these patients at the advanced stage have a poorer prognosis depending on the extent of vascular microinvasion and tumor location<sup>[17]</sup>. Pagetoid spread of the signet ring cells beneath the epithelial lining of gastric foveolae/glands is likely the cause of early lymphatic/vascular metastasis as in our case.

## Abstract

We present a case of fatal liver failure caused by the activation of lamivudine-resistant hepatitis B virus (HBV) nine months after lamivudine treatment. A 57-year old man visited our hospital for the treatment of decompensated chronic hepatitis B. Lamivudine was started in December 2001. Subsequently, serum HBV was negative for HBV DNA with seroconversion from HBeAg to anti-HBe and improvement of liver function. However, HBV DNA and HBeAg were again detected in September 2002. He was complicated by breakthrough hepatitis and admitted to our hospital in November for severely impaired liver function. Vidarabine treatment was started and serum HBV DNA and alanine aminotransferase (ALT) decreased transiently. However, after the start of  $\alpha$ -interferon treatment, HBV DNA level increased and liver function deteriorated. He died 1 mo after admission. An analysis of amino acid sequences in the polymerase region revealed that rtM204I/V with rtL80I/V occurred at the time of viral breakthrough. After the start of antiviral treatment, rtL180M was detected in addition to rtM204I/V and rtL80I/V, and became predominant in the terminal stage of the disease. HBV clone with a high replication capacity may be produced by antiviral treatment leading to the worsening of liver function. Antiviral therapy for patients with breakthrough hepatitis in advanced liver disease should be carefully performed.

## INTRODUCTION

Lamivudine is a nucleoside analogue that interrupts the reverse transcription of hepatitis B viral (HBV) pregenomic RNA. Lamivudine is effective for controlling chronic hepatitis B and currently recommended as the first line of treatment for chronic active hepatitis B<sup>[1,2]</sup>. Even for patients with decompensated liver cirrhosis, lamivudine improves liver function and extends transplantation free intervals<sup>[3-10]</sup>. Since more than 10% of patients with chronic HBV infection are estimated to develop liver cirrhosis and may eventually suffer from decompensated liver cirrhosis or hepatocellular carcinoma, the role of lamivudine in the treatment of advanced liver disease caused by chronic HBV infection is large<sup>[11-14]</sup>.

The major problems concerning lamivudine treatment are the viral and biochemical breakthroughs caused by drug resistance. Amino acid mutation in the highly conserved tyrosine-methionine-aspartate-aspartate (YMDD) motif can occur six months after treatment and often increases alanine aminotransferase (ALT) level. Although the increase is usually mild, a marked increase in ALT level leading to fatal hepatic failure has been reported<sup>[15-17]</sup>. Factors other than the YMDD motif mutation that are associated with the worsening of liver function remain to be clarified.

Here, we report a case of fatal hepatic failure caused by lamivudine-resistant HBV. A serial analysis of viral amino acid sequences indicated that the acquisition of mutations outside the YMDD motif might be related to the deterioration of the patient's condition.

## CASE REPORT

A 57-year old man visited our hospital in September 2001

**Figure 1** Clinical course of our patient. HBV DNA level was quantified by transcription-mediated amplification assay. The levels of HBV DNA started to increase 8 mo after treatment with reappearance of HBeAg. Breakthrough hepatitis developed 12 mo after treatment. The timing of serum sample analysis for mutations is shown by the arrowhead.

for the treatment of decompensated chronic hepatitis B. In 1978, He was found to be positive for serum HBs antigen (HBsAg). In July 2001, he was admitted to a nearby hospital for ascites where he was diagnosed as having decompensated cirrhosis with exacerbated chronic hepatitis B. The symptomatic control of his ascites improved his general condition. For further treatment, he was referred to our hospital.

On his first visit, he showed no symptoms or signs of worsening hepatic failure or encephalopathy. No ascites or leg edema was observed. His bulbar conjunctiva was slightly jaundiced. Dilated vasculature was observed in his neck and chest. His ALT, total bilirubin and albumin were 50 IU/L, 3.1 mg/dL and 3.7 g/dL, and his prothrombin time was 76%. He was diagnosed as having liver cirrhosis with a Child-Pugh score of 8. He was negative for HBe antigen (HBeAg) and his HBV DNA level measured by transcription-mediated amplification and hybridization protection assay<sup>[18]</sup> was  $10^{6.5}$  genome copies/mL.

In November 2001, he was found to be positive for HBeAg and showed an increase in HBV DNA level. Because he had a history of decompensated chronic hepatitis B, lamivudine treatment (100 mg/d) was started in December. Figure 1 shows the clinical course. The high serum levels of bilirubin and ALT decreased and normalized within 6 mo after lamivudine treatment was started. The patient became negative for HBV DNA and HBeAg.

However, in September 2002, he was found to be positive for HBeAg again and showed an increase in HBV DNA level. In November 2002, he observed jaundice of his bulbar conjunctiva and was admitted to our hospital. Although he was alert, his bulbar conjunctiva and skin were jaundiced. His ALT, total bilirubin, were 474 IU/L, 11.4 mg/dL and 4.3 g/dL. His HBV DNA level was  $10^{8.6}$  genome copies/mL. He was diagnosed as having breakthrough hepatitis caused by lamivudine-resistant mutants of HBV. HBV with an amino acid substitution in the YMDD motif in the domain C of polymerase region

was detected.

Because interferon is not indicated in patients with decompensated cirrhosis, vidarabine, which is effective for the control of active HBV infection<sup>[19-21]</sup>, was administered together with lamivudine under informed consent. Liver function improved transiently with a decrease in HBV DNA within 2 wk. As prolonged vidarabine administration may induce several complications<sup>[22]</sup>, vidarabine was switched to interferon- $\alpha$ . After the start of interferon- $\alpha$  treatment, HBV DNA level increased and liver function worsened. He died of hepatic failure and rupture of esophageal varices 1 mo after his admission.

The histopathology of the patient's liver after necropsy showed cirrhosis with zonal necrosis. Hepatocyte regeneration was scarce (Figure 2).

To elucidate the viral factors affecting early viral breakthrough and fatal outcome, amino acid sequences of the upstream polymerase region (aa 1-250) of HBV DNA in serum were examined at 5 points as shown in Figure 1. The methods were as follows.

First, DNA was extracted from 100  $\mu$ L of a serum sample using the QIAamp DNA blood mini kit (Qiagen Inc., Valencia, CA). Three fragments spanning the upper polymerase region of HBV DNA were amplified by nested PCR with the primers shown in Table 1. The first stage of amplification was carried out using a thermal cycler for 40 cycles (94°C for 1 min, 55°C for 1 min, 72°C for 1 min) in 100  $\mu$ L of reaction mixture containing 200 mmol/L dNTPs, 1.0 mmol/L each of the primers and 1  $\times$  PCR buffer [50 mmol/L KCl, 10 mmol/L Tris-HCl (pH 8.3), 1.5 mmol/L MgCl<sub>2</sub> and 0.001% (w/v) gelatin] and 2 units of Ampli-Taq polymerase gold (Perkin Elmer Cetus Corp., CT). Two microliters of the PCR products was subjected to the second stage of amplification under the same conditions as the first stage.

Second, PCR products were purified using Wizard PCR preps DNA purification resin (Promega, WI) and cloned into a plasmid vector using the TA cloning kit (PCR cloning kit Qiagen, CA). Four clones were selected from

each plate, from which recombinant plasmid DNA was purified using a commercially available kit (Plasmid midi kit, Qiagen, Valencia, CA). Nucleotide sequences were determined bidirectionally using the dye terminator cycle sequencing ready reaction kit (PE Applied Biosystems, CA) and the PCR primers. Sequencing was performed using an automated DNA sequencer (ABI 377: PE Applied Biosystems).

The determined amino acid sequences in the polymerase region are shown in Figure 3. No amino acid sequence changes were found at the start of lamivudine treatment. At the time of viral breakthrough, rtM204I with rtL80I became dominant. After the start of interferon treatment, rtM204I was replaced by rtM204V and rtL80I by rtL80V. At the final stage of the disease, mutation rtL180M appeared besides rtM204V and rtL80V.

## DISCUSSION

Lamivudine monotherapy is effective in suppressing HBV replication and ameliorating liver disease in chronic hepatitis B patients regardless of HBeAg positivity. A one-year study of HBeAg-positive chronic hepatitis B patients showed that 16% of these patients become seroconverted to anti-HBe and 72% of these patients showed normalization of their ALT levels<sup>[23]</sup>. Furthermore, treatment with lamivudine is associated with histologic improvement not only in terms of necroinflammatory score but also in terms of fibrosis score after long-term treatment<sup>[24]</sup>.

One advantage of lamivudine is that it can be used safely in patients with decompensated cirrhosis<sup>[3-10]</sup>. In contrast to IFN- $\alpha$ , lamivudine is well tolerated without any significant side effects even in patients with decompensated cirrhosis. Furthermore, lamivudine can improve liver function and survival prognosis.

However, the emergence of a drug-resistant mutant is a big problem in lamivudine treatment. A large-scale Asian study showed that lamivudine resistant HBV infection occurred in 23% of patients in year one and 65% of patients in year five. Hepatitis flares, which occurred more commonly in patients with lamivudine resistant mutations, occurred in 10% of patients in year one, and in 18% to

**Figure 2** Histopathological findings of liver specimens showing irregularly-shaped parenchymal cells with massive necrosis (A) and scarce hepatocyte regeneration (B) surrounded by extensive fibrosis (A: HE  $\times$  20; B: HE  $\times$  80).

21% of patients in years two to five. Among patients with lamivudine resistant HBV infection, occurrence of hepatic decompensation increased significantly in patients with lamivudine resistant HBV infection for more than 4 years (from 0% to 6%)<sup>[25]</sup>. In this large-scale Asian study, liver-disease-related death occurred in two patients.

The prognosis of patients with lamivudine-resistant HBV infection, particularly those with advanced liver disease, may be determined by the timing and severity of breakthrough hepatitis. However, the viral factors that may influence the severity of this hepatitis remain to be clarified. A recent study indicated that patients with a normal ALT level even after the emergence of a YMDD motif mutant are characterized by HBeAg negativity during pretreatment, HBeAg loss during therapy, a longer duration from the commencement of therapy until the emergence of YMDD mutant, and lack of mixed-type YMDD mutants<sup>[26]</sup>. In contrast, patients with severely exacerbated hepatitis after the emergence of a YMDD mutant tend to have more substitutions in the reverse transcriptase (rt) region within the polymerase gene at the time of hepatitis exacerbation than those without hepatitis exacerbation<sup>[26]</sup>.

Our patient acquired amino acid mutations in the polymerase region one after the other. Amino acid changes in rtM204/I appeared at the time of viral breakthrough. After the initial treatment with vidarabine, rtM204/V substituted for rtM204/I in one of the four clones. During the interferon treatment, rtM204/V became predominant.

Another mutation observed in our patient was rtL80I/V. Ogata *et al*<sup>[27]</sup> showed that rtL180M is accompanied with rtM204I in some patients with resistance to lamivudine. Because the mutation at aa position 80 was found at the same time as that at aa position 204 in our patient, it is not clear whether the mutation at aa position 80 affects the clinical course.

**Figure 3** Comparison of amino acid sequences of HBV polymerase gene of isolates before lamivudine treatment (sample 1) and four sequential isolates (samples 2-5) during treatment. A HBV mutant with substitutions of isoleucine for leucine at residue 80 (rtL80I) in combination with isoleucine for methionine at residue 204 (rtM204I) was observed 12 mo after treatment (sample 3). After vidarabine treatment, another HBV mutant with substitutions of valine for leucine at residue 80 (rtL80V) and valine for methionine at residue 204 (rtM204V) was observed (sample 4). These mutations predominated in combination with methionine for leucine at residue 180 (rtL180M) after interferon treatment (sample 5). The published HBV DNA sequence of hepatitis B virus variant (genotype C, AB033550, Okamoto *et al*) was used for comparison.

At the final stage of the disease with deterioration of the condition of the patient, rtL180M, rtM204I/V and rtL80I/V became predominant. Natsuizaka *et al*<sup>[28]</sup> showed that rtL180M and rtM204V are related to the exacerbation of hepatitis. Interestingly, a patient with a marked elevation in HBV DNA level in Ogata's report had rtL180M in addition to rtL80I and rtM204I. Therefore, the acquisitions of rtL80I/V and rtL180M in addition to rtM204I/V may be associated with a severe exacerbation of hepatitis. Large-scale studies are necessary to elucidate this hypothesis.

In our patient, vidarabine decreased HBV DNA levels and improved liver function. Although the long-term use of vidarabine is contraindicated because of its possible side effects including irreversible neurotoxicity<sup>[22]</sup>, its short-term use is effective for controlling active HBV infection and herpes simplex viral infection.

Vidarabine was replaced by interferon- $\alpha$  because adefovir dipivoxil was not available in 2002. Serum HBV DNA and bilirubin levels increased again, which led to a

fatal outcome, and HBV clones that have rtL180M became predominant, indicating that withdrawal of vidarabine and administration of interferon may be dangerous for the treatment of severe breakthrough hepatitis. Since interferon may potentially precipitate immunological flares and liver failure<sup>[29]</sup>, nucleotide analogues that are effective for lamivudine-resistant HBV such as adefovir dipivoxil<sup>[30-32]</sup>, entecavir<sup>[33-35]</sup> and tenofovir<sup>[36,37]</sup>, should be used for the treatment of severe breakthrough hepatitis instead of vidarabine or interferon.

In conclusion, antiviral therapy should be considered in the treatment of patients with hepatic failure after breakthrough hepatitis caused by HBV mutants to lamivudine. The serial acquisition of amino acid mutations outside the YMDD motif in the polymerase region may be associated with severe hepatitis.

## Abstract

To treat postoperative bleeding after hepato-pancreato-biliary surgery, interventional radiology has become essential. We report a case of coincidental pseudoaneurysm and jejunal varices that were both successfully treated by stent-grafts. After a pancreaticoduodenectomy, the patient developed a pseudoaneurysm in the hepatic artery and a stenosis in its periphery. After establishing hepatic arterial flow by placing stent-grafts over both the pseudoaneurysm and the stenosis, the pseudoaneurysm was embolized with microcoils. Nine months later, the patient developed jejunal varices caused by a severe stricture in the main trunk of the portal vein. Percutaneous transhepatic portography was performed and stent-grafts were placed over the stenotic segment. A venoplasty using stent-grafts normalized the portal blood flow and the jejunal varices vanished. Although stenosis occurred due to scarred tissues from leakage after pancreaticoduodenectomy, stent-grafts were useful for managing jejunal bleeding post-operatively.

## INTRODUCTION

Postoperative bleeding is one of the leading causes of death after pancreaticoduodenectomy<sup>[1]</sup>. In particular, delayed hemorrhage occurring five or more days post-operatively<sup>[2]</sup> is difficult to manage because the hepatic artery and/or the portal vein are frequently affected. That is, not only hemostasis, but also the maintenance of hepatic blood flow has to be considered in treating these patients. Above all other methods, embolization using an interventional radiology (IVR) technique has been used for surgical treatment because of its efficacy and minimal invasiveness<sup>[3]</sup>. In this paper we report jejunal varices due to a portal venous stricture and a coincidental pseudoaneurysm in the hepatic artery after a pancreaticoduodenectomy. These complications occurred metachronously and each was successfully treated with an IVR technique using stent-grafts. Although treatment for this condition has not yet been standardized, we give a detailed account of our approach.

## CASE REPORT

### *Treatment of pseudoaneurysm in the hepatic artery*

In July 2004, a 64-year-old woman underwent a pancreaticoduodenectomy with a Child's reconstruction for carcinoma of the distal bile duct<sup>[4]</sup>. During the postoperative course, a minor leak from the hepaticojejunostomy occurred, which was resolved within ten days. However, on the 26<sup>th</sup> postoperative day, 250 mL of blood through an intraabdominal drain was collected.

Angiography was carried out immediately. As shown in Figure 1A, there was no extravasation, but a severe stricture in the proper hepatic artery and pseudoaneurysm at the cutting stump of the gastroduodenal artery were noted. To secure the hepatopetal arterial flow, an angioplasty was performed. Two pieces of stent-grafts, each 2.5 mm in diameter and 13 mm or 23 mm in length (MULTI LINK Penta®, GUIDANT Indianapolis, IN, USA) were introduced sequentially through the stenotic segment and the pseudoaneurysm in the hepatic artery (Figure 1B). After stenting, embolization of the pseudoaneurysm was attempted using microcoils (GDC Detachable coil®: Boston scientific; Natick, MA, USA) to stop the inflow into the pseudoaneurysmal lumen (Figure 1C). The patency of the hepatic artery and the disappearance of the pseudoaneurysm were confirmed by arteriography 8 d after treatment

**Figure 1** A: A severe stricture of a narrow segment in the proper hepatic artery and a bulging at the stump of the gastroduodenal artery were seen. An arrow indicates a stricture; B: The stent-graft for an angioplasty was introduced through the stenotic segment to secure the hepatopetal arterial flow. Arrow heads indicate the stent-graft placed in the hepatic artery; C: After the stenting, embolization of the pseudoaneurysm was attempted to stop the inflow into the pseudoaneurysmal lumen using microcoils. An arrow head indicates microcoils placed in the pseudoaneurysmal lumen; D: The patency of the hepatic artery and disappearance of the pseudoaneurysm were confirmed by arteriography 8 d after the treatment.

(Figure 1D). The patient was discharged from the hospital 4 wk after treatment.

### **Treatment of jejunal varices caused by extrahepatic obliteration of the portal vein**

This patient did well for 9 mo after hospital discharge. In April 2005, however, she was readmitted with gastrointestinal bleeding. Laboratory data upon admission showed severe anemia and hyperammoninemia. Gastrointestinal fiberoscopy showed bleeding from a varix in the lifted limb of the jejunum near the hepaticojejunostomy.

Angiography was performed. Hepatic arterial flow was normal as seen in Figure 1D. However, celiac and superior mesenteric arteriography during the portal phase (Figure 2A and B) revealed a severe stricture at the main trunk of the portal vein, adjacent to the microcoils that had been inserted 10 mo earlier. Hepatofugal collaterals had also developed *via* the left gastric vein and the inferior mesenteric vein. Moreover, collateral vessels were observed around the hepaticojejunostomy creating jejunal varices in the lifted limb toward the hepatic hilum. These jejunal varices were identified as the source of the intestinal bleeding. Since an abdominal computed tomography showed no recurrent tumor, the portal vein stenosis was most likely caused by inflammatory changes that occurred after a leak at the hepaticojejunostomy.

Because the main flow of the portal vein was not completely interrupted, percutaneous transhepatic portography (PTP) into the mesenteric side of the portal vein beyond the stenosis was performed. As seen in Figure 2A and B, PTP findings were consistent with those obtained by conventional angiography. To maintain the main stream of the portal vein, two pieces of uncovered-type, self-expandable metallic stent-grafts, 8 mm in diameter and 20 or 30 mm in length (LUMINEXX®, BARD, Covington,

**Figure 2** A: Portal phase of the celiac arteriography showed a severe stricture at the main trunk of the portal vein. Hepatopetal collaterals through mesenteric veins were observed forming jejunal varices (black arrow heads) in the lifted jejunal limb. A white arrow head indicates the stricture and white arrows indicate the direction of blood flow; B: Portal venous phase of the superior mesenteric arteriogram also depicts hepatopetal collaterals and jejunal varices (black arrows) around the hepaticojejunostomy. White arrow heads indicate the stricture of the portal vein adjacent to the microcoils placed in the pseudoaneurysm.

**Figure 3** Portography after urokinase infusion showed a good portal blood flow and collaterals forming jejunal varices had disappeared. A: Catheter tip was placed in the splenic vein; B: Catheter tip was placed in the superior mesenteric vein.

GA, USA) were placed in succession over the stenotic segment. The stent-grafts were then mechanically dilated using a balloon dilator (Power Flex®; Cordis, Miami, FL, USA), resulting in full expansion of the grafts. However, portal blood flow was not corrected immediately. We speculated that possible causes for this were vasospasm of the portal system and/or thrombi generated during stenting and dilation. Therefore, a heparin-coated catheter was left in the mesenteric side of the portal trunk, and urokinase (Nihon Pharmaceutical Co., Tokyo, Japan) 240 000 U a day (Nihon Pharmaceutical Co., Tokyo, Japan) was infused for 7 d. As shown in Figure 3A and B, portography after the urokinase infusion revealed good portal blood flow through the stent-grafts and the jejunal varices had disappeared. Before placement of the stent-grafts, portal venous pressure was 32 cmH<sub>2</sub>O, which dropped to 25 cmH<sub>2</sub>O after correcting portal blood flow. Gastrointestinal fiberoscopy confirmed the absence of jejunal varices around the hepaticojejunostomy. Currently, the patient is doing well without repetitive episodes of gastrointestinal bleeding for 9 mo after the procedure.

## **DISCUSSION**

### **Treatment of pseudoaneurysms in the hepatic artery**

Rupture of a pseudoaneurysm of the hepatic artery is the main cause of postoperative death after pancreaticoduodenectomy<sup>[5]</sup>. In the majority of cases, there is concurrent leakage at the site of the pancreatico-intestinal or

choledocho-jejunal anastomosis. Therefore, reentering the previously scarred operative field for repair is not easy and hemostasis by suturing the bleeding point often fails because of a re-encroachment on the affected vessels<sup>[6]</sup>. On the other hand, using a remote approach like IVR *via* blood vessels is minimally invasive, thus preferable in these situations. However, when hepatic arterial flow is interrupted by IVR to stop hemorrhage, consecutive events such as liver cell necrosis, a breakdown of the choledochojejunostomy, and multiple liver abscesses could occur. Therefore, when using IVR after embolizing pseudoaneurysms, patient outcomes depend a great deal on the maintenance of hepatic arterial flow. In this case, stent-grafts in the hepatic artery prior to the embolization of a pseudoaneurysm were used. However, using stent-grafts in these cases is controversial. For example, several radiologists have suggested that placing a stent-graft in blood vessels with inflammatory changes is inappropriate<sup>[7]</sup>. Conversely, Paci *et al*<sup>[8]</sup> reported the efficacy of stent-grafts in the treatment of pseudoaneurysms in hepatic arteries. We used stent-grafts to secure hepatic arterial flow by dilating the stenotic part of the artery and guiding the blood flow into the proper direction out of the pseudoaneurysmal lumen, avoiding the possibility of migrating microcoils interfering with arterial flow to the liver.

### **Treatment of jejunal varices caused by extrahepatic obliteration of the portal vein**

In cases of varices generated in the intestines, extrahepatic portal obstruction often plays a causative role<sup>[9]</sup>. Jejunal varices caused by portal venous obliteration could be treated with either a shunt for portal decompression<sup>[10,11]</sup>, an angioplasty by an IVR technique such as balloon dilation, stenting to correct the portal blood flow<sup>[12]</sup> or embolizing varices by an IVR technique to stop inflow<sup>[13,14]</sup>. Making a treatment choice is complex, involving various factors such as portal hemodynamics, the extent of liver fibrosis, and the cause of portal venous obliteration. However, a priority is establishing a permanent correction of portal blood flow assuring long-lasting effectiveness of hemostasis. That is, re-bleeding from jejunal varices or newly-developed gastroesophageal varices could occur if hepatopetal flow through the main portal trunk is impaired.

Since in this case, there was a possibility for normal portal venous flow, an angioplasty using either stent-grafts or balloons was used. If the portal vein had been completely obstructed by inflammatory changes and the obstructed segments were wider than an inch in length as occurred in our previous cases<sup>[15,16]</sup>, treatments other than angioplasty would have been chosen.

In addition, it was possible to dilate the stricture and secure a lumen of 8 mm in diameter using a balloon dilator. This mechanically-forced dilation could inadvertently interfere with an immediate correction of portal blood flow, however, a urokinase infusion through the portal vein to resolve thrombi attached was valuable<sup>[15,16]</sup>.

Another unsolved issue using this intervention is

the duration of patency of the stent-grafts. Funaki *et al*<sup>[17]</sup> reported that patency was maintained with their stents in portal veins for lengths of time ranging from 4 to 29 mo, and in most cases stents were obstructed by malignancies. Since we have only followed our patient for 14 mo, continued surveillance to determine patency of the stent is essential.

## INTRODUCTION

During the past 3 decades, enteral nutrition has become increasingly popular because of improved nutritional formulas, advances in catheter technology, and development of less invasive techniques (including endoscopic, fluoroscopic, and laparoscopic techniques) for placement of feeding tubes for this purpose<sup>[1]</sup>. As a result, jejunostomy tubes are used more frequently than before. Despite the benefit of the enteral route for maintaining nutrition, complications have been reported in 2%-12% of patients in whom jejunostomy tubes were placed<sup>[2]</sup>.

## CASE REPORT

Here we present a case of 76-year old man who had a history of bilateral middle cerebral artery stenosis with multiple cerebral infarctions and was bedridden for five years. He was living in a nursing home when he was admitted to our hospital due to the impression of aspiration pneumonia with acute respiratory failure and septic shock. He underwent exploratory laparotomy with feeding jejunostomy using a 14-French nasogastric tube for enteral feedings. However, occlusion of the feeding tube was found 30 d after operation. We tried flushing the tube with warm water through a large piston syringe by gentle push-and-pull motions, but in vain. So we replaced it with a new tube. When we inserted the 14-French nasogastric tube into the upper jejunum, we advanced it at least one third of a meter distally beyond its entrance site. When the patency of the tube was checked, we were unable to put any feedings through the tube. An abdominal roentgenographic study demonstrated that a knot was formed in the tube (Figure 1, arrow).

On the following day, with the patient under intravascular general anesthesia and local anesthesia, the tube was removed (Figure 2), and replaced with a similar tube which was inserted into the jejunum only for 15 cm. The patient's feedings were maintained smoothly for two months.

## DISCUSSION

An enterostomal device, which is inserted percutaneously

## Abstract

Jejunostomy feeding tubes provide surgeons with an excellent method for providing nutritional support, but there are several complications associated with a tube jejunostomy, including complications resulting from placement of the tube, mechanical problems related to the location or function and development of focally thickened small-bowel folds. A 76-year old man who presented with multiple medical diseases was admitted to our hospital due to aspiration pneumonia with acute respiratory failure and septic shock. He underwent exploratory laparotomy with feeding jejunostomy using a 14-French nasogastric tube for nutritional support. However, occlusion of the feeding tube was found 30 d after operation, and a rare complication of knot formation in the tube occurred after a new tube was replaced. On the following day, the tube was removed and replaced with a similar tube, which was placed into the jejunum for only 15 cm. The patient's feedings were maintained smoothly for two months. Knot formation in the feeding tube seems to be very rare. To our knowledge, this is the third case in the literature review. Its incidence is probably related to the length of the tube inserted into the lumen.

**Figure 2** Knot formation in the feeding tube.

through a stoma created on the abdomen (gastrostomy or jejunostomy), can be placed by surgical, endoscopic, laparoscopic, or radiologic techniques<sup>[3]</sup>. It is indicated when the nasal route is contraindicated or when the patient is expected to need long-term enteral feedings. Jejunostomy tube may be placed for long-term postpyloric enteral feedings when bypassing the stomach is desirable. Patients who will benefit from jejunostomy feedings include those with gastric disease, abnormal gastric and duodenal emptying, upper gastrointestinal obstruction or fistula, absent gag reflex, or significant risk of esophageal reflux and aspiration<sup>[4,5]</sup>.

Abnormalities related to the placement of the tube include complications resulting from placement of the tube (i.e., small-bowel obstruction, nonobstructive small bowel narrowing, sealed-off extraluminal tracks or collections, extravasation of contrast material to the skin, jejunal hematomas, small bowel intussusception, and pneumatosis cystoides intestinalis), mechanical problems related to the location or function (i.e., coiling, kinking, occlusion, malpositioning, disruption, or knotting of the jejunostomy tube and retrograde flow of contrast material) and development of focally thickened small bowel folds as an isolated finding at or just distal to the intraluminal end of the tube<sup>[1,6-8]</sup>.

To avoid a clogged feeding tube, enteral feeding devices should be thoroughly flushed every 4 to 6 h during continuous feedings and whenever feedings are on hold, before and after administration of feedings and medications or after the residuals are checked. A large syringe (30 to 60 mL) should always be used for flushing to prevent rupture of the tube. The tube should be irrigated with 20 to 30 mL of tepid water. No fluid has been found to be superior to water for maintaining patency. A stylet should never be used to unclog a tube because it can puncture the tube or part of the gastrointestinal tract. We may try one of the newer plastic declogging devices to mechanically unclog a feeding tube<sup>[9-11]</sup>.

Coiling, kinking, malpositioning, occlusion, or disruption of the jejunostomy tube have been frequently found in patients, but knot formation in the feeding tube seems to be rare<sup>[12,13]</sup>. To our knowledge, this seems to be the third case in the literature review. Its occurrence is

probably greater when the tube is inserted farther into the lumen, suggesting that the mechanism of knot formation is similar to that of supercoiling and concatenate formation. To avoid knot formation the feeding tube should not be inserted too long into the lumen. No more than 15 cm seems appropriate in our experience.

### Abstract

Amiodarone, a class III antiarrhythmic drug, is one of the most effective drugs used in the treatment of ventricular and paroxysmal supraventricular tachyarrhythmia. Adverse effects of amiodarone including pulmonary toxicity, hepatotoxicity, aggravation of arrhythmia, and thyroid diseases are well understood. A 66-year old woman with acute pancreatitis was admitted to our hospital with the complaint of epigastralgia radiating to both flanks for two months. Her symptoms and elevation of pancreatic enzymes did not respond to conventional medical treatment of pancreatitis for 18 d. No known causal factors for pancreatitis such as biliary tract stone, hypertriglyceridemia and alcohol consumption could be identified. Under the suspicion of amiodarone-induced acute pancreatitis, amiodarone was substituted by propafenone. Her symptoms soon alleviated and serum lipase level declined. Three months after hospital discharge, the abdominal pain did not recur. Amiodarone was approved to treat recurrent ventricular fibrillation or sustained ventricular tachyarrhythmia that has been resistant to other medications since 1986. Pancreatitis is a very rare adverse effect associated with the use of amiodarone, and only four cases of amiodarone-induced pancreatitis have been reported in literature. We report a patient who developed acute pancreatitis during amiodarone therapy.

### INTRODUCTION

Amiodarone has been approved to treat recurrent ventricular fibrillation or sustained ventricular tachyarrhythmia which has been resistant to other medications since 1986. A recent study showed that amiodarone is more effective than propafenone and sotalol against paroxysmal atrial fibrillation, suggesting that amiodarone is the first choice of treatment for maintaining sinus rhythm in patients with paroxysmal atrial fibrillation<sup>[1]</sup>. Although amiodarone is effective in treating atrial and ventricular arrhythmias, adverse effects are common and increase markedly after a year of treatment. Adverse effects may occur in many organ systems, such as pulmonary, cardiac, central nervous systems, as well as in thyroid, liver and gastrointestinal tract, and some of them can be very serious and even fatal<sup>[2]</sup>. Pancreatitis is a very rare adverse effect associated with the use of amiodarone, and only four cases of acute pancreatitis induced by amiodarone have been reported in the literature<sup>[3-6]</sup>. We report a patient who developed acute pancreatitis during amiodarone therapy.

### CASE REPORT

A 66-year old woman was admitted to our hospital because of epigastralgia and flank pain for two months. The patient had a long history of rheumatic heart disease involving mitral and aortic valves. She received aortic valve replacement in 1973 and mitral valve replacement in 1999. She had paroxysmal atrial fibrillation with rapid ventricular response controlled by quinidine and digoxin for many years. However, tachyarrhythmia attacked her very frequently in recent years, so she received a radiofrequency catheter ablation in 2000. At that time, electrophysiological study revealed sick sinus syndrome and a cardiac pacemaker (DDDR) was implanted. After ablation therapy, she experienced exertional dyspnea and orthopnea with the severity of New York Heart Association function class II. Coronary angiography revealed no sign of coronary artery stenosis. She visited the heart clinic regularly and was treated with warfarin, spirolo lactone, furosemide and digitalis.

She did not smoke cigarettes or drink alcoholic beverages. According to her medical records, she had no chronic diseases such as diabetes mellitus, hypertension, hyperlipidemia and chronic hepatitis. She did not have any exposure to toxic chemicals or travel overseas. Cholecystectomy was performed in 1981 due to gall bladder stones and acute cholecystitis. She did not

experience any right upper abdominal discomfort after the operation. Total hysterectomy and bilateral salpingo-oophorectomy were done in 1984 due to uterine myoma and right ovarian cyst. The post-operation course was uneventful.

Approximately three months before this admission, amiodarone (200 mg per day) was given due to recurrent paroxysmal atrial fibrillation. The dosage was reduced to 100 mg daily one month before admission. About two months before this admission, she began to suffer from a constant pain at her epigastrium. It was a dull pain with radiation to her flanks. The pain did not change with body positions, but it slightly got worse after meals. She had no nausea, vomiting or diarrhea. She lost her appetite and 2 kilograms of her body weight within one month.

On admission, physical examination was unremarkable except for mild knocking pain on both flanks. The patient had no fever and jaundice. Laboratory examinations including urine analysis, complete blood count, liver and renal functions were within normal range. Serum amylase was 109 U/L (normal value < 220 U/L) and serum lipase was 395 U/L (normal value < 30 U/L). Ultrasound and triphase dynamic computer tomography of the abdomen demonstrated no dilatation of intrahepatic ducts or common bile duct, no stones, no pancreatic enlargement or necrosis, and no fluid accumulation. Because of the persisted elevation of serum lipase, endoscopic ultrasonography was done for a better visualization of the pancreas. The result revealed a reticular pattern over the whole pancreas that suggested the diagnosis of pancreatitis. Under the impression of pancreatitis, her oral intake was prohibited except for medications including amiodarone. Her abdominal symptoms persisted and serum lipase level was still high after three weeks of conventional medical treatments.

Because no causal factor for pancreatitis was found after the initial work-up, acute pancreatitis induced by amiodarone was suspected. So amiodarone was substituted by propafenone (400 mg) after a three-day overlapping of both drugs. After amiodarone was discontinued, her abdominal pain soon subsided and serum lipase gradually returned to nearly normal level at discharge. Three months after discharge, she was totally free of abdominal symptoms and her follow-up check of serum amylase and lipase level was normal.

## DISCUSSION

Pancreatitis is usually presented with moderate to severe abdominal pain sometimes radiated to the flanks,

accompanied with increased serum amylase and lipase and a variable degree of morphological changes in the pancreas. Gallstones and alcohol are the most common causes of acute pancreatitis. Other etiologies include hypertriglyceridemia, trauma, infection and drugs. Many medications have been reported in the literature to be related to the development of pancreatitis<sup>[7,8]</sup>. However, there is no clinical feature that can differentiate drug-induced pancreatitis from other factor caused-pancreatitis. Drug-induced pancreatitis is diagnosed by the following criteria: pancreatitis developed during treatments, resolved following the removal of the drug, and re-development following re-challenge of the offending drug<sup>[9]</sup>. A "definite" association can be made if the suspected drug meets all three criteria. If a relationship is supported by not all three criteria, the drug is classified as having a "possible" association. A drug is classified as "questionable" if it is supported by inadequate or contradictory evidence<sup>[9]</sup>. The summaries of four reported cases and our present case and the association between pancreatitis and amiodarone are shown in Table 1.

How do we explain the discrepancy between serum amylase and lipase in our patient? Although the elevation of amylase and lipase is an important indicator for acute pancreatitis, normoamylasemia has been reported in 19% of patients with acute pancreatitis<sup>[10]</sup>. Elevated lipase and normal amylase may occur in acute pancreatitis due to a longer time interval since onset of attack, pancreatitis caused by alcohol abuse or by hypertriglyceridemia<sup>[11]</sup>. Lipase level usually peaks at 24 h after the onset of acute pancreatitis and normalizes within 8 to 14 d from the onset of acute pancreatitis. Compared with serum amylase, serum lipase rises slightly later and remains elevated longer. Since our patient sought medical help two months after the onset of acute abdominal pain, her serum amylase might have returned to a normal limit. Therefore, the possibility of acute pancreatitis could not be excluded due the normoamylasemia from the very beginning. Postmortem samples from patients who have received a long-term treatment with amiodarone reveal high concentrations of amiodarone and its metabolites in adipose tissue, liver, lung and pancreas<sup>[12]</sup>. Chronic deposition of amiodarone in pancreatic tissues may explain the prolonged elevation of lipase in our patient. The findings in ultrasound and computer tomography of the abdomen are required for the diagnosis of pancreatitis. However, in our patient, no obvious abnormality was found in abdominal ultrasonography and computer tomography. The only abnormal finding was a reticular

**Figure 1** Temporal relationship between amiodarone therapy and the change of clinical symptoms and major laboratory data.

pattern in endoscopic ultrasonography that highly suggested pancreatitis. Our finding is similar to Bosch's patient whose abdominal ultrasonography and computer tomography were normal<sup>[5]</sup>. The temporal relationship between amiodarone therapy and the change of clinical symptoms and major laboratory data of this patient are shown in Figure 1.

Before reaching the conclusion that pancreatitis is induced by amiodarone, other etiological factors of pancreatitis should be ruled out. In our patient, no other etiological cause was found from her medical history, physical examination, laboratory results and image studies. Since we did not re-challenge with amiodarone due to ethical concerns, our patient fulfilled the "possible" diagnosis of amiodarone-induced pancreatitis. The possible mechanisms of drug-induced acute pancreatitis include pancreatic duct constriction, immunosuppression, direct cellular toxicity, osmotic or metabolic changes, and arteriolar thrombosis<sup>[13]</sup>, but the exact mechanism of pancreatitis induced by amiodarone is still unknown.

Only four cases of acute pancreatitis induced by amiodarone have been reported in the literature<sup>[3-6]</sup>. Our case is the first Asian patient with acute pancreatitis

induced by amiodarone. Although acute pancreatitis induced by amiodarone seems to be less severe than pancreatitis caused by gallstones or alcohol abuse, physicians and patients should completely understand the adverse effects of amiodarone including acute pancreatitis when they decide to use amiodarone.

## CASE REPORT

# Virtual colonoscopy-induced perforation in a patient with Crohn's disease

## Abstract

We report a case of sigmoid colon perforation in a patient with Crohn's disease undergoing computed-tomographic (CT) colonography. A 70-year-old patient with Crohn's disease with terminal ileitis and sigmoid stricture underwent CT colonography after incomplete conventional colonoscopy. During the procedure, the colon was inflated by air insufflation and the patient developed abdominal pain with radiological evidence of retroperitoneal and intraperitoneal free gas. Hartmann's operation was performed. This case highlights that CT colonography is not risk-free. The risk of perforation may be higher in patients with inflammatory bowel disease.

## INTRODUCTION

Computed-tomographic (CT) colonography is a relatively non-invasive tool to examine the colon. It was once thought to be almost risk-free when compared to conventional colonoscopy. However, cases of colonic perforation during CT colonography were reported in normal subjects undergoing primary screening of colonic carcinoma. It is obvious that CT colonography carries a low but definite risk of colonic perforation. A few cases of perforation were also reported in diseased colons, as in patients suffering from ulcerative colitis and colonic

carcinoma. In this article, we report a case of colonic perforation in a patient with Crohn's disease undergoing CT colonography.

## CASE REPORT

A 70-year-old gentleman suffered from Crohn's disease for more than 10 years. He presented with chronic loose stool diarrhea. He did not have per-rectal bleeding, abdominal pain or other extra-intestinal symptoms. His body weight remained static at around 42 kg. Colonoscopy in 2005 showed a stricture at the sigmoid colon with aphthous ulcers, and a barium enema follow-through study showed terminal ileal narrowing. Tissue biopsy of the colon showed active chronic colitis with hyperplastic crypts consistent with Crohn's disease.

Since 2004, the patient had worsened diarrhea and progressive weight loss to 40 kg. His hemoglobin dropped from 13.1 to 12.0 g/dL. Plasma C-reactive protein increased to 33.5 mg/L. He was treated with sulphasalazine and iron supplements. A regular colonoscopy was arranged to assess disease extent and to rule out colorectal cancer, but the endoscope failed to advance beyond the tight sigmoid stricture even using a pediatric colonoscope.

The patient was admitted to our hospital for computed tomographic (CT) colonography on 7 July 2006 for further evaluation. A 20-French Foley catheter without balloon inflation was inserted with the tip in the rectum, and air was introduced into the large bowel through manual insufflation. Immediately after air insufflation, the patient complained of lower abdominal pain. Plain CT film demonstrated large amounts of free retroperitoneal air and a small amount of intraperitoneal free gas (Figure 1).

The patient was diagnosed to have iatrogenic colonic perforation. During emergency surgery, a 3 mm perforation at the anti-mesenteric side of proximal sigmoid was noticed, and there was a tight stricture at descending colon just 1 cm proximal to the perforation. A left hemicolectomy was performed to resect the stricture and perforated segment. The distal transverse colon was brought out as end colostomy. He subsequently had uneventful recovery apart from transient perioperative atrial fibrillation.

## DISCUSSION

CT colonography is a relatively non-invasive imaging technique to examine the colon. Adequate bowel preparation is essential. During the procedure, air or

**Figure 1** Plain CT scan of the abdomen after air insufflation during CT colonoscopy. Extensive retroperitoneal gas was detected (arrow).

carbon dioxide is insufflated through a rectal catheter. Helical CT scans of the abdomen and pelvis during a breath-hold are then performed to give a 3-dimensional 'fly-through' reconstruction, allowing examination of the colonic surface with a simulated endoscopic view.

CT colonography has been most extensively evaluated for the detection of colonic polyps and cancer. In 1233 asymptomatic patients in the United States, the sensitivity and specificity of CT colonography in detecting adenomatous polyps of at least 10 mm in size were 92 percent and 96 percent, respectively<sup>[1]</sup>. Less commonly, CT colonography has also been utilized in patients with Crohn's disease. The greatest advantage of CT colonography lies in patients with strictures, adhesions or obstructing tumors which prevent complete colonoscopic examination. Studies have shown that CT colonography can detect thickened bowel wall and deep ulcers in patients with Crohn's disease<sup>[2]</sup>.

Since CT colonography does not involve the insertion of an endoscope, it is generally perceived as a safe procedure. The International Working Group on Virtual Colonography reviewed a total of 21 923 CT colonography

procedures and reported only 2 cases of colonic perforations with a rate of 0.009%<sup>[3]</sup>. Nevertheless, it is noteworthy that most of the reported series involve people with normal colon, some undergoing primary screening only. In patients with colonic diseases, the diseased colonic wall may not accommodate a high intraluminal pressure as well as a normal colon. In addition, strictures may prevent the even distribution of the air insufflated, resulting in an increased intraluminal pressure locally. This may have accounted for the close proximity between the perforation site and stricture in our patient. There are case reports of colonic perforations in patients with ulcerative colitis<sup>[4]</sup> or carcinoma of the colon<sup>[5]</sup>.

In conclusion, our case highlights that CT colonography is not risk-free. The risk of perforation may be higher in patients with inflammatory bowel disease. Prospective studies should be conducted to further evaluate the risk of CT colonography in these patients.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (WJG, *World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly journal of more than 48 000 circulation, published on the 7<sup>th</sup>, 14<sup>th</sup>, 21<sup>st</sup> and 28<sup>th</sup> of every month.

Original Research, Clinical Trials, Reviews, Comments, and Case Reports in esophageal cancer, gastric cancer, colon cancer, liver cancer, viral liver diseases, etc., from all over the world are welcome on the condition that they have not been published previously and have not been submitted simultaneously elsewhere.

#### Indexed and abstracted in

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, *Index Medicus*, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, *Nature Clinical Practice Gastroenterology and Hepatology*, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

#### Published by

The WJG Press

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297 mm × 210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, acknowledgements, References, Tables, Figures and Figure Legends. Neither the editors nor the Publisher is responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part without the written permission of both the authors and the Publisher. We reserve the right to put onto our website and copy-edit accepted manuscripts. Authors should also follow the guidelines for the care and use of laboratory animals of their institution or national animal welfare committee.

Authors should retain one copy of the text, tables, photographs and illustrations, as rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for the loss or damage to photographs and illustrations in mailing process.

#### Online submission

Online submission is strongly advised. Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/index.jsp>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. Authors encountering problems with the Online Submission System may send an email you describing the problem to [wjg@wjgnet.com](mailto:wjg@wjgnet.com) for assistance. If you submit your manuscript online, do not make a postal contribution. A repeated online submission for the same manuscript is strictly prohibited.

#### Postal submission

Send 3 duplicate hard copies of the full-text manuscript typed double-spaced on A4 (297 mm × 210 mm) white paper together with any original photographs or illustrations and a 3.5 inch computer diskette or CD-ROM containing an electronic copy of the manuscript including all the figures, graphs and tables in native Microsoft Word format or \*.rtf format to:

#### Editorial Office

##### *World Journal of Gastroenterology*

Editorial Department: Apartment 1066, Yishou Garden,  
58 North Langxinzhuang Road,  
PO Box 2345, Beijing 100023, China

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

Telephone: +86-10-85381892

Fax: +86-10-85381893

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using a word-processing software. All submissions must be typed in 1.5

line spacing and in word size 12 with ample margins. The letter font is Tahoma. For authors from China, one copy of the Chinese translation of the manuscript is also required (excluding references). Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was accomplished, disclosure of any financial support for the research, and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (removing all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s) and full family name.

#### Abstract

An informative, structured abstract of no more than 250 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipments, and the experimental procedures should be included. RESULTS: The observatory and experimental results, including data, effects, outcome, etc. should be included. Authors should present *P* value where necessary, and the significant data should accompany. CONCLUSION: Accurate view and the value of the results should be included.

The format of structured abstracts is at: <http://www.wjgnet.com/wjg/help/11.doc>

#### Key words

Please list 5-10 key words that could reflect content of the study mainly from *Index Medicus*.

#### Text

For most article types, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include in appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both.

#### Illustrations

Figures should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. No detailed legend should be involved under the figures. This part should be added into the text where the figures are applicable. Digital images: black and white photographs should be scanned and saved in TIFF format at a resolution of 300 dpi; color images should be saved as CMYK (print files) but not as RGB (screen-viewing files). Place each photograph in a separate file. Print images: supply images of size no smaller than 126 mm × 85 mm printed on smooth surface paper; label the image by writing the Figure number and orientation using an arrow. Photomicrographs: indicate the original magnification and stain in the legend. Digital Drawings: supply files in EPS if created by freehand and illustrator, or TIFF from photoshops. EPS files must be accompanied by a version in native file format for editing purposes. Existing line drawings should be scanned at a resolution of 1200 dpi and as close as possible to the size where they will appear when printed. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes of atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...

#### Tables

Three-line tables should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each table. No detailed legend should be included under the tables. This part should be added into the text where the tables are applicable. The information should complement but not duplicate that contained in the text. Use one horizontal line under the title, a second under the column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

#### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup>*P*<0.05, <sup>b</sup>*P*<0.01 should be noted (*P*>0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P*<0.05 and <sup>d</sup>*P*<0.01 are used. Third series of *P* values can be expressed as <sup>e</sup>*P*<0.05 and <sup>f</sup>*P*<0.01. Other notes in tables or under

illustrations should be expressed as  $^1F$ ,  $^2F$ ,  $^3F$ ; or some other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, etc. in a certain sequence.

### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions are included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should code the references according the citation order in text in Arabic numerals, put references codes in square brackets, superscript it at the end of citation content or the author name of the citation. For those citation content as the narrate part, the coding number and square brackets should be typeset normally. For example, Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>. If references are directly cited in the text, they would be put together with the text, for example, from references [19,22-24], we know that...

When the authors code the references, please ensure that the order in text is the same as in reference part and also insure the spelling accuracy of the first author's name. Do not code the same citation twice.

### PMID requirement

PMID roots in the abstract serial number indexed by PubMed (<http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed>). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information of the journal citations is very important. Through reference testing system, the authors and editor could check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in ASP file so that the readers can read the abstract of the citations online immediately.

### Style for journal references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). Title of the cited article and italicized journal title (Journal title should be in its abbreviation form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634]

Note: The author should test the references through reference testing system (<http://www.wjgnet.com/cgi-bin/index.pl>)

### Style for book references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

**Electronic journal (list all authors)**

**Morse SS**. Factors in the emergence of infectious diseases. Emerg Infect Dis serial online, 1995-01-03, cited 1996-06-05; 1(1): 24 screens. Available from: URL: <http://www.cdc.gov/ncidod/EID/eid.htm>

**Patent (list all authors)**

- 16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

### Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those that are linked with a hyphen and the difference between the two numbers at two sides of the hyphen is more than 5. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered as inappropriate references. Authors should not cite their own unrelated published articles.

### Statistical data

Present as mean  $\pm$  SD or mean  $\pm$  SE.

### Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\gamma$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

### Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p*(B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6  $24.5 \mu\text{g/L}$ ; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub> not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format about how to accurately write common units and quantum is at: <http://www.wjgnet.com/wjg/help/15.doc>

**Abbreviations**

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further mention.

**Italics**

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kbo I*, *Kpn I*, etc.

Biology: *H pylori*, *E coli*, etc.

**SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED**

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. Author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, the final check list for authors, and responses to reviewers by a courier (such as EMS) (submission of revised manuscript by e-mail or on the *WJG* Editorial Office Online System is NOT available at present).

**Language evaluation**

The language of a manuscript will be graded before sending for revision.

(1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing; (4) Grade D: rejected. The revised articles should be in grade B or grade A.

**Copyright assignment form**

Please download CAF from <http://www.wjgnet.com/wjg/help/9.doc>.

We certify that the material contained in this manuscript:

**Ms:**

**Title:**

is original, except when appropriately referenced to other sources, and that written permission has been granted by any existing copyright holders. We agree to transfer to *WJG* all rights of our manuscript, including: (1) all copyright ownership in all print and electronic formats; (2) the right to grant permission to republish or reprint the stated material in whole or in part, with or without a fee; (3) the right to print copies for free distribution or sale; (4) the right to republish the stated material in a collection of articles or in any other format. We also agree that our article be put on the Internet.

**Criteria for authorship:** The *WJG* requests and publishes information about contributions of each author named to the submitted study. Authorship credit should be based on (1) direct participation in the study, including substantial contributions to conception and design of study, or acquisition of data, or analysis and interpretation of data; (2) manuscript writing, including drafting the article, or revising it critically for important intellectual content; (3) supportive work, including statistical analysis of data, or acquisition of funding, or administration, technology and materials support, or supervision, or supportive contributions. Authors should meet at least one of the three conditions. The *WJG* does not publish co-first authors and co-corresponding authors.

We hereby assign copyright transfer to *WJG* if this paper is accepted.

Author Name in full (Full names should be provided, with first name first, followed by middle names and family name at the last, eg, Eamonn MM Quigley). Handwritten names are not accepted.

Author Name in abbreviation (Family name is put first in full, followed by middle names and first name in abbreviation with first letter in capital, eg, Quigley EMM). Handwritten names are not accepted.

**Final check list for authors**

The format is at: <http://www.wjgnet.com/wjg/help/13.doc>

**Responses to reviewers**

Please revise your article according to the comments/suggestions of reviewers. The format for responses to the reviewers' comments is at: <http://www.wjgnet.com/wjg/help/10.doc>

## Contents

<b>REVIEW</b>	<b>985</b>	p53 gene in treatment of hepatic carcinoma: <i>Status quo</i> <i>Guan YS, La Z, Yang L, He Q, Li P</i>
	<b>993</b>	Metallothionein: An overview <i>Thirumoorthy N, Manisenthil Kumar KT, Shyam Sundar A, Panayappan L, Chatterjee M</i>
<b>ESOPHAGEAL CANCER</b>	<b>997</b>	Cytochrome P450 levels are altered in patients with esophageal squamous-cell carcinoma <i>Bergheim I, Wolfgarten E, Bollschweiler E, Hölscher AH, Bode C, Parlesak A</i>
<b>LIVER CANCER</b>	<b>1003</b>	Successful initial ablation therapy contributes to survival in patients with hepatocellular carcinoma <i>Morimoto M, Numata K, Sugimori K, Shirato K, Kokawa A, Oka H, Hirasawa K, Koh R, Nihommatsu H, Tanaka K</i>
	<b>1010</b>	Rab23 is a potential biological target for treating hepatocellular carcinoma <i>Liu YJ, Wang Q, Li W, Huang XH, Zhen MC, Huang SH, Chen LZ, Xue L, Zhang HW</i>
<b>COLORECTAL CANCER</b>	<b>1018</b>	Decreased fragile histidine triad expression in colorectal cancer and its association with apoptosis inhibition <i>Cao J, Chen XP, Li WL, Xia J, Du H, Tang WB, Wang H, Chen XW, Xiao HQ, Li YY</i>
<b>VIRAL HEPATITIS</b>	<b>1027</b>	Hepatitis B virus infection and replication in primarily cultured human fetal hepatocytes <i>Lin M, Chen Q, Yang LY, Li WY, Cao XB, Wu JR, Peng YP, Chen MR</i>
<b>BASIC RESEARCH</b>	<b>1032</b>	Role of soluble factors and three-dimensional culture in <i>in vitro</i> differentiation of intestinal macrophages <i>Spoettl T, Hausmann M, Menzel K, Piberger H, Herfarth H, Schoelmerich J, Bataille F, Rogler G</i>
	<b>1042</b>	Evidence for a sequential transfer of iron amongst ferritin, transferrin and transferrin receptor during duodenal absorption of iron in rat and human <i>Kolachala VL, Sesikeran B, Nair KM</i>
	<b>1053</b>	Influence of heme oxygenase-1 gene transfer on the viability and function of rat islets in <i>in vitro</i> culture <i>Chen XB, Li YX, Jiao Y, Dong WP, Li G, Chen J, Tan JM</i>
	<b>1060</b>	Uric acid enhances T cell immune responses to hepatitis B surface antigen-pulsed-dendritic cells in mice <i>Ma XJ, Tian DY, Xu D, Yang DF, Zhu HF, Liang ZH, Zhang ZG</i>
<b>CLINICAL RESEARCH</b>	<b>1067</b>	Feasibility and safety of autologous bone marrow mononuclear cell transplantation in patients with advanced chronic liver disease <i>Lyra AC, Soares MBP, da Silva LFM, Fortes MF, Silva AGP, Mota ACA, Oliveira SA, Braga EL, de Carvalho WA, Genser B, dos Santos RR, Lyra LGC</i>

<b>RAPID COMMUNICATION</b>	<b>1074</b>	Hepatitis C risk assessment, testing and referral for treatment in urban primary care: Role of race and ethnicity <i>Trooskin SB, Navarro VJ, Winn RJ, Axelrod DJ, McNeal AS, Velez M, Herrine SK, Rossi S</i>
	<b>1079</b>	A new oral formulation for the release of sodium butyrate in the ileo-cecal region and colon <i>Roda A, Simoni P, Magliulo M, Nanni P, Baraldini M, Roda G, Roda E</i>
	<b>1085</b>	Possible role of human cytomegalovirus in pouchitis after proctocolectomy with ileal pouch-anal anastomosis in patients with ulcerative colitis <i>Casadesus D, Tani T, Wakai T, Maruyama S, Iiai T, Okamoto H, Hatakeyama K</i>
	<b>1090</b>	Frequent loss of heterozygosity in two distinct regions, 8p23.1 and 8p22, in hepatocellular carcinoma <i>Lu T, Hano H, Meng C, Nagatsuma K, Chiba S, Ikegami M</i>
	<b>1098</b>	KIT-negative gastrointestinal stromal tumors with a long term follow-up: A new subgroup does exist <i>Kontogianni-Katsarou K, Lariou C, Tsompanaki E, Vourlakou C, Kairi-Vassilatou E, Mastoris C, Pantazi G, Kondi-Pafiti A</i>
	<b>1103</b>	NCB-02 (standardized Curcumin preparation) protects dinitrochlorobenzene-induced colitis through down-regulation of NF- $\kappa$ -B and iNOS <i>Venkataranganna MV, Rafiq Md, Gopumadhavan S, Peer G, Babu UV, Mitra SK</i>
	<b>1108</b>	Primary duodenal neoplasms: A retrospective clinico-pathological analysis <i>Bal A, Joshi K, Vaiphei K, Wig JD</i>
	<b>1112</b>	Aqueous suspension of anise " <i>Pimpinella anisum</i> " protects rats against chemically induced gastric ulcers <i>Al Mofleh IA, Alhaider AA, Mossa JS, Al-Sohaibani MO, Rafatullah S</i>
	<b>1119</b>	<i>H. pylori</i> are associated with chronic cholecystitis <i>Chen DF, Hu L, Yi P, Liu WW, Fang DC, Cao H</i>
	<b>1123</b>	Effect of parenteral and early intrajejunal nutrition on pancreatic digestive enzyme synthesis, storage and discharge in dog models of acute pancreatitis <i>Qin HL, Su ZD, Hu LG, Ding ZX, Lin QT</i>
	<b>1129</b>	Mechanisms involved in ceramide-induced cell cycle arrest in human hepatocarcinoma cells <i>Wang J, Lv XW, Shi JP, Hu XS</i>
<b>CASE REPORTS</b>	<b>1135</b>	Pancreatic metastasis of leiomyosarcoma in the right thigh: A case report <i>Koh YS, Chul J, Cho CK, Kim HJ</i>
	<b>1138</b>	A prophylactic approach for bone marrow transplantation from a hepatitis B surface antigen-positive donor <i>Sobhonslidsuk A, Ungkanont A</i>
	<b>1141</b>	Lipoma within inverted Meckel's diverticulum as a cause of recurrent partial intestinal obstruction and hemorrhage: A case report and review of literature <i>Karadeniz Cakmak G, Emre AU, Tascilar O, Bektaş S, Ucan BH, Irkorucu O, Karakaya K, Ustundag Y, Comert M</i>
<b>ACKNOWLEDGMENTS</b>	<b>1144</b>	Acknowledgments to Reviewers of World Journal of Gastroenterology
<b>APPENDIX</b>	<b>1145</b>	Meetings
	<b>1146</b>	Instructions to authors

*World Journal of Gastroenterology* ( *World J Gastroenterol* , *WJG* ), a leading international journal in gastroenterology and hepatology, has an established reputation for publishing first class research on esophageal cancer, gastric cancer, liver cancer, viral hepatitis, colorectal cancer, and *H pylori* infection, providing a forum for both clinicians and scientists, and has been indexed and abstracted in Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, *Index Medicus*, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, *Nature Clinical Practice Gastroenterology and Hepatology*, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993. *WJG* is a weekly journal published by The WJG Press. The publication date is on 7<sup>th</sup>, 14<sup>th</sup>, 21<sup>st</sup>, and 28<sup>th</sup> every month. The *WJG* is supported by The National Natural Science Foundation of China, No. 30224801 and No.30424812, which was founded with a name of *China National Journal of New Gastroenterology* on October 1,1995, and renamed as *WJG* on January 25, 1998.

### Abstract

Hepatocellular carcinoma (HCC) is one of the 10 most common cancers worldwide. There is no ideal treatment for HCC yet and many researchers are trying to improve the effects of treatment by changing therapeutic strategies. As the majority of human cancers seem to exhibit either abnormal p53 gene or disrupted p53 gene activation pathways, intervention to restore wild-type p53 (wt-p53) activities is an attractive anti-cancer therapy including HCC. Abnormalities of p53 are also considered a predisposition factor for hepatocarcinogenesis. p53 is frequently mutated in HCC. Most HCCs have defects in the p53-mediated apoptotic pathway although they carry wt-p53. High expression of p53 *in vivo* may exert therapeutic effects on HCC in two aspects: (1) High expression of exogenous p53 protein induces apoptosis of tumor cells by inhibiting proliferation of cells through several biologic pathways and (2) Exogenous p53 renders HCC more sensitive to some chemotherapeutic agents. Several approaches have been designed for the treatment of HCC *via* the p53 pathway by restoring the tumor suppression function from inactivation, rescuing the mutated p53 gene from instability, or delivering therapeutic exogenous p53. Products with p53 status as the target have been studied extensively *in vitro* and *in vivo*. This review elaborates some therapeutic mechanisms and advances in using recombinant human adenovirus p53 and oncolytic virus products for the treatment of HCC.

### INTRODUCTION

The concept of human gene therapy<sup>[1,2]</sup> derives from fundamental discoveries<sup>[3,4]</sup> on the nature and working<sup>[5]</sup> of the gene. Since the essential principles of molecular genetics and gene transfer in bacteria were established in the 1960s, gene transfer into animals and humans using either viral vector and/or genetically modified cultured cells has become inevitable<sup>[6]</sup>. Since then, this concept has promoted thousands of researchers to attempt to realize their long-cherished dreams of eradicating some of the obstinate human diseases. Broadly defined, the concept of gene therapy involves transfer of genetic materials<sup>[6]</sup> into cells, tissues, or whole organs, with the goal of eliminating diseases or at least improving the clinical condition of patients<sup>[7]</sup>. As a milestone of gene therapy, the first approved clinical protocol started trials in September, 1990<sup>[8]</sup>. Gene therapy provides great opportunities for treating diseases due to genetic disorders, infections and cancer<sup>[9]</sup>. Hepatocellular carcinoma (HCC) is one of the 10 most common cancers worldwide with its highest prevalence in Southeast Asia and sub-Saharan Africa<sup>[10]</sup>. Although great efforts have been made to overcome this cancer, no ideal treatment is available at present<sup>[11]</sup>. In recent years, many researchers are trying to improve the effects of treatment by changing therapeutic strategies<sup>[12]</sup>. As the majority of human cancers seem to exhibit either abnormal p53 gene<sup>[13]</sup> or disrupted p53 gene activation pathways<sup>[14]</sup>, intervention to restore wild-type p53 (wt-p53) activities is an attractive anti-cancer therapy<sup>[14,15]</sup>. This review elaborates some therapeutic mechanisms and advances in using recombinant human adenovirus p53<sup>[16]</sup> and oncolytic virus<sup>[17]</sup> products for the treatment of HCC.

### CARCINOGENESIS OF LIVER CELLS AND p53 GENE

Cancer predisposition, onset and therapeutic response can be critically determined by the integrity of tumor suppressor p53<sup>[15]</sup>. Tumor suppressor protein p53 can protect cells from growth and division<sup>[18]</sup>, thus mediating cell-cycle arrest<sup>[19]</sup>, DNA repair<sup>[20]</sup> and apoptosis<sup>[13,14,19,21]</sup> after its activation by multiple forms of cellular stresses<sup>[19]</sup>. p53 mutations<sup>[22]</sup> in plasma DNA are associated with several cancers, and abnormalities of p53 are also considered a predisposition factor for HCC (Table 1). Mutant p53 (mt-p53) may be a marker of HCC carcinogen exposure<sup>[22]</sup>. For example, in aflatoxin B1-exposed patients<sup>[23]</sup>, R249S tumor protein p53<sup>[24]</sup>, one of the cancer-associated mutants, encodes p53, and is considered a

**Table 1** Abnormal p53 status detected in HCC with probable mechanisms

Endogenous status of p53 or its pathways	Probable mechanisms
Mutation of p53 gene	Point mutation, allele deletion, insertion, etc.
Loss of or decrease in wt-p53 expression	Enhanced p53 degradation, complex formation
Hyperactivities of negative regulators of p53	No p53 mutation, over-expressed negative regulators of p53 attenuate its function
Increased diversity of p53 aberration	Progression of HCC
Presence of serum anti-p53 antibodies	Over-expression of wt-p53, presence of mt-p53, or both

**Table 2** Approaches for restoring tumor suppression function of p53 in the treatment of HCC

Strategies	Therapeutic effects
Chemotherapy or radiotherapy	Inducing p53-dependent apoptosis in tumor cells with wt-p53
Supplying exogenous wt-p53 by gene delivery	Suppressing growth of both mutant and wild-type p53-containing tumor cells
Overexpression of ARF	Blocking p53 degradation pathways to induce p53 triggered tumor cell death
Interruption of MDM2-p53 interaction	Preventing MDM2-mediated p53 ubiquitination and degradation to restore transactivation
Molecules stabilizing the active conformation of the protein	Rescuing mt-p53 to restore p53 function

genetic alteration during hepatocarcinogenesis<sup>[23]</sup>. Here R249S as a mutant of p53 core domain, is a structural mutation<sup>[25]</sup>, and constitutes one of the “hot spots” associated with cancer.

There is evidence that the level of p53 alterations is high in HCC, since it was reported that p53 increases the frequency of HCC prediction from 79.5% to 86.3%<sup>[26]</sup>, showing that serum concentration of p53 protein may be a convenient and useful non-invasive screening test for prediction of HCC. A study<sup>[27]</sup> showed that attenuated p53 function and telomere-induced chromosomal instability play a critical and cooperative role in the progression of chronic liver damage to hepatocellular carcinoma. Loss of p53 expression or presence of abnormal forms of the protein is frequently associated with HCC cell lines. Bressac *et al*<sup>[28]</sup> studied the p53 gene at the DNA, RNA, and protein level in seven human HCC-derived cell lines, and found that six of them show p53 abnormalities, suggesting that alterations in p53 may be important events in the transformation of hepatocytes<sup>[29]</sup> into the malignant phenotype. p53 gene is frequently mutated in high-grade<sup>[30]</sup> HCC. Inactivation of this multiple tumor suppressor gene plays an important role in the progression of chronic liver damage to hepatocellular carcinoma by directly or indirectly inducing chromosome instability, cell proliferation and neovascularization<sup>[31]</sup>. Kondo *et al*<sup>[32]</sup> performed dual-color fluorescence *in situ* hybridization to evaluate loss of the p53 gene, and revealed that loss of the p53 gene occurs in HCC, and diversity of the p53 gene aberration increases with the progression of chronic liver damage to HCC.

Other factors for hepatocarcinogenesis are correlated with abnormal functioning of p53, such as hepatitis B virus (HBV)<sup>[23,33]</sup> and hepatitis C virus (HCV)<sup>[34]</sup>. HBV gene encodes HBV protein x (HBx)<sup>[33]</sup>, a protein as a transcriptional activator<sup>[35]</sup> and plays an important role in viral replication in HBV-infected cells. HBx as an oncoprotein<sup>[36]</sup>, can bind to the C terminus of p53 and inhibit several critical p53-mediated cellular processes, including DNA sequence-specific binding, transcriptional transactivation, and apoptosis<sup>[37]</sup>. HBx integration and inactivation of p53 by mutations and regional allelic deletions are frequently found in tumors associated with HBV infection<sup>[38]</sup>. HBx up-regulates survivin<sup>[39]</sup> expression in hepatoma tissues. Survivin is an inhibitor of apoptosis and found in many common human cancers but not in

normal tissues. Survivin is suppressed by wt-p53 and over-expressed in 41%-70% of HCCs from Asia, its over-expression is associated with aberrant p53 nuclear positivity<sup>[40]</sup>.

In addition to its aberration, as p53 responds to a variety of genotoxic<sup>[34]</sup> and cytotoxic<sup>[41]</sup> agents in the presence of a potent inhibitor<sup>[42]</sup> of p53, the liver's ability to handle such toxic agents is influenced, thus inducing hepatocarcinogenesis.

Anti-p53 antibodies (p53-Abs) are products triggered by accumulation of a mutated form of p53 protein and probably a large quantity of wt-p53 protein<sup>[43]</sup>. As a specific serological marker for p53 gene expression changes in HCC, the presence of p53-Abs is independent of serum alpha fetoprotein and other conventional tumor markers<sup>[44]</sup>. It was reported that serum p53-Abs have a specificity of 100% for detecting malignancy<sup>[44]</sup>, suggesting that its use in combination with markers may increase the diagnostic sensitivity of cancer.

## MECHANISMS OF p53 THERAPY FOR HCC

Restoration of tumor suppression function of p53 has been speculated in several clinical lines for the treatment of HCC (Table 2).

p53 is frequently mutated in HCC<sup>[31]</sup>. Most HCCs have defects in the p53-mediated<sup>[37]</sup> apoptotic pathway although they carry wt-p53. Sometimes, p53 in HCC is wild-type but has inactive function<sup>[45]</sup>. Signal to and activation of p53 can lead to wt-p53 expression, thus suppressing the transformed phenotype of hepatocytes and increasing the effects of both chemotherapeutic agents and radiation therapy<sup>[46]</sup>. Repression of p53 can be partial or complete<sup>[45]</sup> in HCC, and activation of p53 can be achieved by single small molecules, such as the well known antimalaria drug quinacrine<sup>[45]</sup>. Supplying exogenous wt-p53 in cancer cells by gene delivery is effective in suppressing tumor growth of both mutant and wild-type p53-containing tumors<sup>[14]</sup>. The murine double minute 2 gene (MDM2) is an oncogene and contains a p53-DNA binding site and produces a phosphoprotein that forms a tight complex with both mutant and wild-type p53 protein, thus inhibiting p53-mediated transactivation and inducing p53 degradation<sup>[47]</sup>. There is a MDM2-p53 auto-regulatory feedback loop<sup>[48]</sup> that regulates the function of p53 protein and expression

of the MDM2 gene. Expression of the MDM2 gene can be regulated by the level of wild-type p53 protein, while the MDM2 protein, in turn, can form a complex with p53 and decrease its ability to act as a positive transcription factor at the MDM2 gene-responsive element. Several approaches have now been used to interrupt MDM2-p53 interaction to increase functional p53 levels and p53-mediated therapeutic effectiveness<sup>[49]</sup>. ADP-ribosylation factor (ARF) proteins are critical regulators of the protein secreting pathway<sup>[50]</sup>. In a human HCC cell line<sup>[51]</sup>, adenosine diphosphate (ADP) and adenosine triphosphate (ATP) are degraded to adenosine and treatment of HCC cells with adenosine can inhibit growth of HCC cells and activate caspase-3, indicating that adenosine is an apoptotic agent with cytotoxicity. ARF is considered a tumor suppressor<sup>[52]</sup>, and can initiate cellular response to aberrant oncogene activation by binding to and inhibiting the activity of MDM2. The human counterpart<sup>[53]</sup> of MDM2 (HDM2), like the murine protein, can inactivate the transactivation ability of human p53. ARF and p53 bind to MDM2 on different sites. ARF-p53 complex is formed depending on the mediation by MDM2 and can enhance p53 stability<sup>[54]</sup>. Blockage of p53 degradation pathways either by over-expression of ARF or interruption of MDM2-p53 interaction can effectively induce p53-triggered tumor cell death<sup>[14]</sup>.

High expression of p53<sup>[55]</sup> *in vivo* may exert therapeutic effects on HCC in two aspects: (1) High expression of exogenous p53 protein induces apoptosis of tumor cells by inhibiting proliferation of cells through several biologic pathways and (2) exogenous p53 renders HCC more sensitive to some chemotherapeutic agents.

In addition, p53 down-regulates the expression of genes involved in angiogenesis<sup>[56]</sup>, by the angiogenesis-inhibiting properties of wt-p53 protein<sup>[13]</sup>.

It is very difficult to treat HCC due to drug resistance. It is necessary to reverse multiple drug resistance to human HCC cells and to find out the related mechanisms. The expression and activity of P-glycoprotein as well as the multiple drug resistance gene (MDR) products, are elevated in HCC cells with mt-p53<sup>[57]</sup>. Expression of mt-p53 enhances drug resistance to HCC cells and reduces their uptake of chemotherapeutic agents. In contrast to the increased expression of MDR by mt-p53, wt-p53 inhibits transcription of MDR<sup>[58]</sup>. Therefore, restoration of wt-p53 activity in HCC cells leads to the sensitivity of HCC cells to chemotherapeutic agents because of the decreased expression of P-glycoprotein encoded by MDR.

## APPROACHES OF p53 THERAPY FOR HCC

Studies indicate that it is necessary to deliver therapeutic genes into cells with high specificity and efficiency in order to increase the effect of gene therapy against cancer<sup>[5,7,9,11]</sup>. A key factor for the success of gene therapy is the development of delivery systems<sup>[5,7,9]</sup> that are capable of efficiently transferring genes into a variety of tissues, without any associated pathogenic effects<sup>[7]</sup>. These techniques permit the isolation and insertion of genes into the recombinant delivery systems<sup>[5]</sup>. Two kinds of gene

transfer vectors, namely viral and non-viral, are available at present.

Viruses are recognized natural gene carriers<sup>[5]</sup> and provide inspiration of gene therapy. Viruses have been engineered as gene delivery vectors<sup>[59]</sup>. However, their limits such as selective disadvantage<sup>[60]</sup>, immunogenicity and toxicity<sup>[61]</sup>, inefficient gene transfer and short-lived<sup>[62]</sup> or inadequate expression in transfected liver cells<sup>[63]</sup>, require us to search other delivery systems.

Non-viral vectors have several advantages over viral vectors<sup>[61]</sup>. The transferred gene is in the form of a plasmid<sup>[64]</sup> that is on the surface or in the interior of the vector. Such vectors include liposome<sup>[61]</sup>, molecular conjugates<sup>[65]</sup>, nanoparticles<sup>[66]</sup> with strong anti-tumor effect on human HCC, naked DNA<sup>[67]</sup> and complexed DNA<sup>[68]</sup>. Better transfection efficiency can be achieved with delivery systems such as cationic lipids and cationic polymers<sup>[63]</sup>.

To date, tissue-specific expression<sup>[69]</sup>, self-replicating<sup>[70]</sup> and integrating plasmid<sup>[71]</sup> systems have been reported for gene therapy of HCC. Iodized oil emulsion<sup>[72]</sup> has a particular affinity to hypervascular hepatic tumors and is now commonly used in HCC chemoembolization, suggesting that it can be applied to the liver as a non-viral gene transfer system for intra-arterial gene delivery with selective gene expression in tumor cells.

## THERAPEUTIC PRODUCTS WITH p53 STATUS AS TARGET

Recombinant adenovirus p53 (rAd-p53) and oncolytic virus are the promising therapeutic products for the treatment of HCC mostly applied *in vitro* and *in vivo* at present. With the introduction of exogenous wt-p53 expressed by the recombinant adenoviral vector, the expression of both p53 and p21 proteins is found to be up-regulated in cells<sup>[55]</sup>. Inhibition of cell growth and apoptosis can be achieved<sup>[55]</sup>. Oncolytic viruses<sup>[73,74]</sup> are a number of defective viruses, which cannot replicate in normal cells but are able to grow in tumor cells, finally leading to their lysis.

The two kinds of viruses and their characteristics were compared (Table 3).

### Recombinant adenovirus p53 (rAd-p53)

Since human adenovirus vector systems have a larger host range and lower pathogenicity to humans<sup>[75]</sup>, and the binding affinity for epithelium<sup>[76]</sup> is important because most of human tumors are of the epithelial origin, and serotype 4 of species E<sup>[77,78]</sup> shows a specific binding affinity for HCC cells<sup>[76]</sup>, they are generally used for the expression of proteins in human beings or other species with some advantages. The E1 region of adenovirus has been identified as a subregion of the viral genome present in transformed cells and is responsible for transformation<sup>[79]</sup>. Recombinant human adenoviruses constructed with the E1 region replaced by exogenous DNA become replication-defective and yield a relatively low degree of acute toxicity<sup>[80]</sup>. Since recombinant adenoviral vector expresses wt-p53 (Ad-p53), p53 gene can be transfected into HCC cell lines<sup>[55]</sup>. Experiments showed that tumor cells transduced with the wt-p53 gene can inhibit *in vivo*

Table 3 Comparison of several characteristics of rAd-p53 with oncolytic virus products

Products	Characteristics
rAd-p53	p53 gene is transfected into HCC cells with recombinant adenoviral vector expressing wt-p53
Advexin	Larger host range, low pathogenicity to human, replication-impaired adenoviral vector carrying the p53 gene
Gendicine	The first commercial gene therapy product in the world approved by SFDA
SCH58500	Replication-deficient type 5 adenovirus vector expressing human wt-p53 under control of cytomegalovirus promoter
Oncolytic viruses	Incapable of replicating in normal cells but selectively replicating in p53-defective tumor cells to lyse them
ONYX-015	Tumor-selective replicating virus, the prototype for oncolytic adenoviral therapy
CNHK300-mE	Replication-competent with advantages of both gene and virus therapies

tumor growth of adjacent nontransduced cells, suggesting that Ad-p53 is also anti-angiogenic<sup>[81]</sup>, partially by the bystander effect induced by the wt-p53 gene transfer on adjacent tumor cells.

### Oncolytic viruses

As HCC cells with p53 defects have lost their cellular surveillance mechanisms, oncolytic viruses interfering with the main surveillance pathways such as those controlled by p53<sup>[73]</sup>, could replicate selectively in them and cause lysis. E1A gene of adenovirus is an apoptosis-inducing gene and E1B gene of adenovirus is an apoptosis-inhibiting gene. The 55-kilodalton (55kDa) protein from the E1B-region of adenovirus binds to and inactivates the p53 gene<sup>[82]</sup>. Because of a deletion in E1B, the 55-kDa E1B protein is not expressed and the mutant adenovirus, termed ONYX-015<sup>[83]</sup>, is able to replicate only in wt-p53 deficient cells. The E1B55K-defective adenovirus ONYX-015 is a prototype<sup>[73,82,83]</sup> of oncolytic viruses and can selectively replicate in and kill p53-deficient HCC cells, the success of cancer gene therapy is not promising unless it is carefully designed based on the biology of a specific<sup>[84]</sup> tumor type. To enhance the efficiency of such oncolytic viruses, another E1B 55kDa-deficient adenovirus armed with a mouse endostatin gene has been constructed for anti-tumor activities against HCC, and termed as CNHK200-mE<sup>[85]</sup>. With the synergistic effect of carrier virus and therapeutic gene, a novel approach has been established with the vector system termed as gene-viral vector<sup>[86]</sup> or gene-viral therapeutic system wherein an anti-tumor gene is inserted into the genome of a replicative virus specific for tumor cells to combine the advantages of gene and virus therapies. Using the human telomerase reverse transcriptase (hTERT) promoter to drive the expression of adenovirus E1A gene and clone the therapeutic gene mouse endostatin into the adenovirus genome, CNHK300-murine endostatin (CNHK300-mE)<sup>[87]</sup> is constructed, showing potential effects in the treatment of HCC.

## EMPIRICAL STUDIES OF p53 THERAPY FOR HCC

Activation of p53 by either chemotherapy or radiotherapy induces p53-dependent apoptosis in tumor cells with wt-p53<sup>[14]</sup>.

In the treatment of HCC, p53 products are injected into liver tissue by a variety of routes<sup>[55,72,82,88-92]</sup>. When p53 products are injected intratumorally<sup>[55,88,89]</sup>, introduction of exogenous wt-p53 can inhibit cell growth, the expression

of both p53 and p21 proteins is up-regulated in tumor cells. Intraarterial gene delivery into animal hepatic tumors can lead to selective gene expression in tumor cells<sup>[72]</sup>. Antegrade intraportal and retrograde intrabiliary routes are compared, induce transgene expression in periportal areas of liver with no significant difference in transduction efficacy, and no apparent complications are observed apart from very mild elevation of serum biochemical parameters<sup>[90]</sup>. The effect of bile and pancreatic juice on gene delivery has been studied under the guide of endoscopic retrograde cholangiopancreatography (ERCP)<sup>[92]</sup>, showing that neither bile nor pancreatic juice affects transgene expression. Intrasplenic injection of p53 products can transfer gene into the portal venous circulation. When p53 products are injected intravenously, barriers such as the endothelial lining of tumor vasculature impair the efficiency of adenoviral vectors for gene delivery into HCCs<sup>[65,82]</sup>, which can be overcome by direct injection of p53 products into tumor tissues<sup>[89]</sup>. Other gene delivery routes have also been reported<sup>[91]</sup>.

High-volume hydrodynamic injection of a gene *via* the hepatic artery with inferior vena cava/portal vein occlusion can achieve a high level of gene expression in HCC rat model<sup>[67]</sup>. This gene transfer technique may have potential in clinical gene therapy for HCC. Oncolytic adenovirus-mediated gene therapy induces tumor-cell apoptosis and reduces tumor angiogenesis, leading to inhibition of HCC growth in animal model<sup>[88]</sup>. Because CNHK200-mE is capable of selectively replicating in HCC cells, thus suppressing tumor growth and antiangiogenic activity in nude mice<sup>[85]</sup>, it can be used as a potential agent in the treatment of HCC.

## CLINICAL RESEARCHES OF p53 THERAPY FOR HCC

After *in vitro* and *in vivo* experiments, different adenovirus-mediated p53 gene therapies for various tumors have been evaluated<sup>[46]</sup>. It was reported that when recombinant adenovirus p53 (SCH 58500) is administered by hepatic arterial infusion, and it distributes more predominantly in liver tissues than in tumors<sup>[93]</sup>.

Intratumoural injection of Ad-p53 can lead to over-expression of p53 in cancer cells by inducing cell growth arrest and apoptosis, and overcome resistance or increase the effectiveness of radiation therapy and chemotherapy<sup>[94]</sup>.

Hepatic artery embolization for the treatment of HCC was first reported in 1979<sup>[95]</sup>. Since the 1980s, transcatheter arterial chemo-embolization (TACE) has been applied

to various HCCs apart from those with humoral hypercalcemia<sup>[96]</sup>. TACE as a local ablative treatment is able to control local disease and prolong a similar survival to that of surgical resection<sup>[11]</sup>. However, the recurrence of HCC after successful control of local tumor spread is high due to the non-curative procedure. In contrast to necrosis resulting from TACE, apoptosis is not commonly accompanied with inflammation that causes collateral cell damage, suggesting that the effects of intra-tumoral or intraarterial injection of p53 products in combination with TACE, on tumor tissue ischemia and necrosis, may be synergic and can improve survival.

In addition, inhibitors of p53-mediated apoptosis might be used to transiently decrease apoptosis in normal tissues when patients receive high doses of radiation or chemotherapy<sup>[97]</sup>. Emulsion of iodized oil and contrast medium can be used as a nonviral gene transfer system for intraarterial gene delivery<sup>[72]</sup>.

## CHALLENGES AND PROSPECTS

p53 is an ideal target for anti-cancer drug design<sup>[14]</sup>. Blockage of p53 degradation pathways can effectively induce p53 triggered tumor cell death<sup>[14]</sup>. Since unlike most other tumor suppressor genes, mt-p53 is over-expressed in tumor cells, a promising approach involving reactivation of tumor-suppressing function to mt-p53<sup>[21,25]</sup>. Further understanding of the mechanisms of how to restore p53 activity, may lead to discovery of more potent analogs and new strategies<sup>[11,73,91]</sup> for p53-targeting in tumor therapy.

More genes previously unknown have been identified that are involved in the regulation of p53 transcriptional activity and their over-expression inhibits p53 target promoters and p53-mediated apoptosis, suggesting that these genes play a role as p53 inhibitors and may have oncogenic activity<sup>[98]</sup>.

As hepatocarcinogenesis is a multistage process involving a number of genes<sup>[99,100]</sup>, attention should be paid to the target genes whose altered expression actually mediates neoplastic phenotype. There is an urgent need to establish simple and low-cost tests for detecting expression of p53-related genes in HCC<sup>[99,100]</sup> that are hallmarks of HCC development. Continuous monitoring of serum p53 protein is important in early detection of recurrence of HCC, and immunodetection of serum p53 is valuable<sup>[101]</sup> for post-operative monitoring during follow-up in preoperatively positive patients.

Nevertheless, about 40% of cancers retain wt-p53, and there may be mutations of other genes in cells with p53 mutations. Therefore, the mechanisms of p53 in HCC therapies should be further studied.

It was reported that hepatic arterial administration of p53 products cannot substantially increase transduction of tumor cells, and ligation of the hepatic artery following infusion of adenovirus or addition of lipiodol infusion has no effect on the transduction of tumor cells<sup>[102]</sup>, suggesting that better administration approaches must be developed for more efficient transduction of tumor cells.

Safety and research ethics must be emphasized. Human gene therapy can lead to serious adverse effects and even death<sup>[103]</sup>. In a gene therapy experiment in 1999<sup>[104]</sup>, death

of Jesse Gelsinger was found to be directly linked to the viral vector used for the treatment. This tragic event has raised new questions about the prospects for human gene therapy, which not only achieves a therapeutic effect but also has potential adverse effects.

Another task at present is to find out the key points of tumor resistance to rAd-p53<sup>[105-108]</sup>. Since exogenous wt-p53 was introduced, inhibition of tumor growth has become unnecessary for human cancer cells carrying mt-p53<sup>[105]</sup>. In some cancer cells, wt-p53 is inactivated by different mechanisms. Since the presence of mt-p53 may induce genome instability of human cancer cells and mutator ability, they can escape the effects of exogenous wt-p53 and contribute to the failure of wt-p53 gene therapy. On the contrary, exogenous wt-p53 in other cancers can have effects only on those expressing wt-p53. For example, alterations of p53 gene are uncommon in differentiated thyroid neoplasm but can be frequently detected in anaplastic thyroid carcinoma<sup>[107]</sup>, suggesting that impaired p53 function may contribute to the undifferentiated and highly aggressive phenotype of these tumors. It was reported that exogenous expression of wt-p53 has influence on thyroid tumorigenic properties only in cells bearing altered p53, whereas it has no effect on cells expressing wt-p53 activity<sup>[106]</sup>, indicating that the endogenous p53 status seems to be essential for the effectiveness of p53-based gene therapy for some cancers. Another study<sup>[108]</sup> evaluated the therapeutic effects of truncated Bid gene (tBid) on p53-resistant HCC and demonstrated that this gene only targets AFP-producing cells but not non-AFP producing ones<sup>[109]</sup>. The introduction of tBid can not only significantly but also specifically kill HCC cells that produce AFP, indicating that death of HCC cells is induced by an apoptotic pathway independent of p53 status<sup>[108]</sup>.

## CONCLUSION

p53 is an ideal target for the design of anti-cancer therapeutic strategies. p53 is frequently mutated in a significant portion of HCCs, and can mediate defective apoptotic pathways in HCC carrying wild type of p53. Several approaches have been designed for the treatment of HCC *via* the p53 pathway by restoring tumor suppression function from inactivation, rescuing mutated p53 gene from instability, or delivering therapeutic exogenous p53. Products with p53 status as the target have been studied extensively *in vitro* and *in vivo*. Although their therapeutic effects are limited, further study is needed to elucidate the mechanisms of p53 in HCC therapies, the role of endogenous p53 status, novel genes involved in the regulation of p53 transcriptional activity, the establishment of simple and low-cost tests for detecting expression of p53-related genes in HCC, better administration approaches of exogenous p53, safety and research ethics, and the key points of resistance to rAd-p53 in HCC.

## COMMENTS

### Background

Hepatocellular carcinoma (HCC) is one of the 10 most common cancers

worldwide. There are no ideal therapies for advanced HCC so far, and many researchers are trying to improve the effects of treatment by changing therapeutic strategies including application of gene therapy.

### Research frontiers

About 50% of human cancers are associated with mutations in the core domain of tumor suppressor p53, thus p53 is regarded as the most frequently mutated gene. It is an attractive approach to the treatment of HCC by restoring wild type p53 activity.

### Innovations and breakthroughs

Several approaches have been designed for the treatment of HCC via the p53 pathway by restoring tumor suppression function from inactivation, rescuing the mutated p53 gene from instability, or delivering therapeutic exogenous p53. Products with p53 status as the target have been studied extensively *in vitro* and *in vivo*.

### Applications

p53 pathway can be used as a target in the treatment of HCC.

### Terminology

**Gene Therapy:** The treatment of certain disorders, especially those caused by genetic anomalies or deficiencies, by introducing specifically engineered genes into patient cells. **p53 gene:** It is a tumor suppressor gene providing instructions for making a protein called tumor protein 53 (TP53). Through the effect of the protein it produces, TP53 is a tumor suppressor gene regulating the cycle of cell division by protecting cells from growing and dividing too fast or in an uncontrolled way. The p53 protein is located in the nuclei of cells throughout the body and can bind directly to DNA. When the DNA in cells becomes damaged, this protein plays a critical role in determining whether the DNA is repaired or the cells undergo programmed cell death (apoptosis). If the DNA can be repaired, p53 activates other genes to repair the damage. If the DNA cannot be repaired, the p53 tumor protein protects cells from dividing and signals it to undergo apoptosis. This process protects cells with mutated or damaged DNA from dividing, which helps prevent the development of tumors. Because the p53 tumor protein is essential for regulating cell division, it has been nicknamed the "guardian of the genome". **Vector:** Any device of transportation or movement. In this article, it denotes "a virus used to deliver genetic material into cells" or "a piece of DNA carrying DNA fragments into host cells".

### Peer review

This review elaborates some therapeutic mechanisms and advances in using recombinant human adenovirus p53 and oncolytic virus products in the treatment of HCC. This review is helpful for many readers. The prospects should be expanded.

### Abstract

Metallothioneins (MTs) were discovered in 1957 by Margoshes and Vallee and identified as low-molecular weight and sulphhydryl rich proteins. It is not surprising that most mammalian tissues contain age related basal levels of MTs since they are involved in metalloregulatory processes that include cell growth and multiplication. In an effort to understand the biology of this intriguing tumor, various biomarkers such as oncogenes, p53 tumor suppressor gene, waf 1 protein, proliferating cell nuclear antigen, telomerase, microsatellite markers and cytogenetic changes have been examined. One biomarker which has recently shown to be expressed in various human tumors but still less reported in carcinoma is MT. Immunohistochemical detection of MT proteins in cold acetone-fixed paraffin embedded liver sections was performed by the streptavidin-avidin-biotin immunoperoxidase complex method.

### INTRODUCTION

Metallothioneins (MTs) were discovered in 1957 by Margoshes and Vallee and identified as low-molecular weight sulphhydryl rich proteins. Due to their high metal content and unusual bioinorganic structure, they are

distinguished as metalloproteins. It is not surprising that most mammalian tissues contain age related basal levels of MTs since they are involved in metalloregulatory processes that include cell growth and multiplication. The presence of high levels of MTs in developing mammalian cells is well documented and it has been suggested that the MT-expressed protein is similar to onco-developmental gene products such as alpha-fetoprotein<sup>[1]</sup>.

### Classification of MTs

MT is a small protein with a high affinity for divalent heavy metal ions. MTs are a family of Mr 6000 proteins comprised of MT-I, MT-II, MT-III and MT-IV classes with multiple isoforms within each class. MT-I and MT-II are ubiquitously expressed and are stress inducible. MT-I isoform inducibility is reported to depend on the embryonic germ layer from which a tumor is derived<sup>[2]</sup>.

MTs are a group of ubiquitous low molecular mass cysteine-rich intracellular metal binding proteins. In human, MTs are encoded by a family of genes consisting of 10 functional MT isoforms and the encoded proteins are conventionally subdivided into four groups: MT-1, MT-2, MT-3 and MT-4 proteins. While a single MT-2A gene encodes MT-2 protein, MT-1 protein comprises many subtypes encoded by a set of MT-1 genes (MT-1A, MT-1B, MT-1E, MT-1F, MT-1G, MT-1H and MT-1X), accounting for the micro-heterogeneity of the MT-1 protein. Different MT genes in humans possibly play different functional roles during development or under various physiological conditions<sup>[3,4]</sup>.

The known functions of MTs include metalloregulatory roles in cell growth and differentiation, and enhanced synthesis of MTs in rapidly proliferating tissues suggests its crucial role in normal and neoplastic cell growth<sup>[5]</sup>.

### Characteristics of MTs

These intracellular proteins are characterized by their unusual high cysteine content (30%) and lack of aromatic amino acids. Because of their rich thiol content, MTs bind a number of trace metals including cadmium, mercury, platinum and silver, and also protect cells and tissues against heavy metal toxicity. Additionally MTs are among the most abundant intracellular aspects for biologically essential metals, zinc and copper. MT metal-thiolate fractions being dynamic and of high affinity also facilitate metal exchange in tissues<sup>[6]</sup>.

They are present in a great variety of eukaryotes<sup>[3]</sup>, functioning as anti-oxidants; they also play a protective role against hydroxyl free radicals. This is relevant in tumors (nasopharyngeal carcinoma) which are known to be

markedly radio-sensitive, where radiotherapy (which kills cells *via* free-radical-induced apoptosis) is the treatment of choice<sup>[7]</sup>.

## MT AS TUMOR MARKER

### *Alteration in MT function due to carcinogenesis*

Development of carcinogenesis is a dynamic process in which irregularation of gene function occurs. Time is crucial in this process. During a latency period of several years or even decades, the genetic material of cells is subject to multiple 'hits' by damaged substances, carcinogens, etc. Accumulation of damage leads to altered gene function and clonal expansion of mutated cells. However, most of these early lesions never develop into more aggressive and invasive states, but disappear spontaneously. This feature of carcinogenesis does not solely influence the initial phase of this process but actively intervenes and changes the course of the disease<sup>[5]</sup>.

### *Protective functions of MT*

MTs have a high binding affinity to bivalent metal ions. A number of studies have demonstrated the presence or enhanced synthesis of MT in rapidly proliferating normal cells, regenerating cells and cancer cells. The studies have suggested a relationship between high expression of MT protein and aggressive neoplastic cell growth. Due to their nucleophilicity, MTs have been shown to protect cells against the cytotoxic effects of electrophilic anticancer drugs. However, protection of cells by MT from the cytotoxic effect of agents such as 1- $\beta$ -D-arabinofuranosyl cytosine and nuclear factor DF- $\alpha$  must involve mechanisms other than simple covalent binding<sup>[8]</sup>.

### *Relation between MT and apoptosis*

Recent reports of various studies have shown that the enhanced expression of MT in cells induces the anti-apoptotic effects and a lack of MT in MT null cells increases the susceptibility to apoptotic cell death after exposure to certain anticancer drugs. The down-regulation of MT in MCF-7 cells within 18-mer antisense has not only shown inhibition in growth but also initiated apoptosis<sup>[8]</sup>.

## MTs INVOLVED IN PATHOPHYSIOLOGICAL PROCESSES IN HUMAN

### *Role of MT in detoxification*

MTs play a homeostatic role in the control and detoxification of the heavy metals; several evidences indicate that MT has the capacity to scavenge reactive oxygen metabolite (ROM), particularly the hydroxyl radical. These substances which are produced continuously during normal aerobic metabolism may become noxious in situations of imbalance with endogenous antioxidants and then can induce DNA damage, lipid peroxidation, enzyme oxidation, *etc.*, leading to cellular destruction, chromosomal aberrations and finally to cancer. Paradoxically, by anticancer treatment such as radiotherapy, chemotherapy and photodynamic therapy, tumor cells are killed by generating toxic amounts

of ROM<sup>[2]</sup>.

MT was considered as a potential prognostic marker in invasive ductal carcinoma of the breast<sup>[9]</sup>, skin<sup>[10]</sup>, cervix<sup>[11]</sup> and pancreas<sup>[12]</sup>. Irregular cell growth, due to increased cell proliferation or failure of cells to undergo apoptosis is recognized as a major contributory factor to the malignant process.

### *Dual functions of MT*

MTs appear to perform dual functions of influencing the growth and survival of tumor cells as they are known to have metallo-regulatory functions in cellular repair processes, growth and differentiation and to play a protective role in oxidative stress by scavenging free radicals, thus protecting the cell against apoptosis induced by oxidative stress. MT can be induced by a number of endogenous and exogenous stimuli including glucocorticoids, interferon, interleukin-1, progesterone, vitamin D<sub>3</sub> endotoxins, serum factors, and heavy metals, storage of metal ions and regulation of cellular zinc<sup>[1]</sup>.

### *MT and its response to anti-cancer drugs*

The association of MT expression with spontaneous mutagenesis response to anti-cancer drugs and tumor progression has emerged in recent years. This has been more significant in the later stage, with reliable methods for detecting the two isoforms of MT- I and MT- II by immunohistochemistry in archival tissues. MT over expression has been associated with more malignant and higher grade tumors in some cancers and with more differentiated lower grade tumors in others<sup>[6]</sup>.

### *Over expression of MT*

The *in vitro* studies suggest that MT over expression in ovarian cancer may induce chemo-resistance. It has been proposed that the sequestration of drugs or their metabolites may prevent the reaction of these compounds with the respective intracellular target, thus decreasing the efficacy of certain anti-cancer drugs.

Recurrence of drug resistant ovarian tumors that initially appear to respond well to chemotherapy may be explained by over expression of drug resistance proteins such as MT.

Another opinion of the same investigators is that growth factor signals might activate transcription factors that control the expression of drug-resistant enzymes and proteins. However, two independent groups of investigators were unable to find a direct causal relationship between MT expression and chemo-resistance<sup>[1]</sup>.

### *Genotoxic and non-genotoxic effects*

Humans are exposed to mixtures of genotoxic and non-genotoxic environmental chemicals that may be linked to cancer. Robust biomarkers of somatic stem cell mutation and mutant clonal expansion may provide cancer surrogates that are useful for risk assessment. Acquired mutation of a selectable endogenous reporter gene like glucose-6-phosphate dehydrogenase (G6PD) within a colonic crypt stem cell induces a crypt-restricted phenotype change.

### Stem cell mutation

Stable crypt-restricted immunopositivity for MT is a recently described stem cell mutation marker for mouse colon that can be assayed in paraffin-fixed tissue sections and has been validated against the G6PD assay. MT-immunopositive crypt frequency has shown a dose response to three different chemical mutagens that further confirmed the evidence that it is a somatic mutation marker<sup>[13]</sup>.

### Low levels of MTs and their susceptibility

Accumulating evidence indicates that cells with low levels of intracellular MT are more susceptible to DNA damage and apoptotic death after exposure to stress stimuli including oxidative stress, whereas prior induction of MT appears to confer protection. The findings of changes in unicellular localization of MT from cytoplasm to the nucleus during early differentiation of myoblasts coincide with increased apoptosis of newly formed myotubes<sup>[14]</sup>.

### Markers of carcinogenesis

The basal expression of MT in normal cells has generally been associated with heavy metal detoxification, intracellular trace elements storage and scavenging of free radicals. Authors Tridip and Thirumoorthy studied the roles of alterations of hepatic levels of trace elements and significance of the expression of MT and Ki-67 proteins as important markers of carcinogenesis in the development of pre-malignant phenotype and the reported dose (0.5 ppm) of vanadium in suppressing 2-AAF-induced carcinogenicity. Several reports are available to show that, over expression and up-regulation of MT and Ki-67 proteins are associated with the carcinogenic processes. But the reports documenting the anti-neoplastic potential of chemo-preventive agents in modulating these indicts are meager.

It was reported that the chemo-preventive potential of vanadium is suppressing in MT and Ki-67 expression in preneoplastic rat liver. The role of vanadium on p53 expression and induction of apoptosis in a defined rat model of experimental hepato-carcinogenesis has also been brought into focus<sup>[15]</sup>.

### MT as anti-oxidants

MTs can function as antioxidants. It has been suggested that intracellular oxidants may play a role in anticancer drug mediated programmed cell death and it was observed that MT expression can be regulated by ambient oxygen levels. This has led to speculation that MT may be an inducible anti-apoptotic gene product<sup>[6]</sup>.

Proteins like MT may play an important role in carcinogenesis, including tumor cell pathology and drug resistance. It was shown that colorectal and gastric carcinogenesis was associated with a significant increase in the level of manganese (Mn-SOD) containing superoxide dismutase, an antioxidant enzyme that detoxifies superoxide to hydrogen peroxide<sup>[2]</sup>.

### Factors influencing synthesis of MT

The synthesis of MT is regulated by polymorphic genes

and induced by many factors such as metals, hormones, cytokines, drugs and physical and oxidative stresses. Tumor MT levels have also been reported to correlate with resistance to anticancer reagent<sup>[16]</sup>.

MT regulates intracellular concentration of zinc and other metal ions. MT over expression can influence transcription, replication and protein synthesis, and might explain why MT over expression is associated with high-grade tumors, including carcinomas of the head and neck<sup>[17]</sup>.

## IMMUNOSTAINING OF MT

### Positive control

Immunohistochemical detection of MT protein in cold acetone-fixed paraffin embedded liver sections was performed by the streptavidin-avidin-biotin-immunoperoxidase complex method (Jin *et al*, 2002). Briefly, 5 µm thin sections on poly-L-lysine coated slides were deparaffinized and rehydrated. Endogenous peroxidase activity was blocked with 1% H<sub>2</sub>O<sub>2</sub> in 0.1 mol/L Tris-NaCl (pH 7.6) for 30 min. After incubation with 5% normal goat serum for 1 h at 37°C, sections were incubated overnight at 40°C with the primary antibody rabbit anti-rat MT-1 in 1% BSA using 1:50 dilution. Sections were then incubated with a bio-tinylated secondary antibody goat anti-rabbit IgG (Sigma) for 30 min at 37°C with 1:200 dilutions.

This was followed by incubation with streptavidin peroxidase (1:100) for 1 h and subsequent chromogen development with 0.5% of 3, 3'-diamino benzedrine tetra hydrochloride (DAB) and 0.33% H<sub>2</sub>O<sub>2</sub> in 0.5 mol/L Tris-NaCl as substrate. The sections were then counterstained with Harris haematoxylin (H&E), then dehydrated, mounted and served as positive control.

### Negative control

Negative control was prepared following the above steps but by omitting the primary antibody. MT immunostaining was considered positive when the nuclei and cytoplasm of the hepatocytes were stained prominently (purplish brown/reddish brown). MT immunoreactivity was expressed as percentage of immuno-positive cells. A total of 10 high power fields were randomly chosen. The numbers of positive cells were determined in relation to the total number of cells in the field<sup>[15]</sup>.

### Abstract

**AIM:** To investigate the role of cytochrome P450 (CYP) in the carcinogenesis of squamous-cell carcinoma (SCC) in human esophagus by determining expression patterns and protein levels of representative CYPs in esophageal tissue of patients with SCC and controls.

**METHODS:** mRNA expression of CYP2E1, CYP2C, CYP3A4, and CYP3A5 was determined using RT-PCR in both normal and malignant esophageal tissues of patients with untreated esophageal SCC ( $n = 21$ ) and in controls ( $n = 10$ ). Protein levels of CYP2E1, CYP2C8, CYP3A4, and CYP3A5 were measured by Western blot.

**RESULTS:** Within the group of SCC patients, mRNA expression of CYP 3A4 and CYP2C was significantly lower in malignant tissue (-39% and -74%, respectively,  $P < 0.05$ ) than in normal tissue. Similar results were found in CYP3A4 protein levels. Between groups, CYP3A4, CYP3A5, and CYP2C8 protein concentration was significantly higher in non-malignant tissue of SCC patients (4.8-, 2.9-, and 1.9-fold elevation,  $P < 0.05$ ) than in controls. In contrast, CYP2E1 protein levels were significantly higher in controls than in SCC patients (+46%,  $P < 0.05$ ).

**CONCLUSION:** Significant differences exist in protein levels of certain CYPs in non-malignant esophageal tissue (e.g. CYP2C8, CYP3A4, CYP3A5, and CYP2E1) between SCC patients and healthy subjects and may contribute to the development of SCC in the esophagus.

### INTRODUCTION

Worldwide, esophageal cancer is one of the ten most common cancers<sup>[1]</sup> with an overall 5-year survival rate of 3%-10%<sup>[2]</sup>. Although the entity of adenocarcinoma is rising<sup>[3]</sup>, the majority of carcinomas of the esophagus are squamous-cell carcinoma (SCC)<sup>[1]</sup>. Results of several epidemiological studies indicate that hot beverage, alcohol and tobacco are key risk factors for the development of carcinoma in the esophagus<sup>[1,4]</sup>. However, despite intense research<sup>[5]</sup>, the role of xenobiotica-metabolizing enzymes in the development of esophageal SCC is not fully understood due to the lack of successful pharmacological therapies.

Cytochrome P450 (CYP) is a multi-gene superfamily of heme-containing enzymes catalyzing the oxidative metabolism of many compounds<sup>[6]</sup>. CYP families 1, 2, and 3, which are the main CYP families participating in the metabolism of xenobiotics, are highly expressed within the liver. However, several CYPs have been shown to be also expressed in extrahepatic tissues such as the esophagus<sup>[7]</sup>. CYPs not only function in the detoxification but may also be involved in the activation of potential (pro-) carcinogens. The alimentary tract is exposed to a large variety of compounds, including potential (pro-) carcinogens. Indeed, it has been proposed that extrahepatic tissue might play an important role in the CYP-mediated metabolism of xenobiotic compounds and therefore might affect the susceptibility of certain organs to the development of malignancies. However, knowledge on regulation and localization of CYPs outside the liver (i.e., the esophagus) is limited and should be clarified.

CYPs may play a critical role not only in the development of SCC in the esophagus but also in the treatment of SCC. Therefore, the aim of the present study was to determine mRNA expression and protein concentrations of representative CYPs (e.g., CYP2C, CYP2E1, CYP3A4, and CYP3A5) in macroscopically normal esophageal tissue of patients with untreated SCC and in disease-free controls. Furthermore, as the expression of CYPs may be altered throughout the development of carcinoma, levels of CYPs were also

measured in SCC and compared to those determined in macroscopically normal neighboring esophageal tissue of the same patients.

## MATERIALS AND METHODS

### Subjects and tissue specimens

The study was approved by the Ethics Committee of the Medical Clinic of the University of Cologne, Germany. Informed consent was obtained from all subjects included in the study. All subjects underwent endoscopy for medical screening. Of the 31 subjects enrolled, 21 had an untreated SCC of the esophagus. Ten subjects with a negative diagnosis of SCC in the esophagus or malignancies in the gastrointestinal tract and no history of esophageal SCC or other malignancies served as controls. Only subjects without medication known to affect expression of the investigated CYPs were included in the current study. All study participants completed a questionnaire concerning smoking and anthropometrical parameters (Table 1). Using a standard pinch forceps, two biopsies were obtained from macroscopically normal esophageal tissue of controls and patients with SCC. Furthermore, in SCC subjects two biopsies were taken from carcinoma. Biopsies were placed immediately in liquid nitrogen, and stored at -80°C until analysis. Histopathological analysis of SCC was performed by an experienced pathologist. Tumor staging was based on differentiation and varied from poorly differentiated (G1:  $n = 2$ , G1-2:  $n = 2$ ), moderately differentiated (G2:  $n = 8$ , G2-3:  $n = 4$ ) to well differentiated (G3:  $n = 5$ ). In controls, the absence of SCC, inflammation, and any other pathological changes of the esophagus were confirmed endoscopically by an experienced physician.

### Isolation of total RNA-protein

Both total RNA and protein were isolated using Trizol reagent following the instructions of the manufacturer (Invitrogen, Gaithersburg, MD, USA). Briefly, tissue was homogenized in Trizol reagent, chloroform was added and phases were separated into RNA and protein phases. RNA was precipitated using isopropanol, washed with ethanol and resuspended in RNAase-free water. Protein was precipitated using isopropanol and washed three times in 0.3 mol/L guanidin hydrochlorid in 95% ethanol solution. The protein pellet was dried, resuspended and the concentration of protein in each sample was determined using a commercially available Bradford assay (BioRad, Munich, Germany).

### Reverse transcription and PCR

Using a first-strand cDNA synthesis kit (Invitrogen, Gaithersburg, MD, USA) cDNA was synthesized from 200 ng of total RNA. For the amplification of CYPs the following primer sequences were used: CYP2C8-19, detecting CYP2C isoforms 8 to 19: sense GCTAAAGTCCAGGAAGAGATTGA and antisense TCCTGCTGAGAAAGGCATGAAGT<sup>[8]</sup>; CYP2E1: sense AGCACAACCTCTGAGATATGG and antisense ATAGTCACTGTACTTGAAGT<sup>[8]</sup>; CYP3A4:

**Table 1** Characteristics of untreated esophageal SCC patients and controls (mean  $\pm$  SE)

sense CCAAGCTATGCTCTTCACCG and antisense TCAGGCTCCACTTACGGTGC<sup>[9]</sup>; CYP3A5: sense TGTCCAGCAGAACTGCAAA and antisense TTGAAGAAGTCCTTGCGTGTC<sup>[9]</sup>. The PCR reaction mixture consisted of 0.6  $\mu$ L of cDNA, 10  $\times$  PCR buffer, 200  $\mu$ mol/L dNTPs (Boehringer, Mannheim, Germany), BSA (0.25 mg/mL), DMSO (2% v/v), 0.5  $\mu$ mol/LM of specific primer and 0.5 U Taq-polymerase (Promega, Madison, WI, USA), and water to a final volume of 10  $\mu$ L. For amplification of the four cytochrome P450 cDNAs, PCR-conditions were as follows: at 94°C for 3 s, at 45°C for 3 s, at 72°C for 30 s, for 32 cycles. Amplification of histone 3.3 (primer sequences: sense CGTGCTAGCTGGATGTCTT and antisense CCACTGAACCTCTGATTCGC<sup>[10]</sup>) was performed applying the following conditions: at 94°C for 3 s, at 45°C for 3 s, and at 72°C for 30 s, for 30 cycles. All measurements were carried out at least in duplicate in a rapid cycler (Idaho Tec., USA) within the linear range of the reaction. PCR products were separated in a 1.5% agarose gel, stained with ethidium bromide and photographed using a digital camera from Biometra (Goettingen, Germany). To ensure the success of PCR, human liver cDNA was used as a positive control. RT-PCR analysis was performed in triplicate, whenever possible. However, in case of a reduced mRNA availability, measurements were conducted in duplicate.

### Immunoblot analysis

Antibodies used for the detection of CYP2E1 and CYP3A4 were a generous gift of Dr. M. Ingelman-Sundberg, Karolinska Institute, Stockholm, Sweden. Primary antibodies for the measurements of CYP2C8 and CYP3A5 were purchased from Chemicon, Inc. (Frankfurt, Germany).

On each blot, protein extracted from human liver was used as standard. Twenty to 30  $\mu$ g of total protein and serial dilutions of standard protein (12.5, 25, and 50  $\mu$ g) were separated by sodium dodecylsulphate-polyacrylamide gel electrophoresis (SDS-PAGE) and transferred to nitrocellulose membranes. After blocked in 5% non-fat milk in Tris-buffered saline-Tween 20 (TBST, 0.01% v/v Tween 20), membranes were probed with dilutions of primary antibodies in TBS, followed by an incubation with the secondary antibody. The protein/antibody complex was visualized by enhanced chemiluminescence (SuperSignal<sup>®</sup> West Dura, Pierce, KTM, Bad Godesberg,

**Figure 1** CYP3A5, CYP2E1, CYP3A4, and CYP2C mRNA expression in esophagus of untreated SCC patients. **A:** Representative photomicrograph of RT-PCR products of untreated esophageal SCC patients (N = normal esophageal tissue, T = tumor tissue obtained from SCC patients). Measurements were carried out either in triplicate or in case of reduced mRNA availability in duplicate. Lanes 1, 6: histone 3.3, lanes 2, 7: CYP2C, lanes 3, 8: CYP2E1, lanes 4, 9: CYP3A4, lanes 5, 10: CYP3A5; **B:** Densitometric analysis of CYP2C, CYP2E1, CYP3A4, and CYP3A5 mRNA expression in normal esophageal tissue and SCC. Results are normalized to histone 3.3 expression. Data are means  $\pm$  SE. <sup>a</sup> $P < 0.05$  vs normal tissue.

Germany). Densitometric analysis was performed using the software AIDA (Raytest, Isotopenmessgeraete, Straubenhardt, Germany). Signal intensities of the samples were adjusted to the intensities of the serially diluted standards. To ensure equal loading, all blots were stained with Ponceau red. Haptene signals were normalized to  $\beta$ -actin using a commercially available antibody (Sigma Chemical Co., Munich, Germany).

### Statistical analysis

Results are presented as means  $\pm$  SE unless otherwise indicated. Fisher's exact test was used to compare lifestyle data. The Mann-Whitney *U*-test was used for the comparison of relative mRNA concentration and protein levels measured in normal esophageal tissue obtained from patients with SCC and disease-free controls. Wilcoxon's *t*-test was used for the comparison of relative mRNA expression and protein concentration measured in normal esophageal tissue and SCC of the same patient.  $P < 0.05$  was considered statistically significant.

## RESULTS

The majority of the 31 patients were of normal weight and their age ranged from 38-71 years. No differences were

**Figure 2** Protein levels of CYP2C8, CYP2E1, CYP3A4, and CYP3A5 in macroscopically normal tissue and SCC patients **A:** Representative Western blots of CYP2C8, CYP2E1, CYP3A4, and CYP3A5 in macroscopically normal esophageal tissue (N) and SCC (T) esophageal SCC patients; **B:** Quantitative analysis of blots. Results are normalized to  $\beta$ -actin. Data are means  $\pm$  SE. <sup>a</sup> $P < 0.05$  vs normal tissue.

found in smoking habits between patients and controls (Table 1).

### CYP expression and protein levels in normal esophageal tissue and untreated esophageal SCC patients

High quality of undegraded mRNA from normal esophageal tissue and SCC was obtained from 12 out of 21 patients with esophageal SCC. Expression of histone 3.3 mRNA, used as housekeeping gene, was detected in all samples. The results of RT-PCR measurements are summarized in Figure 1. In addition to RNA measurements, protein levels of CYPs were determined in normal esophageal tissue and in patients with SCC ( $n = 21$ ) (Figure 2).

**CYP2E1:** In SCC patients, expression of CYP2E1 did not differ between normal esophageal tissue and SCC. Similarly, no differences were found in CYP2E1 protein levels between normal tissue and SCC.

**CYP 3A5:** CYP3A5 mRNA expression and CYP3A5 protein levels were comparable in normal esophageal tissue and SCC.

**CYP2 (8-19):** Expression of CYP2C (8-19) was significantly lower in tissue obtained from SCC patients than in normal neighboring esophageal tissue. Specifically, mRNA expression of CYP2C (8-19) was about 39%

**Figure 3** Expression of CYP2C8, CYP2E1, CYP3A4, and CYP3A5 in macroscopically normal tissue of SCC patients and controls. **A:** Representative photomicrograph of RT-PCR products determined in normal tissue of patients with untreated esophageal SCC (S) and controls (C). All measurements were carried out in duplicate. Lanes 1, 6: histone 3.3, lanes 2, 7: CYP2C, lanes 3, 8: CYP2E1, lanes 4, 9: CYP3A4, lanes 5, 10: CYP3A5; **B:** Quantitative analysis of CYP2C, CYP2E1, CYP3A4, and CYP3A5 mRNA expression in normal esophageal tissue of SCC patients and controls. Results are normalized to histone 3.3 expression. Data are means  $\pm$  SE. <sup>a</sup> $P < 0.05$  vs normal tissue.

**Figure 4** CYP3A5, CYP2E1, CYP3A4, and CYP2C protein levels in esophagus of SCC patients and disease-free controls. **A:** Representative Western blot of CYPs determined in normal tissue of untreated esophageal SCC patients (S) and disease-free controls (C); **B:** Quantitative analysis of CYP2C, CYP2E1, CYP3A4, and CYP3A5 protein levels in normal esophageal tissue of SCC patients and disease-free controls. Results are normalized to  $\beta$ -actin. Data are means  $\pm$  SE. <sup>a</sup> $P < 0.05$  vs disease-free controls.

lower ( $P < 0.05$ ) in tissue of SCC patients than in normal tissue. In addition, protein concentration of CYP2C8 was determined, however no differences were found between SCC and normal tissue.

**CYP3A4:** CYP3A4 mRNA expression was significantly lower in SCC than in normal neighboring esophageal tissue. Specifically, mRNA expression of CYP3A4 was about 74 % lower in SCC than in normal tissue ( $P < 0.05$ ). Furthermore, protein levels of CYP3A4 were significantly lower (by about 51%) in SCC than in normal esophageal tissue ( $P < 0.05$ ).

#### Expression and protein levels of CYPs in normal esophageal tissue of SCC patients and controls

Furthermore, expression of CYP2C, CYP2E1, CYP3A4, and CYP3A5 mRNA and CYP2C8, CYP2E1, CYP3A4, as well as CYP3A5 protein concentrations were determined in normal esophageal tissue of untreated SCC patients ( $n = 21$ ) and compared with those in 10 disease-free controls. Representative agarose gels depicting RT-PCR measurements and semiquantitative analysis of RT-PCR are shown in Figure 3. Expression of the housekeeping gene histone 3.3 was detected in all samples. Results of the comparisons of protein levels are summarized in Figure 4.

**CYP2E1:** Expression of CYP2E1 was found to be

significantly higher by about 43 % in normal tissue obtained from patients with esophageal SCC than in disease-free controls ( $P < 0.05$ ). Interestingly, CYP2E1 protein levels were significantly lower in normal tissue of SCC patients than in esophageal tissue obtained from disease-free controls (about -46%,  $P < 0.05$ ).

**CYP3A5:** Expression of CYP3A5 mRNA in normal esophageal tissue was about 37 % higher in tissue obtained from SCC patients than in controls. Similar differences were found in protein levels, with protein levels of CYP3A5 being significantly higher by about 2.9-fold in normal esophageal tissue obtained from patients with esophageal SCC than in controls ( $P < 0.05$ ).

**CYP2C (8-19):** No differences were found in CYP2C (8-19) mRNA expression between normal tissue of patients with esophageal SCC and controls. CYP2C8 protein levels were about 1.9-fold higher in normal tissue of SCC patients than in controls ( $P < 0.05$ ).

**CYP3A4:** Similar to CYP2C (8-19), mRNA expression did not differ between normal tissue of patients with SCC and controls. However, when protein levels of CYP3A4 were compared between normal tissue of patients with SCC and controls, CYP3A4 protein concentration was found to be about 4.8-fold higher in normal tissue of SCC patients than in controls ( $P < 0.05$ ).

**Table 2** Correlation between mRNA expression and protein levels of CYP2E1, CYP3A4, CYP3A5, and CYP2C8 in normal esophageal tissue and SCC

Normal esophageal tissue	Spearman R	P
CYP2E1	-0.09	0.72
CYP3A4	0.07	0.76
CYP3A5	0.19	0.41
CYP2C8	0.07	0.76
Esophageal SCC		
CYP2E1	0.02	0.96
CYP3A4	0.16	0.65
CYP3A5	0.49	0.15
CYP2C8	-0.22	0.53

### Relation of protein levels and mRNA expression of CYPs in normal esophageal mucosa of SCC patients and disease-free controls

Since it has been shown before by others and our group<sup>[11-13]</sup> that mRNA expression and protein concentration of CYP450 are not related in tissues of some digestive organs (e.g. colon), non-parametric correlation analysis of mRNA expression and protein levels for each CYP investigated was performed. Indeed, no significant correlations were found between mRNA expression and protein levels in any of the CYPs investigated (Table 2).

## DISCUSSION

### Different protein levels of CYPs in normal tissue of untreated esophageal SCC patients and controls

Esophageal cancer is the third most common gastrointestinal cancer<sup>[1]</sup> with the majority of tumors being SCC<sup>[4]</sup>. It was reported that interindividual differences in CYP gene expression may contribute to the interindividual susceptibility to environmental (pro-) carcinogens and subsequently the development of malignancies<sup>[14]</sup>. Despite this hypothesis, only a few extensive studies have determined mRNA and/or protein expression of CYPs in esophageal tissue and esophageal carcinoma of humans, respectively<sup>[14-17]</sup> and most of these studies did not distinguish between adenocarcinoma and SCC. The presence of CYP2C-, CYP2E- and CYP3A- in normal esophageal tissue and SCC has been shown by others before<sup>[14-17]</sup>. However, some of the available data are contradictory and most studies determined either the expression or the protein levels in normal esophageal tissue and SCC. For example, using immunohistochemistry Murray *et al.*<sup>[16]</sup> detected CYP3A, CYP1A, and CYP2C9 in most of the malignant tissue from patients with esophageal malignancies, but only CYP1A was detected in unaffected normal tissue of patients. Lechevrel *et al.*<sup>[14]</sup> detected CYP3A4/5 and CYP2E1 protein and mRNA in some patients with adenocarcinoma or SCC in the esophagus. However, CYPs levels varied considerably between individuals and only CYP3A5 and CYP2E1 mRNA could be identified by RT-PCR. In the current study, CYP3A4 protein levels and CYP3A4 and CYP2C mRNA expres-

sion were found to be significantly lower in SCC than in its neighboring normal tissue. However, even more important, protein concentrations of CYP3A4, CYP3A5, and CYP2C8 were significantly higher in non-malignant esophageal tissue of patients with SCC than in tissues of healthy controls, while those of CYP2E1 were moderately reduced. At the level of mRNA expression, only CYP2E1 and CYP3A5 expression differed between groups. This finding can be considered to be of higher importance in carcinogenesis of the esophagus, as perpetually modified metabolism patterns of xenobiotics might result either in reduced detoxification of carcinogens or in elevated production of carcinogens from pro-carcinogens. The latter case might be of special importance due to strikingly increased amounts of CYP3A4 and CYP3A5 protein in non-malignant specimens from patients with SCC. These data suggest that the amount of CYPs might not only vary extensively between SCC and normal surrounding tissue but also between patients with SCC and healthy subjects. However, as in the present study CYP levels were only determined in SCC, it remains to be determined if expression and protein levels of CYPs are also altered in earlier stages of the disease (e.g., intraepithelial neoplasia of low and high grade). Furthermore, protein concentration of some CYPs (e.g., CYP2E1, CYP2C8, CYP3A4, and CYP3A5) is considerably altered in normal tissue of patients with SCC compared to control subjects without malignancies. Hence, significant differences in protein concentration of these CYPs appear to be present before the development of malignancies in patients with SCC, suggesting that these enzymes are likely associated with the development of malignancies in the esophagus.

### CYP mRNA is not related to protein levels either in normal esophageal tissue or in esophageal SCC

It has been suggested that expression of CYPs is not solely regulated at the level of gene transcription<sup>[18]</sup>. For instance, several studies performed in rodents and humans have reported a dissociation of mRNA expression and protein levels of CYP2C8 and CYP2E1, CYP3A4 and CYP3A5 in colon, duodenum and kidney, respectively<sup>[12,13,18]</sup>. Furthermore, *in vitro* studies performed in rat hepatocytes indicate that CYP2E1 is regulated by posttranscriptional ligand-dependent stabilization of the enzyme<sup>[19]</sup>. Similar mechanisms have been described for CYP3A in rats and humans<sup>[20,21]</sup>. Using cultured hepatocytes it also has been shown that only 60%-70% of mRNAs encoding for CYP2E1 are translated<sup>[22]</sup>. Indeed, in the present study, no correlation was found between protein and mRNA levels, suggesting that expression of certain CYPs (e.g., CYP2C8, CYP2E1, CYP3A4, and CYP3A5) in esophageal mucosa might not solely be regulated at the level of transcription.

In conclusion, similar to the findings of others<sup>[14-17]</sup> interindividual variability along with a substantial dissociation of mRNA expression pattern and protein levels seems to be a characteristic of CYP expression. Although it is difficult to interpret the higher and lower levels of CYPs found in the present study, continued work focussing on the CYPs identified to have differential expression in pa-

tients with SCC is needed to determine their metabolic implications.

## ACKNOWLEDGMENTS

The antibodies against human CYP2E1 and CYP3A4 were kindly provided by Dr. M Ingelman-Sundberg.

### Abstract

**AIM:** To evaluate the outcome predictors of percutaneous ablation therapy in patients with unresectable hepatocellular carcinoma (HCC), especially to identify whether the initial treatment response contributes to the survival of the patients.

**METHODS:** The study cohort included 153 patients with single (102) and two or three (51) HCC nodules 5 cm or less in maximum diameter. As an initial treatment, 110 patients received radiofrequency ablation and 43 patients received percutaneous ethanol injection.

**RESULTS:** The Kaplan-Meier estimates of overall 3- and 5-year survival rates were 75% and 59%, respectively. The log-rank test revealed statistically significant differences in the overall survivals according to Child-Pugh class ( $P = 0.0275$ ), tumor size ( $P = 0.0130$ ), serum albumin level ( $P = 0.0060$ ), serum protein induced by vitamin K absence or antagonist II level ( $P = 0.0486$ ), and initial treatment response ( $P = 0.0130$ ). The independent predictors of survival were serum albumin level (risk ratio, 3.216; 95% CI, 1.407-7.353;  $P = 0.0056$ ) and initial treatment response (risk ratio, 2.474; 95% CI, 1.076-5.692;  $P = 0.0330$ ) based on the Cox proportional hazards regression models. The patients had a serum albumin level 3.5 g/dL and the 3- and 5-year survival rates of 86% and 82%.

**CONCLUSION:** In HCC patients treated with percutaneous ablation therapy, serum albumin level and initial treatment response are the independent outcome predictors.

### INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most prevalent human cancers with an increasing incidence worldwide<sup>[1]</sup>, and about 70% of HCC is found in Asia<sup>[2]</sup>. Surveillance with ultrasonography (US) and alpha-fetoprotein in cirrhosis can detect small HCC at an early stage. For early stage patients (single HCC  $\leq 5$  cm or  $\leq 3$  nodules  $\leq 3$  cm), surgery is considered the first treatment option, however, because of accompanying chronic liver disease, many HCC patients can not undergo surgical resection<sup>[3-5]</sup>. As non-surgical treatment, various local ablation therapies such as percutaneous ethanol injection (PEI)<sup>[6,7]</sup> or percutaneous radiofrequency (RF) ablation have been proposed, and encouraging results of survival rates have been reported<sup>[8-10]</sup>.

Although many reports of the prognostic predictors after surgical resection of early stage HCC have been reported<sup>[11-13]</sup>, there have been few reports of the prognostic predictors after percutaneous ablation therapy. Sala *et al* in recent years reported that "Child-Pugh class" and "initial treatment response" as prognostic factors of the survival in those who received percutaneous ablation therapy<sup>[14]</sup>; however, most of the cases (83%) were treated with PEI. The current state of the main percutaneous ablation therapy changes from PEI to RF ablation; therefore, to establish an optimal therapeutic strategy based on the current state, we started this cohort study after 2000 when RF ablation was introduced in our institution.

In this study, we examined a group of HCC patients whose tumors were percutaneously treated using RF ablation or PEI and analyzed the factors pertinent to the prognosis. This approach permits (1) establishment of an

optimal protocol in the percutaneous ablation therapy; and (2) assessment of the prognostic factors in RF ablation and PEI.

## MATERIALS AND METHODS

### Patients

Between May 2000 and March 2005, 226 patients were diagnosed for the first time as having HCC lesions using US and contrast-enhanced CT and were hospitalized at Yokohama City University Medical Center. The criteria for entry in this study were (1) the presence of either a solitary lesion or up to three lesions, (2) a maximum tumor diameter of 5 cm or less, (3) patients who did not meet with the surgical criteria (resection or transplantation), (4) the lesion was detectable using US, and (5) no evidence existing of portal thrombosis, extrahepatic metastasis, or uncontrollable ascites. Seventy-three patients were excluded from the study and 153 patients were enrolled. The patients' characteristics are depicted in Table 1. Ninety-three of the enrolled patients were men and 60 were women, ranging in age from 51 to 87 years (mean, 69 years). One hundred and thirty-three patients were Child-Pugh class A, and 20 patients were Child-Pugh class B. All had underlying cirrhosis due to hepatitis C virus ( $n = 134$ ), hepatitis B virus ( $n = 8$ ), alcohol use ( $n = 7$ ), or other factors ( $n = 4$ ). One hundred and two patients presented with solitary tumors and 51 patients had 2-3 lesions. The greatest tumor diameters  $\leq 3$  cm were seen in 120 patients, and  $> 3$  cm in 33 patients. A confirmed diagnosis of HCC was made by the pathological examination of biopsied specimens obtained using a 21-gauge fine needle (Sonopsy, Hakko, Tokyo, Japan) and/or the radiological criteria<sup>[15]</sup> in all patients. Patients with a tumor more than 3 cm in maximum diameter were treated with transcatheter arterial chemoembolization (TACE) followed by RF ablation or PEI.

The entire protocol was approved by the hospital ethics committee and was performed in compliance with the Helsinki Declaration. Written informed consent was obtained from all patients and relatives.

### Treatment procedures

**Percutaneous ethanol injection:** Based on the reports of Llovet *et al*<sup>[16]</sup> and Livraghi *et al*<sup>[17]</sup>, we selected PEI without selecting RF ablation when a tumor satisfied the following criteria: (1) existing in a subcapsular location, (2) existing in a location adjacent to a major vessel and another organ (heart, gallbladder, stomach and bowel), and (3) demonstrating poor differentiation. Patients with impaired clotting tests, or with a lower platelet count less than  $5 \times 10^{10}/L$  were considered as being contraindicated for RF ablation and were treated by PEI. Ten patients (23% of patients treated by PEI) with tumors more than 3 cm in diameter were treated with TACE followed by PEI<sup>[18]</sup>.

We used a real-time convex scanner or linear-array scanner with 3.5-MHz probes and a lateral attachable apparatus for needle guidance (Core-Vision 6000™, Toshiba Medical Co., Tokyo, Japan). First, it was confirmed

under US guidance that a 15- or 20-cm, 21-gauge puncture needle with a closed conical tip and three terminal side holes (PEIT needle; Hakko, Tokyo, Japan) was correctly positioned within the lesion, and 99.5% absolute ethyl alcohol was then slowly injected. Caution was taken to inject the deepest portions of the lesion first and then the more central and superficial portions, to prevent superficial spreading of the ethanol from masking the view for subsequent injections. We usually used one or more PEIT needles for each treatment session, and ethanol was injected into the tumor at one or more locations until the lesion was completely filled. Treatment was given twice a week. A treatment series usually consisted of six or more sessions, and the total dose of ethanol varied with the volume of the lesion, the texture, patient compliance, and distribution of the ethanol.

**Radiofrequency ablation:** We selected the RF ablation for the cases with low risks of tumor seeding and the hemorrhage based on the previous reports<sup>[16,17,19]</sup>. Twenty-three patients (21% of patients treated by RF ablation) with tumors more than 3 cm in diameter were treated with TACE followed by RF ablation<sup>[20]</sup>.

At the beginning, grounding was achieved by attaching 2 or 4 pads to the patient's thighs. A conscious sedation, consisting of a combination of intramuscular

administration of pentazocine (Pentazin<sup>TM</sup> 15 mg, Sankyo Pharmaceuticals, Tokyo, Japan) and hydroxyzine chloride (Atarax-P<sup>TM</sup> 25 mg, Pfizer Japan, Tokyo, Japan), was administered before treatment. Local anesthesia was achieved by injecting 1% lidocaine hydrochloride (Xylocaine<sup>TM</sup>, Astra Japan, Tokyo, Japan). Sixty-five of 112 patients were treated with hooked, 15-gauge, 25-cm-long electrodes, which are expandable by 10 hooks to a maximum dimension of 3 or 3.5 cm (Le Veen Needle Electrode; Radiotherapeutics, Mountain View, CA), and RF ablation was applied using a generator (RTC 2000; Boston Scientific Japan, Tokyo, Japan). For the remaining 47 tumors, 17-gauge, cooled electrodes with a dimension of 2 or 3 cm (Cool-tip needle; Radionics, Burlington, MA) were used, attached to a 500-kHz RF generator (Radionics, Burlington, MA) capable of producing power of 200 W. A peristaltic pump (Watson-Marlow, Wilmington, MA) was used to infuse 0°C normal saline solution into the lumen of the electrodes to maintain the temperature below 25°C. For tumors more than 2 cm in diameter, several insertions were performed to obtain complete ablation of the entire tumors.

**Transcatheter arterial chemoembolization:** Thirty-three patients with tumors more than 3 cm in diameter were treated with TACE followed by RF ablation or PEI. We performed TACE by selectively introducing a microcatheter into the right or left hepatic artery or a segmental branch of the hepatic artery and injecting a mixture of iodized oil (Lipiodol; Andre Guerbet, Aulnay-sous-Bois, France) and epirubicin hydrochloride (30-50 mg per body surface) (Farmorubicin; Pharmacia and Upjohn, Tokyo, Japan) or styrene maleic acid neocarzinostatin (1.0-3.0 mg per body surface) (SMANCS; Yamanouchi Pharmaceutical, Tokyo, Japan). This was followed by introduction of a gelatin sponge (1 mm × 1 mm × 1 mm) (Spongel; Yamanouchi Pharmaceutical, Tokyo, Japan).

#### Evaluation of initial treatment response and follow-up

Initial treatment response was assessed by contrast-enhanced CT 1, 3, and 6 mo after initial treatment session. Successful initial treatment was defined as the absence of an enhanced area within the tumor assessed by contrast enhanced CT 6 mo after initial treatment session. If the presence of residual viable tumor within the treated area was defined by CT within 6 mo after initial treatment, the case was judged to be unsuccessful in the initial treatment. After the evaluation of initial treatment response, patients were followed up every 3 mo by contrast enhanced CT and/or US.

When the residual viable tumor and/or distant recurrence were detected by the follow-up CT, percutaneous ablation therapy was added if they were within 3 lesions, and TACE was selected for patients who were ineligible for percutaneous ablation therapy, with large and/or multifocal HCC who did not have vascular invasion or extrahepatic spread<sup>[15]</sup>. The above-mentioned treatment was repeated at once whenever the tumor recurrence was detected, until uncontrolled ascites or intravascular tumor thrombus appeared and serum bilirubin level reached 3 mg/dL or higher.

#### Statistical analysis

The end point of the study was the survival. The baseline characteristics of patients were expressed as mean ± standard deviation. Differences in proportions among the groups were analyzed by the Chi-square test. Mean quantitative values were compared by the Student's *t* test. Follow-up data was dealt with from the beginning of the treatment and was maintained until the death or the last visit of the patients before April 30, 2006. The Kaplan-Meier method was used to calculate the survival rate and the log-rank test was used to analyze differences.

As pretreatment factors, fifteen variables were assessed in the univariate analysis: age (< 70 *vs* ≥ 70 years); sex (male *vs* female); cause of underlying cirrhosis (HCV *vs* HBV *vs* alcohol *vs* others); Child-Pugh class (A *vs* B); tumor size (≤ 3 cm *vs* > 3 cm); tumor number (single *vs* multiple); serum alpha-fetoprotein levels (<400 *vs* ≥ 400 ng/mL); serum protein induced by vitamin K absence or antagonist II (PIVKA-II) level (< 300 *vs* ≥ 300 ng/mL); and serum albumin level (≤ 3.5 *vs* > 3.5g/dL); serum alanine aminotransferase (ALT) level (<80 *vs* ≥ 80 U/L); serum bilirubin level (<2 *vs* ≥ 2 mg/dL); serum platelet count (<9 *vs* ≥ 9 × 10<sup>9</sup>/L); prothrombin activity (≤ 70 *vs* > 70%); encephalopathy (none *vs* yes); and ascites (none *vs* yes). As treatment factors, two variables were assessed in the univariate analysis: type of treatment (PEI *vs* RF ablation); and initial treatment response (successful *vs* unsuccessful). Significant variables (*P* < 0.05) were included in a stepwise Cox regression analysis. Data analyses were performed with SPSS software (version 10.0J; SPSS, Tokyo, Japan). All *P* values were derived from two-tailed tests and *P* < 0.05 was accepted as statistically significant.

## RESULTS

#### Treatment response and survival

In general, the percutaneous ablation procedures were well tolerated in all the patients. Both cardiac and respiratory parameters remained stable throughout the treatment. The regimen of conscious sedation and local anesthesia used in this study was adequate for these ablation methods. None of the patients experienced bleeding as a result of these percutaneous ablation techniques.

No local tumor residue was found in 125 of 153 (82%) patients as assessed by contrast enhanced CT 6 mo after the initial treatment (defined as successful initial treatment) (Figure 1). The remaining 28 (18%) patients judged as having residual viable tumor by contrast enhanced CT within 6 mo after the initial treatment (defined as unsuccessful initial treatment), were re-treated by RF ablation or PEI until no vascularities could be recognized within the tumor by contrast enhanced CT. With regard to the type of treatment, successful initial treatment was obtained in 90 (82%) of 110 patients treated with RF ablation, and in 35 (81%) of 43 patients treated with PEI, and no significant difference was observed between the two types of treatment. After a median follow-up of 34 mo (range, 1-66), the 1-, 3-, and 5-year survival rates were 95%, 75%, and 59%, respectively (Figure 2). At the time of the analysis, 83 (54%) patients had tumor recurrence

25 (58%) of 43 patients treated with PEI. Death was due to tumor progression in 18 patients and due to liver failure in 6 patients.

### Factors for survival

In the univariate analysis, 5 variables were associated with survival (Table 2). Of the pre-treatment factors, Child-Pugh classification, tumor size, serum albumin level, and serum PIVKA-II level were found to be significant predictors of survival. And of the treatment factors, initial treatment response was found to be a significant predictor of survival while the type of ablation therapy (RF ablation *vs* PEI) was not ( $P = 0.9829$ ). Multivariate analysis disclosed two independent predictors: serum albumin level ≤ 3.5g/dL *vs* > 3.5g/dL (risk ratio 3.216, 95%CI: 1.407-7.353,  $P = 0.0056$ ) and successful initial treatment *vs* unsuccessful initial treatment (risk ratio 2.474, 95%CI: 1.076-5.692,  $P = 0.0330$ ) (Table 3). When only pre-treatment factors were included in the multivariate analysis, serum albumin level (risk ratio 3.199, 95%CI: 1.405-7.281,  $P = 0.0056$ ) was proved to be an independent predictor.

The sole predictive factor for survival in patients with a serum albumin level > 3.5g/dL proved to be the initial treatment response; therefore the survival was examined

**Figure 3** Overall probability of survival according to initial treatment response. **A:** In patients with a serum albumin level > 3.5 g/dL; **B:** In patients with a serum albumin level ≤ 3.5 g/dL.

in case groups with serum albumin levels > 3.5g/dL (*n* = 103) and ≤ 3.5g/dL (*n* = 50) according to the initial treatment response. In patients with a serum albumin level > 3.5g/dL, the 1-, 3-, and 5-year survival rates in patients who were judged as having had a successful initial treatment were 100%, 86%, and 83%, respectively (*n* = 82), and the survival rates in patients who were judged as having had an unsuccessful initial treatment were 91%, 51%, and 51% at 1-, 3-, and 5-year, respectively (*n* = 21) (*P* = 0.0014) (Figure 3A). On the other hand, in patients with a serum albumin level ≤ 3.5g/dL, the multivariate analysis proved no independent predictors for survival. The survival rates in 43 patients with a successful initial treatment were 88% and 68% at 1 and 3 years, and in 7 patients with an unsuccessful initial treatment, the survival rates were 86% and 51% at 1 and 3 years, respectively (*P* = 0.3813) (Figure 3B).

Initial treatment response was significantly associated with the tumor number (*P* = 0.0031), tumor size (*P* = 0.0441), serum alpha-fetoprotein level (*P* = 0.0156), and serum PIVKA-II level (*P* = 0.0071), however it was not associated with the etiology of underlying cirrhosis, Child-Pugh class, and type of ablation therapy (Table 4).

## DISCUSSION

In the current study, we examined a group of HCC patients whose tumors were percutaneously treated using RF ablation or PEI and analyzed the predictors that contributed to the prognosis. Multivariate analysis

disclosed two independent predictors: serum albumin level and initial treatment response. In the cases with a serum albumin level > 3.5 g/dL, our data consistently showed that a successful initial treatment was the most predictive factor for long-term survival.

Examinations of the factor that could contribute to the long-term survival of patients undergoing percutaneous ablation therapy, have been reported previously; however, most of them were evaluations using PEI. Pompili *et al* evaluated the therapeutic efficacy of PEI for patients with Child-Pugh class A and tumors > 5 cm in diameter, and reported that alpha-fetoprotein level and liver function were factors which contributed to survival<sup>[21]</sup>. Ebara *et al* evaluated the therapeutic efficacy of PEI for patients with ≤ 3 lesions of small HCC, and found that alpha-fetoprotein level and liver function were factors contributed to the survival<sup>[22]</sup>. Recently, Sala *et al*<sup>[14]</sup> and Xu *et al*<sup>[23]</sup> reported the prognostic predictors after percutaneous ablation therapies. However, most of the cases were treated with PEI in the former study<sup>[14]</sup>, and in the latter study<sup>[23]</sup>, 63% of treated cases were recurrent HCC and the selection for ablation procedures (microwave *vs* RF ablation) was not fully clarified. To establish an optimal therapeutic protocol after the introduction of RF ablation, we started this cohort study after 2000 when RF ablation was introduced in our institution. In this study, 72% of the patients were treated with RF ablation, and this may reflect the current state of the available percutaneous ablation procedures.

In our study, the serum albumin level was shown as the most important pre-treatment predictor for survival. Hepatic functional reserve as indicated by the serum albumin level has generally been identified to be a good

prognostic factor for survival. The serum albumin level has been shown to be one of the prognostic factors in HCC patients treated with hepatic resection<sup>[24]</sup> and PEI<sup>[25]</sup>. Ikeda *et al* reported that the serum albumin level was one of the independent factors associated with the carcinogens in HCV positive viral hepatitis<sup>[26]</sup>. In this study, 88% of patients had hepatitis C virus infection; therefore, the serum albumin level is selected as a significant factor that may provide for the recurrence of HCC after successful percutaneous local ablation therapy.

Furthermore, initial treatment response was shown as a second significant predictor for survival. Sala *et al* recently reported that initial treatment response was an outcome predictor of the survival after ablation therapy and initial complete tumor necrosis should be considered a relevant therapeutic target irrespective of tumor size and liver function<sup>[14]</sup>. In the present study, the impact of extensive tumor necrosis on survival has been observed in patients with good liver functional reserve (serum albumin level > 3.5 g/dL); however, it was not found in patients with poor liver functional reserve (serum albumin level ≤ 3.5 g/dL). Therefore, in patients with poor liver function reserve, optimal selection of patients as candidates for ablation therapies and of the appropriate therapeutic schedule for each single patient to control the tumor growth, avoiding a clinically significant worsening of liver function, is essential to obtain an improvement in survival.

Treatment response was generally judged by CT at one month after the treatment based on the WHO criteria<sup>[15]</sup>, however in this study, the initial treatment response was judged by CT at 6 mo after the initial treatment. This difference of the surveillance after the initial treatment may be explained as follows. First, 22% of our patients underwent TACE prior to ablation therapy, so it was difficult to achieve a detailed evaluation of treatment response with CT because of dense lipiodol accumulation in the treated area<sup>[27]</sup>. Second, 72% of the patients received RF ablation therapy, resulting in an inflammatory increased vascular flow rim of the outline of the ablated zone for about one month following treatment, which can disturb the evaluation of the local treatment by contrast-enhanced CT<sup>[28]</sup>.

In this study, alpha-fetoprotein level, PIVKA-II level, tumor size, and tumor number were significant factors for the initial treatment response by univariate analysis. Although there are few reports which have examined the factors for initial treatment response following percutaneous ablation therapy, there are several reports as to what contributes to local recurrence when RF ablation is selected. Lencioni *et al* showed that tumor size and type of ablation therapy were the factors for local recurrence-free survival in those cases treated with RF ablation and PEI<sup>[29]</sup>. Lin *et al* reported that tumor number, tumor size, histopathological (Edmondson's) grade, and type of ablation therapy were significant factors of local recurrence<sup>[30]</sup>.

In summary, we demonstrated that the best candidates for percutaneous ablation therapy are those patients who have good hepatic functional reserve and can be expected to achieve successful initial treatment. Attempts to fully ablate large tumors (3-5 cm in diameter) are

achieved successfully by the combined use of TACE, however, further studies are needed to clarify whether or not the combined use of TACE in RF ablation will be a therapeutic option to achieve complete tumor necrosis for the treatment of large HCC tumors.

## Abstract

**AIM:** To elucidate the role of Rab23 in hepatocellular carcinoma (HCC) by assessing the expression of Rab23 in HCC tissue and in HCC cell lines.

**METHODS:** Primary tumors ( $n = 100$ ) were stained with Rab23 antibodies using immunohistochemistry and *in situ* hybridization in tissue microarrays. Relationships between gene expression and pathology parameters were analysed. The biological significance of Rab23 in Hep-3B cells was examined by knocking down Rab23 gene expression. We designed a pair of double-stranded RNAs against human rab23 and transfected siRNA into Hep-3B cells. Rab23 expression in these cells was examined using RT-PCR and Western blots. We investigated cell growth by MTT assays and fluorescence-activated cell sorting.

**RESULTS:** High cytoplasmic and nuclear expression of Rab23 was found in 38 of 71 (53.5%) and in 49 of 68 HCC patients (72%) respectively, which correlated with tumor size. HCC cell lines expressed Rab23. In Hep3B cells, siRNA for Rab23 decreased Rab23 mRNA by 4.5-fold and protein expression by 2-fold. Survival rates at 24 and 48 h for Hep-3B cells transfected with siRNA were lower and about 30% Hep-3B cells were apoptotic. Knocking down rab23 suppressed Hep3B cell growth, suggesting that rab23 could play an important role in Hep3B cell growth.

**CONCLUSION:** Rab23 is overexpressed and/or activated

## INTRODUCTION

Hepatocellular carcinoma (HCC) is the most frequent primary malignant tumor of the liver. HCC is the third leading global cause of cancer-related death. Over 54% of HCC cases occur in China. Hepatitis B virus is a common causal agent of liver cancer, and other factors have also been found. However, the molecular mechanisms contributing to tumor progression to HCC remain unknown<sup>[1]</sup>.

In recent years, targeted therapies for a variety of HCCs have achieved clinically significant response rates and have given oncologists the chance to develop individual-based strategies for patient therapy. One rationale for such therapeutic approaches is to detect target molecules in the tumor. There is a growing list of such target molecules, the levels of which are now routinely estimated by IHC staining in biopsy specimens or surgically removing tumor material. Such assays not only generate important data for therapeutic decisions, but also provide information relevant to the prognosis of patients<sup>[2]</sup>.

An example is targeting of the hedgehog (Hh) pathway. Dysregulation of this pathway has been implicated in the genesis of cancers from multiple tissue types<sup>[3]</sup>. Moreover, from embryogenesis to adulthood, skin and gastrointestinal progenitors are regulated by Hh signaling<sup>[4-6]</sup>. This pathway is activated when sonic hedgehog (SHH) or Indian hedgehog (IHH) ligands bind to their receptor, patched (PTC). When unoccupied by ligand, PTC is a tumor suppressor that binds to and represses smoothened (SMO)<sup>[7]</sup>, preventing the SMO proto-oncoprotein from

activating downstream transcription factors, such as Gli1. Conversely, when ligand binds to PTC, SMO is released and Gli1 is activated, resulting in the transcription of target genes including PTC and Gli1<sup>[7]</sup>. Hh signaling is now known to play a critical role in the gastrointestinal tract in both health and disease. Most recently, two research groups have simultaneously reported abnormal activation of the SHH pathway in HCC<sup>[8,9]</sup>. Although the investigators paid much attention to the relationships between hedgehog signaling and HCC, little is known about this pathway in carcinogenesis.

One regulator of SHH signaling is Rab23. In 1994, the full-length cDNA encoding Rab23, a novel Ras-related small GTPase, was isolated using the sequence of a previously described GTPases<sup>[10]</sup>. Northern analysis revealed that Rab23 mRNA is predominantly expressed in the brain, which places the protein together with Rab3a and Rab15, in the group of small GTPases characteristic of the nervous system<sup>[11]</sup>. Rab23, a new member of the RAB family expressed in retina, is composed of 7 exons spanning a 34 kb domain of genomic DNA. It is located in the pericentromeric region of chromosome 6 between microsatellite markers D6S257 and D6S1659, within the critical region of RP25<sup>[12]</sup> and localized at the plasma membrane and the endocytic pathway<sup>[12,13]</sup>. Rab23 is a negative regulator of SHH<sup>[13,14]</sup>. It acts on upstream of Gli transcription factors in patterning neural cell types in the spinal cord. The primary target of Rab23 is the Gli2 activator. Rab23 and Gli3 repressors have additive effects on patterning. Analysis of Gli3 protein suggests that Rab23 also has a role in promoting the production of Gli3 repressor. Although the patched and smoothened membrane proteins can change subcellular location in response to SHH, analysis demonstrates that Rab23 does not work through either patched or smoothened membrane protein. Instead, Rab23 appears to regulate subcellular localization of essential components of the hedgehog pathway that act both on downstream of smoothened and on upstream of Gli proteins<sup>[15]</sup>.

Until now there have no reports about Rab23 expression in HCC or even in other human tumors. Since Rab23 is a negative regulator of SHH signaling which can induce malignant carcinoma, dysregulation of Rab23 also may result in HCC. If it is true, we may be able to find a new target for diagnosis and treatment of HCC. In the present study, we evaluated the hypothesis that increases in Rab23 signaling induce hepatocarcinogenesis by regulating Hh signaling in HCC tissues.

## MATERIALS AND METHODS

### Overall experimental design

We compared Rab23 expression in non-neoplastic and malignant human livers by IHC and *in situ* hybridization using tissue microarrays. Furthermore, since it has been confirmed that there is hedgehog signaling in Hep-3B cells<sup>[8,9]</sup>, we examined the biological significance of the Rab23 gene in Hep-3B cells by knocking down Rab23 gene expression. To identify a possible role of Rab23

**Figure 1** *In situ* hybridization using tissue microarrays.

in HCC, we designed a pair of double-stranded RNAs (dsRNAs) against human Rab23, and transfected siRNAs into Hep-3B cells. We examined Rab23 expression in these cells using RT-PCR and Western blots. We investigated cell growth by MTT assays and fluorescence-activated cell sorting.

### Patient material

HCC samples from 100 patients were used in this study. All of them were from Sun Yat-Sen University (Guangzhou, China) and selected over a 4-year period (1993-1997). Twenty-five tumor adjacent liver tissue samples were also used. None of the patients received chemotherapy or radiation therapy. Each specimen was fixed in alcoholic formalin for 8-12 h and embedded in paraffin.

### Construction of tissue microarray

A hundred archived formalin-fixed and paraffin-embedded anonymous, representative specimens of HCC were also assessed. Non-necrotic areas in tumor for coring into a tissue microarray (TMA) were marked using an indelible pen on a hematoxylin and eosin (HE) stained whole section from donor blocks. TMAs were assembled from formalin-fixed and paraffin-embedded tumor tissue samples as previously described<sup>[16]</sup> by using a precision instrument (Beecher Instruments, Silver Spring, MD). Cores (600  $\mu$ m in diameter) were randomly arrayed in triplicate across the recipient block with asymmetrical placement for orientation. TMA coordinates and clinicopathological data were stored for reference. TMA slides were sectioned and mounted on Superfrost<sup>®</sup>/Plus microscope slides as 6- $\mu$ m sections (Figure 1). Hematoxylin and eosin (H&E) stained TMA sections were used as morphological references.

### Immunohistochemistry

Paraffin-embedded tissue sections were deparaffinized. Slides from each case were exposed to affinity purified rabbit anti-Rab23 primary antibody (BD Biosciences, San Jose, CA, USA) and diluted in PBS for 2 h at room temperature. Detection was carried out using Elivision™ Plus Polymer HRP (Mouse/Rabbit) immunohistochemistry kits (Maixin.Bio, Fuzhou, China). Location of peroxidase was visualized with diaminobenzidine (DAB). Hematoxylin was used for counterstaining. Sections were thoroughly washed with PBS between steps. Negative controls (absence of primary antibody) were run for each experiment. We defined a positive sample as one in which more than one third of one tissue chip was stained brown.

### In situ hybridization

*In situ* hybridization was performed according to the manufacturer's instructions (Roche Molecular Biochemicals, Mannheim, Germany) and the published *in situ* hybridization protocol<sup>[17,18]</sup>. Sense and antisense probes were obtained by T3 or T7 *in vitro* transcription using a DIG RNA labeling kit from Roche (Mannheim, Germany). Rab23 (AY585189) was cloned into BamHI of pBluescriptSK+. Tissue sections (8-μm thick) were mounted onto poly-L-lysine slides. Following deparaffinization, tissue sections were rehydrated in a series of ethanol dilutions. To enhance the signal and facilitate probe penetration, sections were immersed in 0.3% Triton X-100 solution for 15 min at room temperature and in proteinase K solution (20 μg/mL) for 20 min at 37°C, respectively. Sections were incubated with 4% (w/v) paraformaldehyde/phosphate-buffered saline (PBS) for 5 min at 4°C. After washed with PBS, slides were incubated with prehybridization solution (50% formamide, 50% 4 × SSC) for 2 h at 37°C. Probe was added to each tissue section at a concentration of 1 μg/mL and hybridized overnight at 42°C. After high stringency washing, the sections were incubated with an alkaline phosphatase-conjugated sheep anti-digoxigenin antibody, which catalyzes a color reaction with nitro-blue-tetrazolium (NBT)/5-bromo-4-chloro-3-indolyl phosphate (BCIP) substrate (Roche, Mannheim, Germany). A blue color indicated strong hybridization.

### Culture of Hep-3B cell line

Hep-3B cells kindly donated by Professor Shi-Gang Xiong (Department of Pathology, Keck School of Medicine, University of Southern California, USA.), were cultured in Dulbecco's minimal essential medium (DMEM; Gibco BRL, Gaithersburg, MD, USA) supplemented with 10% fetal bovine serum (FBS; Bio-Whittaker, Walkersville, MD, USA), 100 IU/mL penicillin, and 100 μg/mL streptomycin. Cultures were incubated at 37°C in a humidified atmosphere containing 50 mL/L CO<sub>2</sub>, and the medium was changed twice a week. Cell viability was tested by trypan blue exclusion. All experiments were performed with Hep-3B cells from passages 6-15, which were exposed to serum-free culture medium containing 0.1% bovine serum albumin for 24 h.

**Figure 2** Rab23 gene silencing in Hep-3B cells. Green fluorescence could be detected in siRNA-transfected Hep-3B cells (negative control group).

### Rab23 gene silencing in Hep-3B cells

Hep-3B cells were harvested by trypsinization and seeded 24 h prior to transfection, on 6-well plates at a density of 300 000 cells/well in 2 mL DMEM with 10% FBS. When the Hep-3B cells were at 90%-95% confluence, the culture medium was replaced with 1 mL of DMEM with or without 10% FBS. Following an overnight incubation, cells received 1 mL of complete medium and were incubated until 72 h post transfection.

According to the design principle of siRNA<sup>[19-21]</sup>, short interfering RNA for Rab23 and negative control siRNA were designed. The target gene sequence of Rab23 is 5'-3' CCA GAA CTA ACG CAT TCA TCA A. The siRNA sequence (siRNA Duplex) is CCA GAA CUA ACG CAU UCA A dT dA dAdT GGU CUU GAU UGC GUA AGU U. The sequence of negative control siRNA is: sense 5'-UUC UCC GAA CGU GUC ACG UTT-3', Anti-sense 5'-ACG UGA CAC GUU CGG AGA ATT-3'. Short interfering RNAs (siRNAs) for Rab23 were purchased from Guangzhou Ribobio CO., Ltd (Guangzhou, China) and negative control siRNAs were purchased from Shanghai GenePharma Co., Ltd (Shanghai, China). Double-strand RNA (final concentration of 50 and 100 nmol/L) in OPTI-MEM (80 μL) and oligofectamine (4 μL) in OPTI-MEM (15 μL) were mixed and allowed to stand at room temperature for 20 min according to the manufacturer's directions (Invitrogen, Carlsbad, USA). The mixture was added directly into a culture of Hep-3B cells (1 × 10<sup>5</sup>/mL) in OPTI-MEM (0.4 mL). After 24 h, the consequences of transfection were watched through fluorescence of the cells (Figure 2). Transfection efficiency was normalized by monitoring luciferase activity from total cell lysates using the firefly luciferase (FLuc) assay kit (Promega, madison, USA). Cells were analyzed after 12 h by MTT assay. After 48 h they were analyzed by fluorescence-activated cell sorting, Western blots and RT-PCR. All experiments were performed in triplicate.

### RNA isolation and two-step real-time RT-PCR

Two-step real-time RT-PCR was performed to compare the expression of Rab23 in normal liver tissue samples and Hep-3B cell lines. Total RNA was extracted using

TRIzol reagent (Sigma) according to the manufacturer's instructions. Reverse transcription with oligo (dT) priming was used to generate cDNAs from total RNA (2 µg) extracts. The synthesized cDNAs for Rab23 and  $\beta$ -actin were amplified using specific sets of primers. Optimal oligonucleotide primers were designed using Beacon Designer 2.0 software (MWG Biotech, High Point, NC). The primers used to amplify human Rab23 were synthesized according to the following sequences: forward primer: 5' GTA GTA GCC GAA GTG GGA 3', reverse primer: 5' CCT TTG TTT GTT GGGTCT C 3' according to ABO34244 in the gene bank.  $\beta$ -actin primer was designed based on published cDNA sequences: forward primer 5'TCA TCA CCA TTG GCA ATG AG3', reverse primer 5' CAC TGT GTT GGC GTA CAG GT 3'. Each PCR mixture contained the appropriate set of forward and reverse primers (0.2 µmol/L), each dNTP at 0.25 mmol/L, 1.25 U Taq polymerase, and 2.5 mmol/L MgCl<sub>2</sub> in a PCR buffer. The PCR procedure consisted of 28 cycles of denaturation at 95°C for 1 min, annealing at 58°C for 1 min, and extension at 72°C for 1 min, with initial denaturation of sample cDNA at 95°C for 3 min and an additional extension period of 10 min after the last cycle. The PCR products were subjected to 1.5% agarose gel electrophoresis stained with ethidium bromide and quantitated by densitometry using an Image Master VDS system and associated software (Pharmacia, USA).

#### Protein extraction and Western blotting

Cells were washed with cold PBS and lysed by the addition of a lysis buffer containing 1% Nonidet P-40, 50 mmol/L Tris (pH 7.5), 150 mmol/L NaCl, 0.1% SDS, and protease inhibitor cocktail (Boehringer Mannheim, Lewes, U.K.) for 20 min at 4°C. Insoluble materials were removed by centrifugation at 15000 r/min for 15 min at 4°C. The supernatant was saved and the protein concentration was determined using a Bio-Rad protein assay kit (Bio-Rad, Hercules, CA). Cell extracts (50 µg/lane) were separated *via* 10% gel electrophoresis and electroblotted onto PVDF membranes. Nonspecific binding sites were blocked by incubating nitrocellulose sheets for 1 h in phosphate-buffered saline containing 5% low-fat dry milk. Membranes were probed with primary antibodies overnight at 4°C, followed by a secondary horseradish peroxidase-conjugated second antibody. Blots were developed using an enhanced chemiluminescence detection system (ECL, Amersham Pharmacia Biotech) according to the manufacturer's instructions.

#### MTT assay

The cell proliferation and viability were determined by MTT assay as previously described<sup>[18]</sup>. Briefly, cells (5 × 10<sup>3</sup> cells per well) were seeded in 96-well microtiter plates (Nunc, Denmark). After different treatments for 12, 24, 48 h or 72 h, an aliquot (50 µL) of MTT (Sigma) solution (2 mg/mL in PBS) was added to each well and the plates were incubated for an additional 4 h at 37°C. MTT solution in medium was aspirated off. To achieve solubilization of the formazan crystal formed in viable cells, 150 µL DMSO was added to each well. The absorbance was read

at 490 nm on a Dias automatic microwell plate reader with DMSO as the blank.

#### Fluorescence-activated cell sorting

After treatment for 48 h, cells were washed with cold sterile phosphate-buffered saline (PBS), and harvested in 70% cold alcohol solution for immediate analysis in a Becton Dickinson FACScan flow cytometer (Becton Dickinson, San Jose, CA). Data were acquired and analyzed using CellQuest software (BD Biosciences). The flow cytometer was calibrated daily with CaliBRITE 3 (BD biosciences) for fluorescence sensitivity and spectral overlap.

#### Statistical analysis

For immunohistochemistry and *in situ* hybridization results, Fisher's exact test or a binomial proportion analysis was used.  $P < 0.05$  was considered statistically significant. Results of RT-PCR, Western blotting and MTT assays were expressed as mean ± SE of at least three separate experiments. Results were analyzed by one-way analysis of variance (ANOVA) followed by the Student-Neumann-Keuls test. Again, differences with  $P$  values of  $< 0.05$  were considered statistically significant.

## RESULTS

#### Expression of Rab23 in normal liver tissues and HCCs by immunohistochemistry

The expression of Rab23 in normal liver tissues has not been reported. Slight or no membranous staining of Rab23 in normal liver tissue was detected in our study. There was also no cytoplasmic or nuclear staining of Rab23 in normal liver tissues (Figure 3A). Conversely, expression of Rab23 was found in HCCs, and the expression rate was 53.5% (38 of 71 samples were positive, Table 1). Most samples expressed Rab23 in nuclei of HCC cells (Figure 3B and C). The results of expression of Rab23 correlated with tumor size ( $P < 0.01$ , Table 1), suggesting that Rab23 might be a useful prognostic indicator in HCC.

#### Expression of Rab23 in normal liver tissue and HCCs by *in situ* hybridization

No expression of Rab23 could be detected by *in situ* hybridization in five normal liver tissue samples (Figure 3D). To confirm this result, we also checked the transcripts by RT-PCR, and got the same result (data not shown).

To assess the frequency of Rab23 activation in HCC, we examined its expression in tissue samples derived from 100 different HCC cases (Table 1). We found positive staining for Rab23 in 38 of 71 (72%) HCC cases (Figure 3E and F). Further analyses again showed that activation of Rab23 correlated with tumor size ( $P < 0.01$ , Table 1).

#### Low expression of Rab23 in Hep-3B cell line when it was silenced by siRNA

Hep-3B cells were divided into three groups: a transfected group, a blank control group, and a negative control group. After 24 h of treatment with siRNA, Hep-3B cells were

Statistical analysis was performed by Fisher's exact test or Binomial proportions analysis. A *P* value < 0.05 was considered statistically significant. Pos: positive signal; Neg: Negative signal; Well: Well-differentiated tumors; Mod-poor: Moderately to poorly differentiated tumors.

**Figure 4** Electrophoresis of the RT-PCR products of Rab23 mRNA in Hep-3B cells after being silenced by siRNA. Lane 1: marker 1500; Lane 2: blank control group; Lane 3: transfection group; Lane 4: negative control group.

harvested and total RNA was extracted. RT-PCR was done as described previously<sup>[18]</sup>. The expression levels in the transfected group decreased almost 4.5 fold compared with the blank control group. There was no statistical significance between the blank control group and the negative control group (Figure 4, Figure 5, Figure 6).

#### Expression of Rab23 protein in Hep-3B cells decreased when it was silenced by siRNA

We used the same method for preparing Hep-3B cells for Western blots as for preparing cells for RT-PCR. After 24 h of treatment, Hep-3B cells were harvested and protein was extracted. Western blots were run according to a protocol described previously<sup>[22]</sup>. The expression levels in the transfected group decreased to almost half the level of the blank control group. There was no statistical

**Figure 5** Electrophoresis of the RT-PCR products of  $\beta$ -actin mRNA in Hep-3B cells. Lane 1: marker 1500; Lane 2: blank control group; Lane 3: transfection group; Lane 4: negative control group.

**Figure 7** Western blot results for Rab23 in Hep-3B cells after being silenced by siRNA. Lane 1: blank control group; Lane 2: transfection group; Lane 3: negative control group.

**Figure 9** The results of MTT assays. At 48 h and 72 h, growth of Hep-3B cells was inhibited after being interfered by siRNA against Rab23 gene. the survival rate of the transfection group decreased compared with controls.  $P < 0.01$  vs control group. Again, there was no significant difference between blank and negative control groups,  $P > 0.05$ .

significance between the blank control group and the negative control group (Figure 7, Figure 8).

#### Viability of Hep-3B cells decreased after being transfected

Here we determined whether inhibition of the expression of Rab23 in Hep-3B cells also inhibits the proliferation of these cells by MTT assay. Forty-eight hours and 72 h after adding siRNA, the survival rate of the transfected group decreased compared with controls ( $P < 0.05$ , Figure 9). Again, there was no significant difference between the blank and negative control groups.

**Figure 6** Electrophoresis of the RT-PCR products of Rab23 mRNA in Hep-3B cells after being silenced by siRNA. Lane 1: blank control group; Lane 2: transfection group; Lane 3: negative control group. <sup>a</sup> $P < 0.05$  vs control.

**Figure 8** Western blot result for Rab23 in Hep-3B cells after being silenced by siRNA. Lane 1: blank control group; Lane 2: transfection group; Lane 3: negative control group. <sup>a</sup> $P < 0.05$  vs control.

#### Apoptosis rate of Hep-3B cells increased after the Rab23 gene was silenced by siRNA

Forty-eight hours after siRNA treatment, Hep-3B cells were tested by fluorescence-activated cell sorting. Apoptosis skewness was seen in the transfected group. The apoptotic rate of Hep-3B was 30% in the blank control group but 0% in the negative control groups (Figure 10).

## DISCUSSION

The worldwide incidence of liver cancer is expected to rise over the next decade. This is serious because the prevalence and mortality rate of HCC are rather high at present<sup>[23]</sup>. Furthermore, the mechanisms underlying the initiation and progression of HCC remain elusive. One candidate mechanism involves the hedgehog (Hh) pathway. Dysregulation of this pathway has been implicated in the genesis of several kinds of cancer derived from multiple tissue types<sup>[3]</sup>, including HCC<sup>[8,9]</sup>. One aspect of Hh signaling is negative regulation of this pathway by Rab23<sup>[13,15]</sup>. Rab23 acts on upstream of Gli transcription factors in patterning neural cell types in the spinal cord. The primary target of Rab23 is the Gli2 activator. Rab23 and Gli3 repressor have additive effects on patterning. Analysis of the Gli3 protein suggests that Rab23 also has a role in promoting the expression of Gli3 repressor. Although the membrane proteins patched and smoothened can change subcellular location in response to SHH, analysis demonstrates that Rab23 does not work through either patched or smoothened. Instead, Rab23 appears to

**Figure 10** Apoptotic rate of Hep-3B cells measured by flow cytometry. in negative control (A), blank control (B) and transfected (C) groups.

regulate subcellular localization of essential components of the hedgehog pathway that act both on downstream of smoothened and on upstream of Gli proteins<sup>[14]</sup>.

There are no reports about studies of Rab23 in HCC or even in any other human tumors. Since Rab23 is a negative regulator of SHH which can induce malignant carcinoma, Rab23 may also contribute to tumorigenesis in HCC.

Our results identify one potential mechanism underlying hepatocarcinogenesis, namely dysregulation of Rab23 and SHH signaling. In this study, we found that the aberrant expression of Rab23 was a general event during the development of HCC, and that the expression of the Rab23 gene correlated with tumor size. These findings are strongly supported by our studies of Hep3B cells in

which Rab23 was silenced by siRNA, which inhibited cell proliferation and increased apoptosis. Further studies are now needed to identify the mechanisms by which Rab23 expression might contribute to dysregulation of SHH signaling and HCC tumorigenesis. Rab23 plays an important role in tumorigenesis of HCC and other human tumors. Also, Rab23 may be a new biological target for prognosis and treatment of HCC.

normal tissue and colorectal adenoma tissue by nested RT-PCR assay. The positive rate of FHIT gene expression in normal colorectal tissue, colorectal adenoma and carcinoma tissue was 93.75%, 68.75% and 46.25%, respectively. Clinicopathological analysis of patients showed that the decreased FHIT gene expression was not associated with age, sex, serum CEA levels, tumor site and size, histological classification. However, the expression of FHIT was correlated with differentiation grades, pathological stages, lymph node metastases and 5-year survival rate after operation. The positive rate of apoptosis-associated proteins (Bax, Bcl-2 and survivin) in CRC tissue was 72.50%, 51.25% and 77.50%, respectively. The expression of these apoptosis-associated proteins in CRC tissue was correlated with the expression of FHIT. The mean apoptosis index in FHIT negative tumors was significantly lower than that in FHIT positive tumors ( $5.41 \pm 0.23$  vs  $0.56 \pm 0.10$ ,  $P < 0.01$ ).

**CONCLUSION:** The FHIT gene plays an important role in the regulation of apoptosis and decreased FHIT expression plays a key role in the initiation and progression of colorectal carcinoma.

### Abstract

**AIM:** To detect the expression of fragile histidine triad (FHIT) in normal colorectal tissue, colorectal adenoma and colorectal cancer (CRC) tissue, and to analyze its relationship with the clinicopathological features of CRC, and apoptosis-associated proteins (Bcl-2, Bax, survivin) and apoptosis in colorectal cancer.

**METHODS:** FHIT mRNA analysis was performed by nested reverse transcription-polymerase chain reaction (RT-PCR) assay. Tissue microarray (TMA) was established to detect the expression of FHIT, Bcl-2, Bax and survivin genes in 80 CRC tissue specimens, 16 colorectal adenoma tissue specimens and 16 hemorrhoid (PPH) tissue specimens during the same period of time as the control. Citrate-microwave-SP was used as immunohistochemical method. The relationship between clinicopathological factors, such as differentiation grades and 5-year survival rate was observed. TUNEL assay was used to detect the apoptosis index in 80 CRC tissue specimens.

**RESULTS:** Ten out of 26 (38.5%) CRC tissue specimens expressed aberrant FHIT transcripts, none of the aberrant FHIT transcripts was observed in the matched

### INTRODUCTION

Colorectal cancer is the second leading cause of death in the United States, where the cumulative lifetime risk of developing colorectal cancer in both men and women is 6%<sup>[1]</sup>. In China, colorectal cancer is the fourth leading cause of death<sup>[2]</sup>.

The fragile histidine triad (FHIT) gene, is a tumor suppressor gene located at the fragile site FRA3B on chromosome 3p14.2 that can be identified by positional

cloning, a region of the genome showing loss of heterozygosity (LOH) in a variety of cancers<sup>[3,4]</sup>. FHIT is involved in carcinogenesis of many human tissues, including digestive tract tissue. The FHIT gene contains an open reading frame (ORF) of 444 base pairs (bps) encoding a protein of 147 amino acids, which appears to be ubiquitously expressed in human tissues. Large deletions within FHIT transcripts occur frequently in multiple malignancies<sup>[5,6]</sup>. Most of the deletions described to date in the FHIT gene involve loss of one or more coding exons and lead to a truncated protein<sup>[6]</sup>. Loss of FHIT protein expression and abnormal FHIT transcripts, including deletions and insertions of exons, have been found in lung and breast cancers, as well as in head and neck cancers<sup>[7-11]</sup>. Ohta *et al.*<sup>[3]</sup> reported that aberrant transcripts of the FHIT gene have been observed in 38% of CRC cases. It was also reported that the FHIT gene plays an important role in both oncogenesis and progression of CRC<sup>[12-14]</sup>. However, Thiagalingam *et al.*<sup>[15]</sup> showed that there is no evidence that the FHIT gene is involved in CRC carcinogenesis. The clinicopathological significance of FHIT alterations in CRC still remains unclear.

The role of FHIT expression in the development of colorectal cancer (CRC) is poorly understood. Recently, tissue microarray (TMA) technique has been developed, which can significantly increase the throughput of immunohistochemistry (IHC) tumor analysis. TMA is composed of a large number of small tissue cores punched out from different tumors. These tissue core specimens obtained from tissue blocks, are then arranged into a single recipient paraffin block<sup>[16]</sup>. This approach allows analysis of a large number of different tumor samples in one IHC experiment. Arrays as large as 1000 samples have been reported<sup>[17]</sup>. TMA can be used to test the prognostic significance of antibodies against proteins encoded by differentially expressed genes using a large number of archival patient samples. Decreased p53 expression is correlated with lymph node metastasis in CRC<sup>[18]</sup>. In our present study, an expanded repertoire of TMA technique was used to demonstrate the novel relationship between FHIT expression and clinicopathological factors, such as differentiation, pathological stages, lymph node metastasis and 5-year survival rate.

The presence of FHIT gene mutations correlates significantly with decreased FHIT expression in human CRC. Several well integrated biochemical subroutines promote CRC cell growth and inhibit apoptosis, tipping the balance of colon epithelial cells towards an unrestricted proliferation and outliving the sequence of mutations required for carcinogenesis. Apoptosis is essential for successful embryonic development and maintenance of normal tissue homeostasis<sup>[19]</sup>. The present study was to test the hypothesis that decreased FHIT expression inhibits apoptosis and decreases apoptosis-associated protein expression, to characterize FHIT mRNA and protein expression in normal colorectal tissue, and adenoma and adenocarcinoma tissue, and to investigate the mechanism of FHIT gene inactivation and its association with apoptosis inhibition in the development and progression of human CRC.

## MATERIALS AND METHODS

### *Colorectal carcinoma tissue samples*

Human colorectal tissue specimens were obtained from patients at the Department of Gastrointestinal Surgery, Affiliated Guangzhou First People's Hospital, Guangzhou Medical College, China, from January 1997 to June 2000. All tissue specimens were snap-frozen and stored at -80°C. There were 48 male and 32 female patients with an average age of 62 years (range 32-81 years). Of the 80 specimens of human colorectal carcinoma we examined, 20, 22, 23 and 15 were classified as Dukes' stage A, B, C and D, respectively. Histologically, well-differentiated CRC was found in 16, moderately-differentiated CRC in 44, and poorly-differentiated in 22 specimens, respectively (Table 1). As a control, 16 normal colorectal tissue specimens and 16 colorectal adenoma specimens were also obtained. These tissue specimens were snap-frozen in liquid nitrogen, embedded in paraffin and stored at -80°C. Sections of each paraffin block were stained with hematoxylin and eosin.

### *RT-PCR assay*

Total RNA was isolated from 26 colorectal cancer and 26 normal adjacent colonic tissue specimens, and 14 adenoma and 14 normal adjacent colonic tissue specimens with TRIzol<sup>TM</sup> reagent (Life Technologies). Nested RT-PCR was carried out as described previously<sup>[20]</sup>. A 24 µL mixture of total RNA (10 µg), 0.4 mmol/L oligo (dT) (New England Biolabs), and QH<sub>2</sub>O was prepared. After incubation for 10 min at 70°C, the mixture was quickly cooled on ice, and 16 µL of RT-PCR mixture containing 8 µL of 5 × first strand buffer (Invitrogen) (250 mmol/L Tris-HCl pH 8.3, 375 mmol/L KCl, 15 mmol/L MgCl<sub>2</sub>), 4 µL of 0.1 M DTT (Invitrogen), 2 µL 10 mmol/L deoxynucleotide mixture (dATP, dTTP, dCTP and dGTP, 10 mmol/L each) (Roche), 2 µL of RNase inhibitor (40 U/µL) (Roche) was added. The reaction proceeded in GeneAmp 2400 (Applied Biosystems) at 45°C for 2 min. After 400 U of SuperScript<sup>TM</sup> RnaseH-reverse transcriptase (200 U/µL) (Invitrogen) was added and incubated for 45 min at 60°C, the reaction was inactivated at 70°C for 15 min and at 94°C for 3 min. cDNA was used as a template in the following RT-PCR.

### *Mutation analysis of FHIT mRNA transcripts and aberrant splicing in human CRC by sequencing*

Mutation screening in aberrant RT-PCR products was performed using an ABI 377 automated sequencer with a pEGM-T vector as described previously<sup>[21]</sup>. Aberrant migrating bands were directly sequenced after isolation of bands from low melting agarose and purification on columns.

### *Analysis of FHIT, Bax, Bcl-2 and survivin protein expression by TMA-IHC*

**Construction of tissue microarray (TMA):** Archival paraffin-embedded, formalin-fixed tissues from 80 Chinese CRC, 16 colonic adenoma and 16 noncancerous normal mucosa patients were collected. Two independent experienced pathologists selected representative areas from

each donor tumor block, and then one 1-mm core was taken from a representative area of the tumor and inserted into a recipient paraffin block to create the TMA<sup>[6]</sup>. One TMA slide contained 112 samples. We employed the TMA technique to explore the expression of FHIT, Bax, Bcl-2 and survivin in colorectal tumor specimens and its correlation with apoptosis status by TMA-IHC and TMA-TUNEL. We investigated consecutively-cut serial sections and examined the same tumor region in three dimensions.

**Immunohistochemical analysis of FHIT, Bax, Bcl-2 and survivin expression in human CRC by TMA-IHC:** Immunohistochemical studies were performed using a citrate-microwave-streptavidin peroxidase technique. Immunohistochemical detection was done using anti-FHIT, anti-Bax, anti-Bcl-2 and anti-survivin antibodies, respectively. Endogenous peroxidase activity was quenched by methanol containing 3% hydrogen peroxide (Sigma, Taufkirchen, Germany). Nonspecific binding was blocked by applying normal rabbit serum in a humidity chamber at a dilution of 1:10 for 30 min. Primary antibodies were applied overnight at 4°C. The secondary antibody (goat to mouse immunoglobulins, DAKO, Denmark) was applied for 1 h at room temperature. Peroxidase-antiperoxidase (PAP rabbit, DAKO) conjugate diluted at 1:100 in phosphate-buffered saline (PBS) was applied for 45 min at room temperature. The sections were stained with diaminobenzidine tetrahydrochloride (DAB, Sigma) and then counterstained with hematoxylin. Negative control staining was performed by omitting the primary antibody. As a positive control for FHIT protein in immunohistochemical studies, we used paraffin sections of lung cancer positive for FHIT protein.

**Quantitative measurements:** Quantitative analysis of immune reactions related to the total tissue area was performed. We measured the percentage of positive immune reactivity with these antibodies in the tissue epithelium (normal and tumor). Histological images were

captured with an OLYMPUS BX50 system microscope with an objective at magnification X 40, through a video camera, and digitized by appropriate software. In each section, 500 cells per core were calculated. The relative level of specific immunostaining and its localization were also judged. The relative intensity of cell immunostaining was evaluated semi-quantitatively. The data of tissue array were confirmed by a pathologist at the Department of Pathology of Affiliated Guangzhou First People's Hospital.

**Hierarchical clustering and tree-view analysis:** Hierarchical clustering was performed by the Cluster program (available at <http://rana.lbl.gov/>) as described previously in two dimensions: tumors were grouped together based on the relation of their immunostaining profiles, and antibodies were grouped based on tumors they stained. The clustered data were visualized with the Tree-view software tool programs originally developed for analyzing cDNA microarray data (Available at <http://rana.lbl.gov/>), which graphically displayed the results of the analysis as dendrograms and arrays, wherein the rows and columns corresponded to the raw staining data, presented in the order determined.

#### Detection of cell apoptosis state in human CRC by TUNEL assay

Cell apoptosis was detected in 80 CRC specimens by TMA-TUNEL assay (Apotag Peroxidase Kit, Oncor, Gaithersburg, MD) with the Apop-Tag<sup>TM</sup> peroxidase kit (Zhongshan Biotech, Beijing). For the evaluation of TUNEL index, the number of TUNEL-positive colonic epithelial cells was recorded using the × 40 objective lens. The case was considered positive for TUNEL if any colonic epithelial cells showed TUNEL staining. The TUNEL index was determined as the number of TUNEL-positive colonic epithelial cells expressed as a percentage of the total number of counted colonic epithelial cells. Necrotic areas were excluded.

#### Statistical analysis

Results were presented as mean ± SD. All statistical analyses were carried out using SPSS 11.0 for Windows statistical software (SPSS Inc, USA). The relationship between the clinicopathological variables and FHIT loci and protein alterations was examined by Fisher's exact test. The relationship between the expression of FHIT and prognosis of CRC was analyzed by Cox-Mantel test. *P* < 0.05 was considered statistically significant. All experiments were performed three times.

## RESULTS

#### Analysis of aberrant splice of FHIT gene in human CRC

Expression of FHIT mRNA was detected by nested RT-PCR. According to the results, 34.6% samples with abnormal FHIT expression displayed two transcript categories: normal FHIT transcript (PCR products = 707 bp) and aberrant FHIT transcript (PCR products = 336 bp and 239 bp), respectively (Figure 1). However, the samples with normal FHIT expression only showed a normal FHIT transcript size.

**Figure 1** Frequency of intragenic deletions in FHIT transcripts in human CRC. Gel photo of FHIT RT-PCR products showing that the full length FHIT was the predominant transcript in samples 1-3, 5, 7 and 9. Both full length FHIT and shorter fragments representing transcripts containing deletions in FHIT could be seen in samples 4, 6 and 7. The arrow shows the gel position of splice variants.

**Figure 2** Sequencing analysis of aberrant FHIT transcripts. **A:** Deletion of exons 4-6 in the FHIT gene; **B:** Deletion of exons 4-8 in the FHIT gene.

**Figure 3** TMA-IHC assay showing significantly decreased FHIT expression in normal colonic mucosal samples (**A**), CRC tissue samples (**B**), and magnified views of the respective samples **A** and **B** (**C** and **D**).

### Mutation analysis of FHIT gene in human CRC by sequencing

Aberrant RT-PCR products were sequenced after isolation of bands from low melting agarose and purification on columns. In the 336 bp fragment, Exon 3 was spliced to exon 7 (E3/E7), and thus the transcript lacked exons 4-6 (Figure 2A). In the 239 bp fragment, Exon 3 was spliced to exon 9 containing an E3/E9 aberrant transcript (Figure 2B).

### Clinicopathological features and their relation to expression of FHIT in human CRC

The correlation between FHIT protein expression and clinicopathological data in the 80 carcinoma specimens is shown in Table 1, and a photograph of a representative specimen is provided in Figure 3. FHIT negative CRC was found in 43 and FHIT positive CRC was found in 37 specimens. Fifty-three percent (32 of 60) of specimens with well-differentiated CRC had positive

**Figure 4** Relationships between FHIT expression and CRC differentiation grade (A) and stage (B), and survival rate (C) CRC patients.

FHIT expression, whereas 25% (5 of 20) of specimens with poorly-differentiated CRC had positive FHIT expression ( $P < 0.05$ ), while 93.75% (15 of 16) and 75% (12 of 16) had positive FHIT expression in the normal colorectal tissue specimens and colorectal adenoma specimens, respectively (Figure 4A and Table 1). Sixty percent (27 of 45) of specimens with Dukes' A and B had positive FHIT expression, whereas only 28% (10 of 35) of specimens with Dukes' C and D had positive FHIT expression ( $P < 0.005$ ) (Figure 4B and Table 1). Moreover, prognosis of the FHIT-negative cases was much poorer than the FHIT-positive cases (Figure 4C and Table 1). There was no significant correlation between other

**Figure 5** TUNEL assay showing significantly decreased apoptosis in FHIT-negative CRC cells (A), FHIT-positive CRC cells (C), and magnified views of the respective samples A and C (B and D).

clinicopathological factors and FHIT expression.

#### Apoptosis status in human CRC as assessed by TUNEL

The role of FHIT protein in apoptosis as a proapoptotic factor was detected by TUNEL assay. Aberrant expression of the FHIT gene was related to colonic epithelial cell apoptosis (Figures 5 and 6, Table 2). The apoptosis index was  $5.41 \pm 0.23$  in colorectal cancer with normal FHIT

**Figure 6** Decreased FHIT expression and apoptosis inhibition in human CRC. Reduced apoptosis index was detected in the same number of cells per field in CRC with FHIT-negative expression.

**Table 2** Relationship between FHIT expression and apoptosis index (AI) in human CRC

FHIT	n	AI
-	11	0.56 ± 0.10
+/-	15	1.07 ± 0.16
+	17	2.99 ± 0.32
++	37	5.41 ± 0.23

expression and  $0.56 \pm 0.10$  in tumors with absent FHIT expression. The rate of apoptosis was significantly lower in tumors with aberrant FHIT expression than in tumors with normal FHIT expression ( $P < 0.05$ ).

#### Expression of Bax, Bcl-2 and survivin and its correlation with FHIT alteration

Since growth inhibitory effect of FHIT-expressing cells is related to apoptosis, we determined whether FHIT protein is related with other members in the apoptotic pathway. Of the CRC tissue specimens, 54% (43 of 80) had positive FHIT expression, whereas the remaining 46% (37 of 80) had no detectable FHIT expression by TMA-IHC assay (Figure 7, Figure 8, Figure 9 and Figure 10). Seventy-seven percent of FHIT protein-negative CRC specimens showed decreased Bax expression, whereas 75% and 60% FHIT protein-negative specimens displayed increased Bcl-2 and survivin expression (Figure 7, Figure 8, Figure 9 and Figure 10). The difference was statistically significant (Table 3).

## DISCUSSION

In the present study, frequent allelic loss was observed on chromosome 3p in lung cancer and preneoplastic bronchial lesions, indicating that inactivation of putative tumor suppressor genes on chromosome 3p may be involved in early steps of lung carcinogenesis. Ohta *et al.*<sup>[3]</sup> have identified the FHIT gene on chromosome 3p14.2, spanning the FRA3B common fragile site and the t (3:8) break point associated with hereditary renal cell carcinomas. The FHIT

**Figure 7** TMA-IHC showing significantly decreased Bax expression in FHIT positive CRC tissue samples (A), FHIT-negative CRC tissue samples (C), and magnified views of the respective samples A and C (B and D).

gene is more than 1 Mb in size, encoding a 1.1-kb cDNA with 10 small exons and a cytoplasmic Mr 16 800 protein with diadenosine triphosphate (Ap3A) hydrolase activity<sup>[4]</sup>. In this study, truncated FHIT transcripts were observed frequently alongside full-length transcripts and sequence analysis of the truncated gene transcripts revealed mainly

**Figure 8** TMA-IHC showing significantly increased Bcl-2 expression FHIT positive CRC tissue samples (A), FHIT-negative CRC tissue samples (C), and magnified views of the respective samples A and C (B and D).

exon skipping and alternate RNA processing events. To elucidate the possible molecular mechanisms responsible for this loss of protein expression, we used RT-PCR for FHIT transcript analysis and cDNA sequencing for mutation detection. We found that 34.6% of the samples with decreased FHIT expression had an additional aberrant FHIT transcript product. However, aberrant FHIT was not identified in the samples with normal FHIT expression. These data suggest that loss and rearrangement of the FHIT gene derived from FRA3B breaks or gaps in the large FHIT intronic region may give rise to aberrant cDNA splicing and result in loss of FHIT protein, suggesting that the majority of aberrant FHIT transcripts

lack exons 4-6 and 4-8. Our results indicate that higher incidence of aberrant processing of FHIT mRNA and mutation result in FHIT down-regulation in human CRC.

Loss of FHIT protein expression has been found in lung and breast cancers, as well as in head and neck cancers<sup>[7-10]</sup>. Ohta and colleagues<sup>[2]</sup> have reported significant loss or reduction of FHIT expression in 39% CRC patients. However, Thiagalingam *et al*<sup>[15]</sup> showed that the FHIT gene is not involved in CRC carcinogenesis. In this study, we demonstrated that loss of FHIT expression was associated with poorly- and well-differentiated CRC and frequent lymph node metastasis by TMA-IHC assay, indicating that FHIT plays a role in the progression of

**Figure 10** Tree-view of differential protein expression data from 80 CRC tissue samples. Tree-view demonstrated the FHIT protein expression related to Bax, Bcl-2 and survivin protein expression. Red indicates up-regulation, green indicates down-regulation, and yellow indicates no significant change.

CRC because loss of FHIT protein is intimately associated with the development of CRC. Lack of FHIT gene expression and consequent protein expression can be due to deletions, mutations, or epigenetic modifications.

These results strongly indicate that aberrant expression of the FHIT gene is related to the development and progression of CRC. However, the relationship between FHIT expression and apoptosis has not been studied in human CRC, and the decreased apoptosis in FHIT deficient CRC has not been explained. We therefore designed this study to investigate the differential patterns of apoptosis-related protein expression associated with difference in FHIT expression, in order to identify specific changes that might reflect the pathway by which FHIT affects apoptosis. We performed TUNEL analysis in this study to assess apoptosis status and observed decreased apoptosis in FHIT negative CRC tissue samples compared to FHIT-positive CRC tissue samples. The apoptosis index was  $5.41 \pm 0.23$  in tumors with normal FHIT expression and  $0.56 \pm 0.10$  in tumors with aberrant expression. The rate of apoptosis in tumors with aberrant FHIT expression was significantly lower than that in tumors with normal FHIT expression ( $P < 0.01$ ). Furthermore, we conducted tissue microarray analysis to identify differentially expressed proteins in relevant apoptosis pathways. For this initial pathway, we chose three key proteins belonging to the Bcl/Bax pathway (Bcl2 and Bax) and survivin-caspase pathway (survivin). In this study, the FHIT-negative CRC tissue samples were associated with down-regulation of Bax and up-regulation of Bcl-2. It is known that the Bax gene is an apoptosis-promoting member of the BCL-2 gene family, and apoptosis is known to be accelerated when the Bax function is predominant<sup>[22]</sup>. On the other hand, over-expression of Bcl-2 seems to be associated with the blocking of apoptosis. The ability of Bcl-2 to inhibit apoptosis is dependent on the expression of Bcl-2 and formation of hetero- and homo-dimers between members of the Bcl-2 family<sup>[23]</sup>. We observed a significant correlation between FHIT protein expression and members of the Bcl/Bax pathway in human CRC ( $P < 0.05$ ). Survivin is minimally expressed in normal adult tissues but over-expressed in a wide range of human cancers, including cancer of the breast, lung, esophagus

**Table 3** Expression of Bax, Bcl-2, survivin and correlation with FHIT alteration

		<i>n</i>	FHIT expression		$\chi^2$	<i>P</i>
			Positive	Negative		
Bax	+	62	25	37	3.89	0.048
	-	18	12	6		
Bcl-2	+	58	32	26	6.75	0.009
	-	22	5	17		
Survivin	+	41	11	30	12.76	0
	-	39	26	13		

and urinary bladder. Survivin is one member of inhibitors of apoptosis and appears to block apoptosis by interfering with the caspase activation pathway<sup>[24]</sup>. In the present study, we demonstrated that survivin, an inhibitor of apoptosis protein family, was significantly increased in FHIT-negative CRC, indicating that FHIT plays a critical role in FHIT-induced apoptosis, occurring through inactivation of the survivin-caspase signal pathway. Accordingly, future investigations must address protein-protein interactions that lead to these changes in expression and apoptosis, thus allowing us to place FHIT at its correct position within the pathways, ultimately helping to elucidate the precise mechanism by which its expression modulates apoptosis in human CRC.

In conclusion, decreased FHIT expression is caused by mutations of the FHIT gene in human CRC. Down-regulation of FHIT is associated with down-regulation of Bax and up-regulation of Bcl-2 and survivin, which results in alterations in apoptosis status. Differential FHIT expression in human CRC plays a role in control of cell growth and apoptosis. FHIT is a potentially important growth suppressor gene that plays a role in the development and progression of human CRC. FHIT may be a candidate for therapeutic modulation of apoptosis in human CRC.

## Abstract

**AIM:** To investigate the infection and replication of hepatitis B virus (HBV) in primarily cultured human fetal hepatocytes (HFHs).

**METHODS:** The human fetal hepatocytes were cultured in serum-free medium, HBV-positive serum was added into the medium to study the susceptibility of hepatocytes to HBV infection. The supernatant was collected for ELISA assay of HBsAg and HBeAg, and quantitative fluorescence PCR for HBV-DNA assay daily. Albumin and HBcAg, CK8 and CK18 expressions were detected by immunohistochemistry in cultured hepatocytes. Content of lactate dehydrogenase (LDH) was measured to find out the integrity of the cell membrane.

**RESULTS:** A stable hepatocyte culture system was established. HBV could infect the hepatocytes and replicate, and HBcAg expression could be detected by immunohistochemistry in hepatocyte-like cells. HBV-DNA in the supernatant could be detected from d 2 to d 18 and HBsAg and HBeAg were positive on d 3-d 18 after HBV infection. HBV in medium increased from d 0 to d 6 and subsequently decreased as the cells were progressively losing their hepatocyte phenotypes.

**CONCLUSION:** HBV could infect human fetal hepatocytes and replicate. This *in vitro* model allowed a detailed study on early events associated with human HBV entry into cells and subsequent replication.

## INTRODUCTION

Hepatitis B virus (HBV) infection is one of the commonest infections in the world. According to some reports, about 400 million people have been infected with HBV, and about 5% are chronically infected<sup>[1]</sup>. Chronic hepatitis B can cause cirrhosis and liver cancer<sup>[2-4]</sup>. It is estimated that there are more than one million deaths of this infection and 320 thousand deaths from liver cancer associated with HBV each year in the world<sup>[5]</sup>. There are about 400 million people with chronic hepatitis B worldwide<sup>[6]</sup>. HBV exhibits a very narrow host range and shows a strong tropism for liver parenchyma cells. It has therefore, been assumed that the susceptibility to HBV infection is restricted to differentiated cells. It was found by some authors that human primarily cultured hepatocytes were more susceptible than other kinds of cells to HBV infection<sup>[7,8]</sup>. Here we describe a system of experimental infection by HBV virus using primary human fetal hepatocytes. Infection was obtained by co-cultivation of human fetal hepatocytes with HBV-positive serum. The infected fetal hepatocytes *in vitro* were found to initiate viral DNA replication, and they produced infectious viral particles into medium.

## MATERIALS AND METHODS

### Primary culture of human fetal hepatocytes

Hepatocytes were prepared from 6 wk old human fetal liver. Embryos procurement was approved by the Ethics Committee of Chaozhou Central Hospital. The sera from the mothers were negative for hepatitis C virus (HCV), HBV and human immunodeficiency virus (HIV) by ELISA (Shanghai SIIC Ke-Hua Biotechnology). Firstly, we used Hank's liquid to wash the aborted fetus 3 times, and liver tissues were taken out. Secondly, the liver tissues were cut with scissors into 0.1-0.5 mm<sup>3</sup> pieces. At last, the little pieces were shattered with 5 mL syringe to single cells or cell aggregates. Viability, assessed by the trypan blue exclusion test, was between 70% and 90%. The cells

were seeded into 12-well culture dishes (Orange Scientific) at about  $2 \times 10^5$  cells per well and incubated with 1 mL of 10% FBS (Gibco) in DMEM (Dulbecco's Modified Eagle's Medium)/F12 (Nutrient Mixture F-12 HAM) (1:1) (Sigma-Aldrich) supplemented with 0.1 U/L penicillin, 0.1 ng/L streptomycin, and 0.1 ng/L fluconazole at 37°C under 5% CO<sub>2</sub> in air. The medium was changed after the first 48 h with serum-free medium. The serum-free medium was composed of DMEM/F12 (1:1) and 0.01 nmol/L nicotinamide, 0.02 ng/L epidermal growth factor (EGF), 0.02 ng/L basic fibroblast growth factor (bFGF), 0.365 ng/L glutamate, B27 (1:50) (Sigma), 0.1 U/L penicillin, 0.1 ng/L streptomycin, and 0.1 ng/L fluconazole.

### **Viral sources**

A serum sample for infection test from HBV carriers was analyzed. The patient was anti-HbsAb positive as detected by the ELISA (Shanghai SIIC Ke-Hua Biotechnology), and HBV-DNA in the serum sample was quantified with fluorescence quantitative polymerase chain reaction (FQ-PCR) assay (Da-An Gene Corp). The patient had received no antiviral therapy prior to the study, and not infected with HCV or HIV. The sera were stored at -80°C until use. The number of serum HBV was  $7.6 \times 10^7$  copy/mL as quantified by FQ-PCR.

### **In vitro infection**

After 24 h culture in serum-free medium as mentioned above, infection was obtained by incubation 1 mL serum-free culture medium with 5% dimethyl sulphoxide (DMSO) and 100 µL HBV serum. Following 24 h exposure, cells were washed 6 times with 3 mL Hank's liquid and incubated in 1 mL fresh serum-free medium as described above. The medium was changed every day, and the supernatant was collected at various times during the culture period and stored at -80°C. We used one-well cells without HBV serum sample as negative control.

### **Detection of HBV-DNA by FQ-PCR**

To qualify these DNA molecules, virus DNA was extracted from the culture medium using an alkaline lysis method for FQ-PCR analyses<sup>[9]</sup>. For detection of HBV-DNA in cultured cells, all of the cells were digested by trypsin-EDTA (0.25%-0.01 mmol/L) solution and centrifugated, then were washed six times with PBS. Cells were lysed with 0.05 mol/L Tris-HCl (pH 7.4)-1% sodium dodecyl sulfate (SDS)-0.02 mol/L NaCl-0.02 mol/L EDTA and incubated with 0.5 g/L of proteinase K at 37°C overnight<sup>[9]</sup>. Total DNA was extracted by an alkaline lysis method.

HBV-DNA was measured by FQ-PCR diagnostic kit from Da-An Gene Corp. with Lightcycler<sup>TM</sup> Roche. In this reaction, the nucleotide sequences of the primers were as follows: P1: 5'ATCCTGCTGCTATGCCTCATC TT3' (23 bp), P2: 5'ACAGTGGGGGAAAGCCCTACG AA3' (23 bp), FISH: 5'TGGCTAGTTTACTAGTGCCA TT3' (25 bp)<sup>[10]</sup>.

QT-PCR amplification was performed using Roche QT-PCR system with 2 min initial denaturation at 93°C for 40 cycles of 5 s at 93°C and 45 s at 57°C, followed by 1 s of extension at 37°C.

### **Detection of HBsAg and HbeAg by ELISA**

HBsAg and HBeAg levels in the supernatant were detected using the monoclonal II enzyme-linked immunosorbent assay. ELISA kits were obtained from Shanghai SIIC Ke-Hua Biotechnology. Titers were expressed as the ratios against cut-off values (A450 of negative control + 0.05 for HBsAg and + 0.05 for HBeAg).

### **Periodic acid- Schiff's staining**

To discriminate liver cells from stromal cells for general observation of morphology, cells were stained with periodic acid-Schiff's reagent (PAS) by standard methods<sup>[12]</sup>. The reagents were from Shanghai Zhu-Chun Biotechnology.

### **Detection of albumin and HBcAg by immunohistochemical staining**

The cells were fixed in 0.4% formaldehyde in PBS at room temperature for 15 min, and washed 3 times by PBS. After that, they were incubated for 15 min with 0.25% Triton-X100 and washed 3 times by PBS. Cells were then incubated with the following dilutions of primary antibodies for 1 h at room temperature: antibody to cytokeratin-8 (CK-8) and cytokeratin-18 (CK-18) (Beijing Zhong-Shan Biotechnology), which were diluted at 1:100 in PBS; antibody to HBcAg (1:1) (Fuzhou Maxim Biotechnology); and antibody to human albumin diluted at 1:1000 in PBS (Sigma). Other steps were performed according to manufacturer's instruction of SP-9000 kits, and AEC served as chromagens.

### **Determination of integrity of cell membranes**

Content of LDH was measured using automatic blood biochemistry analysis (HITACHI 7060) with Roche reagents. LDH was expressed as U/L released into the medium to find out the integrity of the cell membrane every 24 h.

### **Statistical analysis**

The statistical analysis was performed with SPSS 13.0 statistic software.

## **RESULTS**

### **Properties and phenotypes of cultured hepatocytes**

Single cells or cell aggregates were isolated from fetal human livers. The initial cell population was an obvious mixture of hematopoietic and epithelial cells. For instance, red blood cells were copious, although these were rapidly removed at the first medium change. They were plated onto plastic dishes with serum containing medium. After 12 h, the hepatocytes started to attach to the dishes but did not proliferate. After 48 h, the media became serum free, and the HFHs began to show two kinds of state, including cell aggregates or spheroid and scattered cells. The spheroid was made up of many epithelial cells, and fibroblast-like cells migrated from them (Figure 1A). With the elongation of culture time, the percentage of fibroblast-like cells gradually increased and the percentage of flat epithelial cells gradually decreased. After 3-5 wk, fibroblast-like cells proliferated to form a monolayer (Figure 1C).

**Figure 1** Morphology, PAS and S-P staining of the HFHs under light microscope. **A:** Isolated HFHs formed epithelial-like spheroid and they were surrounded by fibroblast-like cells in culture after 48 h; **B:** HFHs were stained by PAS, the majorities of cultured cells were positive; **C:** HFHs state *in vitro* for 50 d; **D:** HFHs were positive for CK8 in hepatocytes *in vitro* for 50 d (S-P); **E:** HFHs expressed liver marker CK18 *in vitro* for 14 d (S-P); **F:** Only a few of hepatocytes were positive for CK18 *in vitro* for 50 d (S-P); **G:** HFHs expressed ALB *in vitro* for 14 d (S-P). (Original magnification,  $\times 40$ ).

To confirm the phenotypes of HFHs after 2 wk, cells were analyzed by PAS staining. The majority of cells were stained, and these cells were multiangular and flat, their morphology were similar to that of hepatocytes (Figure 1B). Furthermore, we performed S-P staining using primary antibodies against ALB, CK8 and CK18, the results showed clearly that these proteins were expressed in about 90% cells, confirming that the cells expressed hepatocyte phenotypes (Figure 1E and 1G). After 50 d, only less than 1% cells expressed CK8 and CK18 (Figure 1F). The above-mentioned results were also reported by HU *et al.*<sup>[11]</sup>. CK8 and CK18 are cytoskeletal proteins characteristic of hepatocytes, they play a very important role in maintaining the structure of hepatocytes, and are expressed in the hepatocyte cytoplasm of the fetal hepatocytes *in vivo*. Thus, they are good markers for hepatocytes. As culture time extending, the cells that expressed hepatocyte phenotypes gradually decreased, while those cells that expressed fibroblast phenotypes gradually increased. In our opinion, there were two factors to explain this situation: (1) the fibroblast-like cells

**Figure 2** Lactate dehydrogenase (LDH) released in primary human hepatocytes.

proliferated faster than hepatocyte-like cells. Therefore, after several weeks culture, fibroblast-like cells proliferated to form a monolayer and few hepatocyte-like cells could be observed; (2) HFHs could change their phenotypes from hepatocytes to mesenchymal cells, this phenomenon has also been reported by other studies<sup>[9]</sup>.

In the course of this study, it was visually apparent that the tendency of LDH increased with culture time in serum-free medium (Figure 2). The amount of LDH in the supernatant ranged from 620 nkat/L to 130 nkat/L.

#### Production of viral antigens in fetal liver cells

The serum-free culture medium was collected periodically and the levels of HBsAg and HBeAg were analyzed. As shown in Figures 3A and 3B, the HBsAg and HBeAg were first detected at d 3 after the infection and continued to appear positive during the following 16 d. They must have been synthesized in liver cells because the wash liquid (time zero) and medium from d 1 to d 2 were negative for HBsAg and HBeAg. Thus, the human fetal hepatocytes should be infected by wild virus and replicated HBV.

Human fetal hepatocytes were cultured for 24 h with HBV serum, washed, and incubated with serum-free medium. The supernatant was taken every day and assayed for HBsAg and HBeAg.

#### Detection of HBV-DNA in media and cultured cells

The culture media were collected from d 0 to d 18 (the day of human HBV serum deprivation was indicated as d 0), and were measured by FQ-PCR. HBV-DNA appeared at d 2, and reached a secretion peak from d 3 to d 6. The tendency began to decrease on d 6. Because there was no HBV-DNA in the medium at d 0-2 after infection, HBV-DNA was detected in the serum-free medium from d 3 to d 18 (Figure 4). Therefore, they must have been released from the infected hepatocytes, and the hepatocytes must release and replicate virus DNA. The results of HBV-DNA in liver cells are shown in Table 1.

#### Detection of HBcAg by immunohistochemical staining

To estimate the population of infected cells, immunohistochemical staining was used to assay HBcAg. HBcAg was detected in about 10% of hepatocyte-like cells 3 d after infection (Figure 5A), whereas no HBcAg was found

**Figure 3** HBsAg (A) and HBeAg (B) in supernatant detected by ELISA (OD: optical density).

**Table 1** Cells quantified by FQ-PCR on d 18

Well	Cell number	HBV-DNA (copy/L)
1	$1.0 \times 10^4$	$2.092 \times 10^9$
2	$1.5 \times 10^4$	$8.506 \times 10^9$

in the negative control (Figure 5 B).

## DISCUSSION

Replication of HBV has been achieved in human hepatoma cell lines using integrated or transfected HBV genomes as templates<sup>[13-16]</sup>. Duck cells and adult human liver cells were also successfully infected by HBV<sup>[17,18]</sup>. However, no signs of viral penetration, replication, or particle production have been observed except for a transient expression of some viral markers in hepatoma cell lines<sup>[14-15]</sup>. Duck cells and adult human liver cells could not perfectly analogue the process of the HBV infection in human fetal hepatocytes<sup>[17,18]</sup>, and human fetal hepatocytes were used in a few experiments for HBV infection<sup>[19,20]</sup>. We demonstrated in this study that primary cultures of fetal human hepatocytes could maintain HBV infection *in vitro* and support the replication of HBV DNA.

In this study, an evidence of virus DNA replication in primary human fetal hepatocytes was testified from d 2 to d 18 after infection by FQ-PCR, another evidence was that HBsAg and HBeAg appeared positive from d 3 to d 18 by ELISA. The process of HBV replication and

**Figure 4** HBV-DNA in media detected by FQ-PCR.

release continued for 16 d. The results were similar to other experiments with DMSO supplement<sup>[18]</sup>. But the HBV secretion time in our experiment was longer than the experiments without DMSO<sup>[19-21]</sup>. The data demonstrated that viral replication *in vitro* might be strongly enhanced by DMSO.

Previous studies of primary hepatocytes provided very little information about the quantity of HBV-DNA in the culture medium<sup>[21-23]</sup>. In their reports, DNA or RNA used to be detected by Southern blot or Northern blot<sup>[14,18,23]</sup>. The procedures of these methods were complicated, and the results were not stable. In our experiment, we used FQ-PCR to measure the HBV-DNA in the supernatant and cultured cells. FQ-PCR combines gene amplification and molecule hybridization with fluorescence physics, conducts the whole process of DNA amplification and PCR products analysis in an enclosed tube, and real-time detection as well as auto-analysis under computer control<sup>[10]</sup>. As a result, the cross-contamination of conventional PCR products and incapacity of quantification can be eliminated fundamentally<sup>[10]</sup>. Furthermore, the specificity and sensitivity increased remarkably. This method could provide reliable and precise data for HBV quantification.

The quantity of HBV in medium increased from d 0 to d 6 and decreased from d 7 to d 18 in the infection process. From d 0 to d 6, HBV replicated in infected cells and released to the medium, and then the free HBV infected other hepatocytes. With the increasing number of hepatocytes, it formed one infected cycle in cells and

the quantity of HBV increased in the medium. From d 7 to d 18, a part of cells gradually lost their hepatocyte phenotypes and HBV infection susceptibility, and the cycle was broken. Meanwhile, a part of floating cells and cell spheroid died gradually, subsequently, the quantity of HBV decreased.

In this study, we found that the presence of HBeAg was more correlated with HBV-DNA in the medium than that of HBsAg. According to our knowledge, HBeAg was a marker of extensive viral replication in HBsAg-positive sera of patients with hepatitis B virus infection<sup>[24]</sup>. The presence of HBeAg in the serum correlated well with hepatitis B-DNA<sup>[24]</sup>. Therefore, our results were similar to the status in human body.

By immunohistochemical analysis, we were able to observe a part of infection of the hepatocytes in the cultures. Similar results have previously been reported<sup>[23]</sup>. Recently, Tuttleman *et al*<sup>[17]</sup> used primary duck hepatocytes to infect HBV and only 10% of the primary duck hepatocytes displayed HBcAg<sup>[25]</sup>. The events could be observed in duck hepatocytes and human fetal liver cells. According to some reports, the procedure of liver cell isolation could destroy the capacity for infection of all but some cells. As it is well known, human hepatocytes were hard to maintain in cultures, such as albumin expression. Such phenotypes are easily lost within one week culture when the cells are inoculated in serum-containing medium. In our observation, the shape of the hepatocytes was polygonal at 48 h. With elongation of culture time, some hepatocytes gradually changed and extended in shape and became fibroblast-like, meanwhile they lost hepatocyte phenotypes such as ALB, CK18 and CK8 expressions. So it is likely that some flat cells may lessen the susceptibility to HBV infection.

HBV infection in primary fetal hepatocyte cultures is suitable for cloning virus because of the limited infectivity of the cells. However, our system *in vitro* has been found very useful for studying the early events in viral entry into cells as well as viral replication.

### Abstract

**AIM:** To examine the factor(s) involved in differentiation of intestinal macrophages (IMACs) using a recently established *in vitro* model.

**METHODS:** To test whether soluble or membrane bound factors induce IMAC-differentiation, freshly elutriated monocytes (MO) were incubated with conditioned media or cell membranes of intestinal epithelial cells (IEC) or cultured with IEC in transwell systems. To determine the importance of an active migration of MO, three-dimensional aggregates from a 1:1-mixture of MO and IEC were examined by immunohistochemistry and flow cytometry. Apoptosis was examined by caspase-3 Western blots. Extracellular matrix production in differentiation models was compared by immunohistochemistry.

**RESULTS:** IMAC differentiation was observed in a complex three-dimensional co-culture model (multicellular spheroid, MCS) with IEC after migration of MO into the spheroids. By co-culture of MO with conditioned media or membrane preparations of IEC no IMAC differentiation was induced. Co-culture of MO with IEC in transwell-cultures, with the two cell populations separated by a membrane also did not result in intestinal-like differentiation of MO. In contrast to IEC-spheroids with immigrating MO in mixed MCS of IEC and MO only a small subpopulation of MO was able to survive the seven day culture period.

**CONCLUSION:** Intestinal-like differentiation of MO *in vitro* is only induced in the complex three-dimensional MCS model after immigration of MO indicating a role

of cell-matrix and/or cell-cell interactions during the differentiation of IMACs.

### INTRODUCTION

Macrophages represent a component of the innate immune system which is of central importance. One of the largest populations of macrophages in the body is intestinal macrophages (IMACs)<sup>[1]</sup>. They are localized directly underneath the epithelial barrier at the sites of antigen entry, in particular in the sub-epithelial region of the small and large intestine and in the subepithelial domes of Peyer's patches<sup>[2-4]</sup>. IMACs constitute 10%-20% of mononuclear cells in the human lamina propria<sup>[2,5-8]</sup>. They undergo a specific process of differentiation. This specific differentiation is believed to be essential for the specific functions of IMACs in the mucosal innate but also adaptive immune system. As IMACs are central players of both systems, a better understanding of the factors determining their differentiation may allow the definition of new targets for therapeutic interventions during acute and chronic mucosal inflammation. The importance of IMACs is supported by the finding that NOD2/CARD15, the first gene identified to increase susceptibility to Crohn's disease, is mainly expressed in macrophages in the colonic mucosa<sup>[9,10]</sup>.

The phenotype of IMACs is remarkable: Less than 10% of the macrophages (MACs) isolated from normal colonic mucosa express the typical MO/MAC-specific surface markers CD14, CD16, CD11b, CD11c<sup>[11-13]</sup>. Furthermore, the expression of co-stimulatory molecules B7-1 (CD80) and B7-2 (CD86) on IMACs is low<sup>[14,15]</sup>. In

addition, the expression of pattern recognition receptor (PRR) toll like receptor (TLR) 2 and TLR 4 is also down-regulated in IMACs on transcriptional and translational levels<sup>[16]</sup>. The prototypic MO/MAC functions such as generation of superoxide radicals (oxidative burst reaction) are absent in normal mucosal IMACs due to a lack of NADPH-oxidase subunit expression<sup>[17]</sup>, indicating that normal IMACs constitute a non-reactive cell population, which might be important for the induction of tolerance in the intestinal mucosa. A disturbance of the differentiation process followed by a reactive cell type retaining PRRs and activation functions could be followed by chronic inflammation.

Recently we used a three-dimensional co-culture model (multicellular spheroid model, MCS-model) of intestinal epithelial cells (IEC) and monocytes (MO) to induce the *in vitro* differentiation of intestinal-like macrophages<sup>[18]</sup>. We demonstrated that IEC clearly play an important role in the differentiation of IMACs. Freshly elutriated MO, which adhered and infiltrated IEC-MCS, changed their phenotype during a seven-day co-culture period<sup>[18]</sup>. Typical MO/MAC specific surface antigens such as CD14, CD16, CD11b and CD11c, which were detectable on invading cells after 24 h, were down-regulated after seven days. This differentiation was of functional relevance as seen by the loss of LPS-induced IL-1 $\beta$  transcription in IEC-MCS/MO co-cultures compared to control experiments<sup>[18]</sup>. As the gut specific differentiation of IMACs is of great functional importance and the MCS-model resembled the differentiation process *in vitro*, we addressed the question of which factor(s) induce the specific IMAC-differentiation.

Little is known about the direct interaction between IEC and MO/MAC. In normal intestinal mucosa tissue IMAC are separated from IEC by the basement membrane<sup>[2,4]</sup>. Doe and co-workers<sup>[19]</sup> have localized IMACs beneath the luminal epithelium<sup>[19]</sup>. It has been shown that IMACs or dendritic cells can transmigrate and return again across the basement membrane<sup>[20]</sup> and that the basement membrane is as easily permeable for large molecules as complement factors<sup>[21]</sup>. Martin and co-workers<sup>[22]</sup> found that murine MO/MAC and IEC are coupled by gap junctions and that gap junctional communication may provide a tool by which inflammatory cells regulate IEC function and vice versa.

In the present study, we aimed to study whether the induction of intestinal like differentiation of MAC is induced by soluble or secreted proteins, whether direct cell-cell interactions are necessary, whether cell-matrix interactions play a major role and whether all MO or just a subpopulation of MO is capable of differentiating into IMACs.

## MATERIALS AND METHODS

### *Monocyte isolation and cell culture*

Primary blood MO were obtained by leukapheresis of healthy donors, followed by density gradient centrifugation over Ficoll/Hypaque as described previously<sup>[18]</sup>. Two intestinal epithelial cell lines (HT-29 and WiDr) and a control cell line of non-intestinal origin (urothelial

carcinoma, J82) were used. All cell lines were cultured under standard tissue-culture conditions<sup>[23,24]</sup>. The isolation of monocytes was approved by the local institutional review board.

### *Conditioned medium*

Confluent monolayers of IEC lines or the control cell line were incubated with cell culture medium with or without fetal calf serum (FCS). After 48 h the medium was removed, centrifuged and stored at -20°C. Freshly elutriated MO were incubated in conditioned medium for up to seven days.

### *Immunohistochemistry*

Immunohistochemical staining was carried out according to the standard alkaline phosphatase anti-alkaline phosphatase (APAAP) or diaminobenzidine (DAB) technique<sup>[25]</sup>. The following monoclonal antibodies against MO/MAC-antigens were used: anti-CD68 (clone: KP1, Dako, Hamburg, Germany), anti-CD11b (clone: BEAR1, Immunotech, Hamburg, Germany), anti-CD11c (clone: BU15, Immunotech, Hamburg, Germany), anti-CD14 (clone: RMO52, Immunotech, Hamburg, Germany) and anti-CD16 (clone: 3G8, Immunotech, Hamburg, Germany). For detection of extracellular matrix antibodies against fibronectin (clone: 568, Progen, Heidelberg, Germany), laminin (clone: 4C7, Dako, Hamburg, Germany) and collagen IV (clone: CIV 22.(1), Dako, Hamburg, Germany) were used.

### *Cell ELISA*

Fixed MO were washed with NKH buffer (0.14 mol/L NaCl, 5 mmol/L KCl and 2 mmol/L HEPES, all Merck, Darmstadt, Germany) and unspecific binding was blocked with 10% FCS in NAG buffer (0.1% NaN<sub>3</sub>, 2 mmol/L HEPES, 0.2% gelatine, all Merck, Darmstadt, Germany and 0.2% BSA, Sigma-Aldrich, Deisenhofen, Germany). Antibodies against CD68, CD14, CD16 and  $\beta_2$ -microglobuline (anti- $\beta_2$ M, Dianova, Hamburg, Germany) as a positive control were applied. After rinsing, rabbit anti-mouse IgG (Dako, Hamburg, Germany) was added and incubated with peroxidase-conjugated goat-anti-rabbit antibody (Immunotech, Hamburg, Germany). Subsequent incubation with 1.2-phenyldiamine-dihydrochloride substrate (OPD, Fluka, Deisenhofen, Germany) for exact 12 min resulted in a yellow color. The reaction was stopped with 1 mol/L H<sub>2</sub>SO<sub>4</sub> (Merck, Darmstadt, Germany) and the extinction was determined photometrically. As a reference value the extinction of  $\beta_2$ M was set 1. All measured values were standardized on the  $\beta_2$ M-extinction.

### *Proliferation and cell viability assay (MTS-test)*

A total of 100 000 MO per well were grown either in conditioned media of IEC or in control media in 96-well plates for seven days. A colorimetric assay (MTS, Endogen, Woburn, Germany) for quantification of cell proliferation and cell viability was performed according to the manufacturer's protocol. The absorption was measured 8 h after addition of the MTS-labeling mixture.

### Cell membranes

IEC or control cells were washed with PBS, resuspended in homogenization buffer (Iris 50 mmol/L, EDTA 1 mmol/L, PMSF 1 mmol/L, benzamidine 1 mmol/L, saccharose 0.25 mmol/L) and lysed by sonification. Cell membranes were isolated in three subsequent centrifugation steps ( $400 \times g$  for 10 min,  $8500 \times g$  for 10 min,  $25000 \times g$  for 30 min). During the third centrifugation step, the cell membranes were sedimented, re-suspended in PBS and incubated in 96-well plates to allow adherence to the plastic surface. After 30 min the supernatants were removed and replaced by a suspension of freshly elutriated MO.

### Transwell co-cultures

IEC were seeded onto filter inserts with a pore size of 12  $\mu\text{m}$  or 3  $\mu\text{m}$  (preventing IEC from transmigration through the membranes). After formation of an IEC-monolayer the supernatant was removed and freshly elutriated MO in medium supplemented with 2% of human AB-serum were added to each filter insert. After seven days of incubation migrated cells were fixed for immunohistochemistry. Cells in suspension were collected separately and subjected to flow cytometrical analysis.

### Generation of MCS

MCS from only IEC or from a 1:1 mixture of IEC and MO were generated according to the liquid overlay culture technique<sup>[18]</sup>. Mixed spheroids were also generated with addition of a blocking anti-Fas antibody (Upstate Biotechnology, Lake Placid, USA) to the cell suspension 30 min before seeding.

### Flow cytometry

Flow cytometry was performed using a Coulter EPICS<sup>®</sup> XL-MCL (Coulter, Krefeld, Germany). Cells were double stained with a FITC-conjugated anti-CD14 antibody (clone Tük4, Coulter, Krefeld, Germany) and a PE-conjugated anti-CD33 antibody (clone MY9, Coulter, Krefeld, Germany) as described previously.

Data acquisition and analysis were performed using WIN-MDI software (<http://facs.scripps.edu/help/html/>).

### Immunoblotting

Cells were resuspended in RIPA buffer (1% Nonidet P-40, 0.5% sodium deoxycholate, 0.1% SDS, 1 mmol/L  $\text{Na}_3\text{VO}_4$ , 50 mmol/L NaF and 1 tablet of complete proteinase inhibitor cocktail [Boehringer, Mannheim, Germany] per 50 mL PBS) for 10 min on ice and centrifuged ( $12000 \times g$  for 15 min at 4°C). The protein concentration of the supernatant (protein fraction) was determined by BCA protein assay (Sigma-Aldrich Chemie, Deisenhofen, Germany). Thirty  $\mu\text{g}$  of protein was mixed with an equivalent volume of 2  $\times$  protein loading buffer containing 2- $\beta$ -mercaptoethanol and boiled for 5 min before it was loaded onto SDS polyacrylamide gels. After electrophoresis, proteins were transferred onto nitro-cellulose membranes using the Xcell blot module (Invitrogen BV/NOVEX; Gronigen, Netherlands) and blocked in TBST (50 mmol/L Tris-HCl, pH 7.5, 150 mmol/L NaCl, 0.05% Tween 20) containing 5%

non-fat dry milk powder. Protein immunoblots were performed using specific antibodies to caspase-3 (clone 19, Transduction Laboratories, Lexington, USA) and  $\beta$ -actin (clone JLA20, Calbiochem, Cambridge, USA). The membranes were further incubated with peroxidase-conjugated secondary antibodies and protein bands were visualized using a chemoluminescence kit (ECL Plus <sup>™</sup>, Amersham, Buckinghamshire, UK) according to the manufacturer's protocol.

## RESULTS

Recently we demonstrated *in vitro* differentiation of MO into IMACs in complex three-dimensional co-culture models (MCS model) with IEC after migration of MO into the IEC complexes. Here we further studied whether soluble factors or cell-cell interactions might be more relevant to this differentiation.

### IEC-conditioned media did not induce differentiation of IMACs

To test whether soluble factors secreted by IEC induce the intestinal-like differentiation of MO, freshly elutriated MO were incubated with IEC-conditioned medium for seven days. Immunohistochemical analysis of MO showed no intestinal-like differentiation. CD14, CD16, CD11b and CD11c, which are down-regulated during differentiation of IMACs and therefore absent on MAC from normal non-inflamed mucosa, were all detectable. CD14 was expressed by 70%-80%, CD16 by 50%-60%, CD11b by 80%-90% and CD11c by 90%-100% of the MO/MAC incubated in HT-29-conditioned medium for seven days. Same results obtained with conditioned medium of the second tested IEC line WiDr were not significantly different from the values obtained with the MO/MAC incubated in control media (Figure 1). When cells were analysed by flow cytometry these findings were confirmed as no down-regulation of CD14, CD16, CD11b and CD80 expression could be observed in MO after seven-day co-culture with IEC-conditioned media (CD14 expression shown in Figure 2).

The results were further confirmed and quantified using the cell-ELISA technique able to detect minor changes in antigen expression. As a positive control and for reference values we determined the expression of the MAC housekeeping gene  $\beta_2\text{M}$  (Figure 3A). All other values were standardized in relation to  $\beta_2\text{M}$ -expression. The antigen expression of MO/MAC, incubated in IEC-conditioned medium did not differ significantly from that of cells, incubated in control medium. The expression of CD16 was always slightly decreased, but could also be observed in control experiments and was not specific for IEC-conditioned media (Figure 3B).

### IMAC differentiation was not induced by IEC-membrane bound factors

To determine whether membrane-bound factors of IEC induce the intestinal-like differentiation of MO, freshly elutriated blood MO were co-cultured with membrane preparations of IEC as described in Materials and

**Figure 1** Immunohistochemical detection of MO/MAC antigen expression after 7 d of culture in IEC conditioned medium. Freshly elutriated MO were incubated in unconditioned control media, conditioned media of the IEC lines HT-29 and WiDr and conditioned medium of the control cell line J82 of non-intestinal origin for seven days. Antigen expression was determined by immunohistochemistry (APAAP-method). Expression of the MO/MAC specific antigens CD14, CD16, CD11b and CD11c was determined. All tested antigens were detectable on the cells after the seven-day culture period. Incubation in IEC-conditioned medium had no influence on antigen expression.

**Methods.** After an incubation period of seven days MO co-cultured with IEC-membranes showed no differentiation into intestinal-like MAC. The tested antigens CD14, CD16, CD11b and CD11c were still detectable after seven days of culture of MO/MAC together with membrane preparations of the IEC line HT-29. MO/MAC incubated for seven days without membrane preparations showed the same pattern of antigen expression (Figure 4).

Same results were obtained with membranes of a second intestinal epithelial cell line (WiDr) and the control cell line J82 (data not shown).

#### **IMAC differentiation was not observed in transwell culture**

To test whether a short direct contact between MO and IEC is able to induce intestinal-like differentiation of MO, we incubated MO and IEC in so called “transwell-cultures”. MO were added to IEC grown in filter inserts. When

filters with a pore size of three  $\mu\text{m}$  were used, only MO were able to migrate through the membrane as confirmed by negative staining for the epithelial cell marker EP-4 and positive staining for the MO/MAC-marker CD33 (Figure 5A). Twelve- $\mu\text{m}$  long filters allowed also IEC to migrate through the membranes. IEC could be easily distinguished from MO/MAC by morphology and showed no expression of the tested MO/MAC-specific antigens. MO either migrated through the IEC layer or stayed in the upper compartment of transwell-culture. Antigen expression of cells adherent to the plastic dishes after transmigration was examined by immunohistochemistry. MO/MAC were all positive for the intracellular MO/MAC marker CD68 and showed a high expression of CD14, CD16, CD11b and CD11c after the seven day culture period (Figure 5B). Non adherent cells from the upper or lower compartment of the filter insert were analysed by

**Figure 2** Flow cytometrical quantification of MO/MAC antigen expression after seven days of culture in IEC conditioned medium. **A:** Ninety-two percent of CD33+ cells (MO/MAC) showed expression of CD14 in MO cultured in unconditioned control medium (RPMI) without FCS supplemented with 2% human AB serum for seven days; **B:** Ninety-five percent of CD33+ cells (MO/MAC) were CD14-positive in MO cultured in WiDr conditioned medium without FCS supplemented with 2% human AB serum for seven days; **C:** Ninety-two percent of CD33+ cells (MO/MAC) were CD14-positive in MO cultured in J82 conditioned medium (control cell line of non-intestinal origin) without FCS supplemented with 2% human AB serum for seven days; **D:** Ninety-four percent of CD33+ cells (MO/MAC) showed expression of CD14 in MO cultured in unconditioned control medium (DMEM) without FCS supplemented with 2% human AB serum for seven days; **E:** Ninety-eight percent of CD33+ cells (MO/MAC) were CD14-positive in MO cultured in HT-29 conditioned medium without FCS supplemented with 2% human AB serum for seven days; **F:** No down-regulation of CD14 expression was observed on histogram of CD14 expressing mononuclear cells after seven days of culture in RPMI (control medium), J82 (control cell line) or WiDr conditioned medium; **G:** Histogram of CD14 expressing mononuclear cells after seven days of culture in DMEM (control medium) and HT-29 conditioned medium.

flow cytometry and showed a similar antigen pattern with high CD14, CD16 and CD11b expressions (Figure 5C and D).

### Immigration of MO into MCS was relevant to IMAC differentiation

To test whether the process of invading the three-dimensional IEC-spheroids is necessary for the differentiation of MO into IMACs, we generated “mixed spheroids” from a 1:1-mixture of IEC and MO. In these experiments MO were added during the generation of MCS and did not invade the three-dimensional aggregates.

Flow cytometrical analysis showed 15.2% MO/MAC inside spheroids of the control cell line J82 after 24 h of co-culture. This percentage was nearly constant during a seven-day culture period (13.2%, d 7,  $n = 5$ ). In spheroids with the IEC line HT-29 a different effect could be observed. After 24 h 21.7% MO/MAC inside the spheroids could be detected. On day seven of co-culture the percentage of MO/MAC inside the spheroids

decreased to 1.4% ( $n = 4$ ). Similar results could be obtained with spheroids of the IEC line WiDr. The percentage of MO/MAC inside the spheroids decreased from 14.6% (24 h) to 2.4% (d 7,  $n = 4$ ) (Figure 6A). Remaining MO/MAC inside the aggregates showed no differentiation into IMACs. The results showed that active invasion of the aggregates by MO was an essential step in the process of IMAC differentiation.

To test whether the observed decrease in the relative amount of MO in “mixed spheroids” is due to Fas-induced apoptosis, we added a blocking anti-Fas antibody to the cell suspensions before generating “mixed spheroids”. Addition of the anti-Fas antibody did not change the results significantly. The number of MO/MAC decreased from 14.2% (24 h) to 0.8% (7d) in HT-29 MCS and from 20% (24 h) to 2.3% (7d) in WiDr spheroids. In control experiments with J82 spheroids the number of MO/MAC was almost constant with 13.9% at 24 h and 12% on day seven ( $n = 3$ ) (Figure 6B).

In addition, Western-blots for caspase-3 were

**Figure 3** Cell ELISA of MO/MAC antigen expression after seven days of co-culture with IEC conditioned media. **A:** Freshly elutriated MO were incubated in conditioned medium of the IEC line WiDr or control media (left graph) of HT-29 and control media (right graph) for seven days. Expression of the housekeeping antigen  $\beta$ 2M was determined an extinction is given as absolute value; **B:** CD68, CD14 and CD16 antigen expression of MO incubated in conditioned medium of the IEC line WiDr or non-conditioned control medium (left graph) or HT-29 and control medium (right graph) after seven days was also determined by cell ELISA. Values are standardized on  $\beta$ 2M-extinction.

**Figure 4** MO/MAC antigen expression after seven days of culture with IEC membranes. Freshly elutriated MO were incubated for seven days with membrane preparations of the IEC line HT-29 or without membranes. Antigen expression was determined by immunohistochemistry (APAAP-method). There was no difference in expression of CD14, CD16, CD11b and CD11c in cells incubated with or without IEC membranes.

performed. After 24 h and three days no activated caspase-3 was detected in "mixed MCS" of IEC and MO or in control cells and MO (Figure 7).

#### Potential role of extracellular matrix in IMAC differentiation

The expression of extracellular matrix (ECM)

proteins (fibronectin, laminin and collagen IV) in the "normal" and mixed spheroids was determined by immunohistochemistry. Laminin and collagen IV were not detectable in both mixed spheroids and spheroids invaded by MO. In contrast, a strong expression of fibronectin could be detected in spheroids invaded by MO, which was

**Figure 5** Antigen expression of MO/MAC incubated with IEC in trans-well cultures. Freshly elutriated MO were incubated with the IEC line HT-29 seeded on filter inlays for seven days. Depending on pore size of the inlays only MO or MO and IEC could migrate through the filter. Antigen expression of migrating and non-migrating cells was examined by immunohistochemistry (APAAP-method) and flow cytometry. **A:** Migrating cells adhered to the plastic surface of the cell culture plate. When filters with a pore size of 3  $\mu$ m were used, only MO were able to migrate through the membrane. Migrating cells were all negative for the epithelial cell specific marker EP-4 and positive for the MO/MAC-marker CD33; **B:** Migrating cells showed expression of CD68, CD14, CD16, CD11b and CD11c (left column). Twelve  $\mu$ m pores allowed migration of MO and IEC. None of the tested antigens was expressed by IEC (right column); **C:** Non migrating cells which remained in the upper compartment of the filter insert were examined by flow cytometry. The CD33-positive cell population (MO/MAC) showed also expression of CD14, CD16 and CD11b; **D:** Migrating cells which did not adhere to the plastic dish were examined by flow cytometry. Cells showed CD33-expression and were positive for CD14, CD16 and CD11b.

up-regulated from three to seven days of culture and was absent in mixed spheroids incubated for the same time. The expression of fibronectin was localized in the inner region of aggregates (Figure 8).

## DISCUSSION

As IMACs are essential players in local immune responses and the innate immune system of intestinal barrier, their specific phenotype must be of importance. Compared to IMACs from inflammatory bowel disease (IBD) patients, IMACs from normal intestinal mucosa show a down-regulation of several surface markers, co-stimulatory molecules and proteins necessary for LPS-induced signal transduction<sup>[11-13,16]</sup>, which may be responsible for the induction of tolerance.

Recently we have shown that MO differentiate into

IMACs after immigration into the MCS co-culture with IEC *in vitro*<sup>[18]</sup>. In this study, factor(s) inducing IMAC differentiation *in vitro* were analysed. We showed that the specific IMAC differentiation was not mediated by soluble or membrane bound factors of IEC alone, as no intestinal-like differentiation was observed in freshly elutriated MO cultured together with IEC-conditioned medium or IEC-membranes. Also “weak interactions” between MO and IEC in trans-well cultures, in which MO and IEC (monolayers) were only separated by filter membranes, were not sufficient for differentiation. IMAC differentiation could only be induced in the complex three-dimensional MCS model with close contact between MO, IEC and ECM<sup>[18]</sup>. Loss of MO observed in 1:1 “mixed spheroids” of the IEC lines HT-29 and WiDr was obviously not due to apoptosis, as we could neither block this effect by adding an anti-Fas antibody nor detect

**Figure 6** Mixed spheroids of MO and IEC or the control cell line. Mixed spheroids of the IEC lines HT-29 and WiDr or the control cell line J82 and MO were generated and cultured for seven days, disaggregated and examined by flow cytometry. **A:** There was a strong decrease of surviving MO/MAC (CD33+ cells) inside IEC spheroids compared to control spheroids over the seven-day culture period. In HT-29 spheroids the percentage decreased from 21.7% (24 h) to 1.4% (7 d). In WiDr spheroids a slighter decrease was observed with 14.6% MO/MAC after 24 h and 2.4% after seven days. In spheroids of the control cell line J82 no selection of a MO/MAC subpopulation could be observed. The number of MO/MAC inside the aggregates was nearly constant with 15.2% (24 h) and 13.2% (7 d); **B:** Addition of a blocking anti-Fas antibody 30 min before generation of the mixed spheroids did not change the results. In IEC-MCS a strong decrease of MO/MAC was observed (HT-29: 14.2% 24 h, 0.8% 7 d, WiDr: 20.1% 24 h, 2.3% 7 d). The MO/MAC number in control cell MCS was nearly constant with 13.9% (24 h) and 12.0% (7 d).

activated caspase-3 during the incubation period.

Although MCS do not resemble the *in vivo* situation where IMACs are separated from the IEC by the basement membrane, many conditions such as  $O_2$ -gradient, pH or ECM production are similar to those in the body<sup>[26-28]</sup>. In MCS, cells are also able to form cell-cell and cell-matrix contacts which are found *in vivo*<sup>[29-31]</sup> and may therefore be regarded as a useful model to study the important aspects of IMAC differentiation.

In general, interactions between different cell types, special cytokine milieu and contact with components of the ECM can trigger cells to develop a special phenotype. Hohn and co-workers<sup>[32]</sup> showed that components of the basement membrane and ECM are involved in choriocarcinoma cell differentiation. Hanspal *et al.*<sup>[33]</sup> have demonstrated the importance of cell-cell interactions during the regulation of erythropoiesis. The ECM protein, vitronectin, controls the differentiation of cerebellar granular cells<sup>[34]</sup>. It was reported that ECM also plays a

**Figure 7** Western-blot for caspase-3 of mixed spheroids after 24 h and three days. Mixed spheroids of IEC and MO, control cells and MO or control spheroids generated only from IEC or control cells were disaggregated after 24 h and three days of culture. Western-blot for activated caspase-3 were performed. Lane 1: HT-29 without MO 24 h; lane 2: HT-29/MO (1:1) 24 h; lane 3: J82 without MO 24 h; lane 4: J82/MO (1:1) 24 h; lane 5: HT-29 without MO 3 d; lane 6: HT-29/MO (1:1) 3 d; lane 7: J82 without MO 3 d; lane 8: J82/MO (1:1) 3 d; lane 9: positive control for activated caspase-3. No activated caspase-3 could be detected in co-cultures of MO and IEC or in spheroids generated only from IEC.

**Figure 8** Immunohistochemical staining for the ECM-protein fibronectin in "normal" and mixed spheroids of the IEC line HT-29 after seven days. Fibronectin could be detected in spheroids invaded by MO and cultured for seven days. Expression was preferentially localized in the center of aggregates. In mixed spheroids cultured for seven days no fibronectin expression was observed.

role in the differentiation of embryonic stem cells<sup>[35]</sup> and skeletal muscle cells<sup>[36]</sup>. Armstrong *et al.*<sup>[37]</sup> have shown that ECM proteins have effects on MAC differentiation, growth and function.

Jacob *et al.*<sup>[38]</sup> induced differentiation of MO to MAC *in vitro* by culturing MO on different ECM protein substrates, and found that specific markers associated with differentiation are changes in the expression of cell surface antigens. FACS analysis showed a down-regulation of CD14 occurring in a substrate dependent manner, which was the highest in MO maintained on fibronectin in their study<sup>[38]</sup>.

In our experiments, MCS invaded by MO and cultured

for seven days contained a large amount of ECM protein fibronectin. In addition, the expression of fibronectin was up-regulated during the culture period, which is correlated with the previously described down-regulation of CD14 and other MO-specific surface markers<sup>[18]</sup>. In mixed spheroids no fibronectin expression could be detected, which could be due to a stronger degradation of ECM proteins by the larger amount of MO added or a lack of synthesis induction. Fibronectin present in the described co-culture model seems to be an important factor contributing to the *in vitro* differentiation of IMACs as well as the active invasion of MO into the three-dimensional aggregates, indicating that only a subpopulation of blood MO is able to differentiate into IMACs.

The loss of MO in the “mixed spheroids” could have several reasons. First, differentiation into the intestinal phenotype is necessary for survival in the epithelial cell environment. Second, the higher number of mononuclear cells in the mixed spheroids compared to the model with MO invasion induces factors that lead to cell death or prevent the synthesis of survival factors. Third, we cannot exclude that this is a self protection effect of the tumor cell lines used and that MO only enter the MCS in the MCS model.

We cannot exclude that there is a pre-primed subpopulation of MO in the peripheral blood that is especially suited to get in contact with IEC. According to such a hypothesis only this pre-primed subpopulation would enter the MCS model or the mucosa and further differentiate into IMACs. This natural selection would not be observed in co-cultures of all elutriated peripheral MO with conditioned media, membrane preparations or in mixed spheroids. The number of differentiating cells would be too low to reach a significant difference. In the present study, we investigated this possibility of a pre-primed subpopulation of MO suited for IMAC differentiation.

To understand the differentiation process of IMACs in healthy individuals may further help to find an approach for the therapy of IBD. Local induction of a tolerogenic and anergic IMAC cell type could down-regulate or stop mucosal inflammation. A therapeutic approach inducing differentiation of this cell type would be one step up the inflammatory cascade not aimed at T-cells but at the site of the first contact with antigen entry in the mucosa.

### Abstract

**AIM:** To elucidate the sequential transfer of iron amongst ferritin, transferrin and transferrin receptor under various iron status conditions.

**METHODS:** Incorporation of  $^{59}\text{Fe}$  into mucosal and luminal proteins was carried out in control WKY rats. The sequential transfer of iron amongst ferritin, transferrin and transferrin receptor was carried out in iron deficient, control and iron overloaded rats. The duodenal proteins were subjected to immunoprecipitation and quantitation by specific ELISA and *in situ* localization by microautoradiography and immunohistochemistry in tandem duodenal sections. Human duodenal biopsy ( $n = 36$ ) collected from subjects with differing iron status were also stained for these proteins.

**RESULTS:** Ferritin was identified as the major protein that incorporated iron in a time-dependent manner in the duodenal mucosa. The concentration of mucosal ferritin was significantly higher in the iron excess group compared to control, iron deficient groups ( $731.5 \pm 191.96$  vs  $308.3 \pm 123.36$ ,  $731.5 \pm 191.96$  vs  $256.0 \pm 1.19$ ,  $P < 0.005$ ), while that of luminal transferrin which was significantly higher than the mucosal did not differ among the groups ( $10.9 \pm 7.6$  vs  $0.87 \pm 0.79$ ,  $11.1 \pm 10.3$  vs  $0.80 \pm 1.20$ ,  $6.8 \pm 4.7$  vs  $0.61 \pm 0.63$ ,  $P < 0.001$ ). *In situ* grading of proteins and iron, and their superimposition, suggested the occurrence of a sequential transfer of iron. This was demonstrated to occur through the initial binding of iron to luminal transferrin then to absorptive cell surface transferrin receptors. The staining intensity of these proteins varied

according to the iron nutrition in humans, with intense staining of transferrin receptor observed in iron deficient subjects.

**CONCLUSION:** It is concluded that the intestine takes up iron through a sequential transfer involving interaction of luminal transferrin, transferrin-transferrin receptor and ferritin.

### INTRODUCTION

Iron homeostasis is accomplished by regulating absorption in the proximal small intestine and is regulated according to the body's needs. Failure to maintain this equilibrium leads to pathological conditions resulting in either iron deficiency or iron overload. Iron deficiency anemia remains the most important micronutrient deficiency world wide. Iron is essential because of its unique ability to serve as both an electron donor and acceptor. Because of iron's virtual insolubility and potential toxicity under physiological conditions, special molecules have evolved for its acquisition, transport and storage in soluble, nontoxic form. In humans, heme iron is absorbed more efficiently than non-heme iron<sup>[1]</sup>. Recent studies demonstrate that non-heme iron is transported into the cell in the ferrous [ $\text{Fe}(\text{II})$ ] form, mainly by carrier divalent metal transporter 1 (DMT1)-also known as natural resistance associated macrophage protein 2 (Nramp2) or divalent cation transporter 1 (DCT1)<sup>[2]</sup>. However, iron absorption is not impaired by mutation of DMT-1, suggesting that DMT-1 is not the only transporter operating within the endosomes of crypt cells. Studies of Conrad *et al*<sup>[3]</sup>, showed that ferric iron is absorbed by  $\beta 3$  integrin and mobilferrin pathway which is shared with other nutritional metals.

In last few decades, several candidate proteins involved

in the transmembrane transport of iron have been identified<sup>[4]</sup>. Several years ago, Granick *et al* demonstrated that ferritin sequesters iron and provides the block to iron uptake. Although this model remains unproven, the hypothesis that the amount of mucosal ferritin dictates the extent of iron absorbed by the enterocytes is still intriguing. It has been postulated that iron absorption was the primary method of maintaining body iron homeostasis and was regulated by a mucosal receptor that blocked iron absorption when it became satiated with iron. For two decades, it was believed that ferritin was the receptor that regulates iron absorption, and that apoferritin enhances iron absorption while holoferritin blocks iron uptake. This hypothesis was disproved by immunological studies showing that there was little or no apoferritin in the absorptive cells of iron deficient animals<sup>[5]</sup>. Despite the close relationship between ferritin levels and intestinal iron absorption<sup>[6]</sup> it is not clear whether this protein plays a passive or active role in transport regulation.

There are studies to argue for<sup>[7-11]</sup> and against<sup>[12-14]</sup> the view that transferrin (Tf) is an important mediator of iron absorption. The proposal that mucosal Tf acts as a shuttle protein for iron absorption was suggested by Huebers *et al*<sup>[15]</sup>. Selective localization of transferrin in the duodenal epithelium in rat<sup>[16,17]</sup> and in human<sup>[17]</sup>, and the co-localization of transferrin receptor (TfR) and transferrin in coated pits on the basal and lateral membranes of crypt cells in mouse have been demonstrated<sup>[18]</sup>. However, an ultrastructural study of Parmley *et al*<sup>[19]</sup> failed to identify TfR on the surface of enterocyte microvilli. Thus, the role of transferrin and transferrin receptor in the duodenal uptake was not identified with certainty. In 1983, it was postulated that transferrin was secreted into the intestinal lumen to bind iron and enter the absorptive cell as a transferrin iron complex in a manner similar to non-intestinal cells<sup>[15]</sup>. Recent studies of transferrin receptor knockout mice (TfR<sup>-/-</sup>) provide new insights regarding the physiologic role of the transferrin/transferrin receptor cycle. Homozygous TfR<sup>-/-</sup> animals die *in utero* with impaired erythropoiesis and defective neurological development. Thus, the TfR<sup>-/-</sup> mice provide a convincing demonstration that the transferrin/transferrin receptor cycle plays a central role in the maintenance of normal iron metabolism. Whether transferrin is associated with receptor and whether it plays any role in iron absorption at this site is yet to be determined. A protein called hereditary hemochromatosis (HFE) has been shown to interact with transferrin receptor 1 (TfR1)<sup>[20]</sup> to influence the rate of receptor mediated uptake of transferrin-bound iron<sup>[21-24]</sup>. Thus, these investigations of exact localization of mucosal transferrin and transferrin receptor, inside or outside the enterocytes, are conflicting. Therefore, an attempt was made to describe the sequential movement of iron across intestine. The events were sequenced by *in situ* localization of iron by microautoradiography and immunohistochemistry of ferritin, transferrin and transferrin receptor in serial sections of intestine.

## MATERIALS AND METHODS

Radioactive <sup>59</sup>FeCl<sub>3</sub> (sp.act 4.0 Ci/g iron in 0.01 mol/L

HCl) was obtained from BRIT (Mumbai, India). Photographic emulsion LM-1 was obtained from Amersham (Amersham International plc, UK). SIH universal anti-rabbit kit, human and rat serotransferrin was obtained from Sigma Aldrich Co (St. Louis, USA). Ferritin, transferrin antisera against purified proteins were produced in New Zealand white rabbits. Polyclonal antiserum against rat placental transferrin receptor was a gift from James D. Cook, M.D (University of Kansas Medical Center, Kansas City, USA). All other chemicals used were of analytic grade and procured locally.

## Studies in rats

Rats from National Centre for Laboratory Animal Sciences (National Institute of Nutrition, Hyderabad) were used for the study. All animal experiments were approved by the institutional animal ethics committee.

Incorporation of radioactive iron into various iron binding protein was carried out in *Wistar/Kyoto (WKY)* adult male normal rats (body weight 200 g). Food was withheld for 16-18 h before administering 1 mL of 7-10  $\mu$ ci of <sup>59</sup>FeCl<sub>3</sub> in 0.01N HCl by gavage. Rats were sacrificed at various time intervals starting at 15, 30 min, 1, 2, 4 and 12 h to study the time-dependent incorporation of iron into luminal and mucosal proteins of various segments. All the subsequent operations were carried out on ice. The luminal content was collected by flushing with 5-10 mL of saline containing protease inhibitors. The mucosal scrapings were obtained by scrapping off the everted segments with a glass slide. The intestinal contents obtained from three rats from each group were pooled together for each time point. The contents were homogenized in 1:4 v/v of saline containing a cocktail of protease inhibitors (PMSF 75  $\mu$ g/mL, leupeptin 1  $\mu$ g/mL and iodoacetate 186  $\mu$ g/mL), and subjected to 60% ammonium sulphate fractionation. A clear supernatant was prepared for subsequent analysis.

Further to explore the specific role of duodenal transferrin and ferritin during iron absorption, time-dependent (5 min-4 h) incorporation of radioactive iron into these proteins, along with quantitation by specific ELISA and immunoprecipitation techniques for ferritin and transferrin, was carried out in control, iron-deficient, and excess iron fed rats. For this, 74 *WKY* male weanling rats (body weight 37.5  $\pm$  7.63) were randomly selected and housed individually into iron deficient ( $n = 30$ ), control ( $n = 24$ ) and iron excess ( $n = 24$ ) groups. They were allowed to have free access to food and water for 7 weeks. The rats were placed on one of the three diets each containing identical protein, fat, carbohydrate, and complete vitamin and fiber supplements. The diets were produced in accordance with the recommendations of American Institute of Nutrition (AIN93)<sup>[25]</sup>. The diet also contained a balanced mineral mix, differing only in the iron content. The deficient group received iron deficient semi-synthetic diet containing < 10 mg iron/kg diet, while the iron adequate and excess groups received diet containing 35 and 250 mg/kg diet, respectively. At the end of this period rats were administered 7-10  $\mu$ Ci of radioactive iron and sacrificed at different time points. Duodenal segments

of intestine were collected at 5, 15, 30 min, 1, 2, 4 h and processed. Homogenates of luminal and mucosal contents were analyzed for ferritin and transferrin by specific sandwich ELISA. Incorporation of radiolabelled iron into these proteins was studied by immunoprecipitation with specific antibodies.

Finally, studies were carried out to understand the sequential movement of iron across intestine under various iron status conditions. *WKY* male weanling rats (body weight  $36.8 \pm 6.56$ ) were equally ( $n = 8$ ) distributed into iron deficient, control and iron overload groups. For iron overloading, in addition to iron excess diet as mentioned above, we gave 4 intra-peritoneal injections of 1 mL of imferon, an iron sorbitol citric acid complex in water (50 mg of iron/mL, Rallies India Ltd, Mumbai, India) at weekly intervals. After 7 wk, rats were fasted overnight and given 100  $\mu$ Ci of  $^{59}\text{FeCl}_3$  with 0.25 mg of carrier iron as ferrous sulphate by gavage. Duodenal segment of intestine were collected at 5, 15, 30 min, 1, 2, 4, 16 h. The segments were flushed with formalin, cut opened longitudinally and fixed in 10% neutral formalin for 12 h. These intestinal segments were rolled longitudinally (Swiss-roll), and further processed for microautoradiography and immunohistochemistry.

#### **Western blotting and autoradiography**

The protein content was estimated by the method of Bradford<sup>[26]</sup>. Both luminal and mucosal proteins (100  $\mu$ g) were subjected to 4%-20% PAGE along with rat liver ferritin as a marker. The separated protein bands were visualized by autoradiography and probed with ferritin antibody.

#### **ELISA of ferritin and transferrin**

Ferritin and transferrin proteins in the luminal and mucosal contents were quantified using a specific sandwich ELISA system developed by us.

#### **Immunoprecipitation**

In order to understand the role of different iron binding proteins during absorption, luminal contents and mucosal proteins were lyophilized. Duodenal mucosal and luminal proteins obtained at initial time points (5, 15, 30 min) were reconstituted and subjected to immunoprecipitation with ferritin and transferrin antisera. Equal volumes (1 mL) of duodenal mucosal and luminal proteins (2-4 mg) and 1:32 diluted ferritin and transferrin antisera were incubated at 37°C for 1 h and at 4°C overnight. The specificity of ferritin and transferrin antisera was demonstrated by replacing immune serum with non-immune serum in the immunoprecipitation protocol. The immunoprecipitate was collected and washed three times with PBS.  $^{59}\text{Fe}$  radioactivity in the fraction was counted in a gamma counter (Packard Autogamma, Cobra II). A known activity of  $^{59}\text{FeCl}_3$  was run with samples to correct for decay and counting efficiency of the gamma counter.

#### **Preparation of intestinal sections for microautoradiography and immunohistochemistry**

An automatic tissue processor (Shandon, Processor

2LE) using ascending grades of isopropyl alcohol and chloroform was used. The processed tissue samples were embedded in paraffin (58-60°C) using a Leica tissue-embedding unit. A set of 10 serial sections of 4  $\mu$  thickness were taken from each block using Reichert-Jung 2030 rotary manual microtome. The sections were mounted on chromalum-gelatin coated glass slides and further processed for immunohistochemistry and microautoradiography according to standard procedures.

#### **Microautoradiography**

*In situ* localization of radiolabelled iron was carried out in dehydrated sections. The sections were processed with photographic emulsion according to the manufacturer's guidelines (Amersham LM-1, Amersham UK). These sections were stained with hematoxylin, dehydrated and mounted with DPX mounting medium. For signals, the sections were viewed under light microscope (Leitz Ortholux) and photographed.

#### **Immunohistochemistry**

Serial sections were used for immunohistochemical localization of transferrin, transferrin receptor and ferritin, using respective antisera. The binding of each antiserum to their respective proteins was done using Sigma SIH kit. Counter-staining was done with Mayer's hematoxylin. Control slides were layered with non-immune serum instead of primary antiserum. The localization of the antigen was done using goat anti-rabbit HRP conjugate. The comparison of staining intensity and the quantification of positively stained cells was carried out under light microscope with the magnification set at 10 $\times$ , 25 $\times$  or 40 $\times$ . In addition, the distribution of intestinal mucosal ferritin, transferrin and transferrin receptor in relation to iron status was evaluated in human biopsy specimens.

#### **Human duodenal mucosal biopsy**

Endoscopic intestinal (duodenal) biopsy specimens were collected by a gastroenterologist from 30 males and 6 females attending the Gastroenterology Department of Gandhi Hospital (Secunderabad, India) for various upper GI tract related ailments. Informed oral consent was obtained from all the subjects. All the subjects were classified based on their hematological and iron status parameters. Accordingly, a cut off value of hemoglobin < 13 g/dL for male and < 12 g/dL for female was classified as anemia, while anemia with serum ferritin < 12  $\mu$ g/L as iron deficiency anemia. Biopsy specimens of 3-4 mm were collected and immediately spread on a wire mesh. These specimens were then immersed in 10% neutral buffered formalin solution and processed for immunohistochemistry of ferritin, transferrin and transferrin receptor, as described earlier.

#### **Haematological and iron status indicators**

Fasting blood samples were collected from rats and human subjects to estimate haemoglobin and iron status parameters. Hemoglobin was estimated by an automated hematology counter (Serono system 9000 Rx). Quantitation

**Figure 1** Ferritin takes up radiolabelled iron in a time dependent manner and has a direct role in iron absorption: Upper panel: Autoradiogram of duodenal proteins. Duodenal mucosal proteins (100 µg) obtained after 15 min, 30 min, 1 h after an oral dose of 7-10 µCi of  $^{59}\text{FeCl}_3$  were subjected to 4%-20% PAGE and dehydrated. The radioactive bands were developed on X-ray film. As shown in the figure, one radioactive band corresponding to ferritin whose intensity was maximal at 30 min and then decreased with time. Lower panel: These proteins were subjected to western blot with ferritin antibody.

of human and rat serum ferritin, rat mucosal, and luminal ferritin and transferrin was estimated by homologous sandwich ELISA systems developed by us. Liver iron was estimated by dry ashing followed by an estimation of iron in the mineral solution by bathophenanthroline method<sup>[1]</sup>.

## RESULTS

Initially, a kinetic study was carried out to understand the *in vivo* time course of iron absorption of  $^{59}\text{Fe}$  given by oral gavage to rats with normal iron status condition. Specific activity of duodenal mucosa was found to be highest, followed by jejunum, ileum and stomach at all time points studied. The specific activity of  $^{59}\text{Fe}$  was found to increase with time and attained a peak at 30 min in duodenal mucosa (data not shown).

### Ferritin takes up radio-labelled iron in a time dependent manner and has a direct role in iron absorption

In order to understand the role of ferritin in iron absorption, an autoradiogram was performed with proteins obtained from 60% ammonium sulphate precipitation of luminal and mucosal fractions after oral administration of  $^{59}\text{Fe}$ . As shown in Figure 1, upper panel, rats with normal iron status showed a single radioactive protein band identical to purified rat liver ferritin. The intensity of the radioactive band associated with ferritin increased with time and showed maximal band intensity at 30 min and decreased subsequently with no change in the ferritin protein band intensity (Figure 1, lower panel). These results suggested that intestinal ferritin is an important component of the intestinal iron transport system and seems to take up iron and facilitate its transfer across the mucosal cells. Thus these results demonstrate that ferritin is not just a sink but takes up iron and releases it in a time-dependent manner during the absorptive process.

To determine the specific role of iron binding proteins like ferritin, transferrin and transferrin receptor, rats were given different amounts of iron. Haematological and iron status parameters indicated the induction of iron deficiency and iron overloading in respective groups (data not shown). Table 1 shows the ferritin and transferrin concentrations in the intestinal luminal and mucosal contents of rats with various iron status parameters. The concentration of ferritin was higher in mucosa than in the lumen of duodenum in all the groups. In iron excess

**Table 1** Ferritin and transferrin concentrations in rat duodenum under various iron status conditions

Parameter	Control	Iron deficient	Iron excess
Ferritin (ng/mg protein)			
Lumen	126.0 <sup>a</sup> ± 61.42	105.8 <sup>a</sup> ± 35.81	228.8 <sup>c</sup> ± 73.54
Mucosa	308.3 <sup>c</sup> ± 123.36	256.0 <sup>c</sup> ± 1.19	731.5 <sup>e</sup> ± 191.96
Transferrin (µg/mg protein)			
Lumen	10.9 <sup>b</sup> ± 7.6	11.1 <sup>b</sup> ± 10.3	6.8 <sup>b</sup> ± 4.7
Mucosa	0.87 <sup>d</sup> ± 0.79	0.80 <sup>d</sup> ± 1.20	0.61 <sup>d</sup> ± 0.63

Values with different superscript letters within each column and row are significantly different at <sup>a,c,e</sup> $P < 0.005$  for ferritin and <sup>b,d</sup> $P < 0.001$  for transferrin by one way ANOVA ( $n = 5$ ).

group, there was a significantly higher concentration of ferritin, both in lumen and mucosa, compared to deficient and control groups. In contrast, the transferrin concentration was significantly higher in lumen than in mucosa within the group and was similar between the groups.

### Reciprocal relationship between luminal transferrin and mucosal ferritin iron

To understand the interaction between luminal transferrin and mucosal ferritin after oral administration of  $^{59}\text{Fe}$ , rats were sacrificed at 5, 15 and 30 min. As shown in Figure 2A the percentage of radioactive iron in duodenal lumen was found to decrease with time. The highest luminal specific activity was seen in iron-deficient rats followed by control and iron excess fed rats. In deficient and control rats, there was a progressive increase in specific activity while in the excess iron fed group, the radioactivity was retained at the site of absorption (Figure 2B). This was supported by the findings on luminal and mucosal radioactivity, which showed a faster transit of iron from lumen to mucosa in iron-deficient and control rats. On the other hand, in the iron excess fed rats luminal radioactivity showed slower transit as indicated by increase in the radioactivity from 30 min onwards. The plasma radioactivity during the same time periods reflected the slower transit of duodenal iron in iron excess fed rats (plasma specific activity of  $150 \pm 20$  dpm/mL during 15-60 min) which showed no peak in plasma iron as compared to the iron-deficient and control groups (plasma specific activity of  $700 \pm 50$  and  $400 \pm 50$  dpm/mL, respectively). The luminal transferrin iron declined with time in all the groups while that of mucosal ferritin increased only in deficient and sufficient groups during the 5-30 min of iron uptake (Figure 2). As shown in Figure 2B percentage of ferritin bound iron reached a peak and showed a decline confirming the release of iron from ferritin in deficient and control groups. In the iron excess group the percentage ferritin-bound iron did not change with time, confirming the blockage of iron in this group.

### Microautoradiography demonstrate the sequential transfer of radiolabelled iron

In order to study the *in vivo* translocation of iron after oral administration of radiolabelled iron, duodenal

segments were processed for microautoradiography under various iron status conditions. Table 2 shows the grading of staining intensities of radiolabelled iron, ferritin, transferrin/transferrin receptor in the iron deficient and iron excess groups. The radioactivity at 5 min was localized on the surface of the villi in the iron deficient group (top left panel ID, 5 min) (Figure 3). Subsequently, the radioactivity was present in the columnar epithelial cells (absorptive cells) at the tip of the villi between 15 min to 1 h in iron deficient (top right, panel ID, 15, 30 min, 1 h, and Table 2). At 2 and 4 h most of the radioactive iron was seen inside the villi in the lamina propria. A similar trend was observed in the control group (middle, panel C, 5 min and 15, 30 min, 1 h). However, in iron-overloaded intestine, high intensity radioactivity was noticed at 5 min on the surface (bottom left, panel OL, 5 min) but was minimal signals at 15 and 30 min (bottom right panel OL, 15 min and Table 2). The radioactive signals at 15 and 30 min associated with iron were maximal intraepithelially in iron-deficient rats and plasma radioactivity indicated

**Figure 3** Microautoradiography demonstrated the sequential transfer of iron: Microautoradiography of duodenal sections of intestine obtained after oral administration of 100  $\mu\text{Ci}$  of  $^{59}\text{FeCl}_3$  and 250 g of carrier iron in iron deficient top panel (ID), control middle panel (C) and iron overload bottom panel (OL) rats. These photographs illustrate the progressive transfer of iron into the villi (25  $\times$ ).

maximum absorption. In iron-overloaded rats the signal was maximal at 5 min and seen only at the absorptive surface and retained at the site of absorption (Table 2).

### Ferritin appears in the epithelial cells after oral administration of iron

Immunohistochemistry with ferritin antibody demonstrated that at 5 min, ferritin staining was maximal intraepithelially in iron-deficient intestine (Figure 4), while intense staining was seen both intraepithelially and intravascularly, in iron-overloaded intestine (Figure 4 top right, panel OL, 5 min Fe). The intensity of staining within the villi at 1 h (bottom left panel ID-1 h, Fe) was minimal and similar to that seen at basal status in iron deficient intestine. On the other hand, the staining intensity was

**Figure 4** Ferritin appears in the epithelial cells after oral administration of  $^{59}\text{Fe}$ : Immunohistochemical localization of ferritin (Fe) in the duodenal sections of intestine of iron deficient left panel (ID) and iron overload right panel (OL) rats at various time points after oral administration of radioactive iron (25 X).

lower in iron-loaded intestine after 15 min indicating the presence of holoferritin and blocking of iron absorption (Table 2).

#### **Microautoradiography and immunohistochemistry with transferrin and transferrin receptor demonstrates the *in vivo* uptake of iron through transferrin receptor**

The *in situ* localization of radioactive iron in the iron deficient group indicated its presence on the cell surface (5 min) and then intraepithelially (15, 30 min) in the villi (Table 2). The intensity of transferrin staining was found to be maximal at the tip of the epithelial cells at 15 min (Figure 5, left panel ID 15 min Tf) and subsequently decreased to basal status. Staining of the blood vessels for transferrin started to appear from 2 h onwards in ID (bottom left panel ID, 2 h Tf). The staining for transferrin at 15 min within the epithelial cells was not observed in iron-overload group (Table 2). In the iron-overload group, staining due to transferrin was minimal at 5-30 min (Figure 5B, top left panel Tf, OL 30 min). In both groups, the transferrin receptor was localized mainly on the surface of the duodenal villi, thus demonstrating margination of transferrin receptor after oral administration of iron (right top panel Figure 5A, TfR, Basal). This, however, at 15 min was internalized at the tip of the epithelial cells along with iron and transferrin (Figure 5A). After 2hr TfR reappeared on the surface of the villi in the iron deficient (Figure 5A, middle right panel, TfR, ID, 15 min, 2 h) demonstrating the *in vivo* receptor recycling. In contrast, in the iron-overload group TfR was seen only at the surface even at 30 min and 1 h (Figure 5B, bottom panel, TfR, OL, 15 min, 1h) showing no internalization of receptor.

The radioactive signals at 15 min were maximal intraepithelially in the iron deficient group. During this time period, transferrin and its receptor were also co-localized maximally within the epithelial cells (Figure 5C). The intensities of both these proteins subsequently

diminished and minimal staining was seen at the margin of the absorptive surface. The intensity of transferrin receptor staining was maximal along the entire margin during different time points in the iron-overloaded intestine. This was a striking difference between the two extreme conditions. Microautoradiography along with the immunohistochemistry of ferritin and the transferrin/transferrin receptor demonstrated the *in vivo* internalization of transferrin and its receptor along with radiolabelled iron and recycling of the receptor to the surface. This clearly shows a transferrin-mediated iron uptake at the absorptive surface of the rat intestine.

#### **Staining intensity of ferritin, transferrin/ transferrin receptor in human duodenal biopsy under different iron nutritional status**

In addition, we have performed immunohistochemistry of ferritin, transferrin/transferrin receptor in human duodenal biopsy specimens collected from various iron status conditions. All the subjects were classified according to their indicators of iron status such as haemoglobin, serum ferritin (Table 3). According to these parameters, 13 of them belonged to normal group, 6 had iron-deficient anemia, 14 anemia, one each had blood transfused, iron injected and iron given orally as supplement. Representative immunohistochemical images for ferritin, transferrin and transferrin receptor of duodenal biopsy from normal, iron deficient anemia and blood transfused are given in Figure 6. The staining intensity for ferritin varied according to iron status and thus staining was +++ normal (top left),  $\pm$  iron deficient (middle left panel Fe ID) and ++ in blood transfused (Figure 6 bottom left panel Fe BT) subjects. The intensity of transferrin staining was also similar to that of ferritin staining in normal, iron-deficient and in blood transfused subjects (center top, middle and bottom panels respectively). The transferrin receptor on the other hand, stained more intensely with a grading score of (+++) in

**Figure 5** Microautoradiography and immunohistochemistry with transferrin and transferrin receptor demonstrates the in vivo uptake of iron through transferrin receptor. **A:** Immunohistochemical localization of transferrin left panel (Tf) and transferrin receptor right panel (TfR) in the duodenal sections of intestine of iron deficient rat (ID); **B:** transferrin stain in iron over loaded rat (OL) at basal status and transferrin receptor on the surface of the epithelial cells showing no internalization (bottom panel) in iron overloaded condition after oral administration of radioactive iron (10X); **C:** Co-localization of iron, transferrin and transferrin receptors in the duodenal sections of intestines of iron deficient rats obtained 15 min after oral administration of radioactive iron. the iron-deficient subjects (Figure 6 middle right panel ID TfR) compared to + in normal (top right panel, TfR) and blood transfused subjects (bottom right panel BT TfR).

## DISCUSSION

Ferritin, transferrin and transferrin receptor are the important proteins that regulate iron homeostasis in almost all the cells. However, the actions of these proteins in the

absorptive cells remain unclear. Data on the role of these proteins were obtained mainly by studying one protein at a time. By attempting to sequence serially the role of these proteins together, during intestinal uptake, we were able to provide evidence for *in vivo* receptor mediated uptake of iron.

The radioactive signals at 15 to 30 min associated with iron were maximal intraepithelially in iron deficient rats. Along with iron, both transferrin and transferrin receptor

were co-localized at this time. The intensities of both these proteins were subsequently decreased and minimal amounts were seen at the margin of absorptive surface in iron deficient intestine. In addition, ferritin appeared intraepithelial in iron deficient and control groups, suggesting its modulation during the absorptive phase. Presence of most of the radiolabelled signal only on absorptive surface at 5 min and beyond in iron-overloaded rats suggest its restricted entry into the duodenum due to the presence of mucosal holo ferritin. This is supported by the intense ferritin staining seen both intraepithelial and intravascular in iron overloaded intestine, especially during absorptive phase and beyond. Further, the presence of transferrin receptor along the entire margin during different phases of iron uptake suggests no internalization of transferrin receptor in iron excess condition.

It is interesting to note that the concentration of mucosal ferritin and the iron associated with it was similar in control and iron deficient groups, and was significantly lower than that seen in the excess iron fed group. This could be due to the regulatory role of mucosal ferritin at the site of adsorption in the case of iron excess, while in the case of normal and iron deficient duodenum it could release the incorporated iron.

A positive relationship between *in situ* localization of ferritin and better iron status was demonstrated in rats and humans. The results on autoradiography of rat duodenal mucosal and luminal preparations suggests that intestinal ferritin takes up iron and releases it in a time dependent manner during the absorptive process. This is supported by the findings on localization of iron in the duodenal mucosa during absorption which showed a positive relationship, with better iron status at 5 min and a negative relationship at 15 min-1h. Similarly in human subjects, the intensity of ferritin staining was lowest in iron deficient subjects, highest in normal subjects and in between in the case of the blood transfused subjects. These observations suggest that mucosal ferritin is an important component of the intestinal iron transport system which takes up iron and facilitates its transfer across the mucosal cells.

The studies of Miyoshi *et al*<sup>[27]</sup> support the presence of ferritin in duodenum. Their studies showed accumulation of iron in the apical area of duodenal villous cells with in ferritin. The presence of maximal <sup>55</sup>Fe radioactivity at 5 min over the brush border and terminal web was demonstrated by Bedard *et al*<sup>[28]</sup>. They observed that during the next 3 h, radioactivity was present almost exclusively in absorptive cells and in lamina propria. In contrast, Conrad and Crosby<sup>[29]</sup> observed very little radioactivity in the small intestinal mucosa of iron-depleted and iron overload rats from 2-48 h after gastric administration of <sup>59</sup>Fe. This discrepancy may be due to the fact that they did not included time points earlier than 2 h. Because it is an inducible protein, it is possible that ferritin expression at the sites of absorption may be related to the iron status. This suggests that iron absorption is probably dependent on the relative concentrations of mucosal apo and holo ferritins, and is inhibited in conditions of iron overload and enhanced in iron deficiency.

Quantitatively, the amount of transferrin in the lumen is 10 times higher than that of mucosa and is not dependent on iron nutritional status (Table 1). The observation on identical amounts of luminal transferrin, irrespective of iron nutritional status, implies that this protein may be presenting equal amount of iron for absorption. The net amount of iron, which is taken up by the mucosa, thus depends on mucosal transferrin receptors. Duodenal mucosal transferrin receptor showed reciprocal relationship with iron status. The significance of this may be to present equal amounts of iron for absorption through binding to luminal transferrin. Consequently, the amount of iron absorbed by the mucosa may depend only on the mucosal transferrin receptor which has inverse relationship with better iron status.

Huebers *et al*<sup>[8,15]</sup> suggest that luminal transferrin acts as a shuttle protein for iron uptake. Autoradiographic studies by Conrad and Crosby<sup>[30]</sup> and Bedard *et al*<sup>[28]</sup> also suggest that intestinal crypt cells are able to take up transferrin-bound iron from circulation. According to some other investigators, however, transferrin is unlikely to be a major transporter of iron from lumen to the baso-lateral membrane<sup>[31-33]</sup>. According to Idzerda<sup>[34]</sup>, the transferrin gene is not expressed in the intestine and, therefore, cannot be synthesized. Thus, it is possible that the luminal transferrin may be imported from plasma, as hypothesized by Parmley *et al*<sup>[19]</sup>.

Although the receptor mediated cellular uptake of iron is well known and takes place in all dividing cells, such a mechanism operating in the intestine has not been documented earlier. The results of this study, in conjunction with earlier observations<sup>[5,35-37]</sup>, allow us to propose a model for intestinal iron absorption whereby, the recycling of transferrin and transferrin receptors enables luminal transferrin bound iron to enter the enterocytes. The receptor density at the absorptive surface, which is inversely proportional to better iron nutritional status, might regulate this iron uptake process.

The presence of transferrin and its receptor on the margin during basal condition, and the appearance of both the receptor and the ligand at 15 min intraepithelially along with the radiolabelled iron in iron depleted rat intestine, support the above model. The appearance of TfR after 2 h on the margin of villi suggests that the receptor protein returned to the surface after releasing iron. In contrast, there was no evidence of intraepithelial transferrin and transferrin receptor in iron overloaded intestine, as evidenced by the presence of receptor on the margin even at 30 min.

Though the staining intensity of transferrin in duodenal section was high in control subjects, there was no obvious difference between iron deficient subject and blood transfused subjects. Staining for transferrin was intense in the apical portion and blood vessels, while that of transferrin receptor was more concentrated at the epithelial lining of duodenum (Figure 6). The higher intensity of transferrin receptor in iron deficient subjects and minimal in control and blood transfused subjects suggests a role for it in iron absorption. This is supported

by the reciprocal relationship observed between transferrin receptor and ferritin staining. Similar finding on TfR staining at the margin of the villi was observed by Banerjee *et al.*<sup>[36]</sup>. The ultrastructural studies of Levine *et al.*<sup>[35]</sup> have shown that transferrin receptor and transferrin are co-localized in coated pits on the basal and lateral membranes of crypt cells. Further, Anderson *et al.*<sup>[35]</sup> confirmed that the TfR is a prominent protein on the basal and lateral membranes of intestinal epithelial cells.

The above findings, along with earlier observation, suggest that luminal transferrin must be presenting equal amount of iron for absorption since this protein does not respond to iron status. The net amount of iron taken up by mucosa depends on mucosal transferrin receptors, which respond reciprocally with better iron status. These results suggest that mucosal ferritin, luminal transferrin and mucosal cell surface transferrin receptors are closely related to iron status and interact with each other in carrying iron across the intestinal mucosa.

### Abstract

**AIM:** To investigate the influence of heme oxygenase-1 (HO-1) gene transfer on the viability and function of cultured rat islets *in vitro*.

**METHODS:** Islets were isolated from the pancreata of Sprague-Dawley rats by intraductal collagenase digestion, and purified by discontinuous Ficoll density gradient centrifugation. Purified rat islets were transfected with adenoviral vectors containing human HO-1 gene (Ad-HO-1) or enhanced green fluorescent protein gene (Ad-EGFP), and then cultured for seven days. Transfection was confirmed by fluorescence microscopy and Western blot. Islet viability was evaluated by acridine orange/propidium iodide fluorescent staining. Glucose-stimulated insulin release was detected using insulin radioimmunoassay kits and was used to assess the function of islets. Stimulation index (SI) was calculated by dividing the insulin release upon high glucose stimulation by the insulin release upon low glucose stimulation.

**RESULTS:** After seven days culture, the viability of cultured rat islets decreased significantly ( $92\% \pm 6\%$  vs  $52\% \pm 13\%$ ,  $P < 0.05$ ), and glucose-stimulated insulin release also decreased significantly ( $6.47 \pm 0.55$  mIU/L/30IEQ vs  $4.57 \pm 0.40$  mIU/L/30IEQ,  $14.93 \pm 1.17$  mIU/L/30IEQ vs  $9.63 \pm 0.71$  mIU/L/30IEQ,  $P < 0.05$ ). Transfection of rat islets with adenoviral vectors at an MOI of 20 was efficient, and did not impair islet function. At 7 d post-transfection, the viability of Ad-HO-1 transfected islets was higher than that of control islets

( $71\% \pm 15\%$  vs  $52\% \pm 13\%$ ,  $P < 0.05$ ). There was no significant difference in insulin release upon low glucose stimulation (2.8 mmol/L) among Ad-HO-1 transfected group, Ad-EGFP transfected group, and control group ( $P > 0.05$ ), while when stimulated by high glucose (16.7 mmol/L) solution, insulin release in Ad-HO-1 transfected group was significantly higher than that in Ad-EGFP transfected group and control group, respectively ( $12.50 \pm 2.17$  mIU/L/30IEQ vs  $8.87 \pm 0.65$  mIU/L/30IEQ;  $12.50 \pm 2.17$  mIU/L/30IEQ vs  $9.63 \pm 0.71$  mIU/L/30IEQ,  $P < 0.05$ ). The SI of Ad-HO-1 transfected group was also significantly higher than that of Ad-EGFP transfected group and control group, respectively ( $2.21 \pm 0.02$  vs  $2.08 \pm 0.05$ ;  $2.21 \pm 0.02$  vs  $2.11 \pm 0.03$ ,  $P < 0.05$ ).

**CONCLUSION:** The viability and function of rat islets decrease over time in *in vitro* culture, and heme oxygenase-1 gene transfer could improve the viability and function of cultured rat islets.

### INTRODUCTION

Diabetes affects more than 200 million people worldwide<sup>[1]</sup>. The mainstay treatment for type I diabetic patients is chronic insulin injection. While exogenous insulin therapy has dramatically reduced mortality in diabetes, patients often succumb to the long-term sequelae of diabetic angiopathy, either in the form of nephropathy, neuropathy or retinopathy. Vascularized pancreas transplantation reliably restores normoglycemia and maintains long-term glucose homeostasis, but it has significant surgical morbidity and mortality<sup>[2]</sup>. In 2000, with the success of the 'Edmonton protocol', which had produced insulin independence in 85% of type I diabetic patients one year after allogeneic islets transplantation combined with a non-steroid immunosuppressive regimen, islet transplantation has progressed from research to clinical reality<sup>[3]</sup>.

The technique to maintain isolated islet preparations in tissue culture has been adopted by most islet transplant centers. Islet culture for a brief period (24 to 72 h) has emerged as the current standard procedure prior to clinical transplantation<sup>[4,5]</sup>. It offers advantages over immediate infusion post-isolation, enabling assessment of islet quality and safety, and reducing islet immunogenicity as well as recipient travel to the transplantation site and immunosuppression before transplantation<sup>[6]</sup>. But *in vitro* culture of islets has been shown to result in loss of viable tissue over time, and a decrease in glucose responsiveness has been observed in those islets which survive<sup>[7,8]</sup>.

Several phenomena, including activation of free radicals, apoptosis and necrosis, may be responsible for these effects. Therefore, approaches towards enhancing islets resistance to these insults would facilitate both clinical and investigative trials. As a cellular graft, islets are especially suited for gene therapy. An attractive strategy for protecting islets in *in vitro* culture is to use gene therapy to transduce islets with cytoprotective genes that can make islets more resistant to injury.

Heme oxygenase-1 (HO-1) is the rate-limiting enzyme in the heme degradative pathway that catalyzes the oxidation of heme into biliverdin, carbon monoxide (CO), and free iron<sup>[9,10]</sup>, and it has been described as a ubiquitous inducible stress protein capable of cytoprotection *via* radical scavenging and apoptosis prevention. Overexpression of HO-1 by chemical induction or gene therapy has been used to reduce the deleterious effects of oxidative stress and apoptosis in various cell types and animal models<sup>[11-14]</sup>.

Compared with chemical induction, gene transfer can provide effective, targeted, and relatively persistent expression of HO-1. The aim of the present study was to investigate the influence of HO-1 gene transfer on the viability and function of cultured rat islets, and to explore the potential value of HO-1 gene transfer in islet transplantation.

## MATERIALS AND METHODS

### Animals

Twenty male Sprague-Dawley rats weighing 250 to 300 g were purchased from Shanghai Experimental Animal Center of Chinese Academy of Sciences.

### Rat islet isolation and culture

Rat islets were isolated from the pancreata of the outbred male Sprague-Dawley rats by a collagenase digestion technique and discontinuous Ficoll density gradient centrifugation<sup>[15]</sup>. The main bile duct was located and clamped at both ends. Ten milliliters of collagenase P (Roche Applied Science, Indianapolis, Ind, USA) solution (1 g/L, pH 7.8) was injected into the duct and then the distended pancreas was surgically resected, and incubated at 38°C for 15 min. The digested gland was vigorously shaken for 10 s and the digestion was stopped by Hank's solution (4°C) with 100 mL/L fetal calf serum (Gibco, BRL, USA). The tissue was filtered through a 600 µm screen, and then washed by Hank's solution twice. Islets were purified by centrifugation at 3000 r/min for 20 min on discontinuous Ficoll (Pharmacia Fine Chemicals,

Uppsala, Sweden) gradients. After several washes with Hank's solution, islets were suspended in RPMI-1640 medium (Gibco, BRL, USA) containing 100 mL/L fetal calf serum (Gibco, BRL, USA), 20 mmol/L HEPES (Sigma-Aldrich Chemicals, Louis Mo, USA), 100 kU/L of penicillin and 100 g/L of streptomycin at 37°C in a humidified atmosphere of 50 mL/L CO<sub>2</sub>. Islets purity was assessed by dithizone (Sigma-Aldrich Chemicals, Louis Mo, USA) staining, and islets were counted and scored in size. An algorithm was used for the calculation of 150 µm-diameter islet equivalent number (IEQ).

### Adenoviral vectors

Adenoviral vectors were prepared by use of the AdEasy system (Stratagene, Baltimore, USA). Human HO-1 cDNA was cloned into pAdTrack-CMV. Once constructed, the shuttle vector was linearized with *Pme* I and co-transformed into *E. coli* BJ5183 together with pAdEasy-1, the supercoiled viral DNA plasmid. Transformants were selected on kanamycin and the recombinants were subsequently identified by restriction digestion. Once a recombinant was identified, it was produced in bulk using the recombination-deficient XL10-Gold<sup>®</sup> strain. Purified recombinant adenoviral plasmid DNA was then linearized by *Pac* I to expose its inverted terminal repeats (ITR) and transfected into HEK293 cells where deleted viral genes necessary for virus assembly were complemented *in vivo*. The pAdEasy-1 vector will not replicate in cells other than complementing cells (293 cells). This vector has been developed to infect but not replicate in non-permissive target cells. Ad-EGFP was generated using the same system and supplied by the Institute of Genetics of Fudan University. Viral titers were determined by plaque assay and expressed as plaque forming units per mL (pfu/mL). Viral titers of Ad-HO-1 and Ad-EGFP were  $1.96 \times 10^9$  and  $1.99 \times 10^9$  pfu/mL, respectively.

### Adenovirus infection

Aliquots of 30 IEQ were resuspended in 0.5 mL serum-free culture medium and placed in a 24-well culture plate and incubated with Ad-HO-1 and Ad-EGFP vectors at a multiplicity of infection (MOI) of 20 at 37°C for 4 h with agitation every 1 h. MOI was calculated using the assumption that islets contain on average 1000 cells. After infection, islets were washed twice with culture medium and incubated for at least 48 h before further analysis to allow for transgene expression. Control islets were mock infected. Mock infected islets underwent a similar procedure, but were not exposed to viruses during the incubation period and were not incubated with any vectors.

### Western blot analysis

Islet cells (48 h post-transfection) were washed with cold phosphate buffered saline (PBS) and lysed in 2% SDS, Tris-HCl 60 mmol/L (pH 6.8) buffer, incubated at 95°C, sonicated in a water bath at 37°C and centrifuged at 12000 r/min for 15 min. Assessment of the total protein content was carried out with the BCA detection kit (Pierce Biotechnology, Rockford, IL, USA). Aliquots corresponding to 100 µg of protein were subjected to electrophoresis on a 15% SDS-PAGE pre-cast gel

**Figure 1** Purity and viability of freshly isolated rat islets. **A:** Islets stained with DTZ (red staining indicates islets; islet purity was above 90%); **B:** Islets stained with AO/PI (green staining indicated live cells, red staining indicated dead cells; islet viability was above 90%). Bar = 150  $\mu$ m,  $\times$  200 magnification.

and transferred electrophoretically to a nitrocellulose membrane. The membranes were incubated with 50 g/L non-fat dry milk in TBS (20 mmol/L Tris, 500 mmol/L NaCl, pH 7.5) overnight at 4°C to block non-specific binding. The blots are then incubated with the murine antihuman HO-1 monoclonal antibodies (StressGen, Victoria, BC, Canada) at a dilution of 1:200 for 2 h at room temperature; this was followed by a 1 h incubation with the AP-conjugated rabbit antimouse polyclonal antibody (Promega, USA) at a dilution of 1:1000. The protein bands were visualized by the NBT + BCIP staining system (Haoyang Biological Manufacture Co, Ltd, Tianjin, China).

### Islet viability

Islet viability was evaluated by acridine orange (AO)/propidium iodide (PI) (Sigma-Aldrich Chemicals, Louis Mo, USA) fluorescent staining. The fluorescent dye, containing 10  $\mu$ L AO (670  $\mu$ mol/L) and 1 mL PI (750  $\mu$ mol/L), was used at a 1:10 dilution. After the islets were washed twice with Hank's solution, the fluorescent dye was added to each well. Ten minutes later, islets were analyzed under a fluorescence microscope. Living cells were identified by green staining (AO), whereas dead cells showed a brown-red staining (PI).

### Islet function

*In vitro* function of freshly isolated islets and cultured islets was assessed by glucose-stimulated insulin release. Islets of different groups were washed with PBS twice, and incubated first in low (2.8 mmol/L) and then in high (16.7 mmol/L) concentrations of glucose in culture medium. The static incubation assay was performed in a 24-well flat-bottomed culture plate with 30 IEQ/well and 3 duplicate wells for each islet group. Supernatant from each well was collected after each 1 h incubation, and the concentration was measured using an insulin radioimmunoassay kit (Jiuding Biotech Co, Ltd, Tianjin, China). Stimulation index (SI) was calculated by dividing the insulin release upon high glucose by the insulin release upon low glucose stimulation.

### Statistical analysis

Data are expressed as mean  $\pm$  SD. Statistical and graphical analysis was performed with software of SPSS10.0. Analyses were performed using the two-tailed Student's t-test where appropriate.

**Figure 2** Effect of culture on glucose-stimulated insulin release. The insulin release upon either high or low glucose stimulation decreased conspicuously after seven days culture,  $P < 0.05$

## RESULTS

### Purity and viability of freshly isolated rat islets

The purity of freshly isolated islets was above 90% calculated from the ratio of dithizone stained cells to dithizone nonstained cells as a percentage of the total cell number (Figure 1A). The viability of freshly isolated islets was above 90% calculated from the ratio of AO staining cells (living cells) to PI staining cells (dead cells) as a percentage of the total cell number (Figure 1B).

### Effect of *in vitro* culture on insulin release

The glucose-stimulated insulin release was used to assess the function of cultured rat islets. As shown in Figure 2, after 7 d culture, the insulin release upon low and high glucose stimulation decreased from  $6.47 \pm 0.55$  to  $4.57 \pm 0.40$  mIU/L/30IEQ, and from  $14.93 \pm 1.17$  to  $9.63 \pm 0.71$  mIU/L/30IEQ, respectively. In other words, islet function decreased conspicuously over time in *in vitro* culture.

### Exogenous gene expression in adenovirus-transduced rat islets

Typical fluorescence micro-photographs of rat islets transfected with Ad-EGFP at an MOI of 20 were taken at 48 h post-transfection. As shown in Figure 3A and B, the fluorescence in Ad-EGFP transfected islets was intense. Western blot was used to detect the expression of human HO-1 protein in three groups of islets. Figure 4 shows that human HO-1 protein was detected in Ad-HO-1 transfected islets but not in uninfected or Ad-

**Figure 3** Ad-EGFP transduced islets. Microphotographs were taken at 48 h post-transfection (A, B). Fluorescence was intense at an MOI of 20 (B). Bar = 200  $\mu$ m,  $\times$  100 magnification.

**Figure 4** Western blot for hHO-1. Islets infected with Ad-HO-1, Ad-EGFP, or mock infected for 48 h were examined by Western blot. HO-1 expression was only detected in Ad-HO-1 group. A: control group; B: Ad-HO-1 group; C: Ad-EGFP group.

EGFP transfected islets. Therefore, adenovirus mediated exogenous gene transfer into rat islets was successful.

#### Effect of HO-1 gene transfer on the viability of cultured rat islets

The viability of islets was assessed by AO/PI fluorescent staining.

Representative pictures are shown in Figure 5. The viability of control islets was greatly reduced as shown by the large number of dead cells within the islets (Figure 5A). Nevertheless, the number of dead cells was reduced when islets were transfected with HO-1 gene (Figure 5B). Quantitative analysis of islet viability was performed by using fluorescence microscopy to determine the proportion of living cells within islets. As shown in Figure 5C, islet viability decreased greatly after 7 d culture ( $92\% \pm 6\%$  vs  $52\% \pm 13\%$ ,  $P < 0.05$ ), but HO-1 gene transfer could reverse the viability reduction ( $71\% \pm 15\%$  vs  $52\% \pm 13\%$ ,  $P < 0.05$ ).

#### Influence of adenoviral transfection on insulin release

Since adenoviral transfection at a high transfecting dose may damage islets and interfere with their biologic function<sup>[16]</sup>, glucose-stimulated insulin release was employed to evaluate the influence of adenoviral transfection at an MOI of 20 on insulin release. As shown in Figure 6, there was no significant difference in glucose-stimulated insulin release between Ad-EGFP transfected islets and control islets at 7 d post-transfection ( $4.30 \pm 0.40$  vs  $4.57 \pm 0.40$  mIU/L/30IEQ,  $8.87 \pm 0.65$  vs  $9.63 \pm 0.71$  mIU/L/30IEQ, respectively). It demonstrated that adenoviral transfection at an MOI of 20 was safe for islets.

#### Effect of HO-1 gene transfer on the function of cultured rat islets

After 7 d culture post transfection, the insulin release upon low and high glucose of uninfected (control islets),

Ad-EGFP transfected, and Ad-HO-1 transfected islets were  $4.57 \pm 0.40$  vs  $9.63 \pm 0.71$  mIU/L/30IEQ,  $4.30 \pm 0.40$  vs  $8.87 \pm 0.65$  mIU/L/30IEQ,  $5.67 \pm 0.99$  vs  $12.50 \pm 2.17$  mIU/L/30IEQ, respectively. SI of control group, Ad-EGFP group, and Ad-HO-1 group were  $2.11 \pm 0.03$ ,  $2.08 \pm 0.05$ ,  $2.21 \pm 0.02$ , respectively. As shown in Figures 6 and 7, the insulin release upon high level glucose stimulation and SI of Ad-HO-1 transfected islets were significantly higher than those of Ad-EGFP transfected islets and control islets ( $P < 0.05$ ). Therefore, HO-1 gene transfer can improve the function of cultured islets.

## DISCUSSION

With recent advances in techniques of islet isolation and the introduction of more potent and less diabetogenic immunosuppressive therapies, islet transplantation has progressed from research to clinical reality, and it has been regarded as a safe and viable route to achieve insulin independence in a population of patients with type I diabetes<sup>[3]</sup>. Many transplant protocols incorporate a period of short-term (24 to 72 h) islet culture before transplantation for the recipient to be treated with immunodepleting agents<sup>[4,5,17,18]</sup>, and to provide time for *in vitro* assessment of islet quality. Short-term islet culture indeed has some benefits, such as purification of the islet preparation, immunomodulation<sup>[6]</sup>, and possibly improved allograft survival. However, cultured islets are known to degrade rapidly<sup>[19,20]</sup>, and lose viability and functional responsiveness to glucose stimulation with the extension of culturing time<sup>[7,8]</sup>. Islet loss as high as 30% to 50% has been reported after 48 hours of culture<sup>[21]</sup>.

The islet, once removed from its natural surroundings within the pancreas and placed within the alien environment of the culture plate, becomes deprived of normal physiological organization and exposed to a number of hostile factors, such as hypoxia, activation of free radicals, apoptosis and necrosis that cause its premature demise. The quality of the transplanted islets is of the utmost importance to successfully achieve normal levels of glucose in transplant recipients, therefore, preservation of viability and function of islets post-isolation is a pre-requisite in islet transplantation. Pancreatic islets, as a cellular graft, are especially suited for gene therapy, as they can be infected efficiently *ex vivo* and then transplanted with minimal systemic exposure of the recipient to the vector.

**Figure 5** Effect of HO-1 gene transfer on the viability of cultured rat islets. At 7 d post-transfection, the control group showed the presence of numerous dead cells (red) at the center of the islets (A), while the Ad-HO-1 group showed more living cells (B). Bar = 200  $\mu$ m,  $\times$  100 magnification. The islet viability was decreased greatly after 7 d culture ( $P < 0.05$ ), whereas HO-1 gene transfer could reduce the loss of islet viability ( $P < 0.05$ ).

**Figure 6** Effect of HO-1 gene transfer on insulin release of cultured rat islets. At 7 d post-transfection, no significant difference in glucose-stimulated insulin release was detected between Ad-EGFP transfected islets and control islets, however, the insulin release upon high glucose stimulation of Ad-HO-1 transfected islets was significantly higher than that of Ad-EGFP transfected islets and control islets,  $P < 0.05$ .

**Figure 7** Effect of HO-1 gene transfer on stimulation index of cultured rat islets. The SI of Ad-HO-1 transfected islets was significantly higher than that of Ad-EGFP transfected islets and control islets,  $P < 0.05$ .

HO-1 has been identified as a ubiquitous stress protein induced in many cell types by various stimulants, such as hemolysis, inflammatory cytokines, oxidative stress, heat shock, heavy metals, and endotoxin<sup>[22]</sup>. HO-1 is the rate-limiting enzyme of heme degradation into its byproducts biliverdin, CO, and iron<sup>[9,10]</sup>. Biliverdin is subsequently reduced into bilirubin, a powerful anti-oxidant, and it may inhibit the generation of reactive oxygen species<sup>[23]</sup>.

CO has a cytoprotective role in different systems<sup>[24-26]</sup>, including pancreatic  $\beta$ -cells<sup>[27]</sup>. Heme catabolism by HO-1 also releases free iron, which has the potential to exacerbate the cytotoxic effects of reactive oxygen species<sup>[28,29]</sup>.

However, generation of intracellular free iron upregulates the expression of ferritin<sup>[28,29]</sup>, which has a high capacity to store free iron<sup>[29]</sup>. Ferritin has been shown to protect endothelial cells against activated neutrophils as well as H<sub>2</sub>O<sub>2</sub>-mediated cytotoxicity<sup>[29]</sup>, suggesting that some of the effects of HO-1 may be mediated by ferritin<sup>[28,29]</sup>. As HO-1 is not expressed constitutively, it has been demonstrated that overexpression of HO-1 by chemical induction can protect islet cells from apoptosis and improve *in vivo* function after transplantation<sup>[22]</sup>. Compared with chemical induction, gene transfer can provide effective, targeted, and relatively persistent expression of HO-1.

Adenoviral vectors are useful for efficient gene delivery

to differentiated and non-proliferating cells, such as isolated pancreatic islets<sup>[30]</sup>. In addition, adenoviral vectors can be produced in high titers and there is no risk of insertional mutagenesis as their genomes are not integrated into chromosomes. In the present study, recombinant adenoviral vectors were generated by use of the AdEasy system, and employed to transfect rat islets at an MOI of 20. According to fluorescence photographs taken at 48 h post-transfection, the expression of EGFP was intense. Furthermore, human HO-1 protein was detected by Western blot in Ad-HO-1 transfected islets at the same time. This demonstrated that recombinant adenoviral vectors were efficient to deliver exogenous genes into rat islets *in vitro*. Insulin release upon glucose stimulation was a measure of islet function, which was a prerequisite to any gene therapy program for diabetes treatment by islet transplantation<sup>[31]</sup>. In our experiments, no significant difference in glucose-stimulated insulin release was detected between Ad-EGFP transfected islets and control islets at 7 d post-transfection. This is consistent with the results reported by others showing that adenoviral vectors at a low transfecting dose (MOI 20) provided effective transfer of a marker gene into islet cells without impairing cell function<sup>[16]</sup>.

Even though many clinical islet transplant protocols culture islets for only 24 to 72 h, islets were cultured for seven days in our study. This culture period was selected to minimize the effects of isolation factors on islet function, while maximizing the effect of culture. After

seven days culturing, the insulin release upon either low or high concentration glucose stimulation was significantly lower than that of freshly isolated islets ( $P < 0.05$ ). This is consistent with previous reports showing that islet function degrades in *in vitro* culture over time. Nevertheless, the insulin release upon high concentration glucose stimulation and stimulation index (SI) of Ad-HO-1 transfected islets were significantly higher than those of Ad-EGFP transfected islets and control islets ( $P < 0.05$ ). As glucose-stimulated insulin release was a favourable marker of the function of islets, our study demonstrated that HO-1 gene transfer conferred cytoprotection and improved islet function in *in vitro* culture. This was probably related to the effect of CO, which was not only a stimulator of insulin release but also a trigger of the transients of  $[Ca^{2+}]_i$  assumed to coordinate the secretory activity of the  $\beta$ -cells<sup>[32]</sup>. Furthermore, results of fluorescence microscopy studies with AO/PI staining indicated that HO-1 gene transfection significantly improved islet viability and survival during *in vitro* culture.

Despite the efficient transfection capacity of adenoviral vectors, the transgene cannot integrate into the host cell genome, leading to transient transgenic expression. In our study, we found that the EGFP expression time in cultured islets was more than 3 wk (data not shown). However, for some therapeutic strategies, such as islet cytoprotection in *in vitro* culture or early after transplantation, temporal expression of the cytoprotective transgene mediated by adenoviral vectors is still recommended because the factors related to early islet injury usually play a major role in the outcome of islet transplantation.

In summary, we demonstrated that adenoviral vectors could successfully transfer exogenous HO-1 gene into rat islet cells, and HO-1 gene transfer could improve rat islet viability and function in *in vitro* culture. Strategies using HO-1 gene transfer to islets might lead to better outcome in islet transplantation.

## ACKNOWLEDGMENTS

We thank the staff of the Diabetes Research Laboratory, the First Affiliated Hospital of Shanghai Jiao Tong University, for helping us to isolate rat islets.

## COMMENTS

### Background

With recent advances in methods of islet isolation and the introduction of more potent and less diabetogenic immunosuppressive therapies, islet transplantation has progressed from research to clinical reality. Islet culture for a brief period (24 to 72 h) has emerged as the current standard procedure prior to clinical transplantation. Short-term islet culture indeed have some benefits, such as purification of the islet preparation, immunomodulation, assessment of islet quality, and possibly improved allograft survival. But *in vitro* culture of islets has been shown to result in a loss of viability over time, and a decrease in glucose responsiveness has been observed for those islets which survive.

As a cellular graft, islets are especially suited for gene therapy applications. HO-1 has been described as a ubiquitous inducible stress protein capable of cytoprotection via radical scavenging and apoptosis prevention. Overexpression of HO-1 can be chemically induced, but compared with chemical induction, gene transfer can provide effective, targeted, and relatively persistent expression of HO-1. It's an attractive strategy to protect islets *in vitro* culture by using gene therapy to transduce islets with cytoprotective gene that can make islets more resistant to injury.

### Research frontiers

Although advances in islet isolation and less diabetogenic immunosuppression have moved islet transplantation forward from research to clinical reality, many challenges have to be faced with, such as keeping islet viable, single donor grafts, limited donor supply, tolerance induction.

### Innovations and breakthroughs

Overexpression of HO-1 by chemical induction can protect islet cells from apoptosis and improve islet function. We used gene technique to modify rat islets *in vitro*, and found that HO-1 gene transfer could protect islet viability and function after seven days culture. Compared with chemical induction, gene transfer can provide effective, targeted, and relatively persistent expression of HO-1.

### Applications

HO-1 gene transfer can improve islet viability and function. It suggests a potential therapeutic application for HO-1 gene in improving islet survival/function in islet transplantation.

### Terminology

Islet equivalent (IEQ): islets with an average diameter of 150  $\mu$ m.

### Peer review

In this manuscript, Chen *et al.* have analyzed whether adenovirus-mediated gene transfer of heme oxygenase-1 into rat isolated pancreatic islets, affect the long term viability of the cells. This manuscript is well written, experiments and analyses of data are adequately performed.

### Abstract

**AIM:** To study the induction of T cellular immune responses in BALB/c mice immunized with uric acid and dendritic cells (DCs) pulsed with hepatitis B virus surface antigen (HBsAg).

**METHODS:** DCs were generated from bone-marrow cells of BALB/c mice, and then pulsed or unpulsed with HBsAg protein (HBsAg-pulsed-DCs or unpulsed-DCs) *in vitro*. BALB/c mice were immunized with HBsAg-pulsed-DCs ( $1 \times 10^6$ ) and uric acid, injected through the tail vein of each mouse. The mice in control groups were immunized with HBsAg-pulsed-DCs alone, unpulsed-DCs alone or 200  $\mu$ g uric acid alone or PBS alone. The immunization was repeated 7 d later. Cytotoxic T lymphocytes (CTLs) *in vivo* were determined by the CFSE labeled spleen lysis assay. Spleen cells or spleen T cells were isolated, and re-stimulated *in vitro* with HBsAg for 120 h or 72 h. Production of IFN- $\gamma$  and IL-4 secreted by spleen cells were determined by ELISA method; proliferation of spleen T cells were detected by flow cytometry.

**RESULTS:** The cytotoxicities of HBsAg-specific-CTLs, generated after immunization of HBsAg-pulsed-DCs and uric acid, were  $68.63\% \pm 11.32\%$  and significantly stronger than that in the control groups ( $P < 0.01$ ). Compared with control groups, in mice treated with uric acid and HBsAg-pulsed-DCs, the spleen T cell proliferation to HBsAg re-stimulation was stronger ( $1.34 \pm 0.093$  vs  $1.081 \pm 0.028$ ,  $P < 0.01$ ), the level of IFN- $\gamma$  secreted by splenocytes was higher ( $266.575 \pm 51.323$  vs  $135.223 \pm 32.563$ ,  $P < 0.01$ ), and IL-4 level was

### INTRODUCTION

It is generally accepted that dendritic cells (DCs) are the most efficient and powerful antigen presenting cells and play a center role in exciting T cell immune reactions. T-cell mediated immune responses, especially Hepatitis B virus (HBV) specific- cytotoxic T lymphocyte (CTL) response, may play an important role in resolving HBV infection<sup>[1,2]</sup>. hepatitis B surface antigen (HBsAg) pulsed DCs can activate lymphocytes to become HBsAg-specific CTLs or specific CD4<sup>+</sup> T cells *in vivo*<sup>[3]</sup>. Shimizu *et al*<sup>[4]</sup> immunized HBV transgenic mice with DCs loading HBsAg, and found that DC vaccine could break tolerance to HBV and induce an effective anti-viral immune response. Chen *et al*<sup>[5]</sup> reported that HBsAg-pulsed DCs from the peripheral blood could effectively suppress HBV replication in chronic hepatitis B patients. However, anti-HBV immune effects of DC vaccine are varied and instable. This may be due to the diversity of DC vaccine preparations; however, the main cause may be the insufficiency of DC vaccines. For example, some researchers carried out similar immune therapy in volunteers, but no evident immune response was shown<sup>[3,6-8]</sup>. Therefore, the basic research of DC vaccine as well as how to improve the immune response to DC vaccine is still a significant challenge.

Recently, it was reported that uric acid (UA) could stimulate DCs to mature, promote DCs to present foreign antigens and stimulate T lymphocytes<sup>[9,10]</sup>. These findings demonstrate the adjuvant effects of uric acid and encourage the potential application of uric acid in

vaccination.

This study aimed to observe the T cell immune response after immunization with HBsAg pulsed DCs (HBsAg-pulsed-DCs) and uric acid in mice. The results demonstrated that administration of uric acid could enhance the T cell immune response to HBsAg-pulsed-DCs.

## MATERIALS AND METHODS

### Mice

Male or female BALB/c (H-2<sup>d</sup>) mice aged 8 to 10 wk were obtained from the Department of Experimental Animals, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China. All animal experiments followed the guidelines for the care and use of animals established by Tongji Medical College, Huazhong University of Science and Technology, and were approved by the Ethics Committee of Tongji Medical College.

### Agents

Uric acid (UA, Sigma-aldrich) was dissolved at a concentration of 5 mg/mL in 0.1 mol/L sodium borate buffer (pH 8.5) for more than 72 h<sup>[9,11]</sup>. The HBsAg protein was synthesized by Shanghai SanGon Company, China. The purity (> 99%) of the protein was confirmed by high performance liquid chromatography (HPLC) and mass spectrometry. Carboxy-fluorescein diacetate, succinimidyl ester (CFSE, Molecular Probes, USA) was dissolved in dimethyl sulfoxide (DMSO) at a concentration of 10 mmol/L.

### Preparation and culture of bone marrow DCs

DCs were prepared as described previously<sup>[12]</sup>. Briefly, bone marrow cells were collected from the femur and tibiae of BALB/c mice, and DCs were grown from precursors at a starting concentration of  $2 \times 10^6$  cells per ml in complete RPMI 1640 (RPMI 1640 supplemented with 10% inactivated fetal calf serum, 2 mmol/L L-glutamine, 100 U/mL penicillin G and 100 µg/mL streptomycin), and cultured in six-well flat bottom plates (Falcon) at 37°C, 5% CO<sub>2</sub> for 3 h and then non-adherent cells were washed out. rmGM-CSF at 10 ng/mL (PeproTech, Rocky Hill, NJ) and rmIL-4 at 10 ng/mL (PeproTech, Rocky Hill, NJ) were added to the culture. On days 3, 5 and 7, half of the medium was replaced with a fresh medium. On day 7, cells were incubated with uric acid (100, 200 and 400 µg/mL) or 1 µg/mL lipopolysaccharide (LPS, Sigma), respectively. Serum-free RPMI 1640 was used as control. On day 9, cells and culture supernatants were collected for further experiments and analysis.

### Analysis of cell surface markers on DCs by flow cytometry

Expression of DC cell surface molecules (CD11c, CD83, IA/IE, CD86) were determined by flow cytometric analysis. Cells were washed twice with an ice cold FACSscan buffer (PBS containing 2% FCS and 0.1% sodium azide). The same buffer was used for the incubation with antibodies as well as for all washes. Twenty percent of mixed sera of mice and rats were used to prevent nonspecific antibody binding. FITC-conjugated anti-mouse

CD11c (Clone: N418, eBioscience) and IA/IE (Clone: M5/114.15.2, eBioscience) or PE-conjugated anti-mouse CD83 (Clone: Michel-17, eBioscience) and CD86 (Clone: RMMP-2, Caltag Laboratories) were added, respectively, to the cells and the samples were left on ice for 45 min in the dark. Fluorescence profiles were generated on an FACSscan flow cytometer (Becton Dickinson). Histogram was produced with the CellQuest software package.

### Measurement of IL-12P70 concentrations

The concentration of IL-12P70 in DC culture supernatants was determined by using an enzyme-linked immunosorbent assay (ELISA) kit (R&D Systems) according to the manufacturer's instructions.

### Preparation of HBsAg-pulsed-DCs

Mature DCs stimulated by 1 µg/mL LPS were collected and used to pulse with HBsAg. The procedure for pulsing DCs was the same as previously described<sup>[13]</sup>. Briefly,  $1 \times 10^6$  mature DCs were incubated with 10 µg/mL HBsAg for 6 h. DCs were washed three times and resuspended in PBS.

### Immunization of mice

Totally  $1 \times 10^6$  HBsAg-pulsed-DCs (total volume 200 µL) were injected through the tail vein of each mouse, together with 200 µg uric acid. The mice immunized with HBsAg-pulsed-DCs ( $1 \times 10^6$ ) or unpulsed-DCs ( $1 \times 10^6$ ) alone were used as controls. The mice treated with 200 µg uric acid or 200 µL PBS alone were used as controls as well. Ten mice were in each group. The immunization was repeated 7 d later.

### Assay of CTL cytotoxic activity in vivo

Seven days after immunization with DCs for the second and last time, each mouse received spleen cells labeled with CFSE. To prepare target cells to detect in vivo cytotoxic activity<sup>[14,15]</sup>, erythrocytes were removed from naive BALB/c spleen cell suspensions by lysis in ammonium chloride solution. The cells were then washed and split into two populations. One population was pulsed with 10 µg/mL HBsAg, incubated at 37°C for 4 h, and labeled with a high concentration of CFSE (5.0 µmol/L) (CFSE<sup>high</sup> cells). Another population as control target cells was left without HBsAg and was labeled with a low concentration of CFSE (0.5 µmol/L) (CFSE<sup>low</sup> cells)<sup>[16]</sup>. An equal number of cells from each population were mixed together, and each mouse received a total of  $2 \times 10^7$  mixed cells in 400 µL of PBS. Cells were intravenously injected into all mice as above. And 10 h later, the mice were sacrificed and their spleen cells were obtained. Cell suspensions were analyzed by flow cytometry, and each population was detected for their differential CFSE fluorescence intensities. Up to  $1 \times 10^4$  CFSE-positive cells were collected for analysis. To calculate specific lysis, the following formula was used: Ratio = (percentage CFSE<sup>low</sup>/percentage CFSE<sup>high</sup>). Percentage specific lysis = [1 - (ratio unprimed/ratio primed) × 100]<sup>[14,15]</sup>.

### Cytokine production by spleen cells

Spleen cells from the immunized mice were depleted

**Figure 1** The cell surface markers analysis on dendritic cells by flow cytometry after exposure to uric acid or LPS. Bone marrow-derived DCs were stimulated with 100, 200 and 400 µg/mL uric acid or 1 µg/mL LPS or Serum-free RPMI media 1640 for 48 h and immunostained with mAbs against CD11c, CD83, CD86 and IA/IE molecules (open histograms). Shade histograms represent the isotype control mAb staining of the cells. The histograms (Figure 1) and data (Table 1) are representative of five independent experiments.

of erythrocytes and washed twice with PBS. The cells obtained were resuspended with complete RPMI 1640, and seeded in duplicate into flat-bottomed 24-well microtitration plates (Costar, Brumath, France) at  $2 \times 10^6$  cells per well in 1 mL of culture medium containing 10 µg/mL HBsAg. The cell-free culture supernatants were harvested after 72 h and assayed for IFN- $\gamma$  and IL-4 activity. The cytokine concentrations were determined by using a commercial ELISA kit (eBioscience Inc.) according to the manufacturer's instructions, and the standard curves corresponding to known amounts of mouse recombinant IFN- $\gamma$ , IL-4. The sensitivity limits for the assays are 15 pg/mL for IFN- $\gamma$ , and 4 pg/mL for IL-4.

#### Cell proliferative response of spleen T cells

Erythrocytes were removed from the spleen cells of mice 14 d after immunization as above. The cells were resuspended with complete RPMI 1640, and then T cells were separated by a nylon wool column method<sup>[17]</sup>. In brief,  $1 \times 10^8$  cells were drained through a nylon wool column (Polysciences, Inc., Warrington, PA) for 45 min at 37°C, and then nonadherent T cells were collected after two washes. T cells were labeled with 2.5 µmol/L CFSE and washed three times in the medium as described above, counted, and resuspended at a concentration of  $1 \times 10^6$  cells/mL.

The samples were seeded in triplicate into 24-well microtitration plates (Costar, Brumath, France) at  $2 \times 10^6$  cells per well in 2 mL of culture medium containing 10 µg/mL HBsAg or PBS. T cells from the untreated mice were used as the negative control; and T cells from the untreated mice stimulated with 10 µg/mL concanavalin A (ConA) and 10 µg/mL HBsAg or PBS was served as the positive controls. The plates were incubated for 72 h in 5% CO<sub>2</sub> at 37°C. Cell proliferation was estimated by flow cytometry<sup>[16]</sup>. Histogram was produced with the Motif 3.0 software package.

#### Statistical analysis

All data were presented as mean  $\pm$  SD and analyzed using the Student-Newman-Keuls test and LSD multiple comparisons with SPSS11.5 software in the experiments.  $P < 0.05$  was regarded as statistically significant.

## RESULTS

#### Cell surface markers on DCs

We demonstrated an increase in CD83, IA/IE, and CD86 expression by DCs, stimulated with uric acid previously (Figure 1, Table 1). The effect of uric acid was dose-dependent and was still observed when the uric acid was

UA-DC	15.123 $\pm$ 1.353 <sup>d</sup>	429.216 $\pm$ 59.232 <sup>d</sup>

<sup>b</sup>*P* < 0.01, <sup>d</sup>*P* < 0.001 *vs* PBS group.

administered at 100  $\mu$ g/mL. After stimulation with uric acid (100-400  $\mu$ g/mL), the percentage of various markers increased from 2.0- fold to 3.0-fold. The stimulatory effect elicited by uric acid at a concentration of 200-400  $\mu$ g/mL was similar to that induced by LPS (1  $\mu$ g/mL). After stimulation with uric acid or LPS, the CD11c expression in each group was high and similar, including the imDC group.

### IL-12 p70 production in DC supernatants

Using the ELISA technique, the IL-12 p70 secretion by DCs was detected 48h after stimulation with uric acid or LPS. IL-12p70 production was markedly increased in response to uric acid stimulation in a dose-dependent manner. The IL-12p70 production stimulated by 200-400  $\mu$ g/mL uric acid was similar to LPS treatment (Table 2).

### Cytokine production by spleen cells

The supernatants of cultured immune spleen cells were evaluated for the production of IL-4 (Th2 cytokine) or IFN- $\gamma$  (Th1 cytokine) in response to HBsAg re-stimulation on day 14 (Figure 2, Table 3).

The production of IL-4 in mice immunized with HBsAg-pulsed-DCs and uric acid was lower than that of mice immunized with HBsAg-pulsed-DCs alone or unpulsed-DCs alone or PBS alone (*P* < 0.001 for all) (Figure 2A).

**Figure 2** Cytokine production by splenocytes. Fourteen days after immunization, spleen cells were isolated, then stimulated with HBsAg (10  $\mu$ g/mL) *in vitro*. Values were measured at 72 h for IL-4 (A), IFN- $\gamma$  (B) by ELISA. The results are representative of ten samples from each group. The data show the mean  $\pm$  SD.

The production of IFN- $\gamma$  (Figure 2B) in mice immunized with HBsAg-pulsed-DCs and uric acid was significantly greater (*P* < 0.001 for all) than that in mice immunized with HBsAg-pulsed-DCs alone. Spleen cells from mice immunized with unpulsed-DCs alone or PBS alone produced a few IFN- $\gamma$ .

Spleen cells from mice immunized with uric acid alone failed to enhance the secretion of IFN- $\gamma$  or inhibit the secretion of the IL-4 (Figure 2).

### Cell proliferative response in spleen T cells

Fourteen days after immunization, CFSE-labeled-T cells from each mouse were re-stimulated with 10  $\mu$ g/mL HBsAg or PBS for 72 h *in vitro*, and cellular proliferations were assayed by flow cytometry (Figure 3, Table 4).

A strong proliferative response to HBsAg re-stimulation was observed in T cells of mice immunized with HBsAg-pulsed-DCs and uric acid (Figure 3).

Proliferative response to HBsAg re-stimulation was also observed in T cells of mice treated with HBsAg-pulsed-DCs. Insignificant proliferation was observed in T cells of mice treated with unpulsed-DCs. No proliferation to HBsAg re-stimulation was observed in T cells of mice treated with uric acid alone or PBS (Figure 3).

PBS re-stimulation *in vitro* failed to stimulate T cell proliferation in each mouse (Table 4).

### Determination of HBsAg-specific-CTL cytotoxicity

We directly determined the activity of HBsAg-specific-CTLs with an *in vivo* cytotoxicity assay. The extent of lysis of HBsAg-pulsed spleen cells was expressed as R-values (Figure 4) and the cytotoxicity activity of HBsAg-specific-CTLs were calculated (Table 5).

A significant strong cytotoxicity of HBsAg-specific CTLs was observed in the mice immunized with HBsAg-pulsed-DCs and uric acid; whereas immunization with

**Figure 3** Cellular proliferative response in spleen T cells after stimulation with HBsAg or PBS for 72 h *in vitro*. Cellular proliferative response was estimated by flow cytometry. Spleen T cells of PBS group mice were cultured with HBsAg or PBS and ConA, used as ConA group. Histogram was produced by the modfit 3.0 software packages. These results showed were from individual mice that were representative of per experiment group.

**Table 4** T cell proliferative response

Group	n	SI (HBsAg)	SI (PBS)
PBS	10	1.09 ± 0.028	1.062 ± 0.027
UA	10	1.17 ± 0.035	1.067 ± 0.031
Unpulsed-DC	10	1.19 ± 0.055	1.076 ± 0.035
HBsAg-pulsed-DC	10	1.34 ± 0.093 <sup>b</sup>	1.081 ± 0.028
UA-DC	10	1.59 ± 0.156 <sup>d</sup>	1.081 ± 0.029
ConA	10	2.53 ± 0.179 <sup>d</sup>	2.487 ± 0.146

<sup>b</sup>*P* ≤ 0.01, <sup>d</sup>*P* ≤ 0.001, *vs* PBS group.

**Table 5** HBsAg-specific CTL cytotoxicity (% , mean ± SD, *n* = 10)

Group	PBS	UA	Unpulsed-DC	HBsAg-pulsed-DC	UA-DC
Cytotoxicity	3.51 ± 1.14	3.52 ± 1.15	6.32 ± 2.18	27.32 ± 7.32 <sup>b</sup>	68.63 ± 11.32 <sup>d</sup>

<sup>b</sup>*P* ≤ 0.01, <sup>d</sup>*P* ≤ 0.001, *vs* PBS group.

**Figure 4** Analyze CTL activity against HBsAg of immunization mice by flow cytometry in vivo at 2 wk. Flow cytometric analysis of each mouse was adoptively transferred with a 1:1 mixture of Protein-pulsed (CFSE<sup>high</sup>) and unpulsed (CFSE<sup>low</sup>) naive mouse splenocytes 10 h previously. Then ratio between percentage of CFSE<sup>low</sup> cells and CFSE<sup>high</sup> cells were calculated. HBsAg-specific CTL cytotoxicity was determined (Table 5). These histogram results were from individual mice that were representative of ten experiments.

HBsAg-pulsed-DCs alone or unpulsed-DCs induced low cytotoxicities of HBsAg-specific CTLs (Table 5).

In mice immunized with uric acid 200 µg alone or PBS, R values or CTL cytotoxicity were similar (*P* > 0.05) (Figure 4). It demonstrated that no significant specific lysis was observed and immunization with uric acid 200 µg alone failed to induce HBsAg-specific CTLs.

## DISCUSSION

It has been shown that T-cell mediated immune responses are very important in overcoming HBV infection<sup>[1,2]</sup>

and DCs can efficiently prime T-cell response, so the development of a vaccine of DCs has attracted considerable interest<sup>[18,19]</sup>.

Several studies indicated that uric acid had excellent immune adjuvant activity, which could promote the specific immune response to vaccines efficiently<sup>[9,11]</sup>. Shi and colleagues have shown that the generation of responses from specific CTL activity was significantly enhanced, when uric acid was injected into mice along with the gp120 protein of the human immunodeficiency virus (HIV)<sup>[9]</sup>. Hu and colleagues showed that eliminating uric acid, by administration of allopurinol or uricase, delayed tumor

immune rejection, whereas subcutaneous administration of uric acid enhanced the rejection process<sup>[11]</sup>.

Uric acid crystals might be the biologically active form. It was shown that preformed crystals were highly stimulatory, whereas soluble uric acid was not<sup>[9-11]</sup>. The concentrations of uric acid that stimulated DCs corresponded to one at which uric acid crystals were precipitated. Injection of purified uric acid (> 70 µg/mL) was shown to boost CTL responses in spleen cells isolated from mice, which had been primed with particulate antigens, by triggering increased DC expression of the costimulatory molecules CD86 and CD80<sup>[9,11]</sup>. Allopurinol and uricase treatment, which substantially reduced plasma uric acid concentrations, was shown to markedly inhibit this T-cell priming. Uric acid crystals are known to stimulate monocytes to produce inflammatory mediators<sup>[20]</sup>, and it seems likely that DCs are stimulated in a similar way.

As highly specialized antigen presenting cells (APC), DCs play a central role in antigen presentation to CD4<sup>+</sup> or CD8<sup>+</sup> T cells and allogeneic T cell proliferation<sup>[8]</sup>. It has been known that phenotypic and functional maturation was critical for DCs to activate immune responses effectively<sup>[21]</sup>. In a previous study, it was reported that uric acid could promote expression of co-stimulatory molecules (CD86, CD80) on DC surfaces<sup>[9]</sup>. Our data showed that uric acid promoted maturation of DCs (CD83<sup>high</sup>) and up-regulated the expression of co-stimulatory molecules CD86, and IA/IE (MHC-I molecule).

DCs have a crucial role in determining the type of T cell mediated response<sup>[22,23]</sup>. IL-12 is an important immune modulatory molecule, which specifically promotes Th1 cell differentiation and suppresses Th2 cell function, and induces a Th1 cell immune response<sup>[24]</sup>. In this study, uric acid could promote DCs to secrete IL-12p70 in vitro; after combination of immunization with uric acid, in spleen cells of mice, production of IFN-γ was significantly up-regulated, and IL-4 production was down-regulated. This indicated that uric acid might enhance Th1 cell immune responses by promoting DC to secrete IL-12. And then Th1 cells can induce the proliferation of CTLs and amplification of CD8<sup>+</sup> T cell responses<sup>[25]</sup>.

In addition, we showed that combination immunization of uric acid and HBsAg-pulsed-DCs could elicit a strong T cell-mediated immune response. Compared with HBsAg-pulsed-DCs vaccine alone, combination immunization elicited significantly greater T cell immune responses as evidenced by T cell proliferation to HBsAg re-stimulation, Th1 cytokine secretion and HBsAg-specific CTL responses. Uric acid may enhance the T cell immune responses by stimulating DC maturation and enhance its functions.

In hyperuricemia, it is well-known that uric acid can precipitate in the joints, where they cause gout, and/or in other tissues causing inflammation<sup>[26]</sup>. Therefore, the dose of uric acid administration is of crucial importance. In our study, the dose of uric acid was 200 µg. According to Shi and Hu *et al.*<sup>[9,11]</sup>, this dose of uric acid was safe and had an adjuvant effect.

We immunized both treated and control mice with

200 µg uric acid alone for two weeks. As expected, the T cell mediated immune responses were not enhanced. It demonstrated that uric acid has no adjuvant activity in the absence of exogenous antigens. It is important that no autoimmunity is induced, using uric acid as an adjuvant of vaccine.

In the murine model, combination of uric acid and HBsAg-pulsed-DCs seemed to be very effective. However, the anti-HBV effect of this vaccine strategy must be tested further in the HBV animal model.

In summary, we have demonstrated that uric acid can strongly enhance T cell immune responses to HBsAg-pulsed-DCs. We conclude that uric acid might serve as an effective adjuvant for DC vaccine against HBV infection. This strategy provides a model to develop therapeutic vaccines against HBV infection.

### Abstract

**AIM:** To evaluate the safety and feasibility of bone marrow cell (BMC) transplantation in patients with chronic liver disease on the waiting list for liver transplantation.

**METHODS:** Ten patients (eight males) with chronic liver disease were enrolled to receive infusion of autologous bone marrow-derived cells. Seven patients were classified as Child-Pugh B and three as Child-Pugh C. Baseline assessment included complete clinical and laboratory evaluation and abdominal MRI. Approximately 50 mL of bone marrow aspirate was prepared by centrifugation in a ficoll-hypaque gradient. At least of 100 millions of mononuclear-enriched BMCs were infused into the hepatic artery using the routine technique for arterial chemoembolization for liver tumors. Patients were followed up for adverse events up to 4 mo.

**RESULTS:** The median age of the patients was 52 years (range 24-70 years). All patients were discharged 48 h after BMC infusion. Two patients complained of

mild pain at the bone marrow needle puncture site. No other complications or specific side effects related to the procedure were observed. Bilirubin levels were lower at 1 ( $2.19 \pm 0.9$ ) and 4 mo ( $2.10 \pm 1.0$ ) after cell transplantation than baseline levels ( $2.78 \pm 1.2$ ). Albumin levels 4 mo after BMC infusion ( $3.73 \pm 0.5$ ) were higher than baseline levels ( $3.47 \pm 0.5$ ). International normalized ratio (INR) decreased from 1.48 (SD = 0.23) to 1.43 (SD = 0.23) one month after cell transplantation.

**CONCLUSION:** BMC infusion into hepatic artery of patients with advanced chronic liver disease is safe and feasible. In addition, a decrease in mean serum bilirubin and INR levels and an increase in albumin levels are observed. Our data warrant further studies in order to evaluate the effect of BMC transplantation in patients with advanced chronic liver disease.

### INTRODUCTION

Chronic liver disease may progress to end-stage liver disease (ESLD), liver failure and death. Patients with ESLD may experience serious complications such as encephalopathy, ascites and esophagogastric variceal hemorrhage. Liver transplantation is the only available therapy for patients with chronic liver failure. Because of the shortage of donated organs, up to 10%-15% of these patients die without receiving an organ in developed countries<sup>[1]</sup>. In some undeveloped countries the number of deaths on the waiting list might be greater. In some regions

of Brazil it takes an average of more than two years until liver transplantation. Therefore, alternative methods such as cell therapy are necessary to increase patient survival on the liver transplant waiting list. Several sources of stem cells have been proposed for cell therapy. Embryonic stem cells are the most potent in terms of their differentiation potential but may be oncogenic when transplanted *in vivo* and their use has been a matter of controversy because of ethical issues<sup>[2]</sup>. A number of studies during the last decade have identified cells both within and outside the liver that have properties of hepatic stem cells and might differentiate into hepatocytes or bile duct epithelial cells<sup>[3-5]</sup>. Hematopoietic tissue is most accessible and of special interest, and it has been demonstrated that bone marrow contains multipotent adult progenitor cells that can generate a variety of cell types found in other tissues<sup>[6-8]</sup>.

Studies in animal models of liver diseases have demonstrated that bone marrow cell (BMC) transplantation may accelerate the liver regeneration process, reduce hepatic fibrosis and improve liver function and survival rate<sup>[9-11]</sup>. However, its mechanism is still controversial. Several studies have suggested that hematopoietic cells may generate hepatocyte-like cells, while others hypothesized that they should act mainly by fusion with hepatocytes or by paracrine effect<sup>[12-15]</sup>. Fusion between hepatocytes and hematopoietic cells produces heterokaryotic hybrid cells that initially contain the genetic elements and organelles of both cell types and may then express the hepatocyte phenotype. Several studies suggest that cytokines and growth factors produced by infused hematopoietic cells may support liver function and repair in adult animals without forming new hepatocytes from the infused cells<sup>[15]</sup>. Based on the findings from other studies that suggest improvement of liver fibrosis in experimental models of liver disease and because bone marrow cell transplantation itself is already an established treatment for hematological and oncological diseases, we conducted a clinical trial to evaluate the safety and feasibility of autologous BMC therapy in patients with chronic liver disease on the waiting list for liver transplantation.

## MATERIALS AND METHODS

### Subjects

The study group comprised 10 patients with chronic liver disease (8 males, 2 females, age: 24 to 70 years) on the waiting list for liver transplantation. They were enrolled to receive infusion of autologous BMC from September 2005 to January 2006. Informed written consent was obtained from all subjects. The study protocol conformed to the ethical guidelines of the 1975 Declaration of Helsinki and was approved by the Ethics Committee of Hospital São Rafael, Salvador, Brazil and by the Brazilian National Ethics Committee (CONEP). Eligible patients had all the following inclusion criteria: age range between 18-75 years, advanced chronic liver disease of different etiologies classified as Child Pugh B or C, absence of liver tumors and appropriate use of contraception method for women of child-bearing potential. Patients were excluded from the study if they had one or more of the following

exclusion criteria: risk for bone marrow aspiration, sepsis, human immunodeficiency virus infection, active hepatic encephalopathy, liver tumor, history of malignant neoplasm except for non-melanoma skin cancer, decompensated heart failure, platelet count  $< 30\,000/\text{mm}^3$ , international normalized ratio (INR)  $> 2.2$ , renal failure (creatinine  $> 2.5 \text{ mg/dL}$ ), participation in other clinical trials, pregnancy or lactation.

Baseline assessment included complete clinical and laboratorial evaluation as well as abdominal magnetic resonance imaging to exclude liver tumor. Laboratory tests consisted of complete blood count, serum bilirubin levels, prothrombin time, serum blood glucose, urea, creatinine, alpha-fetoprotein, total proteins and albumin levels, serum aminotransferase concentrations, alkaline phosphatase and gamma-glutamyl transferase levels, thyroid stimulating hormone (TSH) concentrations. Patients were followed up for adverse events with clinical and laboratory evaluations on d 1, 2, 3, 7, 15, 30, 45, 60, 90, 120 after BMC transplantation.

### Bone marrow cell therapy

Approximately 50 mL of bone marrow was aspirated from the iliac crest. An enriched fraction of bone marrow mononuclear cells was prepared by centrifugation of total bone marrow in a ficoll-hypaque gradient. At least 100 millions of mononuclear-enriched BMC suspended in 20 mL of saline was infused into the hepatic artery of included patients by a catheter, using the routine technique for arterial chemoembolization of liver tumors<sup>[16]</sup>.

### Statistical analysis

Exploratory data analysis was conducted to calculate means, standard deviations and 95% confidence intervals of measurements (laboratory tests, Child Pugh score at baseline at 1 and 4 mo). Relative mean changes at 1 and 4 mo with respect to the baseline level were calculated. To examine the development of laboratory parameters after BMC infusion individual response profiles were plotted as a function of weeks after intervention. In addition, estimates of the mean response profiles and 95% confidence intervals were obtained by calculating moving averages of patients' measurements over a period of 4 weeks and by applying linear interpolation. All statistical analyses were conducted by the statistical software package STATA (StataCorp. 2005. Stata Statistical Software: Release 8. College Station, TX: StataCorp LP).

## RESULTS

The median age of the study population was 52 years (range 24-70 years). Four patients had alcoholic liver disease, 4 had chronic hepatitis C, one had chronic cholestatic liver disease and one cryptogenic cirrhosis (Table 1). Seven patients were classified as Child-Pugh B and 3 patients as Child-Pugh C. None had a liver tumor.

The number of BMCs infused in each patient is shown in Table 1. All patients were discharged 48 h after BMC infusion. Two patients complained of mild pain at the bone marrow needle puncture site. No other complications

**Table 1** Clinical characteristics of studied patients and the number of transplanted autologous BMCs

Patient ID	Age (yr)	Sex	Etiology of cirrhosis	BMCs transplanted (n)
JWOR	49	Male	Alcohol + HCV	$2.8 \times 10^8$
FMB	60	Male	Alcohol	$5.2 \times 10^8$

Baseline	2.5	4.4	3.47	3.5	0.51	
1 mo	2.9	4.5	3.44	3.25	0.52	-1
4 mo	3.1	4.8	3.73	3.6	0.51	7
INR (unit)						
Baseline	1.08	1.89	1.46	1.48	0.23	
1 mo	1.1	1.94	1.44	1.43	0.23	-1
4 mo	1.16	1.75	1.42	1.43	0.18	-3

**Figure 1** Serum bilirubin levels in 10 patients with chronic liver disease as a function of weeks after transplantation of autologous BMCs.

or specific side effects related to the infusion procedure were reported. A 70-year old patient with a history of previous episodes of hepatic encephalopathy developed reversible grade I encephalopathy 33 d after BMC infusion. The episode was controlled without requirement of hospitalization and was not considered an adverse event since 3 identical episodes were documented for this patient in the last year before his inclusion in the study.

Total bilirubin levels were 21% lower at 1 mo ( $2.19 \pm 0.91$ ) and 24% lower at 4 mo ( $2.10 \pm 1.04$ ) after BMC

transplantation that baseline levels ( $2.78 \pm 1.16$ ) (Table 2). When individual response profiles were evaluated, a decrease in total bilirubin levels was observed in 7 of 10 patients after BMC transplantation (Figure 1). The mean profile of bilirubin levels after BMC infusion is shown in Figure 2.

Albumin levels were 1% lower at 1 mo ( $3.44 \pm 0.52$ ) and 7% higher at 4 mo after BMC infusion ( $3.73 \pm 0.51$ ) than baseline levels ( $3.47 \pm 0.51$ ) (Table 2). The analysis of individual levels showed an increase in albumin levels

**Figure 2** Mean profile of serum total bilirubin levels including a 95% confidence band in 10 patients with chronic liver disease as a function of weeks after transplantation of autologous BMCs.

in 6 patients and a reduction in 1 patient 4 mo after BMC transplantation (Figure 3). The mean profile of serum albumin levels is shown in Figure 4.

INR levels were 1% lower at 1 mo ( $1.44 \pm 0.23$ ) and 4% lower at 4 mo ( $1.42 \pm 0.18$ ) after BMC transplantation that baseline levels ( $1.46 \pm 0.23$ ) (Table 2). INR levels reduced in 7 patients and increased in 1 patient after BMC transplantation (Figure 5). The mean profiles of INR levels are shown in Figure 6.

The data about other relevant laboratory parameters (WBC, hemoglobin, ALT, AST, GGT, creatinine) before and after the intervention are shown in Table 3.

## DISCUSSION

There is an urgent need to search for alternatives to whole organ transplantation. Based on the ability of stem cells to differentiate into specific cell types according to their environment, cell transplantation has become an attractive therapeutic method for the treatment of patients with liver disease aiming, at least, at a temporary support of hepatic function until a liver becomes available for organ transplantation.

This phase I study aimed to evaluate the feasibility and safety of autologous bone marrow cell transplantation into the hepatic artery of patients with advanced chronic liver disease. In the present study, we infused BMCs into the hepatic artery using the same routine technique for arterial chemoembolization of liver tumors which is feasible and not associated with serious local side effects<sup>[16]</sup>, and used the hepatic artery for cell infusion since the blood inflow to the liver could be mostly secured. Our results confirmed the feasibility and safety of BMC infusion into hepatic artery in such patients. BMC transplantation was well tolerated to all patients and only two patients complained of mild pain at the bone marrow needle puncture site. We did not detect any other side effects. The episode of reversible hepatic encephalopathy 33 d after BMC infusion in a 70-year old man with alcoholic cirrhosis was not interpreted as an adverse event related to the procedure because identical episodes were observed in the previous

year.

In addition to the evaluation of safety and feasibility, our results indicated that there were alterations of liver function parameters after transplantation of autologous BMCs in patients with advanced chronic liver disease. Four months after BMC transplantation the mean serum bilirubin and INR levels decreased while the mean albumin levels increased. Of note, 7 patients had their bilirubin levels reduced while 6 patients had their albumin levels increased. The greatest reduction in the bilirubin levels was observed in a 24-year old patient (R.N.R.) with chronic cholestatic liver disease who had the highest amount of transplanted BMCs ( $13.1 \times 10^8$ ) compared to the others (Table 1). The number of transplanted BMCs was lower in patients with cirrhosis caused by HCV and in the 70-year old patient.

Recently, two phase I studies using granulocyte-colony stimulating factor (G-CSF) to mobilize BMCs in patients with chronic liver disease were conducted<sup>[17,18]</sup>. Gaia *et al*<sup>[17]</sup> evaluated the feasibility and safety of BMC mobilization in 8 patients with end stage liver cirrhosis following G-CSF administration. Mobilization (monitored by the number of CD34 + ve cells) was observed in all patients after G-CSF administration, which was well tolerated and free of adverse events. Child-Pugh score decreased by 2 or more points in four patients, increased in one patient, while it was unchanged (or decreased by less than 2 points) in three patients. Overall, the MELD score decreased from a median pre-treatment value of 17.5 (range 11-20) to 14.5

**Figure 3** Serum albumin levels in 10 patients with chronic liver disease as a function of weeks after transplantation of autologous BMCs.

**Figure 4** Mean profile of serum albumin levels including a 95% confidence band in 10 patients with chronic liver failure as a function of weeks after transplantation of autologous BMCs.

(range 9-20) at end of follow-up. In another study Gordon *et al.*<sup>[18]</sup> evaluated the safety and tolerability of autologous CD34+ cell injection into five patients with liver insufficiency. Included patients were given subcutaneously 520  $\mu$ g G-CSF and CD34+ cells were collected and then returned to the patients via the hepatic artery or the portal vein. No major complications or specific side effects related to the procedure were observed. Three of the five patients showed a reduction in serum bilirubin and four of five showed an increase in serum albumin. The results of these two studies appear to be in agreement with ours.

The choice of utilizing purified stem cells instead of mononuclear cell fraction depends on a future comparison of the efficacy in the two cell populations. In addition, purification procedures to obtain a specific cell population increase the costs of the therapy.

Studies in animal models of liver diseases have demonstrated that bone marrow cell transplantation decreases hepatic fibrosis and improves survival rate. Sakaida *et al.*<sup>[11]</sup> investigated the effect of BMC transplantation on mice with established liver fibrosis induced by carbon tetrachloride (CCl<sub>4</sub>) administration. Four weeks after BMC transplantation, the mice had significantly reduced liver fibrosis, as assessed by hydroxyproline content in the livers, compared to mice treated with CCl<sub>4</sub> alone. Similar results have been observed in other studies<sup>[9,19,20]</sup>. In addition, improvement in several parameters of liver function, such as albumin and bilirubin levels and prothrombin time has been reported<sup>[8,12,21]</sup>. These experimental studies suggest that BMC infusion may be responsible for the potential beneficial effects on liver function as observed in our clinical study.

Our study was not able to evaluate the efficacy of BMC infusion in patients with liver disease due to its design. Controlled studies would be required to address this issue. Further studies are also necessary to determine the number of BMCs required for achievement of therapeutic effect, which may vary with the patient's age and the etiology of liver disease.

In summary, BMC infusion into the hepatic artery of patients with advanced chronic liver disease is safe and

**Figure 5** INR levels in 10 patients with chronic liver failure as a function of weeks after transplantation of autologous BMCs.

**Figure 6** Mean profile of INR levels including a 95% confidence band in 10 patients with chronic liver failure as a function of weeks after transplantation of autologous bone marrow cells.

feasible. In addition, in most patients there is a decrease in mean serum bilirubin and INR levels, and an elevation of serum albumin. Our results warrant further studies in order to evaluate the effects of BMC transplantation in patients with advanced chronic liver disease.

### Abstract

**AIM:** To determine rates of hepatitis C (HCV) risk factor ascertainment, testing, and referral in urban primary care practices, with particular attention to the effect of race and ethnicity.

**METHODS:** Retrospective chart review from four primary care sites in Philadelphia; two academic primary care practices and two community clinics was performed. Demographics, HCV risk factors, and other risk exposure information were collected.

**RESULTS:** Four thousand four hundred and seven charts were reviewed. Providers documented histories of injection drug use (IDU) and transfusion for less than 20% and 5% of patients, respectively. Only 55% of patients who admitted IDU were tested for HCV. Overall, minorities were more likely to have information regarding a risk factor documented than their white counterparts (79% vs 68%,  $P < 0.0001$ ). Hispanics were less likely to have a risk factor history documented, compared to blacks and whites ( $P < 0.0001$ ). Overall, minorities were less likely to be tested for HCV than whites in the presence of a known risk factor (23% vs 35%,  $P = 0.004$ ). Among patients without documentation of risk factors, blacks and Hispanics were more likely to be tested than whites (20% and 24%, vs 13%,  $P < 0.005$ , respectively).

**CONCLUSION:** (1) Documentation of an HCV risk factor history in urban primary care is uncommon, (2)

### INTRODUCTION

Several studies have suggested that hepatitis C (HBV) management is suboptimal in primary care settings<sup>[1-3]</sup>. In fact, only 59% of primary care physicians (PCPs) reported asking patients about HCV risk factors<sup>[3]</sup>. A similar conclusion was made by another study which found that 46% and 62% of physicians reported that they routinely asked patients about a history of blood transfusion and injection drug use, respectively<sup>[4]</sup>. Shehab reported that HCV testing is rarely initiated in primary care clinics based on physician identified risk factors such as transfusion prior to 1992 or a history of injection drug use<sup>[1]</sup>. Similar studies among urban primary care practices, comprising patients at highest risk for exposure to HCV risk factors, have not been reported. Such a study would be important to better assess the feasibility of implementing wide scale risk assessment, testing, and treatment strategies.

The purpose of this retrospective cohort study is to assess the rates of HCV risk factor ascertainment, testing and referral for treatment in urban primary care practices, with particular attention to the effect of race and ethnicity as determined by systematic review of the medical records.

### MATERIALS AND METHODS

A retrospective chart review was conducted in four

Table 1 Population demographics

Primary care practice	Total	Mean age	Gender (% male)	Insured (%)	Race				
					White (%)	Black (%)	Hispanic (%)	OTH (%)	Unknown (%)
Clinic #1	1182	40	34	62	1	4	84	< 0.5	11
Clinic #2	948	41	62	57	4	65	7	1	24
Clinic #3	1089	42	34	95	26	37	2	5	31
Clinic #4	1188	48	43	98	45	22	2	6	26

urban primary care clinic sites in Philadelphia. These sites included two federally qualified health clinics serving predominantly minority populations and two university-based primary care practices; a family medicine practice and an internal medicine practice. Each of the four study sites is unique in the population that it serves. Clinic #1 is a community clinic which serves a predominantly Hispanic population (84%), comprised of mostly female patients (66%); in 2005 this clinic served approximately 15 000 patients. Clinic #2 is a community clinic which serves a predominantly black population (65%-70%); this clinic served approximately 7000 patients in 2005. The majority of the patients attending the two community clinics are either uninsured, or covered by a Medicaid HMO. The two university-based practices serve racially diverse populations. Approximately 60% of the patients attending the Family Medicine university-based practice (clinic #3, patient population served in 2005, 23 000) are black. The majority of the patients attending the practice have traditional insurance. Those with Medicare coverage and the uninsured make up a small percentage of the patient population, 6% and 5% respectively. Approximately 45% of the patients attending the Internal Medicine university-based practice (patients served in 2005, 21 000) are black (clinic #4), and the majority of the patients attending the practice have traditional insurance.

Random charts were selected at systematic intervals, based upon practice size, so that a total of approximately 1000 charts were reviewed from each practice. The number of charts required was calculated by taking into account the prevalence of risk factors among minority and non-minority subjects, the rate of risk factors recognized, the proportion of persons at risk screened for HCV and of those who tested positive. All these assumptions were derived from previous studies and from the authors' experience.

All patient visits in each selected chart were reviewed by a team of trained chart reviewers. No identifying information was collected. Data were available dating back to the patients' first visit, with a mean of 3.6 years (standard deviation 4.9 years) prior to the patients' most recent documented visit. Specific data collected included sex, age, race/ethnicity, as well as documentation of HCV risk factors. An HCV risk factor was broadly defined as any potential exposure to HCV; these included injection drug use, blood transfusion prior to 1992, percutaneous exposure as in the case of an exposed health care worker), non-injection drug use, tattoos, body piercing, history of sexually transmitted diseases, incarceration, and unprotected sex<sup>[9]</sup>. When documentation of an HCV risk

factor was identified, it was determined if HCV testing was ordered and if the patient was referred for subspecialty care.

### Statistical analysis

Data were collected using a standardized data collection instrument. All chart reviewers were trained and accompanied by an investigator. An investigator (SBT, VJN) re-reviewed at least 10% of all charts at random to check for accuracy. Trained data entry personnel entered the data into data management software (Microsoft Access). All data were analyzed using SAS v 9.14. Descriptive statistics and frequency tables were generated. Chi-square tests and logistic regression were used to assess statistical differences.

## RESULTS

### Study cohort

The total number of charts reviewed was 4407. One thousand one hundred eighty two charts were sampled from clinic #1; 948 charts from clinic #2; and 1089 from clinic #3 and 1 188 charts were reviewed from clinic #4 (Table 1). In order to facilitate a comparison of HCV management practices between races, we included only those charts in which race information was recorded. Approximately 23% of the charts reviewed did not include the race or ethnicity of the patient with clinic #1 having the lowest percentage of undocumented race/ethnicity (11%). Clinic #2 was missing approximately 24% of race/ethnicity documentation as compared to 26% for the Internal Medicine university-based practice and 31% for the Family Medicine university-based practice. Of the 3 413 charts with documented race/ethnicity which were included in the analysis, 1333, 1103, and 846 were reported as black, Hispanic, and white patients, respectively. Racial/ethnic groups were similar with respect to the average age of patients at the time of review (mean age 43). Forty-four percent of blacks were male, as compared to 34% of Hispanics and 45% of whites.

### Documentation rate of HCV risk factors and the effect of race/ethnicity

Primary care providers documented a history (positive or negative) of IDU and/ or transfusion, arguably the most important risk factors for HCV acquisition, for 12% and 2% of patients, respectively. Only 0.48% ( $n = 21$ ) of the total study population ( $n = 4407$ ) were documented as having a positive history of transfusion prior to 1992. A history of percutaneous exposure as a health care

Table 2 Prevalence of HCV risk factors documented in patient charts by race/ethnicity

HCV risk factor	Black <i>n</i> = 1333		Hispanic <i>n</i> = 1103		White <i>n</i> = 846	
	Info available <i>n</i> (%)	With risk factor <i>n</i> (%)	Info available <i>n</i> (%)	With risk factor <i>n</i> (%)	Info available <i>n</i> (%)	With risk factor <i>n</i> (%)
IDU	241 (18)	54 (22)	48 (4.4) <sup>e</sup>	19 (40)	134 (16)	11 (8.2)
Transfusion	22 (1.7)	7 (32)	11 (1.0)	2 (18)	29 (3.4)	9 (31)
HCV needle stick	1 (0.1)	1 (100)	2 (0.2)	2 (100)	1 (0.1)	1 (100)
History of drug use	957 (72) <sup>a</sup>	359 (38) <sup>bc</sup>	820 (74) <sup>a</sup>	94 (11)	535 (63)	53 (10)
History of STD	517 (39) <sup>b</sup>	350 (68) <sup>bc</sup>	550 (50) <sup>b</sup>	185 (34)	164 (19)	53 (32)
History of HIV testing	452 (34) <sup>b</sup>	390 (86)	396 (36) <sup>b</sup>	305 (77) <sup>a</sup>	119 (14)	108 (91)
Tattoos	15 (1.1)	11 (73)	2 (0.2)	1 (50)	21 (2.5)	17 (80)
Piercing	2 (0.2)	0 (0)	1 (0.1)	0 (0)	1 (0.1)	1 (100)
Prostitution	9 (0.7)	6 (67)	3 (0.3)	2 (67)	1 (0.12)	1 (100)
Incarceration	38 (2.8)	36 (95)	12 (1.1)	12 (100)	4 (0.5)	3 (75)

<sup>a</sup>*P* < 0.05 vs whites; <sup>b</sup>*P* < 0.05 vs Hispanics; <sup>c</sup>*P* < 0.001 vs whites; <sup>e</sup>*P* < 0.05 vs blacks and whites.

worker was rarely specified (*n* = 4). Patients' histories of prostitution, incarceration, tattoos or body piercing were recorded for less than 2% of patients. Ascertainment of a history of non-injection drug use and sexually transmitted diseases occurred for 67% and 34% of patients, respectively (Table 2).

When documentation of HCV risk factor ascertainment was compared between different races/ethnicities, overall, minorities were more likely to have information regarding a risk factor documented than their white counterparts (79% vs 68%, *P* < 0.0001). Hispanics were much less likely to have had a history of IDU (positive or negative) documented than other groups; (4.4% ascertainment rate compared with 18% and 16% for blacks and whites, respectively) (*P* < 0.0001). Blacks and Hispanics were more likely to have had a documented history of non-IDU (72% and 74%, respectively) as compared to whites (63%, *P* < 0.05). Hispanics were more likely to have a chart entry regarding sexually transmitted diseases than were blacks (50% vs 39%) and blacks were more likely to have this history documented than whites (39% vs 19%, *P* < 0.001). Statistical comparisons were not used to assess differences between racial/ethnic groups for prostitution, incarceration, tattoos or body piercing due to the low rate of ascertainment.

Among patients who denied IDU, higher rates of other risk factors were reported among minorities. For example, 64% (29/45) of the minorities who denied IDU admitted non-injection drug use as compared to 31% (5/16) of the whites (*P* < 0.05). In addition, 25% of minorities (55/216) who denied IDU had a history of an STD documented as compared to 5% (7/123) of whites (*P* < 0.05).

Overall, females (74%, *n* = 2 469) were more likely than males (71%, *n* = 1 818) to have information regarding a risk factor history (positive or negative history) documented in the chart (*P* = 0.0091). However, among those individuals who had risk factor information documented, males (54%) were more likely to have a positive risk factor history than females (30%) (*P* < 0.0001). Among individuals with a documented positive HCV risk

factor, there was no difference in the percentage of males and females tested for HCV (*P* = 0.176).

The odds of having documented information regarding HCV risk factors decreased by 1.4% with each additional year of age (*P* < 0.0001). Among those individuals who had risk factor information documented (*n* = 3113), the odds of having a positive risk factor history decreased by 1.7% with each additional year of age (*P* < 0.0001). Among individuals with a documented positive HCV risk factor (*n* = 1158), the odds of being tested increased by 1.3% with each additional year of age (*P* = 0.025).

### HCV testing

Overall, minorities were less likely to be tested for HCV than whites in the presence of a known risk factor (23% vs 35%, *P* = 0.004). Of the 12% of patients for whom information regarding IDU was recorded (*n* = 531), 19% admitted this behavior. Of this group (blacks *n* = 54, Hispanics *n* = 19, whites *n* = 11), 55%-58% were tested for HCV, with no differences among the race or ethnic groups. Of the 21 patients documented as having a history of blood transfusion prior to 1992, approximately 67% were tested for HCV. Because the rate of documentation was so low for a history of transfusion, comparisons between racial/ethnic groups could not be made with respect to the rate of testing in the presence of this risk factor. Thirty-six percent of patients with tattoos and 50% of individuals with body piercing and with no identified other risk factor were tested for HCV (Table 3). Of those patients with a history of incarceration, 30% were tested. In the absence of IDU or prior blood transfusion, a history of sexually transmitted disease, non-injection drug use, engaging in sexual activity with or as a commercial sex worker, or a history of HIV testing were associated with testing rates of 19%, 22%, 33% and 24%, respectively. Due to the low rate of documentation of risk factors by the physicians, it was not possible to compare rates of testing between racial groups for piercing, incarceration, prostitution, and tattoos.

Among patients who denied risk factors when asked,

**Table 3** Rates of testing among individuals with a documented non conventional HCV risk factor but no conventional risk factors

	Number with only non-conventional risk factors <sup>1</sup>	Tested (%)
Tattoos	33	36.4
Piercing	4	50.0
History of drug use	513	21.6
Prostitution	6	33.3
Incarceration	60	30.0
History of STD	706	19.4
History of HIV testing	903	24.1

<sup>1</sup>Patient may be included in more than one category.

the proportion tested for HCV was higher for blacks (20%,  $n = 187$ ) and Hispanics (24%,  $n = 29$ ) than for whites (13%,  $n = 123$ ) ( $P < 0.05$ ).

Overall, seven percent of patients in whom no risk factors were documented ( $n = 3212$ ) were still tested for HCV. Hispanics (9.9%,  $n = 848$ ) were more likely to be tested than both blacks (5.4%,  $n = 737$ ) and whites (6.4%,  $n = 733$ ) in the absence of any documented risk factor.

### HCV referral practices

Of the 93 patients who were identified as being HCV positive (and for whom race/ethnicity was known), 37 (40%) had chart documentation of referral to a specialist. Of this group, 71% of white patients were referred, as compared to 40% of Hispanics ( $P = 0.06$ ), and 32% of blacks (Figure 1). Among HCV positive patients whose race was not known ( $n = 15$ ), 47% were referred to a specialist. Of these, 10 patients were from clinic #2, which serves a predominantly black population.

## DISCUSSION

Overall, minorities were more likely to have information regarding HCV risk factors documented than their white counterparts. However, the ascertainment of IDU and blood transfusion prior to 1992, arguably the most important risk factors for HCV acquisition, was low, 12% and 1.8% respectively. Perhaps the greatest significance of these findings is that even in populations with expected high rates of risk factors, recommended management practices for risk factor ascertainment are infrequently followed<sup>[9]</sup>.

Overall, minorities were less likely to be tested for HCV than whites in the presence of a known risk factor. The underlying reason for this is unknown but deserves further study. Rates of testing among patients who had a documented history of IDU or blood transfusion prior to 1992 were low, regardless of race. This finding demonstrates that recommendations regarding HCV testing practices are infrequently followed<sup>[9-12]</sup>. The reason for low rates of testing among minorities in the presence of a risk factor is likely to be multifactorial. Practitioners may be more likely to ask minority patients about risk behaviors, given an implicit understanding of the

**Figure 1** HCV referral practices.

surrounding urban community and the epidemiology of HCV, but less likely to test if the provider feels that the patient would not be a candidate for treatment or if the patient would not opt for treatment.

Minorities were more likely than non-minorities to be tested for HCV in the absence of a recorded risk factor, or if such a history was denied. This finding could be explained by undocumented factors which might have led to testing, or the more frequent documentation of non-intravenous drug use in this population, which might be, in turn, interpreted as a risk for the acquisition of HCV. Unfortunately, medical record information did not allow us to more carefully assess these factors.

The rate of referral among patients who tested positive for HCV differed among the race groups. Specifically, minorities were less likely than whites to be referred for subspecialty evaluation. Although of potential significance, this finding may have been affected by missing referral information, local resources, as well as patient and provider perception of the need for and benefit of treatment.

Our study is limited in scope due to several factors. We performed the study in a relatively small number of practices which may reflect idiosyncrasies of a few treating physicians or have been affected by patient demographics which were unique to the local area. Moreover, we could not assess whether cultural, educational, or economic factors affected risk assessment and testing practices. Despite these limitations, the low rate of testing in a potentially high-risk population has serious implications; any strategy to test patients at risk for acquisition of HCV must be preceded by a plan that increases the rate of risk factor ascertainment in primary care.

Therefore, recommendations must be developed for physicians to increase the rate of identification of individuals who may have been exposed to HCV in the past as well as appropriate testing. Although primary care physicians are responsible for screening for multiple health problems during a routine health care visit, the benefits of identifying HCV risk factors and infection must not be overlooked. Risk factor screening and identification allows for patients to be educated regarding the risks of injection drug use and needle sharing. Appropriate testing and diagnosis of HCV allows for the patient to be evaluated

for treatment and receive counseling regarding alcohol cessation. In addition to physician education, patient education campaigns must also be developed to increase patient compliance with testing recommendations made by their physicians.

## COMMENTS

### Background

The increasing prevalence of hepatitis C virus (HCV) infection in the United States makes it an important challenge for primary care physicians (PCPs) and subspecialists. There are several potential benefits to diagnosing hepatitis C in a primary care setting. Diagnosis provides the patient with the opportunity to be counseled regarding behaviors that may transmit the infection to others such as sharing needles in the context of IDU. Diagnosis also allows the health care provider to educate the patient regarding behaviors that may hasten the progression of liver disease such as alcohol intake. Furthermore, early diagnosis allows the patient to be provided with appropriate preventive services such as hepatitis A and B vaccines. Lastly, early diagnosis allows the patient to be evaluated for hepatitis C therapy at a time when treatment may be more effective; prior to progression to fibrotic liver disease.

### Research frontiers

Several studies have suggested that hepatitis C management is suboptimal in primary care settings. The purpose of this retrospective cohort study is to assess the rates of HCV risk factor ascertainment, testing and referral for treatment in urban primary care practices, with particular attention to the effect of race and ethnicity as determined by systematic review of the medical records.

### Related publications

This publication is the first to result from our studies related to HCV management in primary care settings. Three additional manuscripts are in preparation. However, there are several articles, cited throughout this manuscript, from other investigators, that can provide additional information related to HCV management in primary care.

### Innovations and breakthroughs

Very few studies have examined hepatitis C risk assessment, testing and referral for treatment in urban primary care settings. Moreover, no studies have examined racial differences within these practices. The findings indicate that (1) Documentation of an HCV risk factor history in urban primary care is uncommon, (2) Racial differences exist with respect to HCV risk factor ascertainment and testing, and (3) Minority patients, positive for HCV, were less likely to be referred for subspecialty care and treatment. Overall, minorities were less likely to be tested for HCV than whites in the presence of a known risk factor.

### Applications

The findings presented may be applied in a number of settings where advances in the identification, testing and referral of primary care patients, specifically racial

and ethnic minorities are sought. The results of this study may be of interest to epidemiologists and other public health professionals. The findings of this study address a deficit in the literature related to HCV in minorities and provide the background for future studies and intervention endeavors aimed at improving HCV identification and management in primary care settings.

### Peer review

The results show that risk factors are often missed and minority patients are less likely to be tested for HCV and to be referred for treatment. The authors conclude that, although their investigation has some selection biases, the results indicate the existence of a consistent reservoir of infection in subgroups of patients, [specifically] black and Hispanic. Although "expected" given the characteristics of the population selected, the results are interesting.

### Abstract

**AIM:** To develop a new formulation with hydroxy propyl methyl cellulose and Shellac coating for extended and selective delivery of butyrate in the ileo-caecal region and colon.

**METHODS:** One-gram sodium butyrate coated tablets containing  $^{13}\text{C}$ -butyrate were orally administered to 12 healthy subjects and 12 Crohn's disease patients and the rate of  $^{13}\text{C}$ -butyrate absorption was evaluated by  $^{13}\text{CO}_2$  breath test analysis for eight hours. Tauroursodeoxycholic acid (500 mg) was co-administered as a biomarker of oro-ileal transit time to determine also the site of release and absorption of butyrate by the time of its serum maximum concentration.

**RESULTS:** The coated formulation delayed the  $^{13}\text{C}$ -butyrate release by 2-3 h with respect to the uncoated tablets. Sodium butyrate was delivered in the intestine of all subjects and a more variable transit time was found in Crohn's disease patients than in healthy subjects. The variability of the peak  $^{13}\text{CO}_2$  in the kinetic release of butyrate was explained by the inter-subject variability in transit time. However, the coating chosen ensured an efficient release of the active compound even in patients with a short transit time.

**CONCLUSION:** Simultaneous evaluation of breath  $^{13}\text{CO}_2$  and tauroursodeoxycholic acid concentration-time curves has shown that the new oral formulation consistently releases sodium butyrate in the ileo-cecal region and colon both in healthy subjects and Crohn's disease patients with variable intestinal transit time. This formulation may be of therapeutic value in inflammatory bowel disease patients due to the appropriate release of the active compound.

### INTRODUCTION

Butyric acid, a short chain fatty acid, is the main colonic bacterial product of non-starch polysaccharides<sup>[1]</sup>. Impaired butyric acid metabolism (usually as butyrate species) has been implicated in the development of ulcerative colitis (UC)<sup>[2]</sup> but there are conflicting data regarding its role in the pathogenesis of UC<sup>[3-11]</sup>. Large bowel mucosa biopsy specimens from quiescent UC patients have also shown reduced oxidation of butyrate but not of glucose and glutamine, the two other major fuel sources for colonic epithelium<sup>[3]</sup>. *In vitro* studies conducted in terminal ileal mucosa biopsy specimens from UC patients support this concept<sup>[4]</sup>. A study on colonic sodium butyrate (NaB) metabolism using  $^{14}\text{C}$ -butyrate rectal instillation and  $^{14}\text{CO}_2$ -breath test in patients affected by extensive UC showed a reduction in NaB oxidation, which returned to normal on remission<sup>[10]</sup>. The authors concluded that while impaired NaB metabolism is unlikely to be a primary cause of UC, impairment of short chain fatty acid metabolism by colonocytes may be a pathogenic factor. Another study indicated that in quiescent UC patients, the rate of NaB metabolism is not impaired<sup>[11]</sup>.

It has recently been demonstrated that NaB exhibits anti-inflammatory properties as documented by a strong inhibition of interleukin (IL)-12 production by suppressing both IL-12p35 and IL-12p40 mRNA accumulation, and enhances IL-10 secretion in *Staphylococcus aureus* cell-stimulated human monocytes<sup>[12]</sup>. Investigation of the effects of NaB on some G1 phase-related proteins in a colon carcinoma cell line (HT29) has revealed another potential pharmacological property, since NaB is able to reduce cyclin D1 and p53 level in a dose-dependent

fashion and to suppress cell growth<sup>[13]</sup>. Thus, the lack of NaB in diets poor in carbohydrates could lead to clinically relevant functional alterations. In vivo, the growth inhibitory effects of NaB on colon cancer cells appear to be somewhat less marked<sup>[14,15]</sup>.

Some clinical applications of NaB treatment have already been successfully evaluated. NaB enemas seem to provide an effective treatment for acute radiation proctitis, accelerating the healing process<sup>[16,17]</sup>. Oral co-administration of NaB and mesalazine in patients with active UC seems to improve the efficacy of mesalazine monotherapy<sup>[18,19]</sup>.

These considerations prompted us to develop a new oral formulation in which NaB is released in the terminal ileum and colon, the target of its potential pharmacological activity<sup>[19]</sup>.

The main problem in the development of controlled release formulation is to extrapolate *in vitro* release data to those achieved during *in vivo* studies. This is particularly crucial for drugs used in patients with gastrointestinal diseases in which the intestinal transit time shows a high variability.

The colonic target release of enteric coated butyrate requires an optimized coating able to prevent an early release (duodenum-jejunum-ileum) resulting in an absorption and metabolism of butyrate before reaching the colon. The coating is expected to release NaB from the ileo-caecal region as a result of a variation of intestinal pH but a delayed release delivery kinetic would result in a loss of a relatively high amount of butyrate in the stools.

Tuleu *et al*<sup>[20]</sup> have developed pellets for colonic delivery of NaB *via* oral route. When they are administered to rats a large amount is lost in the caecum for coating dissolution problems.

Optimization of the tablets is therefore crucial to determine in the healthy subjects and patients with Inflammatory bowel disease (IBD) the exact delivery site of butyrate in the intestine thus reducing false negative data in term of efficacy due to a poor delivery of the active compound in the target area.

Sodium butyrate tablets (1 g) coated with hydroxyl propyl methylcellulose (HPMC) and natural polymer Shellac have been developed and optimized by conventional *in vitro* studies. In the present study the optimal coating thickness was optimized *in vivo* by evaluating the release of the active ingredient by the kinetics of <sup>13</sup>CO<sub>2</sub> excretion in the breath of healthy subjects and Crohn's disease patients after oral administration of <sup>13</sup>C-labeled NaB included in the 1 g tablets. The rate of <sup>13</sup>CO<sub>2</sub> production is the result of <sup>13</sup>C-NaB intestinal absorption and metabolism that was evaluated by the rate of production of <sup>13</sup>CO<sub>2</sub> in exhaled breath over 8 h. The <sup>13</sup>C/<sup>12</sup>C isotope ratio was measured by isotope ratio mass spectrometry (IRMS). The intestinal transit time was evaluated by simultaneous co-administration of tauroursodeoxycholic acid (TUDCA).

TUDCA was selected as a biomarker of oro-ileal transit time since it is absorbed actively only in the ileum, the time of its peak serum level reflects the oro-ileal transit time. A sensitive and specific enzyme immunoassay was performed to evaluate serum TUDCA concentration at various time intervals after administration as previously described<sup>[21]</sup>.

To evaluate the kinetics of the release of NaB from

the tablets, we compared the time of maximum <sup>13</sup>CO<sub>2</sub> excretion with that of peak serum TUDCA concentration within individual subjects in order to overcome the high variability in intestinal transit time.

## MATERIALS AND METHODS

### Oral NaB formulation

Plain and coated tablets containing hydroxyl propyl methylcellulose and shellac with a pH dependent extended release coating were used in the study. Both formulations contained 1 g of NaB and three batches of tablets containing 5%, 10% and 20% w/w of <sup>13</sup>C-NaB (CIL, Andover MA, USA) were prepared.

The difference between the two tablets was the internal pre-coating of HPMC and external coating of shellac, which is resistant to desegregation up to pH 7. All other excipients of the formulations were identical. The pre-coating of HPMC was made to avoid that basic characteristics of the active ingredient in the tablet nucleus would induce an early dissolution of shellac which is resistant to acid pH and soluble to basic pH. In order to optimize the release of NaB in the colon, different thickness films of shellac (50, 80 and 120 µm) were studied. Coated tablets (Sobutir) were supplied by Promefarm srl, Milan, Italy. The different formulations were then administered to the same subjects in order to verify simultaneously the kinetic of NaB release in relation to the oro-ileal transit time evaluated by the time of the serum TUDCA peak and select the formulation that would be admitted to the complete study.

### Subjects studied

The study was carried out in 12 healthy subjects (6 males and 6 females, median age 42 years, range 18-60 years) and 12 Crohn's disease patients (9 females and 4 males, median age 40 years, range 18-65 years) with a relatively mild activity index ranging from 320 ≥ C.D.A.I. ≥ 220<sup>[22]</sup>. To avoid any difference in the transit time, we studied only patients with the same level of activity index. In addition, the patients studied had no pure ileal or ileo-colonic involvement and they did not receive steroid or immunosuppressive treatment. All patients during the study presented diarrhoea. Before this final controlled study volunteers received the different formulations under development and between the different studies a washout period of one week was used. Thirty minutes before the study, 2 mL of blood was collected for the baseline values, as were two separate samples of breath in a 10 mL capped glass tube. After administration of the 1 g <sup>13</sup>C-NaB tablet and of 500 mg TUDCA as gelatine capsules (Tudcabil<sup>®</sup>, Pharmacia Upjohn, Milan, Italy), the subjects received a standard liquid test meal of 375 Kcal, containing 17 g of fat, 10.4 g of protein and 10 g of carbohydrates. Breath and blood samples were collected at 30 min intervals over an 8-h period (unless otherwise specified). The oro-ileal transit time was defined as the time interval between administration of TUDCA and the peak serum TUDCA (C<sub>max</sub>) time<sup>[21]</sup>. The time of the maximum <sup>13</sup>CO<sub>2</sub> breath excretion was used to represent the time of release and absorption of sodium butyrate. The study approved by

**Figure 1** Excretion of breath  $^{13}\text{CO}_2$  after oral administration of uncoated (A) and shellac-coated (B) 1 g NaB tablets containing 10% w/w of  $^{13}\text{C}$ -NaB in 12 healthy subjects. The experiment of each formulation was repeated three times in the same subject for different weeks.

the Ethical Committee of University of Bologna was conducted according to the institutional guidelines.

### Analytical methods

**$^{13}\text{CO}_2$  breath test:**  $^{13}\text{CO}_2$  in each of the duplicate breath samples was analyzed by continuous flow isotope ratio mass spectrometry (IRMS; ANCA, PDZ Europa Ltd, Cheshire U.K.). The results were expressed as  $\delta^{13}\text{C}$  that was calculated from:

$$\delta^{13}\text{C} = \left( \frac{^{13}\text{C}/^{12}\text{C} (\text{sample})}{^{13}\text{C}/^{12}\text{C} (\text{std})} - 1 \right) \times 1000$$

where  $^{13}\text{C}/^{12}\text{C}$  (std) is the Pee Dee Belemnite (PDB) reference standard  $^{13}\text{C}/^{12}\text{C}$  ratio, the final value was expressed as a milli percentage ( $\delta^{13}\text{C}\%$ ).

### Serum TUDCA enzyme immunoassay

Serum TUDCA levels were determined by a specific chemiluminescent enzyme immunoassay previously developed and optimized in our laboratory<sup>[21]</sup>. The method is a solid-phase competitive format with a TUDCA-specific polyclonal antibody immobilized on 96 wells black polystyrene microtiter plates. A horseradish peroxidase (HRP)-UDCA conjugate was synthesized, purified, properly characterized, and used as enzymatic tracer.

For the TUDCA assay 100  $\mu\text{L}$  of the sample (serum diluted 1/50, v/v with assay buffer: 0.05 mol/L phosphate/EDTA buffer, pH 7.4, containing 1 g/L bovine serum albumin) or of six standard TUDCA solutions with a concentration ranging from 0.01 to 1000 nmol/L was incubated in the 96-well microtiter plates coated with the antibody for 1 h at 37°C with 100  $\mu\text{L}$  of the properly diluted HRP-UDCA tracer. After washed with assay buffer, 100  $\mu\text{L}$  of the chemiluminescent substrate ( $\text{H}_2\text{O}_2$ /luminol/enhancer SuperSignal ELISA Pico, Pierce, II, USA) was added and the light signal was measured using a PMT based luminometer microtiter reader (Luminoskan Ascent, Thermo Electron Corporation MA, USA).

TUDCA concentrations were determined by a plot of chemiluminescent (CL) signal *vs* the log of concentration

and the best data fit was obtained by linear regression of the six point standards. Serum TUDCA was expressed as nmol/L of serum.

## RESULTS

### Optimization of NaB oral formulation

The  $^{13}\text{C}$ -NaB dose to include in the 1 g NaB tablet was standardized by quantifying the amount of label to produce a breath  $\text{CO}_2$  enrichment of the  $^{13}\text{C}$ -isotope that could be accurately evaluated with respect to the baseline value representing its natural abundance.

During the course of three separate weeks, three 1-g NaB tablets containing 5%, 10% and 20% w/w of  $^{13}\text{C}$ -NaB respectively, were administered to six healthy subjects. The excretion rate of  $^{13}\text{CO}_2$  in breath was measured and the maximum value was calculated. The dose of 100 mg of the label was chosen giving a  $\delta^{13}\text{C}\%$  of 15.3 that was much higher than the baseline value of -28%. This wide cut off could allow the accurate evaluation of not only the maximum excretion of  $^{13}\text{CO}_2$  but also small variations during the 8-h study period and eventually low  $^{13}\text{CO}_2$  excretion resulting in patients with impaired metabolism of NaB. The coating thickness was optimized according to the kinetics of the  $^{13}\text{CO}_2$  excretion accounting for the release and absorption of butyrate from the tablet. The results obtained with 50, 80 and 120  $\mu\text{m}$  thickness coating suggested that the coating size of 80  $\mu\text{m}$  was the most adequate to prevent a too early release and absorption of NaB as occurred with the 50  $\mu\text{m}$  thickness and to ensure complete release of the active ingredient in a time comparable with the oro-ileal transit time.

The NaB tablet containing 10% w/w of  $^{13}\text{C}$ -NaB and 80  $\mu\text{m}$ -thick coating was used to evaluate the final performance of the formulation. The intra-subject variability was evaluated by administering either coated or uncoated NaB formulations three times to the same subject in separate experiments and monitoring the excretion of  $^{13}\text{CO}_2$  at 15 min time intervals (Figure 1). In the uncoated tablet, the intra-subject variability was very low and the curves were almost super impossible.

**Figure 2** Profiles of the mean  $^{13}\text{CO}_2$  breath excretion (▲) and serum TUDCA concentrations (■) plotted against time. Data were collected after administration of the Shellac-coated tablet containing 10% w/w of  $^{13}\text{C}$ -butyrate and two gelatine capsules containing 250 mg each of TUDCA. Data are expressed as mean  $\pm$  SD in 12 healthy subjects (A) and 12 Crohn's disease patients (B).

**Figure 3** T<sub>max</sub> obtained in control subjects (A) and Crohn's disease patients (B) using serum TUDCA and  $^{13}\text{CO}_2$  breath tests.

The maximum excretion was achieved 45 min after administration of the dose and the absorption started just in the first 15 min. A slightly higher variability was observed when the coated formulation was administered as a result of an intra-subject variability in gastric emptying and overall gastrointestinal transit. The mean peak  $^{13}\text{CO}_2$  excretion time of the coated tablets was 180 min (range 150-225 min), showing the extended release of NaB caused by the shellac coating.

#### Serum TUDCA chemiluminescent enzyme immunoassay

Chemiluminescent enzyme immunoassay fulfilling all the standard requirements of accuracy and precision was used. The intra and inter studies showed that the coefficient of variation was always below 9%. The limit of quantification of 10 nmol/L allowed direct analysis of TUDCA in a 20-fold diluted serum sample.

The mean serum TUDCA profiles together with the kinetics of  $^{13}\text{CO}_2$  excretion obtained in the healthy subjects and Crohn's disease patients are shown in Figure 2. The serum TUDCA profile was characterized by two peaks. The first peak was reached 180-200 min after TUDCA

administration and represented the oro-ileal transit time, the second peak was observed after 300-400 min as a result of the enterohepatic circulation of the absorbed TUDCA.

In the healthy subjects peak of serum TUDCA concentration was achieved at a median of 4 h (range 3-5 h) after NaB administration. The mean peak  $^{13}\text{CO}_2$  excretion time occurred slightly earlier at 3.5 h and the range of variability was similar to that of TUDCA. A similar behavior was observed in Crohn's disease patients with a higher variability due to variation in the intestinal transit time.

Top panel and bottom panel are shown in Figure 3. The T<sub>max</sub> was obtained in control subjects and Crohn's disease patients using the serum TUDCA and  $^{13}\text{CO}_2$  breath tests. No subject and Crohn's disease patient had an earlier release of  $^{13}\text{CO}_2$  after administration of the coated tablets with respect to the T<sub>max</sub> of TUDCA. Similarly no subject and patient missed to give a peak of  $^{13}\text{CO}_2$  excretion or reported the loss of intact tablets in stools.

The ileal release was defined (a priori) as the  $^{13}\text{CO}_2$  peak occurring within 30 min from the time of TUDCA peak whereas colonic release was considered as the  $^{13}\text{CO}_2$

peak occurring after this interval.

The temporal correspondence between the maximum  $^{13}\text{CO}_2$  excretion times, with the TUDCA time at the Cmax representing the biomarker oro-ileal transit time even if occurring at different times, usually slightly earlier suggested that the active ingredient was still delivered in the colon in high concentration and therefore we expected that it would exert its activity in IBD patients.

In all the studied subjects, NaB was efficiently released by the coated tablet, suggesting that the formulation developed could be used in these subjects to prevent an early absorption and deliver a large amount of NaB in the colon just starting from the terminal ileum as shown by the kinetic profile of  $^{13}\text{CO}_2$  and serum TUDCA.

## DISCUSSION

The present study was designed to evaluate a new NaB formulation able to deliver the active ingredients of 1 g tablets coated with shellac into the colon by oral administration. The coating delayed the release of the active ingredients by two-three hours with respect to the uncoated formulation, thus a large amount of NaB could reach the colon, as demonstrated by the temporal similarity between the profiles of  $^{13}\text{CO}_2$  breath test and serum TUDCA concentration. In fact, TUDCA is absorbed by an active carrier-mediated mechanism only in the ileum<sup>[23, 24]</sup>, and previous studies comparing the TUDCA serum levels after its oral administration with other markers of intestinal transit-time such as sulfasalazine showed that this method provides a valid and practical means of assessment of the oro-ileal transit-time<sup>[21]</sup>. Comparison of the peak times of  $^{13}\text{CO}_2$  excretion and serum TUDCA concentration could confirm the efficacy of shellac coating in delivering NaB to the colon independently of intestinal transit-time variability. The dissolution of Shellac coating at pH 7 and its thickness driving the kinetics of the dissolution process has been well optimized and a large amount of NaB which starts to be delivered after two hours reaches the intact ileo-cecal region as shown by the kinetics of TUDCA intestinal absorption.

It was recently reported that topical butyrate improves the efficacy of 5-ASA in refractory distal ulcerative colitis<sup>[17]</sup>, due to the presence of NaB in the colon administered topically *in situ*. Vernia *et al*<sup>[16]</sup> demonstrated in a pilot study that oral butyrate may improve the efficacy of oral mesalazine in active ulcerative colitis but a large scale investigation to confirm the present findings is still required. In this case the NaB was administered as tablets coated with a pH-dependent soluble polymer. More recently it has been reported that chronic feeding (tablets, 4 g a day for 8 wk) of this enteric coated NaB formulation (tablets, 4 g a day for 8 wk) (tablets, 4 g a day for 8 wk) can effectively induce clinical improvement/remission in mild Crohn's disease<sup>[25]</sup>.

An adequate enteric coating is needed for therapy of ileo-colonic disorders since when uncoated uncoated oral formulation of NaB is administered in an uncoated oral formulation, the compound is promptly dissolved and rapidly metabolized before reaching the colon as shown by the time of the maximum  $^{13}\text{CO}_2$  excretion occurring

within 30-45 min after the  $^{13}\text{C}$  butyrate oral administration. A specific enteric coated formulation has been therefore designed to deliver the drug in that portion of the intestine keeping into account the high variability of the intestinal transit time observed in IBD patients.

The amount of  $^{13}\text{CO}_2$  excreted in breath was similar among the Crohn's disease patients, showing that the rate and efficiency of NaB metabolism are similar in the healthy subjects. The patients were characterized by a mild active disease accounting for the efficient metabolism of butyrate and the oral formulation was expected to deliver NaB into the colon in a similar extent as to enema administration.

Furthermore the new coated  $^{13}\text{C}$ -NaB oral formulation containing  $^{13}\text{C}$ -labeled butyrate can also be used to evaluate the rate of colocyte-metabolized NaB by performing  $^{13}\text{CO}_2$  breath test before and after chronic administration of NaB. The impairment of NaB utilization by colonocytes that has been observed in previous studies<sup>[2-4]</sup> can then readily be evaluated by measuring the reduction in cumulative  $^{13}\text{CO}_2$  excretion in the 8-h period following oral administration of colon-targeted NaB tablets. A similar approach could also be used to evaluate the effectiveness of therapies for IBD patients with mesalazine (either alone or in combination with NaB) and new formulations designed to improve NaB absorption and metabolism. The reported NaB formulation can effectively improve oral administration of NaB ensuring the release of the active compound in the lower intestine portion which is the target for its pharmacological activity.

### Abstract

**AIM:** To detect the presence of human cytomegalovirus (HCMV) proteins and genes on the ileal pouch of patients with ulcerative colitis who have undergone proctocolectomy with ileal pouch-anal anastomosis (IPAA).

**METHODS:** Immunohistochemistry, polymerase chain reaction (PCR) and PCR sequencing methods were utilized to test the presence of HCMV in pouch specimens taken from 34 patients in 86 endoscopies.

**RESULTS:** HCMV genes and proteins were detected in samples from 12 (35.2%) patients. The rate of detection was significant in the endoscopies from patients diagnosed with pouchitis (5 of 12, 41.6%), according to the Japanese classification of pouchitis, in comparison to patients with normal pouch (7 of 62, 11.2%;  $P = 0.021$ ). In all patients with pouchitis in which the HCMV was detected, it was the first episode of pouchitis. The virus was not detected in previous biopsies taken in normal endoscopies of these patients. During the follow-up, HCMV was detected in one patient with recurrent pouchitis and in 3 patients whose pouchitis episodes improved but whose positive endoscopic findings persisted.

**CONCLUSION:** HCMV can take part in the inflammatory process of the pouch in some patients with ulcerative colitis who have undergone proctocolectomy with IPAA.

**Key words:** Human cytomegalovirus; Pouchitis;

### INTRODUCTION

Human cytomegalovirus (HCMV) is a ubiquitous, species-specific beta-herpes virus that can establish lifelong latency in the host after the primary infection. HCMV infection is endemic within the human population, and its role as a pathogen in the colon and ileum is still unclear. Early studies suggested that HCMV infection initiates some cases of ulcerative colitis (UC)<sup>[1,2]</sup>, plays a role in UC exacerbation<sup>[3]</sup>, causes self-limited colitis<sup>[4]</sup>, and increases the incidence of complications, emergency surgery or death in patients with UC<sup>[3,5,6]</sup>.

Pouchitis is a frequent complication in patients with UC who have undergone colectomy with ileal pouch-anal anastomosis (IPAA). The etiology of pouchitis is still unknown, but several theories have been proposed, such as genetic susceptibility, a possible novel third form of inflammatory bowel disease (IBD) in the pouch, recurrence of UC in the pouch, misdiagnosis of Crohn's disease, ischemic complication of surgery, fecal stasis, and bacterial overgrowth. Recent studies have reported HCMV infection as a cause of pouchitis in 3 immunocompetent patients<sup>[7,8]</sup>. The diagnosis of this specific infectious agent as a possible cause of pouchitis is crucial before initiating immune modifier therapy, fecal diversion, or pouch excision. We explored the presence of viral gene products and proteins in the pouches of a series of patients who have undergone proctocolectomy with IPAA.

### MATERIALS AND METHODS

#### Patients

Enrolled in this study were 34 Japanese patients (17 females, 17 males) who underwent proctocolectomy

with IPAA at the Department of General and Digestive Surgery, Niigata University Hospital between 1990 and 2003. The patients' age ranged from 24 to 68 years (mean  $34.8 \pm 15.4$  years). Oral and written informed consent was obtained from each patient. The study protocol adhered to the ethical guidelines of the 1975 Declaration of Helsinki and was approved by the institution's ethical committee. We reviewed the clinical and endoscopic records of all the enrolled patients. The patients had a history of UC between 1 to 5 years and underwent the operation in two or three steps. The diagnosis of pouchitis was based on clinical and endoscopic criteria according to the modified pouchitis disease activity index (mPDAI)<sup>[9]</sup> and the Japanese classification of pouchitis (JCP)<sup>[10]</sup>. JCP defines pouchitis as a condition with severe endoscopic findings, or with two or more clinical symptoms and moderate endoscopic findings. Eighty-six endoscopies were performed in 34 patients. Twenty-eight endoscopies were performed in patients complaining of symptoms, 46 endoscopies were carried out in routine controls after surgery, and 12 were performed during pouchitis follow-up. Biopsies were performed both in areas with pathological findings (edema, granularity, friability, erythema, loss of vascular pattern, mucous exudates, erosion or ulceration) and in areas with mucosa of normal appearance.

### Immunohistochemistry (IHC)

Immunostaining for HCMV was performed on paraffin-embedded sections with a cocktail of two monoclonal mouse antibodies against human cytomegalovirus (clone CCH2 & DDG9, Dako Cytomation, CA, USA) at a dilution of 1:100. All paraffin-embedded samples from each patient were used for IHC. According to the company specifications, antibody CCH2 reacts with an early nuclear protein identical with non-structural DNA-binding protein p52 (UL44), whereas antibody DDG9 reacts with an immediate-early nuclear protein with a molecular weight of about 76 kDa. For both antibodies, the reactivity persists also at later stages during HCMV infection where the localization is less distinctly nuclear and appears to be in the cytoplasm. Five- $\mu$ m thick sections were deparaffinized and rehydrated using graded alcohol concentrations, then the sections were digested with trypsin (Sigma Chemicals, Germany) at 37°C for 20 min. After endogenous peroxidase was blocked by incubation with 30 mL/L hydrogen peroxide for 20 min, the sections were incubated overnight at 4°C with the cocktail of anti-human cytomegalovirus antibodies. Control slides from the same biopsy block were incubated with PBS without the primary antibody. They were then incubated at room temperature for 30 min with goat anti-mouse immunoglobulin conjugated to a peroxidase-labeled amino-acid polymer, Simple Stain Max PO (Nichirei Histofine, Tokyo, Japan). The sections were reacted with diaminobenzidine in 50 mol/L Tris-HCL (pH 7.5) with 0.3% (vol/vol) hydrogen peroxide for 5 min and counterstained with hematoxylin.

### Polymerase chain reaction (PCR) and PCR sequencing

To confirm that our probe was specific for HCMV nucleic acids, DNA samples were extracted from two paraffin sections 20  $\mu$ m in size, and cut from the same

biopsy specimens described above with a QIAamp DNA minikit (Qiagen, Tokyo, Japan). From each sample, 200 ng of DNA was amplified by PCR with the primer 5'-TGCAGTTTGGTCCCTTAAAG-3' and 5'-AAGAATCCTCACCTGGCTTA-3' from the HCMV large structural phosphoprotein (UL32) and the primer 5'-TCCAACACCCACAGTACCCGT-3' and 5'-CGGAAACGATGGTGTAGTTTCG-3' from the HCMV glycoprotein B (UL55), using a method specific for UL32 gene<sup>[11]</sup> and UL55 gene<sup>[12]</sup>. The amplified DNA products were visualized on 2% agarose gel (NuSieve GTG agarose, FMC Bio Products, Rockland, USA) stained with 0.01% (vol/vol) ethidium bromide and visualized under ultraviolet light. The bands of UL32 gene were cut out and the DNA was analyzed by automated sequencing (ABI Prism 310 Diagnostics Systems, Applied Biosystems, Tokyo, Japan). The HCMV sequence was confirmed by NCBI Blast, and found to be identical to that of UL32. To avoid potential PCR contamination, all preparations were processed masked, no positive controls were used in any PCR reactions and a separated room was used for the preparation of the reaction mixture. The distilled water control gave negative results in each assay run, and confirmed the efficiency of these preventive measures. When IHC and/or PCR were positive, the sample was considered to be HCMV-positive, and when both of them were negative, the sample was considered to be HCMV-negative.

### Statistical analysis

The results of HCMV detection are expressed in numbers of patients and percentages. The results of the cumulative-life steroid dose are given as means  $\pm$  SD. Statistical significance was calculated with SPSS 13 (SPSS Inc., Chicago, IL, USA) using Fisher's exact test and Student's *t*-test when appropriate, and the results were considered significant at  $P \leq 0.05$ .

## RESULTS

Twenty-eight endoscopies were performed in patients complaining of symptoms and 46 endoscopies were performed in routine controls at different time points after surgery. Four hundred and seventy-three specimens were evaluated, 103 from patients with pouchitis and 370 from patients with a normal pouch. We detected HCMV in samples from 12 endoscopies using IHC and PCR. These endoscopies were performed because the patients were complaining of symptoms (8 endoscopies) or during routine controls after surgery (4 endoscopies). Immunoreactivity was observed in the submucosal layer with predominant nuclear staining of cells (Figure 1). There were not any differences in the staining pattern between the HCMV-positive patients with and without pouchitis either using mPDAI or JCP. We performed PCR for all samples, and amplified products from both genes were detected in the same sample with positive IHC (Figure 2). No HCMV was detected in the distilled water control that was run through the same PCR reaction.

HCMV was significantly detected in endoscopies of patients diagnosed with pouchitis (5 of 12, 41.6%)

**Figure 1** Immunohistochemical staining for HCMV of biopsy samples from ileoanal pouch. Cells in the submucosa (arrows) show strong nuclear staining. Original magnification x 600.

**Figure 2** Agarose gel showing UL32 gene products (lanes 1-4, 5 and 6) and UL55 gene products (lanes 8-12). W: Water; N: HCMV-negative patient.

**Table 1** HCMV detection during endoscopic examinations of UC patients with proctocolectomy and ileal pouch-anal anastomosis *n* (%)

	HCMV positive	HCMV negative	<i>P</i>
mPDAI <sup>[10]</sup>			
Pouchitis	3 (27.2)	8 (72.7)	NS
No pouchitis	9 (14.2)	54 (85.7)	
JCP <sup>[11]</sup>			
Pouchitis	5 (41.6)	7 (58.3)	0.021
No pouchitis	7 (11.2)	55 (88.7)	

mPDAI: modified pouchitis disease activity index; JCP: Japanese classification of pouchitis, NS: not significant.

compared to those with normal pouch (7 of 62, 11.2%;  $P = 0.021$ , Table 1). According to mPDAI, HCMV was more frequently detected in patients with pouchitis (3 of 11, 27.2%) than in those with normal pouch (9 of 63, 14.2%), but this result was not statistically significant. In all patients with pouchitis in which the HCMV was detected in endoscopy, it was the first episode of pouchitis. In these patients HCMV was not detected in biopsies taken in previous normal endoscopies. The odds ratio suggested that the presence of HCMV was 5 times more frequent in patients with episodes of pouchitis than in patients without.

There was not correlation between the presence of HCMV and the duration of UC, the period of pouchitis, the number of operations, the age, and the gender of the patients. There was no significant difference between the cumulative-life steroid dose and HCMV presence. The mean of the cumulative-life steroid dose was  $17152.5 \text{ mg} \pm 16999.0 \text{ mg}$  in HCMV-negative patients, and  $13347.8 \text{ mg} \pm 12966.7 \text{ mg}$  in HCMV-positive patients ( $P = 0.52$ ). After the diagnosis of pouchitis, all patients began treatment with oral metronidazole (500 mg/d). During the follow-up, 2 patients diagnosed with pouchitis were lost and one of them was HCMV-positive. In the samples from 12 endoscopies performed during follow-up, HCMV was detected using IHC and PCR in 4 (4 of 10, 40%) patients. One of these patients had recurrent pouchitis and 3 showed improvement of pouchitis episodes but persistent positive endoscopic findings.

## DISCUSSION

It has been suggested that HCMV plays a role in the onset, exacerbation and complication of inflammatory

bowel disease (IBD)<sup>[2-6,13-18]</sup>. However, the etiology of pouchitis is still unknown and the role of HCMV as a possible etiologic factor has not been studied yet. This is the first report exploring the correlation between HCMV and pouchitis in a group of patients with UC who underwent proctocolectomy with IPAA. There are three possible causes for this association: (1) the virus is a simple bystander in the inflammatory process of the pouch, (2) the virus takes part in the inflammatory process after reactivation and productive infection due to another pathogen infection, (3) the virus induces the inflammatory process after infection.

The differentiation of latently infected monocytes<sup>[19-23]</sup> into tissue macrophages, as occurs with intercurrent infections, could lead to the productive infection and dissemination of HCMV in the digestive tract mucosa of infected patients. No single identifiable causative organism has been detected as the cause of pouchitis, but the infiltration of neutrophils and the proven response to antibacterial therapy suggest that pouchitis could have a bacterial cause<sup>[24-27]</sup>. However, different facts suggest that HCMV is a real gastrointestinal pathogen and that it can be partly related to the development of pouchitis in some patients. HCMV is often detected in the absence of other pathogens, and some UC complications have been associated with the presence of HCMV<sup>[3,5,6]</sup>. Moreover, colitis and pouchitis caused by HCMV infection are known to respond to antiviral therapy<sup>[8,9,15]</sup>, and immediate-early HCMV gene products enhance cytokine production and cytokine gene expression<sup>[28,29]</sup> which *in vivo* would lead to the pronounced inflammation in UC

and pouchitis. Although the pathway of HCMV infection and inflammation is still unclear, the increased production of different cytokines and arachidonic acid, as well as the increased activity of cyclooxygenase 2 after HCMV infection<sup>[30-34]</sup>, could explain the inflammatory response in IBD and pouchitis. In our study on a small series of patients with pouchitis, we hypothesized that HCMV may have played an important role in the etiology of pouchitis in those cases. We detected by IHC an early protein and an immediate-early protein present during an early stage of viral infection. This result corresponds to the detection by PCR of genes that appear early after infection and then frequently decline to undetectable levels with the passage of time<sup>[35]</sup>. The presence of HCMV turned positive in the episode of pouchitis. However, other factors such as bacterial overgrowth and fecal hydrogen sulfide production<sup>[36]</sup> could also be implicated in the etiology of pouchitis episode in patients with no detectable HCMV.

The true incidence of HCMV infection in pouchitis as well as in IBD may be underestimated, as diagnostic evaluation for HCMV is not pursued in many of these patients. In our series, the patients did not receive antiviral therapy and HCMV antigenemia was not measured because a diagnosis of HCMV pouchitis was not sought on the occasion of endoscopy. However, after the antibacterial treatment, HCMV persisted in 4 patients with positive endoscopic findings, confirming the possibility of a possible role of HCMV in the etiology of pouchitis in those patients. Since multiple factors play a role in pouchitis, the clinician must exclude HCMV infection as the cause of pouchitis, especially in patients resistant to treatment, before performing fecal diversion, or pouch excision. Concomitant evaluation of the presence of HCMV may be a clinically significant component of the successful treatment of pouchitis.

In conclusion, the presence of HCMV in pouchitis could partly explain the inflammatory response in some patients with UC who have undergone proctocolectomy with IPAA. Therefore, prospective studies with a large number of patients and an analysis of the correlation between antigenemia of HCMV and immunohistological data are definitely needed to identify the specific role of this virus.

### Abstract

**AIM:** To identify the precise location of putative tumor suppressor genes (TSGs) on the short arm of chromosome 8 in patients with hepatocellular carcinoma (HCC).

**METHODS:** We used 16 microsatellite markers informative in Japanese patients, which were selected from 61 published markers, on 8p, to analyze the frequency of loss of heterozygosity (LOH) in each region in 33 cases (56 lesions) of HCC.

**RESULTS:** The frequency of LOH at 8p23.2-21 with at least one marker was 63% (20/32) in the informative cases. More specifically, the frequency of LOH at 8p23.2, 8p23.1, 8p22, and 8p21 was 6%, 52%, 47%, and 13% in HCC cases. The LOH was significantly more frequent at 8p23.1 and 8p22 than the average (52% vs 22%,  $P = 0.0008$ ; and 47% vs 22%,  $P = 0.004$ , respectively) or others sites, such as 8p23.2 (52% vs 6%,  $P = 0.003$ ; 47% vs 22%,  $P = 0.004$ ) and 8p21 (52% vs 13%,  $P = 0.001$ ; 47% vs 13%,  $P = 0.005$ ) in liver cancer on the basis of cases. Notably, LOH frequency was significantly higher at *D8S277*, *D8S503*, *D8S1130*, *D8S552*, *D8S254* and *D8S258* than at the other sites. However, no allelic loss was detected at any marker on 8p in the lesions of nontumor liver tissues.

**CONCLUSION:** Deletion of 8p, especially the loss of 8p23.1-22, is an important event in the initiation or promotion of HCC. Our results should be useful in identifying critical genes that might lie at 8p23.1-22.

### INTRODUCTION

Primary liver cancer is one of the most frequent neoplasms worldwide, with both an incidence and a mortality rate that are increasing markedly. According to a recent report, the global number of new cases annually rose from 437 400 to 564 000 between 1990 and 2000, and is expected to continue to rise in the future<sup>[1-4]</sup>.

Hepatocellular carcinoma (HCC), the predominant histological subtype of primary liver cancer, mostly arises against a background of chronic liver disease, usually in association with cirrhosis. Several risk factors for HCC have been reported, such as chronic infection with hepatitis B virus (HBV), and C virus (HCV) or both, alcohol-induced liver injury, and dietary exposure to aflatoxin B1 and others. Prolonged exposure to these risk factors is thought to cause an accumulation of chromosomal aberrations and altered gene expression, and eventually results in hepatocarcinogenesis<sup>[4-6]</sup>. In Japan, more than 70% of HCCs develop in patients with chronic infections with HCV<sup>[7]</sup>. Carcinogenesis is mainly researched based on virology and the viral gene itself. However, the mechanisms by which inflammation and cirrhosis contribute to tumor development and/or progression remain unclear. After the human genome was sequenced, the mechanism of generation and subsequent progression was researched at a molecular level for HCC. Histological findings suggest that the initiation and subsequent development of HCC are multistep processes involving qualitative and quantitative changes in sequentially expressed genes, especially the inactivation of tumor suppressor genes (TSGs) related to the deletion of chromosomal regions critical for hepatocarcinogenesis<sup>[8,9]</sup>. A typical alteration in many TSGs, the mutation of one allele, can be detected as a loss of heterozygosity (LOH) with informative markers in TSG regions. Therefore, LOH assays have been widely used as an indirect approach in the search for a new TSG<sup>[10]</sup>. In the last few years, genetic approaches to the detection of genome-wide LOH using microsatellite markers and chromosomal aberrations detected by comparative genomic hybridization (CGH) have indicated that frequent allelic loss in many different chromosomal regions, including 1p<sup>[11,12]</sup>, 3p<sup>[13]</sup>,

4q<sup>[14]</sup>, 6q<sup>[15]</sup>, 8p<sup>[16-19]</sup>, 9p<sup>[20]</sup>, 10p<sup>[21]</sup>, 13q<sup>[22]</sup>, 22q<sup>[23]</sup>, 16q, 17p and Xq<sup>[24,25]</sup>, is closely associated with the tumorigenesis of HCC.

We have performed a genome-wide search for LOH with human genetic markers in several types of human cancer and confirmed that loss of 8p is the most frequent chromosomal alteration in prostate cancer, especially allelic loss at 8p22, which not only is an important event in the initiation of tumor, but also is closely associated with the progression of primary cancer to metastatic cancer<sup>[26]</sup>.

In our comprehensive allelotyping, less than 30% of microsatellite markers located at 8p21-23, were recognized as informative for Japanese patients. We therefore undertook an allelotype based study of 33 HCCs using the selected informative markers to obtain a comprehensive view of the LOH on the most frequent altered chromosome, and to identify the location of the putative TSGs in HCC.

## MATERIALS AND METHODS

### *Tissue collection, histopathology, and DNA extraction*

Thirty-three patients with hepatocellular carcinoma who underwent liver resection were included in this study. Of these, fifty six tumor lesions and 33 adjacent morphological non-tumor lesions were obtained from surgically resected specimens. All specimens were formalin-fixed, and paraffin wax-embedded tissues were processed with routine histological methods. Use of the tissues was approved by the Ethics Committee of the Jikei University School of Medicine before the study. The study group included 26 men and 7 women, ranging in age from 31 to 76 years. Of the 33 patients, 24 (73%) had a chronic infection with HCV, HBV or both and 15 (45%) had cirrhosis in the background liver tissues. Histological diagnoses were made according to the WHO Histological Classification of Tumors of the Liver and Intrahepatic Bile Ducts (2000). According to histological grade, HCC was classified into well differentiated (WD), moderately differentiated (MD), and poorly differentiated (PD) types. In this study, clinicopathological characteristics were also classified, such as solitary or multiple tumor, growth pattern of tumor (expansive or infiltrative), infiltration of capsule or not, histological grading of tumor (well, moderately or poor differentiation), and with or without vascular and bile duct infiltration. Simultaneously, we also compared LOH frequency and etiological factors, such as chronic hepatitis with HCV or HBV infection, and cirrhosis in the background liver tissues. Fibrosis degree was classified as F1, F2, F3, and F4 according to the histological grading and staging of chronic hepatitis. In this system, liver cirrhosis was classed as F4, which is the end-stage form of liver fibrosis. Of the 33 patients who underwent liver resection, 18 had a solitary tumor nodule and 15 had multiple tumor nodules. All lesions from each case were selected and reviewed by two pathologists in order to confirm the original diagnosis. The tumor (T) and corresponding non-tumor hepatocytes (H), and remaining nonhepatocytes that were portal vein lesions (P) were micro-dissected from 15-μm tissue specimens after deparaffinization and nuclear staining. Normal tissues were obtained from the gallbladder or lymph nodes collected from the same patients (Figure 1). DNA was ex-

tracted using the standard phenol/chloroform method as described previously<sup>[26]</sup>.

### **LOH analysis**

Matched tumors, corresponding non-tumor liver tissues, and normal tissue DNAs were analyzed for LOH by amplification of polymorphic microsatellite markers using the polymerase chain reaction (PCR). Sixty-one published microsatellite markers, located at 8p23.3, 8p23.2, 8p23.1, 8p22, and 8p21, were selected from the Genome Database (available at <http://www.gdb.org>). A total of 16 microsatellite markers were identified as informative in Japanese patients and used (Table 1).

DNA amplification was performed in 10-μL volumes containing 100 ng of genomic DNA as a template. Each PCR mixture contained 1.5 mmol/L MgCl<sub>2</sub>, 100 μmol/L forward and reverse primers, 200 μmol/L each of dATP, dGTP, dTTP and dCTP, 10 μCi of [ $\alpha$ -<sup>32</sup>P] dCTP (6000 Ci/mmol, Amersham Biosciences Corp., Piscataway, NJ), 1 U of Taq DNA polymerase (Wako Pure Chemical Industries, Ltd., Osaka, Japan), and 1 × PCR buffer. After the initial denaturation at 94°C, 35 PCR cycles, each consisting of denaturation at 94°C for 30 s, annealing at 65°C -50°C for 30 s, elongation at 72°C for 1 min, and a final extension at 72°C for 5 min, were performed in a 96-well Hybaid thermocycler (Gene Amp PCR System 9600, Takara, Tokyo, Japan). Ten microliters of PCR products were denatured with 30-60 μL of dye solution (95% formamide, 10 mmol/L EDTA (pH 8.0), 0.2% xylene cyanol FF, and 0.02% bromophenol blue) at 95°C for 3 min and then cooled on ice immediately. Three microliters of denatured products were separated on a 6% urea-formamide-polyacrylamide gel and electrophoresed at 40 W for 2-3 h at room temperature. The dried gel was exposed to Hyperfilm MP (Amersham Biosciences Corp.) for 3-7 d and reexposed to another film for 2-3 wk.

### **Criteria for LOH**

A pair of regular and longer-exposed autoradiographs was reviewed independently by two of the authors (T. L. and CX. M.). Informative pairs were judged by visual inspection to show LOH, no loss or to be noninformative.

LOH was defined as a loss of intensity of 60% or greater in 1 or more alleles in the tumor (T) or corresponding hepatocytes (H) compared with the identical allele in the normal tissue (N) (Figure 1).

### **Statistical analysis**

The differences in LOH frequency between tumor, nontumor and normal tissues for individual markers and background values were determined with Fisher's exact test.

## RESULTS

The distribution of the frequency of LOH at 8p23.2, 8p23.1, 8p22 and 8p21 for hepatocellular carcinoma is shown in Table 2. Allelic loss at 8p23.2-21 was detected with at least 1 marker in 18 of 32 (56%) cases of liver cancer. More specifically, the frequency of LOH at 8p23.2, 8p23.1, 8p22, and 8p21 with at least 1 marker was 6% (1

**Figure 1** Representative examples of LOH in two cases of hepatocellular carcinoma (N: normal; H: hepatocytes; P: portal vein; T: tumor; number beside T indicates different lesion): case 7 showing partial loss of upper alleles in lesions of tumor 1 and tumor 2 but not in lesions of hepatocytes and portal vein at *D8S1130*; case 20 showing complete loss of upper alleles in lesion of tumor but not in surrounding non-tumor tissues at *D8S503*.

of 16), 52% (16 of 31), 47% (15 of 32), and 13% (4 of 32) for liver cancer cases respectively (Table 2). A similar result was obtained in the lesion-to-lesion comparison (data not shown). In contrast, no allelic loss at any markers on 8p was detected in the background liver tissue. The average frequency of LOH at 8p23.2-21 was 22% (58 of 264) in informative cases. We found that LOH at the 8p23.1 and 8p22 loci was significantly higher than the average in HCC cases ( $P = 0.0008$ , and  $P = 0.004$ , respectively). But allelic loss at 8p23.2 and 8p21, the loci on either side of the 8p23.1-22 region, tended to be lower than the average. On the other hand, no allelic loss (0 of 52 lesions) was detected at any informative markers on 8p23.2-21 in the surrounding liver tissues. Moreover, allelic loss at *D8S277*, *D8S503*, *D8S1130*, *D8S552*, *D8S1109*, *D8S254*, and *D8S258* was 25%, 42%, 39%, 43%, 24%, 43% and 50%, respectively, significantly higher than that elsewhere and the average frequency at 8p.

Correlations between LOH frequency and clinicopathological variables are summarized in Table 3. To determine whether allelic loss at 8p was associated with clinicopathological characteristics and reveal its biological role in the initiation and/or progression of tumors, we compared the frequency of LOH based on almost all of the clinicopathological findings. Corresponding to the result described above, the LOH frequency tended to be higher at 8p23.1 and 8p22 loci than at 8p23.2 and 8p21 loci for all clinicopathological findings, but no significant difference in LOH frequency was found between the liver cancer positive or negative for malignant factors. In other words, no association was detected between the deletion of 8p23.1-22 and subsequent progression of the tumors.

The distribution of LOH frequency based on the fibrosis (F) of background liver tissues, which is usually thought to be associated with hepatocarcinogenesis, was also analyzed. The frequency of LOH at 8p23.1 or 8p22 in F1, F2, F3, and F4 was 75% (3 of 4), 78% (7 of 9), 20% (1 of 5), and 38% (5 of 13), or 100% (2 of 2), 56% (5 of 9), 40% (2 of 5), and 46% (6 of 13), respectively. No statistically significant difference in LOH frequency was found on the basis of the fibrosis staging at 8p. Allelic loss at 8p even tended to be slightly more frequent in cases of tumor with earlier-stage fibrosis than in cases with advanced stage fibrosis of the background liver tissues.

## DISCUSSION

Previous studies of LOH have reported that allelic loss of 8p is the most frequent chromosomal alteration in a variety of human cancers and have suggested that one or several tumor suppressor genes (TSGs) may lie within the short arm of chromosome 8<sup>[16-19]</sup>. To further identify the precise location of the putative TSGs that might potentially be involved in the tumorigenesis of HCC, we performed a high-density LOH study of HCC at 8p using recently developed microsatellite markers. Only 16 of 61 (less than 30%) were identified as informative for Japanese patients. Furthermore, among the informative markers, the informative cases for all specimens were usually lower (from 20% to 70%) for Japanese than for Westerners. The same-general tendency has been found in various other types of cancer, possibly because Japan is not multiracial like Western countries. This has led us to suggest that using this characteristic might be more efficient for identifying

Table 1 Informative microsatellite markers were selected and used in this study

candidate regions of deletion at 8p.

In this study, LOH at 8p was detected in 56% of informative cases of HCC. However, no allelic loss was found

in corresponding hepatocytes including 18 lesions of morphogenetic non-tumor tissues and 14 lesions of cirrhotic liver tissues at any markers, the latter usually considered a

A total of 32 informative liver cancer cases were analyzed for LOH at the sixteen microsatellite markers. The number of informative cases and frequency of LOH was shown at the bottom. St: solitary tumor; Mt: multiple tumor; WD: well differentiation; MD: moderately differentiation; PD: poorly differentiation; CH: chronic hepatitis; LC: liver cirrhosis. • LOH; o retention of heterozygosity; ni: noninformative. Significant different from the average, 52% vs 22%, <sup>b</sup>*P* = 0.0008; 47% vs 22%, <sup>c</sup>*P* = 0.004; 63% vs 22%, <sup>e</sup>*P* = 0.007; No statistically significant different from the average, 6% vs 22%, <sup>a</sup>*P* = 0.207; 13% vs 22%, <sup>d</sup>*P* = 0.257.

pre-malignant liver lesion. Our result suggests that allelic loss at 8p is an important event in the initiation or promotion of HCC.

Furthermore, among the informative regions 8p23.2, 8p23.1, 8p22, and 8p21, allelic loss was significantly more frequent at 8p23.1 and 8p22 than at 8p23.2 and 8p21 on both sides of the loci. Several minimal regions adjacent to frequently deleted markers were also identified, such as

*D8S277*, *D8S503*, *D8S1130*, and *D8S552* at 8p23.1, and *D8S254* and *D8S258* at 8p22. On the basis of the minimal regions of overlapping deletions at 8p, we identified two sites, 8p23.1 and 8p22, possibly containing TSGs involved in human liver carcinogenesis. That is to say, the commonly deleted regions were restricted to 8p23.1-22 suggesting that the key genes exist in two distinct regions that might be closely related to the carcinogenesis of

HCC. Our results are consistent with previously reported patterns of molecular change in HCC and other epithelial tumors. No statistically significant differences were detected in the candidate regions 8p23.1 and 8p22 between the frequency of LOH and any clinicopathologic characteristics, including etiological factors considered to contribute to tumorigenesis, and malignant factors usually important to the subsequent progression of tumors. These results led us to the hypothesis that loss of 8p is not essential for the subsequent development or progression of HCC.

Moreover, with respect to the results of allelotyping, several genes, such as angiopintin 2 (ANGPT2), AGPAT5, LOC648814, DEFB 137 and DEFB 136, LONRF1, and FLJ36980, which were adjacent to the candidate markers D8S277, D8S503, D8S1130, D8S552, and D8S1109 at 8p23.1, respectively, were analyzed for somatic mutations or expression by single nucleotide polymorphisms (SSCPs) and the reverse transcription polymerase chain reaction (RT-PCR) methods. However, no significant mutation or absence of expression of these adjacent genes was found (data not shown), indicating that alterations of those genes may not be closely related to the carcinogenesis<sup>[16-19,26]</sup>. Several new candidate cancer-susceptibility genes at 8p22, such as deleted in breast cancer 2 (DBC2), leucine zipper tumor suppressor 1 (LZTS1), and deleted in liver cancer 1 (DLC1), and mitochondrial tumor suppressor 1 (MTUS1) have been cloned<sup>[27-30]</sup>. We have analyzed these genes in the same HCC samples, but a somatic mutation or absence of expression of these candidate genes is rare in Japanese patients (data not shown), indicating that these well-known candidate genes are not the main targets of the observed LOH at 8p22. Although no significant genetic alterations were detected in HCC in the present study, it could not be denied that they had already had some epigenetic change during the pre-cancer stage or earlier in the carcinogenesis. Although detailed data have not been published, the present results strongly suggest that other unknown genes in the region 8p22-23.1 play an important role in HCC. Further studies are needed to identify critical oncogenes or TSGs, including those in 8p22-23.1. Our results should be useful for identifying the targets of deletion at 8p.

## ACKNOWLEDGMENTS

We thank Miss Kana Tamura and Ms. Michiko Kasai for their help in collecting samples, Mrs. Misako Shirai and Mrs. Mamiko Owada for technique help, and Miss Michiko Takagi for photographic help.

### Abstract

**AIM:** To investigate the incidence of KIT immunohistochemical staining in (GI) stromal tumors (GISTs), and to analyze the clinical manifestations of the tumors and prognostic indicators.

**METHODS:** We retrospectively analyzed 50 cases of previously diagnosed GISTs. Tissue samples were assessed with KIT (CD117 antigen), CD34, SMA, desmin, S-100, NSE, PCNA, Ki-67, and BCL-2 for immunohistochemical study and pathological characteristics were analyzed for prognostic factors.

**RESULTS:** Fifteen tumors (30%) were negative in KIT staining. A significant association was observed between gender (male patients: 14/15) and KIT-negative staining ( $P = 0.003$ ). The patients's mean age was 56.6 years. Tumors developed in stomach ( $n = 8$ ), small intestine ( $n = 5$ ), large intestine ( $n = 1$ ) and oesophagus ( $n = 1$ ). The mean tumor size was 5.72 cm. The mitotic count ranged from 0-29/50 HPF (mean: 3.4) and 73% of tumors showed no necrosis. The majority of the tumors (67%) had dual or epithelioid differentiation. Tumors were classified as very low or low risk ( $n = 7$ ), intermediate risk ( $n = 5$ ), and high risk ( $n = 3$ ) groups. Twelve (80%) patients were alive without evidence of residual tumor for an average period of 40.25 mo (12-82 mo); three patients developed metastatic disease to the liver and eventually died within 2-12 mo (median survival: 8.6 mo).

**CONCLUSION:** A small subgroup of GISTs fulfils the clinical and morphological criteria of these tumors, and lacks KIT expression. These tumors predominantly developed in the stomach, being dual or epithelioid in morphology, which are classified as low risk tumors and presented a better survival status than KIT-positive tumors. The ability to diagnose GISTs still depends on immunohistochemical staining but the research should extend in gene mutations.

### INTRODUCTION

Most gastrointestinal mesenchymal neoplasms are gastrointestinal stromal tumors (GISTs). Their definitions follow the WHO histological classification where the term GIST is now used for a specific group of tumors comprising the majority of all gastrointestinal stromal tumors<sup>[1]</sup>. Typically, GISTs are immunohistochemically positive for KIT tyrosine kinase receptor which is perhaps their single best defining feature<sup>[2]</sup>. Most GISTs are positive for KIT (CD117 antigen), which may show membrane, diffuse cytoplasmic or a perinuclear accentuation pattern.

Histological assessment of malignancy is essentially based on mitotic counts, the size of the lesion and presence or absence of metastasis<sup>[3-5]</sup>. A proportion of GISTs, especially the malignant tissues show mutations in the regulatory juxtamembrane domain (exon 11) of the KIT gene<sup>[6]</sup>. Until now, the treatment with selective tyrosine kinase inhibitors, such as imatinib mesylate, for patients with GISTs has hinged on the KIT positive immunostaining tumors. Although the KIT positivity by immunohistochemistry becomes invaluable in the diagnosis of GISTs, some authors believe that a small subgroup of these tumors fulfils the clinical and morphological criteria

of GISTs, and lacks KIT expression. The biological features of these tumors have rarely been addressed.

Our aim was to investigate the incidence of KIT immunohistochemical staining in 50 cases of previously diagnosed GI stromal tumors, to carry out a comprehensive examination of GISTs that are negative in CD117 expression, and to analyze the clinical manifestations and prognostic indicators of the tumors.

## MATERIALS AND METHODS

Using the database of Surgery and Pathology Departments of “Evangelismos” General Hospital and Areteion University Hospital, we collected records with a pathologic diagnosis of stromal tumor of GI tract. Fifty patients with the diagnosis of GIST between 1994-2004 were retrieved from the archives. Patient age, gender, clinical manifestations, tumor size, pathological characteristics, the presence of distant metastasis and the outcome were recorded.

Tumor specimens were fixed in 10% buffered formalin after gross examination and embedded in paraffin. Histologic sections stained with hematoxylin and eosin were evaluated for all cases. Tumors were classified as very low risk, low risk, intermediate or high risk groups based on histological parameters according to NIH Consensus Guidelines for Grading<sup>[4]</sup>.

### Immunohistochemistry

The tumor samples from all 50 cases were examined for various markers using commercially available immunohistochemical antibodies against KIT (CD117 antigen), (A4502, polyclonal, Dako, USA; 1:50 dilution), CD34 (clone QBEnd/10) (Novocastra Labs; 1:50), S-100 (clone S1/61/69) (Novocastra Labs; 1:40), smooth-muscle actin (SMA) (clone asm-1) (Dako; 1:200), desmin (clone DE-R-11) (Novocastra Labs; 1:100), neuron-specific enolase (NSE) (clone 5E2) (Novocastra Labs; 1:100), neurofilament protein (NFL) (clone NR4) (Novocastra Labs; 1:50), bcl-2 (clone 124) (Dako; 1:40), proliferating cell nuclear antigen (PCNA) (clone PC10) (Novocastra Labs; 1:200), Ki-67 (clone MM1) (Novocastra Labs; 1:200) by a standard three-step immunoperoxidase procedure (APAAP, DAKO, Glostrup, Denmark). Appropriate positive controls were run concurrently for all antibodies tested. According to the percentage of tumor cells showing an immunopositive reaction among the total tumor cells, tumors were reported as negative ( $\leq 10\%$ ) or positive ( $> 10\%$ ).

### Statistical methods

Data was analyzed using statistical software SPSS version 12.0. Chi-square test or Fisher's exact test was done for categorical variables to assess differences among baseline patient features. Overall survival was computed by the Kaplan-Meier method. Comparison of survival between subgroups was performed by the log-rank test. The relative importance of prognostic factors for the survival was analyzed with Cox's proportional hazard model. Statistical significance would be inferred at a two-tailed  $P$  value  $< 0.05$ .

**Figure 1** Histological section of GIST showing positive immunostaining for KIT (CD117 antigen)  $\times 400$ .

## RESULTS

### Clinical and pathological data of patients with GISTs

Thirty-one (62%) patients were male and 19 (38%) female. Their age at diagnosis ranged from 26 to 89 years (mean:  $62 \pm 14.5$ ). The most common symptoms were abdominal pain (72%). The most common anatomic sites of tumor origin were the small intestine ( $n = 23$ ) and the stomach ( $n = 19$ ). Three tumors were located in oesophagus and 5 tumors in large intestine.

The size of the tumor ranged from 0.2 cm to 30 cm (mean:  $4.58 \pm 5.2$ ). The mitotic count was 0-29 per 50 HPF ( $\times 400$ ) (mean:  $4.25 \pm 2$ ). Necrosis was present in 13 (26%) tumors. Twenty-four (48%) tumors showed evidence of dual differentiation toward smooth muscle and neural elements. Reactivity for either SMA or desmin (epithelioid features) was observed in 8 (16%) cases. There was neural differentiation (spindled features) in 7 (14%) cases. No evidence of differentiation toward either cell type, was formed even after exhaustive immunohistochemistry in 11 (22%) cases. Of the 50 tissues tested, 35 (70%) were positive for KIT staining (Figure 1), while 15 (30%) tumors lacked KIT expression. The high incidence of KIT-positive staining (57%) was in tissues diagnosed as “high risk” tumors. Twenty-four (48%) tumors were CD34 positive. The proliferative activity (PCNA labeling index) was high ( $> 10\%$  labeled nuclei) in 62% of our specimens. Only 6 (12%) cases were characterized by high ( $> 20\%$  labeled nuclei) Ki-67 immunoreactivity percentages. Bcl-2 protein was positively expressed in the cytoplasm of tumor cells in 26 (52%) specimens.

Complete information on patients' clinical course could be obtained in 50 (100%) cases. According to the available follow-up, patients with KIT-positive staining tumors were alive without evidence of residual tumor for an average period of 32.3 mo (12-82 mo). Tumor location, mitotic counts, risk group and metastasis seem to be related to survival, since partial likelihood ratio test of Cox regression for each of these patient's feature was less than 0.05 (Figure 2, Figure 3, Figure 4). There was an indication of association between tumor size and mitoses ( $P = 0.055$ , Fisher's Exact test).

### Clinicopathological features of KIT (CD117) negative GISTs

Of the 50 tissues tested, a small subgroup of tumors ( $n = 15$ ) fulfilled the clinical and morphological criteria of GISTs and lacked KIT antigen immunoreexpression. The clinicopathological features of KIT-negative cases

**Figure 2** Cumulative survival for patients with GISTs based on tumor location.

**Figure 3** Cumulative survival for patients with GISTs based on mitotic counts.

**Figure 4** Cumulative survival for patients with GISTs based on metastasis status.

are shown in Table 1. A highly significant association was observed between gender and CD117 staining ( $P = 0.003$ ). All, except one, KIT-negative tumors were observed in male patients, while the majority of female patients (18/19) expressed CD117 immunostaining (Table 2).

Patients' age at diagnosis ranged from 26 to 82 years (mean: 56.6). The majority of them (11/15) presented at the hospital with symptoms, as abdominal pain. KIT-negative GISTs developed in stomach ( $n = 8$ ), small intestine ( $n = 5$ ), large intestine ( $n = 1$ ) and oesophagus ( $n = 1$ ) (Table 3).

Tumors size ranged from 0.5 cm to 30 cm (mean: 5.72). The majority of tumors were smaller than 5 cm (9/15), and only one was > 10 cm. The mitotic count ranged from 0-29 per 50 HPF ( $\times 400$ ) (mean: 3.4). Twelve (80%) tumors contained less than 5/50 HPF mitoses, 2 (13%) tumors contained mitoses between 5 and 10/50 HPF and 1 (7%) tumor contained mitoses > 10/50 HPF. Absence of necrosis was present in 73% (11/15) of tumors.

Of the 15 KIT-negative samples, 6 (40%) cases had dual differentiation showing histologically mixed spindle and epithelioid type features, four (27%) cases showed histologically predominantly epithelioid type features, two (13%) cases spindle type features, and 3 (20%) cases were classified as anaplastic (Table 4).

KIT-negative tumors were diagnosed as "very low" and "low risk" (benign) ( $n = 7$ ), "intermediate risk" (uncertain malignant potential) ( $n = 5$ ), and "high risk" tumors (malignant potential) ( $n = 3$ ).

The clinical status was primary presentation in 12 patients. According to the available follow-up, twelve patients (80%) were alive without evidence of residual tumor for an average period of 40.25 mo (12-82 mo);

three patients developed metastatic disease to the liver and eventually died within 2-12 mo (median survival: 8.6 mo).

## DISCUSSION

The classification of GISTs has been a continually evolving process reflecting our increasing understanding of the biological nature of these tumors. One of the most important concepts of the recent years is that GISTs show the differentiation of the interstitial cells of Cajal (ICC)<sup>[2]</sup>. Mesenchymal tumors of GI can be identified based on the features of ICCs and can therefore designated as GISTs<sup>[4]</sup>.

Histological and immunohistochemical advances, and molecular genetics provide a new era for GISTs. KIT, a type III tyrosine kinase growth factor receptor, is the common denominator in most GISTs<sup>[7-9]</sup>. CD117, the epitope for KIT, is introduced as a new phenotypic marker for distinguishing between GISTs and non-GIST spindle cell tumors of the GI. A small subgroup of GISTs that fulfill the clinical and morphological criteria of these tumors is essentially KIT-negative by immunohistochemistry. The biological features of these tumors have rarely been addressed. In the absence of CD117 immunopositivity, the diagnosis of GISTs is challenging.

Based on this and using the latest clinical and histological criteria, we screened 50 cases of gastrointestinal stromal tumors with a long term follow-up. Generally, as it was expected, tumor location, mitotic counts, risk group and metastasis were significantly associated with survival. Of the 50 tissues tested, 35 (70%) were positive for CD117 staining and 15 (30%) were negative. A significant association was observed between gender and KIT (CD117) immunostaining. KIT-negative tumors were observed in male patients, while the majority of female patients expressed CD117 immunostaining.

The majority of KIT-negative tumors developed in stomach while KIT-positive tumors developed in small intestine. This finding is in accordance with recent studies<sup>[10]</sup>. The majority of KIT-negative tumors were smaller than 5 cm (9/15), and 80% contained mitoses less than 5/50 HPF.

Of the 15 CD117-negative samples, 6 cases had evidence of dual differentiation, 4 cases showed histologically epithelioid type features, two had spindle type features, and 3 cases were negative for all markers,

Table 1 Clinicopathological features of KIT-negative cases

Case No.	Sex	Age (yr)	Symptoms	Site	Size (cm)	Mitoses (/50 HPF)	Presence of necrosis	Morphology	Risk category	Clinical status	Survival data/mo
1	M	60	Yes	Small Intestine	4.30	1	No	Epithelioid	Low risk	Primary	Alive/12

tumors.

Benign and malignant GISTs carry mutations in KIT gene. It is still not clear whether mutations are independent prognostic factors<sup>[12,13]</sup>. We believe that a search for gene mutation, as the c-kit gene, in KIT-negative staining tumors might clarify the diagnosis status (unpublished observations), as other authors believe that KIT mutations<sup>[11]</sup> or intragenic platelet-derived growth factor- $\alpha$  (PDGFR- $\alpha$ ) activating mutations are present in some of these tumors<sup>[10]</sup>. The pharmaceutical development and therapeutic implications of protein tyrosine kinase inhibitors has refocused the attention on GIST. Until recently, no patient with complete response to therapy was reported<sup>[14]</sup>. Is there any value in separating these tumors with epithelioid or dual differentiation because they are often KIT-antigen negative<sup>[15]</sup>? Is this going to be the result of a better differentiation status, detection of certain molecular alterations or it may be related to more traditional criteria as size and mitosis rate? There is still challenge to identify those patients who would benefit

from receiving the new therapy.

In conclusion, our study confirms that traditional histologic criteria alone are not enough to confirm GISTs diagnosis, but are still the only criteria to estimate biological behavior in these tumors. A small subgroup of GISTs fulfils the clinical and morphological criteria of these tumors, and lacks KIT expression. These tumors predominantly develop in stomach, showing dual or epithelioid morphology; they are classified as "low risk" tumors, and present with a better survival status than KIT-positive staining tumors. The ability to diagnose GISTs still depends on the immunohistochemical staining but the research should expand in gene mutations.

### Abstract

**AIM:** To evaluate the efficacy and mechanism of action of NCB-02, a standardized Curcumin preparation, against 2, 4-dinitrochlorobenzene (DNCB)-induced ulcerative colitis in rats.

**METHODS:** Ulcerative colitis was induced in male rats by sensitizing with topical application of DNCB in acetone for 14 d and intra-colonol challenge with DNCB on day 15. A separate group of animals with vehicle treatment in similar fashion served as control group. Colitis rats were divided into different groups and treated with NCB-02 at doses of 25, 50 and 100 mg/kg b.wt p.o. for 10 d. Sulfasalazine at a dose of 100 mg/kg b.wt for 10 d served as a reference group. On day 10 after respective assigned treatment, all the animals were euthanized and the length of the colon, weight of entire colon and distal 8 cm of the colon were recorded. The distal part of the colon was immediately observed under a stereomicroscope and the degree of damage was scored. Further distal 8 cm of the colon was subject to the determination of colonic myeloperoxidase (MPO), lipid peroxidation (LPO) and alkaline phosphatase (ALP) activities. A small piece of the sample from distal colon of each animal was fixed in 10% neutral buffered formalin and embedded in paraffin wax and sectioned for immunohistochemical examination of NF $\kappa$ -B and iNOS expression.

**RESULTS:** NCB-02 showed a dose dependent protection against DNCB-induced alteration in colon length and weight. NCB-02 treatment also showed a dose dependent protection against the elevated levels of MPO, LPO and ALP, induced by DNCB. NCB-02 demonstrated a significant effect at a dose of 100 mg/kg b.wt., which was almost equipotent to 100 mg/kg b.wt. of sulfasalazine. Treatment with sulfasalazine and curcumin

at a dose of 100 mg/kg b.wt. inhibited the DNCB-induced overexpression of NF $\kappa$ -B and iNOS in the colon.

**CONCLUSION:** Curcumin treatment ameliorates colonic damage in DNCB-induced colitic rats, an effect associated with an improvement in intestinal oxidative stress and downregulation of colonic NF $\kappa$ -B and iNOS expression.

### INTRODUCTION

Inflammatory bowel disease (IBD), including Crohn's disease and ulcerative colitis (UC), is a chronic and relapsing inflammatory disease caused by the inflammation and sores in the lining of large intestine and characterized clinically by recurrent episodes of bloody diarrhea, cramping, abdominal pain and histologically by mucosal inflammation and injury<sup>[1]</sup>. Conventional therapy for UC includes sulfasalazine and other 5-aminosalicylic acid (5-ASA) type of compounds, and in more persistent and/or severe cases, oral, rectal and parenteral corticosteroids and immunosuppressants are administered<sup>[2]</sup>. All of these have significant toxicities and are partly or completely ineffective in significant numbers of patients<sup>[3]</sup>.

Several agents used in the management of IBD, such as corticosteroids, sulfasalazine and 5-ASA, have documented regulation of Nuclear Factor Kappa-B (NF $\kappa$ -B) function<sup>[2]</sup>. Given the importance of inflammatory cell activation involved in the development of IBD, there is a need for a treatment modality against IBD that can block the inflammatory processes. There is substantial evidence for the involvement of oxidative stress and profound alterations in the biosynthesis of the labile free

radical nitric oxide from L-arginine in the pathogenesis of colitis<sup>[4]</sup>. The use of medicinal plants or their active components has become an increasingly attractive approach for the treatment of UC. Curcumin, the active principle in turmeric, is a polyphenolic antioxidant and a natural yellow orange dye. Turmeric contains three curcumin analogues based on the number of hydroxyl groups present in the parent molecule. They are Curcumin (Curcumin I), demethoxy curcumin (Curcumin II) and bis-demethoxy curcumin (Curcumin III). Curcumin is a active constituent of *Curcuma longa*, whose anti-inflammatory properties are related in part to inhibition of the activities of the cyclooxygenase, lipoxygenase and NF $\kappa$ -B in several cell systems<sup>[5-9]</sup>. Many experimental studies have demonstrated the important role of Curcumin in the attenuation of IBD and colonic cancer and it is also known to exhibit a variety of beneficial effects including antitumor, anti-HIV, antioxidant, anticataract development, septic shock, promotion of wound healing in normal and diabetic conditions, anti-asthmatic, anti-colitis, anti-fibrosis, reduction of mucosal damage, prevention of UV damage to skin, inhibition of development of cancers of the skin, stomach, colon, prostate, oral cavity and liver. Furthermore, Curcumin could also inhibit tumor metastases, pancreatitis, drug or alcohol-induced liver fibrosis, cystic fibrosis and Alzheimer's disease<sup>[10,11]</sup>.

NCB-02 is a standardized extract of *Curcuma longa* containing 78% curcuminoids, 72% of which is Curcumin, 18.08% demethoxy curcumin and 9.42% bis-demethoxy Curcumin. This study was designed to evaluate its efficacy and mechanism of action against 2, 4-dinitrochlorobenzene (DNCB)-induced ulcerative colitis in rats.

## MATERIALS AND METHODS

### Animals

Laboratory bred Wistar male rats weighing between 220-250 g were used for the experiments. The animals were housed and acclimatized to a constant temperature of  $22 \pm 3^\circ\text{C}$  and were exposed to 12 h day and night cycle. The animals were fed with synthetic diet and water *ad libitum*.

### Effect of NCB-02 on UC in rats induced by DNCB<sup>[12]</sup>

Forty-eight rats were divided into six groups of eight animals each and, the nape hair was depleted. About 300  $\mu\text{L}$  DNCB in acetone (20 g/L) was dropped to the nape of the rats once a day for 14 d. On the 15th day, animals of Groups II-VI were subject to intracolonic challenge of DNCB. Intra-colon challenge was done by infusing 0.25 mL of 0.1% DNCB in 50% alcohol into colon by a nylon catheter (3 mm in diameter), which was inserted into the colon at the site of 8 cm from the anus. Group I served as normal control and received 50% alcohol instead of DNCB. The animals were kept in Trendelenburg position for 1 min after DNCB administration and maintained in cages with free access to water and food.

Rats of Groups I and II served as normal and positive controls respectively and were administered with water (vehicle) at a dose of 10 mL/kg b.wt. p.o. and

Group III rats with 100 mg/kg b.wt. p.o. of reference drug, sulfasalazine. Rats of groups IV-VI received 25, 50 and 100 mg/kg b.wt. p.o. of NCB-02, respectively. The treatment was carried out for 10 d, after challenge with DNCB. On d 10, after assigned treatment, all the animals were euthanized by exsanguinations. The entire length of the colon starting from the ceecal end was excised, opened and gently rinsed with ice-cold saline. The colon was kept flat with the mucosal surface upward on a plate prechilled to  $4^\circ\text{C}$ . The length of the colon, weight of entire colon and distal 8 cm of the colon were recorded. The distal part of the colon was immediately observed under stereomicroscope to note any visible damage. The degree of damage was scored macroscopically on a 0-5 scale by independent observers<sup>[13]</sup>. Further distal 8 cm of the colon was subject to the determination of colonic myeloperoxidase<sup>[14]</sup>, lipid peroxides<sup>[15]</sup> and ALP activity. A small piece of the sample from distal colon of each animal was fixed in 10% neutral buffered formalin and embedded in paraffin wax and sectioned for immunohistochemical examination<sup>[16]</sup>.

### Myeloperoxidase (MPO) activity

MPO is an enzyme found in cells of myeloid origin, and has been used extensively as a biochemical marker of granulocyte (mainly neutrophil) infiltration into gastrointestinal tissues<sup>[14]</sup>. Samples of distal colon were homogenized in 10 mmol/L potassium phosphate buffer, pH 7.0 containing 0.5% hexadecyltrimethylammonium bromide and centrifuged for 30 min at  $20000 \times g$  at  $4^\circ\text{C}$ . An aliquot of the supernatant was then allowed to react with a solution of 1.6 mmol/L O-dianisidine and 0.1 mmol/L  $\text{H}_2\text{O}_2$ . The rate of change in absorbance was measured spectrophotometrically at 650 nm. One unit of myeloperoxidase activity was defined as degrading 1 mmol of  $\text{H}_2\text{O}_2$  per min at  $37^\circ\text{C}$  and was expressed as units per milligram of tissue sampled (U/mg tissue).

### Estimation lipid peroxidation and ALP

The tissue was homogenized at a concentration of 10% w/v in 0.15 mol/L potassium chloride using a glass homogenizer. The homogenate was centrifuged at  $800 \times g$  and the supernatants were used for the estimation of lipid peroxides<sup>[15]</sup> and alkaline phosphatase (ALP) using Boehringer Mannheim kit.

### Immunohistochemistry for NF $\kappa$ -B and inducible nitric oxide synthase (iNOS)<sup>[16]</sup>

Colon sections were deparaffinized in xylene, for 2-5 min and dehydrated with 100% ethanol for 2-3 min followed with 95% ethanol for 1 min, then rinsed in distilled water. Tissue sections were incubated with primary antibody at appropriate dilution in phosphate buffered saline (PBS) for 1 h at room temperature, then incubated in biotinylated secondary antibody in PBS for 1 h at room temperature. After rinsing in PBS for 3 changes of 2 min each, sections were incubated in freshly prepared peroxidase substrate solution for 10 min at room temperature and counterstained with weak haematoxylin for 10 min after rinsing with PBS.

<sup>b</sup>*P* < 0.001, <sup>d</sup>*P* < 0.01 vs control; <sup>f</sup>*P* < 0.001, <sup>h</sup>*P* < 0.01, <sup>j</sup>*P* < 0.05 vs positive control.

### Statistical analysis

The values were expressed as mean ± SE. The results were analyzed statistically using one-way ANOVA followed by Dunnett's multiple comparison test using GraphPad Prism software package (Version 4.0) to find the level of significance. The minimum level of significance is fixed at *P* < 0.05.

## RESULTS

Rats sensitized and challenged with DNCB showed ulcers with severe macroscopic inflammation in the colon as assessed by the colonic damage score. Colon length was significantly reduced with a significant increase in total and distal colon weight in colitic rats as compared with non-colitic control rats. There was also a significant increase in colonic MPO, LPO and ALP activity as compared with non-colitic rats (Table 1). Treatment with NCB-02 showed a dose dependent protection against DNCB-induced colonic damage as indicated by normalization of colon length, reduction in colon weight (total and distal) and decrease in the levels biochemical markers such as MPO, LPO and ALP. NCB-02 at a dose of 100 mg/kg b.wt. p.o. showed a significant effect on various parameters (Table 1). Reference drug sulfasalazine presented with a significant reversal of DNCB-induced alterations at a dose of 100 mg/kg b.wt. p.o. (Table 1).

Sulfasalazine treatment resulted in significant protection with the mean ulcer score of 2.75 ± 0.39 and NCB-02 had a dose dependent protection at 25, 50 and 100 mg/kg b.wt. with ulcer scores of 3.75 ± 0.23, 3.00 ± 0.18 and 2.63 ± 0.25 (*P* < 0.001), respectively (Table 1).

Myeloperoxidase activity is an established marker for inflammatory cell (mainly neutrophils) infiltration in rodent models of colitis, and was thus examined. MPO activity was significantly increased in colitis rats as compared with the control. NCB-02 treatment inhibited DNCB-induced MPO activity in a dose dependent manner. Both sulfasalazine and NCB-02 at a dose of 100 mg/kg b.wt. significantly protected DNCB-induced elevation of MPO activity (Table 1).

High level expression of iNOS and NFκ-B were observed in colitis rats, which is revealed by immunohistochemistry (Figures 1 and 2). This immunohistochemistry for NFκ-B and iNOS expression revealed that NCB-02 at a dose 100 mg/kg b.wt. inhibited the DNCB-induced

expression of these pro-inflammatory mediators of ulcerative colitis.

From the various parameters evaluated it was observed that 100 mg/kg b.wt. of NCB-02 was almost equipotent to sulfasalazine at 100 mg/kg b.wt.

## DISCUSSION

In the present investigation, the beneficial effects observed with NCB-02 (Standardized Curcumin preparation) treatment were assessed based on the improvement of colon weight and length, and histologically by preservation of the colon architecture in comparison with the rats from the non-treated colitic group. The biochemical assays, such as MPO and ALP, performed in the colonic specimens confirmed the anti-inflammatory effect exerted by Curcumin at a dose of 100 mg/kg, since it was associated with significant reduction in MPO and ALP activities. MPO activity has been widely used to detect and follow intestinal inflammation, and a reduction in the activity of this enzyme can be interpreted as a manifestation of the anti-inflammatory activity of a given compound. Alkaline phosphatase activity is considered as one of the sensitive markers of inflammation in the intestine, as this enzyme activity is invariably augmented in these experimental conditions of colitis. The results obtained in this study confirm the intestinal anti-inflammatory effect previously demonstrated for Curcumin<sup>[9,17]</sup>.

Earlier studies provided evidence of significantly elevated activation of NFκ-B in ulcerative colitis and Crohn's disease<sup>[18,19]</sup>. Several therapeutic agents with NFκ-B inhibitory activity, such as sulfasalazine, mesalamine, and corticosteroids have been used for the treatment of IBD. They have sundry defects such as steroid dependence and steroid resistance, decreasing glucose tolerance, hepatotoxicity and pancreatitis<sup>[2]</sup>. Now, more potent and selective treatment strategies for IBD aim at preventing NFκ-B activation in mucosal macrophages and T lymphocytes.

According to the well-described role of NFκ-B in inflammatory regulation and iNOS expression, the degree of NFκ-B expression was determined in the colonic tissue samples from animals subjected to DNCB sensitization and challenge. The inflammatory status induced by DNCB was associated with increased colonic NFκ-B expression when compared to normal tissues. Curcumin treatment resulted in inhibition of NFκ-B expression and similar

**Figure 1** A: Section of colon in normal control showing normal structure and architecture (immunohistochemistry, 40 x); B: Section of colon in DNCB control showing extensive NF $\kappa$ -B (brown) expression in tissue (immunohistochemistry, 40 x); C: Section of colon in sulfasalazine treated group showing limited NF $\kappa$ -B (brown) expression (immunohistochemistry, 40 x); D: Section of colon in NCB-02 treated group showing minimal NF $\kappa$ -B (brown) expression (immunohistochemistry, 40 x).

response was observed with sulfasalazine treatment.

Nitric oxide is one of the important pro-inflammatory mediators, which plays a key role in the pathogenesis of IBD. In our study, we evaluated the effect of Curcumin

**Figure 2** A: Section of colon in normal control showing normal structure and architecture (immunohistochemistry, 40 x); B: Section of colon in DNCB control showing extensive iNos (brown) expression in tissue (immunohistochemistry, 40 x); C: Section of colon in sulfasalazine treated group showing limited iNos (brown) expression (immunohistochemistry, 40 x); D: Section of colon in NCB-02 treated group showing minimal iNos (brown) expression (immunohistochemistry, 40 x).

on colonic iNOS activity in the DNCB-induced model of experimental colitis. DNCB administration increased colonic iNOS activity expression in rats, as detected by immunohistochemistry (Figure 2B). The intestinal anti-

inflammatory effect exerted by NCB-02, was associated with a reduction of iNOS expression (Figure 2D) when compared with DNCB control animals.

Myeloperoxidase is an enzyme found in cells of myeloid origin, and has been used extensively as a biochemical marker of granulocyte (mainly neutrophil) infiltration into gastrointestinal tissues. Our study showed that DNCB raised the levels of colonic MPO, which was ameliorated in NCB-02 and sulfasalazine treated groups.

In addition, our study gives some evidence about the mechanisms involved in the intestinal anti-inflammatory effect of Curcumin. One of the mechanisms could be its inhibition of free radical generation and antioxidant properties, which is evident from several earlier observations<sup>[9,10]</sup>. This activity may play a crucial role in the intestinal anti-inflammatory effect of the Curcumin, because intense oxidative insult is a common feature in human IBD and in the different experimental models of rat colitis, such as the trinitrobenzene sulfonic acid (TNBS) and the DNCB models in rats, and is an important mechanism for tissue damage during chronic intestinal inflammation<sup>[18]</sup>.

In the last decade, it became increasingly clear that NO overproduction by iNOS is deleterious to intestinal function, which contributes significantly to gastrointestinal immunopathology in the chronic inflammatory events in IBD<sup>[16,18]</sup>. The important role attributed to NO in these intestinal conditions prompted us to study whether the beneficial effects of Curcumin on DNCB-induced colitis could be related to an effect on colonic NO production. The results in this study reveal that colonic inflammation is associated with a higher colonic iNOS expression, as evidenced by immunohistochemistry. Treatment of colitic rats with NCB-02 effectively inhibited the upregulated colonic iNOS expression.

The present study revealed that oral treatment of NCB-02 in colitic rats significantly inhibited the NF $\kappa$ -B pathway, which is reported to be activated as a consequence of the intestinal inflammatory process induced by DNCB. The molecular mechanism involved in the suppressive effects of Curcumin on NF $\kappa$ -B could be due to the inhibition of NF $\kappa$ -B by acting as antioxidants, since NF $\kappa$ -B is a redox-sensitive transcription factor and activated by oxidative stress in the inflamed intestinal mucosa via blocking the phosphorylation and degradation of I $\kappa$ B protein, as previously reported *in vitro* and *in vivo*<sup>[7,19]</sup>.

In conclusion, Curcumin treatment ameliorates colonic damage in DNCB-induced colitic rats, an effect associated with an improvement in intestinal oxidative stress and a downregulation in colonic iNOS and NF $\kappa$ -B expression. Therefore, Curcumin (NCB-02) may hold promise for the treatment of inflammatory bowel disease.

### Abstract

**AIM:** To analyze the clinico-pathological spectrum of primary duodenal neoplasms.

**METHODS:** A total of 55 primary duodenal neoplasms reported in the last 10 years after excluding ampullary and periampullary tumors were included in the study. Clinical details were noted and routine hematoxylin and eosin stained paraffin sections were studied for histological subtyping of the tumors.

**RESULTS:** On histopathological examination primary duodenal neoplasms were categorized as: epithelial tumor in 27 cases (49.0%) including 10 cases of adenoma, 15 cases of adenocarcinoma, and 2 cases of Brunner gland adenoma; mesenchymal tumor in 9 cases (16.3%) consisting of 4 cases of gastrointestinal stromal tumor, 4 cases of smooth muscle tumor and 1 case of neurofibroma; lymphoproliferative tumor in 12 cases (21.8%), and neuroendocrine tumor in 7 cases (12.7%).

**CONCLUSION:** Although non-ampullary/periampullary duodenal adenocarcinomas are rare, they constitute the largest group. Histopathological examination of primary duodenal tumors is important for correct histological subtyping.

### INTRODUCTION

Although the small intestine constitutes 75% of the gastrointestinal tract, tumors arising from it are rare. Small intestine tumors account for about 5% of all alimentary tract tumors and the duodenum has a higher proportion of these tumors than the jejunum and ileum<sup>[1]</sup>. Duodenal carcinomas account for 20%-25% of all small bowel malignancies, whereas sarcomas, carcinoid and lymphomas are less common<sup>[2]</sup>. Duodenal tumors pose diagnostic difficulties because of their rarity, non-specific signs and symptoms and the fact that duodenum is usually overlooked during upper gastrointestinal endoscopy. The present study was undertaken to analyze the clinico-pathological spectrum of primary duodenal neoplasms reported in the last 10 years.

### MATERIALS AND METHODS

A retrospective analysis of duodenal tumors retrieved from the Department of Histopathology, PGIMER, over a period of 10 years (1997-2006) was done. A total of 60 duodenal neoplasms after excluding 163 ampullary/periampullary carcinomas were retrieved from the records. All the clinical details like age, sex, presenting symptoms were noted from the patient record files. Relative laboratory and radiological findings were obtained. The specimens were fixed in buffered formalin and processed for paraffin sections. Routine hematoxylin and eosin-stained paraffin sections were studied for histological subtyping of the tumors. Histochemical stains like periodic acid Schiff (PAS), mucicarmine and immunohistochemical stains like c-kit, smooth muscle antigen (SMA), leukocyte common antigen (LCA), CD3, CD20, cytokeratin (CK) and chromogranin, were performed wherever required for exact categorization of the tumors.

### RESULTS

Of the 60 duodenal neoplasms retrieved from records, 2 metastatic tumors and 3 with direct infiltration into duodenum from the subjacent site were excluded from the study. The study comprised of 55 cases of primary duodenal neoplasm. The age of the patients ranged from 7 to 70 years and the male to female ratio was 1.9:1. On histopathological examination primary duodenal neoplasms were categorized as: epithelial tumor, mesenchymal tumor, lymphoproliferative tumor, and neuroendocrine tumor (Table 1).

**Table 1** Histopathological sub-classification of primary duodenal tumors (excluding ampullary and peri-ampullary tumors)

Pathological diagnosis	Cases <i>n</i> (%) <i>n</i> = 55
Epithelial tumors	27 (49.0)
Adenoma	10
Adenocarcinoma	15
Brunneroma	2
Mesenchymal tumors	9 (16.3)
GIST	4
Benign	1
Borderline	1
Malignant	2
Smooth muscle tumors	4
Leiomyoma	2
Leiomyosarcoma	2
Neurofibroma	1
Lymphoproliferative tumors	12 (21.8)
Non-Hodgkin's lymphoma	12
B-Cell lymphoma	10
T Cell lymphoma	2
Neuroendocrine tumors	7 (12.7)
Carcinoid	5
Gastrinoma	1
Neuroendocrine carcinoma	1

**Epithelial tumor**

There were 27 cases (49.0%) of epithelial tumor including 10 cases of adenoma, 15 cases of adenocarcinoma, and 2 cases of Brunner gland adenoma.

**Adenoma:** The age range of patients with adenoma was 10-60 years and the male to female ratio was 1:2.3. All adenomas were seen in D1-D2 portion of the duodenum and classified as flat adenoma in 1 case, tubular adenoma in 4 cases, tubulovillous adenoma in 3 cases (Figure 1A), and villous adenoma in 2 cases. Two cases were associated with multiple polyposis coli.

**Adenocarcinoma:** The age range of patients with adenocarcinoma was 38-70 years and the male to female ratio was 2:1. Of the 15 cases, 10 were found to have adenocarcinoma in D1-D2 portion of the duodenum and 5 were found to have adenocarcinoma in D3-D4 portion of the duodenum. Adenocarcinomas were sub-categorized as well-differentiated adenocarcinoma in 8 cases, moderately-differentiated adenocarcinoma in 2 cases, poorly-differentiated adenocarcinoma in 2 cases, and signet ring cell type adenocarcinoma in 3 cases. One adenocarcinoma was documented to be arising from pre-existing adenoma (Figure 1B).

**Brunner gland adenoma:** They were both seen in males and in D1 portion of the duodenum. The size of tumor ranged from 3 to 4 cm and microscopic examination showed lobules of Brunner glands separated by fibrovascular septa (Figure 1C).

**Mesenchymal/stromal tumor**

Nine cases (16.3%) were included in this group including 4 cases of gastrointestinal stromal tumor, 4 cases of smooth muscle tumor and 1 cases of neurofibroma. The age of

the patients ranged from 32 to 70 years and the male to female ratio was 1.2:1.

**Gastrointestinal stromal tumor (GIST):** On pathological examination of 4 cases of GIST, 2 cases were diagnosed as malignant GIST based on the mitotic count of > 10/50HPF and tumor deposits in the omentum. One case was categorized as borderline GIST (5 cm in diameter) with its mitotic count of < 5/50HPF and one case was labeled as benign GIST (Figure 1D). All the cases were positive for c-kit immunostain and negative for SMA and S-100.

**Smooth muscle tumor:** Leiomyoma was found in 2 cases and leiomyosarcoma in 2 cases, respectively. Leiomyosarcoma showed high mitotic count of > 5/10HPF and areas of necrosis. All the tumors were positive for SMA and negative for c-kit.

**Neural tumor:** There was a single case of plexiform neurofibroma positive for S-100 immunostain.

**Lymphoproliferative tumor**

Twelve cases (21.8%) of non-Hodgkin's lymphoma (NHL) were included in this group (Figure 1E). Their age ranged from 7 to 85 years and the male to female ratio was 5:1. All the cases were found to have primary duodenal lymphoma because of the absence of disease in other organs. On immunohistological examination of 12 cases, B-cell phenotype was documented in 10 cases (83.3%) and T-cell phenotype in 2 cases (16.6%). B-cell lymphomas were further categorized as diffuse large cell lymphoma in 8 cases and MALT lymphoma in 2 cases. T-cell duodenal lymphomas were not associated with enteropathy as there was no histologic evidence of villous atrophy.

**Neuroendocrine tumor**

Seven tumors (12.7%) were located in this histologic category. Of the 7 tumors, 5 were benign and labeled as carcinoid based on their characteristic organoid pattern, granular cytoplasm, salt and pepper nuclear chromatin as well as chromogranin positivity (Figure 1F). One case was suggestive of gastrinoma based upon serum gastrin levels and was associated with parathyroid and adrenal hyperplasia. However, confirmation was not possible on histopathological sections because of non-availability of gastrin immunostain. One case was labeled as malignant as it had metastatic tumor deposits in lymph nodes.

**DISCUSSION**

Primary neoplasms of the small intestine constituting 90% of mucosal surface area of the gastrointestinal tract are extremely rare. Duodenum constituting only 4% of the small intestine has a relatively high proportion of all the tumors as compared to the jejunum and ileum. Primary malignant duodenal tumors are uncommon accounting for only 0.3% of all gastrointestinal tumors but about 50% of all small intestinal malignancies<sup>[3]</sup>. Many hypotheses have been proposed for the low incidence of small intestinal tumors as compared to large intestine including greater fluidity of contents in the small intestine which are less irritating as compared to solid contents, rapid transit

**Figure 1** Photomicrograph showing tubulovillous adenoma of the duodenum (A) (HE  $\times$  100), adenocarcinoma arising in tubulovillous adenoma of the duodenum (B) (HE  $\times$  200), Brunner glands separated by fibrovascular septa in Brunner gland adenoma of the duodenum (C) (HE  $\times$  40), spindle cell gastrointestinal stromal tumour in submucosa of the duodenum (D) (HE  $\times$  100), non-Hodgkin's lymphoma showing diffuse monotonous population of large cells infiltrating duodenal glands (E) (HE  $\times$  100), and circumscribed tumour nodule with tumour cells arranged in organoid pattern in carcinoid of the duodenum (F) (HE  $\times$  40).

time through small intestine thus reducing exposure to potential carcinogens, low bacterial population producing carcinogens and high concentration of lymphoid tissue producing IgA immunoglobulins<sup>[4]</sup>. It is often difficult to diagnose early duodenal tumors because of their non-specific and insidious presentation.

Adenomas are the most common duodenal tumors including adenomatous polyps and Brunner adenoma. Adenomatous polyps are more common at gastroduodenal junction and have 3%-5% risk of developing adenocarcinoma in life time<sup>[5]</sup>. Brunner gland adenomas are very rare tumors and less than 150 cases have been reported in the English literature<sup>[6]</sup>. Size of the tumor is important in differentiating adenoma from Brunner gland hyperplasia. The size less than 1 cm is referred to as Brunner gland hyperplasia. Adenocarcinoma of the duodenum not originating from the region of ampulla is an uncommon neoplasm. Since it was first described in 1746 by Hamburgur, approximately 800 cases have been described in the literature. However in these cases there is a mix of ampullary and peri-ampullary carcinomas<sup>[7]</sup>. Because of rarity of these tumors, the exact

etiological factors have not been defined. Patients with familial adenomatous polyposis and Crohn's disease or celiac disease have a higher risk of developing duodenal carcinoma<sup>[8]</sup>. In the present study, there were no such associations. Only one case was arising in the background of adenoma and two cases of tubulovillous adenoma were associated with polyposis coli. Heniford *et al*<sup>[8]</sup> reported that D3-D4 is the most common site of primary duodenal adenocarcinoma. However, in the present study 10/15 adenocarcinomas were seen in D1-D2 region. D3-D4 carcinomas have better prognosis as compared to D1-D2 carcinomas because the former behave like hind gut tumors and the latter as foregut tumors<sup>[9]</sup>.

The relative frequency of duodenal stromal tumors is not known. Only one study has presented a series of 190 duodenal stromal tumors<sup>[10]</sup>. According to their findings, gastrointestinal stromal tumors (GIST), the c-kit positive primary mesenchymal tumor, constitute the largest group of mesenchymal tumors in contrast to smooth muscle tumors i.e. leiomyoma and leiomyosarcoma which are now thought to be rare in the duodenum. In the present series, there were an equal number of GISTs and smooth muscle

tumors. However, the number of cases was too small to comment on the relative frequency of these tumors in duodenum. Neural tumors are extremely rare in duodenum and we encountered only one case of neurofibroma. Subclassification into benign, borderline and malignant stromal tumors based upon size, mitosis, necrosis and metastasis must be made for prognosis<sup>[11,12]</sup>.

Gastrointestinal tract is the most common extranodal site of involvement by non-Hodgkin's lymphoma (NHL). Primary lymphomas of the small intestine are relatively rare and account for 4%-12% of all NHLs and 19%-38% of small bowel malignancies<sup>[13]</sup>. In the present study, duodenal lymphomas accounted for 21.8% all duodenal tumors. Recently reports have emerged about the increasing frequency of primary MALT lymphomas in the small intestine and it is proposed that small intestinal MALTs are of gastric origin due to the probable role of *H pylori*. In this review of duodenal tumors, only two cases were of MALT lymphomas, the remaining were of diffuse large B cell type and T cell lymphomas. It was reported that intestinal T cell lymphomas are more common in small intestine and a term "enteropathy associated T-cell lymphoma" (EATL) has been introduced based upon their existence in coeliac disease<sup>[14]</sup>. However, no such association was seen in our cases. Histopathological examination and exact immunophenotyping of NHLs based on WHO classification are important from the prognosis point of view as T cell lymphomas have poor prognosis as compared to B cell lymphomas. MALT lymphomas in B cell group have a better prognosis.

Duodenal neuroendocrine tumors (NETs) comprise 2%-3% of all gastrointestinal endocrine tumors including gastrinoma, somatostatinoma, nonfunctional NET, and poorly-differentiated NE carcinoma and their frequency is increasing<sup>[15]</sup>. Although the majority of these tumors are nonfunctional, they can cause Zollinger-Ellison syndrome and other clinical hormonal syndromes. Gastrinomas defined as gastrin secreting tumors are associated with Zollinger-Ellison syndrome (ZES) and hereditary gastrinomas, which are associated with endocrine neoplasia type 1 (MEN1) syndrome. In the present study, there was only one case of gastrinoma associated with parathyroid and adrenal hyperplasia.

In conclusion, although non-ampullary/perampullary duodenal adenocarcinomas are rare, they constitute the largest group. Histopathological examination of primary duodenal tumors is important for the correct histological

subtyping of these tumors and collecting prognostic information which influences the management.

### Abstract

**AIM:** To substantiate the claims of Unani and Arabian traditional medicine practitioners on the gastroprotective potential effect of a popular spice anise, "*Pimpinella anisum* L." on experimentally-induced gastric ulceration and secretion in rats.

**METHODS:** Acute gastric ulceration in rats was produced by various noxious chemicals including 80% ethanol, 0.2 mol/L NaOH, 25% NaCl and indomethacin. Anti-secretory studies were undertaken using pylorus-ligated Shay rat technique. Levels of gastric non-protein sulfhydryls (NP-SH) and wall mucus were estimated and gastric tissue was also examined histologically. Anise aqueous suspension was used in two doses (250 and 500 mg/kg body weight) in all experiments.

**RESULTS:** Anise significantly inhibited gastric mucosal damage induced by necrotizing agents and indomethacin. The anti-ulcer effect was further confirmed histologically. In pylorus-ligated Shay rats, anise suspension significantly reduced the basal gastric acid secretion, acidity and completely inhibited the rumenal ulceration. On the other hand, the suspension significantly replenished ethanol-induced depleted levels of gastric mucosal NP-SH and gastric wall mucus concentration.

**CONCLUSION:** Anise aqueous suspension possesses significant cytoprotective and anti-ulcer activities against experimentally-induced gastric lesions. The anti-ulcer effect of anise is possibly prostaglandin-mediated and/or

### INTRODUCTION

Peptic ulcer is one of the most common gastrointestinal diseases. Nowadays proton pump inhibitors and H<sub>2</sub>-receptor antagonists are the most widely used drugs to treat peptic ulcer disease. However, the use of these anti-secretory drugs may be associated with adverse events and ulcer relapse<sup>[1]</sup>. Thus, there is a need for more effective, less toxic and cost-effective anti-ulcer agents. In recent years, a widespread search has been launched to identify new anti-ulcer drugs from natural sources. Spices comprising the most important products used for flavouring foods and medicinal herbs are considered nowadays as potential bioactive agents that can interfere positively or negatively with different cellular processes. They are extensively used in medicine, pharmaceuticals, perfumery and cosmetics. Additionally they possess antioxidant, antispasmodic, carminative, anti-inflammatory and other properties<sup>[2]</sup>. A number of spices, namely large cardamom<sup>[3]</sup>, black pepper<sup>[4]</sup>, caraway<sup>[5]</sup>, cardamom<sup>[6]</sup>, clove<sup>[7]</sup>, coriander<sup>[8]</sup>, ginger<sup>[9]</sup>, peppermint<sup>[10]</sup>, saffron<sup>[11]</sup>, turmeric<sup>[12]</sup> among others have been shown to possess significant gastroprotective activities. The fruits of anise plant, *pimpinella anisum* L. are locally known as aniseed and yansoon. The powder and concoction of anise in hot water are used as carminatives, antiseptics, diuretics, digestives, aphrodisiacs, and as a remedy for insomnia and constipation<sup>[13]</sup>. Furthermore, anise is used to promote digestion, improve appetite, alleviate cramps and nausea, and relieve flatulence and colic. In Unani and Arabian traditional medicine, anise fruit and its oil have been used for the treatment of various conditions including dyspepsia, nausea, abdominal colic,

seizures and epilepsy<sup>[14]</sup>. The phytotherapeutic applications of anise are based on its digestive, carminative, diuretic and expectorating action<sup>[15]</sup>. It has been recently reported that the essential oil of anise is highly effective as both larvicidal and ovicidal agents<sup>[16]</sup>. The principal constituents of anise are volatile oil, coumarins, fatty acids, flavonoid glycosides, proteins and carbohydrates. Among others, anise oil contains anethole and caryophyllene<sup>[17]</sup>. Since we have not come across a scientific report on potential gastroprotective claims of anise aqueous suspension, the present study was carried out to assess its effect on chemically induced gastric ulcers in rats.

## MATERIALS AND METHODS

### **Plant material and preparation of aqueous suspension**

Seeds of anise "*Pimpinella anisum* L" (family, Apiaceae) were purchased from local herb shops in Riyadh and identified by an expert taxonomist. The sample was preserved (voucher # Sp.Pr.17-16-37) at the herbarium of Department of Pharmacognosy, College of Pharmacy, King Saud University, Riyadh, for future reference. The seeds were ground to very fine powders (75 micron), and used as an aqueous suspension for treatment in different experiments.

### **Animals**

Wistar albino rats of either sex, approximately at the same age, weighing 150-200 g were obtained from Animal Care Center, College of Pharmacy, King Saud University, and maintained under standard conditions of temperature, humidity and light (12 h dark, 12 h light) with free access to Purina chow and water. Before testing, the animals were fasted for 36 h with access to water *ad libitum*. The conduct of experiments and the procedure of sacrifice (using ether) were approved by the Ethics Committee of the Experimental Animal Care Society, College of Pharmacy, King Saud University, Riyadh, Saudi Arabia.

### **Dose selection and route of administration**

The doses (250 and 500 mg/kg, body weight) selected for the experiments were based on the maximum tolerable dose value (MTD) (30 g/kg, body weight) and the preliminary experiments conducted on the pharmacological activity of anise. The aqueous suspension was administered intragastrically (i.g.) through gastric intubation in all experiments, unless stated otherwise intraperitoneally (i.p.) in anti-secretory studies.

### **Gastric lesions induced by necrotizing agents**

The rats were administered ig 1 mL of different necrotizing agents (80% ethanol, 0.2 mol/L NaOH and 25% NaCl)<sup>[18]</sup>. Anise suspension was given 30 min before the administration of necrotizing agents. One hour after the administration of ethanol and alkalis, the rats were sacrificed and examined for lesions in the stomach. The scoring of lesions, assays of gastric wall mucus and sulfhydryls as well as histological changes in the stomach were observed as follows. The patchy lesions of stomach induced by ethanol were scored according to the method

described by Schiantarelli *et al*<sup>[19]</sup> using the following scale: 0 = normal mucosa, 1 = hyperemic mucosa or up to 3 small patches, 2 = 4 to 10 small patches, 3 = more than 10 small or up to 3 medium-sized patches, 4 = 4 to 6 medium-sized patches, 5 = more than 6 medium-sized or up to 3 large patches, 6 = 4 to 6 large patches, 7 = 7 to 10 large patches, 8 = more than 10 large patches or extensive necrotic zones. "Small" was defined as up to 2 mm across (max. diameter), "medium-sized" between 2 and 4 mm across and "large" more than 4 mm across.

### **Histopathological evaluation**

Gastric tissue samples were fixed in neutral buffered formalin for 24 h. Sections of gastric tissue were histopathologically examined to study the ulcerogenic and/or anti-ulcerogenic activity of anise. The tissues were fixed in 10% buffered formalin and processed using a VIP tissue processor. The processed tissues were embedded in paraffin blocks and sections of about 5 µm thickness were cut by employing an American optical rotary microtome. These sections were stained with haematoxylin and eosin using routine procedures<sup>[20]</sup>. The slides were examined microscopically for pathomorphological changes such as congestion, hemorrhage, edema and erosions using an arbitrary scale for severity assessment of these changes.

### **Gastric lesions induced by indomethacin**

Indomethacin was suspended in 1.0% carboxymethylcellulose (CMC) in water (6 mg/mL) and administered orally to the rats fasted for 36 h at a dose of 30 mg/kg, body weight. Control rats were treated similarly with an equivalent amount of the vehicle<sup>[21]</sup>. The animals were sacrificed 6 h after the treatment. Stomachs of the animals were excised off the body, rinsed with normal saline and studied accordingly<sup>[22]</sup>.

### **Estimation of non-protein sulfhydryls**

Gastric mucosal non-protein sulfhydryls (NP-SH) were measured according to the method of Sedlak and Lindsay<sup>[23]</sup>. The glandular part of the stomach was homogenized in ice-cold 0.02 mmol/L ethylenediaminetetraacetic acid (EDTA). Aliquots of 5 mL of the homogenates were mixed in 15 mL test tubes with 4 mL of distilled water and 1 mL of 50% trichloroacetic acid (TCA). The tubes were shaken intermittently for 10 min and centrifuged at 3000 g. Two milliliters of supernatant was mixed with 4 mL of 0.4 mol/L Tris buffer at pH 8.9, 0.1 mL of 5, 5'-dithio-bis- (2-nitrobenzoic acid) (DTNB) was added and the sample was shaken. The absorbance was measured within 5 min after addition of DTNB at 412 nm against a reagent blank.

### **Pylorus-ligated rats (anti-secretory studies)**

The rats were fasted for 36 h with access to water *ad libitum* before the pylorus was ligated under ether anesthesia and care was taken to avoid bleeding and occlusion of blood vessels<sup>[24]</sup>. Anise suspension was administered immediately after pylorus ligation (Shay) by ip route. The rats were sacrificed at 6 h after the pylorus ligation. The stomachs were removed, with the contents collected, volumes measured, centrifuged and analyzed for titratable acidity

against 0.01 mol/L NaOH (pH 7) and the titratable acidity was calculated.

### Determination of gastric wall mucus

Gastric wall mucus was determined according to the modified procedure of Corne *et al*<sup>[25]</sup>. The glandular segment of the stomach was separated from the rumen of the stomach, weighed, and transferred immediately to 10 mL of 0.1% w/v Alcian blue solution (in 0.16 mmol/L sucrose solution buffered with 0.05 mL sodium acetate at pH 5). Tissue was stained for 2 h in Alcian blue, and excess dye was removed by two successive rinses with 10 mL of 0.25 mmol/L sucrose, first for 15 min and then for 45 min. Dye complexed with the gastric wall mucus was extracted with 10 mL of 0.5 mmol/L magnesium chloride which was intermittently shaken for 1 min at 30 min intervals for 2 h. Four milliliters of blue extract was then vigorously shaken with an equal volume of diethyl ether. The resulting emulsion was centrifuged at 4000 r/min for 10 min and the absorbance of aqueous layer was recorded at 580 nm. The quantity of Alcian blue extracted from per gram of wet glandular tissue was then calculated.

### Statistical analysis

The readings shown are means  $\pm$  SD. The mean determination of treatment groups was compared statistically with that of control group using *t*.

## RESULTS

### Effect of anise suspension on gastric lesions induced by necrotizing agents

The treatments of rats with 80% ethanol, 0.2mol/L

NaOH and 25% NaCl produced extensive gastric lesions mainly confined to glandular part of the stomach in all the control (only necrotizing agents treated) animals. The ulcer index in ethanol, sodium hydroxide and sodium chloride treatment groups was 7.16  $\pm$  0.40, 8.00  $\pm$  0.0 and 7.66  $\pm$  0.33, respectively. Pretreatment of rats with anise suspension at the dose of 250 mg/kg significantly prevented gastric mucosal lesions induced by all necrotizing agents used. The ulcer index was 6.00  $\pm$  0.51 ( $P < 0.01$ ), 4.66  $\pm$  0.80 ( $P < 0.001$ ), 6.00  $\pm$  0.44 ( $P < 0.001$ ), respectively. In stomach of rats treated with 500 mg/kg of anise suspension, the ulcer index was 4.00  $\pm$  0.44 ( $P < 0.001$ ), 3.66  $\pm$  0.66 ( $P < 0.001$ ) and 4.00  $\pm$  0.51 ( $P < 0.001$ ) in ethanol, sodium hydroxide and sodium chloride groups respectively (Table 1).

### Effect of anise suspension on histopathological changes

Histological examination of gastric mucosa showed various histopathological changes including congestion, haemorrhage, edema, necrosis, inflammatory and dysplastic changes, erosions and ulcers in ethanol-treated rats. The histological indices such as necrosis, inflammatory and dysplastic changes and ulceration were completely inhibited in rats pretreated with both doses of anise suspension (Table 2).

### Effect of anise suspension on gastric lesions induced by indomethacin

To study the anti-ulcerogenic effects of anise suspension on indomethacin-induced gastric lesions in rats, two doses of anise were used (250 and 500 mg/kg). Data on ulcer index in rats pretreated with both doses are reported in Table 3. The increased ulcer index in the gastric mucosa of

Six rats were used in each group. <sup>b</sup>*P* < 0.01, <sup>d</sup>*P* < 0.001 *vs* control (distilled water) group.**Table 6** Effect of aqueous anise suspension on ethanol-induced gastric wall mucus concentration changes (mean  $\pm$  SD)

Group serial	Treatment	Dosage (mg/kg, i.g.)	Gastric wall mucus ( $\mu$ g Alcian blue of wet glandular tissue)
1	Control (distilled water)	-	474.98 $\pm$ 13.86
2	80% ethanol only	-	307.92 $\pm$ 10.69 <sup>d</sup>
3	<i>Pimpinella anisum</i> 80% ethanol	250	372.75 $\pm$ 20.87 <sup>a</sup>
4	<i>Pimpinella anisum</i> 80% ethanol	500	391.60 $\pm$ 20.19 <sup>b</sup>

<sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 *vs* 80% ethanol group only; <sup>d</sup>*P* < 0.001 *vs* control (distilled water) group.

indomethacin-treated rats (control) decreased significantly in animals treated with lower and higher anise doses (32.16  $\pm$  5.22 *vs* 9.66  $\pm$  1.96 and 6.00  $\pm$  2.68, *P* < 0.001), respectively.

#### Effect of anise suspension on ethanol-induced mucosal NP-SH depletion

The level of NP-SH in the gastric mucosa of control rats was 11.70  $\pm$  0.86 mmol/g of tissue, significantly decreased to 6.31  $\pm$  0.23 mmol/g following the administration of ethanol. Pretreatment of rats with anise suspension at a higher dose (500 mg/kg) significantly replenished the ethanol-induced depletion of NP-SH (*P* < 0.05, Table 4).

#### Effect of anise suspension on gastric secretion in pylorus-ligated rats

In control rats, pylorus ligation for 6 h resulted in an accumulation of 7.83  $\pm$  0.38 mL of gastric secretions,

titrateable acidity 127.21  $\pm$  2.64 in mEq/L and an ulcer index 0.66  $\pm$  0.33 (Table 5). The volume of gastric secretion in the rats treated with 250 and 500 mg/kg of anise suspension significantly reduced to 3.00  $\pm$  0.51 and 0.33  $\pm$  0.33 mL, respectively (*P* < 0.001). A significant decrease in titrateable acid was also observed in the rats treated with 250 mg/kg (109.33  $\pm$  4.64 mEq/L) and 500 mg/kg (108.33  $\pm$  5.00 mEq/L) (*P* < 0.001). A complete inhibition of rumenal ulcers was noted in both groups of rats treated with anise suspension as compared to control group (Table 5).

#### Effect of anise suspension on ethanol-induced changes in gastric wall mucus

The treatment of rats with ethanol significantly decreased the Alcian blue binding capacity of gastric wall mucus (307.92  $\pm$  10.69  $\mu$ g Alcian blue/g of tissue) as compared to control rats (474.98  $\pm$  13.86  $\mu$ g/g). Pretreatment of rats with anise suspension at 250 mg/kg (372.75  $\pm$  20.87  $\mu$ g/g) and 500 mg/kg (391.60  $\pm$  20.19  $\mu$ g/g) significantly enhanced Alcian blue binding capacity of gastric mucosa (*P* < 0.05, *P* < 0.01), respectively (Table 6).

## DISCUSSION

Anise spice is added to foods in several forms as whole spice, as ground spice or as isolates from its extracts and volatile oils<sup>[26]</sup>. We adopted the suspension dosage form in our experiments. In necrotizing agents-induced gastric ulcers, the lesions were characterized by multiple haemorrhage red bands of different sizes along the longitudinal axis of the glandular stomach. This model is extensively used to screen drugs for cytoprotection<sup>[27]</sup>. This study provided a substantial evidence for anti-ulcer and

anti-secretory effects of an aqueous suspension of anise. Anise suspension significantly inhibited the ulcerative lesions in all animals treated with necrotizing agents, which was further confirmed by histological findings in which necrosis, inflammatory, dysplastic changes and ulcers were abolished in rats pretreated with anise suspension. The ability of gastric mucosa to resist injury by endogenous secretions (acid, pepsin and bile) and ingested irritants (e.g., alcohol), can be attributed to a number of factors that have been referred to collectively as mucosal defense<sup>[28]</sup>. Gastric mucosal lesions induced by necrotizing agents such as ethanol and strong alkalis are due to depression of the gastric defensive mechanisms<sup>[29]</sup>. Although ethanol-induced ulcers are not inhibited by anti-secretory agents such as cimetidine, they are inhibited by agents that enhance mucosal defensive factors such as prostoglandins<sup>[30]</sup>. The current results suggest that the anti-ulcerogenic effect of anise suspension may be related to its cytoprotective activity.

Gastroduodenal ulceration is a major limitation to the use of non-steroidal anti-inflammatory drugs (NSAIDs)<sup>[31]</sup>. NSAIDs can cause damage to the gastroduodenal mucosa via several mechanisms, including their topical irritant effect on the epithelium, impairment of the mucosal barrier function, suppression of gastric prostaglandin synthesis, reduction of gastric mucosal blood flow and interference with the repair of superficial injury. The presence of acid in the lumen of stomach also contributes to the pathogenesis of NSAIDs-induced ulcers and bleeding by impairing the restitution process, interfering with haemostasis and inactivating several growth factors that are important in mucosal defence and repair<sup>[32,33]</sup>. In the present study, indomethacin-induced gastric lesions were extensively prevented by anise suspension.

Sulphydryl compounds have been significantly implicated in the maintenance of gastric integrity, particularly when reactive oxygen species are involved in the pathophysiology of tissue damage<sup>[34]</sup>. Since anise suspension significantly enhances gastric tissue NP-SH concentration, it is conceivable that it is endowed with antioxidant properties accounting for its gastroprotective action. Hence, it may be presumed that the replenishing potential of sulphydryl levels might play an important role in the gastroprotective activity of anise suspension-treated rats. Furthermore, the ability of anise suspension to protect against ulcers in NSAID-induced gastric damage may be due to the enhanced synthesis of mucus, bicarbonates and prostaglandins, as well as reduced acid output. Consequently these activities can promote the inhibition of basal gastric acid secretion as observed in our pylorus-ligated shay rat model<sup>[35,36]</sup>. On the other hand, it is also important to note that NSAIDs can increase gastric acid secretion, through prostaglandin inhibitory effects on parietal cells<sup>[37,38]</sup>. In the present study, anise aqueous suspension treatment significantly reduced basal gastric acid volume, titratable acidity and completely inhibited ulcer formation in rats. However, to date it is still controversial about relationship between the acid output and the genesis of acute gastric mucosal lesions (AGML). Our results support this correlation as anise

suspension significantly reduced basal gastric secretion and prevented the occurrence of AGML in pylorus-ligated rats and thus, supporting the hypothesis of "no acid no ulcer"<sup>[39]</sup>. It has been postulated that histamine may be involved in the formation of pylorus-ligated ulcers and play a mediating role in the gastric secretion stimulated by gastrin, vagal stimulation, and cholinergic agents<sup>[40]</sup>. The correlation between gastric mucus and acid secretions in our experiments, clearly demonstrated that the gastric protective activity observed may be associated with correction or normalization of the altered balance between erosive action of acid and gastric mucosal defence. Gastric wall mucus is thought to play an important role as a defensive factor against gastric mucosal damage<sup>[41]</sup>. The determined gastric wall mucus is used as an indicator for gastric wall mucus secretion<sup>[42]</sup>. In the present investigation, anise suspension caused a significant enhancement of ethanol-induced gastric wall mucus depletion in rats, which further confirms the ability of anise to prevent and/or ameliorate the effects of damaging agents. These findings indicate that anise suspension preserves gastric mucus secretion and strengthens gastric mucosa defense factors in experimental rats<sup>[43,44]</sup>.

The chemical constituents of anise responsible for its anti-ulcer activity are not known. However, chemical studies demonstrated that anise contains estrarole<sup>[45]</sup>, anethol<sup>[46]</sup>, eugenol<sup>[47]</sup>, anisaldehyde, methylchaniol<sup>[48]</sup>, coumarins<sup>[49]</sup> and terpenes<sup>[50]</sup> among others as the major compounds. Anise and its compounds have been identified as free radicals or active oxygen scavengers<sup>[51]</sup>. In addition, the ability of anise suspension to protect gastric mucosa against lesions induced by chemical irritants is likely by maintaining the structural integrity of gastric epithelium and balance of aggressive factors and inherent protective mechanisms<sup>[52]</sup>. Furthermore, the mucus gel and its bicarbonate gradient seem to be an important first-line defense against harmful stimuli<sup>[53]</sup>.

In conclusion, anise suspension exhibits an anti-ulcer potential activity through at least one or more possible mechanisms including inhibition of basal gastric secretion, stimulation of mucus secretion, endogenous gastric mucosal prostaglandin synthesis and possible antioxidative activity.

### Abstract

**AIM:** To study whether *H. pylori* are associated with chronic cholecystitis.

**METHODS:** The subjects were divided into three groups: *H. pylori*-infected cholecystitis group, *H. pylori*-negative cholecystitis group and control group. Pathologic changes of the gallbladder were observed by optic and electronic microscopes and the levels of interleukin-1, 6 and 8 (IL-1, 6 and 8) were detected by radioimmunoassay.

**RESULTS:** Histological evidence of chronic cholecystitis including degeneration, necrosis, inflammatory cell infiltration, were found in the region where *H. pylori* colonized. Levels of IL-1, 6 and 8 in gallbladder mucosa homogenates were significantly higher in *H. pylori*-infected cholecystitis group than those in *H. pylori*-negative cholecystitis group and control group.

**CONCLUSION:** *H. pylori* infection may be related to cholecystitis.

### INTRODUCTION

*H. pylori* have definite pathogenic action and related to

gastritis, peptic ulcer and gastric carcinoma<sup>[1-3]</sup>. Previous studies have demonstrated that *H. pylori* correlate with diseases of the extra-gastrointestine, the liver and the cholecyst<sup>[4-8]</sup>. We have isolated *H. pylori* from the gallbladder and cultured *H. pylori*, and preliminarily proved that there exist live *H. pylori* in the gallbladder. In the present study, we carried out electron microscopic observation and immunohistochemistry to the relationship between *H. pylori* and chronic cholecystitis.

### MATERIALS AND METHODS

#### Subjects

A total of 81 cases with chronic cholecystitis were divided into *H. pylori*-negative group ( $n = 59$ ) and *H. pylori*-infected group ( $n = 22$ ), based on previous studies, PCR amplification and culture results for *H. pylori*. Besides, a control group was used including another 20 cases who were proved to have no obvious inflammation in the gallbladder mucosa except polyps or *H. pylori* infection after a cholecystectomy due to a gallbladder polyp.

#### Investigation of gastric mucosa metaplasia of epithelial cells of gallbladder mucosa

By histochemical staining of AB/PAS mucus, and based on histology of mucosal epithelial cells and characteristics of cells secreting mucus, an observation was made on gastric mucosa metaplasia of epithelial cells of gallbladder mucosa and colonization of *H. pylori* in the epithelial cells of gallbladder mucosa. The relationship between *H. pylori* and the epithelial cells of the gallbladder was observed by optic microscopy, W-S silver stain and immunohistochemical stain using anti-*H. pylori* antibodies. The resected gallbladder specimens from cases with chronic cholecystitis were immobilized with 3% glutaral, embedded and sliced for transmission electron microscopic investigation.

#### Relationship between *H. pylori* and cholecystitis

Inflammatory changes of epithelial cells of the gallbladder mucosa in regions where *H. pylori* colonized were observed by optic microscopy and ultrastructural changes of epithelial cells of the gallbladder were observed by electron microscopy.

#### Assay of interleukins in homogenates of gallbladder mucosa

The radio-immune analytical reagent kits including IL-1, IL-6 and IL-8 were purchased from Dongya Research Institute of Biotechnology, Beijing. About 1 g of resected

**Figure 1** Specimens of chronic cholecystitis. Many positive PAS materials appear in epithelial cells of gallbladder mucosa (PAS × 200).

Negative <i>H pylori</i>	59	7	52

gallbladder mucosa was added into ultrapure water (Center of Molecular Biology, Research Institute of Surgery, Daping Hospital, Third Military Medical University, Chongqing) and homogenized in an IS-1 homogenizer (Medical Machine Factory, Zhejiang) and the homogenates were centrifuged at 4000 r/min for 15 min, after which the supernatants were collected and frozen at -70°C. The EC-1200 radio-immune auto-γ counting device (Zhongjia Corporation of China Academy of Sciences) was employed for radio-immune assay and a fully automatic biochemical assay device of Beckman Synchron CX (USA) was used for quantification of proteins of gallbladder mucosa homogenates.

### Statistical analysis

Data were expressed as mean ± SD and processed with Chi-square test and Student's t-test.  $P < 0.05$  was considered significant.

## RESULTS

### Metaplasia of gastric mucosa in gallbladder

In cases with a gallbladder polyp, no mucus stained positive for PAS was found in gallbladder mucosa in the region beyond the polyp, nor was positive substance of PAS, i.e., metaplasia of gastric mucosa, found in epithelial cells of mucosa. In cases with chronic lithic cholecystitis, the epithelium of gallbladder mucosa was column-like. AB/PAS stain showed that neutral mucus was positive, with metaplasia of epithelial cells of gastric mucosa (Figure 1).

Gastric metaplasia of gallbladder mucosa appeared in

25 cases, accounting for 30.86% (25/81) of all cases with chronic cholecystitis, however, it was not found in the control group (Table 1). This suggested that gallbladder mucosa was apt to gastric metaplasia in cases with chronic lithiasis cholecystitis, especially in those with *H pylori* infection in the gallbladder, of gastric metaplasia of gallbladder mucosa (18/22, 81.82%) was significantly higher than that in cases with negative *H pylori* (7/59, 11.86%,  $P < 0.01$ ). It indicated that gastric metaplasia of gallbladder mucosa might relate to *H pylori* infection in the gallbladder.

### Colonization of *H pylori* in gallbladder and its relation to cholecystitis

The optic microscopy showed that *H pylori* were scattered or aggregated on, or located within certain distance from the epithelial cells of gallbladder mucosa and that individual *H pylori* distributed inside epithelial cells or existed in intercellular space. At the regions with *H pylori*, column-like cells secreted neutral mucus by AB/PAS stain, indicating that the gallbladder mucosa had gastric metaplasia and that gastric mucosa were absent in some regions where *H pylori* located. Electron microscopy showed that *H pylori* were located on, stuck to, or entered the epithelial cells of gallbladder mucosa, where, however, no tight junction or adhesiveness could be seen. Moreover, optic microscopy revealed degeneration of the epithelial cells of gallbladder mucosa, infiltration and exudation of inflammatory cells, exfoliation of the epithelial cells, or chronic inflammation such as mucous layer shrinkage, decrease or even disappearance of epithelial cells and glands at sites where *H pylori* were present. Sometimes, there could be seen that inflammatory cells aggregated around *H pylori* and the latter were swallowed (Figure 2). On the other hand, only a few inflammatory cells infiltrated the mucosa, with intact epithelial cells, in most cases with chronic cholecystitis without *H pylori* infection. Exceptionally, even in these cases, there emerged acute inflammatory manifestations including infiltration of large numbers of inflammatory cells, degeneration, apoptosis and exudation of epithelial cells or chronic inflammatory manifestations including atrophy of glands. In the gallbladder epithelial cells that were proved to have

**Figure 3** Electron microscopic images of *H pylori* on the epithelial cells of gallbladder ( $\times 6000$ ).

*H pylori* infection by electron microscopy, changes such as destructed epithelial cell membranes, loose cellular connection, dilatation of mitochondria, decrease or disappearance of crest, and dilatation of endoplasmic reticulum could be seen, which were severer compared with those without *H pylori* infection (Figure 3). The levels of IL-1, IL-6 and IL-8 of gallbladder mucosa homogenates were expressed as ng/g protein, and are shown in Table 2.

In cases with chronic cholecystitis, the levels of IL-1, IL-6 and IL-8 in gallbladders in both negative *H pylori* group and positive *H pylori* group were significantly higher than those in control group ( $P < 0.01$ ). Moreover, there was a significant difference between positive *H pylori* group and negative *H pylori* group in levels of IL-1, IL-6 and IL-8 in the gallbladder ( $P < 0.01$ ).

## DISCUSSION

The gallbladder and stomach are originated from endoblasts and have similar tissue structures, with the mucosa covered with a slime layer<sup>[9-11]</sup>. AB/PAS stain showed that the epithelial cells of gallbladder mucosa secreted neutral mucus, with gastric metaplasia, in about 31% (25/81) of cases with cholecystolithiasis. Caselli *et al*<sup>[12-14]</sup> also demonstrated that the epithelial cells of gallbladder mucosa had gastric metaplasia in cases with cholecystolithiasis. Roa *et al*<sup>[15,16]</sup> found that pepsinogen I, II were expressed in the epithelial cells of the gallbladder. The significance of gastric metaplasia of gallbladder mucosa lies in that the gastric metaplasia provides conditions for *H pylori* colonization in the gallbladder. The results of our study showed that compared with cases without *H pylori* infection in the gallbladder, there was a significantly higher incidence rate of gastric metaplasia in epithelial cells of gallbladder mucosa in cases with *H pylori* infection. It also proved that the gastric metaplasia of gallbladder mucosa closely correlated with *H pylori* infection in the gallbladder. Nevertheless, there were cases with *H pylori* infection but without gastric metaplasia in the gallbladder; meanwhile, there were cases with gastric metaplasia but without *H pylori* infection. These findings indicate that there is no absolute causality between gastric metaplasia and *H pylori* infection in the

Positive <i>H pylori</i>	22	142.68 $\pm$ 25.41 <sup>b,d</sup>	241.50 $\pm$ 80.60 <sup>b,d</sup>	593.18 $\pm$ 93.59 <sup>b,d</sup>

<sup>b</sup> $P < 0.01$  vs control group; <sup>d</sup> $P < 0.01$  vs negative *H pylori* group.

gallbladder. We hypothesize that many epithelial cells of the gastrointestinal tract have receptors for *H pylori* colonization factors. Therefore, *H pylori* can colonize on the epithelial cells of the gallbladder mucosa with no gastric metaplasia<sup>[17]</sup>.

We also found that *H pylori* were separated from or adhered to the epithelial cells of gallbladder mucosa and that some *H pylori* penetrated through epithelial cells of the gallbladder. It that *H pylori* had a weak ability to pass through cells. At sites where *H pylori* aggregated, the epithelial cells of gallbladder mucosa were degenerated, erosive and even apoptotic. In some parts, inflammatory cells infiltrated, which became more obvious with increases in the number of *H pylori*. Electron microscopy revealed that at sites infected with *H pylori*, the integrity of the cell membrane of epithelial cells was destructed, with swelling of mitochondria and dilatation of endoplasmic reticulum. It showed that colonization of *H pylori* in the gallbladder cause inflammation of the gallbladder, mainly chronic nonsuppurative inflammation, which in turn provides an important condition for *H pylori* as one of the etiological factors leading to cholecystitis. Damage of the epithelial cells of gallbladder mucosa caused by *H pylori* may relate to specific virulence factors of *H pylori* such as cytotoxin-associated protein (CagA) and vacuoles toxin (VacA), as well as urease, lipopolysaccharides and mucus enzyme of *H pylori*<sup>[18]</sup>.

*H pylori* can also damage the epithelial cells of gallbladder mucosa through mediating inflammation and immunoreaction. The levels of IL-1, IL-6 and IL-8 in gallbladder mucosa homogenates in both *H pylori* negative and positive groups were significantly higher than those in control group ( $P < 0.01$ ). It indicates that chronic lithic cholecystitis is associated with these three cytokines. We also found that in cholecystitis specimens with or without *H pylori* infection, levels of IL-1, IL-6 and IL-8 were significantly higher than those in control group, indicating that these interleukins may participate in pathogenesis of chronic cholecystitis. This may accord with the function of IL in *H pylori*-related gastritis and gastric ulcer<sup>[19,20]</sup>. After infection with *H pylori*, the urease, lipase and heat shock proteins secreted by *H pylori* can activate regional epithelial cells of mucosa and vascular endothelial cells expressing IL-1, IL-6 and other cytokines such as ICAM-I, hence stimulating and chemotaxy intravascular lymphocytes and monocytes to shift to *H pylori*-infected sites. IL-6 can activate and induce differentiation of T cells through other cytokines and enhance the function of

monocytes and NK cells, resulting in inflammation and injury at sites infected with *H pylori*. Our study verified that CagA of *H pylori* exerted strong action in stimulating epithelial cells and other cells expressing IL-8, which can activate and chemotactic neutrophils and lymphocytes<sup>[21]</sup>. In cases with chronic cholecystitis infected with *H pylori*, levels of IL-1, IL-6 and IL-8 of gallbladder mucosa were significantly higher than those in cases without *H pylori* infection. It suggests that *H pylori* participate in and aggravate cholecystitis, destruction of epithelial cells of the gallbladder and atrophy of the gallbladder<sup>[22]</sup>. Taken together, our study indicates that *H pylori* infection in the gallbladder may be one of the etiological factors leading to cholecystitis. The precise mechanism requires further verifications.

### Abstract

**AIM:** To study the effect of early intrajejunal nutrition on enzyme-protein synthesis and secretion during acute pancreatitis.

**METHODS:** Fifteen dogs were randomly divided into parenteral nutrition ( $n = 7$ ) and early intrajejunal nutrition groups ( $n = 8$ ). An acute pancreatitis model was induced by injecting 5% sodium taurocholate and trypsin into the pancreas via the pancreatic duct. Intrajejunal nutrition was delivered with a catheter via a jejunostomy tube after the model was established for 24 h. On d 1 and 7 and at the beginning of nutritional support, radioactive tracing and electron microscopes were used to evaluate the enzyme-protein synthesis in acinar cells, the subcellular fractionation and the change in zymogen granules after  $1.85 \times 10^6$  Bq L<sup>-3</sup>H phenylalanine was infused at 30, 60, 120, and 180 min.

**RESULTS:** The <sup>3</sup>H radioactivity in pancreatic acinar cells reached its peak level at 60 min, and the contents in the early intrajejunal nutrition group were higher than those in the parenteral nutrition group, which were then decreased. The mean number and area of zymogen granules did not show any significant statistical difference in both groups on d 1 or on d 7 ( $P > 0.05$ ).

**CONCLUSION:** Early intrajejunal nutrition might be effective in dogs with acute pancreatitis.

### INTRODUCTION

Beneficial effects of total enteral nutrition (TEN) have been noted in a number of diseases, such as burn, trauma, and sepsis. In comparison with parenteral nutrition (PN), TEN can reduce nosocomial infection, multiple organ failure (MOF), and the length of hospitalization<sup>[1-4]</sup>. Early enteral nutritional (EEN) support in patients with acute pancreatitis (AP) has been evaluated by some authors who reported that it can moderate the acute phase response and improve disease severity and clinical outcome<sup>[5-10]</sup>. However, the commonly encountered problems of gastric atony and outlet obstruction have limited the successful delivery of enteral nutrition to patients with severe acute pancreatitis. In addition, many surgeons believe that EEN may lead to recurrence of symptoms and delayed complications, because EEN may increase the release of digestive enzymes and lysosomal hydrolases. This action of digestive enzymes and lysosomal hydrolases may be important in the development of acute pancreatitis, as lysosomal enzymes such as cathepsin B, are known to be capable of activating trypsinogen and intracellular digestive enzymes that may trigger the autodigestive phenomenon of the pancreas<sup>[11]</sup>. However, these problems may be overcome if enteral nutrition is delivered to the jejunum as distal as possible from Treitz's ligament, thereby avoiding stimulation of the cephalic and gastric phase. Therefore, it is necessary to investigate the effect of early intrajejunal nutrition (EIN) on pancreatic acinar cell uptake of <sup>3</sup>H phenylalanine, digestive enzyme synthesis, storage and discharge in dogs with AP.

### MATERIALS AND METHODS

#### Materials

<sup>3</sup>H phenylalanine (5mCi/mL) was obtained from Amersham. CBZ-arginine-naphthalamide, thymus DNA

and RNA-naphthalamide, cytochrome c, 3- (N-morpholino) propanesulfonic acid (MOPS), phenylmethyl- sulfonyl fluoride (PMSF), and Triton X-100 were from Sigma Chemical. All other commercially available reagents were of the highest purity.

### Animal model

Twenty-two dogs weighing 18-22 kg had free access to water. After fasting for 12-14 h, all dogs were anesthetized by intramuscular injection of ketamine (10 mL/kg) and intravenous injection of sodium pentobarbital (30 mg/kg). Under sterile conditions, middle laparotomy and duodenotomy were performed. An AP model was induced by injecting 1mg/kg of a combined solution of 5% sodium taurocholate and trypsin 8000-10000 BAEF units/mL into the pancreatic duct at a pressure of 30 cm H<sub>2</sub>O. The common biliary duct was clamped. A catheter was placed at 30 cm distal to Treitz's ligament *via* jejunostomy. After the AP model was established, the duodenum and abdomen were closed. The neck regions of dogs were shaved and prepared in a sterile manner for catheterization. A silastic catheter (1.0 mm in inner diameter, 1.5 mm in outer diameter) was inserted through the external jugular vein to reach the superior vena cava and connected to the infusion solution. Fifteen dogs with AP survived after 7 d, and the death rate was 32% (7/22). The study was approved by our Institutional Animal Committee.

### Experimental groups and nutritional solution preparation

Fifteen dogs with AP were randomly divided into PN group ( $n = 7$ ) and EIN group ( $n = 8$ ). The two groups were isocaloric and isonitrogenous. PN solutions consisted of 7% Vamin (SSPC, 9.4 g/1000 mL), 20% intralipid (SSPC), and 50% glucose (GS). Non-protein calorie was 50 kC (209.2 kJ/kg) and nitrogen was 0.3 g/kg.d. The total volume of solution infused was 70 mL/kg.d. The energy index supported with glucose and fat emulsion was 1:1. Multivitamins and electrolytes were also included in TPN solutions. The 0.9% saline solution was infused at 250 mL/kg during operation and postoperatively for 8 h, thereafter at 125 mL/kg. The nutrient solution was infused at a constant infusion rate by a pump (100-120 mL/h).

The EIN solution was Nutrison (Nutricia). The jejunum was infused through a jejunostomy catheter with 250 mL Nutrison and 500 mL 0.9% saline at 24 h after AP was induced, 500 mL Nutrison and 250mL 0.9% saline were infused after 48 h and continued for 7 d. The infusion rate was controlled by microcomputer-pump (Nutricia). During the EIN support period, the insufficient amount of calorie and nitrogen was supplemented by partial parenteral nutrition<sup>[4]</sup> (Table 1).

### Amino acid uptake

Dogs with AP were infused with radioactive <sup>3</sup>H phenylalanine ( $1.85 \times 10^6$  Bq) at beginning of PN or EIN on d 1 and 7, respectively. The abdomen was opened twice and partial pancreas was rapidly removed at 30, 60, 120 and 180 min after <sup>3</sup>H phenylalanine pulse infusion. After rinsed with a cold homogenization buffer containing 5 mmol/L MOPS (pH 7.0), 250 mmol/L sucrose,

Table 1 Calories, nitrogen and liquid supplemented between two groups

Group	20% Intralipid (mL/kcal)	50% glucose (mL/kcal)	Vamin (9.4g/L) (mL/g)	0.9% saline (mL)	Nutrison (1 kal/mL)
PN group (1-7 d)	227/500	500/500	640/6.0	2500	0
EIN group (1 d)	170/375	187.5/375	468/4.4	1750	250 mL (1.6 g) + NS500 mL
EIN group (2-7 d)	113.6/250	125/250	298/2.8	1750	500 mL (3.2 g) + NS 250 mL

NS: natural saline.

1 mmol/L MgSO<sub>4</sub>, and 0.1 mmol/L PMSF and trimmed of fat, the pancreas was homogenized in this cold buffer using a Brinkman polytron. The homogenate was centrifuged at  $150 \times g$  for 15 min at 4°C to pellet unbroken cells and the resulting supernatant was used to measure <sup>3</sup>H phenylalanine uptake. For this purpose, an aliquot of the supernatant was mixed with an equal volume of cold 20% trichloroacetic acid (TCA) and centrifuged at  $4000 \times g$  for 15 min. The remaining radioactive <sup>3</sup>H phenylalanine in the resulting supernatant was quantified using a Packard liquid scintillation counter.

### Protein synthesis

The pancreas was sampled at the above fixed time points. The pancreas was rinsed in cold homogenization buffer, trimmed of fat, and divided into small fragments, which were homogenized in 8 mL of homogenization buffer using 5 full up- and down strokes of a motorized glass-Teflon homogenizer. The homogenate was centrifuged at  $150 \times g$  for 15 min at 4°C to remove unbroken cells and debris. An aliquot was mixed with an equal volume of cold 20% TCA. After incubation on ice for 1 h to precipitate proteins, the sample was centrifuged at  $4000 \times g$  for 15 min at 4°C. The pellet was washed twice in 2 mL of 10% TCA. The final pellet was dissolved using a Packard liquid scintillation counter after addition of 10 mL of Beckman Ready-Solv.

### Subcellular fractionation

The pancreas was removed, homogenized and subcellularly fractionated using the method of Tartakoff and Jamieson<sup>[12]</sup> with some modifications by DeLisle *et al*<sup>[13]</sup>. Briefly, the pancreas was divided into fragments, homogenized in 8 mL homogenization buffer by 5 full up- and -down strokes of a motorized glass-Teflon homogenizer, unbroken cells and debris were removed by centrifugation at  $150 \times g$  for 15 min at 4°C. The resulting supernatant was considered to be the entire sample for later calculation and to contain 100% of all measured components, and centrifuged at  $1300 \times g$  for 15 min at 4°C, yielding the "zymogen granule" pellet and a supernatant. The latter was harvested and centrifuged at  $12000 \times g$  for 12 min at 4°C to obtain the "lysosome-mitochondria" pellet and a  $12000 \times g$  supernatant. This supernatant was centrifuged at  $105000 \times r/min$  for 60 min at 4°C

**Figure 1** Change of <sup>3</sup>H radioactivity in acinar cell uptake (A), enzyme-protein synthesis (B), zymogen granules (C), lysosomal mitochondria (D), and microsomal (E) at different time points in two groups.

to produce a “microsomal” pellet and postmicrosomal or soluble fraction. The pellets described above were individually resuspended in 2 mL of homogenization buffer prior to measurement of marker enzymes and DNA. To measure the content of newly synthesized protein in each fraction, an aliquot of the sample or the resuspended pellet was mixed with an equal volume of 20% TCA, incubated for 1 h at 4°C and centrifuged at 4000 × *g*. The pellet was washed as described above prior to measurement of TCA-precipitable radioactivity.

### Electron microscopy

The fixation procedure used for conventional thin-section electron microscopy involved incubation with OsO<sub>4</sub> alone (1% or 2% in phosphate buffer) at 0°C for 30 min. After fixation, the sample was washed extensively in Veronal acetate buffer (90 mmol/L, pH 6.0), stained by incubation at 0°C for 60 min in uranyl-magnesium acetate (0.5%) in the same buffer, washed again, dehydrated and embedded. Thin sections were doubly stained with uranyl acetate and lead nitrate, and examined under Philip EM 400 electron microscope.

A systematic randomized protocol was used to select tissue areas for morphometric analysis<sup>[14]</sup>. In each grid, 10 pictures were taken by one operator at a magnification of 150 for a total of ten negatives per sample. Two hundred and thirty pictures (PN group, *n* = 110; EIN group, *n* = 120) were printed and observed by one operator with

a semi automated method using a digitizing tablet and pen, and a PC with dedicated software (Image Measure, Microscience, USA). The interstitial and vascular space, nonexocrine cells, exocrine cell nuclei, and acinar lumen space were not considered. The cross-sectional cytoplasmic area (mm<sup>2</sup>) of exocrine cells and mature exocrine enzyme granules was directly measured on prints. In each group of samples, the mean zymogen granular number and area were obtained.

### Statistical analysis

The data were collected by two blinded observers and presented as mean ± SE for multiple determinations. The statistical significance of observed changes was evaluated by *t* test using SPSS 10.0 statistical-software. *P* < 0.05 was considered statistically significant.

## RESULTS

### Pancreatic exocrine secretion stimulation test (PESST) on the first day

**Acinar cell uptake of <sup>3</sup>H phenylalanine:** The pancreatic acinar cell uptake of <sup>3</sup>H phenylalanine was evaluated at 60 min after the start of pulse infusion, and <sup>3</sup>H radioactivity in the EIN group was higher than that in PN group (*P* < 0.05), and then gradually decreased. There was no statistical difference between the two groups (Figure 1A).

**Enzyme-protein synthesis:** The maximal values for

**Figure 2** Change of MZGA in EIN group (A) and PN group (B) at different time points.

both groups were similar in acinar cell uptake of  $^3\text{H}$  phenylalanine. The incorporation of  $^3\text{H}$ -phenylalanine into enzyme protein was maximal at 60 min in both groups, and then gradually decreased. There was no difference between the two groups at 180 min (Figure 1B).

#### Intracellular transport of newly synthesized protein:

The peak level of  $^3\text{H}$  radioactivity was reached in the three subcellular fractionations at 60 min, and  $^3\text{H}$  radioactivity in zymogen granules in the EIN group was higher than that in the PN group at 60 min ( $P < 0.05$ ).  $^3\text{H}$  radioactivity in lysosomal-mitochondria and the microsomal subcellular fractionation did not reach statistical difference at the fixed time between the two groups, and then gradually decreased, the changes did not reach statistical difference (Figure 1C-E).

#### Electron microscopy

There was no difference in the submicroscopic cytology of acinar cells between the two groups. In particular, the fine structure of mature secretory granules was consistently similar. The electron density of membrane-bound mature exocrine granules had no change in this study in both PESST determinations. However, the mean zymogen granule number (MZGN) and mean zymogen granule area (MZGA) were not apparently changed on d 1 and 7 in either group, and the change in their number and unit area at different time points did not reach statistical difference (Figure 2A and B).

## DISCUSSION

Traditionally, enteral nutrition is implemented after a 2-3 wk period of parenteral nutritional support<sup>[15]</sup>. This clinical strategy has been developed to provide a sufficient time period for the pancreas to rest and rehabilitate. The concept of pancreatic rest stems from the belief that stimulation of pancreatic exocrine function in patients with acute pancreatitis releases large quantities of proteolytic enzymes which result in autodigestion of the pancreas and peripancreatic tissues, causing deterioration in the patient's condition. The presence of food in the stomach and duodenum elicits gastropancreatic and duodenopancreatic reflexes that result in the stimulation of pancreatic exocrine secretion. However, these effects are insignificant when nutrients are delivered directly into the jejunum<sup>[16-25]</sup>.

Kaushik *et al*<sup>[26]</sup> reported that enteral feeding can be given without stimulating pancreatic trypsin secretion provided it is delivered into the mid-distal jejunum, because the avoidance of trypsin stimulation may optimize enteral feeding in patients with acute pancreatitis.

It is known that digestive proteins and lysosomal enzymes are synthesized by polyribosomes binding to the cytoplasmic surface of endoplasmic reticulum (ER) membrane, and then transferred to the lumen of ER cisternae<sup>[27]</sup>. They are transported together to the Golgi, and normally separated from each other in the Golgi complex and condensing vacuole (CV) stage of intracellular transport. Normally, digestive enzymes and lysosomal hydrolases, which are synthesized in ribosomes attaching to the rough-surfaced endoplasmic reticulum and migrating to the Golgi complex and CV, are separated from each other by a complex sorting mechanism. Eventually, they are targeted for inclusion in distinct organelles: zymogen granules and lysosomes. In order to evaluate the effect of EIN on pancreatic acinar cell uptake of  $^3\text{H}$ -phenylalanine and incorporation into zymogen protein in acute pancreatitis dogs, morphological changes were observed by determining the process of amino acid uptake, enzyme-protein synthesis, intracellular transport, and discharge of newly synthesized proteins from the pancreas within 3 h after beginning of PN and EIN on the first day. The results showed that  $^3\text{H}$  phenylalanine radioactivity due to amino acid uptake and the extent of incorporation into newly synthesized proteins reached its peak level at 60 min in both groups. The parameters in the EIN group were higher than those in the PN group ( $P < 0.05$ ), and then gradually decreased. To further analyze the effect of EIN on uptake of amino acids and enzyme-protein synthesis in subcellular fractions on the first day, we used differential and density-gradient centrifugation to determine the  $^3\text{H}$  radioactivity in zymogen granules, lysosome-mitochondria and microsomal subcellular fractionation. In this study, the maximal values were obtained at 60 min in each of these fractions in lysosomes (cathepsin B), mitochondria (cytochrome oxidase) and zymogen granules (amylase), and then gradually decreased. These results suggest that the EIN alters neither amino acid uptake nor the extent of incorporation of  $^3\text{H}$  radioactivity into newly synthesized proteins.

To study the possibility of recurrent pancreatitis,

PESST was performed to determine whether EIN increases  $^3\text{H}$  radioactivity in lysosomes, mitochondria, and zymogen granules during AP. The results showed that the  $^3\text{H}$  radioactivity in amino acid uptake, enzyme-protein synthesis, and subcellular fractionation reached its peak level at 60 min in both groups, which was higher in the EIN group than in the PN group ( $P < 0.05$ ), and then gradually decreased. The content of  $^3\text{H}$  in zymogen granules, lysosome-mitochondria and microsomal subcellular fractionation were consistent with the changes of amino acid uptake. The peak level of radioactivity on d 7 was higher than that on d 1. The tissue level of pulse-labeled proteins declined as expected due to secretion of labeled digestive zymogens into the duodenum via the pancreatic duct system. These results suggest that 7 d continuous intrajejunal nutrition can neither over-stimulate acinar cell uptake of  $^3\text{H}$  nor enhance enzyme-protein synthesis and release. Cell fractionation studies indicated that intracellular transport of granules was not affected by EIN stimulation. Indeed, disappearance of pulse-labeled proteins from  $10\,500 \times g$  pellet (total microsomal fraction enriched in rough endoplasmic reticulum elements and expected to contain Golgi elements as well) and their appearance in the  $1300 \times g$  pellet (enriched in zymogen granules and presumably condensing vacuoles) were not significantly different in EIN stimulation.

It is known that stored zymogens granules and lysosomal enzymes could play a key role in the development of pancreatitis and may, in fact, explain the intrapancreatic activation of digestive enzymes occurring in the course of many forms of pancreatitis<sup>[28]</sup>. Secretory proteins, on the other hand, progressively increase their concentration within the dilated Golgi cisternal rims and/or CV. The CV ultimately matures to ZG which is transported to the luminal plasmalemma and releases its contents by exocytosis. The large vacuoles containing both secretory and lysosomal enzymes in acute pancreatitis suggest that AP stimulates the process of CV maturation. Therefore, theoretically, EIN might increase intracellular transport and expand the CV compartment (formation of large vacuoles). To quantitatively assess the effect of EIN on the secretory granule cell compartment, ultrastructural morphometrical study of the pancreas under electron microscope was designed. The results showed that more ZG was accumulated in the interstitial space. The number and area of ZG were higher than those in normal. However, no gross difference in acinar cell ultrastructure was observed. These findings did not reach statistical difference between the two groups on d 1 and 7 during the nutritional support period, suggesting that EIN does not promote pancreatic acinar cell enzyme protein synthesis and release. The precise mechanism of EIN-stimulating acinar cells is unclear. However, some results indicate that receptor-triggered events of transmembrane signaling (rise of cytoplasmic  $\text{Ca}^{2+}$ ) and the responsiveness and sensitivity to gastrointestinal hormones in pancreatic acinar cells are significantly inhibited<sup>[29]</sup>.

In conclusion, early intrajejunal nutrition might be effective in dogs with acute pancreatitis. However, further

study is needed to evaluate the effects of EIN and PN in patients with AP.

## Abstract

**AIM:** To investigate the effect of ceramide on the cell cycle in human hepatocarcinoma Bel7402 cells. Possible molecular mechanisms were explored.

**METHODS:** [3- (4, 5)-dimethylthiazol-2-yl]-2, 5-diphenyltetrazolium bromide (MTT) assay, plasmid transfection, reporter assay, FACS and Western blotting analyses were employed to investigate the effect and the related molecular mechanisms of C2-ceramide on the cell cycle of Bel7402 cells.

**RESULTS:** C2-ceramide was found to inhibit the growth of Bel7402 cells by inducing cell cycle arrest. During the process, the expression of p21 protein increased, while that of cyclinD1, phospho-ERK1/2 and c-myc decreased. Furthermore, the level of CDK7 was downregulated, while the transcriptional activity of PPAR $\gamma$  was upregulated. Addition of GW9662, which is a PPAR $\gamma$  specific antagonist, could reserve the modulation action on CDK7.

**CONCLUSION:** Our results support the hypothesis that cell cycle arrest induced by C2-ceramide may be mediated *via* accumulation of p21 and reduction of cyclinD1 and CDK7, at least partly, through PPAR $\gamma$  activation. The ERK signaling pathway was involved in this process.

## INTRODUCTION

Ceramide has emerged as a novel lipid second messenger with specific roles in mediating cell growth, differentiation, stress responses and apoptosis<sup>[1-3]</sup>. Ceramide is generated through the hydrolysis of sphingomyelin by the activation of sphingomyelinase (SMase). A number of stimuli have been reported to activate SMase<sup>[4-6]</sup>. Exogenously administered synthetic ceramide mimicked the action of these inducers in the regulation of various cell functions. Ceramide mediates numerous cellular functions such as differentiation, growth arrest, apoptosis and proliferation<sup>[7,8]</sup>. Ceramide is thought to be involved in modulating ceramide-activated protein kinase (CAPK), mitogen-activated protein kinase (MAPK), ceramide-activated protein phosphatase (CAPP) and phospholipaseA2 (PLA2), *etc*<sup>[9]</sup>. Apoptosis induction by ceramide is associated with Bcl-2 phosphorylation, SAPK/JNK and caspase pathway activation<sup>[10]</sup>. On the other hand, activation of PKC and Bcl-2 expression can inhibit the ceramide signal pathway<sup>[11,12]</sup>. However, the link between ceramide signaling and the cell cycle is poorly understood.

To exploit the effect of ceramide on the cell cycle, human hepatocarcinoma Bel7402 cells were employed and treated with C2-ceramide. Hepatocarcinoma occurs with high incidence in southern China and southeast Asia. Radiation is one of the agents that activates ceramide signaling<sup>[13]</sup>, and therefore, it is of interest in investigating the effect of ceramide on Bel7402 cells. In this study, we observed inhibition of cell proliferation and cell cycle arrest in the G1 phase following C2-ceramide treatment in Bel7402 cells. Subsequent studies suggested that modulation might be mediated *via* accumulation of p21 and reduction of cyclinD1 and CDK7, at least partly, through PPAR $\gamma$  activation. The ERK signaling pathway was also involved in this process.

## MATERIALS AND METHODS

### Materials

C2-ceramide was purchased from Sigma. Co (St Louis Mo, USA); mouse monoclonal anti-p21, anti-cyclinD1,

anti-CDK7, anti-p-ERK and anti-c-myc were purchased from Santa Cruz Biotechnology, Inc (CA, USA); antibody of PE-E-cadherin was purchased from DAKO Co. Horseradish peroxidase-conjugated secondary antibodies were purchased from Jackson Immuno-Research Laboratories, Inc (West Grove, PA, USA). Lipofectamine and lipofectin reagents were from Gibco, Inc. RNaseA, MTT, propidium iodide and other chemicals were all from Sigma.

### Cell culture

Bel7402 cells were provided by the Institute of Zoology, Chinese Academy of Sciences, China. Cells were maintained in Dulbecco's minimal essential medium (DMEM) supplemented with 10% fetal bovine serum (FBS) in a humidified atmosphere of 95% air/5% CO<sub>2</sub> at 37°C. A subculture of cells was processed by enzymatic digestion (trypsin/EDTA solution: 0.25/0.02%). C2-ceramide dissolved in ethanol was used without filtration. The final concentration of ethanol in culture medium was < 0.3%.

### MTT assay

Bel7402 cells were seeded onto 96-well plates at a concentration of  $2.5 \times 10^3$  cells/well in DMEM plus 5% FBS. The stock of C2-ceramide was diluted with medium, and then added to wells for desired final concentrations. After exposure to C2-ceramide for the desired time, 10  $\mu$ L of 5 mg/mL MTT was added to each well and incubated for 4 h, and the liquid in wells was evaporated. To dissolve the formazan, 100  $\mu$ L of DMSO was added. The absorbance was determined with a microplate reader model 550 at the wavelength of 570 nm.

### Cell cycle analysis

The proportions of cells in G0-G1, S, and G2-M were determined by flow cytometric analysis of DNA content. Briefly, cells were obtained by trypsinization following treatment with C2-ceramide, and then washed twice with PBS. Cells were then incubated with RNase at a concentration of 0.25 mg/mL at 37°C for 1 h following incubation with PI (50  $\mu$ g/mL in PBS) for 30 min at 4°C in the dark. Before flow cytometry, samples were syringed through a 25-gauge needle to prevent nuclear clumping. PI was excited at 488 nm, and fluorescence was analyzed at 620 nm. All measurements were carried out under the same instrumental settings.

### PE-E-cadherin labeling

Cells were washed once with cold PBS, and centrifuged to collect the cell pellet (350 g  $\times$  5 min) following treatment with C2-ceramide. The cell pellet was resuspended in cold PBS (4°C) and PE-E-cadherin and the corresponding isotype antibodies were added to the cell suspension and mixed gently. The tube was then incubated for 30-60 min in the dark at room temperature prior to flow cytometry. PE-E-cadherin binding was analyzed by flow cytometry collecting the fluorescence of 10 000 cells using a FACScan (Becton Dickinson) according to the manufacturer's instructions. All experiments were replicated three times.

### Western blot analysis

To determine the expression levels of E-cadherin, p21, cyclinD1, CDK7 and c-myc, cells were lysed in buffer (150 mmol/L NaCl, 1% NP-40, 0.5% sodium deoxycholate, 0.1% SDS, 50 mmol/L Tris, pH 8.0, 1 mmol/L phenylmethylsulfonyl fluoride (PMSF), and 10  $\mu$ g/mL aprotinin). To determine the level and phosphorylation state of ERK, cells were harvested in lysis buffer containing 50 mmol/L TES (N-tris [hydroxymethyl] methyl-2-aminoethane sulfonic acid) (pH 7.4), 2 mmol/L EGTA, 1 mmol/L EDTA, 250 mmol/L sucrose, 40 mmol/L phenylphosphate, 1 mmol/L MgCl<sub>2</sub>, 2 mmol/L Na<sub>3</sub>VO<sub>4</sub>, 10 mmol/L Na<sub>4</sub>P<sub>2</sub>O<sub>7</sub>, 100 mmol/L NaF, 5  $\mu$ g/mL aprotinin, 1 mmol/L PMSF, 1  $\mu$ g/mL leupeptin, 5 mmol/L benzamidine, and 10 mmol/L dithiothreitol. Protein (40-80  $\mu$ g) was separated by 12%-15% SDS-polyacrylamide gel in the separation buffer (25 mmol/L Tris, 250 mmol/L Glycine, 0.1% SDS). Total proteins were transferred onto a PVDF membrane after electrophoresis. Western blot analyses using anti-p21, anti-cyclinD1, anti-CDK7, anti-c-myc, anti-phospho-p42/p44ERK and anti-totalERK antibodies were performed. As an internal control, mouse monoclonal anti- $\beta$ -actin antibody was used.

### Transient transfection and luciferase assay for PPAR $\gamma$ activity

Bel7402 cells were seeded at a concentration of  $1 \times 10^5$  cells/35 mm dish. After 12 h, the medium was changed from complete medium to DMEM without antibiotic. Transfection was done using LipofectAMINE reagent mixed with 2  $\mu$ g of acyl-CoA oxidase promoter-luciferase plasmid pAOXPPRELuc and the control pAOXBluc basic vector (kindly donated by Dr. Osumi) for 8 h. After the transfection mixture was replaced by a medium containing 10% FBS, cells were then incubated with or without different concentrations of ceramide for a desired time. Luciferase activity was measured according to the manufacturer's protocol (Promega).

### Statistical analysis

All statistical analyses were performed with SPSS 10.0 statistical package for Microsoft Windows. Data were expressed as mean  $\pm$  SE for all measurements.  $P < 0.05$  was considered statistically significant.

## RESULTS

### Ceramide inhibited proliferation by halting the cell cycle in Bel7402 cells

Treatment with different concentrations of C2-ceramide for 24 h exhibited significant inhibition of cell proliferation of human hepatocarcinoma Bel7402 cells as suggested by MTT assay. Under concentrations of 0, 5, 10, 15, 30 and 60  $\mu$ mol/L, inhibitory rates were 0, 21.5%  $\pm$  1.3%, 52.7%  $\pm$  0.9%, 69.3%  $\pm$  1.2%, 77.2%  $\pm$  0.8% and 83.8%  $\pm$  1.2%, respectively (Figure 1A). Cytotoxicity was further indicated by determination of E-cadherin, which is a marker for many tumor cells with high expression. PE-E-cadherin antibodies were stained with cells to determine

**Figure 1** Ceramide inhibited proliferation by halt of cell cycle in Bel7402 cells. **A:** ceramide inhibited cell proliferation in Bel7402 cells. Cells were cultured in the medium with different concentrations of C2-ceramide for 24 h. Cell viability was analyzed by MTT assay and presented as cell proliferative rates. The results show the mean  $\pm$  SE ( $n = 3-4$ ); **B** and **C:** ceramide down-regulated the expression of E-cadherin. Bel7402 cells were incubated with or without 30  $\mu$ mol/L of ceramide for 24 h. Cells were then harvested and stained with anti-E-cadherin directly labeled by PE. The protein levels of E-cadherin were determined by flow cytometry. Data was represented by the mean  $\pm$  SE of 3 or 4 separate experiments (**B**). Bel7402 cells were incubated with or without 30  $\mu$ mol/L of ceramide for 24 h. Cells were then harvested, lysed and resolved in 12% SDS-PAGE. The expression of E-cadherin was determined by Western blot. Actin was used as a control. Data represent the results of three separate experiments (**C**).

the expression of E-cadherin on the cell surface. Flow cytometry analysis results indicated that E-cadherin was significantly down-regulated by C2-ceramide (Figure 1B), which was also suggested by blot assay (Figure 1C). To test whether the cytotoxicity was derived from the effect on the cell cycle, flow cytometry analysis was applied following treatment with different concentrations of C2-ceramide at 0, 5, 15, 30 and 60  $\mu$ mol/L. As shown in Table 1, the cell cycle was halted in the G1 phase, and the percentage of cells in the G1 phase was  $35.3\% \pm 0.7\%$ ,  $36.8\% \pm 1.2\%$ ,  $43.9\% \pm 1.2\%$ ,  $57.2\% \pm 0.6\%$  and  $76.2\% \pm 1.3\%$ , respectively.

#### Ceramide up-regulated the expression of p21<sup>WAF1/BIP1</sup> and down-regulated that of cyclinD1

In order to elucidate whether molecules were involved in the G1/S transition following C2-ceramide treatment,

**Table 1** Ceramide halted cell cycle in Bel7402 cells (mean  $\pm$  SE,  $n = 3$ )

Ceramide ( $\mu$ mol/L)	G <sub>0</sub> /G <sub>1</sub> (%)	S (%)	G <sub>2</sub> /M
0	35.3 $\pm$ 0.7	44.3 $\pm$ 0.3	20.4 $\pm$ 0.1
5	36.8 $\pm$ 1.2	43.9 $\pm$ 0.4	19.3 $\pm$ 1.8 <sup>a</sup>
15	43.9 $\pm$ 1.2 <sup>a</sup>	41.9 $\pm$ 0.7 <sup>a</sup>	14.2 $\pm$ 0.8 <sup>a</sup>
30	57.2 $\pm$ 0.6 <sup>a</sup>	28.8 $\pm$ 0.5 <sup>a</sup>	14.0 $\pm$ 0.5 <sup>a</sup>
60	76.2 $\pm$ 1.3 <sup>a</sup>	8.2 $\pm$ 0.2 <sup>a</sup>	15.6 $\pm$ 1.3 <sup>a</sup>

<sup>a</sup> $P < 0.05$  vs control.

**Figure 2** Ceramide up-regulated the expression of p21<sup>WAF1/BIP1</sup> and down-regulated that of cyclinD1. Bel7402 cells were incubated with different concentrations of ceramide as indicated for 24 h. Cells were harvested, lysed and resolved in 15% SDS-PAGE. The expression of p21 and cyclinD1 were determined by Western blot. Actin was used as a control. Data represent the results of three separate experiments.

cell extracts were prepared from Bel7402 cells treated with different concentrations of C2-ceramide. Protein expression was indicated by blot using anti-p21 and anti-cyclinD1 antibodies, respectively. As shown in Figure 2, C2-ceramide increased the expression of p21 protein, but decreased that of cyclinD1 protein.

#### CDK7 and PPAR $\gamma$ pathways involved in cell cycle arrest induced by C2-ceramide

In our previous study, we reported that C2-ceramide could activate PPAR $\gamma$  transcription activity in human colon cancer HT29 cells<sup>[14]</sup>. In this study, as shown in Figure 3A, C2-ceramide could also markedly activate the transcriptional activity of PPAR $\gamma$  in hepatocarcinoma Bel7402 cells.

Cyclin-dependent kinase 7 (CDK7) is critical for cell cycle and transcriptional programs<sup>[15]</sup>. Therefore, we investigated the expression of CDK7 by blotting. It was observed that CDK7 expression decreased following treatment with 30  $\mu$ mol/L C2-ceramide for 24 h. However, addition of the PPAR $\gamma$  specific antagonist GW9662 markedly reversed the inhibition (Figure 3B).

#### Ceramide inhibited the activation of ERK1/2 in Bel7402 cells

ERK plays a key role in cell survival in many cells. To examine whether ceramide inhibited the activation of ERK, Bel7402 cells were treated with different concentrations of C2-ceramide and phospho-ERK1/2 was determined. As shown in Figure 4, the expression of p-ERK decreased significantly with the treatment of

**Figure 3** CDK7 and PPAR $\gamma$  pathways involved in cell cycle arrest induced by C2-ceramide. **A:** activation of PPAR $\gamma$  transcriptional activity induced by C2-ceramide. Bel7402 cells were transiently transfected with the PPAR responsive element (PPRE) reporter construct (pAoxPPREluc) or the promoter-less control vector pAoxBluc following the treatment of different concentrations of C2-ceramide as indicated, PPAR $\gamma$  transcriptional activity was measured as described. The bar represents the relative fold increase of luciferase activity. The results show means  $\pm$  SE ( $n = 3$ ); **B:** C2-ceramide down-regulated the expression of CDK7, which was blocked by GW9662. Bel7402 cells were cultured with 30  $\mu$ mol/L C2-ceramide in the presence or absence of GW9662, which was claimed as a specific PPAR $\gamma$  antagonist for 24 h. Total proteins were extracted and resolved on SDS-PAGE followed by Western blot assay using anti-CDK7 antibody. Data represents the results of three separate experiments.

C2-ceramide, while total ERK protein expression was unaffected.

To complete the study of the MAPK pathway, c-myc content was also indicated by blot using anti-c-myc antibodies. As shown in Figure 4, the modulation pattern on the expression of c-myc induced by C2-ceramide was similar to that of p-ERK.

## DISCUSSION

Since ceramide was affirmed as an important lipid second messenger in 1994, the importance of ceramide in cell metabolism has been broadly investigated. Ceramide has shown inhibition of cell growth *via* apoptosis in a variety of cancers. However, the link between ceramide signaling and the cell cycle is poorly understood. The present work demonstrates that C2-ceramide halted the distribution of cell cycles in G1 phase, and the mechanisms involved were explored.

As displayed in Table 1, C2-ceramide induced cell cycle arrest in the G1 phase. Accordingly, down-regulation of E-cadherin, a marker for many tumor cells with high expression, suggested that C2-ceramide inhibited cancer cell growth (Figure 1B).

In order to elucidate the mechanisms involved in cell

**Figure 4** Ceramide inhibited activation of ERK pathway in Bel7402. Bel7402 cells were incubated with different concentrations of ceramide as indicated. Total proteins were extracted and resolved on SDS-PAGE. Phospho-ERK1/2 and c-myc were normalized to total Erk1/2 and internal standard actin was determined by Western blot. Data represents the results of three separate experiments.

cycle arrest following treatment with C2-ceramide in Bel7402 cells, we firstly investigated whether the cell cycle control genes; i.e., cyclin D1 and the cyclin-dependent kinase inhibitor p21, are involved in ceramide-mediated cell cycle regulation in Bel7402 cells.

Cell cycle progression is regulated by interactions between cyclins and cyclin-dependent kinases, which are modulated by a family of negative cell cycle regulators; i.e., cyclin-dependent kinase inhibitors, which are especially involved in controlling the transition from G1 to S-phase<sup>[16,17]</sup>. The latter includes two families, the CIP/KIP family and the INK4 family. p21 is a member of the CIP/KIP family and plays a crucial role in growth arrest by a variety of mechanisms<sup>[18]</sup>. Consistent with this idea, we showed that C2-ceramide up-regulated the expression of p21 protein concomitant with inhibition of cyclin D1 protein (Figure 2).

PPAR $\gamma$  is clearly involved in lipid metabolism and is essential for cell differentiation<sup>[19,20]</sup>. Activation of PPAR $\gamma$  by its ligands can induce growth inhibition and cytotoxicity in human prostate cancer cells, colon cancer cells and liposarcoma cells, and their biological activities are attributed to inhibition of proliferation and induction of apoptosis by PPAR $\gamma$ <sup>[21,22]</sup>. We have previously shown C2-ceramide could induce apoptosis *via* a PPAR $\gamma$  dependent pathway in human colon cancer HT29 cells<sup>[14]</sup>. To examine whether the PPAR $\gamma$  pathway was involved in the modulation of cell cycle arrest induced by ceramide in human hepatocarcinoma Bel7402 cells, the luciferase reporter of PPRE3x-tk-luc was transfected and luciferase activity was assayed. The result shown in Figure 3A suggested that ceramide activated the transcriptional activity of PPAR $\gamma$  in a dose-dependent manner.

CDK7 distributes normally throughout the nucleus and cytoplasm, and in the nucleus, it attaches to a DNA template with other TF II H subunits initiating gene transcription<sup>[23]</sup>, which is very important in modulating cell proliferation. Participating in basal transcription by phosphorylating the carboxy-terminal domain of the largest subunit of RNA polymerase II, CDK7 is critical for the cell cycle and transcriptional programmes, which also phosphorylate other CDKs as an essential step for their activation<sup>[24,25]</sup>. Often, phosphorylation of NRs by kinases that are associated with general transcription factors (e.g. CDK7 within TF II H), or activated in response to a variety of signals (MAPKs, Akt, PKA, PKC),

facilitates the recruitment of coactivators or components of the transcription machinery and, therefore, cooperates with the ligand to enhance transcription activation.

Though there is much to be explored, data have shown that C2-ceramide inhibited cell proliferation through attenuation of CDK7 (Figure 3B). However, GW9662, which is a PPAR $\gamma$  specific antagonist, could markedly block this action. These data suggested that CDK7 was related to PPAR $\gamma$ , which was consistent with the opinion described above.

ERK signaling plays a key role in cell survival, and Erk1/2 are proteins belonging to the MAPK pathway, whose members are active when phosphorylated. Consequently, dephosphorylation of these proteins inhibits their activity and the transcription factor c-myc. The increase of PP2A, which is a serine/threonine phosphatase causing dephosphorylation of MAPKs<sup>[26]</sup>, is one of the causes of Erk1/2 dephosphorylation. Indeed, the ERK1/2 pathway, that regulates cellular growth and proliferation, has been shown to be pro<sup>[27-30]</sup> or anti-apoptotic<sup>[31-33]</sup>, depending on experimental conditions and/or cell types. To examine whether C2-ceramide can inhibit activation of ERK, phospho-ERK was determined. It was found that phospho-ERK decreased with the treatment of C2-ceramide in Bel7402 cells, however, the expression level of total ERK protein was unaffected. Accordingly, the protein expression of c-myc also decreased (Figure 4).

In summary, with consideration that there is much to be explored, it was concluded that C2-ceramide plays an important role in the inhibition of cell growth in Bel7402 cells. Our results showed that there is p21 accumulation in accordance with decreased cyclinD1, inactivation of the ERK pathway, downregulation of CDK7 and stimulation of PPAR $\gamma$  transcriptional activity. As such, our results support the hypothesis that suppression of hepatocarcinoma cell growth through cell cycle arrest induced by C2-ceramide may be mediated *via* accumulation of p21 and reduction of cyclinD1 and CDK7, at least partly, through PPAR $\gamma$  activation. The ERK signaling pathway was involved in this process.

## Abstract

Pancreatic tumors are primary in most of the cases. Pancreatic metastases associated with other primary malignancies, especially pancreatic metastasis of leiomyosarcoma, are uncommon. A 66-year-old woman underwent surgical resection of malignant mesenchymoma (70% osteosarcoma and 30% leiomyosarcoma) in the right thigh. In the postoperative period, a pancreatic mass was identified radiologically by abdominal computed tomography. Pylorus-preserving pancreaticoduodenectomy was performed. The surgical specimen revealed leiomyosarcoma metastasized to the pancreas. A metastatic nodule on the remnant pancreatic tail was discovered 9 mo after the first pancreatic resection, and distal pancreatectomy was performed. Cases of pancreatic metastasis from leiomyosarcoma are extremely rare, especially when the tumor was resectable. We report here a unique case of pancreatic metastasis from a leiomyosarcoma in the right thigh that had been treated surgically.

## INTRODUCTION

The occurrence of metastatic lesions in the pancreas is very uncommon. The incidence of metastatic pancreatic

tumors is 1.6%-11% at autopsy<sup>[1,2]</sup>. The majority of patients with pancreatic metastasis have widespread diseases. Isolated, potentially resectable pancreatic metastasis is detected infrequently. Therefore, resection of metastatic tumors of the pancreas has been occasionally reported, and its role in improving the survival or quality of life is not clearly defined<sup>[3,4]</sup>. However, some recent studies have reported that surgical resection can be performed in selected patients with isolated pancreatic metastases, achieving long-term survival and good palliation<sup>[1,5]</sup>. We report here a case of pancreatic metastatic from leiomyosarcoma of the right anterior thigh, which was treated by surgical resection, and review the literature about pancreatic metastasis.

## CASE REPORT

A 66-year-old woman was referred to our hospital with a mass in the right thigh (Figure 1). In September 2005, she had undergone surgical resection for this mass. Malignant mesenchymoma (70% osteosarcoma and 30% leiomyosarcoma) was diagnosed histologically. In the postoperative period, abdominal computed tomography (CT) identified a pancreatic mass. The patient complained of non-specific abdominal discomfort. Laboratory findings were all within normal limits. The levels of the tumor markers including carcinoembryonic antigen and carbohydrate antigen 19-9, were within the normal ranges. Abdominal CT revealed a mass at the head of the pancreas. Magnetic resonance imaging of the abdomen showed a low-intensity mass on T1-weighted images and a non-homogeneous high-intensity mass on T2-weighted images. No evidence of other distant metastases was seen (Figure 1). At laparotomy, a fixed mass of 4 cm or so in length was palpated at the head of the pancreas, displacing the surrounding duodenum. Therefore, pylorus-preserving pancreaticoduodenectomy was performed. Macroscopic examination of the operative specimen showed a 4 cm × 3 cm lobulated solid mass with a thin wall. Microscopic examination revealed a malignant neoplasm with predominance of spindle cells. The tumor cells were immunoreactive for desmin. Metastatic leiomyosarcoma was diagnosed histologically (Figure 2). The postoperative course was uneventful. We recommended systemic chemotherapy to the patient, but she declined. Nine months after the first pancreatic resection, a follow-up abdominal CT showed development of a new 1-cm mass in the remnant tail of the pancreas (Figure 1). Distal

**Figure 1** Radiological findings. **A:** Gadolinium-enhanced T1 weighted image showing a soft tissue tumor in the muscle of the anterior thigh; **B:** Contrast-enhanced abdominal CT scan showing a heterogeneously enhanced mass at the head of the pancreas; **C:** Gadolinium-enhanced T1 weighted image showing a well-enhanced mass with necrotic foci at the head of the pancreas; **D:** Follow-up CT obtained after 10 mo showing a low attenuated mass in the tail of the pancreas.

**Figure 2** Gross and microscopic findings for metastatic leiomyosarcoma. **A:** The section reveals a whitish solid tumor with a lobulated pattern and a yellowish necrotic portion, abutting duodenal wall on the left side, and compressed pancreatic head tissue on the right side; **B:** Low-power view displaying eosinophilic intersecting fascicles circumscribed by a fibrous capsule (a) and adjacent normal pancreatic tissue (b) (hematoxylin and eosin stain  $\times 40$ ); **C:** Cellular proliferation of atypical spindle tumor cells is accompanied by nuclear atypia and hyperchromasia (hematoxylin and eosin stain  $\times 200$ ); **D:** Tumor cells show immunoreactivity for desmin.

pancreatectomy was performed. The tumor showed the same microscopic findings, and leiomyosarcoma was also diagnosed histologically.

## DISCUSSION

Metastatic lesions in the pancreas are uncommon. Adsay *et al*<sup>[1]</sup> reviewed pathological specimens from 4955 adult autopsy cases in an attempt to identify tumors that had metastasized to the pancreas. There were only 81 (1.6%)

cases of metastatic tumors, the majority of which were of epithelial origin, and the most common sites of the primary lesions were the lung, kidney, and gastrointestinal tract. However, a few cases of leiomyosarcoma with metastases to the pancreas have been reported. Primary sites of leiomyosarcomas included the uterus<sup>[6,7]</sup>, ovary<sup>[8]</sup>, veins<sup>[9]</sup>, spermatic cord<sup>[10]</sup>, intestine<sup>[3,10]</sup>, retroperitoneum<sup>[2,11]</sup>, and soft tissue<sup>[11,12]</sup>. To the best of our knowledge, including the present case, only 16 cases of pancreatic metastasis from leiomyosarcoma have been reported to

date in the English language literature<sup>[7,8,12]</sup>.

The differential diagnosis between a solitary metastatic tumor and primary pancreatic carcinoma may be very difficult as signs and symptoms are similar for both primary and secondary tumors, and radiological imaging is unable to differentiate primary from secondary pancreatic lesions<sup>[13]</sup>. In our case, non-specific abdominal pain appeared to be the most common symptom. The symptoms of pancreatic metastases often include pain, weight loss, obstructive jaundice, and duodenal obstruction, which are very similar to the symptoms of primary pancreatic cancer<sup>[1,3,9]</sup>. Therefore, pre-operative diagnosis is challenging, and considerable caution is needed for patients with a previous history of non-pancreatic neoplastic disease. The pre-operative diagnosis of our case was primarily a non-functioning islet cell tumor of pancreas, although the patient had previously undergone surgical treatment for mesenchymoma of the left leg. Various diagnostic tools have been used to assess tumors. In recent years, 18-FDG-PET has proven to be useful for the accurate staging of tumors<sup>[3]</sup>. Percutaneous fine-needle aspiration (FNA) is found helpful in establishing the correct preoperative diagnosis, especially in patients who are not amenable to surgery, and in assisting in decisions related to the possibility and type of chemotherapy<sup>[3]</sup>. However, with the exception of postoperative histology, there is no definitive method for unambiguous diagnosis.

Metastatic tumors of the pancreas are usually diagnosed at an advanced stage, and solitary resectable metastasis occurs less frequently. Therefore, metastatic tumors of the pancreas are rarely treated surgically. Sperti *et al*<sup>[3]</sup> reported that 8/259 (3%) pancreatic resections were performed for pancreatic metastases. Therefore, our patient represents a very unusual case.

Only a few cases of pancreatic metastasis from sarcomas have been reported. Experience is limited, and the effectiveness of surgery for these types of lesions has not been clearly established. However, long-term survival may be conferred by "curative" resection for pancreatic metastasis from visceral or soft tissue sarcoma<sup>[3,7,9,14]</sup>. It is clear that surgical excision has the potential to improve prognosis if the primary site and other metastases are well-controlled. In the present unique case, pancreatic

metastasis from leiomyosarcoma was diagnosed, and the patient underwent pancreatectomy twice in 10 mo. An attempt at complete tumor resection can offer patients the best hope of prolonged survival.

CASE REPORT

## A prophylactic approach for bone marrow transplantation from a hepatitis B surface antigen-positive donor

### Abstract

It has been accepted that bone marrow transplantation (BMT) is the only curative therapeutic option for certain hematologic malignancies. The southeast Asia region is an endemic area of hepatitis B virus (HBV) infection; thus, BMT using a hepatitis B surface antigen (HBsAg)-positive donor is occasionally unavoidable. Organ transplantation using a HBsAg-positive donor can lead to post-transplantation de novo HBV infection and severe HBV-related hepatitis if no effective prophylactic measures are taken prior to and after transplantation. In this report, a four-level approach was designed for a patient with chronic myeloid leukemia, beginning with a booster HBV vaccination before performing BMT with a HBsAg-positive donor. Prior to BMT, the HBV viral load of the donor was reduced to an undetectable level by antiviral therapy. After BMT, hepatitis B immunoglobulin was administered intramuscularly for 1 wk together with a long-term antiviral drug, lamivudine. One year after discontinuation of lamivudine, the patient is still free of HBV infection.

### INTRODUCTION

Certain hematologic malignancies can only be cured by

bone marrow transplantation (BMT). In the southeast Asian region, hepatitis B virus (HBV) infection is highly prevalent. BMT from donors exhibiting the hepatitis B surface antigen (HBsAg) is therefore occasionally unavoidable. Intensive chemotherapeutic drugs used in a conditioning regimen and post-transplantation immunosuppressive drugs are required to suppress host immunity and to prevent graft versus host disease (GVHD). Using grafts with HBsAg-positive hematopoietic stem cells is associated with severe liver injury and a high mortality rate<sup>[1-3]</sup>. In this report, we present a long-term follow-up study of a seronegative patient who underwent BMT with a HBsAg-positive donor in which a four-level approach for the prevention of HBV infection was utilized.

### CASE REPORT

A thirty-seven year old man, a known case of chronic myeloid leukemia with positive Philadelphia chromosome in chronic phase, was previously treated with hydroxyurea. The patient planned to receive BMT from his sole HLA-identical sibling, his sister, who had been a known hepatitis B carrier. She was anti-HBe positive and had an HBV viral load of 5260 copies/mL, as indicated by the Amplicor HBV Monitor Test (Roche Diagnostics, NJ, USA). Lamivudine (100 mg/d) was initiated to suppress HBV DNA; and 3 mo later, her HBV viral load became undetectable. His antibody to HBsAg (anti-HBs) was firstly positive at a level of 10.3 mIU/mL. A booster dose of hepatitis B vaccine was given to him, and the subsequent anti-HBs level rose to 83 mIU/mL. A conditioning regimen for BMT containing busulfan (16 mg/kg) and cyclophosphamide (120 mg/kg) was started before the initiation of BMT. GVHD was prevented using methotrexate and tacrolimus. Lamivudine (100 mg/d) was initiated 7 d prior to BMT and was continued thereafter. From the day of BMT to the 7<sup>th</sup> d post-BMT, hepatitis B immunoglobulin (HBIG) 800 IU was injected intramuscularly daily in order to maintain the anti-HBs level > 1000 IU/L. From the 7<sup>th</sup> d post-BMT, the anti-HBs level was persistently over 1000 IU/L without HBIG administration. One month after BMT, while on tacrolimus for GVHD suppression and lamivudine for HBV prophylaxis, the patient's blood test results were as follows: HBsAg negative, anti-HBs positive (at 400 mIU/mL), anti-HBe positive, HBV viral load < 200 copies per ml and HBV PCR positive. HBV PCR became negative by 6 mo after BMT. The patient had only grade I acute GVHD and limited chronic GVHD. Tacrolimus was gradually tapered

off and then discontinued at the 15<sup>th</sup> mo post-BMT, and lamivudine was stopped 3 mo later. Two and a half years after BMT or 1 year after discontinuation of lamivudine, the patient felt well, and his blood tests indicated that he was HBsAg negative, anti-HBc positive, anti-HBs positive (at 14 mIU/mL) and HBV PCR negative.

## DISCUSSION

The Asia-Pacific region is an endemic area of HBV infection, with a prevalence of more than 8%<sup>[4]</sup>. Most transplantation centers have regarded HBV infection as a relative contraindication for organ transplantation<sup>[5,6]</sup>. BMT with HBsAg-positive donors has been reported to be associated with an increased incidence of HBV-related hepatitis, severe liver-related complications, fatal liver failure and death<sup>[1,2,6-11]</sup>. However, a few reports show that HBsAg might be present transiently in some patients after receiving bone marrow graft from HBsAg-positive donors<sup>[1,2]</sup>. High HBV viral load in BMT donors and the absence of anti-HBs in BMT patients are two important risk factors predisposing a patient to the development of HBV-related hepatitis post-BMT<sup>[1,2]</sup>. Oral antiviral drugs are suitable to decrease the HBV viral load of the HBsAg-positive BMT donor. Lamivudine seems to be an appropriate antiviral drug in this situation because it causes rapid viral load reduction and because HBV resistance rarely occurs in a short period of lamivudine treatment<sup>[12]</sup>. Before BMT, the anti-HBs level in the present case report was increased to 83 mIU/mL by a booster dose of HBV vaccination. In general, the persistence of anti-HBV activity after BMT may be caused by residual recipient lymphocytes that have survived intensive conditioning regimens<sup>[3]</sup>. We decided to administer HBIg intramuscular injection from d 0 to d 8 post-BMT because the residual number of patient lymphocytes was uncertain. Anti-HBs level monitoring during the early post-BMT period showed that anti-HBs levels were over 1000 mIU/mL, resulting in the decision to discontinue HBIg 7 d post-BMT. HBIg was injected intramuscularly according to the protocol employed in HBV-related liver transplantation<sup>[13]</sup>. The mechanisms by which HBIg prevents graft re-infection are not completely understood. They may decrease the spread of HBV infection by neutralizing circulating viral particles and by inducing lyses of infected cells through pathways such as antibody-dependent cellular cytotoxicity<sup>[13]</sup>. Combination therapy of HBIg and lamivudine offers synergistic protection against HBV infection and appears to be more effective than a single agent for prophylaxis after HBV-related liver transplantation<sup>[13]</sup>. A recent study proposed a three-level approach when hematopoietic stem cell transplantation (HSCT) was performed with a HBV-positive donor<sup>[6]</sup>. The three-level approach consisted of a pre-HSCT reduction of HBV viral replication in donors by lamivudine, a pre-HSCT enhancement of the recipient's anti-HBV immunity by HBV vaccination, and finally, a post-HSCT suppression of HBV viral replication in recipients with lamivudine<sup>[6]</sup>. In that paper, patients received lamivudine for 52 wk after HSCT; however, our patient received lamivudine for 72 wk, and treatment with

this drug was stopped 12 wk after the discontinuation of tacrolimus. A flare of HBV infection and severe hepatitis was reported if antiviral drug was withdrawn in patients with immunosuppressive status or upon completion of chemotherapy<sup>[14]</sup>. Continuing lamivudine for at least 3 mo after completion of chemotherapy or immunosuppressive drugs has been recommended by a recent practice guideline<sup>[15]</sup>. The HBV viral load, as determined by the Amplicor HBV monitor test used in this report, is far more sensitive than the Digene Hybrid Capture assay used in a previous report<sup>[6,16]</sup>. De novo HBV infection might appear in the long-term follow-up of antiviral-prophylactic BMT patients with HBV-positive donors whose viral load was determined to be negative using a low sensitivity assay. An additional benefit of post-transplantation HBIg may be anticipated in hematopoietic stem cell transplantation. Recently, HBIg and lamivudine treatment during BMT in a child who received BMT from her HBsAg-positive mother has been reported<sup>[17]</sup>. The child received lamivudine only 1 d before BMT and continued the drug for 102 d. The details of HBV viral load and HBV PCR, however, were not mentioned in that paper<sup>[17]</sup>. The authors suggested that HBIg and lamivudine combination may be useful during the early period of BMT<sup>[17]</sup>. Intramuscular injection of HBIg sometimes requires the correction of thrombocytopenia or changing the route of administration from intramuscular to intravenous injection. Due to the large dosage of intravenous HBIg and its high cost, it may not be affordable for all patients. Our strategies for using BMT from HBsAg-positive donors will require multicenter studies with a large number of patients and a longer follow-up before this costly, four-level prophylactic approach can be put into practice.

## Abstract

Lipoma within an inverted Meckel's diverticulum presenting with hemorrhage and partial intestinal obstruction is an exceptional clinical entity. We report a case of 47-year-old male with a history of recurrent episodes of partial intestinal obstruction and melena due to a subserosal lipoma located in the base of an inverted Meckel's diverticulum. According to our knowledge, this is the first case of a lipoma within a Meckel's diverticulum giving rise to this clinical scenario without the existence of heterotrophic gastric or pancreatic tissues.

## INTRODUCTION

Tumor of Meckel's diverticulum occurs infrequently.

Moreover, the association of a lipoma within the inverted Meckel's diverticulum as a leading point of bleeding and recurrent episodes of partial intestinal obstruction is such an unusual circumstance that might be considered quite impossible.

Meckel's diverticulum is the most prevalent congenital anomaly of the gastrointestinal tract, which is reported to occur in 1%-3% of the general population and autopsy series<sup>[1,2]</sup>. However, the lifetime risk of complication development in patients with Meckel's diverticulum was proposed to be less than 5% in recent investigations<sup>[3]</sup>. These complications included intestinal obstruction, intussusceptions, inflammation and bleeding.

Lipomas are the rare benign tumors of the small intestine with no malignant potential and mostly encountered incidentally during investigation of the gastrointestinal tract for another reason, since they are usually asymptomatic<sup>[4]</sup>. As small intestinal lipoma is relatively infrequent, it is even a rarer source of gastrointestinal bleeding.

We present a case of a 47-year-old man with fatigue, chronic abdominal pain and tarry stool due to an inverted Meckel's diverticulum with a subserosal lipoma. This is a special case that has not appeared in literature over the past 4 decades. Although the incidence of Meckel's diverticulum is high, inversion is a scarcely diagnosed entity and the association of a lipoma within the inverted Meckel's diverticulum as a leading point of lower gastrointestinal hemorrhage without the existence of heterotopic gastric and pancreatic tissues and recurrent partial intestinal obstruction is an exceptional case.

## CASE REPORT

A 47-year-old man was admitted to our clinic with fatigue, recurrent episodes of constipation and abdominal pain. Melena was mentioned on admission. He denied vomiting, fever, or chills. He had had symptoms intermittently for about 4 mo, leading to several hospital visits. Over the previous 2 mo, the episodes of pain became more pronounced with radiation to his back. The patient was not using any specific medication and his medical history did not suggest a major disease. Physical examination revealed a temperature of 37°C, a pulse rate of 90 beats per minute (bpm), a blood pressure of 110/70 mmHg, and a respiration rate of 18 breaths per minute. The

**Figure 1** Contrast enhanced CT shows a hypodense, regular contoured, polypoid, 4 cm × 2 cm mass lesion with fatty density.

**Figure 3** Microscopic appearance of a subserosal lipoma within the inverted Meckel's diverticulum (HE).

patient was pale-looking without abdominal tenderness, guarding or rebound and norm active bowel sounds were auscultated. Examination of heart and lungs revealed no abnormal findings. Rectal examination revealed tarry fecal content. Clear gastric content was obtained on nasogastric aspiration. The initial laboratory workup was as follows: hematocrit, 33%; hemoglobin, 11.2 g/dL; white blood cells, 10 500/mm<sup>3</sup> with a normal differential count; platelets, 195 000/mm<sup>3</sup>; blood glucose, 87 mg/dL; blood urea, 25 mg/dL; creatinine, 0.8 mg/dL; SGOT, 32 IU/L; SGPT, 25 IU/L; LDH, 54 IU/L; total bilirubin, 0.4 mg/dL; direct bilirubin, 0.2 mg/dL; and Na<sup>+</sup>, 138 meq/L; and K<sup>+</sup>, 3.7 meq/L. Fecal occult blood test was positive. A gastrointestinal cause was sought in order to explain the patient's hemorrhage. He had received upper and lower gastrointestinal tract endoscopic examinations without identification of a specific bleeding etiology except a little amount of blood residue in terminal ileum. A computed tomography (CT) scan of the abdomen and pelvis revealed mildly dilated loops of proximal small bowel and a polypoid, 4 cm × 2 cm mass lesion with fatty density localized in the left lower quadrant and a suspicious filling defect in cecum (Figure 1). A pedunculated lipoma was assumed to be the underlying cause of recurrent partial intestinal obstruction and bleeding. He was taken to the operating room with the diagnosis of symptomatic

**Figure 2** A pedunculated mass lesion within the inverted Meckel's diverticulum.

small bowel lipoma. At surgery, an inverted Meckel's diverticulum induced by a pedunculated subserosal lipomatous solid mass nearly obstructing the lumen with ulcer and hemorrhage was found 40 cm from the ileocecal valve (Figure 2). Segmental resection of the ileal loop harboring the lesion was carried out and an end-to-end ileo-ileal anastomosis was performed. The lipoma within the inverted Meckel's diverticulum as a leading point of obstruction and bleeding was 5 cm long and 3 cm in diameter. Pathologic evaluation of the specimen confirmed the diagnosis of a subserosal lipoma within the inverted Meckel's diverticulum and revealed neither heterotrophic gastric and pancreatic tissue nor signs of malignancy (Figure 3). Five days after intervention, the patient was discharged from the hospital without any complication.

## DISCUSSION

The omphalomesenteric duct connects the mid gut and yolk sac in seven weeks of gestation and during the eighth week, it normally undergoes obliteration<sup>[5]</sup>. Under circumstances of failure or incomplete vitelline duct obliteration, a spectrum of abnormalities appears, the most common of which is Meckel's diverticulum. Omphalomesenteric fistula, enterocysts or a fibrous band connecting the small intestine to the umbilicus are the other pathologies that can be encountered. As the location of the Meckel's diverticulum varies among individuals, they are usually detected in the antimesenteric side of the ileum within 100 cm of ileocecal valve. Meckel's diverticulum possesses various complication risks including intestinal obstruction, intussusception, inflammation and bleeding. Inversion of a Meckel's diverticula is a scarce entity with a potential of intestinal obstruction due to direct luminal obliteration or causing a lead point for intussusception<sup>[6-8]</sup>. The pathophysiology of the disease process leads to a complicated and confusing clinical picture of recurrent obstructive symptoms, chronic abdominal pain and lower gastrointestinal bleeding that may cause a delay in diagnosis and waste time. In our case, we have detected a lipoma as a leading point of inversion which causes partial obstruction and bleeding. Recurrent partial obstructive periods and abdominal pain of our patient might be attributed to luminal obstruction due to inversion

of Meckel's diverticulum which might be induced by lipomatous development. An other possible mechanism for this symptomatology might be the probable intussusceptions according to the inverted diverticulum, which has been reported as a lead point previously<sup>[6,7]</sup>. Intestinal obstruction due to intussusception as a result of a lipoma within Meckel's diverticulum has only been reported twice in literature<sup>[9,10]</sup>. Primary pathophysiologic process responsible for bleeding in Meckel's diverticulum is the ileal mucosal ulceration due to the existence of heterotrophic gastric or pancreatic tissues which has not been verified in our patient; instead a subserosal lipoma has been demonstrated with ulceration and hemorrhage.

Lipomas of the small intestine are the second most common benign tumors next to leiomyomas<sup>[11]</sup>. Their location and the peak age vary, however approximately 50% were found in the ileum, and the sixth to seventh decades of life were considered to be the most risky period<sup>[4,11]</sup>. In general, lipomas are defined to originate in the submucosal layer and are usually solitary, with variable sizes ranging from 1 cm to 30 cm<sup>[12]</sup>. They usually appear as a sessile protrusion into the lumen of the intestine. Due to motor activity of underlying muscularis propria, they tend to extrude into the bowel wall or through the luminal area progressively, which might be the responsible reason for the inversion of the Meckel's diverticulum in our case. In this manner, a pseudopedicle is formed, providing a polypoid appearance to the lesion. Although the majority of these lesions are asymptomatic and detected incidentally during the routine examinations or in surgical specimen removed for various other reasons, on rare occasions they might present with symptoms depending on their size and location. Lipomas smaller than 1 cm are generally incapable of producing symptoms, however 75% of lipomas with a size > 4 cm might give rise to gastrointestinal symptoms. Intestinal obstruction is one of the major result due to the occlusion of lumen by a large protruding lesion. Hemorrhage which is an other possible consequence might be based on an ulceration of the overlying mucosa caused by direct pressure from the lipoma or due to intussusception per se<sup>[4,12]</sup>. Preoperative diagnosis of small intestinal lipomas can be established by means of endoscopic and radiologic evaluation. Radiolucency and the so-called "squeeze sign" implying an altered configuration during peristalsis are suggestive findings observed in small intestinal series. Detection of fatty tissue density within the mass on CT scans supports the diagnosis. The "naked fat sign" which can be defined as the protrusion of fat through mucosal disruption following multiple biopsy sampling of the submucosal mass during endoscopic examination is believed to be pathognomonic<sup>[4,11]</sup>.

Although more common in children, the complications of Meckel's diverticulum have also been described in adults. Gastrointestinal bleeding and intestinal obstruction are the two most common clinical problems associated with Meckel's diverticulum. Tumor within a Meckel's diverticulum is a scarce clinical entity with a reported incidence of only 2%<sup>[13]</sup>. Intestinal obstruction caused by a lipoma within the Meckel's diverticulum is so uncommon that we could only find three cases in the literature, two of which were due to intussusception<sup>[9,10]</sup>, and one case of direct lumen occlusion by a large protruding lesion<sup>[14]</sup>. Moreover, the association of gastrointestinal hemorrhage and recurrent episodes of partial intestinal obstruction caused by a subserosal lipoma within an inverted Meckel's diverticulum without the existence of heterotrophic gastric or pancreatic tissue is an exceptional case, which has not been reported over the last 40 years in literature.

## Meetings

### MAJOR MEETINGS COMING UP

Meeting Falk Research Workshop: Morphogenesis and Cancerogenesis of the Liver  
25-26 January 2007  
Goettingen  
symposia@falkfoundation.de

Meeting Canadian Digestive Diseases Week (CDDW)  
16-20 February 2007  
Banff-AB  
cagoffice@cag-acg.org  
www.cag-acg.org/cddw/cddw2007.htm

Meeting Falk Symposium 158: Intestinal Inflammation and Colorectal Cancer  
23-24 March 2007  
Sevilla  
symposia@falkfoundation.de

Meeting BSG Annual Meeting  
26-29 March 2007  
Glasgow  
www.bsg.org.uk/

### NEXT 6 MONTHS

Meeting 42nd Annual Meeting of the European Association for the Study of the Liver  
11-15 April 2007  
Barcelona  
easl2007@easl.ch  
www.easl.ch/liver-meeting/

Meeting Falk Symposium 159: IBD 2007 - Achievements in Research and Clinical Practice  
4-5 May 2007  
Istanbul  
symposia@falkfoundation.de

Meeting European Society for Paediatric Gastroenterology, Hepatology and Nutrition Congress 2007  
9-12 May 2007  
Barcelona  
espghan2007@colloquium.fr

Digestive Disease Week  
19-24 May 2007  
Washington Convention Center, Washington DC

Meeting Gastrointestinal Endoscopy Best Practices: Today and Tomorrow, ASGE Annual Postgraduate Course at DDW  
23-24 May 2007  
Washington-DC  
tkoral@asge.org

Meeting ESGAR 2007 18th Annual Meeting and Postgraduate Course  
12-15 June 2007  
Lisbon  
fca@netvisao.pt

Meeting Falk Symposium 160: Pathogenesis and Clinical Practice in

Gastroenterology  
15-16 June 2007  
Portoroz  
symposia@falkfoundation.de

Meeting ILTS 13th Annual International Congress  
20-23 June 2007  
Rio De Janeiro  
www.ils.org

Meeting 9th World Congress on Gastrointestinal Cancer  
27-30 June 2007  
Barcelona  
meetings@imedex.com

### EVENTS AND MEETINGS IN 2007

Meeting Falk Research Workshop: Morphogenesis and Cancerogenesis of the Liver  
25-26 January 2007  
Goettingen  
symposia@falkfoundation.de

Meeting Canadian Digestive Diseases Week (CDDW)  
16-20 February 2007  
Banff-AB

Meeting 9th World Congress on Gastrointestinal Cancer  
27-30 June 2007  
Barcelona  
meetings@imedex.com

Meeting 15th International Congress of the European Association for Endoscopic Surgery  
4-7 July 2007  
Athens  
info@eaes-eur.org  
congresses.eaes-eur.org/

Meeting 39th Meeting of the European Pancreatic Club  
4-7 July 2007  
Newcastle  
www.e-p-c2007.com

Meeting XXth International Workshop on Helicobacter and related bacteria in chronic digestive inflammation  
20-22 September 2007  
Istanbul  
www.heliobacter.org

Meeting Falk Workshop: Mechanisms of Intestinal Inflammation  
10 October 2007  
Dresden  
symposia@falkfoundation.de

Meeting Falk Symposium 161: Future Perspectives in Gastroenterology  
11-12 October 2007  
Dresden  
symposia@falkfoundation.de

Meeting Falk Symposium 162: Liver Cirrhosis - From Pathophysiology to Disease Management  
13-14 October 2007  
Dresden  
symposia@falkfoundation.de

American College of Gastroenterology Annual Scientific Meeting  
12-17 October 2007  
Pennsylvania Convention Center Philadelphia, PA

Meeting APDW 2007 - Asian Pacific Digestive Disease Week 2007  
15-18 October 2007  
Kobe  
apdw@convention.co.jp  
www.apdw2007.org

15th United European Gastroenterology Week, UEGW  
27-31 October 2007  
Le Palais des Congrès de Paris, Paris, France

Meeting The Liver Meeting® 2007 - 57th Annual Meeting of the American Association for the Study of Liver Diseases

2-6 November 2007  
Boston-MA  
www.aasld.org

*Gastro 2009, World Congress of Gastroenterology and Endoscopy London, United Kingdom 2009*

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (WJG, *World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly journal of more than 48 000 circulation, published on the 7<sup>th</sup>, 14<sup>th</sup>, 21<sup>st</sup> and 28<sup>th</sup> of every month.

Original Research, Clinical Trials, Reviews, Comments, and Case Reports in esophageal cancer, gastric cancer, colon cancer, liver cancer, viral liver diseases, etc., from all over the world are welcome on the condition that they have not been published previously and have not been submitted simultaneously elsewhere.

#### Indexed and abstracted in

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, *Index Medicus*, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, *Nature Clinical Practice Gastroenterology and Hepatology*, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

#### Published by

The WJG Press

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297 mm × 210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, acknowledgements, References, Tables, Figures and Figure Legends. Neither the editors nor the Publisher is responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part without the written permission of both the authors and the Publisher. We reserve the right to put onto our website and copy-edit accepted manuscripts. Authors should also follow the guidelines for the care and use of laboratory animals of their institution or national animal welfare committee.

Authors should retain one copy of the text, tables, photographs and illustrations, as rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for the loss or damage to photographs and illustrations in mailing process.

#### Online submission

Online submission is strongly advised. Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/index.jsp>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. Authors encountering problems with the Online Submission System may send an email you describing the problem to [wjg@wjgnet.com](mailto:wjg@wjgnet.com) for assistance. If you submit your manuscript online, do not make a postal contribution. A repeated online submission for the same manuscript is strictly prohibited.

#### Postal submission

Send 3 duplicate hard copies of the full-text manuscript typed double-spaced on A4 (297 mm × 210 mm) white paper together with any original photographs or illustrations and a 3.5 inch computer diskette or CD-ROM containing an electronic copy of the manuscript including all the figures, graphs and tables in native Microsoft Word format or \*.rtf format to:

#### Editorial Office

##### *World Journal of Gastroenterology*

Editorial Department: Apartment 1066, Yishou Garden,  
58 North Langxinzhuang Road,  
PO Box 2345, Beijing 100023, China  
E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)  
<http://www.wjgnet.com>  
Telephone: +86-10-85381892  
Fax: +86-10-85381893

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using a word-processing software. All submissions must be typed in 1.5

line spacing and in word size 12 with ample margins. The letter font is Tahoma. For authors from China, one copy of the Chinese translation of the manuscript is also required (excluding references). Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was accomplished, disclosure of any financial support for the research, and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (removing all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s) and full family name.

#### Abstract

An informative, structured abstract of no more than 250 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipments, and the experimental procedures should be included. RESULTS: The observatory and experimental results, including data, effects, outcome, etc. should be included. Authors should present *P* value where necessary, and the significant data should accompany. CONCLUSION: Accurate view and the value of the results should be included.

The format of structured abstracts is at: <http://www.wjgnet.com/wjg/help/11.doc>

#### Key words

Please list 5-10 key words that could reflect content of the study mainly from *Index Medicus*.

#### Text

For most article types, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include in appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both.

#### Illustrations

Figures should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. No detailed legend should be involved under the figures. This part should be added into the text where the figures are applicable. Digital images: black and white photographs should be scanned and saved in TIFF format at a resolution of 300 dpi; color images should be saved as CMYK (print files) but not as RGB (screen-viewing files). Place each photograph in a separate file. Print images: supply images of size no smaller than 126 mm × 85 mm printed on smooth surface paper; label the image by writing the Figure number and orientation using an arrow. Photomicrographs: indicate the original magnification and stain in the legend. Digital Drawings: supply files in EPS if created by freehand and illustrator, or TIFF from photoshops. EPS files must be accompanied by a version in native file format for editing purposes. Existing line drawings should be scanned at a resolution of 1200 dpi and as close as possible to the size where they will appear when printed. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes of atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...

#### Tables

Three-line tables should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each table. No detailed legend should be included under the tables. This part should be added into the text where the tables are applicable. The information should complement but not duplicate that contained in the text. Use one horizontal line under the title, a second under the column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

#### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup>*P*<0.05, <sup>b</sup>*P*<0.01 should be noted (*P*>0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P*<0.05 and <sup>d</sup>*P*<0.01 are used. Third series of *P* values can be expressed as <sup>e</sup>*P*<0.05 and <sup>f</sup>*P*<0.01. Other notes in tables or under

illustrations should be expressed as  $^1F$ ,  $^2F$ ,  $^3F$ ; or some other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, etc. in a certain sequence.

### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions are included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should code the references according the citation order in text in Arabic numerals, put references codes in square brackets, superscript it at the end of citation content or the author name of the citation. For those citation content as the narrate part, the coding number and square brackets should be typeset normally. For example, Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>. If references are directly cited in the text, they would be put together with the text, for example, from references [19,22-24], we know that...

When the authors code the references, please ensure that the order in text is the same as in reference part and also insure the spelling accuracy of the first author's name. Do not code the same citation twice.

### PMID requirement

PMID roots in the abstract serial number indexed by PubMed (<http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed>). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information of the journal citations is very important. Through reference testing system, the authors and editor could check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in ASP file so that the readers can read the abstract of the citations online immediately.

### Style for journal references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). Title of the cited article and italicized journal title (Journal title should be in its abbreviation form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634]

Note: The author should test the references through reference testing system (<http://www.wjgnet.com/cgi-bin/index.pl>)

### Style for book references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

*Electronic journal (list all authors)*

**Morse SS**. Factors in the emergence of infectious diseases. Emerg Infect Dis serial online, 1995-01-03, cited 1996-06-05; 1(1): 24 screens. Available from: URL: <http://www.cdc.gov/ncidod/EID/eid.htm>

*Patent (list all authors)*

- 16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

### Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those that are linked with a hyphen and the difference between the two numbers at two sides of the hyphen is more than 5. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered as inappropriate references. Authors should not cite their own unrelated published articles.

### Statistical data

Present as mean  $\pm$  SD or mean  $\pm$  SE.

### Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\gamma$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

### Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p*(B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5  $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub> not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format about how to accurately write common units and quantum is at: <http://www.wjgnet.com/wjg/help/15.doc>

**Abbreviations**

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further mention.

**Italics**

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kbo I*, *Kpn I*, etc.

Biology: *H pylori*, *E coli*, etc.

**SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED**

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. Author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, the final check list for authors, and responses to reviewers by a courier (such as EMS) (submission of revised manuscript by e-mail or on the *WJG* Editorial Office Online System is NOT available at present).

**Language evaluation**

The language of a manuscript will be graded before sending for revision.

(1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing; (4) Grade D: rejected. The revised articles should be in grade B or grade A.

**Copyright assignment form**

Please download CAF from <http://www.wjgnet.com/wjg/help/9.doc>.

We certify that the material contained in this manuscript:

**Ms:**

**Title:**

is original, except when appropriately referenced to other sources, and that written permission has been granted by any existing copyright holders. We agree to transfer to *WJG* all rights of our manuscript, including: (1) all copyright ownership in all print and electronic formats; (2) the right to grant permission to republish or reprint the stated material in whole or in part, with or without a fee; (3) the right to print copies for free distribution or sale; (4) the right to republish the stated material in a collection of articles or in any other format. We also agree that our article be put on the Internet.

**Criteria for authorship:** The *WJG* requests and publishes information about contributions of each author named to the submitted study. Authorship credit should be based on (1) direct participation in the study, including substantial contributions to conception and design of study, or acquisition of data, or analysis and interpretation of data; (2) manuscript writing, including drafting the article, or revising it critically for important intellectual content; (3) supportive work, including statistical analysis of data, or acquisition of funding, or administration, technology and materials support, or supervision, or supportive contributions. Authors should meet at least one of the three conditions. The *WJG* does not publish co-first authors and co-corresponding authors.

We hereby assign copyright transfer to *WJG* if this paper is accepted.

Author Name in full (Full names should be provided, with first name first, followed by middle names and family name at the last, eg, Eamonn MM Quigley). Handwritten names are not accepted.

Author Name in abbreviation (Family name is put first in full, followed by middle names and first name in abbreviation with first letter in capital, eg, Quigley EMM). Handwritten names are not accepted.

**Final check list for authors**

The format is at: <http://www.wjgnet.com/wjg/help/13.doc>

**Responses to reviewers**

Please revise your article according to the comments/suggestions of reviewers. The format for responses to the reviewers' comments is at: <http://www.wjgnet.com/wjg/help/10.doc>

## Abstract

In recent years, great progress has been made regarding the treatment of inflammatory bowel disease (IBD), particularly in the field of biological therapies. Nevertheless, the ultimate treatment is not in sight. With the development of new medication, it has become clear that we need a new understanding of IBD. Therapy needs to fit the different subtypes of IBD; e.g. mild disease in comparison to severe chronic active disease or Crohn's disease with or without fistulation or stenosis. The following article gives a practical overview of actual treatments for IBD. The intention of this article is not to provide a complete review of all new scientific developments, but to give a practical guideline for therapy of IBD.

## INTRODUCTION

Crohn's disease and ulcerative colitis are both defined as inflammatory bowel diseases (IBD), characterized by a chronic inflammation of the gut mucosa. The clinical course of both diseases can differ from a mild form, in which the patient reaches long-term remission without taking permanent medication, to a chronic active form,

in which remission is only reached by permanently taking immunosuppressives and/or biologics or by taking them for a long period of time. Patients are not only burdened by the most common symptoms of IBDs; e.g. diarrhea, bowel pain, fever and complications such as fistulation, stenosis and abscesses in Crohn's disease and megacolon in ulcerative colitis, but are also burdened by the side-effects of the therapeutics, which the patients take to achieve a normal quality of life. Therefore, it is a great responsibility for a physician to consider treatment for an individual patient.

Recent discussions in the field of IBD are concerned with recommendations for a step-down or step-up therapy. A step-down therapy means using the most effective biologic or immunosuppressive treatment on the market, even without prior use of therapeutics such as steroids, in order to reach an effective remission as soon as possible. A step-up therapy means using a "classical" treatment by, for example, starting with aminosalicylates and ending up with an immunosuppressive and/or biological. Even if using a common step-up therapy treatment, the decision about which drug to use should be based on the individual patient, considering the clinical course and diagnosed complications according to current treatment guidelines.

This article provides a short overview of IBD and practical guidelines for the actual treatment of IBD (Figures 1 and 2). It is recognized that there is still an urgent medical need for improvement in the treatment in IBD and that treatments may not be sufficient for all patients, although great progress has been made in therapeutic approaches in the last decades (especially regarding biological therapeutics). The current guidelines for IBD therapy are distinguished by the course, place and severity of the clinical disease<sup>[1-7]</sup>. In Crohn's disease, a mild active form, a moderate or severe active form or a severe chronically active form can be differentiated. Patients can also be defined as steroid-dependent or steroid-refractory. The endoscopic and clinical pattern, the segments of the body that are involved (e.g. only small colon or small and large colon and/or stomach), the complications (such as fistulation and/or stenosis) as well as the duration of the inflammation and the response (or loss of response) to steroids are taken into account in the evaluation. In ulcerative colitis, differentiation is easier because inflammation only involves the large colon, starting from the rectum to the caecum. Therefore, treatment is determined by the clinical disease course and the involved segments of the colon, such as left-sided disease or pancolitis, as well as the response to steroids

**Figure 1** Short overview of the treatment regime of ulcerative colitis.

**Figure 2** Short overview of treatment regimen in Crohn's disease.

(steroid-dependent or steroid-refractory). In the following paragraphs the treatment of IBD will be discussed according to use of different therapeutic drugs.

### 5-Aminosalicylates (5-ASA)

5-ASA are bowel-specific drugs that are metabolized in the gut where the predominant actions occur. As a derivative of salicylic acid, 5-ASA is also an antioxidant that traps free radicals, which are potentially damaging by-products of metabolism. In the radical induction theory of ulcerative colitis, 5-ASA functions as a free radical trap as well as an anti-inflammatory drug. 5-ASA is considered to be the active moiety of sulphasalazine, which metabolizes to it. Oral and/or topical 5-ASA is recommended for mild to moderate ulcerative colitis to induce and maintain remission. The dosage of 5-ASA should be no less than 3 g/d. In practice, most patients do not like a topical treatment, but in left-sided disease, an enema with 4 g of 5-ASA 2 times per day or suppositories with 500 mg 5-ASA 3 times per day are most effective. Sometimes it is helpful for the patient to use the enema only in the evening and the suppositories in the morning. In Crohn's disease, aminosaliclates should also be used in initial therapy for mild disease, although discussion about efficacy has increased recently. In contrast to ulcerative colitis, the use of aminosaliclates for the maintenance of remission is not

recommended for Crohn's disease because clinical studies have not shown success in remission maintenance<sup>[8,9]</sup>. 5-ASA is a standard treatment for ulcerative colitis, but not for Crohn's disease. In the last few years, new formulations have been on the market with varying clinical value. In some special cases; e.g. patients with an ileostoma, a formulation that sets metabolites free prior to the large bowel may be helpful. In patients with IBD and arthritis, sulphasalazine rather than 5-ASA formulations seems to be more effective regarding arthritis. In most patients, the side-effects are not very severe with headache as one of the most common side-effects. However, in some cases nephritis, pancreatitis and hair loss have been reported, which suggests regular monitoring of renal and liver enzymes at least once in three months.

### Antibiotics

Antibiotics (e.g. metronidazole) play only a minor role in the additional treatment of fistulizing disease<sup>[10]</sup>. Although metronidazole (for up to 3 mo in a dosage of 400 mg 2 times per day) is often used in post-operative management after an ileocecal resection or fistula/abscess operation for Crohn's disease, this therapy is not based on study evidence. A side-effect of long-term treatment with metronidazole is polyneuropathy and monitoring is, therefore, required. Antibiotics are also used in the conservative treatment of small abscesses. Understanding the role of microbiota and antibiotics in IBD may become important in the future, but currently clinical studies have not provided support for this concern.

### Corticosteroids

In patients with moderate to severe Crohn's disease or ulcerative colitis, corticosteroids are effective for the induction of clinical response and remission<sup>[11-16]</sup>. Dosages from 40-60 mg/d or 1 mg/kg per day orally are effective for the induction of remission. After the induction of remission, the steroid dose should be tapered (10 mg/wk until 40 mg; 5 mg/wk until 20 mg, followed by a tapering of 2.5 mg/wk). In severe disease, the application of parenteral glucocorticoids as soon as possible is useful for an anti-inflammatory response. Before the initiation of steroid treatment, the presence of an abscess should be excluded. In patients who have been on glucocorticoids

for more than one month, an ACTH (Adrenocorticotrophic hormone)-Test should be performed before beginning tapering of the steroid. The ACTH-test can detect deficient cortisol production in the body. If there is a deficiency, hydrocortisone should be used as a substitute.

### **Budesonide**

The benefits of glucocorticoid therapy should be carefully balanced against possible side-effects. Budesonide can reduce typical steroid side effects by a 90% first-pass metabolism in the liver and erythrocytes. Due to a special structural formulation, budesonide achieves the best anti-inflammatory effect in ileocecal inflammation<sup>[17-20]</sup>. Therefore, it is useful in therapy for Crohn's disease with ileocecal inflammation only. However, neither budesonide nor any other glucocorticosteroid should be used for a maintenance therapy due to the side-effects (e.g. Cushing-syndrome, osteoporosis or cardiomyopathy<sup>[21,22]</sup>). All patients treated with corticosteroids should additionally receive vitamin D and calcium substitution to avoid bone loss.

### **Immunosuppressives**

The clinical course of 36% of IBD patients is defined as steroid-refractory and in 20% as steroid-dependent<sup>[23]</sup>. Immunomodulators are, therefore, recommended for the treatment of chronic active IBD. Studies have shown an efficacy for immunosuppressives that is similar to azathioprine and its metabolite, 6-mercaptopurine (6-MP; 2-3 mg/kg per day, resp. 1-1.5 mg/kg per day), in the long-term use of chronic active disease. Immunomodulators have been shown to be efficient for the control of inflammation and remission maintenance. Only limited data exists on the efficacy of immunosuppressants in fistulizing Crohn's disease and the prevention of post-operative recurrence<sup>[24-30]</sup>. Evidence-based data is missing on the post-operative use of azathioprine and many IBD referral centers are using azathioprine for the prevention of post-operative recurrence. Prior to an initiation of treatment with azathioprine or 6-MP, patients should be thiopurine methyltransferase (TPMT) genotype assessed in order to detect for a homozygous deficiency in TPMT in an effort to avert AZA or 6-MP-induced potential adverse events. All patients on azathioprine or 6-MP should be monitored weekly in the first month and after that once a month regarding their white blood count and liver enzymes because a myelosuppression or an elevation of liver enzymes subsequent to the use of azathioprine or 6-MP can occur. In such cases, the dosage of azathioprine or 6-MP should be reduced or paused until lab values are normal. In patients with gastrointestinal side-effects after the intake of azathioprine, a change to 6-MP should be considered.

### **Methotrexate and cyclosporine**

Methotrexate is another immunomodulatory agent that is used in long-term treatment of IBD. The dosage for induction of remission in chronic active disease is 25 mg i.m. per week for 16 wk, followed by a maintenance treatment of 15 mg i.m. per week. In contrast to azathioprine and 6-MP, the data on use of methotrexate

is rather scarce<sup>[31-33]</sup>. Cyclosporine is reserved for the treatment of severe steroid-refractory ulcerative colitis only. Intravenous cyclosporine (2-4 mg/kg) was able to prevent a decided colectomy in two of three patients with severe ulcerative colitis. Due to its toxicity, use should be considered carefully; i.e. it should be used only in very severe active disease cases to avoid a colectomy. In Crohn's disease, cyclosporine has been shown to be effective only in fistulizing, but not luminal disease<sup>[34-37]</sup>.

### **Tacrolimus**

Only very inadequate data is available for tacrolimus. Improvement of fistula drainage, but not closure was demonstrated in a randomized, placebo-controlled trial with tacrolimus<sup>[38,39]</sup>.

### **Infliximab**

Biological therapies, especially anti-TNF agents, play a pivotal role in the treatment of chronic active IBD and fistulizing disease<sup>[40-43]</sup>. The first anti-TNF agent on the market, infliximab, is a chimeric IgG1 mouse/human monoclonal antibody. Randomised, placebo-controlled trials (ACCENT I and II) demonstrated the efficacy of infliximab (5 mg/kg, i.v.) in the induction of clinical response and remission in patients with active Crohn's disease. In fistulizing disease, complete fistula closure of at least 50% of the fistulas could be seen in 55% of the patients after three infusions of infliximab at wk 0, 2 and 6 (ACCENT II). Given on a regular basis in intervals of 8-12 wk (5 mg/kg i.v.), infliximab is able to maintain remission<sup>[44-50]</sup>.

In ulcerative colitis, the recently completed ACT I and ACT II randomised, placebo-controlled trials demonstrated the efficacy of infliximab treatment in induction of remission and mucosal healing in 61.2% of the infliximab treated patients *versus* 32.4% of placebo treated patients<sup>[51,52]</sup>.

Contraindications and side-effects should be taken into consideration carefully prior to infliximab therapy<sup>[53]</sup>. Due to immunogenicity, infliximab can lead to the formation of human anti-chimeric antibodies (HACA) in 30% to 75% of the patients. Additional administration of immunosuppressants; e.g. azathioprine and/or pretreatment with intravenous prednisolone, can reduce the risks of HACA formation. The main reported side-effect is an infusion reaction, which can occur as an acute allergic/anaphylactic reaction or a delayed hypersensitivity reaction. In clinical trials, observations have included infections, drug-induced lupus, cardiac failure, non-Hodgkin's lymphoma and, in post-marketing surveillance, tuberculosis, pneumonia, histoplasmosis, listeriosis and aspergillosis. To avoid a potential tuberculosis reactivation, a purified protein derivative (PPD) skin test and a chest-X-ray should be performed prior to infliximab treatment<sup>[54-67]</sup>. Patients with perianal or enterocutaneous fistulizing Crohn's disease should be treated first with infliximab. The effect of infliximab is not as effective on entero-enteral or recto-vaginal fistulas. Patients with steroid-refractory or chronic active Crohn's disease or ulcerative colitis who do not respond to immunosuppressive therapy alone should also be treated with infliximab. The recommended

treatment regimen is an induction scheme with three infusions (5 mg/kg i.v.) at 0, 2 and 6 wk, followed by a maintenance treatment of infliximab every 8 wk (5 mg/kg i.v.). Additionally, immunosuppressive therapy with azathioprine, for example, is recommended. HACA testing is not recommended routinely for every patient on infliximab, but it is recommended if there is a delayed hypersensitivity reaction or if the last infliximab infusion was more than 12 wk previous.

### **Adalimumab**

Other TNF agents also showed efficacy in Crohn's disease. The human IgG1 antibody adalimumab, which is a therapeutic agent used for rheumatoid arthritis, was effective in open-label experience. A placebo-controlled, randomised trial was also conducted. One advantage, in comparison to infliximab, might be the completely human structure of the antibody, which leads to better tolerance and a subcutaneous route of administration. Data on adverse reactions in Crohn's disease patients are still not available, but adalimumab is well-tolerated in patients with rheumatoid arthritis<sup>[68-71]</sup>.

### **CDP-870**

Certolizumab pegol (CDP-870), which is a polyethylene-glycolated Fab-fragment of the anti-tumour necrosis factor, has been shown to be effective in the treatment of Crohn's disease in a recent published, randomised, placebo-controlled trial. At week ten, 52.8% of the certolizumab (400 mg) treated patients showed a clinical response versus 30.1% in the placebo treated group (the high placebo response was seen in a large patient subgroup with low C-reactive protein levels; this might have been due to statistical separation between treatment and placebo group<sup>[72]</sup>). The antibody was well tolerated. Ongoing trials, however, are necessary to establish efficacy in Crohn's disease.

### **CDP-571**

CDP-571, which is a humanized IgG4 monoclonal antibody against tumour necrosis factor alpha, initially showed an induction of clinical response in controlled trials, but failed in a phase III trial which was discontinued<sup>[73]</sup>.

### **Onercept and eterncept**

Onercept, which is a recombinant human p55 soluble receptor to TNF, and also eterncept, which is a recombinant human p75 soluble receptor to TNF, failed in a phase II trial with Crohn's disease and both trials were discontinued<sup>[74-76]</sup>.

### **Natalizumab**

Adhesion molecule inhibiting agents, such as natalizumab, which is a humanized IgG4 antibody, demonstrated a clinical response in a clinical trial in Crohn's disease, but all trials had to be stopped immediately after cases of progressive multifocal leucoencephalopathy in patients receiving natalizumab for multiple sclerosis were reported<sup>[77-79]</sup>.

The antisense oligonucleotide of the adhesion

molecule ICAM-1 (anti-ICAM-1) was ineffective in Crohn's disease<sup>[80]</sup>.

A hopeful, novel approach for the treatment of Crohn's disease is an anti-IL-12/IL-23p40 antibody that proved effective for induction of response and remission in a phase II study<sup>[81]</sup>.

### **$\beta$ -Interferon**

The use of  $\beta$ -Interferon, which has been investigated in a small pilot study in ulcerative colitis with a subcutaneous administration, seems to be effective, but larger, randomised, placebo-controlled studies need to be performed to clarify the clinical efficacy<sup>[82]</sup>.

In conclusion, the only biological therapeutic today, which has been proven effective in IBD and is available on the market is infliximab. The market release of new TNF agents might happen in the near future.

### **Probiotics**

A different group of therapeutic agents for therapy of IBD are probiotics. The use of probiotics has been advocated in colonic inflammatory disease for a long time. Only recently, two controlled trials demonstrated that *E. coli* nissle is as effective as 5-ASA for remission maintenance in ulcerative colitis<sup>[83,84]</sup>. For remission maintenance and pouchitis, studies demonstrated the benefit of probiotics<sup>[85,86]</sup>. Due to a better understanding of the molecular events and the pathophysiological processes of this disease, it is hoped that more probiotic agents will be developed in the near future.

### **5-ASA**

A short, practical guideline would be incomplete without discussing IBD and pregnancy. 5-ASA is not harmful during pregnancy and there is very little placental transport. 5-ASA should be avoided during breast feeding because there are no studies on 5-ASA use during breast feeding<sup>[87]</sup>. Acute disease or a flare up of IBD can be treated throughout an entire pregnancy with steroids. Glucocorticoids pass the placental barrier, but there has been no significant evidence of teratogenesis. There have been some observations of cleft lip and palate associated with the intake of steroids. In general, no increase in fetal complications have been found with use of 5-ASA compared to the general population<sup>[88]</sup>.

### **Azathioprine or 6-mercaptopurine**

The use of azathioprine or 6-mercaptopurine should not be completed during pregnancy. Extensive experience with use of these substances during pregnancy exists with other autoimmune diseases and patients who received renal transplants. No teratogenic effects in humans have been reported so far. However, it is very important to discuss all the data and possible complications with the patient and it is essential that the decision to take the drug should be made by the patient<sup>[89]</sup>.

Methotrexate is contraindicated during pregnancy as it is mutagenic and teratogenic<sup>[90]</sup>. Cyclosporine is not teratogenic, but due to its side-effects, it needs to be considered very carefully and should only be used to avoid a colectomy<sup>[91]</sup>. Infliximab should not be given as

maintenance therapy during pregnancy. In very severe disease, it can be considered as an emergency therapy<sup>[92]</sup>. Nutrition has not been discussed in this article so far. However, the balance of trace elements and vitamins is essential for successful therapy. Vitamin B12 and folic acid, for example, should be monitored in Crohn's disease patients with ileal inflammation to avoid a deficiency syndrome, which can lead to severe anemia. Also ferritin should be monitored and, if necessary, substituted orally or intravenously to avoid severe iron deficiency anemia. In severe cases of iron deficiency anemia, erythropoietin (10000IE s.c. 3 times per week) plus iron i.v. (62.5 mg in 250 mL NaCl) is effective<sup>[93]</sup>. In severe ulcerative colitis or Crohn's disease, patients profit from short term parenteral or additional high calorie nutrition<sup>[94]</sup>.

All above treatment regimens attempt to avoid complications and inflammation in IBD. However, all conservative therapy sometimes fails or is not effective enough. Examples might be therapy for refractory ulcerative colitis, which can only be successfully treated by an operation (e.g. a colectomy with an ileoanal pouch anastomosis), non-inflammatory stricture in Crohn's disease or severe fistulizing disease, in which a protective ileostoma can be very useful for supporting conservative treatment. In such cases, close collaboration with an experienced IBD surgeon is essential.

It can be summarized that although a number of new biological agents have been developed in the last decades for the treatment of IBD, there is still a great need for new pharmacotherapeutics, particularly for chronic refractory disease patients with multiple complications.

## Abstract

Celiac disease (CD) is a common autoimmune disorder characterized by an immune response to ingested gluten and has a strong HLA association with HLA-DQ2 and HLA-DQ8 molecules, but human HLA-DQ risk factors do not explain the entire genetic susceptibility to gluten intolerance. CD is caused by the lack of immune tolerance (oral tolerance) to wheat gluten. In this sense, the expression of soluble HLA-G in CD is of special interest because the molecule plays an important role in the induction of immune tolerance. The enhanced expression of soluble HLA-G found in CD may be part of a mechanism to restore the gluten intolerance. In this editorial, we review recent progress in understanding CD in relation to its prevalence, diagnosis and possible mechanisms of pathogenesis.

## INTRODUCTION

Celiac disease (CD) is a chronic inflammatory disease which develops in genetically predisposed individuals. CD is a T cell-mediated inflammatory disorder with autoimmune features and it has environmental and immunologic components<sup>[1,2]</sup>. It is characterised by an immune response to ingested wheat gluten and related proteins of rye and barley that leads to inflammation, villous atrophy and crypt hyperplasia in the proximal

part of the small intestine<sup>[2,3]</sup>. The common presentation symptoms and signs of CD include diarrhea, abdominal distention, abdominal pain, weight loss, fatigue, and malnutrition.

The clinical classification of CD is based on the presence or lack of gastrointestinal symptoms: "classical" or "symptomatic" CD refers to presentations with diarrhea and with malabsorption syndrome, whereas "atypical" or "asymptomatic" form has no gastrointestinal manifestations<sup>[4]</sup>. CD is defined as silent when the typical enteropathy is found in patients who apparently are healthy. Potential CD refers to a risk for developing a typical CD later in life; the patients have Endomysial antibody (EMA) and tissue transglutaminase (tTG) antibodies with HLA DQ2 or DQ8 predisposing genotype<sup>[6,7]</sup>, and normal or minimal abnormal mucosa. Finally, a specific manifestation of CD is refractory sprue defined as symptomatic, severe villous atrophy with increased intraepithelial lymphocytes (IELs) despite maintenance of a strict gluten-free diet<sup>[5]</sup>.

Although there have been major advances in our knowledge of the disease, there are few advances in the therapy. The only accepted treatment for CD is a nutritional therapy with a gluten-free diet for lifelong<sup>[8]</sup>. Here, we review recent advances in our understanding of CD with respect to its prevalence and diagnosis, and possible mechanisms underlying the gluten intolerance.

## PREVALENCE

CD is the most common food-sensitive enteropathy in humans. The prevalence is estimated in the range of 1:100 to 1:300 in North America and Europe<sup>[9,10]</sup>. Recently, it has become clear that CD is much more prevalent than previously thought. We observed in our pediatric population (south-east of Spain) a 1:75 prevalence, which is in good agreement with the studies by Fasano et al<sup>[9]</sup> and Ciclitira et al<sup>[10]</sup> showing a prevalence of 1:133 in the United States and 1:100 in Europe, respectively.

At the present time, the form of clinical presentation of CD is changing. In our experience, CD is a very common disorder, and most affected individuals have the atypical and silent forms of the disease, which are also the prevalent forms of disease presentation in our population. Indeed, we observed a more elevated percentage of patients associated with HLA-DQ8 molecule in CD (around 20%-25%) than have been described previously by other studies, which estimated the percentage of HLA-DQ8 patients to be about 10%<sup>[11]</sup>. Furthermore, the HLA-DQ8 CD patients are commonly associated with extraintestinal symptoms presentations, and are frequently

Table 1 Clinical manifestations of untreated celiac disease

Manifestations	Associated diseases	Genetic associated diseases
<b>Classic symptoms:</b>	Autoimmune diseases:	Down syndrome

Vomiting	Intestinal adenocarcinoma	
Inflammatory bowel disease	Non-Hodgkin lymphoma	
Migraine headaches		

associated with others autoimmune diseases (unpublished results).

## DIAGNOSIS

We believe that the current diagnostic criteria for CD need a revision. CD is often missed during diagnosis because many individuals do not present the disease with the classical gastrointestinal symptoms. In fact, the percentage of undiagnosed population has markedly increased, and significant risks and complications are associated with untreated CD (Table 1).

As a multi-factorial disorder, CD may present highly diverse clinical manifestations<sup>[12]</sup>. CD patients typically display extraintestinal (non-classical) symptoms or lack classical gastrointestinal symptoms such as diarrhea, abdominal pain, distention, or weight loss. In our pediatric population, the non-classical symptoms are often the most common presentation in newly diagnosed CD cases. These include autoimmune alopecia, iron deficiency, or elevated levels of liver transaminases, and they often may be the only manifestation of CD in an affected individual (Table 1).

In our experience, small bowel biopsy is critical for diagnosing symptomatic patients with negative serology for CD and with HLA compatible with the disease. Although we consider intestinal biopsy as the gold standard for CD diagnosis, in many occasions the permission for intestinal biopsy is refused. Both serologic tests and genetic study are necessary to select subjects who need intestinal biopsy (Table 2).

CD is more common in certain risk groups. Family members of known celiac patients represent the most important group of study patients. The determination of HLA typing as a first step is useful as it would exclude approximately one third of first degree relatives in a CD family. We found a high prevalence of CD between

relatives, and the highest percentage was observed among daughters. The CD relatives are a population at high risk of developing gluten intolerance and we propose that an extensive study of such group should be undertaken. It is noteworthy that after the first diagnosis of CD, the family will become more self-aware in recognizing early symptoms related to the disease.

## PATHOGENESIS

A defect in antigen processing by epithelial cells, together with the intrinsic properties of the gliadins, as well as the HLA-DQ haplotype of the individual are considered the principal factors involved in the pathogenesis of CD<sup>[3]</sup>. CD is strongly associated with HLA class II genes that map to the DQ locus. It has been shown that CD is associated with the expression of HLA-DQ2 and HLA-DQ8<sup>[6,7]</sup>. Several studies found that the majority of celiac patients carry DQ2 (DQA1\*05/DQB1\*02), with the remaining patients displaying an association with DQ8 (DQA1\*0301/DQB1\*0302). Collectively, these HLA genes confer up to 40% of the genetic risk for CD development.

Gliadin peptide presentation and T-cell activation are critical events in the pathogenesis of CD. Gluten peptides are not fully digested by the action of gastric, intestinal and pancreatic enzymes in CD patients. A 33-mer peptide was isolated and identified as the primary initiator of the inflammatory response to gluten in celiac patients<sup>[16]</sup>. This peptide reacted with tissue transglutaminase (tTG), the major autoantigen in CD that deamidates certain glutamine residues of gluten to glutamic acid. This in turn produces a negative charge that favours binding and presentation by HLA-DQ2 and DQ8 molecules, which are responsible for T-cell activation and subsequent production of cytokines, leading to tissue damage<sup>[17,18]</sup>. The inappropriate CD4+ T-cell activation in the lamina propria commonly observed in CD is triggered by specific gluten peptides bound to DQ2 and DQ8 heterodimers on the surface of antigen presentation cells<sup>[2,6]</sup>. The mucosal intestinal lesion is believed to be mainly induced by the production of IFN-gamma from these gluten specific T cells<sup>[1,2]</sup>. Moreover, changes in intestinal permeability, secondary to alterations in intercellular tight junctions or in the processing of the food antigen, have also been recently implicated in the loss of tolerance to gluten<sup>[19]</sup>.

### Immune (oral) tolerance

The gut immune system is exposed to a wide variety of antigens derived from foods, resident bacteria and invading microorganisms. Oral tolerance is a physiological condition characterized by induction of immune unresponsiveness toward intestinal alimentary and bacterial antigens of the intestinal flora. Multiple cellular and molecular mechanisms are involved in the regulation of this fundamental property of the gut immune system<sup>[20]</sup>.

CD is the most common food-sensitive enteropathy in humans and is caused by the lack of immune tolerance (oral tolerance) to wheat gluten and the prolamins fractions of rye and barley. Many different gluten peptides recognized by intestinal T cells have been identified<sup>[21]</sup>. The activation

Table 2 Diagnosis in celiac disease

Diagnostic criteria used in celiac disease	Diagnostic propose for celiac disease	Comments
Serological test: Tissue transglutaminase antibody (tTGA) Endomysial antibody (EMA) Gliadin antibodies (AGA) Total IgA	With classical symptoms: Serological test: Tissue transglutaminase antibody (tTGA) Endomysial antibody (EMA) Gliadin antibodies (AGA)	Positive serology supports a diagnosis of CD, but they are not essential. Compatible with HLA-DQ2/D8 testing and identify individuals for further biopsy evaluation. Small bowel biopsy is critical in symptomatic patients with negative serology for CD and with HLA compatible with the disease
Endoscopy	HLA-DQ2/DQ8 testing	Determination of HLA typing as a first step in diagnosis in CD family
	Capsule endoscopy (with adequate pathological interpretation) Without classical symptoms HLA-DQ2/DQ8 testing	Adequate number of biopsies and well oriented. Estimate lymphocyte infiltration and partial or total villus atrophy  Primordial role of HLA-typing if serology is negative and with biopsy refused or equivocal to identify individuals
	Serologic test: Tissue transglutaminase antibody (tTGA) Endomysial antibody (EMA) Gliadin antibodies (AGA)	Adequate number of biopsies and well oriented. Estimate lymphocyte infiltration and partial or total villous atrophy
	Capsule endoscopy (with adequate pathological interpretation)	

of these gluten-reactive T cells represents a key event in the pathogenesis of CD<sup>[1,2]</sup>. The mucosa of CD patients is characterized by a high proportion of intraepithelial T cells bearing gamma-delta chain of the antigenic T cell receptors ( $\gamma\delta$  IEL)<sup>[22]</sup>.

Ingested gliadin, the triggering agent of the disease, can cross the epithelial barrier and elicit a harmful T cell-mediated immune response. Dendritic cells are supposed to play a pivotal role in shaping the immune response<sup>[23]</sup>. Immature dendritic cells are characterised by low levels of MHC class II expression and co-stimulatory molecules and can mediate tolerance presumably by induction of T regulatory cells (Treg cells)<sup>[24]</sup>. Moreover, IL-10 released by Treg cells can modulate the function of immature dendritic cells and inhibit their differentiation, amplifying the local presence of "tolerizing dendritic cells"<sup>[25]</sup>. IL-10-modulated dendritic cells induce anergy of effector T cells through still undefined mechanisms requiring cell-cell contact.

Therefore, the direction of the immune response toward immunity or tolerance depends on the stage of maturation and the functional properties of the dendritic cells. Gliadin peptides can contribute to overcoming the stage of unresponsiveness of immature dendritic cells by inducing phenotypic and functional dendritic cell maturation, resulting in more efficient processing and presentation of gliadin peptides to specific T lymphocytes<sup>[26]</sup>.

### HLA-G: molecule of immune tolerance

HLA-G is a non-classical major histocompatibility complex class I molecule selectively expressed at the maternal-foetal interface on cytotrophoblast cells, protecting the fetus from the maternal immune rejection, and creating a general state of tolerance<sup>[27]</sup>. HLA-G exhibit tolerogenic properties via interaction with inhibitory receptors presented in natural killer (NK) cells, T cells and antigen-presenting

cells (APC)<sup>[28]</sup>.

The presence of soluble HLA-G (sHLA-G) in the cerebrospinal fluid of multiple sclerosis<sup>[29]</sup> and allograft acceptance after transplantation<sup>[30]</sup> suggests a tolerogenic function for this molecule against innate and adaptive cellular immune responses. Interestingly, work from our lab and others have suggested that HLA-G antigens may play a protective role in inflammation<sup>[31,32]</sup>. Further analysis revealed that, sHLA-G molecules inhibit lytic activity of NK cells, induce apoptosis of CD8+ CTLs and affect CD4+ alloproliferation<sup>[33]</sup>. Thus, the immune modulatory properties of sHLA-G may suggest a potentia role in CD.

We have demonstrated an association of CD with sHLA-G expression (Figure 1A) and we found a correlation between increased levels of sHLA-G expression and CD associated with other autoimmune diseases, being dependent on a genetic link of these diseases through HLA genes<sup>[34]</sup>.

The expression of soluble HLA-G in CD is of special interest because its molecule plays an important role in the induction of immune tolerance<sup>[35]</sup>. We propose that the enhanced expression of sHLA-G found in CD could be part of a mechanism to restore the gluten intolerance. HLA-G may act through inhibitory receptor (ILT) interactions that lead to development of tolerogenic dendritic cells with the induction of anergic and immunosuppressive T cells, and an arrest of maturation/activation of dendritic cells. The expression of these ILT receptors on dendritic cells is tightly controlled by inflammatory stimuli, and by cytokines<sup>[36]</sup>.

Thus, a powerful anti-inflammatory response to gliadin might occur during the development of the disease with uncontrolled production of HLA-G and anti-inflammatory cytokines, such as IL-10 and TGF-beta, which counteract the inflammation and/or may cause recruitment of intraepithelial lymphocytes, maintaining the intestinal lesions presented in CD<sup>[34]</sup>.

**Figure 1** Immunohistochemistry analysis in celiac patients. **A:** Immunohistochemical staining for HLA-G in the Lieberkühn crypts; **B:** Immunohistochemical staining for IL-10 at the lamina propria level; **C:** Immunoreaction for TGF-beta in areas of infiltrated inflammatory cells. Arrows and asterisks: cells showing immunoreactivity (x 200).

### Cytokines

The characteristics of an intestinal inflammatory response depend on the cytokines produced during this response. The production of cytokines from T cells and macrophages is of potential importance for the histological lesions that appear in CD. The CD lesions are associated with a marked infiltration of Th1 cells dominated by the synthesis of the pro-inflammatory cytokines, IFN-gamma and TNF-alpha<sup>[37]</sup>. IL-15 also has an important role in CD, because it orchestrates intraepithelial lymphocytes changes in the disease. Certain parts of gluten may stimulate the innate part of the immune system, and IL-15 is a central player in this immune response-induced by gluten, inducing the activation of IEL in CD<sup>[38]</sup>. Engineered IL-15 over-expression by epithelial cells in the intestine leads to a massive expansion of CD8+ intestinal T cells accompanied by a CD-like enteropathy<sup>[39]</sup>. Furthermore,

**Table 3** Future directions in celiac disease

Unanswered questions	Future directions
Immunopathogenesis	
How is oral tolerance broken?	Restoring immunological tolerance to gluten would represent the ideal cure for CD
Gluten-specific T cells	Gluten-specific T cells could be inactivated or deleted, tolerance to gluten should be restored
Diagnosis	
What is the significance of the vast number of currently undiagnosed people with the disease?	The rate of the diagnosis will continue to increase with better diagnosis.
What is the significance of the increase number of people with extraintestinal symptoms or without classical symptoms in CD?	"the suspicion of the disease"
Genetics	
Identify the genetic risk factors that predispose to CD	Polymorphic genes located in the MHC region and CD Genetic polymorphism of cytokine genes may influence the risk of CD Associated polymorphism with serological markers HLA-G polymorphism?

IL-15 induces the expression of MICA, the epithelial ligand of NKG2D<sup>[40]</sup>.

We found in the celiac patients increased levels of anti-inflammatory cytokines IL-10 and TGF-beta at the lamina propria level in biopsy samples of patients with villous atrophy and elevated lymphocyte infiltration (Figure 1B and C). IL-10 predominantly acts as a potent anti-inflammatory factor and a suppressive agent for Th1 responses<sup>[41]</sup>. TGF-beta is a major factor for the production of immunoglobulin A (IgA) and acts as a potent mediator of the tissue repair<sup>[42]</sup>. Interestingly, tTG, described as the major endomysial autoantigen in CD, is necessary for the activation of TGF-beta<sup>[43]</sup>. The elevated levels of IL-10 and TGF-beta are insufficient for the inhibition of the autoimmune reaction, and would modulate the immune response and induce the activation of B lymphocytes. These cytokines may play important roles in inducing HLA-G. In this regard, the possible role of IL-10 in inducing HLA-G protein expression has been already previously described in CD<sup>[34]</sup>.

### FUTURE DIRECTIONS

There are many unanswered questions about CD. What is responsible for the collapse of CD oral tolerance? Restoring immunological tolerance to gluten would represent the ideal way to treat or cure this disease. However, if gluten-specific T cells could be inactivated or deleted, tolerance to gluten should be restored. What is the significance of the vast number of currently undiagnosed people with the disease? What is the significance of the increased number of people with extraintestinal symptoms

or without classical symptoms in CD? As we anticipate that the rate of the diagnosis will continue to increase, it will be important to further our understanding of the pathogenesis of CD and improve its diagnosis (Table 3). The diversity of the clinical presentation in CD can complicate the diagnosis and delay the treatment initiation. In our experience, the most important diagnostic test in CD is "the suspicion of the disease". The screening of CD should start with a serologic test (for IgA and IgG anti-endomysial and anti-tTG antibodies), and HLA typing. If the patient is genetically compatible with the disease (even with negative serology), a confirmatory small biopsy by capsule endoscopy should be followed.

Recently, many efforts have been made to identify the genetic risk factors that predispose to CD. The lack of immune tolerance in CD could occur due to genetic polymorphisms in any of the non-MHC molecules involved in the induction, regulation or expression of mucosal immune responses, such as IL-10, TGF-beta, IFN-gamma. Most of these polymorphisms affect gene transcription influencing the individual susceptibility to CD<sup>[44]</sup>. In addition, several associations between different polymorphic genes located in the MHC region and CD have been reported<sup>[45]</sup>. Furthermore, we found evidence that HLA-G is an interesting candidate as susceptibility gene in CD. These findings should open new perspectives for the identification of genetic susceptibility to CD.

### Abstract

**AIM:** To investigate the effect of (-)-epigallocatechin-3-gallate (EGCG) on growth of gastric cancer and its possible mechanism.

**METHODS:** Heterotopic tumors were induced by subcutaneously injection of SGC-7901 cells in nude mice. Tumor growth was measured by calipers in two dimensions. Tumor angiogenesis was determined with tumor microvessel density (MVD) by immunohistology. Vascular endothelial growth factor (VEGF) protein level and activation of signal transducer and activator of transcription 3 (Stat3) were examined by Western blotting. VEGF mRNA expression was determined by RT-PCR and VEGF release in tumor culture medium by ELISA. VEGF-induced cell proliferation was studied by MTT assay, cell migration by gelatin modified Boyden chamber (Transwell) and *in vitro* angiogenesis by endothelial tube formation in Matrigel.

**RESULTS:** Intraperitoneal injection of EGCG inhibited the growth of gastric cancer by 60.4%. MVD in tumor tissues treated with EGCG was markedly reduced. EGCG treatment reduced VEGF protein level *in vitro* and *in vivo*. Secretion and mRNA expression of VEGF in tumor cells were also suppressed by EGCG in a dose-dependent manner. This inhibitory effect was associated with reduced activation of Stat3, but EGCG treatment did not change the total Stat3 expression. EGCG also inhibited VEGF-induced endothelial cell proliferation, migration and tube formation.

**CONCLUSION:** EGCG inhibits the growth of gastric

### INTRODUCTION

Gastric cancer is the leading cause of cancer-related death in most countries, but the incidence has steadily decreased throughout the world in recent decades<sup>[1]</sup>. Although the exact reason for the decline is uncertain, it was reported that dietary factors play a role<sup>[2]</sup>. Epidemiological studies showed that regular drinking of green tea significantly reduces the occurrence and mortality of many types of cancer<sup>[3]</sup>. Case-control studies have provided evidence for protective effect of green tea against gastric cancer<sup>[4]</sup>. Experiment and animal model studies also demonstrated that green tea and its components have anti-cancer effect against gastric cancer<sup>[5,6]</sup>, but conclusive results are not available at present<sup>[7]</sup>.

(-)-Epigallocatechin-3-gallate (EGCG) is the most abundant and active component of green tea, and the beneficial properties of green tea appear to be ascribed to EGCG. The effect of EGCG on cell proliferation and apoptosis has been well established. EGCG suppresses tumor growth by inhibiting proliferation and inducing apoptosis through a variety of mechanisms<sup>[8]</sup>. Recent studies showed that EGCG has anti-angiogenic property and reduces tumor growth in mouse model by inhibiting angiogenesis<sup>[9,10]</sup>. Angiogenesis, the growth of new blood vessels from preexisting capillaries, is necessary for solid tumor growth and metastasis. Angiogenesis is initiated by the release of certain angiogenic factors from tumor cells. Vascular endothelial growth factor (VEGF), which has

been shown to be the most potent angiogenic factor, is associated with tumor-induced angiogenesis. Angiogenesis is closely associated with progression and prognosis of gastric cancer, and VEGF expression is a predictive and prognostic factor of gastric cancer<sup>[11]</sup>. Anti-angiogenic therapy targeting VEGF can inhibit growth and metastasis of gastric cancer<sup>[12]</sup>. However, whether EGCG suppresses growth of gastric cancer by anti-angiogenesis remains to be elucidated.

In this study, we investigated the effect of EGCG on angiogenesis and growth of gastric cancer with an *in vitro* and *in vivo* model. Data reported here show that EGCG suppresses growth of gastric cancer by reducing VEGF production and VEGF-induced angiogenesis.

## MATERIALS AND METHODS

### Cell culture

Human gastric cancer cells (SGC-7901 cells, Cell Bank of Sun Yat-Sen University, Guangzhou, China) were maintained in Dulbecco's modified Eagle's medium (DMEM) supplemented with 10% (v/v) fetal bovine serum (FBS, Gibco BRL, Gaithersburg, MD) and incubated at 37°C in a humidified incubator containing 50 mL/L CO<sub>2</sub>. Human umbilical vein endothelial cells (HUVECs) were prepared from fresh human umbilical cord and grown in human endothelial-serum free medium (endothelial-SFM, Gibco BRL, Gaithersburg, MD) supplemented with 10% FBS, 100 U penicillin, streptomycin and fungizone, and incubated at 37°C in a humidified incubator containing 50 mL/L CO<sub>2</sub>. To maintain uniform conditions, all experiments were carried out between cell passages 4-6.

### Tumor growth assay

SGC-7901 cells ( $5 \times 10^6$  cells/0.2 mL) in SFM were inoculated subcutaneously into the dorsal area of 6-8-wk female BALB/c nude mice, weighing 18-22 g (Experimental Animal Center of Sun Yet-Sen University, Guangzhou, China). When tumors reached a volume of 50 mm<sup>3</sup>, intraperitoneal injection of EGCG was carried out at the dosage of 1.5 mg/d per mouse ( $n = 6$ ). The control group ( $n = 6$ ) was treated with the same volume of PBS. Tumor growth was monitored by external measurement in two dimensions every other day with calipers. Tumor volume was determined according to the equation:  $V = (L \times W^2)/2$ , where V is volume, L is length and W is width. Twenty-eight days after EGCG injection, all animals were sacrificed, tumors were excised and weighed. The tumor inhibition ratio was calculated as follows: inhibition ratio (%) =  $[(C-T)/C] \times 100\%$ , where C is the average tumor weight of the control group and T is the average tumor weight of the EGCG-treated group. Some tumor tissues were frozen at -80°C for Western blot analysis and others fixed in 4% formaldehyde for immunohistochemistry analysis.

All animal studies were performed according to the guides for the Care and Use of Laboratory Animals approved by Sun Yat-Sen University.

### Determination of tumor microvessel density

Histologic 4-μm thick sections prepared from form-

aldehyde fixed and paraffin embedded tumor tissues were used for immunohistochemical analysis. After deparaffinization, rehydration, antigen retrieval and blocking of endogenous peroxidase, the specimens were incubated overnight at 4°C with goat polyclonal anti-CD34 antibodies diluted at 1:100 (Santa Cruz Biotechnology, Santa Cruz, CA, USA). The sections were rinsed and incubated with peroxidase-conjugated second antibody followed by enzyme conjugate (HRP-streptavidin). Microvessels were revealed with diaminobenzidine (DAB) and the sections were counterstained with Mayer's hematoxylin. In negative-control staining, the primary antibodies were omitted. Tumor vasculature was quantified by the Weidner's method<sup>[13]</sup>. The area of tumor containing the maximum number of microvessels to be counted was identified by scanning the entire tumor at low power (100 ×). The number of highlighted vessels from 3 fields was then counted in this area at high power (200 ×).

### Western blot analysis

SGC-7901 cells were seeded in 90 mm plates and cultured in growth medium until 70%-80% confluence. The culture medium was replaced with SFM supplemented with different concentrations of EGCG (0, 5, 10, 20, and 40 μmol/L). The cells were incubated for another 24 h. Total protein from cell lysates and tumor tissue homogenizations was extracted with mammalian cell lysis kit (Bio Basic Inc., Ontario, Canada). Protein levels were quantified with Bio-Rad protein assay kit (Bio-Rad Laboratories, Richmond, CA). Total protein (100 μg) was separated in 12% SDS-PAGE, and transferred onto PVDF membrane (Invitrogen, Carlsbad, CA, USA). The membrane was blocked with 5% skim milk and incubated at 4°C overnight with rabbit polyclonal anti-VEGF antibody (Santa Cruz Biotechnology, Santa Cruz, CA, USA), rabbit polyclonal anti-Stat3 antibody (Santa Cruz Biotechnology, Santa Cruz, CA, USA), or goat polyclonal anti-p-Stat3 antibody (Phospho-Stat3 [tyr-705], Santa Cruz Biotechnology, Santa Cruz, CA, USA). After washing three times with 0.1% Tween 20 in Tris-saline, the membranes were incubated with biotin-labeled anti-rabbit or anti-goat IgG for 1 h at room temperature with agitation. The probe proteins were detected using enhanced chemiluminescence system (Amersham International, Piscataway, N.J., USA).

### Measurement of VEGF in supernatant by ELISA

The effect of EGCG on VEGF release in tumor cells was measured by ELISA. SGC-7901 cells seeding in 90 mm plates were cultured until 70%-80% confluence. The cells were washed three times with PBS and the culture medium was replaced with SFM. EGCG was added to the medium to various concentrations (0, 5, 10, 20 and 40 μmol/L) and incubated with the cells for 24 h. The conditioned medium was harvested and centrifuged. VEGF concentration in the supernatant was measured using a VEGF ELISA kit (R & D systems, Minneapolis, Minn., USA).

### RT-PCR analysis

SGC-7901 cells were seeded in 90 mm plates and cultured in growth medium until 90% confluence. The culture medium was replaced with SFM supplemented

with EGCG at different concentrations (0, 5, 10, 20 and 40  $\mu\text{mol/L}$ ). The cells were incubated for another 24 h. Total RNA was extracted from the cell lysates. The levels of human VEGF cDNAs were evaluated by RT-PCR and normalized by the levels of human cytoplasmic  $\beta$ -actin. Reverse transcription was performed with 1  $\mu\text{g}$  total RNA and 100 pmol random hexamers in a total volume of 20  $\mu\text{L}$  to produce first-strand cDNA. PCR experiments were performed with 1  $\mu\text{L}$  of the first-strand cDNA in a 50  $\mu\text{L}$  reaction mixture. Human VEGF cDNA was amplified with specific primers (sense primer: 5'TGC ATT CAC ATT TGT TGT GC 3'; antisense primer: 5'AGA CCC TGG TGG ACA TCT TC-3', a 200 bp product) and  $\beta$ -actin specific primers (sense primer: 5'-TCA TCA CCA TTG GCA ATG AG-3'; antisense primer: 5'-CAC TGT GTT GGC GTA CAG GT-3'; a 150 bp product). Amplification conditions were as follows: denaturation at 94°C for 1 min, annealing at 60°C (for  $\beta$ -actin at 55°C) for 1 min, and extension at 72°C for 1 min. All PCRs were linear up to 30 cycles.

#### Cell proliferation assay by MTT assay

The effect of EGCG (Sigma, St. Louis, MO., USA) on endothelial cell proliferation induced by VEGF was determined by MTT assay (Sigma, St. Louis, MO., USA). Briefly,  $2.5 \times 10^4$  HUVECs were plated in 24-well plates pre-coated with 2.0% gelatin in triplicate and cultured overnight in growth medium. Then the culture medium was changed with endothelial-SFM supplemented with 2% FBS and 20 ng/mL recombinant human vascular endothelial growth factor (hrVEGF; R & D Systems, Minneapolis, Minn., USA) in the presence of EGCG at various concentrations (0, 5, 10, 20 and 40  $\mu\text{mol/L}$ ). The viable cells were quantified by MTT assay at indicated time point following the manufacturer's instructions.

#### Cell migration assay

Endothelial cell migration induced by VEGF was assessed using a modified Boyden chamber (8  $\mu\text{mol/L}$  pores, Transwell®; Corning Costar Corp., Cambridge, MA). The transwell inserts were coated with 2.0% gelatin. HUVECs were treated with EGCG at various concentrations (0, 5, 10, 20 and 40  $\mu\text{mol/L}$ ) for 24 h. Cells were harvested by trypsinization, washed twice with PBS, and resuspended in endothelial-SFM containing 2% FBS and EGCG at the indicated concentrations. Then the treated cells were added to the upper chamber at  $2 \times 10^5$  cells per well and 0.6 mL endothelial-SFM containing 2% FBS and 20 ng/mL VEGF was added to the bottom chamber. After 4-h incubation at 37°C, cells on the upper surface of the membrane were mechanically removed, and the migrated cells on the lower surface of the membrane were fixed and stained with hematoxylin. The average number of migrated cells from 5 randomly chosen fields ( $\times 200$ ) on the lower surface of the membrane was counted. Each experiment was performed in triplicate.

#### Tube formation assay

Matrigel was thawed at 4°C in an ice-water bath, and 300  $\mu\text{L}$ /well was carefully added to a pre-chilled 24-well plate using a cold pipette. Matrigel was allowed to

**Figure 1** Inhibition of growth of human gastric cancer xenografts in an athymic mouse model. **A:** tumor tissues treated with EGCG or PBS on d 28 after treatment; **B:** an average of 60.4% suppression of primary tumor growth in the EGCG treatment group compared with control group; **C:** tumor growth suppression curve: volumes of EGCG treatment group versus PBS treatment group on indicated days. Data are presented as mean  $\pm$  SE ( $n = 6$ , <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$ ).

polymerize for 1 h at 37°C. After polymerization,  $5 \times 10^4$  cells/well in endothelial-SFM with 2% serum, 20 ng/mL VEGF and EGCG at different concentrations (0, 5, 10, 20 and 40  $\mu\text{mol/L}$ ) was layered on top of polymerized gel. Cells were incubated for 48 h and photographed. For quantification of tube formation, the total length of tubes formed in a unit area was measured using an NIH Image program.

#### Statistical analysis

Student's *t* test was used in all statistical analyses.  $P < 0.05$  was considered statistically significant.

## RESULTS

### EGCG suppressed growth of human gastric cancer xenografts in athymic mice

To evaluate the effect of EGCG on tumor growth, tumor xenografts were created by implanting SGC-7901 cells into the dorsal area of athymic mice. Nine days after implantation, tumors reached a size of 50 mm<sup>3</sup>. The mice were randomized into two groups and received intraperitoneal injection of EGCG or PBS, respectively. EGCG treatment markedly inhibited tumor growth when compared to control group (Figure 1A). The mean weight of tumors of EGCG treatment was significantly lower than that of control group, and an average of 60.4% suppression of primary tumor growth was observed ( $P < 0.01$ , Figure 1B). From d 16 after EGCG

**Figure 2** MVD in tumor tissues determined by a specific antibody against mouse endothelial CD34 in PBS group (A) and EGCG group (B) (200 ×) while quantitative analysis showing significant reduction of tumor MVD after EGCG treatment (C). Data are presented as mean ± SE ( $n = 6$ , <sup>b</sup> $P < 0.01$ ).

injection, the average volume of tumors was significantly lower in EGCG treatment group than in control group (Figure 1C).

#### EGCG inhibited tumor neovascularization

To elucidate the anti-angiogenic activity of EGCG *in vivo*, the effect of EGCG on tumor angiogenesis was evaluated by CD34 immunostaining for capillaries in tumor tissues. The density of CD34-stained capillaries was significantly lower in EGCG treatment group (Figure 2A) than in control group (Figure 2B). Microvessel density in tumors receiving EGCG treatment was markedly reduced ( $P < 0.01$ , Figure 2C), and an average of 38.2% suppression was observed.

#### EGCG inhibited VEGF expression and Stat3 activation in vitro and in vivo

Gastric cancer had a high expression level of VEGF and Stat3, and activation of Stat3. To determine the effect of EGCG on Stat3 activation and expression of VEGF and total Stat3, the protein level of VEGF, total Stat3 and phosphorylated Stat3 in tumor cells and tissues was examined by Western blot. As shown in Figure 3, EGCG treatment down-regulated VEGF expression in cultured tumor cells in a dose-dependent manner. VEGF expression in tumor tissues treated with EGCG was also markedly reduced. Consistent with the results of VEGF expression, activation of Stat3 in cultured tumor cells was decreased in a concentration-dependent manner, and also apparently reduced in EGCG treated tumor tissues. However, EGCG treatment did not change the expression of total Stat3 either in cultured cells or in tumor tissues.

#### EGCG decreased VEGF secretion from tumor cells

Angiogenesis is initiated by the release of angiogenic factors from tumor cells. VEGF is the most potent angiogenic factor and associated with tumor-induced

**Figure 3** Suppression of VEGF expression and Stat3 activation in tumor cells and tissues by EGCG. Protein level of VEGF and phosphorylated Stat3 was dose-dependently reduced in tumor cells treated with EGCG and also markedly in EGCG treated tumor tissues. EGCG did not change expression of Stat3 in tumor cells or tumor tissues.

angiogenesis. To examine the effect of EGCG on VEGF secretion, VEGF protein level in the conditioned medium was measured by ELISA. EGCG treatment reduced VEGF secretion in the culture medium in a dose-dependent manner (Figure 4A). EGCG at the concentration of 5 μmol/L significantly reduced VEGF secretion by 16.0% ( $P < 0.05$ ).

#### EGCG inhibited VEGF expression at transcription level

To determine whether the inhibitory effect of EGCG on VEGF expression is at the transcriptional level, we examined VEGF mRNA expression in tumor cells by RT-PCR, showing that VEGF mRNA expression in EGCG treated cells was reduced in a dose-dependent manner (Figure 4B). These results suggested that EGCG reduced VEGF expression by inhibiting VEGF gene transcription and decreasing VEGF mRNA expression.

#### EGCG inhibited endothelial cell proliferation induced by VEGF

Tumor angiogenesis is induced by VEGF mainly produced by tumor cells. VEGF-induced angiogenesis is very important

**Figure 4** Decreased VEGF secretion (A) and inhibition of VEGF mRNA expression (B) in tumor cells. SGC-7901 cells were treated with various concentrations of EGCG for 24 h and VEGF protein level in the supernatant was measured by ELISA and mRNA expression in tumor cells was examined by RT-PCR. Data are presented as mean  $\pm$  SE ( $n = 3$ , <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$ ).

for tumor growth and metastasis. To further investigate whether EGCG inhibits VEGF-induced angiogenesis, we examined the effect of EGCG on VEGF-induced endothelial proliferation, migration and tube formation. The effect of EGCG on VEGF-induced proliferation of HUVECs was determined by MTT assay. HUVECs were treated with 20 ng/mL VEGF and EGCG at the indicated concentrations for 24, 48 and 72 h. As shown in Figure 5, EGCG treatment abrogated VEGF-induced proliferation of HUVECs in a time- and dose-dependent manner.

#### **Inhibitory effect of EGCG on endothelial cell migration induced by VEGF**

Endothelial cell migration is one of the key steps in angiogenesis. We examined the inhibitory effect of EGCG on endothelial cell migration induced by VEGF. As shown in Figure 6, EGCG treatment significantly and dose-dependently inhibited migration of HUVECs induced by VEGF. EGCG at the concentration of 5  $\mu$ mol/L could effectively reduce VEGF-induced endothelial cell

**Figure 5** Inhibitory effects of EGCG on VEGF-induced proliferation of endothelial cells. HUVECs were treated with 20 ng/mL VEGF and EGCG at the indicated concentration and time. EGCG time- and dose-dependently inhibited HUVEC proliferation induced by VEGF. Values are expressed as percent of control (means  $\pm$  SE,  $n = 3$ ).

**Figure 6** EGCG inhibits endothelial cell migration induced by VEGF. EGCG inhibited migration of HUVECs induced by VEGF in a dose-dependent manner. Data are presented as mean  $\pm$  SE ( $n = 3$ ). VEGF-induced migration without EGCG treatment was used as a control. Values significantly lower than control are indicated (<sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$ ).

migration ( $P < 0.05$ ).

#### **Inhibition of VEGF-induced tube formation by EGCG**

We determined the effect of EGCG on tube formation induced by VEGF. When treated with EGCG, tube formation induced by VEGF was inhibited in a concentration-dependent manner. EGCG reduced the length of endothelial tubes even at the concentration of 5  $\mu$ mol/L, and an average of 24.2% inhibition was observed ( $P < 0.01$ ). At the concentration of 40  $\mu$ mol/L, EGCG abrogated almost all tube formations induced by VEGF (Figure 7).

## **DISCUSSION**

Despite significant advance in treatment, gastric cancer remains one of the leading causes of cancer-related death in many countries such as China<sup>[14]</sup>. Tremendous efforts

**Figure 7** Inhibition of EGCG on VEGF-induced tube formation of endothelial cells. EGCG dose-dependently inhibited tube formation induced by VEGF on Matrigel. Data are expressed as percent of control. VEGF-induced tube formation without EGCG treatment was used as a control. Values significantly lower than control are indicated (<sup>b</sup> $P < 0.01$ ).

have been made to identify new chemopreventive and chemotherapeutic agents and strategies. Anti-angiogenic therapy is one of the most promising novel strategies and many attempts have been made to prevent or delay tumor growth by anti-angiogenesis. As the most potent angiogenic factor, VEGF has become one of the most common targets in anti-angiogenic therapy. In this study, we demonstrated that EGCG suppressed growth of gastric cancer by reducing VEGF production and VEGF-induced angiogenesis.

Green tea has been shown to have anti-angiogenic activity and drinking tea can significantly prevent VEGF-induced corneal neovascularization<sup>[15]</sup>. As the most abundant and active component of green tea, EGCG has also been shown to have anti-angiogenic property<sup>[9]</sup>. Treatment with EGCG can inhibit tumor growth<sup>[10]</sup>. In this study, intraperitoneal injection of EGCG markedly suppressed growth of gastric cancer, and an average of 60.4% inhibition was observed. MVD in tumor tissues treated with EGCG were significantly decreased. These results suggest that EGCG inhibits growth of gastric cancer.

Previous studies indicated that EGCG inhibits VEGF expression in tumor cells<sup>[10,16]</sup>. Treatment with EGCG also dose-dependently suppresses the secretion of VEGF both in endothelial cells and in tumor cells<sup>[17]</sup>. To evaluate the effect of EGCG on expression of VEGF in gastric cancer, we determined the expression of VEGF in cultured cells and tumor tissues. As shown in Figure 3, EGCG treatment dose-dependently decreased the expression of VEGF in cultured tumor cells. In tumor tissues treated with EGCG, the expression of VEGF was markedly reduced. Treatment with EGCG also reduced VEGF secretion in tumor cells in a dose-dependent manner. EGCG dose-dependently suppressed VEGF mRNA expression

(Figure 4B). These findings suggest that EGCG inhibits angiogenesis in gastric cancer by reducing production of VEGF at transcriptional level.

VEGF expression is associated with a variety of transcription factors, genes and modulators<sup>[18]</sup>. Several mechanisms have been proposed for the inhibitory effect of EGCG on VEGF expression. EGCG strongly inhibits the transcriptional activity of transcription factors, such as NF-kappa B<sup>[16,19]</sup> and activator protein-1<sup>[20]</sup>. Treatment with EGCG also decreases the constitutive activation of EGFR<sup>[16]</sup> and the expression of protein kinase C<sup>[19]</sup>, transcription modulators of VEGF, suggesting that these changes are associated with inhibition of VEGF promoter activity and cellular production of VEGF. Recent studies showed that EGCG strongly inhibits the constitutive activation of Stat3 in tumor cells<sup>[16]</sup>. Stat3 is one of the key transcription factors in regulation of VEGF expression<sup>[18]</sup>. Stat3 activation directly promotes VEGF expression and stimulates tumor angiogenesis<sup>[21]</sup>. In this study, high activation level of Stat3 was observed in gastric cancer, showing that abnormally activated Stat3 expression significantly correlates with VEGF expression and microvessel density (MVD), and is an independently prognostic factor of poor survival<sup>[22]</sup>. EGCG can reduce VEGF expression by inhibiting activation of Stat3 in human head, neck and breast cancer<sup>[16]</sup>. In this study, EGCG dose-dependently inhibited activation of Stat3. In tumor cells and tissues treated with EGCG, the protein level of phosphorylated Stat3 was markedly reduced, but the total Stat3 level remained unchanged, suggesting that EGCG down-regulates VEGF expression at least in part by inhibiting Stat3 activation in gastric cancer.

It was reported that EGCG is most effective in inhibiting angiogenesis among the four main catechins of green tea<sup>[23]</sup>. Angiogenesis is initiated by the release of angiogenic factors from tumor cells, and VEGF is the most potent angiogenic factor. In this study, EGCG directly inhibited VEGF-induced angiogenesis. As shown in Figure 5, treatment with EGCG inhibited VEGF-induced HUVEC proliferation in a time- and dose-dependent manner and endothelial cell migration and tuber formation were also abrogated by EGCG, suggesting that EGCG inhibits angiogenesis in gastric cancer by inhibiting VEGF-induced angiogenesis and reducing production of VEGF.

VEGF induces angiogenesis by binding to its receptors on endothelial cell surface. It was reported that EGCG dose-dependently inhibits VEGF binding to its receptors on endothelial cell surface, and EGCG is the only catechin of green tea that could disrupt VEGF receptor binding<sup>[23]</sup>. Importantly, EGCG at low doses (0.5-10 μmol/L) markedly inhibits formation of VEGFR-2 complex<sup>[19]</sup>. The exact mechanism underlying the inhibition of VEGF receptor binding is unclear. A recent report suggested that green tea extract dose-dependently inhibits expression of VEGFR-1 and -2 on HUVECs<sup>[24]</sup>. But in our study, EGCG could not modulate VEGFR-1 and VEGFR-2 expression (data not shown). Disruption of VEGF receptor binding would block receptor tyrosine phosphorylation and VEGF-induced growth and survival signaling. Treatment with EGCG inhibits VEGF-induced VEGFR-1 and VEGFR-2

phosphorylation on endothelial cells in a time- and dose-dependent manner<sup>[25]</sup>. This disruption decreases PI3-kinase activity in a dose-dependent manner<sup>[19]</sup>, suppresses VE-cadherin tyrosine phosphorylation and Akt activation<sup>[26]</sup>, and also decreases the PI3 kinase-dependent activation and DNA-binding ability of NF-kappaB<sup>[19]</sup>, suggesting that EGCG inhibits VEGF-induced angiogenesis by disrupting VEGF signaling pathway.

In the present study, EGCG suppressed growth of gastric cancer by targeting multiple steps of angiogenesis. EGCG at the concentration 5  $\mu\text{mol/L}$  effectively inhibited VEGF production and VEGF-induced angiogenesis. EGCG at 40  $\mu\text{mol/L}$  almost totally abolished tube formation induced by VEGF. Previous studies also showed that concentrations of EGCG used in anti-angiogenesis experiments are usually lower than those in anti-cancer experiments, thus strongly supporting the concept that EGCG represents a potent angiogenic inhibitor and EGCG has dual anti-angiogenesis and anti-cancer activities. EGCG might mainly act as an angiogenic inhibitor *in vivo*, and this might in part explain the discrepancy between cell line and animal model studies. The concentration of EGCG tested in cell line system usually is 10-100  $\mu\text{mol/L}$ , or higher. It is much higher than that observed in plasma or tissues of animals or human beings after ingestion of tea or related tea preparations for the poor bioavailability of EGCG<sup>[27]</sup>.

As an angiogenic inhibitor targeting tumor-induced angiogenesis, EGCG might have some advantages over conventional cytotoxic chemotherapy for genetic stability of endothelial cells and abnormality of tumor vasculature. EGCG is less likely to induce drug resistance and has little or no toxicity. During the treatment, EGCG treated mice did not show weight loss or unusual behavior, histopathological examination also did not reveal any detectable toxicity to liver or kidney (data not shown), suggesting that EGCG at the concentrations used does not cause any detectable toxicity. Previous studies also showed that EGCG induces apoptosis and cell cycle arrest in many cancer cells without affecting normal cells<sup>[28]</sup>. It was reported that EGCG has anti-cancer effect without any severe side effects<sup>[29]</sup>. Taken together, as a natural and non-toxic product, EGCG might be a promising candidate for anti-angiogenic treatment of gastric cancer.

## Abstract

**AIM:** To investigate the inhibitory effect of a specific small survivin interfering RNA (siRNA) on cell proliferation and the expression of survivin in human gastric carcinoma cell line SGC-7901.

**METHODS:** To knockdown survivin expression, a small interfering RNA targeting against survivin was synthesized and transfected into SGC-7901 cells with lipofectamine<sup>TM</sup>2000. The downregulation of survivin expression at both mRNA and protein levels were detected by reverse transcription-polymerase chain reaction (RT-PCR) and Western blot analysis. Cell proliferation inhibition rates were determined by methyl thiazolyl tetrazolium (MTT) assay. The effect of survivin siRNA on cell cycle distribution and cell apoptosis was determined by flow cytometry (FCM).

**RESULTS:** RNA interference could efficiently suppress the survivin expression in SGC-7901 cells. At 48 h after transfection, the expression inhibition rate was 44.52% at mRNA level detected by RT-PCR and 40.17% at protein level by Western blot analysis. Downregulation of survivin resulted in significant inhibition of tumor cell growth *in vitro*. The cell proliferation inhibition rates at 24, 48 and 72 h after survivin siRNA and non-silencing siRNA transfection, were 34.06%, 47.61% and 40.36%, respectively. The apoptosis rate was 3.56% and the number of cells was increased in G<sub>0</sub>/G<sub>1</sub> phase from 38.2% to 88.6%, and decreased in S and G<sub>2</sub>/M phase at 48 h after transfection.

**CONCLUSION:** Downregulation of survivin results in significant inhibition of tumor growth *in vitro*. The inhibition of survivin expression can induce apoptosis of SGC-7901 cells. The use of survivin siRNA deserves further investigation as a novel approach to cancer therapy.

## INTRODUCTION

Survivin was initially identified as a member of the inhibitor of apoptosis protein (IAP) family. Up to the present, overexpression of survivin has not been reported in differentiated normal tissues with exception of thymus, basal colonic epithelium endothelial cells and neural stem cells during angiogenesis<sup>[1]</sup>. However, the highly specific expression of survivin was found in many human cancers, including gastric cancer. By inhibiting apoptosis and promoting mitosis, survivin facilitates cancer cell survival and growth<sup>[2-6]</sup>. Several studies have revealed that survivin as an indispensable factor can regulate and assist completion of cytokinesis<sup>[7-10]</sup>. Recently, it has been also proven that overexpression of survivin can protect cells from apoptosis by inhibiting pro-apoptotic caspases-3 and caspases-7; when acting as a microtubule stabilizer during mitosis, it promotes cell cycle progression as well<sup>[11-14]</sup>. In addition, Asanuma K *et al*<sup>[15]</sup> reported that survivin enhanced the expression of the Fas ligand in cancer cells through up-regulation of specific protein-1-mediated gene transcription, and enabled cancer cells to counter-attack immune cells by inducing FasL-triggered apoptosis of cells in the immune surveillance system.

RNAi is a genetic interference phenomenon that is effective for suppressing gene expression. It involves post-transcriptional gene silencing *via* a process in which double-stranded RNA (dsRNA) inhibits gene expression in a sequence-dependent manner through degradation of the corresponding mRNA. Its blocking action on gene expression has been successfully observed in rat and human cells cultured *in vitro*, and the knockdown of genes in cells has been achieved<sup>[16,17]</sup>.

In the present study, siRNA targeting to the survivin gene was introduced into gastric carcinoma cell line SGC-7901, which overexpresses survivin. Its effect on cancer cell growth was investigated.

## MATERIALS AND METHODS

### Cell lines and culture

Human gastric carcinoma cell line SGC-7901 was a present from Dr. Wei Liu. The cells were cultured in RPMI 1640 medium supplemented with 100 mL/L fetal bovine serum (FBS),  $8 \times 10^5$  U/L penicillin and 0.1 g/L streptomycin in humidified incubator containing 50 mL/L CO<sub>2</sub> at 37°C.

### siRNA preparation and transfection of short interfering RNA

siRNA oligonucleotides with two thymidine residues (tt) at the 3' end of the sequence were designed for survivin (sense, 5'-GCAUUCGUCCGGUUGCGCUtt-3'; antisense, 5'-AGCGCAACCGGACGAAUGCtt-3'). Cells were treated in parallel with a non-silencing-siRNA (sense, 5'-UUCUCCGAACGUGUCACGUtt-3'; antisense, 5'-ACGUGACACGUUCGGAGAAtt-3') as control oligonucleotides were synthesized by Shanghai Genechem Co. These cells were cultured in medium without antibiotics, and 24 h before transfection resulting in a confluence of the cell monolayer by 50%-70%. Specific survivin siRNA or non-silencing siRNA (70 nmol) were mixed with lipofectamine<sup>TM</sup> 2000 (Invitrogen) according to manufacturer's recommendation and added to the cells. After 6 h at 37°C, the medium was changed, and the cells were cultivated in RPMI 1640 supplemented with 10% heat-inactivated FBS.

### 3-(4, 5-methylthiazol-2-yl)-2, 5-diphenyl-tetrazolium bromide (MTT) assay

SGC-7901 cells ( $5 \times 10^5$ ) were placed onto 96-well plates in RPMI-1640 containing 10% FBS in a final volume of 0.1 mL. The next day, the cells were treated with siRNA. MTT was added (20 µL/well of 5 g/L solution in PBS) after culture for 24 h, 48 h and 72 h. When incubated at 37°C for 4 h, the reaction was stopped by addition of 100 µL DMSO. The reaction product was quantified by measuring the absorbance at 490 nm using an ELISA reader (WALLAC 1420 VICTOR 2, Victor Co, Finland) and Software HT-Soft (Perkin-Elmer). All samples were assayed repeatedly in six wells.

### Reverse transcription polymerase chain reaction

SGC-7901 cells ( $5 \times 10^5$ ) were seeded onto 6-well plates. Total RNA was extracted 48 h after transfection using trizol reagent. Reverse transcription was performed using one step RT-PCR kit. The primers of human survivin were 5'-GGACCGCCTAAGAGGGCGTGC-3' (forward primer) and 5'-AATGTAGAGATGCGGTGGTCCTT-3' (reverse primer). The primers of human  $\beta$ -actin were 5'-GTGGGCATGGGTCAAGAAG-3' (forward primer) 5'-GAGGCGTACAGGGATAGCAC-3' (reverse primer). Thermal cycle conditions were as follows: 42°C for 30 min, 94°C for 2 min, followed by 28 cycles of 94°C 15 s, 55°C 30 s, 72°C 1 min, with a final extension at 72°C for 10 min. RT-PCR products were visualized by ethidium bromide-stained agarose gels.

### Western immunoblot analysis

SGC-7901 cells ( $5 \times 10^5$ ) were seeded onto 6-well plates.

Forty-eight hours after transfection, cells were collected and washed twice by cold PBS, and each well was treated with 50 µL lysis buffer (2 mmol/L Tris-HCl pH 7.4, 50 mmol/L NaCl, 25 mmol/L EDTA, 50 mmol/L NaF, 1.5 mmol/L Na<sub>3</sub>VO<sub>4</sub>, 1% Triton X-100, 0.1% SDS, supplemented with protease inhibitors 1 mmol/L phenylmethylsulfonylfluoride, 10 mg/L pepstatin, 10 mg/L aprotinin, and 5 mg/L leupeptin) (all from Sigma). Protein concentrations were determined using the bicinchoninic acid protein assay. Equal amounts of protein (40 µg) were separated on a 15% SDS polyacrylamide gel and transferred to a nitrocellulose membrane (Hybond C, Amersham, Freiburg, Germany). Membranes were blocked in 5% nonfat dry milk in TBS for 1 h at room temperature and probed with rabbit antisurvivin antibodies (dilution, 1:500 Santa Cruz Biotechnology, USA) overnight at 4°C. After 3 times washing with TBS containing 0.1% Tween 20, membranes were incubated with anti-rabbit IgG-horseradish-peroxidase (1:5000, Santa Cruz Biotechnology, USA), and developed by luminol mediated chemiluminescence (Appylgen Technologies Inc, China). To confirm equal protein loading, membranes were reprobed with a 1:1000 dilution of an anti-actin antibody (Santa Cruz Biotechnology, USA). Densitometric analyses were performed using Scion Image software.

### Flow cytometry

SGC-7901 ( $5 \times 10^5$ ) cell lines were seeded in triplicate onto 6 well-plates, and cultured in RPMI-1640 supplemented with 100 mL/L FBS. When transfected for 48 h, the cells were collected and washed with ice-cold PBS, and fixed in 70% ethanol overnight at 4°C. The fixed cells were pelleted, washed in PBS, resuspended in PBS containing 0.1 mg/mL of propidium iodide, and analysed by flow cytometry.

### Statistical analysis

Data were expressed as mean  $\pm$  SD. All statistical analyses were performed using the SPSS 10.0 software package for Windows (SPSS Inc., Chicago, IL). One-way ANOVA followed by Bonferroni correction was used to compare the data among three or more groups. A value of  $P < 0.01$  was considered statistically significant.

## RESULTS

### Expression of survivin gene in SGC-7901 cells

To examine the specific effect of survivin siRNA treatment on survivin expression in SGC-7901 line, the survivin mRNA and protein expression levels were determined quantitatively with RT-PCR and Western blot analyses, respectively. Results are displayed in Figure 1 and Figure 2. Survivin mRNA and protein were strongly expressed in gastric cancer SGC-7901 cells as reflected by RT-PCR and Western blot. The inhibition rate of survivin mRNA after transfection with specific survivin siRNA was 44.52%. The inhibition rate of survivin protein after transfection with specific survivin siRNA was 40.17%. Survivin expression was decreased significantly at 48 h after transfection with specific survivin siRNA.

**Figure 1** Expression of survivin mRNA in different groups of SGC-7901 cells. **A:** Survivin mRNA expression in RT-PCR assay; **B:** Survivin mRNA expression in SGC-7901. 1: treated with survivin siRNA; 2: treated with non-silencing siRNA; 3: untreated. Data are expressed as mean  $\pm$  SD of three experiments, survivin siRNA group vs non-silencing siRNA group,  $^bP < 0.01$ ; survivin siRNA group vs untreated group,  $^bP < 0.01$ .

**Figure 3** Effects on cell viability after non-silencing siRNA and survivin siRNA treatment. 1: untreated; 2: non-silencing siRNA; 3: survivin siRNA. Data are expressed as mean  $\pm$  SD, survivin siRNA group vs non-silencing siRNA group,  $^bP < 0.01$ ; survivin siRNA group vs untreated group,  $^bP < 0.01$ .

### Effect of survivin siRNA on cell proliferation of gastric cancer cells

To determine whether inhibition of survivin affects cell proliferation in SGC-7901, metabolic activity at 24, 48, and 72 h was determined by the MTT assay. The cell viability was reduced significantly after treatment with specific survivin siRNA ( $P < 0.01$ ) at 24, 48, and 72 h as compared with non-silencing siRNA treatment or untreated controls (Figure 3). The cell proliferation inhibition rates were

Data are expressed as mean  $\pm$  SD of the three experiments, sur-siRNA group vs non-silencing group,  $^bP < 0.01$ ; sur-siRNA group vs untreated group,  $^bP < 0.01$ .

34.06%, 47.61% and 40.36%, respectively.

### Effect of survivin siRNA on cell cycle distribution and apoptosis

Survivin has been reported to express in the G<sub>2</sub>/M phase of the cell cycle and to contribute to the aberrant progression of cancer cells through mitosis. In our study, in comparison of non-silencing siRNA group and untreated controls, specific survivin siRNA caused accumulation in the G<sub>0</sub>/G<sub>1</sub> phase, and decreased the number of cells of G<sub>2</sub>/M phase and increased hypodiploid DNA content ( $P < 0.01$ ) at 48 h after transfection. Apoptosis rate was 3.56% in the group of specific survivin siRNA transfection (Table 1).

## DISCUSSION

The balance between apoptosis and anti-apoptosis signal pathways plays a role in the pathogenesis of a variety of

cancers. It has been demonstrated that the inhibition of apoptosis promotes the mitotic progression in cancer cells<sup>[18]</sup>. Based on its specific overexpression in a vast majority of solid cancers and its anti-apoptotic function, survivin represents a suitable target for antitumor approaches. The inhibition of survivin would block the anti-apoptosis and mitotic progression in tumor cells<sup>[19]</sup>, as a result, tumor development is suppressed. So, survivin has attracted considerable attention as a novel member of IAP family.

RNAi is an evolutionarily conserved phenomenon in which gene expression is suppressed by the introduction of homologous double-stranded RNAs (dsRNAs). Synthetic siRNA can trigger an RNA interference response in mammalian cells and induce strong inhibition of specific gene expression<sup>[20]</sup>. Therefore, it can be used as a powerful approach to silence mammalian gene expression for gene function studies<sup>[21-24]</sup>.

Since survivin is important for the survival of various human tumors, survivin siRNA could become an effective therapeutic agent for tumors with overexpression of survivin. Survivin has been successfully down-regulated by RNAi in some previous studies<sup>[25-29]</sup>. However, the down-regulation of survivin expression by RNAi in gastric cancer SGC-7901 cells has not been performed until now.

In addition, it is reported that the effect of RNAi may be greatly different, targeting to different sequence of the gene<sup>[30-32]</sup>. It is therefore, very important to find the proper sequence. The sequence designed by Williams *et al*<sup>[26]</sup> has been confirmed effective in their research. So in our study, we synthesized this siRNA duplex with a thymidine overhang on 3' terminus *in vitro* to diminish the survivin expression of gastric carcinoma SGC-7901 cell line and to impair its growth potential. We observed that SGC-7901 cells transfected with survivin siRNA grew slowly as compared with the control groups. Survivin siRNA showed anti-proliferation function. RT-PCR and Western blot findings demonstrated that survivin mRNA and protein expression were reduced by over 40%, and survivin gene was blocked in SGC-7901 cells transfected with surviving siRNA at the level of transcription and protein expression. Flow cytometry revealed that the cell growth inhibition by survivin siRNA was a result of cell cycle arrest at G<sub>0</sub>/G<sub>1</sub>-phase and induction of apoptosis indicated by increased hypodiploid DNA content. The possible mechanism is that survivin is characterized by cell cycle dependent expression, i.e., it is expressed in G<sub>2</sub>/M. Ito and co-workers transfected survivin into four human hepatocellular carcinoma cell lines and found that the number of cells in G<sub>0</sub>/G<sub>1</sub> was remarkably reduced, and the number of cells in S or G<sub>2</sub>/M increased. In our study, after SGC-7901 cells were transfected with survivin siRNA, the number of cells in G<sub>0</sub>/G<sub>1</sub> was remarkably increased, and the number of cells in S or G<sub>2</sub>/M decreased. The effect showed the same mechanism. However, in the study by Kappler and co-workers, five human sarcoma cell lines transfected with specific survivin siRNA showed G<sub>2</sub>/M arrest<sup>[26]</sup>. Ning *et al*<sup>[33]</sup> also observed a specific G<sub>2</sub>/M arrest when using survivin-directed siRNA as a gene therapeutic approach to human bladder cancer cells. The reason remains unclear, and it may be due to different cell lines.

The above-mentioned findings confirm that chemically synthesized siRNAs can specifically block survivin gene expression, inducing cell apoptosis and inhibiting the growth of carcinoma cells.

In conclusion, our data suggest that survivin gene can be regarded as a very good target gene in genetic therapy for gastric carcinomas and the use of survivin siRNA deserves further investigations as a novel approach to cancer therapy.

## ACKNOWLEDGMENTS

We would thank Dr. Juan Li (Central Laboratory of First Affiliated Hospital of Lanzhou University) for her excellent technical assistance. We would also thank Dr. Liu Wei (Institute of Pathology, Lanzhou University) for providing us the cell lines.

## Abstract

**AIM:** To investigate the growth inhibitory mechanism of NS-398, a selective cyclooxygenase-2 (COX-2) inhibitor, in two hepatocellular carcinoma (HCC) cell lines (HepG2 and Huh7).

**METHODS:** HepG2 and Huh7 cells were treated with NS-398. Its effects on cell viability, cell proliferation, cell cycles, and gene expression were respectively evaluated by water-soluble tetrazolium salt (WST-1) assay, 4'-6-diamidino-2-phenylindole (DAPI) staining, flow cytometer analysis, and Western blotting, with dimethyl sulfoxide (DMSO) as positive control.

**RESULTS:** NS-398 showed dose- and time-dependent growth-inhibitory effects on the two cell lines. Proliferating cell nuclear antigen (PCNA) expressions in HepG2 and Huh7 cells, particularly in Huh7 cells were inhibited in a time- and dose-independent manner. NS-398 caused cell cycle arrest in the G1 phase with cell accumulation in the sub-G1 phase in HepG2 and Huh7 cell lines. No evidence of apoptosis was observed in two cell lines.

**CONCLUSION:** NS-398 reduces cell proliferation by inducing cell cycle arrest in HepG2 and Huh7 cell lines, and COX-2 inhibitors may have potent chemoprevention effects on human hepatocellular carcinoma.

## INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common malignancies worldwide<sup>[1]</sup>. Although HCC is significantly more prevalent in Asia and Africa, a rising incidence has been reported in Western countries. Most patients present at an advanced stage when successful surgical treatment is no longer feasible and current therapeutic options achieve clinical responses in only a small percentage of cases. As a consequence, effective approaches for prevention and treatment need to be established.

Epidemiological and experimental studies have demonstrated the effect of non-steroidal anti-inflammatory drugs (NSAIDs) in the prevention of human cancers, especially those in the gastroenterological tract<sup>[2-4]</sup>. Epidemiological studies have shown that the rate of mortality of colorectal cancer in individuals taking NSAIDs is 40%-50% lower than that in non-users<sup>[4]</sup>. NSAIDs inhibit endogenous prostaglandin synthesis. The key step in the enzymatic conversion of arachidonic acid to prostaglandins is catalyzed by cyclooxygenases (COX), and represents the specific target of NSAIDs.

Two forms of cyclooxygenase, COX-1 and COX-2 have been identified. COX-1 is expressed constitutively in most tissues and appears to be responsible for prostaglandin production in various physiological functions such as platelet aggregation and maintenance of gastric mucosa. In contrast, COX-2 is induced by several inflammatory cytokines and growth factors<sup>[5]</sup> and frequently over-expressed in various tumor cells. Selective COX-2 inhibitors do not affect platelet aggregation or bleeding time and cause far fewer acute gastric erosions than several nonselective inhibitors. Therefore, selective COX-2 inhibitors such as celecoxib and NS-398 are preferable to nonselective COX-2 inhibitors.

The role of COX-2 in hepatocellular carcinogenesis

is still unclear. Previous studies have shown increased expression of COX-2 in patients with various liver diseases, suggesting its possible role in chronic liver disease and during HCC progression<sup>[6-8]</sup>. In addition, some studies have described the possible benefits of treatment with COX-2 inhibitors as indicated by their effects on human HCC cell lines<sup>[8-10]</sup>. However, contrasting results have also been reported about the expression of COX-2 or the effects of COX-2 inhibitors on HCC cell lines<sup>[11]</sup>. COX-2 may be a logical therapeutic target in various human cancers including HCC. However, information regarding the mechanisms involved in these effects is scant and sometimes contradictory<sup>[12-15]</sup>.

In this study, we examined the effects and possible mechanism of NS-398, a selective COX-2 inhibitor in two human hepatoma cell lines, HepG2, and Huh7.

## MATERIALS AND METHODS

### Materials

Human hepatoma cell lines HepG2 (showing wild-type p53) and Huh7 (showing mutant-type p53) were obtained from the American Type Culture Collection (Rockville, MD, USA). Each cell line was cultured in Dulbecco's modified Eagle's medium (DMEM; Invitrogen, Carlsbad, CA) supplemented with 10% fetal bovine serum (FBS), essential amino acids, 100 units/mL penicillin (Invitrogen), and 100 µg/mL streptomycin (Invitrogen, Carlsbad, CA). All cells were maintained in a humidified atmosphere containing 950 mL/L air and 50 mL/L CO<sub>2</sub> at 37°C. NS-398 was purchased from Cayman Chemical (Ann Arbor, MI, USA) and dissolved in dimethyl sulfoxide (DMSO).

### Cell viability assay

To evaluate the inhibitory growth effect of NS-398, we confirmed its cytotoxicity and proliferating activity by water-soluble tetrazolium salt (WST-1) assay (Roche Diagnostics, Mannheim, Germany). The WST-1 assay is a colorimetric method in which the dye intensity is proportional to the number of viable cells. Cells were seeded into 96-well microtiter plates at a concentration of  $5 \times 10^3$  cells/well. After 12-h incubation, cells were treated with serum-free media containing various concentrations of NS-398 (0, 50, 100, and 200 µmol/L) for 24, 48, and 72 h. Because we used DMSO-dissolved NS-398, cells cultured in the serum-free media containing an equivalent volume of DMSO without NS-398 respectively were used as controls to ensure DMSO not to promote unwanted cellular effects. The final concentration of DMSO was < 0.3%. After incubation, the cells were washed with PBS and the cell proliferation reagent WST-1 was added with cell culture medium, and incubated for 4 h. Sample absorbance was analyzed using a bichromatic ELISA reader at 450 nm. All experiments were performed in triplicate.

### Nuclei staining and FACS analysis

Characterization of apoptosis and/or necrosis was carried out after propidium iodide (PI) and Annexin V-FITC

staining with apoptosis detection kit I (Pharmingen, San Diego, CA, USA) followed by flow cytometric analysis after 24, 48 and 72 h of 100 µmol/L NS-398 treatment in HepG2 and Huh7 according to the manufacturer's instructions. For histogram analysis after PI staining, the cells were fixed with 70% ethanol in PBS for 15 min at -20°C. The fixed cells were incubated with RNase A (100 µg/mL) for 30 min at 37°C and then stained with PI (50 mg/mL in PBS). Fluorescence of individual nuclei and intact cells was determined using a FACScalibur flow cytometer (Beacton Dickinson, San Jose, CA).

For detection of apoptosis, cells were washed twice with ice cold PBS and stained simultaneously with FITC-conjugated Annexin V and PI for 20 min on ice in the dark with a binding buffer. Within the next hour, cells were analyzed for apoptosis. The total number of apoptotic cells was determined by calculation of Annexin V+ and PI-cells (reflecting early apoptosis) together with annexin V+ and PI+ cells (reflecting late apoptosis/secondary necrosis).

### DAPI staining

4',6-diamidino-2-phenylindole (DAPI), a DNA-binding fluorescent dye, was used to determine whether the mechanism of growth inhibition upon NS-398 treatment is apoptosis. After treatment with 100 µmol/L NS-398 for 0, 24, 48, and 72 h, the cells were washed three times with PBS, fixed in a 3.7% formaldehyde solution for 10 min, fixed once in 1 mL of methanol, and then stained with 4 µg/mL DAPI (Oncor, Gaithersburg, MD) for 10 min. Results were determined by visual observation of nuclear morphology *via* fluorescence microscopy.

### Immunoblot analysis

HepG2 and Huh7 cells were seeded on 100-mm dishes at a density of  $1.5 \times 10^6$  cells/dish. After seeding and overnight incubation, cells were serum-starved for 24 h and incubated in serum-free media with 100 µmol/L NS-398 for 0, 24, 48 and 72 h. Attached and floating cells were harvested together. Cells cultured in the same condition without NS-398 were used as controls. Proteins extracted from either treated or control cells were measured by Bradford assay, and subjected to SDS-PAGE. The proteins were then transferred electrophoretically to nitrocellulose membrane (Schleicher & Schuell, Dassel, Germany) at 100 V for 1 h at 4°C. To stain the proteins and to validate that equal amounts of protein were loaded in each lane and transferred efficiently, the membrane was immersed in 0.5% Ponceau S (Sigma Chemical Co., St. Louis, MD) in 1% acetic acid. The membrane was washed three times with TBS containing 0.1% Tween 20 (TBS-T). After blocking with 5% skim milk in TBST buffer for 1 h, the membrane was incubated with primary antibodies (anti-mouse COX-2 antibody, 1:500; anti-rabbit caspase-9, caspase-3 and caspase-8, 1:1000; anti-mouse poly [ADP-ribose] -polymerase (PARP) antibody, 1:1000; anti-mouse proliferating cell nuclear antigen (PCNA) antibody, 1:1000 and anti-mouse β-actin antibody, 1:2500) overnight at 4°C. The membrane was incubated with secondary antibodies for 1 h and detected with ECL reagent (Amersham-Pharmacia, UK).

**Figure 1** Immunoblot analysis for COX-2 protein levels in HepG2 and Huh7 cells. Cells were treated with 100  $\mu\text{mol/L}$  NS-398 for 0, 24, 48 and 72 h. Control cells were treated with DMSO without NS-398. The upper bands represent 72 kDa COX-2-specific staining while the lower bands are  $\beta$ -actin controls. COX-2 expression was detectable but low in both cell lines. Decreased changes were observed in COX-2 expression with increasing time.

### Statistical analysis

One-way analysis of variance (ANOVA) was performed to test the differences in cellular proliferation and apoptosis of the two cell lines treated with different NS-398 concentrations for varying times.  $P < 0.05$  was considered statistically significant. Data were analyzed using the Statistical Package for Social Sciences (SPSS) (version 11.0).

## RESULTS

### Inhibition of COX-2 expression by NS-398

We first characterized the hepatoma cell lines by their expression of COX-2. Samples containing 50  $\mu\text{g}$  of extracted protein were loaded onto the gel. Immunoblot analysis revealed that both cell lines expressed COX-2 protein. The expression of COX-2 was inhibited by NS-398. Immunoblot analysis also demonstrated different COX-2 expressions after treatment with 100  $\mu\text{mol/L}$  NS-398 for different periods of time (Figure 1).

### Inhibition of HepG2 and Huh7 cell viability by NS-398

To determine the effect of the selective COX-2 inhibitor NS-398 on HepG2 and Huh7 cells, cell viability was determined by WST-1 assay. Growth-inhibitory experiments were performed by treating cells with various doses of NS-398 for different periods of time. As shown in Figure 2, NS-398 reduced cell viability in a time- and dose-dependent manner on both cell lines. However, treatment with only DMSO as a control did not alter HepG2 and Huh7 cell proliferation ( $P > 0.05$ ).

### No evidence of apoptosis was observed in two cell lines

To confirm that NS-398 induces apoptosis of COX-2-expressing HepG2 and Huh7 cells, a double-staining method using FITC-conjugated Annexin V and PI, DAPI staining and Western blotting were done. In the Annexin and PI staining, the percentages of apoptotic and necrotic cells at 0, 24, 48 and 72 h after 100  $\mu\text{mol/L}$  of NS-398 treatment were not significantly different in HepG2 and Huh7 cells (Figure 3). Moreover, no condensed and fragmented nuclei were found in DAPI staining (data not shown). Immunoblot analysis showed that there was no activation of caspase-3, caspase-8, caspase-9 and PARPs in HepG2 and Huh7 cells treated with 100  $\mu\text{mol/L}$  of NS-398 (Figure 4). Taken together, NS-398 did not induce apoptosis in HepG2 and Huh7 cells.

### NS-398 suppressed cell proliferation by inducing cell cycle arrest, especially in Huh7 cell lines

To test the effects of NS-398 on cellular proliferation, the two HCC cell lines were treated with 100  $\mu\text{mol/L}$  of NS-398. We detected PCNA protein by IB analysis. As shown in Figure 5, both cell lines showed a down-regulation of PCNA expression after treatment with 100  $\mu\text{mol/L}$  of NS-398 in a time dependent manner. In particular, NS-398 treatments significantly suppressed the cellular proliferation in Huh7 cells.

To determine whether suppressions of proliferation in Huh7 cells induced by NS-398 are associated with cell-cycle arrest, we measured DNA content by flow cytometry. We observed that the population of cells in sub-G1 phase increased after 100  $\mu\text{mol/L}$  NS-398 treatment in both cell lines for different periods of time. A significant correlation was observed between the growth inhibition and accumulation of cells in sub-G1 phase for Huh7 at 48 h (Figure 6).

## DISCUSSION

COX-2 is involved in several pathological processes such as inflammation and cancer, and inhibition of apoptosis is regarded as one mechanism by which COX-2 contributes to tumorigenesis. Recent studies demonstrated that selective COX-2 inhibitors (including NS-398) which can inhibit cell proliferation or induce apoptosis are found not only in HCC cell lines but also in colorectal<sup>[2,3]</sup>, esophageal<sup>[14]</sup>, bladder<sup>[15]</sup>, prostatic<sup>[16]</sup>, lung<sup>[17]</sup>, cervix<sup>[18]</sup> carcinoma cells.

Over-expression of COX-2 has been demonstrated in patients with HCC and high COX-2 expression in non-tumor liver tissue is significantly associated with inflammatory activity<sup>[6,8,19]</sup>. These findings indicate that COX-2 expression plays an important role in hepatic inflammation and malignant transformation of hepatocytes<sup>[20]</sup>. However, the key mechanism by which COX-2 affects HCC cell growth remains unclear.

In this study, we detected the expression of COX-2 protein in HepG2 and Huh7 cells by Western blotting. Decreased changes in COX-2 protein expression were observed during the course of growth inhibition by NS-398 treatment (Figure 1). Our findings suggest that the growth-inhibitory effect on hepatocellular carcinoma cell lines is dependent on COX-2 expression<sup>[10]</sup>. However, several other studies have shown that there is no correlation between COX-2 expression and growth-inhibitory effects induced by NSAIDs<sup>[9,11,21]</sup>.

NS-398-induced inhibition of cell growth is both dose- and time-dependent (Figure 2). The association of COX-2 inhibition with suppression of tumor cell proliferation remains unclear in HCC. Our findings demonstrate that NS-398 may inhibit cell growth in a dose- and time-dependent manner, due to the result of evident cell cycle arrest at G1 (Figures 2 and 6)<sup>[11]</sup>. Decreased PCNA expression supports the finding of a reduced number of cells in S phase by cell cycle analysis, which is an important event in cell cycle arrest of HepG2 (wild-type p53) and Huh-7 (p53-220Cys) induced by NS-398.

**Figure 2** Proliferation of HepG2 and Huh7 cells inhibited by NS-398. **A:** Time-dependent growth-inhibitory effect of NS-398. One hundred μmol/L NS-398 was added to HepG2 and Huh7 cells, which were cultured for 24, 48 or 72 h, and subjected to WST-1 assay. Absorbance was detected at 450 nm with an ELISA plate reader, and the growth rates of both cell lines treated with NS-398 were reduced compared to controls. Control cells were treated with an equivalent volume of DMSO without NS-398, respectively; **B:** Dose-dependent growth-inhibitory effect of NS-398. Cells treated with various concentrations of NS-398 were cultured for 72 h, and quantified by WST-1 assay. Data from 3 independent experiments are shown as mean ± SD ( $P < 0.05$ ).

**Figure 3** Flow cytometric analysis after exposure of HepG2 (A) and Huh7 (B) cells to NS-398. Cells were treated with 100 μmol/L NS-398 for 24, 48, and 72 h, stained with annexin V-FITC and propidium iodide and analyzed on a FACScalibur flow cytometer. Quadrants 2-4 represent secondary necrotic cells, viable cells, and apoptotic cells, respectively.

In particular, NS-398 treatment significantly suppressed Huh7 proliferation. Recent reports indicate a complex relationship between the tumor suppressor p53 and

COX-2<sup>[22,23]</sup>. While wild-type p53 over-expression leads to increased COX-2 levels<sup>[24]</sup>, opposite effects where p53 inhibits COX-2 transcription have been reported<sup>[25]</sup>. Thus,

**Figure 4** No evidence of activation of the caspase pathway and PARP by NS-398. No evidence of apoptosis in HepG2 and Huh7 cells was observed after NS-398 treatment. No caspase pathway activation or PARP cleavage was detected in both cell lines.

**Figure 5** Inhibition of PCNA expression by NS-398. **A:** Down-regulation of PCNA expression in both cell lines after NS-398 treatment. Cells were treated for 24, 48, and 72 h with 100  $\mu\text{mol/L}$  NS-398. Controls were treated with an equivalent volume of DMSO without NS-398. PCNA expressions in HepG2 and Huh7 cells were inhibited in a time-dependent (as shown above) and dose-independent (data not shown) manner; **B:** Quantification of the relative amount of each band by image analysis.

**Figure 6** Inhibition of cell cycle arrest in Huh7 by NS-398. The cell cycle distribution was determined using a FACScan flow cytometer. Cells were harvested at 24, 48 and 72 h after treatment with 100  $\mu\text{mol/L}$  NS-398 and collected. RNA was digested and DNA content was stained with propidium iodide (PI). Representative DNA histograms for Huh7 cells were shown.

different chemosensitivity to the selective COX-2 inhibitor NS-398 might be associated with different p53 status, including Huh-7 (mutated p53) and HepG2 (wild-type p53).

Several other studies, however, have shown that NS-398 inhibits cell proliferation and induces apoptosis *via* caspase-dependent or caspase-independent pathway in hepatoma cell lines<sup>[7,26,27]</sup>. But in our experiments, we obtained all negative data in Western blots and DAPI staining. This discrepancy may be due, at least in part, to sub-clone variation and different culture conditions<sup>[9,28]</sup>.

Alteration of apoptosis is considered an important mechanism of carcinogenesis<sup>[21,26]</sup>. Caspases can be divided, based on their activity, into initiator caspases (caspase-8 and -9) and effector caspases (caspases-3, -6 and -7). In our study, no definite evidence of apoptosis was found after NS-398 treatment of both cell lines, suggesting that the major mechanism of growth inhibition by NS-398 may be anti-proliferation by cell cycle arrest rather than apoptosis.

In conclusion, selective COX-2 inhibitor, NS-398, inhibits the growth of HepG2 and Huh7 cells by inducing cell cycle arrest and is a potential candidate as an effective chemopreventive tool against human HCC.

### Abstract

**AIM:** To investigate the hemodynamic changes in a precancerous lesion model of hepatocellular carcinoma (HCC).

**METHODS:** Hemodynamic changes in 18 Wistar rats were studied with non-invasive magnetic resonance (MR) perfusion. The changes induced by diethylnitrosamine (DEN) developed into liver nodular lesions due to hepatic cirrhosis during the progression of carcinogenesis. The MR perfusion data [positive enhancement integral (PEI)] were compared between the nodular lesions corresponding well with MR images and pathology and their surrounding hepatic parenchyma.

**RESULTS:** A total of 46 nodules were located by MR imaging and autopsy, including 22 dysplastic nodules (DN), 9 regenerative nodules (RN), 10 early HCCs and 5 overt HCCs. Among the 22 DNs, 6 were low-grade DN (LGDN) and 16 were high-grade DN (HGDN). The average PEI of RN, DN, early and overt HCC was  $205.67 \pm 31.17$ ,  $161.94 \pm 20.74$ ,  $226.09 \pm 34.83$ ,  $491.86 \pm 44.61$  respectively, and their liver parenchyma nearby was  $204.84 \pm 70.19$ . Comparison of the blood perfusion index between each RN and its surrounding hepatic parenchyma showed no statistically significant difference ( $P = 0.06$ ). There were significant differences in DN ( $P = 0.02$ ). During the late hepatic arterial phase, the perfusion curve in DN declined. DN had an iso-signal intensity at the early hepatic arterial phase and a low signal intensity at the portal venous phase. Of the 10

### INTRODUCTION

The changes of blood flow in dysplastic and regenerative nodules in patients with hepatic cirrhosis have been evaluated in previous studies with computed tomography (CT) arterial portography (CTAP) and CT hepatic arteriography (CTHA) techniques<sup>[1-3]</sup>. It has been demonstrated that during the late stage of hepatic cirrhosis, sequential hemodynamic changes in blood supply of dysplastic nodules lead to the development of early hepatocellular carcinoma (HCC). The main portal venous blood supply of these nodules gradually changes into the hepatic arterial supply. However, invasive methods require simultaneous catheterization of hepatic artery and superior mesentery artery to inject contrast enhancement substances. Because of their invasiveness, these methods have limited clinical application. With the development of techniques, especially the reduction of scanning time, magnetic resonance imaging (MRI) following intravenous injection of extracellular contrast agents has recently been described and validated to assess perfusion parameters in liver<sup>[4-7]</sup>. With this method, the contrast agent in blood flow of arterial and portal vein can be measured non-invasively. The purpose of this study was to assess experimentally whether MR perfusion can demonstrate the hemodynamic changes of liver nodular lesions.

## MATERIALS AND METHODS

### Animal model

The study protocol was reviewed and approved by the Institutional Committee for Animal Care of Fudan University. Experiments were performed on 18 6-wk old male Wistar rats weighing  $150 \pm 10$  g (Experimental Animal Center of Fudan University, Shanghai, China). All animals were housed in independent ventilating cabinets (IVC) at 18–22°C with 55% humidity in a 12 h light/dark cycle with free access to clean diet. Lesions in rats were induced by diethylnitrosamine (DEN, 0.99 mg/mL, Sigma, USA) in order to develop hepatocellular carcinoma during carcinogenesis. The animals received DEN (10 mg/kg per day) in drinking water at 0.01% g/L from a fresh DEN solution prepared every two days for 100 d.

### Magnetic resonance imaging

A 1.5 Tesla magnetic resonance (MR) system with a 40 mT/m maximum gradient capability (TwinSpeed, Excite II, double gradient field, General Electric, USA) and 3-inch surface coil was employed and two rats were scanned every week from the 12th wk to the 20th wk after they were exposed to carcinogen. The rats were deeply anesthetized with a mixture of urethane (25%) and diazepam (2 mg) before MR scanning. Plain scanning was performed first in order to show the position of nodules, including sequences of 3-planar-localization scanning, axial and coronal T2 weighted scanning (T2WI), and axial T1 weighted (T1WI) scanning (in-phase and out-phase).

MR perfusion scanning was only performed on the nodules of interest demonstrated by T2WI. Fast spoiled gradient-echo sequence (FSPGR) was selected and the time resolution was 4 sections/2 s. Major protocol parameters included TR/TE: 5.8–8 ms/4–2.7 ms; band width: 31.3–19.2 kHz; section thickness: 2 mm; intersection gap: 0.5 mm; matrix:  $128 \times 128$ ; excitation time: 1; FOV: 8. The time of acquisition of perfusion-weighted images was at the 8th phase after the starting point of tail vein bolus injection of diluted gadolinium (0.1 mmol/mL, Magnevist; Schering, Guangzhou, China) (0.2 mmol/kg). The total scanning time was 2 min.

### Pathological analysis

Within 24 h after MR imaging, the rats were killed and their liver was removed at autopsy. The whole liver was serially sectioned into 1 mm-thick sections corresponding to the coronal plane MR image. The sections were fixed in a 10% formalin solution for 48 h and paraffin-embedded. Standard hematoxylin-eosin staining was used to assess the nature of nodules and immunohistochemical staining was performed for reticulin protein, CD31, CD34 antibodies. Transmission electron microscopy was also performed to study the ultrastructure of hepatic cancer cells. Pathologic diagnosis was made by two specialists independently and all nodules were defined grossly and microscopically following the criteria and nomenclature of the International Working Party on the Terminology of Nodular Hepatocellular Lesions<sup>[8]</sup>.

### Image evaluation

Data processing was performed at a workstation with

Table 1 Average of PEI in nodules and adjacent parenchyma

	PEI	SD	<i>t</i>	<i>P</i>
RN	205.67	31.17	5.30	0.06
DN	161.94	20.74	3.64	0.02 <sup>a</sup>
eHCC	226.09	34.83		
HCC	491.86	44.61	3.74	0.02 <sup>a</sup>
Parenchyma	204.84	70.19		

<sup>a</sup>*P* < 0.05.

AW 4.2 software package (General Electric, USA). Signal intensity and time curves were derived from manually drawing regions of interest (ROIs) on nodules and surrounding hepatic parenchyma. Positive enhancement integral (PEI) representing the blood perfusion could be obtained by setting the start (8th) and end (12th) phases. Values were expressed as mean  $\pm$  SD. Statistical analysis was performed with SPSS 11.0. Perfusion data between nodules and parenchyma nearby were compared with *t* test. *P* < 0.05 was considered statistically significant.

## RESULTS

A total of 46 nodules were located by MR imaging and autopsy, including 22 dysplastic nodules (DN), 9 regenerative nodules (RN), 10 early HCCs and 5 overt HCCs. Among the DN (2–7 mm, average 4.6 mm), 6 were low grade DN (LGDN) and 16 were high grade DN (HGDN). The average positive enhancement integral (PEI) of DN, early and overt HCCs was  $205.67 \pm 31.17$ ,  $161.94 \pm 20.74$ ,  $226.09 \pm 34.83$ ,  $491.86 \pm 44.61$  respectively, and their adjacent liver parenchyma was  $204.84 \pm 70.19$  (Table 1).

By comparing the blood perfusion index between nodules and their surrounding hepatic parenchyma, we found no difference in RN (*t* = -5.303, *P* = 0.06) showing the same signal intensity as its adjacent parenchyma at both hepatic artery phase and portal vein phase of MR perfusion. There were significant differences in dysplastic nodules (*t* = -3.63, *P* = 0.02) which manifested decreased blood perfusion. At the later phase of hepatic artery, the perfusion curve in DN declined when compared with surrounding parenchyma. DN showed an iso-signal intensity at hepatic artery phase and a low signal intensity at portal vein phase (Figure 1).

Of the 10 early HCCs, 4 manifested low perfusion and the average PEI value was smaller than that of adjacent parenchyma, showing an iso-signal intensity at the phase of artery and a low signal intensity at portal vein phase. The PEI values were higher in 6 early HCCs than in parenchyma nearby, which had a relatively higher signal intensity at hepatic artery phase and a low signal intensity at portal vein phase (Figure 2). Five overt HCCs had a remarkably higher signal intensity at hepatic artery phase and their perfusion curves ran up when compared with the surrounding parenchyma at early artery phase. The PEI value of HCC was much higher than that of adjacent parenchyma and the difference was significant (*t* = 3.74, *P* = 0.02) (Figure 3).

**Figure 1** DN showing a high signal intensity on T2, but not on T1 and PWI.

**Figure 2** Early HCC showing an iso-signal intensity on T1, a high signal intensity on T2 or on T2 coronal.

## DISCUSSION

There is cumulative evidence that RN at the late stage of hepatic cirrhosis can develop into HCC through an intermediate step of DN which has been considered as a precancerous lesion by the International Working Party since 1995<sup>[8,9]</sup>, even though the hepatocarcinogenesis has not been clarified thoroughly. Early detection of HCC is critical to patient treatment and survival because of improved surgical techniques for resection and transplantation and new alternative therapeutic options, such as transcatheter chemoembolization or radiofrequency ablation. For surveillance of patients at

risk, accurate methods capable of revealing not only HCC but also the premalignant precursor, namely DN, are required.

The imaging characteristics of DN have been previously reported<sup>[10-12]</sup>. However, the diagnosis of precancerous lesions is still difficult because of the overlapping between DN and RN, DN and early HCC on ultrasound, CT and MRI. Meanwhile, some researchers demonstrated that RN has almost the same blood flow as liver, which is mainly supplied by portal vein, and hepatic artery accounting for only a small part of total blood flow<sup>[13]</sup>. When RN progresses into DN, the blood flow in most parts of DN decreases (mainly portal vein

**Figure 3** HCC showing an iso/low-signal intensity on T1WI, a hyper-intensity on T2.

blood supply) compared with surrounding parenchyma, and HCC always has increased blood flow (mainly hepatic artery blood supply) than its adjacent parenchyma. Until now this change has been regarded as the key-point to differentiate the nodules in liver. CTAP and CTHA are considered the best ways to make their differential diagnosis. But the application is limited in clinical practice due to their invasiveness. Non-invasive methods at present mainly focus on multi-detector spiral CT, MRI, PET and harmonic ultrasound<sup>[14-17]</sup>. To our knowledge, hemodynamic changes in hepatic nodules studied with MR perfusion have not been previously reported.

In the present study, MR perfusion demonstrated hemodynamic changes during the transition of RN to DN, early and overt HCC. The results obtained by ultra-fast MR perfusion scanning are consistent with those by invasive methods of CTAP or CTHA<sup>[18]</sup>. Moreover, hepatic artery segment of the perfusion curve in nodules declined slightly compared with surrounding parenchyma at the stage of HGDN and early HCC, suggesting that the preexisting hepatic artery is destructed in nodules. Otherwise, the positive enhancement integral representing the total blood flow would show polarization during this period. Part of them presented as increased blood flow (6/10 in early HCC; 5/16 in HGDN), but decreased blood flow was also observed at the same time in others (4/10 in early HCC; 11/16 in HGDN). The results of our pathology showed that the blood vessels in DN (including HGDN and LGDN) decreased compared with its surrounding hepatic parenchyma, and an increased number of tumor vessels were seen in HCC and even in early HCC. However, sinusoidal capillarization inside the nodules became gradually prominent during the process from RN, LGDN to HGDN and finally to HCC. This discrepancy cannot be clearly explained at present. The explanation of this phenomenon and the answer to its relationship with the alteration of nodular characteristics, and whether it

corresponds with the different changes in tumor cells or in microvessels, depend on further pathologic studies.

The main advantage of MR perfusion is that this procedure provides ample information not only on the hemodynamic changes of nodular lesions in liver, but also on the parenchyma of the tumor. Therefore, this technique may be more valuable for the differential diagnosis of nodules in liver. The sequence we used in this study was fast spin gradient echo (FSPGR) which is as fast as echo-planar imaging (EPI). The ratio of time resolution was 0.5 s/section, but its signal-noise ratio (SNR) and spatial resolution were much higher than those of EPI, suggesting that this sequence is suitable for liver MR perfusion.

Nowadays, although CT perfusion (CTP) and PET are also used to study the hemodynamics, MR perfusion shows more advantages when small nodular lesions in liver and precancerous lesion of HCC are analyzed. It has been reported that MRI is more sensitive than CT and PET in revealing the small nodules in liver, especially in the hepatic parenchyma with the background of serious cirrhosis<sup>[19,20]</sup>. Moreover, MR perfusion has no side effects of radiation and has a better prospect than CT in study of hemodynamics. However, both MR imaging and CT have their technical defects at present. The scan of perfusion could only focus on ROI of one or several sections and could not cover the whole liver, while nodular lesions liver are usually multiple and located in different lobes, thus limiting its application in clinical practice. Newly developed harmonic ultrasound showing the vascular structure inside nodules more clearly, may have a broader prospect. Reports on the application of this technique in liver are few and further investigation is needed<sup>[21]</sup>.

## Abstract

**AIM:** To investigate the significance of *p16* and *O*<sup>6</sup>-methylguanine-DNA methyltransferase (*MGMT*) genes promoter hypermethylation and *K-ras* mutations on colorectal tumorigenesis and progression.

**METHODS:** *p16* and *MGMT* methylation status was examined on 47 tumor samples, and *K-ras* mutational status was examined on 85 tumor samples. For methylation analysis, a methylation specific PCR (MS-PCR) method was used.

**RESULTS:** *p16* and *MGMT* promoter methylation was found in 51% (24/47) and 43% (20/47) of CRCs, respectively, and the *K-ras* mutation was found in 44% (37/85) of CRCs. Comethylation of *p16* and *MGMT* genes was significantly associated with lower aggressiveness of the disease within a two-year period of observation. Only 27% of patients with simultaneous *p16* and *MGMT* methylation showed the detectable occurrence of metastasis and/or death, compared to 67% of patients without double methylation or with no methylation (3/11 vs 22/33,  $P < 0.05$ ,  $\chi^2$ -test). In addition, *p16* and *MGMT* comethylation showed a trend toward an association with longer survival in patients with CRCs ( $35.5 \pm 6.0$  mo vs  $23.1 \pm 3.2$  mo,  $P = 0.072$ , Log-rank test). Progression of the disease within a two-year period was observed in 66% of patients carrying the *K-ras* mutation, compared to only 19% of patients with wild type *K-ras* (29/44 vs 7/37,  $P < 0.001$ ,  $\chi^2$ -test). The presence of the *K-ras* mutation significantly correlated to shortened overall survival ( $20.0 \pm 1.9$  mo vs  $37.0 \pm 1.8$  mo,  $P < 0.001$ , Log-

rank test). The comethylation of *p16* and *MGMT* genes was significantly associated with lower aggressiveness of the disease even when *K-ras* mutations were included in the analysis as an independent variable.

**CONCLUSION:** Our data suggest that comethylation of promoters of *p16* and *MGMT* genes could have a prognostic value in patients with CRC. Specifically, concurrent methylation of both genes correlates with better prognosis.

## INTRODUCTION

Point mutations in the *K-ras* gene are among the most common genetic features of colorectal cancers (CRCs)<sup>[1]</sup>. In addition to mutational changes, epigenetic mechanisms also play an important role in the pathogenesis of this tumor type. The main epigenetic modification observed in the human genome is methylation of cytosine residues within CpG dinucleotides. Aberrant *de novo* methylation of CpG islands within the promoter region may lead to silencing of gene transcription through a complex process involving chromatin condensation and histone deacetylation<sup>[2,3]</sup>. Epigenetic silencing through DNA methylation can begin very early in tumor progression and may affect multiple genes involved in different cellular pathways, including cell cycle control, DNA repair and many others<sup>[4,5]</sup>.

Inactivation of cell cycle regulatory genes, such as *p16*, confers a selective growth advantage to affected cells. This tumor suppressor gene encodes a cyclin-dependent kinase inhibitor, which is critical for maintaining the retinoblastoma (Rb) protein in its active,

non-phosphorylated state in the cyclin D-Rb pathway<sup>[6]</sup>. Promoter hypermethylation may lead to transcriptional inactivation of *p16* resulting in abnormal cell cycling and uncontrolled cell growth, which are the hallmarks of cancer cells<sup>[7]</sup>.

In addition, epigenetic modification can cause inactivation of DNA repair genes, such as O<sup>6</sup>-methylguanine-DNA methyltransferase (*MGMT*)<sup>[8]</sup>. *MGMT* is a DNA repair protein that removes mutagenic and cytotoxic alkyl adducts from the O<sup>6</sup> position of guanine<sup>[9]</sup>. In the absence of *MGMT* activity, the adducts are not removed allowing the O<sup>6</sup>-alkyl guanine to mispair with thymine during DNA replication, resulting in a G-to-A transition<sup>[10]</sup>. This kind of mutation may accumulate in the genes specifically associated with particular tumor types, such as *K-ras* in CRCs<sup>[9]</sup>.

The literature suggests that hypermethylation of *p16* and *MGMT* genes occurs as frequently in CRCs as previously reported for the *K-ras* gene<sup>[7,11,12]</sup>. Epigenetic changes usually begin very early in carcinogenesis, are potentially reversible, and can advance to gene alterations. For this reason, detection of aberrant methylation can be important for early diagnosis, prognosis and treatment of patients affected by this disease<sup>[5,13]</sup>.

In the present study, we analyzed the methylation status of *p16* and *MGMT* gene promoters in patients with primary CRC and compared the frequency of these changes with the occurrence of the *K-ras* gene mutations. In addition, we evaluated the correlation of these gene alterations with standard clinicopathological parameters, such as Dukes' stage, differentiation, location, histological and macroscopical type of tumor, patient gender and age. We also examined the possible correlation between these gene alterations and some immunohistochemical parameters that are known to be indicators of cell transformation, migration and metastasis of tumor cells. These parameters include altered expression of adhesive molecules E-cadherin and CD44, decrease or loss of laminin, which is a major component of epithelial basal membrane, and increased proliferate activity of the neoplastic cell. The ultimate aim of this study was to evaluate the influence of these genetic and epigenetic changes on disease progression and patient survival.

## MATERIAL AND METHODS

### Patients and tumor specimens

Tumor material in the form of formalin-fixed and paraffin-embedded tissue was obtained from 85 patients who underwent radical surgical resection (R0) at the Institute for Pathology and Forensic Medicine, Military Medical Academy, Belgrade. All patients gave informed consent prior to specimen collection according to institutional guidelines. None of the patients had preoperative or postoperative chemotherapy. The progression of the disease (occurrence of metastasis or/and death) was monitored during the two-year period following surgery, and survival over a five-year period was estimated. Mean follow-up was 31, 4 mo (range, 2 to 66 mo).

Tumor tissue chosen for analysis was routinely processed and microscopically examined for the regions

enriched in neoplastic cells. Several 10  $\mu$ m sections with neoplastic cell content greater than 85% were taken from each specimen and used for direct *in vitro* amplification of the *K-ras* gene by polymerase chain reaction (PCR). For *K-ras* mutational analysis, the sample of 47 was augmented with 38 samples from our previous study<sup>[14]</sup>. For analysis of *p16* and *MGMT* methylation status, DNA was isolated from 47 samples.

### Analysis of mutation status of the *K-ras* gene

Sections (10  $\mu$ m thick) of the formalin-fixed and paraffin-embedded tumor specimens were de-paraffined and kept under 70% ethanol at 4°C until PCR. *In vitro* amplification of 111-bp DNA fragments encompassing codons 12 and 13 of the *K-ras* gene was performed on tissue from sections as described by Almoguera *et al*<sup>[15]</sup>. Detection of *K-ras* mutations was performed on 85 patients with primary CRC by a highly selective oligonucleotide hybridization technique, as described earlier<sup>[14]</sup>. Two specimens were analyzed by single strand conformation polymorphism (SSCP) electrophoresis.

### Analysis of methylation status of the *p16* and *MGMT* genes

DNA methylation patterns in the promoter CpG islands of the *p16* and *MGMT* genes were determined in 47 samples by methylation-specific PCR (MSP) following the bisulfite modification of isolated genomic DNA, as described by Herman *et al*<sup>[16]</sup>, with some modifications<sup>[17]</sup>. Briefly, DNA was isolated from deparaffined tumor specimens using standard Proteinase K, phenol/chloroform/isoamyl alcohol extraction, and ethanol precipitation. Two  $\mu$ g of isolated DNA were denatured by NaOH (final 0.3 mmol/L) at 42°C for 30 min and modified by sodium bisulfite (5.20-5.69 mol/L, pH 5.0, Sigma, USA) for 4 hr at 55°C. After incubation, DNA was purified using the DNA extraction KIT (MBI Fermentas, Lithuania), again treated by NaOH (final 0.3 mol/L), at 37°C for 20 min, precipitated with ethanol/ammonium acetate and resuspended in 40  $\mu$ L of 1 mmol/L Tris-HCl, pH 8.0. Aliquots of 4  $\mu$ L of bisulfite modified DNA were used for MSP reactions. The PCR mixture contained 1 x PCR buffer (16 mmol/L ammonium sulfate, 67 mmol/L Tris-HCl, pH 8.8, 10 mmol/L 2-mercaptoethanol), 6.7 mmol/L MgCl<sub>2</sub>, dNTP (each at 1.25 mmol/L) and primers (300 ng each per reaction) in a final volume of 50  $\mu$ L. Reactions were hot-started at 95°C for 5 min before the addition of 1.25 units of Taq polymerase (MBI Fermentas, Lithuania). Amplification was carried out in a Hybaid OmniGene temperature cycler for 35 cycles (30 s at 95°C, 30 s at the adequate annealing temperature, and 30 s at 72°C), followed by a final extension for 4 min at 72°C. Primers for a methylated and unmethylated promoter of the *p16* gene were used from Herman *et al*<sup>[16]</sup> and for the *MGMT* gene from Esteller *et al*<sup>[8]</sup>. The annealing temperatures for unmethylated and methylated *p16* amplification were 60°C and 65°C, respectively, whereas the annealing temperature for both unmethylated and methylated *MGMT* amplification was 57°C. Controls without DNA were performed for each set of PCRs. Modified DNA from the human lymphoma cell line Raji (ECACC No:

85011429) served as positive control for methylated alleles, and modified DNA from normal lymphocytes as negative control for methylated alleles of *p16* and *MGMT* genes. 10  $\mu$ L of each PCR reaction were directly loaded on to nondenaturing 8% polyacrylamide gels, stained with AgNO<sub>3</sub> and visualized by Na<sub>2</sub>CO<sub>3</sub>, or 2% agarose gels, stained with SYBR Green I and visualized under UV illumination.

### Immunohistochemistry

Immunohistochemistry was performed using the labeled streptavidin-biotin method (LSAB Kit+, Dako, Denmark) with microwave pretreatment for antigen retrieval. Endogenous peroxidase activity was blocked by incubating with 3% H<sub>2</sub>O<sub>2</sub>. Sections were then incubated with primary monoclonal antibodies against E-cadherin (HECD-1, Zymed Laboratories, San Francisco, USA), CD44 (Clone DF 1485, Dakocytomation, Denmark) and Laminin (4C7, Dakocytomation, Denmark) and Proliferation Cell Nuclear Antigen-PCNA (PC-10, Dakocytomation, Denmark) in optimal concentrations. Amino-ethyl carbazole was used as chromogen and finally Mayer's hematoxylin was used for counterstaining. The presence of a positive reaction in some normal tissue structures served as a positive control. Negative controls were prepared by replacing the primary antibody with Tris-buffered saline.

Immunostaining (membrane cytoplasmic immunoreactivity) for CD44 was calculated as the percentage of positive tumor cells in relation to the total number of tumor cells in representative fields. The presence of less than 10%, from 10% to 50%, and for more than 50% of positive tumor cells of CD44 were considered as low, moderate and extensive expression, respectively. Present, heterogenous and absent expression in the case of E-cadherin were distinguished. The loss of laminin immunoreactivity at the tumor-stroma borders was considered according to a three-point semiquantitative scale as follows: in more than 75%, between 25%-75% and in less than 25% of glandular structures. The PCNA index was considered to be low if less than 10% of tumor cell nuclei were positive, moderate for 10%-50%, and high for more than 50% of PCNA positive tumor cell nuclei.

### Statistical analysis

Contingency tables were analyzed using Pearson's  $\chi^2$ -test or Fisher's exact two-tailed test (*F*-test), when expected frequencies were lower than five. Continuous variables were compared with the use of Student's *t*-test. Overall survival distributions were estimated by the Kaplan-Meier method and differences were evaluated by the Log-rank test. The data was fitted to Cox's proportional risks regression model. In all tests, a *P* value less than 0.05 were considered as statistically significant.

## RESULTS

### *K-ras* mutations, *p16* and *MGMT* promoter methylation in primary colorectal carcinomas

We detected *K-ras* mutations in 44% (37/85) of patients with CRC. The distribution of mutations was 57% (21/37) of G-to-T transversions, 32% (12/37) of G-to-A transitions and 11% (4/37) of G-to-C transversions. In

**Figure 1** Analysis of *p16* (A) and *MGMT* (B) gene methylation by MSP. The presence of a visible PCR product in lanes U indicates the presence of unmethylated genes of *p16* (151 bp) and *MGMT* (93 bp); the presence of product in lanes M indicates the presence of methylated genes of *p16* (150 bp) and *MGMT* (81 bp). The samples of colorectal carcinoma 1, 2 and 4 show *p16* promoter hypermethylation, while 6, 8 and 9 show *MGMT* promoter hypermethylation. NL-normal lymphocytes as a positive control for unmethylated alleles; Raji-commercial cell line as a positive control for methylated alleles; St-molecular weight marker (50 bp).

codons 12 and 13, we detected mutations in 73% (27/37) and 27% (10/37), respectively.

Aberrant methylation of *p16* and *MGMT* genes was detected in 51% (24/47) and 43% (20/47) of patients, respectively. Representative examples of the methylation analysis are shown in Figure 1A and B.

Of the total number of cases analyzed for methylation, 45% (21/47) had a mutant *K-ras* gene. Simultaneous alterations of *K-ras* and *p16* genes were detected in 26% (12/47) of tumors. These events seemed to occur independently, as estimated by a  $\chi^2$ -test (results not shown). The type of mutation at *K-ras* did not show a significant association with the *p16* methylation by an *F*-test, although 55% (6/11) of samples with the hypermethylated *p16* promoter carried G-to-T transversions in *K-ras*.

Simultaneous occurrence of *K-ras* mutation and *MGMT* methylation was detected in 21% (10/47) of the patients. Our results showed that *MGMT* methylation is significantly associated with a G-to-A transition in the *K-ras* gene (*P* = 0.01, *F*-test). This type of oncogene transition mutation occurs in 67% (6/9) of tumors carrying *MGMT* methylation, in contrast to only 10% (1/10) of tumors without *MGMT* methylation, but with the same type of *K-ras* mutation.

Concurrent methylation of *p16* and *MGMT* genes was detected in 11 out of 47 (23%) cases, while simultaneous *K-ras*, *p16* and *MGMT* alterations were present in 6 out of 47 cases (13%). Methylation of *p16* and *MGMT* as well as *K-ras* mutation vs comethylation of *p16* and *MGMT* genes seemed to occur independently as assessed by a  $\chi^2$ -test (results not shown).

### Correlation of *K-ras* mutations and hypermethylation of *p16* and *MGMT* genes with clinicopathological and immunohistochemical parameters

We further examined correlation between genetic and epigenetic alterations and some clinicopathological and

Complete clinicopathological data were missing on one sample of colorectal cancer, and it was only included in analysis of genetic alterations; <sup>a</sup> $P < 0.05$ ; <sup>b</sup> $P < 0.001$  (all  $P$  values were revealed by  $\chi^2$ -test); Data are missing on two<sup>1</sup> subjects for *p16* and *MGMT* methylation status analysis, and on one<sup>2</sup> and three<sup>3</sup> subjects for *K-ras* mutation analysis, respectively. <sup>4</sup>Data for C and D Dukes' stages are considered together for *K-ras* mutation analysis.

immunohistochemical parameters that might be important for disease prognosis in CRC patients. The results of these analyses are summarized in Tables 1 and 2.

The presence of *K-ras* mutations was significantly more frequent in female than in male patients ( $P < 0.05$ ,  $\chi^2$ -test, Table 1). In addition, the average age of female patients carrying *K-ras* mutations was  $53.3 \pm 11.8$  years, which was significantly lower ( $P < 0.01$ ,  $t$ -test) than the average age for males with *K-ras* mutations ( $64.1 \pm 8.7$  years). As presented in Table 1, there was no significant association between the presence of the *K-ras* mutations and other clinicopathological features. However, the presence of *K-ras* mutations correlated significantly with the lack of E-cadherin expression, extensive expression and cytoplasmic type of CD44 antigen, decreased expression of laminin and the high PCNA index ( $P < 0.001$  by  $\chi^2$ -test in all cases; Table 2). These correlations were independent of the type of *K-ras* mutation, except in the case of E-cadherin, where the lack of expression of this adhesive molecule showed a significant correlation with the G-to-T transversions ( $P < 0.05$ ,  $\chi^2$ -test, results not shown).

*p16* methylation was not associated with any of the variables considered, as presented in Table 1 and 2, though *p16* methylation tended to be more prevalent in tumors not expressing E-cadherin ( $P < 0.1$ ,  $\chi^2$ -test). Methylation of *MGMT* gene was significantly more prevalent in polypoid than in flat colorectal carcinomas ( $P < 0.05$ ,  $\chi^2$ -test,

Complete immunohistochemical data were missing on one sample of colorectal cancer, and it was only included in analysis of genetic alterations; <sup>b</sup> $P < 0.001$  (all  $P$  values were revealed by  $\chi^2$ -test); Data are missing on two<sup>1</sup> and three<sup>2</sup> subjects for *p16* and *MGMT* methylation status analysis, respectively, and on three<sup>3</sup> and four<sup>4</sup> subjects for *K-ras* mutation analysis, respectively.

Table 1). There was no significant association between *MGMT* methylation and any other clinicopathological features studied. In addition, comethylation of *p16* and *MGMT* genes did not correlate with any clinicopathological or immunohistochemical parameters considered.

### Survival analysis

In this study, we also monitored the progression of the disease in the two-year period following surgery. Methylation of *p16* and *MGMT* genes, when they were considered separately, showed slight but insignificant correlation with slower progression of disease (Table 1). However, during that period, only 27% (3/11) of patients with simultaneous *p16* and *MGMT* methylation showed the occurrence of metastasis and/or death, compared to 67% (22/33) of patients without this double or any gene methylation ( $P < 0.05$ ,  $\chi^2$ -test, Figure 2A).

This association was preserved and was even higher ( $P < 0.01$ ,  $F$ -test, Figure 2B) when *K-ras* mutations were included as an independent variable. Namely, the progression of the disease occurred in only 2 of 6 (33%) patients with *p16* and *MGMT* comethylation and *K-ras* mutations, while disease recurred in 13 of 14 (93%) patients with the *K-ras* mutation, but with only one methylated or both unmethylated genes. However, when both genes were unmethylated in the presence of the mutant *K-ras* gene, it was observed that all 4 patients from this group exhibited the progression of the disease within two years, compared to only 2 of 6 patients with *p16* and *MGMT* comethylation and *K-ras* gene mutations ( $P = 0.076$ ,

**Figure 2** Graphical distribution of progression of the disease in the two-year period, as a function of simultaneous *p16* and *MGMT* methylation status (A); simultaneous *p16*, *MGMT* methylation and mutated *K-ras* gene compared either to no simultaneous or any methylation of two genes (B) or to unmethylated both (C), respectively.

*F*-test, Figure 2C).

When the analyzed group was augmented with 38 patients from our previous study on CRC<sup>[14]</sup>, we observed the progression of disease within a two-year period in 66% (29/44) of patients carrying the *K-ras* mutation, compared to only 19% (7/37) of patients with the wild type *K-ras* gene ( $P < 0.001$ ,  $\chi^2$  test, Table 1).

The Kaplan-Meier analysis of the few-year survival rate revealed a slight but insignificant influence of *p16* and *MGMT* gene methylation on longer overall survival when the alterations of these genes were considered separately (results not shown). However, simultaneous *p16* and *MGMT* methylation showed a trend toward association with longer survival in patients with CRCs who underwent curative surgery ( $P = 0.072$ , Log-rank-test, Figure 3A), as the median survival for these patients was  $35.5 \pm 6.0$  mo in contrast to  $23.1 \pm 3.2$  mo for patients without simultaneous or any methylation of examined genes. Multivariate analysis revealed that *p16* and *MGMT* comethylation had no prognostic value without additional variables. By the same analysis, the presence of *K-ras* mutations significantly correlated to shortened overall survival ( $20.0 \pm 1.9$  mo *vs*  $37.0 \pm 1.8$  mo) for 85 patients included in the analysis ( $P < 0.001$ , Log-rank test, Figure 3B). However, a Kaplan-Meier analysis considering simultaneous presence of *K-ras* mutations according to the methylated status of *p16* and *MGMT* was not possible because there was a small number of samples.

## DISCUSSION

The significance of *p16* and *MGMT* methylation for tumor formation and progression, as well as correlation with the

**Figure 3** Overall survival among the patients with CRC according to the methylation status of *p16* and *MGMT* genes (A), and mutational status of *K-ras* gene (B). Overall survival is longer in the group of the patients with simultaneous methylation of *p16* and *MGMT* gene than in group with no simultaneous or any methylation ( $P = 0.072$ , Log-rank test). Overall survival is significantly lower in the group of patients with mutated *K-ras* than in group with unchanged, wild type *K-ras* gene ( $P < 0.001$ , Log-rank test). Survival curves were constructed by Kaplan-Meier method.

occurrence of classical genetic changes in *K-ras* genes, was the major subject of this study. While the frequency of the genetic and epigenetic alterations in these genes was similar to those previously reported<sup>[7,8,11,18,19]</sup>, this is the first study to assess their cumulative and individual effects on disease progression.

While there was no clear association between methylation and standard prognostic parameters in CRC, the data obtained from survival analysis suggest that the simultaneous methylation of *p16* and *MGMT* genes could be a better predictive factor for the course of disease. The most important finding of the current study was that comethylation of *p16* and *MGMT* genes was significantly associated with lower aggressiveness of the disease and tended to associate with longer overall survival in patients with CRC who underwent curative surgery. More importantly, the influence of the double gene alteration was significant in spite of the simultaneous presence of *K-ras* mutations, which is another well established molecular marker of unfavorable prognosis in CRCs. Consistent with our previous findings<sup>[14]</sup> and those of the multicentric RASCAL study<sup>[20]</sup>, our present results confirm that the mutated *K-ras* gene is a molecular marker for the more aggressive course of disease and was connected to reduced overall survival. In addition, we demonstrated

that K-*ras* mutation is strongly associated with parameters that are indicators of poor prognosis. These include the absence of E-cadherin expression<sup>[21]</sup>, extensive expression of the cytoplasmic type of CD44 antigen<sup>[22]</sup>, low expression of laminin<sup>[23]</sup> and high PCNA index<sup>[24]</sup>.

The functional association between the effect of *p16* and *MGMT* gene inactivation and K-*ras* mutation on the progression of disease is not clear. Yet, in the absence of methylation of both *p16* and *MGMT* genes together with the mutated K-*ras*, a severe form of the disease is likely to commence. There is evidence that CRC does not evolve through a single sequence of molecular alterations, but evolves through different pathways. Each of them has distinct clinical, pathological and molecular characteristics<sup>[25]</sup>. One possible explanation for our findings could be that the colorectal tumors without comethylation of the two genes could arise through different mechanisms. These include large genetic rearrangements and chromosomal instability, with a significant degree of gene amplification and deletion<sup>[26,27]</sup> and such changes could be associated with a more aggressive course of the disease as proposed by Verma and Srivastava<sup>[13]</sup>. The other proposed pathway of colorectal carcinogenesis involves the occurrence of microsatellite instability (MSI), which is a phenotype resulting from alteration in the mismatch repair genes; e.g. *bMLH1* and *bMLH2*<sup>[28,26]</sup>. Some authors reported a relationship between MSI and CpG island methylator phenotype (CIMP+), as *bMLH1* is frequently inactivated by aberrant promoter methylation in sporadic MSI-H CRCs<sup>[29]</sup>. On the other hand, the CIMP+ phenotype is described as the occurrence of simultaneous methylation of a large number of genes, including *p16* and *bMLH1*<sup>[29,30]</sup>. Though the biological and clinical properties of CIMP+ CRCs remain largely unknown, there is no longer doubt that those epigenetic changes mark a distinct group of tumors that have unique molecular profiles and etiology. More over, Wynter *et al*<sup>[31]</sup> demonstrated that there are at least two pathways for colorectal carcinogenesis, both implicating CIMP-high status. One group of tumors arises through *BRAF* mutations and *bMLH1* methylation, and another with K-*ras* instead of *BRAF* mutations and with *MGMT* instead of *bMLH1* promoter hypermethylation. Whitehall *et al*<sup>[32]</sup> demonstrated that methylation of *MGMT* has been linked to low levels of MSI (MSI-L) and Samowitz *et al*<sup>[33]</sup> demonstrated that the appearance of K-*ras* mutations is rare in high level MSI-H CRC. It is also known that MSI-H CRC associated with a CIMP+ phenotype is mostly located within the proximal colon<sup>[27,29]</sup>. In our study, all but three tumors have been located within the distal colon, so we can only speculate that they may not belong to the MSI-H group. We propose that in our group of analyzed patients who mostly have distal CRC, comethylation of *p16* and *MGMT* genes together with other molecular changes suggest a pathway in signal transduction that could increase survival. Importantly this is in spite of the opposing effect of K-*ras* mutations. It would, therefore, be interesting to determine the MSI phenotype in this patient population in order to establish a possible association with observed genetic and epigenetic alteration.

Though all these questions cannot be fully resolved in the present study, our results confirm the multifactorial nature of cancer development, highlighting the molecular differences across the various classes of lesions, and exclude a single linear model of accumulating genetic alterations. In this report, we describe the association of concurrent methylation of *p16* and *MGMT* genes with the course of disease in unselected group of CRCs. At this point, it must be noted that we did not analyze a large group of patients. However, the size of our study is still large enough to interpret the results correctly.

While some studies reported a correlation between promoter hypermethylation of the *p16* gene and prognosis in patients with colorectal cancers<sup>[34-38]</sup>, others observed no significant role of *p16* methylation as a prognostic factor<sup>[30]</sup>. In addition, Nagasaka *et al*<sup>[39]</sup> found that methylated *MGMT* was significantly related to lower risk of recurrence in CRC. They proposed that colorectal tumors with methylated *MGMT* are less aggressive than tumors without such epigenetic change. Liang *et al*<sup>[34]</sup> proposed that geographical differences or other unknown factors supplementary to *p16* methylation might increase tumor aggressiveness. Considering these and our previous results<sup>[14]</sup>, we speculate that different geographic, environmental, and lifestyle factors could affect the genesis and clinical behavior of CRCs with different molecular profiles. Nevertheless, prospective studies that incorporate a larger number of genes and environmental factors are required to determine the relative contribution of each factor to the risk of developing CRCs with specific epigenetic and genetic profiles. We further support the notion that precise determination of molecular changes in CRCs is needed in order to overcome the risk of oversimplifying the role of a single or few genetic or epigenetic changes in tumorigenesis. Such analysis, supplemented by the conventional study of prognostic factors, introduces quality to prognostication of patients with CRC and aids the design of more efficient treatment modalities.

## COMMENTS

### Background

Colorectal carcinogenesis is a multistep process in which the progressive accumulation of genetic and epigenetic changes leads to a malignant transformation of normal epithelial cells of colon and rectum. Point mutations in K-*ras* gene are among the most common genetic features of colorectal cancers. In the past decade it has been shown that methylation of the promoter region of many tumor suppressor and DNA repair genes, such as *p16* and *MGMT* has the important role in pathogenesis of this tumor type too, but its influence on disease progression remain inconclusive.

### Research frontiers

Epigenetic changes usually begin very early in carcinogenesis, they are potentially reversible, and they can advance to gene alterations. For this reason, detection of aberrant methylation can be important for early diagnosis, prognosis and treatment

of patients affected by this disease.

### Innovations and breakthroughs

Comethylation of *p16* and *MGMT* genes was significantly associated with lower aggressiveness of disease within two-year period of observation ( $P < 0.05$ ), and showed the trend toward the association with longer survival in patients with CRCs ( $P = 0.072$ ). On the other hand, the presence of K-ras mutations was associated with higher aggressiveness and shortened overall survival ( $P < 0.001$ ). The comethylation of *p16* and *MGMT* genes was significantly associated with lower aggressiveness of disease even when K-ras mutations were included in analysis as an independent variable ( $P < 0.01$ ). This is the first attempt to assess the cumulative and individual effect of these genes on the disease progression.

### Applications

The results presented in this article have demonstrated that the precise determination of molecular changes in CRCs is needed in order to overcome the risk of oversimplifying the role of single or a few genetic or epigenetic changes in tumorigenesis. In addition, this study underlines the need for considering the different geographic, environmental, and lifestyle factors that could affect the genesis and clinical behavior of CRCs with different molecular profiles. Prospective studies supplemented by the conventional study of prognostic factors, could improve the quality and accuracy of patients prognosis and aid design of the more efficient treatment modalities.

### Terminology

Epigenetic changes: heritable changes in gene function that do not include the changes in DNA sequence. DNA methylation: the addition of a methyl group to a cytosine residue that lies next to guanine within CpG dinucleotides. Aberrant *de novo* methylation of CpG islands within the promoter region may lead to silencing of gene transcription through a complex process involving chromatin condensation and histone deacetylation. CpG islands: CpG rich areas located in the promoter regions of many genes. Methylation-specific PCR (MSP): amplification of modified DNA by sodium bisulfite that converts unmethylated cytosines to uracils, while methylated cytosines remains unmodified.

### Peer review

The authors found some interesting findings where they showed that patients with tumors where both promoters were methylated showed less death and had longer survival rates than patients with unmethylated promoters. The data is straightforward and convincing. The authors address a clinically relevant issue on CRC prognosis. They have also demonstrated initial and unique findings examining K-ras, *p16* and *MGMT* modifications and patient outcome.

## Abstract

**AIM:** To evaluate the implication of substitutions in the hepatitis C virus (HCV) non-structural 5A (NS5A) protein in the resistance of HCV during mono-interferon (IFN) or combined IFN-ribavirin (IFN-R) therapy. Although NS5A has been reported to interact with the HCV RNA-dependent RNA polymerase, NS5B, as well as with many cellular proteins, the function of NS5A in the life cycle of HCV remains unclear.

**METHODS:** HCV quasispecies were studied by cloning and sequencing of sequential isolates from patients infected by HCV genotype 1b. Patients were treated by IFN- $\alpha$ 2b for 3 mo followed by IFN- $\alpha$ 2b alone or combined IFN-R therapy for 9 additional months. Patients were categorized into two groups based on their response to the treatments: 7 with sustained virological response (SVR) (quasispecies = 150) and 3 non-responders (NR) to IFN-R (quasispecies = 106).

**RESULTS:** Prior to treatment, SVR patients displayed a lower complexity of quasispecies than NR patients. Most patients had a decrease in the complexity of quasispecies during therapy. Analysis of amino acids substitutions showed that the degree of the complexity of the interferon sensitivity-determining region (ISDR) and the V3 domain of NS5A protein was able to discriminate the

## INTRODUCTION

In Western countries, the hepatitis C virus (HCV) is the major cause of chronic hepatitis, cirrhosis and hepatocellular carcinoma<sup>[1]</sup>. HCV is a RNA virus belonging to the *Flaviviridae*. It has a single-stranded plus-sense genome of approximately 9.6 kb with a single open reading frame (ORF) encoding four structural (C, E1, E2 and p7) and six non-structural proteins (NS2, NS3, NS4A, NS4B, NS5A and NS5B). Current combination therapy of pegylated interferon (IFN) alpha and ribavirin (IFN-R) is not universally effective in patients with chronic hepatitis C; patients infected with genotypes 2 or 3 show a high rate of sustained virological response (SVR) (90%) whereas the HCV genotype 1 infected patients have the lowest level of SVR (40% to 50%)<sup>[2-4]</sup>. Factors that can predict the response to antiviral therapy are not well established; the accepted predictive parameters are: age, sex, pre-treatment viral load, fibrosis stage and HCV genotype<sup>[5]</sup>. Numerous studies have been undertaken to explain the resistance of genotype 1-infected patients to IFN therapy. Causes and mechanisms are not well understood, but several viral genomic regions have been suggested to antagonize the antiviral effect of IFN alpha, such as the E2, NS3/4A and NS5A regions<sup>[6]</sup>.

The non-structural 5A (NS5A) protein is the ninth

protein coded by the ORF of HCV. It has a length of 447 amino acids (aa) for genotype 1b. An interaction with the double-stranded RNA protein kinase (PKR) has been described for NS5A within the codons 2209 and 2274 (NS5A<sub>2209-2274</sub>)<sup>[17-9]</sup>. This interaction can block the IFN signalling pathway in cultured cells, and certain authors have suggested that this mechanism may be implicated in HCV resistance to IFN therapy. In 1995, Enomoto *et al*<sup>[10]</sup> described a correlation between the number of mutations within a 40 aa sequence of the NS5A region and the response to IFN therapy in genotype 1b-infected patients. This sequence has been termed the interferon sensitivity-determining region (ISDR). These results were then confirmed by other Japanese studies<sup>[11-15]</sup>, but were never in accordance with most Western European<sup>[16-20]</sup> and American studies<sup>[21-23]</sup>, in which most of the ISDR sequences harbored an intermediate profile. A recent meta-analysis focusing on the number of mutations within NS5A ISDR confirmed the predictive usefulness of ISDR, but a real geographical difference between Caucasian and Asiatic patients was underlined<sup>[24]</sup>.

Recently, it was suggested that NS5A protein may also inhibit the antiviral effect of IFN in a PKR-independent manner in a human hepatocytic cell line<sup>[25]</sup>. Furthermore, another domain in the NS5A region, named V3 (NS5A<sub>2356-2379</sub>)<sup>[26]</sup>, could also be linked to IFN resistance. It has been suggested that mutations in the V3 domain may correlate with IFN response<sup>[17]</sup>. However, two reports have shown that insertion and deletion around the ISDR and the V3 domain had no impact on HCV RNA replication in cell culture<sup>[27,28]</sup>.

In the present study, we examined mutations in the complete NS5A region, including its ISDR, PKR binding domain (PKRbd) and V3 domain, of HCV genotype 1b from patients treated with IFN or combined IFN-R therapy. HCV quasiespecies of ten patients were selected for the analysis based on their response to the treatments combined IFN-R therapy.

## MATERIALS AND METHODS

### Study population

We analyzed PCR products from ten HCV genotype 1b infected patients included in a therapeutic trial<sup>[29]</sup>. Seven of them had SVR - three early and four slow responders according to HCV RNA clearance during therapy at mo 3 (M3) - and three were non-responders to IFN-R (NR). Patients were all studied at baseline (D0), M3 and M6, when gene amplification was possible (positive PCR). Patients received 6 million units of IFN- $\alpha$ 2b three times weekly. If HCV RNA was still detectable at M2, ribavirin was combined with IFN at M3 and continued up to M12. SVR was defined as undetectable HCV RNA during treatment and six months after the end of therapy (EOT). Non-SVR was defined as detectable HCV RNA during treatment and six months after the EOT.

### HCV RNA quantification

Quantification of serum HCV RNA was performed using VERSANT HCV RNA 3.0 assay (Bayer Diagnostics, Emeryville, CA, USA) with a detection threshold at 615 IU/mL (2.79 log IU/mL).

Table 1 Sequences of amplification and sequencing primers

Forward primers		Positions nt
E1	5' GAGGGGGCTGTGACGTGGATG 3'	6057-6077
I3	5' TCCGGCTCGTGGCTAAGGGA 3'	6246-6265
S2	5' GGATTTCCTACGTGACGGG 3'	6620-6640
S4	5' GGGTCTCCCCCTCTTGCC 3'	6906-6926
S31	5' GGACTACGTCCCTCCGGTGG 3'	7241-7260
Reverse primers		
AS2	5' CGTCACGTAGTGGAAATCCCC 3'	6618-6638
AS32	5' GGGACGTAGTCCGGGTCCTTC 3'	7232-7252
I4	5' GCAGCAGACGAGATCCTCAC 3'	7567-7586
E2	5' GCTGCGAGATGTTGTGGCGTA 3'	7698-7718
Cloning primers (pMOS vector)		
SeqS1	5' GGGAAAGCTTGCATGCCTGC 3'	
SeqAS2	5' GACGTTGTAAAACGACGGCC 3'	

Nucleotide positions are numbered according to the HCV-J sequence and the NS5A region is within positions 6246-7586.

### RNA extraction and amplification by RT-PCR

HCV RNA was extracted from 200  $\mu$ L of serum by guanidinium thiocyanate and silica method<sup>[30]</sup>. The full-length NS5A gene was amplified by nested RT-PCR. RT was combined with the first round of PCR with outer primers E1 and E2 while second amplification was performed with inner primers I3 and I4 as previously described (Table 1)<sup>[17,31]</sup>. PCR products were then subjected to electrophoresis in a 1% agarose gel (NuSieve GTG, FMC) and visualized by ethidium bromide staining before purification. In this study, we sequenced 343296 nts from 256 clones of the complete NS5A region. According to *Taq* error rate ( $0.182 \times 10^{-4}$ )<sup>[32]</sup>, 6.247 RT-PCR-introduced errors could have been analyzed as substitutions for all clones, i.e. 0.024 RT-PCR-introduced errors per clone.

### PCR products cloning

PCR fragments cut out from the agarose gel were purified using a mini-column system (Wizard PCR Preps DNA purification system, Promega) and then were ligated into 50 ng of pMOS vector (pMOS<sub>Blue</sub> blunt-ended cloning kit, Amersham Bioscience). Transformants were grown on LB-agar plates containing 100  $\mu$ g/mL ampicillin and 15  $\mu$ g/mL tetracycline. The presence of HCV insert was confirmed by plasmid amplification using SeqS1 and SeqAS2 primers (Table 1). We produced between 4 and 17 clones per patient.

### DNA sequencing

Cycle sequencing was performed using the CEQ 8000 Dye Terminator Cycle Sequencing kit following the manufacturer's instructions (Beckman Coulter) before automatic electrophoresis of the sequencing products using a CEQ 8000 (Beckman Coulter). Inner PCR primers S2, S4, S31, AS2 and AS32 were used as sequencing primers (Table 1). Sequences were analyzed using the CEQ 8000 software.

### Sequence analysis

Multiple nucleotide (nt) sequence alignment and ambiguity were carried out with CLUSTAL X interface<sup>[33]</sup>. The nucleotide substitution rate over sites within each set of variants was estimated by using DAMBE software. The

**Figure 1** Schematic localisation of the six studied regions in NS5A protein. Amino acids positions are numbered according to the HCV-J polyprotein and the NS5A region is within positions 1973-2419.

F: Female; M: Male; *n*: number of PCR products analyzed; D0: beginning of the treatment; M3: 3 mo of treatment; SVR: Sustained Virological Responders; NR: Non-Responders to IFN-ribavirin therapy.

variability at each site *i* was measured by calculating the Shannon entropy at the site *i* ( $H_i$ ) with the following formula:  $H_i = -(\sum_{j=1}^4 p_j \log_2 p_j)$ , where  $j = 1, 2, 3, 4$  corresponding to nucleotide A, C, G and T, and  $p_j$  is the proportion of nucleotide *j* at site *i*. The normalized entropy  $S_n$  was calculated as  $S_n = H/\log N$ , where *N* is the total number of analysed sequences<sup>[34]</sup>. Types of mutational changes were also determined by means of MEGA 2.3 software. Genetic distances between pairs of sequences were performed using Kimura 2-parameters method<sup>[35]</sup>. The frequency of synonymous (dS) and non-synonymous (dN) substitutions per site were calculated with Nei-Gojobori method using the Jukes-Cantor correction to account for multiple substitution at the same site<sup>[36]</sup>. The dN/dS ratio is a measure of immunity pressure on a region. Construction of the phylogenetic tree of NS5A variants obtained from ten patients was performed using MEGA 2.3 software. The phylogenetic tree was constructed with the neighbour-joining method and bootstrap resampling (1000 replicates were used to test reliability of the tree topology)<sup>[37]</sup>. Master sequence was defined as the sequence obtained from direct sequencing of PCR products obtained before cloning.

A multiple alignment of the translated aa sequences was generated. Alignment analysis of nucleotides and

proteins was performed using HCV-J (genotype 1b, D90208) as reference and HCV-H (genotype 1a, M67463) as out-group for the construction of the phylogenetic tree.

Six regions were studied: the ISDR (NS5A<sub>2209-2248</sub>), PKR binding domain (PKRbd) (NS5A<sub>2209-2274</sub>), V3 (NS5A<sub>2353-2379</sub>), the N-terminal element of NS5A protein until ISDR (NS5A<sub>1973-2208</sub>), the C-terminal element of NS5A protein from ISDR to the end (NS5A<sub>2209-2419</sub>), and the complete sequence of NS5A (NS5A<sub>1973-2419</sub>) (Figure 1).

### Statistical analysis

Values for quantitative variables were expressed as means  $\pm$  SD. Comparisons between groups were performed using the Student *T*-test or the non-parametric Mann-Whitney *U*-test or Kruskal-Wallis *K*-test for quantitative variables. The Pearson's correlation coefficient was used. A *P*-value of less than 0.05 was considered to be statistically significant.

## RESULTS

### Phylogenetic and heterogeneity analysis of HCV quasispecies

Characteristics of each patient are summarized in Table 2. We studied ten patients (four males and six females). Average

**Figure 2** Phylogenetic tree of NS5A region (codon 1973-2419) of amino acids HCV variants obtained from ten patients at different time of treatment. D0: beginning of the treatment; M3: 3 mo of treatment; SVR: Sustained Virological Responders to IFN-ribavirin therapy; NR: Non-Responders to IFN-ribavirin therapy. HCV-H strain was used as outgroup. The internal node numbers represent the bootstrap values. Distance scale represents 2% of difference between sequences. When all NS5A sequences within a patient at one time point of treatment are grouped in a cluster, this cluster is presented by only one node.

**Table 3** Characteristics of HCV quasiespecies in pre-treatment isolates from SVR and NR patients

Region and patient type	Genetic distance	dS	dN	dN/dS	Num. amino acid mutations
NS5A					
SVR ( <i>n</i> = 99)	0.1027	0.3239	0.039	0.120	33.9
NR ( <i>n</i> = 48)	0.0698	0.1216	0.025	0.206	29.8
ISDR					
SVR ( <i>n</i> = 99)	0.0834	0.3084	0.0295	0.096	1.3
NR ( <i>n</i> = 48)	0.0765	0.2645	0.0271	0.102	1.9

V3					
SVR ( <i>n</i> = 99)	0.1836	0.3264	0.1282	0.393	6.0
NR ( <i>n</i> = 48)	0.1372	0.4482	0.0556	0.124	4.7

Values were calculated as described in methods; amino acids sequences were compared to HCV-J; *n*: number of PCR products analyzed; dS: frequency of synonymous substitutions per site; dN: frequency of non-synonymous substitutions per site; SV: Sustained Virological Responders; NR: Non-Responders to IFN-ribavirin therapy.

patient age was 49.5 years and HCV viral load was 5.35 log IU/mL (mean at baseline). We found a significant difference in viral load between the three groups of early, slow SVR and NR ( $P = 0.034$ ), whereas no significant difference was found between the SVR and NR groups at baseline. The genetic variability of the NS5A region was confirmed by cloning NS5A PCR products obtained from the ten patients (7 SVR and 3 NR) into the pMOS vector. In total, PCR products from 256 clones of the NS5A region were analyzed (Table 2). No cluster in correlation with treatment response was observed in the phylogenetic tree (Figure 2). However, in two slow SVR patients (SVR4 and SVR5) two different clusters were individualized with two populations of variants (D0 and M3, respectively). In the two other slow SVR patients (SVR6 and SVR7) and in NR patients, we found mixed populations of variants at the beginning of treatment (D0) and during treatment (M3 or M6). Genetic complexity of nt and aa sequences calculated by Shannon entropy showed no significant difference between the two groups studied (Figure 3, A and B). Interestingly, when we looked at early SVR in comparison with slow SVR, we observed a significant difference between these three groups of patients,  $P = 0.026$  and  $P = 0.024$ , respectively, for nt and aa complexity calculated by Shannon entropy. At baseline, we observed that PCR products from the SVR group displayed more frequently synonymous substitutions (dS) and non-synonymous substitutions (dN) than PCR products from the NR group along the NS5A region, ISDR and PKRbd domains, but not in the V3 domain for dS (Table 3, columns 3 and 4). dN/dS ratios were similar in the two groups in ISDR and PKRbd domains. This ratio was two times higher in SVR patients than in NR patients along the NS5A region and three times higher in the V3 domain (Table 3, column 5).

Among the aa sequences of the PKRbd and V3 domains, we observed that NR patients exhibited a higher variant complexity than SVR patients before initiation of IFN therapy in the three domains ISDR, PKRbd and V3 (Table 4). In ISDR, after three months of IFN therapy,

**Figure 3** Genetic complexity of HCV quasispecies (A: nucleotide; B: amino acid) calculated by normalized entropy in seven sustained virological responders and three non-responders with median indicated by horizontal bar for each group. *P*-value calculated by Mann-Whitney *U*-test.

Amino acids sequences were compared to HCV-J; *n*: number of PCR products analyzed.

two out of four slow SVR patients and the three NR patients showed a decrease in variant complexity (SVR5; SVR6; NR1; NR2 and NR10). The two other slow SVR patients displayed stability in variant complexity (SVR4 and SVR7). The three NR patients had a continuous decrease in the complexity under combined IFN-R regimen at M6 (NR1; NR2 and NR3).

Within PKRbd, after three months of IFN therapy, three out of four slow SVR patients and one out of three NR patients displayed a decrease in variant complexity (SVR4; SVR5; SVR6 and NR2) (Table 4). The two other NR patients exhibited stability in variant complexity (NR2 and NR3) and the fourth slow SVR patient showed an increase in variant complexity (SVR7). The three NR patients had a decrease in complexity under combined IFN-R therapy at M6.

After three months of IFN therapy, three out of four slow SVR patients (SVR4; SVR6 and SVR7) displayed a decrease in variant complexity in the V3 domain, as did two out of three NR patients (NR1 and NR3) (Table 4). The two other patients were found to contain an increase in variant complexity (SVR5 and NR2). Under combined IFN-R therapy, two NR patients had a low decrease in variant complexity (NR1 and NR3), whilst the third NR

patient showed an increase (NR2) in variant complexity.

#### Variability in six different regions along the NS5A gene

**Comparison to master sequence:** Among the 256 PCR products studied, before and during treatment, we observed a mean of  $11.7 \pm 7.9$  nt substitutions with a median of 10 nt substitutions.

At baseline, we observed  $13.6 \pm 9.1$  nt substitutions (median of 12 nt substitutions) among the 147 clones analyzed, in comparison to the master sequence (Table 2, column 6). The aa variations were  $4.8 \pm 3.1$  substitutions (with a median at 4) among all 256 clones and  $5.4 \pm 3.5$  aa substitutions in clones analyzed before treatment, with a median of 5 aa substitutions. We also observed that all variants from SVR patients had a higher genetic diversity than all variants from NR patients in the four regions studied, including ISDR, PKRbd, V3 domain and complete NS5A (Table 3, column 2). Within patients, we observed that the 3 early SVR had a lower genetic diversity than the four slow SVR and the three NR.

We observed significantly more aa substitutions in SVR clones than in NR clones in two out of six regions (complete NS5A,  $P = 0.013$ ; the first half of NS5A,  $P = 0.032$ ). Interestingly, NR clones presented more aa substitutions in the V3 domain than SVR clones, but this was not statistically significant (Table 3).

During treatment, the genetic distance and numbers of substitutions (nt and aa) in SVR PCR products decreased between the baseline and M3 (Table 2, columns 6, 7 and 8). PCR products from NR patients also showed a decrease of the genetic distance, but this was lower than those from SVR patients. However, clones from NR patients had either stability or an increase in the number of aa substitutions observed under treatment. NS5A variants had a high heterogeneity without clonal selection of quasispecies and a low variation in ISDR and V3 domains during therapy.

**Comparison to HCV-J sequence:** Among the 256 clones analyzed, we observed a mean of  $32.1 \pm 5.2$  aa substitutions. At baseline, a mean of  $36.6 \pm 5.6$  aa substitutions (median at 32 aa substitutions) was observed among the 147 clones analyzed, in comparison to the

n: number of PCR products analyzed; SVR: Sustained Responders; NR: Non-Responders to IFN-ribavirin therapy; D0: beginning of the treatment; M3: 3 mo of treatment; M6: 6 mo of treatment.

HCV-J sequence (Tables 2 and 5). Next, we determined for each group the level of aa substitutions in each site, with a threshold at 15 aa substitutions (this threshold was defined as half of the maximum ( $n = 31$ ) of aa substitutions observed for the 256 clones; in position 2218). In ISDR, aa variations were found at positions 2218, 2224, 2232, 2234 and 2237, in the V3 domain at position 2377 and along NS5A protein at positions 2251 (PKRbd), 2280 and 2408.

At baseline, among the two group of patients (SVR and NR), the comparison of the different clone populations showed that all except one (PKRbd) of the six regions studied were able to differentiate the two groups (Table 5).

We observed more aa substitutions in SVR clones than in NR clones in four out of six regions (complete NS5A,  $P < 0.001$ ; the first half of NS5A,  $P = 0.010$ ; the second half of NS5A,  $P < 0.001$  and V3,  $P < 0.001$ ). Interestingly, NR clones presented more aa substitutions in ISDR than SVR clones,  $P = 0.011$ , and the PKRbd domain was not able to discriminate the two groups of patients. In contrast to previous findings, NR clones had more aa substitutions than SVR clones in ISDR and PKRbd regions. We did not find any correlation between HCV viral load and the number of mutations observed in ISDR and the V3 domains. A fair correlation was observed between HCV viral load and PKRbd ( $r = 0.724$ ;  $P = 0.018$ ). A good correlation was observed between HCV viral load and complete NS5A ( $r = 0.855$ ;  $P = 0.002$ ) and with the second half of NS5A ( $r = 0.782$ ;  $P = 0.008$ ).

During treatment, a decrease of aa substitutions occurred in the six studied regions for the two groups of patients. Only ISDR and the complete NS5A sequence showed a significant decrease in aa substitutions under treatment in comparison with populations studied at baseline ( $P = 0.019$  and  $P = 0.005$ , respectively). In the NR clones, stability or a low decrease in aa substitutions was observed in the six regions, at baseline, M3 and M6.

#### Possible mutagenic effect of ribavirin during combination therapy

Among the three populations of clones from NR patients, we did not find any aa substitutions between M3 and M6 treatment points, as recently described in NS5A during ribavirin monotherapy<sup>[38]</sup>. No other specific aa substitutions were found in the NS5A protein.

## DISCUSSION

Numerous viral and host factors have been described

as predictors of response to therapy. HCV genotype 1, particularly genotype 1b, are most resistant to combined IFN-R therapy<sup>[5]</sup>. Among viral factors, genetic variability has been studied in many regions of the HCV genome, mainly in hypervariable region 1 (HVR1) and PKR-eIF2 $\alpha$  phosphorylation homology domain (PePHD) of E2 region and in PKRbd (including ISDR) of NS5A<sup>[17,22,39-43]</sup>. However, few reports have studied the complete NS5A region<sup>[17,22]</sup>. Most of these studies examined patients treated by IFN monotherapy, with few studies of patients treated by combined IFN-R therapy.

A recent study examining viral sequence differences between African American and Caucasian patients treated by IFN with or without ribavirin found that the NS5A region did not cluster by race, but treatment response and IFN effectiveness did<sup>[44]</sup>. In this study, our analysis of the number of substitutions in the V3 domain showed a significant difference between the two groups of patients and a significant correlation between IFN effectiveness and a high number of mutations in the V3 domain<sup>[45]</sup>.

In another study examining the second half of the NS5A region, especially ISDR, PKRbd and V3 domains, in patients treated by combined IFN-R therapy, the authors also found that the V3 domain showed more accumulation of substitutions than other domains in NS5A<sup>[45]</sup>. SVR patients had lower complexity and diversity than NR patients before treatment. During therapy, the investigators observed a decrease in complexity and diversity in SVR patients, and an increase in complexity with accumulation of non-synonymous mutations in NR patients.

In our study, we analyzed sequence variations of NS5A quasiespecies in patients who received adapted therapy according to virological response during treatment. Among SVR patients, we analyzed three early SVR and four slow SVR patients compared to three NR patients. The construction of a phylogenetic tree did not allow us to distinguish the two groups of patients (SVR and NR). Before treatment, the analysis of genetic complexity and diversity did not show a significant difference between the seven SVR and the three NR patients. However, the genetic complexity and diversity were lower in early SVR than in the seven other SVR patients. The analysis of the immunity pressure in different domains of the NS5A gene did not show differences between the SVR and NR groups except for the V3 domain and the complete NS5A region where the SVR group presented a higher immunity pressure than NR patients. Generally, the analysis of mutations compared to the master sequence or HCV-J

sequences requires long fragments (a half or a complete NS5A protein) to distinguish SVR and NR. We did not observe any difference in specific aa substitutions between the two groups of patients.

During treatment, we observed a decrease of genetic complexity and diversity in slow SVR and NR patients. A very low complexity was found in the V3 domain in eight out of ten patients (6/7 of SVR and 2/3 of NR patients). In the PKRbd and V3 domains, we often observed complexity decrease or stability. Only one out of seven SVR and one out of three NR patients displayed complexity increase either under IFN therapy or under combined IFN-R therapy. Thus, we observed a different evolution of quasispecies under IFN alone or under combined therapy. This is in contrast to a recent study by Puig-Basagot *et al.*<sup>[45]</sup> where they observed a decrease in quasispecies complexity in SVR patients and a stability or increase in quasispecies complexity in NR patients. In this study, the analysis of the quasispecies was done at wk 1, 2 and 4, whereas in our study we analyzed quasispecies after a first three-month period of treatment under IFN alone and after a second three-month period under combined IFN-R therapy. We observed the same rate of appearance of aa substitutions in the ISDR domains for the two categories of patients. However, the instauration of a real modification of aa in a quasispecies was more often observed in SVR patients than in NR patients in the complete NS5A protein and in the PKRbd and V3 domains. Interestingly, in three slow SVR (SVR4-SVR5-SVR6) patients the main variant from the ISDR domain remained unchanged after three months of treatment. The same observation was made in two out of three NR patients who also exhibited complexity stability in the different NS5A regions.

Asahina *et al.*<sup>[38]</sup> studied the possible mutagenic effect of ribavirin during a period of 28 days of ribavirin monotherapy before combined IFN-R therapy. During the first phase of ribavirin monotherapy, they observed an accumulation of non-synonymous substitutions located in NS5A. These substitutions were observed in ten patients and eight of them had SVR after treatment. In our study, we did not observe these substitutions in PKRbd nor in any part of NS5A. However, our treatment regimen was different and we only studied the effect of ribavirin during three months of combined therapy in NR patients. It is also possible that substitutions did arise during combined therapy, but were subsequently eliminated by the treatment.

In conclusion, our study reinforces the potential role of NS5A polymorphism, particularly in the V3 domain, in regulating HCV resistance to IFN treatment. Nevertheless, the underlying molecular mechanisms remain unclear. Mutations in the V3 domain may affect the interaction between NS5A and one or several IFN-induced antiviral effectors. Some studies found high mutation frequency in ISDR being associated with low HCV RNA titer, suggesting that NS5A may play a role in HCV replication. In our study, at baseline, we did not find any relationship between HCV viral load and the number of mutations observed in the ISDR and V3 domains. The number of mutations observed in PKRbd has shown a fair correlation with HCV viral load, but we found a better correlation

when we analyzed the second half or the complete NS5A region. These results support the notion that mutations in the NS5A region may influence on HCV replication, and suggest that the entire NS5A region should be analyzed for mutations that may correlate with IFN response. Further clinical studies with new therapeutic approaches such as pegylated IFN, as well as the use of the recently developed HCV infection cell culture systems should further improve our understanding of the role of NS5A in regulation of the IFN response.

The authors thank Schering-Plough for supporting the therapeutic protocol and all hepatologists and virologists of the Group of Fontevraud who participated to this therapeutic protocol. The authors thank Kevin L Erwin for his careful proofreading of the manuscript.

## COMMENTS

### Background

In this article, we analyzed NS5A HCV quasispecies evolution during antiviral treatment. Since the NS5A protein is implicated in HCV resistance, this study should enhance the knowledge of evolution of the resistance during treatment.

### Research frontiers

Many previous articles focused on a small region(s) of NS5A without studying the complete gene. We believe that an analysis of the entire NS5A region is necessary because some sections of NS5A may be important for homologous and/or heterologous RNA-protein or protein-protein interactions and thus may play a role in conferring HCV resistance to IFN therapy.

### Innovations and breakthroughs

To the best of our knowledge, only two reports studied quasispecies along the complete NS5A region and did not observe quasispecies evolution during therapy. In contrast, our results suggest that V3 domain plays a role in HCV resistance to IFN therapy.

### Applications

Our study may help identify mutations within the HCV genome that can be used to predict patients' response to IFN treatment or future new antiviral modalities, as well as provide molecular hints for the mechanisms underlying HCV resistance to the therapy.

### Peer review

Study is important with findings supporting previous results as well as novel findings. The biggest problem is the very small size of the patients analyzed. The paper is well written and concise.

## Abstract

**AIM:** To investigate the epidemiology of hepatitis B virus (HBV) and hepatitis C virus (HCV) infection in the two major ethnic groups in Kazakhstan.

**METHODS:** A cross-sectional prospective study of HBV and HCV seroprevalence was performed among individuals born in Kazakhstan with no history of chronic hepatitis or liver disease.

**RESULTS:** There were 290 volunteers (140 Russians and 150 Kazakhs) aged 10 to 64 years, males accounted for 46%. Active HBV infection (HBsAg positive) was present in 3.8%, anti-HBc in 30%. The prevalence was similar in females and males (33% vs 25%) ( $P = 0.18$ ). The prevalence of anti-HBc increased from 19% in 10-29 years old volunteers to 53% in 50-years and older volunteers. The prevalence of HBV infection was higher in married than in single adults (38% vs 26%, respectively) ( $P = 0.2$ ) and more common in Kazakhs (35%) than in Russians (24%) ( $P = 0.07$ ). HCV infection was present in 9 subjects (3.2%), 5 of them also were positive for anti-HBc in the absence of HBsAg.

**CONCLUSION:** The frequency of active HBV infection (3.8%) coupled with a high prevalence of HBV exposure in those > 50 years of age increases with age, which suggests that horizontal transmission likely relates to

the use of contaminated needles. The low prevalence of HCV infection suggests that HBV and HCV are acquired differently in this group of subjects.

## INTRODUCTION

Kazakhstan has two major ethnic groups: Kazakhs who trace their origins back to Genghis Khan, and ethnic Russians. Each constitutes approximately 40% of the population. The different ethnic groups share similar living and socioeconomic conditions.

Kazakhstan is part of a nine-country subregion in which the mortality due to chronic liver disease and cirrhosis has been estimated to be 21.8 per 100 000 population<sup>[1]</sup>. The mortality rate of hepatocellular carcinoma is also high, with liver cancer representing approximately 4% of all malignant neoplasms<sup>[2]</sup>. Hepatitis B virus (HBV) and hepatitis C virus (HCV) infections are both common causes of hepatocellular carcinoma. We conducted a cross-sectional study in Kazakhstan to examine the epidemiology and risk factors associated with HBV and HCV infections. We gave particular emphasis on possible relationships between chronic hepatitis B or C virus infections and a history of intravenous injections, blood transfusions, vaccinations, needle sticks, surgeries, having tattoos, and shared use of tooth brushes, body brushes and towels.

## MATERIALS AND METHODS

We performed a cross-sectional seroepidemiologic study in Almaty, Kazakhstan. Both Russians and Kazakhs were entered if they were unrelated and born in Kazakhstan with no prior history of clinical hepatitis or chronic liver disease. An attempt was made to obtain an equal number

**Figure 1** Prevalence of anti-HBc antibodies (A), HBsAg (B), and anti-HCV antibodies (C) in relation to age in Kazakhstan.

of volunteers per decade from each of these two major ethnic groups.

A trained physician interviewed each volunteer and completed a detailed questionnaire. Demographic data focusing on the environment during the subject's childhood included social and economic data (parent's education, occupation and family income) as well as histories of blood transfusions, intravenous injections, vaccinations, needle sticks, surgeries, having tattoos, and the shared use of tooth brushes, body brushes or towels. In women, we obtained data about miscarriages and abortions.

### Serologic methods

Each volunteer provided a blood sample. Sera were stored at  $-20^{\circ}\text{C}$  until analyzed. Serum samples were tested for hepatitis A and B serology using kits (Abbott Diagnostic Laboratories, Abbott Park, IL), including enzyme immunoassays (EIA) for the qualitative detection of total antibody to hepatitis A virus (anti-HAV; HAVAB

**Table 1** Concentration of anti-HBs in four HBsAg and anti-HBc positive subjects

I.D.	mIU/mL
11	16.1
180	3.4
249	4.0
143	5.7

EIA), hepatitis B surface antigen (HBsAg; AUSZYME Monoclonal), and total antibody to hepatitis B core antigen (anti-HBc; Corzyme). Antibody to hepatitis B surface antigen (anti-HBs; AUSAB, human subtypes ad and ay) was evaluated by solid phase radioimmunoassay. Antibody to hepatitis C (anti-HCV; HCV Version 3.0, Ortho-Clinical Diagnostics, Inc, Raritan, NJ) was detected by EIA. The interpretation of the results was done according to the manufacturer's instructions.

### RESULTS

Two hundred and ninety volunteers were enrolled in the study including 150 Kazakhs and 140 ethnic Russians ranging in age from 10 to 64 years. One hundred and thirty-four (46%) of the subjects were men.

#### Risk factors and prevalence of HBV

Total anti-HBc was found in 30% of the population, being similar in women (33.3%) and men (25.4%) ( $P = 0.18$ ). There was an age-specific significant increase in the prevalence of anti-HBc antibody: from 19.2% in 10-29 years old individuals to 53.4% in those who were 50- years old and older (Figure 1A) ( $P < 0.01$ ). The prevalence of anti-HBc was more common in Kazakhs (34.7%) than in Russians (24.3%) ( $P = 0.07$ ). Among those who were 21-years old and older, the prevalence of hepatitis B infection was similar in married and single adults (38% *vs* 26%,  $P = 0.2$ ) (data not shown).

The overall seroprevalence rate of active HBV infection (HBsAg positive) was 3.8% (11 of 290 subjects), none of these individuals tested was positive for anti-HCV. There was no significant difference in the prevalence of detectable HBsAg in men and women (3.7% of men *vs* 3.8% of women) ( $P = 0.7$ ) nor between ethnic groups (4.3% of Russians *vs* 3.3% of Kazakhs) ( $P = 0.9$ ). The prevalence of HBsAg peaked in those whose age was 30-49 years (6.3%) and was lower in those whose age was 10-29 years (2.5%) ( $P = 0.3$ ) and lowest in those whose age was 50 years and more (1.7%) ( $P = 0.4$ , Figure 1B). Four of the 11 HBsAg positive individuals (36%) were anti-HBs positive. However, the concentrations of antibodies were low in this group of individuals (Table 1). Three of four individuals with concurrent HBsAg and anti-HBs positivity were Kazakhs, but gender distribution was equal.

Table 2 shows unadjusted and adjusted (for socio-economic status, gender, and ethnicity) incidence rates and risk factors possibly associated with acquisition of hepatitis B. The highest risks associated with hepatitis B infection were having been a blood donor or having a history of dental surgery. The risk factors for positive anti-HBc and

**Table 2** Effect of selected risk factors on the incidence rate of anti-HBc in a study population from Kazakhstan ( $n = 86$ )

Risk factor	Unadjusted OR	P	95% CI	Adjusted <sup>1</sup> OR	P	95% CI
Blood transfusion	2.11	0.19	0.67-6.48	1.26	0.72	0.36-4.40
Blood donor	1.77	0.03	1.05-2.98	1.38	0.48	0.56-3.42
Tattoo	1.67	0.19	0.77-3.65	1.26	0.62	0.51-3.12

Dental surgery	1.93	0.02	1.10-3.31	1.29	0.29	0.80-2.08

<sup>1</sup>Adjusted OR for socioeconomic status, ethnicity and gender.

HBsAg included dental surgery (73%), frequent injections (64%), and ear piercing (54%).

### Risk factors and prevalence of viral hepatitis C

Anti-HCV was detected in only 9 subjects (3.2%) including 3 Kazakh women and 6 Russians (three women and three men). Five of the 9 subjects also had detectable levels of anti-HBc, but were negative for anti-HBs. Figure 1C and Table 3 display age-specific prevalence rates of anti-HCV in this study population and selected risk factors associated with anti-HCV seropositivity. A history of tattoos was a common risk factor for hepatitis C with a trend in risk toward towel sharing.

## DISCUSSION

Almost 30% of the study population examined had evidence of current or past HBV infection which is similar to the results of a prior study in northwestern Kazakhstan, showing that 22% ( $n = 579$ ) of the healthy population had detectable anti-HBc antibodies<sup>[3]</sup>. The prevalence of anti-HBc seropositivity in Kazakhstan is substantially lower than that reported in 110 Bukharian Jews who immigrated from Uzbekistan and Tajikistan (former Soviet Union) to Israel, 66% of them had evidence of exposure to HBV<sup>[4]</sup>. However, the prevalence of past or current hepatitis B infection is much higher in Central Asia than in Pakistan, Ethiopia, Sweden, England and Wales<sup>[5-8]</sup>.

The primary mode of transmission of HBV in Kazakhstan is unsettled. The prevalence of infection increasing with age could result from either birth cohort effects and continuing gradual horizontal acquisition, or both. Demographic factors associated with risk of acquisition (i.e. history of blood donation and dental surgery) found in a recent study in Pakistan are blood transfusions and use of contaminated syringes, and contaminated dental and surgery equipment are the main risk factors for acquiring HBV infections<sup>[9]</sup>. However, in our study, adjustments for socioeconomic status, ethnicity and gender eliminated these significantly associated risk factors (Table 2).

In countries of European Region C, including Kazakhstan, the annual number of injections was reported to be 11.3 per person in 2000 and this estimate is the highest among countries recognized as having a global burden of disease. The same is true for the Russian

**Table 3** Effect of selected risk factors on the incidence rate of anti-HCV in a study population from Kazakhstan ( $n = 9$ )

Risk factor	Unadjusted OR	P	95% CI	Adjusted <sup>1</sup> OR	P	95% CI
Blood transfusion	2.48	0.41	0.29-21.20	1.42	0.76	0.15-13.38
Tattoo	4.02	0.05	0.90-16.44	14.40	0.01	1.76-118.32
Ear piercing	2.58	0.18	0.65-10.18	3.05	0.29	0.38-24.4
Dental surgery	1.65	0.48	0.42-6.52	1.46	0.64	0.29-7.26
Towel sharing	3.25	0.09	0.82-12.83	3.87	0.07	0.91-16.4

<sup>1</sup>Adjusted OR for socioeconomic status, ethnicity and gender.

Federation where the annual number of injections per person is also 11.3 and different from neighboring countries such as Kyrgyzstan and Uzbekistan where this estimate is 5.2 or China where the annual number of injections per person is only 2.4<sup>[10]</sup>. Several studies conducted in Russia showed that 85%-99% of injections are unnecessary with a ratio of 20:1 for injections being given with therapeutic intent compared to those for disease prevention<sup>[11,12]</sup>. In addition, the proportion of equipments being reused was reported to be 11%. Of interest in this study, the common factor for having both anti-HBc and HBsAg was a history of frequent injections.

In the current study, 4 of the 11 HBsAg positive subjects also had anti-HBs antibodies (36%). It was reported that the rate of concurrent HBsAg and anti-HBs positivity is between 21% and 32%<sup>[13-16]</sup> and is associated with evidence of viral replication and features of active inflammation<sup>[13]</sup> or with progressive liver disease<sup>[14]</sup>. Most probably, these discordant serologic results reflect a low concentration of non-complexed anti-HBs that fails to recognize insertions or deletions that occur in the pre-S/S region of the HBV genome<sup>[16,17]</sup>. Heterotypic antibody is often observed in these situations<sup>[13,15]</sup>.

The prevalence of anti-HCV in this study population was 3.2% which is somewhat higher than the prevalence of anti-HCV antibodies observed in northwestern Kazakhstan (1.7%;  $P = 0.3$ )<sup>[3]</sup>, or in Siberian natives from the Kamchatka Peninsula of Russia (1.4%,  $n = 348$ )<sup>[18]</sup>. In contrast, in the Republic of Azerbaijan<sup>[19]</sup>, 8.7% of screened serum samples are anti-HCV reactive<sup>[20]</sup>. We feel certain that virtually all of our reactive samples represented a past or present infection with HCV based on strong EIA ratios of 3.0 or greater. However, we did not do HCV RNA testing to confirm its active infection. It also is possible that we underestimated the prevalence of hepatitis C in that a proportion of the population may have resolved their infection and subsequently lost their anti-HCV<sup>[21]</sup>.

The risk factors related to HCV infection (Table 3) have very wide confidence intervals indicative of the small sample size which precludes making firm conclusions regarding transmission. However, the low prevalence of hepatitis C infection compared with the relatively high prevalence of HBV infection suggests that different modes of transmission are active in this population due to the sexual or vertical transmission of HBV and the

parenteral transmission of HCV. Overall, the use of unsafe (contaminated) needles remains of great concern in this population as a vehicle for transmission of these viruses.

### Abstract

**AIM:** To evaluate the effect of antisense oligonucleotide targeting midkine (MK-AS) on angiogenesis in chick chorioallantoic membrane (CAM) and *in situ* human hepatocellular carcinoma (HCC).

**METHODS:** An *in situ* human hepatocellular carcinoma (HCC) model and CAM assay were used in this experiment. The effect of MK-AS on angiogenesis was evaluated by cell proliferation assay and hematoxylin-eosin (HE) staining.

**RESULTS:** MK-AS significantly inhibited human umbilical vein endothelial cells (HUVEC) and *in situ* human HCC growth. At the same time, MK-AS suppressed the angiogenesis both in human hepatocellular carcinoma cell line (HEPG2)-induced CAM and *in situ* human HCC tissues.

**CONCLUSION:** MK-AS is an effective antiangiogenesis agent *in vivo*.

### INTRODUCTION

Angiogenesis is a process leading to formation of new blood vessels, which plays a central role in survival of cancer cells, growth of local tumors, and development of distant metastasis<sup>[1]</sup>. It is believed that tumor cells require the ability to stimulate angiogenesis, and angiogenesis induced by tumor cells, leads to hypervascularization of tumor tissue<sup>[2]</sup>. More recently, it has been found that tumor cells also produce angiogenesis inhibitors<sup>[3]</sup>. The angiogenic phenotype of a solid tumor is accepted as a result of the net balance between the activities of angiogenesis promoters and inhibitors<sup>[4]</sup>. Preclinical testing of these antiangiogenic factors in animal models suggested that they can effectively suppress the growth and/or metastasis of experimental tumors<sup>[5-7]</sup>. Inevitably, identification of angiogenic inhibitors and demonstration of their angiostatic functions would provide rational foundations for the development of tumor-specific antiangiogenic therapy.

Up to now, different growth factors, such as basic fibroblast growth factor (bFGF), vascular endothelial growth factor (VEGF), transforming growth factor- $\alpha$  (TGF- $\alpha$ ) and midkine (MK) have been identified as positive regulators of angiogenesis and are secreted by cancer cells to stimulate normal endothelial cell growth through paracrine mechanisms<sup>[8-11]</sup>. MK was first identified in early stage embryonal carcinoma cells during retinoic acid-induced differentiation<sup>[12]</sup>. MK and pleiotrophin comprise a family of heparin-binding growth/differentiation factors, which are different from other heparin-binding growth factors such as fibroblast growth factor and hepatocyte growth factor<sup>[13-15]</sup>. MK is over-expressed in various malignant tumors<sup>[16-24]</sup>, and low or undetectable in normal adult tissues<sup>[13,24]</sup>. It is accepted that MK promotes the survival<sup>[25,26]</sup>, growth<sup>[27,28]</sup> and migration<sup>[29-31]</sup> of many cells, involved in activating mitogen-activated protein kinase (MAPK), extracellular signal-regulated kinases 1 and 2 or protein kinase B (PKB/AKT) pathways<sup>[25,32]</sup>. Recently, it was reported that midkine binds to anaplastic lymphoma kinase (ALK) and acts as a growth factor for different cell types<sup>[33]</sup>.

There is evidence that MK plays an important role in angiogenesis, which is an important event in tumor development and progression. It was reported that enhanced tumor growth in MCF-7 breast carcinoma cells due to high MK expression is correlated with increased vascular density and endothelial proliferation, implicating an angiogenic role of MK in tumor growth<sup>[11]</sup>. Additionally, MK, an angiogenic factor, is expressed in bladder cancer,

and its over-expression correlates with a poor outcome in patients with invasive cancers<sup>[20]</sup>. In fact, we have confirmed that MK-AS transfer can significantly inhibit the growth of hepatocellular carcinoma cells, which is associated with increased Caspase-3 activity<sup>[34]</sup>. The present study was to determine whether MK-AS can suppress angiogenesis, which is an important mechanism underlying inhibition of tumor cell proliferation.

## MATERIALS AND METHODS

### Antisense oligodeoxynucleotides

MK-AS (5'-CCCCGGGCGCCCTTCTTCA-3') and MK-SEN phosphorothioate oligonucleotide (5'-TGAAGAAGGGCGGCCCCGGGG-3') were synthesized with an applied biosystem model 391 DNA synthesizer using Oligo Pilot II DNA (Amersham-Pharmacia, Piscataway, NJ, USA) and purified by high-performance liquid chromatography (HPLC) (Waters Delta Prep 4000, Milford, MA, USA) with SOURCE 15Q (Amersham Pharmacia, Piscataway, NJ, USA) as previously described<sup>[34]</sup>.

### Cultured cell lines

Human umbilical vein endothelial cells (HUVECs), a gift of the Chinese Academy of Medical Sciences, Beijing, China, were pooled after collagenase type I treatment and seeded on cell culture plates. The cells were grown in RPMI 1640 medium (Invitrogen Corporation, CA, USA) supplemented with 20% fetal calf serum (FBS; GIBCO BRL, Grand Island, NY, USA), 100 U/mL penicillin and 100 µg/mL streptomycin at 37°C in an atmosphere containing 5% CO<sub>2</sub>.

### Cell proliferation assay

A total of  $3 \times 10^3$  cells were seeded in each well of a 96-well microtiter plate and allowed them to attach overnight. Oligonucleotides at the concentrations of 0.2, 0.4, 0.8 µmol/L were transfected into the cells with Lipofectin (Invitrogen, Carlsbad, CA, USA) following the manufacturer's instructions. Transfection medium was replaced by normal culture medium after 6 h. The effects of antisense oligodeoxynucleotide (ASODN) on cellular viability were measured by 3-[4, 5-dimethylthiazol-2-yl]-5-[3-carboxymethoxyphenyl]-2-[4-sulfophenyl]-2H-tetrazolium, inner salt (MTS) assay. After 48 h of incubation following transfection, 20 µL MTS (Sigma, St Louis, MO, USA) was added to each well and incubated at 37°C for 2 h. The absorbance value was determined at 490 nm by a MR600 microplate reader (Wallac 1420 Multilable counter, Wallac, Turku, Finland).

### In vivo tumor studies

*In situ* HCC models were established as previously described<sup>[35]</sup>. Two days after *in situ* HCC models were established, mice were injected intravenously with saline (vehicle control) and MK-AS (25, 50 and 100 mg/kg per day) for 20 d. Body weight and general physical status of the animals were recorded daily. At the endpoint of the study, mice were killed by cervical dislocation and tumors were removed and weighed. Tumor sizes were monitored

with calipers, the tumor volume ( $V$ , mm<sup>3</sup>) was calculated as  $(L \times W^2)/2$ , where  $L$  = length (mm) and  $W$  = width (mm). The percentage of tumor growth inhibition was calculated as: inhibitory rate (%) =  $(W_{\text{control}} - W_{\text{treat}})/W_{\text{control}} \times 100$ .

### Immunohistochemistry analysis for microvessel formation

Tumor specimens were fixed and frozen in tissue freezing medium (Triangle Biomedical Sciences, Durham, NC). Five-µm thick cryosections were cut and stained with HE for histopathological analysis. To analyze the microvessel formation in tumors, sections were stained with anti-CD34 monoclonal antibody (DAKO Corp., Carpinteria, CA) and subsequently with the avidin-biotin-peroxidase (ABC) method. Positively stained vascular endothelial cells (brown) were visualized and imaged using a digital camera attached to an Olympus microscope. Microvessel density was determined as previously described<sup>[36]</sup>. Briefly, regions of the highest vessel density ("hot spot" regions) were scanned at low magnification ( $\times 40$ -100) and counted at higher magnification ( $\times 200$ ). Three such "hotspot" fields were counted in each tumor section, and the mean microvessel density value was recorded. Any endothelial cell or endothelial cell cluster that was clearly separated from adjacent microvessels was considered a single, countable microvessel. Positively stained vascular endothelial cells were visualized and imaged using a Magnifire camera (Olympus, Melville, NY) attached to an Olympus Provis microscope.

### Western blot analysis

After transfection with MK-AS for 24 h, cells in the microplates were collected into 1.5 mL Eppendorf tubes on ice and centrifuged at 2000 r/min for 5 min at 4°C. Pellets were then lysed with lysis buffer [50 mmol/L Tris-HCl (pH 7.4), 0.5 mmol/L EDTA, 0.5% NP40, and 150 mmol/L NaCl] in the presence of protease inhibitors. Lysates were centrifuged at  $12000 \times g$  for 15 min to remove debris. Proteins (30 µg) were separated from samples by 12% sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) and transferred onto hybond-polyvinylidene difluoride (PVDF) membranes (Amersham Biosciences). Midkine protein was identified using the primary antibody (Santa Cruz Biotechnology, Santa Cruz, CA, USA). The reactive band was visualized with an ECL-plus detection kit (Amersham Biosciences, Piscataway, NJ) and scanned by Gel Doc 1000 (Bio-Rad CA, USA).  $\beta$ -actin was used as a control.

### Chick chorioallantoic membrane assay

Angiogenesis assay in chick chorioallantoic membranes (CAM) was performed as previously described<sup>[37]</sup>. Fertilized eggs were incubated at 38°C. On d 7, a window was opened on the eggshell to expose the CAM, and the window was covered with a tape for further incubation. Filter paper discs (0.5 cm in diameter) containing HepG2 cells (18000/disc) or PBS was placed on the surface of each CAM on d 8. After 24 h, 100 µL of 0.4 µmol/L MK-AS was given using a 30-gauge needle. Two days later, the CAM were fixed in 3.7% formaldehyde. Pictures were taken with a stereoscope, and the number of vessel

**Figure 1** RT-PCR (A) and Western blotting analysis (B) of MK expression in human umbilical vein endothelial cells (HUVEC) after transfection with 0.4  $\mu$ mol/L MK-AS (lane 4), MK-SEN (lane 3), Lipofectin alone (lane 2) for 24 h. Lane 1 represents cells without transfection. GAPDH and  $\beta$ -actin were used as control respectively.

**Figure 2** Effect of MK on growth of HUVEC. Cells after transfection with 0.4  $\mu$ mol/L MK-AS or MK-SEN for 24 h were analyzed by MTS assay. Data were expressed as mean  $\pm$  SD from four independent experiments.

branches was counted. Ten eggs were used for each experimental condition.

### Statistical analysis

Data were expressed as mean  $\pm$  SD, statistical analysis was carried out using Student's *t*-test (two tailed),  $P < 0.05$  was considered statistically significant.

## RESULTS

### Effect of MK-AS on MK expression in HUVEC

Our previous studies showed that antisense oligonucleotide targeting MK down regulates MK expression in hepatocellular carcinoma cells<sup>[34]</sup>. In this study, we measured the effect of MK-AS on MK expression in HUVEC. After MK compounds were transfected for 24 h, total RNA and protein of HUVEC were extracted for analysis of the effect of MK-AS transfer on MK expression. Our results indicated that MK-AS could efficiently decrease the mRNA and protein content of MK in HUVEC (Figure 1A and B).

### Effects of MK-AS treatment on HUVEC growth

To investigate the effect of MK-AS on endothelial cell proliferation, we analyzed the growth of HUVEC transfected with MK-SEN or MK-AS. MK-AS transfer significantly inhibited HUVEC proliferation (Figure 2), suggesting that MK signaling might directly contribute to endothelial cell growth. In contrast, no significant inhibition of HUVEC transfected with MK-SEN was observed.

**Figure 3** Angiogenesis in normal chick CAM (A), HepG2-induced CAM (B), and HepG2-induced CAM treated with 0.4  $\mu$ mol/L MK-AS (C). Chick CAM assays were used to assess the impact of MK-AS on angiogenesis *in vivo*.

### MK-AS inhibited angiogenesis in chick CAM

It is widely accepted that tumors can stimulate angiogenesis by releasing angiogenesis stimulators such as bFGF and VEGF<sup>[8,9]</sup>. HepG2 induced noticeable angiogenesis (Figure 3B). When paper discs absorbing PBS alone were placed onto the CAM, a few vessels occupied the CAM area covered by the paper discs (Figure 3A). Interestingly, when CAM implanted with HepG2 were treated with MK-AS (0.4  $\mu$ mol/L), the number of vessels under the paper discs was significantly reduced (Figure 3C). Similar results were obtained when the mean vessel length was measured (data not shown). Chick embryos treated with MK-AS were alive and showed the same extent of motility as embryos from PBS-treated eggs at the end of the experiment.

### Effects of MK-AS treatment on *in situ* HCC xenograft growth

We have reported that MK-AS inhibits tumor proliferation<sup>[38]</sup>. In the present study, an *in situ* HCC model of mice was used to evaluate the effect of MK-AS on *in vivo* tumor proliferation. MK-AS at 25 mg/kg, 50 mg/kg, 100

**Table 1** Effect of MK-AS on weight and inhibition of *in situ* HCC

Treatment group	Tumor weight (g)	Inhibition rate (%)
Saline	1.29 ± 0.13	-
MK-AS 100 mg/kg per day	0.44 ± 0.18 <sup>b</sup>	65.89
MK-AS 50 mg/kg per day	0.64 ± 0.18 <sup>b</sup>	50.39
MK-AS 25 mg/kg per day	0.70 ± 0.14 <sup>b</sup>	45.74
MK-Sen 50 mg/kg per day	1.04 ± 0.14 <sup>a</sup>	19.38

<sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 vs control group.**Figure 4** Immunohistochemical analysis of HCC xenograft angiogenesis after treatment with MK-SEN (A), 25 mg/kg of MK-AS per day (B), 50 mg/kg of MK-AS per day (C), and 100 mg/kg of MK-AS per day (D). Representative views of anti-CD34 antibody-stained vascular endothelium (brown) (x 200).

mg/kg per day and saline were intravenously administered for 20 d. Tumors were removed, measured and weighed. MK-AS treatment significantly inhibited tumor growth compared to saline treatment (Table 1). The highest inhibitory efficacy was 65.89% in MK-AS treatment group compared to saline treatment group. The effects of MK-AS on tumor growth are shown in Table 1. The final tumor volumes after 20-d treatment are shown in Table 2 (*P* < 0.01). No difference was found in the mean body weight of mice between the groups during the study (data not shown).

#### Effects of MK-AS treatment on *in situ* HCC xenograft angiogenesis

To determine whether the antitumor effect of MK-AS therapy is associated with angiogenesis suppression, the status of vessel formation in *in situ* HCC xenograft was assessed by immunohistochemistry with endothelial cell-specific CD34 staining. A representative result of immunostaining is shown in Figure 4. High density of microvessels was present in untreated tumor samples, whereas MK-AS treatment significantly reduced vascularization (Figures 4 and 5).

**Table 2** Effect of MK-AS on growth of *in situ* human HCC

Treatment group	Tumor volume (mm <sup>3</sup> )
Saline	807.75 ± 195.19
MK-AS 100 mg/kg per day	294.50 ± 70.66 <sup>b</sup>
MK-AS 50 mg/kg per day	532.00 ± 121.57 <sup>b</sup>
MK-AS 25 mg/kg per day	552.75 ± 84.38 <sup>b</sup>
MK-Sen 50 mg/kg per day	630.88 ± 188.76 <sup>a</sup>

<sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 vs control group.**Figure 5** Tumors resected from mice at the experimental end point. Resected tumors were sectioned and stained as described in the text. Microvessel densities (MVD) were determined by counting CD34-positive endothelial cells in the sections and presented as mean ± SE positive cells/field from the three "hot-spot" fields. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 vs control group.

## DISCUSSION

Tumor-induced neovascularization plays a key role in the development, progression and metastasis of neoplasm<sup>[39]</sup>. Angiogenesis is regulated by several endogenous stimulators and inhibitors of endothelial cell migration, proliferation and tube formation<sup>[4]</sup>. Tumor growth progression is correlated to the serum concentration of angiogenic mediators<sup>[40]</sup>. Furthermore, vascular density of tumor tissues is correlated to the clinical course of tumors<sup>[2]</sup>. MK is heparin binding to cytokines involved in neurogenesis, cell migration and mesoderm-epithelial interactions<sup>[41]</sup>. Choudhuri *et al*<sup>[11]</sup> reported that *in vitro* tumor cell growth is not affected by these growth factors, while *in vivo* tumor cell growth is correlated to increased vascular density of tumors. Since MK plays an important role in angiogenesis, it may be a possible therapy target to suppress angiogenesis of tumor proliferation.

Under physiological conditions the vasculature is quiescent in normal adults. Only 0.01% of endothelial cells in normal adult vessels are in the cell division cycle at any given time<sup>[42]</sup>. However, in response to an appropriate angiogenic stimulus, endothelial cells can be activated to grow new vessels. In the present study, down regulation of MK expression could restrain HUVEC proliferation, suggesting that endothelial cells can also inhibit angiogenesis *in vivo*. Chick CAM assay showed that MK-AS could inhibit local CAM vasculogenesis.

Furthermore, we developed an *in situ* HCC model of mice to determine the effect of MK-AS on tumor proliferation and angiogenesis *in vivo*. Our results indicate that MK-AS administration significantly inhibited tumor growth in the *in situ* HCC model of mice (Tables 1 and 2). Furthermore, Mk-AS administration also suppressed tumor angiogenesis *in vivo* (Figures 4 and 5). It should be noted that the tumor cell line originated from human HCC maintained the complete characteristics of human HCC tissue, such as AFP secretion, drug sensitivity. In addition, the pathological evidence also suggests that this model exhibits various features seen in clinical HCC patients, indicating that the information provided by this model can reflect the true clinic results of patients. In fact, angiogenesis suppressed by transfection with SiRNA targeting MK in human prostate cancer cell line (PC-3) has also been reported<sup>[43]</sup>.

It has been well established that tumor growth and metastasis depend on the induction of new blood supply<sup>[44,45]</sup>. Angiogenic activity as determined by MVD, has been shown to correlate with worse prognosis in a number of solid tumors<sup>[46-48]</sup>. Therefore, antiangiogenic agents targeting either these factors or vascular endothelial cells can be used as promising therapeutic modalities in treatment of tumors<sup>[49]</sup>. In the present study, significant inhibition of angiogenesis was achieved using MK-AS, indicating that MK-AS is an effective antiangiogenesis agent.

## COMMENTS

### Background

Midkine (MK) is a 13kDa protein, a heparin-binding growth factor. Subsequent studies suggest that MK plays an important role in carcinogenesis.

### Research frontiers

MK plays an important role in angiogenesis, which is an important event in tumor development and progression. Antisense oligonucleotide targeting MK is employed in cancer therapy as it can inhibit hypervascularization of tumors and is of great clinical interest.

### Innovations and breakthroughs

In this study, MK inhibited angiogenesis in chicken chorioallantoic membrane and human hepatocellular carcinoma (HCC) xenograft. Meanwhile MK inhibited proliferation of human umbilical vein endothelial cells (HUVEC) and growth of HCC xenograft.

### Applications

In this study, we addressed the potential therapeutic effect of MK on angiogenesis. Significant inhibition of angiogenesis was achieved using MK, indicating that MK is an effective anti-angiogenesis agent.

### Peer review

The manuscript by Li-Cheng Dai *et al* describes the successful use of midkine to inhibit angiogenesis in chicken chorioallantoic membrane and human HCC xenograft. The results were found to be important for HCC therapy. The findings are of clinical interest.

## Abstract

**AIM:** To investigate the therapeutic effect of tetrandrine on liver fibrosis induced by thioacetamide in rats *in vivo* and *in vitro*.

**METHODS:** *In vitro* study: we investigated the effect of tetrandrine on the apoptosis of rat hepatic stellate cells transformed by simian virus 40 (T-HSC/Cl-6), which retains the features of activated cells. *In vivo* study: hepatic fibrosis was induced in rats by thioacetamide. Tetrandrine was given orally to rats at doses of 5, 10 or 20 mg/kg for 4 wk compared with intraperitoneal injection of interferon- $\gamma$ .

**RESULTS:** *In vitro* study: 5, 10 or 25  $\mu\text{g/mL}$  of tetrandrine-induced activation of caspase-3 in t-HSC/Cl-6 cells occurred dose-dependently. *In vivo* study: tetrandrine treatment as well as interferon- $\gamma$  significantly ameliorated the development of fibrosis as determined by lowered serum levels of aspartate aminotransferase (AST), alanine aminotransferase (ALT), total bilirubin (T-Bil) and the levels of liver hydroxyproline (Hyp), hyaluronic acid (HA), laminin (LN) and also improved histological findings. The effects of tetrandrine at the concentration of 20 mg/kg were better than the other concentration groups.

**CONCLUSION:** Tetrandrine promotes the apoptosis of activated HSCs *in vitro*. Tetrandrine administration can prevent liver fibrosis and liver damage induced by

## INTRODUCTION

Fibrosis represents the response of the liver to diverse chronic insults such as chronic viral infection, alcohol, immunological attack, hereditary metal overload, parasitic diseases and toxic damage. Because of the worldwide prevalence of these insults, liver fibrosis is common and ultimately results in cirrhosis that is associated with significant morbidity and mortality. Hepatic fibrosis, regardless of the causes, is characterized by an increase in extracellular matrix constituents, leading to complications of portal hypertension, esophageal varices and hepatic failure. The excessive accumulation of extracellular matrix is characteristic of hepatic fibrosis<sup>[1-3]</sup>. It is accepted that hepatic stellate cells (HSCs) play a central role in the development and resolution of liver fibrosis. HSCs are localized within the space of Disse and function to store retinoids in normal liver. In response to liver damage, HSCs are "activated" to a myofibroblast-like phenotype. It has recently been shown that recovery from established experimental fibrosis can occur through apoptosis of HSCs and is associated with reductions in liver collagen and expression of the tissue inhibitor of metalloproteinases. During chronic liver diseases, HSCs are activated into proliferative, fibrogenic, and smooth muscle  $\alpha$ -actin ( $\alpha$ -SMA) positive myofibroblasts, resulting in liver fibrosis<sup>[4,5]</sup>. Recently it was reported that during recovery from acute human and experimental liver injury, a number of activated HSCs undergo apoptosis, and there is a significant decrease in the extent of fibrosis within the same livers in association with this HSC apoptosis<sup>[6]</sup>.

Therefore, induction of HSC apoptosis might be an important therapeutic strategy for hepatic fibrosis, while inhibition of HSC activation might have a role in the prevention of hepatic fibrosis. The development of approaches to prevent fibrotic changes in the liver or reverse the fibrosis is important<sup>[7]</sup>. However, therapeutic antifibrotic drugs are still at an experimental stage<sup>[8,9]</sup>. The major problems of antifibrotics are toxicity owing to the chronic administration and the lowered therapeutic effects of the agents used clinically as compared with *in vitro* studies. Therefore, developing antifibrotics from the natural products used in traditional medicine with little acute toxicity, may improve therapies<sup>[10]</sup>.

Tetrandrine is a bis-benzyl isoquinoline alkaloid from the Chinese herb radix *Stephania tetrandra* S Moore. This compound has been characterized pharmacologically to exhibit hypotensive, anti-inflammatory, and immunosuppressive properties, to inhibit lipid peroxidation, and to have an antifibrogenic activity against pulmonary fibroblasts and an inhibitory effect on type I and III collagen gene mRNA levels in the lung tissue of rats<sup>[11-13]</sup>. The dried root of *S. tetrandra* is one of the traditional Chinese medicines that have long been used to treat human liver fibrosis and cirrhosis<sup>[14]</sup>. Tetrandrine also shows a blocking action of calcium channels, which are known to play an important role in the regulation of hepatic stellate cell contractility, a marked phenotype of activated HSCs<sup>[15,16]</sup>. For many years, our laboratory has been screening candidate antifibrotic agents from natural products that have been used in traditional medicine to treat liver disease<sup>[10,17]</sup>. It was previously reported that tetrandrine has an antifibrotic function on liver fibrosis in rats induced by bile duct ligation and scission and tetrandrine exerts a direct inhibitory effect on rat HSCs<sup>[18]</sup>. We were intrigued to know if tetrandrine could improve the liver injury induced by thioacetamide (TAA). In a preliminary assay, we found that tetrandrine did induce apoptosis in HSCs. The aim of the present study was to explore the sequential pattern of apoptosis and the antifibrotic effect of tetrandrine on hepatic fibrosis induced by TAA in rats. Our results suggest that tetrandrine ameliorates development of fibrosis in a TAA rat model, accompanied by activation of caspase-3 and reduced number of activated HSCs.

## MATERIALS AND METHODS

### Reagents

Tetrandrine was purchased from Sigma-Aldrich (St Louis, MO, USA) and was dissolved in dimethyl sulphoxide (DMSO). The concentration of tetrandrine used for *in vitro* experiment was prepared by dilution with Williams' medium E (WME; Sigma-Aldrich). DMSO in cells was maintained at 0.5%. Thioacetamide (TAA) was also from Sigma-Aldrich. Hyaluronic acid RIA (HA) kit and laminin RIA (LN) kit were purchased from Shanghai HaiYan Medical Biotechnology Center. Interferon- $\gamma$  was from Livzon Biotechnology Co., Zhuhai, China.

### Isolation of hepatic stellate cells and establishment of t-HSC/CI-6 cell line

The transformed rat hepatic stellate cell line was generated

as described by Kim *et al.*<sup>[19]</sup> with some modifications. t-HSC/CI-6 cells were cultured in WME medium supplemented with 10% fetal bovine serum (FBS; US Biotechnologies Inc., Parkerford, PA, USA) and 100 units/mL penicillin G and 100  $\mu$ g/mL streptomycin (Gibco-Invitrogen Corp., Grand Island, NY, USA) and maintained at 37°C with 5% CO<sub>2</sub>/95% O<sub>2</sub>. Cells were routinely passaged before reaching confluence.

### Assay of caspase activity

After different treatments, cells were collected and washed with ice-cold phosphate-buffered saline (PBS). Cell lysates were prepared with caspase colorimetric assay kits (R&D Systems Inc.), according to the manufacturer's instructions. Protein concentrations in t-HSC/CI-6 cell lysates were determined with a Bio-Rad DC Protein Assay kit (Bio-Rad Laboratories, Hercules, CA, USA). All of the samples were assayed in three independent experiments.

### Tetrandrine treatment for TAA induced liver injury

Male Wistar rats (initial body weight 200-220 g) were purchased from the Animal Center of Changchun Agriculture University. All rats were housed and treated in accordance with the recommendations of the American Physiological Society (Council of Europe, 1982). On receipt, they received normal chow and water ad libitum and were maintained at 20°C-25°C, relative humidity of 50%-60% with a 12 h light/dark cycle throughout the experimentation. The rats were divided into six groups of 10 rats each. The hepatic fibrosis was established with TAA, which was diluted and administered to the rats by intraperitoneal injection (200 mg/kg mixed with water) twice weekly. Rats were given orally by gavage at a daily dose of 5, 10 or 20 mg/kg of tetrandrine group. Interferon- $\gamma$  group was given intraperitoneal injection of  $5 \times 10^4$  U per rat every day. The normal and control groups received equal amounts of saline for 28 d. Three days after the last dose of TAA, the rats were anesthetized and sacrificed. Then blood was obtained by cardiac puncture for serum biochemical testing. Blood samples were kept at room temperature for 1 h and centrifuged at 3000 r/min for 30 min to obtain sera. The livers were immediately removed and a slice of the right lobe was fixed in formaldehyde solution. The rest were divided into equal parts, frozen in liquid nitrogen and stored at -70°C.

### Determination of serum and liver biochemical indices

The level of serum aspartate aminotransferase (AST), alanine aminotransferase (ALT), and total bilirubin (T-bil) were measured on an Autodry chemistry analyzer (Spotchem SP4430, Arkray, Kyoto, Japan). While serum hyaluronic acid (HA) and laminin (LN) content in the liver were determined by radioimmunoassay. All procedures were in accordance to the instructions of the manual.

### Determination of hydroxyproline contents in liver

The hydroxyproline content in the liver was determined by the method described by Jamall *et al.*<sup>[20]</sup>. Briefly, specimens of the liver were weighed and completely hydrolyzed in 6 mol/L HCl. A fraction of the sample was derivatized using chloramine T solution and Ehrlich's reagent, and optical

**Figure 1** Caspase activity analysis. The caspase activity of normal cells was set at 100% and relative changes in activity are shown in association with drug doses. Values represent the results of three separate experiments. <sup>b</sup> $P < 0.001$ , vs normal control values.

density was measured at 558 nm. A standard calibration curve was prepared using trans-4-hydroxy-L-proline. The level of hydroxyproline reflects collagen in the liver.

### Histological and immunohistochemical examinations

Liver specimens were preserved in 4% buffered paraformaldehyde and dehydrated in a graded alcohol series. Following xylene treatment, the specimens were embedded in paraffin blocks and cut into 5-µm thick sections, which were placed on plain glass microscopic slides. The sections were then stained with haematoxylin and eosin (HE) or Sirius-red staining, and observed under a light microscope.

Alpha-smooth muscle actin ( $\alpha$ -SMA) for detection of activated HSCs was assessed immunohistochemically by the Polymer Detection System using an immunohistological staining kit and anti- $\alpha$ -SMA monoclonal antibodies.

### Statistical analysis

All values are expressed as means  $\pm$  SD. The results were evaluated by one-way ANOVA and Tukey's multiple comparison tests. Statistically significant differences between groups were defined as  $P$  values less than 0.05. Calculations were performed with the GraphPad Prism program (Graphpad Software, Inc, San Diego, USA).

## RESULTS

### Caspase-3 activation in tetrandrine-induced apoptosis

To assess the involvement of caspases in t-HSC/CI-6 cell apoptosis, we detected the enzymatic activity of caspases-3, a downstream caspase. Activation of caspase-3 occurred dose dependently induced by the 5, 10 or 25 µg/mL of tetrandrine (Figure 1).

### Liver/weight index

The conditions of rats did not change in control group, but the activity level of the rats was reduced. The general states of rats in other groups were much better than those in control group. Liver/weight index in model group was

**Table 1** Serum biochemical values in fibrotic rats induced by TAA treated with tetrandrine for 4 wk

Group	AST (IU/L)	ALT (IU/L)	T-Bil (µmol/L)
Normal	102 $\pm$ 24	34 $\pm$ 11	11.10 $\pm$ 1.29
TAA (200 mg/kg)	356 $\pm$ 70	198 $\pm$ 32	18.63 $\pm$ 2.50
TAA + tetrandrine (5 mg/kg)	266 $\pm$ 38 <sup>a</sup>	142 $\pm$ 29 <sup>b</sup>	15.70 $\pm$ 1.42 <sup>a</sup>
TAA + tetrandrine (10 mg/kg)	259 $\pm$ 45 <sup>a</sup>	139 $\pm$ 29 <sup>b</sup>	15.11 $\pm$ 2.26 <sup>b</sup>

<sup>a</sup> $P < 0.05$ ; <sup>b</sup> $P < 0.01$ ; <sup>d</sup> $P < 0.001$ , vs control group.

slightly higher than that in other groups, with no statistical significant difference (data not shown).

### Serum biochemical parameters

In rats treated with thioacetamide (TAA; 200 mg/kg, ip), serum levels of AST, ALT and T-Bil were increased to 349%, 618% and 168%, respectively, compared with that of normal rats (Table 1). Tetrandrine (5, 10 or 20 mg/kg per day, po, for 4 wk) significantly lowered serum AST, ALT and T-Bil levels in rats intoxicated by TAA. In 5 mg/kg tetrandrine-treated rats, serum AST, ALT and T-Bil levels were lowered to 74.7% ( $P < 0.05$ ), 71.7% ( $P < 0.01$ ) and 84.0% ( $P < 0.05$ ) compared with that of control fibrotic rats, respectively. In 10 mg/kg tetrandrine treated rats, AST, ALT and T-Bil levels were lowered to 72.7% ( $P < 0.05$ ), 70.2% ( $P < 0.01$ ) and 81.1% ( $P < 0.01$ ) compared with that of control fibrotic rats, respectively. In 20 mg/kg tetrandrine treated rats, AST, ALT and T-Bil levels were lowered to 63.7% ( $P < 0.001$ ), 58.1% ( $P < 0.001$ ) and 79.9% ( $P < 0.01$ ) compared with that of control fibrotic rats, respectively. In interferon- $\gamma$  treated fibrotic rats, AST, ALT and T-Bil levels were lowered to 74.4% ( $P < 0.05$ ), 69.1% ( $P < 0.01$ ) and 82.8% ( $P < 0.05$ ) compared with that of control fibrotic rats, respectively.

### Hydroxyproline matrix contents in the liver

As shown in Figure 2A, liver contents of hydroxyproline increased to 229%, 4 wk after TAA-treatment ( $P < 0.001$ ). Compared with the control fibrotic rats, in fibrotic rats treated with 5, 10 or 20 mg/kg tetrandrine, the hydroxyproline contents in the liver reduced to 73.3% ( $P < 0.05$ ), 67.8% ( $P < 0.01$ ) or 61.5% ( $P < 0.001$ ), respectively. In interferon- $\gamma$  treated fibrotic rats, the hydroxyproline contents in the liver reduced to 64.6% ( $P < 0.001$ ).

### Extracellular matrix content in serum

As shown in Figures 2B and 2C, serum contents of HA and LN increased to 251% and 233%, 4 wk after TAA treatment ( $P < 0.001$ ). In the fibrotic rats treated with 5, 10, 20 mg/kg tetrandrine or interferon- $\gamma$ , HA content in the serum reduced to 68.2% ( $P < 0.05$ ), 62.32% ( $P < 0.01$ ), 50.73% or 47.09% ( $P < 0.001$ ), respectively, compared with the control fibrotic rats. Compared with the control fibrotic rats, in fibrotic rats treated with 5, 10, 20 mg/kg tetrandrine or interferon- $\gamma$ , LN content in the serum reduced to 53.59% ( $P < 0.05$ ), 55.09% ( $P < 0.01$ ), 65.09% ( $P < 0.01$ ) or 68.30% ( $P < 0.05$ ), respectively.

**Figure 2** Liver hydroxyproline (A); HA (B) and LN (C) content of the TAA rats treated with tetrandrine. T-5: treated with 5 mg/kg tetrandrine; T-10: treated with 10 mg/kg tetrandrine; T-20: treated with 20 mg/kg tetrandrine; IFN: treated with interferon- $\gamma$   $5 \times 10^4$  U. Results represent the mean  $\pm$  SD. <sup>a</sup> $P < 0.05$ ; <sup>b</sup> $P < 0.01$ ; <sup>d</sup> $P < 0.001$ , vs control group.

**Figure 3** Light microscopic appearance (HE  $\times 100$ ) of fibrotic rat liver induced by TAA treated with tetrandrine for 4 wk. A: normal group; B: control group; C: TAA group; D: TAA group with tetrandrine (5 mg/kg); E: TAA group with tetrandrine (10 mg/kg); F: TAA group with tetrandrine (20 mg/kg); F: TAA group with interferon- $\gamma$  ( $5 \times 10^4$  U).

### Morphological changes in the liver

In control fibrotic group, the liver stained with HE and Sirius-red showed inflammation and an extensive accumulation of collagens (Figures 3B and 4B), fibrotic septa were increased and seen between areas of portal to portal and portal to central vein in some parts of liver lobules, and in some serious units pseudolobules presented. In tetrandrine and interferon- $\gamma$  treated fibrotic rats, there was a tendency towards less pronounced destruction of the liver architecture, compared with control fibrotic rat liver (Figure 3C-F, and Figure 4C-F).

As shown in Figures 3 and 4, TAA treatment for 4 wk resulted in liver injury, with loss of normal lobular architecture and a marked increase of collagen deposition throughout the liver. However, tetrandrine treatment resulted in reduced collagen deposition in the liver of TAA-treated rats.

HSC activation was examined immunohistochemically by determining  $\alpha$ -SMA-positive areas in injured rat livers

treated with TAA. Considerable expression was detected in areas of centrilobular and periportal fibrotic bands in TAA treated rats (Figure 5B). In normal livers, collagen was observed only around the central and portal veins (Figure 5A). Activated HSCs were characterized by expression of  $\alpha$ -SMA. In tetrandrine-treated or interferon- $\gamma$  groups, the expression of  $\alpha$ -SMA was much lower than that in control fibrotic group and the distribution of  $\alpha$ -SMA positive cells was similar to that of collagen in the liver (Figure 5C-F). In contrast, 20 mg/kg tetrandrine-treated rats notably reduced the positive areas of  $\alpha$ -SMA in the livers of rats treated with TAA.

### DISCUSSION

Thioacetamide (TAA) is a thiono-sulfur containing compound, undergoing an extensive metabolism to acetamide and TAA-S-oxide. Whereas acetamide is devoid of liver-necrotizing properties, TAA-S-oxide

**Figure 4** Light microscopical appearance (sirius red staining) of fibrotic rat liver induced by TAA treated with tetrandrine for 4 wk. **Figure 5** Representative liver section showing reaction of alpha-smooth muscle cell like actin ( $\alpha$ -SMA) with mouse anti- $\alpha$ -SMA monoclonal antibody.  $\alpha$ -SMA immunoreactivity (arrows) was seen in stellate cells in the fibrotic area. **A:** normal group; **B:** control group; **C:** TAA group with tetrandrine (5 mg/kg); **D:** TAA group with tetrandrine (10 mg/kg); **E:** TAA group with tetrandrine (20 mg/kg); **F:** TAA group with interferon- $\gamma$  ( $5 \times 10^4$  U).

is further metabolized, at least in part, by cytochrome P-450 monooxygenases to other products, including a polar product that is thought to be the sulfene, TAA-S-dioxide, a highly reactive compound<sup>[21]</sup>. Therefore, TAA is a typical hepatotoxin and causes centrilobular necrosis by generation of ROS. Although TAA is known mainly to cause necrosis in the liver, it has been reported recently that TAA induced apoptosis in rat liver within a few hours after its administration<sup>[22]</sup>. The present study showed that a low dose of TAA induced apoptosis in the pericentral

areas, whereas a high dose of TAA induced necrosis. Excessive ROS causes necrosis.

The mechanism by which tetrandrine inhibits rat hepatic stellate cell activation is not clear. Tetrandrine administration has been shown to block the calcium channels in various cell types<sup>[23]</sup>. Moreover, activated hepatic stellate cells have receptors for a number of vasoconstrictor substances such as endothelin, angiotensin II, vasopressin, thrombin and thromboxan A<sub>2</sub><sup>[24-26]</sup>. Therefore, it is likely that the inhibitory effect of tetrandrine on hepatic stellate

cell activation is, at least in part, through the blocking of calcium channels. However, further study is needed to understand the precise mechanism of tetrandrine on activated hepatic stellate cells.

Here we showed that tetrandrine is toxic against t-HSC/Cl-6 cells and antifibrotic. Previous studies demonstrated that tetrandrine induced apoptosis in t-HSC/Cl-6 cells, and activated rat hepatic stellate cells transformed by SV40. The morphologies of tetrandrine-treated cells revealed the typical features of apoptosis and these apoptotic phenomena were further confirmed by DNA laddering and annexin v-propidium iodide double staining<sup>[27]</sup>. Previous reports have demonstrated that the caspase family proteases play essential roles in the process of apoptosis<sup>[28]</sup>. Caspase-3, which has a short prodomain and is localized near nuclei, cleaves substrates at the downstream end of the cascade<sup>[29]</sup>. This study demonstrated that the activation of caspase-3 is involved in tetrandrine-induced cell death including apoptosis. Moreover, we have shown that tetrandrine is also effective in mediating HSC apoptosis *in vivo* after the development of fibrosis. It suggests that apoptosis of activated HSCs plays a key role in resolution of hepatic fibrosis.

Our data provide evidence that tetrandrine will effectively induce HSC apoptosis. In addition, we have demonstrated evidence that induction of apoptosis in HSCs enhances the resolution of experimental fibrosis. Taken together, these observations suggest that a strategy based on inducing HSC apoptosis may be an effective antifibrotic approach. The effects of tetrandrine at 20 mg/kg dose are better than the other groups. In conclusion, our results demonstrate that tetrandrine administration could prevent liver fibrosis and liver damage induced by TAA in rats. In this study, tetrandrine reduced the degree of hepatocellular injury as determined by lower serum levels of AST, ALT, T-bil and liver hydroxyproline, serum HA and LN, and also improved morphological structure of the fibrotic liver. Our study shows a direct inhibitory effect on rat HSC activation and an antifibrogenic potential of tetrandrine in fibrotic rats induced by TAA. Tetrandrine may have therapeutic effects in human liver fibrosis.

## COMMENTS

### Background

Fibrosis represents the response of the liver to diverse chronic insults such as chronic viral infection, alcohol, immunological attack, hereditary metal overload, parasitic diseases and toxic damage. It is accepted that HSCs play a central role in the development and resolution of liver fibrosis. Recently it was reported that during recovery from acute human and experimental liver injury, a number of activated HSCs undergo apoptosis, and there is a significant decrease in the extent of fibrosis within the same livers in association with this HSCs apoptosis.

### Research frontiers

Tetrandrine promotes HSC apoptosis in hepatic fibrosis. The study of its mechanism might lead to a new approach for fibrosis therapy. Further studies of the roles and regulation of HSC apoptosis and its possible mechanism are important for understanding the mechanism of resolution of liver fibrosis.

### Innovations and breakthroughs

In this research, we investigated the effect of tetrandrine on the apoptotic death of rat HSCs *in vitro* and whether tetrandrine can prevent thioacetamide-induced fibrosis *in vivo*. The results showed that tetrandrine promotes the apoptosis of

activated HSCs *in vitro* and prevent liver fibrosis and liver damage induced by thioacetamide in rats *in vivo*.

### Applications

The results provide significant evidence illustrating the key feature of recovery from liver fibrosis is HSC apoptosis.

### Terminology

HSCs: hepatic stellate cells; Caspase: Caspases, closely associated with apoptosis, are aspartate-specific cysteine proteases and members of the interleukin-1b-converting enzyme family. The activation and function of caspases, involved in the delicate caspase-cascade system, are regulated by various kinds of molecules, such as the inhibitor of apoptosis protein, Bcl-2 family proteins, calpain, and Ca<sup>2+</sup>.

### Peer review

In this manuscript by Yin *et al.*, the authors report effect of tetrandrine on the treatment of liver fibrosis-induced by thioacetamide in rats *in vivo* and *in vitro*. They employed assay of caspase activity to observe the enzymatic activity of caspases-3, a downstream caspase, occurred dose-dependently and investigated tetrandrine treatment as well as interferon- $\gamma$  significantly ameliorates the development of fibrosis as determined by lowered serum levels of AST, ALT, T-Bil and the levels of liver hydroxyproline, HA, LN and also improved histological findings. Their data may be critical for the study of the mechanism of resolution of rat liver fibrosis and shed new light on the liver fibrosis therapy.

## Abstract

**AIM:** To investigate the contribution of variants of CARD15, OCTN1/2 and DLG5 genes in disease predisposition and phenotypes in a large Italian cohort of pediatric patients with inflammatory bowel diseases (IBD).

**METHODS:** Two hundred patients with Crohn's disease (CD), 186 ulcerative colitis (UC) patients, 434 parents (217 trios), and 347 healthy controls (HC) were studied. Polymorphisms of the three major variants of CARD15, 1672C/T and -207G/C SNPs for OCTN genes, IGR2096a\_1 and IGR2198a\_1 SNPs for the IBD5 locus, and 113G/A variant of the DLG5 gene were evaluated. Potential correlations with clinical sub-phenotypes were investigated.

**RESULTS:** Polymorphisms of CARD15 were significantly associated with CD, and at least one variant was found in 38% of patients (15% in HC, OR = 2.7,  $P < 0.001$ ). Homozygosity for both OCTN1/2 variants was more common in CD patients (1672TT 24%, -207CC 29%) than in HC (16% and 21%, respectively;  $P = 0.03$ ), with an increased frequency of the TC haplotype (44.8% vs 38.3% in HC,  $P = 0.04$ ). No association with the DLG5 variant was found. CD carriers of OCTN1/2 and DLG5 variants more frequently had penetrating disease ( $P = 0.04$  and  $P = 0.01$ ), while carriers of CARD15 more frequently had ileal localization ( $P = 0.03$ ). No gene-gene interaction was found. In UC patients, the TC haplotype was more

## INTRODUCTION

The inflammatory bowel diseases (IBD), Crohn's disease (CD) and ulcerative colitis (UC) have become increasingly common causes of morbidity in children<sup>[1,2]</sup>. Their prevalence has been on rise with children and adolescent currently accounting for approximately 30% of IBD patients<sup>[3,4]</sup>. Although the precise etiology of IBD remains elusive, both animal models and human studies point towards a strong genetic susceptibility.

The characterization of the NOD2/CARD15 gene at the IBD1 locus (16q12) in 2001 as the first gene conferring susceptibility to CD represented a milestone observation<sup>[5-7]</sup>. Although the role of NOD2 protein in CD remains under evaluation<sup>[8]</sup>, it is surely involved in the innate immune response to bacterial pathogens<sup>[9,10]</sup>. CARD15 major variants are mostly associated with ileal disease and stricturing behaviour<sup>[7]</sup>. In pediatric series, a correlation with ileal localization<sup>[11-14]</sup>, stricturing behaviour<sup>[12,13,15]</sup>, early surgery<sup>[12,13]</sup>, growth delay<sup>[13,14]</sup>, and higher disease activity<sup>[13,16]</sup> has been reported, although with conflicting findings<sup>[17-19]</sup>.

Functional polymorphisms in the carnitine organic cation transporter cluster (OCTN1/2)<sup>[20]</sup> on chromosome 5q31 and mutations in disc large gene 5 (DLG5)<sup>[21]</sup> on

the long arm of chromosome 10 (10q23) have also been reported to be associated with CD. Linkage on the 5q31 genomic area, the so-called IBD5 risk haplotype, was first reported by Rioux *et al*<sup>[22]</sup>. This 250-kilobase region contains 5 genes and multiple genetic variants with strong linkage disequilibrium<sup>[22]</sup>. A number of studies have confirmed the association of the IBD5 risk haplotype with CD<sup>[23-28]</sup> and UC<sup>[28,29]</sup>. Peltekova *et al*<sup>[20]</sup> found two novel single nucleotide polymorphisms (SNPs) with functional mutations, generating a 2-alleles risk haplotype (TC) predisposing to CD. Replication studies have found inconsistent genotype/phenotype correlation<sup>[30-34]</sup> with some concordance for presence of perianal fistulae<sup>[31,33]</sup>, which is similar to that observed for the IBD5 risk haplotype<sup>[25,28]</sup>. More importantly, although Peltekova *et al*<sup>[20]</sup> in preliminary functional studies demonstrated that the OCTN1/2 variants resulted in impaired transport function of various organic cations and carnitine, but the precise link with IBD pathogenesis remains unexplained. All subsequent replication studies were unable to confirm the association of TC haplotype in the absence of the IBD5 risk haplotype<sup>[30-33]</sup>, making the assumption of OCTN variants as causal genes still disputable<sup>[35]</sup>.

Concerning the DLG5 gene, Hampe *et al*<sup>[36]</sup> initially described a susceptibility locus on chromosome 10 in a genome linkage study. Stoll *et al*<sup>[21]</sup> further narrowed down this risk region and identified two distinct haplotypes associated with IBD and CD. More specifically, the “risk haplotype D” was defined by a single non-synonymous SNP 113G→A; this nucleotide change resulting in the amino acid substitution R30Q, probably impedes scaffolding of the protein evaluated in silico analysis. A collaborative study<sup>[37]</sup>, investigating two independent case-control cohorts and one family-based collection confirmed the association in 2 of the 3 cohorts, although with a modest effect on the relative risk to IBD (OR = 1.25). Other groups, however, reported negative findings<sup>[30,31,38]</sup>. More recently, a more thorough evaluation of the previously reported cohorts with other large control populations, has demonstrated that the DLG5 gene is a risk factor for CD only for men (OR = 2.49, CI 1.5-4), but not for women (OR = 1.01)<sup>[39]</sup>. Intriguingly, this difference is driven by a gender-dependent transmission ratio distortion among healthy controls (frequency of A allele: men 5.2%, women 11.3%).

In young patients, IBD might offer the opportunity to understand the pathophysiology of the diseases in a form that is closer to their underlying cause and mechanisms than in adult, because of a lower influence of environmental risk factor (i.e. smoking). Paradoxically, in contrast to the data in adults, there are studies mainly looking at CARD15 polymorphisms<sup>[11-19,40]</sup>, while being scarce and conflicting on OCTN1/2 and DLG5 genes<sup>[41-44]</sup>. Moreover, many pediatric series are flawed by a small sample size<sup>[11,12,15,16,18,19,43,44]</sup>, little information on UC patients<sup>[13,15,41]</sup>, and lack of control populations<sup>[11,12,16,17,19]</sup>.

In this study we have investigated the contribution of variants of CARD15, OCTN1/2 and DLG5 genes in IBD predisposition in a large Italian pediatric cohort. We also examined the genotype/phenotype relationships and gene-gene interactions.

## MATERIALS AND METHODS

### Study population

Patients under age of 18 at diagnosis were recruited into this study from 16 tertiary pediatric and gastroenterologic centres in Italy, in cooperation with a multicenter study endorsed by the SIGENP (Italian Society for Pediatric Gastroenterology, Hepatology and Nutrition). Ethical approval was obtained at all participating centres. All study participants were Caucasian and their parents gave a written informed consent.

The diagnosis of CD or UC was established by conventional clinical, radiological, endoscopic and histological criteria<sup>[45]</sup>. Indeterminate colitis was excluded from the study.

The recruited population was comprised of 200 patients with CD and 186 patients with UC. Blood samples were also taken from 434 parents, making 217 complete family trios (108 CD and 109 UC, respectively) available for analysis.

A total of 347 adult healthy unrelated blood donors (184 male, mean age 32 years, range 20-45) who served as controls were randomly recruited from their sites to minimize the potential geographic differences among San Giovanni Rotondo (Southern Italy, *n* = 147), Rome (Centre, *n* = 100) and Padova (Northern Italy, *n* = 100).

### Data collection

Retrospective data were collected on patients using a standardized questionnaire obtaining information on patient and parental smoking details (at least one cigarette/d), ethnicity, and IBD family history. Additional clinical data were collected on patient demographics, age at IBD diagnosis, medications, extra-intestinal manifestations and need for resective surgery. Standard investigations employed in these patients were upper GI endoscopy, ileo-colonoscopy, and barium examination. CD disease location and behavior were categorized according to the Vienna classification<sup>[46]</sup>. Presence of perianal fistulae was analysed separately according to the Montreal's proposal<sup>[47]</sup>.

In all patients, weight and height percentiles were calculated at diagnosis. Presence of growth retardation was defined as a reduction below the 5<sup>th</sup> percentile for weight, height or both.

### Genotyping

Genomic DNA was extracted from peripheral blood leukocytes according to standard protocols<sup>[48]</sup>, and genotyped in the laboratory of San Giovanni Rotondo Hospital.

Genotyping for Arg702Trp and Leu1007fsinsC common CARD15 variants was performed by DHPLC (denaturing high performance liquid chromatography, Wave System, Transgenomic Ltd, UK) and restriction fragment length polymorphisms (RFLP) assay was used for Gly908Arg (G/C). The 380 base pairs PCR product was digested with Hha I (New England Biolabs, Ipswich, MA), yielding 2 fragments of 138 and 242 base pairs in the presence of C allele and visualized on 2% (w/v) agarose gel. One hundred random samples were also confirmed by sequencing on ABI 310 DNA sequencer (Applied

DHPLC: Denaturing high performance liquid chromatography; RFLP: Restriction fragment length polymorphisms; TaqMan: ABI Prism 7700 sequencer detector.

Biosystems, Foster City, CA, USA) according to the manufacturer's recommendations.

For OCTN1/2 genotyping, the SLC22A4 1672C/T and SLC22A 5-207G/C primers were designed using Primer Express V 1.5 (Applied Biosystems). SNPs were genotyped using the Taqman system ABI PRISM 7700 (Applied Biosystems, Foster City, CA, USA) as previously described<sup>[33]</sup>.

For the IBD5 locus, the IGR2096a\_1 and IGR2198a\_1 SPNs were selected from the haplotype originally described by J. Rioux<sup>[22]</sup> (<http://www.genome.wi.mit.edu/IBD5>). Genotyping was performed by restriction fragment analysis as previously described<sup>[28]</sup>. Results were confirmed by direct sequencing of representative samples for each genotype, using ABI cycle sequencing kit V 1.1 and the ABI 310 genetic analyzer.

For the DLG5 gene, we genotyped the 113 G→A variant (rs1248696) tagging the haplotype D, the over-transmitted haplotype in the study by Stoll *et al.*<sup>[21]</sup>, with 7700 TaqMan bi-allelic discrimination system. PCR reactions (15 mL) were performed in 1 × TaqMan Universal PCR Master Mix, 1 × Genotyping Assay Mix, and 50 ng of genomic DNA. After 2 min at 50°C, and 10 min at 94°C initial denaturation, reaction was amplified for 40 cycles: 15 s at 94°C, and 60 s at 60°C.

A summary of primer sequences and methods is depicted in Table 1.

### Detection of antibodies

Whenever serum samples were available, anti-nuclear cytoplasmatic antibodies (ANCA) were tested by a standard immuno-fluorescence technique<sup>[49]</sup>. In addition, presence of anti-saccharomyces cerevisiae antibodies (ASCA) was investigated by means of a commercial ELISA assay (Quanta Lite<sup>TM</sup> ASCA, Inova Diagnostics Inc, San Diego, USA)<sup>[50]</sup>.

### Data analysis

Comparison of allele and genotype frequencies was performed by Chi-square and Fisher exact tests when appropriate. Student's *t* test was used to compare means of continuous variables with the SPSS software ver. 11.5. Tests for Hardy-Weinberg equilibrium, linkage disequilibrium, haplotype frequency analysis and transmission disequilibrium were performed by the Haploview Software ver. 3.2 (<http://www.broad.mit.edu/personal/jvbarret/haploview>).

Power calculation was performed using the PS software (<http://biostat.mc.vanderbilt.edu/twiki/bin/view/Main/PowerSampleSize>).

Genotype-phenotype associations were analysed by means of univariate and multivariate stepwise logistic regression with the SPSS software. This approach allowed to take into account a dose-response effect (heterozygote or homozygote), the possible interactions between genes, and the effect of potential confounding variables (duration of follow-up, disease localization, etc.). The obtained *P* values were corrected (exact *P* value) for multiple comparisons. A possible interaction between CARD15, OCTN1/2, and DLG5 genes was also investigated.

## RESULTS

### Clinical findings

Main clinical characteristics of patients included in the study are depicted in Table 2.

The 200 CD patients had a mean age of  $21 \pm 8$  years (range 1-18) with a slight male predominance (male/female = 115/85). The 186 UC patients had a mean age of  $19 \pm 9$  years (range 1-18) with a female predominance (73/113). The mean age at diagnosis and the mean duration of follow-up (8-9 years) were similar between the two groups of patients. Eighteen percent

EIM: Extra-intestinal manifestations. <sup>1</sup>One patient had upper G-I involvement only.

of CD had an upper G-I involvement. The incidence of resective surgery (26% *vs* 7%,  $P < 0.01$ ), extra-intestinal manifestations (40% *vs* 25%,  $P = 0.002$ ), growth delay (42% *vs* 14%,  $P < 0.001$ ) and perianal fistulae (18% *vs* 0.5%,  $P < 0.001$ ) was significantly higher in CD than in UC patients. In the latter group, almost half of the patients had a pancolitis (47%). The incidence of ASCA and ANCA was 71% and 17% in CD patients, and 24% and 57% in UC patients, respectively, with a significant difference ( $P < 0.0001$  and  $P < 0.0001$ , respectively).

### Genotyping findings

The error rate of genotyping (defined as the percentages of disagreement in genotypes among 200 random samples tested in duplicate) was  $< 1\%$  for all SNPs.

All genotypes in patients and healthy controls were in Hardy-Weinberg equilibrium. A strong linkage disequilibrium ( $D' > 91$ ) was identified between the two OCTN1/2 variants, and between each OCTN1/2 variant and the IBD5 risk haplotype markers as well ( $r^2 > 0.62$ ,  $P < 0.001$ ) (Figure 1).

Table 3 summarizes the distribution of genotypes for the CARD15 variants (Arg702Trp, Gly908Arg and Leu1007fsinsC), OCTN1/2 variants (SLC22A4 and SLC22A5), the IBD5 risk haplotype SNPs (IGR2096a\_1 and IGR2198a\_1), and DLG5 gene polymorphism (113G $\rightarrow$ A).

Regarding the CARD15 gene, all three variants were frequently seen in CD patients as compared to controls ( $P < 0.001$ ). By combining the three variants,

**Figure 1** Evaluation of linkage disequilibrium in control subjects between IBD5 risk haplotype SNPs and OCTN1/2 variants ( $r^2 > 0.62$ ;  $P < 0.001$ ).

38% of CD patients had at least one mutation, and 15% had two mutations (homozygosity or compound heterozygosity). Respective figures in healthy controls were 15% and 1%. In carriers of one mutation, the odd risk was 2.7 (CI = 1.7-4.2;  $P < 0.001$ ) while that for two mutations was 17 (CI = 5-58;  $P < 0.001$ ).

As for the OCTN1 and OCTN2 variants, they were both significantly increased in CD patients for the homozygous genotype (1672TT: 24% *vs* 16% in controls,  $P = 0.03$ ) (-207CC: 29% *vs* 21% in controls,  $P = 0.03$ ). Moreover, the two-point haplotype, consisting of the 1672T and -207C alleles (OCTN-TC), was associated with CD (44.8% *vs* 38.3% in controls,  $P = 0.043$ ). The 1672TT (22% *vs* 16% in controls) and -207CC (29% *vs* 21% in controls) genotypes were also increased in UC patients, the difference being statistically significant ( $P = 0.10$  and  $P = 0.05$ , respectively). Accordingly, the frequency of TC haplotype was significantly increased also in UC patients (45.4% *vs* 38.3% in controls,  $P = 0.03$ ).

The markers of IBD5 (IGR2096a\_1 and IGR2198a\_1) risk haplotype were both increased for the homozygous genotype in CD patients compared to controls, although with this sample size, only the AA genotype of the SNP IGR2096a\_1 was significantly increased (23% *vs* 14% of controls,  $P = 0.01$ ). Among individuals lacking the IBD5 risk haplotype (homozygous with respect to the non-risk associated allele of IGR2096a\_1), only 7% of patients with CD and 5% of controls carried the TC haplotype, while in presence of the IBD5 risk haplotype, the TC haplotype was found in 61.9% of CD patients and 58.7% of controls. Similar data were obtained in UC patients (data not shown, available on request).

The distribution of 113G $\rightarrow$ A polymorphism of DLG5 was similar in patients and controls. No significant differences in allele or genotypes frequencies were noted. We also attempted to analyse the data based on gender of cases and controls based on the recent findings of male predominance<sup>[39]</sup>, but results did not differ.

### TDT analysis

TDT analysis of UC trios did not show significant transmission distortion of any genetic markers. As expected, a significant over-transmission towards affected

Table 4 Analysis of possible interaction between OCTN TC-haplotype and DLG5 variant with presence (or absence) of at least one CARD15 variant

CARD15		CD		UC		Controls	
		DLG5	OCTN TC haplotype (%)	DLG5	OCTN TC haplotype (%)	DLG5	OCTN TC haplotype (%)
CARD15+	DLG5+	5 (3)	42.6	7 (4)	35.2	11 (3)	44.8
	DLG5-	56 (34)		27 (16)		38 (12)	
CARD15-	DLG5+	12 (7)	46.2	20 (12)	48.7	44 (13)	39.1
	DLG5-	92 (56)		116 (68)		241 (72)	

DLG5-positive was defined as the AA or AG genotypes. Data expressed as absolute values or percentages (between brackets). All comparison had a  $P$  value  $> 0.05$ .

offspring was observed for CARD15 variants in CD trios: the Arg702Trp (transmitted/untransmitted [T/U], 24/8,  $P = 0.004$ ) and Leu1007fsinsC variants (T/U, 14/2,  $P = 0.027$ ) were significantly over-transmitted. We did not observe distortion of transmission towards affected offspring for the Gly908Arg CARD15 variant, OCTN1/2 variants, and for the two IBD5 risk-haplotype-tagging SNPs IGR2198a\_1 and IGR2096a\_1. Regarding the DLG5 variant, an over-transmission of the wild-type allele of the 113G→A SNP towards affected offspring was found (T/U, 21/9,  $P = 0.02$ ).

### Gene-gene interaction

For the evaluation of gene-gene interactions, all subjects were stratified according to their CARD15 genotype. Genotypes and allele frequencies for the investigated variants of OCTN1/2 and TC haplotype, and for G113A variant of DLG5 were not different between CARD15-positive (carrying at least 1 CARD15 variant)

and CARD15-negative subjects (Table 4). Similarly, no interactions between OCTN1/2 and DLG5 variants were found (data not shown, available on request).

### Genotype-phenotype analysis

For the analysis of possible correlation between genotype and phenotype, patients were classified on the basis of presence or absence of at least one CARD15 variant, TC haplotype, and DLG5 risk genotype (carriers of the A allele). Data are shown in Table 5 and Table 6. CD patients carrying the CARD15 variants had more frequently ileal localization and less frequently a colonic localization (OR = 2.8,  $P = 0.029$ ). Carriers of TC haplotype of OCTN1/2 variants had more occurrence of a penetrating disease (48.7% vs 43.5%) as compared with inflammatory/stricturing behaviour; this difference was statistically significant when perianal fistulae were not taken into account (62% vs 43%;  $P = 0.038$ ) according to Montreal's classification. Similarly, a more frequent penetrating disease

**Table 5** Genotype-phenotype correlation in CD patients evaluated by comparisons of carriers and non-carriers of at least one CARD15 variant (CARD15+), AA/AG genotypes of DLG5 variant (DLG5+) and presence of TC haplotype of OCTN1/2 variants (TC+)

(not including perianal fistulae) was found in CD patients with DLG5 risk variant (24% vs 6%; *P* = 0.011). No other significant differences were found between CD and UC patients (Table 6). No further correlation at this sample size could be observed when considering patients with two CARD15 variants, homozygous for TC haplotype or DLG5 variant. Similarly, no correlation could be found when evaluating subjects with all three concomitant gene variants (at least one CARD15 variant, OCTN TC-haplotype and DLG5 113G/A).

The correlations between at least one CARD15 variant with ileal localization (OR = 2.8, CI = 1.1-7.5; *P* = 0.031), OCTN TC-haplotype and DLG5 113G/A variant (OR = 4.05, CI = 1.05-15.5; *P* = 0.041) with penetrating disease were also confirmed at the stepwise logistic regression, after correction for potential confounders (duration of follow-up).

## DISCUSSION

This study reports in the largest available cohort of

pediatric IBD patients the contribution of variants of CARD15, OCTN1/2 and DLG5 genes on disease predisposition and correlation with phenotype. Reports of pediatric series to date available have been limited to mainly CARD15 variants<sup>[11-19]</sup>, small number of subjects<sup>[11,12,15,16,18,19]</sup>, and scarce information on UC patients<sup>[13,15,41]</sup>.

The carriage rate of CARD15 variants in our pediatric population was 38% for CD patients and 20% for UC patients, not significantly different from figures in adult Italian population (36% for CD and 15% for UC, respectively)<sup>[51]</sup>. This finding is in agreement with previously reported frequencies in CD pediatric series ranging from 8.6% up to 60%, with lowest incidence in Swedish and Scottish population, similarly to the rates reported in corresponding adult population. Accordingly, this figure does not support the hypothesis of a stronger effect of CARD15 variants in early onset of CD. The relative contribution of each of the three common variants in our data is consistent with data from adult populations of IBD patients: 1007finsC confers the greatest risk (OR = 4.6, CI = 2.2-9.5) and G908R the least

(OR = 2.9, CI = 1.5-5.4). More specifically, the 1007fsnC and R702W variants were associated with susceptibility to CD both in case control and family-based analysis, while the G908R variant was associated only in case control studies.

Homozygous carriers of OCTN1/2 variants were significantly more frequent in CD patients as compared to controls (OR = 1.6,  $P = 0.03$ ). The TC haplotype was found in 44.8% of CD patients and 38.3% of controls ( $P = 0.04$ ). No evidence of interaction with CARD15 gene was found since the frequency of TC haplotype was similar in CARD15-positive and CARD15-negative patients. Furthermore, a trend towards an increase of the homozygous carriers of OCTN1/2 variants was noticed in UC patients ( $P = 0.05$ ), with a significant increase of TC haplotype (45.4%;  $P = 0.03$ ), with similar finding in Italian adult population<sup>[33]</sup> and two other pediatric cohorts<sup>[41,42]</sup>. In contrast, no correlation of OCTN1/2 variants has been found in other pediatric series<sup>[43,44]</sup>, perhaps for the smaller sample size of patients and controls. Our study confirmed the strong linkage disequilibrium between OCTN1/2 variants and SNPs tagging the IBD5 risk haplotype. Contrary to the Peltekova's study<sup>[20]</sup>, the large majority of homozygous carriers of OCTN1/2 variants and TC haplotype were found in the background of IBD5-positive risk allele<sup>[35]</sup>. Although the possible causal role of the OCTN1/2 variants could not be excluded, further functional studies are needed to confirm and explain the role of these genes in IBD.

The DLG5 variant (G113A) was not correlated with pediatric IBD, even after stratifying patients and controls for gender in both the association study and family-based analysis. In addition, the A (risk) allele was significantly under-transmitted ( $P = 0.02$ ), similarly to another adult series<sup>[31]</sup>. This might reflect a reduced effect of this variant in pediatric onset of IBD (5% *vs* > 10% in corresponding adult population)<sup>[39]</sup> and/or an insufficient power of the study sample. Based on the observed frequency of this variant in the control population (9%), our study sample could detect a  $\pm 4.5\%$  difference with a power of 90% and significance of 0.01.

No interaction between DLG5 variant and CARD15 or OCTN1/2 variants was found.

When the genotype-phenotype correlation was explored, there was only a weak correlation with ileal disease for CARD15 variants ( $P < 0.03$ ) and penetrating disease for OCTN1/2 and DLG5 ( $P < 0.04$ , and  $P < 0.02$ , respectively). All these correlations were confirmed in the stepwise logistic regression analysis.

The correlation of CARD15 variants with ileal disease has been widely reported in most studies of adult<sup>[7]</sup> and child<sup>[11-14,41,44]</sup> Caucasian populations. Although some explanations for this consistent association have been put forward (e.g. presence of NOD2 in Paneth cells in terminal ileum, impaired regulation of Paneth-cell mediated antimicrobial response, perhaps through impaired production of  $\alpha$ -defensin)<sup>[52]</sup>, the clinical implications are unclear yet. Less than 50% of CD patients with ileal localization in this and other studies carry one CARD15 variant; moreover, carriers of this variant do not have a disease course and response to therapy, being

different from non-carriers<sup>[53]</sup>.

The association of OCTN1/2 and DLG5 variants with penetrating disease is intriguing since both genes are involved in maintaining mucosal integrity and permeability. A correlation between OCTN1/2 variants and penetrating disease has been reported in adult population<sup>[31-33]</sup>, but not in the only two available studies in children with CD, in which no correlation<sup>[44]</sup> or only a correlation with growth delay was found<sup>[41]</sup>. Obviously, difference in selection of patients and duration of follow-up may explain this discrepancy. In our series, patients with penetrating disease were more than double than in the above-mentioned studies<sup>[41,44]</sup>. Moreover, our definition of growth delay (below 5<sup>th</sup> percentile) was more stringent than that of the Scottish study<sup>[41]</sup> (below 9<sup>th</sup> percentile). Nevertheless, when considering patients with both height and weight delay below the 5<sup>th</sup> percentile, a trend towards a correlation with TC-haplotype was found in our study ( $P = 0.07$ ).

Regarding the correlation of DLG5 variant with penetrating disease, no reports are available so far in children with IBD. Moreover, data in adult population are very conflicting with no clear genotype-phenotype correlation demonstrated.

Finally, no correlation with age at diagnosis, family history, active and passive smoking, previous appendectomy, presence of ANCA and ASCA, growth delay, use of steroids, or need for surgery could be demonstrated in our series. Moreover, despite a significant increase of TC-haplotype of OCTN1/2 variants in UC patients, no correlation with any clinical phenotype was found. A potential limitation of this study lies in the large number of centres involved and the possible lack of reproducibility of clinical classification (disease behaviour). This choice allowed, however, to accomplish the study in the largest population of pediatric IBD patients so far for genetic purpose. Moreover, all patients were enrolled at academic referral centres and sorting of clinical features was obtained through a previously validated standardized questionnaire.

In conclusion, this study has demonstrated that the three common CARD15 variants and the recently described OCTN1/2 variants, but not the 113G/A DLG5 variant, are associated with susceptibility to CD in children. Furthermore, all three investigated genes exert a weak influence on clinical expression of CD; CARD15 variants (Arg702Trp, Gly908Arg and Leu1007fsinsC) are slightly more frequent in subjects with ileal localization, while OCTN (1672C/T and -207G/C) and DLG5 (113G/A) polymorphisms correlate with presence of penetrating behaviour.

## ACKNOWLEDGMENTS

We thank Ms Ermelinda De Santo, Ms Tiziana Latiano, Ms Carla Zagaria and Mr Giuseppe Corritore for their skillful technical support. The following physicians contributed to the study by providing DNA samples and clinical information of their patients (number of probands between brackets): Roma: Cucchiara S, Borrelli O, Bascietto C (69); S. ## Abstract

**AIM:** To study milk consumption and subjective milk-related symptoms in adults genotyped for adult-type hypolactasia.

**METHODS:** A total of 1900 Finnish adults were genotyped for the C/T-<sup>13910</sup> variant of adult-type hypolactasia and filled in a structured questionnaire concerning milk consumption and gastrointestinal problems.

**RESULTS:** The C/C-<sup>13910</sup> genotype of adult-type hypolactasia was present in 18% of the study population. The prevalence of the C/C-<sup>13910</sup> genotype was higher among subjects who were undergoing investigations because of abdominal symptoms (24%,  $P < 0.05$ ). Those with the C/C-<sup>13910</sup> genotype drank less milk than subjects with either the C/T-<sup>13910</sup> or the T/T-<sup>13910</sup> genotype of lactase persistence (18% vs 38%; 18% vs 36%,  $P < 0.01$ ). Subjects with the C/C-<sup>13910</sup> genotype had experienced more gastrointestinal symptoms (84%) during the preceding three-month period than those with the C/T-<sup>13910</sup> (79%,  $P < 0.05$ ) or the T/T-<sup>13910</sup> genotype (78%,  $P < 0.05$ ). Only 9% (29/338) of the subjects with the C/C-<sup>13910</sup> genotype consumed milk and reported no symptoms from it.

## INTRODUCTION

Gastrointestinal symptoms are a frequent cause for seeking medical advice in adult working age population<sup>[1]</sup>. Adult-type hypolactasia, characterised by the down regulation of lactase enzyme activity in the intestine during development is the most common enzyme deficiency in humans<sup>[2]</sup>. The symptoms caused by undigested lactose, bloating, diarrhoea and bowel gas are unspecific making the assessment of the diagnosis of adult-type hypolactasia a challenge to clinical practice. Symptoms vary greatly in severity and depend on the amount of lactose ingested and on individual sensitivity and may overlap with those of other gastrointestinal diseases such as irritable bowel syndrome (IBS) or diseases presenting with secondary lactose malabsorption, i.e. celiac disease<sup>[3]</sup>. Cases of individuals suspecting they have lactose intolerance are more common than the true prevalence of adult-type hypolactasia<sup>[4-9]</sup>. It has been shown that lactose-restricted diets improve symptoms markedly for example in IBS patients with lactose malabsorption and reduce the number of visits to the outpatient clinics<sup>[10]</sup>. Accurate diagnosis of lactose malabsorption, which is easily treatable by diet modification, would therefore be cost effective and time saving.

Diagnosis of adult-type hypolactasia has been based

on indirect methods, the lactose tolerance test (LTT) or breath hydrogen test (BHT). Specificity of the LTT ranges from 77% to 96%, and that of BHT from 89% to 100%. Sensitivities vary from 76% to 94% for LTT and from 69% to 100% for BHT<sup>[11]</sup>. These methods are time consuming for the patient and need substantial assistance by medical personnel. The determination of disaccharidase activities and lactase/sucrase ratios from the intestinal biopsy specimen would be the most accurate diagnostic method<sup>[12]</sup> but this invasive method is not suitable for everyday clinical practice.

It has been demonstrated that lactase non-persistence is inherited as an autosomal recessive trait. A proportion of the human population can digest lactose (lactase persistence) due to a mutation retaining lactase activity<sup>[13]</sup>. A single nucleotide polymorphism C to T located 13910 base pairs upstream the lactase gene is associated with the persistence/non-persistence trait in the Finnish families<sup>[14]</sup>. Analyses of several hundreds of intestinal biopsies have demonstrated that the C/C-13910 genotype is associated with low lactase activity (< 10 U/g/protein) and the C/T-13910 and T/T-13910 genotypes with high activity<sup>[14-16]</sup>. The prevalence of the C/T-13910 variant is compatible with the previously published figures for adult-type hypolactasia in European, Asian, African-American and Northern African populations<sup>[14-19]</sup>. It has been suggested, however, that in some African tribes the frequency of T-13910 allele does not parallel with the prevalence of lactase persistence<sup>[18]</sup>. Lactase mRNA transcribed from the C-13910 allele declines in the intestinal mucosa of children around five years of age<sup>[20]</sup>, paralleling with the age of developmental down regulation of lactase enzyme activity<sup>[16]</sup>. *In vitro*-studies of the C/T-13910 variant have demonstrated greater increase in lactase promoter activity by the T-13910 variant<sup>[21,22]</sup>. This could possibly be explained by the recent finding of the T-13910 allele binding more strongly the transcription factor Oct-1 compared to the C-13910 allele<sup>[23]</sup>. Thus, the obtained functional data has given evidence for the use of the C/T-13910 variant as a robust marker for adult-type hypolactasia.

Here we have genotyped 1900 working-age people attending primary health care for the C/T-13910 variant associating with adult-type hypolactasia, and addressed the question about the prevalence and frequency of gastrointestinal symptoms as well as consumption of milk products.

## MATERIALS AND METHODS

### Participants

1902 adults from the capital area of Finland attending laboratory investigations in primary health care were asked to give a blood sample for genotyping of the C/T-13910 variant of adult-type hypolactasia and to fill in a questionnaire concerning the daily consumption of dairy products (normal and delactated milk, sour milk, yoghurt or ice cream, cheese) and possible milk related symptoms. The questions asked concerned whether or not a specific dairy product is included in the diet. Each participant was asked whether he/she had experienced any gastrointestinal

complaints during the preceding three-month period. Frequency of gastrointestinal symptoms was also evaluated on daily and weekly basis. The questions on gastrointestinal symptoms covered: (1) the frequency of gastrointestinal symptoms such as flatulence, bloating, diarrhoea, heartburn, and constipation (2) the relation of their symptoms to meals, (3) correlation of the symptoms to different types of milk products or other foods, (4) previous diagnosis of lactose intolerance or a GI-disease such as colon cancer, celiac disease, or *Helicobacter pylori* infection. The age of the participants was ticked in questionnaire in three age groups (18-35 years, 36-51 years, and 52-64 years) due to the extensive number of study population. The formulated questionnaire was pre-tested on a small group of healthy adults. The collection of the questionnaires and blood samples occurred during a three-month period from February to May 2004. The study was approved by the Ethical Committee of the Helsinki University Central Hospital. All the subjects signed their written informed consent.

### Genotyping

DNA of the study subjects ( $n = 1900$ ) was isolated from peripheral blood samples by submerging a blank strip (Merck, Darmstadt, Germany) into EDTA blood. Strips were dried and heated in 1 × PCR reaction buffer (Dynazyme; Finnzymes, Espoo, Finland) containing 10 mmol/L Tris HCl (pH 8.8 at 25°C), 50 mmol/L KCl, 1.5 mmol/L MgCl<sub>2</sub>, and 0.1% Triton X-100 to degrade proteins. After centrifuging 10 µL of the supernatant containing the DNA, the sample was amplified in a total volume of 50 µL, containing primers (one biotin-labeled 5'-(Biotin) CCTCGTTAATACCCACTGACCTA-3') (5 µmol/L) and one unmodified 5'-GTCACTTTGATATG ATGAGAGCA-3' (50 µmol/L), dNTPs (1000 µmol/L), 0.5 U of Taq polymerase (Dynazyme, Finnzymes) in a standard buffer. The PCR cycle conditions used were as following: an initial round of denaturation at 94°C for 4 min, then 35 cycles at 94°C for 30 s, 53°C for 30 s, 72°C for 1.15 min, and a final extension of 72°C for 10 min. The resulting PCR products were analyzed by 1.5% agarose gel electrophoresis to verify the amplification and the size of the PCR product.

The C/T-13910 single nucleotide polymorphism was analysed using the solid-phase mini-sequencing method<sup>[24]</sup> that is based on the detection of tritium-labeled T-13910 and C-13910 alleles in the PCR reaction and measurement of their ratio using scintillation counter that directly reflects the ratio between the two sequences in the original sample. Briefly, in the mini-sequencing of the C/T-13910 single nucleotide polymorphism, two 10-µL aliquots of the biotin-labeled PCR product were captured to streptavidin coated microtitre wells (Thermo Electron, Helsinki, Finland). The reaction mixture contained 10 pmol of the detection primer (5'-GGCAATACAGATAAGATAATGT AG-3'), 0.1 µL of either <sup>3</sup>H-dCTP or <sup>3</sup>H-dTTP (Amersham Biosciences, Little Chalfont, Buckinghamshire, UK) and 0.05 U of DNA polymerase (Dynazyme II, Finnzymes, Espoo, Finland). The reactions were allowed to occur for 15 min at 56°C before washing off the unattached

label. Finally, the attached detection primer was eluted by NaOH treatment and the radioactivity measured in a liquid scintillation counter (Rackbeta 1209; Wallac, Turku, Finland).

Two samples of the 1902 were disqualified after being found infected with hepatitis B.

### Statistical analyses

Statistical analyses were conducted using Tixel (version 8.1), which is a VBA-program for Excel. Descriptive analyses were conducted with simple logistic regression. Proportions were compared by using Chi-squared tests with continuity correction or Fisher's exact test when appropriate. Two-sided significance tests were used throughout.

## RESULTS

The frequency of the C/C-<sup>13910</sup> genotype associated with lactase non-persistence among the participants was 18% (Table 1). This figure corresponds to the earlier published prevalence of adult-type hypolactasia in the Finnish population<sup>[14-16]</sup>, implying that the study population is representative for the general population. There was no difference in genotype distribution among male and female subjects, and no difference in separate age groups (data not shown).

The response rate for the questionnaire was high; a total of 99% ( $n = 1885$ ) of the participants returned the questionnaire. A total of 42% of the patients reported a new, not gastrointestinal related disease as the reason for their laboratory visit. Earlier diagnosed diseases (25%) were the second most common cause for the visit, followed by gastrointestinal symptoms that were reported by 19% (348/1787) of the participants. Of these 348 subjects, the adult-type hypolactasia genotype C/C-<sup>13910</sup> was observed in 24% (84/348), which was significantly more than in the study population ( $P < 0.05$ , Table 1).

Subjects with the C/C-<sup>13910</sup> genotype had experienced more gastrointestinal symptoms (84%; 280/330) during the preceding three-month period than those with the C/T-<sup>13910</sup> (79%; 698/885;  $P < 0.05$ ) or the T/T-<sup>13910</sup> genotype (78%; 501/641;  $P < 0.05$ , Table 2). Those with the C/C-<sup>13910</sup> genotype reported more frequently gastrointestinal symptoms compared to C/T-<sup>13910</sup> or T/T-<sup>13910</sup> genotypes, but the difference was not significant (Table 2).

Gastrointestinal symptoms associated with lactose intolerance, namely flatulence, bloating and diarrhoea, were frequent among all genotype groups (Table 3). Flatulence was the only symptom significantly more frequent among the subjects with lactase non-persistent genotype compared to those with genotypes of lactase persistent ( $P < 0.05$ ). Those with the C/C-<sup>13910</sup> genotype experienced more bloating (61%) than those with the T/T-<sup>13910</sup> genotype (55%) and C/T-<sup>13910</sup> genotype (58%) but the difference did not reach statistical significance (Table 3).

As many as 45% of the participants informed having experienced gastrointestinal symptoms after drinking milk (Figure 1) and 25% of the participants reported symptoms from food containing milk. It is notable, that only 18%

Table 1 Frequency of the C/T-<sup>13910</sup> genotypes

Genotype	% (n)	GI-complaints % (n)	P
C/C- <sup>13910</sup>	18 (341)	24 (84)	< 0.05
C/T- <sup>13910</sup>	47 (901)	43 (148)	NS
T/T- <sup>13910</sup>	35 (658)	33 (116)	NS
Total	100 (1900)	100 (348)	

(60/338;  $P < 0.01$ ) of the subjects with the C/C-<sup>13910</sup> genotype of adult-type hypolactasia informed drinking milk with meals, which is significantly less ( $P < 0.01$ ) than those with the lactase persistent genotypes C/T-<sup>13910</sup> (38%; 333/894) and T/T-<sup>13910</sup> (36%; 236/653; Figure 1). The fat content of the milk was not questioned, but in Finland the vast majority of people use low-fat or fat-free milk as a drink. The number of people using low lactose containing milk as a drink was marginal according the questionnaire.

Only 9% (29/338) with the C/C-<sup>13910</sup> genotype of adult-type hypolactasia consumed milk daily and reported no symptoms from milk. However, one third (18/60) of the milk drinkers with the C/C-<sup>13910</sup> genotype did not answer the question about milk related symptoms. Most people with C/C-<sup>13910</sup> genotype reporting GI-problems from milk (69%; 190/274) did not drink milk. The respective number of people with lactase persistence genotypes who reported milk-related problems and did not drink milk was 54% (299/554) for the C/T-<sup>13910</sup> genotype and 50% (207/411) for the T/T-<sup>13910</sup> genotype.

Cheese caused gastrointestinal symptoms for 11% of the participants according to their own judgment: for 17% of those with the C/C-<sup>13910</sup> genotype, 10% of those with the C/T-<sup>13910</sup> genotype and 9% of the ones with the T/T-<sup>13910</sup> genotype ( $P < 0.05$ , Figure 2). Among all participants 14% experienced symptoms from cereal or bread, and 37% from ingested fat (Figure 1) and these were not related to the genotype of adult-type hypolactasia.

Among the study population, 15% (245/1649) reported having had a pathological LTT earlier: 36% (109/299) of those with the C/C-<sup>13910</sup> genotype, 11% (82/777) with the C/T-<sup>13910</sup> and 9% (54/573) with the T/T-<sup>13910</sup> genotype.

A previous, pathological LTT was reported by 19% (64/341) of participants with the C/C-<sup>13910</sup> genotype, by 10% (89/901) with the C/T-<sup>13910</sup>, and by 14% (91/658) with the T/T-<sup>13910</sup> genotype. Five out of these 180 subjects with the C/T-<sup>13910</sup> or T/T-<sup>13910</sup> genotype with a pathological LTT reported a previously diagnosed possible secondary cause for hypolactasia i.e. celiac disease. An undiagnosed celiac disease in two other participants of these 180 subjects was suggested due to elevated level of transglutaminase antibodies in their sera<sup>[25]</sup>.

## DISCUSSION

The inability to absorb lactose is frequently suspected to underlie gastrointestinal symptoms in populations with high prevalence of adult-type hypolactasia and frequent dairy consumption. In this study we show that subjects with the C/C-<sup>13910</sup> genotype, having low lactase activity in the intestinal wall<sup>[14-17,20]</sup> indeed do seek medical advice for

**Table 2** The frequency of gastrointestinal symptoms according to the three genotype groups of lactase persistence/nonpersistence during previous three months

Abdominal complaints	C/C % (n)	C/T % (n)	T/T % (n)	OR C/C vs C/T (95% CI)	P	OR C/C vs T/T (95% CI)	P
During previous three months	84 (280/332)	79 (698/885)	78 (501/641)	1.44 (1.03-2.02)	< 0.05	1.50 (1.06-2.14)	< 0.05

**Figure 1** Frequency of gastrointestinal symptoms experienced by various foods in the study population.

abdominal symptoms more often than subjects with high lactase activity. This occurred although they already had self restricted their milk consumption.

The response rate in this study was extremely high, 99%, thus the data about GI-symptoms was comprehensive. This exceptionally high response rate was achieved by the sound motivation of both the study subjects and the laboratory personnel. As expected, gastrointestinal symptoms were very common (80%) during the previous three months comparable to the earlier findings<sup>[1]</sup>. Flatulence was the only symptom that in this study was significantly more common among subjects with low lactase (C/C-13910 genotype). Diarrhoea and bloating, which according to earlier published studies are more common among lactose malabsorbers<sup>[4]</sup> were not more frequent among those with adult-type hypolactasia. These symptoms, however, were very common in the study population (40%-60%) pointing out the high prevalence of functional GI-symptoms<sup>[26]</sup>.

The great majority of the study subjects did not drink milk at all. Milk consumption was rarest in the group

**Figure 2** Flow-chart of the use of cow's milk as a drink in different genotype groups.

of lactase non-persistent subjects: only 18% reported drinking milk daily, which might indicate that a natural aversion of milk has been developed by the subjects with low lactase activity. This is in agreement with our findings in a paediatric population in which children with the C/C-13910 genotype consumed less milk than children with a non-C/C-13910 genotype<sup>[16,27]</sup>. The majority of the children with the lactase non-persistent genotype C/C-13910 reported that they never drank milk<sup>[16]</sup>. At the age of 8-9 years, more than 40% of the subjects with the C/C-13910 genotype reported drinking less than one dl of milk daily, compared to 20% of the subjects with the C/T-13910 and T/T-13910 genotype, respectively<sup>[26]</sup>.

Only 9% of those with the C/C-13910 genotype used daily milk and did not experience symptoms from ingested milk. This is in line with other studies<sup>[6,8,9]</sup> showing that not all individuals with lactose malabsorption report symptoms from food containing lactose. The colonic micro biota is variable<sup>[28]</sup> and the individual sensitivity to feel distension of the colon and to sense discomfort varies<sup>[29]</sup>. Accordingly, the recognition of the possible link between milk consumption and abdominal symptoms is not always easy<sup>[30]</sup>. The meal content has an effect on emptying of the stomach and thereby affects the lactose load in the

intestine<sup>[31,32]</sup>. Most lactose malabsorbers seem to tolerate small amounts of milk especially during meals<sup>[5,33]</sup>. Further studies are warranted to evaluate the amount of lactose tolerated by different genotype groups.

In this study population, 10% of those with the genotypes associated with lactase persistence (the C/T-13910 genotype or T/T-13910 genotype) reported that they had been earlier diagnosed lactose intolerant based on results of LTT. A possible cause for secondary hypolactasia, i.e. celiac disease, was found in 3% of these individuals. These findings imply that LTT, a commonly used method for diagnosis of lactose intolerance, produces high numbers of false positive test results as has been earlier observed<sup>[11]</sup>. One third of those with the C/C-13910 genotype associated with low lactase reported that they had previously had a positive LTT. Due to the way our question on earlier diagnosis of lactose intolerance was formulated, we do not know the extent of subjects with the C/C-13910 genotype who might have had a negative result for their LTT.

In conclusion, gastrointestinal symptoms are more common among adults with the C/C-13910 genotype of adult-type hypolactasia than in those with genotypes of lactase persistence. This was seen although individuals with the C/C-13910 genotype had restricted their milk consumption. Genotyping of the C/T-13910 polymorphism is a practical means for defining adult-type hypolactasia.

## ACKNOWLEDGMENTS

We are grateful to the participants and the laboratory personnel of the outpatient clinics of the city of Espoo and the Central Military Hospital for their contribution.

### Abstract

**AIM:** To investigate the relationship among the presence of ulcer lesions, underlying disease, and clinical course in patients with ischemic colitis.

**METHODS:** The subjects were 41 patients (10 male and 31 female; mean age 70 years) with ischemic colitis who were admitted to and received treatment in our hospital from 2000 to 2006. We compared their characteristics and analyzed the mean lengths of admission and fasting for 9 patients with ulcer lesions (ulcer group) and 32 without (non-ulcer group).

**RESULTS:** The groups with presence and absence of ulcer differed significantly only in white blood cell (WBC) count. Lengths of fasting and admission were 7.9 d and 17.9 d for the ulcer group and 4.4 d and 10.7 d for the non-ulcer group, respectively, and significantly longer in the ulcer group ( $P = 0.0057$  and  $0.0001$ ). There was no correlation between presence of ulcer and presence of underlying diseases.

**CONCLUSION:** Lengths of fasting and admission were significantly longer in patients with ischemic colitis with ulcer than for those without ulcer.

### INTRODUCTION

Ischemic colitis was first reported as a result of reversible vascular occlusion of the colon in 1963 by Boley *et al*<sup>[1]</sup>, and in 1966 Marston *et al*<sup>[2]</sup> suggested the name “ischemic colitis” for it and clarified its clinical and histopathological features.

Marston *et al*<sup>[2]</sup> classified this disease into 3 forms, transient, strictures, and gangrene. It is defined as a “reversible condition caused by obstruction of blood flow in intestinal tract mucosa without apparent blockage of the main artery”. In general, it is common in the elderly<sup>[3]</sup>, and its prevalence increases with age, although it is seen in younger patients as well<sup>[4-6]</sup>. Its causes include vascular factors such as ischemia and embolus<sup>[7-9]</sup>, intestinal factors such as constipation<sup>[5,10]</sup>, irritable bowel syndrome<sup>[11,12]</sup> and history of intestinal surgery<sup>[13,14]</sup> as well as administration of drugs such as alosetron<sup>[11]</sup>, cocaine<sup>[15]</sup>, non-steroidal anti-inflammatory drugs<sup>[16]</sup>, oral contraceptives<sup>[17]</sup> and oral laxatives<sup>[18]</sup>.

While surgery is indicated for the gangrenous form of this disease, transient and stricturing forms are often ameliorated by bowel rest, fasting, and parenteral fluid administration alone. The lengths of fasting and admission vary among individuals. Significant prolongation of healing is sometimes observed, especially in patients with ulcer. We therefore examined the associations among etiology, clinical course, and presence of ulcer lesions in patients with transient and stricturing forms of ischemic colitis.

### MATERIALS AND METHODS

The subjects were 41 patients (10 male and 31 female; mean age 70 years) with ischemic colitis who were admitted to and received treatment in our hospital from 2000 to 2006. Patients who developed ischemic colitis during admission for other diseases were excluded. Ischemic colitis was diagnosed comprehensively based on the essential criteria including lack of antibiotic administration, negative bacterial culture of feces or biopsy, lack of history of inflammatory bowel disease (IBD), as well as endoscopic and histopathological findings on biopsy. Age and mode of disease onset, symptoms and affected sites were included as complementary parameters.

Patients were divided into 2 groups by the presence of ulcer lesions and compared for age, gender, affected sites, hematological findings, performance status (0-4, 0: asymptomatic; 1: symptomatic but completely ambulant; 2: symptomatic, < 50% in bed during day time; 3:

Table 1 Clinical features of ischemic colitis patients: Comparison between ulcer and non-ulcer groups (mean  $\pm$  SD)

Clinical features	Ulcer group (n = 9)	Non-ulcer group (n = 32)	Statistical significance
Age (mean, range, yr)	68 $\pm$ 19 (35-87)	71 $\pm$ 11 (42-92)	NS
Percentage of females (%)	77.8	75.0	NS
Lesion location: left colon (%)	88.9	100	NS
Performance status 0-1 (%)	77.8	87.5	NS
WBC ( $\times 10^9$ /L)	12.27 $\pm$ 4.67	8.44 $\pm$ 3.17	P = 0.0065
CRP (mg/dL)	2.6 $\pm$ 4.1	1.5 $\pm$ 2.3	NS
K (mEq/L)	3.8 $\pm$ 0.4	4.0 $\pm$ 0.5	NS
Total cholesterol (mg/dL)	179.3 $\pm$ 30.6	191.4 $\pm$ 35.6	NS
TG (mg/dL)	93.3 $\pm$ 41.0	73.2 $\pm$ 23.4	NS
LDH (IU/L)	190.0 $\pm$ 42.8	203.8 $\pm$ 37.8	NS
CPK (IU/L)	80.7 $\pm$ 38.9	82.7 $\pm$ 39.5	NS

Percentage of females and lesion location were evaluated with an  $\chi$ -square test; Other data were evaluated with Student's *t* test after skewing with log transformation. CRP: C-reactive protein; K: potassium; TG: triglyceride; LDH: lactate dehydrogenase; CPK: creatinine phosphokinase.

Table 2 Underlying diseases: Comparison between ulcer and non-ulcer groups n (%)

	Ulcer group (n = 9)	Non-ulcer group (n = 32)	Statistical significance
Hypertension	6 (66.7)	19 (59.4)	NS
Hyperlipemia	0	6 (18.8)	NS
Diabetes mellitus	1 (11.1)	3 (9.4)	NS
Atrial fibrillation	1 (11.1)	1 (3.1)	NS

Chronic constipation	5 (55.6)	19 (59.4)	NS
Medications			
NSAIDS	0	1 (3.1)	NS
Antihypertensive agents	5 (55.6)	18 (56.3)	NS
Others	2 (22.2)	5 (15.6)	NS
History of abdominal surgery	4 (44.4)	14 (43.8)	NS

Percentages were evaluated with an  $\chi$ -square test. NSAIDS: non-steroidal anti-inflammatory agents.

symptomatic, > 50% of time in bed, but not bed bound; 4: bed bound, using the WHO score criteria), underlying disease (hypertension, hyperlipemia, diabetes, chronic atrial fibrillation, cerebral infarction, constipation, and history of abdominal surgery), oral medications, and mean lengths of fasting and admission.

All patients underwent endoscopy of the lower gastrointestinal tract within 3 d after admission and 5 d after disease onset. As treatment, fasting and bowel rest with fluid replacement were used in all patients. Twenty-two (53.7%) patients received oral antifoatants and 13 (31.7%) patients a combination with antibiotics. Total parenteral nutrition *via* a central venous line was performed in none of the patients. After disappearance of abdominal pain, patients were allowed to begin oral ingestion. Patients were discharged if they exhibited no relapse of symptoms after restarting oral ingestion.

### Statistical analysis

Data are expressed as mean  $\pm$  SD or percentage. Percentage of females, lesion location, performance status and underlying systemic diseases were evaluated with an X-square test. Other data were evaluated with Student's *t* test after skewing variable with log transformation. All data analysis was performed with the StatView 5.0. Statistical significance was set at *P* < 0.05.

## RESULTS

Forty-one patients were analyzed (10 male and 31 female; mean age 70 years). Affected sites included the sigmoid colon (70.7%), descending colon (51.2%), transverse colon (12.2%), rectum (4.9%), and ascending colon (2.4%), with some overlap. The disease developed in 92.7% of the patients for the first time, and the remaining 7.3% for the second time. The disease was accompanied by ulcer in 9 (22.0%) patients.

Nine patients had ulcer (2 male and 7 female; mean age 66, range 35-87 years), the affected site was the left hemicolon in 8 patients. On the other hand, 32 patients had no ulcer (8 male and 24 female; mean age 71, range 42-92 years), the affected site was in the left hemicolon in all of them. In both groups, underlying diseases including hypertension, hyperlipemia, diabetes, atrial fibrillation, cerebral infarction, chronic constipation, and history of abdominal surgery, as well as oral medications, performance status, and hematological findings were examined as parameters. The significant difference was found between groups only in white blood cells (WBC), which was higher in the ulcer group ( $12.27 \times 10^9$ /L) than in the non-ulcer group ( $8.44 \times 10^9$ /L, *P* = 0.0065; Table 1). There were no statistically significant differences between groups in other parameters (Table 1 and Table 2).

Lengths of fasting and admission were 7.9 d and 17.9 d for the ulcer group and 4.4 and 10.7 d for the non-ulcer

Table 3 Durations of fasting and hospitalization: Comparison between ulcer and non-ulcer groups (mean  $\pm$  SD)

	Ulcer group (n = 9)	Non-ulcer group (n = 32)	Statistical significance
Fasting (d)	7.9 $\pm$ 4.1	4.4 $\pm$ 2.9	P = 0.0057
Hospitalization (d)	17.9 $\pm$ 6.8	10.7 $\pm$ 3.6	P = 0.0001

group, respectively, being significantly longer in the ulcer group ( $P = 0.0057$  and  $0.0001$ ; Table 3).

## DISCUSSION

The etiology of ischemic colitis remains unclear. However, it may involve combination of vascular factors such as hypertension or hyperlipemia and intestinal factors such as chronic constipation and history of abdominal surgery. These may cause reduction of blood flow in the mucosa or wall of the intestinal tract, leading to ischemia. In the present study, patients with hypertension (61%), chronic constipation (58.5%), and history of abdominal surgery (43.9%) exhibited higher prevalence of ischemic colitis, which are consistent with previous reports<sup>[19,20]</sup>.

Tohda *et al*<sup>[7]</sup> detected the correlation between arteriosclerosis and ischemic colitis using pulse wave velocity (PWV) as an indicator related to vascular factors, and reported higher PWV levels for the elderly. Similarly, we compared the contributions of vascular and intestinal factors to the occurrence of ischemic colitis in age, and observed that 2 (25%) patients developed the disease because of vascular factors and 7 (87.5%) patients because of intestinal factors among the eight younger patients aged less than 60 years. This indicates that vascular factors contribute predominantly to development of ischemic colitis.

In the present study, only WBC at admission was correlated with presence of ulcer. Notably, no difference in number of WBC between *H pylori*-infected patients with gastritis and those with ulcer has been noted<sup>[21]</sup>. Additionally, little difference has been reported in number of WBC between those with active disease and those with inactive disease in patients with inflammatory bowel disease<sup>[22]</sup>. Bjornestad *et al*<sup>[23]</sup> performed three routine laboratory tests (white blood cell count, hemoglobin concentration and erythrocyte volume fraction) in patients with four acute abdominal diseases (acute mesenteric ischemia: AMI, perforation of colon, perforation of peptic ulcer and intestinal obstruction). The WBC in patients with AMI was significantly higher than the normal range. The three variables were higher in AMI patients than in the other patients ( $P < 0.001$ ). The discriminant analysis of the variables classified 80% of the patients correctly into AMI and non-AMI groups. This difference may reflect the inflammatory response in the acute stage and biological reactions associated with continued chronic inflammation.

This is the first report on lengths of fasting and admission in patients with ischemic colitis. In the present study, these lengths were 7.9 d and 17.9 d for the ulcer group and 4.4 d and 10.7 d for the non-ulcer group, respectively, being significantly longer in the ulcer group. Although we did not evaluate patient quality of life

(QOL), stress on patients due to fasting and prolonged admission may cause a decrease in QOL. In addition, the costs associated with prolonged admission also causes a problem.

Strategies for the treatment of ischemic colitis are determined based on the severity of ischemia. Surgery is indicated for the gangrenous form of the disease. On the other hand, for transient and stricturing forms of the disease, younger patients may obtain prompt relief solely with follow-up, while older patients or those who have severe abdominal pain will require hospitalization, fasting, and management using parenteral fluid administration.

Lengths of fasting and admission were significantly longer in patients with ischemic colitis with ulcer than in those without ulcer. Ulcer associated with ischemic colitis is often localized in the left hemicolon. Noninvasive and local ulcer treatment such as use of enema preparations in addition to conventional treatment centering on bowel rest should be considered for ischemic enteritis accompanied by ulcer.

### INTRODUCTION

Pancreaticoduodenectomy is a challenging operation and is associated with high morbidity<sup>[1]</sup>. In the last two decades peri-operative mortality has decreased to less than 5% in published series from specialized centers<sup>[2,3]</sup>, although the morbidity remains high (25%-50%). The impact of jaundice on post-operative morbidity and mortality is well known. However the routine use of pre-operative biliary drainage (PBD) remains controversial<sup>[4]</sup>. The potential advantages of preoperative stenting include improved nutritional, metabolic and immune function, and the possibility of reduced postoperative morbidity and mortality rates<sup>[5-7]</sup>. Opponents of PBD argue that it increases infective complications and morbidity<sup>[8,9]</sup>. There are, however, certain clinical situations such as acute suppurative cholangitis and severe malnutrition where urgent biliary drainage is indicated and can be life-saving<sup>[10]</sup>. It is not clear whether the procedure itself or its complications influence the morbidity after pancreaticoduodenectomy. The optimal duration of preoperative drainage also remains unknown. Experimental studies have indicated that a period of 6 wk is necessary to obtain clinical benefit with PBD<sup>[11]</sup>. On the other hand, a clinical study has shown a higher incidence of morbidity and mortality when surgery was carried out within 6 wk of stent placement<sup>[12]</sup>. Although several reports have been published, still there are no clear guidelines regarding use of PBD in these patients. The aim of this study was to evaluate the effect of endoscopic PBD on morbidity and mortality after pancreatico-duodenectomy in a low volume center.

### MATERIALS AND METHODS

Details of 48 patients who underwent Kosch-Whipple's pancreaticoduodenectomy for periampullary tumors (excluding tumor of the pancreatic head) from March 1994 to March 2004 were entered into a database that included patient characteristics, details of biliary stenting and stent-related infective complications, surgery, morbidity and mortality. Pancreaticoduodenectomy was performed in the Department of Surgery, S.M.S. Hospital, Jaipur by a single surgical team using a standard Kosch-Whipple's

### Abstract

**AIM:** To investigate the role of preoperative biliary drainage (PBD) in the outcome of classical pancreaticoduodenectomy.

**METHODS:** A 10-year retrospective data analysis was performed on patients ( $n = 48$ ) undergoing pancreaticoduodenectomy from March 1994 to March 2004 in department of surgery at SMS medical college, Jaipur, India. Demographic variables, details of preoperative stenting, operative procedure and post operative complications were noted.

**RESULTS:** Preoperative biliary drainage was performed in 21 patients (43.5%). The incidence of septic complications was significantly higher in patients with biliary stent placement ( $P < 0.05$ , 0 vs 4). This group of patients also had a significantly higher minor biliary leak rate. Mortality and hospital stay in each group was comparable.

**CONCLUSION:** Within this study population the use of PBD by endoscopic stenting was associated with a high incidence of infective complications. These findings do not support the routine use of biliary stenting in patients prior to pancreatico-duodenectomy.

technique. Before year 2000 most reconstructions involved a pancreatojejunostomy ( $n = 17$ ), but after year 2000 pancreatogastrostomy ( $n = 31$ ) was performed according to the surgeon's preference. Patients with chronic and benign diseases were excluded from this study. The data were collected retrospectively as well as prospectively and were reviewed.

Pancreatic leak was defined according to the criteria described by Yeo *et al*<sup>[9]</sup>: pancreatic fistula was diagnosed when more than 50 mL of drainage fluid with an amylase concentration of more than 3 fold the normal upper limit in serum was obtained on or after postoperative d 5, or when pancreatic anastomotic disruption was shown radiologically. Biliary leak was defined as more than 50 mL bile per day in the drain for at least three consecutive days after postoperative d 7. Biliary leak less than 50 mL per day in drain after postoperative d 3 was considered minor bile leak. Infectious morbidity was defined as any complication with evidence of associated localized or systemic infection indicated by fever, leucocytosis and positive culture.

### Statistical analysis

Results are expressed as medians and ranges or as numbers and percentages of patients. Two tailed *t* test, chi-square test and binary logistic regression analysis were used for data analysis. SPSS statistical package was used (SPSS v13.0, Chicago, USA) for analysis. Differences were considered statistically significant at  $P < 0.05$ .

## RESULTS

Forty eight patients had Whipple's operation for periampullary tumors. Twenty five patients (52.1%) were male and 23 (47.9%) were female. Median duration between onsets of symptoms to presentation was 3 mo (range 1 mo to 17 mo). The median age at presentation was 49 years (range 25 to 72). At admission 44 patients (91.7%) had jaundice [mean preoperative total bilirubin level was 10.09 mg/dL (SD  $\pm$  7.91)], 33 (68.8%) had abdominal pain, and 6 (12.5%) had a history of vomiting. Twenty-five (52.1%) patients noticed weight loss, and 27 (56.3%) had anemia. Preoperative liver function tests and other investigations are outlined in Table 1.

Forty three (89.6%) patients underwent side-viewing endoscopy for diagnosis. Preoperative histological diagnosis was obtained in 29 (60.4%) patients. Twenty one

Table 2 Morbidity and mortality in the two groups

	PBD	No PBD	Significance
Sepsis	4	0	0.018 <sup>a</sup>
Wound infection	5	1	0.037 <sup>a</sup>

Pancreatic leak	6	2	0.106
Bleeding	1	0	0.252
Lymphorrhoea	2	4	0.580
Median hospital stay (d)	13 (1-147)	12 (9-32)	0.943
Mortality	3	5	0.690

<sup>a</sup> $P < 0.05$ , PBD *vs* No PBD.

(43.8%) underwent preoperative biliary stenting at the time of preoperative instrumentation with drainage established successfully in all stented patients. All patients in stented group (21) underwent stenting by an endoscopical approach and plastic stents were used for drainage. There were no statistically significant differences in the demographics and pre-operative variables between patient groups with or without PBD (Table 2). Mean pre-operative serum bilirubin in the PBD group was 7.85 (SD  $\pm$  9.05) and 11.83 (SD  $\pm$  5.59) in non PBD group ( $P \geq 0.05$ ).

Thirty one (64.6%) patients had pancreatogastrostomy and 17 (35.4%) patients had pancreatojejunostomy. The majority of the patients (43; 89.6%) had ampullary (ampula of Vater) carcinoma, whilst 4 (10.4%) patients had duodenal carcinoma and one patient had cholangiocarcinoma. Histopathological examinations of specimens revealed well differentiated tumors in 43 patients (89.6%); whilst other 5 were poorly differentiated. Only 8.3% of patients had lymph node involvement identified in surgical specimens and only 3% of the patients had positive resection margins.

All postoperative complications and subpopulation analyses between PBD and non-PBD groups are shown in Table 2. Postoperative sepsis occurred in 8.3% (4/48) of patients. Median hospital stay was 13 d (1-147 d) and overall mortality was 16.67%. One patient had postoperative bleeding that required re-exploration. There were 6 (12.5%) patients with wound infection and lymphorrhoea each and one patient developed delayed gastric emptying. Subpopulation analysis demonstrated a higher occurrence of infection and wound infection in PBD group ( $P \geq 0.05$ ).

## DISCUSSION

Pancreatico-duodenectomy is recognized as an acceptable surgical option in patients with pancreatic malignancies although the routine use of PBD remains controversial. In general, our unit's protocol is against PBD but within this series almost half of the patients (21/48) were already stented as they were referred from other centers. This may be reflected by the late presentation of patients in this series (the duration of symptoms varied from 1 mo to over one year).

There were some changes in the surgical technique in our study over the study period. During the initial years, classical pancreaticoduodenectomy was done with

pancreatico-jejunal (Dunking) anastomosis and 17 patients had pancreaticojejunal anastomosis (35.4%). Later on pancreatico-gastric direct duct to mucosa anastomosis was favoured in 31 patients. The morbidity and mortality rates were not significantly affected by the technique of pancreatic anastomosis to the gastrointestinal tract.

Half of the patients had bilirubin levels more than 10 mg% and only 4 cases (8%) presented without jaundice at the time of admission to our surgical unit. An average bilirubin level of 10 mg% at presentation has been reported in other studies. Earlier studies reported that there is an increased morbidity and mortality associated with severe jaundice ( $> 10$  mg%)<sup>[13,14]</sup>. On the contrary, some recent studies have reported that the severity of jaundice has no influence on postoperative morbidity and mortality<sup>[15]</sup>. Pivoski *et al*<sup>[8]</sup> concluded in their study that PBD, but not preoperative biliary instrumentation alone, was associated with increased morbidity and mortality rates in patients undergoing pancreaticoduodenectomy. In a prospective review, Sohn *et al*<sup>[9]</sup> reported the incidence of wound infection and pancreatic fistula to be significantly higher in stented patients.

The overall morbidity in our study of 48 cases was 35.41% (17 cases) and mortality was 16% (8 cases). In the first 5 years of our experience with pancreaticoduodenectomy, the operative mortality rate was 17.6%, which reduced to about 9% in last five years. Two patients died because of non surgical complications; one from dengue fever and one of myocardial infarction at the time of discharge. In our study, PBD was associated with increased morbidity following pancreaticoduodenectomy while mortality rates were unchanged. Although recent reports have shown that there is no change in infectious complication rates, notably wound infection, after PBD<sup>[16,17]</sup>, our experience was different. The stented group had significantly higher morbidity (41%) in comparison to the non-stented group (30.7%). Wound infection, sepsis and minor bile leak were found to be main complications in the stented group. The wound infection rate was 27.2%, and fever 18.1%, both significantly higher in the stented group ( $P \geq 0.05$ ). Minor biliary leak was significantly higher in the stented group ( $n = 3$ ) ( $P \geq 0.05$ ) (Table 2). Further regression analysis showed that PBD was associated with infective morbidity arising from stent placement. Larger prospective studies are needed to resolve the issue of duration of PBD. Other complications such as pancreatic leak, hemorrhage and lymphorrhoea were not influenced by stenting. The mean hospital stay in the two groups was comparable in spite of septic complications.

Some published studies suggest that stenting may have an effect on bile duct bacterial colonization and cause more infective complications<sup>[8,12]</sup>. Supporting the data above, our study confirms that PBD may have a negative impact on postoperative outcome after pancreaticoduodenectomy. However, judicious use may reduce the incidence of septic complications in selective patients. Randomized controlled trials in patient groups such as those with severe obstructive jaundice are required to address these controversies and improve outcomes and avoid unnecessary morbidity and

mortality associated with PBD.

### Abstract

**AIM:** To investigate the relationship between myeloperoxidase polymorphisms as a host-related factor and atrophy caused by *H pylori*.

**METHODS:** Our study enrolled 77 patients. Biopsy materials obtained during gastrointestinal endoscopies were evaluated for the presence of *H pylori*. Polymerase chain reaction-restriction fragment length polymorphism assay was used to characterize myeloperoxidase genotypes.

**RESULTS:** Forty four patients (57.1%) were *Hp* (+) and 33 (42.9%) were *Hp* (-). Sixty six (85.7%) had GG genotype, 10 (12.9%) had GA genotype and 1 (1.29%) had AA genotype. The change in atrophy in relation to neutrophil infiltration was significant in *Hp* (+) patients ( $P = 0.0001$ ). The change in atrophy in relation to neutrophil infiltration in patients with GG genotype was significant ( $P = 0.002$ ). However, the change in atrophy in relation to neutrophil infiltration was not significant in patients with *Hp* (+) GG genotype ( $r = 0.066$ ,  $P = 0.63$ ).

**CONCLUSION:** Myeloperoxidase genotype is critical for development of atrophy in relation to the severity of inflammation. However, it is interesting to note that, *H pylori* does not show any additive effect on development of atrophy.

Yılmaz Ö, Dursun H, Gürsan N, Pirim İ, Yılmaz A, Okcu N. Effects of the myeloperoxidase 463 gene polymorphisms on development of atrophy in *H pylori* infected or noninfected gastroduodenal disease. *World J Gastroenterol* 2007; 13(8): 1243-1246

<http://www.wjgnet.com/1007-9327/13/1243.asp>

### INTRODUCTION

*H pylori* is an agent that produces chronic infection in more than half of the world population<sup>[1]</sup>. The most important characteristic of *H pylori* infection is that it causes chronic active inflammation in the gastric mucosa, which involves neutrophils and monocytes<sup>[2]</sup>. While 100% of the persons carrying this microbe develops gastritis, the lifetime risk of peptic ulcer is 15%-20% and that of gastric cancer is 1%-3%<sup>[1]</sup>.

The role of host-related factors in the pathogenesis of diseases caused by *H pylori* has been greatly ignored up to date<sup>[3,4]</sup>. It was demonstrated that the ability of the host to regulate the production of cytokines is influenced by the presence of polymorphisms in the promoter region of the relevant genes<sup>[5]</sup>. The polymorphisms in the genes affecting the production of cytokines might be one of the factors that lead to the interpersonal differences in the severity of gastric inflammation<sup>[3,5]</sup>.

Myeloperoxidase (MPO) is a lysosomal enzyme found in the azurophilic granules of polymorphonuclear leukocytes (PNL)<sup>[6-9]</sup>. There are two promoter regions affecting MPO; -463G/A and -129G/A<sup>[10]</sup>. Allele A of this polymorphism reduces mRNA expression and thus, tissue damage in local inflammation is decreased<sup>[8,9,11]</sup>. Allele G has 25 times more transcriptional efficacies compared to allele A. The G/G genotype confers higher risk for persistent *H pylori* infection<sup>[12,13]</sup>.

*H pylori* activates the oxidative metabolism in neutrophils<sup>[14]</sup>. Reactive oxygen products such as free oxygen radicals released from neutrophils, ( $O_2^{\cdot-}$ ),  $H_2O_2$  and hydroxyl ion ( $OH^{\cdot}$ ) reacts with MPO and hypochloric acid (HOCl) is formed. Monochloroamines ( $NH_2Cl$ ) are formed when HOCl reacts with the ammonium produced by the urease enzyme of *H pylori*. Monochloroamines are oxidizing agents that are able to induce DNA fragmentation<sup>[4,8,14-16]</sup>. Thus, it has been advocated that

myeloperoxidase is involved in gastric damage induced by *H pylori*<sup>[4,11,17]</sup>. We assessed the association between neutrophil infiltration and atrophy caused by *H pylori* and MPO gene polymorphisms.

## MATERIALS AND METHODS

We enrolled 77 patients (46 males, 31 females) who had undergone endoscopic examinations due to epigastric pain, dyspepsia, nausea and vomiting or weight loss. Patients who received antibiotic therapy, proton-pump inhibitors or non-steroid anti-inflammatory drugs within 3 mo prior to endoscopies were excluded.

Based on the endoscopic findings, 24 patients had gastritis, 26 had ulcers (duodenal or gastric ulcers) and 27 had gastric cancers. Diagnosis of patients who showed malignant findings in their endoscopies was confirmed by pathologic examination. In the light of endoscopic findings, two biopsies were obtained each from the antrum, angulus and corpus mucosa of the tissue adjacent to ulcer region and regions distant to malignant lesions. Biopsy materials were transferred into 3 separate small bottles containing formaldehyde and sent to the laboratory for evaluation of *H pylori* and pathologic examinations. Also, peripheral blood samples (3 mL) were collected from enrolled patients simultaneously and transferred into EDTA hemogram tubes. The tubes were transferred to the genetic laboratory under appropriate conditions avoiding coagulation.

### Histopathologic examinations

The materials brought to the pathology laboratory were embedded in paraffin after follow-up procedures. Subsequently, cross-sections of 3-4 microns thick were obtained from the paraffin blocks. These cross-sections were stained by hematoxylin-eosin, Giemsa and Warthin-Starey stains, respectively. Preparations were divided into two groups as negative or positive based on the presence of *H Pylori* during direct visualization under a light microscope. Biopsy materials were staged according to neutrophilic activity, chronic inflammatory cell infiltration, glandular atrophy, intestinal metaplasia and *H pylori* density using criteria from the modified Sydney classification system. Each feature was evaluated as none (0), mild (1), moderate (2) or apparent (3)<sup>[18]</sup>. After all patients were scored according to 4 parameters of Sydney classification, sum of the parameters was calculated for three biopsy regions.

### Myeloperoxidase genotyping

Patient blood samples transferred into EDTA tubes were used for DNA isolation. DNA isolation was performed using the column method (Gentra DNA isolation kit). Myeloperoxidase polymorphism analysis was performed by PCR and restriction fragment length polymorphism (RFLP) methods. Primers to be used were designed to detect Codone 463 of the myeloperoxidase gene.

### Preparation of DNAs for PCR

Twenty microlitres DNA from each patient was transferred into 0.2 mL Eppendorf tubes. After addition of two

**Table 1** Distribution of myeloperoxidase genotypes in *Hp* (+) and *Hp* (-) patients according to endoscopic findings

	<i>Hp</i> (+)	<i>Hp</i> (-)	Total
<i>n</i> (%)	44 (57.1)	33 (42.9)	77 (100.0)
Gastritis	13	11	24
Ulcer (gastric or duodenum)	18	8	26
Gastric cancer	13	14	27
Myeloperoxidase GG	37	29	66
Myeloperoxidase GA	7	3	10
Myeloperoxidase AA	-	1	1
Neutrophil infiltration	2.80 ± 1.94 <sup>1</sup>	0.88 ± 1.24	1.97 ± 1.91

*Hp* (+): *H pylori* positive group; *Hp* (-): *H pylori* negative group; *P* < 0.0001, vs the *Hp* (-) group. <sup>1</sup>Mean ± SD of a score of 0-3 according to the updated Sydney system.

different primers (forward primer 5'-CCGTATAGGCAGA GAATGGTGAG-3' and reverse primer 5'-GCAATGGT TCAAGCGATTCTTC-3'), 1.5 µL; dNTP mix, 1 µL; Taq DNA polymerase, 1 µL; PCR buffer, 10 µL and distilled water, 15 µL, these tubes were placed into a PCR machine. PCR conditions were primer annealing at 56°C for 1 min, polymerization at 72°C for 1 min, and denaturation at 94°C for 1 min. Thirty cycles were carried out<sup>[19]</sup>. The PCR product (amplicon) was incubated with *Acl*-I enzyme at 37°C for 1.5 h and separated on a 2% agarose gel. DNA fragments on the gel were visualized after staining with 0.5 µg/mL ethidium bromide (EtBr).

### Statistical analysis

Statistical analyses were performed using SPSS 11.0 for Windows statistical software, Kendall's Tau test and Linear regression analysis. *P* values < 0.05 were considered significant.

## RESULTS

The mean age of the patients was 54.9 ± 14.1 years (19-82). Pathologic examination revealed that 44 of them were *Hp* (+) and 33 were *Hp* (-). Based on MPO gene polymorphism, 66 patients (85.7%) had GG genotype, 10 (12.9%) had GA and 1 (1.29%) had AA genotype. The patient with genotype A was an *Hp* (-) ulcer patient (Table 1).

There was a difference between *H pylori* (+) and *H pylori* (-) patients with respect to PNL infiltration (*P* = 0.0001). The change in atrophy in relation to neutrophil infiltration was significant in *Hp* (+) patients (*y* = 0.700*x* + 0.051) (*P* = 0.0001) (Figure 1). No such correlation was found for *Hp* (-) patients (*y* = 0.1214*x* + 0.50) (*y*: atrophy, *x*: neutrophil infiltration) (Figure 2).

We found a significant correlation between atrophy and neutrophil infiltration in patients with GG genotype (*n* = 66) (*y* = 0.252*x* + 0.239) (*P* = 0.002). There was an insignificant correlation between atrophy and neutrophil infiltration in patients with GA genotype (*n* = 10) (*y* = 0.15*x* + 1.387) (*P* = 0.56).

Among the *Hp* (+) patients, the correlation between atrophy and neutrophil infiltration was insignificant for patients with both GG (*n* = 37) and GA genotypes (*n* = 7) (*r* = 0.066, *P* = 0.63; *r* = -0.474, *P* = 0.18, respectively).

**Figure 1** Changes in the atrophy in relation to neutrophil infiltration in *Hp* (+) patients.

**Figure 2** Changes in the atrophy in relation to neutrophil infiltration in *Hp* (-) patients.

Among the patients with *Hp* (-), we found an insignificant correlation between atrophy and neutrophil infiltration in patients with both GG ( $n = 29$ ) and GA genotypes ( $n = 3$ ) ( $r = 0.316$ ,  $P = 0.06$ ;  $r = 0.816$ ,  $P = 0.22$ , respectively). Since our sample size was small, a statistical analysis for MPO AA ( $n = 1$ ) genotype could not be performed.

## DISCUSSION

About 60% of the world population is infected with *H pylori*<sup>[1]</sup>. Hyperproliferation induced by *H pylori* gastritis has been assumed as a starting point for events that trigger gastric cancer. Moreover, this hyperproliferation has been suggested to initiate changes in DNA<sup>[4,20,21]</sup>. The World Health Organization (WHO) has declared *H pylori* as the leading carcinogenic factor. In a cohort study conducted by WHO in 3 different regions, anti-*Hp* antibody levels were measured in blood samples obtained within the last 24 years from patients diagnosed with gastric cancer. It was stated that *H pylori* seropositivity increased the relative risk for developing gastric cancer<sup>[1]</sup>. Yamagato *et al*<sup>[22]</sup> reported that 3% of 1721 patients with *H pylori* developed gastric cancer during 9 years of follow up. Also, Uemura *et al*<sup>[23]</sup> reported that 2.9% of 1246 *Hp* (+) patients developed gastric cancer during 7.6 years of follow up. While there was a significant difference in *Hp* (+) patients with respect to atrophy and neutrophil infiltration, no such correlation was found for *Hp* (-) patients. Thus, inflammation induced by *H pylori* could be one of the predisposing factors in carcinogenesis.

Recently studies have been published on cytokine production in several conditions caused by *H pylori* infection as a host response and genetic polymorphisms<sup>[4]</sup>. Zamboni *et al*<sup>[3]</sup> found that bacterial and virulence factors were associated with mucosal inflammation and severity of the illness. They found that *H pylori* virulence genes and a host genotype of IL-1 RN were directly correlated with peptic ulcer and intestinal metaplasia and they suggested that the interaction between cytokine genotypes and bacterial virulence factors are fundamental to development of *H pylori*-related lesions. Nardone *et al*<sup>[24]</sup> reported that, first atrophy localized in the antrum regresses or disappears subsequent to *H pylori* eradication. The changes seen in these lesions as a result of eradication show that, neutrophil infiltration plays a major role in these events above all.

Polymorphisms, defined as known changes in the genomic sequence, occur frequently throughout the

human genome. It is known that in some cases, they modify the expression or function of gene products. Any polymorphism could affect susceptibilities to and outcome of an illness through the interaction of environment and genetics<sup>[25]</sup>.

The question of how the variations in the genes associated with inflammation affect the inflammatory response induced by *H pylori* and accompanying gastric pathologies is an interesting one<sup>[26]</sup>. It has been stated that MPO itself might modulate susceptibilities to clinical outcomes of several illnesses where neutrophils are involved<sup>[10]</sup>. In a number of studies, the association between MPO polymorphisms and several conditions including chronic granulomatous illness, Alzheimer's disease, malignancies such as the lung or pharyngeal cancer, some types of leukemia, atherosclerosis, periodontal diseases, multiple sclerosis and cystic fibrosis were reported<sup>[4,8,11-13]</sup>. Hamajima *et al*<sup>[12]</sup> investigated a myeloperoxidase genotype with low expression, which was negatively correlated with *H pylori* infection in 241 patients having complaints of dyspepsia, without a history of cancer. They found 79.7% of GG genotype, 19.5% of GA genotype and 0.8% of AA genotype. In another study assessing the association between MPO polymorphisms, atrophy and neutrophil infiltration, Roe *et al*<sup>[4]</sup> found 81.9% of GG genotype, 18.1% of GA genotype and 0.0% of AA genotype. It was indicated that while there was a positive correlation between the degree of atrophy and neutrophil infiltration in individuals with GG polymorphism, no such association was found in individuals with GA polymorphism. Also, in our study we found that while the correlation between atrophy and neutrophil infiltration was significant in patients with GG genotype, it was insignificant in patients with GA genotype.

Our results show that generally myeloperoxidase GG genotype is a critical host-related factor for development of atrophy that occurs in the setting of inflammation, and is considered as a cancer precursor. However, it is interesting to note that on the contrary to what is expected, GG genotype and *H pylori* positivity does not potentiate each other for development of atrophy. More studies are needed to elucidate this point in larger patient groups.

## Abstract

**AIM:** To study the prevalence, predictors and control of bleeding following N-butyl 2 cyanoacrylate (NBC) sclerotherapy of gastric varix (GV).

**METHODS:** We analyzed case records of 1436 patients with portal hypertension, who underwent endoscopy during the past five years for variceal screening or upper gastrointestinal (GI) bleeding. Fifty patients with bleeding GV underwent sclerotherapy with a mean of 2 mL NBC for control of bleeding. Outcome parameters were primary hemostasis (bleeding control within the first 48 h), recurrent bleeding (after 48 h of esophago-gastro-duodenoscopy) and in-hospital mortality were analyzed.

**RESULTS:** The prevalence of GV in patients with portal hypertension was 15% (220/1436) and the incidence of bleeding was 22.7% (50/220). Out of the 50 bleeding GV patients, isolated gastric varices (IGV-I) were seen in 22 (44%), gastro-oesophageal varices (GOV) on lesser curvature (GOV-I) in 16 (32%), and GOV on greater curvature (GOV-II) in 15 (30%). IGV-I was seen in 44% (22/50) patients who had bleeding as compared to 23% (39/170) who did not have bleeding ( $P < 0.003$ ). Primary hemostasis was achieved with NBC in all patients. Re-bleeding occurred in 7 (14%) patients after 48 h of initial sclerotherapy. Secondary hemostasis was achieved with repeat NBC sclerotherapy in 4/7 (57%). Three patients died after repeat sclerotherapy, one during transjugular intrahepatic portosystemic stem shunt (TIPSS), one during surgery and one due to uncontrolled bleeding. Treatment failure-related mortality rate was 6% (3/50).

**CONCLUSION:** GV can be seen in 15% of patients with

portal hypertension and the incidence of bleeding is 22.7%. NBC is highly effective in controlling GV bleeding. In hospital mortality of patients with bleeding GV is 6%.

## INTRODUCTION

Gastric varix (GV) and its association with portal hypertension were first described in 1913<sup>[1]</sup>. Since then, there have been reports on different aspects of gastric varices including prevalence, bleed tendency and treatment options. The prevalence of GV in patients with portal hypertension varies from 18% to 70%<sup>[2,3]</sup>, although the incidence of bleeding from gastric varices is relatively low ranging from 10% to 36%<sup>[3]</sup>.

Management of GV presents is a challenging problem, because (1) since there is no consensus regarding the optimum treatment of GV, treatment tends to be empiric; (2) GV is not a homogeneous entity, and accurate classification defines its natural history and dictates its management; (3) although GV bleeding occurs less frequently than esophageal varix (EV) bleeding<sup>[4,5]</sup>, whenever bleeding occurs it tends to be more severe and requires more red blood cell transfusions and has a higher mortality than EV bleeding<sup>[5]</sup>; (4) after control of acute bleeding, GV has a high rebleeding rate of 34% to 89%<sup>[6]</sup>; and (5) there is no consensus regarding subsequent sclerotherapy for prophylaxis against recurrent bleeding in GV patients. Optimal management of GV requires a multidisciplinary approach and close cooperation between gastroenterologists, interventional radiologists and the surgical team.

Sohendra *et al*<sup>[7]</sup> first reported in 1986 that bleeding from gastric varices could be controlled by sclerotherapy

using the tissue adhesive agent butyl cyanoacrylate. Since then several authors have used different sclerosing agents to achieve hemostasis in bleeding gastric varices, including N-butyl-2 cyanoacrylate (histoacryl)<sup>[4,8]</sup>, 2-octyl cyanoacrylate<sup>[9]</sup>, ethanolamine oleate injection<sup>[10]</sup>, gastric variceal banding<sup>[11]</sup>, thrombin<sup>[12]</sup>, sodium tetradecyl sulfate<sup>[13]</sup>. However, N-butyl 2 cyanoacrylate (NBC) is the only promising agent.

Most reports on endoscopic treatment of bleeding gastric varices are small series, case reports, or retrospective reviews<sup>[14,15]</sup>. Not more than 1000 patients with bleeding GV have been treated with different sclerosing and coagulating agents. Cyanoacrylate injection can achieve primary hemostasis in 70% to 95% of patients with acute GV bleeding, with an early rebleeding rate ranging from 0% to 28% within 48 h<sup>[5,7,16]</sup>. Different doses of cyanoacrylate are used by different gastroenterologists<sup>[16,17]</sup>. Moreover, dilution ratio of NBC to lipoidal is different<sup>[18,19]</sup>. However, there is no consensus regarding effective dose and dilution of sclerosing agents.

This study was to analyze patients with GV in order to establish predictors of bleeding GV, and the efficacy and safety of NBC in treatment of bleeding GV.

## MATERIALS AND METHODS

From March 2000 to March 2005, 1036 patients with portal hypertension underwent endoscopy in our hospital. Out of 220 GV patients with or without esophageal varices, 50 had active bleeding gastric varices which were treated with N-Butyl cyanoacrylate injection.

The cause of portal hypertension was defined on the basis of ultrasound and/or computed tomographic scan of abdomen along with Doppler ultrasound to study the patency and spleno-portal axis in all patients with bleeding GV.

The location of gastric varices was determined according to the classification described by Sarin and Kumar<sup>[3]</sup> and divided into gastroesophageal varices type 1 (GOV-1) GV continuing as an extension of esophageal varices on the lesser curve of the stomach), gastroesophageal varices type 2 (GOV-2) on the greater curvature or fundal varices communicating with esophageal varices. Isolated gastric varices type 1 (IGV-1) and fundal varices within a few centimeters of the gastric cardia, or isolated gastric varices type 2 (IGV-2) and isolated ectopic gastric varices. Active bleeding was defined as bleeding or oozing of blood from a gastric varix, a clot or blackish ulcer or rent over a gastric varix, or the presence of distinct large gastric varices and absence of esophageal varices or other cause of gastrointestinal (GI) bleeding.

The clinical characteristics of patients including age, gender, Child-Pugh classification, type of varix, etiology and complications in patient with gastric varices were recorded and compared between groups with or without bleeding (Table 1).

Endoscopic sclerotherapy with n-butyl cyanoacrylate and lipoidal injection was performed by experienced endoscopists using a GIFQ160 gastroscope (Olympus, Tokyo, Japan). The sclerosant was injected into bleeding gastric varices using the 23 G disposable needle injector

Table 1 Clinical characteristics of patients with gastric varices

Characteristics	n	(%)
Number of patients	220	
Male:Female	141:79	(65:35)
Mean age (yr)	50 ± 11

(Wilson Cook Medical Inc., Winston-Salem, NC).

The injection needle was primed with lipoidal (approximately 0.5 mL) to fill the dead space within the injection catheter. After the gastric varix lumen was punctured with the needle, 2 mL of NBC (histoacryl 100%) in aliquots of 1 mL, diluted in 0.5 mL lipoidal, was injected over 45-90 s, thus a dilution of 2:1 was achieved in all cases (Figure 1 and Figure 2). Distilled water was used to flush the injection needle before and after sclerotherapy. Additional NBC was not injected if bleeding was immediately controlled in patients. All patients received octreotide infusion (50 mg/per hour) at admission and continued for 3 d. All patients were given a proton pump inhibitor, initially intravenously for 48 h and then orally for 4-6 wk as per our endoscopy unit protocol.

## Outcome measures

Primary hemostasis was defined as stability of vital clinical signs, no drop in hemoglobin concentration and no recurrent bleeding within the first 48 h after the initial sclerotherapy<sup>[16]</sup>. Re-bleeding was defined as hematemesis and/or melena, hypotension (a drop in systolic blood pressure of > 20 mmHg from baseline), fall in 2 gm/dL of hemoglobin and/or transfusion requirement of ≥ 2 units of packed red cells within that time.

## Data analysis

Statistical interpretation of data was performed using Statistical Program for Social Sciences (SPSS) version 13. Results were expressed as mean ± SD for all continuous variables (e.g., age, gender, hospital stay, units of packed cells *etc.*) and numbers (percentage) for categorical data (e.g., gender, Child's class, *etc.*). Analysis was performed by using the independent *t*-test, chi-square test and Fisher's exact test wherever appropriate. *P* < 0.05 was considered statistically significant.

**Figure 1** Isolated gastric varices with a nipple suggesting recent bleeding.

**Figure 2** Injector needle with N-butyl cyanoacrylate in a large gastric fundal varix.

**Figure 3** X-ray showing N-butylcyanoacrylate deposition in a gastric varix after sclerotherapy.

## RESULTS

The prevalence of bleeding gastric varices in patients with portal hypertension was 15% (220/1436) and the incidence of bleeding was 22.7% (50/220). The mean age of our patients with gastric varices was  $50 \pm 11$  years, male patients accounting for 65% (141). The main etiology of bleeding gastric varices was hepatitis C-related cirrhosis in 34 (68%), followed by hepatitis B virus in 6 and non B non C cirrhosis in 6 (12%) patients, respectively. Alcoholic liver disease was found in 2 patients (4%), non cirrhotic portal hypertension in 1 patient and Wilson's disease in 1 patient, respectively. Twelve patients (24%) belonged to Child-Pugh A, 26 (52%) to Child-Pugh B, and 12 (24%) to Child-Pugh C.

Out of the 50 bleeding GV patients, IGV- I was seen in 22 patients (44%), GOV- I in 16 patients (32%), and GOV- II in 15 patients (30%), concomitant GOV- I with GOV- II in 3 patients. N-butyl cyanoacrylate (2 mL diluted in 1 cc lipoidal) was injected intravariceally in all patients with bleeding GV. The characteristics of bleeding and non bleeding gastric varices are shown in Table 2.

Among these 50 patients, 43 (86%) had active bleeding and 7 (14%) showed evidence of recent bleeding. Most varices ( $n = 48$ ) were large (F3) according to Hashizume classification<sup>[20]</sup>. We compared bleeding and non bleeding GV and found that IGV- I was seen in 22/50 (44%) patients who had bleeding and in 39/170 patients (23%)

**Table 2** Comparison between bleeding and non bleeding varices

Characteristics	Bleeding GV <i>n</i> (%)	Non bleeding GV <i>n</i> (%)	<i>P</i>
Age	50.48 ± 11.2	47.52 ± 12.7	0.14

patients who did not have bleeding ( $P < 0.003$ ). Similarly, IGV- II was observed in 0/50 (0%) and 11/170 (6.4%), GOV- I in 16/50 (32%) and 77/170 patients (45.2%) who did not have bleeding, GOV- II in 15/50 (30%) and 50/170 patients (29.4%) who did not have bleeding from gastric varices, respectively.

The overall success rate for achieving primary hemostasis with NBC was 100% without recurrent bleeding within 48 h. A mean of  $2.0 \pm 0.5$  cc NBC was injected in each patient.

Re-bleeding occurred in 7 (14%) patients after 48 h. Secondary hemostasis with repeat NBC sclerotherapy was achieved in 4 (57%) patients. Three patients died after repeat sclerotherapy: one during transjugular intrahepatic portosystemic stem shunt (TIPSS), one during surgery and one due to uncontrollable torrential bleeding. Treatment failure-related mortality rate was 6 % (3/50).

No major side effects occurred in most patients during and after NBC sclerotherapy. Three patients reported mild retrosternal chest pain which subsided within the next 24 h (Figure 3).

## DISCUSSION

The overall incidence of gastric varices in patients with portal hypertension is 2%-70%<sup>[3]</sup>. Furthermore, we found that the incidence of bleeding from gastric varices in our patients is 22.7%, which is also similar to other reports<sup>[5]</sup>.

In this study, the rate for primary hemostasis with NBC injection is consistent with the reported rate of 90% to 97% in other studies<sup>[8,14,16,21-23]</sup>. In our study, sclerotherapy with 2 mL NBC diluted in 1 mL lipoidal was effective in control of bleeding in all our patients during the first 48 h.

We used a higher dose of NBC with 2:1 dilution. Our technique avoids dilution of NBC, thus decreasing chances of migration and embolization as instantaneous polymerization is delayed.

It was reported that a hemostasis rate of 95% can be achieved without dilution of NBC, but serious side effects such as embolization may occur<sup>[24]</sup>.

The risk of embolization increases with over dilution of cyanoacrylate which can slow down the process of polymerization. We avoided this problem by diluting 2 mL of NBC in 1 mL of lipoidal which was injected slowly over 45-90 s. Although the volume of injection was large, the side effects of a large volume were avoided and good hemostasis was achieved by keeping a balanced dilution.

We also studied the predictors of the first gastric variceal bleeding, showing that the increased risk of bleeding is associated with larger varices including predominant IGV- I and GOV- I<sup>[5]</sup>. Kim *et al*<sup>[23]</sup> found that advanced Child-Pugh class and varix > 5 mm in size are associated with an increased risk of bleeding. Unlike esophageal varices, a high porto-systemic pressure > 12 mmHg does not cause GV bleeding, which is probably related to the high frequency of spontaneous gastro-renal shunts<sup>[17]</sup>.

Cyanoacrylate therapy can improve and control re-bleeding. The high mortality rate is primarily a reflection of underlying advanced liver disease unaffected by the injection of cyanoacrylate<sup>[25,26]</sup>. This is further explained by a study of Kim *et al*<sup>[23]</sup> in which they prospectively followed a cohort of patients with gastric varices who did not undergo endoscopic therapy and found that the mortality rate is 35% over a median of 15 mo. Therefore, the role and efficacy of sclerotherapy for prophylaxis against recurrent bleeding are questionable.

In the present study, re-bleeding occurred after 48 h in 7 (14%) patients and was controllable in 4 (57%) with repeat injection of NBC. It was reported that the incidence of re-bleeding ranges from 23% to 35%<sup>[8,10,16]</sup>. However, Kind *et al*<sup>[14]</sup> reported that the incidence of re-bleeding is 15.5%.

Treatment failure-related mortality in our study was 6%, which is consistent with the reported mortality<sup>[16]</sup>. Another study showed that the mortality is 12.5% due to re-bleeding immediately after NBC sclerotherapy<sup>[8]</sup>. Kind *et al*<sup>[14]</sup> reported that the hospital mortality rate is 19.5% in patients with bleeding gastric varices.

In conclusion, endoscopic injection of NBC at a dilution of 2:1 appears to be effective and safe for the control of hemostasis in patients with bleeding gastric varices. If NBC is injected slowly, a large amount of

NBC in proper dilution can be used without serious side effects.

### Abstract

**AIM:** To compare the gadolinium-enhanced multiphase dynamic magnetic resonance imaging (MRI) and multiphase multirow-detector helical CT (MDCT) scanning for detection of small hepatocellular carcinoma (HCC).

**METHODS:** MDCT scanning and baseline MRI with SE T1-WI and T2-WI sequence combined with FMPSPGR sequence were performed in 37 patients with 43 small HCCs. Receiver operating characteristic (ROC) curves were plotted to analyze the results for modality.

**RESULTS:** The areas below ROC curve (Az) were calculated. There was no statistical difference in dynamic enhancement MDCT and MRI. The detection rate of small HCC was 97.5%-97.6% on multiphase MDCT scanning and 90.7%-94.7% on MRI, respectively. The sensitivity of detection for small HCC on MDCT scanning was higher than that on dynamic enhancement MRI. The sensitivity of detection for minute HCC (tumor diameter  $\leq 1$  cm) was 90.0%-95.0% on MDCT scanning and 70.0%-85.0% on MRI, respectively.

**CONCLUSION:** MDCT scanning should be performed for early detection and effective treatment of small HCC in patients with chronic hepatitis and cirrhosis during follow-up.

### INTRODUCTION

Hepatocellular carcinoma (HCC) is the most common primary malignancy tumor of the liver. Dual-phase CT scanning is a sensitive method for the detection of HCC. The developments in rapid magnetic resonance imaging (MRI) in combination with gadolinium-enhanced multiphase multirow-detector helical CT (MDCT) scanning can obviously improve the detection of small HCC. However, MRI and MDCT have a lower sensitivity for detecting small HCC, especially minute HCC. MDCT scanning has a higher sensitivity for detection of small HCC<sup>[1-5]</sup>. The purpose of this study was to compare the dynamic enhancement MRI and MDCT for the detection of small HCC in patients with chronic liver disease and cirrhosis and to value the clinical role of new imaging technology in detection of small HCC.

### MATERIALS AND METHODS

#### Patient Sample

Between October 2002 and December 2004, 37 patients (29 men, 8 women, mean age: 56 years, range: 29-70 years) with chronic hepatic disease and cirrhosis who were suspected of having HCC during postoperative follow-up were included in this study. All the patients underwent multiphase contrast enhanced dynamic MDCT and gadolinium-enhanced dynamic MRI at 7 d intervals.

#### Lesion confirmation

Small HCC was confirmed in 24 of 37 patients. Fifteen of the 24 patients with 43 small HCCs underwent surgery and pathologic examination. Of the 15 patients undergoing surgery, small HCC was found in 2 by needle biopsy, in

**Table 1** Area under the ROC curve and *P* value for MRI and MDCT in detecting HCC

Imaging techniques	Observer 1		Observer 2	
	Az value	95% CI	Az value	95% CI
MDCT	0.983	0.950-1.013	0.99	0.968-1.012
MRI	0.951	0.901-1.001	0.94	0.882-0.999
<i>t</i> value	-0.425		-0.956	
<i>P</i> value	0.672		0.348	

5 by digital subtraction angiography (DSA), and in 2 by iodized oil CT and elevated serum  $\alpha$ -fetoprotein level ( $> 400$  ng/mL) and ultrasound examination. Two out of 37 patients undergoing multiphase dynamic contrast enhanced MDCT and dynamic gadolinium enhancement MRI respectively, were suspected of having small HCC. Their serum  $\alpha$ -fetoprotein level was decreased. Ultrasound examination one month after follow-up and multiphase dynamic contrast enhanced MDCT examination three months after follow-up showed that the lesions remained unchanged. Five out of 37 patients with liver cirrhosis undergoing gadolinium enhancement dynamic MRI scanning and multiphase dynamic contrast enhanced MDCT imaging were suspected of having small HCC. However, small HCC could not be found. Small HCC was not found in 3 of 5 patients who were followed up for 2-3 mo by contrast-enhanced MDCT, and in 2 of 5 patients who were followed up for 3 months by enhancement dynamic MRI. Multiphase dynamic contrast-enhanced MDCT and MRI examination displayed no new liver lesions in another 6 patients who were not diagnosed having small HCC during the three-month follow-up period. The size of small HCC was  $\leq 1$  cm in 20, and  $> 1$  cm or  $\leq 3$  cm in 23 of 43 small HCCs, respectively.

### MDCT

All CT examinations were performed using a commercially available multidetector CT scanner (Marconi Mx 8000) with 0.5-0.75 s gantry rotation speed, 23.3 mm/s table speed, 5.0 mm-thick section, reconstruction interval 2.5 mm, 120 Kv and 200-250 mA.

Entire pre-contrast hepatic scanning was followed by a nonionic contrast enhancement (Omnipaque 300 mg I/mL) with 1.5 mL/kg and injection rate of 3 mL/s *via* an antecubital vein. Multiphase acquisitions were performed. The scanning delay set for early arterial phase (EAP), late arterial phase (LAP) and portal venous phase (PVP) was 21 s, 34 s and 85 s, respectively. Each of the entire liver scanning in cephalad-caudal orientation was completed in 4-8 s with patient's breath held.

### MRI

MRI was performed with a GE Signa 1.5 T MR imaging system. A standard whole-body coil was used as the receiver coil for examinations. All the 37 patients underwent baseline MR imaging, including breath-hold spin-echo T1-weighted imaging (TR 500-700 ms, TE 14-20 ms), fat-suppressed fast spin-echo T2-weighted imaging (TR 2000-4000 ms, TE 80-120 ms) and gadolinium-enhanced triphasic dynamic gradient-recalled echo imaging

with a fast multiplanar spoiled-gradient-recalled echo breath-hold imaging (FMPSPGR TR/TE/Flip Angle = 100-150 ms/4.6 ms/60-90°), matrix (256  $\times$  128), 7 mm-thick section, and 1 acquisition. MR imaging was performed before and after gadolinium-enhanced dynamic gradient-recalled echo imaging (Gd-DTPA, Magnevist, Germany, NJ). Dynamic imaging was performed with a fast multiplanar spoiled-gradient-recalled echo breath-hold imaging. The contrast material was 0.2 mL/kg of body weight administered as a rapid IV bolus. After un-enhanced imaging, arterial phase image was obtained during 20-25 s. The second and third sets of images were obtained after approximately 60-90 s and 3 min, respectively.

### Imaging analysis

All MRI and MDCT images were reviewed by two experienced radiologists, who knew that patients with liver cirrhosis were at risk of developing HCC, but were unaware of the presence and location of liver lesions and the result of other imaging examinations. The size and number of lesions were analyzed for the various multiphase dynamic contrast-enhanced MR sequences and MDCT images (early arterial, later arterial, portal phases) of the 37 patients.

The readers scored each image for the presence or absence of focal hepatic lesions, and assigned confidence levels to their observation: 1 = definite presence, 2 = probable presence, 3 = equivocal, 4 = probable absence, 5 = definite absence<sup>[6]</sup>.

### Statistical analysis

For each imaging method, a binomial receiver operating characteristic (ROC) curve was fitted to each radiologist's confidence rating using maximum likelihood estimation. The diagnostic accuracy of each imaging set for each observer and the composite data were calculated by measuring the area under the alternative free response ROC curve. The differences between imaging sets in terms of the mean Az value, were statistically analyzed using the two-tail Student's *t* test for paired data. The sensitivity and positive predictive values for each image set were then calculated. The sensitivity of each observer was determined by detecting the number of lesions assigned a confidence level of 1 or 2 from 42 HCCs. The degree of inter-observer agreement was calculated with chance-corrected kappa statistics. In general, a kappa statistic value greater than 0.75 is considered excellent agreement, 0.4-0.75 good agreement, and less than 0.4 poor agreement<sup>[6-8]</sup>. Statistical analyses were performed using the SPSS Statistical Programs, version 10.0. *P* < 0.05 was considered statistically different (Figure 1).

## RESULTS

The kappa values were excellent between observers 1 and 2 for multiphase dynamic contrast-enhanced MDCT ( $\kappa$  value = 0.883) and MRI ( $\kappa$  value = 0.812). The Az values calculated by each observer with multiphase dynamic contrast-enhanced MDCT and MRI for 42 lesions are shown in Table 1. For detection of lesions, two observers achieved a slightly higher diagnostic performance with

**Figure 1** A 42-yr old man with pathologically proven hepatocellular carcinoma. **A:** Plan scanning; **B:** early arterial phase MDCT image showing slightly enhanced nodule in right lobe; **C:** later arterial phase MDCT image showing obvious enhanced lesion; **D:** on the portal venous phase MDCT image showing slight low attenuation.

**Table 2** Sensitivity and positive predictive value for MRI and MDCT in detecting small HCC ( $n = 43$ )

Imaging Technique		Sensitivity (%)			Positive predictive value (%)
		$\leq 1$ cm SHCC $n = 20$	$> 1$ cm $\leq 3$ cm SHCC $n = 23$	Total SHCC $n = 43$	
Observer 1	MDCT	19 (95.0)	22 (95.7)	41 (95.31)	97.6
	MRI	17 (85.0)	22 (95.72)	39 (90.7)	90.7
Observer 2	MDCT	18 (90.0)	21 (91.31)	39 (90.79)	97.5
	MRI	14 (70.0)	22 (95.7)	36 (83.7)	94.7

MDCT than with MRI, but the difference in the mean Az values of both image sets was not significant. The chance-corrected kappa values indicated the confidence levels for the image interpretation of the ROC analysis between the two observers.

The sensitivity and positive predictive values obtained with dynamic contrast-enhanced MDCT and MRI are shown in Table 2. For less than or equal to 1 cm minute HCC, the sensitivity of MRI was 85% and 70%, respectively for the two observers, but the sensitivity of MDCT for the two observers was higher than that of MRI (95% and 90%, respectively). The positive predictive value for MDCT was 97.5%-97.6% for MDCT and 90.7%-94.7% for MRI, respectively. There were less false-positive findings on MDCT.

## DISCUSSION

Most HCCs occur in cirrhotic liver. Oka *et al*<sup>[9]</sup> in a 6-year follow-up study of 140 patients with cirrhosis, Oka *et al*<sup>[9]</sup> found that the cumulative incidence of HCC is 39% and

its per year occurrence rate is 5.3%-8.8%. Small HCC results from cirrhosis. Early detection and diagnosis of small HCC are important in its effective treatment. Lim *et al*<sup>[10]</sup> have analyzed the sensitivity and specificity of double phase SCT in detecting small HCC. It was reported that imaging technology should be used in detecting small HCC<sup>[9,11]</sup>.

Multiphase dynamic CT using a helical scanner has become the standard technology for detection and diagnosis of small HCC. The detection of hepatic nodular lesions by CT depends on the attenuation difference in the normal parenchyma and enhancement nodule lesions. Multiphase dynamic CT scanning can show the change between the tumor and its surrounding parenchyma. This may in part be a result of the difference in uptake and secretion of contrast material by hepatocytes of the normal liver parenchyma and HCC cells. Because the arterial phase is shorter than the portal venous phase, the scanning time of hepatic lesions is not the optimal time of tumors. Therefore, the dual-phase scanning is difficult to detect small HCC<sup>[7,9,11,12]</sup>.

MRI is a less invasive and more feasible technique. The spin-echo sequence and gadolinium-enhanced triphasic dynamic breath-hold imaging are more effective. The advantage of contrast enhancement MRI is to deliver a small contrast material volume over a shorter period of time, which results in a tighter bolus. MRI has several advantages over dual-phase SCT in detection and characterization of small HCC, including greater soft-tissue contrast and sensitivity to intravascular contrast agent, and more types of sequences<sup>[6,14,16]</sup>.

Tang *et al*<sup>[17]</sup> reported that 94% of small HCC can be found in cirrhotic liver by dynamic gadolinium-enhanced MRI. Yan *et al*<sup>[18]</sup> reported that 94.12% of small HCC (diameter  $< 1$  cm) can be detected by MRI. Kim *et al*<sup>[19]</sup>

reported that 67% of small HCC (diameter < 1 cm) can be displayed by MRI.

The optimal imaging technology can detect most of small HCC. MDCT scanner recently has been introduced into clinical CT practice, and allows faster Z-axis coverage speed and hepatic imaging with thin image thickness in a very short time. MDCT can scan the entire liver during the double arterial phase. In addition, it improves the sensitivity of depicting small HCC and increases conspicuity for hypervascular lesions, and sensitivity of detecting small HCC<sup>[4,5,24]</sup>.

The ROC curve analysis revealed that there was a higher validity for two imaging methods. Two observers achieved slightly higher diagnostic efficiency with multiphase contrast-enhanced MDCT than with dynamic enhanced MRI, but the difference in the areas below the ROC curve was not statistically significant (observer 1,  $P = 0.672$ ; observer 2,  $P = 0.348$ ). Multiphase contrast-enhanced MDCT had slightly higher predictive values than dynamic contrast enhanced MRI. The positive predictive value for MDCT and MRI by observer 1 was 97.6% and 90.7%, and 97.5% and 94.7% by observer 2, respectively. There were less false-positive findings on MDCT, but whether the diagnostic efficiency of multiphase contrast-enhanced MDCT is superior to dynamic contrast enhancement MRI needs further study with a large sample.

It was reported that the sensitivity of MRI in detection small HCC is lower<sup>[20-22]</sup>. However, several factors can affect the visualization of primary focal hepatic lesions during contrast-enhanced or un-enhanced MRI, including the functionality of normal hepatic parenchyma, as well as the dimension, composition, and degree of visibility of the lesions, and the residual hepatic functionality of neoplastic cells themselves<sup>[23,24]</sup>. Since these factors tend to vary from patient to patient, it is often difficult to predict the behavior of a given lesion. There is a very good correlation between the blood supply and the degree of pathologic characteristics of hepatic lesions.

In our study, the sensitivity of MRI in detecting small HCC ( $\leq 1$  cm) was 70% and 85%, respectively. Seventy percent of 20 small HCCs showed isointensity, 4 demonstrated the signal change from isointensity to hyperintensity during arterial phase, portal venous phase, and delay phase. The other lesions displayed the signal change from hyperintensity to isointensity. These different findings may be due to the following reasons. First, cirrhotic liver has homogeneous or nonhomogeneous density, the signal intensity of cirrhotic liver parenchyma is higher than normal liver parenchyma, and the high patching signal intensity on T1-weighted images is due to fatty deposition or hepatitis. Second, since the degree of the liver parenchyma is lower because of hemosiderin deposition and large fibrous tissue in the liver parenchyma, the impaired hepatic cells could not absorb contrast material. Third, the portal hypertension splits liver blood flow into collateral vessels, thus reducing the contrast material in the liver parenchyma. Fourth, since the time window of arterial phase is narrower and the imaging time of MRI is fixed at the arterial phase 20-25 s, portal venous phase 60-90 s, and delayed phase 120 s, it is difficult to show a real arterial phase<sup>[4]</sup>.

In conclusion, small HCC often manifests as relatively small lesions in cirrhotic livers. There is an obviously enhanced small nodule in hepatic arterial phase whether it has homogeneous or nonhomogeneous density. The signal intensity and contrast enhancement patterns cannot be used in the final diagnosis of small HCC. It is important for patients with cirrhosis to undergo follow-up imaging more frequently. Nodule growth is highly predictive of small HCC<sup>[21,26]</sup>. Further study is needed since our study has some limitations.

### Abstract

**AIM:** To study the expression of ether à go-go (Eag1) potassium channel in colorectal cancer and the relationship between their expression and clinico-pathological features.

**METHODS:** The expression levels of Eag1 protein were determined in 76 cancer tissues with paired non-cancerous matched tissues as well as 9 colorectal adenoma tissues by immunohistochemistry. Eag1 mRNA expression was detected in 13 colorectal cancer tissues with paired non-cancerous matched tissues and 4 colorectal adenoma tissues as well as two colorectal cancer cell lines (LoVo and HT-29) by reverse transcription PCR.

**RESULTS:** The frequency of positive expression of Eag1 protein was 76.3% (58/76) and Eag1 mRNA was 76.9% (10/13) in colorectal cancer tissue. Expression level of Eag1 protein was dependent on the tumor size, lymphatic node metastasis, other organ metastases and Dukes' stage ( $P < 0.05$ ), while not dependent on age, sex, site and degree of differentiation. Eag1 protein and mRNA were negative in normal colorectal tissue, and absolutely negative in colorectal adenomas except that one case was positively stained for Eag1 protein.

**CONCLUSION:** Eag1 protein and mRNA are aberrantly expressed in colorectal cancer and occasionally expressed in colorectal adenoma. The high frequency of expression of Eag1 in tumors and the restriction of normal expression to the brain suggest the potential of this protein for diagnostic, prognostic and therapeutic purposes.

**Key words:** Colorectal cancer; Adenoma; Ether à go-go

### INTRODUCTION

Ion channels play a vital role in the function of diverse cell types. In recent years, the concept of ion channels as therapeutic targets and diagnostic and prognostic biomarkers has attracted increasing interest, and triggered a wave of experimental results, identifying individual ion channels relevant with specific cancer types.

In 1969, several mutants from the fruit fly *Drosophila melanogaster* were produced following the treatment of adult males with ethyl methane sulfonate<sup>[1]</sup>. The mutants presented shaking of the legs under ether anesthesia and independent gene loci were found to be involved. One of these mutants exhibited a slow and rhythmic leg-shaking behavior; the locus involved was then named ether à go-go. Homology screening helped to identify other two sequences closely related to eag: the eag-related gene (erg) and the eag-like gene (elk); thus the EAG channels family comprises three subfamilies: EAG, ERG and ELK<sup>[2]</sup>. Two members for the eag subfamily, three for erg and two for elk are differentially expressed in different species including rat, bovine and humans. Two members of the eag subfamily are Eag1 (KCNH1, Kv10.1) and Eag2 (KCNH5, Kv10.2)<sup>[3]</sup>.

Eag1 is detected only in the brain and placenta in the process of myoblast fusion, indicating that the channel is not expressed in differentiated peripheral tissues<sup>[4]</sup>. On the other hand, eag1 is expressed in several cell lines derived from human malignant tumors, such as neuroblastoma<sup>[5,6]</sup>, melanoma<sup>[7]</sup>, breast<sup>[5]</sup>, and cervical carcinoma<sup>[5]</sup>. In these cell lines, Eag1 enhances the proliferation of the cells, and is required for the maintenance of growth. One of the most intriguing aspects of human eag1 channels is its relationship to cellular transformation. Cells transfected with Eag1 are able to grow in the absence of serum, lose contact inhibition, and induce aggressive tumors when implanted into immune-depressed mice<sup>[5]</sup>. Recently, functional expression of Eag1 has been described in clinical samples of cervical carcinoma<sup>[8]</sup>. Similarly, aberrant

expression of the channel has also been detected in sarcomas<sup>[9]</sup> and other tumors from diverse origins<sup>[12]</sup>, while the surrounding tissues are devoid of Eag1 expression. Moreover, specific inhibition of Eag1 expression by antisense technique<sup>[5]</sup>, siRNA<sup>[9,10]</sup> or by non-specific blockers<sup>[7,11]</sup> leads to a reduction in tumor cell proliferation *in vitro*.

The membrane protein Eag1 is accessible from the extracellular side and is predominantly present in tumor cells, represents a potential tumor marker and an interesting therapeutic target for cancer. For any potential clinical application it is an essential prerequisite that samples from human tumors overexpress the target Eag1. Colorectal cancer is a malignancy with a worldwide distribution, and the actual frequency of expression of Eag1 in colorectal tissue remained unknown. In this study, we explored the expression of Eag1 potassium channel in colorectal cancer and the relationship between their expression and clinicopathological features.

## MATERIALS AND METHODS

### Patients

Samples were obtained from Renmin Hospital of Wuhan University, according to a protocol approved by the Committee for the Conduct of Human Research. These patients had surgery between 2004 and 2005. Resected tissues were formalin-fixed and paraffin-embedded in the Department of Pathology. For immunohistochemical analysis, colorectal cancer tissue with paired non-cancerous matched tissue (NCMT) ( $n = 76$ ) as well as colorectal adenoma tissue (from endoscopic biopsy) ( $n = 9$ ) were obtained. For reverse transcription polymerase chain reaction, 13 colorectal cancer tissues with NCMT as well as 4 colorectal adenoma tissues (obtained from endoscopic biopsy) were examined during March to June 2006. These fresh specimens were kept in liquid nitrogen immediately after excision until use. Two pathologists screened histological sections and selected areas of the representative tumor cells. Tumor stage was classified according to Dukes' criteria.

### Immunohistochemistry

For immunohistochemical analysis, 5  $\mu\text{m}$  sections were sliced and mounted on poly-L-lysine-coated slides the day before use. Immunohistochemistry was conducted according to instructions of Histostain<sup>TM</sup>-Plus kits (Beijing Zhongshan Golden Bridge Biotechnology Co., LTD). The primary antibody Eag1 (Sigma-Aldrich, USA) was diluted 1:200 with 0.1% bovine serum albumin. As negative controls, the slides were treated by replacement of primary antibody with non-immune serum.

To achieve a semi-quantitative estimation of Eag1 expression levels, we used an immunohistochemical score method: Scores were 0, less than 10% of the tumor cells stained; 1+, faint staining in more than 10% of the cells; 2+, moderate staining in more than 10% of tumor cells; and 3+, strong staining in more than 10% of the cells. The immunohistochemical score was evaluated as negative (0), weakly positive (1+), and

strongly positive (2+, 3+). Each stained slide was scored by two independent observers. There were no major disagreements regarding scoring and the average scoring was reported.

### Cell culture

HT29 and LoVo cells (obtained from Cell Bank, Chinese Academy of Sciences) were maintained in T75 flasks in a humidified atmosphere at 37°C with 50 ml/L carbon dioxide and passaged every 4-5 d. The HT-29 line was isolated from primary tumor, and LoVo line was isolated from metastatic tumor nodules in the left supraclavicular region. HT29 cells were cultured in McCoy's 5a medium (modified) with 1.5 mmol/L L-glutamine adjusted to contain 2.2 g/L 90% sodium bicarbonate, 10% fetal bovine serum. LoVo cells were grown in Ham's F12K medium with 2 mmol/L L-glutamine adjusted to contain 1.5 g/L 90% sodium bicarbonate, 10% fetal bovine serum. All media were also supplemented with 100 units/mL penicillin plus 100  $\mu\text{g}/\text{mL}$  streptomycin.

### RNA preparation and reverse transcription PCR

Total RNA was isolated from colorectal tissue and HT29 and LoVo cells using TRIzol<sup>®</sup> reagent (Invitrogen Corporation, USA) following instructions of the TRIzol kit.

We designed specific primers for Eag1 (Genbank accession: AF078741) and  $\beta$ -actin. The primers were as follows: For Eag1 (bp966-bp1441, 475 bp), sense primer 5'-GCTTTTGAGAACGTGGATGAG-3'; antisense primer 5'-CGAAGATGGTGGCATAGAGAA-3'. For  $\beta$ -actin (479 bp): sense primer 5'-TGACGGGGTACCCACACTGTGCC-3'; antisense primer: 5'-CTGCAFCCTGTCCGCAATGCCAG-3' (479 bp). The primers were synthesized by Shanghai Sangon (China).

One step reverse transcription PCR (RT-PCR) was performed using One Step mRNA Selective PCR Kit 1.1 (TaKaRa Dalian, China) according to the manufacturer's specifications. The RT-PCR reaction mixture contained 25  $\mu\text{L}$  of 2  $\times$  mRNA selective PCR buffer reaction buffer I, 10  $\mu\text{L}$  of  $\text{MgCl}_2$ , 5  $\mu\text{L}$  of dNTP/analog mixture, 1  $\mu\text{L}$  of RNase Inhibitor, 1  $\mu\text{L}$  of AMV Rtase XL, 1  $\mu\text{L}$  of AMV-Optimized taq, 1  $\mu\text{L}$  sense primer (20  $\mu\text{mol}/\text{L}$ ), 1  $\mu\text{L}$  of antisense primer (20  $\mu\text{mol}/\text{L}$ ), 1  $\mu\text{L}$  of total RNA, 4  $\mu\text{L}$  of RNase free  $\text{dH}_2\text{O}$  to a final volume of 50  $\mu\text{L}$ . Reactions without template RNA were used as a negative control. The RT-PCR for  $\beta$ -actin was used to check the quality of the RNA extraction and RT-PCR. The following RT-PCR conditions were used for Eag1: 1 cycle of 45°C for 25 min; 30 cycles of 88°C for 30 s, 50°C for 45 s, and 72°C for 1 min; and a final cycle of 72°C for 7 min. The conditions for  $\beta$ -actin: 1 cycle of 50°C for 15 min; 30 cycles of 85°C for 30 s, 45°C for 45 s, and 72°C for 1 min; and a final cycle of 72°C for 7 min.

Fifteen microliters of PCR products were analyzed by electrophoresis on a 1.5% agarose gel. DNA fragments were visualized and photographed under UV light after ethidium bromide staining. The expected band for each marker was identified by comigration of a DNA marker ladder electrophoresed in an adjacent lane.

**Figure 1** Typical immunohistochemical staining for Eag1 in colorectal cancer and adenoma. **A, B, C:** Positive staining of colorectal cancers; **D:** Positive staining of metastasis tissue from greater omentum; **E:** Negative control of colorectal cancer; **F:** Positive staining from one case of colonic adenoma.

### Statistical analysis

The  $\chi^2$ -test was used for analysis. Differences between the values were considered significant when  $P < 0.05$ .

## RESULTS

### Eag1 channel is aberrantly expressed in colorectal cancer

Immunopositivity for Eag1 protein was clearly marked on the cytoplasm and/or membrane of cells. Using immunohistochemistry, aberrant expression of Eag1 was detected in tissue of colorectal cancer and negative expression was detected in NCMT. The frequency of expression of Eag1 in colorectal cancer averaged 76.3% (58/76) of the cases studied. Figure 1 shows representative positive expression of neoplastic tissue of colorectal cancer and metastatic cancer. Again, using reverse transcription PCR, positive expression of Eag1 was found in 10/13 (76.9%) of colorectal cancer samples and negative expression was found in 13 cases of NCMT (Figure 2, negative expression of NCMT was not shown here). Positive expression of Eag1 was also detected in HT29 and LoVo colorectal cancer cell lines (Figure 2).

### Eag1 channel is occasionally expressed in colorectal adenoma

Nine cases of colorectal adenoma were also studied by immunohistochemistry, which were negative for Eag1

**Figure 2** Eag1 mRNA expression in colorectal cancer and adenoma. Eag1 mRNA positively expressed in LoVo and HT29 cell lines and in 10/13 of colorectal cancer tissues, but negatively expressed in NCMT (not shown) and colorectal adenoma. M, molecular weight marker; 0, water.

**Table 1** Eag1 immunoreactivity in the colorectal cancers

Stage	Eag1 expression <sup>1</sup>			Positive cases n (%)
	Negative	Weak	Strong	
A	3	2	2	4/7 (57.1)
B	13	14	12	26/39 (66.7)
C	2	5	9	14/16 (87.5)
D	0	5	9	14/14 (100)
Total	18	26	32	58/76 (76.3)

<sup>1</sup>Intensity of expression was interpreted as negative, weakly positive, and strongly positive,  $P < 0.05$ .

protein in most of the cases except that in 1 case weak positive expression was detected (Figure 1). In addition, Eag1 mRNA expression was not detected in 4 samples of colorectal adenomas by RT-PCR (Figure 2).

### Relationship of Eag1 expression and clinic-pathological features

The immunohistochemistry results showed that no association was detected between Eag1 expression and sex, age, site, differentiation, while expression levels of Eag1 protein were found to be dependent on the tumor size, lymphatic node metastasis, other organ metastases and Dukes' stage ( $P < 0.05$ ). Especially, all the tissues from metastatic cancer of other organ or Dukes' D stage cancer showed an intensively positive immunostaining (Figure 1 and Table 2). Table 1 summarizes the relationship of Eag1 protein expression with clinico-pathological features.

## DISCUSSION

Because of its restricted distribution in normal tissue and its more ubiquitous distribution in cancer cells and its oncogenic properties, Eag1 channels have gained interest

Table 2 Clinico-pathological features and Eag1 protein expression

Clinico-pathological features	Number of tumor n (%)	Positive Eag1 expression n (%)	$\chi^2$ value
Sex			0.70

<sup>a</sup>P < 0.05.

as promising tools for the development of novel diagnostic and therapeutic methods of cancers.

Recently, a few published papers have documented the contribution of potassium channels in the pathological status of cells other than neural or lymphoid origin. A paper of Pardo's group represents a milestone in the link between Eag1 and cancer<sup>[5]</sup>. Furthermore, they found that Eag1 expression was limited outside the CNS, but was frequently expressed in clinic tumors from diverse origins, including colon carcinoma<sup>[12]</sup>. They reported that 6/8 of colon carcinomas were positively expressed. However, the actual frequency of expression of hEAG1 in colorectal cancer remained unknown. Here, we have provided that EAG1 protein and Eag1 mRNA were negatively expressed in normal colorectal tissue, but aberrantly expressed in a large fraction of colorectal cancer tissue and colorectal cell lines. These results strongly suggest the possibility of the use of Eag1 as a tool for the differential diagnosis of malignant transformation together with morphological criteria.

We also found that EAG1 protein was occasionally expressed in colorectal adenoma. Similar, Farias's group found one of negative pap smears of control cervical samples that presented human papilloma virus infection (the most important etiological factor for cervical cancer) was positive for Eag1 expression<sup>[8]</sup>. A plausible scenario is that the increase in Eag1 expression in precancer

pathological changes could be an early sign of tumor development, namely, Eag1 may be involved in the early development of cancer.

We analyzed relationship of Eag1 expression detected by immunohistochemistry with clinico-pathological features, and found that there was no association between Eag1 expression and sex, age, site, differentiation, while expression of Eag1 was dependent on the tumor size, lymphatic node metastasis, metastases to other organs and Dukes' stage. Especially, all the tissues from metastatic cancers of other organ showed intensively positive immunostaining. Such a correlation would obviously be of great interest, since the channel could thus serve as a prognostic marker. These conclusions are somewhat different from opinions held by the Pardo's group. They found there were no correlations between Eag1 expression and demographic factors (sex, age, grade and site of tumor) of soft tissue sarcoma<sup>[9]</sup>. However, they also found that the tumors from patients who died over the two-year follow up period were much more likely to express significant levels of Eag1. To address this question precisely, quantitative studies of Eag1 expression and prospective studies with larger samples and longer time period will be needed.

Studies of Eag1 in cancer treatment have also provided some promising conclusions. Recently, the Pardo's group reported siRNA sequences acting specifically on Eag1, reproducibly induced a significant decrease in the proliferation of tumor cell lines while did not trigger any observable non-specific responses<sup>[10]</sup>. So, siRNA would serve as tools in the future to facilitate the elucidation of both the physiological and pathophysiological functions of this intriguing protein. We are also investigating the roles of Eag1-siRNAs served as tools in colorectal cancer therapy, and trying to clarify the effect of silencing the channel activity on tumor cells.

In conclusion, Eag1 potassium channels are aberrantly expressed in colorectal cancer patients and cell lines. These findings strongly suggest that Eag1 might be used as a potential diagnostic and prognostic marker as well as a potential membrane therapeutic target for colorectal cancer.

### Abstract

**AIM:** To comparatively study the preventive effect of gelatinizedly-modified chitosan film on peritoneal adhesions induced by four different factors in rats.

**METHODS:** Chitosan was chemically modified by gelatinization, and made into films of 60  $\mu\text{m}$  in thickness, and sterilized. Two hundred Sprague-Dawley rats were randomly divided into five groups, Sham-operation group (group A), wound-induced adhesion group (group B), purified talc-induced adhesion group (group C), vascular ligation-induced adhesion group (group D), and infection-induced adhesion group (group E), respectively. In each group, the rats were treated with different adhesion-inducing methods at the cecum of vermiform processes and then were divided into control and experimental subgroups. Serous membrane surface of vermiform processes were covered with the films in the experimental subgroups, and no films were used in the control subgroups. After 2 and 4 wk of treatments, the abdominal cavities were reopened and the adhesive severity was graded blindly according to Bhatia's method. The cecum of vermiform processes were resected for hydroxyproline (OHP) measurement and pathological examination.

**RESULTS:** Adhesion severity and OHP level: After 2 and

4 wk of the treatments, in the experimental subgroups, the adhesions were significantly lighter and the OHP levels were significantly lower than those of the control subgroups in group B (2 wk:  $0.199 \pm 0.026$  vs  $0.285 \pm 0.041$   $\mu\text{g}/\text{mg}$  pr,  $P < 0.001$ ; 4 wk:  $0.183 \pm 0.034$  vs  $0.276 \pm 0.03$   $\mu\text{g}/\text{mg}$  pr,  $P < 0.001$ ), D (2 wk:  $0.216 \pm 0.036$  vs  $0.274 \pm 0.040$   $\mu\text{g}/\text{mg}$  pr,  $P = 0.004$ ; 4 wk:  $0.211 \pm 0.044$  vs  $0.281 \pm 0.047$   $\mu\text{g}/\text{mg}$  pr,  $P = 0.003$ ) and E (2 wk:  $0.259 \pm 0.039$  vs  $0.371 \pm 0.040$   $\mu\text{g}/\text{mg}$  pr,  $P < 0.001$ ; 4 wk:  $0.242 \pm 0.045$  vs  $0.355 \pm 0.029$   $\mu\text{g}/\text{mg}$  pr,  $P < 0.001$ ), but there were no significant differences in groups A (2wk:  $0.141 \pm 0.028$  vs  $0.137 \pm 0.026$   $\mu\text{g}/\text{mg}$  pr,  $P = 0.737$ ; 4 wk:  $0.132 \pm 0.031$  vs  $0.150 \pm 0.035$   $\mu\text{g}/\text{mg}$  pr,  $P = 0.225$ ) and C (2 wk:  $0.395 \pm 0.044$  vs  $0.378 \pm 0.043$   $\mu\text{g}/\text{mg}$  pr,  $P = 0.387$ ; 4 wk:  $0.370 \pm 0.032$  vs  $0.367 \pm 0.041$   $\mu\text{g}/\text{mg}$  pr,  $P = 0.853$ ); Pathological changes: In group B, the main pathological changes were fibroplasias in the treated serous membrane surface and in group D, the fibroplasia was shown in the whole layer of the vermiform processes. In group E, the main pathological changes were acute and chronic suppurative inflammatory reactions. These changes were lighter in the experimental subgroups than those in the control subgroups in the three groups. In group C, the main changes were foreign body giant cell and granuloma reactions and fibroplasias in different degrees, with no apparent differences between the experimental and control subgroups.

**CONCLUSION:** The gelatinizedly-modified chitosan film is effective on preventing peritoneal adhesions induced by wound, ischemia and infection, but the effect is not apparent in foreign body-induced adhesion.

### INTRODUCTION

Peritoneal adhesion is a kind of defensive reaction to

peritoneal injury. However, it can also result in intestinal obstruction and cause severe clinical disorders. Therefore, it is important to prevent peritoneal adhesion in abdominal surgical operations. Unfortunately up to now, there have been no ideal methods to prevent peritoneal adhesion in clinical practice. Chitosan is a deacetylated derivative from chitin. Many previous studies showed that chitosan has effects of haemostasis, and sterilization, facilitates epithelial reparation and inhibits fibroblastic growth<sup>[1-3]</sup>. Chitosan has been used to prevent tissue adhesions, such as peritoneal adhesion, tendon adhesion and synarthrophysis<sup>[4-6]</sup>. In clinical application, it was found that the gel flows easily and is difficult to stay in the target regions for sufficient time, and the gel also degrades so fast that it could only maintain effectiveness for a short duration. In order to delay the degradation and decrease the fluidity of the gel, in our previous study, we processed the chitosan to films and transplanted it into the abdominal cavity of rats. But the film degraded too slowly and 8 wk after the transplantation, most of the films resided in the cavity. The residual film was encapsulated by the surrounding tissue and the peritoneal adhesion was worsened. In order to overcome these disadvantages, we mixed gelatin to chitosan and produced blending films. The blending film degraded much faster than the previous pure chitosan film, but it also produced foreign body reactions and formed severe foreign body granuloma around the blending film<sup>[7]</sup>.

To solve the above problems and develop a useful chitosan film to prevent the peritoneal adhesion, in the present study we chemically modified the chitosan by gelatinization to develop a new sort of chitosan film, and comparatively studied the preventive effect of the film on peritoneal adhesions induced by wound, infection, ischemia and foreign body in rats.

## MATERIALS AND METHODS

### *Animals and grouping*

Two hundred Sprague-Dawley rats, one half for each gender, weighing 200-250 g, were provided by the Experimental Animal Center of Zhejiang Province. They were randomly divided into five groups: sham-operation group (group A), wound-induced adhesion group (group B), purified talc-induced adhesion group (group C), vascular ligation-induced adhesion group (group D), and infection-induced adhesion group (group E). Each of the above groups was subdivided into two subgroups, experimental and control subgroups (20 rats for each subgroup and one half for each gender). All the rats were fed under the same conditions: at 24-26°C of environmental temperature, about 40% humidity, with an alternate 12 h light/dark cycle, and free access to food and water.

### *Preparation of chitosan film*

The chitosan (from Yuhuan Aoxing Chitin Ltd., Zhejiang Province, China) was dissolved, purified, gelatinized, modified, filtered and made into films. The films were dried and dissected to patches of 10 cm × 10 cm in

size and 60 µm in thickness, and the film patches were sterilized by radiation of <sup>60</sup>Co for later use.

### *Surgical operation*

Under general anaesthesia with intraperitoneal injection of 3% amobarbital (60-90 mg/kg), the rats were immobilized in dorsal position, routinely degermed, abdominally incised through a median incision of 2-3 cm long, and their vermiform processes were searched and pulled out of the incisions, then the terminal vermiform processes within a length of 3 cm were treated as follows: In group A, the vermiform processes were exposed to air for 5 min; in group B, the anterior surface of serous membrane was scraped slightly with surgical blade till obvious congestion and small bleeding drops appeared; in group C, 10 mg of talc powders were evenly smeared over the anterior surface of serous membrane; in group D, the vermiform artery stem was ligated with 0<sup>#</sup> surgical thread at a point of 3 cm from the dead end in the following way: loosely knotting the first loop, thrilling a thread with equivalent diameter to the vermiform artery stem through the first loop, tightening the first loop, pulling out the thrilled thread, and knotting and tightening the second loop of the ligation knot. The ligation resulted in a stricture of vermiform artery, which induced ischemia of the distal vermiform tissue from the ligation point. In group E, the dead end of the vermiform process was poked out with a hole using a 16<sup>#</sup> needle, a drop of intestinal content was extruded out and evenly smeared over the anterior surface of serous membrane, and then the remaining content in the vermiform process was pushed to the cecum. After the above treatments, for the experimental subgroups, the treated serous membranes were covered with the prepared chitosan films, and the vermiform processes were put back into the abdominal cavity, which were then closed. For the control subgroups, all the treatments were the same as those of the experimental subgroups except that the chitosan film was not placed. The duration from opening to closing the abdominal cavity was 5 min, so that the duration of exposure of intestines to air was the same for each rat.

At 2 and 4 wk after the surgery, 10 rats (5 female and 5 male) in each subgroup were randomly selected respectively and their abdominal cavities were reopened under anaesthesia, and the grades of peritoneal adhesion were evaluated, which existed between the treated vermiform processes and intestines, mesenteries and abdominal walls. After that, the vermiform processes with adhesions were resected and washed with normal saline, and then were divided into two segments for each resected process. The proximal segments were fixed with formalin and histopathologically examined, and the distal segments were stored at -80°C for measurement of hydroxyproline (OHP).

### *Grading standard for peritoneal adhesion*

According to Bhatia's<sup>[8]</sup> grading method of 5 levels and considering the characteristics of peritoneal adhesion in rats, we formulated the following grading standard:

Table 1 Comparison of peritoneal adhesive grades between experimental and control subgroups within each group

Group	Control group ( <i>n</i> = 10)					Experimental group ( <i>n</i> = 10)					<i>U</i>	<i>P</i>
	0	I	II	III	IV	0	I	II	III	IV		
Group A: sham-operation												
2 wk	9	1	0	0	0	10	0	0	0	0	45.000	0.317
4 wk	10	0	0	0	0	9	1	0	0	0	45.000	0.317
Group B: wound-induced adhesion												
2 wk	0	5	4	1	0	6	3	1	0	0	14.500	0.005
4 wk	0	5	5	0	0	7	3	0	0	0	7.500	0.001
Group C: purified talc-induced adhesion												
2 wk	0	0	1	3	6	0	0	1	2	7	45.500	0.687
4 wk	0	0	1	4	5	0	0	0	4	6	43.000	0.547
Group D: vascular ligation-induced adhesion												
2 wk	0	4	4	2	0	3	6	1	0	0	18.000	0.009
4 wk	1	4	4	1	0	5	4	1	0	0	21.500	0.023
Group E: infection-induced adhesion												
2 wk	0	0	1	4	5	0	4	5	1	0	5.500	0.001
4 wk	0	0	1	5	4	0	6	4	0	0	2.000	< 0.001

Grade 0: no adhesions; Grade I: the ratio of adhesive area/total treated area in the vermiform processes is < 50%, and the adhesion is easily to be dissected bluntly; Grade II: the ratio is  $\geq$  50%, and the adhesion is easily to be dissected bluntly; Grade III: area of the adhesion is out of consideration. Although blunt dissection for the adhesion can be carried out, it is difficult and the intestinal wall will be impaired after the blunt dissection; Grade IV: area of the adhesion is out of consideration. The adhesion is fast and cannot be bluntly dissected. Each rat was graded by three referees blindly and the average grade of the three was accepted as the adhesive grade of the rat.

#### Determination of total protein and OHP

The levels of total protein and OHP in the adhesive tissue were determined using the corresponding kits supplied by Nanjing Jiancheng Bioengineering Institute, China. The determining processes completely followed the instructions of the kits. Contents of OHP in the adhesive tissue were calculated as micrograms of OHP in each milligram of total protein ( $\mu\text{g}/\text{mg}$  pr).

#### Statistical analysis

All the data were processed with SPSS10.0. Mann-Whitney *U* test of non-parametric statistics for independent samples was used to analyze differences in the peritoneal adhesive grades and *t*-test was used to analyze differences in OHP levels between the experimental and control subgroups within each group.

## RESULTS

#### Gross findings

Abdominal incisions healed in first grade in all rats of all groups. There was no obvious postoperative abdominal infection in groups A, B, C and D at 2 and 4 wk after the surgical operations. There was no residual chitosan film in the abdominal cavities of rats in all experimental subgroups.

#### Comparison of peritoneal adhesion grade

As it shows in Table 1, within group A (sham-operation

group) and group C (talc-induced adhesion group), there was no significant difference in peritoneal adhesion between the experimental and control subgroups both at 2 and 4 wk ( $P > 0.05$ ). Within group B (wound-induced adhesion group), group D (vascular ligation-induced adhesion group) and group E (infection-induced adhesion group), the peritoneal adhesion grades of experimental subgroups were significantly lower than those of corresponding control subgroups ( $P < 0.05$ ) both at 2 and 4 wk after the surgical treatments. It indicates that the gelatinizedly modified chitosan film has remarkable effect on preventing peritoneal adhesions induced by wound, ischemia and infection, but no obvious effect on adhesion induced by talc powders. From the results in Table 1, we also concluded that in group E, the mean decreased adhesion grades were 1.7 and 1.4 from experimental to control group at 2 and 4 wk respectively. While in group B, the mean decreased grades were 1.1 and 1.2, and in group D, the mean decreased grades were 1.0 and 0.9. It suggests that the modified chitosan film is more effective on preventing infection-induced peritoneal adhesion than on wound and ischemia induced adhesion.

#### Comparison of OHP levels in adhesive tissue

As it shows in Table 2, in groups A and C, there were no significant differences in OHP levels between the experimental and control subgroups both at 2 and 4 wk ( $P > 0.05$ ). In groups B, D and E, the OHP levels of experimental subgroups were significantly lower than those of corresponding control subgroups ( $P < 0.05$ ) both at 2 and 4 wk after the surgical treatments. The changes in OHP levels were concordant with the changes in the adhesive grades, and it was confirmed to have a peritoneal adhesion-preventive effect when the gelatinizedly modified chitosan film was applied to regions with wound, ischemia and infection in abdominal surgical operations.

#### Comparison of pathological changes

In group A, there were no obvious pathological changes in vermiform processes of all rats. In groups B and D, there were obvious fibroplasias and sporadic infiltration of lymphocytes in serous membrane (group B) and the whole

Table 2 Comparison of OHP levels between experimental and control subgroups within each group ( $\mu\text{g}/\text{mg pr}$ )

Group	Control group ( $n = 10$ )	Experimental group ( $n = 10$ )	$t$	$P$
Group A: sham-operation				
2 wk	$0.137 \pm 0.026$	$0.141 \pm 0.028$	0.331	0.737
4 wk	$0.150 \pm 0.035$	$0.132 \pm 0.031$	1.217	0.225
Group B: wound-induced adhesion				
2 wk	$0.285 \pm 0.041$	$0.199 \pm 0.026$	5.602	< 0.001
4 wk	$0.276 \pm 0.038$	$0.183 \pm 0.034$	5.768	< 0.001
Group C: purified talc-induced adhesion				
2 wk	$0.378 \pm 0.043$	$0.395 \pm 0.044$	0.874	0.387
4 wk	$0.367 \pm 0.041$	$0.370 \pm 0.032$	0.182	0.853
Group D: vascular ligation-induced adhesion				
2 wk	$0.274 \pm 0.040$	$0.216 \pm 0.036$	3.408	0.004
4 wk	$0.281 \pm 0.047$	$0.211 \pm 0.044$	3.438	0.003
Group E: infection-induced adhesion				
2 wk	$0.371 \pm 0.040$	$0.259 \pm 0.039$	6.34	< 0.001
4 wk	$0.355 \pm 0.029$	$0.242 \pm 0.045$	6.675	< 0.001

layer (group D) of the adhesive vermiform processes at 2 wk, and the main pathological change was fibroplasia at 4 wk after the surgical treatments. The above pathological changes were milder in experimental subgroups than those in control subgroups except for changes in group D and at 4 wk. In group C at 2 wk, there occurred obvious foreign-body giant cell reactions, granuloma, fibroplasias and sporadic infiltration of lymphocytes at the treated serous membranes of adhesive vermiform processes, and the granuloma and fibroplasias became severer at 4 wk. There were no significant differences in the above pathological changes between the experimental and control subgroups. In group E, the main pathological change in the treated region was acute suppurative inflammation at 2 wk, and chronic inflammatory reaction characterized with granulation and fibroplasias at 4 wk after the surgical treatments. The above inflammatory reactions were milder in experimental subgroup than those in control subgroup both at 2 and 4 wk.

## DISCUSSION

Chitosan is chemically termed  $\beta$ -(1, 4)-2-amino-2-deoxy-D-dextran, and its main component is glucosamine. Glucosamine is also a sort of internal substance in human bodies, therefore, chitosan is biocompatible. If the chitosan is introduced into animal or human bodies, it will be degraded into small molecules of oligosaccharides and absorbed by the bodies without causing any acute or chronic toxicity. Chitosan is a derivant of deacetylated chitin, and the chitin is the major component of outer shells of invertebrates. Because of these characteristics of chitosan, it is widely and deeply researched in areas of pharmaceutical preparations and medical polymer synthesis<sup>[9]</sup>.

Peritoneal adhesion occurs in more than three fourths of patients following laparotomy. The outcomes of adhesion are unpredictable and diverse, causing a significant health care burden. Intestinal obstruction, infertility, problems at reoperative surgery and cumulative costs of care over many years are the key concerns<sup>[10]</sup>. The peritoneal adhesion develops only several hours

after the abdominal surgical operations. At first, the serous fluid exudes from the injured sides of intestinal wall, and then fibrinogen in the serous fluid transforms to fibrin and coagulates, thereby membranous peritoneal adhesion in the injured intestinal wall is formed. After that, the fibrinolytic system is activated and the fibrin is lyzed, thereby the membranous peritoneal adhesion is gradually eliminated. If the fibrin cannot be totally lyzed, the left fibrin will be organized and develop fibrinous adhesion, which usually forms at 2 wk after the surgical operation<sup>[11]</sup>. Based on the mechanisms through which the chitosan prevents peritoneal adhesion: inhibiting growth of fibroblasts, facilitating reparation of the epithelium, and disinfection, it is concluded that the chitosan can only prevent against pre-fibrinous adhesion. Once the fibrinous adhesion is formed, chitosan is useless. Therefore, when we use chitosan film to prevent peritoneal adhesion, the optimal duration for the film to stay in the abdominal cavity is within 2 wk. Firstly, the film can exert an effect of mechanical isolation in a solid state before it is completely degraded; On the other hand, when the film is degraded, the released chitosan monomers can also take anti-adhesive effect. In the present study, we gelatinizedly modified the chitosan to develop a new sort of chitosan film, which can be slowly dissolved in water. The experiments demonstrated that, within 2 wk after the film was transplanted into the abdominal cavity of the rats, it was completely degraded and absorbed without any foreign-body granuloma reaction. This suggests that the gelatinizedly modified chitosan film has the potential to be biomaterial for adhesion-prevention.

There are many factors that can induce peritoneal adhesions, of which the main factors are wound, ischemia, infection and foreign bodies. In most cases of clinical peritoneal adhesion, the adhesions are caused by combined factors, among which one or several factors play major roles<sup>[11,12]</sup>. The present study utilized rat models to investigate effects of the gelatinizedly modified chitosan film on peritoneal adhesions induced by four different factors. The results demonstrated that, at 2 and 4 wk after the surgical operations, the chitosan films significantly reduced the adhesion grades in groups of wound, ischemia

and infection-induced adhesions. This suggests that the chitosan films have obvious preventing effects on wound, ischemia and infection-induced peritoneal adhesions. The results also demonstrated that the films are more effective on infection-induced peritoneal adhesion. The mechanism may be as follows: The chitosan film prevents infection-induced peritoneal adhesion not only through promoting the epithelium recovery and inhibiting the growth of fibrous tissue, but also through its anti-infection effect by inhibiting hyperplasia of granulation and fibrous tissue. Through the double pathways the chitosan may inhibit the adhesion more strongly. It also seemed that healing of the abdominal incisions is not obviously affected by the chitosan transplantation. With respect to effects of the chitosan film on intra-abdominal anastomotic stoma healing, it needs to be clarified further.

Within the talc powder-induced adhesion group, there were no significant differences in adhesive grades between the experimental and control subgroups both at 2 and 4 wk. This showed that the gelatinizedly modified chitosan film has no obvious preventive effect on foreign body-induced peritoneal adhesion. The reason is as follows: For the talc powder-induced adhesion, the main pathological changes are foreign-body granuloma complicated with a large quantity of fibroplasias, and these changes will maintain as long as the foreign bodies exist. However, the chitosan film degraded in a relative fast rate in the abdominal cavity and there was no obvious residual film at 2 wk after the transplantation. Therefore, the fast degraded film cannot exert a strong effect on a chronic and persistent foreign-body granuloma reaction.

There is a high content of OHP in collagen protein, a very low content in elastin protein, and none in other sorts of proteins. Ozogul *et al*<sup>[13]</sup> reported that there existed positive correlation between adhesive grades and OHP levels in the adhesive tissue, and concluded that OHP is a significant index to measure the adhesive degree of tissue, which is more sensitive and objective than the index of gross adhesive grade. In the present study, the OHP changing tendency within each group and differences in OHP levels between subgroups were concordant to those of adhesive grades. This further confirms the preventive effect of gelatinizedly modified chitosan film on wound, ischemia and infection-induced peritoneal adhesions.

## COMMENTS

### Background

Peritoneal adhesion can cause intestinal obstruction and other severe clinical disorders, so it is very important to prevent peritoneal adhesion in abdominal surgical operations. But up to now, there are still no ideal methods to prevent peritoneal adhesion in clinical practices. Chitosan is a deacetylated derivate from chitin. Many studies reported that chitosan was applied to prevent tissue adhesions, such as peritoneal adhesion, tendon adhesion and synarthrophysis, but the effect was not satisfactory.

### Research frontiers

Chitosan is a sort of natural biological material and it has been processed into many forms for medical use. In the area of prevention of peritoneal adhesion with chitosan, the research hotspot is how to modify the chitosan by chemical and physical methods to improve its effectiveness on preventing the adhesion, and simultaneously reduce its adverse reactions.

### Innovations and breakthroughs

In the previous application of chitosan gels to the prevention of peritoneal adhesion, it was found that the gel was much fluid and was difficult to stay in the target places for sufficient time, and moreover, the gel degraded so fast that it could only maintain the effectiveness for a short duration. In order to delay the degradation and decrease the fluidity of the gel, we processed pure chitosan into films, but the film degraded too slowly and the residual film was encapsulated by surrounding tissue and the peritoneal adhesion was worsened. In order to overcome these disadvantages, we mixed chitosan with gelatin and produced blending films. The blending film degraded much faster than the previous pure chitosan film, but it also created foreign body reaction and formed severe foreign body granuloma around the blending film. In the present study we chemically modified the chitosan in gelatinization to develop a new sort of chitosan film, and showed that the film is remarkably effective on preventing peritoneal adhesions induced by wound, ischemia and infection except the foreign body-induced adhesion.

### Applications

The study results suggest that the gelatinizedly-chitosan film is a potential therapeutic material that could be used in preventing peritoneal adhesions induced by wound, ischemia and infection.

### Terminology

Peritoneal adhesion: Peritoneal adhesion is a sort of defensive reaction to the peritoneal injury mainly including wound, infection, ischemia and foreign body, but it can also develop intestinal obstruction and cause severe clinical disorders; chitosan: Chitosan is a deacetylated derivate from chitin, and chitin is the second most abundant natural biopolymer derived from exoskeletons of crustaceans and also from cell walls of fungi and insects.

### Peer review

This is a good descriptive study in which authors analyze the preventive effect of gelatinizedly-modified chitosan on peritoneal adhesions induced by different factors in rats. The results are interesting and suggest that gelatinizedly-chitosan is a potential therapeutic substance that could be used in preventing peritoneal adhesions induced by wound, ischemia and infection.

## Abstract

Ampullary carcinoid is a rare tumor that can present with gastrointestinal bleeding, obstructive jaundice or pancreatitis. Some of these tumors are associated with Von Recklinghausen disease. The usual surgical options are a biliary-enteric anastomosis, Whipple procedure or rarely a local resection. The mean survival does not appear to be much different after a pancreaticoduodenectomy versus local surgical excision. We report a very rare case of a non-metastatic ampullary carcinoid causing upper gastrointestinal bleeding, which was managed by endoscopic ampullectomy.

## INTRODUCTION

Despite being rare, carcinoids are the most common neuroendocrine tumors of the gastrointestinal (GI) tract<sup>[1,2]</sup>. Carcinoid of the ampulla is an extremely rare tumor (0.05%) for which the correct pre-operative diagnosis is very low (14%) and very rarely they present with an ulceration of the overlying duodenal mucosa<sup>[2]</sup>. Less than 3% of ampullary carcinoids patients experience carcinoid syndrome<sup>[3]</sup>. These tumors generally have an indolent course, but more aggressive behavior in the

form of distant metastases has been reported. We report a case of an ampullary carcinoid that manifested as an upper gastrointestinal bleeding and was managed with endoscopic snare resection of the ampulla of Vater.

## CASE REPORT

A 71-year old man underwent upper endoscopy for the work up of a recent history of epigastric pain, melena and a 4 g decrease in hemoglobin. The esophagogastroduodenoscopy (EGD) was unremarkable except for a prominent ampullary area. A sideviewing scope showed an approximately 1.5 cm mass with an overlying superficial ulcer (Figure 1A). Biopsy specimen revealed a carcinoid tumor involving the muscularis propria (Figure 2A and B). The tumor lacked mitotic activity and psammoma bodies (sometimes associated with duodenal somatostatinomas). The tumor was positive for chromogranin, synaptophysin and somatostatin, and negative for gastrin, insulin, glucagon and human pancreatic polypeptide. The patient denied flushing, diarrhea, weight loss or wheezing. His liver enzymes were normal. A CT and an octreotide scan were unremarkable. EUS revealed no regional lymph nodes and tumor free pancreatic and common bile ducts. A serum serotonin level was normal at 80 ng/mL (22-180 ng/mL) and urinary 5-HIAA was 6.1 mg/24 h (normal up to 6 mg/24 h).

The patient declined aggressive surgical options but agreed to undergo an endoscopic ampullectomy with its modest risk of complications. After submucosal saline injection in the ampullary area, a snare assisted ampullectomy was performed with blended current (cut to coagulation ratio 5:1) at a setting of 150:30 watts using an electrosurgical unit (ERBE ICC-200, Tubingen, Germany). The tumor was removed piecemeal. A 5 Fr, 3 cm pancreatic stent was placed to prevent pancreatitis. The procedure was uneventful except for mild oozing which promptly stopped with local infiltration of 4 cc of 1/10000 epinephrine. The patient remained stable except for an asymptomatic transient elevation of transaminases and was discharged the next evening. The pancreatic stent was removed two weeks later and there was no residual tumor seen at this examination (Figure 1B). He did not have any further episodes of GI bleeding in the last three years. His hemoglobin and liver related tests were normal. Subsequent follow-up endoscopies using a side-viewing scope showed no residual tumor and biopsies (using jumbo

**Figure 1** Endoscopic view showing an ampullary tumor (A) and the same area weeks after endoscopic resection of the tumor (B).

forceps) of the area remained negative for tumor cells. A follow-up EUS and two CT scans were also unremarkable.

## DISCUSSION

Neuroendocrine neoplasms only rarely occur at the ampulla of Vater, and consist mostly of carcinoids and occasionally of poorly differentiated endocrine carcinomas (small cell carcinomas)<sup>[4]</sup>. Up to 26% of patients may have associated Von Recklinghausen disease<sup>[5]</sup>. There is a higher incidence (46%) of finding metastatic disease at diagnosis in carcinoids of the ampullary area. Jaundice (53%), pain (24%), pancreatitis (6%) and weight loss (3.6%) are common presenting symptoms<sup>[6]</sup> but upper GI bleeding from ulceration is rare<sup>[7]</sup>. Carcinoids have an intact overlying mucosa which may explain a high rate of false negative biopsies<sup>[2,6]</sup>. Examination using a side-viewing scope and obtaining deep excavating biopsies is essential towards establishing the diagnosis. The possibility of the bile duct involvement should be ascertained with ERCP and/or EUS. In detecting smaller tumors and for local angio-invasion, EUS could be extremely sensitive<sup>[8]</sup>. CT scan and MRI have a low sensitivity for the primary lesion<sup>[8]</sup>. Somatostatin receptor scan is 86% sensitive for duodenal carcinoids of  $\geq 1$  cm, in detecting both primary and metastatic disease<sup>[9]</sup>. A capsule endoscopy should be considered to rule out synchronous small bowel lesions.

Re-classified by WHO, carcinoids are now called neuroendocrine tumors. Ampullary carcinoids range from highly differentiated (probably benign) to well differentiated endocrine carcinomas and poorly differentiated carcinomas. The overall survival appears to be excellent at 90% for well differentiated tumors<sup>[2]</sup>, but poor when these are not so well differentiated<sup>[10]</sup>.

Choosing the best treatment option for ampullary carcinoids could be challenging. Although tumor size is not a good prognostic predictor<sup>[2,10]</sup>, most experts still recommend either a Whipple or a pylorus preserving pancreatico-duodenectomy (PPPD) for tumors over 2 cm in size<sup>[11]</sup>. Metastatic disease has been found in 48% and 40% of the patients with tumor sizes of more than 2 cm and less than 2 cm, respectively<sup>[12]</sup>. Thus, some experts recommend a Whipple pancreatico-duodenectomy for all size tumors. On the other hand long-term survival has been achieved with local resection only<sup>[2,13]</sup>. In a study of

**Figure 2** Histological examination of the resected specimen revealing carcinoid in the mucosa and submucosa, composed of discrete solid nests of round tumor cells with central nuclei and occasionally with gland-like lumina (A) and solid nests of tumor cells involving the muscularis propria (B) (HE, x 100).

90 patients with ampullary carcinoids, 52 had a PPPD (majority > 2 cm), while 22 underwent a local resection (majority < 2 cm). Post-operative mortality was 3/52 in the PPPD group compared to 0/22 in the group with local resection<sup>[14]</sup>. Therefore, less radical approaches should be considered in highly differentiated, slow growing tumors. In relatively high surgical risk patients with a small, non-metastatic tumor, local excision seems to be a reasonable operative choice, whereas the least invasive approach should be reserved for those who are not surgical candidates. An endoscopic ampullectomy which seems to be an effective treatment in the management of ampullary adenomas, could also be a viable option in selected patients with tumors *in situ* (Tis)<sup>[15]</sup> and carcinoids of the ampulla of Vater, without vascular invasion.

### Abstract

We describe a rare case of the transformation of a dysplastic nodule into well-differentiated hepatocellular carcinoma (HCC) in a 56-year-old man with alcohol-related liver cirrhosis. Ultrasound (US) disclosed a 10 mm hypoechoic nodule and contrast enhanced US revealed a hypovascular nodule, both in segment seven. US-guided biopsy revealed a high-grade dysplastic nodule characterized by enhanced cellularity with a high N/C ratio, increased cytoplasmic eosinophilia, and slight cell atypia. One year later, the US pattern of the nodule changed from hypoechoic to hyperechoic without any change in size or hypovascularity. US-guided biopsy revealed well-differentiated HCC of the same features as shown in the first biopsy, but with additional pseudoglandular formation and moderate cell atypia. Moreover, immunohistochemical staining of cyclase-associated protein 2, a new molecular marker of well-differentiated HCC, turned positive. This is the first case of multistep hepatocarcinogenesis from a dysplastic nodule to well-differentiated HCC within one year in alcohol-related liver cirrhosis.

### INTRODUCTION

In Western countries and in Japan, hepatocellular carcinoma (HCC) usually develops in close association with pre-existing liver cirrhosis (LC). The cirrhotic liver is therefore believed to have a precancerous lesion recognizable as a small nodule, referred to as the dysplastic nodule<sup>[1]</sup> or adenomatous hyperplasia<sup>[2]</sup>. The mean size of most dysplastic nodules is 7-8 mm, seldom larger than 20 mm in diameter. Among LC cases, the dysplastic nodule is usually hepatitis C virus (HCV)-related, rarely hepatitis B virus (HBV)-related, and has not been reported as alcohol-related. HCC usually develops in chronic liver diseases such as HCV and HBV. In Japan, HCC occurs in 81% of HCV and 14% of HBV carriers<sup>[3]</sup>, but seldom in alcohol-related LC, whereas in the United States HCC occurs in 30% of alcohol-related LC<sup>[4]</sup>. Herein we describe a rare case of multistep hepatocarcinogenesis from a dysplastic nodule to well-differentiated HCC in a patient with alcohol-related LC.

### CASE REPORT

A 56-year-old man was admitted to Kobe Asahi Hospital in April 2005 for further examination of a 10 mm hypoechoic nodule in the liver. In April 2001, histologic analysis of tissue obtained at biopsy because of his abnormal liver function had revealed alcohol-related LC (Figure 1); no nodule was detected. His alcohol consumption over 35 years was 120 mL/d. A physical examination on admission in April 2005 showed no remarkable abnormalities. There was no evidence of

**Figure 1** Histological features of liver biopsy (April 2001), alcohol-related liver cirrhosis, micronodular liver cirrhosis with fatty change (HE  $\times$  100).

**Figure 3** Histological features of US-guided liver biopsy of the liver. **A:** High grade dysplastic nodule (April 2005): increased cellularity with a high N/C ratio, increased cytoplasmic eosinophilia, and slight atypia (HE  $\times$  200); **B:** Non nodular lesion (HE  $\times$  200) (April 2005), well-differentiated HCC (May 2006): increased cellularity with a high N/C ratio, increased cytoplasmic eosinophilia, moderate atypia, and pseudoglandular formation (arrow) (HE  $\times$  200); **C:** Non-nodular lesion (May 2006); **D:** Immunohistochemical finding (May 2006) (HE  $\times$  200), CAP2 positive HCC cells are observed (more than 30%); **E:** Immunohistochemical finding (May 2006) (HE  $\times$  200): Liver cirrhosis is negative for CAP2; CAP2 positive HCC cells are observed (more than 30%); **F:** Immunohistochemical finding (May 2006) (HE  $\times$  200): Liver cirrhosis is negative for CAP2.

lymph adenopathy or splenomegaly. The serum was negative for HCV antibody (anti-HCV), hepatitis B surface antigen (HBsAg), and hepatitis B core antibody (anti-HBc). Laboratory data on admission in April 2005 disclosed the following abnormal values: platelets  $7.1 \times 10^4/\mu\text{L}$  (normal 13.1-36.2), aspartate aminotransferase 88 IU/L (8-38),  $\gamma$ -glutamyl transpeptidase ( $\gamma$ -GTP) 677 IU/L (16-84), total bilirubin 1.4 mg/dL (0.2-1.0), and indocyanine green (ICG) 15 min retention rate 35% (0%-10%). Alpha-fetoprotein (AFP), lens culinaris agglutinin A-reactive fraction of alpha fetoprotein (AFP L3) and protein-induced vitamin K absence (PIVKA II) were within normal ranges. Immunological examinations revealed the following: IgG 1452 mg/dL (870-1700), IgM 235 mg/dL (33-190), IgA 207 mg/dL (110-410), B cell 8% (14%-13%), T cell 83% (66%-89%), CD4/CD8 ratio 2.08 (0.40-2.30), and NK cell activity 50% (18%-40%). Ultrasound (US) disclosed a 10 mm hypoechoic nodule in segment seven (S7) (Figure 2A). Plain computed tomography (CT) did not show any nodule, and contrast enhanced CT and magnetic resonance imaging (MRI) did not reveal any enhanced nodule. MRI revealed an isointensive nodule at both T1- and T2-weighted sequences. CT hepatic arteriography (CTA) did not show any enhanced nodule, and CT during arterial portography

**Figure 2** **A:** US imaging (April 2005). A 10 mm hypoechoic nodule in S7; **B:** contrast enhanced US (April 2005). Hypovascularity in the early phase; **C:** US imaging (May 2006). A 10 mm hyperechoic nodule in S7.

(CTAP) did not show any perfusion defect. Contrast enhanced US revealed a hypovascular nodule (Figure 2B). A US-guided biopsy revealed a high grade dysplastic nodule characterized by increased cellularity with a high N/C ratio, increased cytoplasmic eosinophilia, and slight cell atypia (Figure 3A and B). Immunohistochemical staining of both heat shock protein (HSP) 70 and cyclase-associated protein (CAP) 2 was negative.

In May 2006, the US pattern of the nodule changed from hypoechoic to hyperechoic (Figure 2C), although the size of the nodule did not change. Contrast enhanced US revealed a hypovascular nodule, and AFP, AFP L3, and PIVKA II were within normal ranges. The findings of imaging studies including contrast enhanced CT and MRI were all the same as in April 2005. A US-guided biopsy revealed well differentiated HCC of the same features as those in April 2005 with additional pseudoglandular formation and moderate cell atypia (Figure 3C and D). Immunohistochemical staining of CAP2 was over 30% positive (Figure 3E and F), although HSP70 staining was negative.

## DISCUSSION

According to the classification by the International Working Party of the World Congress of Gastroenterology, hepatic nodules in patients with chronic liver diseases are subdivided into regenerative nodules (mono acinus and multi acinus), low-grade dysplastic nodules, high-grade dysplastic nodules, well-differentiated HCC, moderately-differentiated HCC, and poorly-differentiated HCC, in an ascending order of histologic grades, representing a sequence of multistep hepatocarcinogenesis<sup>[1]</sup>.

It is often difficult-even for the hepatopathologist - to differentiate among regenerative nodules, precancerous lesions, and early HCC, especially from the examination of biopsy specimens. Therefore, the uncovering of an

objective molecular marker that would help to standardize histological diagnosis of early HCC and to lead to appropriate treatment is eagerly anticipated. Also, the molecular mechanisms of hepatocarcinogenesis are far from clear. A molecular understanding of multistep hepatocarcinogenesis is an important step toward the identification of additional biomarkers and new therapeutic targets of a greater specificity for HCC management. Diagnosis is based on histologic analysis of liver samples for identifying cytoarchitectural features (cell atypia, increased cellularity, increased cytoplasmic eosinophilia, fatty change, pseudoglandular formation, trabecular thickness, etc) and on information from immunocytochemical staining, such as that with HSP70<sup>[5]</sup>, and CAP2<sup>[6]</sup>.

Chuma *et al*<sup>[5]</sup> have found several up-regulated genes involved in HCC progression by comparing expression profiles among early and progressed components of seven nodule-in-nodule-type HCCs (1 HBV-positive case, 5 HCV-positive cases and 1 negative for both B and C) and their corresponding non-cancerous liver tissues, with the use of an oligonucleotide array: HSP70 (a molecular marker of early HCC) and CAP2, with up-regulated expression in a stepwise manner in multistage hepatocarcinogenesis<sup>[6]</sup>.

Immunohistochemically, HSP70 is significantly overexpressed in early HCC compared with its expression in dysplastic nodules, reaching 80% in most cases of well-differentiated HCC<sup>[5]</sup>.

All cases of dysplastic nodules were negative or focally positive (about 5%-10% of the lesions) for CAP2; in contrast, most cases of HCC (27 of 29 cases) were positive for CAP2, to some extent. Of the lesions, 70%-100% were positive in the progressed components, and the positivity of well-differentiated HCC ranged from 10% to 100%<sup>[6]</sup>.

In our case, although CAP2 staining of the first biopsy (April 2005) was negative, that of the second (May 2006) was positive over 30%. Histopathologically, the distinct difference between the two biopsies was the pseudoglandular formation and the moderate cell atypia of the second biopsy that are specific to well-differentiated HCC.

Consequently, we made the definite diagnosis of a high-grade dysplastic nodule after the first biopsy and a well-differentiated HCC after the second biopsy.

In our case, immunohistochemical staining of HSP70 was negative in the second biopsy, whereas that of CAP2 was positive. One explanation for this discrepancy is the difference in the positivity of immunohistochemical staining of well-differentiated HCC between HSP70 (72%)<sup>[5]</sup> and CAP2 (93%)<sup>[6]</sup>.

It is well accepted that HCC can in a multistep manner develop from a dysplastic nodule<sup>[7,8]</sup> into HCC. Among LC cases, the dysplastic nodule is usually HCV-related, rarely HBV-related, and has not been reported as alcohol-related. Similarly, multistep hepatocarcinogenesis from a dysplastic nodule to well-differentiated HCC is usually HCV-related, rarely HBV-related, and has not been reported as alcohol-related<sup>[4]</sup>.

In April 2001, no nodule was detected; in April 2005, a 10 mm hypoechoic nodule with the background of

alcohol-related LC appeared in S7. Imaging studies by contrast enhanced US, CT, MRI, CTA, and CTAP revealed a hypovascular nodule compatible with a dysplastic nodule or well-differentiated HCC. The histopathological findings revealed a high-grade dysplastic nodule. In May 2006, the US pattern of the nodule changed from hypoechoic to hyperechoic without any change in size, and the imaging findings other than US were all the same as those in April 2005. Tumor markers such as AFP, AFP L3 and PIVKA II were within normal ranges. The histopathological findings of the hyperechoic nodule revealed well-differentiated HCC. Alcohol abuse in some cases induces hyperplastic nodules that are usually associated with hypervascularity<sup>[9-11]</sup> and that are often misdiagnosed as HCC from imaging studies, as are dysplastic nodules from histopathological findings. Hyperplastic nodules do not, however, transform to HCC and often disappear subsequent to discontinued alcohol intake. The dysplastic nodule in our case is, in this respect, different from the hyperplastic nodule associated with hypervascularity. The clinical course of the patient showed multistep hepatocarcinogenesis from a dysplastic nodule to well-differentiated HCC within one year with the background of alcohol-related LC. The mechanism by which alcohol causes HCC is not known, but has been hypothesized to include oxidative stress, changes in retinoic acid metabolism and DNA methylation, decreased immune surveillance and genetic susceptibility<sup>[4]</sup>. The former three factors are common in patients with alcohol abuse. The latter two factors are specific to patients with individual differences of alcohol intake. In this case immunological examinations including immunoglobulin, the percentage of B cells and T cells, CD4/CD8 ratio, and NK cell activity were within almost normal limits. Therefore, one explanation for the transformation from a dysplastic nodule to an HCC may be genetic susceptibility that was not examined at the time.

To the best of our knowledge, this is the first case of multistep hepatocarcinogenesis from a dysplastic nodule to a well-differentiated HCC in alcohol-related LC.

Further study is needed to clarify the objective criteria for the definite diagnosis of dysplastic nodules and well-differentiated HCC, and the precise mechanism of hepatocarcinogenesis in alcohol-related LC.

## Abstract

Schwannoma is a myelin sheath tumor complicated with neurofibroma, neurofibromatosis and neurogenic sarcoma. Peripheral nerve sheath tumors represent 2%-6% of gastrointestinal tract stromal tumors (GIST), but there are deficient data about location of neurogenic tumors in the biliary system and only nine cases of schwannoma of the extrahepatic biliary tract have been reported. These tumors are clinically non-specific. They are usually symptomatic by compressing the close or adjacent structures when being retroperitoneal, and their preoperative diagnosis is extremely difficult. This paper reviews the literature data and describes a case of schwannoma of the common bile duct associated with cholestasis in a healthy young woman, diagnosed and treated in our department. This case is of interest on account of the complexity of its diagnosis and the atypical macroscopic growth pattern of the tumor.

**Key words:** Schwannoma; Neurinoma; Common bile duct; Biliary tract

## INTRODUCTION

Myelin sheath tumors comprise schwannoma, neu-

rofibroma, neurofibromatosis and neurogenic sarcoma. More than 90% are benign<sup>[1]</sup> and present in young to middle-aged subjects (twice in women than in men). They are usually asymptomatic and hence discovered incidentally<sup>[2]</sup>. Schwannoma is more common than neurofibroma. Its origin is often single. The 10% with a multiple origin<sup>[3]</sup> are classified as neurofibromatosis II, a disorder of autosomal dominant inheritance<sup>[4]</sup>. When located in gastrointestinal tract, schwannoma, leiomyoma, leiomyosarcoma and leiomyoblastoma constitute the gastrointestinal stromal tumors (GIST)<sup>[5]</sup>. Peripheral nerve sheath tumors account for 2%-6% of the GIST, but there are few reports of neurogenic tumors in the biliary system. The retroperitoneum is rarely involved<sup>[6]</sup>. Schwannomas arise only occasionally in the extrahepatic ducts and provoke symptoms by compressing adjacent structures<sup>[7]</sup>. Their symptoms were so varied to make their preoperative diagnosis very difficult. A cholestatic syndrome in a healthy woman is described in this report.

## CASE REPORT

The patient was a 41-year-old woman who presented with ingravescant pruritus lasting one month, a 4 kg weight loss and scleral subicterus. Her clinical and family history were devoid of significance. There was no history of drug intake. The physical examination evidenced a normal spleen and the absence of lymphadenopathies in the explorable sites. There was evidence of diffuse scratching lesions on the lower limbs and subicteric sclerae.

Laboratory results: RBC  $4.49 \times 10^6/L$  (4.2-5.4), WBC  $4.76 \times 10^3/L$  (4-10), hemoglobin 14.4 g/dL (12-16), ESR 21 mm/s, PCR 0.76 mg/L (< 3), LDH 412 U/L (313-618), total proteins 8.7 g/dL (6.3-8.2), total bilirubin 2.1 mg/dL (0.2-1.3), conjugated bilirubin 1.4 mg/dL (0-0.4), bile acids 6.8  $\mu\text{mol/L}$  (0-6), AST 90 U/L (< 40), ALT 161 U/L (9-56), GGT 290 U/L (12-58), ALPh 192 U/L (38-126), amylase 60 U/L (30-110), antimitochondrial antibody negative, CEA 1.3 ng/mL (< 5), CA 19-9 48.5 U/mL (< 37), CA-125 39.6 U/mL (< 35).

A CT scan (Figure 1A) revealed a lesion between the head of the pancreas and the gall bladder infundibulum near to the middle segment of the common bile duct. The mass was heterogeneous with a diameter of 3 cm. The upstream bile ducts were slightly dilated. The gall bladder was overdistended and contained a 2 cm stone in the fundus. Cholangio-MRI with the secretin test (Figure 1B-D) disclosed a hypointensive signal in the weighted

**Figure 1** A: CT scan showing a very heterogeneous formation with a liquid content in close contiguity to the CBD (white arrow); B, C, D: Cholangio-MRI reveals a solid formation with a hypointense signal in the weighted T1 sequences at the pancreatic isthmus (white arrows) with dilation of the upstream bile ducts.

**Figure 2** Intraoperative view of involvement of the intermediate tract of the common bile duct between its confluence with the cystic duct (A) and the prepancreatic tract (B) and (C) Gross inspection showing that the lesion (arrows) is solid and situated intramurally and below the mucosa in close contiguity with the CBD.

T1 sequences. The mass was assigned to the pancreatic isthmus. Its size and lack of uniformity were confirmed and a neoplastic origin was suspected. A good response to secretin showed that the function of the pancreas was unimpaired. Biliopancreatic echoendoscopy ruled out involvement of the pancreas, confirmed distention of the gall bladder and disclosed a solid, non-vascularised formation with many anechogenic areas. Its contiguity with the portal axis rendered percutaneous biopsy inadvisable and exploratory laparotomy was performed. The formation involved the intermediate tract of the common bile duct between its confluence with the cystic duct and the prepancreatic tract (Figure 2A). The middle segment of the common bile duct was resected, together with the gall bladder (overdistended, but uninflamed) and the lymph nodes. A bilio-digestive Roux-en-Y anastomosis was performed on the loop. Gross inspection showed an intramural lesion under the mucosa with a diameter of 4 cm (Figure 2B and C). Histological examination revealed the proliferation of interwoven bundles of fused cells, occasionally separated by slacker, oedematous areas with

a pseudocystic appearance (Figure 3A). There were also a few cells with an hyperchromic, atypical and bizarre nucleus (Figure 3B), ectatic, congested and partially thrombosed vessels (Figure 3C), and signs of perivascular hyalinisation (Figure 3D).

Immunohistochemical investigation showed that the tumor cells were vimentin and protein S-100 positive, and alpha-actin, desmin, CD34, cytokeratin pan (clone ARE1/E3) and CD117 negative. The postoperative course was uneventful. The cholestatic and hepatic cytolytic indices normalised after two months, with definite disappearance of pruritus, which continue to be normal after one year.

## DISCUSSION

Schwannoma of the bile ducts is particularly rare, and it usually arises in the head, neck, spinal cord and the extremities<sup>[8]</sup>, but rarely in retroperitoneum (6% of primary retroperitoneal tumors)<sup>[9]</sup>. It is usually located in the paravertebral regions or in the pre-sacral pelvic zone<sup>[2,10]</sup>. The bladder and abdominal wall are occasionally involved.

**Figure 3** **A:** Histological examination showing that inter-woven bundles of fused cells separated by slacker, oedematous areas with a pseudocystic appearance (Antoni A schwannoma growth pattern); **B:** Histological examination showing a few cells with hyperchromatic, atypical and bizarre nuclei. Histological examination showing a few cells with hyperchromatic, atypical and bizarre nuclei; **C:** Histological examination showing hyalinisation and ectatic and partially thrombosed vessels; **D:** Histological examination showing perivascular hyalinisation.

Liver, rectal colon and esophageal involvement has been described<sup>[11-14]</sup>, whereas only nine cases of schwannoma of the extrahepatic biliary tract and one case of benign schwannoma in the hepatoduodenal ligament have been reported since the 1970s<sup>[7,15-23]</sup>. Determination of tumor location must be done with great care when mass exists between the liver and the retroperitoneum, especially when the mass is hypovascular. Pre-surgical diagnosis of the tumor is very difficult because early clinical detection is limited until it gives a palpable mass or compresses the surrounding organs<sup>[6]</sup>.

Diagnosis is usually entrusted to CT and MRI. The gastrointestinal schwannomas appeared as a round or oval homogeneously attenuating, well-defined mass with frequent signs of degeneration, such as cysts and calcifications on CT<sup>[24]</sup>. Recently it was reported that CTs do not reveal tumor capsule, cystic change, necrosis or calcification in any of the observed schwannomas<sup>[25]</sup>. Weighted T1 images disclose masses with low-medium signal intensity, whereas this is high in the weighted T2 images owing to alternation of the Antoni A and B areas and secondary degeneration<sup>[26]</sup>.

In the present case, CT illustrated a hypodense and very heterogeneous formation initially referable to duodenal diverticulum. The MRI images were marked by slight weighted T2 hyperintensity due to the partially fluid content. A good response to secretin showed that the function of the pancreas was unimpaired.

We did not employ PET with fluorodeoxyglucose (FDG) uptake since it has been widely used to quantify the metabolism of malignant bone and soft-tissue malignant tumors, whereas little is known about FDG uptake in benign lesions. FDG PET is of limited value for the preoperative differentiation of schwannoma versus sarcoma<sup>[27]</sup>. Thus, a high FDG uptake is rather common in

schwannoma<sup>[28]</sup>.

The macroscopic growth pattern of the tumor mass was atypical. The two schwannoma growth patterns are called Antoni A and Antoni B. Elongated cells form an irregular, but compact palisade and the tissue arrangement is loose and there are cystic spaces between the cells<sup>[29]</sup>. In some cases, insufficient vascularisation of the mass may lead to degeneration in the form of cysts, calcifications, haemorrhages and hyalinisation<sup>[30]</sup>. These degenerative tumors are called “ancient schwannomas”. Morphologic and immunophenotypic features of the lesion pointed to a so-called “ancient schwannoma”, with reactive lymph nodes as described in the literature<sup>[31]</sup>. Digestive tract schwannomas are different from their soft tissue counterpart; they are not encapsulated and have an intramural growth pattern. Moreover, they are different both histologically and immunohistochemically from peripheral schwannomas. Gastrointestinal schwannomas, as in our case, are usually negative for CD34, CD117 and muscle cell markers, whereas they are strongly positive for vimentin and S100 protein. This typical combination differentiates schwannomas of the digestive tract from GIST. This differentiation is of practical importance. Gastrointestinal schwannomas are benign and associated with a good prognosis since post-surgical recurrences are unusual<sup>[32]</sup>, even when treated only with enucleation. Gastrointestinal stromal tumors, on the other hand, present a negative course in more than 50% of the cases<sup>[33,34]</sup>.

The distinctive feature of this case is the complexity of its diagnosis. Conventional radiography was unable to provide a precise picture of the nature and location of the mass. A diagnosis deduced from the instrumental finding often awaits intraoperative and definitive histological

confirmation<sup>[6]</sup>. Despite its complications, resection remains the treatment of choice. In the present case, only explorative laparotomy was able to demonstrate the seat and the nature of the lesion.

Lastly, in our case the postoperative course was uneventful and the cholestatic symptoms regressed two months after the operation.

### Abstract

Gastrointestinal duplication is a congenital rare disease entity. Gastric duplication cysts seem to appear even more rarely. Herein, two duplications cysts of the stomach in a 46 year-old female patient are presented. Abdominal computed tomography demonstrated a cystic lesion attached to the posterior aspect of the gastric fundus, while upper gastrointestinal endoscopy was negative. An exploratory laparotomy revealed a non-communicating cyst and a smaller similar cyst embedded in the gastrosplenic ligament. Excision of both cysts along with the spleen was performed and pathology reported two smooth muscle coated cysts with a pseudostratified ciliated epithelial lining (respiratory type).

### INTRODUCTION

Gastrointestinal duplications are rare and even more exceptional are those occurring in the stomach. As a general definition, a gastrointestinal duplication is a

spherical hollow structure with a smooth muscle coat, lined by a mucous membrane and attached to any part of the gastrointestinal (GI) tract from the base of the tongue to the anus<sup>[1]</sup>. These malformations are believed to be congenital and are formed before differentiation of the lining epithelium and, therefore, are named for the organs with which they are associated<sup>[2]</sup>. Foregut duplications may or may not communicate with the GI tract and usually are diagnosed in a younger age; in adults non-specific symptoms delay diagnosis, which is established during surgical exploration<sup>[3]</sup>. Herein, two gastric duplication cysts with respiratory epithelium are reported.

### CASE REPORT

A 46-year-old female patient was admitted to our Surgical Department from another medical center, where the patient was evaluated for an episode of loss of consciousness. Past medical history, present status and physical examination were non disease-specific. Diagnostic workup included an abdominal computed tomography (CT) which demonstrated a cystic lesion measuring 6 cm × 6 cm × 7 cm attached to the posterior wall of the gastric fundus, was well circumscribed and had no contrast enhancement (Figure 1). Interestingly CT coronary sections revealed a pulmonary sequestration in the basal segment of the left lower lobe (Figure 2). Moreover, upper GI endoscopy showed a bulging deformation of the gastric fundus by an extrinsic mass, without any mucosal abnormalities. An exploratory laparotomy was performed and revealed two cystic lesions; the first was attached to the fundus of the stomach and the second was embedded within the gastrosplenic ligament, close to the spleen. Therefore, intact excision of both cysts and splenectomy were carried out. Postoperative course was uneventful and the patient has been asymptomatic since then.

Pathologic examination of the surgical specimens reported a large cyst, measuring 8 cm × 5.5 cm in diameter and 0.3 cm thick and a smaller cyst (removed from the gastrosplenic ligament), measuring 3 cm in diameter and 0.2 cm thick. Both consisted of a smooth muscular wall, were lined by a pseudostratified, ciliated and columnar (respiratory type) epithelium and contained a clear, gelatinous fluid. Sub-epithelium seromucous glands were microscopically identified (Figure 3), a histologic appearance reminiscent of bronchial wall; however no cartilage was present.

**Figure 1** Abdominal CT scan demonstrating a cystic lesion attached to the posterior gastric wall (black arrow) and a pulmonary sequestration in the left pulmonary base (white arrow).

**Figure 2** Coronal CT plate showing the pulmonary sequestration of the basal segment of the left lower lobe (arrow).

**Figure 3** Histological section of the cyst wall lined by a respiratory-type epithelium and containing seromucinous glands (HE, x 100).

## DISCUSSION

Gastric duplications account for between 3% and 20% of gastrointestinal duplications<sup>[2,4,5]</sup> and occur twice as frequent in females as in males. Controversy exists over the embryological origin of these anomalies. Duplications of the stomach are usually single, less than 12 cm in diameter and located on the greater curvature or on the posterior or anterior gastric wall<sup>[2]</sup>. Wiczeorek *et al*<sup>[6]</sup> reported that gastric duplications can be tubular or cystic; the cystic type does not communicate with the gastric lumen (about 80% of gastric duplication cysts<sup>[7]</sup>). The first case report of a gastric duplication was published in 1911 by Wendel<sup>[8]</sup> and approximately 150 cases have been reported since then<sup>[2]</sup>.

Due to their position and mass effect, gastric duplications cysts are usually diagnosed in a younger age. However, in adults diagnosis may be difficult. A wide range of symptoms and signs have been reported and vary from asymptomatic to non disease-specific presentations, e.g. vague abdominal complaints, nausea, vomiting, epigastric fullness, weight loss, anemia, dysphagia, dyspepsia, etc. Vomiting usually occurs due to partial or complete gastric outlet obstruction, while even more emergent cases have been reported such as pancreatitis<sup>[9]</sup>, hemoptysis<sup>[10]</sup> and gastrointestinal hemorrhage<sup>[11]</sup>. In our case, the female patient presented with loss of consciousness due to de-

hydration occurring as a result of excessive vomiting and concomitant anemia. Associated pathologic conditions including pulmonary sequestration<sup>[12]</sup>, multicystic kidney<sup>[13]</sup> and neoplasias<sup>[14]</sup> have been reported. The presence of respiratory type mucosa and seromucinous glands along with the presence of pulmonary sequestration in the lower lobe of the ipsilateral lung in our case supports the theory of embryologic origin from supernumerary foregut buds.

Foregut duplications cysts of the stomach are usually incidentally diagnosed. Although upper gastrointestinal series demonstrate external pressure on the stomach, preoperative workup mainly includes abdominal ultrasonography and computed tomography scans, as well as endoscopic ultrasonography and magnetic resonance imaging<sup>[15,16]</sup>.

Due to malignant transformation and the report of gastric cancer arising in duplications of the stomach<sup>[17]</sup>, surgical excision is considered to be the best treatment. Complete resection of the cyst is the ideal technique achieved with both open and laparoscopic<sup>[18]</sup> approaches. Unsuccessful approaches including percutaneous or endoscopic aspiration of cystic fluid have been reported<sup>[19]</sup>, but are associated with complications, such as fistula formation and hemorrhage. When the recommended complete excision is not possible, converting both stomachs into one using a stapling device<sup>[20]</sup> or performing a segmental gastrectomy<sup>[21]</sup> are the possible alternatives.

In conclusion, foregut duplication cysts of the stomach are rare entities diagnosed incidentally and usually intraoperatively in adults and should be treated surgically by complete resection.

## Abstract

Small bowel metastases from primary carcinoma of the lung are very uncommon and occur usually in patients with terminal stage disease. These metastases are usually asymptomatic, but may present as perforation, obstruction, malabsorption, or hemorrhage. Hemorrhage as a first presentation of small bowel metastases is extremely rare and is related to very poor patient survival. We describe a case of a 61-year old patient with primary adenocarcinoma of the lung, presenting with melena as the first manifestation of small bowel metastasis. Both primary tumor and metastatic lesions were diagnosed almost simultaneously. Upper gastrointestinal endoscopy performed with a colonoscope revealed active bleeding from a metastatic tumor involving the duodenum and the proximal jejunum. Histological examination and immunohistochemical staining of the biopsy specimen strongly supported the diagnosis of metastatic lung adenocarcinoma, suggesting that small bowel metastases from primary carcinoma of the lung occur usually in patients with terminal disease and rarely produce symptoms. Gastrointestinal bleeding from metastatic small intestinal lesions should be included in the differential diagnosis of gastrointestinal blood loss in a patient with a known bronchogenic tumor.

## INTRODUCTION

Metastases affecting the small bowel and originating from carcinoma of the lung are rare, but recent reports suggest that they may be more frequent than previously thought as they rarely produce symptoms<sup>[1-3]</sup>.

The majority of patients with metastases of the small bowel reported in the literature, present with bowel perforation<sup>[2-4]</sup>. Overt gastrointestinal hemorrhage has been described in a few cases as a prelude to bowel perforation, whilst it has been described only rarely as the main presentation<sup>[5-7]</sup>.

We present a case of a 61-year old patient with upper gastrointestinal bleeding due to small bowel metastases from a primary adenocarcinoma of the lung with secondary deposits in the abdominal lymph nodes. Metastatic involvement of the duodenum presenting with melena has been described rarely in the literature.

## CASE REPORT

A 61-year old man was admitted to our hospital with a two-day history of melena. He reported a four-month history of weakness, anorexia, 5 kg loss of weight, cough, dyspnea on exertion, and blood-stained sputum, and a two-month history of fatigue and altered bowel habits. He was a cigarette smoker with chronic obstructive airway disease and arterial hypertension.

On examination he was pale, with normal blood pressure and pulse rate. He had wheezy breathing and decreased breath sounds in the upper right lung region. Melena was proved by digital examination.

Hematocrit was 35% and hemoglobin 9.5 g/dL. Chest x-ray demonstrated a density in the upper region of the right lower lobe. Endoscopy of the upper gastrointestinal tract up to the second part of the duodenum revealed erosive antral gastritis, but no active bleeding site. CT scan of the thorax disclosed an irregularly-shaped nodular mass measuring 4 cm in diameter, in the upper region of the right lower lobe of the lung. Bronchial biopsy revealed the presence of blood clots and desquamated bronchial epithelial cells, without signs of malignancy. The results of cytological examination of bronchial excretions, however, proved positive for non-small cell carcinoma of the lung. Staging of the disease followed by CT scan of the upper and lower abdomen and the retroperitoneal space showed multiple, enlarged bilateral para-aortic, and mesenteric

**Figure 1** Endoscopic appearance of a large hemorrhagic polypoid mass at the proximal jejunum, representing metastatic lung carcinoma.

**Figure 2** Gatherings of poorly-differentiated neoplastic cells invading the mucosal bed, and extending into the intestinal villi (long arrow), with sparing of the superficial epithelium (short arrow).

**Figure 3** Embolus of neoplastic cells in lymph vessels of the intestinal villi.

lymph nodes.

The patient was started on combined chemotherapy with cisplatin and hydrochloric gemcitabine. His bowel motions became normal by the third day of hospitalization and he was subsequently discharged, denying further investigation.

During admission for the second round of chemotherapy and one month after diagnosis, the patient complained of diffuse abdominal pain and tenderness. Shortly afterwards this was accompanied with hemodynamic instability and tachypnea. Melena was proved by digital examination. Hematocrit fell from 34% to 26%, hemoglobin from 9 g/dL to 6 g/dL, and serum urea/creatinine ratio was greater than 40 (urea being 60mg/dL and creatinine 1.3 mg/dL). Plain abdominal X-ray showed no abnormalities and the patient underwent endoscopy of the upper and lower gastrointestinal tract using a Pentax® 160 cm colonoscope for both examinations. In the 4<sup>th</sup> part of the duodenum three irregular, nodular protrusions of the mucosa measuring 0.5-1.5 cm in diameter were observed. They were friable and slightly hemorrhagic. At the proximal jejunum there was a larger hemorrhagic polypoid mass about 2.5 cm in diameter (Figure 1). Biopsies of these lesions revealed gatherings of poorly-differentiated neoplastic cells invading the mucosal bed and extending into the intestinal villi with sparing of the superficial epithelium (Figure 2). Infiltration of the lymph vessels was also noted (Figure 3). These findings were

consistent with metastatic disease. Immunohistochemical staining for keratins 8, 18, 19 and thyroid transcription factor 1 (TTF 1) as well as histochemical staining for periodic acid schiff (PAS) strongly supported the diagnosis of poorly-differentiated metastatic adenocarcinoma of the lung. Radiological examination of the small bowel was not completed due to patient discomfort. The patient was transfused with 3 units of packed erythrocytes and 3 units of fresh frozen plasma.

Only four cycles of chemotherapy were carried out due to deterioration of the patient. In addition, he received 4000 U of erythropoietin per week. Three months after his last episode of melena the patient continued to have occult upper gastrointestinal bleeding and was admitted on several occasions for blood transfusion. The patient died seven months after the diagnosis of end stage cancer of the lung.

## DISCUSSION

Small bowel metastases usually originate from primary carcinomas of the gastrointestinal or genital organs, and more specifically from the large bowel, uterus, cervix, ovaries, and testes. Thoracic malignancies metastasize less frequently to the small bowel. Apart from carcinoma of the lung, these also include malignant melanoma, carcinoma of the breast, carcinoma of the salivary glands, carcinoma of the esophagus, and rhabdomyosarcoma of the lung<sup>[1,8,9]</sup>.

Our patient had histologically-proven small intestinal lesions originating from primary lung adenocarcinoma. A review of the literature revealed few studies of patients with lung cancer and metastases to the small bowel. An extensive eleven-year study of patients with primary lung cancer revealed that at autopsy, 46 out of 431 patients (10.6%) had secondary deposits in the small bowel<sup>[1]</sup>. These patients had an average of 4.8 metastatic sites. A more recent study of patients with non-small cell carcinoma of the lung revealed small bowel metastases in 4.6% of cases<sup>[9]</sup>. It should be emphasized that all these cases had adenocarcinomas, with a disease stage greater than IIIA, as well as a minimum of two other metastatic sites before the development of bowel metastases. Another

large study involved 1399 patients with lung cancer who underwent surgical resection of the primary tumor<sup>[2]</sup>. This study revealed a much smaller percentage (0.5%) of symptomatic patients having small bowel metastases. In direct contrast to the previous study, which concludes that adenocarcinoma is the cell type resulting more frequently in small bowel metastasis, this study concludes that squamous cell carcinoma is the more frequent cause, accounting for 61% of cases.

Patients with primary lung cancer with metastases to the small bowel are usually asymptomatic<sup>[10,11]</sup>. Less frequently these metastases can cause symptoms which vary according to the way the metastatic tumor invades the bowel wall. Rapid tumor growth leads to symptoms of obstruction, although it seems that perforation occurs more commonly probably due to central tumor necrosis. Most cases of primary lung cancer and small bowel metastasis present with small bowel perforation<sup>[3,4,10]</sup>. According to a recent study, 98 cases of perforated lung cancer metastasis to the small intestine have been described in the literature since 1960<sup>[3]</sup>. When ulceration of the mucosa occurs the metastatic tumor may bleed, whilst large extension of tumor may lead to symptoms of malabsorption<sup>[1]</sup>.

Hemorrhage from a metastatic tumor in the small bowel is uncommon, explaining the absence of large studies on this issue. A small number of isolated cases, however, have been described. They describe patients over the age of 55 years, with primary lung carcinoma of large or small cell types, who have already developed distant metastases, and these patients usually present with acute hemorrhage from ulceration of the metastatic tumor, and less frequently with iron deficiency anemia, or with non-specific abdominal symptoms before the onset of melena<sup>[12-15]</sup>. In one case report, the patient presented with iron-deficiency anemia and melena, and the diagnosis of primary lung cancer was made after surgical resection of the intestinal metastasis, as no tumor evidence was found on chest x-ray<sup>[2]</sup>. The presence of small bowel metastases in this patient was confirmed by CT scanning, as upper and lower gastrointestinal endoscopies were negative.

A very small number of cases of upper gastrointestinal bleeding due to duodenal metastases from lung cancer have been reported<sup>[5-7,12]</sup>. Small intestinal metastases have been reported to occur more frequently in the jejunum and terminal ileum than the duodenum<sup>[2,3,16]</sup>. As in our case, metastatic lesions of the small bowel from lung carcinoma are usually multiple<sup>[1,11]</sup>.

Our patient is one of the very few cases described where melena as the first manifestation of small bowel metastasis, has arisen from the duodenum and jejunum<sup>[5-7,12,16]</sup>. Also it is interesting to note that the time interval was short between diagnosis of cancer and metastasis to the small bowel, as the patient presented with melena before the establishment of the diagnosis of lung carcinoma and was still in a good general state of health. The diagnosis of metastatic involvement of the small bowel was suspected, but not confirmed at the beginning. This emphasizes the importance of considering the presence of small bowel metastases in a patient with lung

cancer displaying symptoms of hemodynamic instability, melena, or abdominal symptoms such as dyspepsia, distention and pain, even if the time elapsed from the time of diagnosis of cancer is short. It should be noted that occult gastrointestinal bleeding must be suspected if laboratory investigations reveal iron deficiency anemia, or a fall in hematocrit or hemoglobin, even in an asymptomatic patient.

Gastrointestinal hemorrhage can usually be managed conservatively with intravenous fluids and red blood cell transfusion until the patient is hemodynamically stable and hemorrhage ceases. However, cases requiring surgical resection of small bowel in order to control massive hemorrhage have also been reported<sup>[12,16]</sup>. Only a few patients have survived more than 9 mo after surgical resection of intestinal metastases, with the exception of one patient who survived 22 mo after peritonitis<sup>[2]</sup>. Perioperative mortality has decreased considerably, and the question of whether surgery should be considered as palliative therapy not only for symptomatic patients remains to be solved. After hemorrhage from small bowel metastases, patient survival varies between several weeks to several months<sup>[6,13]</sup>. It seems that hemorrhage originating from small bowel metastases, is related to a very poor patient survival. The patient we presented, survived for a considerably long time (7 mo after his first episode of bleeding). During this period of time he continued to have microscopic bleeding requiring occasional blood transfusion. Active gastrointestinal bleeding from small bowel metastases has never been described as the cause of death in patients suffering from carcinoma of the lung.

In conclusion, small bowel metastases from primary carcinoma of the lung occur usually in patients with terminal disease and rarely produce symptoms. Hemorrhage as a first presentation of small bowel metastases is extremely rare, especially when these are located in the duodenum, with a poor prognosis. Gastrointestinal bleeding from metastatic small intestinal lesions should be included in the differential diagnosis of gastrointestinal blood loss in a patient with a known bronchogenic tumor.

## Abstract

We report here a case of clinically significant liver toxicity after a brief course of rosuvastatin, which is the first statin approved by the regulatory authorities since the withdrawal of cerivastatin. Whether rosuvastatin has a greater potential compared with other statins to damage the liver is unclear and the involved mechanisms are also unknown. However, rosuvastatin is taken up by hepatocytes more selectively and more efficiently than other statins, and this may reasonably represent an important variable to explain the hepatotoxic potential of rosuvastatin. Our report supports the view that a clinically significant risk of liver toxicity should be considered even when rosuvastatin is given at the range of doses used in common clinical practice.

## INTRODUCTION

Liver toxicity is a well recognized adverse effect of treatment with statins<sup>[1]</sup>. However pre-marketing studies have suggested that rosuvastatin may have a lesser potential to cause liver toxicity as compared with other statins<sup>[2]</sup>. We report here a case of clinically significant liver toxicity after a brief course of rosuvastatin.

## CASE REPORT

A 64-year-old man presented with a seven-days history

of malaise, anorexia, upper abdominal discomfort, and jaundice. Four months earlier the patient had an acute myocardial infarction that was treated with angioplasty and stenting of a culprit lesion in the right coronary artery; liver function tests were normal and he was discharged on clopidogrel, aspirin, metoprolol, ramipril, and atorvastatin (40 mg daily). One week later, rosuvastatin (10 mg daily) was prescribed instead of atorvastatin as the patient reported an itching skin rash that developed soon after he took the second tablet of atorvastatin; at that time serum levels of aspartate aminotransferase (AST) and alanine aminotransferase (ALT) were 55 U/L and 45 U/L (normal range 10-36 U/L for both), respectively, with bilirubin,  $\gamma$ -glutamyltransferase ( $\gamma$ -GT), and alkaline phosphatase (AP) within the normal limits.

At the present admission, he was fully alert and oriented, afebrile, with mild cutaneous and scleral jaundice, and no flapping tremor or stigmata of chronic liver disease; the remaining physical examination was normal. A laboratory work-up revealed AST 880 U/L, ALT 775 U/L, total bilirubin 2.6 mg/dL (normal range 0.2-1) with conjugated bilirubin 0.8 mg/dL;  $\gamma$ -GT, AP, ammonia,  $\alpha$ -fetoprotein, electrolytes, hematologic and coagulation parameters, and renal function tests were normal. Serological screening for viral hepatitis (hepatitis A, B, C, E and G virus; cytomegalovirus; herpes simplex; and Epstein-Barr virus) was negative and HBV-DNA and HCV-RNA were not detected in the peripheral blood. Search for autoimmune liver disorders (antinuclear antibodies, anti-smooth-muscle antibodies, and antimitochondrial antibodies) was also negative as were results of iron, copper, ceruloplasmin metabolism and  $\alpha$ 1-antitrypsin concentrations.

Ultrasonography and contrast-enhanced computed tomography (CT) showed a normal liver and no expanded bile ducts or gallbladder abnormalities; there was no caval or portal thrombosis and no peri-hepatic or perisplenic intraperitoneal fluid. Echocardiography was also normal with no evidence of valvular disease, pericardial effusion, pulmonary hypertension, or left ventricular systolic or diastolic dysfunction.

The patient had an otherwise unremarkable medical record with no previous history of acute or chronic liver disease. He also denied toxic and alcoholic habits or using any other medications, including over-the-counter medications, or herbal remedies.

Rosuvastatin was withdrawn and AST and ALT levels fell to 216 U/L and 198 U/L, respectively, and bilirubin to 1.8 mg/dL on the 3<sup>rd</sup> day; ammonia and coagulation parameters remained within the normal range. Over the subsequent course symptoms gradually resolved, which

was paralleled by declining levels of liver enzymes and bilirubin; at no time were flapping tremor or other signs or symptoms of liver failure or encephalopathy observed and the patient was discharged on the 6<sup>th</sup> day with instructions for close follow-up as an outpatient. At that time, AST and ALT were 40 U/L and 32 U/L, respectively; bilirubin, ammonia, and coagulation parameters were normal. The patient refused a liver biopsy and a re-challenge test with rosuvastatin was not done for ethical reasons. At a follow-up visit two weeks later, he was doing well with normal liver function tests and a normal coagulation profile. The clinical and biochemical course of this patient is summarized in Figure 1.

## DISCUSSION

Until today the incidence of elevated serum liver enzymes among patients on treatment with statins generally ranges from 2% to 3%<sup>[1]</sup> while pre-marketing studies have shown a 20 to 30-fold lower incidence if rosuvastatin is used<sup>[2]</sup>. We report here a case of clinically significant liver toxicity after a brief course of rosuvastatin, which is the first statin approved by the regulatory authorities since the withdrawal of cerivastatin. According to the Naranjo probability scale our patient had a highly probable rosuvastatin-related adverse event<sup>[3]</sup>; furthermore, liver function tests were normal before statin treatment was started and we did not find any other plausible alternative cause to explain the onset of such a severe hepatitis in this case. As a matter of fact, we identified a clear temporal relationship between initiation of rosuvastatin therapy and the elevation of liver enzymes and the patient rapidly achieved a complete clinical and biochemical recovery after rosuvastatin was interrupted.

The episode of urticaria accompanied by a modest increase of liver enzymes after the patient was given atorvastatin, which was his first exposure to a statin, raises the view of an idiosyncratic or hypersensitivity cross-reaction between atorvastatin and rosuvastatin as an underlying mechanism of the liver injury that occurred during treatment with rosuvastatin. Even though the true correlation remains to be understood, we might reasonably conceive that allergic cross-reactions between the two statins might have contributed, at least to a certain extent, to the onset of severe liver damage in this case. Our patient had normal eosinophil count and remained afebrile throughout the entire course. However all these features along with the absence of lymphadenopathy and the negative search for antinuclear and anti-smooth-muscle antibodies do not substantially argue against an allergic or immune-mediate mechanism of liver injury.

The patient was also receiving other medications in combination with rosuvastatin, but this is not a true confounding factor in our opinion. Our Medline search yielded only a few anecdotal reports of hepatitis associated with the use of clopidogrel or ramipril<sup>[4-7]</sup> and none of liver toxicity linked with metoprolol. In addition, aspirin-related hepatitis has been described, but this is a dose-related phenomenon caused by the intrinsic salicylate hepatotoxicity which generally does occur only when aspirin is given in full anti-inflammatory doses and not

Figure 1 Course of liver enzymes and exposure to statins and other medications.

with the 75-300 mg used for anti-platelet indications<sup>[8]</sup>. One important point is that rosuvastatin is neither an inhibitor nor an inducer of cytochrome P450 isoenzymes and rosuvastatin itself is a poor substrate for these isoenzymes. It suggests that fewer drug interactions resulting from cytochrome P450-mediated metabolism should be expected with rosuvastatin compared with other statins<sup>[9,10]</sup>. There is no available evidence of any clinically significant pharmacokinetic interactions in subjects taking concomitant rosuvastatin and clopidogrel, ramipril, metoprolol, or aspirin.

Whether rosuvastatin has a greater potential compared with other statins to damage the liver is unclear and the involved mechanisms are also unknown. Results from a recent meta-analysis demonstrate that treatment with statins as a class is not associated with a significant risk of liver dysfunction and hepatitis, but studies with rosuvastatin were not included in this meta-analysis<sup>[11]</sup>. In contrast, a post-marketing analysis has shown that use of rosuvastatin, at least over its first year of marketing, was significantly more likely than atorvastatin, pravastatin, and simvastatin to be associated with a composite end point of adverse events including rhabdomyolysis, proteinuria, nephropathy, and renal failure, and there was also a significant trend in favor of an increased liver toxicity with rosuvastatin compared with the other statins even though this was not targeted as the primary end point of the study<sup>[11]</sup>. Furthermore, rosuvastatin is taken up by hepatocytes more selectively and more efficiently than other statins, and this may reasonably represent an important variable associated with the hepatotoxic potential of rosuvastatin<sup>[12]</sup>.

Our report supports the view that a clinically significant risk of liver toxicity should be considered even when rosuvastatin is given at the range of doses used in common clinical practice.

### Abstract

Capsule endoscopy is an easy and painless procedure permitting visualization of the entire small-bowel during its normal peristalsis. However, important problems exist concerning capsule retention in patients at risk of small bowel obstruction. The present report describes a young patient who had recurrent episodes of overt gastrointestinal bleeding of obscure origin, 18 years after small bowel resection in infancy for ileal atresia. Capsule endoscopy was performed, resulting in capsule retention in the distal small bowel. However, this event contributed to patient management by clearly identifying the site of obstruction and can be used to guide surgical intervention, where an anastomotic ulcer is identified.

### INTRODUCTION

Capsule endoscopy allows direct visualization of the entire

small bowel in a noninvasive manner and has become the gold standard in evaluating suspected disease of the small bowel<sup>[1-4]</sup>. Capsule retention remains a major concern for physicians performing capsule endoscopy, since it can lead to a need for surgery to remove the capsule in a patient who otherwise might have been treated medically for the same illness. Nevertheless, it has been postulated that capsule endoscopy in certain patients with suspected small bowel obstruction, contributes to patient management by clearly identifying the site of obstruction and can be used to guide surgical intervention<sup>[5-7]</sup>.

### CASE REPORT

A 22-year old patient was admitted to our hospital for evaluation of recurrent episodes of overt gastrointestinal (GI) bleeding of obscure origin. The patient presented at birth with ileal atresia and underwent partial small bowel resection (excision of 30 cm of ileal loop sparing ileocaecal valve). He was reoperated three times during the first years of his life, initially due to anastomotic leak and subsequently twice for postoperative repair of fistulae. Since then, the patient had remained free of symptoms and developed normally. At the age of 18 years (in 2001), he had a severe episode of overt GI bleeding requiring blood transfusion, and two new bleeding episodes during the next two years. Upper and lower GI endoscopy, computed tomography of the abdomen, Meckel scintigraphy and enteroclysis, revealed no remarkable findings. In 2004 he had symptoms of incomplete intestinal obstruction, which resolved after conservative treatment. A new episode of GI bleeding with negative GI endoscopy requiring transfusion a few days before admission was the reason for referral to our unit, in order to carry out capsule endoscopy.

Because of his medical history, a patent capsule (Given Imaging Ltd., Yoqneam, Israel) was given prior to Pillcam SB, in order to avoid capsule retention. The patent capsule was impacted in the distal small bowel, causing temporary abdominal pain, which was confirmed by two abdominal X-rays on the second and forth day, as the patent capsule was detected at the lower abdomen to the middle line. On the sixth day, a new abdominal X-ray showed that the patent capsule was dissolved. Considering that the patent capsule stopped in a stenotic lesion, probably on the level of entero-enteric ileal anastomosis, surgical management

**Figure 1** PillCam SB enteroscopy showing the point of capsule retention (Bezoar).

**Figure 2** Plain abdominal film on the fifth day after capsule ingestion.

was decided. After discussion with the surgeons and based on data supporting that capsule endoscopy in patients with suspected small bowel obstruction can guide surgical intervention by identifying the site of obstruction<sup>[5]</sup>, capsule endoscopy was carried out after a written consent was obtained from the patient. Four sachets of PEG preparation were given the day before capsule endoscopy procedure was performed.

The capsule passed through the stomach, duodenum and jejunum in 2 h and 30 min, with no evidence of disease and remained impacted in an ileal loop, where a food bezoar was observed (Figure 1). Abdominal X-rays after 24 h and on the fifth day confirmed capsule retention (Figure 2). The patient was operated on the sixth day. Loose adhesions were identified and resected. The capsule was palpated 50 cm proximal to the ileocaecal valve, on the level of the entero-enteric anastomosis and an anastomotic ulcer causing stenosis was found after incision. Intraoperative enteroscopy through the incision point was performed in order to examine the ileal segment from the stenosis to the ileocaecal valve that was found normal. The lesion was resected (Figure 3) and histology demonstrated focal ulceration with chronic inflammation, but no evidence of granulomata, crypt abscesses or malignancy. The patient was discharged on the fifth postoperative day and remained asymptomatic 12 mo post-surgery.

## DISCUSSION

Atresia and stenosis are common birth defects affecting the small intestine, but few population-based studies have examined the epidemiology of small intestinal atresia and stenosis. It was reported that the rate of small intestinal atresia and stenosis is 2.9 per 10000 live births (I 95% CI = 2.3-3.6)<sup>[8]</sup>. Current operative techniques and contemporary neonatal critical care result in a 5% morbidity and mortality rate, with late complications not uncommon<sup>[9]</sup>. Protein-losing enteropathy and gastrointestinal bleeding due to anastomotic ulcer after 4-12 years have been reported<sup>[10]</sup>. Actually, gastrointestinal bleeding occurred in our patient due to anastomotic ulcer 18 years after small bowel resection. For these reasons, follow-up of these patients in their adulthood is recommended and physicians must be aware to identify and address these late occurrences<sup>[9]</sup>.

Capsule endoscopy is currently the preferred test for mucosal imaging of the entire small intestine<sup>[4]</sup>. When integrated into a global approach to the patient, capsule endoscopy can achieve effective decision-making,

**Figure 3** Surgical specimen with ulceration and retained PillCam SB capsule.

concerning subsequent investigations and treatments. Capsule retention remains the major concern for physicians performing capsule endoscopy, since retention could lead to a need for an otherwise unnecessary surgery to remove the capsule. As there is no accepted imaging method for completely avoiding capsule retention, it is clear that obtaining a good medical history is the best single method<sup>[11]</sup>.

Our patient had two risk factors for capsule retention: a history of previous small-bowel resection and a distant history of partial small-bowel obstruction. For these reasons, a patent capsule was given initially to the patient. The retention of patent capsule in the small intestine, confirmed our suspicions. Nevertheless, Cheifetz *et al*<sup>[5]</sup> showed that capsule retention in the small intestine could help a pre-decided operation by guiding the surgeons to clearly indentify the site of obstruction in patients with suspected small-bowel obstruction. Even though capsule endoscopy did not help us to diagnose a definite lesion, as we did not take clear images of the site of capsule retention, palpation of the capsule by the surgeons during operation, could lead them directly to the site of stenosis.

In conclusion, capsule retention is not always an adverse event, as in certain patients with suspected small bowel obstruction, the retained capsule can be used as a “guiding point” for a pre-decided surgical intervention.

## Abstract

Classical interferon-alpha has been shown to be correlated with the development of a variety of autoimmune disorders. A 38 year-old female patient developed simultaneously diabetic ketoacidosis and hyperthyroidism 5 mo following initiation of treatment with pegylated interferon- $\alpha$  and ribavirin for chronic hepatitis C. High titers of glutamic acid decarboxylase, antinuclear and thyroid (thyroid peroxidase and thyroglobulin) antibodies were detected. Antiviral treatment was withdrawn and the patient was treated with insulin for insulin-dependent diabetes mellitus and propranolol for hyperthyroidism. Twelve months after cessation of pegylated interferon- $\alpha$  therapy the patient was euthyroid without any medication but remained insulin-dependent.

## INTRODUCTION

Interferon-alpha (IFN- $\alpha$ ), a natural protein with anti-viral, anti-proliferative and immunomodulatory effects

is routinely administered in chronic hepatitis C (CHC). Classical IFN- $\alpha$  has been correlated with the development of a variety of autoimmune disorders including Hashimoto thyroiditis, immune-mediated thrombocytopenia, hemolytic anemia, psoriasis, rheumatoid arthritis, systemic lupus-like syndromes, primary biliary cirrhosis and sarcoidosis. The reported cumulative incidence of all autoimmune disorders ranged from 1% to 3%<sup>[1,2]</sup>.

Clinical thyroid disease has been reported to develop in 10%-15% of patients treated with IFN- $\alpha$  for CHC<sup>[3,4]</sup>. However, it was not established whether IFN- $\alpha$  treatment is associated with the development of insulin dependent diabetes mellitus (IDDM). The prevalence of diabetes mellitus development in patients receiving classical IFN- $\alpha$  for CHC is very low ranging from 0.08% to 0.7%<sup>[1,2]</sup>. The prevalence of pancreatic auto-antibodies appeared to rise from 3% to 7% prior to and following initiation of IFN- $\alpha$  treatment, respectively, in a review of 9 relative studies by Fabris *et al*<sup>[5]</sup>. In those studies different types of IFN- $\alpha$  and variable schedules were used.

Pegylated IFN- $\alpha$  has been recently approved for the treatment of CHC and has been associated with only a few cases of autoimmune thyroiditis<sup>[6]</sup>. We herein describe the simultaneous development of diabetic ketoacidosis and Hashitoxicosis in a patient treated with pegylated IFN- $\alpha$  for CHC.

## CASE REPORT

A 38-year-old female patient presented with a two fold increase of aminotransferases and positive hepatitis C virus (HCV) antibodies. HCV RNA was high ( $> 1\,000\,000$  copies/mL, genotype 1b) and liver histology revealed an activity grade of 4/18 and a fibrosis score of 3/6 according to Ishak's modified HAI classification system<sup>[7]</sup>. Treatment with pegylated IFN- $\alpha$ -2 $\alpha$  180  $\mu$ g/wk, in combination with oral ribavirin 1000 mg/d was initiated in February 2004. During treatment alanine aminotransferase (ALT) flares did not occur. Virological response (negative HCV RNA) was achieved at the fourth week of treatment.

In July 2004 the patient developed weakness and rapid weight loss up to 12 kg within 2 wk. Thyroid function tests revealed hyperthyroidism of autoimmune etiology, i.e. thyroid stimulating hormone (TSH): 0.008  $\mu$ IU/mL (normal values: 0.15-6.1), free triiodothyronine (FT<sub>3</sub>): 6.90 pg/mL (normal values: 2.03-4.6), free thyroxine (FT<sub>4</sub>): 1.8 ng/dL (normal values: 0.9-1.7), positive thyroid peroxidase

(anti-TPO > 1300 IU/mL, normal values < 2 IU/mL), thyroglobulin (anti-Tg 18.6 IU/mL, normal values < 2 IU/mL) and thyroid stimulating immunoglobulin antibodies (TSI 96%, normal values: 0.02%-15%). Propranolol was administered. A few days later the patient was admitted with clinical and laboratory features indicating diabetic ketoacidosis (blood glucose: 470 mg/dl, pH: 7.08, HCO<sub>3</sub>: 5 mmol/L). The antiviral treatment was withdrawn. Her clinical condition was improved with i.v. fluids and insulin therapy. Following normalization of the acute metabolic profile, intensive insulin therapy was recommended. The patient had no family history of diabetes mellitus. The HLA class II typing revealed a genetic predisposition to IDDM as demonstrated by the presence of type 1 diabetes associated DRB1\*03 (A\*01, A\*02/B\*08, B\*35/Cw\*04, Cw\*07, DRB1\*03, DRB1\*03/DQB1\*02) haplotype (Diabetes, Pathogenesis of type 1A Diabetes In: <http://www-endotext.com>). Glutamic acid decarboxylase (GAD) antibodies were strongly elevated (725.52 RU/units) whereas insulin autoantibodies (IA-2) were undetectable at the onset of IDDM (< 5.3 RU/units). Additional immunological profile showed positive antinuclear antibodies (> 1:640). All the other auto-antibodies including anti-smooth muscle, anti-dsDNA, anti-ENA, anti-RNP, anti-SSA, anti-SSB, p-ANCA, c-ANCA, anti-MPO, anti-PR3, anti-LF, anti-mitochondrial were negative. The value of plasma C peptide with test glucagon was 0.61 ng/mL and 0.76 ng/mL at 0 and 6 min, respectively (normal values: 0.5-3.2 ng/mL), indicating an insulin secretion deficiency.

Twelve months after cessation of pegylated IFN- $\alpha$  and ribavirin therapy, the patient remained insulin dependent with a daily requirement of insulin 35 units (C-peptide levels remained low), but no medication was required for the thyroid. Last thyroid evaluation revealed a reversible condition with a decrease in the anti-TPO titers (109.5 IU/mL) and normal TSH. HCV RNA in serum was undetectable.

## DISCUSSION

Classical IFN- $\alpha$  has been reported to induce insulin resistance<sup>[8-11]</sup> although there are also reports suggesting a beneficial effect on glucose metabolism<sup>[12-14]</sup>. However, the potential of classical IFN- $\alpha$  to induce IDDM has not been well established.

There have been a variety of mechanisms that may account for the effect of IFN- $\alpha$  on pancreatic beta cell dysfunction in patients with CHC. First, it has been reported that viral dsRNA activates the toll-like receptor-3 and the nuclear factor NF $\kappa$ B to induce pancreatic beta cell apoptosis and also the production of IFN- $\alpha$ , which is directly cytotoxic to beta cells of the pancreas. Second, IFN- $\alpha$  activates the oligoadenylate synthase-RnaseL pathway and the protein kinase R pathway thus inducing apoptosis of pancreatic beta cells<sup>[15]</sup>. Third, IFN- $\alpha$  may stimulate a counter regulatory hormone secretion (growth hormone, glucagon, etc.), thus resulting in impaired glucose tolerance<sup>[8]</sup>. Regarding IDDM, IFN- $\alpha$  may favour the development of Th1 immune reaction and thereby contribute to the development of autoimmune disease by

the activation of CD4 lymphocytes secreting interleukin IL-2, IFN-gamma, and tumor necrosis factor<sup>[15]</sup>. IFN- $\alpha$  expression has also been associated with over-expression of MHC class I antigens in human islets of pancreas<sup>[16]</sup>.

Thirty five cases of IFN- $\alpha$  related IDDM had been reported<sup>[17-20]</sup> up to 2005. In 2003 Fabris *et al*<sup>[5]</sup> reviewed 31 cases of classical IFN- $\alpha$  related IDDM. A family history of IDDM was present in 3 cases and HLA haplotypes conferring susceptibility to IDDM were present in 89% of the reviewed cases. A time-period of 10 d to 4 years elapsed between the onset of treatment and the clinical development of IDDM. Fifty percent of the patients were positive for at least one pancreatic autoantibody before therapy. The rate increased to 77% during IFN- $\alpha$  treatment whereas 5 patients initially negative for pancreatic autoimmunity were seroconverted during therapy. Clinical manifestations included polyuria, polydipsia and weight loss in the vast majority of patients. Permanent insulin administration was required in 75% of the cases<sup>[5]</sup>.

To date, the development of IDDM during pegylated IFN- $\alpha$  and ribavirin therapy for CHC was documented in only two cases in the English literature<sup>[21,22]</sup>. In the case reported by Jabr *et al*<sup>[21]</sup>, pegylated IFN- $\alpha$  and ribavirin were administered in a patient with CHC and human immunodeficiency virus infection. Seven months following initiation of treatment, polyuria, generalized weakness, increased thirst and loss of appetite were manifested. Hyperosmolarity and ketoacidosis eventually developed. The patient required permanent insulin therapy thereafter. Pancreatic autoimmunity markers were not assessed. In the case presented by Cozzolongo *et al*<sup>[22]</sup>, IDDM developed following a 3-mo treatment with pegylated IFN- $\alpha$ -2b and ribavirin for CHC. An increase in the titers of islet-cell and glutamic acid decarboxylase antibodies before the start of therapy and 2 mo after the diagnosis of diabetes mellitus was documented. HLA class II typing showed a predisposition to IDDM. The patient eventually required permanent insulin therapy.

Diabetic ketoacidosis was reported in a few classical IFN- $\alpha$  related cases<sup>[23-26]</sup>, in one pegylated IFN- $\alpha$  related case<sup>[21]</sup> and the case herein described. The development of diabetic ketoacidosis and the permanent insulin dependency thereafter indicated a severe metabolic disturbance, which may be attributed to a rapidly developing Th1-mediated pathogenic reaction<sup>[23]</sup>.

Co-existence of positive thyroid and pancreatic autoimmunity markers was documented in a few cases in the literature<sup>[23,27-29]</sup>. In the case presented by Bosi *et al*<sup>[23]</sup>, clinical features of autoimmune hyperthyroidism and IDDM coexisted. In the current case the multiple autoimmune manifestations, ie. IDDM and Hashitoxicosis with highly elevated GAD and anti-TPO antibodies and additional autoimmunity markers, illustrated a vigorous triggering of the immune system by pegylated IFN- $\alpha$  in a genetically predisposed individual.

Gogas *et al*<sup>[30]</sup> have suggested a predictive model to identify patients with a predisposition to autoimmunity disease before the start of IFN- $\alpha$  therapy for melanoma. Prospective identification of the individual benefit/risk ratio would facilitate personalized treatment strategies

when IFN- $\alpha$  treatment is planned.

In conclusion, it seems that pegylated IFN- $\alpha$  shares common features with classical IFN- $\alpha$  as far as autoimmunity is concerned. A high clinical awareness is recommended in patients with known genetic susceptibility or positive autoimmunity markers prior to or during IFN- $\alpha$  therapy.

### Abstract

Gallstone ileus is a rare disease and accounts for 1%-4% of all cases of mechanical intestinal obstruction. It usually occurs in the elderly with a female predominance and may result in a high mortality rate. Its diagnosis is difficult and early diagnosis could reduce the mortality. Surgery remains the mainstay of treatment. We report two cases of gallstone ileus. The first was a 78-year old woman who had a 2-d history of vomiting and epigastralgia. Plain abdominal film suggested small bowel obstruction clinically attributed to adhesions. Later on, gallstone ileus was diagnosed by abdominal computed tomography (CT) based on the presence of pneumobilia, bowel obstruction, and an ectopic stone within the jejunum. She underwent emergent laparotomy with a one-stage procedure of enterolithotomy, cholecystectomy and fistula repair. The second case was a 76-year old man with a 1-wk history of epigastralgia. Plain abdominal film showed two round calcified stones in the right upper quadrant. Fistulography confirmed the presence of a cholecystoduodenal fistula and gallstone ileus was also diagnosed by abdominal CT. We attempted to remove the stones endoscopically, but failed leading to an emergent laparotomy and the same one-stage procedure as for the first case. The postoperative courses of the two cases were uneventful. Inspired by these 2 cases we reviewed the literature on the cause, diagnosis and treatment of gallstone ileus.

### Cholecystoduodenal fistula

Chou JW, Hsu CH, Liao KF, Lai HC, Cheng KS, Peng CY, Yang MD, Chen YF. Gallstone ileus: Report of two cases and review the literature. *World J Gastroenterol* 2007; 13(8): 1295-1298

<http://www.wjgnet.com/1007-9327/13/1295.asp>

### INTRODUCTION

The cause of mechanical small bowel intestinal obstruction includes gallstones, foreign bodies, bezoars, tumors, adhesions, congenital abnormality, intussusceptions, and volvulus<sup>[1]</sup>. Among these causes, a gallstone-induced intestinal obstruction is also referred to as a "gallstone ileus". Gallstone ileus is a rare and potentially serious complication of cholelithiasis<sup>[2]</sup>. It accounts for 1%-4% of all cases of mechanical intestinal obstruction, but for up to 25% of those in patients over 65 years of age with a female to male ratio of 3.5-6.0:1<sup>[3-6]</sup>. The morbidity and mortality rate of gallstone ileus remain very high, partly because of misdiagnosis and delayed diagnosis<sup>[7]</sup>. Thus, early diagnosis and prompt treatment could reduce the mortality rate. Here, we report two cases of gallstone ileus and review the literature of this rare disease.

### CASE REPORTS

#### Case 1

A 78-year old woman presented to our emergency department (ED) with a 2-d history of vomiting and epigastric pain. She had a past medical history of hypertension and underwent a hysterectomy for a myoma at the age of 38. On physical examination, her abdomen was mildly distended without tenderness or rebound or Murphy's sign. The white blood count was 16 630/ $\mu$ L with 87.6% neutrophils, blood urea nitrogen 67 mg/dL, 2.3 mg/dL creatinine 2.3 mg/dL and k 2.7 mmol/L. The other tests were unremarkable. A plain abdominal film demonstrated mildly dilated bowel loops, but a vague stone was not identified in the left iliac fossa (Figure 1). The diagnostic impression was ileus due to adhesions. Abdominal ultrasound (US) disclosed a shrunken gallbladder with internal air, but without stones. An abdominal computed tomography was performed, demonstrating air in the biliary tree (Figure 2A). Moreover,

**Figure 1** Plain abdominal film showing a vague stone not identified in the left iliac fossa (arrow).

**Figure 3** Plain abdominal film showing two round calcified stones in the right upper quadrant of abdomen (arrow).

an ectopic stone impacted in the jejunal lumen was seen in the left lower quadrant along with dilatation of the proximal small bowel (Figure 2B). The diagnosis of gallstone ileus was made and she underwent an emergent laparotomy. At operation a small shrunken gallbladder with dense adhesion to the stomach was found. After lysis of adhesion, a fistula between the gallbladder dome and the lesser curvature of gastric antrum was confirmed. Moreover, a stone was palpated in the jejunum about 140 cm distal to the ligament of Treitz causing total obstruction of the lumen. When the jejunum was opened, the stone was laminated and cylinder shaped, measuring 3 cm × 3 cm × 2 cm in diameter. Enterolithotomy, cholecystectomy and repair of the cholecystogastric fistula were performed. The pathology showed chronic cholecystitis and a fistula walled by granulation tissue. The postoperative course was uneventful except for mild wound infection, and she remained in good health after one-year follow-up.

## Case 2

A 76-year old man was brought to our ED because of epigastric pain for one week. He denied any history of abdominal surgery or biliary disease. On physical examination his abdomen was soft, but tender in the epigastric area. Laboratory tests were unremarkable. Abdominal X-ray showed two round calcified stones in the right upper quadrant of the abdomen (Figure 3). An EGD disclosed a deep hole in the posterior wall of the duodenal bulb, but no stone was identified. Fistulography confirmed the presence of a cholecystoduodenal fistula.

**Figure 2** Abdominal computed tomography scan showing air in the biliary tree (arrow) (A) and an ectopic stone (arrow) impacting the jejunal lumen accompanying dilatation of proximal small bowel loops (white arrow) (B).

**Figure 4** Abdominal computed tomography scan showing two round calcified stones impacting the proximal third portion of the duodenum (arrowhead) (A) and a thickened wall gallbladder with internal air and small calcified content (arrow) (B).

An abdominal CT was performed, showing two round calcified stones located in the proximal third portion of the duodenum causing dilatation of proximal bowel lumen (Figure 4A). There was a thickened wall gallbladder with internal gas and small calcified content was also discovered (Figure 4B). Duodenoscopy was performed again, showing two stones impacted in the proximal third portion of the duodenum. We attempted to catch the stones with a Dormia basket, but failed because of their larger size. Therefore, he was referred to our department of surgery for emergent laparotomy. Laparotomy displayed that the gallbladder was adhered to the duodenum accompanying a cholecystoduodenal fistula. A large black stone, measuring 5 cm × 4 cm × 3 cm in diameter, impacted the proximal third portion of the duodenum. No other stones were found in the gastrointestinal (GI) tract. Enterolithotomy, cholecystectomy, duodenorrhaphy, feeding jejunostomy, and repair of the cholecystoduodenal fistula were performed. Microscopically, the gallbladder showed cholelithiasis with acute and chronic inflammation and a fistula walled by fibrous and granulation tissue. The postoperative course was complicated by a wound infection, and he was discharged 2 mo later.

## DISCUSSION

Gallstone is a common disease with a prevalence in 10% of the adult population in the United States<sup>[8]</sup>. However, it is only symptomatic in 20%-30% of patients, with biliary colic being the most common symptom<sup>[9]</sup>. The most common complications of gallstone disease include acute cholecystitis, acute pancreatitis, choledocholithiasis with or without cholangitis, and a gangrenous gallbladder. Other uncommon complications include Mirizzi syndrome,

cholecystocholedochal fistula, and gallstone ileus<sup>[2,10]</sup>.

The term “gallstone ileus” was first coined by Bartolin in 1654 and referred to the mechanical intestinal obstruction due to impaction of one or more large gallstones within the GI tract. Biliary-enteric fistula is the major pathologic mechanism of gallstone ileus<sup>[11]</sup>. The gallstone enters the GI tract through a fistula between a gangrenous gallbladder and the GI tract. Occasionally a stone may enter the intestine through a fistulous communication between the common bile duct and the GI tract. Although the gallstone can impact anywhere in the GI tract, its size should be at least 2 cm to 2.5 cm in diameter to cause obstruction<sup>[6]</sup>. Reisner and Cohen<sup>[5]</sup> reviewed 1001 cases of gallstone ileus and reported that the most common locations of impaction of gallstone are the terminal ileum and the ileocecal valve because of the anatomical small diameter and less active peristalsis. They also found that the less common locations for impaction are the jejunum, the ligament of Treitz, and the stomach, while the duodenum and colon are the rare locations for impaction<sup>[5]</sup>.

The clinical manifestations of gallstone ileus are variable and usually depend on the site of obstruction. The onset may be manifested as acute, intermittent or chronic episodes<sup>[12]</sup>. The most common symptoms include nausea, vomiting and epigastric pain. Moreover, a small portion of patients may present with hematemesis secondary to duodenal erosions. Laboratory studies may show an obstructive pattern with elevated values of bilirubin and alkaline phosphatase.

The diagnosis of gallstone ileus is difficult, usually depending on the radiographic findings. In 50% of cases the diagnosis is often only made at laparotomy<sup>[5]</sup>. The classic Rigler's triad of radiography includes mechanical bowel obstruction, pneumobilia, and an ectopic gallstone within bowel lumen. However, air in the gallbladder is also a frequent finding in gallstone ileus<sup>[13]</sup>. Plain abdominal films usually show non-specific findings because only 10% of gallstones are sufficiently calcified to be visualized radiographically. For example, in our first case, although the ectopic gallstone appeared on the initial plain abdominal film, it was misdiagnosed as fecal material due to insufficient calcification. But in our second case, two gallstones were definitely identified on a plain abdominal film. Upper or lower GI barium studies occasionally identify the site of obstruction or fistula. Abdominal US is useful to confirm the presence of cholelithiasis and may identify fistula, if present<sup>[14]</sup>. Abdominal CT becomes the more important modality in diagnosing gallstone ileus because of its better resolution. By comparing with plain abdominal film and abdominal US, it can provide a more rapid and specific diagnosis in emergency use. Lassandro *et al.*<sup>[15]</sup> compared the clinical value of plain abdominal film, abdominal US and abdominal CT in diagnosing 27 cases of gallstone ileus, and found that the Rigler's triad presents 14.81% in plain abdominal film, 11.11% in abdominal US, and 77.78% in abdominal CT, respectively. Additionally, Yu *et al.*<sup>[16]</sup> studied the value of abdominal CT in the diagnosis and management of gallstone ileus and concluded that the abdominal CT offers crucial evidence not only for the diagnosis of gallstone ileus but also for decision making

in management strategy<sup>[16]</sup>. Rarely, laparoscopy is used to diagnose this disease<sup>[17]</sup>.

Gallstone ileus usually requires emergent surgery to relieve intestinal obstruction. Bowel resection is only indicated when there is intestinal perforation or ischemia<sup>[18]</sup>. There is no uniform surgical procedure for this disease because of its low incidence. Although enterolithotomy alone remains the popular operative method in most reports, the one-stage procedure composed of enterolithotomy, cholecystectomy and repair of fistula is necessary, if indicated<sup>[19]</sup>. Tan *et al.*<sup>[20]</sup> compared the two surgical strategies of enterolithotomy alone and enterolithotomy with cholecystectomy for the emergent treatment of gallstone ileus, and concluded that both procedures are safe with no mortality, but the better surgical option is enterolithotomy. Doko *et al.*<sup>[21]</sup> agreed that the one-stage procedure should be reserved only for highly selected patients with absolute indications. Recently, laparoscopy-guided enterolithotomy has become the preferred surgical approach in treating gallstone ileus<sup>[22]</sup>. Additionally, the non-surgical treatment of gallstone ileus has been suggested, including endoscopic removal and shockwave lithotripsy, but this depends on the location of obstruction<sup>[23,24]</sup>. In our second case, the two stones were detected by radiography preoperatively, but they were not found on the first EGD. The second duodenoscopy revealed two stones impacting the third portion of the duodenum. We attempted to remove them endoscopically, but failed due to their larger size.

The prognosis of gallstone ileus is usually poor and worsens with age. Previous studies reported that the mortality rate is 7.5%-15%<sup>[5,6]</sup>, largely due to delayed diagnosis and concomitant conditions such as cardiorespiratory disease, obesity and diabetes mellitus. The postoperative recurrence rate of gallstone ileus is 4.7% and only 10% of patients require secondary biliary surgery for recurrent biliary symptoms<sup>[5,25]</sup>.

In conclusion, gallstone ileus is a rare cause of intestinal obstruction. It must be considered in intestinal obstruction patients with a past history of gallstone, especially in elderly females. Abdominal CT is the preferred modality because of its rapid diagnosis of gallstone ileus. Surgical treatment is emergent when the radiological finding is highly or even suspicious or confirmed.

## INTRODUCTION

Malignant fibrous histiocytoma (MFH) is a common soft tissue sarcoma, usually occurring in the extremities. Primary intestinal MFH is a very rare neoplasm, with not more than 40 cases reported in international literatures<sup>[1-5]</sup>. Here we report two cases of primary intestinal MFH and review other reported cases.

## CASE REPORTS

### Case 1

A 70-year old man was admitted for recurrent right lower quadrant abdominal pain for about 50 d. He had no recent history of fever, vomiting, diarrhea, or constipation. Physical examination revealed a slightly tender fist-size mass in the right lower quadrant of the abdomen. Laboratory examination showed a white blood cell count of  $5.02 \times 10^9/L$ , and a neutrophil count of 68.3%. Abdominal ultrasonography revealed a large hypo-echoic mass in the right lower quadrant and an abdominal computed tomography demonstrated a large soft-tissue mass in the right lumbar region and iliac fossa (Figure 1A). Chest X-ray and computed tomography showed a mass on the hilum of the right lung (Figure 1B). Barium enema and colonofiberscopy were not performed owing to the patient's abdominal pain. At laparotomy, a tumor was found originating from the cecum and infiltrating into the right lateral peritoneum. There was a suspicious metastatic nodule located on the surface of the right lobe of the liver. A right hemicolectomy was carried out, and reconstruction was performed by an ileotransverse end-to-end anastomosis. Grossly, an ulcerative annular tumor undergone necrosis was seen in the cecum, measuring 12 cm  $\times$  10 cm. There was a tumor nodule on the mesentery, measuring 3 cm  $\times$  2 cm. On cut section, the tumor was soft in consistency, solid and grayish-white in color. Microscopic examination revealed that the tumor was pleomorphic and consisted of spindle-shaped cells, oval cells, pleomorphic giant cells, and inflammatory cells. There were involvements of two lymph nodes. Immunohistochemical stains were positive for vimentin (Figure 2), KP-1,  $\alpha$  1-antitrypsin, LYS, P53, Ki67, and

## Abstract

Malignant fibrous histiocytoma (MFH) occurs most commonly in the extremities and trunk, but rarely in the intestine. Here we report two cases of primary intestinal MFH. The first case was a 70-year old man admitted for recurrent right lower quadrant abdominal pain. At laparotomy, a tumor was found originating from the cecum, with a suspicious metastatic nodule on the surface of the right lobe of the liver. A right hemicolectomy was performed followed by an ileotransverse end-to-end anastomotic reconstruction. The second case was a 43-year old man with intussusceptions of the small intestine. An emergent laparotomy revealed 4 pedunculated masses in the small bowel and a partial resection of the small intestine was performed. Though the symptoms were not typical, based on histological and immunohistochemical studies, the patients were diagnosed as MFH of the intestine. They were not treated with chemotherapy or radiotherapy and both died within 3 mo. MFH of the intestine is an extremely rare neoplasm with an aggressive biological behavior. The pathogenesis of this disease has not been clarified to date. Complete surgical excision is preferred, adjuvant chemotherapy or radiotherapy may be advisable.

negative for S-100, CD1a, CD34, CD117, HMB45, CK, and SMA. The final histopathological diagnosis was MFH of the cecum. Postoperatively, the patient developed pyrexia for about one week which was subsequently followed by breathlessness as a result of lung metastasis. He was not treated with chemotherapy or radiotherapy, and died a month later.

## Case 2

A 43-year old man with a history of melena for 10 d had intermittent abdominal pain, fever, vomiting and diarrhea. Physical examination revealed a slightly distended tender abdomen. Laboratory findings showed a white blood cell count of  $23.39 \times 10^9/L$ , and an elevated C-reactive

protein level of 193.0 mg/L. Plain abdominal X-ray films showed small bowel obstruction. Computed tomography demonstrated features of multiple intussusceptions, i.e. some portions of the small intestine were seen invaginating into contiguous segments (Figure 3). Chest X-ray and computed tomography showed a mass on the apex of the right lung. The diagnosis of intussusceptions of the small intestine was made, and an emergency operation was performed. At laparotomy, 4 masses measuring 8, 5, 5, 3 cm in diameter were seen in the small bowel and local partial resections of the small intestine were performed. The resected specimens contained pedunculated tumors. Some metastatic nodules were also noted on the mesentery. Microscopic examination demonstrated fibroblast-like cells, histiocyte-like cells and pleomorphic giant cells within the tumor substance (Figure 4). Immunohistochemical stains were positive for vimentin, Ki67 (Figure 5A), P53 (Figure 5B), CK, KP-1 (Figure 5C), LYS, and negative for ER, PR, c-erbB2, MMP2, MMP9, S-100 and HMB45. The pathological findings were compatible with MFH of the small intestine. Postoperatively, the patient had high fever, vomiting and abdominal pain. White blood cell count varied from  $26.64 \times 10^9/L$  to  $55.5 \times 10^9/L$ , and plain abdominal X-ray films demonstrated partial bowel obstruction. The patient was not treated with chemotherapy or radiotherapy, and died 2 mo later.

## DISCUSSION

Malignant fibrous histiocytoma (MFH) was first described

**Figure 5** Tumor cells showing positive staining for Ki67 (A), P53 (B), and KP-1 (C) (EnVision  $\times 200$ ).

as malignant histiocytoma and fibrous xanthoma by Ozello *et al* in 1963, and was established by O'Brien and Stout in 1964 to describe soft tissue sarcomas arising from fibroblasts and histiocytes<sup>[3,5]</sup>. The peak incidence of extraintestinal MFH occurs in the sixth and seventh decades of life. It usually occurs in the extremities, presenting as a painless mass, and less commonly in the retroperitoneal space, associated with weight loss and increased intra-abdominal pressure<sup>[6]</sup>. Five histological subtypes of MFH have been described: pleomorphic storiform, myxoid, giant cell, inflammatory, and angiomatoid; the most common being pleomorphic storiform and myxoid types. The first two subtypes tend to be high-grade neoplasms, while the others are usually low-grade sarcomas<sup>[7]</sup>. The karyotypic abnormalities in MFH are usually complex, with multiple numerical and structural rearrangements<sup>[8]</sup>. Schmidt<sup>[9]</sup> reported that chromosomes 1, 3, 6, 9, 12, 16, 18, and 20 are involved in structural aberrations, and that the breakpoint regions are most frequently observed in 1p32, 3p25, and in the centromeric

region of chromosomes 1 and 16. The pathogenesis of MFH has not been clarified to date. However, it has been recognized as a complication of radiation, resulting from chronic postoperative repair, trauma, surgical incisions or burn scars<sup>[10-13]</sup>.

Primary MFH of the intestine is very rare. Not more than 40 cases have been reported in international literatures<sup>[1-4]</sup>. We reviewed the total 37 cases of intestinal MFH, including ours, and summarized the findings as follow. The ratio of men to women was 2.4:1, with an average age of 54.2 years and a range of 12-84 years. The tumor originated from the duodenum in 2 patients, the jejunum in 5, the ileum in 6, the jejunum and the ileum in 1, the cecum in 4, the ascending colon in 6, the transverse colon in 5, the descending colon in 2, the sigmoid colon in 2, the rectum in 3, and from the anal canal in 1. In most patients, the tumor was solitary, while in 4 cases multiple tumors were observed. The distribution of the colorectal MFH was different from that of carcinoma. Despite the fact that most of the tumors were large, ranging from 2 to 19 cm in diameter, their early detection was difficult. The symptoms were not typical: most patients complained of abdominal pain, fever, anorexia, bloody stools and diarrhea, but few had constipation. Thirty-five of the patients were treated surgically, 3 received adjuvant chemotherapy, one was given radiotherapy, and one underwent chemoradiation. In some patients, initial laparotomy revealed metastatic masses, especially in the regional lymph nodes, liver and lungs. Local recurrence was the most common pattern of recurrence in MFH of the intestine. Several patients died of local recurrence or metastasis including our reported two cases.

The diagnosis of MFH depends on an accurate differential diagnosis from other sarcomas, observation of karyomorphism and differential figures, and positive results on immunohistological staining. It was reported that MFH frequently expresses vimentin, actin, CD-68, and  $\alpha$  1-antitrypsin and  $\alpha$  1-antichymotrypsin<sup>[14]</sup>. Thus, the final diagnosis of our patients was MFH. The differential diagnosis of MFH should include pleomorphic liposarcoma and rhabdomyosarcoma. The former lacks the storiform pattern and shows evidence of cellular differentiation, while the latter shows cross striations on histological examination.

Murata<sup>[15]</sup> reported that colorectal MFH of the inflammatory type produces granulocyte colony-stimulating factor (G-CSF). Liesveld<sup>[16]</sup> reported that patients with MFH have leukocytosis, leukemoid reaction, and paraneoplastic syndrome because of various cytokines produced by tumor cells. Thus, postoperative recurrent leukocytosis and elevated CRP level might be predictors for recurrence of MFH. The second case presented to our center had leukocytosis and leukemoid reaction postoperatively.

The treatment for MFH is early and complete surgical excision with en-bloc regional lymph node dissection. Postoperatively, our patients were not given chemotherapy due to their poor general condition. Chemotherapy and radiotherapy were used, but without success. Zagars<sup>[17]</sup> reported that adjuvant chemotherapy cannot minimize the rate of metastasis. Patients with myxoid tumors do

not require systemic therapy. However, patients with nonmyxoid disease exceeding 5 cm are at a significant risk of developing metastases and the development of effective adjuvant treatment is an important research goal. Another report stated that inadequate peritumoral excision is a cause for recurrence<sup>[18]</sup>.

Most of the reports suggest that the prognosis associated with colonic MFH is poor. Weiss and Einzinger's analysis of MFH<sup>[6]</sup> showed that the 2-year survival rate of patients with pleomorphic/storiform type of MFH is 60% and the rate of metastases is 42%. Tumor site (extremity *vs* nonextremity), location (proximal *vs* distal), size ( $\leq 5$  cm *vs*  $> 5$  cm), and histology (myxoid *vs* nonmyxoid) are not significant determinants for final outcome<sup>[17]</sup>. For metastatic relapse, the major determinants were histology (myxoid *vs* nonmyxoid) and tumor size. Myxoid tumors have a low metastatic propensity (13% 10-year metastatic rate) compared to nonmyxoid tumors (40% 10-year metastatic rate).

In conclusion, primary intestinal MFH is an extremely rare neoplasm with an aggressive biological behavior. Clinicians and pathologists must consider the possibility of this tumor and include it in the differential diagnoses of intestinal lesions. Complete surgical excision is preferred and adjuvant chemotherapy or radiotherapy may be advisable. Due to the high recurrence, life-long surveillance should be carried out.

## Abstract

Eosinophilic gastroenteritis is a rare gastrointestinal disorder with eosinophilic infiltration of the gastrointestinal wall and various gastrointestinal dysfunctions. Diagnosis requires a high index of suspicion and exclusion of various disorders that are associated with peripheral eosinophilia. We report a case of eosinophilic gastroenteritis, which had features of the predominant subserosal type presenting with ascites and hepatic dysfunction, and which responded to a course of low-dose steroid.

## INTRODUCTION

Eosinophilic gastroenteritis, first reported by Kaijser in 1937, is a rare gastrointestinal disorder that can present with various gastrointestinal manifestations, depending on the specific site of the affected gastrointestinal wall. Klein *et al*<sup>[1]</sup> have demonstrated that this disorder could be pathologically classified into three major types: predominant mucosal layer, predominant muscle layer, and predominant subserosal layer. However, its clinical features, etiology, and treatment have not yet been definitely established. We report a case of eosinophilic gastroenteritis with features of the predominant subserosal type, including ascites and liver dysfunction.

## CASE REPORT

In July 2006, a 33-year-old man presented with mild upper abdominal pain and, three days later, with abdominal distention, frequency of bowel motion and fever. His temperature was 38.5°C. He had no past history of ulcer pain and never had any abdominal operation. There had been no weight loss and neither blood nor mucus was present in the stool. The patient denied taking any drugs or herbal medicine. There was a history of allergy to levofloxacin. Chest examination showed no abnormality. Abdominal examination revealed a soft, mildly tender abdomen, and shifting abdominal dullness.

The patient was admitted to the Second Affiliated Hospital of Zhejiang University in July 2006. The hemoglobin level was 13.0 g/L (normal range, male, 11-16 g/L) and white cell count was  $13.6 \times 10^9/L$ , with 41.1% neutrophils, 27.9% lymphocytes, 8% monocytes and 22.5% eosinophils. The platelet count was  $138 \times 10^9/L$ , and the sedimentation rate was 8 mm/h. The tests for antinuclear factor, rheumatoid factor, serum hepatitis B surface antigen and serum hepatitis A, C, E antibodies gave negative results. The alanine aminotransferase level was 337 U/L (normal range, 0-50 U/L) and the aspartate aminotransferase was 223 U/L (normal range, 0-40 U/L). The anti-amoebic titer was negative and stool microscopy for ova and cysts was negative. Ultrasonography of the abdomen revealed a moderate amount of ascites (Figure 1). Gastroscopy showed mild antral gastritis. Biopsy of gastric antrum and proximal duodenum revealed inflammation with marked eosinophilic infiltration (Figure 2 and Figure 3). Colonoscopy showed mild proctitis and sigmoid colitis.

After excluding the possibilities of a malignancy, parasitic disease, and autoimmune disease, eosinophilic gastroenteritis was diagnosed. This diagnosis was supported by the presence of peripheral eosinophilia and eosinophilic infiltration of the serosa and subserosa of the gastric antrum and proximal duodenum. A small daily dose of steroid (prednisolone 20 mg) was given. Four days later, the patient recovered from his symptoms. The white cell count was  $9.5 \times 10^9/L$ , with 49.1% neutrophils, 27.2% lymphocytes, 7.7% monocytes and 15% eosinophils. Seven days later, the alanine aminotransferase level was 128 U/L and the aspartate aminotransferase was 38 U/L. Ultrasonography of the abdomen revealed no ascites. Steroid treatment was gradually tapered and eventually terminated after 4 wk.

**Figure 1** Ultrasonography of the abdomen revealed a moderate amount of ascites.

**Figure 2** Histologic section of proximal duodenum showed inflammation with marked eosinophilic infiltration (HE,  $\times 100$ ).

**Figure 3** Histologic section of proximal duodenum showed inflammation with marked eosinophilic infiltration (HE,  $\times 400$ ).

## DISCUSSION

The important feature in this case of eosinophilic gastroenteritis is the extremely high eosinophil count in the peripheral blood and the serosa and subserosa of the gastric antrum and proximal duodenum. The diagnosis of eosinophilic gastroenteritis was confirmed after the exclusion of other disorders that have similar features, such as gut lymphoma, parasitic infection, carcinoma, inflammatory bowel disease, and allergy.

Eosinophilic gastroenteritis is a rare disease, which was first reported by Kaijser in 1937. In 1970, Klein demonstrated that this disorder could be pathologically classified into three major types: predominant mucosal, predominant muscle layer, and predominant subserosal. The involvement of different layers usually gives rise to different clinical manifestations. Mucosal disease generally presents with bleeding, protein-losing enteropathy, or malabsorption. Involvement of the muscle layer may cause bowel wall thickening and subsequent intestinal obstruction. The subserosal form usually presents with peritonitis and eosinophilic ascites, which was the case in this patient.

Eosinophilic gastroenteritis can involve any part of the gastrointestinal tract from the esophagus down to the rectum. The stomach and duodenum, however, are the most common sites of involvement<sup>[2-5]</sup>. The etiology of

eosinophilic gastroenteritis is currently unknown. Allergies to certain foods or immunological abnormalities have been speculated as its etiology<sup>[6-8]</sup>. On the other hand, some investigators<sup>[9,10]</sup> have demonstrated that the etiology of this disorder is not associated with allergic reactions. In our case, there was a past history of levofloxacin allergy. However, the patient denied taking any drugs or herbal medicine. The finding of high eosinophil count in the peripheral blood suggested allergic disorder or parasitic disorders, or abdominal lymphoma. The likelihood of parasitic disorders and abdominal lymphoma was remote because of the history of the patient's illness, the physical findings, and the findings on gastroscopy, colonoscopy and ultrasonography.

In the mucosal form of eosinophilic gastroenteritis, multiple biopsies must be taken during endoscopy, because mucosal involvement is often patchy in nature. When there is a submucosal disease, biopsy of the mucosal layer sometimes fails to expose eosinophilic gastroenteritis. Laparotomy or laparoscopy is often required to make a diagnosis in such cases.

Treatment with a steroid is the mainstay in the management of eosinophilic gastroenteritis. Clinical improvement usually is seen after treatment with a low dose of steroid. Surgical intervention may sometimes be required for patients with complicating obstruction or when performing a full thickness intestinal biopsy to establish the diagnosis.

## TO THE EDITOR

The dramatic increase of allergic and autoimmune diseases such as asthma, atopic dermatitis (eczema), allergic rhinitis, inflammatory bowel disease (IBD, including both Crohn's disease and ulcerative colitis), multiple sclerosis, and insulin-dependent diabetes mellitus (type I diabetes) in the developed countries in the last century<sup>[1-3]</sup> is a big puzzle. "Hygiene Hypothesis" was proposed more than two decades ago and it suggested that the increase in these allergic and autoimmune diseases is caused by the aberrant development and response of the immune system due to a reduced exposure to microorganisms along with the improved hygiene<sup>[2-4]</sup>. Interestingly, recent studies revealed that these allergic and autoimmune diseases are closely related to the microbes in the gut<sup>[5]</sup>. For instance, even asthma, an allergic reaction of the lung to inhaled antigens, is closely related to a reduced exposure to foodborne and orofaecal microbes, rather than the amount of allergens in the air or the exposure to airborne microbes<sup>[5-7]</sup>. It is known that bacteria in the gut could be 10 times in number of the eukaryotic cells of the body<sup>[8]</sup>. Therefore, it would be not too surprising that microbes in the gut may have a great impact on these autoimmune and allergic diseases.

On the other hand, many studies revealed that an

increase in intestinal permeability was shown in patients with these autoimmune and allergic diseases, such as those with IBD<sup>[9,10]</sup>, multiple sclerosis<sup>[11]</sup>, type I<sup>[12,13]</sup> (but not type II<sup>[14]</sup>) diabetes, asthma<sup>[15,16]</sup>, and atopic eczema<sup>[17,18]</sup>. The increased intestinal permeability in these patients seems to be a prerequisite rather than a consequence of these diseases, as it could precede the clinical onset of these diseases<sup>[12,19,20]</sup>. In addition, increased intestinal permeability was also seen not only in healthy relatives<sup>[10,21]</sup>, but also in spouses of these patients<sup>[10,22]</sup>. An increase in intestinal permeability would result in an increased infiltration of the luminal components. Therefore, it would be reasonable to ask what have caused the increase of these autoimmune and allergic diseases: is it a decreased exposure to luminal microbial components due to the improved hygiene, or an increased exposure to luminal microbial components due to the increased intestinal permeability?

There is a large amount of microbes in the gut. The endotoxin in gut bacteria could be enough to kill the host thousands of times over<sup>[23]</sup>. Therefore, it would be more likely that the tightness of the gut barrier would have played a more important role in determining the extent of exposure rather than the absolute number of microbes in the gut. Actually, there could be an intrinsic link between the increased intestinal permeability and improved hygiene. An effective inactivation of the digestive proteases depends on gut bacteria<sup>[24,25]</sup>. The increased intestinal permeability could be a result of the improved hygiene and a reduction in gut bacteria, by a mechanism such as the impaired inactivation of digestive proteases by gut bacteria, and thus an over-digestion of gut barrier. A reduction in gut bacteria not only can be the result of improved sanitary conditions, along with the more clean food and water, it also can be caused by an inhibition of gut bacteria by factors such as the widely used sweetener saccharin<sup>[26]</sup>. Interestingly, saccharin consumption correlated well with the ups and downs of the IBD, and probably had played a causative role in IBD<sup>[27,28]</sup>. This would lead us to raise a more general question: Will the improved hygiene and thus a reduction in gut bacteria necessarily result in a decreased exposure to luminal microbial components, the fundamental assumption of the "Hygiene Hypothesis"<sup>[29,30]</sup>. Further study in this area would be worthwhile. It would help better understand why both Th1 type diseases such as Crohn's diseases and type I diabetes, and Th2 type diseases such as ulcerative colitis and atopic diseases increase with the improved hygiene<sup>[29,30]</sup>.

### EVENTS AND MEETINGS IN 2007

Meeting Falk Research Workshop: Morphogenesis and Cancerogenesis of the Liver  
25-26 January 2007  
Goettingen  
symposia@falkfoundation.de

Meeting Canadian Digestive Diseases Week (CDDW)  
16-20 February 2007  
Banff-AB  
cagoffice@cag-acg.org  
www.cag-acg.org/cddw/cddw2007.htm

Meeting Falk Symposium 158: Intestinal Inflammation and Colorectal Cancer  
23-24 March 2007  
Sevilla  
symposia@falkfoundation.de

Meeting BSG Annual Meeting  
26-29 March 2007  
Glasgow  
www.bsg.org.uk/

Meeting 42nd Annual Meeting of the European Association for the Study of the Liver  
11-15 April 2007  
Barcelona  
easl2007@easl.ch  
www.easl.ch/liver-meeting/

Meeting Falk Symposium 159: IBD 2007 - Achievements in Research and Clinical Practice  
4-5 May 2007  
Istanbul  
symposia@falkfoundation.de

Meeting European Society for Paediatric Gastroenterology, Hepatology and Nutrition Congress 2007  
9-12 May 2007  
Barcelona  
espghan2007@colloquium.fr

Meeting Gastrointestinal Endoscopy Best Practices: Today and Tomorrow, ASGE Annual Postgraduate Course at DDW  
23-24 May 2007  
Washington-DC  
tkoral@asge.org

Meeting ESGAR 2007 18th Annual Meeting and Postgraduate Course  
12-15 June 2007  
Lisbon  
fca@netvisao.pt

Meeting Falk Symposium 160: Pathogenesis and Clinical Practice in Gastroenterology  
15-16 June 2007  
Portoroz  
symposia@falkfoundation.de

Meeting ILTS 13th Annual International Congress  
20-23 June 2007

Meeting 39th Meeting of the European Pancreatic Club  
4-7 July 2007  
Newcastle  
www.e-p-c2007.com

Meeting XXth International Workshop on Helicobacter and related bacteria in chronic digestive inflammation  
20-22 September 2007  
Istanbul  
www.heliobacter.org

Meeting Falk Workshop: Mechanisms of Intestinal Inflammation  
10 October 2007  
Dresden  
symposia@falkfoundation.de

Meeting Falk Symposium 161: Future Perspectives in Gastroenterology  
11-12 October 2007  
Dresden  
symposia@falkfoundation.de

Meeting Falk Symposium 162: Liver Cirrhosis - From Pathophysiology to Disease Management  
13-14 October 2007  
Dresden  
symposia@falkfoundation.de

American College of Gastroenterology Annual Scientific Meeting  
12-17 October 2007  
Pennsylvania Convention Center Philadelphia, PA

Meeting APDW 2007 - Asian Pacific Digestive Disease Week 2007  
15-18 October 2007  
Kobe  
apdw@convention.co.jp

*Gastro 2009, World Congress of Gastroenterology and Endoscopy London, United Kingdom 2009*

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (WJG, *World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly journal of more than 48 000 circulation, published on the 7<sup>th</sup>, 14<sup>th</sup>, 21<sup>st</sup> and 28<sup>th</sup> of every month.

Original Research, Clinical Trials, Reviews, Comments, and Case Reports in esophageal cancer, gastric cancer, colon cancer, liver cancer, viral liver diseases, etc., from all over the world are welcome on the condition that they have not been published previously and have not been submitted simultaneously elsewhere.

#### Indexed and abstracted in

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, *Index Medicus*, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, *Nature Clinical Practice Gastroenterology and Hepatology*, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

#### Published by

The WJG Press

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297 mm × 210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, acknowledgements, References, Tables, Figures and Figure Legends. Neither the editors nor the Publisher is responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part without the written permission of both the authors and the Publisher. We reserve the right to put onto our website and copy-edit accepted manuscripts. Authors should also follow the guidelines for the care and use of laboratory animals of their institution or national animal welfare committee.

Authors should retain one copy of the text, tables, photographs and illustrations, as rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for the loss or damage to photographs and illustrations in mailing process.

#### Online submission

Online submission is strongly advised. Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/index.jsp>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. Authors encountering problems with the Online Submission System may send an email you describing the problem to [wjg@wjgnet.com](mailto:wjg@wjgnet.com) for assistance. If you submit your manuscript online, do not make a postal contribution. A repeated online submission for the same manuscript is strictly prohibited.

#### Postal submission

Send 3 duplicate hard copies of the full-text manuscript typed double-spaced on A4 (297 mm × 210 mm) white paper together with any original photographs or illustrations and a 3.5 inch computer diskette or CD-ROM containing an electronic copy of the manuscript including all the figures, graphs and tables in native Microsoft Word format or \*.rtf format to:

#### Editorial Office

##### *World Journal of Gastroenterology*

Editorial Department: Apartment 1066, Yishou Garden,  
58 North Langxinzhuang Road,  
PO Box 2345, Beijing 100023, China

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

Telephone: +86-10-85381892

Fax: +86-10-85381893

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using a word-processing software. All submissions must be typed in 1.5

line spacing and in word size 12 with ample margins. The letter font is Tahoma. For authors from China, one copy of the Chinese translation of the manuscript is also required (excluding references). Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was accomplished, disclosure of any financial support for the research, and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (removing all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s) and full family name.

#### Abstract

An informative, structured abstract of no more than 250 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipments, and the experimental procedures should be included. RESULTS: The observatory and experimental results, including data, effects, outcome, etc. should be included. Authors should present *P* value where necessary, and the significant data should accompany. CONCLUSION: Accurate view and the value of the results should be included.

The format of structured abstracts is at: <http://www.wjgnet.com/wjg/help/11.doc>

#### Key words

Please list 5-10 key words that could reflect content of the study mainly from *Index Medicus*.

#### Text

For most article types, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include in appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both.

#### Illustrations

Figures should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. No detailed legend should be involved under the figures. This part should be added into the text where the figures are applicable. Digital images: black and white photographs should be scanned and saved in TIFF format at a resolution of 300 dpi; color images should be saved as CMYK (print files) but not as RGB (screen-viewing files). Place each photograph in a separate file. Print images: supply images of size no smaller than 126 mm × 85 mm printed on smooth surface paper; label the image by writing the Figure number and orientation using an arrow. Photomicrographs: indicate the original magnification and stain in the legend. Digital Drawings: supply files in EPS if created by freehand and illustrator, or TIFF from photoshops. EPS files must be accompanied by a version in native file format for editing purposes. Existing line drawings should be scanned at a resolution of 1200 dpi and as close as possible to the size where they will appear when printed. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes of atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...

#### Tables

Three-line tables should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each table. No detailed legend should be included under the tables. This part should be added into the text where the tables are applicable. The information should complement but not duplicate that contained in the text. Use one horizontal line under the title, a second under the column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

#### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup>*P*<0.05, <sup>b</sup>*P*<0.01 should be noted (*P*>0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P*<0.05 and <sup>d</sup>*P*<0.01 are used. Third series of *P* values can be expressed as <sup>e</sup>*P*<0.05 and <sup>f</sup>*P*<0.01. Other notes in tables or under

illustrations should be expressed as  $^1F$ ,  $^2F$ ,  $^3F$ ; or some other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, etc. in a certain sequence.

### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions are included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should code the references according the citation order in text in Arabic numerals, put references codes in square brackets, superscript it at the end of citation content or the author name of the citation. For those citation content as the narrate part, the coding number and square brackets should be typeset normally. For example, Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>. If references are directly cited in the text, they would be put together with the text, for example, from references [19,22-24], we know that...

When the authors code the references, please ensure that the order in text is the same as in reference part and also insure the spelling accuracy of the first author's name. Do not code the same citation twice.

### PMID requirement

PMID roots in the abstract serial number indexed by PubMed (<http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed>). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information of the journal citations is very important. Through reference testing system, the authors and editor could check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in ASP file so that the readers can read the abstract of the citations online immediately.

### Style for journal references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). Title of the cited article and italicized journal title (Journal title should be in its abbreviation form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634]

Note: The author should test the references through reference testing system (<http://www.wjgnet.com/cgi-bin/index.pl>)

### Style for book references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

**Patent** (list all authors)

- 16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

### Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those that are linked with a hyphen and the difference between the two numbers at two sides of the hyphen is more than 5. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered as inappropriate references. Authors should not cite their own unrelated published articles.

### Statistical data

Present as mean  $\pm$  SD or mean  $\pm$  SE.

### Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\gamma$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

### Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p*(B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5  $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub> not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format about how to accurately write common units and quantum is at: <http://www.wjgnet.com/wjg/help/15.doc>

**Abbreviations**

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further mention.

**Italics**

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kbo I*, *Kpn I*, etc.

Biology: *H pylori*, *E coli*, etc.

**SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED**

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. Author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, the final check list for authors, and responses to reviewers by a courier (such as EMS) (submission of revised manuscript by e-mail or on the *WJG* Editorial Office Online System is NOT available at present).

**Language evaluation**

The language of a manuscript will be graded before sending for revision.

(1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing; (4) Grade D: rejected. The revised articles should be in grade B or grade A.

**Copyright assignment form**

Please download CAF from <http://www.wjgnet.com/wjg/help/9.doc>.

We certify that the material contained in this manuscript:

**Ms:**

**Title:**

is original, except when appropriately referenced to other sources, and that written permission has been granted by any existing copyright holders. We agree to transfer to *WJG* all rights of our manuscript, including: (1) all copyright ownership in all print and electronic formats; (2) the right to grant permission to republish or reprint the stated material in whole or in part, with or without a fee; (3) the right to print copies for free distribution or sale; (4) the right to republish the stated material in a collection of articles or in any other format. We also agree that our article be put on the Internet.

**Criteria for authorship:** The *WJG* requests and publishes information about contributions of each author named to the submitted study. Authorship credit should be based on (1) direct participation in the study, including substantial contributions to conception and design of study, or acquisition of data, or analysis and interpretation of data; (2) manuscript writing, including drafting the article, or revising it critically for important intellectual content; (3) supportive work, including statistical analysis of data, or acquisition of funding, or administration, technology and materials support, or supervision, or supportive contributions. Authors should meet at least one of the three conditions. The *WJG* does not publish co-first authors and co-corresponding authors.

We hereby assign copyright transfer to *WJG* if this paper is accepted.

Author Name in full (Full names should be provided, with first name first, followed by middle names and family name at the last, eg, Eamonn MM Quigley). Handwritten names are not accepted.

Author Name in abbreviation (Family name is put first in full, followed by middle names and first name in abbreviation with first letter in capital, eg, Quigley EMM). Handwritten names are not accepted.

**Final check list for authors**

The format is at: <http://www.wjgnet.com/wjg/help/13.doc>

**Responses to reviewers**

Please revise your article according to the comments/suggestions of reviewers. The format for responses to the reviewers' comments is at: <http://www.wjgnet.com/wjg/help/10.doc>

**Proof of financial support**

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

**Publication fee**

Authors of accepted articles must pay publication fee.

EDITORIAL and LETTERS TO THE EDITOR are free of charge.
