CS is a stabilizing agent of mast cell which prevents histamine and TNF- α released from IMMC^[30]. Szabo *et al*^[31] reported that 30 min segmental ischemia and 120 min reperfusion induced significant tissue injury, elevated the segmental vascular resistance, and decreased intramucosal pH (pHi), and CS pretreatments prior to ischemia significantly inhibited the permeability changes, but did not influence the pHi and morphological alterations induced by ischemia-reperfusion, they conclude that intestinal mast cells and mast cell-induced reactions contribute to the mucosal permeability alterations during reperfusion, but play only a minor role in ischemia-reperfusion-induced structural injury. Pretreatment with CS protecting against degranulation, caused a significant impairment of plasma exudation at 30 min of inflammation corresponding to a significantly decreased level of histamine, one of the most potent vasoactive factors released from activated mast cells^[32].

The results in our study showed that the injury of small intestinal villus and microvillus was alleviated after CS pretreatment prior to reperfusion and that the ultrastructure of IMMC was basically normal. The expression of tryptase and TNF- α concentration were also alleviated by CS pretreatment prior to reperfusion, and the concentration of histamine in intestine was increased compared with the model group after CS pretreatment prior to reperfusion. The results indicated that CS decreased ischemia-reperfusion injury by prevention of IMMC degranulation, thus it decreased the release of histamine and TNF- α . This protection may be dose-dependent as high dose of CS with

more powerful effect.

There were many reports about intestinal ischemia and reperfusion resulted in the increase of MDA and decrease of SOD activity, toxic-free oxygen radicals are produced in the ischemic tissue^[33,34]. Our study also demonstrated that ischemia-reperfusion injury elevated the oxygen radicals and lipid radicals. Frossi^[35] reported that oxidative stress could induce a pro-type 2 inflammatory response and degranulation of mast cells. Fukuishi^[36] found the compound 48/80, a typical histamine liberator elicited superoxide anion generation in mast cells in a dose-dependent fashion. These studies indicated that degranulation of mast cells was able to induce oxidative stress injury and oxygen radicals could make mast cells to degranulate. In this study we found there were correlations among the MDA, SOD activity and the concentration of histamine, the other findings of our study were that MDA content increased and SOD activity decreased remarkably in the model group, while pretreatment by cromolyn sodium prior to reperfusion could attenuate the up-regulation of MDA content and the down-regulation of SOD activity. The results were indicating that IMMC degranulation and oxidative stress can affect each other, and the less IMMC degranulation can make less oxidative stress. Future studies are need to focus on the relationships *in vitro*.

In conclusion, pretreatment of Cromolyn Sodium prior to reperfusion could attenuate early reperfusion injury after the small intestine ischemia in rats. The mechanisms includes: inhibited IMMC from degranulation, decreased the release of histamine and TNF- α from IMMC, and decreased oxidative stress.

COMMENTS

Background

Intestinal mucosal mast cells (IMMCs) is associated with the mucosal damage. The aim of this study was to investigate the effects of Cromolyn Sodium (CS) pretreated prior to reperfusion on the activity of IMMC and mucous membrane of the small intestine in ischemia-reperfusion (IR) injury of rats.

Research frontiers

Previous studies proved that IMMC are associated with the small intestine injury after ischemia-reperfusion, and MC membrane stabilizer pretreatment prior to ischemia can protects against the injury, such as CS and MAR-99.

Innovations and breakthroughs

While the studies about the intestinal mucosal injury with CS pretreatment after the small intestine ischemia before reperfusion were few. Oxidative stress is one of the mechanism about the small intestine ischemia-reperfusion injury has been generally acknowledged. We hypothesized that CS have an influence on the oxidative stress during the small intestine ischemia-reperfusion, and the purpose of our present study was to to investigate whether CS pretreatment prior to reperfusion could protect against early intestinal mucosal damage induced by ischemia-reperfusion through inhibition of IMMC degranulation or oxidative stress.

Applications

Pretreated of CS prior to reperfusion protects the small intestine mucous from ischemia-reperfusion damage, the mechanism is inhibited IMMC from degranulation.

Terminology

Restoration of blood supply to tissue which is ischemic due to decrease in normal blood supply. The decrease may result from any source including atherosclerotic obstruction, narrowing of the artery, or surgical clamping. It is primarily a procedure

for treating infarction or other ischemia, by enabling viable ischemic tissue to recover, thus limiting further necrosis. However, it is thought that reperfusion can itself further damage the ischemic tissue, causing REPERFUSION INJURY.

Peer review

This paper reports an experimental study very well designed and performed and very elegant results and discussion. The final conclusions are nicely shown. Their english is of good quality. The purpose of this paper was to determine whether cromolyn sodium reduces or prevents injury of the small intestine of rats following ischemia-reperfusion. To this end the authors perform a number of biochemical measurements (MDA, TNF α , histamine, SOD) as well as ultrastructural studies of mast cells and microscopical investigations of the small intestine.

Abstract

AIM: To study mutations in the P-type ATPase (ATP7B) gene responsible for Wilson disease (WD) in the Eastern Chinese population, and the possible correlation of specific mutations with clinical characteristics.

METHODS: Mutations of the ATP7B gene were sought by means of direct sequencing in 50 Eastern Chinese WD patients of Han ethnic origin.

RESULTS: Two novel mutations, Asp96Gly and Asp196Glu, were first identified. We also compared the characterization of mutations in ATP7B with the clinical findings, and a significant correlation with hepatic manifestations between patients carrying the Arg778Leu mutation and those without was found.

CONCLUSION: Gene sequencing analysis was shown to have a high detection rate and accuracy. It may become the first priority in screening of WD patients.

INTRODUCTION

Wilson disease (WD, hepatolenticular degeneration) is an autosomal recessive disorder with an incidence of 1 in 35 000 to 100 000 live births^[1-3]. It is characterized by pathological copper accumulation in different tissues, especially in the liver and brain. As a result of defective putative copper-transporting ATPase in the liver, copper remains in the liver and causes hepatic dysfunction. The clinical presentation of WD consists of hypoceruloplasminemia, presence of Kayser-Fleischer (KF) rings, and hepatic, psychiatric and/or neurological disturbance^[4]. Treatment of WD has progressed from chelation therapy using D-penicillamine and trientine to the more recent use of zinc, and finally to liver transplantation for fulminant presentation^[5]. Timely diagnosis and treatment may protect patients from severe organ damage. The diagnosis of WD is determined by clinical presentation and laboratory testing for KF rings, hepatic injury and low serum ceruloplasmin. However, some asymptomatic patients do not receive effective treatment before irreversible injury is present. Genetic diagnosis may detect presymptomatic patients, in whom initiation of prophylactic therapy can effectively prevent the otherwise inevitable hepatic and neurological injury^[6,7].

Mutations in the P-type ATPase (ATP7B, MIM#277900) gene are responsible for WD. The ATP7B gene, which was identified in 1993, is located on chromosome 13q14.3, which spans a genomic region of ~80 kb. It comprises 21 exons and encodes for a P-type copper-transporting ATPase^[8-10]. Direct mutation analysis has been performed in many WD patients and > 200 different ATP7B mutations have been detected^[11-13]. H1069Q is the most common type of mutation, with an allelic frequency of 10%-40% in European patients^[14-16]. However, Arg778Leu in exon 8 is the most frequently observed mutational type in Chinese, Japanese and Korean patients^[17-22]. It has been reported that the Arg778Leu mutation may be correlated with hepatic manifestations in Chinese patients^[12]. However, the mutations in Chinese patients with WD, and the possible correlation of specific mutations with clinical characteristics, have not been addressed.

In the present study, mutations of the ATP7B gene were sought by means of direct sequencing in 50 Eastern Chinese WD patients of Han ethnic origin, who comprise 99% of the population of mainland China. We also

compared the characterization of mutations in ATP7B with the clinical findings, and report the preliminary results of the genotype/phenotype correlation.

MATERIALS AND METHODS

Subjects

A total of 50 unrelated Han ethnic subjects (24 female, 26 male) in mainland Eastern China were diagnosed as being affected by WD. They were mainly from Zhejiang, Anhui and Fujian Provinces. They were recruited when they came to the hospital for seeking assistance. The diagnosis was based on the presence of hepatic disturbance, typical neurological symptoms, KF rings, biochemical tests (low serum concentrations of ceruloplasmin and copper, and high urinary and hepatic copper content). Each of these patients had a score of at least 3 according to a scoring system based on clinical and biochemical parameters^[23]. DNA samples from 100 healthy Chinese individuals (50 female, 50 male) were screened to determine whether the missense/splicing mutations identified in this study were present in the normal population. The healthy subjects were mainly students in our teaching hospitals. Informed consent was obtained from all patients or their parents before inclusion in the study.

PCR and DNA sequencing

Anticoagulated blood samples were obtained from the WD patients. Genomic DNA was isolated from peripheral blood lymphocytes by a DNA extractor kit (Qiagen, Germany). All 21 exons of ATP7B were amplified by polymerase chain reaction (PCR). PCR was performed in a 50- μ L reaction volume containing 800 ng genomic DNA, 2.5 U Taq polymerase (Takara, Japan), 12.5 pmol each primer, 3 mmol/L MgCl₂, 200 μ mol/L each dNTP, and 1 \times PCR Buffer (Takara, Japan). The PCR reaction conditions were as follows: 15 min initial activation step at 94°C; 35 cycles of denaturation at 94°C for 30 s, annealing at 55°C for 30 s and extension at 72°C for 120 s; and a final extension at 72°C for 10 min. PCR products were visualized on 2% agarose gel containing ethidium bromide, and subsequently purified using QIAEX II (Qiagen, Germany). Direct sequencing was performed using an ABI 377 fluorescent sequencer (Applied Biosystems, Foster City, CA, USA).

Analysis of genotype-phenotype correlations

We analyzed the correlation between Arg778Leu genotype and WD phenotype, including age of onset and initial symptoms. Data were analyzed using SPSS 13.0. Age of onset of symptoms was compared using Student's *t* test. Categorical variables were compared between groups by the χ^2 test or Fisher's exact test. Differences were considered to be significant at the $P < 0.05$ level.

RESULTS

Mutation analysis

DNA from the 50 patients with WD was screened for mutations. Exons 1-21 were PCR-amplified and the products were sequenced bidirectionally. Mutations in

ATP7B were found in at least one of the alleles in all the patients with WD, distributed throughout the gene. In eight patients, only one allelic change was detected, which suggests that the other one might have been located in the introns or regulatory regions. We identified five different mutations (Table 1). Two different mutations found in exons 8 and 13 account for about 77% of all 100 WD alleles studied, thereby indicating that these exons are important regions for detecting mutations in Eastern Chinese patients with WD. The most frequent mutation, Arg778Leu, was found in 32 (64%) patients, in at least one allele. The frequency of the other most prevalent mutation Pro992Leu was 27%. In the copper-binding domain, we found two novel mutations: one non-conservative, which replaced a highly conserved acidic amino acid with a small non-polar amino acid (Asp96Gly); and the other conservative (Asp196Glu), but lying at a highly conserved position in Menkes disease and other copper-transporting ATPases. The two novel mutations were both missense mutations, and the nucleotide changes were not found in the 100 normal individuals. The novel features of these mutations were identified according to the database that is maintained by the University of Alberta (<http://www.medicalgenetics.med.ualberta.ca/wilson/index.php>).

DNA polymorphism

Seven DNA sequence polymorphisms were identified (Table 2). DNA sequence polymorphisms were those nucleotide changes that either did not modify the amino acid sequence of the polypeptide, resulted in conservative changes in the amino acid residues, or that were found in normal chromosomes or chromosomes with known disease-causing mutant alleles. In order to clarify these nucleotide and amino acid sequence changes were mutations or polymorphisms, we analyzed 100 normal individuals with direct sequencing of their PCR products. The nucleotide changes present in those 100 normal individuals were considered to be polymorphisms, and those which were not present, were considered to be mutations.

Genotype-phenotype correlations

A total of 50 patients with WD were analyzed. The mean age of patients at disease manifestation was 8.9 ± 1.9 years (median, 8 years; range, 4-13 years). Thirty patients (60%) had a primary hepatic manifestation, 13 showed a primary neurological manifestation, and five had combined hepatic and neurological manifestations. Two patients (4%) identified by family screening had no symptoms; they were classified as asymptomatic, and were not included in analysis of genotype-phenotype correlations.

We identified 18 homozygotes and 14 heterozygotes for Arg778Leu. In the 32 patients carrying Arg778Leu, 25 (78.1%) had hepatic manifestations (age of onset, 8.1 ± 1.7 years). There were a total of 18 patients (36%) without the Arg778Leu mutation, 10 (55.6%) with hepatic manifestations (age of onset, 9.2 ± 2.3 years). The Arg778Leu homozygous patients were not significantly younger at the time of symptom onset (8.5 ± 2.1 years), compared with compound heterozygotes (7.9 ± 1.8

Table 1 Mutations identified in WD chromosomes

years). However, the number of Eastern Chinese patients with hepatic manifestations among those carrying the Arg778Leu mutation was significantly greater than that among those without the mutation ($\chi^2 = 5.26$, $P < 0.05$).

DISCUSSION

Mutation analysis is important in the early diagnosis of patients with a family history of WD, as well as in prenatal diagnosis. Here, we report a group of 50 subjects affected with WD, analyzed by direct sequencing of the entire coding sequence of ATP7B gene. We found mutations in 50 patients. The detection rate of mutation was 92%. Seventy-seven percent of the mutations detected were lying in exons 8 and 13. According to this study, we recommend screening of exons 8 and 13 by sequence analysis. Mutations in exons 14 and 18, which have been found to have a high frequency among Caucasian patients^[24-27], were not detected in our study. As reported previously^[12], Arg778Leu was the most common WD chromosomal mutation detected in the present study (50%). However, Arg778Gln was not detected in our study, which is similar to the results of previous research in Shanghai^[12]. The unusual high frequency of codon 778 mutation may have been due to sampling disequilibrium or to the presence of a founder effect among the Eastern Chinese population. Pro992Leu was the second most frequent allele, with a frequency of 27%. The above-mentioned two mutations accounted for ~80% of all mutations detected in our study. In eight patients, only one allelic change was detected, which suggests that the other change might be located in the introns or regulatory regions. Incomplete assessment of intronic and regulatory sequences may have

accounted for the second unidentified mutation.

We could not find any significant difference between Arg778Leu homozygosity and heterozygosity with regard to the mean age of onset of symptoms, although Wu *et al.*^[7] have reported that the average age of onset in 18 Chinese homozygotes was significantly lower than that in 11 Chinese compound heterozygotes for Arg778Leu. However, the number of patients with hepatic manifestations among those carrying Arg778Leu mutation was significantly greater than that among patients without the mutation. Caca *et al.*^[28] have reported that symptoms in most His1069Gln homozygotes started between 16 and 25 years of age. In our study, symptoms in most Arg778Leu homozygotes (15/18) started before 10 years of age, which suggests that the age of onset in Arg778Leu homozygotes in Eastern Chinese patients is earlier than that in His1069Gln homozygotes in East German patients. His1069Gln is the most common WD mutation found in the European population^[29-31], but it was not detected in our study in Eastern Chinese patients.

Molecular diagnosis of pre-symptomatic WD patients is important in the control of disease progression and treatment. Mutation detection in WD is challenging because of the presence of a large number of mutations in a 4.4-kb coding region in 21 exons spread over 80 kb of genomic DNA. The mutation detection rate among the WD chromosome was > 90% in our study. This gene sequencing analysis method was shown to have a high detection rate and accuracy. It may become the first priority in the screening of WD patients.

COMMENTS

Background

Direct mutation analysis has been performed in many WD patients, and more than 200 different ATP7B mutations have been detected.

Research frontiers

The mutations in the Chinese population with WD, and the possible correlation of specific mutations with clinical characteristics have not been investigated. In the present study, mutations of the ATP7B gene were sought by means of direct sequencing in 50 Eastern Chinese patients of Han ethnic origin with WD.

Innovations and breakthroughs

Two novel mutations were identified in our normal individuals. The novel features of the mutations were identified according to a database that is maintained by the University of Alberta.

Peer review

It is an interesting manuscript. The first concern is on the study population. The

subjects were from mainland Eastern China, which covers a large area. More specific information on subject source, which clinic they attended, and conditions under which they were recruited would be helpful.

Abstract

Sirolimus is an immunosuppressant with expanding use in pediatric organ transplantation, dermatology and rheumatology. We report two cases of children who developed asthma like symptoms and were diagnosed with interstitial lung disease, which responded to discontinuation of sirolimus. Pediatricians should be aware about the pulmonary side effects of sirolimus.

INTRODUCTION

Sirolimus (rapamycin) is a macrolide immunosuppressant with increasing use in various pediatric subspecialties^[1,2]. Its dose-related side effects leading to thrombocytopenia and hypercholesterolemia are widely known. Pulmonary toxicity associated with sirolimus therapy has only been recently recognized as a potentially serious complication^[3]. Among the twenty-eight children (18 with liver transplant and 10 with small bowel transplant) treated with sirolimus in our center, two developed pulmonary complications which are described in this case report.

CASE REPORT

Case 1

A 2-year-old girl with microvillous inclusion disease underwent combined small bowel and liver transplantation (CSBLTx). She received tacrolimus and prednisolone according to our immunosuppression protocol. She developed severe rejection at the age of 2 years due to poor compliance with medications. Sirolimus (0.1 mg/kg per day) was added to her immunosuppression regime aiming at levels of 8-10 ng/mL for both tacrolimus and sirolimus.

Four months after starting sirolimus treatment, she developed a perforation near the anastomotic site of the intestinal allograft and sirolimus was stopped. She remained generally well in the next year, but in view of deteriorating renal function, and persistent hypomagnesaemia, the tacrolimus dose was halved (target level 3-5 ng/mL) and sirolimus was added (target level 8-10 ng/mL). Two months after commencing sirolimus she acquired adenovirus infection which required mechanical ventilation and reduction of immunosuppression (target level of tacrolimus and sirolimus 3-5 ng/mL). After the reduction of immunosuppression, she showed an uneventful recovery.

During the next 5 mo (now 4 years and 9 mo after transplantation), in which sirolimus was re-introduced, she developed a dry cough and increased respiratory rate with mild subcostal recession. Her clinical examination was otherwise unremarkable. Initially she had no response to bronchodilators for possible asthma. Pulmonary function tests were normal. Her chest X-ray showed some loss of volume in the left lower lobe and coarse interstitial shadowing throughout both lung fields. Immunofluorescence and viral culture of nasopharyngeal aspirates and broncho-alveolar lavage (BAL) including adenovirus were all negative. The BAL fluid grew haemophilus influenzae, which was treated with amoxicillin. Blood cultures for fungi and bacteria were negative, as was PCR for CMV and EBV. A high resolution CT scan of the chest demonstrated fine nodular changes in the interstitial air spaces. A lung biopsy was considered but deferred. Sirolimus-associated pulmonary toxicity was suspected and sirolimus was discontinued. Her respiratory symptoms of cough and dyspnea improved within 3 mo and her chest X-ray changes resolved within 6 mo.

Case 2

A 9-mo-old boy with Hirschsprung disease with

Figure 1 Chest X-ray showing bilateral interstitial shadowing and nodularity.

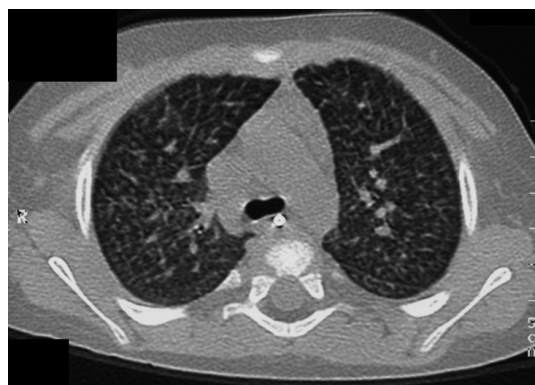

Figure 2 CT scan of the chest showing thickening of the interlobular septae with fine nodular changes.

total aganglionosis extending proximally to the pylorus underwent CSBLTx. He was commenced on tacrolimus and prednisolone according to our standard immunosuppression protocol. An episode of moderate acute rejection 10 d after transplant was treated with a single dose of steroids and two doses of basiliximab four days apart. Sirolimus (0.14 mg/kg) was commenced 6 wk after transplant. The aim was to maintain tacrolimus and sirolimus levels at 8-10 ng/mL and 6-8 ng/mL, respectively. Five months after commencing sirolimus, he showed features of bone marrow suppression with neutropenia and anemia. A bone marrow aspirate showed myeloid maturation arrest and responded well to weekly injection of granulocyte colony stimulating factor for 3 mo and supportive treatment.

In view of bone marrow suppression, the dose of sirolimus was reduced to maintain a level 4-6 ng/mL. Seven months after introduction of sirolimus, he presented with a persistent dry cough and breathlessness on exertion. Respiratory examination was normal. Chest X-ray showed bilateral interstitial shadowing and nodularity (Figure 1), but overnight pulse oximetry observation was normal. A comprehensive evaluation for post-transplant lymphoproliferative disease (PTLD), including biopsies from upper GI endoscopy, liver biopsy, and ileoscopy was negative. EBV PCR titer was low with a level of 1000 genome copies/mL. Investigations for respiratory infection, including BAL, revealed no infection and special staining for pneumocystis carinii pneumonia, acid-fast bacilli staining and immunochemistry for cytomegalovirus and Epstein-Barr virus were negative. A high resolution CT scan revealed thickening of the interlobular septae with fine nodular changes (Figure 2). A lung biopsy was considered and deferred. Following discontinuation of sirolimus, his symptoms resolved within 4 wk, but radiological changes were not resolved after 18 mo of follow-up.

DISCUSSION

The resolution of clinical symptoms and improvement in radiological changes after withdrawal of sirolimus in our patients, with the absence of other infectious factors, strongly implicates that sirolimus is the causative factor for the pulmonary changes.

Sirolimus-associated pulmonary toxicity is mostly described in the adult literature and actually represents a spectrum of clinico-pathologic syndromes characterized clinically by dyspnea, cough, fever, fatigue or haemoptysis, and histologically by the presence of organizing pneumonia, interstitial pneumonitis, focal fibrosis or by the presence of alveolar haemorrhage^[4]. In the largest report on sirolimus-associated pulmonary toxicity in adult kidney transplant recipients, features of pneumonitis were seen within 6-12 mo after commencing sirolimus therapy^[3]. Our patients showed a similar time course.

The children in this report exhibited 'asthma like' symptoms with recurrent episodes of dry cough and breathlessness on exertion. In children on immunosuppressive drugs, the diagnostic challenge is to rule out opportunistic infections. Lung biopsy looking for any histological changes was not performed due to the invasive nature of the procedure and resolution of the symptoms and radiological changes on cessation of sirolimus. A review of drug history did not identify any other medicines in the complex cases, which could give rise to the 'asthma' like symptoms.

The management consists of excluding other etiologies, especially opportunistic infections, and discontinuation or dose reduction of sirolimus^[3]. As in the previous reports, respiratory symptoms resolved within 2-4 wk after cessation of sirolimus therapy with improvement of CXR changes in 6-18 mo, which is consistent with other case reports^[3,5]. We opted to stop the treatment as the long-term outcome of interstitial lung changes in children is not known. It is possible that the degree of reversal of pulmonary symptoms depends on the extent and the chronicity of parenchymal and interstitial changes. The children reported were on low dose steroids as a part of their immunosuppression regime and developed interstitial lung disease despite being on steroids.

The exact pathogenic mechanism of sirolimus-induced pulmonary toxicity is not known. Possible mechanisms include idiosyncratic cell-mediated autoimmune response due to the exposure of cryptic antigens and T cell-mediated delayed type hypersensitivity reaction^[3,6]. Of the 28 children (10 with small bowel transplant, 18 with liver transplant) treated with sirolimus in the liver unit at BCH, two children with small bowel transplant developed the

changes, while none of the children with liver transplants developed this complication. It is entirely possible that the complication may be related to the higher intensity of immunosuppression used in the children with intestinal transplantation. However, a simple dose-dependant toxicity reaction seems less likely since other dose-dependent side effects such as thrombocytopenia or hypercholesterolemia were absent. Morath C *et al*^[7] have documented that an increase in sirolimus levels 3 wk prior to the onset of symptoms and an older age are the risk factors for developing interstitial lung disease. Similar observations could not be made from our two cases.

In conclusion, with the expanding use of sirolimus in children, the appearance of persistent respiratory symptoms, especially cough and dyspnea, should alert the pediatrician to the possibility of sirolimus-associated pulmonary toxicity and the drug may have to be discontinued.

ACKNOWLEDGMENTS

The authors gratefully acknowledge the help from Dr. M Sood (Paediatric Gastroenterologist, Booth Hall Children's Hospital, Manchester) and Dr. S Mitton (Paediatric

Gastroenterologist, St George's Hospital, London) in the shared care of these complex patients.

Abstract

We report a cirrhotic patient with duodenal vascular ectasia and spontaneous bleeding. The bleeding was successfully controlled with argon plasma coagulation. Duodenal vascular ectasia may be a cause of upper gastrointestinal bleeding in patients with cirrhosis, and argon plasma coagulation may be effective and safe to achieve hemostasis of this lesion.

Lee BJ, Park JJ, Seo YS, Kim JH, Kim A, Yeon JE, Kim JS, Byun KS, Bak YT. Upper gastrointestinal bleeding from duodenal vascular ectasia in a patient with cirrhosis. *World J Gastroenterol* 2007; 13(38): 5154-5157

<http://www.wjgnet.com/1007-9327/13/5154.asp>

INTRODUCTION

Vascular ectasia of the duodenum is rare^[1] and an uncommon source of upper gastroduodenal bleeding. It is associated with chronic illnesses such as aortic valve disease and end-stage renal disease when patients are under long-term hemodialysis^[2-4]. Gallagher *et al*^[5] reported a patient with small bowel capillary dilatation and cirrhosis, and suggested that small bowel capillary dilatation appears to be unique in patients with portal hypertension, and may play a role in causing gastrointestinal bleeding. However,

to our knowledge, only a few cases of duodenal vascular ectasia have been reported in patients with cirrhosis^[5-7]. We report a case of upper gastrointestinal bleeding in a patient with cirrhosis and duodenal vascular ectasia, which was successfully controlled by argon plasma coagulation (APC).

CASE REPORT

A 62-year-old man was admitted because of melena, dizziness, and anemia with a follow-up history for chronic hepatitis B infection, liver cirrhosis, and hepatocellular carcinoma. About a 2 cm-sized tumor mass was located in subcapsular portion of segment 7. After two sessions of transarterial chemoembolization for the tumor mass, no visible tumor was found. He visited the emergency room two years ago because of hematemesis, and an endoscopic examination revealed esophageal varices with bleeding, which were treated with endoscopic band ligation.

Physical examination revealed blood pressure of 100/80 mmHg, pulse rate of 72 beats per minute, respiratory rate of 14 breaths per minute, and body temperature of 36.8°C. He was alert and oriented to person, place, and time. His sclera was nonicteric and conjunctiva was pale. Chest and heart examinations were normal. Abdominal examination revealed a distended abdomen with prominent shifting dullness. Pitting edema was noted in both lower extremities.

The results of initial laboratory tests were as follows: white blood count (WBC) = 3700/mm³, hemoglobin = 7.3 g/dL, platelets = 34000/mm³, prothrombin time = 23.8 s, international normalized ratio = 2.05, C-reactive protein = 82.6 mg/dL, total bilirubin = 2.07 mg/dL, direct bilirubin = 0.96 mg/dL, protein = 5.23 g/dL, albumin = 2.83 g/dL, alanine aminotransferase = 67 IU/L, aspartate aminotransferase = 62 IU/L, gamma-glutamyl transferase = 38 IU/L, alkaline phosphatase = 87 IU/L, glucose = 142 mg/dL, blood urea nitrogen (BUN)/creatinine (Cr) = 19.57/0.75 mg/dL, and Na/K/Cl = 120/4.1/87 mEq/mL. Paracentesis revealed clear yellow-colored ascitic fluid, which on analysis showed 0/mm³ WBC, 2000/mm³ red blood cells, 242 mg/dL glucose, and 252 mg/dL protein. The serum α -fetoprotein concentration was 6.2 ng/mL. He was positive for hepatitis B surface antigen and negative for hepatitis B envelope antigen.

Bleeding from the esophageal varices was suspected and urgent endoscopic examination was performed. However, the urgent endoscopy showed small esophageal varices

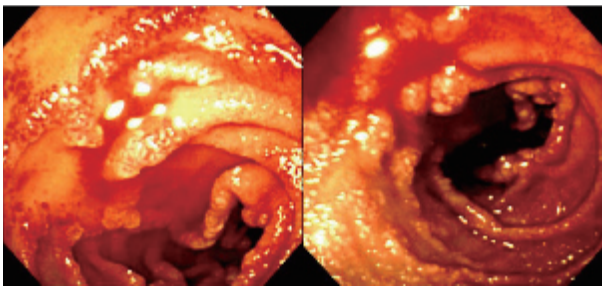

Figure 1 Endoscopy showing a vascular ectasia with active bleeding on the second portion of duodenum.

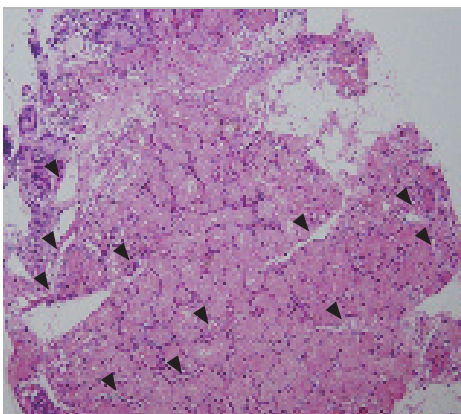

Figure 2 Biopsy from duodenal mucosa showing grossly dilated blood vessels (arrowheads) in the Brunner's glands (HE, $\times 100$).

with no evidence of bleeding, and unexpectedly, vascular ectasia with oozing was found on the duodenal bulb and second portion (Figure 1). Endoscopic biopsy was performed on the vascular ectatic mucosa and histological examination revealed grossly dilated blood vessels in the Brunner's glands at the mucosal layer (Figure 2). To achieve hemostasis, APC (Arco-2000, Soring, Germany) was performed (argon gas flow = 1.5 L/min, power = 50 W), which controlled the bleeding without any complications such as bowel perforation (Figure 3). Follow-up endoscopic examination after one week showed minimal blood oozing on the telangiectatic duodenal mucosa, and a second session of APC was performed (Figure 4A). After endoscopic treatment, his hemoglobin concentration did not decrease and his symptoms improved, and the patient was discharged.

Two months after discharge, endoscopic examination revealed a remnant vascular ectatic duodenal mucosa but no spontaneous bleeding (Figure 4B).

DISCUSSION

Upper gastrointestinal bleeding is one of the most frequent causes of morbidity and mortality during the clinical course of liver cirrhosis^[8-11] and has an overall mortality rate of 24% at six weeks and 40% at one year^[12]. A recent study showed that gastroesophageal varices (59.1%) comprise the most frequent bleeding lesion in patients with cirrhosis^[13]. Others have reported a similar frequency

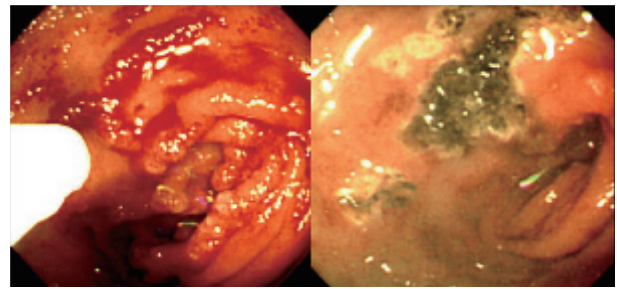

Figure 3 Induction of hemostasis by APC (Arco-2000, Soring, Germany) (left) with blood oozing controlled without complications (right).

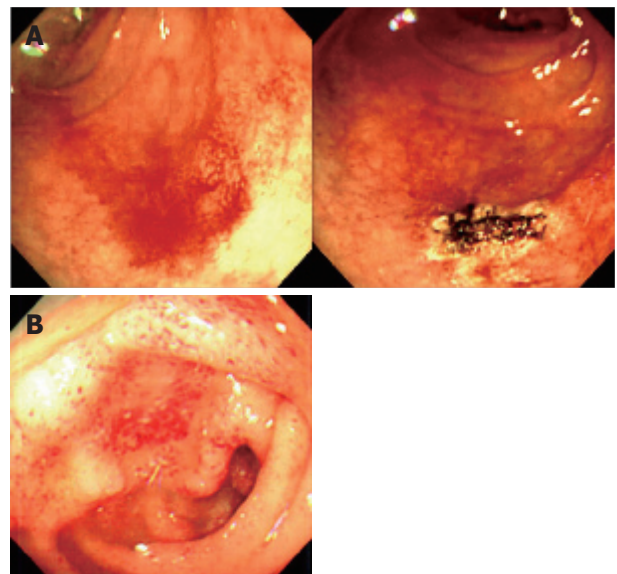

Figure 4 A one-week follow-up endoscopy showing the successfully controlled blood oozing from vascular ectasia on the second portion of the duodenum with APC (A) and a two-month follow-up endoscopy showing the ectatic vascular duodenal mucosa with no further spontaneous bleeding (B).

of esophageal varices bleeding, ranging 49%-72%^[12,14,15]. Peptic ulcer bleeding is the second most frequent type of bleeding lesion (15.7%)^[13].

Upper gastrointestinal vascular ectasia is recognized as an increasingly important source of gastrointestinal bleeding, and can present as that of either overt or of an obscure cause^[3,16-19]. Gastric antral vascular ectasia (GAVE) is a distinct vascular abnormality involving mainly the gastric antrum. Endoscopic examination shows linear, friable red streaks radiating from the pylorus. Angiodysplastic lesions are typically discrete, flat, or slightly raised bright-red lesions 2-10 mm in size, often with fern-like margins and a surrounding pale rim^[20]. The clinical presentation is either chronic, low-grade bleeding, which often leads to iron-deficiency anemia, or acute bleeding with hematemesis or melena. Patients may have recurrent episodes of bleeding which require multiple transfusions, and become transfusion dependent^[20]. A recent study showed that 29% of patients with vascular ectasia also have chronic liver diseases^[21].

By definition, GAVE occurs only in the antrum. However, ectopic ectasia has been reported in the cardiac region^[22], gastric corpus^[23], duodenum^[22,24], and possibly in

the colon^[22]. **Astaldi and Strosseli**^[25] suggested that small bowel biopsies from patients with hepatic cirrhosis might show vascular stasis arising from portal stasis. **Bank et al**^[26] have noted a 'striking increase in vascularity of the villi' in a small bowel biopsy of a patient with cirrhosis and esophageal varices. **Gallagher et al**^[5] suggested that capillary dilatation is probably caused by increased pressure in the portal system.

To our knowledge, only a few cases of vascular ectasia of the duodenum have been reported in patients with cirrhosis^[5-7]. In one report, **histology of the endoscopic duodenal biopsy** revealed grossly dilated capillaries in the villi of the duodenum and jejunum, the patient received a portacaval shunt, but died postoperatively^[5]. **Arendse et al**^[6] reported a fatal case of vascular ectasia of the duodenum in a patient with cirrhosis, which was revealed by autopsy. **Cales et al**^[7] reported an ectasia in a patient with cirrhosis, which was revealed by autopsy. The patient was treated with endoscopic sclerotherapy and a portosystemic shunt to control the bleeding, although neither was successful. Our study seems to be the first to report successful control of bleeding from vascular ectasia of the duodenum by APC in a patient with cirrhosis.

We attempted to treat bleeding from duodenal vascular ectasia by APC and found a certain improvement on endoscopic examination of the duodenum. However, we did not eradicate the duodenal vascular ectasia. **Pavey et al**^[20] reported that patients with GAVE require more sessions to fully control the bleeding and more transfusion than patients with angiodysplasia. Our patient also seemed to need more sessions of APC to completely eradicate ectasia, although this was not possible because he did not visit our hospital after the last endoscopic examination.

Before the widespread availability of therapeutic endoscopy, vascular ectasia was treated with surgical resection^[27,28]. More recently, upper gastrointestinal vascular ectasias have been treated with various endoscopic techniques including heater probe coagulation^[29], bipolar electrocautery^[30] and Nd: YAG laser^[31-33], and APC^[20]. APC is a no-touch electrocoagulation technique in which a high-frequency monopolar alternating current is delivered to the tissue through ionized argon gas^[34,35]. The advantages of this method include the technical ease in treating large areas and the ability to achieve superficial coagulation with a controllable depth of injury. The treated areas heal faster and the endpoint of therapy can be reached sooner^[34,35]. In our patient, to reduce the risk of bowel perforation, we applied irradiation for 4-6 s with a current of 50 W, and were able to successfully control the bleeding without any serious complications.

In conclusion, duodenal vascular ectasia may be a cause of upper gastrointestinal bleeding in patients with cirrhosis. APC can be used as an effective and safe therapeutic tool to achieve hemostasis of this lesion.

Abstract

We describe the clinical, imaging and cytopathological features of solid pseudopapillary tumor of the pancreas (SPTP) diagnosed by endoscopic ultrasound-guided (EUS-guided) fine-needle aspiration (FNA). A 17-year-old woman was admitted to our hospital with complaints of an unexplained episodic abdominal pain for 2 mo and a short history of hypertension in the endocrinology clinic. Clinical laboratory examinations revealed polycystic ovary syndrome, splenomegaly and low serum amylase and carcinoembryonic antigen (CEA) levels. Computed tomography (CT) analysis revealed a mass of the pancreatic tail with solid and cystic consistency. EUS confirmed the mass, both in body and tail of the pancreas, with distinct borders, which caused dilation of the peripheral part of the pancreatic duct (major diameter 3.7 mm). The patient underwent EUS-FNA. EUS-FNA cytology specimens consisted of single cells and aggregates of uniform malignant cells, forming microadenoid structures, branching, papillary clusters with delicate fibrovascular cores and nuclear overlapping. Naked capillaries were also seen. The nuclei of malignant cells were round or oval, eccentric with fine granular chromatin, small nucleoli and nuclear grooves in some of them. The malignant cells were periodic acid Schiff (PAS)-Alcian blue (+) and immunocytochemically they were vimentin (+), CA 19.9 (+), synaptophysin (+), chromogranin (-), neuro-specific enolase (-), α 1-antitrypsin and α 1-antichymotrypsin focal positive. Cytologic findings were strongly suggestive of SPTP. Biopsy confirmed the above cytologic diagnosis. EUS-guided FNA diagnosis of SPTP is accurate. EUS findings,

cytomorphologic features and immunostains of cell block help distinguish SPTP from pancreatic endocrine tumors, acinar cell carcinoma and papillary mucinous carcinoma.

INTRODUCTION

Solid pseudopapillary tumor of the pancreas (SPTP) is a rare neoplasm with a reported frequency of between 0.17% and 2.7% of all nonendocrine tumors of the pancreas^[1], and 6.5% of all pancreatic tumors and tumor-like lesions resected in one large institute^[2]. This tumor seems to preferentially occur in young females with a reported mean age of 25 to 30 years, ranging 11-73 years^[2,3]. In the elderly population it has been suggested that SPTP tend to be malignant^[4,5]. It was first described by Frantz in 1959^[6]. Multiple descriptive names have been used for this tumor, including papillary epithelial neoplasm, papillary/cystic neoplasm, solid-and-papillary epithelial neoplasm, papillary-cystic carcinoma, solid-and papillary neoplasm, low-grade papillary neoplasm, and the Frantz tumor^[7]. The WHO pancreatic tumor working group recently recommended the use of the term solid-pseudopapillary neoplasm^[8], a term that has been widely used and accepted by pathologists and clinicians in daily practice^[9,10].

Almost 610 SPTPs, including more than 57 diagnosed by percutaneous fine-needle aspiration (FNA), have been reported since the initial description in 1959^[6]. In recent years, image-guided FNA has been increasingly performed for pancreatic lesions. Endoscopic ultrasound (EUS)-guided FNA can have an important role and provide an

accurate preoperative diagnosis particularly when the EUS findings of the mass are inconclusive. EUS-guided FNA can differentiate SPTP from other pancreatic neoplasms of similar radiologic and cytologic appearance but with different biologic behaviour and treatment, such as pancreatic endocrine tumors, acinar cell carcinoma, and papillary mucinous carcinoma^[11-17]. The cytomorphology of this tumor is highly characteristic, with features that are distinctive from those of other cystic and solid tumors of the pancreas. It is important that this tumor is accurately diagnosed because management protocols differ from other tumor types originating in the pancreas.

In this paper, we describe the clinical, imaging, cytomorphologic features and differential diagnosis of a new case of SPTP diagnosed by EUS-guided FNA with a review of the literature.

CASE REPORT

A 17-year-old woman was admitted with complaints of an unexplained episodic pain for 2 mo and a short history of hypertension in the endocrinology clinic of our hospital (Athens General Hospital, Greece). Clinical laboratory examinations revealed polycystic ovary syndrome (PCOs), splenomegaly and low serum amylase and carcinoembryonic antigen (CEA) levels. CT-scan revealed a mass of the pancreatic tail with solid and cystic consistency.

EUS-guided FNA was performed using 22-gauge needles *via* a transgastric approach. Smears were made at the bedside in the endoscopy suite. The aspirated material was smeared onto glass slides, air-dried, and immediately stained with rapid Hemo-color stain for specimen adequacy assessment and preliminary diagnostic interpretation. Other smears also were fixed immediately in 95% alcohol for subsequent Papanicolaou staining. Additional aspirated material was fixed in formalin, embedded in paraffin, and processed for routine histologic examination using standard techniques. Staining with periodic acid Schiff (PAS) and Alcian-blue (AB) stains was performed. Immunohistochemical stains for vimentin (Dako; 1:100), neuron-specific enolase (NSE) (Dako; 1:100), synaptophysin (NovoCastra, Newcastle UK), chromogranin (Dako; 1:800), CA 19.9 (Dako), α 1-antitrypsin (Dako; 1:3200), α 1-antichymotrypsin (Dako; 1:800), were also performed. Avidin-biotin peroxidase complex technique was used.

Smears and cell block sections were examined with an emphasis on the evaluation of cytomorphologic features and immunohistochemical results.

EUS confirmed a mass, both in body and tail of the pancreas, with distinct borders, which caused dilation of the peripheral part of the pancreatic duct [major diameter (m.d.) 3.7 mm]. More specifically the tumor mass was solid and cystic, hypoechoic and heterogenous with a size measuring 65.4 mm \times 54.2 mm (Figure 1). The EUS differential diagnosis included serous cystadenoma, mucinous cystadenoma, mucinous cystadenocarcinoma, adenocarcinoma with cystic degeneration, endocrine tumor and SPTP.

Smears were hypercellular and characteristically showed branching papillary arrangements composed of delicate fibrovascular cores and microadenoid structures with at-

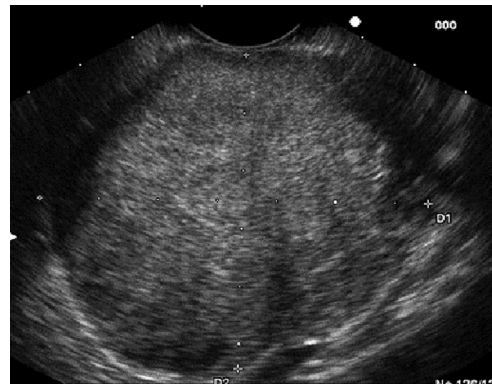

Figure 1 Endoscopic ultrasound image (EUS) showing a mass in body and tail of the pancreas.

tached monotonous cuboidal neoplastic cells (Figure 2A-B). The nuclei of malignant cells were round or oval, eccentric with finely granular chromatin, small nucleoli and in some of them nuclear grooves. Cytoplasm was granular or finely vacuolated with wispy borders. No mitotic activity or significant atypia was observed. The architectural features were more evident in the cell block sections. Histochemically, tumor cells revealed PAS Alcian-blue (+) (Figure 3A-B). Immunostains performed on the cell block yielded vimentin positivity (Figure 4A), CA 19.9 positivity (Figure 4B), synaptophysin, α 1-antitrypsin and α 1-antichymotrypsin focal positivity whereas NSE and chromogranin were negative. These findings were strongly suggestive of SPTP.

DISCUSSION

Solid-pseudopapillary neoplasm is an exceedingly rare pancreatic tumor with a reported frequency of less than 1% of all pancreatic diseases. Most of these reports are in the form of small case series with only few reports with greater than 50 cases identified in the literature.

It predominantly occurs in adolescent girls and young women with a reported frequency of 87% to 90% (mean age of 25 to 35 years)^[2,3]. Such a striking predilection of SPTP occurring in women has suggested a hormonal influence on the pathogenesis of this tumor^[18,19]. Cases occurring at the first decade of life are rare and less than 10% of SPTP cases have been reported in patients older than 40 years^[2,20]. Occurrence of SPTP in men is rare, accounting for 7% of cases^[21].

Clinically, SPTP may present as an abdominal mass with discomfort or pain, or it may be an incidental finding in work up for unrelated conditions. These tumors are generally large with a mean diameter of 10.3 cm and approximately 72% arise in the body and tail of the pancreas and less frequently in the head^[2]. Unusual presentations of SPTP include multicentricity^[22,23], occurrence in extra-pancreatic sites such as mesocolon^[24], retroperitoneum^[25], omentum^[26], liver^[27] and duodenum^[28]. In our case, the sex (female), age (17 years old) and tumor localization (body and tail of the pancreas) were typical of SPTP.

In most patients, the tumor follows an indolent clinical course and complete resection is often curative^[20,29]. Up to 15% of cases have shown aggressive behaviour consisting of extension into adjacent blood vessels and organs, local recurrence and distant metastasis^[20,28,30,31]. However, even metastatic SPTPs are growing slowly and have excellent prognosis. Only one death, due to metastatic spread of

SPTP has been reported^[32]. Also, spontaneously regressing tumors have been reported^[33].

Benign-appearing SPTP might contrast with cellular anaplasia present in the metastatic deposits^[34]. Thus, there are no histological features that can predict aggressive clinical behaviour. Proposed pathologic features related to aggressive behaviour or metastatic potential include diffuse growth pattern, venous invasion, nuclear pleomorphism, mitotic rate, necrosis and areas of dedifferentiation^[35]. Most SPTPs display diploid DNA content^[1]. However, DNA aneuploidy is more prominent in malignant SPTPs^[34,36]. Chromosomal abnormalities, including double loss of X chromosomes and trisomy for chromosome 3, and unbalanced translocation between chromosomes 13 and 17 have been found in SPTP associated with aggressive behaviour and might be indicators of possible metastatic potential^[37,38]. Thus, since the malignant potential of SPTP is difficult to determine, this tumor is considered a low malignant or borderline malignant potential.

The histogenesis of SPTP has been, and to date remains, elusive. Multiple theories have been proposed, including origin from small duct epithelium, derivation from acinar cells, endocrine pancreas, totipotent stem cells, or primitive cells capable of differentiating exocrine and endocrine^[4,39-41], along with genital ridge-related cells that are incorporated in the pancreas during early embryogenesis^[42]. Another recent report showed that SPTP is positive for melanocytic markers (S-100 protein, human melanoma black 45 (HMB45) and melanoma antigen recognized by T-cells 1 (MART-1) by immunohistochemistry and demonstrated the presence of premelanosomes and melanosome granules in the tumor cells by transmission electron microscopy, suggesting that this tumor may be of neural

crest origin^[43]. Also, predilection in young women suggests that sex hormones play a role in the histogenesis or progression of this tumor. However, the ER and PR expression are not consistent in the literature. Using a binding assay, Ladanyi *et al*^[18] demonstrated the expression of ER in SPTP and proposed that this tumor is hormone sensitive.

Diagnosis of SPTP is important for the clinical management of patients with this tumor. Diagnostic modalities including CT and magnetic resonance imaging can only suggest a diagnosis of SPTP. CT findings include an encapsulated lesion with well-defined borders and variable central areas with cystic degeneration, necrosis, or hemorrhage. Calcifications may occasionally be seen. Magnetic resonance imaging is helpful for identifying the characteristic internal signal intensities of blood products, which help distinguish this tumor from other cystic pancreatic tumors^[44].

In recent years, advances in technology have permitted the performance of fine-needle aspiration biopsy under EUS guidance^[45,46]. The overall accuracy of EUS is superior to CT scan and magnetic resonance imaging for detecting pancreatic lesions. It has been shown that EUS alone (94%) is more sensitive than CT scan (69%) and magnetic resonance imaging (83%) for detecting lesions, especially when they are smaller than 3.0 cm^[47]. EUS permits a better evaluation of SPTPs, but the findings also are not specific. A small SPTP, often a monocystic tumor most frequent in males, might have the EUS appearance of a solid endocrine neoplasm, and it might be difficult to distinguish between the two^[48].

An accurate preoperative diagnosis is highly desirable, since local surgical excision is usually curative and this is possible by EUS-guided FNA cytology. Bondeson *et al*^[49] were the first to correctly diagnose SPTP by preoperative FNA.

Since then, to our knowledge, cytologic findings of percutaneous FNA-diagnosed SPTP have been described in 57 cases^[9,21,22,31,37,49-53]. However, only few cases have been diagnosed by EUS-guided FNA^[9,54]. FNA cytomorphologic features are highly characteristic and distinct from those of other cystic or solid tumors of the pancreas. On aspirated materials, the most frequent features are the presence of marked cellularity with pseudopapillary fragments composed of fibrovascular stalks lined with one to several layers of tumor cells intermingled with discohesive neoplastic cells^[1,21,22,49,51]. Careful evaluation of smears for mitotic activity is recommended, since this parameter has recently been considered one predictive criterion for biologic aggressiveness^[55]. Inter or intracellular pink hyaline globules, mucus-like globules, as in our case, surrounded by stromal cells and cellular debris are also frequent features.

Immunohistochemically, most SPTPs are immunoreactive for vimentin (vim), a1-antitrypsin (AAT), a1-antichymotrypsin (AACT)^[56], occasionally positive for neuron-specific enolase and synaptophysin (syn)^[9], and nonreactive for S-100, CA 19.9 and chromogranin A. In our case, SPTP was vim (+), AAT (+), AACT (+), CA 19.9 (+) and syn (+). The above-mentioned cytologic and immunohistochemical features are strongly suggestive of SPTP.

The differential diagnosis of SPTP includes pancreatic

neuroendocrine tumor, acinar-cell carcinoma, papillary mucinous carcinoma and intraductal papillary mucinous tumor. Pancreatic endocrine tumors predominantly occur in older patients and can be associated with a variety of clinical syndromes. These tumors share some cytological features with SPTP. The presence of rosettes without papillary structures and typical "salt and pepper" chromatin indicates a pancreatic endocrine tumor^[20,16]. Additionally, these tumors express neuroendocrine markers such as chromogranin, neuron-specific enolase, and synaptophysin which are usually nonreactive in cases of SPTP. Acinar-cell carcinoma occurring in a wide range of age, is more commonly observed in males, and shows no predilection for head, body or tail location in the pancreas. Aspirates are cellular and composed only of acinar neoplastic cells containing enlarged nuclei with irregular membranes and distinct nucleoli. Patients with papillary mucinous carcinoma often have a single, large unilocular cystic mass and the neoplastic cells are columnar with cytoplasmic vacuoles, variable nuclear anaplasia, prominent nucleoli and mucinous background that should not be mistaken for the myxoid stroma^[22,57]. Also, the thick, glistening and viscid mucus almost always present in intraductal papillary mucinous tumor is an important feature that distinguishes this neoplasm from SPTP^[58].

In conclusion, we believe that EUS-FNA provides an excellent cellular yield and an overall sensitivity for the diagnosis of SPTP. Clinical correlation, radiological findings and cytomorphologic features from EUS-guided FNA achieve the accurate diagnosis of SPTP.

ACKNOWLEDGMENTS

Acknowledgments to Reviewers of *World Journal of Gastroenterology*

Many reviewers have contributed their expertise and time to the peer review, a critical process to ensure the quality of *World Journal of Gastroenterology*. The editors and authors of the articles submitted to the journal are grateful to the following reviewers for evaluating the articles (including those published in this issue and those rejected for this issue) during the last editing time period.

Meetings

MAJOR MEETINGS COMING UP

Meeting Falk Research Workshop: Morphogenesis and Cancerogenesis of the Liver
25-26 January 2007
Goettingen
symposia@falkfoundation.de

Meeting Canadian Digestive Diseases Week (CDDW)
16-20 February 2007
Banff-AB
cagoffice@cag-acg.org
www.cag-acg.org/cddw/cddw2007.htm

Meeting Falk Symposium 158: Intestinal Inflammation and Colorectal Cancer
23-24 March 2007
Sevilla
symposia@falkfoundation.de

Meeting BSG Annual Meeting
26-29 March 2007
Glasgow
www.bsg.org.uk/

NEXT 6 MONTHS

Meeting 42nd Annual Meeting of the European Association for the Study of the Liver
11-15 April 2007
Barcelona
easl2007@easl.ch
www.easl.ch/liver-meeting/

Meeting Falk Symposium 159: IBD 2007 - Achievements in Research and Clinical Practice
4-5 May 2007
Istanbul
symposia@falkfoundation.de

Meeting European Society for Paediatric Gastroenterology, Hepatology and Nutrition Congress 2007
9-12 May 2007
Barcelona
espghan2007@colloquium.fr

Digestive Disease Week
19-24 May 2007
Washington Convention Center, Washington DC

Meeting Gastrointestinal Endoscopy Best Practices: Today and Tomorrow, ASGE Annual Postgraduate Course at DDW
23-24 May 2007
Washington-DC
tkoral@asge.org

Meeting ESGAR 2007 18th Annual Meeting and Postgraduate Course
12-15 June 2007
Lisbon
fca@netvisao.pt

Meeting Falk Symposium 160: Pathogenesis and Clinical Practice in

Gastroenterology
15-16 June 2007
Portoroz
symposia@falkfoundation.de

Meeting ILTS 13th Annual International Congress
20-23 June 2007
Rio De Janeiro

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (WJG, *World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly journal of more than 48 000 circulation, published on the 7th, 14th, 21st and 28th of every month.

Original Research, Clinical Trials, Reviews, Comments, and Case Reports in esophageal cancer, gastric cancer, colon cancer, liver cancer, viral liver diseases, etc., from all over the world are welcome on the condition that they have not been published previously and have not been submitted simultaneously elsewhere.

Indexed and abstracted in

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, *Index Medicus*, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, *Nature Clinical Practice Gastroenterology and Hepatology*, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

Published by

The WJG Press

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297 mm × 210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, acknowledgements, References, Tables, Figures and Figure Legends. Neither the editors nor the Publisher is responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part without the written permission of both the authors and the Publisher. We reserve the right to put onto our website and copy-edit accepted manuscripts. Authors should also follow the guidelines for the care and use of laboratory animals of their institution or national animal welfare committee.

Authors should retain one copy of the text, tables, photographs and illustrations, as rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for the loss or damage to photographs and illustrations in mailing process.

Online submissions

Online submissions are strongly advised. Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/index.jsp>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. Authors encountering problems with the Online Submission System may send an email you describing the problem to wjg@wjgnet.com for assistance. If you submit your manuscript online, do not make a postal contribution. A repeated online submission for the same manuscript is strictly prohibited.

Postal submission

Send 3 duplicate hard copies of the full-text manuscript typed double-spaced on A4 (297 mm × 210 mm) white paper together with any original photographs or illustrations and a 3.5 inch computer diskette or CD-ROM containing an electronic copy of the manuscript including all the figures, graphs and tables in native Microsoft Word format or *.rtf format to:

Editorial Office

World Journal of Gastroenterology

Editorial Department: Apartment 1066, Yishou Garden,
58 North Langxinzhuang Road,
PO Box 2345, Beijing 100023, China

E-mail: wjg@wjgnet.com
<http://www.wjgnet.com>
Telephone: +86-10-85381892
Fax: +86-10-85381893

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using a word-processing software. All submissions must be typed in 1.5

line spacing and in word size 12 with ample margins. The letter font is Tahoma. For authors from China, one copy of the Chinese translation of the manuscript is also required (excluding references). Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was accomplished, disclosure of any financial support for the research, and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (removing all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s) and full family name.

Abstract

An informative, structured abstract of no more than 350 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipments, and the experimental procedures should be included. RESULTS: The observatory and experimental results, including data, effects, outcome, etc. should be included. Authors should present *P* value where necessary, and the significant data should accompany. CONCLUSION: Accurate view and the value of the results should be included.

The format of structured abstracts is at: <http://www.wjgnet.com/wjg/help/11.doc>

Key words

Please list 5-10 key words that could reflect content of the study mainly from *Index Medicus*.

Text

For most article types, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include in appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both.

Illustrations

Figures should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. No detailed legend should be involved under the figures. This part should be added into the text where the figures are applicable. Digital images: black and white photographs should be scanned and saved in TIFF format at a resolution of 300 dpi; color images should be saved as CMYK (print files) but not as RGB (screen-viewing files). Place each photograph in a separate file. Print images: supply images of size no smaller than 126 mm × 85 mm printed on smooth surface paper; label the image by writing the Figure number and orientation using an arrow. Photomicrographs: indicate the original magnification and stain in the legend. Digital Drawings: supply files in EPS if created by freehand and illustrator, or TIFF from photoshops. EPS files must be accompanied by a version in native file format for editing purposes. Existing line drawings should be scanned at a resolution of 1200 dpi and as close as possible to the size where they will appear when printed. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes of atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...

Tables

Three-line tables should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each table. No detailed legend should be included under the tables. This part should be added into the text where the tables are applicable. The information should complement but not duplicate that contained in the text. Use one horizontal line under the title, a second under the column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. ^a*P*<0.05, ^b*P*<0.01 should be noted (*P*>0.05 should not be noted). If there are other series of *P* values, ^c*P*<0.05 and ^d*P*<0.01 are used. Third series of *P* values can be expressed as ^e*P*<0.05 and ^f*P*<0.01. Other notes in tables or under

illustrations should be expressed as 1F , 2F , 3F ; or some other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, etc. in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions are included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should code the references according the citation order in text in Arabic numerals, put references codes in square brackets, superscript it at the end of citation content or the author name of the citation. For those citation content as the narrate part, the coding number and square brackets should be typeset normally. For example, Crohn's disease (CD) is associated with increased intestinal permeability^[1,2]. If references are directly cited in the text, they would be put together with the text, for example, from references [19,22-24], we know that...

When the authors code the references, please ensure that the order in text is the same as in reference part and also insure the spelling accuracy of the first author's name. Do not code the same citation twice.

PMID requirement

PMID roots in the abstract serial number indexed by PubMed (<http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed>). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information of the journal citations is very important. Through reference testing system, the authors and editor could check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in ASP file so that the readers can read the abstract of the citations online immediately.

Style for journal references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). Title of the cited article and italicized journal title (Journal title should be in its abbreviation form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634]

Note: The author should test the references through reference testing system (<http://www.wjgnet.com/cgi-bin/index.pl>)

Style for book references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those that are linked with a hyphen and the difference between the two numbers at two sides of the hyphen is more than 5. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered as inappropriate references. Authors should not cite their own unrelated published articles.

Statistical data

Present as mean \pm SD or mean \pm SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as γ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p*(B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 $24.5 \mu\text{g/L}$; CO₂ volume fraction, 50 mL/L CO₂ not 5% CO₂; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format about how to accurately write common units and quantum is at: <http://www.wjgnet.com/wjg/help/15.doc>

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further mention.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kbo I*, *Kpn I*, etc.

Biology: *H pylori*, *E coli*, etc.

SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. Author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, the final check list for authors, and responses to reviewers by a courier (such as EMS) (submission of revised manuscript by e-mail or on the *WJG* Editorial Office Online System is NOT available at present).

Language evaluation

The language of a manuscript will be graded before sending for revision.

(1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing; (4) Grade D: rejected. The revised articles should be in grade B or grade A.

Copyright assignment form

Please download CAF from <http://www.wjgnet.com/wjg/help/9.doc>.

We certify that the material contained in this manuscript:

Ms:

Title:

is original, except when appropriately referenced to other sources, and that written permission has been granted by any existing copyright holders. We agree to transfer to *WJG* all rights of our manuscript, including: (1) all copyright ownership in all print and electronic formats; (2) the right to grant permission to republish or reprint the stated material in whole or in part, with or without a fee; (3) the right to print copies for free distribution or sale; (4) the right to republish the stated material in a collection of articles or in any other format. We also agree that our article be put on the Internet.

Criteria for authorship: The *WJG* requests and publishes information about contributions of each author named to the submitted study. Authorship credit should be based on (1) direct participation in the study, including substantial contributions to conception and design of study, or acquisition of data, or analysis and interpretation of data; (2) manuscript writing, including drafting the article, or revising it critically for important intellectual content; (3) supportive work, including statistical analysis of data, or acquisition of funding, or administration, technology and materials support, or supervision, or supportive contributions. Authors should meet at least one of the three conditions. The *WJG* does not publish co-first authors and co-corresponding authors.

We hereby assign copyright transfer to *WJG* if this paper is accepted.

Author Name in full (Full names should be provided, with first name first, followed by middle names and family name at the last, eg, Eamonn MM Quigley). Handwritten names are not accepted.

Author Name in abbreviation (Family name is put first in full, followed by middle names and first name in abbreviation with first letter in capital, eg, Quigley EMM). Handwritten names are not accepted.

Final check list for authors

The format is at: <http://www.wjgnet.com/wjg/help/13.doc>

Responses to reviewers

Please revise your article according to the comments/suggestions of reviewers. The format for responses to the reviewers' comments is at: <http://www.wjgnet.com/wjg/help/10.doc>

Abstract

RNA interference (RNAi) is an evolutionally conserved gene silencing mechanism present in a variety of eukaryotic species. RNAi uses short double-stranded RNA (dsRNA) to trigger degradation or translation repression of homologous RNA targets in a sequence-specific manner. This system can be induced effectively *in vitro* and *in vivo* by direct application of small interfering RNAs (siRNAs), or by expression of short hairpin RNA (shRNA) with non-viral and viral vectors. To date, RNAi has been extensively used as a novel and effective tool for functional genomic studies, and has displayed great potential in treating human diseases, including human genetic and acquired disorders such as cancer and viral infections. In the present review, we focus on the recent development in the use of RNAi in the prevention and treatment of viral infections. The mechanisms, strategies, hurdles and prospects of employing RNAi in the pharmaceutical industry are also discussed.

INTRODUCTION

RNA interference (RNAi), a highly conserved gene silencing mechanism plays an important role in the

regulation of gene expression. This system was examined in a broad variety of species including plants, fungi, yeasts, nematodes, flies and mammals. In fact, RNAi serves as a safeguard for the preservation of genomic integrity. It protects the host from viral infections and invasion by mobile genetic elements by degrading the exogenous genomic material (e.g., viral RNAs).

RNAi is triggered by small double-stranded RNA (dsRNA) and functions at all levels, including transcription^[1], post-transcription^[2] and translation^[3]. The first reports on RNA-induced post-transcriptional gene silencing (PTGS) phenomena were published in the early 90s, when Napoli^[4] and Van der Krol^[5] described the co-suppression of both viral transgenes and their homologous endogenous genes in transgenic plants. Similar inactivation of gene expression called "Quelling" was observed in *Neurospora crassa* by transformation with homologous sequences^[6]. In 1995, sense RNA was demonstrated to be as effective as antisense RNA in disrupting the expression of *par-1* in *Caenorhabditis elegans*^[7]. The mechanism of action remained enigmatic until 1998, when Fire and Mello discovered that dsRNA, instead of the single-stranded sense or antisense RNA, mediated gene silencing by degrading endogenous mRNAs in a sequence-specific manner^[8]. They also challenged a previous report published in 1995 claiming it to be an artificial effect of dsRNA contamination. Further studies have revealed that RNAi can occur at both the transcription and post-transcription levels. Transcriptional gene silencing involves histone H3 methylation and the formation of heterochromatin^[9-11]. Post-transcriptional gene silencing includes small interfering RNA (siRNA) that mediates sequence-specific target RNA degradation, and micro RNA (miRNA) which promotes blockage of protein translation at the 3'-untranslated region (3'UTR)^[12].

In recent years, RNAi has become a powerful tool to probe gene functions and to rationalize drug design. It has been employed as a prophylactic and therapeutic agent for combating a wide range of disorders, including infectious diseases, tumors and metabolic disorders. Several lethal viruses, including human immunodeficiency virus (HIV), the hepatitis C and B viruses (HCV & HBV), coronavirus, influenza A virus (IAV), human papillomavirus (HPV), have been shown to be inhibited or eliminated by RNAi. These findings have emphasized the potential of RNAi in clinical applications. In the present review, we discuss the mechanism of RNAi, and its role in the prevention and the treatment of viral infections.

Mechanisms of RNAi

Biochemical and genetic studies have revealed the detailed

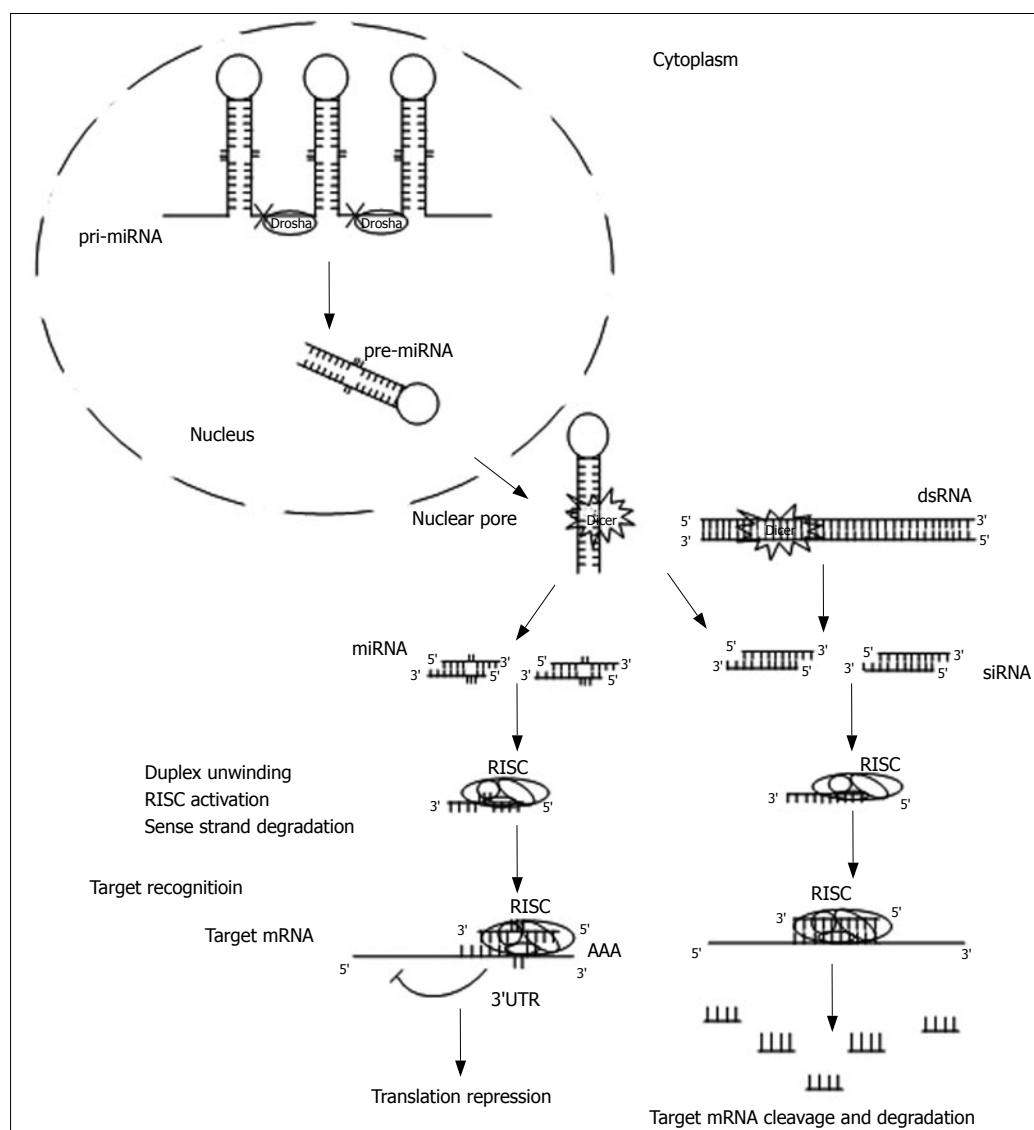

Figure 1 The RNA interference pathways.

mechanism by which dsRNA-mediated gene silencing takes place. In general, the mechanism includes two major steps: the initiator step and the effector step (Figure 1).

In the initiator step, long dsRNAs, which are produced by endogenous genes, invading viruses, transposons or experimental transgenes, are initially recognized by a dsRNA-binding protein, RDE-4/R2D2^[13,14]. They are then submitted to and cleaved by the RNase III-like nuclease Dicer^[15], which generates 21-23 nucleotide duplex RNAs with overhanging 3' ends^[16], called small interfering RNAs (siRNAs). The presence of highly conserved Dicer in yeast^[11], plants^[17,18], *C. elegans*^[19], *Drosophila*^[15], mice^[20] and humans^[21,22], suggests that the RNAi pathways share similar basic mechanisms in these organisms.

In the effector step, siRNAs are incorporated into a multicomponent nuclease complex, the RNA-induced silencing complex (RISC)^[23]. The antisense strand of the duplex directs RISC to recognize and to cleave cognate target RNAs, which undergoes specific base pairing and endonucleolytic cleavage. This leads to the degradation of the unprotected and single-stranded target RNA. To date,

several components of the RISC have been identified, including some conserved argonaute proteins that share the PAZ domain with Dicer family proteins^[24].

The Dicer also cleaves the 60-70nt long precursor miRNA (pre-miRNAs) into miRNAs, which are of similar size as siRNAs. This pathway is referred to as miRNA-dependent gene silencing. The pre-miRNAs, whose structures are imperfectly complementary to each strand, are generated from endogenous stem loop precursors or hairpins, named primary-miRNA (pri-miRNA). The pri-miRNAs are first cleaved by Droscha RNase III in the nucleus^[25]. The resulting pre-miRNAs are then exported into the cytoplasm for further processing by Dicer. The complex of the activated RISC and miRNA binds the 3'UTR of specific mRNAs, which triggers cleavage by perfect base-pairing, or translational repression by partial base-pairing recognition^[26-29].

Strategies for RNA interference

In order to study the functional genomics and biology of RNA interference, much effort has gone into the study of

artificial RNAi-inducing gene silencing. Strategies for delivery of RNAi reagents into mammalian cells can be divided into two types, the transient RNAi and the stable/inducible RNAi.

The methods commonly used in producing siRNA extraneously include chemical synthesis, *in vitro* transcription, and recombinant human Dicer/*E. coli* RNase III digestion of long dsRNAs. These siRNAs can be transiently transfected into target cells. Alternatively, the short hairpin RNAs (shRNAs) are expressed endogenously from plasmids and viral vectors. The shRNA expression cassettes can be stably integrated into the genome of target cells, transcribed intranuclearly and processed into siRNAs by Dicer in the cytosol. In general, RNA Pol III promoters (i.e., U6, H1 and tRNA promoters) are commonly used to drive shRNA expression in the RNAi studies. The viral vectors including retro-^[30-33], lenti-^[34-36], adeno- and adeno-associated viral vectors^[37-39] have been demonstrated to feature high-efficiency gene delivery and can overcome the obstacles of cell-type-dependent transfection. The development of an inducible RNAi system has certainly enhanced our understanding of candidate genes' functions, as it provides an invaluable genetic switcher that allows the inducible and reversible control of specific gene's expression *in vitro*^[40-42] and *in vivo*^[43-45].

RNAi applications to combat viral infection

Viral infection is a serious public health, social and economic problem. More effective approaches are urgently needed to prevent viral propagation. Several studies have shown that RNAi technology has potential advantages over traditional measures such as the use of anti-viral drugs and vaccines, because of its ease of use, rapidity of action, high efficiency and specificity of activity when applied to the different stages of virus-host interactions^[46]. In this section we will focus on the prospective use of RNAi in several common human pathogens such as HIV, HCV, HBV, SARS-coronavirus and influenza virus.

Human immunodeficiency virus

Human immunodeficiency virus type 1 (HIV-1) is the first primate virus shown to be inhibited by RNAi. HIV is a retrovirus that has been categorized into the subgroup of lentiviruses. Upon infection, the positive strand of the HIV's RNA genome is reversely transcribed into a linear dsDNA soon after the virus enters the host cells by receptor recognition and cell adhesion. The linear dsDNA becomes circularized, is then transported into the nucleus and integrated into the host chromosome as a provirus. By utilizing the host enzymes, HIV provirus converts viral genes into mRNAs, which are used as blueprints for the subsequent expression of viral structure proteins and enzymes. It has been suggested that the genomic RNA or the newly transcribed viral mRNAs are good targets for siRNAs intervention.

It is unclear whether RNAi can target RNA genome of HIV-1 infectious particles. Jacques reported siRNA-mediated inhibition of the early and late steps of HIV-1 replication, by targeting various regions of the HIV-1 genome and by preventing the formation of viral complementary-DNA intermediates^[47]. Other workers

have suggested that the incoming HIV-1 RNA genome may not be accessible to siRNAs^[48,49]. To date, several viral target sequences have been identified. These include the structure proteins, Gag^[48,50-52] and Env^[52,53]; the reverse transcriptase Pol^[48]; the regulatory proteins, Tat^[54,55] and Rev^[54,56], and the two accessory proteins Nef^[47,57,58] and Vif^[47] (Table 1). The long terminal repeats that the integrase employs to insert HIV's DNA genome into host DNA, have also been targeted^[47,51].

Several studies have demonstrated that HIV may be able to escape RNAi target by mutations^[58-60]. To overcome this problem, lentiviral vectors incorporated with different shRNA-expressing-cassettes, which can simultaneously target multiple sequences including conserved sequences of the HIV genome, have been constructed^[61,62]. Another proposed strategy using RNAi application is the targeting of host genes. Some host genes are essential for viral replication but have a much slower mutation rate than the viral genes. These genes have been targeted by RNAi, and the results are very encouraging^[63-69] (Table 1). Down-regulation of the cell surface CD4 receptor and/or one of the co-receptors CCR5 and CXCR4 by RNAi has led to dramatic reduction of viral entry into cells^[34,70,71]. Compared with CD4 and CXCR4, CCR5 has been found to be a preferential target, since no immune defects or host mortality was observed on its deletion^[72,73]. Therefore, careful selection of host immutable co-factors that are important for viral replication, but not for host survival, is of prime importance in the development of anti-HIV strategies. Furthermore, simultaneous targeting by RNAi of both the virus and host factors^[50,74] has been shown to be more effective in inhibiting HIV-1 replication than the targeting of either virus or host factors alone.

Hepatitis C virus

Hepatitis C virus infection is a major cause of chronic liver diseases, including liver cirrhosis and hepatocellular carcinoma (HCC). The estimated number of infected individuals are about 170 million worldwide^[75], which accounts for nearly 3% of the world's population. The World Health Organization (WHO) has recognized HCV infection as a global health problem.

HCV is a small, enveloped RNA virus that belongs to the Flaviviridae family. The cytoplasmic replicating virus contains a 9.6 kb RNA genome that functions as the messenger RNA and replication template. The development of anti-HCV drugs has accelerated since the replicon-based culture system was established a few years ago^[76,77]. Several regions of the HCV's RNA genome, including 5'UTR and the coding sequences of Core, NS3, NS4B and NS5B, are sensitive to the action of siRNA^[78-83] (Table 2). The therapeutic potential of RNAi was further emphasized by *in vivo* studies^[84,85]. The administration of siRNA and shRNA to target cell surface receptor FAS^[86], caspase 8^[87] and NS5B^[84], has resulted in the destruction of cognate mRNAs and protection of mice from liver failure. The use of multiple siRNAs against highly conserved HCV sequences with and without host cell cofactors may limit the emergence of resistant viruses as has been demonstrated in several studies^[88-92] (Table 2).

The fold inhibition of virus production refers to the results obtained with the most potent siRNA/shRNA tested in a specific cell model. All siRNAs were prepared by chemical synthesis unless indicated otherwise. LTR: Long terminal repeat; PBLs: Peripheral blood lymphocytes; PBMC: Peripheral blood mononuclear cell; Pol: Polymerase; Env: Envelope; Tsg101: Tumor susceptibility gene 101; LEDGF/P75: Lens epithelium-derived growth factor/transcription co-activator p75; NR: Not reported; P-TEF: Positive transcription elongation factors; hRIP: Human Rev-interacting protein; HRP2: Hepatoma-derived growth factor related protein 2; RT: Reverse transcriptase; NF-κB: Nuclear factor-NF-κB. ¹shRNA expressed from a transfected plasmid under the control of a T7 promoter. ²dsRNA produced by *in vitro* T7 promoter-mediated transcription. ³dsRNA produced by *in vitro* SP6/T7 promoter-mediated transcription. ⁴shRNA and siRNA expressed from transfected plasmids under the control of one and two U6 promoters respectively, shRNA further stably expressed from a recombinant lentiviral vector driven by a U6 promoter. ⁵siRNA expressed from a transfected plasmid under the control of two U6 tandem promoters that drive the synthesis of each of the siRNA strand. ⁶shRNA produced by *in vitro* T7 promoter-mediated transcription.

Hepatitis B virus

Hepatitis B virus infection is a major public health problem. It is estimated that, approximately 2 billion people are infected with HBV worldwide, and about 400 million are HBV chronic carriers^[93]. HBV infection is highly prevalent in Asia and South Africa and results in over one million deaths worldwide annually.

Although the clinical symptoms caused by HBV and HCV infection are very similar, the viruses are completely unrelated^[94]. HBV, the prototypical member of the Hepadnaviridae family, is one of the smallest DNA viruses (-3.2 kb), which can undergo reverse-transcription for viral replication. The HBV genome contains four overlapping open reading frames: P (polymerase-reverse transcriptase), C (core structure protein), S (surface glycoprotein) and X (HBx protein). After the uncoated nucleocapsids enter the nucleus, the HBV genome is repaired to form a covalently closed circular DNA (cccDNA), which is a template for messenger RNA transcription. The RNA

intermediates-pregenomic and subgenomic RNAs, coding for viral multifunctional proteins, are transported into the cytoplasm where translation is initiated. After the pregenomic transcript is packaged into virion core particle, it is reversely transcribed by viral reverse transcriptase, thus producing a single stranded (-) DNA. Based on the structure of the (-) stranded DNA, a complementary (+) DNA strand is synthesized. Due to the lack of proofreading function of its polymerase, HBV undergoes rapid mutagenesis, with the creation of a large number of drug-resistant variants. These drug-resistant variants are further amplified under selective pressure during antiviral treatment, resulting in the elimination of the anti-viral effect and virus rebound during treatment. In severe cases, this can lead to death, even after cessation of treatment. Because of this challenge, new drugs with different targets or drug metabolism mechanisms are urgently required for better treatment outcome.

Several sites of the HBV genome including the *P*, *Pre*

The fold inhibition of virus production represents the most potent effect caused by a specific siRNA or combinatorial siRNAs. All siRNAs were prepared by chemical synthesis unless indicated otherwise. UTR: Untranslated region; NS: Non-structural; IRES: Internal ribosomal entry site; C: Core protein; esiRNA: Endoribonuclease-prepared siRNA; Mo-MuLV: Moloney murine leukemia virus; PTB: Polypyrimidine tract-binding protein; eIF2B γ : Subunit gamma of human eukaryotic initiation factors 2B; hVAP-33: Human VAMP-associated protein of 33 kDa; Cyp: Cyclophilin; PSMA7: Proteasome α -subunit 7; HuR: Hu antigen R; N.R: not reported. ¹stem-loop- and tandem-type siRNA expressed from DNA-based vectors driven by one and two U6 promoters respectively. ²shRNA expressed from a transfected plasmid under the control of two H1 tandem promoters that drive the synthesis of each of the siRNA strand. ³esiRNA generated by *in vitro* T3/T7 promoter-mediated transcription. ⁴shRNA expressed from a transfected plasmid or a lentivirus vector respectively under the control of a U6 promoter. ⁵ shRNA generated by *in vitro* T7 promoter-mediated transcription.

C/C, PreS/S, X gene, have been employed as targets to examine the *in vitro* efficacy of RNAi^[95-99] (Table 3). Some sites have also been tested in hydrodynamic HBV model and transgenic HBV model^[100-104] (Table 3). Our group has successfully designed multiple shRNAs that target DR elements and regions that code for core, polymerase, PreS, S, and X proteins. These shRNA were found to potently inhibit HBV replication and showed synergistic antiviral effects with the commonly used antiviral drug, lamivudine^[105]. In a recent study, we showed that simultaneous delivery of two shRNAs that target different regions, exhibited strong synergistic antiviral effects in a hydrodynamic transgenic mice model. In this study, both S and e antigens were reduced to undetectable levels, and the viral load was reduced by greater than one hundred-fold (He *et al* unpublished observations). These results clearly demonstrate the potential of RNAi application in anti-HBV therapy.

SARS-coronavirus

Severe acute respiratory syndrome (SARS) outbreak affected nearly 30 countries during the years 2002-2003. This epidemic was caused by a novel SARS-associated coronavirus (SARS-CoV)^[106-108]. SARS-CoV is a large (-30 kb), enveloped, positive-stranded RNA virus and its genome is composed of replicase (*rep*), spike (*S*), envelope

(*E*), membrane (*M*), and nucleocapsid (*N*) genes. The prophylactic and therapeutic efficacies of siRNAs were tested because of the absence of any effective drugs or vaccines against SARS-CoV infection. Both *in vitro* and *in vivo* applications proved satisfactory, using synthetic siRNAs as well as vector-based shRNAs against leader sequence^[109,110], 3'-UTR^[110], non-structural^[111] and structural genes^[110,112-115] of SARS-CoV (Table 4). Another recent report revealed that the siRNA-mediated depletion of the host cellular clathrin heavy chain gene, reduced the SARS-CoV infectivity^[116]. Locked nucleic acid (LNA)-modified siRNAs, an RNA-like high affinity nucleotide analogue, has been found to improve the performance of gene silencing via enhancement of siRNA biostability and specialty. The improvement was clearly apparent when siRNA was transfected into Vero cells prior to a lethal SARS-CoV attack^[117].

It is worth mentioning that our group was the first to demonstrate in 2003 the remarkable inhibition and replication of SARS-CoV infection by siRNAs against *rep* gene^[118]. Subsequently, we designed siRNAs that could target both *rep* and structural genes. We also evaluated the antiviral effect, dose response, duration and viral kinetics of siRNAs in foetal rhesus kidney (FRhK-4) cells^[119,120]. Two of the siRNAs were further evaluated for safety and antiviral efficacy in a rhesus macaque SARS model^[119].

The fold inhibition of virus production refers to the results obtained with the most potent siRNA/shRNA. All siRNAs were prepared by chemical synthesis unless indicated otherwise. TRS: Transcription-regulating sequence; UTR: Untranslated region; S: Spike protein; N: Nucleocapsid protein; NR: Not reported; E: Envelope protein; M: Membrane protein; P: RNA polymerase; Rep: Replicase; FRhk-4: Fatal Rhesus monkey kidney cells; CHC: Clathrin heavy chain; NSP: Non-structural protein; *i.t.*: Intratracheal; *i.n.*: Intranasal. ¹siRNA and target-sequence containing reporter plasmid co-administered intratracheally into mouse lungs in D5W or Infasurf solution; ²siRNA instilled intranasally to monkey in D5W solution with different dosing regimens.

These siRNAs relieved SARS-like symptoms, and were safe for prophylaxis and therapeutic treatment. These findings greatly encouraged the clinical testing of siRNAs as an anti-SARS therapy.

Influenza virus

Influenza virus is one of the public health scourges worldwide. Three influenza epidemics have occurred in

the last century and have caused tens of millions of deaths globally. Recent outbreaks of highly pathogenic avian influenza in Asia and Europe have greatly increased public awareness, and accelerated the development of measures for the prophylaxis and therapy of this infection.

Influenza viruses are enveloped, single-stranded, segmented (7-8) RNA viruses which belong to the Orthomyxoviridae family^[121]. They are classified into

influenza virus types A, B, and C, based on their nucleoproteins and matrix proteins. Influenza A virus (IAV) is the most prevalent respiratory pathogen worldwide.

Since it is an RNA virus, IAV has the ability for rapid genetic changes through antigen drift^[122] or antigen shift^[123]. This involves the accumulation of minor mutations within the viral genome, or reassortment of RNA segments between different viruses, which results in the emergence of new viral strains. Ge *et al.*^[124,125] and Tompkins *et al.*^[126] verified the efficacy of siRNAs which specifically target the conserved regions of the influenza virus genome (nucleocapsid and acid polymerase). They confirmed that siRNAs were potent inhibitors of the influenza virus both *in vitro* and *in vivo*, and could be administered both prior to and subsequent to a lethal IAV challenge. Moreover, Ge developed an unconventional delivery system, administering small volumes of siRNAs or DNA vectors encoding shRNA in complex with polyethyleneimine (PEI) by slow intravenous infusion^[127]. This system was effective in reducing virus production in infected mice and provided helpful suggestions for future clinical application of siRNAs.

Progress of RNAi for clinical application

Since RNAi was found to have antiviral activity in transgenic plants, much evidence has emerged with regard to its pivotal role in antiviral therapeutic applications. Numerous investigations have reported successful inhibition of viral replication in cultured cells and in murine/nonhuman primate models using both transient transfection of synthetic siRNA and stable expression of shRNA. To harness the full potential of RNAi for therapeutic applications, pharmaceutical companies are actively engaged in clinical trials. In 2004, Acuity Pharmaceuticals initiated a clinical trial using RNAi in the treatment of macular degeneration; encouraging results have been obtained in the Phase I / II studies^[128]. In 2006, Alnylam Pharmaceuticals launched a Phase I clinical trial in the U.S. of an inhaled formulation of ALN-RSVO1 (an RNAi-based drug) to combat respiratory syncytial virus (RSV) infection^[129]. Other potential indications for RNAi use include asthma, Huntington's disease, spinocerebellar ataxia, and HIV, HAV, HBV and influenza virus infections, and clinical trials are under consideration in many of these conditions^[130].

Challenges and perspectives

Despite the rapid progress in RNAi use, its clinical application still poses several challenges. These include target specificity, biostability, biosafety, and delivery efficacy of the RNAi system in various diseases. Recent studies have indicated off-target effects associated with the use of siRNA^[131-133]. In order to improve the power of gene silencing and to avoid undesirable adverse effects induced by siRNAs, such as nonspecific gene silencing and immunoactivation^[134,135], great effort has been made to improve siRNA design, including its sequence^[136], size^[137] and structure^[138]. However, the poor pharmacokinetic properties of siRNAs have added another hurdle in the development of RNAi-based therapies. Multiple chemical modifications at different positions of the siRNA duplexes,

including sugars^[117,139-141], backbones^[142,143], and bases of oligonucleotides^[144,145] have been found to prolong siRNA half-life in serum. Conjugation of one or both strands of siRNAs with lipids^[146,147] and peptides^[148,149], has been shown to enhance nuclease stability and improve cellular uptake.

The systematic and site-specific deliveries of siRNA also need to be addressed. Non-viral vectors, such as cationic lipids^[150-152] and polymers^[153-156], have been widely used for *in vitro* and *in vivo* siRNA delivery. It has been reported that siRNAs encapsulated into stable nucleic acid lipid particles (SNALPs) improve the potency, lengthen the half-life, lower the effective dose and reduce the dosing frequency. This was observed in a study comparing unformulated siRNAs in rodents challenged with replicating virus^[157,158] and non-human primates^[159]. Besides, Song *et al.* designed a protamine-antibody fusion protein to deliver siRNA to HIV-infected or envelope-transfected cells. This study established a systemic, cell-type specific, antibody-mediated *in vivo* delivery system of siRNAs *via* cell surface receptors^[160]. The current advances have brought siRNA close to the era of clinical trials and real-life therapeutic applications in infected human subjects.

However, before RNAi-based clinical trials can be carried out, the toxicity and side-effects of RNAi, and the harmful potential of viral vectors need careful attention. It has been shown that over-expression of shRNA by double-stranded AAV8 viral vectors resulted in severe hepatic toxicity and even death. Moreover, it has been observed that over-expressed shRNA can saturate the miRNA pathway^[161]. Our studies have shown that simultaneous delivery of two shRNAs using a weaker expressing viral vector (AAV2) did not produce any obvious liver toxicity or side-effects (He *et al.* unpublished). Therefore, it is essential to use safer vectors and in this respect we believe that inducible viral vectors may be good candidates for future clinical studies.

Scientists in different fields, including geneticists, biochemists, pharmacologists, chemists and materials scientists, have supported the use of RNAi in clinical applications. As a part of the research force, our team while being cautious, is optimistic regarding the use of RNAi in human diseases.

Abstract

AIM: To elucidate risk factors contributing to the development of hepatocellular carcinoma (HCC) among patients with sustained viral response (SVR) after interferon (IFN) treatment and to examine whether HCV-RNA still remained in the liver of SVR patients who developed HCC.

METHODS: Two-hundred and sixty-six patients, who achieved SVR, were enrolled in this study. We retrospectively reviewed clinical, viral and histological features of the patients, and examined whether the development of HCC depends on several clinical variables using Kaplan-Meier Method. RT-PCR was used to seek HCV-RNA in 3 out of 7 patients in whom liver tissue was available for molecular analysis.

RESULTS: Among the enrolled 266 patients with SVR, HCC developed in 7 patients (7/266; 2.6%). We failed to detect HCV-RNA both in cancer and non-cancerous liver tissue in all three patients. The cumulative incidence for HCC was significantly different depending on hepatic fibrosis (F3-4) ($P = 0.0028$), hepatic steatosis (Grade 2-3) ($P = 0.0002$) and age (≥ 55) ($P = 0.021$) at the pre-interferon treatment.

CONCLUSION: The current study demonstrated that age, hepatic fibrosis, and hepatic steatosis at pre-interferon treatment might be risk factors for developing HCC after SVR.

INTRODUCTION

Continuous eradication of hepatitis C virus (HCV) with interferon (IFN) therapy significantly inhibits development of hepatocellular carcinoma (HCC) in patients with chronic hepatitis C^[1-3]. However, HCC sporadically developed even after achievement of sustained viral response (SVR) with IFN therapy, especially reported from Japan^[4-14], and therefore it is of clinical importance to identify patients who are at high risk for HCC after achievement of SVR.

Several investigators have made efforts to elucidate risk factors for occurrence of HCC in patients with SVR^[6,15-18], and so far several factors including age^[6,15-18], sex^[6,15], alcohol consumption^[16,17], staging of fibrosis^[15-17], platelet counts^[18], and AST levels^[18] at baseline were regarded as candidate risks. However, these results seem to be controversial, and there may be other crucial contributing factors. In addition, reappearance of HCV in serum after achievement of SVR has also been reported^[19-22]. In some cases, HCV-RNA is still present in liver of patients without detectable HCV-RNA in serum^[19-22]. Therefore, the remaining HCV-RNA in the liver may contribute to the occurrence of HCC in patients with SVR^[23]. Nevertheless, the studies^[6,15-18] describing risk factors for the occurrence of HCC lack any evaluation for the presence of HCV-RNA in the liver.

Furthermore, chronic HCV infection frequently results in hepatic steatosis^[24]. It has been reported that HCV genotype 3 infection is likely to cause steatosis possibly due to direct effect of HCV, whereas steatosis in patients infected with HCV genotype 1 seems to be associated

with co-existing risk factors including an increased body mass index (BMI) or presence of insulin resistance, thus resembling to those non-alcoholic steatohepatitis (NASH)^[25-29]. Apparently hepatic steatosis is not altered in patients infected with HCV genotype 1, even after continuous eradication of HCV with antiviral therapy^[30]. In addition, obesity-related cryptogenic cirrhosis has been recently paid attention as an alternative etiology for HCC^[31,32]. Taken together, it may be possible that hepatic steatosis, still present after achievement of eradication of HCV genotype 1, results in progression of fibrosis as well as occurrence of HCC. The investigators describing risk factors for HCC in patients with SVR^[6,15-18] have not mentioned whether hepatic steatosis is observed in pre-treatment liver histology.

Therefore, in the current study, we aimed to elucidate contributing factors for occurrence of HCC in patients in whom serum HCV-RNA has been eradicated with IFN therapy. First, we examined whether HCV-RNA still remained in the liver at the development of HCC using sensitive reverse-transcriptase polymerase chain reaction (RT-PCR). In addition, we evaluated clinical features and histopathological fibrosis and steatosis of the patients at the pre-IFN treatment, and examined whether the occurrence of HCC depends on these factors using Kaplan-Meier model.

MATERIALS AND METHODS

Patients

This single-center study was conducted at the Department of Medicine, Teikyo University School of Medicine. Since the introduction of IFN therapy for patients with chronic hepatitis C in 1986, 1101 patients were treated with IFN alone or IFN and ribavirin combination therapy. Among them, 266 patients, who achieved SVR, defined as absence of serum HCV-RNA at 6 mo after termination of IFN therapy, and did not fulfill the exclusion criteria described below, were enrolled. We verified that anti-HCV antibody as well as HCV-RNA was detected in sera before IFN treatment in all enrolled patients. Serum anti-HCV antibody was examined using third-generation antibody to HCV (Abbott Japan, Tokyo, Japan). Serum HCV-RNA was sought with Amplicor HCV v2.0 (Nippon Roche, Tokyo, Japan), employing RT-PCR. Also, liver biopsy was performed in all cases as long as 3 mo before beginning of IFN therapy for assuring the presence of chronic hepatitis. Exclusion criteria for this study were hepatitis B virus (HBV) infection determined by seropositivity for HBsAg and/or HBcAb, autoimmune hepatitis, alcoholic abuse (daily alcohol consumption > 60 g), and presence of HCC detected by abdominal ultrasound (US) and/or computed tomography (CT).

Follow-up and diagnosis of hepatocellular carcinoma

After termination of IFN therapy, patients were regularly checked up at the out-patient clinic at every 2-3 mo. The average period of follow-up for the enrolled patients in this study was 9.9 ± 4.1 years. Blood chemistries as well as tumor markers were examined. Additionally, imaging

studies, abdominal US and/or CT, were performed 1-2 times per year. The diagnosis of HCC was made if both abdominal US and CT demonstrated the presence of HCC, and was further confirmed by histopathological studies after surgical resection. In cases without resection, abdominal angiography was used to verify the diagnosis of HCC.

Variables

We selected several pre-IFN treatment valuables of patients to assess risk factors for development of HCC, including the age at pre-IFN treatment and sex of the patient, the stage of liver fibrosis and the grade of hepatic steatosis, HCV genotype and serum ALT level. The stage of liver fibrosis was determined by two independent pathologists according to the classification of the Metavir group^[33] as follows: F0 (no fibrosis); F1 (portal fibrosis); F2 (few bridges); F3 (many bridges); and F4 (cirrhosis). Hepatic steatosis was also graded by two independent pathologists according to Brunt *et al.*^[34]. In short, steatosis observed in up to 33%, 33%-66% and more than 66% of the liver histology was determined as grade 1, 2 and 3, respectively. Hepatic steatosis, if not observed, was graded as grade 0. When two pathologists estimated the classification of fibrosis and the grading of steatosis differently, the mean value of the two was applied for statistical analysis. Genotyping of HCV-RNA was performed with HCV coregenotyping (Nippon Roche).

Detection of HCV-RNA in liver tissue

HCV-RNA in liver tissue was detected by RT-PCR. Formalin-embedded liver biopsy specimens obtained prior to IFN treatment and snap-frozen liver tissue taken at the development of HCC were used as starting materials. Total RNA was extracted using Isogen (Nippon gene, Tokyo, Japan) and was converted into cDNA using Superscript™ II RNase H⁻ Reverse Transcriptase (Invitrogen, Carlsbad, CA). The primer specific to HCV-RNA 5' UTR region (HC1R: ACTCGCAAGCACCCTATCA, nt 293-312) was used for cDNA synthesis. Thereafter HCV-RNA was sought using "semi-nested" PCR consisting of 1st, 2nd and 3rd amplification, using one 5' forward primer (HC1F: GAGCCATAGTGGTCTGCGGA, nt 135-154) and three sets of reverse primers (HC1R, HC2R: ACTCGGCTAGCAGTCTTGCG, nt 240-259; and 2H-AS: GTTTATCCAAGAAAGGACCC, nt 188-207). The 1st PCR consisted of initial denaturing at 95°C for 5 min, followed by 50 amplification cycles at 95°C for 15 s for denaturing and at 62°C for 1 min for primer annealing and extension, and a final extension at 72°C for 7 min. The 2nd PCR was done for 35 cycles by the identical program, but annealing and extension at 63°C. The 3rd PCR consisted of initial denaturing at 95°C for 5 min, followed by 30 amplification cycles at 95°C for 15 s, at 58°C for 30 s for primer annealing and at 72°C for 1 min for extension, and a final extension at 72°C for 7 min. The PCR products of 178, 125 and 73 bp after 1st, 2nd and 3rd PCR, respectively, were electrophoresed on 15 g/L agarose gel, and visualized by ethidium bromide staining. In addition, to ensure the quality of extracted RNA, we also amplified β -actin as positive controls using the identical liver-derived total

Table 1 Viral, clinical and histopathological profiles of patients with SVR who developed HCC

	Age/sex	HCV genotype	Pre-IFN treatment				Occurrence of HCC			Duration until HCC (yr)
			ALT (IU/L)	Fibrosis	Steatosis	BMI	Fibrosis	Steatosis	BMI	
Case 1	67/M	1b	138	F3	Grade 2	28.4	F2	Grade 1	27.4	5.4
Case 2	58/M	2a	39	F1	Grade 1	23.5	F2	Grade 0	22.5	9.5
Case 3	68/M	n.t.	111	F4	Grade 2	24.2	F2	Grade 2	25.0	9.6
Case 4	53/M	1b	82	F2	Grade 1	19.6	NT	NT	20.3	8.4
Case 5	58/M	1b	21	F3	Grade 1	23.5	NT	NT	24.8	3.3
Case 6	65/F	2a	145	F3	Grade 1	25.6	F2	Grade 1	26.7	2.9
Case 7	54/M	1b	85	F2	Grade 2	26.1	F2	Grade 1	22.4	4.9

NT: Not tested; BMI: Body mass index. In cases 4 and 5, the liver tissues with the occurrence of HCC were not obtained because HCC was not treated with surgical operation.

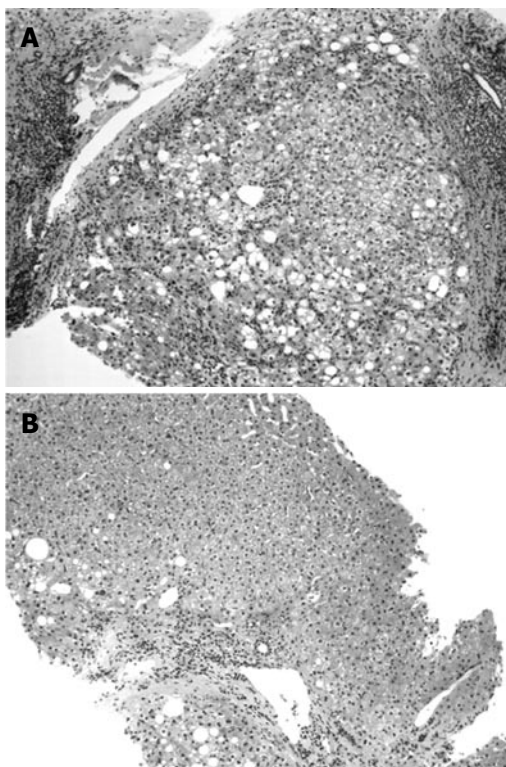

Figure 1 Liver histology of case 1 (HE staining). **A:** Pre-IFN treatment liver histology showing F3 fibrosis grade 2 steatosis; **B:** Liver histology at the occurrence of HCC showing F2 fibrosis and grade 1 steatosis.

RNA. Random primer was used for synthesis of cDNA as template for amplification of β -actin.

Statistical analysis

Statistical analysis was performed using SAS software version 9.1 (SAS Institute, Cary, NC). The kappa value was calculated to evaluate the degree of agreement in two pathologists for histological evaluation. For determining risk factors contributing the occurrence of HCC, continuous variables such as age and pre-treatment ALT value were classified into two categories: age ≥ 55 and age < 55 ; ALT > 80 IU/L and ALT ≤ 80 IU/L. Cumulative incidence for development of HCC was calculated using Kaplan-Meier method, and the differences between groups were analyzed using the log-rank test. *P* value less than 0.05 was considered statistically significant.

RESULTS

Patients with SVR who developed HCC

Of 266 patients, HCC was detected in 7 patients (6 males and 1 female) during follow-up for the patients with SVR after termination of IFN therapy. Clinical and histopathological profiles of these patients are mentioned in Table 1. The age and mean ALT value at the beginning of IFN therapy was 60.4 ± 6.2 (range, 53-68) years, and 89 ± 47 (range, 21-145) IU, respectively. The duration between IFN therapy and development of HCC was 6.3 ± 2.9 (range, 2.9-9.6) years. Undetectable serum HCV-RNA and normal ALT had been continuously maintained since IFN therapy in all patients. All patients denied excess consumption of alcoholic beverage (> 20 g/d), and were seronegative for HBsAg as well as HBcAb. The staging of liver fibrosis on pre-IFN liver biopsy was F1 in one patient, F2 in two, F3 in three and F4 in one. Hepatic steatosis was observed in all patients, grade 1 in four patients and grade 2 in three.

The comparison of liver histological findings at baseline and at the development of HCC is shown in Table 1. Overall, the grading of fibrosis was improved in cases 1, 3 and 6, unchanged in case 7, and worsened in case 2. Steatosis was decreased in cases 1, 2 and 7, and unchanged in cases 3 and 6. In cases 4 and 5, we failed to obtain liver tissue at the development of HCC since these patients were treated by transcatheter arterial embolization, instead of surgical resection of the tumor. Liver histology of case 1 before IFN therapy and at the occurrence of HCC as a representative example is shown in Figure 1.

Failure to detect HCV-RNA in HCC

In 3 patients (cases 1, 2 and 4), we tried to detect HCV-RNA in liver tissue before IFN treatment as well as at the development of HCC to elucidate whether HCV-RNA, which could remain in the liver tissue even long after successful IFN treatment^[22], might be involved in hepatocellular carcinogenesis. The tumors were surgically resected in cases 1 and 2, and the liver specimens were obtained from both the cancerous as well as non-cancerous lesion and snap-frozen at -80°C until use. In case 4, as described above, the HCC was treated by transcatheter arterial embolization, and thus the liver specimens at occurrence of HCC were not available. Instead, biopsied specimen from the liver obtained after

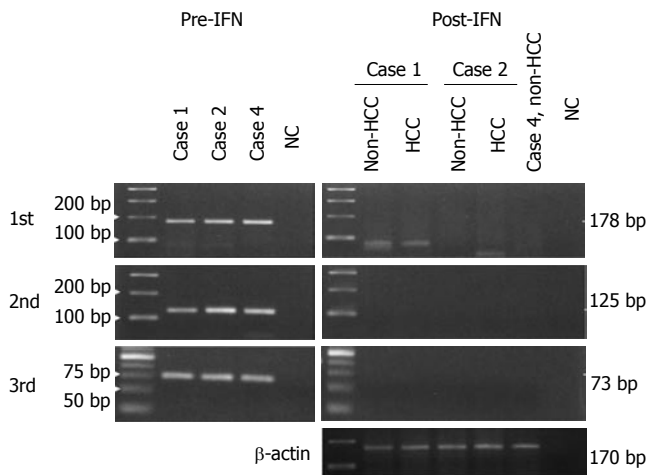

Figure 2 Amplification of HCV-RNA in liver tissues in cases 1, 2 and 4. HCV was detected in all liver tissues at the pre-IFN therapy. NC: Without template cDNA, gave no distinct band. By contrast, HCV was demonstrated in neither HCC nor non-HCC tissue in cases 1 and 2 even after 3 cycles of RT-PCR. In case 4, in whom liver tissue was obtained after IFN therapy with percutaneous biopsy, HCV was not found either. β -actin was well amplified in these post-IFN specimens, demonstrating that total RNA had not been degraded. NC: Negative control.

IFN therapy was used. HCV-RNA was successfully amplified in all specimens before IFN treatment. However, we failed to detect HCV-RNA in any sample, irrespective of cancerous and non-cancerous tissue (Figure 2). β -actin was successfully amplified in all liver tissue after IFN therapy and at HCC development (Figure 2). Therefore, we concluded that failure to detect HCV-RNA in liver tissue at development of HCC was not due to degradation of RNA, but resulted from disappearance of HCV-RNA in the liver with successful IFN treatment.

Cumulative incidence of HCC during follow-up

We demonstrated viral, clinical and histopathological profiles in all enrolled patients, the patients with and without HCC (Table 2). The cumulative incidence of HCC was analyzed for 4 variables which had been reported as risk factors before (Figure 3A-D), and pre-treatment hepatic steatosis (Figure 3E). As for the histopathological evaluation, there was an excellent agreement in the histopathological evaluation by two independent pathologists, since the kappa value was 0.70 in fibrosis and 0.78 in steatosis. The age of patients with/without HCC at baseline was 60.4 ± 6.2 and 44.8 ± 13.3 (Table 2), respectively and the patients with age ≥ 55 were at significantly higher risk for the development of HCC ($P = 0.021$, Figure 3A). The staging of pre-treatment hepatic fibrosis was available in 238 of 266 patients. The number of patients with F1, F2, F3 and F4 was 1, 2, 3, 1 in patients with HCC and 102, 97, 25, 7 in patients without HCC, respectively (Table 2). Log-rank test analysis revealed that advanced hepatic fibrosis (F3-4) was a risk factor for HCC as well ($P = 0.0028$, Figure 3C). Pre-IFN hepatic steatosis was evaluated in 231 of 266 patients, and the number of patients in grade 0, 1, 2 and 3 was 116, 95, 19 and 1, respectively. It is notable that no patient in grade 0 (no steatosis) at the IFN pre-treatment developed HCC, whereas 3 of 19 patients with grade 2 steatosis

developed HCC in the follow-up (4.9, 5.4 and 9.6 years after IFN therapy, respectively) (Table 2). Indeed, log-rank test analysis demonstrated that there was a significant difference in the grade of steatosis for cumulative incidence of HCC ($P = 0.0002$, Figure 3E). By contrast, we failed to demonstrate that sex and pre-treatment ALT value were risk factors for HCC ($P = 0.389$ and 0.251 , respectively, Figure 3C and D).

DISCUSSION

Among 266 cases, who achieved SVR with IFN therapy, 7 patients developed HCC in the follow-up period. Statistical analysis using log-rank test demonstrated that the cumulative incidence of development of HCC after SVR was significantly different depending on age and hepatic fibrosis, as previously suggested, and also on hepatic steatosis in these patients.

In the previous investigations, age^[6,15-18], sex^[6,15], alcohol consumption^[16,17], staging of fibrosis^[15-17], platelet counts^[18], and AST levels^[18] at baseline were regarded as risk factors for occurrence of HCC in patients with SVR. In the current study, we selected age, sex, ALT and staging of fibrosis as candidate contributing variables. Excess consumption of alcohol beverage was not noted in any patient with HCC and therefore was very unlikely to be a risk factor in the enrolled population. Since it is assumed that platelet counts are equivalent to staging of fibrosis and that serum ALT levels are more specific to hepatocellular injury, we adapted fibrosis and ALT values, instead of platelet counts and AST levels.

The exact determination of stage of hepatic fibrosis as well as the grade of hepatic steatosis at pre-IFN treatment is a vital premise in the current study. In this regard, grading of fibrosis and grading of steatosis were performed by two independent pathologists. The kappa values were 0.70 in fibrosis and 0.78 in steatosis, and there was a good agreement in the decision of the two. The results appeared comparable to previous reports^[18]. For instance, the proportion of the patients graded in F1, F2, F3 and F4 was 43%, 42%, 12% and 3% in the current study, and 41%, 30%, 17% and 10% in the report by Ikeda *et al.*^[18] who included 1056 patients with SVR. In addition, hepatic steatosis in our study was observed in 115 of 231 (50%) patients evaluated, and it is generally accepted that steatosis is present in 40%-60% of the patients with chronic hepatitis C^[24]. Therefore, it is conceivable to conclude that hepatic fibrosis as well as steatosis were adequately assessed in this study.

In the current study, the incidence of the patients who developed HCC after SVR was only 2.6% (7/266). Therefore, in the current study, we performed statistical analysis with only Kaplan-Meier method, and thus the effect of confounding factors among each valuable could not be excluded. In this regard, we should be reluctant to conclude that age, hepatic fibrosis and hepatic steatosis, demonstrated in this study as statistically significant, would be the only determinants of risk for developing HCC. Nevertheless, hepatic steatosis, which has never been investigated as a risk factor for developing HCC after SVR, is identified as a statistically significant factor, and

Table 2 Pre-IFN viral, clinical and histopathological profiles of all patients with SVR

	Age (mean \pm SD)	Sex (M/F)	ALT (IU) (mean \pm SD)	Genotype (1/2/NT)	Hepatic fibrosis (F1/F2/F3/F4/NT)	Hepatic steatosis (Grade 0/1/2/3/NT)
All (<i>n</i> = 266)	46.3 \pm 14.3	184/82	112 \pm 99	102/142/20	103/99/28/8/28	116/95/19/1/35
HCC (<i>n</i> = 7)	60.4 \pm 6.2	6/1	89 \pm 47	4/2/1	1/2/3/1/0	0/4/3/0/0
No HCC (<i>n</i> = 259)	44.8 \pm 13.3	178/81	113 \pm 100	98/140/19	102/97/25/7/28	116/91/16/1/35

we believe that it is worth evaluating its potential role for developing HCC after eradication of HCV.

Hepatic steatosis is known to be decreased after eradication of HCV in HCV genotype 3 infection.

However, HCV genotype 3 is very rare in Japan, and indeed we found no patient infected with genotype 3 among the 266 subjects enrolled in the current study. By contrast, it has been reported that hepatic steatosis with HCV genotype 1

infection is not altered after successful antiviral treatment^[30]. In the current study, among 6 patients who developed HCC after SVR and in whom HCV genotype was examined, 4 and 2 were infected with genotype 1 and 2, respectively (Table 1). Disappearance of hepatic steatosis (grade 0) after successful IFN therapy was noted only in 1 patient (case 2), infected with HCV genotype 2a; steatosis still remained in 4 of 5 patients whose histologies on the occurrence of HCC were investigated (Table 1). Thus, hepatic steatosis at baseline continuously remained after eradication of HCV, and might play a role in development of HCC, along with other factors, such as age and fibrosis in the liver.

It has been repeatedly reported that NASH caused by hepatic steatosis eventually could result in development of HCC^[31,32,35-39], and indeed NASH is regarded as an alternative etiology of HCC worldwide^[36,40,41]. It is believed that cryptogenic cirrhosis, occasionally producing HCC, may be a late complication of NASH, even though steatosis is not observed in the end-stage cirrhotic liver^[31,32]. In the current study, however, liver histology on the onset of HCC was not coincident with cryptogenic cirrhosis. Rather, the staging of fibrosis was F2 in 5 of 7 patients who developed HCC, relatively at early stage. Moreover, although hepatic steatosis was noted at the pre-IFN treatment, histological hallmarks of NASH, such as perisinusoidal/pericellular fibrosis or infiltration of polymorphonuclear cells^[42,43], were not observed in our patients. Therefore, hepatic steatosis in these patients should be regarded as non-alcoholic fatty liver diseases (NAFLD), instead of NASH. Taken together, the role of hepatic steatosis in the hepatocarcinogenesis after SVR seems to be different from those in NASH liver. Rather, the results in the current study suggest the possibility that steatosis and HCV infection, even if eradicated, would cooperatively operate for development of HCC.

We should be cautious, however, in concluding that hepatic steatosis would be a risk factor for developing HCC after SVR. First of all, multivariate analysis was not performed in this study and therefore the effect of confounding factors could not be excluded, as described above. Second, it is still controversial whether hepatic steatosis facilitates hepatocarcinogenesis in untreated patients with infection of HCV^[44,45], and prospective well-controlled studies are required to conclude the association between hepatic steatosis and development of HCC. Third, it is also notable that HCC developed within 10 years after successful eradication of HCV in the presented cases, even though almost half of the enrolled 266 patients with SVR had been followed up more than 10 years. Since hepatic steatosis would remain in a similar manner after eradication of HCV, HCC might develop in patients after more than 10 years as well. Finally, very low amount of HCV, even undetectable by RT-PCR, had still remained in the liver after SVR and might play a crucial role in hepatocarcinogenesis. Radkowski *et al.*^[22] recently demonstrated that HCV-RNA was detected in 3 of 11 patients with SVR after treatment, even though previous reports describing the occurrence of HCC in patients with SVR have repeatedly shown the absence of HCV-RNA in the tumor and non-tumor liver tissue^[8,9,12].

In conclusion, the current study demonstrates that development of HCC in patients after SVR depends on age,

hepatic fibrosis, and hepatic steatosis at pre-IFN treatment. As discussed, the remote effect of HCV infection could be more important for hepatocarcinogenesis, and a large-scale, multi-center cooperative study is required to conclude whether hepatic steatosis at baseline is a contributing factor for development of HCC. Nevertheless, it should be kept in mind that patients with hepatic steatosis at pre-IFN treatment may be at a high risk for developing HCC, and therefore should be closely monitored after SVR.

COMMENTS

Background

Continuous eradication of hepatitis C virus (HCV), i.e., sustained viral response (SVR) with interferon (IFN) therapy greatly reduces the risk of developing hepatocellular carcinoma (HCC). However, HCC was sporadically found even in patients with SVR, and it is of clinical importance to elucidate which patients with SVR are at higher risk for HCC.

Research frontiers

In the current study, we retrospectively examined 266 patients with SVR and detected 7 patients among them (2.6%) who developed HCC after SVR. RT-PCR failed to detect HCV-RNA in the liver. The cumulative incidence for HCC was significantly different depending on hepatic fibrosis ($P = 0.0028$), hepatic steatosis ($P = 0.0002$) and higher age ($P = 0.021$) at the pre-interferon treatment.

Innovations and breakthroughs

Although age and fibrosis were previously reported as risk factors, hepatic steatosis was firstly demonstrated as a possible risk in the current study.

Applications

Further large-scale study is warranted to confirm the contribution of hepatic steatosis for developing HCC after SVR. For the moment, patients with high hepatic steatosis should be closely monitored for HCC, even after SVR with successful antiviral treatment.

Peer review

This is a very interesting study. There are few papers with such histological and follow up studies in SVR and the article is well written.

HCC was also higher in the non-IFN group than IFN group (6.7% and 27% vs 0 and 0% at 1- and 3-year, $P = 0.048$, respectively).

CONCLUSION: Low-dose intermittent IFN-alpha therapy for patients with HCV-related compensated cirrhosis after curative HCC treatment was effective by making patients tolerant to medical or surgical treatment for recurrent HCC in the later period of observation.

Abstract

AIM: To assess the efficacy of low-dose intermittent interferon (IFN) therapy in patients with hepatitis C virus (HCV)-related compensated cirrhosis who had received curative treatment for primary hepatocellular carcinoma (HCC).

METHODS: We performed a prospective case controlled study. Sixteen patients received 3 MIU of natural IFN-alpha intramuscularly 3 times weekly for at least 48 wk (IFN group). They were compared with 16 matched historical controls (non-IFN group).

RESULTS: The cumulative rate of first recurrence of HCC was not significantly different between the IFN group and the non-IFN group (0% vs 6.7% and 68.6% vs 80% at 1- and 3-year, $P = 0.157$, respectively). The cumulative rate of second recurrence was not also significantly different between the IFN group and the non-IFN group (0% vs 6.7% and 35.9% vs 67% at 1- and 3-year, $P = 0.056$, respectively). Although the difference in the Child-Pugh classification score between the groups at initial treatment of HCC was not significant, the score was significantly worse at the time of data analysis in the non-IFN group than IFN group (7.19 ± 1.42 vs 5.81 ± 0.75 , $P = 0.0008$). The cumulative rate of deviation from objects of any treatment for recurrent

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common malignant neoplasms worldwide. Approximately 80% of Japanese patients with HCC have a history of hepatitis C virus (HCV) infection, and most such patients have liver cirrhosis^[1-3]. Although recent advances in imaging techniques and treatment of HCC have improved prognosis of patients with HCV-related HCC, the outcome is still unsatisfactory; the 5-year survival rate is only 50% to 70% even after curative treatment such as hepatic resection and local ablation^[4]. The reasons for this unfavorable prognosis is considered to include high intrahepatic tumor recurrence rates and biochemical deterioration by sustained hepatic damage, both resulting from persistent HCV infection^[5]. Even after curative hepatic resection for HCV-related HCC, the rate of intrahepatic tumor recurrence within 1 year is 20% to 40%, rising to about

80% by 5 years^[4,6-8]. Intrahepatic recurrences of HCC may result from intrahepatic metastasis originating from the primary HCC or from ongoing multicentric carcinogenesis related to chronic HCV infection. In addition, sustained underlying HCV-related hepatic damage may compromise hepatic functional reserve, worsening clinical outcome. Thus, prevention of HCC recurrence and preservation of liver function are both highly important priorities in improving prognosis of patients with HCV-related HCC.

Interferon (IFN) therapy for patients with HCV infection is effective as evident by reduction of serum alanine transaminase (ALT) activity and eradication of HCV. Accordingly, IFN is valuable in minimizing hepatic necrosis, inflammation, and fibrosis, as well as reducing the likelihood of hepatocarcinogenesis^[9-16]. The primary goal of treatment of patients with HCV infection is elimination of the virus. Several studies have reported recently that IFN therapy provided after curative treatment for HCV-related HCC prevents HCC recurrences and improves survival^[17-23]. Such improvement of prognosis is more predominant when IFN therapy results in elimination of HCV RNA^[24]. However, most patients with HCV-related HCC also have liver cirrhosis. Many centers do not advocate IFN therapy of patients with compensated cirrhosis, mainly because of the disappointing sustained virological response (SVR) rates in such patients^[25]. Several studies indicated that the response of cirrhotic patients to antiviral therapy is low^[26-28]. The reasons for the low SVR rate in such patients include inability to administer IFN at recommended doses due to adverse effects and dose-limiting cytopenia. On the other hand, several investigators suggested that the use of low-dose IFN therapy for viral elimination was as effective in the treatment of cirrhotic patients with HCV as it is in non-cirrhotic patients^[29,30]. Furthermore, they indicated that the same therapy could improve the underlying liver histology. There is evidence to suggest that low-dose IFN therapy might be beneficial in HCV-related cirrhosis, not only because it prevents the progression of liver disease, but also because it reduces the risk of hepatocarcinogenesis^[31,32]. In this regard, low-dose IFN therapy seems to be tolerable without significant life-threatening adverse effects than the standard dose of IFN.

However, it is not known whether low-dose IFN after curative treatment of primary HCC could slow disease progression or reduce the rate of clinical decompensation in cirrhotic patients, in addition to prevention of HCC recurrence. Several studies used the standard dose of IFN after HCC treatment^[17,23,33], and studies using low-dose IFN therapy for HCV-related cirrhosis after HCC treatment also reported that such regimen may reduce late recurrence of HCC^[34].

In this prospective case controlled trial, we assessed the efficacy of low-dose intermittent IFN therapy on HCV-related liver cirrhosis after curative treatment of primary HCC in terms of overall survival, HCC recurrence, and liver function.

MATERIALS AND METHODS

Patients

A total of 176 consecutive patients received their initial

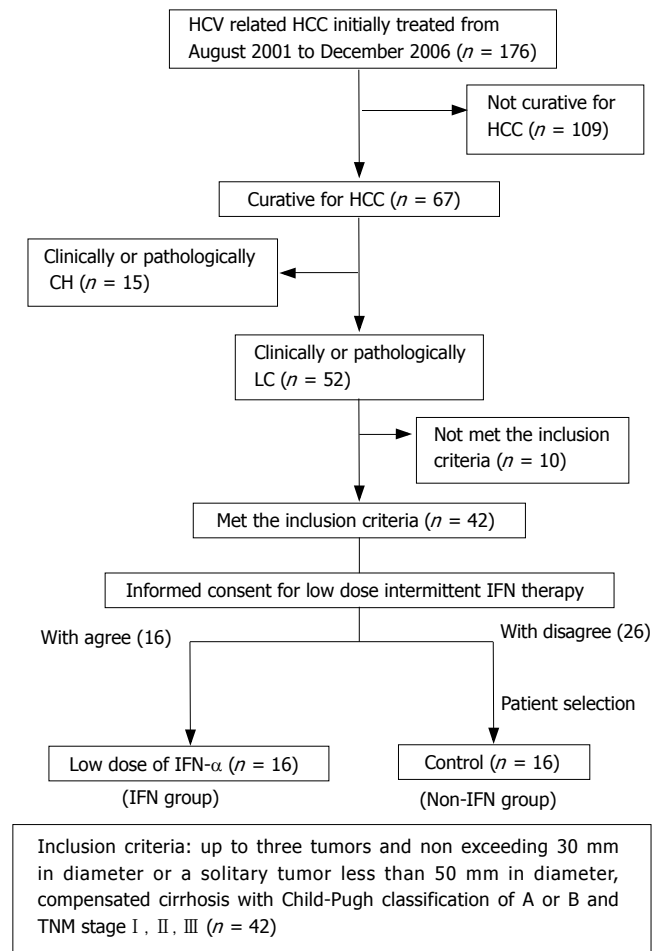

Figure 1 Schematic flow chart of enrolled patients.

treatment for HCV-related primary HCC at Hiroshima University Hospital between August 2001 and December 2006. Of these, 67 patients with HCC underwent first medical or surgical therapeutic intervention with curative intent (defined as complete tumor eradication with no visible residual tumor in computed tomographic images, or resection of all evident tumor tissue). Medical treatments included percutaneous radiofrequency (RF) ablation and ethanol injection, while surgical procedures included hepatic resection and RF ablation under laparotomy. Among these 67 patients, 52 patients with liver cirrhosis (LC), which was diagnosed clinically and pathologically, were considered for this prospective study. Figure 1 shows our study flow. Among these 52 patients with HCV-related LC, we assessed 42 patients who met the following inclusion criteria: (1) the presence of up to three tumors with none exceeding 30 mm in diameter or a solitary tumor less than 50 mm in diameter; (2) tumor-node-metastasis (TNM) stage of I, II or III; (3) detectable serum HCV RNA; (4) all seronegativity for hepatitis B marker including hepatitis B surface antigen, hepatitis B anti-core antibody and hepatitis B surface antibody; (5) compensated cirrhosis with a Child-Pugh class A or B; (6) platelet count $\geq 40000/\mu\text{L}$; and (7) absence of local recurrence during the follow-up period and of any ectopic intrahepatic recurrence within 12 wk after treatment for primary HCC. We used the TNM classification system

of the Liver Cancer Study Group of Japan as a staging system for HCC^[35]. The underlying liver condition leading to LC was identified by histopathological examination of resected tissue samples. When this was not available, laboratory tests were performed including serum albumin, platelet, prothrombin time and indocyanine green retention at 15 min (ICG-R15), and radiological examination such as ultrasonography and computed tomography.

Of the 42 patients with LC who met the above eligibility criteria, 16 patients received low-dose IFN therapy after signing a written informed consent (IFN group). Of the remaining 26 patients who rejected IFN therapy, we selected 16 patients as the control (non-IFN group). These 16 patients, who met the eligibility criteria mentioned above, were matched by age, gender, tumor size, number of tumors, TNM stage of HCC, serum albumin level, platelet counts, ICG-R15 and Child-Pugh class with patients of the IFN group. Thus, a total of 32 patients (16 in the IFN group and 16 in the non-IFN group) were enrolled in this study. All agreed to participate in the research protocol, which was approved by the hospital research ethics board. Table 1 shows the baseline characteristics of patients of the two groups. The data indicates no significant differences between the groups for age, gender, liver function, tumor characteristics, and therapeutic methods used against primary HCC.

IFN therapy

In the IFN group, patients received 3 MIU of natural IFN- α (human lymphoblastoid IFN; Sumiferon, Daiinippon Sumitomo Pharmaceuticals, Osaka, Japan) intramuscularly three times weekly for at least 48 wk as long as possible. IFN therapy commenced within 12 wk after initial treatment for HCC. Patients received post-treatment IFN therapy up to the detection of HCC recurrence, and then patients who could have curative treatment for recurrent HCC restarted IFN therapy when possible. However, patients who had advanced liver dysfunction or untreatable progressive HCC did not receive IFN therapy. In the control group, none of the patients received IFN therapy after curative treatment of HCC; instead, they

were on ursodeoxycholic acid (UDCA) and stronger neomycinophagen C (SNMC).

Follow-up

After curative treatment for primary HCC, all patients underwent liver function tests, serum tumor marker assays such as alpha-fetoprotein (AFP) and protein induced by vitamin K absence or antagonist (PIVKA)-II, every month, abdominal ultrasonography every 3 mo, and dynamic computed tomography (CT) every 6 mo. If recurrences of HCC were suspected, additional examinations including CT during arteriography or tumor biopsy were performed. Recurrence of HCC was defined as any new nodules appearing as hyperattenuation by CT during hepatic arteriography or as hypoattenuation in CT performed during arteriography. Hypovascular HCC was confirmed histopathologically by fine-needle aspiration biopsy. Patients with recurrent HCC were treated medically or surgically, with curative intent if possible. Patients without curative treatment of recurrent HCC then received transcatheter chemoembolization. After repeated transcatheter chemoembolization, patients were finally unable to receive any treatment for recurrent HCC.

End points

We analyzed the outcome of this prospective study in December 2006. We compared the rate of HCC recurrence and the survival rate between IFN group and control group. We assessed whether low-dose of IFN therapy was effective in inhibiting recurrence of HCC, preserving liver function and prolonging survival. In addition, we also assessed the cumulative rate of deviation from objective of any treatment against recurrent HCC due to progression of HCC and/or underlying liver dysfunction.

Statistical analysis

The Chi-square and Fisher exact tests were used for categorical variables, while Student's *t*-test and the Mann-Whitney *U* test were used for continuous and ordinal variables, as appropriate. The Kaplan-Meier method used to assess cumulative survival and recurrence rates calculated from the date of diagnosis to the date of

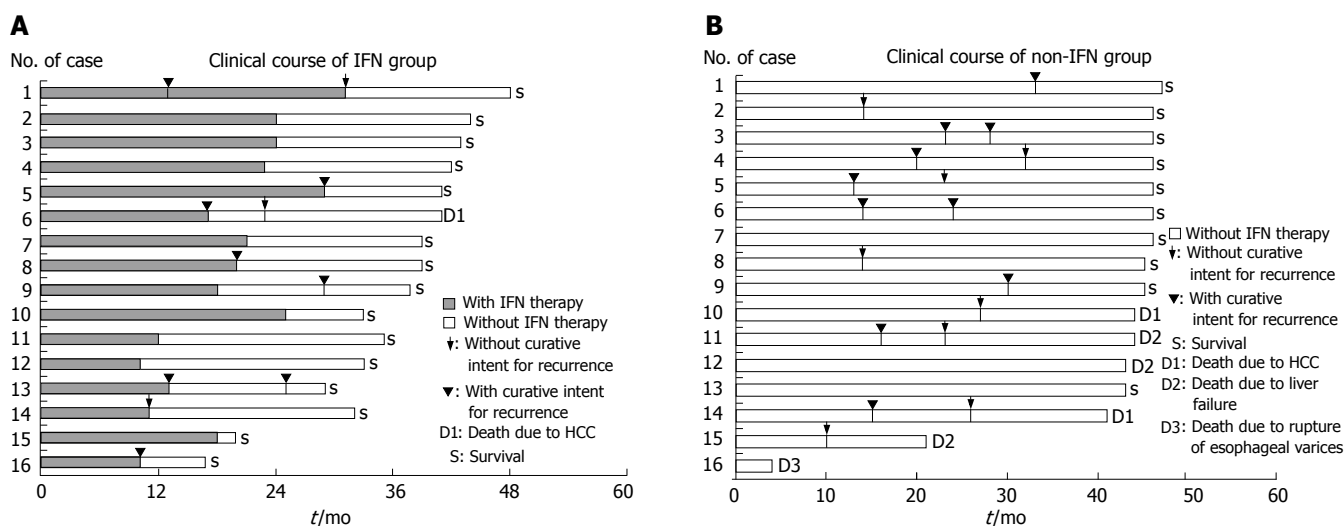

Figure 2 A: Clinical course of the interferon group. Patients who had a curative treatment for primary HCC received 3 MIU of natural interferon- α three times weekly for at least 48 wk as long as possible except Cases 12, 14 and 16. Recurrent HCCs were treated with or without curative treatment; B: Clinical course of the non-interferon group. Patients who had a curative treatment of primary HCC did not receive IFN therapy. Recurrent HCCs were also treated with or without curative treatment.

disease recurrence or death. Surviving patients and patients who died of causes unrelated to the liver were defined as censored cases, while patients who died of causes related to the liver were defined as noncensored cases. The log-rank test was used to compare survival and recurrence curves. *P* values below 0.05 were considered to indicate statistical significance. The JMP version 5.1 statistical software package (SAS Institute, Cary, NC) was used for analysis of data.

RESULTS

Clinical course of IFN group

Figure 2A shows the clinical course of 16 patients of the IFN group from the initial treatment of primary HCC to the date of data analysis. The duration of low-dose IFN therapy ranged from a minimum of 10 mo to a maximum of 25 mo (median 16 mo). Although 8 patients did not have HCC recurrence, HCC recurred in 8 patients after initial treatment of HCC during a median follow-up period of 37 mo. Of the recurred patients, 7 developed HCC recurrence during IFN therapy (Cases 1, 5, 6, 8, 13, 14 and 16) except 1 patient (Case 9) who had HCC recurrence after discontinuation of IFN therapy. Of the 8 patients with HCC recurrence, 4 were treated with surgical resection therapy (Cases 5, 9, 13 and 16), 3 patients with percutaneous RF ablation therapy (Cases 1, 6 and 8) and 1 patient transcatheter chemoembolization (Case 14). Of these patients, a patient with transcatheter chemoembolization (Case 14) could not have curative treatment and repeated transcatheter chemoembolization. He was excluded from the study concerning the next recurrence. Of the 7 patients with curative treatment for HCC recurrence, 2 restarted IFN therapy, one continued IFN therapy until next recurrence (Case 1), which was not curative, and the other continued until intolerant generalized fatigue (Case 8). The remaining 5 patients (Cases 5, 6, 13, 14 and 16) were followed without IFN therapy because of rejection of

IFN therapy. Although one of these 5 patients was not curative for first recurrence (Case 14), he was tolerant to repeated transcatheter chemoembolization and was still alive at the date of data analysis. Two patients without curative treatment at the second recurrence (Cases 1 and 6) were also relatively tolerant to the repeated medical treatment such as transcatheter chemoembolization. Of these patients, one died of progression of HCC in spite of repeated transcatheter chemoembolization and hepatic arterial infusion (Case 6), another was alive at the date of data analysis (Case 1). Of 3 patients without curative treatment of HCC, two survivors' status of HCC were not progressive (stage II and stage III) and underlying liver function could be tolerant to the treatment such as transcatheter chemoembolization because of relatively preserved function (Cases 1 and 14).

The 16 patients who received IFN therapy included 2 patients with virological response (Cases 2 and 3) and 14 patients who did not get SVR [3 transient responders (Cases 8, 9 and 11), and 11 non-responders (Cases 1, 4, 5, 6, 7, 10, 12, 13, 14, 15 and 16)]. Among the 14 patients who did not show SVR, 8 were biochemical responders with normalized ALT (Cases 1, 4, 5, 7, 9, 10, 13 and 16), including 4 transient responders and 4 non-responders. Two sustained virological responders who received IFN therapy for 96 wk have viral characteristics of genotype 1 and low viral load. Among the patients who did not show SVR, 7 discontinued IFN treatment because of recurrence of HCC, while 2 patients restarted IFN therapy after the curative treatment of recurrent HCC. None of the patients who received IFN therapy developed life-threatening side effects.

Clinical course of non-IFN group

Among the non-IFN group, the first recurrence of HCC occurred in 13 patients during a median follow-up period of 45 mo (Figure 2B). HCC recurred in 6 of the 7 non-IFN patients who had a sustained normalized ALT. Of the 13 patients with recurrent HCC among the non-IFN group, 4 were treated with hepatic resection (Cases 1, 4, 9 and 11),

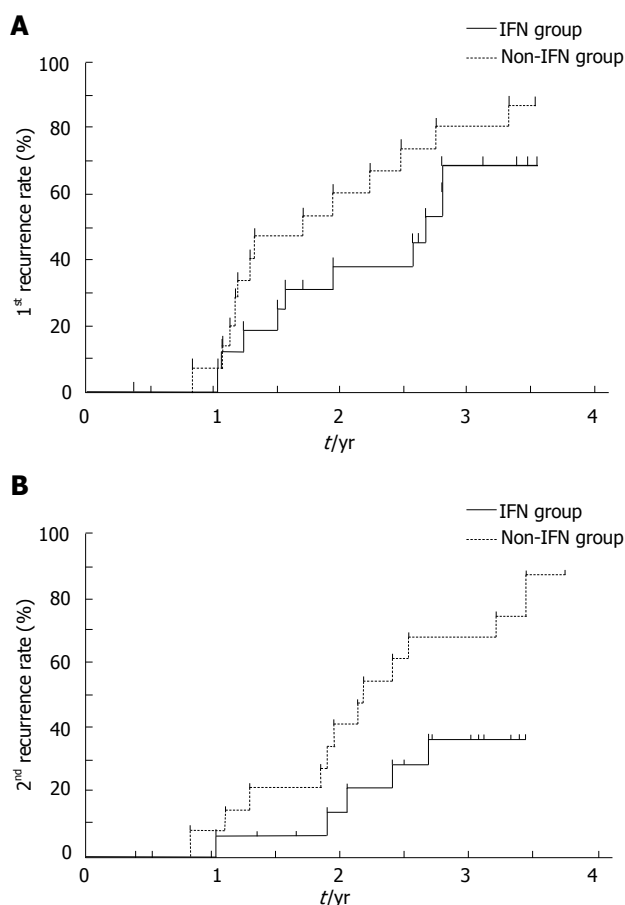

Figure 3 A: Cumulative rate of first recurrence. Rates of first recurrence for the IFN and non-IFN groups. The rate of first recurrence of HCC in the IFN group was not significantly different from that of the non-IFN group ($P = 0.157$); B: Cumulative rate of second recurrence. Rates of second recurrence for the IFN and non-IFN group. The rate of second recurrence of HCC in the IFN group was not significantly different from that of the non-IFN group ($P = 0.056$).

6 with local ablation including percutaneous RF ablation or ethanol injection (Cases 3, 5, 6, 7, 10 and 14) and 3 with transcatheter chemoembolization (Cases 2, 8 and 15). Of the 13 recurrent patients, 5 patients (2 received ethanol injection and 3 transcatheter chemoembolization) could not be treated curatively and was excluded from the study concerning the next recurrence. These 5 patients were treated repeatedly with transarterial chemoembolization after first recurrence. Among the remaining 8 patients who were treated curatively for first recurrence, 7 developed a second recurrence (Cases 3, 4, 5, 6, 9, 11 and 14). Among these 7 patients with second recurrence, 2 were treated curatively for HCC [1 with RF ablation (Case 3) and 1 with hepatic resection (Case 6)], while the remaining 5 patients were not (4 patients due to uncontrolled multiple HCC and one patient due to underlying liver dysfunction). The latter group of 5 patients received transarterial chemoembolization repeatedly after second recurrence.

Comparison of the first and second recurrence rates of HCC

We compared the overall cumulative rates for first and second recurrence between IFN and non-IFN groups (Figure 3). The 1-, 2- and 3- year rates of first recurrence

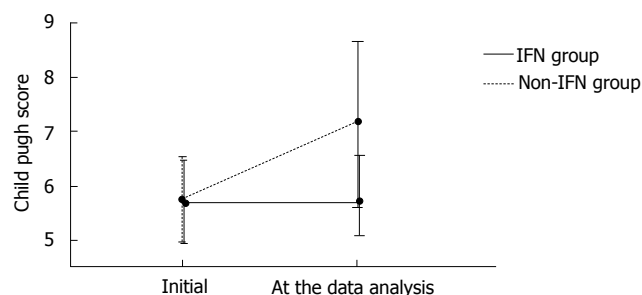

Figure 4 Effect of IFN therapy after curative treatment of HCC on Child-Pugh scores. IFN-treated patients were less likely to show deterioration of hepatic function. The average scores of Child-Pugh of the IFN group were significantly better preserved than the non-IFN group ($P = 0.0008$).

of HCC in the IFN and non-IFN group were not different (0% vs 6.7%, 38.1% vs 60% and 68.6% vs 80%, respectively, Figure 3A, $P = 0.156$). The 1-, 2- and 3-year rates of second recurrence in the IFN and non-IFN groups were 0% vs 6.7%, 13.5% vs 33.3% and 35.9% vs 67%, respectively (Figure 3B, $P = 0.056$).

Liver function

Patients of the IFN group were less likely to develop worsening of hepatic dysfunction compared with the non-IFN group. We compared the average score determined for Child-Pugh classification at initial treatment of HCC with that at the time of data analysis (Figure 4). Although the difference in the Child-Pugh classification score between the two groups at initial treatment of HCC was not significant, the score was significantly worse at the time of data analysis in the non-IFN group than IFN group ($P = 0.0008$).

Deviation from objects of any treatments for recurrent HCC

At the date of data analysis, patients who developed recurrent HCC were treated repeatedly, as possible, for the purpose of curative treatment including surgical resection and ablative therapy such as RF ablation and ethanol injection. Patients who were difficult to treat with curative intent received transcatheter chemoembolization or hepatic arterial infusion. Although patients with recurrent HCC received repeated treatments, some patients finally could not be treated because of excessive progression of HCC or liver dysfunction. Figure 5 shows that the cumulative rate of deviation from objects of any treatment for recurrent HCC between the IFN group and non-IFN group. In the IFN group, one patient could not receive treatment due to progressively advanced HCC in later period. On the other hand, 8 patients in the non-IFN group could not receive treatment because of underlying liver dysfunction ($n = 2$) and progressively advanced HCC ($n = 6$). The 1-, 2- and 3- year rates of deviation from objects of any treatment for recurrent HCC in the IFN and non-IFN group were 0% vs 6.7%, 0% vs 20% and 0% vs 27%, respectively ($P = 0.048$). Thus, the IFN group tended to be treatable for recurrent HCC compared with the non-IFN group.

Survival of patients

At the date of data analysis, 1 patient among the IFN

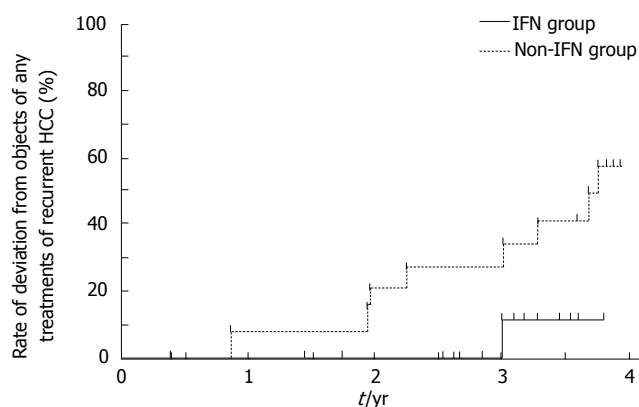

Figure 5 Cumulative rate of deviation from objects of any treatment of recurrent HCC. Recurrent HCC tended to be treatable later in the IFN group than non-IFN group ($P = 0.048$).

group and 6 patients among the non-IFN group had died of liver disease. Of the 8 recurrence patients among the IFN group, 1 died of advanced multiple HCC and none died of liver failure. On the other hand, of the 13 recurrence patients among the non-IFN group, 2 died of advanced HCC and 2 died of liver failure in spite of the relatively early stage of HCC. Among the 3 patients without recurrent HCC of the non-IFN group, 1 died of liver dysfunction and 1 died of ruptured esophageal varices.

With regard to the cumulative survival rates of the IFN and non-IFN groups (Figure 6), the respective rates of survival were 100% *vs* 93.7% at 1 year, 100% *vs* 87.5% at 2 years, 100% *vs* 87.5% at 3 years and 83.3% *vs* 61.4% at 4 years. Thus, the cumulative survival rate was not significantly different between the two groups for first 4 years after curative treatment of HCC ($P = 0.45$). The median survival time following the first treatment of HCC was 37 mo (range, 17 to 45) for the IFN group and 45 mo (range, 4 to 47) for the non-IFN group.

DISCUSSION

HCC recurrence is still a risk even if HCV-related HCC is treated with curative intent. Most of such patients with HCC have underlying liver cirrhosis, and deterioration of underlying hepatic function may be a hindrance to treatment of recurrent HCC and be associated with prognosis. The present prospective case controlled study of cirrhotic patients shows that low-dose intermittent IFN therapy after curative treatment of HCC could preserve liver function and increase the chance of treatment for recurrent tumor.

Previous studies indicated that IFN therapy after curative treatment of HCC was effective in inhibiting or delaying the development of recurrent HCC^[17-23,34,36]. Although several recent studies have reported the efficacy of chemoprevention with IFN therapy after treatment of HCV-related HCC, the basis of the benefit was not clear. Shiratori *et al.*^[23,33] and Ikeda *et al.*^[17] reported that IFN therapy in cirrhotic patients reduced recurrence of HCC and improved prognosis. Although they used standard IFN dosage per time, there are no other reports on the effect of

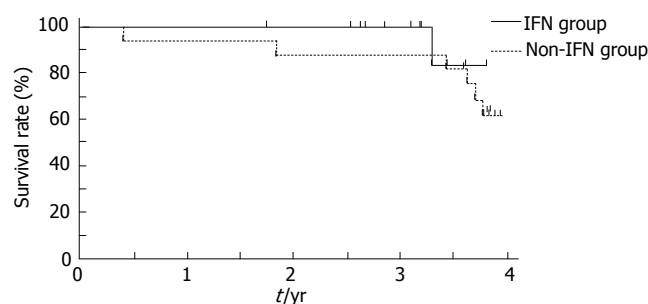

Figure 6 Cumulative survival rate. Comparison of the cumulative survival rates of the IFN and non-IFN groups. The cumulative survival rate was not significantly different between the two groups ($P = 0.45$).

low-dose IFN therapy after curative treatment of primary HCC in cirrhotic patients. Sakaguchi *et al.*^[21] reported that low-dose, long-term, intermittent IFN therapy in patients who had curative HCV-related HCC suppressed recurrence of HCC and improved survival, though it was not clear whether their patients had underlying liver cirrhosis or not. On the other hand, Mazzaferro *et al.*^[34] indicated that low-dose intermittent IFN therapy seemed to reduce late recurrence in patients with HCV-related cirrhosis after resection of HCC. Considered together, these results suggest that low-dose IFN therapy is potentially useful for cirrhotic patients when used as long as possible. However, our results of low-dose intermittent IFN therapy showed no significant difference in recurrence between those who received IFN therapy and those who did not. Unfortunately, since the difference in treatment outcome between the above three studies might be due to the use of different IFN regimens (e.g., dosage and frequency), and background characteristics of cirrhotic patients (e.g., performance status), the results varied and no standard IFN regimen to pursue after curative treatment of HCV-related HCC could be advocated.

The design of the present study was not randomized controlled type, and differed in details of the IFN protocol and characters of patients from the other studies. Although there was no significant difference in the recurrence rate between the IFN and non-IFN groups, the recurrence rate in the later period of observation including second recurrence appeared to be lower in patients with IFN therapy. Furthermore, the recurrent HCC in patients on IFN therapy did not seem to be aggressive compared with that in patients without IFN therapy, probably because they could be treated with curative intent during the observation period. Thus, low-dose intermittent IFN therapy seemed to have delayed or reduced the chance of development of recurrent HCC in the later period of observation, although IFN did not completely inhibit HCC recurrence in our cirrhotic patients.

Most cirrhotic patients cannot receive a standard full-dose IFN regimen due to underlying liver dysfunction and unfavorable complication such as cytopenia. Hence, it could be difficult to achieve SVR in most cirrhotic patients on low-dose intermittent IFN therapy. Valla *et al.*^[37] performed a randomized, controlled trial of IFN- α 2b but the results showed a lack of any benefits in terms of sustained biochemical response, liver function test

results, histology, occurrence of decompensation or HCC, or prolongation of survival. On the other hand, Everson and coworkers^[29,30] suggested that the use of low-dose IFN therapy for viral elimination was as effective in the treatment of cirrhotic patients with HCV as it is in non-cirrhotic patients. Several recent studies have reported that IFN therapy following HCC treatment improved liver function of patients with HCV-related HCC, although it is not clear which specific IFN action is important for these benefits. We also demonstrated that preservation of liver function was significantly better in the IFN group than in the non-IFN group even when HCV was not completely eradicated. Thus, hepatic functional preservation increases the chance of treatment for recurrent. Therefore, the cumulative rate of deviation from objects of any treatment for recurrent HCC might be lower in patients with IFN therapy than in patients without IFN therapy as we showed that low-dose IFN resulted in less advanced recurrence and hepatic functional preservation. Although the survival rates were not significantly different between the two groups in our observation period, we need a longer observation to determine differences in survival rates. Although we also assessed the correlation between the observed beneficial effects of the low-dose intermittent IFN therapy and HCV genotype, we could not reach the clear conclusion due to small sample size. In the future, the study with large sample size may be needed to conclude.

In our study, only about 12.5% (2/16) of patients who received IFN therapy had sustained viral elimination. And there were no significant difference in population of patients with normalized ALT between the IFN and non-IFN group ($n = 10$, $n = 7$, respectively). In spite of these results, patients treated with low-dose intermittent IFN therapy have a hepatic functional preservation greater than IFN untreated patients who received continuous medication with UDCA or SNMC after curative treatment of HCC. Although the mechanism of this reason is not well known, we suggested that the anti-inflammatory activity by low-dose intermittent IFN therapy may be stronger than medication with UDCA or SNMC and induce regression or retardation of underlying hepatic fibrosis, and finally, inhibits the progression of hepatic dysfunction.

Adverse effects such as reduction in blood counts by low-dose of IFN- α were not observed in our study, although neutropenia and/or thrombocytopenia were identified before IFN therapy. Furthermore, none of the patients required dose reduction in our study. Although 4 patients discontinued IFN therapy because of generalized fatigue, 2 of these patients restarted IFN therapy after that. Therefore, low-dose intermittent IFN- α therapy can be used relatively safely for cirrhotic patients with thrombocytopenia. However, patients who can not receive even low-doses of IFN also exist due to severe cytopenia or advanced liver cirrhosis. Medication with UDCA or SNMC or phlebotomy may be useful in decreasing ALT level for those patients.

Most cirrhotic patients who had received curative treatment for primary HCC have a limited hepatic reserve or thrombocytopenia. Therefore, low-dose intermittent IFN therapy might be effective for better prognosis. However, further studies of larger samples followed-up for

longer periods should be conducted to establish a definite conclusion about the effect of low-dose IFN therapy for the prevention of progressive liver disease and effect of treatment for recurrent HCC.

Abstract

AIM: To investigate H^+ , K^+ -ATPase inhibition, anti-*H. pylori*, antioxidant, and the *in vivo* antiulcer potential of a pectic polysaccharide from Swallow root (*Decalepis hamiltonii*; SRPP).

METHODS: SRPP, with known sugar composition [rhamnose: arabinose: xylose: galactose in the ratio of 16:50:2:32 (w/w), with 141 mg/g of uronic acid] was examined for anti-ulcer potency *in vivo* against swim/ethanol stress-induction in animal models. Ulcer index, antioxidant/antioxidant enzymes, H^+ , K^+ -ATPase and gastric mucin levels were determined to assess the anti-ulcer potency. Anti-*H. pylori* activity was also determined by viable colony count and electron microscopic studies.

RESULTS: SRPP, containing phenolics at 0.12 g GAE/g, prevented stress-induced gastric ulcers in animal models by 80%-85%. Down regulation of gastric mucin 2-3 fold, antioxidant/antioxidant enzymes and upregulation of 3 fold of H^+ , K^+ -ATPase in ulcerous animals were normalized upon treatment with SRPP. Histopathological analysis revealed protection to the disrupted gastric mucosal layer and epithelial glands. SRPP also inhibited H^+ , K^+ -ATPase *in vitro*, at an IC_{50} of 77 μ g/mL as opposed to that of 19.3 μ g/mL of Lansoprazole and *H. pylori* growth at Minimum Inhibitory Concentration (MIC) of 150 μ g/mL. In addition, free radical scavenging (IC_{50} -40 μ g/mL) and reducing power (3200 U/g) activities were also observed.

CONCLUSION: SRPP, with defined sugar composition and phenolics, exhibited multi-potent free radical scavenging, antioxidant, anti-*H. pylori*, inhibition of H^+ , K^+ -ATPase and gastric mucosal protective activities. In addition, SRPP is non-toxic as opposed to other known anti-ulcer drugs, and therefore may be employed as a potential alternative for ulcer management.

INTRODUCTION

Ulcer is a common global problem with increasing incidence and prevalence. Worldwide 14.5 million people have ulcers with a mortality of 4.08 million (<http://digestive.nidk.nih.gov/statistics/statistics.htm>/peptic ulcer prevalence). The increasing incidence and prevalence of ulcers have been attributed to several factors encountered during day-to-day life, such as stress^[1], exposure to bacterial infection^[2], and use of non-steroidal anti-inflammatory drugs (NSAIDs)^[3]. Indeed, NSAIDs are used daily by approximately 30 million people world wide, constituting a world market in excess of \$2 billion. Associated serious side effects are ulceration and gastric bleeding, which are due to inhibiting cyclooxygenase-1 activity that is required for mucosal protection^[4]. Gastric lesions develop due to loss of the delicate balance between gastro-protective and aggressive factors. Reduction in gastroprotective factors, such as mucus, bicarbonate secretion and gastric mucosa-blood flow, and enhancement of aggressive factors, such as increase of acid/pepsin secretion and *H. pylori* infection, results in gastric ulceration^[1,2]. Mucosal damage, an initial step in ulcer development, has been known to be due to oxidative stress (OS) by Reactive Oxygen Species (ROS), hypersecretion of HCl through H^+ , K^+ -ATPase action^[5], harboring of *H. pylori* on the damaged mucin layer^[6], and the blockade of the cyclooxygenase enzyme system by NSAIDs^[4], as depicted in Figure 1.

A modest approach to control ulceration, therefore, is *via* stimulation of gastric mucin synthesis, enhancement of antioxidant levels in the stomach, scavenging of ROS, inhibition of H^+ , K^+ -ATPase and *H. pylori* growth^[7]. Although the antisecretory drugs, such as H^+ , K^+ -ATPase pump inhibitors-omeprazole, lansoprazole; histamine H_2 -receptor blockers-ranitidine, famotidine, are being used to control acid secretion and acid related disorders; however, they are not the drugs of choice since they produce

potential adverse effects on human health^[8].

In light of the above, it is pertinent to study natural products from food/plants as potential anti-ulcer compounds. Due to the lack of side effects compared to synthetic drugs, approximately 60% of the world's population relies entirely on such natural medications. In Indian traditional medicine, several plants have been employed to treat gastrointestinal disorders, including gastric ulcers^[9]. Antiulcer properties have been attributed generally to phenolics^[10,11] and occasionally to polysaccharides^[12-14] of plant extracts.

In this paper we report a pectic polysaccharide from *Decalepis hamiltonii* (Swallow root) containing a sulfonamide group and phenolics as an effective antiulcer compound *in vivo*. We envisage a multi-potent role for this phenolic-polysaccharide in the upregulation of mucin, antioxidant levels, modulation of oxidative status, inhibition of H⁺, K⁺-ATPase activity against swim and ethanol stress-induced ulcers in experimental animal models, in addition to its ability to inhibit *H. pylori*. This paper reveals the potency and multi-step action of phenolic polysaccharide in preventing gastric ulceration.

MATERIALS AND METHODS

Chemicals

Monoclonal anti-gastric mucin from Sigma Chemicals (St. Louis, MO, USA), Ham's F-12 media from HiMedia (Mumbai, India), Alkaline phosphatase conjugated-rabbit anti mouse IgG secondary antibody from GENEI (Bangalore, India). All other reagents were of analytical grade purchased from Qualigens fine chemicals (Mumbai, India).

Plant

Decalepis hamiltonii Wight & Arn. (*Asclepiadaceae*) roots (Batch No. 6, 2005) were procured from a local vendor at Devaraja market, Mysore, India, originally collected from the Gumballi forest range located between 11-13 N and 77-78 E, South-East corner of Mysore district in July 2005 and identified by a taxonomist in the herbarium of Vivekananda Girijana Kalyana Kendra, B.R. Hills, Chamaraja Nagar, Karnataka, India, where a voucher specimen is deposited.

Isolation of pectic polysaccharide from swallow root

Pectic polysaccharide was isolated from defatted powder of swallow root as described previously^[15]. Briefly, 10 g of defatted powder were depleted with proteins, amylose and amylopectins by specific enzymatic (protease, termamylase and glucoamylase) digestions at their optimum reaction conditions and centrifuged. Further, the residue was extracted with 200 mL of 0.25% (w/v) ammonium oxalate solution and filtered; the filtrate was precipitated by ethanol at 4°C. The precipitate was resuspended in 10 mL of water and lyophilized to obtain pectic polysaccharide. Total sugar content was estimated by a Phenol-sulphuric acid method. A total yield of 6% was obtained as carbohydrate and this pectic polysaccharide of swallow root is designated as SRPP. Sugar composition analysis revealed the presence of rhamnose: arabinose: xylose: galactose in the ratio 16:50:02:32, in addition to 141 mg uronic acid/g of SRPP.

Determination of the phenolic content and antioxidant activity of SRPP

Since phenolics are generally found to be associated with polysaccharides, we evaluated the phenolic content in SRPP using a Folin-Ciocalteu reagent as described previously^[16]. Gallic acid was used as a standard for the generation of a calibration curve. Total phenolic content is expressed as Gallic Acid Equivalents (GAE) in mg/g of SRPP.

The reducing power and free radical scavenging activity of SRPP was determined according to the method described previously^[16]. SRPP at 10-100 µg was employed for determining the reducing power and free radical scavenging activity. Capability to scavenge the DPPH radical was calculated using the following equation.

Scavenging effect (%) = (Absorbance of control at 517 nm - Absorbance of sample at 517 nm) / Absorbance of control at 517 nm × 100

Characterization of SRPP by Fourier transform infra-red spectroscopy (FTIR)

Pectic polysaccharides, particularly with sulfur, also have been shown to exhibit antioxidant activity and SRPP was subjected to FTIR study. The samples were prepared in the form of pellets by mixing with dry KBr. Potassium bromide discs containing 1% (w/w) of film material were scanned at 4 mm/s with a resolution of 4/cm over 400-4000/cm, averaging over 128 scans for each type of film and determined the presence of sulphur group.

Inhibition of H⁺, K⁺-ATPase in vitro

Fresh sheep stomach was obtained from a local slaughterhouse at Mysore and an enzyme extract was prepared^[17]. The enzyme extract was incubated with different fractions of swallow root polysaccharide, in a reaction mixture containing 16 mmol/L Tris buffer (pH 6.5). The reaction was initiated by adding substrate (2 mmol/L ATP, 2 mmol/L MgCl₂ and 10 mmol/L KCl) and after 30 min of incubation at 37°C, the reaction was stopped by the addition of an assay mixture containing 4.5% ammonium molybdate and 60% perchloric acid. Inorganic phosphate formed was measured spectrophotometrically at 400 nm. Enzyme activity was calculated as micromoles of Pi released per hour at various doses of SRPP.

Toxicity studies

Toxicity studies were carried out in Albino Wistar rats that were orally fed with SRPP at 1 mg/kg b.w. for 15 d. Analysis showed biochemical changes as described previously^[17].

Assessment of antiulcer potential of SRPP against swim/ethanol stress induced ulcers

Wistar albino rats, weighing about 180-220 g and maintained under standard conditions of temperature, humidity and light, were provided with standard rodent pellet diet (Amruth feeds, Bangalore, India) and water *ad libitum*. The study was approved by the institutional ethical committee, which follows the guidelines of CPCSEA (Committee for the Purpose of Control and Supervision of Experiments on Animals, Reg. No. 49, 1999), Government of India, New Delhi, India.

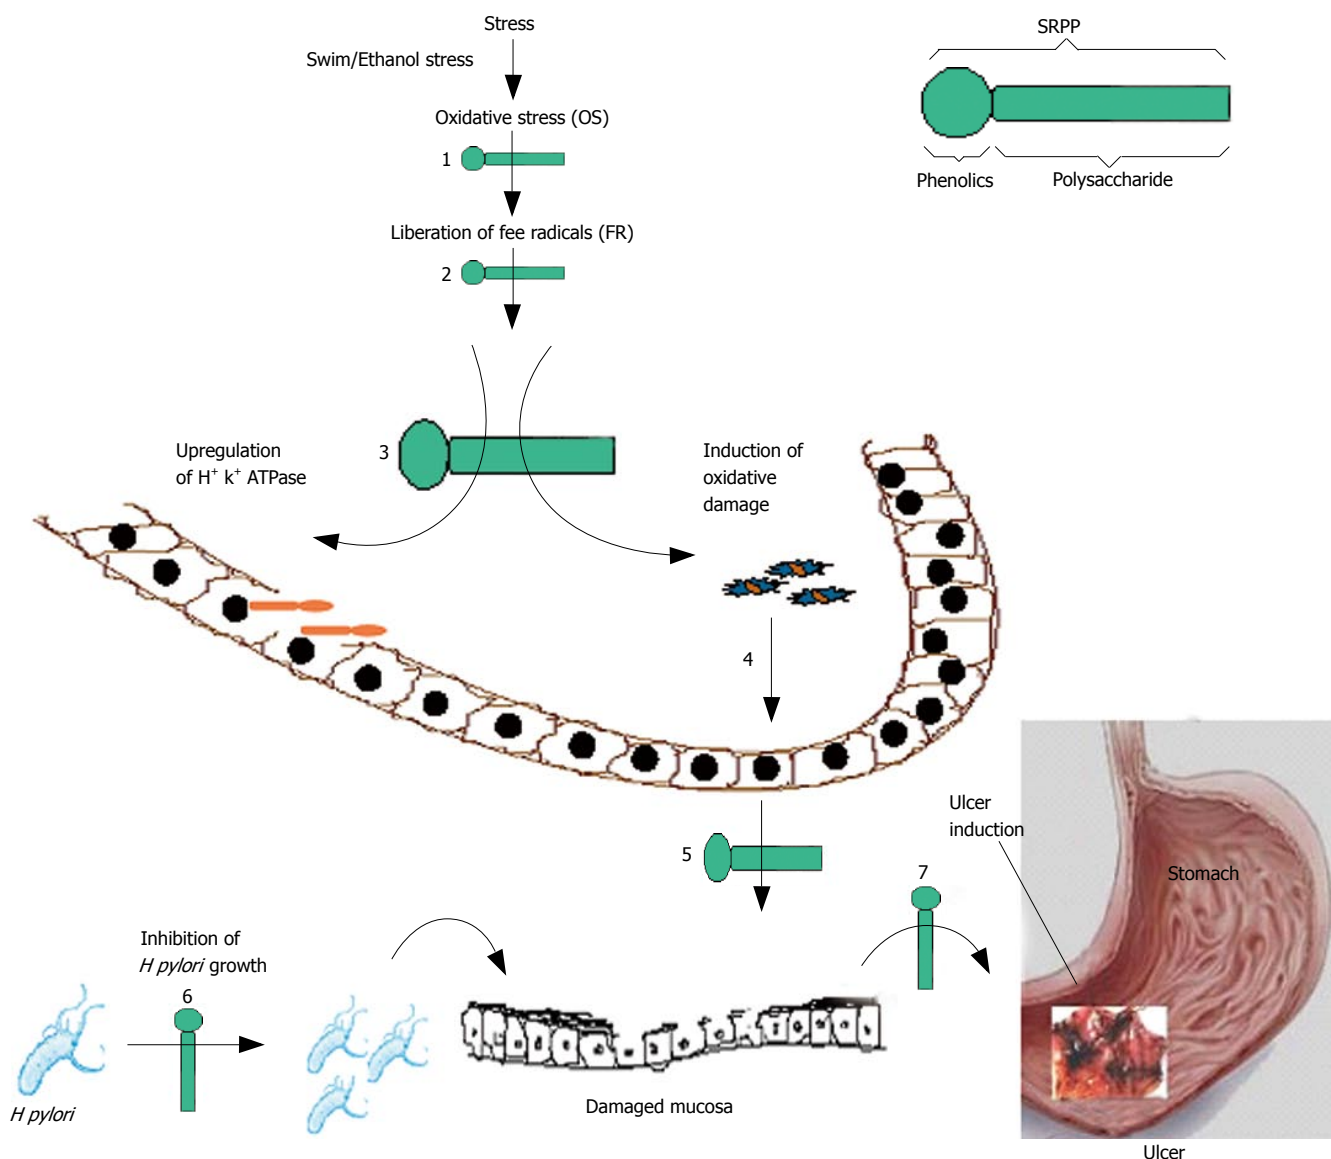

Figure 1 Scheme representing various steps of ulcer pathogenicity and multi-step anti-ulcer action by SRPP (*); (*) and (-) represents phenolic and polysaccharide portions of SRPP respectively. Swim/Ethanol stress leading to OS (1) and liberation of FR (2). FR upregulated H⁺, K⁺-ATPase (3) and induced oxidative damage to mucosa (4) leading to mucosal damage (5). *H. pylori* may invade on to damaged mucosa and together may cause ulcers (7). SRPP has ability to inhibit steps 1-7 including the growth of *H. pylori* in vitro (6).

All the animals were categorized into two sets of five groups with 6 animals in each group ($n = 6$). SRPP and ranitidine at indicated doses were administered orally twice daily for 14 d. At the end of 14 d, animals were fasted for 18 h and then subjected to the ulcer inducing treatment. In the first set, ulcers were induced by forced swim stress per a published protocol^[18], in which rats were briefly subjected to forced swim stress by making them swim in a jar of 30 cm height and 10 cm diameter containing water up to 15 cm height for 3 h. In the second set, ulcers were induced in rats by administering 100% ethanol (5 mL/kg b.w.) for 1 h^[19]. Animals were sacrificed under deep ether anesthesia and stomachs were examined for mucosal integrity and occurrence of ulcers. Lower to higher gradings were assigned to milder to severe symptoms, respectively. The following are descriptions of ulcer scores: 0.5-red coloration, 1.0-spot ulcers, 1.5-hemorrhagic streaks, 2.0-ulcers more than 3 mm and less than 5 mm, 3.0-ulcers more than 5 mm. Mean ulcer scores for each experimental

group were calculated and expressed as the ulcer index (UI)^[20]. Stomach/liver tissues were used for enzyme assays. Serum was collected from the blood of all animals and analyzed for various biochemical parameters.

Preparation of extracts from tissues for biochemical analysis

The stomach and liver tissues were collected, weighed and homogenized in chilled Tris-buffer (10 mmol/L, pH 7.4) at a concentration of 5% (w/v). The homogenates were centrifuged at $1000 \times g$ at 4°C for 20 min using a high speed cooling centrifuge (REMI C 24, Mumbai, India). The clear supernatant was used to analyse biochemical parameters^[21].

Assessment of gastric mucin and H⁺, K⁺-ATPase

Gastric mucin was isolated from the glandular segments of stomach and quantitated employing a monoclonal anti-human gastric mucin antibody (MAb-GM) by ELISA^[5], as well as by Alcian blue dye binding methods^[22]. Histological

Table 1 Toxicity studies with Swallow root pectic polysaccharide ($n = 6$) mean \pm SD

Parameters	Control	SRPP treated
Total protein	348 ^a \pm 32.21	361.81 ^a \pm 28.10
SGOT (U/mg protein)	18.34 ^a \pm 1.55	16.22 ^a \pm 1.34
SGPT (U/mg protein)	21.31 ^a \pm 2.70	23.21 ^a \pm 2.29
ALP (U/mg protein)	35.52 ^a \pm 3.879	33.62 ^a \pm 2.95
TBARS (n moles/mg protein)	0.166 ^a \pm 0.08	0.186 ^a \pm 0.11

SGPT: Serum glutamate pyruvate transaminase; SGOT: Serum glutamate oxaloacetate transaminase; ALP: Alkaline phosphatase; TBARS: Thiobarbituric acid reactive substances. ^a $P < 0.05$ between control and SRPP treated groups.

and immunohistological evaluation was done as described previously^[17]. Equal weight of gastric tissue from animals of each group was homogenized using Tris-HCl buffer pH 7.4. The gastric membrane vesicles enriched in H⁺, K⁺-ATPase were prepared and the activity was assessed as described above.

Assessment of oxidant/antioxidant and antioxidant enzymes

Lipid peroxidation products of serum, stomach and liver homogenates were determined as TBARS and the malondialdehyde (MDA) that formed was quantitated using the molar extinction coefficient of the MDA molecule^[21].

Glutathione (GSH) content was determined as described by Das and Banerjee^[21]. The activity of superoxide dismutase (SOD) was assayed by measuring the reduction in the NBT in the presence of SOD^[23] and catalase (CAT) was assayed by decomposition of H₂O₂ in the presence of catalase at 240 nm^[24]. Glutathione peroxidase (GPx) was estimated based on the degradation of H₂O₂ in the presence of GSH and the decrease in absorbance was read at 340 nm^[25]. SOD and CAT activity was expressed as units per milligram protein per min. The activity of GPx was expressed as nanomoles of NADPH oxidized per min per milligram of protein. The protein content of the homogenate was determined by Lowry's method^[26].

Determination of anti-*Helicobacter pylori* activity of SRPP

H. pylori is a major ulcerogen, and anti-*H. pylori* activity was therefore determined. *H. pylori* was obtained by endoscopic samples of gastric ulcer patients from KCDC (Karnataka Cardio Diagnostic Centre, Mysore, India) and cultured on Ham's F-12 agar medium supplemented with 5% FBS at 37°C for 2-3 d in a microaerophilic condition^[27]. *H. pylori* culture was characterized by specific tests as described by Siddaraju and Shylaja^[16].

Anti-*H. pylori* activity of an aqueous solution of SRPP (200 µg/mL) was determined by a viable colony count method^[28]. 100 µL of SRPP treated *H. pylori* were also processed for scanning electron microscopy (SEM)^[29] and examined by SEM (Model No. LEO 425 VP, Electron microscopy LTD, Cambridge, UK) with an acceleration voltage of 20 KV. Multiple fields of visions were viewed. The MIC value was determined by a conventional broth dilution method^[16]. MIC was defined as the lowest

concentration to restrict the growth to less than 0.05 absorbance units at 625 nm.

Statistical analysis

All values are expressed as mean \pm SE. Significance was calculated with student's *t* test (parametric). When several groups were compared, significance was calculated using an ANOVA. Enzyme estimations were carried out as described and results were tabulated. After calculating means and standard deviations, Dennett's test was performed to obtain the significance between the treated groups and the control groups. A value of $P < 0.05$ was considered to indicate a significant difference.

RESULTS

Toxicity studies

Toxicity studies with aqueous solution of SRPP were carried out in rats for safety evaluation. These studies indicated no lethal effect up to 1 g/kg b.w. when orally fed for 14 d. There were no significant differences in total protein, TBARS levels, SGPT, SGOT and ALP between normal and SRPP treated rats (Table 1), indicating no adverse effect on the major organs. After the above treatment schedules, animals remained as healthy as control animals with normal food and water intake, body weight gain and behavior.

SRPP prevented swim stress/ethanol induced gastric ulcer

Healthy rats showed no lesions in their stomachs (Figure 2A), while rats treated with forced swim stress for 3 h or ethanol stress showed damage in the gastric wall with a hemorrhagic form of lesions and intraluminal bleeding (Figure 2B and C). Rats treated with only SRPP (Figure 2D) also showed no lesions, which is similar to the controls. Oral treatment of SRPP at 100 and 200 mg/kg b.w., as well as Ranitidine at 30 mg/kg b.w., showed protection in a dose dependent manner with no intraluminal bleeding and an insignificant number of gastric lesions (Figure 2E-I). Ranitidine protected both ethanol/swim stress-induced ulcers up to 66%-87% at 30 mg/kg b.w., while SRPP protected up to 80%-85%, respectively, indicating an ulcer preventive effect. Quantitative reduction in the ulcer index (%) in treated rats, compared to either ulcer induced or healthy, is depicted in Figure 3.

SRPP prevents gastric mucosal damage; Alcian blue binding/ELISA/histo-and Immunohistological studies

Gastric wall mucus is damaged during ulcer development and becomes the first target of stress-induced reactive oxygen species. Mucin oxidation or degradation takes place and subsequently loses the protective effect. In the current study, we evaluated the effect of *in vivo* ingestion of SRPP on protection of gastric wall mucus during ulceration induced by swim/ethanol stress. Since Alcian blue binds to carboxylated mucopolysaccharides as well as sulfated and carboxylated glycoproteins, any disruption results in reduction in the dye binding, which can be quantitated. The gastric mucin of stomach tissue was decreased to 17 and 16 mg/g in swim stress/ethanol stress-induced ulcerous rats, respectively, when compared to that of controls (45

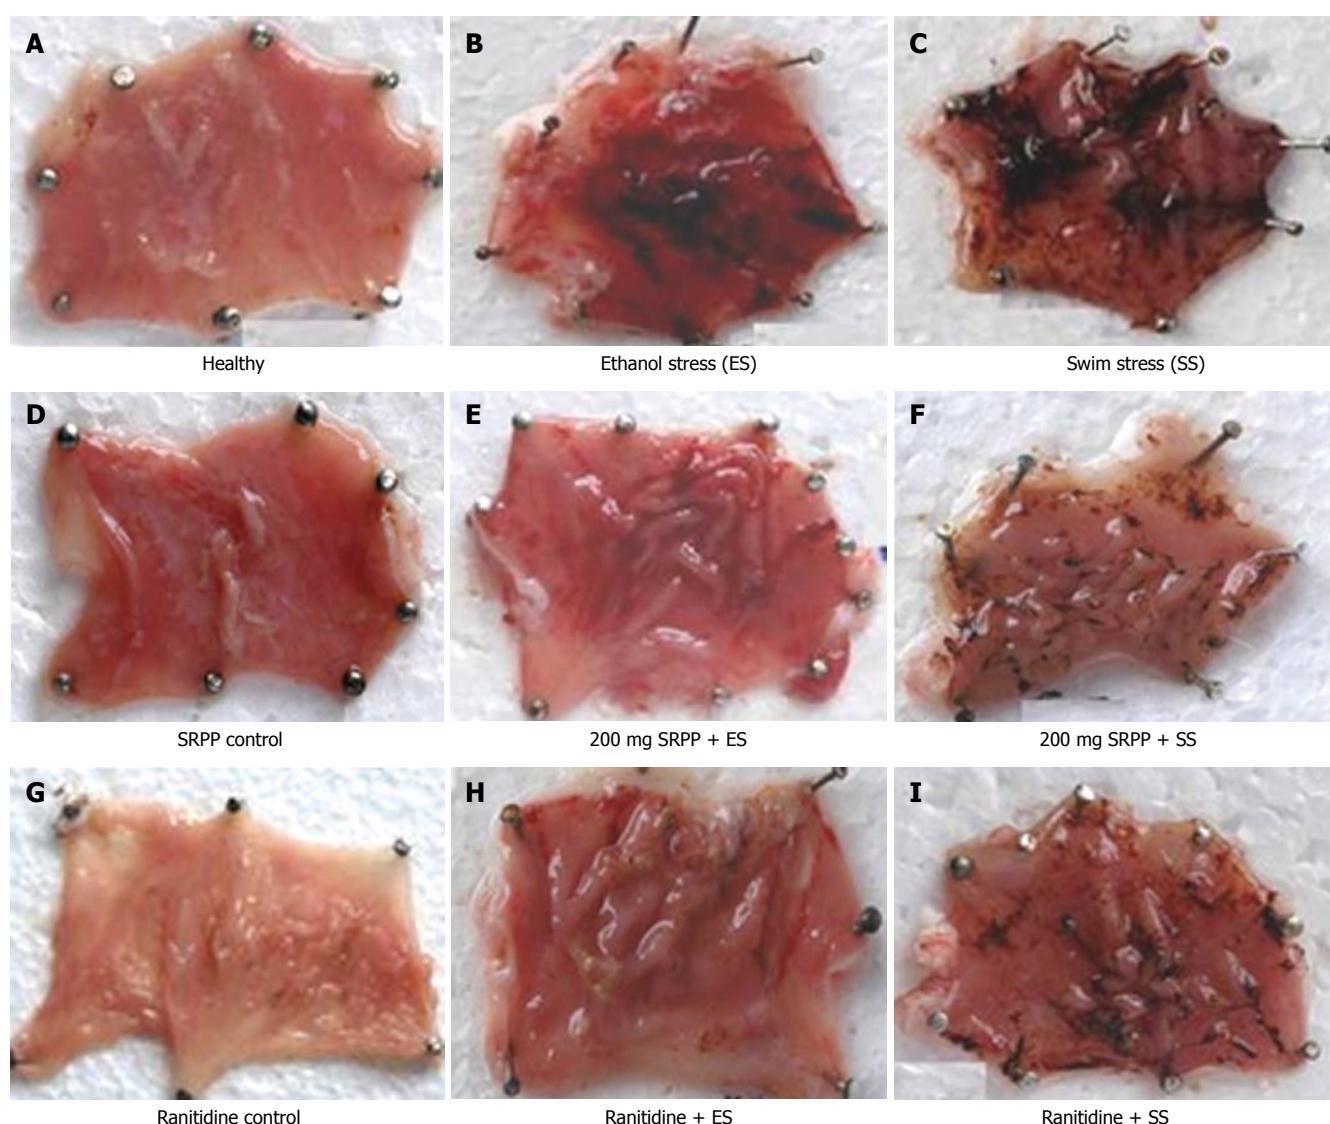

Figure 2 Macroscopic observation of Ulcers in ulcer induced/protected stomachs in swim stress/ethanol stress induced ulcer models; Ulcer was induced in animals by either swim stress (SS) or ethanol stress (ES) in group of pretreated/untreated animals at indicated concentrations. In healthy (A), SRPP control (D), Ranitidine control (G)-no ulcer lesions or damage in the stomach tissue were observed. In ethanol stress (B) and swim stress (C) induced animals ulcers score were very high. SRPP (E and F) and ranitidine (H and I) treated animals showed reduced stomach lesions.

mg/g) (Table 2). Results were substantiated by observing increased gastric mucin content by monoclonal antibody-based immuno histological studies (Figure 4). Hematoxylin and eosin staining of stomach tissue sections in control animals indicated intact structures (Figure 4A). Ulcer induction showed damage in the mucosal epithelium, destruction of regular glandular organization, very high inflammatory exudates, proliferated fibroblasts, infiltration of leucocytes and cellular debris (Figure 4B). SRPP and ranitidine treated rats showed recovery in the mucosal epithelium, regained glandular structure and mucosal regeneration (Figure 4C and D). Immunohistological analysis clearly revealed the intact mucosal epithelium in the control group (Figure 4E) and complete loss or eradication in ulcer-induced tissue sections (Figure 4F). Complete recovery was observed upon treatment with SRPP (Figure 4G) and partial recovery is depicted during ranitidine treatment (Figure 4H).

Evaluation of SRPP potential on oxidant and antioxidant status in ulcerous and treated animals

Tables 3 and 4 indicate antioxidant, antioxidant enzymes and TBARS levels in stomach/liver homogenate and the serum of swim/ethanol stress models. SOD and GPx levels increased in stomach (2 fold) and CAT and GSH decreased (1.8 fold) during stress-induced ulcerous conditions and were normalized upon treatment with SRPP in a dose dependent manner. An approximately 4 fold increase in TBARS levels depicts lipid peroxidation or damage of stomach tissue in ulcerous animals and was recovered up to 80% upon treatment with SRPP. Ranitidine, although showing protection against ulcer, showed no significant improvement in GSH or antioxidant enzyme levels. Similar changes in antioxidant enzymes except catalase was also observed in serum and liver homogenates. A 2 fold increase in TBARS levels was shown in the ulcer condition and, SRPP treatment at 200 mg/kg b.w. showed up to 90% recovery.

Inhibition of *H pylori*

Initially, anti-*H pylori* activity was assayed by a viable colony

Groups of animals (<i>n</i> = 6)	Control	Ulcer induced	SRPP 100 mg/kg b.w.	SRPP 200 mg/kg b.w.	Ranitidine 50 mg/kg b.w.

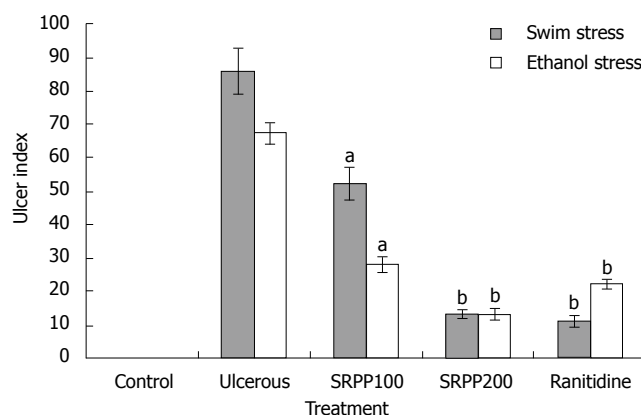

Figure 3 Effect of SRPP on gastric lesions in swim/ethanol stress induced ulcer models; Ulcers were scored as described under the methods and expressed as ulcer index. Maximum ulcer index observed during stress induction was controlled in a concentration dependent manner. Reduction in ulcer index and percent protection is depicted. ^a*P* < 0.05 and ^b*P* < 0.01 between ulcerated and treated groups.

Table 2 Gastric mucin and H⁺, K⁺-ATPase levels in healthy, ulcerated and protected rats (*n* = 6) mean \pm SD

Group, <i>n</i> = 6	Mucin content (mg/g)	H ⁺ , K ⁺ -ATPase (μ moles Pi released/mg/h)
Healthy	45.04 ^d \pm 4.128	0.807 ^d \pm 0.072
Swim stress induced ulcer model		
Swim stress induced	17.78 ^a \pm 2.557	2.209 ^a \pm 0.152
SRPP 100 mg/kg b.w.	27.13 ^b \pm 4.082	1.771 ^b \pm 0.081
SRPP 200 mg/kg b.w.	35.35 ^c \pm 3.221	1.601 ^b \pm 0.091
Ranitidine 50 mg/kg b.w.	31.42 ^{bc} \pm 2.327	1.621 ^b \pm 0.092
Ethanol stress induced ulcer model		
Ethanol stress induced	16.32 ^a \pm 3.821	2.621 ^a \pm 0.211
SRPP 100 mg/kg b.w.	32.13 ^b \pm 3.457	2.123 ^b \pm 0.241
SRPP 200 mg/kg b.w.	39.53 ^{bc} \pm 3.082	1.512 ^c \pm 0.121
Ranitidine 50 mg/kg b.w.	37.13 ^b \pm 1.507	1.485 ^c \pm 0.124

Different letters a to d in the column represents that values are significantly different when compared between ulcer induced with healthy control and SRPP/Ranitidine treated groups. Range was provided by Duncan multiple test at *P* < 0.05. a: Less significant; b: Moderately significant; c: Very significant and d: Most significant.

count method. SRPP showed up to 95% inhibition at a 200 μ g/mL concentration, which is equivalent to that of a susceptible antibiotic amoxicillin at 10 μ g/mL. MIC, determined by a broth dilution method, indicated significant anti-*H. pylori* activity at 55 μ g/mL (*P* = 0.003) (Figure 5A).

SEM observations

Normal *H. pylori* shows uniform rod shaped cells (Figure 5B), whereas the cells treated with SRPP (200 μ g/mL) changed from a helical form to coccoid and became necrotic (showed in arrows in Figure 5C). A similar coccoid form was observed with *H. pylori* treated with amoxicillin (Figure 5D) and this form has been known to result in a loss of infectivity^[30]. A coccoid form with blebs in the bacterial surface,

appearance of vacuoles, granules and an area of low electron density in the cytoplasm (shown in arrow marks) were observed in SRPP treated samples indicating the lysis of *H. pylori*. Substantiating this viable colony test indicates the loss of more than 95% viability upon treatment with SRPP, supporting an antimicrobial nature of SRPP.

Effect of SRPP on H⁺, K⁺-ATPase activity

An approximately 3 fold increase in H⁺, K⁺-ATPase activity in ulcer-induced stomach homogenate was brought to normal levels in a concentration dependent manner by SRPP at 100 and 200 mg/kg b.w. Approximately 58% and 62% (1.5 fold) were reduced at 200 mg/kg b.w. in both ethanol and swim stress-induced ulcer models (Table 2).

To further validate the inhibition of H⁺, K⁺-ATPase enzyme by SRPP, sheep stomach parietal cells were used. Inhibition of H⁺, K⁺-ATPase *in vitro* was examined with different polysaccharide fractions of swallow root including SRPP. Only SRPP inhibited H⁺, K⁺-ATPase activity, with an IC₅₀ of 77 μ g as opposed to that of Lansoprazole (19.3 μ g), whereas other polysaccharide fractions did not show inhibitory activity (Figure 6A).

Characterization of SRPP, an antiulcer compound from swallow root and its relation to antiulcer activity

FTIR spectra obtained using a FTIR spectrometer (Perkin-Elmer 2000 spectrophotometer) equipped with TGS detector with solid samples at a concentration of 1-10 mg provides a signal at 1329 and 1145 cm⁻¹ indicating the presence of sulfonamides where sulfate may be found attached to aminosugars of pectic polysaccharide (Figure 6B).

We evaluated its phenolic content and subsequently its antioxidant property. 0.12 g GAE/g of SRPP yielding 12% of phenolics in SRPP is intriguing since this is the first report of pectic polysaccharides containing such a high level of phenolics. This could be due to the presence

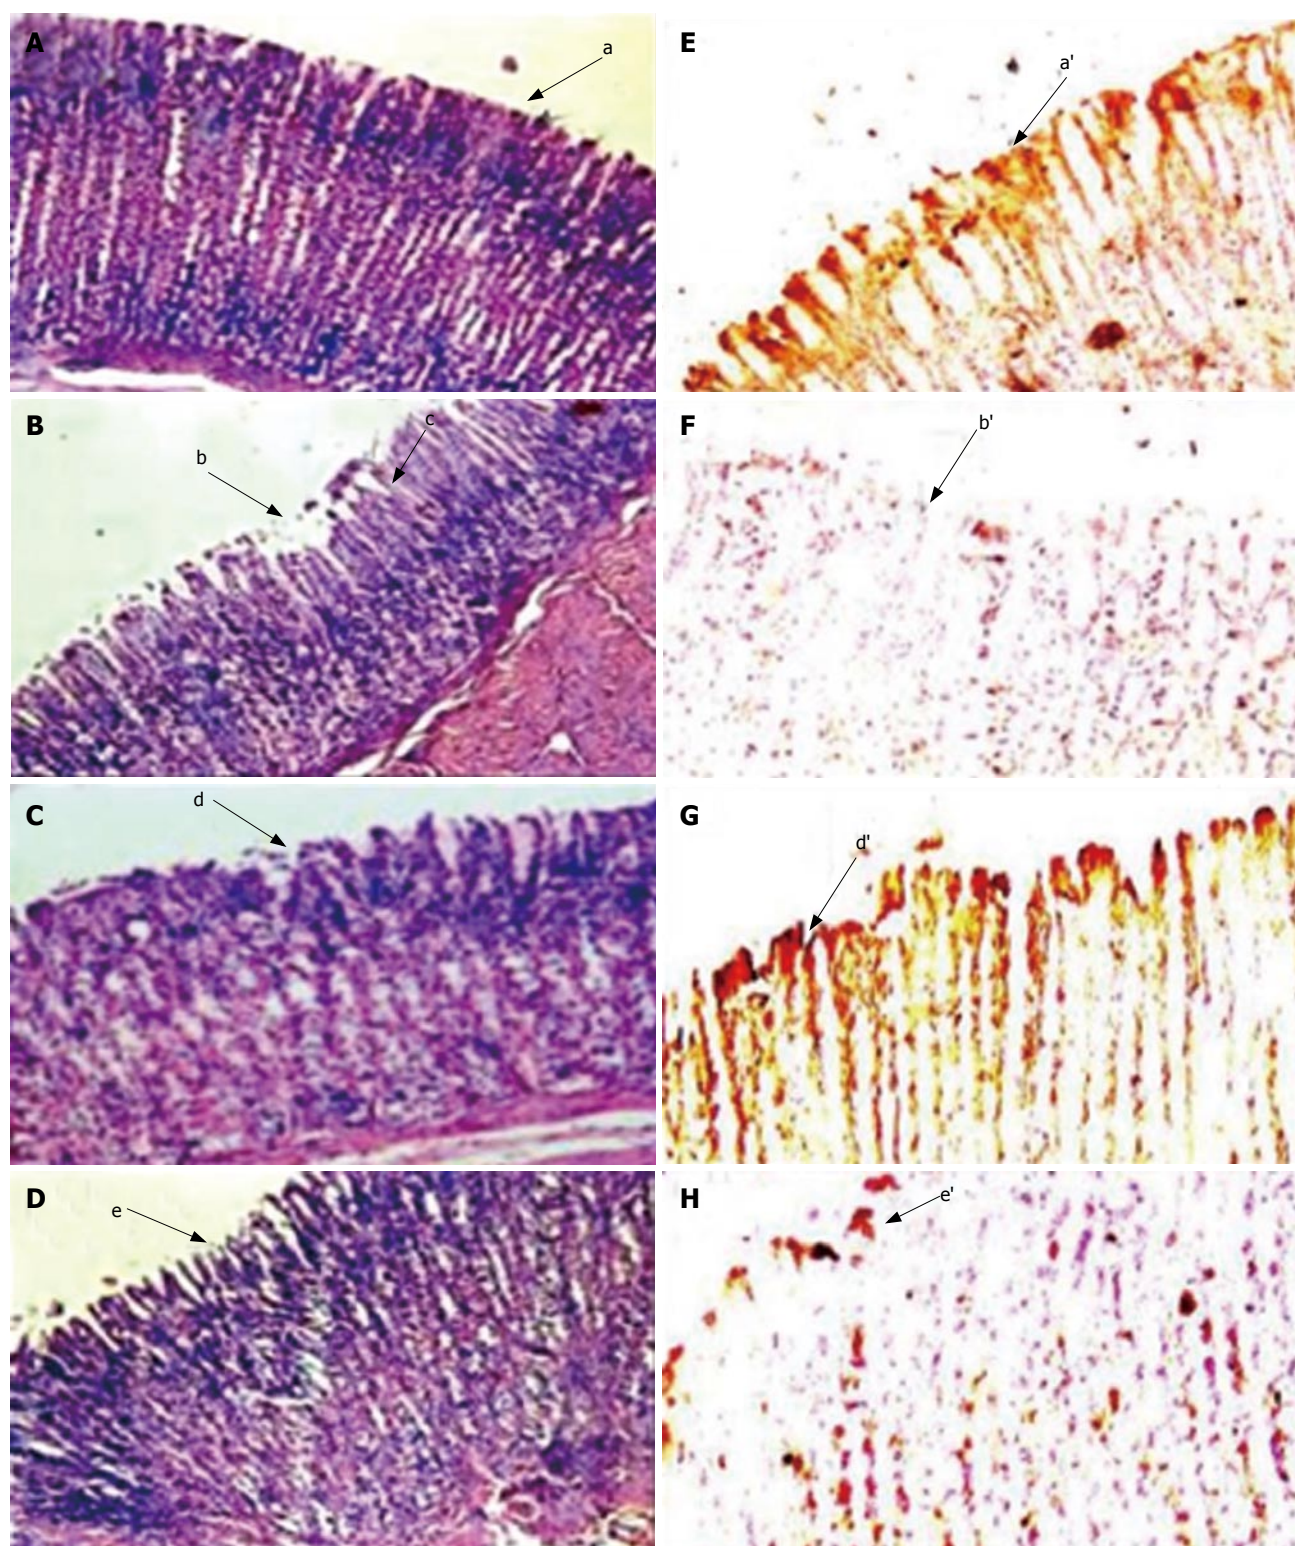

Figure 4 Histopathologic/Immunohistopathologic observation of stomach from ulcer induced/SRPP and Ranitidine treated animals; **A-D** indicates HE staining sections ($\times 40$), while **E-H** reveal anti-gastric mucin stained sections ($\times 40$, and magnified the selected portion in computer photoshop). Control (**A, E**) shows intact mucosal epithelium with organized glandular structure (**a**) and intense brown staining for gastric mucin by antibody (**a'**). Ulcer induction (**B, F**) showed damaged mucosal epithelium (**b**) and disrupted glandular structure (**c**), loss of brown staining (**b'**) in figure **F** indicate the loss of gastric mucin. Complete recovery of mucosal damage (**d** and **d'** of **C, G**) by SRPP and partial recovery by ranitidine (**e** and **e'** of **D, H**) treatments were observed.

of higher levels of phenolics (34 mg/g) in swallow root per se. Presence of higher levels of phenolics was substantiated by expression of potent reducing power ability with 3200 absorbance Units/g of SRPP (Figure 6C). In addition, dose dependent free radical scavenging activity was also found (Figure 6D) with an IC_{50} of 40 $\mu\text{g/mL}$.

DISCUSSION

Recently, phytomedicines from medicinal plants and nutraceuticals from food sources have become attractive sources of new and natural drugs. However, the active

ingredients and mode of action have been rarely established, which is very crucial for understanding the long-term potency of these antiulcer sources. Among the majority of identified sources, flavonoids^[11,31], and occasionally polysaccharides, have frequently been implicated as antiulcer agents^[12-14]. We previously reported on a non-toxic, edible antioxidant source^[17] - *Decalepis hamiltonii*, a significant antiulcerogenic properties *in vitro* and *in vivo*. High levels of antioxidant properties, probably just little less than that found in green tea, with multiple compounds^[32] may play a critical role in inhibiting oxidative induced mucosal damage in ulcers^[33]. In the current paper, we report the antiulcerogenic potential of a combinational

molecule, which is a pectic polysaccharide with bound phenolics from swallow root. In human nutrition, pectic polysaccharides play a key role as low energy foods and break down products have been known to have health beneficial properties.

Gastric ulcers have multiple etiopathogeneses. Stress ulcers are due to both physiological and psychological factors, which affect gastrointestinal defense and increased accumulation of acid due to influx of H^+ into the lumen of the stomach by parietal cell plasma membrane bound H^+ , K^+ -ATPase leading to autodigestion of the gastric mucosa^[34], and generation of free radicals. Ethanol stress, on the other hand, is known to act on the gastric mucin

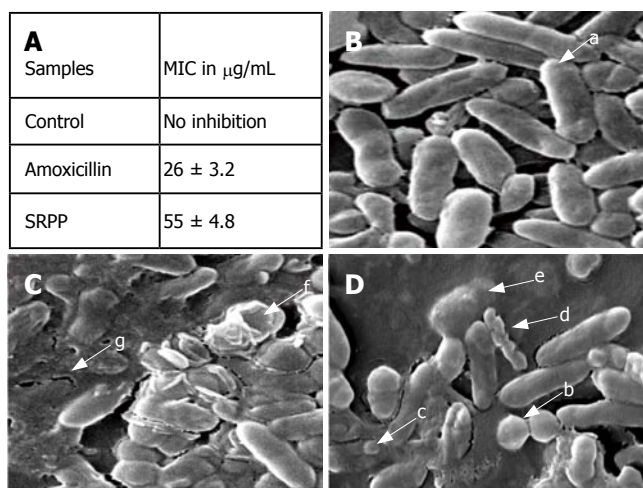

Figure 5 Effect of SRPP on *H. pylori*; Minimum Inhibitory Concentration (MIC) (A) was established by serial dilution technique; B-D indicate the scanning electron microscopic pictures at 15 k magnification of control (B), SRPP (C) and amoxicillin (D) treated *H. pylori*. Untreated control cultures indicate uniform rod shaped (a) *H. pylori* cells. Amoxicillin treatment showed coccoid form (b), blebbing (c), fragmented (d) and lysed (e) cells. SRPP treatment in addition indicates cavity formation (f) with disrupted structures (g).

directly, affecting mucosal defense. Nevertheless, in both cases the causes of severe ulcerations are depicted in the current study in addition to observations from other investigators^[35,1]. Our earlier studies indicated that phenolic antioxidants were efficient in inhibiting upregulated H^+ , K^+ -ATPase and recovering the depleted levels of antioxidant and antioxidant enzymes^[17].

The effect of SRPP on gastric ulcers induced by swim and ethanol stress was investigated in *in vivo* rat models. Oral administration of 100 and 200 mg/kg b.w. reduced gastric lesions. It is evident from our data (Figures 2-4 and Tables 2-4) that swim stress and ethanol stress induced gastrointestinal effects, such as gastric erosions, gastric or duodenal ulcerations, gastrointestinal hemorrhages and perforations. These effects were modulated by the inhibition of upregulated H^+ , K^+ -ATPase, and enhancement of down regulated gastric mucin, antioxidant and antioxidant enzyme levels. Histological studies indicated that characteristic ulcerogenic pathogenicity, with a distinct ulcer margin formed by the adjacent non-necrotic mucosa, the epithelial component, and granulation tissue at the ulcer base, was normalized upon treatment with SRPP. Current data, together with the results of our previous paper^[17], indicate clearly that phenolic antioxidants of SRPP may contribute to H^+ , K^+ -ATPase inhibition, rather than the polysaccharide per se since swallow root antioxidants inhibited H^+ , K^+ -ATPase at 36 $\mu\text{g/mL}$ as apposed to that of SRPP (77 $\mu\text{g/mL}$).

Ethanol induced gastric lesions are thought to arise as a result of direct damage to gastric mucosal cells, resulting in the development of free radicals and hyperoxidation of lipids. Recently, it was discovered that *Solanum nigrum* extract provides significant antioxidant activity as one of the possible gastroprotective mechanisms against ethanol-induced gastric ulceration^[19]. SRPP may also act similarly in reducing ulcerations in stomach since it showed potent antioxidant properties.

In addition, SRPP is a safer source since toxicity studies indicated no lethal effect up to an oral dose of 1 g/kg b.w. for 14 d. To understand the potential role of SRPP in gastric mucosal protection, it is important to know that mucin is an insoluble adherent mucus gel, which is quite stable and has significant buffering capacity for neutralization of luminal acid in the presence of bicarbonate. SRPP showed 2 fold upregulation of gastric mucin as revealed by immunohistological/biochemical and ELISA methods, indicating the stabilization of the mucosal layer.

Further, SRPP possessed H^+ , K^+ -ATPase inhibitory activity, although not as potent as that of phenolic fractions. Phenolics present in SRPP together with those reported in the literature revealed that phenolic antioxidants are potent H^+ , K^+ -ATPase blockers^[11]. The significant levels of phenolics present in SRPP may also contribute towards inhibition of H^+ , K^+ -ATPase activity, which plays a tremendous role in reducing an acidic condition in the gastric lumen.

Results are intriguing that SRPP also showed potential anti-*H. pylori* activity. The results are in accordance with the observation made by Lee *et al.*^[36], where inhibition of *H. pylori* growth by pectic polysaccharide was reported. However the mechanism still needs to be established. Several mechanisms may be proposed for potential inhibition of *H. pylori* by SRPP. SRPP phenolics may inhibit microbial activity as phenolics were thought to exert their antimicrobial effect by causing (1) hyper acidification at the plasma membrane interface of the micro organism, or (2) intracellular acidification, resulting in the disruption of H^+ , K^+ -ATPase required for ATP synthesis of microbes, or (3) may be related to inactivation of cellular enzymes causing membrane permeability changes^[10,37]. The rate of inactivation of microbial cellular enzymes is dependent on the rate of penetration of phenolic antioxidants into the cell. In the case of *H. pylori*, phenolics may be inactivating the urease enzyme, which is specifically expressed at its surface to neutralize hyperacidification to survive in the gastric environment of the stomach^[38]. It is thus clear that SRPP is creating a cavity in the organism (Figure 5C) with the loss of cellular contact resulting in loss of viability of *H. pylori*.

There are several schools of thought that indicate the ulcer healing component must be proliferative, amplify cell migration, and enhance angiogenesis in order to enhance re-epithelialization in the ulcer healing process. However, antiulcer compounds with proliferative ability, and the ability to enhance angiogenesis, may be carcinogenic also. This statement is also substantiated by observation of induction of cancer upon the usage of antiulcer drugs on a long-term basis^[8]. In this context, SRPP, although found to be antiulcerogenic, has been shown to be anticancerous (Unpublished observation, 2006). Hence the treatment of ulcer by SRPP even for longer periods of time may not pose side effects.

Generally antioxidants have been known to be antimicrobial by binding to the microbial membrane leading to disruption^[39]. SRPP, by virtue of phenolics, may be antimicrobial. In addition, SRPP may also participate in enhancement of gastric mucin. The enhancement of gastric mucin contents, as measured by ELISA and Alcian blue binding, may suggest that enhancement is most probably

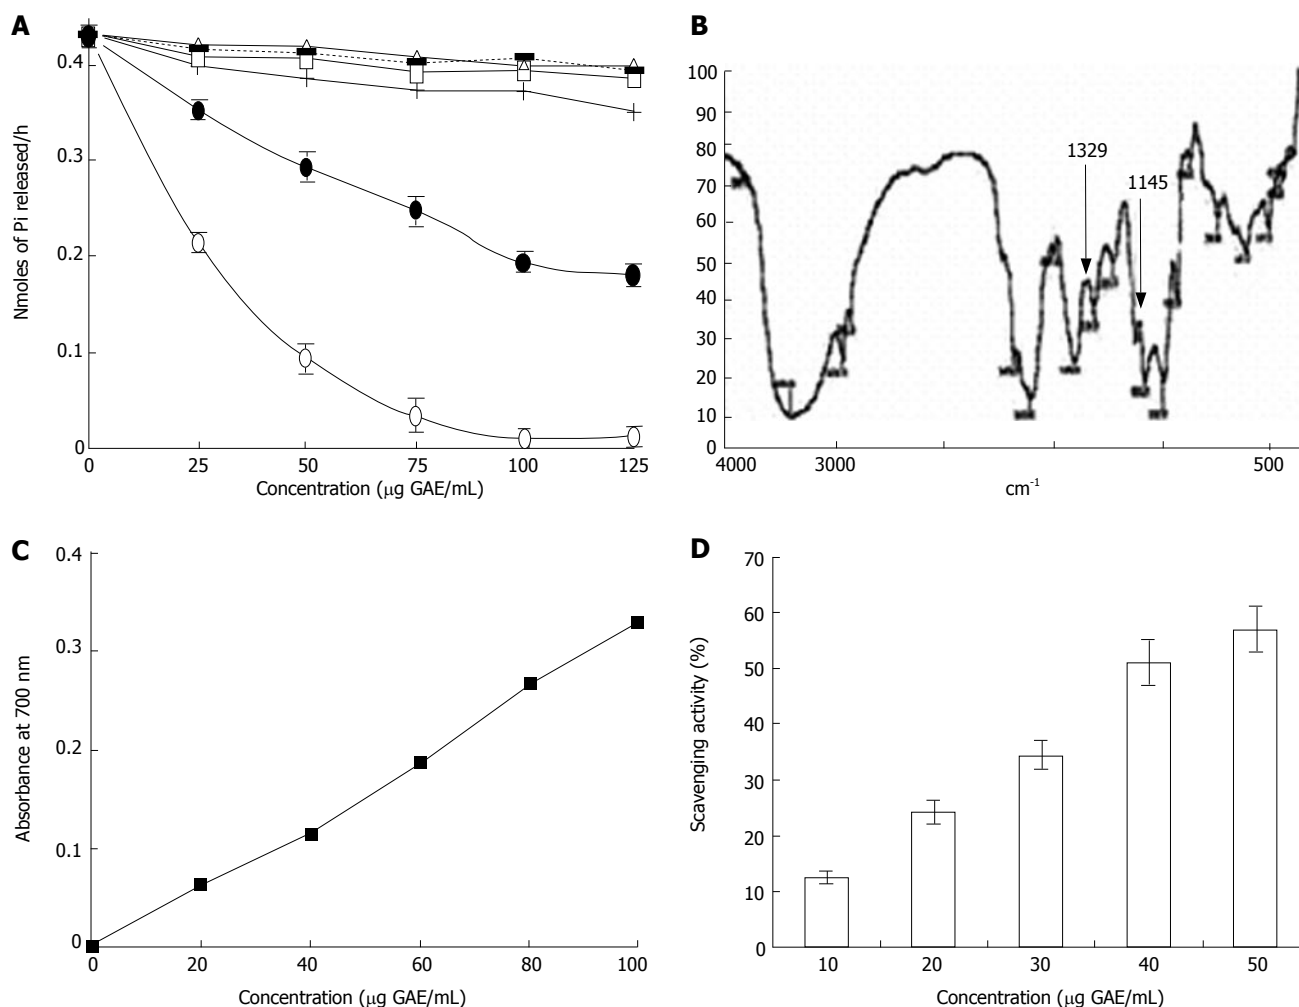

Figure 6 H⁺, K⁺-ATPase (A), Fourier Transform Infra-Red Spectroscopy (B), Reducing power (C) and Free radical scavenging activity (D) of SRPP. A: inhibition of H⁺, K⁺-ATPase only by SRPP (●) and not by other polysaccharides of Swallow root; SR water soluble polysaccharide (◆), SR Hemicellulose A (◊), Hemicellulose B (◻), SR alkali insoluble residue (○) and inhibition by lansoprazole (◐) a known blocker is also depicted in the figure; B: arrow at 1329 and 1145 cm⁻¹ indicate the presence of sulfonamide group in FTIR spectrum. Dose dependent antioxidant activity evaluated as reducing power ability (C) and free radical scavenging ability (D) indicates potential antioxidant activity by phenolics of SRPP.

due to prevention/protection of mucosal injury during ulceration rather than direct increase in synthesis. This is supported by no upregulation of gastric mucin in SRPP controls where animals were fed with SRPP without inducing ulcers. However, regulated synthesis might occur, which may be evaluated by tracer techniques. Antioxidant potency may also be contributed by both phenolics and sulfonamide groups containing polysaccharides^[40,41]. Further, it is also possible that SRPP, by virtue of its anionic nature, may bind effectively to positively charged amino acid residues of gastric mucin as well as sucralfate and other polysaccharides^[42]. This binding may avoid gastric mucin damage and subsequent ulceration. SRPP thus can be a safe and promising multi-step ulcer blocker (Figure 1).

ACKNOWLEDGMENTS

The authors thank Dr V Prakash, Director, Central Food Technological Research Institute, Mysore for his keen interest in the work and encouragement. Authors are thankful to Karnataka Cardio Diagnostic Centre; Mysore for providing *H. pylori*. One of the authors Dr. Shylaja M

Dharmesh acknowledges Department of Biotechnology, New Delhi, India for financial assistance. Mr. Srikanta BM and Mr. Siddaraju MN thank Council of Scientific and Industrial Research, India for Senior Research fellowships.

causative factors being unavoidable such as stress, use of non-steroidal anti-inflammatory drugs; and the side effects of available antiulcer drugs; alternatives that are safer, but effective in ulcer prevention must be envisaged.

Research frontiers

Frontiers of research on development of antiulcer drugs must emphasize on (a) detection and diagnosis of *H. pylori*-a major ulcerogen; (b) identification of ulcerogens and antiulcerogens from diet since some components of food are ulcerogens; (c) antiulcer drugs with less or no side effects, so that it can be used by subjects who are using NSAIDs and also alcohol.

Innovations and breakthroughs

Herbal/dietary sources are the challenging alternatives for potential ulcer management. Since herbal medicines include extracts from either edible or non-edible source, side effect has been a threat. Dietary sources are therefore

optional. We report a novel potent multi-step ulcer blocker which inhibits acid secretion/growth and invasion of *H. pylori* and enhances mucosal defense.

Applications

The antiulcer component identified is inexpensive, effective and nontoxic; hence can be directly applied to human health. Single compound with multi-potency implies a potential reduction in the drug load during ulcer treatment.

Terminology

Ulcer, H⁺, K⁺-ATPase, pectic polysaccharide, *H. pylori*, antioxidant, gastric mucin, mucosal injury, non-steroidal anti-inflammatory drugs.

Peer review

This is a nicely done description of the effects of SRPP. Through *in vivo* studies, the authors concluded that SRPP with defined sugar composition and phenolics exhibited multi-potent free radical scavenging, antioxidant, anti-*H. pylori*, inhibition of H⁺, K⁺-ATPase and gastric mucosal protective activities.

fibrotic GI carcinoids (< 15 ng/mL).

CONCLUSION: SI carcinoid tumor fibrosis is a CTGF/TGF β 1-mediated stellate cell-driven fibrotic response. The delineation of the biology of fibrosis will facilitate diagnosis and enable development of agents to obviate its local and systemic complications.

Abstract

AIM: To investigate the role of small intestinal carcinoid tumor-derived fibrotic mediators, TGF β 1 and CTGF, in the mediation of fibrosis *via* activation of an "intestinal" stellate cell.

METHODS: GI carcinoid tumors were collected for Q RT-PCR analysis of CTGF and TGF β 1. Markers of stellate cell desmoplasia were identified in peritoneal fibrosis by immunohistochemistry and stellate cells cultured from fresh resected fibrotic tissue. CTGF and TGF β 1 were evaluated using quantitative tissue array profiling (AQUA analysis) in a GI carcinoid tissue microarray (TMA) with immunostaining and correlated with clinical and histologically documented fibrosis. Serum CTGF was analyzed using a sandwich ELISA assay.

RESULTS: Message levels of both CTGF and TGF β 1 in SI carcinoid tumors were significantly increased (> 2-fold, $P < 0.05$) versus normal mucosa and gastric (non-fibrotic) carcinoids. Activated stellate cells and markers of stellate cell-mediated fibrosis (vimentin, desmin) were identified in histological fibrosis. An intestinal stellate cell was immunocytochemically and biochemically characterized and its TGF β 1 (10-7M) initiated CTGF transcription response (> 3-fold, $P < 0.05$) demonstrated. In SI carcinoid tumor patients with documented fibrosis, TMA analysis demonstrated higher CTGF immunostaining (AQUA Score: 92 ± 8 ; $P < 0.05$), as well as elevated TGF β 1 (90.6 ± 4.4 , $P < 0.05$). Plasma CTGF (normal 12.5 ± 2.6 ng/mL) was increased in SI carcinoid tumor patients (31 ± 10 ng/mL, $P < 0.05$) compared to non-

INTRODUCTION

Carcinoid (neuroendocrine) tumors are enigmatic, generally slow growing malignancies that occur most frequently (67%) in the GI tract^[1]. They are not rare lesions, arising in 1.68 of every 100 000 people^[1]. The commonest gut tumor is the SI carcinoid tumor^[1,2], which is derived from neuroendocrine enterochromaffin (EC) cells. SI carcinoid tumors are usually identified based on their characteristic paroxysmal symptomatology of flushing, sweating and diarrhea. They are often, however, detected at surgery for unexplained bowel obstruction^[3], as a consequence of the fibrosis that they engender^[4]. The etiology of this desmoplastic response is unknown but is a consequence of conversion of the normally filmy and flexible mesentery into a contracted fibrous adhesive mass with bands and even retroperitoneal desmoplasia^[5,6]. These events are due both to tumor invasion and the ability of secretory products of the EC cell to initiate fibrosis by activating local cells to produce a desmoplastic response^[7]. SI carcinoid tumor patients also develop distant (cardiac) fibrosis suggesting that the bioactive agents involved in the process have both a paracrine and a systemic effect^[6]. In contrast, neither gastric carcinoids (derived from the neuroendocrine EC-like (ECL) cell) nor pulmonary carcinoids are associated with extensive local or systemic desmoplastic responses^[8].

The mechanism whereby such fibrosis occurs is unknown although serotonin has previously been suggested as a mediator^[6]. TGF β 1 and CTGF are well-characterized fibrotic factors^[9-12]. TGF β 1 is a profibrotic mediator that

induces CTGF expression^[10]. Together, these factors stimulate over-production of collagen synthesis^[13,14]. The target cells of TGFβ1 and CTGF are activated myofibroblasts, also known as stellate cells^[15,16]. In the pancreas, TGFβ1 activates pancreatic stellate cells (PSCs) in both experimental and human pancreatic fibrosis; these cells are the main cellular source of collagen in chronic pancreatitis^[17-19]. SI neuroendocrine tumors express TGFβ1 and its receptors, while stromal cellular elements around tumor nests express the TGFβ receptor^[20]. This suggests a mechanism by which tumor cells can interact with and alter the character of the surrounding stroma.

We hypothesized that tumor TGFβ1 and CTGF produced by EC cells is involved in the mechanism of SI carcinoid tumor fibrosis via activation of an “intestinal” stellate cell. The aims of this study were to: (1) quantify CTGF and TGFβ1 message in carcinoid tumor tissue; (2) examine protein expression levels of CTGF and TGFβ1 and matrix proteins using immunohistochemistry in SI carcinoid tumors and intestinal fibrosis; (3) isolate and characterize the “intestinal” stellate cell; (4) examine the effects of TGFβ1 on this cell type; (5) quantitatively analyze CTGF and TGFβ1 protein levels on a GI carcinoid tissue microarray by AQUA analysis; and 6) determine whether serum CTGF discriminated SI carcinoid tumor patients with fibrosis from other non-fibrotic GI carcinoids.

MATERIALS AND METHODS

These studies were approved by the Human Investigations Committee at the Yale University School of Medicine.

Tissue specimens

Tissue for molecular analysis: Tumor tissue from ten GI carcinoid patients (M:F = 6:4; median age [range] = 60 years [40-78]) diagnosed with either SI EC cell carcinoid tumors (*n* = 5) or gastric ECL cell carcinoids (*n* = 5) were collected for this study (Table 1). None of the patients had received therapy (surgery or somatostatin analogues) prior to tissue procurement. Paired normal tissue samples were also obtained from adjacent, macroscopically normal, non-tumor mucosa in nine cases from these patients.

Tissue for cell culture analysis: Tumor tissue and mesenteric fibrotic tissue was obtained from a patient with a fibrotic SI carcinoid tumor (male, 43 years; sample #6) operated on at Yale University (by IMM). This patient had not received medical therapy (somatostatin analogues) prior to surgery and was a de novo case of SI fibrosis.

GI Carcinoid TMA: Formalin-fixed paraffin-embedded tissue blocks containing GI carcinoids (stomach: *n* = 7; and SI: *n* = 36) diagnosed between 1965 and 2001 at the Yale University School of Medicine Department of Pathology were retrieved. Follow-up information was available (median follow-up: 110 mo, range: 24-456 mo) for all patients. The TMA consisted of primary GI carcinoids, matched normal mucosa and peritoneal fibrotic material and was represented by 2 cores/case. Complete clinical details including fibrosis were known for all patients.

¹Normal tissue available, ²Age at time of procedure, ³Identified at surgery;

⁴Used to isolate and culture intestinal stellate cell. H: Hispanic; W: White; G: Gastric ECL carcinoid; SI: SI EC cell carcinoid tumor.

Clinically significant fibrosis was determined at surgery, and all samples were examined by a pathologist (RLC) to histologically confirm fibrosis.

Serum: Twenty-nine subjects (median age [range] = 42 years [20-83]; M:F = 17:12) attending the Neuroendocrine Referral, Oncology and Surgery outpatient clinics at Yale University School of Medicine were recruited for serum analysis. These included 29 patients with GI carcinoids: SI EC cell carcinoid tumors (*n* = 16), gastric ECL cell carcinoids (*n* = 7), and six other GI carcinoids [rectal: *n* = 2, parotid: *n* = 1, appendiceal: *n* = 2, duodenal: *n* = 1]. Serum samples from ten age-, sex-matched control subjects were also collected.

Tissue techniques

Quantitative RT-PCR: Total RNA was isolated from frozen carcinoid tumor tissue (*n* = 10) and normal mucosa (*n* = 9) with TRIzol reagent (Invitrogen, Carlsbad, CA) following the manufacturer's guidelines. RNA was dissolved in DEPC water, measured spectrophotometrically and an aliquot analyzed on a denaturing gel using electrophoresis to check the quality of RNA isolated.

CTGF and TGFβ1 message were quantitatively measured in the ten tumor and nine control samples as described^[21,22]. Briefly, Q RT-PCR was performed using the ABI 7900 Sequence Detection System. Total RNA from each sample was subjected to reverse transcription using the High Capacity cDNA Archive Kit (Applied Biosystems, Foster City, CA). 2 μg of total RNA in 50 μL of water was mixed with 50 μL of 2X RT mix containing Reverse Transcription Buffer, dNTPs, random primers and Multiscribe Reverse Transcriptase. RT reaction was carried out in a thermal cycler for 10 min at 25°C followed by 120 min at 37°C. Real time PCR analysis was performed in triplicate^[21,22]. cDNA in 7.2 μL of water was mixed with 0.8 μL of 20 × Assays-on-Demand primer (CTGF = Hs00170014, TGFβ1 = Hs00171257, GAPDH = Hs99999905) and probe mix, 8 μL of 2 × TaqMan Universal Master mix in a 384 well optical reaction plate. The following PCR conditions were used: 50°C for 2 min, then 95°C for 10 min, followed by 40 cycles at 95°C/0.15

min and 60°C/1 min. A standard curve was generated for each gene using cDNA obtained by pooling equal amounts from each sample ($n = 19$). The expression level of target genes was normalized to internal GAPDH. Data was analyzed using Microsoft Excel and calculated using the relative standard curve method (ABI, User Bulletin #2).

Immunohistochemistry: Serial sections (5 μm) encompassing SI carcinoid tumors or fibrotic tissues were deparaffinized in xylene and rehydrated in graded alcohols. For antigen retrieval purposes, sections were immersed in citrate buffer (10 mM sodium citrate, pH 6.0), and subjected to 1×10 min high temperature-high pressure treatment followed by treatment with 0.3% H_2O_2 in methanol for 30 min at 37°C to inactivate endogenous peroxidase. In some studies, sections were incubated with goat antiserum to CTGF (1:250) or TGF β 1 (1:1000) (both from Santa Cruz Biotechnology, Santa Cruz, CA) diluted in Tris-buffered saline containing BSA and a monoclonal antibody against CgA (0.5 $\mu\text{g}/\text{mL}$) or serotonin (2 $\mu\text{g}/\text{mL}$) (both from DAKO, Carpinteria CA) for 24 hr at 4°C and then with Alexa 488-labeled anti-mouse IgG (1:100 dilution) for 1 hr at RT. Donkey anti-goat antibody conjugated to a horseradish peroxidase-decorated dextran polymer backbone (Envision; DAKO Corp, Carpinteria, CA) was used as a secondary reagent. HRP-amplification was performed. CTGF or TGF β 1 was visualized with a fluorescent chromogen (Cy-5-tyramide; NEN Life Science Products, Boston, MA). Dual-positive cells (CTGF + serotonin or CTGF + CgA) were counted in a minimum of 5-well orientated sections and expressed as a percentage. In other studies, fibrotic areas from the peritoneum of patients with SI carcinoid tumors were stained with mouse anti- α -smooth muscle actin (1:1000) or desmin (1:1000, both DAKO), goat anti-vimentin (1:1000), collagen III (1:1000) or CTGF (1:250). Stromal (myofibroblast) cells were separable from tumor cells that were identified by the use of a fluorescently tagged anticytokeratin antibody cocktail (AE1/AE3; DAKO Corp). Nuclei were visualized by 4', 6-diamidino-2-phenylindole (DAPI 10 mg/mL). Localization of expression of products was used to determine whether stromal (non-cytokeratin staining) or tumor cells expressed these products.

Intestinal stellate cell culture and analysis: Stellate cells were isolated using a modification of the method by Bachem *et al*^[15]. Briefly, cells were isolated from the fibrotic tumor specimen (hand dissected, digested in collagenase (0.25 mg/mL)/DNase (100 U/mL) solution for 60 min at 37°C under constant aeration) and were cultured on 10 cm^2 uncoated culture wells in 10% fetal calf serum in a 1:1 (vol/vol) mixture of DMEM and Ham's F12 medium supplemented with 2% L-glutamine, 100 IU/mL penicillin, 100 $\mu\text{g}/\text{mL}$ streptomycin, and 1% amphotericin. Twenty-four hours after seeding, the culture medium was changed and the myofibroblasts remained attached to the plastic. After reaching confluence, cells were subcultured by trypsinization using a 0.025% trypsin solution containing 0.01% EDTA in PBS. For immunofluorescence microscopy, cells were seeded on 1 cm^2 glass coverslips in six-well (10 cm^2/well ; 2 mL medium) plates (2-3 glass coverslips per well). Phase-contrast microscopy was used

to identify the translucent fat droplets in the cytoplasm and stellate-like morphology that typifies stellate cells^[15]. These studies were undertaken within the first 3-d as culturing cells results in a transdifferentiation from a vitamin A-storing phenotype to a myofibroblastic phenotype^[15]. For immunocytological characterization, cells cultured on uncoated glass coverslips were fixed for 30 min in -20°C acetone and air-dried. Coverslips were preincubated for 15 min in TBS (pH 7.4) with 3% bovine serum albumin and 0.3% hydrogen peroxide. Incubations with the primary antibody (mouse monoclonal: α -smooth muscle actin 1:1000) was performed at room temperature in a humidified chamber for 1 h. Non-specific staining was controlled by omitting the primary antibody and including mouse, non-immune serum at the same dilution as used for the specific primary antibody. After rinsing (three times for 5 min with TBS/Tween-0.5%), the second antibody (HRP goat anti-mouse, diluted 1:100) was added and incubated for 1 h at room temperature. Cy5-labelled tyramide (TSA; NEN Life Science Products, Boston, MA) was used with DAPI (10 mg/mL) to stain nuclei and cells observed with a fluorescence microscope. For RNA studies, cultured cells were stimulated with TGF β 1 (10^{-7} M) for 24 h. Thereafter, RNA was isolated and Q RT-PCR performed as described above to quantitatively measure TGF β 1-stimulated CTGF message.

AQUA Analysis of CTGF and TGF β 1 in the carcinoid TMA: Tissue microarray slides were stained as described^[21,23]. Antigen retrieval and immunostaining for CTGF, TGF β 1 (1:1000, Santa Cruz Biotechnology, Santa Cruz, CA), cytokeratin and nuclei were as above. Protein expression (CTGF or TGF β 1) was determined using an automated tissue microarray reader. Automated image acquisition and analysis using AQUA has been described previously^[21,23]. In brief, monochromatic, high-resolution (1024×1024 pixel; 0.5- μm) images were obtained of each histospot. Areas of tumor separate from stromal elements were distinguished by creating a mask from the cytokeratin signal. Coalescence of cytokeratin at the cell surface localized the cell membranes, and DAPI was used to identify nuclei. The Cy-5 signal from the membrane area of tumor cells was scored on a scale of 0-255 and expressed as signal intensity divided by the membrane area. Histospots containing < 10% tumor, as assessed by mask area (automated), were excluded from further analysis. Previous studies have demonstrated that the staining from a single histospot provides a sufficiently representative sample for analysis^[24].

Serum techniques

CTGF serum ELISA: Serum CTGF-W (whole molecule) and CTGF-N (N-terminal fragment) were assayed by two separate sandwich enzyme-linked immunosorbent assays (ELISA). The CTGF-W ELISA uses a capture mAb reactive to the amino terminus of CTGF, and detects the bound CTGF-W with an alkaline phosphatase labeled mAb reactive to the carboxyl-terminal region of CTGF. A second ELISA uses two non-cross blocking monoclonal antibodies reacting to distinct NH₂-terminal epitopes of CTGF. This assay detected both CTGF-W and CTGF N fragment, so-called CTGF N + W, as described previ-

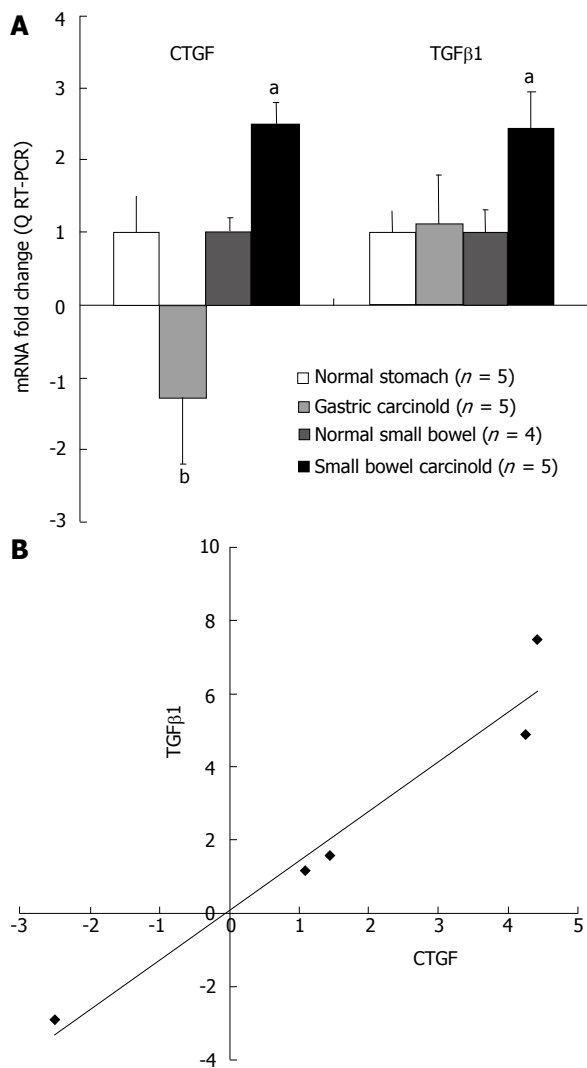

Figure 1 A: Message levels of both CTGF and TGFβ1 determined by Q RT-PCR. Levels were corrected against expression of the housekeeping gene, GAPDH, compared to similarly corrected gene levels in normal mucosa, and represented as fold increase over normal (1.0). TGFβ1 was significantly over-expressed (about 2.5-fold) in SI carcinoid tumor samples compared to normal mucosa ($^aP < 0.05$) but not the gastric carcinoids. CTGF was significantly over-expressed (about 2.5-fold) in SI carcinoid tumor samples compared to normal mucosa ($^bP < 0.05$) while gastric carcinoids had significantly decreased CTGF compared to SI carcinoid tumors ($^bP < 0.01$). Mean \pm SE; B: Correlation analysis of QRT-PCR results in SI EC cell carcinoid tumors. There was a good correlation between CTGF and TGFβ1 transcript levels in tumor samples ($R^2 = 0.9445$, $P < 0.01$, $n = 5$).

ously^[25]. CTGF-N is a value calculated by subtracting CTGF-W from the CTGF N + W level measured by the second assay. Standards for both assays were made from purified full-length CTGF and expressed in nanograms per milliliter. The intra- and interassay coefficient of variation was 5 and 15%, respectively, for both ELISA tests. Data on CTGF-W is presented in this study.

Statistical analysis

Results are expressed as mean \pm SE; n indicates the number of patients in each study group. Statistical significance was calculated by the Student's test for unpaired values or non-parametric statistics as appropriate. On the TMA, the unpaired 2-tailed Student's t -test was used to identify statistically significant differences in fibrotic protein expression

between different patient groups (patients with clinical evidence of fibrosis versus non-fibrosis, fibrosis versus gastric carcinoid).

RESULTS

Quantitative RT-PCR

Q RT-PCR analysis was undertaken using Assays on Demand (Applied Biosystems) on the RNA isolated from SI EC cell carcinoid tumors (fibrosis associated) ($n = 5$); gastric ECL cell tumors (little fibrosis) ($n = 5$); normal SI mucosal samples ($n = 4$) and normal gastric mucosa ($n = 5$) to quantitatively measure the levels of CTGF and TGFβ1 mRNA expression in these two different tumor types. Transcript levels of both CTGF and TGFβ1 were significantly elevated in the five SI carcinoid tumor samples ($P < 0.05$ vs normal mucosa) (Figure 1A). In contrast, TGFβ1 message was not different (+ 1.13-fold) in gastric carcinoid tumor samples compared to normal, and message levels of CTGF were significantly decreased (-1.3-fold; $P < 0.01$) compared to SI carcinoid tumors (Figure 1A). There was a good correlation ($R^2 = 0.95$) between CTGF and TGFβ1 message levels in the SI carcinoid tumor samples demonstrating that transcription of these growth factors was tightly associated in this tumor tissue (Figure 1B). No relationship was noted between TGFβ1 mRNA levels and CTGF mRNA levels in gastric carcinoids ($R^2 = 0.01$). These results demonstrate while both gastric and SI carcinoid tumors express mRNA for TGFβ1, CTGF mRNA is over-expressed only in SI carcinoid tumors. CTGF and TGFβ1 transcript levels are associated in SI carcinoid tumors.

Immunohistochemistry

CTGF and TGFβ1 in tumor samples: CTGF was localized in the cytoplasm of SI carcinoid tumor cells (Figure 2). Co-staining with anti-CgA (Figure 2A) or anti-serotonin (Figure 2B) antibodies demonstrated a significant co-localization with CTGF and either antibody ($80 \pm 12\%$ and $93 \pm 6\%$ respectively) in tumor mucosa. Like CTGF, TGFβ1 was cytoplasmic and was present in $> 75\%$ of tumor cells (Figure 2C). These results demonstrate that TGFβ1 and CTGF expression are characteristic features of SI EC cell carcinoid tumors.

Matrix production in fibrosis: α -smooth muscle actin-positive cells were identified interspersed with carcinoid tumor cells in areas of fibrosis (Figure 3A). α -smooth muscle actin is a marker for activated myofibroblasts (or stellate cells) and indicates that, as for the pancreas, stellate cells are present in peritoneal fibrotic material associated with SI carcinoid tumor mesenteric invasion^[15]. Vimentin, desmin and collagen-III positivity was identified with stellate cells (Figure 3B-D). These are markers of a TGFβ1-mediated stellate-cell driven fibrosis^[15,19,26], and indicate that this response occurs in SI carcinoid tumors. CTGF was present in both tumor cells and stellate cells (Figure 3E and F), consistent with the expression of this fibrotic mediator in both cell types.

Intestinal stellate cell isolation and culture

Myofibroblasts from SI carcinoid tumor fibrotic surgical

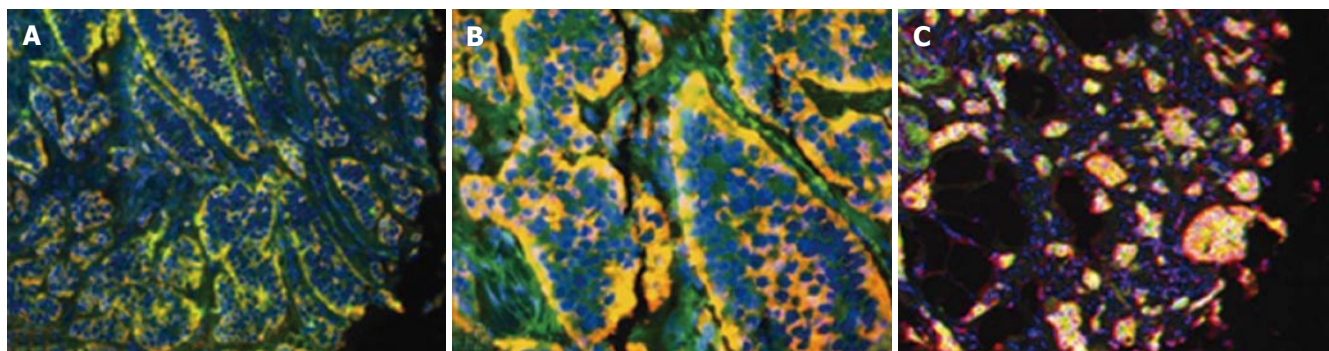

Figure 2 **A:** Triple color staining of nuclei (blue-DAPI), CgA (green-Alexa 488) and CTGF (red-Cy5) in a SI carcinoid tumor from the carcinoid TMA. Staining for both CgA and CTGF was cytoplasmic. Dual-stained (CgA + CTGF) cells are yellow. A majority of CgA cells (about 80%) were also CTGF positive (x 400); **B:** Triple color staining of nuclei, serotonin (green-Alexa 488) and CTGF in a carcinoid tumor from the TMA. Staining for both Serotonin and CTGF was cytoplasmic. Dual-stained (Serotonin + CTGF) cells are yellow. A majority of the serotonin cells (about 95%) were also CTGF positive. (x 600); **C:** Triple color staining of nuclei (blue-DAPI), cytokeratin (green - Alexa 488) and TGF β 1 (red-Cy5) in a carcinoid tumor from the TMA. Staining for TGF β 1 was cytoplasmic. A majority of the carcinoid tumor cells (cytokeratin-positive) (about 85%) were also TGF β 1 positive (x 200).

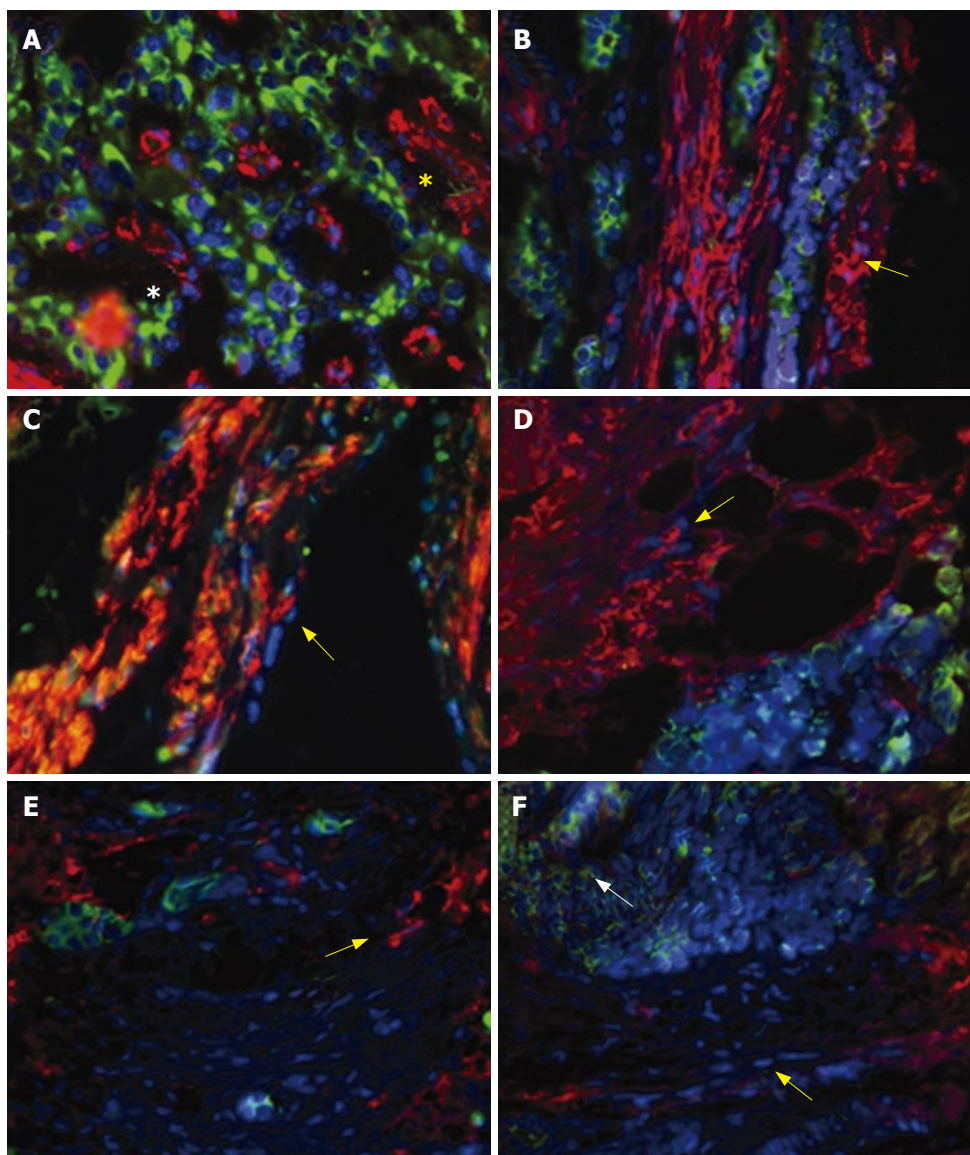

Figure 3: Immunostaining of areas of SI carcinoid tumor fibrosis with α -smooth muscle actin (**A**), vimentin (**B**), desmin (**C**), collagen III (**D**) and CTGF (**E/F**). Triple color staining of nuclei (blue-DAPI), cytokeratin-carcinoid tumor cells (green-Alexa 488) and the protein of interest (red-Cy5). (**A**) Discrete α -smooth muscle actin-positive cells (yellow star) were noted interspersed with tumor cells (white star) in areas of fibrosis. Cells consistent with myofibroblasts were associated with vimentin (**B**), desmin (**C**), collagen-III (**D**) and CTGF (**E/F**) production (yellow arrows). Within the fibrosis, carcinoid tumor cells were also CTGF-positive (**F**) (white arrow) (400 \times magnification).

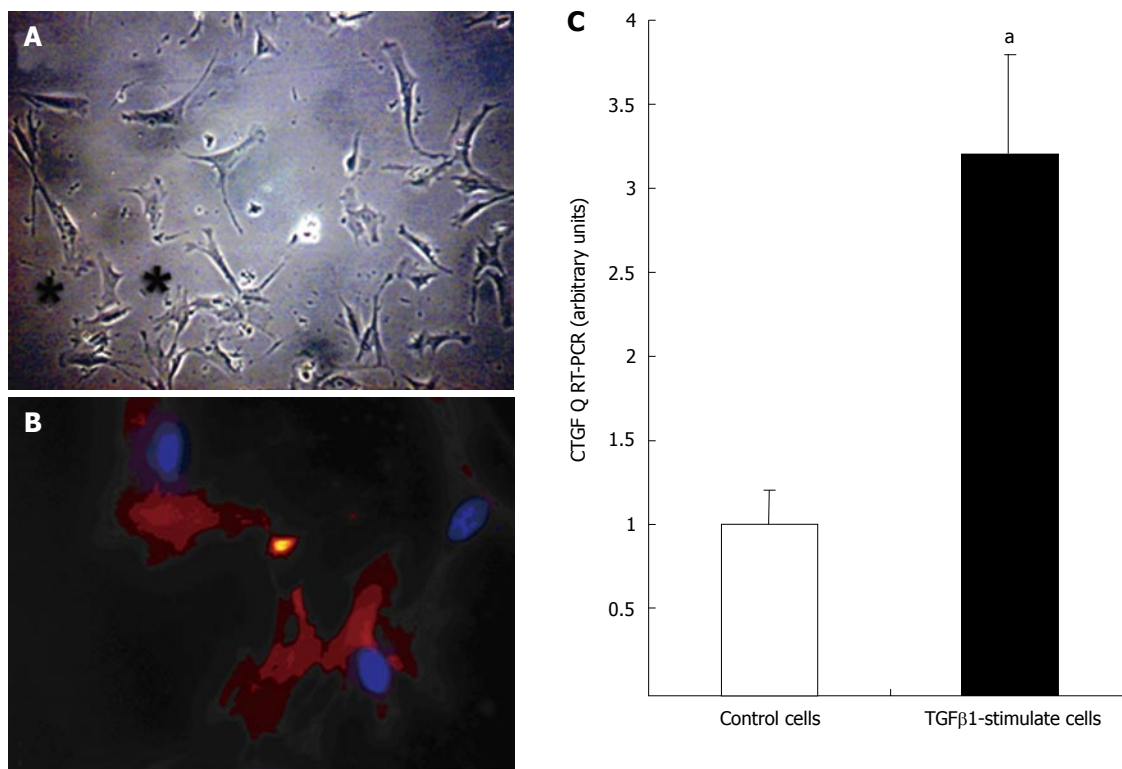

Figure 4 Micrographs of primary cultured human myofibroblasts isolated from human fibrotic material (SI carcinoid tumor). **A:** Light microscopy identified the typical stellate shape (black stars) in 5-day cultured cells (200 × magnification); **B:** Immunostaining with α -smooth muscle actin (Cy-5-red stain; nuclei are blue-DAPI) in same cells after 7-d culture (x 600); **C:** Message levels of CTGF determined by Q RT-PCR in primary cultured human myofibroblasts. CTGF was significantly over-expressed (about 3-fold) in TGFβ1 (10^{-7} mol/L, 24 h) stimulated cells compared to control (un-stimulated) cells ($^aP < 0.05$), mean \pm SE, $n = 3$.

tissue were cultured on plastic as described. Cells in primary cultures flattened and developed long, cytoplasmic extensions. During the 5-7 d in culture, cells developed the typical stellate shape (Figure 4A) and became positive (100%) for α -smooth muscle actin- α marker of myofibroblasts (Figure 4B). This is the classical stellate cell (myofibroblast) activation pathway^[15,19]. Stimulating the cells with TGFβ1 (10^{-7} mol/L) for 24 h significantly increased CTGF mRNA expression (3.2 ± 0.7 , $P < 0.05$ *vs* un-stimulated cells) (Figure 4C).

AQUA Analysis of CTGF and TGFβ1

An examination of the CTGF-stained histospots from the 36 patients with SI carcinoid tumors demonstrated that CTGF expression levels ranged from: AQUA score: 49.7-186.3. Higher levels of CTGF staining (AQUA score: 92.5 ± 8.2 ; $P = 0.017$) were identified in the fifteen SI carcinoid tumor patients with clinical (surgical) and histologically documented evidence of peritoneal fibrosis compared to the twenty-one patients (AQUA score: 72.7 ± 3.2) with no evidence of fibrotic disease (Figure 5). CTGF levels in non-tumor, non-fibrotic normal SI mucosal tissue were significantly lower (59 ± 4 , $P < 0.005$) than in patients with clinically and histologically documented fibrotic disease.

An examination of the CTGF-stained histospots from the seven patients with gastric carcinoids assessed by AQUA demonstrated that expression levels were not elevated in these patients compared to normal matched gastric mucosa (64 ± 3 *vs* 72 ± 3) but were significantly lower than in SI carcinoid tumors associated with fibrosis ($P < 0.03$).

An examination of the TGFβ1-stained histospots from patients with SI carcinoid tumors demonstrated that although TGFβ1 expression levels were elevated in patients with documented fibrosis (AQUA score: 90.6 ± 4.4) compared to the patients with no evidence of fibrotic disease (AQUA score: 82.7 ± 4.0) this did not reach statistical significance ($P = 0.08$). TGFβ1 levels were, however, lower in the matched normal SI mucosal samples (65 ± 4 , $P < 0.05$ versus fibrotic tumor samples). In the gastric mucosa, expression levels were not elevated in patients with gastric carcinoids compared to normal matched mucosa (61 ± 5 *vs* 64 ± 3) but, as for CTGF, values in these non-fibrotic samples were significantly lower than in SI carcinoid tumors associated with fibrosis ($P < 0.03$).

CTGF serum ELISA

Serum levels of CTGF ranged from 7.2-171 ng/mL. Significantly higher serum CTGF levels were found in patients with SI carcinoid tumors (31.0 ± 10) than in patients with ECL cell carcinoids (12.5 ± 4.9 , $P < 0.03$), other GI carcinoids (12.9 ± 0.6 , $P < 0.04$) and control patients (12.4 ± 4 , $P < 0.02$) (Figure 6). A comparison of serum CTGF levels with tissue levels of CTGF (AQUA scores) (where available) identified a strong correlation between these two measurements ($R^2 = 0.91$, $P < 0.005$, $n = 9$).

DISCUSSION

In the current study, we present data in support of our hypothesis that fibrosis is associated with invasion of

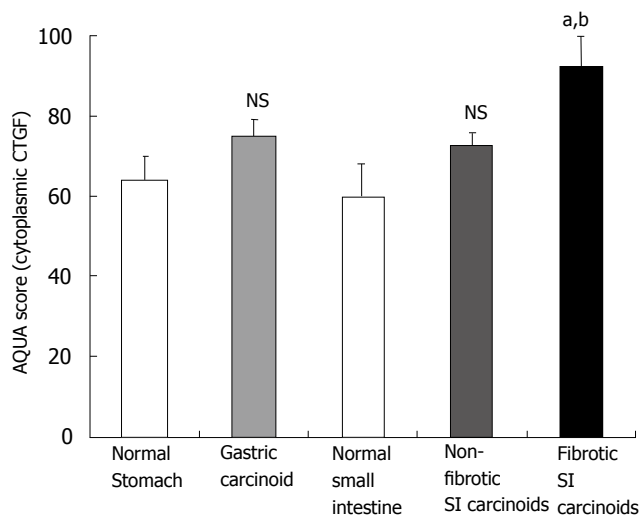

Figure 5 AQUA scores for CTGF protein expression in the TMA. Levels in tumors from carcinoid patients with clinically or histologically documented fibrosis (fibrotic SI carcinoid tumors) were significantly higher than tumors from patients with no evidence of fibrosis (non-fibrotic SI carcinoid tumors and gastric carcinoids) and normal mucosa. No differences in expression were noted between either non-fibrotic SI carcinoid tumors or gastric carcinoids and normal mucosa respectively. (^a $P < 0.05$ vs non-fibrotic SI carcinoid tumors, ^b $P < 0.01$ vs normal SI mucosa). NS = not significant. mean \pm SE.

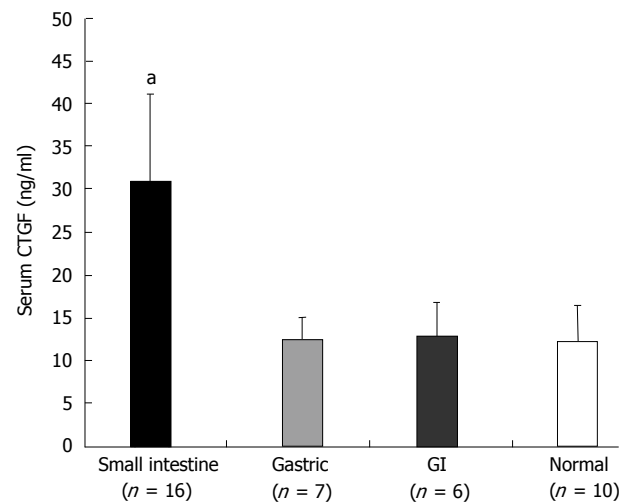

Figure 6 Serum levels of CTGF in patients with SI EC cell carcinoid tumors, gastric ECL cell carcinoids, other GI carcinoids [hepatic, rectal or appendiceal] and normal controls. Levels (ng/mL) were significantly elevated (> 2 -fold versus all other patient groups) in patients with SI EC cell carcinoid tumors compared to the other GI carcinoid tumors. ^a $P < 0.05$ vs all other samples. mean \pm SE.

the mesentery by SI carcinoid tumor cells and is a consequence of the secretory activity of these cells. In addition we have demonstrated that the mechanism may be due to CTGF production, and TGF β related events that activate an intestinal stellate (myofibroblastic) cell resulting in a local desmoplastic response. The latter is responsible for the clinical consequences of mesenteric fibrosis and adhesive obstruction noted in SI carcinoid tumors.

In our studies, Q RT-PCR demonstrated that all samples from patients with SI carcinoid tumors had elevated CTGF message levels (+ 1.1 to + 4.4-fold). In contrast, non-fibrotic gastric ECL cell carcinoids had significantly decreased CTGF levels. This analysis demonstrates that CTGF was quantitatively over-expressed in SI tumors. Message levels for TGF β 1 were elevated in SI carcinoid tumor samples but not in gastric samples. These results indicate that CTGF and TGF β 1 are potentially functionally related in the tumor EC cell but not in the ECL cell. We have previously reported that type I gastric (ECL cell) carcinoids (with no evidence of fibrosis) failed to express detectable levels of CTGF message by standard RT-PCR^[27]. These results suggest that CTGF message produced by a transformed neuroendocrine cell (the SI EC cell) is associated with fibrosis.

Immunohistochemistry demonstrated that the majority ($> 75\%$) of SI carcinoid tumor cells expressed CTGF. In normal mucosa, CTGF immunostaining was restricted to the basal third of the SI crypts with either CgA or serotonin-positive cells. Approximately one-third of serotonin-expressing (EC) cells were CTGF-positive (data not shown). It is likely that the remainder of the CTGF-staining cells are myofibroblasts in the crypts. CTGF-positive myofibroblasts have previously been demonstrated in the rectum^[28].

Carcinoid tumor cells also express TGF β 1, and pre-

sumably this growth factor is secreted by these cells during mesenteric invasion. This was previously noted by Chaudhry *et al*^[20] who reported that stromal cells expressed the TGF β receptor. This suggests a mechanism by which tumor cells can interact with stromal cells and influence their function. Our immunohistochemical analysis demonstrated that stromal cells in areas of mesenteric fibrosis were α -smooth muscle actin positive. α -smooth muscle actin is a marker for activated myofibroblasts (or stellate cells^[15,19]) and indicates that fibrosis-induction in the small intestine is associated with a stellate cell phenotype. This is a typical phenotype of both pancreatic- and hepatic-associated fibrosis^[17,19], and suggests this may be an archetypal GI fibrotic phenomenon. This postulate is supported by evidence that vimentin, desmin and collagen-III, all markers of a stellate-cell driven fibrosis, were present in SI fibrosis.

In order to confirm whether stellate cells were present in this tissue and played a role in fibrosis, we isolated and characterized a cell type from a patient with SI carcinoid tumor fibrosis that exhibited the hallmarks of a stellate cell^[15]. During primary culture, this cell flattened, initially developed long, cytoplasmic extensions, and subsequently, the typical stellate shape of activated myofibroblasts. The presence of α -smooth muscle actin staining confirmed the stellate cell phenotype. Addition of TGF β 1 resulted in activation of CTGF message and demonstrated the cell type to be functionally responsive to this growth factor. These functional data, together with the immunohistochemical evidence of activated intestinal stellate cells in situ, strongly suggest that carcinoid-induced fibrosis is a stellate-cell induced phenomenon. It is possible that the "intestinal stellate" cell could be derived from precursor cells in blood stream and there is some evidence that bone marrow-derived cells can migrate into the SI^[29]. A study of hepatic stellate cells, however, conclusively identified that these cells were not derived from bone marrow derived fibrocytes^[30]. The latter did not stain for α -smooth muscle

actin or desmin and were considered a separate population within the liver. This, as well as our immunohistochemical results strongly suggests the presence of an endogenous intestinal stellate cell population.

Having established that mesenteric fibrosis was associated with elevated CTGF and TGF β 1 in SI carcinoid tumors and identified a mesenteric target cell (intestinal stellate cell), we next used TMA analysis to both quantitate the protein expression as well as the cellular source of CTGF and TGF β 1 and statistically determine whether these proteins were related to clinically and histologically documented evidence of fibrosis. Our results demonstrated that TGF β 1 levels were elevated in patients with fibrosis, and were significantly increased compared to normal SI mucosa and to gastric carcinoids. The difference in protein expression between fibrotic SI carcinoid tumors and non-fibrotic gastric carcinoid samples identified on the TMA further supports a role for TGF β 1 in the etiology of this fibrosis. The role of CTGF was confirmed by the unambiguous relationship between increased expression of CTGF protein in primary SI carcinoid tumors and fibrosis. It is of interest to note that five patients who initially had exhibited elevated CTGF AQUA scores (87 ± 5) on the TMA subsequently developed fibrosis.

In order to identify a clinically useful tool to recognize patients at risk for fibrosis, we sought to measure CTGF in serum. Secreted CTGF protein could be identified in patient serum and was elevated in patients with SI carcinoid tumors compared to patients with gastric ECL cell carcinoids. Serum levels of CTGF from the latter patient group were similar to values in control subjects as might be predicted given that the gastric carcinoids are not associated with carcinoid fibrosis. The highest levels of serum CTGF in this study were identified in two patients with SI carcinoid tumors who also had the typical carcinoid "flushing" symptoms consistent with disseminated disease. This suggests this protein is identifiable in serum and can discriminate SI from gastric carcinoids. Prospective longitudinal studies in patients with and without fibrosis are needed to determine whether plasma levels have clinical significance in the detection, or prediction of peritoneal or cardiac fibrosis.

In conclusion, SI carcinoid tumors over-express CTGF and TGF β 1 mRNA and synthesize CTGF and TGF β 1 protein which are significantly elevated in patients with clinically documented fibrosis. In addition, SI carcinoid tumors secrete CTGF, which is readily detectable in the serum. We have also immunohistochemically identified and biochemically characterized intestinal stellate cells from mesenteric fibrosis. These cells respond to TGF β 1 with CTGF mRNA transcription. In addition, matrix production in SI carcinoid tumor fibrosis was similar to that identified in other stellate cell-driven reactions (e.g., liver or pancreas)^[15,17,19]. We postulate that intestinal stellate cells are the target cells that are activated by profibrotic mediators (TGF β 1 and CTGF) synthesized and secreted by invasive SI carcinoid tumor cells. Furthermore, once activated, these stellate cells may auto-regulate the fibrotic phenotype (by production of CTGF). The detection of blood levels of CTGF may ultimately provide a diagnostic opportunity to predict the development of fibrosis and pre-empt its local and systemic complications.

Abstract

AIM: To test the hypothesis that hydrolysis of sphingomyelin to ceramide changes the composition of tight junctions (TJs) with increasing permeability of the intestinal epithelium.

METHODS: Monolayers of Caco-2 cells were used as an *in vitro* model for the intestinal barrier. Permeability was determined by quantification of transepithelial flux and transepithelial resistance. Sphingolipid-rich membrane microdomains were isolated by a discontinuous sucrose gradient and characterized by Western-blot. Lipid content of microdomains was analysed by tandem mass spectrometry. Ceramide was subcellularly localized by immunofluorescent staining.

RESULTS: Exogenous sphingomyelinase increased transepithelial permeability and decreased transepithelial resistance at concentrations as low as 0.01 U/mL. Lipid analysis showed rapid accumulation of ceramide in the membrane fractions containing occludin and claudin-4, representing TJs. In these fractions we observed a concomitant decrease of sphingomyelin and cholesterol with increasing concentrations of ceramide. Immunofluorescent staining confirmed clustering of ceramide at the sites of cell-cell contacts. Neutralization of surface ceramide prevented the permeability-increase induced by platelet activating factor.

CONCLUSION: Our findings indicate that changes in lipid composition of TJs impair epithelial barrier functions. Generation of ceramide by sphingomyelinases might contribute to disturbed barrier function seen in diseases such as inflammatory, infectious, toxic or radiogenic bowel disease.

INTRODUCTION

Abnormal mucosal permeability is a hallmark of inflammatory bowel disease (IBD)^[1,2]. The epithelial barrier function and its relevance in IBD pathophysiology has gained increasing attention in recent years^[2] as it may contribute to increased bacterial translocation and subsequent inflammatory responses in the mucosa.

Many signaling molecules involved in the pathogenesis of IBD such as TNF- α or IFN- γ may cause an alteration of the lipid composition in the cell membrane by activation of sphingomyelinases (SMases)^[3,4]. SMases are characterized by a specific optimal pH and accordingly are divided into acid, neutral and basic sphingomyelinase species. The acid sphingomyelinase (ASM) contributes to lysosomal sphingomyelin turnover and is also secreted upon cellular treatment with inflammatory stimuli^[5]. In contrast, neutral SMase is membrane-bound, alkaline SMase is found in the bile. Activation of SMases is followed by rapid hydrolysis of plasma membrane sphingomyelin to the second messenger ceramide^[6]. The sphingolipid ceramide is an important messenger involved in many signaling pathways with influences on cell differentiation, growth suppression and apoptosis. It is generated upon ligation of receptors like cluster of differentiation (CD) 40, CD95, IL-1 or TNF receptor^[7-10], as response to ionizing radiation^[11-13], ischemia-reperfusion injury^[14] and infections with bacteria like *Neisseria gonorrhoeae* and *Pseudomonas aeruginosa*^[15-17] or viruses like Sindbis- or Rhinovirus^[18,19]. Ceramide alters the composition of cholesterol- and sphingolipid-enriched membrane microdomains^[20] and thereby promotes transmembrane signaling^[7-9]. It also has the capacity to restructure the membrane to allow the release of vesicles^[21].

Grassme *et al*^[7,8] have demonstrated that cellular stimulation triggers a translocation of the acid sphingomyelinase from intracellular stores onto the extracellular leaflet of the cell membrane. Surface ASM initiates a release of ceramide which mediates clustering of sphingolipid-rich membrane domains, termed “lipid rafts”. Lipid rafts are also described as detergent insoluble cholesterol- and glycosphingolipid-enriched membrane microdomains (DIGs) because the tight packing of the lipids renders rafts resistant to solubilization by non-ionic detergents at low temperatures^[22,23].

Intestinal permeability is influenced by the lipid content of epithelial cells. Dietary fatty acids are known to affect barrier function of the mucosa^[24,25]. Clinical studies showed that omega 3-fatty acids may be of beneficial effect on the course of Crohns disease^[26,27]. Paracellular permeability is controlled by a junctional complex of proteins and lipids which form different strands, commonly described as adherens-junction and tight-junction (TJ). TJs have been identified as microdomains in the plasma membrane with similar characteristics as DIGs^[28,29]. Depletion of cholesterol from Caco-2 cell layers increases permeability^[30], suggesting that cholesterol is critical in maintaining the barrier function.

The proinflammatory cytokines TNF- α and IFN- γ , known to induce ceramide-generation, have recently been shown to disrupt the barrier function of epithelial cells independent from their apoptosis-inducing property^[31]. With regard to the finding that ceramide displaces cholesterol from sphingolipid-enriched microdomains^[20], we hypothesized that formation of ceramide may be an initial event leading to structural lipid-rearrangements of TJs with impaired barrier integrity.

To test this hypothesis we used the intestinal epithelial cell line Caco-2 to assess the effect of exogenous SMase on barrier function and the accompanying lipid composition of TJs.

MATERIALS AND METHODS

Cells and reagents

The human intestinal epithelial cell line Caco-2 was obtained from American Type Culture collection (HTB 37). Cells were maintained in Dulbecco's minimum essential medium (DMEM) supplemented with 10% fetal calf serum (FCS), 1% non-essential amino acids 1% sodium pyruvate in an atmosphere containing 10% CO₂ at 37°C. Sphingomyelinase from staphylococcus aureus, platelet activating factor (PAF) and deoxycholic acid were purchased from Sigma-Aldrich, Germany.

Antibodies

The following antibodies were used for Western-blot analysis: Goat polyclonal anti-occludin (C-19) and goat polyclonal anti-claudin-4 (C-18) from Santa Cruz, CA, USA; mouse anti-E-cadherin (clone HECD-1) from Calbiochem, CA, USA; rabbit polyclonal anti p38 mitogen activated protein kinase (MAPK) from New England Biolabs, Beverly, MA, USA. The rabbit polyclonal anti-toll like receptor 4 (TLR4) Ab was a kind gift from Dr. Werner

Falk, Regensburg, Germany. For immunohistochemical staining of tight junctions we used the rabbit polyclonal anti-ZO-1 Ab from Zymed lab. Inc., CA, USA. For visualization and neutralization of ceramide, the monoclonal mouse IgM anti-Ceramide Ab (MID 15B4) from Alexis, Germany was used.

Measurement of transepithelial permeability and transepithelial resistance

For permeability assays, Caco-2 cells were seeded in 12 well plates with a growth area of 1.0 cm² and a pore size of 3 μ m (Transwell[®] permeable supports by Corning Incorporated, MA, USA) at a density of 2×10^5 cells/cm². Media was replaced every 3 or 4 d. Experiments were performed 13-15 d after cells reached confluency with a transepithelial electrical resistance (TEER) between 500-750 Ω ·cm². Permeability was quantified by measuring the transepithelial flux of fluorescein-sulfonic acid (Molecular Probes Inc., Germany). After treatment of Caco-2 monolayers with the indicated substances, fluorescein-sulfonic acid was added to the apical side of the monolayers at a final concentration of 100 μ g/mL. After incubation for 4 h 100 μ L aliquots of medium were removed from the basolateral chambers, and fluorescence signal by fluorescein was measured using a fluorescence microplate reader. TEER of the Caco-2 monolayers was measured using a Millicell[®]-ERS epithelial volttohmmeter by Millipore with a pair of chopstick electrodes. Untreated monolayers were used as negative controls. All measurements were performed in duplicate.

Caspase-3/7 activity assay

Caco-2 cells were incubated with the indicated substances 6 h before measurement of caspase-activity. As a positive control for induction of apoptosis, cells were treated with deoxycholic acid (DCA) for 1 h. DCA was sonicated at 40°C for 20 min prior to the experiments. The colorimetric caspase-3/7-activity assay Apo-ONE[™] (Promega, WI, USA) was used according to the manufacturer's recommendations. Activity was quantified using a fluorescence microplate reader with appropriate wavelengths for excitation (485 nm) and emission (530 nm).

Fluorescence microscopy

For fluorescence studies Caco-2 cells were grown on chamber slides (Nunc, Germany) and stimulated with 0.25 U/mL SMase for 10 min. After stimulation the cells were washed with phosphate buffered saline (PBS) at 4°C and fixed for 15 min in 1 % (w/v) paraformaldehyde in PBS at room temperature. Then cells were washed three times with PBS and blocked with Tween 20 0.05% in PBS. Cells were washed again and then incubated with anti-ceramide mAb 15B4 (1/50 dilution) and anti ZO-1 Ab for 30 min in washing buffer (PBS with 2% fetal calf serum, 0.01% NaN₃) to block sites of non-specific binding. The anti-ceramide Ab was visualized with a PE-labeled anti-mouse IgM, the anti-ZO-1 Ab with a fluorescein-isothiocyanate (FITC)-anti rabbit Ab. Fluorescence staining was viewed with an Axiovert 100 fluorescence microscope (Zeiss, Germany).

Isolation of detergent resistant microdomains

Confluent layers of Caco-2 cells were stimulated in 75 cm² flasks in 5 mL of culture media. Stimulation was terminated by washing the cells with 5 mL ice-cold TNE (25 mmol/L Tris-HCl, pH 7.4, 150 mmol/L NaCl, and 5 mmol/L EDTA) on ice. Cells were washed twice with TNE at 4°C and lysed for 20 min in 1.5 mL of ice-cold TNE containing 1% of Triton X-100 and protease inhibitors (10 µg of aprotinin and leupeptin and 200 µmol/L phenylmethylsulfonyl fluoride (PMSF)). Cells were then further homogenized with 20 strokes in a Wheaton loose fitting Dounce-homogenizer. Nuclei and cellular debris were pelleted by centrifugation at 600 g for 5 min, 4°C. To isolate low-density, Triton X-100-insoluble complexes, the supernatant was adjusted to 40% sucrose, transferred to an ultracentrifugation tube, and overlaid with a 35% and 5% discontinuous sucrose gradient. Ultracentrifugation was performed at 29000 r/min (110000 × *g*) at 4°C for 16 h in a Beckman SW41 rotor. Gradient fractions (1 mL) were either collected from the top of the tube or from the 35%/5%-interface to compare the effect of cell stimulation on raft fractions. For mass spectrometry, fractions were prepared as described below. For Western blotting, proteins were precipitated using 400 µL of 10% trichloroacetic acid, neutralized and separated by 10% SDS-PAGE.

Immunoblotting

Proteins were separated by 10% SDS-PAGE and electrophoretically transferred to a nitrocellulose membrane (Hybond). Blots were blocked with 5% nonfat dry milk powder and incubated overnight at 4°C with the indicated primary antibodies. All antibodies were diluted 1:750 in Tris-buffered saline supplemented with 0.1% Tween 20. The membranes were further incubated with peroxidase-conjugated secondary antibodies, and protein bands were visualized using a commercial chemiluminescence detection kit (ECL plus, Amersham Biosciences).

Tandem mass spectrometry

Lipids were quantified by electrospray ionization tandem mass spectrometry (ESI-MS/MS) in positive ion mode as described previously^[32-35]. Samples were quantified by direct flow injection analysis using the analytical setup and the data analysis algorithms described by Liebisch *et al.*^[34]. A parent ion scan of *m/z* 184 specific for phosphocholine-containing lipids was used for phosphatidylcholine, sphingomyelin^[33] and lysophosphatidylcholine^[33]. Neutral loss scans of *m/z* 141 and *m/z* 185 were used for phosphatidylethanolamine and phosphatidylserine, respectively. Ceramide was analyzed similar to a previously described method^[35] using N-heptanoyl-sphingosine as internal standard. Free cholesterol and cholesteryl esters were quantified using a fragment ion of *m/z* 369 after selective derivatization of free cholesterol^[36]. Quantification was achieved by calibration lines generated by addition of naturally occurring lipid species to cell homogenates^[32-36].

Statistical analysis

Data are shown using vertical scatter plots with Box-

Whisker plots (25% and 75% values), generated in the basic module of the program SigmaPlot. Statistical analysis was performed by Mann-Whitney *U*-test, with *P* < 0.05 considered statistically significant. Data are given as means ± SE (SD in case of lipid analysis).

RESULTS

Exogenous sphingomyelinase enhances permeability in Caco-2 epithelial cell layers

To study a potential regulation of intestinal permeability by sphingomyelinases, Caco-2 cell layers were exposed to different concentrations of exogenous SMase. Transepithelial permeability was determined by measurement of transepithelial flux of fluorescein-sulfonic acid across a monolayer grown on permeable supports. Incubation with SMase to the apical chamber induced a concentration-dependent increase of permeability which could be detected at concentrations as low as 0.01 U/mL SMase (181.6% ± 16.7%, *P* < 0.01) (Figure 1A). Using 0.05 U/mL SMase, permeability was increased by 201.1% ± 15.8% (*P* < 0.01) and by 224.0% ± 18.0% (*P* < 0.01) when 0.125 U/mL SMase were used. Increase of SMase-concentration to 0.25 U/mL did not further increase transepithelial flux (192.0% ± 15.3%, *P* < 0.01) (Figure 1A). In a different set of experiments with the same experimental conditions, PAF was used as a positive control. At a concentration of 5 µmol/L, PAF increased permeability by 162.8% ± 13.0% (Figure 2).

To gain insight into the mechanisms of ceramide-mediated permeability we measured the transepithelial electrical resistance (TEER). Exogenous SMase produced a significant decline in TEER at concentrations as low as 0.01 U/mL (17.5% ± 6.2%, *P* < 0.05) (Figure 1B). The fall in TEER with 0.05 U/mL was much higher (38.1% ± 6.0%, *P* < 0.01). Using 0.125 U/mL SMase or 0.25 U/mL SMase did not further decrease TEER (32.2% ± 7.3%, *P* < 0.01 and 33.2% ± 6.4%, *P* < 0.01, respectively).

To exclude apoptotic or necrotic cell death caused by SMase within the time frame of our experiments, caspase-3/7-activity and LDH release assays were performed. As shown in Figure 1C, 0.25 U/mL SMase induced no activation of caspase-3/7 within 6 h. Deoxycholic acid (500 µmol/L for 1 h) was used as a positive control. Release of LDH from Caco-2 monolayers by SMase was also not detectable (data not shown).

Neutralization of surface ceramide prevents permeability-increase induced by PAF

Next, we investigated whether the increased permeability induced by PAF might be linked to rearrangement of tight-junctional lipids. Incubation of the monolayers with 5 µmol/L PAF increased permeability by 162.8% ± 13.0% (Figure 2). To examine the role of ceramide in PAF-mediated permeability we co-incubated Caco-2 cell layers with ceramide-antiserum (1/100 dilution). Co-incubation of the Caco-2-monolayer with ceramide-antiserum prevented the increase of permeability induced by 5 µmol/L PAF (111.6% ± 9.86%, *P* < 0.05) (Figure 2), indicating a stabilization of tight-junctional complexes by the IgM-anti-ceramide Abs.

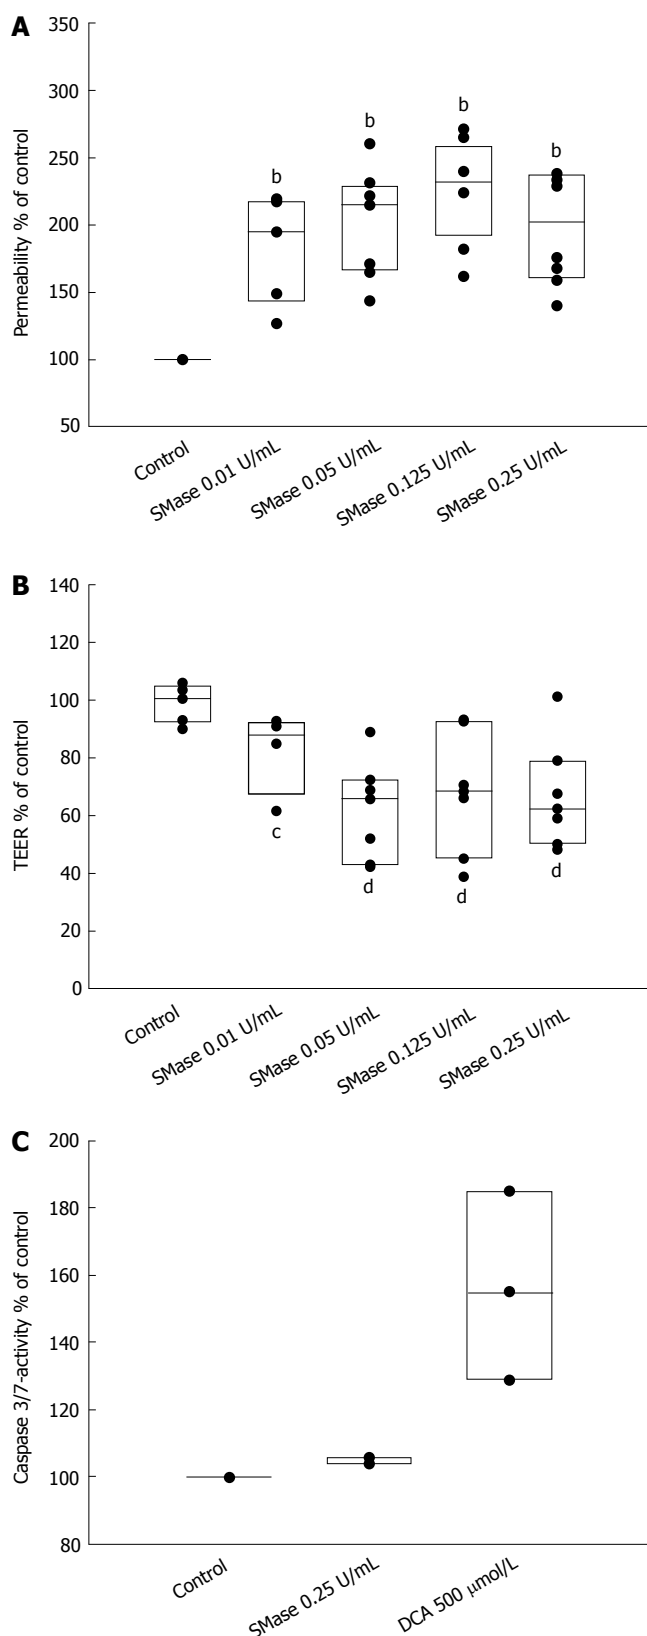

Figure 1 Exogenous sphingomyelinase increases permeability of Caco-2 epithelial monolayers. **A:** Caco-2 monolayers were incubated with different concentrations of exogenous SMase. ^b $P < 0.01$ between control and treated samples; **B:** Transepithelial electrical resistance (TEER) was measured across the cell monolayers 4 h after treatment of the monolayers with exogenous SMase. The data were compared with TEER before treatment and are expressed as % of untreated. ^c $P < 0.05$, ^d $P < 0.01$; **C:** Epithelial apoptosis was monitored 6 h after incubation with 0.25 U/mL SMase by measurement of caspase-3/7-activity with colorimetric assays. As a positive control, deoxycholic acid (DCA) was used for 1 h.

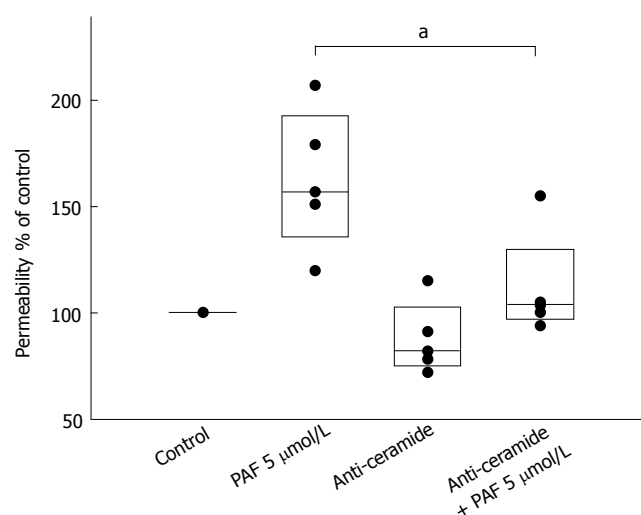

Figure 2 Neutralization of surface-ceramide prevents PAF-mediated increase of permeability. Caco-2 cell layers were incubated with the IgM ceramide-antiserum (15B4) 30 min prior to stimulation with PAF. Permeability was determined by measurement of transepithelial flux of fluorescein sulfonic acid from the upper chamber of the Transwell insert to the lower chamber across the Caco-2-monolayer after 4 h. The data are expressed as % of control. ^a $P < 0.05$ between PAF-treated samples.

Detergent insensitive glycosphingolipid-enriched domains (DIGs) contain major pools of tight junction proteins like occludin and claudin 4

To further test our hypothesis, DIGs were isolated using sucrose gradient techniques and analysed for their lipid- and protein-composition. Analysis of the lipid composition by tandem mass spectrometry revealed the presence of high amounts of sphingomyelin ($12.5\% \pm 1.4\%$), cholesterol ($44.9\% \pm 4.9\%$) and ceramide ($0.74\% \pm 0.18\%$) in DIGs with only $3.8\% \pm 0.6\%$, $19.2\% \pm 3.9\%$ and $0.19\% \pm 0.03\%$ in the total cell lysate (including DIGs), respectively (Figure 3A, values are given as % of analysed lipids \pm SD). This indicated a good separation of DIGs from other membrane components. To ascertain isolation of tight junctions within the Triton X-100 insoluble preparations, Western-blot experiments were performed to prove the presence of tight-junctional proteins. As shown in Figure 3B, major pools of the tight-junctional proteins occludin and claudin-4 were present in Triton X-100 insoluble preparations and to a lesser extent in cell lysate. The basolateral membrane protein E-cadherin was also present in DIGs but was not as prominent. To exclude contamination with proteins not associated with DIGs, Western-blot of TLR4 and p38MAPK were performed which could not be detected in preparations of DIGs (Figure 3B).

Ceramide accumulates in DIGs, whereas sphingomyelin and cholesterol decrease

Tandem mass spectrometry was used to analyze the effect of SMase on the lipid content of DIGs which overlap with tight junctions. Incubation of Caco-2 monolayers with 0.25 U/mL SMase resulted in rapid increase of ceramide in DIGs by $5.0\% \pm 2.4\%$ after 10 min ($P < 0.01$) and $7.3\% \pm 2.6\%$ after 30 min ($P < 0.01$), whereas the increase was

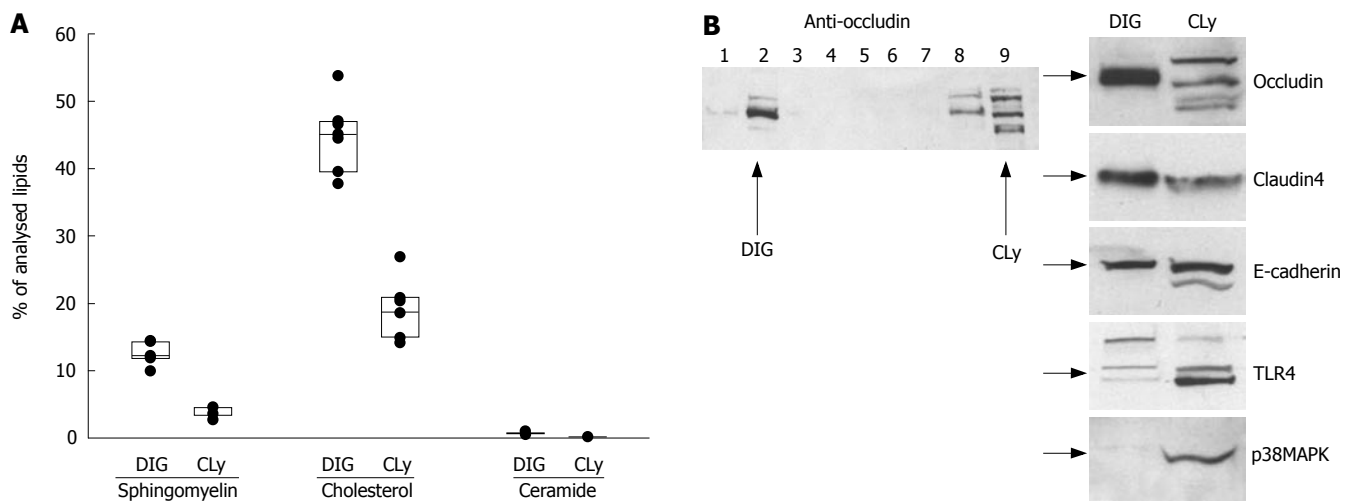

Figure 3 Preparations of detergent insensitive glycosphingolipid-enriched domains (DIGs) contain TJ-proteins. **A:** Lipid analysis of DIGs from non-stimulated Caco-2 cells by tandem mass spectrometry revealed the presence of high amounts of sphingomyelin, cholesterol and ceramide when compared to the total cell lysate; **B:** Gradient fractions were separated by 10% SDS-PAGE and analyzed by Western blot. Fraction No. 2 represents the raft-containing fraction at the 35%/5% interface (DIG); No. 9 represents the soluble fraction (cell lysate = CLy). The presence of high amounts of TJ-proteins occludin and claudin-4 and, to a lesser extent, E-cadherin show a clear association of TJ-proteins with DIGs. The simultaneous absence of other proteins like TLR4 and p38MAPK excludes significant contamination with non-raft fractions.

only $0.84\% \pm 0.14\%$ and $1.25\% \pm 0.23\%$ in the whole cell lysate (including DIGs), respectively (Figure 4A, data shown as % of analysed lipids). In the same preparations of DIGs the concentration of sphingomyelin decreased by $4.73\% \pm 1.4\%$ after 10 min ($P < 0.01$) and $7.6\% \pm 2.2\%$ after 30 min ($P < 0.01$) (Figure 4B). The concentration of cholesterol declined by $5.0\% \pm 3.2\%$ after 10 min and $4.8\% \pm 2.3\%$ after 30 min (Figure 4C). This reflects a decrease of the percentage of cholesterol by $10.9\% \pm 7.3\%$ after 10 min ($P < 0.05$) and $10.6\% \pm 4.8\%$ after 30 min ($P < 0.01$).

Clusters of ceramide colocalize with tight junctions

Fluorescence microscopy was performed to demonstrate the localization of ceramide accumulation. We induced generation of ceramide by incubation of Caco-2 cells with 0.25 U/mL SMase for 10 min. After stimulation, staining of the cells with anti-ceramide 15B4 antibodies revealed the formation of ceramide-clusters (Figure 5A and B) that were frequently located at the sites of cell-cell-contact. Costaining for the tight-junction protein ZO-1 confirmed colocalization of ceramide-clusters with the junctional complexes (Figure 5B).

These data indicate that the generation of ceramide by SMase leads to localized accumulation of ceramide at the sites of cell/cell-contact with increased intestinal permeability and suggest a central role of ceramide in the regulation of barrier integrity.

DISCUSSION

Our data indicate that hydrolysis of sphingomyelin to ceramide increases intestinal epithelial cell permeability in a well-established model of Caco-2 cell monolayers^[37]. To obtain naturally occurring long chain ceramides, formation of ceramide was induced by addition of bacterial sphingomyelinase (SMase). This approach was used because neutral as well as acid SMase are capable of generating ceramide in the outer leaflet of

the cell membrane by rapid hydrolysis of membrane sphingomyelin. Previous studies suggested that, upon cellular stimulation, the acid sphingomyelinase (ASM) translocates onto the outer surface of sphingolipid-rich membrane microdomains^[7,8]. The fact that ASM activity is also increased in the serum of mice treated with endotoxin^[38] or PAF^[39], indicates a possible role of extracellularly located ASM. Another advantage of using exogenous SMase is the enzymatic cleavage of sphingomyelin at the sites of sphingomyelin-enriched domains in the cell membrane, whereas the addition of long chain ceramides might lead to lateral assembly of ceramide to pre-existing DIGs (and/or TJs) without affecting the structure inside these microdomains. Apart from that, exogenous ceramides are likely to be rapidly metabolised, thus having a rather transient effect on lipid composition. Exogenous SMase was effective in terms of increased permeability and decrease of TEER, indicating a reduction of the paracellular barrier by hydrolysis of sphingomyelin. Other possible effects of SMase include an increase of transcellular transport of vesicles. Therefore, we measured intracellular fluorescence after exposure of the cells with SMase and fluorescein-sulfonic acid with colorimetric assays of the cell lysates and performed transepithelial flux experiments with simultaneous colchicine-treatment (data not shown). In both cases we did not observe any differences, making transcellular transport unlikely. To exclude damage of monolayers as a possible cause for increased permeability, activity of caspase-3/7 in the cell lysate and lactate dehydrogenase (LDH) in the supernatant were measured without significant results.

Lipid analysis of Triton X-100 insoluble preparations clearly demonstrated the separation of membrane portions which were enriched in cholesterol, sphingomyelin and ceramide. Western-blot experiments of DIGs revealed that these preparations contained major pools of the TJ-proteins occludin and claudin-4. Upon stimulation with

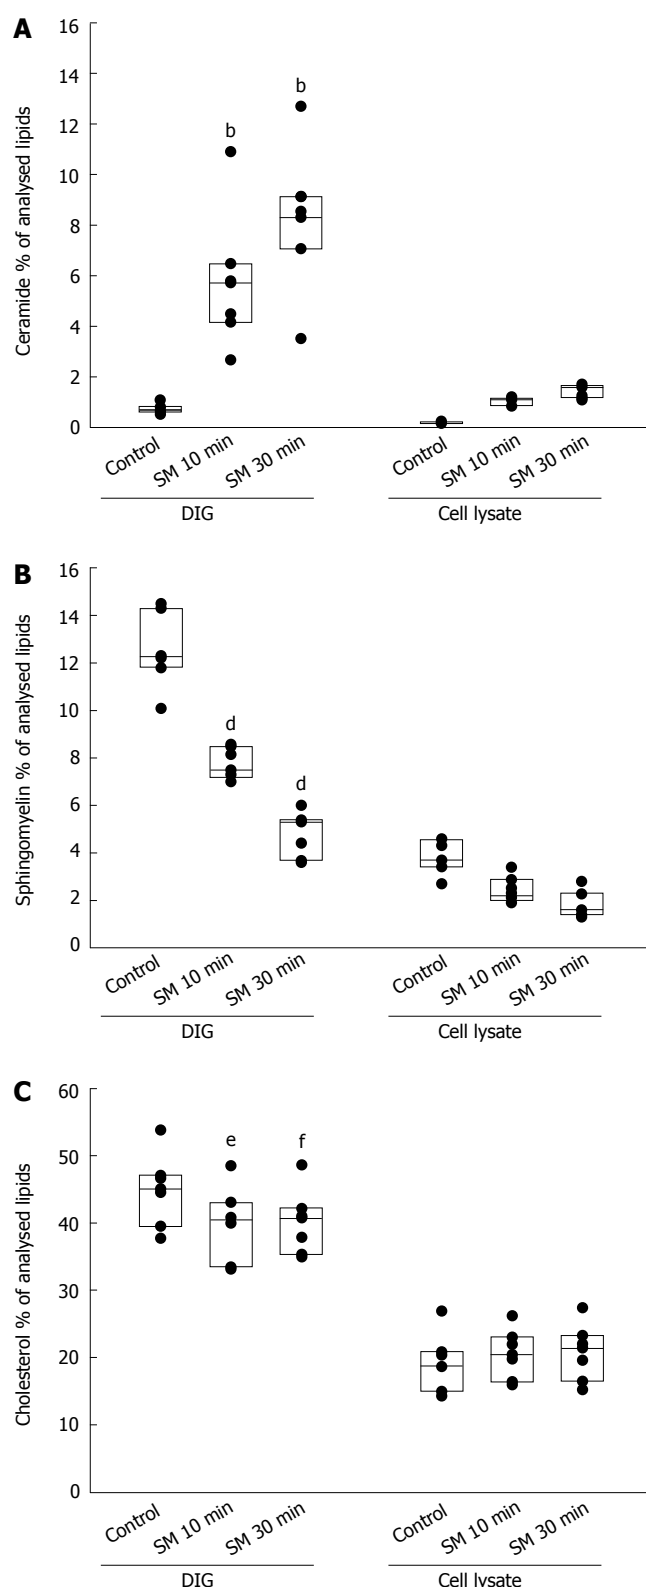

Figure 4 A: Lipid analysis by tandem mass spectrometry revealed a rapid accumulation of ceramide in preparations of DIGs after incubation with 0.25 U/mL SMase for 10 or 30 min whereas the increase of ceramide in the cell lysate was only small in comparison ($^bP < 0.01$); B: The content of sphingomyelin in DIGs decreased at the same time with a relative reduction comparable to the generation of ceramide ($^dP < 0.01$); C: Cholesterol also decreased in DIGs whereas the concentration in the cell lysate remained constant ($^eP < 0.05$ and $^fP < 0.01$).

SMase we detected a rapid accumulation of ceramide in the same membrane fractions, indicating selective

accumulation of ceramide in sphingolipid-enriched membrane microdomains, including junctional complexes.

Previous studies suggested displacement of cholesterol from DIGs by ceramide^[20,40,41]. To our knowledge, there is no data in the available literature about the modulation of ceramide and cholesterol in TJs by sphingomyelinases. Therefore we compared the content of cholesterol in DIGs which overlap with TJs. In accordance with these studies we also observed a decrease of cholesterol in these microdomains with increasing concentrations of ceramide, suggesting a rearrangement of tight junctional lipids by ceramide with impaired barrier function.

Lambert *et al*^[30] showed a decrease of TEER by 80%-90% after extraction of 40%-45% of cholesterol from Caco-2 monolayers. Compared to these results the decrease of tight-junctional cholesterol by ceramide is moderate. Nevertheless, these changes could explain early disturbances of tight-junctional integrity upon cellular stress, deriving from toxic, infectious or immunologic challenges of the intestinal epithelium. Therefore, we propose the following pathophysiologic model: Cellular stimulation leads to localized accumulation of ceramide with concomitant decrease of sphingomyelin and cholesterol leading to destabilization of tight junctional strands and loss of barrier integrity.

Long chain ceramides also have the unique property of fusing membrane domains and tend to form cluster, which was also observed in our studies. Mechanisms of ceramide to modify the structure of bilayers and their effect in promoting efflux and release have been studied in several models^[21,42,43]. Montes *et al*^[21] demonstrated release of molecules with a molecular mass up to 20 kDa upon treatment of unilamellar vesicles with sphingomyelinase. A possible mechanism for this release was suggested by Siskind and Colombini who detected formation of large stable channels by ceramide in planar bilayers through electrophysiological methods^[43]. The influence of ceramide on the architecture of TJs also seems to be important in the PAF-mediated increase of permeability. Pretreatment of Caco-2 cells with a monoclonal IgM ceramide-antiserum prevented the loss of barrier function induced by 5 μ mol/L PAF.

Together, these findings provide evidence for a new aspect of cellular ceramide generation. Lipid rearrangements triggered by enzymatically catalysed formation of ceramide upon cellular stimulation may be a frequent process for localized exposure of intraluminal antigens to the immune system. Repeated stimulation or extension of the stimulated area may lead to an imbalance of the lipid geometry producing a stronger leakiness of the affected junctional complexes resulting in initiation of an inflammatory process which may further perpetuate itself. Better knowledge of the relevant lipids which control this "lipid-barrier" and their modifying enzymes would be helpful to develop treatment strategies to strengthen this barrier. Lipid-enriched diets or inhibition of relevant lipid-modifying enzymes could be possible treatment modalities to control chronic inflammation of the intestine as seen in IBD^[44].

In summary, our data demonstrate that hydrolysis

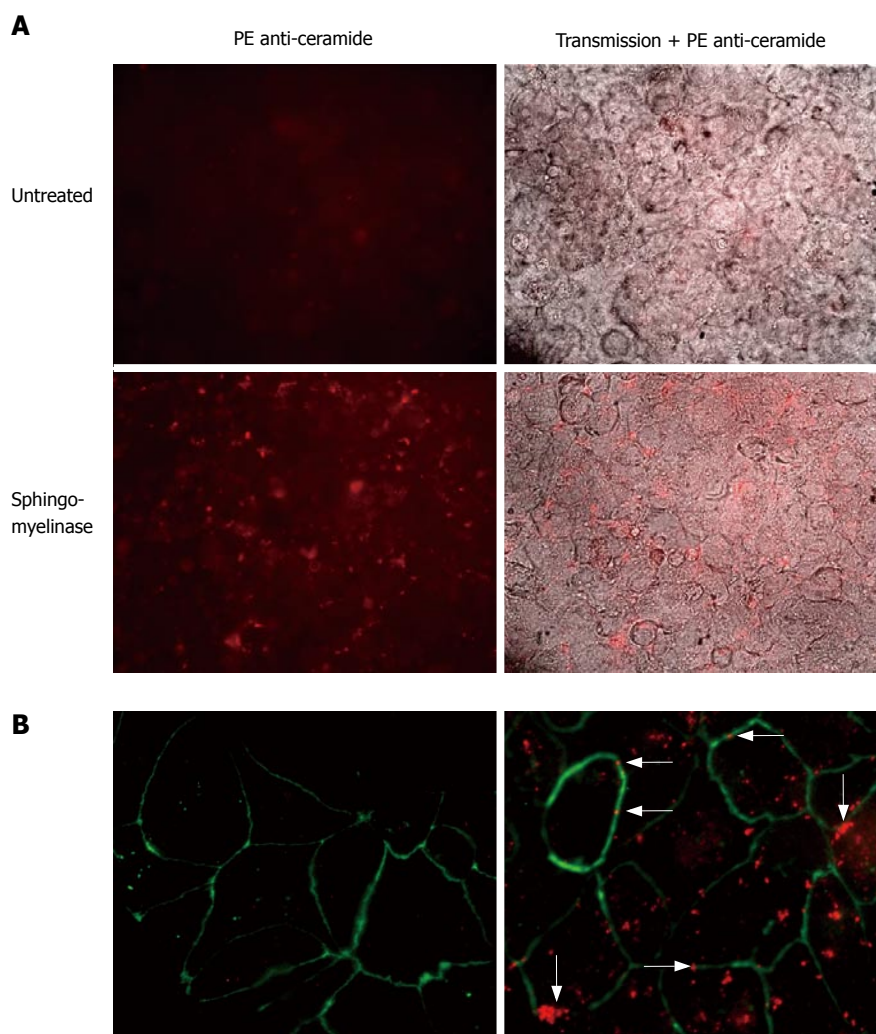

Figure 5 Ceramide clusters at the sites of cell-cell contacts. Caco-2 cell layers were incubated with 0.25 U/mL SMase for 10 min or left untreated. After fixation of the cells with paraformaldehyde, ceramide was visualized by staining of the cells with the monoclonal anti-ceramide 15B4 antibody and PE-coupled anti-mouse antibodies. **A:** Top, left: Non-stimulated cells displayed a certain level of background staining that was used to determine the time of exposure. Top, right: Overlay of fluorescence and transmission. Bottom, left: Incubation with SMase resulted in formation of multiple ceramide-clusters. Bottom, right: Overlay of fluorescence and transmission. Close inspection of the clusters revealed a frequent localization of the clusters at the sites of cell/cell-contact; **B:** Costaining of tight junctions with FITC-labeled anti ZO-1 Abs. Left: non-stimulated. Right: Predominant colocalization of ceramide-clusters with tight junctions upon stimulation with SMase (arrows indicate ceramide-clusters at the sites of cell-cell contact).

of sphingomyelin to ceramide affects transepithelial permeability and resistance. Long chain ceramides, generated by SMase, accumulate in cholesterol- and sphingolipid-enriched membrane microdomains which include TJs. These microdomains fuse to large, ceramide-enriched clusters, located on the surface of the cells and at the sites of cell-cell contact, explaining the effect of long-chain ceramides on barrier integrity. Finally, the effect of PAF on paracellular permeability is inhibited by neutralization of surface ceramide, suggesting a regulation of the paracellular permeability by the arrangement of membrane ceramide.

COMMENTS

Background

The sphingolipid ceramide, generated by signal-activated sphingomyelinases, has emerged as a second messenger of stimuli as diverse as ligation of various receptors, ionizing radiation, chemotherapy or infection with some bacteria and viruses. Upon stimulation of sphingomyelinases, ceramide is generated in distinct sphingolipid-enriched membrane microdomains of the cell membrane, termed "lipid rafts". Tight junctions (TJs) are structurally related to lipid rafts, and thus, we hypothesized that hydrolysis of sphingomyelin to ceramide changes the composition of TJs with increasing permeability of the intestinal epithelium.

Research frontiers

Intestinal permeability is influenced by the lipid content of epithelial cells and some lipids may be beneficial for the course of inflammatory bowel disease. Modification of the lipid

content of TJs may be a possible strategy to improve intestinal barrier functions.

Innovations and breakthroughs

Our data indicate that hydrolysis of sphingomyelin to ceramide by sphingomyelinase (SMase) increases intestinal epithelial cell permeability. Lipid analysis after stimulation with SMase demonstrated rapid accumulation of ceramide in the membrane fractions which contain the TJ-proteins occludin and claudin-4, while sphingomyelin and cholesterol decrease. Pretreatment of cells with a monoclonal IgM ceramide-antiserum prevented the loss of barrier function induced by platelet activating factor.

Applications

Better knowledge of the relevant lipids and their modifying enzymes that control this "lipid-barrier" of the intestine would be helpful to develop treatment strategies to strengthen this barrier. Lipid-enriched diets or inhibition of relevant lipid-modifying enzymes could be possible treatment modalities to control chronic inflammation of the intestine as seen in inflammatory bowel disease.

Terminology

Sphingomyelinase is an enzyme which hydrolyses sphingomyelin to ceramide upon various cellular stimuli. Paracellular permeability is controlled by a junctional complex of proteins and lipids which form different strands, commonly described as adherens-junction and tight-junction (TJ). Platelet activating factor is a lipid messenger which increases paracellular permeability in intestinal epithelial cells.

Peer review

The authors set out to test the hypothesis that hydrolysis of sphingomyelin to ceramide changes the composition of tight junctions (TJs) with increasing permeability of the intestinal epithelium. Their findings suggested that changes in lipid composition of TJs impair epithelial barrier functions. Generation of ceramide

by sphingomyelinases might contribute to disturbed barrier function seen in diseases such as inflammatory, infectious, toxic or radiogenic bowel disease.

Abstract

AIM: To investigate the effects of propolis on bacterial translocation and ultrastructure of intestinal morphology in experimental obstructive jaundice.

METHODS: Thirty Wistar-Albino male rats were randomly divided into three groups, each including 10 animals: group I, sham-operated; group II, ligation and division of the common bile duct (BDL); group III, BDL followed by oral supplementation of propolis 100 mg/kg per day. Liver, blood, spleen, mesenteric lymph nodes, and ileal samples were taken for microbiological, light and transmission electron microscopic examination on postoperative 7th d after sacrifice.

RESULTS: The mean number of villi per centimeter and mean mucosal height of the propolis group were significantly different in the BDL group ($P = 0.001$ and 0.012 , respectively). The electron microscopic changes were also different between these groups. Sham and BDL + propolis groups had similar incidence of bacterial translocation (BT). The BDL group had significantly higher rates of BT as compared with sham and BDL + propolis groups. BT was predominantly detected in MLNs and the most commonly isolated bacteria was *Escherichia coli*.

CONCLUSION: Propolis showed a significant protective

INTRODUCTION

The cytotoxicity of bile salts and the toxicity of high levels of intracellular bilirubin are suspected as mediators of some of the systemic consequences of obstructive jaundice. Recent data suggest that more complex mechanisms involving changes in gut flora, mucosal integrity, and macrophage-immune system interactions may be responsible for the complications of obstructive jaundice^[1].

The gastrointestinal tract is not only a passive organ of nutrient absorption, but it additionally displays important endocrine, immunologic, metabolic, and barrier functions^[2]. Bacterial translocation is the migration of bacteria or bacterial products from the intestinal lumen to mesenteric lymph nodes or other extraintestinal organs and sites^[3]. Obstructive jaundice impairs intestinal barrier function leading to bacterial and endotoxin translocation in experimental and clinical studies. It affects the three levels of gut barrier globally; the immune barrier, the biological barrier, and the mechanical barrier^[2]. Moreover, biliary obstruction in the rats results in a significant depression of the reticuloendothelial system (RES) phagocytic function, which may cause impaired systemic bacterial clearance and is associated with decreased survival following *E. coli* endotoxemia^[4].

Propolis is a natural product collected by honey bees from various plant sources. It has antibacterial,

antifungal, scolicidal, antiinflammatory, antioxidant, immunomodulatory, antiviral and anticarcinogenic properties^[5-13].

According to these properties, we planned to use propolis for determining the effects on bacterial translocation and the ultrastructure of intestinal morphology in experimental obstructive jaundice.

MATERIALS AND METHODS

Animals

Thirty Wistar-Albino male rats, weighing 250 ± 25 g, were housed under constant temperature ($21^\circ\text{C} \pm 2^\circ\text{C}$) individually in wire cages with a 12 h light-dark cycle. Twelve hours before anesthesia, animals were deprived of food, but had free access to water two hours before anesthesia. No enteral or parenteral antibiotics were administered at any time. The rats that died during the experiment were excluded from the experiment and no new rat was included. The procedures in this experimental study were performed in accordance with the National Guidelines for The Use and Care of Laboratory Animals and approved by Animal Ethics Committee of Ankara Research and Training Hospital.

Study groups

Rats were randomly divided into three groups, each including 10 animals: group I, sham-operated; group II, ligation and division of the common bile duct (BDL); group III, BDL followed by oral supplementation of propolis 100 mg/kg per day (Balparmak LTD, Istanbul, Turkey) with a nasogastric tube that was inserted daily and taken off after propolis supplementation. The first dose of propolis was given on postoperative d 1 and continued until the rats were sacrificed. Animals were sacrificed on postoperative d 7 by high-dose diethyl ether inhalation. Liver, blood, spleen, mesenteric lymph nodes, and ileal samples were taken for microbiological, light and transmission electron microscopic examination.

There is no standard dose for propolis based on previous experimental studies. In previous studies the dose ranged between 30-200 mg/kg per day^[14,15]. We gave propolis at a dose of 100 mg/kg per day to each rat.

Operative procedure

Animals were anesthetized by intramuscular injection of 30 mg/kg ketamine hydrochloride (Ketalar®; Parke-Davis, Istanbul, Turkey) and 5 mg/kg xylazine (Rompun®, Bayer, Istanbul, Turkey). Midline laparotomy was performed under sterile conditions. In the sham-operated group (group I) the common bile duct (CBD) was freed from the surrounding soft tissue and was manipulated without ligation and transection. In group II and III, CBDs of the rats were identified, double ligated with 5-0 silk, and divided between the ligatures. The same surgeon performed all procedures. The abdominal incisions were closed in two layers with continuous 3-0 silk sutures. Animals were allowed to feed after the operation.

Microbiological examination

The mesenteric lymph nodes, spleen and liver were

chopped with sterile instruments under aseptic conditions. Then the tissue samples were weighed and placed in tubes containing 1.5 mL broth (thioglycollate, Oxoid, UK) and homogenized. Subsequently, 0.01 mL tissue samples were inoculated on blood agar (Oxoid, UK) and Levine Eosine Methylene Blue (EMB) agar (Oxoid, UK). Plates were incubated at 37°C for examination of bacterial growth. The growth of bacteria in quantitative culture was observed at 24 and 48 h.

One mL blood samples taken from inferior vena cava of rats were inoculated on the media of aerobic and anaerobic blood cultures. The aerobic and anaerobic blood cultures were observed by incubation in BACTEC 9240 blood culture system (Becton Dickinson, USA) at 37°C for seven days. Samples taken from the blood culture bottle, which gives a positive signal, was cultured by inoculating on blood agar and EMB agar. The subcultures were inoculated at 37°C under aerobic and anaerobic conditions and examined at 24 and 48 h.

Histopathological examination

For light microscope analyses, tissue samples from the terminal ileum were obtained from all animals. In order to avoid mucosal suffering, the intestinal lumen was carefully cannulated and gently washed with normal saline solution before the sampling. The ileal samples were fixed in 10% neutral buffered formalin, embedded in paraffin, sectioned at $5\text{ }\mu\text{m}$ by Leica RM 2125 RT, and stained with hematoxylin and eosin (HE) for routine light microscopic examination. Histopathological examinations were performed by a pathologist who was blinded to the study design and photographs were taken with Nikon Eclipse E 600. The number of villi per centimeter (V/cm) and the total mucosal thickness (measured from the tip of the villus to the muscularis mucosa) were assessed in all groups. The mucosal thickness was measured in a minimum of 20 well-preserved villi in each randomly selected sample from each tissue block.

For transmission electron microscopic (TEM) analyses, samples were fixed with phosphate buffered (pH: 7.3) 2.5% glutaraldehyde and 2% PFA mixture solution for 2 h at room temperature. They were washed with phosphate-buffered saline solution (PBS) (pH: 7.3) and were fixed with 1% osmium tetroxide for 2 h as secondary fixation. After washing, they were embedded in Araldite 6005 and were cut with Leica EM FCS (Vien-Austria) ultramicrotome. $1\text{ }\mu\text{m}$ semi-thin sections were stained with Toluidin blue-Azur II to select the region of interest for the following procedures. 60-70 nm thin sections were stained with uranyl acetate and lead citrate. They were examined and photographed using a LEO 906 E TEM (80 kV-Oberkochen-Germany).

Statistical analysis

Differences between the numbers of positive cultures from the groups were evaluated by Chi-square test and *P* values of less than 0.05 were considered to be significant. Scores of total mucosal thickness and number of villi per centimeter were presented as mean \pm SD and compared by One-Way ANOVA or Kruskal-Wallis variance analysis. If the *P* values of the variance analyses were statistically

BDL + Propolis (Group III)	9	80.89 ± 3.87	

^b*P* < 0.001 group I vs II ; ^d*P* = 0.001 group II vs III. BDL: Bile duct ligation.

significant, differences between groups were analysed with the Mann-Whitney *U* test. Statistical analyses were performed with the Statistical Package for the Social Sciences (SPSS), version 13.0 for Windows (SPSS Inc., Chicago, USA). *P* < 0.05 was considered to be statistically significant.

RESULTS

All rats were sacrificed on postoperative d 7. Two rats from group II (BDL group) and one from group III (BDL + propolis group) died in the early postoperative period probably due to anesthesia.

Intestinal morphology

In all specimens of the sham group, the histologic features showed regular appearance of ileal tissue. When we evaluated the specimens systematically, including assessment of villous architecture, surface and crypt epithelia, lamina propria constituents and submucosal structures, no alteration was found in the sham group (Figure 1A). Non specific morphological abnormalities were evident in the intestinal mucosa of the BDL group. The specimens of the BDL group presented villous blunting associated with reduced mucosal thickness. We indicated subepithelial edema mostly located at the tip of the villi, but also extended throughout the villus, with the

Table 2 Mean height of mucosa (μm)

Groups	n	Mean height of mucosa	P values
Sham (Group I)	10	640.02 ± 43.72	0.002 ^b
BDL (Group II)	8	567.50 ± 34.54	0.012 ^a
BDL + Propolis (Group III)	9	612.78 ± 29.69	

^b*P* = 0.002 < 0.01 group I vs II ; ^a*P* = 0.012 < 0.05 group II vs III. BDL: Bile duct ligation.

epithelial layer moderately lifted from the lamina propria. We observed that the crypts were generally preserved. The number of villi per centimeter (V/cm) (villus density) was decreased in the BDL group (Figure 1B). In group III, the subepithelial edema still existed, but villous blunting was not evident. Further, the crypts generally appeared to be preserved (Figure 1C). Although the number of villi per centimeter and the height of the mucosa were higher in the sham group, there was no statistically significant difference between sham and propolis groups (*P* > 0.05). On the other hand, there was a statistically significant difference between the BDL group and other groups (*P* < 0.05). The mean number of villi per centimeter and mean mucosal height of the groups are given in Table 1 and Table 2.

The ultrastructure of the ileum was observed by electron microscopy. The intestinal surface epithelium showed regular architecture with a large number of microvilli exposed to the lumen and the enterocytes, which are tightly bound by junctional complexes, showed the regular architecture of the small intestine surface epithelium in the sham group (Figure 2A). When we evaluated the micrographs of group II, we observed the desquamation of the epithelial tissue, cytoplasmic vacuoles with the inclusion of lipid droplets and phagosomes.

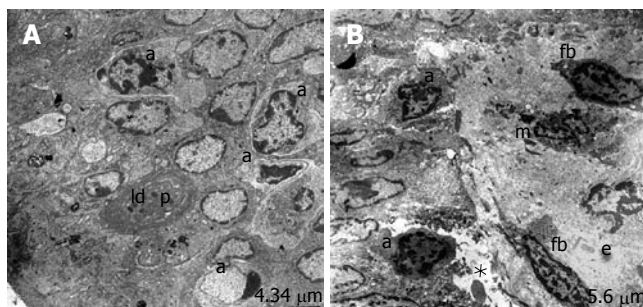

Figure 3 A: The apoptotic cell nuclei (a) and phagosomes (p) with lipid droplets (ld). B: The the apoptotic cell nuclei (a), fibrocytes (fb), macrophage (m) and subepithelial edema (e) with the separation of the basal membrane (*).

The nucleus of the enterocytes were flattened possibly due to both apical surface and subepithelial edema. Ultrastructural findings indicating the invasion of candida, especially located in the desquamated epithelial, were detected in many areas (Figure 2B). The number of apoptotic cells, characterized by cytoplasmic condensation and nuclear fragmentation, was qualitatively increased. The phagosomes, including lipid droplets, were observed in the cytoplasm of the epithelial cells. The infiltration of macrophages and fibrocytes were evident. Basal membranes were separated due to subepithelial edema (Figure 3). Structure of the enterocytes and microvilli were regular in the propolis group. The junctional complexes were in common appearance and adjoining outer membranes of surface absorptive cells were close to each other. The cytoplasmic vacuoles were present but they were smaller than the vacuoles in the BDL group. The nuclei of surface absorptive epithelial cells were regular, in accordance with the regression of the apical surface and subepithelial edema. Findings supporting the invasion of candida were not evident (Figure 2C).

Bacterial translocation

The rates of bacterial translocation (BT) to liver, spleen, MLNs, and blood for all groups are summarized in Table 3. Sham and BDL + propolis groups had similar incidence of BT. The BDL group had significantly higher rates of BT as compared with sham and BDL + propolis groups. Only BT rates to spleen were not statistically different between the BDL and BDL + propolis groups. BT was predominantly detected in MLNs and the most commonly isolated bacteria was *E. coli*.

DISCUSSION

Propolis is a resinous material collected by bees from various plants. Once collected, this material is enriched with salivary and enzymatic secretions of bees. Propolis is used by bees to cover hive walls, fill cracks or gaps and embalm killed invader insects. Hundreds of chemical compounds have been identified from propolis. Propolis contains a variety of flavonoids, phenols, alcohols, terpenes, sterols, vitamins and amino acids. Antimicrobial properties of propolis seem attributable mainly to the flavonoids, pinocembrin, galangin, and pinobanksin.

Table 3 Bacterial translocation rates of the groups

Groups	Liver	Spleen	MLNs	Blood
Sham (Group I)	0/10 (0%)	0/10 (0%)	1/10 (10.0%)	0/10 (0%)
BDL (Group II)	6/8 (75.0%)	4/8 (50.0%)	7/8 (87.5%)	4/8 (50%)
BDL + Propolis (Group III)	2/9 (22.2%)	2/9 (22.2%)	3/9 (33.3%)	0/9 (%)
<i>P</i> values				
I vs II	0.002	0.023	0.002	0.023
II vs III	0.044	> 0.05	0.036	0.029
I vs III	> 0.05	> 0.05	> 0.05	> 0.05

BDL: Bile duct ligation; MLNs: Mesenteric lymph nodes.

Pinocembrin also exhibits antifungal properties. Flavonoids are well-known plant compounds that have antioxidant, antibacterial, antifungal, antiviral, and antiinflammatory properties^[16-18].

Bacterial translocation is defined as the phenomenon by which bacteria, their products, or both bacteria and products, cross the intestinal barrier. The first site encountered by the microorganisms or products undergoing translocation is the mesenteric lymph node. Subsequently, extension to the liver, spleen, and systemic circulation may occur. The mechanisms which are proposed to promote bacterial translocation are small bowel bacterial overgrowth, immune deficiency states, and physical damage to the intestinal mucosa and vasculature that causes increased permeability. Certain enteric organisms such as *E. coli*, *Proteus mirabilis*, *Klebsiella pneumoniae*, seem to undergo translocation more easily. When any of the three mechanisms that promote translocation becomes severe, prolonged, or combined with other mechanisms, bacterial translocation may lead to sepsis and death in experimental animals^[19].

Obstructive jaundice is a common clinical entity complicated by intestinal failure and endotoxemia, leading to high morbidity and mortality rates^[2]. Kuzu *et al*^[20] collected peritoneal swab, mesenteric lymph node, portal venous blood, liver wedge biopsy, and bile samples for culture in patients with obstructive jaundice, and they demonstrated translocation of enteric bacteria despite common use of preoperative antibiotics. Welsh *et al*^[21] demonstrated a reversible impairment in gut barrier function in patients with cholestatic jaundice by using the lactulose/mannitol permeability test and concluded that these data might directly identify an important underlying mechanism contributing to the high risk of sepsis in jaundiced patients.

Obstructive jaundice globally affects three levels of gut barrier: the immune barrier, the biological barrier, and the mechanical barrier. Obstructive jaundice depresses Kupffer cell clearance capacity and natural killer cell activity, reduces T cells in intestinal epithelium, alters intestinal mucosal immunity and deprives the gut from biliary secretory IgA and from other specific and nonspecific antibodies contained in bile that inhibit adhesion of enteric bacteria on the intestinal wall. Bile salts exert bacteriostatic properties, and therefore their absence from the intestinal lumen results in quantitative and qualitative disruption of the indigenous microflora. Absence of intraluminal

bile also deprives the gut from their trophic effect resulting in intestinal atrophy^[2]. The cellular alterations of the mechanical barrier are associated with significant disturbances of intestinal oxidative status, with increased lipid peroxidation, protein oxidation and oxidation of non-protein and protein thiols. These biochemical changes are indicative of high oxidative stress in the intestine after biliary obstruction and represent another significant parameter of intestinal injury leading to barrier failure^[22].

Propolis has antibacterial, antioxidant and anti-inflammatory properties. There are a number of studies documenting the antimicrobial functions of propolis, its extracts, and constituents. This is a broad spectrum activity against Gram-positive (*S. aureus*, *S. pyogenes*, *S. viridens*, *D. pneumoniae*, and *C. diphtheria*) and Gram-negative (*E. coli*, *K. pneumoniae*, *P. vulgaris*, *P. aeruginosa*, *S. typhi*, *S. paratyphi-A*, *S. paratyphi-B*, and *S. flexneri*) rods and cocci, *Helicobacter pylori*, *Trypanosoma cruzi*, *Toxoplasma gondii*, *Trichomonas vaginalis*, *Candida*, *Saccharomyces*, *Cryptococcus*, *Mycobacteria*, as well as viruses (HIV, Herpes viruses, influenza viruses, adenovirus, poliovirus type 2)^[5]. Propolis also possesses potent antimicrobial activity, providing an alternative therapy against infections caused by resistant strains such as methicillin-resistant *Staphylococcus aureus* and vancomycin-resistant *Enterococcus faecium*^[23]. Although the chemical composition of propolis varies depending on the site of its collection, antimicrobial properties seem attributable mainly to the flavonoids pinocembrin, galangin, and pinobanksin. Pinocembrin also exhibits antifungal properties. Other active compounds are ester of coumaric acid and caffeic acids. Prenylated *p*-coumaric and diterpenic acids possess antibacterial and cytotoxic activities. Caffeoylquinic acid derivatives show immunomodulatory and hepatoprotective actions and furofuran lignans inhibit the growth of some bacteria^[24].

Propolis has been used in the treatment of cutaneous lesions such as burns, wounds, and ulcers. Morales *et al*^[25] used a hypoallergic formula of propolis and obtained a very satisfactory evolution and cicatrization in cases of wounds with and without infection. A fast cure, shorter treatment period, and less septic complications were also obtained. The cicatrization was evident between the 4th and 5th d by the early formation of granulation tissue. The antimicrobial capacity was evident with a fast regression of the septic component of the supurated wounds. Propolis exerts a wound healing effect by minimizing acute inflammatory exudate, stimulating macrophage activity, promoting collagen production, and stimulating epithelialization. In our present study, the mean number of villi per centimeter and mean mucosal height of the propolis group were significantly different from the BDL group ($P = 0.001$ and 0.012 , respectively). The electron microscopic changes were also different between these groups (Figures 1-3). We conclude that enhancement of wound healing capacity by the use of propolis might be the reason for decreased atrophy of intestinal mucosal villi.

Propolis also has immunomodulatory activity. In an experimental study, a water-soluble derivative of propolis (WSDP) and its components stimulated macrophages thus influencing specific and nonspecific immune defence mechanisms^[13,26]. In another study, it was shown that

WSDP treatment induced extensive proliferation of nucleated cells in the spleen and bone marrow, which are mainly macrophages and hematopoietic cells^[17].

Ara *et al*^[27] found that intraperitoneal administration of CAPE reduced tissue levels of malondialdehyde and myeloperoxidase, but increased levels of glutathione in the ileum after bile duct ligation. Additionally, CAPE decreased interleukin-1 α , interleukin-6, tumor necrosis factor- α , and intestinal mucosal injury, but the effect of CAPE on bacterial translocation was not revealed. In this study, although bacterial translocation in CAPE-treated rats was lower than in the control group, the difference was not significant.

In our study, bacterial translocation was reduced significantly. The BDL group had significantly higher rates of BT as compared with sham and BDL + propolis groups ($P < 0.05$). Propolis may reduce bacterial translocation by enhancing mucosal barrier function, supporting generalized immune function, and reducing bacterial overgrowth. As we mentioned before, these three mechanisms are the main mechanisms responsible for bacterial translocation.

In conclusion, propolis showed a significant protective effect on ileal mucosa and reduced bacterial translocation in an experimental obstructive jaundice model. Further studies should be carried out to explain the mechanisms of these effects.

Abstract

AIM: To observe whether pancreatic and duodenal homeobox factor-1 enhances the differentiation of pancreatic ductal epithelial cells into insulin-producing cells *in vitro*.

METHODS: Rat pancreatic tissue was submitted to digestion by collagenase, ductal epithelial cells were separated by density gradient centrifugation and then cultured in RPMI1640 medium with 10% fetal bovine serum. After 3-5 passages, the cells were incubated in a six-well plate for 24 h before transfection of recombination plasmid XIHbox8VP16. Lightcycler quantitative real-time RT-PCR was used to detect the expression of PDX-1 and insulin mRNA in pancreatic epithelial cells. The expression of PDX-1 and insulin protein was analyzed by Western blotting. Insulin secretion was detected by radioimmunoassay. Insulin-producing cells were detected by dithizone-staining.

RESULTS: XIHbox8 mRNA was expressed in pancreatic ductal epithelial cells. PDX-1 and insulin mRNA as well as PDX-1 and insulin protein were significantly increased in the transfected group. The production and insulin secretion of insulin-producing cells differentiated from pancreatic ductal epithelial cells were higher than those of the untransfected cells *in vitro* with a significant difference (1.32 ± 0.43 vs 3.48 ± 0.81 , $P < 0.01$ at 5.6 mmol/L; 4.86 ± 1.15 vs 10.25 ± 1.32 , $P < 0.01$ at 16.7 mmol/L).

CONCLUSION: PDX-1 can differentiate rat pancreatic

INTRODUCTION

Diabetes mellitus is a common endocrine and metabolic disease in the world. At present, insulin injection therapy is used in the treatment of type 1 and some type 2 diabetes. However, the results are not satisfactory. Transplantation of islets is one of the promising therapies for type 1 diabetes and can effectively prevent diabetic nephropathy, retinopathy and other complications^[1]. Since it is limited by the shortage of islets, expanding the sources of islet cells (especially beta cells) has become a hot field of research in pancreas transplantation.

In recent years, great efforts have been made to differentiate embryonic stem cells, pancreatic ductal epithelial multipotent progenitor cells and bone marrow stem cells into islet cells^[2-4]. However, it was reported that the most promising way is to differentiate pancreatic stem cells into islet cells, because the process of cell differentiation and growth is shorter than that of bone marrow stem cells and embryonic stem cells, and the induction method *in vitro* is relatively simple^[5]. The amount of islets differentiated from pancreatic stem cells *in vitro* is minimal and insulin released by islets is insufficient to meet the clinical needs^[6]. How to enhance the efficiency of differentiation *in vitro* and increase the output of insulin-producing cells and insulin-release needs to be studied.

The pancreatic and duodenal homeobox factor-1 (PDX-1), also known as islet/duodenum homeobox-1/somatostatin-DE transactivating factor 1/insulin promoter

factor DE 1, a homeodomain containing transcription factor, is homologous to a *Xenopus* endoderm-specific homeodomain protein, XIHbox 8. It plays a central role in regulating pancreatic development and insulin gene transcription^[7]. Transfection of PDX-1 gene into rat intestinal epithelial cell line IEC-6 can produce insulin^[8]. Ferber *et al.*^[9] showed that PDX-1 can endow some cells in the liver with pancreatic beta-cell characteristics *in vivo* using recombinant adenovirus-mediated gene delivery. Bonner-Weir *et al.*^[10] reported that PDX-1 protein can permeate pancreatic duct and islet cells due to an Antennapedia-like protein transduction domain sequence in its structure and transduced PDX-1 functions similarly to endogenous PDX-1. PDX-1 protein transduction is a safe and valuable strategy for enhancing insulin gene transcription and facilitating differentiation of ductal progenitor cells into insulin-producing cells without gene transfer technology. Recently, Yamada *et al.*^[11] showed that mature liver cells can also be induced into insulin-producing cells by *in vitro* PDX-1 gene transfection. These studies have highlighted the potential usefulness of PDX-1 as a reprogramming factor of non-beta-cells toward beta-cell-like cells that can be used in diabetes cell/gene therapy.

Due to the high homology of PDX-1 sequence in different species^[12], we investigated the role of exogenous PDX-1 in pancreatic ductal epithelial cells in adult rats by transfecting exogenous PDX-1 (XIHXbox8) into pancreatic ductal epithelial cells *in vitro*. The results demonstrate that we can enhance the differentiation of pancreatic ductal epithelial cells into insulin-producing cells and insulin-release via PDX-1 (XIHXbox8-VP16) transfection.

MATERIALS AND METHODS

Isolation of cells and culture conditions

Rat (adult male S-D rats, weighing 250-300 g) pancreatic tissue was digested in 1 g/L type V collagenase (Sigma) and incubated at 37°C for 40 min with intermittent shaking and then terminated by Hank's solution, followed by centrifugation at 1000 r/min for 5 min. After purification on a Ficoll gradient, 50%-95% islets were found on the top interface (1.062/1.096 densities) with varying amounts of duct and degranulated acinar tissues, and 1%-15% islets were found on the middle interface (1.096/1.11 densities). Duct, degranulated acini and pellet were composed of well-granulated acinar tissue with less than 1% islets. In the top and middle layers, there were sheets of ductal epithelium from larger ducts whereas the clumps of exocrine cells found in all layers consisted of small intercalated ducts continuing into the acini. The epithelial cells were washed 3 times with Hank's solution containing 5% fetal bovine serum (FBS, Gibco), then put into RPMI 1640 culture medium (Hyclone) containing 10% FBS, 100 U/mL penicillin, and 100 µg/mL streptomycin. Cell suspensions were put into non-treated T-75 flasks and incubated at 37°C in an atmosphere containing 5% CO₂. After 48 h, the nonadherent tissue (both viable and dead) was removed. The medium was changed. The adherent or residual cells were expanded for up to 1 wk with media changed every 2-3 d. The adherent or residual cells were continuously cultured in an atmosphere containing 5%

CO₂ and 95% humidity. After 3-5 passages, the ductal epithelial cells were used in experiments.

Transfection of plasmids

Plasmid pCS2-TTR-XIHXbox8VP16 was kindly provided by Professor J. M.W. Slack (Centre for Regenerative Medicine, Department of Biology and Biochemistry, University of Bath, Bath)^[13]. Plasmids were transfected into pancreatic ductal epithelial cells with Lipofectamine 2000 (Invitrogen) transfection reagent according to the manufacturer's instructions. The medium was replaced with a fresh medium after 24 h of transfection. The cells were cultured for a further 7 d, and analyzed by reverse transcriptase polymerase chain reaction (RT-PCR) or Western blotting at variable time points.

In vitro induction of differentiation

To induce differentiation of pancreatic ductal epithelial cells to insulin-producing cells, forty-eight hours after transfection, pancreatic ductal epithelial cells were transferred to a medium supplemented with 200 µg/mL G418, 10 mmol/L nicotinamide, and insulin/transferrin/selenium (ITS, Sigma). G418-resistant colonies were found about 4 wk after transfection. The resulting clusters were cultured for 1-5 d in RPMI 1640 supplemented with 10% FBS, 10 mmol/L nicotinamide, 200 µg/mL G418, 100 IU/mL penicillin, 0.1 mg/mL streptomycin, and 5.6 mmol/L glucose^[2].

Lightcycler quantitative real-time PCR

Fifty mg pancreatic tissues and 1 mL TRIzol were mixed with 0.3 mL chloroform added, and then centrifuged. Isopropanol (0.5 mL) was added to supernatant and centrifuged with supernatant discarded. Deposit was washed with 70% ethanol, and dissolved in DEPC-treated water to obtain total mRNA. In RT-PCR, 4 µL of mRNA and 0.5 µL of Oligo (dt) were added to 6.5 µL of distilled water. After annealing at 70°C for 5 min and immediate cooling on ice, 4.0 µmol/L of 5 × first strand buffer, 2.0 µL of 10 mmol/L dNTP, 0.5 µL of RNasin and 0.5 µL RTase were added to get a total reaction volume of 20 µL. The reaction was allowed to proceed at 37°C for 60 min, followed by at 95°C for 5 min to inactivate the enzyme. RT-PCR assay was performed three times for each cDNA sample. The total PCR volume consisted of 1 µL of cDNA, 1 µL of SYBRGreen PCR I, 5 µL 10 × buffer, 1.6 µL of primers (rat PDX-1: sense 5'-CTTGGGTATGGATCTGTGG-3' and antisense 5'-CGGACTCATCGTACTCCTGCTT-3'; *Xenopus* PDX-1 homologue XIHXbox8: sense 5'-TGCCAACTTCATCCCAGCCC-3' and antisense 5'-GGCAGATGAAGAGGGCTC-3'; insulin: sense 5'-GCTACAATCATAGACCATC-3' and antisense 5'-GGCGGGGAGTGGTGGACTC-3'; beta-actin: sense 5'-CTTGGGTATGGAATCCTGTGG-3' and antisense 5'-CGGACTCATCGTACTCCTGCTT-3'), 7 µL of MgCl₂, 0.5 µL of Taq DNA polymerase, 1 µL of dNTP and 33 µL of distilled water. After denaturation of the enzyme at 94°C for 2 min, 45 cycles of PCR assay were carried out, with denaturation at 94°C for 30 s, annealing at 57°C for 30 s and extension at 72°C for 30 s. Fluorometric PCR was

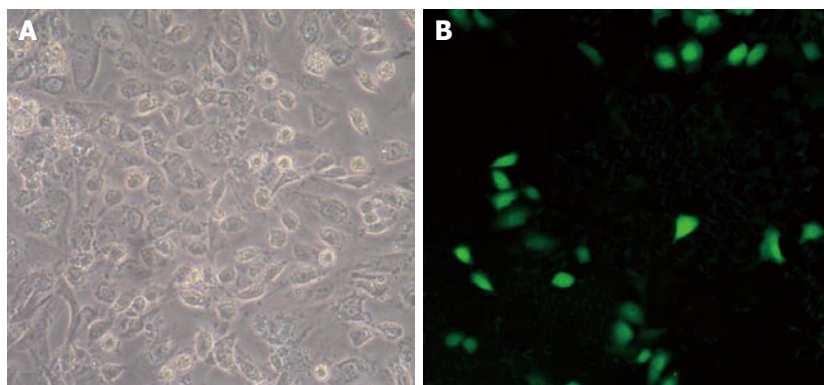

Figure 1 Transfection of recombination plasmids into cultured (A) and non-cultured (B) pancreatic ductal epithelial cells.

performed with the FTC-2000 system. The expression of each transporter protein gene determined was relative to the β -actin RNA gene.

Western blotting

Total protein was obtained as previously described^[14] at various time points (d 0, 1, 3, 5, 7, 14, 21, 28 after transfection). Proteins in samples were separated by polyacrylamide gel electrophoresis, transferred to nitrocellulose membrane and blocked overnight in a blocking solution (5% dry milk in PBS). The membrane was incubated at 37°C for 1 h with goat anti PDX-1 antibody (1:500, Santa Cruz) and goat anti insulin antibody (1:500, Santa Cruz), washed with PBS and incubated at 37°C for 1 h with horseradish peroxidase-labeled secondary antibody (1:2500). Finally, proteins were visualized on a film with the ECL method.

Dithizone staining

A dithizone (DTZ; Sigma) stock solution was prepared with 50 mg of DTZ in 5 mL of dimethylsulfoxide (DMSO) and stored at -15°C^[15]. *In vitro* DTZ staining was performed by adding 10 μ L of the stock solution to 1 mL of culture medium. The staining solution was filtered through a 0.2 μ m filter and used as the DTZ working solution which was added to culture dishes and incubated at 37°C for 15 min. Clusters were examined under a phase contrast microscope.

Secreted insulin measurement

Differentiation of cells transfected with or without TTR-XIHbox8VP16 was induced with either normal dose glucose (5.5 mmol/L) or high dose glucose (16.7 mmol/L). Insulin concentration was measured using an insulin RIA kit (Linco).

Statistical analysis

The data were expressed as mean \pm SD. Individual treatment was compared using Student's *t*-test and ANOVA. *P* < 0.05 was considered statistically significant.

RESULTS

Transfection of XIHbox8 plasmids into cells

Green fluorescence could be seen in pancreatic ductal epithelial cells transfected with XIHbox8. The distribution

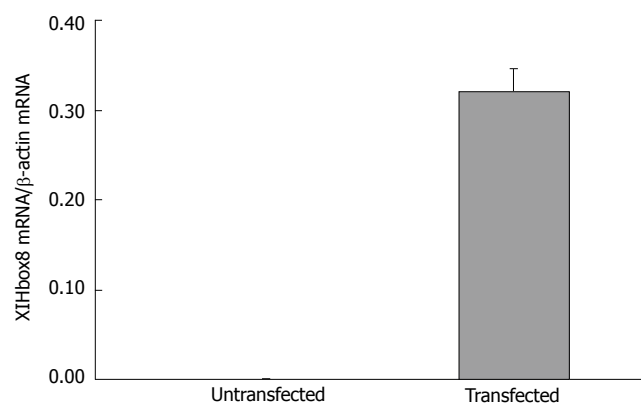

Figure 2 XIHbox8 mRNA expression 24 h after transfection of recombination plasmids.

of green fluorescence in nuclei and cytoplasm indicated the characteristics of location of cytokines in these cells. Twenty-four hours after transfection, the expression of GFP fluorescence was observed under fluorescence microscope (Figure 1). Green fluorescent cells were calculated. The transfection efficiency of pancreatic ductal epithelial cells was 3%-5%. These results suggest that exogenous XIHbox8 could be transfected into nuclei and cytoplasm of pancreatic ductal epithelial cells.

Expression of PDX-1 and insulin in transfected cells

To investigate the change in gene expression patterns caused by exogenous PDX-1 (XIHbox8) expression in pancreatic ductal epithelial cells, we performed RT-PCR analysis. As shown in Figure 2, the cells transfected with TTR-XIHbox8VP16 showed the expression of XIHbox8 mRNA, which was not detectable in the untransfected cells. In addition, the results also showed that the expression of PDX-1 and insulin mRNA increased between the 1st and 7th d after transfection (Figure 3), which is consistent with the reported results^[13]. In contrast, the expression of PDX-1 and insulin mRNA was not detectable in the untransfected cells.

Western blotting showed that PDX-1 and insulin protein were expressed in the transfected cells but not in the untransfected cells. After induction, the untransfected cells also began to express PDX-1 and insulin protein. Moreover, the expression increased between the 14th and 28th d in the transfected cells. The expression of PDX-1

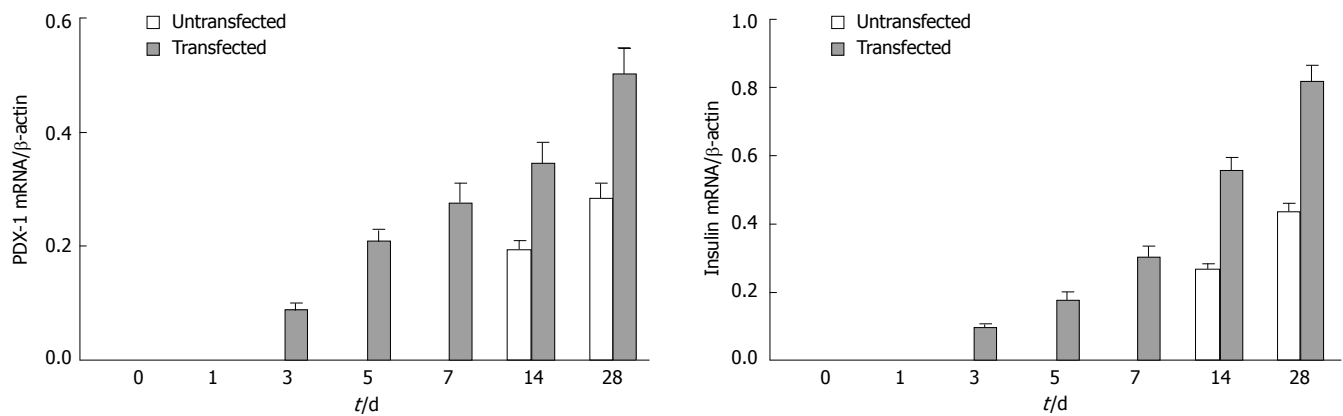

Figure 3 PDX-1 and insulin mRNA expression after transfection of recombination plasmids.

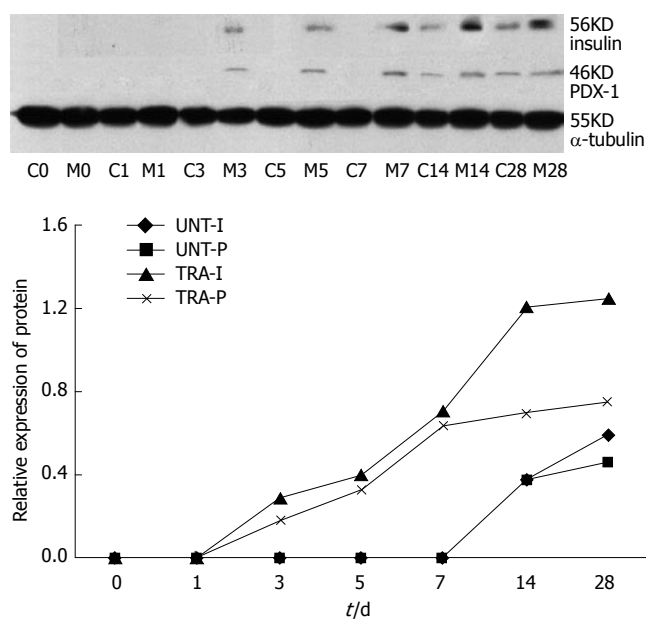

Figure 4 Western blot analysis of PDX-1 and insulin protein showing the increased expression of PDX-1 ($P < 0.01$) and insulin ($P < 0.01$) protein in the transfected cells. C0-C28: Untransfected group on d 0-28; M0-M28: Transfected group on d 0-28; UNT-I: Insulin expression in untransfected group; UNT-P: PDX-1 expression in untransfected group; TRA-I: Insulin expression in transfected group; TRA-P: PDX-1 expression in transfected group.

and insulin protein in the transfected cells increased more obviously (Figure 4).

These results suggest that once XIHbox8 was transfected into pancreatic ductal epithelial cells, endogenous PDX-1 gene transcription was amplified by this XIHbox8 and might enhance differentiation of pancreatic ductal epithelial cells into insulin-producing cells.

Induction of XIHbox8-expressing pancreatic ductal epithelial cells to insulin-producing cells

Pancreatic ductal epithelial cells were transfected with XIHbox8 expression plasmid, and stable transfectants were selected according to G418 resistance. Further differentiation of pancreatic ductal epithelial cells was induced in serum-free medium supplemented with ITS, keratinocyte growth factor (KGF, Sigma) and basic fibroblast growth factor (bFGF, Sigma). During

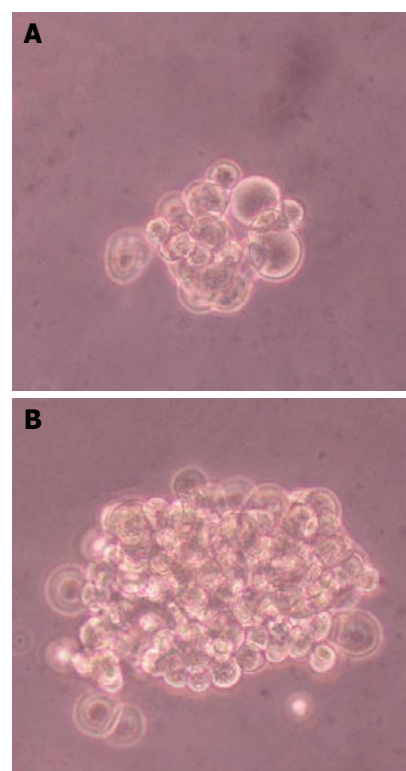

Figure 5 Dithizone staining of insulin-producing cells in untransfected group (A) and transfected group (B).

induction, most insulin-producing cells could be seen under microscope. Dithizone staining showed more insulin-producing cells in the transfected group than in the untransfected group (Figure 5).

Response of differentiated insulin-producing cells to physiological stimuli

The most important and characteristic property of insulin-producing cells is their ability to secrete insulin in response to an elevated external glucose concentration. We examined the insulin concentration in the medium of differentiated cells after challenged with 5.6 and 16.7 mmol/L glucose, using a RIA kit (Figure 6). The results showed that insulin secretion was significantly increased in the transfected group compared with the untransfected group.

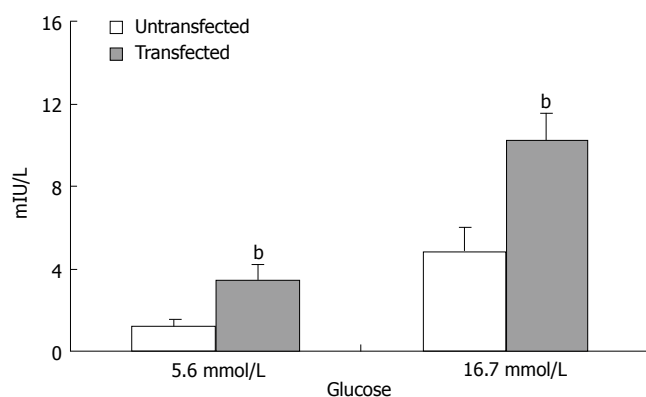

Figure 6 Response of insulin secretion to physiological stimuli. Insulin secretion was significantly increased in the transfected group compared with the untransfected group (^b $P < 0.01$).

DISCUSSION

Pancreas duodenum homeobox-1 (PDX-1) is also known as islet/duodenal homeobox-1 (IDX-1), insulin promoter factor-1 (IPF-1), insulin upstream factor-1 (IUF-1), somatostatin transactivating factor-1 (STF-1) and glucose-sensitive factor (GSF)^[7]. PDX-1 is a transcription factor encoded by Hox-like homeodomain gene and also one of the specific signals of pancreatic stem cells. Human PDX-1 gene consists of two exons and spans a region of about 6 kb in humans and 282 amino acids^[16]. In mice lacking PDX-1, pancreas development is blocked at its very early stage, and there are no or diminished endocrine cells in the rostral duodenum and stomach^[17,18], suggesting that PDX-1 plays a very important role in the development and maintenance of normal pancreatic beta cell function, which also has a potential value in gene therapy for diabetes. Amplifying and inducing differentiation of non-islet cells into insulin-producing cells by PDX-1 has become a hot field of study. Miyazaki *et al*^[19] reported that islet-like cellular clusters are significantly increased and insulin-producing cells can release more insulin by transfecting exogenous PDX-1 into embryonic stem cells. Further investigation found that PDX-1 can enhance the expression of insulin 2, somatostatin and HNF6 genes in the differentiated cells^[19]. XIHbox8 is the homologous of PDX-1. Horb *et al*^[20] transfected XIHbox8-VP16 into liver cells and found that some liver cells could be trans-differentiated into pancreatic cells.

Bonner-Weir *et al*^[3] reported human pancreatic ductal epithelial cells can expand and differentiate into islet cells *in vitro*. In this study, most of early adherent cells and a few fibroblasts were found to be pancreatic ductal epithelial cells. PDX-1 may express in the whole pancreas of an early embryo. However, in pancreas of adult rats, PDX-1 expresses primarily in beta and delta cells, but not in pancreatic ductal epithelium. PDX-1 can also express in activated pancreatic ductal epithelial cells^[12,14]. When pancreatic ductal epithelial cells are transfected with exogenous homologous of PDX-1 and XIHbox8, endogenous PDX-1 gene can be activated, increasing insulin mRNA and protein expression^[9], suggesting that once XIHbox8 is transfected into pancreatic ductal

epithelial cells, endogenous PDX-1 gene transcription is activated by XIHbox8 and insulin gene, thus enhancing its expression. In our study, the expression of insulin mRNA and protein was enhanced after treatment with exogenous XIHbox8, indicating that XIHbox8 may promote differentiation of pancreatic ductal epithelial cells into insulin-producing cells. When pancreatic ductal epithelial cells were transfected with exogenous PDX-1, endogenous PDX-1 gene transcription was amplified, promoting differentiation of pancreatic ductal epithelial cells into insulin-producing cells, which is in agreement with the reported results^[10]. In the present study, after XIHbox8-VP16 was transfected into pancreatic ductal epithelial cells, differentiation of pancreatic ductal epithelial cells to insulin-producing cells was significantly increased, suggesting that this method can produce more insulin-producing cells. It was reported that unmodified PDX-1 is insufficient to activate transcription in the absence of other cofactors, such as Pbx and Meis^[20]. Beta cells are able to secrete insulin in response to an elevated external glucose concentration. In this study, the results of RIA show that the treated cells can produce more insulin than the untreated cells. However, whether differentiated insulin-producing cells have their physiological function *in vivo* still needs to be further tested *in vivo*. Moreover, the low transfection efficiency also limits the production of insulin-producing cells.

In conclusion, PDX-1 (XIHbox8) can significantly promote *in vitro* differentiation of pancreatic ductal epithelial cells into insulin-producing cells. This new method can be used in the treatment of diabetes.

COMMENTS

Background

Diabetes mellitus is a common endocrine and metabolic disease in the world. Although transplantation of islets is one of the promising therapies for type 1 diabetes, its application is limited due to the shortage of islets.

Research frontiers

Expanding the sources of islet cells (especially beta cell) is a hot field of research in pancreas transplantation. Great efforts have made to differentiate embryonic stem cells, pancreatic ductal epithelial progenitor cells and bone marrow stem cells into islet cells. The most promising method is to differentiate pancreatic stem cells into islet cells, but the amount of islets obtained through differentiation of pancreatic ductal cells *in vitro* is minimal and insulin released by islets is insufficient.

Innovations and breakthroughs

The pancreatic and duodenal homeobox factor-1 (PDX-1) plays a central role in regulating pancreatic development and insulin gene transcription. In this study, we transfected PDX-1 (XIHbox8VP16) plasmid into human pancreatic ductal cells.

Applications

PDX-1 (XIHbox8) can significantly promote *in vitro* differentiation of pancreatic ductal epithelial cells into insulin-producing cells. This new method may be used in the treatment of diabetes.

Peer review

This manuscript provides direct evidence for the enhanced differentiation of pancreatic ductal cells into insulin-producing cells. The study is well designed and the results are convincing.

Abstract

AIM: To evaluate the safety and efficacy of a long-term therapy with infliximab in Crohn's disease (CD) and ulcerative colitis (UC) patients retrospectively.

METHODS: The medical charts of 50 patients (40 CD and 10 UC), who received after a loading dose of 3 infliximab infusions scheduled re-treatments every 8 wk as a maintenance protocol, were reviewed.

RESULTS: Median (range) duration of treatment was 27 (4-64) mo in CD patients and 24.5 (6-46) mo in UC patients. Overall, 32 (80%) CD and 9 (90%) UC patients showed a sustained clinical response or remission throughout the maintenance period. Three CD patients shortened the interval between infusions. Eight (20%) CD patients and 1 UC patient underwent surgery for flare up of disease. Nine out of 29 CD and 4 out of 9 UC patients, who discontinued infliximab scheduled treatment, are still relapse-free after a median of 16 (5-30) and 6.5 (4-16) mo following the last infusion, respectively. Ten CD patients (25%) and 1 UC patient required concomitant steroid therapy during maintenance period, compared to 30 (75%) and 9 (90%) patients at enrolment. Of the 50 patients, 16 (32%) experienced at least 1 adverse event and 3 patients (6%) were diagnosed with cancer during maintenance treatment.

CONCLUSION: Scheduled infliximab strategy is effective in maintaining long-term clinical remission both in CD and UC and determines a marked steroid sparing effect. Long-lasting remission was observed following infliximab withdrawal.

INTRODUCTION

Crohn's disease (CD) and ulcerative colitis (UC) are chronic-relapsing diseases the clinical course of which is characterized by periods of remission and periods of acute flare up. The clinical symptoms have a strong impact on the quality of life of patients with inflammatory bowel disease (IBD)^[1-3]. Although many drugs have been used in the treatment of IBD, none has, so far, been shown to modify the natural history of the diseases or to maintain a stable remission over time^[4,5]. For many years, corticosteroids have represented the cornerstone of therapy for induction of remission in IBD, having demonstrated efficacy in inducing a rapid clinical response, in CD as well as in UC; however, long-lasting remission was not achieved and the side-effects emerging with long-term use exceeded the clinical benefits^[6]. Immunomodulators have been demonstrated to be efficacious as adjunctive therapy and as steroid-sparing agents; but their slow onset of action precludes their use in the active clinical setting as a sole therapy^[7].

The introduction of biological agents in the therapeutic armamentarium for CD and UC has significantly changed the treatment strategies and clinical outcomes. Infliximab (IFX) is a chimeric monoclonal IgG1 antibody directed against tumor necrosis factor- α (TNF- α) able to almost completely neutralize its biological activity^[8]. Several placebo-controlled trials have demonstrated the efficacy of IFX treatment in active luminal and fistulizing CD^[9-13]. Recently, IFX has become an alternative choice also in the treatment of UC. Indeed, following the conflicting conclusions of 2 placebo-controlled studies performed in patients with moderately severe steroid-resistant UC^[14,15], showing opposite clinical effects, another two randomized controlled trials have since then been published, demonstrating the clinical efficacy of IFX therapy in patients with moderate-to-severe UC^[16,17].

Some safety issues are associated with IFX use, mostly related to the development of adverse events (e.g., opportunistic infections, autoimmune disorders, and infusion reactions)^[18-20]. Major concerns are related to the reactivation

of latent tuberculosis and development of malignancy, even if there is no clear evidence that the use of IFX increases the incidence of solid cancers^[21,22]. Although the efficacy of a therapeutic strategy consisting of a loading dose of 3 IFX infusions (5 mg/kg) at 0, 2, and 6 wk and, thereafter, every 8 wk is supported by several placebo-controlled studies, very few data are available on the use of IFX for > 12 mo or > 8 doses, either in active CD or in active UC^[23,24].

The aim of the present single-centre study was to retrospectively analyze the prospectively collected data on the safety and efficacy of long-term therapy with IFX in CD and UC patients treated with a scheduled regimen.

MATERIALS AND METHODS

Subjects

The medical charts of 79 patients affected by IBD (59 CD and 20 UC patients, mean age 47.7 years) and treated with IFX (Remicade; Centocor Inc., Malvern, PA, USA) between January 1999 and September 2005 at the Department of Digestive Diseases of the Campus Bio-Medico University Hospital were retrospectively reviewed (Table 1). Diagnosis of IBD was based on the standard combination of clinical, endoscopic, histological, and radiological criteria. Patients were classified into one of 3 groups of treatment, according to IFX infusion administration: (1) episodic therapy only in 10 patients (5 CD, 5 UC), (2) episodic followed by on-demand maintenance in 19 patients (14 CD, 5 UC), and (3) induction therapy followed by scheduled maintenance therapy every 8 wk in 50 patients (40 CD, 10 UC).

Patients presented with mild to moderate IBD, as defined by a score of 150-350 (or less in steroid-dependent patients) on the Crohn's Disease Activity Index (CDAI) for CD patients^[25], and a score of > 10 (or less in steroid-dependent patients) on the Clinical Activity Index (CAI) for UC patients^[26]. Indications for IFX treatment were disease severity, steroid-dependent disease (unable to reduce prednisolone < 10 mg/d), steroid-refractory disease (active disease with prednisolone up to 0.7 mg/kg per day), or contraindication to steroids (e.g., diabetes, osteoporosis, acne, mood disturbance and severe hypertension). Exclusion criteria were cancer or history of cancer, pregnancy, chronic heart failure, previous tuberculosis, or presence of symptomatic intestinal strictures or abscesses.

All patients were allowed to continue concomitant therapies such as 5-aminosalicylates, immunosuppressive agents [azathioprine (AZA), 6-mercaptopurine (6-MP), methotrexate], and antibiotics; patients on steroids discontinued treatment using a tapering regimen of 10 mg weekly starting at the first IFX infusion. The study protocol was approved by the University Ethic Committee.

Pretreatment protocol

Clinical and instrumental assessment was performed within the 3 wk before IFX induction treatment. Blood samples were collected, after overnight fasting, prior to IFX infusion for routine laboratory tests, including inflammatory [C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR)] and biochemical parameters. A chest X ray

¹Mean ± SD; ²5 steroid-dependent patients had baseline Crohn's disease activity index (CDAI) < 150; CAI: Clinical activity index; T0: Baseline time; N/A: Not applicable.

evaluation was performed before the first IFX infusion in order to exclude previous or latent tuberculosis infection. Patients' symptoms were routinely recorded before each infusion, in order to calculate the CDAI and CAI.

Infliximab administration

All 50 IBD patients were treated with an induction regimen consisting of 3 intravenous (iv) infusions of IFX at a dose of 5 mg/kg for induction of remission (wk 0, 2, 6 for CD; wk 0, 4, 8 for UC). Eight weeks after the third infusion, clinical assessment was repeated in all patients to evaluate treatment efficacy: in CD patients, the clinical response was defined as a ≥ 70 point reduction in the CDAI score, and clinical remission was defined as a CDAI score ≤ 150; in UC patients, clinical response was defined as a CAI score ≤ 10 points, and inactive disease as a CAI score ≤ 4. Thereafter, all responders (both CD and UC patients) received IFX maintenance infusions at 8-wk intervals. Written patient's consent was obtained before every IFX infusion.

All adverse events were recorded by means of direct questioning of patients. Infusion reactions to IFX were classified as either acute or delayed. Any adverse reaction, during or within 24 h of an initial or subsequent IFX infusion, was considered as an acute infusion reaction. A delayed infusion reaction refers to any adverse reaction occurring from 24 h to 14 d after re-treatment with IFX. Acute and delayed reactions were further defined as mild, moderate, or severe, according to the severity of signs and symptoms reported by the patient. Serum sickness-like reactions included any IFX-related event that occurred 1 to 14 d after infusion and consisted of a cluster of symptoms such as myalgias and/or arthralgias with fever and/or rash. Severe infection, cancer, and death were considered as serious adverse events if potentially related to IFX treatment.

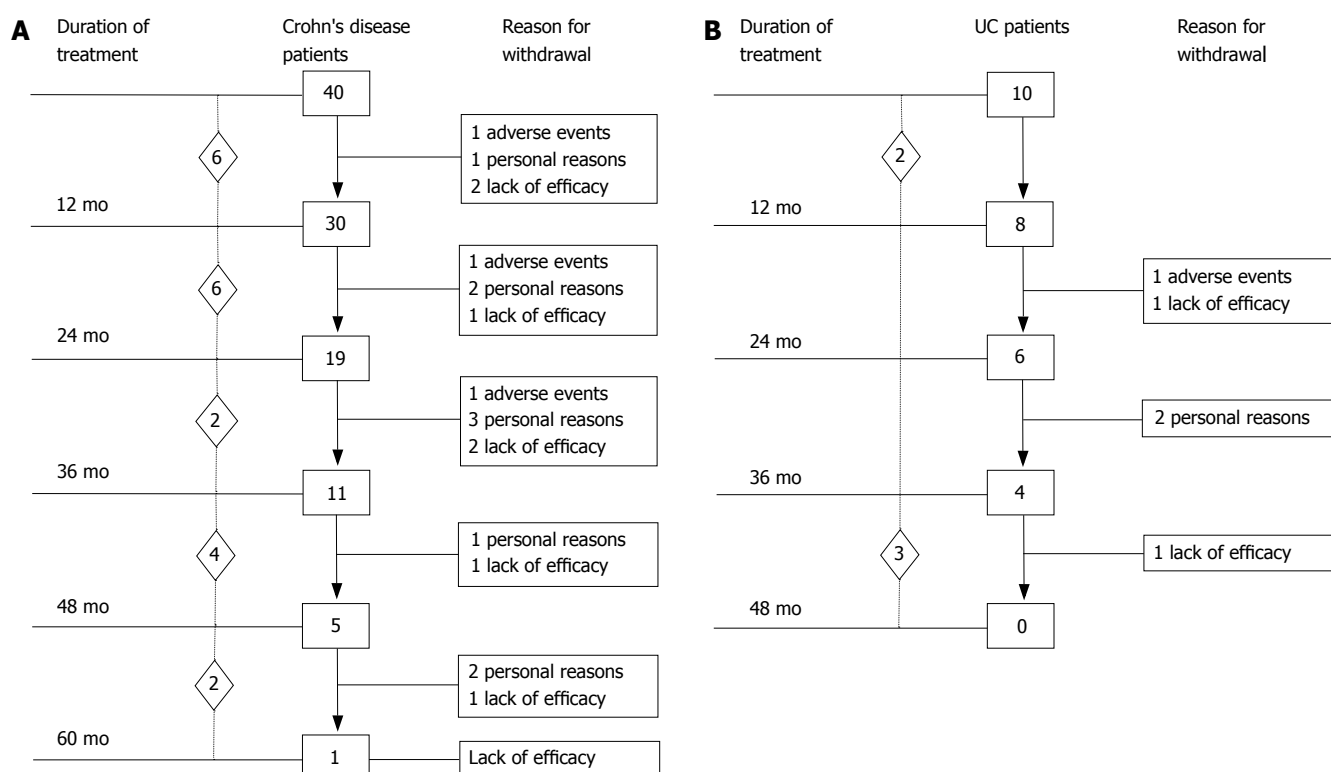

Figure 1 Patients observed at 12-mo intervals (endpoints) during IFX maintenance therapy. **A:** CD; **B:** UC. Numbers in boxes refer to patients reaching each endpoint. Numbers in rhombics refer to patients not reaching 12-mo endpoints.

Statistical analysis

Results related to continuous data are expressed as median (range). The cumulative probability of relapse was calculated using the Kaplan-Meier method.

RESULTS

Baseline demographic and clinical data of the 50 patients (40 CD, 10 UC) who underwent induction therapy followed by scheduled maintenance therapy every 8 wk are outlined in Table 1. The summary of IBD patients' outcome observed at 12-mo intervals (endpoints) during IFX

maintenance therapy is shown in Figure 1. A total of 637 IFX infusions were administered (493 in CD, 144 in UC). The median duration of scheduled IFX treatment in the whole group of IBD patients was 27 (range, 4-64) mo.

Crohn's disease patients

The 40 CD patients undergoing the maintenance treatment strategy had a median disease duration of 9.2 years (range, 0.3-22.2). At baseline, all patients presented luminal disease; 6 patients had also draining fistulas (4 perianal and 2 recto-vaginal fistulas). Median number of IFX infusions was 15 (range, 4-25). The median duration of IFX treatment was 27 (range, 4-64) mo. Of the 40 CD patients, 35 (87.5%) underwent scheduled infusion strategy every 8 wk. In 3 patients (7.5%), showing a progressive loss of response (i.e., increase in CDAI and serum CRP level), the dose intervals were reduced to 6 wk; in 2 patients (5%), on account of stable clinical remission, the infusion intervals were prolonged to 12 wk. In 29 out of 37 CD patients (78%) the initial clinical improvement remained unchanged during IFX scheduled treatment, with CDAI below the remission level (< 150) throughout the maintenance period (Table 2). The median duration of remission during IFX treatment was 25.5 (range, 4-59) mo. Of the 29 CD patients, the 9 (31%) who chose to discontinue IFX scheduled treatment, were still relapse-free at a median of 16 (range, 5-30) mo after the last infusion; all these patients were on concomitant immunomodulatory treatment; 2 CD patients were lost at follow-up. Twenty CD patients are currently on IFX treatment with a median duration of therapy of 20 (range, 5-57) mo. Of the 40 CD patients, 8 patients (20%) who showed worsening of clinical symp-

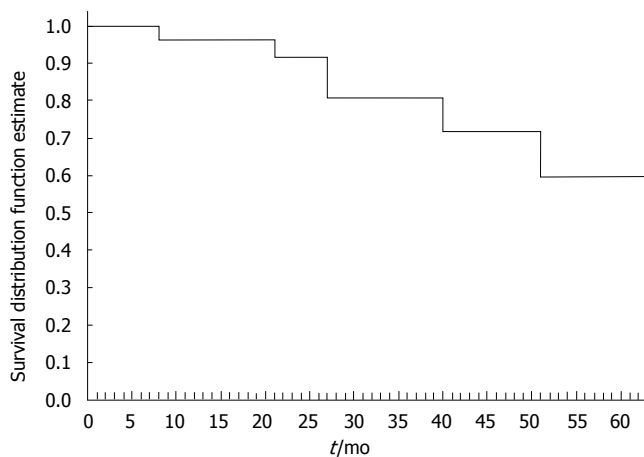

Figure 2 Kaplan-Meier survival curve for CD patients ($n = 40$). The cumulative probability of being free of relapse in CD patients with complete response was: 97.2% (CI: 91.8%-100%) at 12 mo, 90.3% (CI: 79.7%-100%) at 24 mo, 81.7% (CI: 66.9%-96.5%) at 36 mo, 73.5% (CI: 53.3%-93.7%) at 48 mo, and 61.3% (CI: 33.6%-88.9%) at 51 mo.

toms underwent surgery for intestinal strictures and/or abdominal abscesses. These patients presented with higher baseline values of acute phase reactants - in terms of serum ESR and CRP levels - compared to the patients not undergoing surgery. The difference was not significant. The cumulative probability curve of maintaining the initial response in those patients with clinical benefit at the third infusion is shown in Figure 2. The cumulative probability of being free of relapse in CD patients with complete response was: 97.2% (CI: 91.8-100%) at 12 mo, 90.3% (CI: 79.7-100) at 24 mo, 81.7% (CI: 66.9-96.5%) at 36 mo, 73.5% (CI: 53.3-93.7%) at 48 mo, and 61.3% (CI: 33.6-88.9%) at 51 mo. In this study, fistula closure was not considered as a goal of the clinical outcome.

Ulcerative colitis patients

Ten UC patients who underwent scheduled re-treatment every 8 wk as maintenance protocol had a median disease duration of 9.3 (range, 2-15) years (Table 2). The median number of IFX infusions was 14.5 (range, 6-22). Median duration of IFX treatment was 24.5 (range, 6-46) mo. In 9/10 (90%) UC patients, the CAI score remained below the remission level (< 4) throughout the maintenance period. The median duration of remission during IFX treatment was 25 (range, 6-46) mo. Of the 9 UC patients, 4 withdrew from scheduled treatment due to non compliance ($n = 2$) and to adverse events ($n = 2$) after a median time of 24.5 (range, 21-46) mo and were still relapse-free after a median time of 6.5 (range, 4-16) mo after the last IFX infusion; 3 of these patients were on concomitant immunomodulatory treatment. One UC patient, who showed a gradual loss of benefit, underwent surgery for flare up of the disease 24 mo after starting scheduled treatment. Five UC patients are currently on IFX therapy with a median duration of therapy of 36 (range, 6-39) mo. In patients who discontinued IFX treatment, endoscopic evaluation performed before withdrawal revealed complete mucosal healing in all cases.

Steroid-sparing effect

At baseline, 39 (78%) IBD patients were on steroid thera-

py; namely, 30/40 (75%) CD patients and 9 out of 10 (90%) UC patients required a median corticosteroid dose of 0.7 mg/kg per day. All patients were able to discontinue corticosteroids following IFX induction therapy, but 10/40 (25%) CD patients and 1/10 (10%) UC patients required reintroduction of steroid therapy during IFX scheduled treatment. Moreover, in patients who required concomitant steroid therapy, the median daily corticosteroid dose decreased to 0.25 mg/kg per day. The 10 CD and 4 UC patients, who discontinued scheduled treatment and remained relapse-free, did not require steroid therapy after the last IFX infusion.

Safety and infusion reactions

Of the 50 IBD patients, 16 (32%) experienced at least 1 adverse event: number and type of adverse events are listed in Table 3. Of the 50 IBD patients, 3 (6%) experienced moderate acute infusion reactions characterized by headache, dizziness, nausea, flushing, chest pain, dyspnoea, and pruritus, which developed after the second infusion. All 3 patients were successfully reinfused following intravenous hydrocortisone (200 mg) premedication before any subsequent IFX infusion. One patient presented serum sickness-like symptoms within 10 d of the third IFX infusion, developing arthralgias, myalgias, and fever; laboratory tests showed non-viral acute liver failure. The patient was treated with a high dose of iv corticosteroids and fully recovered after prolonged hospitalization. IFX treatment was discontinued in this patient.

Infections

Of the 50 IBD patients, 9 (18%) presented opportunistic infections during maintenance therapy. Six cases of viral infections occurred (5 herpes simplex virus and 1 varicella-zoster virus) in 5 CD patients and 1 UC patient had herpes simplex virus. Atypical pneumonia developed in 2 CD patients; full recovery was achieved in both patients following antibiotic therapy. All these patients were on concomitant immunomodulatory treatment which was withdrawn upon diagnosis. All infections developed within the first year of treatment and, in 3 patients, viral infections recurred during IFX maintenance treatment.

Malignant disorders

Three patients (6%) developed neoplasia during maintenance treatment (Table 4). Median time interval between the first infusion and diagnosis of neoplasia was 21 (range, 14-24) mo. Median number of IFX infusions was 10 (range, 6-13). Two patients with neoplasia were on concomitant immunomodulatory treatment (azathioprine). The histological types of neoplasia were gastric adenocarcinoma (T2aN0M0), which subsequently developed into peritoneal carcinomatosis and Krukenberg tumor, and endometrioid carcinoma (T1cN0M0), both in CD patients; breast cancer (T2mN3M0) developed in one UC patient.

Deaths

One CD patient, aged 68 years, who withdrew from the maintenance treatment protocol (9 infusions within 13 mo) because of complete disease remission, died of acute myocardial infarction 10 mo after the last IFX infusion. The patient did not present with any cardiovascular risk factors,

Table 3 Summary of IFX related adverse events

Adverse event	IBD (CD + UC)	Crohn's disease	Ulcerative colitis
Acute infusion reaction (%) (Mild, moderate, severe)	3/50 (6)	3/40 (7.5)	0
Delayed infusion reaction (%) (Serum sickness-like)	1/50 (2)	1/40 (2.5)	0
Opportunistic infection (%)	9/50 (18)	8/40 (20) 5 HSV 1 VZV 2 atypical pneumoniae	1/10 (10) 1 HSV
Lymphoproliferative diseases	0	0	0
Malignant disorder (%)	3/50 (6)	2/40 (5)	1/10 (10)

HSV: Herpes simplex virus; VZV: Varicella-zoster virus.

except for mild chronic renal failure, not requiring medical therapy and/or dialysis. The event was considered unrelated to IFX as it occurred 10 mo after the last infusion.

DISCUSSION

Despite the large amount of literature demonstrating the efficacy of IFX for the induction of remission in moderate to severe IBD, few data are available regarding the use of IFX for more than 12 mo or for more than 8 doses in IBD patients. Results of this retrospective study confirm current data on the efficacy of IFX in inducing a rapid clinical response in CD and support the finding, emerging from uncontrolled study data, of prolonged clinical efficacy in maintaining long-lasting remission beyond 1 year of treatment. While the efficacy of IFX therapy in the treatment of CD it is well established, only few studies have been performed on the use of IFX in UC. Järnerot *et al*^[16] found IFX to be an effective rescue therapy in patients experiencing an acute flare up of UC, leading to a significant reduction in the emergency colectomy rate. Moreover, Rutgeerts *et al*^[17] were the first to demonstrate that IFX can induce and maintain a clinical response and remission up to 54 wk of scheduled treatment in patients with moderately to severely active UC showing an inadequate response to conventional therapy. No data are yet available concerning the efficacy and safety of IFX treatment lasting for more than 1 year in UC. In our study population the median duration of IFX treatment was 27 mo in CD patients and 24.5 mo in UC patients, during which most of the patients (80 % of CD patients and 90% of UC patients) remained relapse free, following the clinical response or remission obtained with the induction treatment phase. It is worthwhile stressing that at enrolment, all these patients had active disease despite conventional therapy (or had a steroid-dependent disease). At baseline, considering all IBD patients, 58.5% were receiving 5-aminosalicylates, 78% corticosteroids, and 75.6% immunosuppressants. Moreover, compared to the 78% of patients on corticosteroids at baseline, only 25% needed concomitant corticosteroid therapy during IFX maintenance treatment, with a decreased median daily corticosteroid dose (0.7 mg/kg per day *vs* 0.25 mg/kg per day). The steroid-sparing effect of IFX was another important finding emerging from our study, which confirmed

the efficacy of a scheduled treatment regimen in avoiding the well-known morbidity associated with long-term corticosteroid therapy^[4,7].

Interestingly, long-term IFX therapy in IBD has been demonstrated to potentially modify the course of the disease. Indeed, 9 out of the 29 CD and 4 out of the 9 UC patients, who discontinued IFX scheduled treatment were still relapse-free after a median of 16 (range, 5-30) and 6.5 (range, 4-16) mo since the last IFX infusion, respectively. All these patients were off steroids and 12 were on immunosuppressants. Before stopping therapy, endoscopic evaluation was performed only in the subgroup of UC patients, showing complete mucosal healing in all. This result could account for the sustained clinical benefit maintained after withdrawal of treatment.

Long-term safety is an emerging and important issue as IFX use and indications are rapidly increasing worldwide. Recently, large retrospective studies have evaluated the incidence of serious adverse events and onset of neoplasia in CD patients treated with IFX^[18-24,27]. Colombel *et al*^[27], who studied 500 CD patients for a median of 17 (range, 0-48) mo with a median of 3 IFX infusions, reported the presence of 8.6% serious adverse events, 6.0% of which were considered possibly related to IFX therapy. In our study, 32% of IBD patients experienced at least 1 adverse event; 8% of the patients had an infusion reaction (3 patients experienced an acute infusion reaction and 1 a serum sickness-like disease). Moreover, in our study population, the incidence of opportunistic infections was 18%, which is higher than that observed in the study by Colombel *et al*^[27] (8.2%). This finding could be due both to the longer scheduled treatment protocol and the concomitant use of immunomodulatory treatment (AZA or 6-MP). Albeit, the long duration of scheduled treatment associated with the concomitant use of immunomodulators may give rise to the risk of opportunistic infections; regular maintenance therapy has been proven to reduce the number of infusion reactions with respect to episodic dosing, which is more immunogenic, as demonstrated by the results of the AC-CENT I trial^[11]. In fact, in the study by Hanauer *et al*^[11], the antibodies to IFX (ATI), which may be associated with decreased clinical response and increased risk of infusion reactions, were detected at higher rate in the episodic-

treated group (30%) compared to the maintenance strategy protocol (8%). Comparable results emerged from the studies by Baert *et al*^[19] and Farrell *et al*^[28], in which IFX was used episodically, thus demonstrating that the formation and concentrations of ATI were correlated with lower post-infusion serum IFX concentrations and with the need to shorten infusion intervals. Moreover, in patients who underwent bowel surgery after IFX withdrawal, no increase in the number of severe infections or surgical complications was observed in the perioperative period (data not shown).

An interesting finding emerging from our study, for which further investigation is necessary, concerns the relatively large number of malignancies (6%) observed in our IBD patients treated with IFX. In fact, the high incidence of solid tumors is somewhat inconsistent with the results reported so far. Biancone *et al*^[21], in their multi-centre case-controlled study, evaluated the risk of developing neoplasia in IFX-treated CD patients: the incidence of newly diagnosed neoplasia was comparable in the 2 groups of CD patients, treated (2.2%) or not treated (1.73%) with IFX. Colombel *et al*^[27], in a retrospective study found that 3 out of 500 of the CD patients treated with IFX had a malignant disorder, possibly related to biologic therapy. The fact that our study did not include a control group and consisted of a rather heterogeneous and relatively small population makes it difficult to establish a direct cause-effect relationship between anti-TNF- α therapy and the increased risk of developing malignancies. However, it should be pointed out that a slight difference was observed in terms of mean number of IFX infusions between patients who developed malignancies and those who did not (9.66 *vs* 14.6, respectively). This result would appear to suggest that there is no linear dose-dependent increase in risk.

Another important issue concerns the risk of hematologic malignancies related to the use of biologic therapies in IBD. It is well known that patients with long-standing IBD treated with immunomodulatory drugs may be more susceptible to developing lymphoproliferative disease^[29-32]. Even though the use of TNF- α blocking agents has been associated with an increased risk of developing lymphoma^[32], a finding, however, not confirmed by the data of a large US-based CD registry (TREAT)^[22], we did not observe any cases of hematologic malignancy in our study population.

The results from this study need to be interpreted with an understanding of both the strengths and limitations of retrospective analysis of prospectively collected data. Although it allowed us to have a long term follow-up, the patients could have not been monitored as rigorously as prospective, randomized controlled studies. In any event, these limitations are not relevant to the analysis of efficacy of IFX treatment in IBD and of serious infections reported in this setting.

In conclusion, IFX scheduled treatment has proven to be an effective strategy in our IBD patient population for long-term maintenance of clinical remission. The scrupulous selection of patients to be started on IFX therapy is a fundamental issue, not only to obtain maximum efficacy, but also to avoid serious adverse events. A note of caution is mandatory when considering the possible risk of malignancy associated with the use of anti-TNF- α therapy. Fur-

ther studies on larger series are needed to further clarify these important aspects.

COMMENTS

Background

For many years, corticosteroids have represented the cornerstone of therapy for induction of remission in inflammatory bowel disease (IBD); however, long-lasting remission was not achieved and the side-effects emerging with long-term use exceeded the clinical benefits. Immunomodulators have been demonstrated to be efficacious as adjunctive therapy and as steroid-sparing agents. The introduction of biological agents in the therapeutic armamentarium for Crohn's disease (CD) and ulcerative colitis (UC) has significantly changed the treatment strategies and outcomes of these patients.

Research frontiers

Despite the large amount of literature demonstrating the efficacy of infliximab (IFX) for the induction of remission in moderate to severe IBD, few data are available regarding the use of IFX for more than 12 mo or for more than 8 doses in IBD patients. Some safety issues are associated with IFX use, mostly related to the development of adverse events (e.g., opportunistic infections, autoimmune disorders, and infusion reactions). Major concerns are related to the reactivation of latent tuberculosis and development of malignancy, even if there is no clear evidence that the use of IFX increases the incidence of solid cancers.

Related publications

Colombel *et al*^[27] studied 500 CD patients for a median of 17 mo (range, 0-48) with a median of 3 IFX infusions and reported the presence of 8.6% serious adverse events, 6.0% of which were considered possibly related to IFX therapy. Hanauer *et al*^[11] found that the antibodies to IFX, which may be associated with decreased clinical response and increased risk of infusion reactions, were detected at higher rate in the episodic-treated group (30%) compared to the maintenance strategy protocol (8%). Comparable results emerged from the studies by Baert *et al*^[19] and Farrell. Biancone *et al*^[21], in their multi-centre case-controlled study, evaluated the risk of developing neoplasia in IFX-treated CD patients: the incidence of newly diagnosed neoplasia was comparable in the 2 groups of CD patients, treated (2.2%) or not treated (1.73%) with IFX.

Innovations and breakthroughs

IFX scheduled treatment has proven to be an effective strategy in our IBD patient population for long-term maintenance of clinical remission. The scrupulous selection of patients to be started on IFX therapy is a fundamental issue, not only to obtain maximum efficacy, but also to avoid serious adverse events.

Terminology

Infliximab is a chimeric monoclonal IgG1 antibody directed against TNF- α able to almost completely neutralize its biological activity. Crohn's Disease Activity Index was used to monitor Crohn's disease activity and the Clinical Activity Index was used for assessing UC activity.

Abstract

AIM: To determine the gastroesophageal refluxate in the cervical esophagus (CE) and measure transcutaneous cervical esophageal ultrasound (TCEUS) findings [anterior wall thickness (WT) of CE, esophageal luminal diameter (ELD), esophageal diameter (ED)]; to compare TCEUS findings in the patient subgroups divided according to 24-h esophageal pH monitoring and manometry; and to investigate possible cut-off values according to the TCEUS findings as a predictor of gastroesophageal reflux (GER).

METHODS: In 45/500 patients, refluxate was visualized in TCEUS. 38/45 patients underwent esophagogastroduodenoscopy (EGD), 24-h pH monitoring and manometry.

RESULTS: The 38 patients were grouped according to 24-h pH monitoring as follows: Group A: GER-positive ($n = 20$) [Includes Group B: isolated proximal reflux (PR) ($n = 6$), Group C: isolated distal reflux (DR) ($n = 6$), and Group D: both PR/DR ($n = 8$); Group E: no reflux ($n = 13$); and Group F: hypersensitive esophagus (HSE) ($n = 5$). Groups B + D indicated total PR patients ($n = 14$), Groups E + F reflux-negatives with HSE ($n = 18$), and Groups A + F reflux-positives with HSE ($n = 25$). When the 38 patients were grouped according to manometry findings, 24 had normal esophageal manometry; 7 had hypotensive and 2 had hypertensive lower esophageal sphincter (LES); and 5 had ineffective esophageal motility disorder (IEM). The ELD measurement was greater in group A + F than group E ($P = 0.023$, 5.0 ± 1.3 vs 3.9 ± 1.4 mm). In 27/38 patients, there was at least one pathologic acid reflux and/or pathologic manometry finding. The cut-off value for ELD of 4.83 mm had 79% sensitivity and 61% specificity in predicting the PR

between Groups B + D and E (AUC = 0.775, $P = 0.015$).

CONCLUSION: Visualizing refluxate in TCEUS was useful as a pre-diagnostic tool for estimating GER or manometric pathology in 71.1% of adults in our study, but it was not diagnostic for CE WT.

INTRODUCTION

Esophageal ultrasonography (US) is a non-invasive, readily available, repeatable, cheap, fast and highly sensitive technique^[1-4] in the diagnosis of gastroesophageal reflux (GER) in infants and children^[5-8]. The esophageal US studies in GER have mainly focused on the evaluation of the gastroesophageal junction (GEJ)^[9-11] and esophageal motility^[12-14]. These studies were performed by transabdominal or endoluminal routes. Although cervical US is a part of neck US, it has not been routinely used in infants and adults for diagnosis of GER^[9]. There are only a few studies about the transcutaneous cervical esophagus ultrasonography (TCEUS), but these were in normal^[15,16] and pathologic conditions^[17,18].

Intraluminal refluxate can be recognized by US images. Sonographic GER diagnosis was made by backward movement of gastric content into the esophagus and the visualization of the clearance of refluxate material^[15,19,20]. The visualization of GER episodes or gastroesophageal reflux disease (GERD) estimation in the GEJ region in US provided the background for our study. The aims of this study were to evaluate the possible pathologies in 24-h (h) pH monitoring and esophageal manometry in patients with refluxate in the lumen of the cervical esophagus

(CE) during TCEUS; to compare TCEUS findings in the patient subgroups divided according to 24-h esophageal monitoring and manometry; and to investigate possible cut-off values according to the TCEUS findings as a predictor of GER.

MATERIALS AND METHODS

Study design

Patient features: Five hundred patients (45.82 ± 14.15 years, 163 M/337 F) who were admitted to the outpatient clinic between the years from January 2006 to January 2007 with complaints other than of the gastrointestinal system underwent TCEUS. Refluxate material was found in the esophageal lumen in 45 (9%) of the 500 patients during TCEUS. Forty-five patients were questioned regarding GERD symptoms, and all had reflux symptoms.

Thirty-eight of the 45 patients underwent esophagogastroduodenoscopy (EGD), 24-h pH monitoring and esophageal manometry [7 patients were excluded as follows: pH monitoring not accepted ($n = 5$), nasal cannulation could not be performed due to nasal operation history ($n = 1$), inability to continue the 24-h pH monitoring/pH catheter extracted ($n = 1$)]. The period between the TCEUS and the pH monitoring was 1-3 d.

Patients had no history of weight loss, gastrointestinal bleeding, gastrointestinal motility disorder, pneumonic dilatation, collagen vascular disease, any operation around the cervical region, or gastrointestinal operation. None of the patients was taking medications known to affect esophageal motor function, including promotility agents, antacids, H₂ receptor antagonist, or proton-pump inhibitors (PPI); 3 patients had been taking PPI but they had been discontinued for two weeks before manometric investigation and 24-h pH monitoring.

Test techniques

Questionnaire for GERD: All patients were evaluated for typical (acid regurgitation and heartburn) and extraesophageal (hoarseness, asthma-like clinical presentation, nocturnal cough, and nocturnal wake-up) GERD symptoms.

Esophagogastroduodenoscopy (EGD): The procedure was performed by Pentax EG 2940 with 2% xylocaine topical anesthesia after a 12-h overnight fast. Reflux esophagitis was evaluated according to Los Angeles classification^[21]. The presence of hiatal hernia and the distance between GEJ and diaphragmatic impression were recorded.

TCEUS: Each patient was given an 800 kcal standard meal (15% protein, 50% carbohydrate, and 35% fat) and TCEUS was performed at postprandial 1-2 h with patient in supine position (Hitachi EUB, 6-13 MHz linear probe). TCEUS was performed as defined by Zhu and Mateen^[15,16]. The esophagus was demonstrated at thyroid cartilage level with the guidance of thyroid gland acoustic window up to the supraclavicular level to thoracic inlet (manubrium sterni) by linear probe in transverse and longitudinal sections without a pillow under the neck. CE was evaluated

by using a slightly flexed neck position with head turned 45° to the opposite side by left and right lateral approaches over 15 min to determine the presence of refluxate (the luminal anechoic fluid and/or linear bright stratifying small lines indicating gas in refluxate) and its to-and-fro movement, with the patients not swallowing^[15,20,22]. Then all patients were required to swallow and the clearance of refluxate was observed. The presence of comet-tail artifact (during swallowing, the presence of saliva mixed with air and downward movement of refluxate generated a strong echogenic appearance^[15,20,22]) was observed in patients. After the clearance of refluxate was observed, a few patients had backward flow of refluxate into the esophagus, which can perhaps be considered by the terminology "re-reflux"^[23].

Anterior wall thickness (WT) of the esophagus (distance between adventitia and the mucosa, with 5-7 esophageal wall layers), esophageal diameter (ED) [distance between the adventitia (outer to outer)], and esophageal luminal diameter (ELD) with or without refluxed material [distance between the mucosa (inner to inner)] were measured in longitudinal section at left lateral cervical approach. The GEJ was not evaluated during US in this study. The TCEUS appearance with or without refluxate is given in Figure 1.

Ambulatory 24-h pH monitoring: pH monitoring was performed using Synetics Digtrapper MHIII, and double-channel, 15 cm antimony catheter. The esophageal pH catheter was placed 5 cm above the upper border of the lower esophageal sphincter (LES). Findings were evaluated by Microsoft esophagram version 2.04. The pathologic measurements were evaluated as follows: Proximal reflux (PR): The upper esophageal sphincter (UES) localization was determined by manometry and PR was determined by the proximal probe localization and UES. If proximal probe was localized in the UES or above it, a single acid reflux synchronously occurring with distal probe was accepted as pathologic acid reflux; if the probe was localized under the UES, acid contact time above 1% of total time was accepted as pathologic in PR. De Meester score > 14.72 and acid contact greater than 4.0% of total time below pH 4 were accepted as pathologic in distal reflux (DR). Hypersensitive esophagus (HSE) was defined if symptom index (SI) for distal measurements (SI = number of symptoms in pH < 4/total number of symptoms) was $\geq 50\%$ while there was no measurable DR or PR^[23-25].

Esophageal manometry: Esophageal manometry was performed using MMS (ver. 8.4i Beta) and eight-channel Dent-sleeve catheter. After calibration, catheter was sent through the nose to the stomach and advanced 65 cm by swallowing. When all channels were in stomach, with patient in supine position, UES and LES were determined as the catheter was slowly withdrawn back into the esophagus. LES pressure (LESP), relaxation, esophageal body pressure, body contractions, contraction amplitudes and duration, peristalsis and upper esophageal contractions were recorded. Manometric findings were grouped as: normal, spastic (hypertensive LES, if LESP > 45 mmHg),

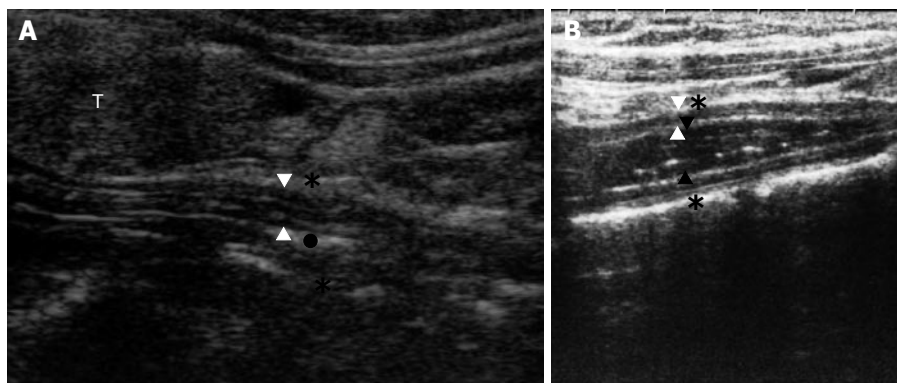

Figure 1 The TCEUS appearance with and without refluxate. **A:** A pattern showing no anechoic fluid in the lumen. Note anterior esophageal wall (distance between the open arrowheads), esophageal lumen without fluid inside and hyperechogenic bands representing collapsed lumen and mucosa (dark dot). T: thyroid; **B:** A pattern showing anechoic fluid in the lumen. Note esophageal wall (distance between the open arrowheads), refluxate in the esophageal lumen (distance between the dark arrowheads) and esophageal diameter (distance between the asterisks).

non-spastic [hypotensive LES, if $LESP < 10$ mmHg] or ineffective esophageal motor contractions (IEM), if contraction amplitude was < 25 mmHg in $> 30\%$ of wet swallows]^[26].

Statistical analysis

Descriptive and comparative statistical analyses were performed using statistical software system (SPSS v11.0). Where appropriate, average data were presented as mean \pm SD. Comparison between groups was performed by Kruskal Wallis analysis. All possible pair-wise comparisons were done by Mann-Whitney *U* test with Bonferroni correction. Fisher-Freeman-Halton test generalized at Fisher's exact test to $m \times n$ tables was used for categorical variables. The cut-off values were determined using receiver operating characteristic (ROC) curve for TCEUS parameters between all possible patient group pairs according to pH-metry and manometry to determine reflux or any pathologic manometry finding. The sensitivity and the specificity were determined according to the measured cut-off values. The significance of the area under curve (AUC) was tested ($P < 0.05$).

Investigators interpreting sonography, 24-h pH monitoring and esophageal manometry were blinded to the patients' features. None of the patients was sedated during EGD. All patients provided written informed consent and the study conformed to the guidelines of the Helsinki Declaration.

RESULTS

Forty-five (9%) of 500 patients who underwent TCEUS were found to have anechoic fluid and/or air echogenicities of refluxate in the cervical esophageal lumen. CE was not visualized clearly in 1 (0.2%) of the 500 patients due to neck anatomy.

Esophagitis (all grade A), hiatal hernia, antral gastritis, and grade 1 bulbitis were diagnosed in 10.7%, 10%, 14%, and 3%, respectively, in EGD. None of the patients had malignancy, or gastric or duodenal ulcer disease.

Thirty-eight patients were grouped according to 24-h pH monitoring as follows: Group A: Acid reflux-positive ($n = 20$, 52.7%) [includes Group B + Group C + Group D] [Group B: Isolated PR but no DR ($n = 6$, 15.8%); Group C: Isolated DR but no PR ($n = 6$, 15.8%); Group D: Both PR and DR ($n = 8$, 21.1%); Group E: No acid reflux ($n = 13$, 34.2%); and Group F: patients with hypersensitive

esophagus (HSE) ($n = 5$, 13.1%). Group B + D indicated total patients with PR ($n = 14$, 36.9%) and Group E + F: acid reflux-negatives with HSE ($n = 18$, 47.3%) and Group A + F: Acid reflux-positives with HSE ($n = 25$, 65.8%). The demographic and TCEUS findings of subjects grouped according to 24-h pH monitoring are given in Table 1.

When the 38 patients were grouped according to manometry findings, 24 (63.2%) patients had normal esophageal manometry; 7 (18.4%) had hypotensive and 2 (5.3%) had hypertensive LES; 5 (13.1%) had ineffective esophageal motility disorder (IEM). Demographic and TCEUS findings of subjects grouped according to manometric results are given in Table 2.

Patient symptoms are given in Table 3. None of the patients had complaints of dysphagia or asthma-like dyspnea.

Statistical analysis was performed between (1) 24-h pH monitoring subgroups, (2) esophageal manometry subgroups, and (3) categorized groups according to combined 24-h pH monitoring and esophageal manometry findings as acid reflux/abnormal, acid reflux/normal, no acid reflux/abnormal, and no acid reflux/normal with the following parameters: Age, sex, body mass index (BMI), LES localization defined during manometry, and TCEUS findings (WT, ED, ELD).

There were no significant differences in BMI, LES localization, and typical and extraesophageal symptoms between subjects grouped according to 24-h pH monitoring and according to esophageal manometric findings. There was no correlation between the TCEUS findings and sex or presence of hiatal hernia or esophagitis.

When 24-h pH monitoring subgroups were compared according to TCEUS findings, the ELD measurement was greater in group A + F than group E ($P = 0.023$). No significant differences were determined between the other subgroups when compared regarding TCEUS findings.

There was a positive significant correlation between ED and ELD ($r = 0.889$, $P = 0.000$) and ED and WT ($r = 0.499$, $P = 0.001$) (Pearson correlation analysis).

There were 2 patients with hypertensive LES. Excluding this group, when the nonspastic esophageal motor disorder group (hypotensive LES, IEM) was compared with the normal manometric group, there was no significant difference with regard to TCEUS findings and the LES localization between subgroups.

There was no significant difference according

to TCEUS findings when 24-h pH monitoring and esophageal manometry subgroups were evaluated together (Table 4). Table 5 shows the detailed 24-h pH monitoring and manometric findings. In 27/38 (71.1%) patients, there was at least an acidic reflux and/or pathologic manometry finding. 11/38 (28.9%) with refluxate in CE had no acid reflux and normal esophageal manometric findings.

We tried to find cut-off values in order to differentiate total GER, PR or the other reflux subgroups from the reflux-negatives and to differentiate each manometry subgroup according to TCEUS parameters. The groups which had significant cut-off values (AUC, *P* < 0.05) are

Table 4 Distribution of patients according to 24-h pH monitoring and manometric findings n (%)

	Manometric findings (abnormal)	Manometric findings (normal)
24-h pH monitoring (Acid reflux)	7 (18.4)	13 (34.3)
24-h pH monitoring (No acid reflux)	7 (18.4)	11 (28.9)

given in Table 6 with their sensitivity and specificity rates for ELD in determining reflux. The ROC curve is given in Figure 2 according to TCEUS findings in patients with total PR (group B + D) (*n* = 14) and in patients without reflux (group E) (*n* = 13).

DISCUSSION

The esophagus is a 23-24 cm muscular channel. The longitudinal scan of the esophagus shows a tubular structure with hypoechogenic muscular layer on the wall and one or two echogenic inner layer(s) representing the mucosa and the collapsed lumen of the esophagus^[3,10,15,16,20,22].

US evaluation is performed at four sites of the esophagus: GEJ^[4,9,27,28], thoracic esophagus^[22], CE^[15,16], and upper esophageal sphincter^[29].

Table 5 24-h pH monitoring and esophageal manometry results

PR + DR	2	2		4
PR				6
DR		3		3
Reflux negatives	3	2	1	7
HSE			1	4

IEM: Ineffective esophageal motility; Hypo LES: Hypotensive lower esophageal sphincter; Hyper LES: Hypertensive lower esophageal sphincter; PR: Proximal reflux; DR: Distal reflux; HSE: Hypersensitive esophagus.

Table 6 Cut-off values for esophageal luminal diameter (ELD) to determine acid reflux

Between groups	Cut off (mm)	AUC	P	Sensitivity (%)	Specificity (%)
Group B + D (total PR) (n = 14)/Group E (reflux negative) (n = 13)	4.83	0.775	0.015 ^a	79	61
Group B + D (total PR) (n = 14)/Group E + F (reflux negative with HSE) (n = 18)	4.95	0.708	0.046	71	77
Group A (n = 20)/Group E (reflux negative) (n = 13)	4.95	0.721	0.034	60	77

HSE: Hypersensitive esophagus; PR: Proximal reflux; AUC: Area under the curve. P values show significance of AUC (^aP < 0.05).

GERD arises from increased exposure and/or sensitivity of the esophageal mucosa to gastric contents^[30,31], and affects 5%-40% of the population^[32,33]. The content of refluxate can be isolated liquid (acid or non-acid nature), isolated gas, or gas/liquid mixture. 24-h pH monitoring and multichannel intraluminal impedance (MII) are the gold standard techniques to evaluate GER^[19,34,35].

US has been used in GERD since 1984^[36]. The GEJ was first described by Westra^[6] and Gomes^[1] during US by transabdominal route. The first-line use of esophageal GEJ US in GERD for infants and children was established by multiple studies^[2,4,6,37]. Sonographic sensitivity was 81%-94%^[3,4]. US provides a morphologic and functional approach. In infants and children, 24-h pH monitoring and esophageal US are the complementary techniques of choice^[2,4].

Zhu points out the importance of conventional US to evaluate the GEJ, but the use of the CE was defined to be restricted. Zhu defined the normal sonographic parameters of the CE (7.5-12 MHz transducer) transcutaneously^[15]. Mateen *et al* used a modified technique which differed from the normal neck US to evaluate the CE. Visualization failure of the right lateral two-thirds CE was decreased from 36% to 2% using this modified technique^[16]. In our study, use of this modified technique resulted in failed visualization in only 1 (0.2%) of 500 patients due to the deformed anatomy of the patient.

GERD was diagnosed in 26% of a healthy population of infants and children according to US^[3]. In our study, postprandial refluxate was seen in 45 of 500 (9%) adults.

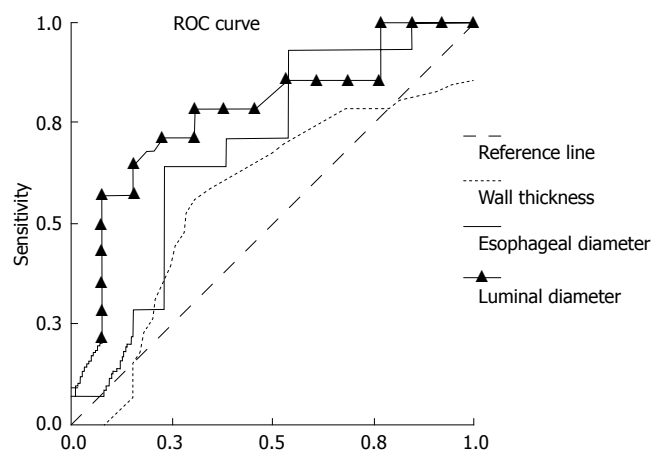

Figure 2 The ROC curve showing the relation between TCEUS findings according to total PR group (B + D) (n = 14) and reflux-negative group (E) (n = 13) (AUC = 0.775, P = 0.015 for ELD). PR: Isolated proximal reflux; ELD: Esophageal luminal diameter.

Furthermore, 20/38 (52.63%) of the patients who admitted to the hospital for other than gastrointestinal symptoms had refluxate in TCEUS and acidic reflux according to the 24-h pH monitoring. Since non-acid reflux was not evaluated, the 18 other patients were not evaluated in this respect.

Cool *et al*^[38] showed that respiratory and ear, nose and throat symptoms were especially related with gas reflux with weak acidity and not abnormal proximal acid reflux. We did not find any correlation in our study between proximal acid reflux, GER and any symptoms.

During the first hour after a meal, 20% more reflux episodes reach a higher proximal extent than during the fasting period and the late postprandial period (after 1 h). Acid reflux can reach 15 cm above the LES in approximately 6.8-21 s^[39,40]. We performed the sonography at the postprandial 1st-2nd h.

The content of liquid refluxate, whether acidic or not, did not affect the sonographic appearance^[41]. The new studies have pointed out that gas reflux with weak acidity is quite often determined in PR studies performed by pharyngeal impedance-pH recordings. Mixed reflux of gas and fluid is more frequent than pure fluid reflux^[39].

In the study of Mittal performed simultaneously with high frequency endoscopic US (HFEUS) and pH-metry, five US refluxate patterns were identified, as fluid, gas, first gas later fluid transition, first liquid later gas transition, or no luminal opening^[19]. In our study, we observed these patterns as fluid with or without gas and its to-and-fro movement during a period patients did not swallow. During swallowing, the comet-tail artifact was detectable in 42.8% of the cases^[15,19]. We observed it in approximately half of the patients. A few patients had reverse movement of refluxate to the esophagus after swallowing. This could be US documentation of a new terminology, "re-reflux"^[23].

Jang *et al* found no correlation between reflux number in 15 min counted during US and the reflux index in the 24-h pH monitoring. Sonographic reflux number was not considered as a specific indicator of disease severity^[2]. We did not count the reflux episodes in our study. Only one reflux episode in CE during US was included. Dickmann *et*

et al^[42] had shown that the acid reflux period below pH 4 was significantly lower when the distal pH probe was located 16 cm above the LES than 1, 6 or 11 cm above the LES in non-erosive reflux disease (NERD).

Transcutaneous CE WT has been reported as 2.3 ± 0.3 (1.3-4.1) mm in healthy adults^[15]. Mateen reported right-side thickness as 2.8 ± 0.4 mm (upper limit of normal, 3.6 mm) and left-side thickness as 2.9 ± 0.2 mm (upper limit of normal, 3.3 mm). We determined the left anterior WT as 2.29 ± 0.38 mm (1.57-4.0) in TCEUS (Table 1).

Dogan *et al*^[43] reported an increase in distal esophageal WT in conjunction with increasing age (1.56 ± 0.32 mm vs 1.29 ± 0.24 mm). In our study, we found no correlation between age, sex and TCEUS findings in subjects with refluxate.

Endosonographically, GEJ and 10 cm above thicknesses were given as 2.43 ± 0.16 and 2.28 ± 0.21 mm in healthy adults, respectively. The distal esophagus wall was thicker than the proximal^[28]. In reflux esophagitis, total esophageal WT and the smooth muscle layer were observed to be thicker than in normal subjects^[19,28,32]. Changchien measured normal GEJ WT as 3.8 ± 1.2 (2-5) mm using real time US. During acute severe inflammation in reflux esophagitis, the GEJ wall was observed as 7.6 ± 2.1 (5-10) mm, which was significantly thicker than normal^[9]. The submucosal healing due to lansoprazole in GERD was evaluated by US and the WT had decreased significantly in the GEJ region^[32,44]. We did not determine any significant difference in WT between patients with or without reflux according to 24-h pH monitoring. The distal esophageal WT increased with reflux according to the literature as described above, but we could not confirm this observation for the proximal esophagus in GER. Although HSE is a new terminology in the GERD spectrum, there was no significant difference between the HSE subgroup and the other subgroups with regard to CE WT.

Zhu reported normal transverse ED as 11.1 ± 1.6 (7.1-13.9) mm and anteroposterior diameter as 7.5 ± 1.2 mm (4.9-10.1)^[15]. Mateen measured the transverse diameter as 6.8 ± 2.7 mm (max 12.2)/ 10.7 ± 4.0 mm (18.7) and anteroposterior diameter as 6.5 ± 1.1 (max 8.7) mm/ 7.4 ± 1.5 (10.4) mm with right and left approaches, respectively, using the modified technique^[16]. We measured the cervical anteroposterior ED as 5.5-12.4 mm, and the ELD with refluxate was 1.5-7.9 mm in patients longitudinally (Tables 1 and 2). No significant differences were determined between proximal and total reflux patient groups and the other subgroups with regard to ED. ELD measurements with refluxate were statistically greater in group A + F than group E ($P = 0.023$). There was no difference between the other groups regarding ELD. Peak ED was given as 22 mm during physiologic swallows with 15 mL water^[19]. PR volume has not been accurately diagnosed to date, though esophageal continuous aspiration and scintigraphic studies have been used in an effort to obtain results about the reflux volume^[39]. In our study, the ED and ELD measurements may be an indirect indicator of reflux amount.

The distal esophageal distension and the cross-sectional area (CSA) are known to be wider than the proximal esophagus^[19]. Mittal reported that healthy asymptomatic

individuals had comparable esophageal diameter and CSA measurements according to spontaneous fluid GER and 5 mL swallow. It is difficult to differentiate between the ingested fluid and the refluxate of esophageal content. Mittal made the differentiation by looking at transient LES relaxations synchronously. In our study, our patients did not drink water during the TCEUS measurements. We measured the esophageal refluxate during a non-swallowing period. Our ED measurements (Table 1) were compatible with the 5 mL water intake in Mittal's studies^[19].

Mittal *et al* observed many reflux episodes determined by pH probe but not concomitant sonographic reflux by HFEUS. Similar observations were also made using impedance techniques. They concluded the gas-dominant or mixed reflux episodes could be the contributory factor^[19]. In our study, we did not perform TCEUS and the 24-h pH monitoring concurrently. This finding points out that US in GERD has some shortcomings. In contrast to this finding is the short reflux period which was determined by color Doppler (CD) US but not by pH monitoring^[45].

There was a positive significant correlation between ED and ELD ($r = 0.889$, $P = 0.000$) and ED and WT ($r = 0.499$, $P = 0.001$) (Pearson correlation analysis). The positive relation could be explained by presence of refluxate in the esophageal lumen. Although there was positive correlation between ED and WT, no significant difference was found between groups. This could be explained by the small patient groups.

Esophageal motor disorders can cause abnormal fluid or viscous bolus transit^[37,46]. Esophageal dysmotility can cause reflux esophagitis and reflux can cause esophageal dysmotility^[12,37]. Patients with normal esophageal motility, diffuse esophageal spasm (DES) and achalasia had 35%, 67%, and 100% abnormal fluid or viscous bolus transit, respectively^[37]. The possible manometric disorders that could be responsible for the PR were also evaluated in our study. We did not observe any patients with achalasia, DES or nutcracker esophagus. The manometric abnormality prevalence in patients with cervical refluxate during TCEUS was 36.84% (14/38 patients) [5 (13.16%) IEM, 7 (18.4%) hypotensive LES, 2 (5.4%) hypertensive LES] (Table 2).

There is a gradual increase in muscle thickness, thickening of the muscularis propria and increase in CSA from the proximal to distal esophagus in primary spastic esophageal motor disorders like achalasia, DES, nutcracker esophagus, hypertensive LES, and atypical LES relaxation, and in non-spastic esophageal motor disorders like hypotensive LES, IEM, and incomplete LES relaxation^[12,15,37,41]. WT according to disorder was achalasia > DES > nutcracker esophagus^[19,41,43]. The normal basal esophageal WTs at 2 cm and 10 cm above the GEJ were measured as 1.45 ± 0.31 mm and 1.24 ± 0.23 mm, respectively, by Dogan *et al*. The corresponding abnormal values were 2.08 mm and 1.71 mm^[43].

We found no difference in anterior CE WT in patient subgroups divided according to esophageal manometry. In our study, the esophageal measurements were taken at the thyroid gland level, while corresponding values in the literature were measured at the GEJ or 2 or 10 cm above

the GEJ. IEM is characterized by low amplitude esophageal contractions, which could cause ineffective acid clearance and aid the reflux pathogenesis^[37]. In our study, 7 of 14 (50%) patients with abnormal esophageal manometry had acid reflux (3 had DR and 4 had both PR and DR) in 24-h pH monitoring. Two of 5 patients who had IEM disorder, 5 of 7 patients with hypotensive LES and 0 of 2 patients with hypertensive LES had reflux (Table 5). The PR rate was higher than DR rate (70%, 30%) in group A. None of the patients with isolated PR had manometric impairment. Twenty-seven patients (71.1%) had at least one pathology in pH monitoring (acid reflux) and/or manometry. We did not observe any pathology which could cause impairment in esophageal transit in 11 of 38 patients (28.9%). Since we did not investigate non-acid reflux, the probable reflux patterns in these 11 patients are unknown.

We aimed to determine the possible cut-off values for TCEUS findings in patients with refluxate as a predictor of GER or pathologic manometry finding. ELD but not WT and ED showed cut-off values (AUC, $P < 0.05$). ELD (with refluxate) of 4.95 mm had 71% sensitivity and 77% specificity in the estimation of total PR patients (Table 6).

The fact that 24-h pH monitoring and manometry were not performed in subjects without refluxate during TCEUS is a limitation of this study.

Esophageal refluxed material can be recognized in ultrasonographic images. TCEUS can not substitute for 24-h pH monitoring or esophageal manometry, but it can serve as a complementary technique by aiding in the estimation of proximal reflux, GER and motility disorders which could cause impairment in bolus transit.

To our knowledge, there is no study in the available literature showing refluxate presence in the cervical esophageal lumen and measuring the TCEUS parameters at the thyroid gland level transcutaneously while correlating pH monitoring and esophageal manometry findings in adults.

ACKNOWLEDGMENTS

We express our thanks to Eylul Ozturk and Mahmut Kacar for their guidance and help.

COMMENTS

Background

Esophageal refluxed material can be recognized in ultrasonographic images. The content of refluxate can be isolated liquid (acid or non-acid nature), isolated gas, or gas/liquid mixture. The content of liquid refluxate, whether acidic or not, did not affect the sonographic appearance. Liquid can be present in the esophageal lumen in gastroesophageal reflux (GER) and esophageal motility disorders. Esophageal ultrasonography is currently being used to evaluate the gastroesophageal junction by transabdominal route, especially in newborns and children, and endosonographic studies have been used especially for motility disorders. The relation between the presence of refluxate in the cervical esophageal lumen and the esophageal pH-metry/manometry findings using transcervical esophageal ultrasonography (TCEUS) has not been studied previously in children and adults.

Research frontiers

We evaluated the possible pathologies in 24-h pH monitoring and esophageal manometry in patients with refluxate in the lumen of the cervical esophagus during TCEUS. In 27/38 (71.1%) patients with refluxate in TCEUS, there was at least one pathologic acid reflux and/or pathologic manometry finding. 24 h pH-metry

and esophageal manometry subgroups were compared statistically according to TCEUS findings [anterior wall thickness (WT) of the esophagus, esophageal diameter (ED), esophageal luminal diameter (ELD)].

Innovations and breakthroughs

Our study is distinct from other studies evaluating the GER and esophageal manometry pathologies with ultrasonographic methods due to our usage of TCEUS. We performed esophageal manometry and 24-h pH monitoring in patients with refluxate in the esophageal lumen. The shortcomings of the study were that 1) we did not perform manometry or pH monitoring in patients without refluxate and 2) we did not evaluate the non-acid reflux.

Applications

Different patient groups and volunteers without refluxate can be evaluated for different study designs.

Terminology

The presence of refluxate in esophageal lumen in TCEUS: The luminal anechoic fluid and/or linear bright stratifying small lines indicating gas in refluxate with the patients not swallowing; The presence of comet-tail artifact: During swallowing, the presence of saliva mixed with air and downward movement of refluxate generated a strong echogenic appearance; TCEUS parameters: Wall thickness (WT) of the esophagus: Distance between adventitia and the mucosa, with 5-7 esophageal wall layers; Esophageal diameter (ED): Distance between the adventitia (outer to outer); Esophageal luminal diameter (ELD) with or without refluxate: Distance between the mucosa (inner to inner).

Peer review

The authors studied transcutaneous cervical esophageal ultrasound (TCEUS) as a possible diagnostic procedure in gastroesophageal reflux. TCEUS has been forgotten in the diagnosis of esophageal diseases, however, it is a non-invasive, available and high sensitive technique. This manuscript is in principle an interesting topic for the readers of World Journal of Gastroenterology.

Abstract

AIM: To evaluate the effectiveness and safety of early nasogastric enteral nutrition (NGEN) for patients with severe acute pancreatitis (SAP).

METHODS: We searched Cochrane Central Register of Controlled Trials (Issue 2, 2006), Pub-Medline (1966-2006), and references from relevant articles. We included randomized controlled trials (RCTs) only, which reported the mortality of SAP patients at least. Two reviewers assessed the quality of each trial and collected data independently. The Cochrane Collaboration's RevMan 4.2.9 software was used for statistical analysis.

RESULTS: Three RCTs were included, involving 131 patients. The baselines of each trial were comparable. Meta-analysis showed no significant differences in mortality rate of SAP patients between nasogastric and conventional routes (RR = 0.76, 95% CI = 0.37 and 1.55, $P = 0.45$), and in other outcomes, including time of hospital stay (weighted mean difference = -5.87, 95% CI = -20.58 and 8.84, $P = 0.43$), complication rate of infection (RR = 1.41, 95% CI = 0.62 and 3.23, $P = 0.41$) or multiple organ deficiency syndrome (RR = 0.97, 95% CI = 0.27 and 3.47, $P = 0.97$), rate of admission to ICU (RR = 1.00, 95% CI = 0.48 and 2.09, $P = 0.99$) or conversion to surgery (RR = 0.66, 95% CI = 0.12 and 3.69, $P = 0.64$), as well as recurrence of re-feeding pain and adverse events associated with nutrition.

CONCLUSION: Early NGEN is a breakthrough in the management of SAP. Based on current studies, early NGEN appears effective and safe. Since the available evidence is poor in quantity, it is hard to make an accurate evaluation of the role of early NGEN in SAP.

INTRODUCTION

Acute pancreatitis (AP) is one of the most common pancreatic diseases, with an incidence rate of 4.9-80/100 000 per year, and there was a trend to increase during the past two decades^[1]. Around 80% of patients with mild acute pancreatitis (MAP) are treatable with a short period of bowel rest, simple intravenous hydration, and analgesia^[1,2]. However, severe acute pancreatitis (SAP) is complicated by systemic inflammatory response syndrome (SIRS), leading to hypermetabolism and high protein catabolism^[3]. Consequently, nutritional stores are rapidly consumed and about 30% of patients with SAP undergo malnutrition^[3,4]. Acute malnutrition is expected to increase morbidity and mortality due to impaired immune function, increased risk of sepsis, poor wound healing, and multiple organ failure^[3]. Thus, current therapy for AP has shifted to intensive medical care, nutrition support, infection control and medicine administration, while early invasive intervention as surgery has been reserved for defined clinical indication^[5,6]. Nutritional management for AP is an important issue and regarded as an indispensable approach.

Oral or enteral feeding may be harmful in AP and is thought to stimulate exocrine pancreatic secretion and consequently autodigestive process^[4]. Up to the mid 1990s, total parenteral nutrition (TPN) and gastrointestinal tract rest have been comprehensively recommended in the acute phase of pancreatitis, which make pancreas at rest to reduce pancreatic exocrine secretion and also meet nutritional need^[6,7]. Intestinal mucosa atrophies during fasting as TPN phase, which would induce bacteria translocation in gastrointestinal tract and cause pancreatic necrotic tissue infection^[8]. Animal experiments and several human studies

have shown that enteral nutrition (EN) is safe and can preserve the integrity of intestinal mucosa to decrease the incidence of infectious complications and other severe complications, such as multiple organ deficiency syndrome (MODS)^[8-10]. Furthermore, EN does not stimulate pancreatic exocrine secretion, if the feeding tube is positioned in the jejunum by nasojejunal or jejunostomy routes^[8,11]. Therefore, TPN or jejunal EN is considered the mainstream of nutritional support for AP.

Recently, some researchers have considered the feasibility of EN through nasogastric (NG) tube to improve the nutrition status of patients with AP in the early phase^[7,12]. However, this breakthrough is potentially opposing to the requirement of pancreatic rest in the acute inflammation phase. The present study was to confirm whether nasogastric EN is safe and effective for patients with AP.

MATERIALS AND METHODS

Search strategy and update

We searched electronic databases of Cochrane Central Register of Controlled Trials (Issue 2, 2006), Pub-Medline (1966-2006), and references from relevant articles. The search strategy used was "Enteral Nutrition" (MeSH) AND ["Pancreatitis" (MeSH) OR "Pancreatitis, Acute Necrotizing" (MeSH)], with limitations to Randomized Controlled Trial, Humans. There was no limitation of publication language. This systematic review will be updated if more randomized controlled trials (RCTs) can be found through the monthly automatic search procedure from National Center for Biotechnology Information (NCBI) at the National Library of Medicine.

Inclusion and exclusion criteria

Only randomized controlled trials were eligible. Eligible patients include those who diagnosed as acute pancreatitis by Atlanta classification, and those with severe diseases assessed by APACHE II criteria, and/or Ranson criteria, and/or Balthazar computer tomography criteria. Any etiology was eligible, and there was no limitation of age, race, and sex distribution. Comparator intervention was considered an early enteral nutritional route through nasogastric tube (NGEN), while control intervention was considered one of the conventional pancreatic-rest nutritional support routes, such as total parenteral nutrition (TPN) or enteral nutrition by nasojejunal tube (NJEN) or jejunostomy tube (JSEN). Additionally, other combined treatments included gastrointestinal decompression, prophylactic antibiotics, fluid management, artificial ventilation or renal replacement therapy for MODS, endoscopic retrograde cholangiopancreatography with endoscopic sphincterotomy for selected biliary patients, and surgery for indicated patients. The primary outcome measure of effectiveness was overall mortality, the secondary outcome measures of effectiveness was hospital stay, complications and their management, while the outcome measures of safety included re-feeding pain recurrence and adverse events related to nasogastric enteral nutrition.

Quality assessment and data collection

To evaluate the methodological quality of included studies,

two reviewers (Jiang K and Chen XZ) assessed the quality of methods used in studies independently. According to the Cochrane Handbook for Systematic Review 4.2.6^[13], we assessed the quality of RCTs using random allocation concealment as adequate (A), unclear (B), inadequate (C), or not used (D); blinding process as double blind (A), single blind (B), unclear (C) or not used (D); intention-to-treat (ITT) as yes (A), unclear (B), or not used (C), or loss, withdrawal, dropout, cross-intervention not reported (D). The criteria proposed by Jadad *et al*^[14] were also used to evaluate the quality of trials.

Data were collected by the two reviewers independently, including study sample (number of each arm), interventions (nutrition management, approach and regimens) and outcomes (overall mortality, time of hospital stay, complications of systematic or local infection, or MODS defined as failure in no less than 2 organs, re-feeding pain defined as pain requiring discontinuation of feeding, elevated serum amylase levels at least two-fold higher than normal^[7], and adverse events related to nutrition), as well as the publication year and country of studies, and the number of withdrawals and dropouts and the reasons.

Any disagreement in quality assessment and data collection was discussed and solved by a third reviewer as the referee.

Statistical analysis

Meta-analysis was performed with the Cochrane Collaboration's RevMan 4.2.9 software. All *P*-values were two-sided and *P* < 0.05 was considered statistically significant. For dichotomous variables, the risk ratio (RR) was calculated with 95% confidence intervals (CI); for continuous variables, weighted mean difference (WMD) was calculated with 95% confidence intervals. Heterogeneity was determined by chi-square test. If any heterogeneity existed, the following techniques were employed to explain it: (1) random effect model, (2) subgroup analysis including different control arms as TPN or EN through nasojejunal or jejunostomy tube, (3) sensitivity analysis performed by excluding the trials which potentially biased the results. Any patients randomly assigned in each trial, but not analyzed in the present meta-analysis, were calculated.

RESULTS

Three RCTs^[15-17] were eligible for the inclusion criteria, and 131 participants were included. Of them, 67 were randomly assigned to NGEN group and 64 to conventional nutritional route group. Conventional routes included TPN and NJEN, but not JSEN. The mean number of samples for each trial was 43.7 (31-50). The baselines of each trial were comparable. The details of included trials are listed in Table 1, and the results of quality assessment in Table 2.

Effectiveness

Overall mortality: Three included RCTs reported the mortality. The overall mortality rate of early NGEN group and conventional route group was 14.9% (10/67) and 18.8% (12/64) respectively, which is consistent with the reported rate^[18]. No heterogeneity was detected (*P* =

Table 1 Details of included RCTs

Reference	Yr	Country	Number of intervention/control	Inclusion/exclusion criteria of participants	Drop-out/withdrawal
[15]	2005	Scotland	27 (NGEN)/23 (NJEN)	Inclusion: both a clinical and biochemical presentation of AP (abdominal pain and serum amylase at least 3 times the upper limit of the reference range), and objective evidence of disease severity (Glasgow prognostic score ≥ 3 , or APACHE II ≥ 6 , or CRP > 150 mg/L). Exclusion: patients under 18 yr of age and pregnant females. Inclusion: severity was defined according to the Atlanta criteria (ie, presence of organ failure and APACHE score of ≥ 8 or CT severity score ≥ 7).	One excluded in NJEN group for misdiagnosed and 2 in NJEN group received NGEN for failure of NJ tube placement.
[16]	2006	India	16 (NGEN)/15 (NJEN)	Exclusion: if there was a delay of more than 4 wk between the onset of symptoms and presentation to the hospital, if they were already taking oral feeding at presentation, if there was acute exacerbation of chronic pancreatitis, or if they were in shock (ie, systolic blood pressure < 90 mmHg at the time of randomization).	One excluded in NJEN group for failure of NJ tube placement.
[17]	2006	Sweden	24 (NGEN)/26 (TPN)	Inclusion: abdominal pain, amylase ≥ 3 times upper limit of normal, onset of abdominal pain within 48 h, APACHE II score ≥ 8 and/or CRP ≥ 150 mg/L and/or peripancreatic liquid shown on CT. Exclusion: AP due to surgery, inflammatory bowel disease, stoma, short bowel, chronic pancreatitis with exacerbation, and patients under 18 yr of age.	One patient from each group was considered as protocol violators due to surgery performed after study inclusion on d 2 in 1 case, and a dislocated tube not accepted to be replaced in the other one

¹According to the Cochrane Handbook for Systematic Review 4.2.6^[13].

0.61). Meta-analysis showed no significant difference in overall mortality between early NGEN and conventional route groups (RR = 0.76, 95% CI = 0.37 and 1.55, $P = 0.45$) (Figure 1). Sub-group analysis showed no significant difference in overall mortality between NGEN and NJEN groups^[15,16] (RR = 0.67, 95% CI = 0.32 and 1.40, $P = 0.28$), as well as between NGEN and TPN groups^[17] (RR = 3.24, 95% CI = 0.14 and 75.91, $P = 0.47$).

Hospital stay: All the included RCTs reported the mean time of total hospital stay, but 2 trials did not mentioned the standard difference (SD)^[15,17], and were excluded from the meta-analysis. There was no significant difference in the mean time of total hospital stay between NGEN and NJEN groups (WMD = -5.87, 95% CI = -20.58 and 8.84, $P = 0.43$) (Figure 2). The weighted mean time of hospital stay of patients in early NGEN and conventional route groups was 15.4 d and 15.3 d, respectively.

Complications and management: Two RCTs reported

the detailed data on infective complications or MODS^[16,17]. The results of meta-analysis showed no significant difference in infective complications, such as sepsis and infected pancreatic necrosis (RR = 1.41, 95% CI = 0.62 and 3.23, $P = 0.41$) (Figure 3), as well as in heterogeneity ($P = 0.15$). There was no significant difference in MODS (RR = 0.97, 95% CI = 0.27 and 3.47, $P = 0.97$) (Figure 3), as well as in heterogeneity ($P = 0.93$). The rate for admission to intensive care unit was reported in 2 RCTs^[15,17], which was 21.6% (11/51) and 20.4% (10/49) in early NGEN and conventional groups respectively (RR = 1.00, 95% CI = 0.48 and 2.09, $P = 0.99$) (Figure 4). Two trials^[16,17] reported that the rate for surgery was 5.0% (2/40) and 7.3% (3/41) in early NGEN and conventional route groups, respectively with no significant difference between the two groups (RR = 0.66, 95% CI = 0.12 and 3.69, $P = 0.64$) (Figure 4).

Safety

Re-feeding pain recurrence: Two RCTs^[16,17] reported the cases needing to withdraw oral feeding due to recurrent re-feeding pain. Meta-analysis showed no significant difference in the recurrent re-feeding pain (RR = 0.94, 95% CI = 0.06 and 13.68, $P = 0.96$) (Figure 5). The pain recurrence rate was 2.5% (1/40) and 2.4% (1/41) in NGEN and conventional route groups, respectively.

Adverse events associated with nutrition: Meta-analysis showed that the main adverse events associated with nutrition support were diarrhea (RR = 1.59, 95% CI = 0.51 and 4.91, $P = 0.42$), tube displacement (RR = 0.45, 95% CI = 0.09 and 2.30, $P = 0.33$), and withdrawal of feeding due to severe complications (RR = 0.30, 95% CI = 0.03 and 2.76, $P = 0.29$) (Figure 6). Other nutrition-associated complications were found in patients of the NJEN group

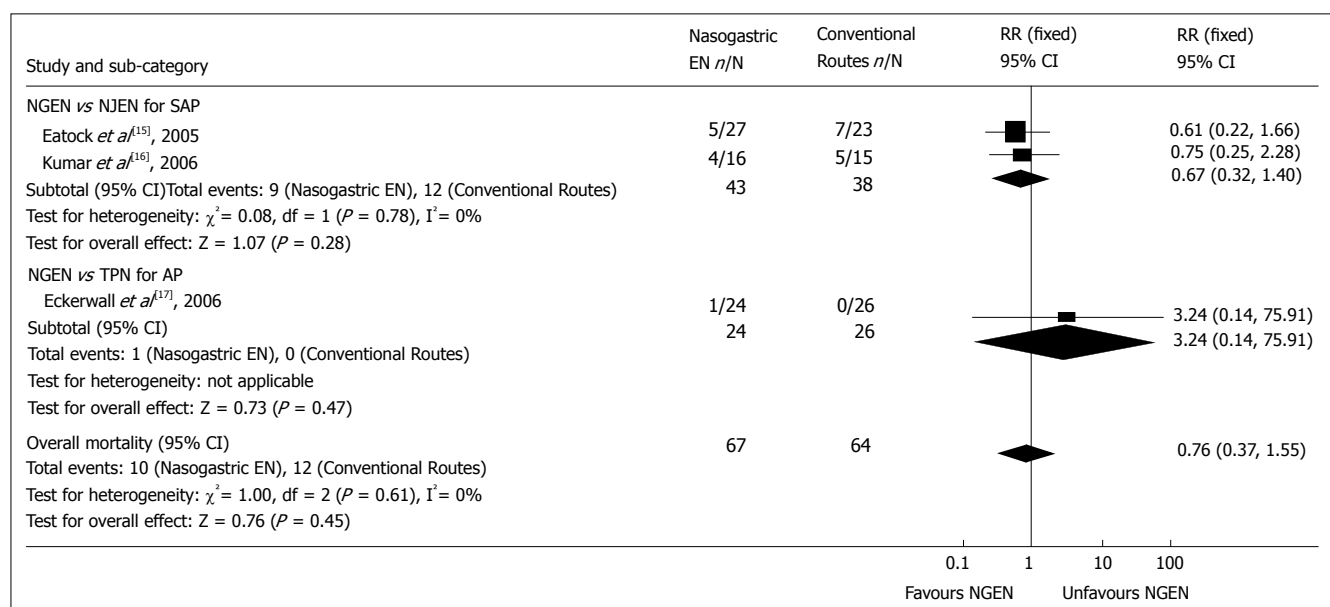

Figure 1 Comparison of overall mortality between nasogastric enteral nutrition and conventional nutritional routes. Abbreviations: AP, acute pancreatitis; SAP, severe acute pancreatitis; EN, enteral nutrition; TPN, total parenteral nutrition; NGEN, nasogastric enteral nutrition; NJEN, nasojejunal enteral nutrition; RR, risk ratio; CI, confidence interval.

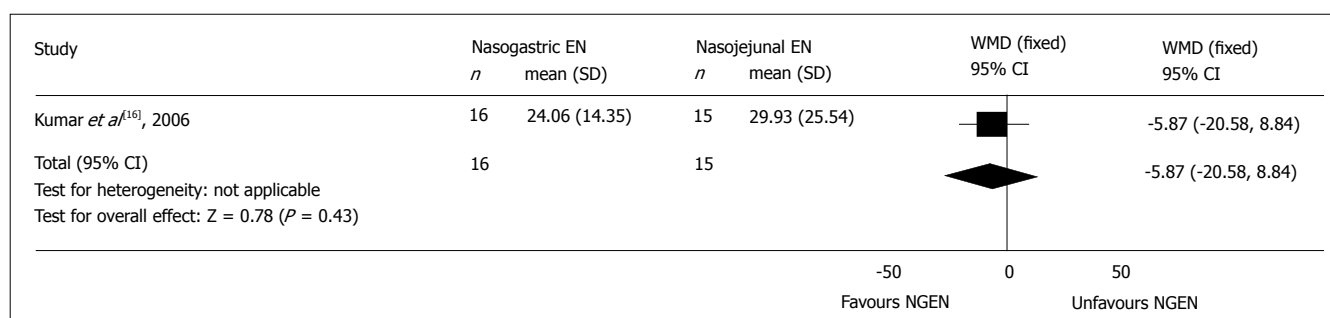

Figure 2 Comparison of total hospital stay (days) between nasogastric and nasojejunal enteral nutrition. WMD, weighted mean difference; SD, standard deviation.

who suffered from cardiorespiratory arrest at the moment of endoscopic tube placement which were successfully resuscitated^[14] and in patients of the NJEN group with sweating and palpitation^[15].

DISCUSSION

The present systematic review was intended to find the feasibility and safety of early nasogastric enteral nutrition in the management of severe acute pancreatitis. We selected 3 randomized controlled trials involving comparison between early NGEN and NJEN or TPN. The total number of samples was limited. All the trials did not perform a blinding process due to the nature of interventions. Two trials reported detailed randomization assignment methods^[15,16], and two were put into practice based on allocation concealment and intention-to-treat method^[15,17]. Sensitivity analysis showed negative results. Potential biases of the present systematic review included selection bias due to the severity criteria of one trial (Eatock 2005)^[15] set at APACHE II > 6, on an international symposium^[19]. Moreover, another concern is the high

mortality (24.5%) in patients with the severity of the illness^[20].

Treatment of SAP has been evolving from routine early aggressive surgical management towards conservative care for patients without evidence of pancreatic infection^[21,22]. However, SAP remains a disease with a poor prognosis^[23]. Artificial nutrition can prevent and provide a long term nutritional support for SAP^[24]. Enteral nutrition is preferred to parenteral nutrition for improving patient outcomes^[25,26], and has largely replaced the parenteral route^[27]. However, early nasogastric enteral nutrition is regarded as a potentially pancreatic-unrest nutritional support route, which is harmful to the early acute phase of AP^[15]. Eatock *et al*^[12] first introduced the early nasogastric feeding into nutritional management of SAP, and then Pandey *et al*^[7] applied oral re-feeding in patients with SAP, suggesting that the nasogastric feeding is feasible in up to 80% cases^[15].

The present meta-analysis showed that early NGEN would be as effective and safe as early NJEN or TPN in SAP patients, without increase in mortality. Pancreatic infection, sepsis, and MODS are the complications

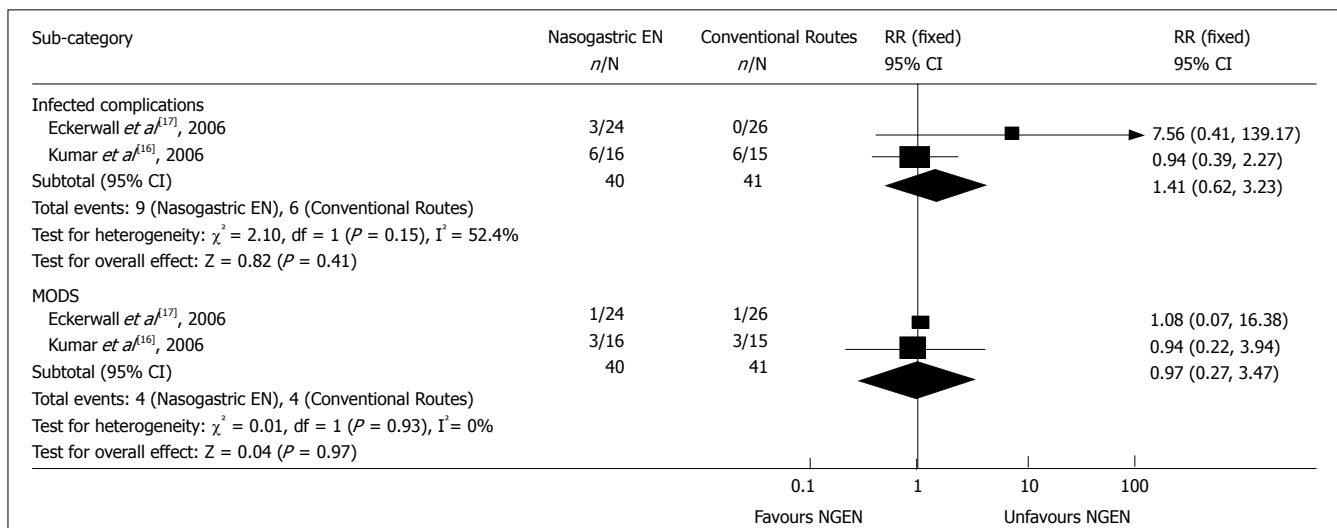

Figure 3 Comparison of complications of acute pancreatitis between nasogastric enteral nutrition and conventional nutritional routes. MODS, multiple organ deficiency syndrome.

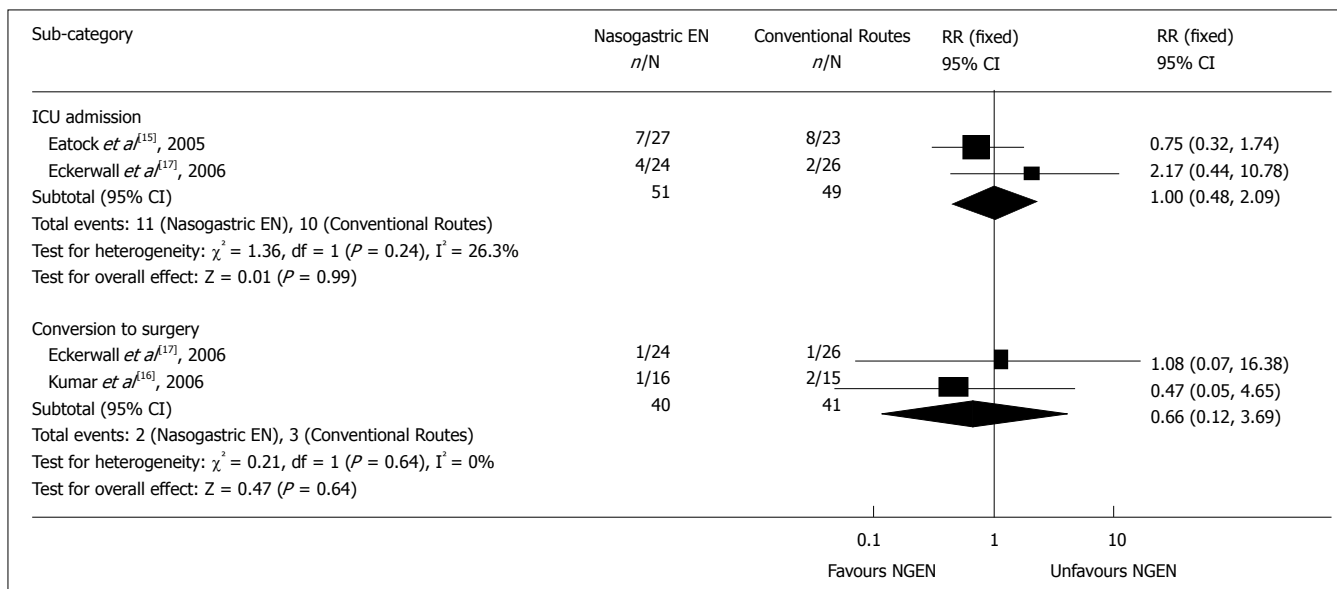

Figure 4 Comparison of management of complications between nasogastric enteral nutrition and conventional nutritional routes. ICU, intensive care unit.

of SAP^[28]. Duration of organ failure during the first week of predicted severe acute pancreatitis is strongly associated with the risk of death or local complications^[29]. Besides, NGEN did not increase severe complications and prolong hospital stay. Bacterial infection is the common complication of acute pancreatitis, and bacterial translocation from the gut is probably the first step in the pathogenesis of these infections^[30]. NGEN could preserve the intestinal permeability including duodenum, proved by the assessment of excretion of polyethylene glycol and antiendotoxin core antibody IgM levels^[17], which would be the best barrier for prevention of certain complications. Interleukin-6 serum levels are elevated very early in patients with necrosis infection^[31], and C-reactive protein (CRP) is considered a valuable independent predictor of mortality^[32]. IL-6 and CRP levels play a similar role in the control of systematic inflammatory response of early

NGEN and TPN groups at each time point^[17]. Moreover, biochemical nutritional parameters, such as serum albumin and prealbumin concentration in early NGEN and NJEN groups, are both well preserved without any significant difference^[16].

After three-month follow-up, about 92% patients in the early NGEN group have no symptoms related to SAP, compared with 82% patients in the TPN group, but all pseudocysts occur in the early NGEN group^[17], suggesting that early nasogastric enteral nutrition is potentially feasible in SAP patients. The clinical outcomes are quite similar to conventional routes, such as early nasojejunal or total parenteral nutrition. However, the incidence of late complications such as pseudocysts is likely higher in early nasogastric enteral nutrition group.

Enteral nutrition has no benefit to the mild acute pancreatitis subset^[24]. However, oral re-feeding is feasible,

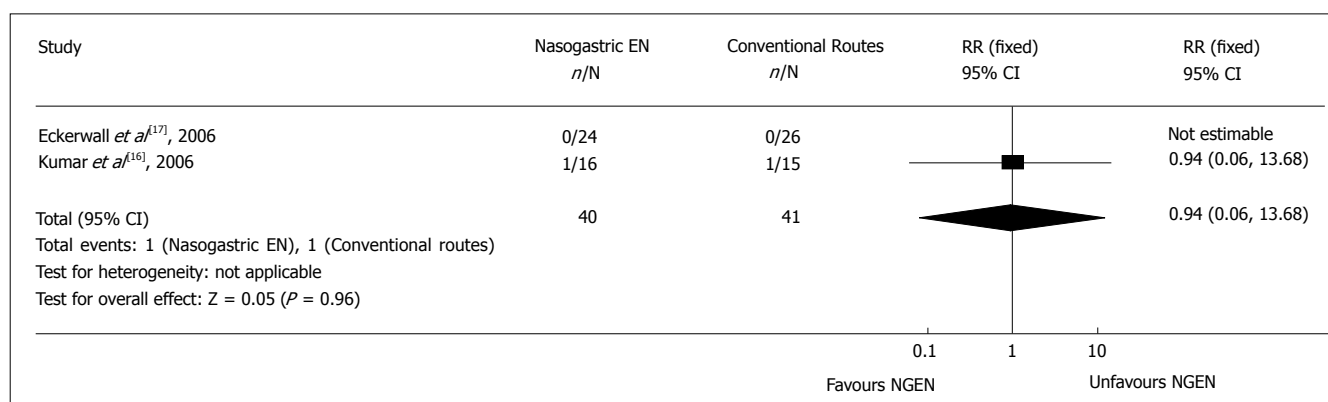

Figure 5 Comparison of refeeding pain recurrence between nasogastric enteral nutrition and conventional nutritional routes.

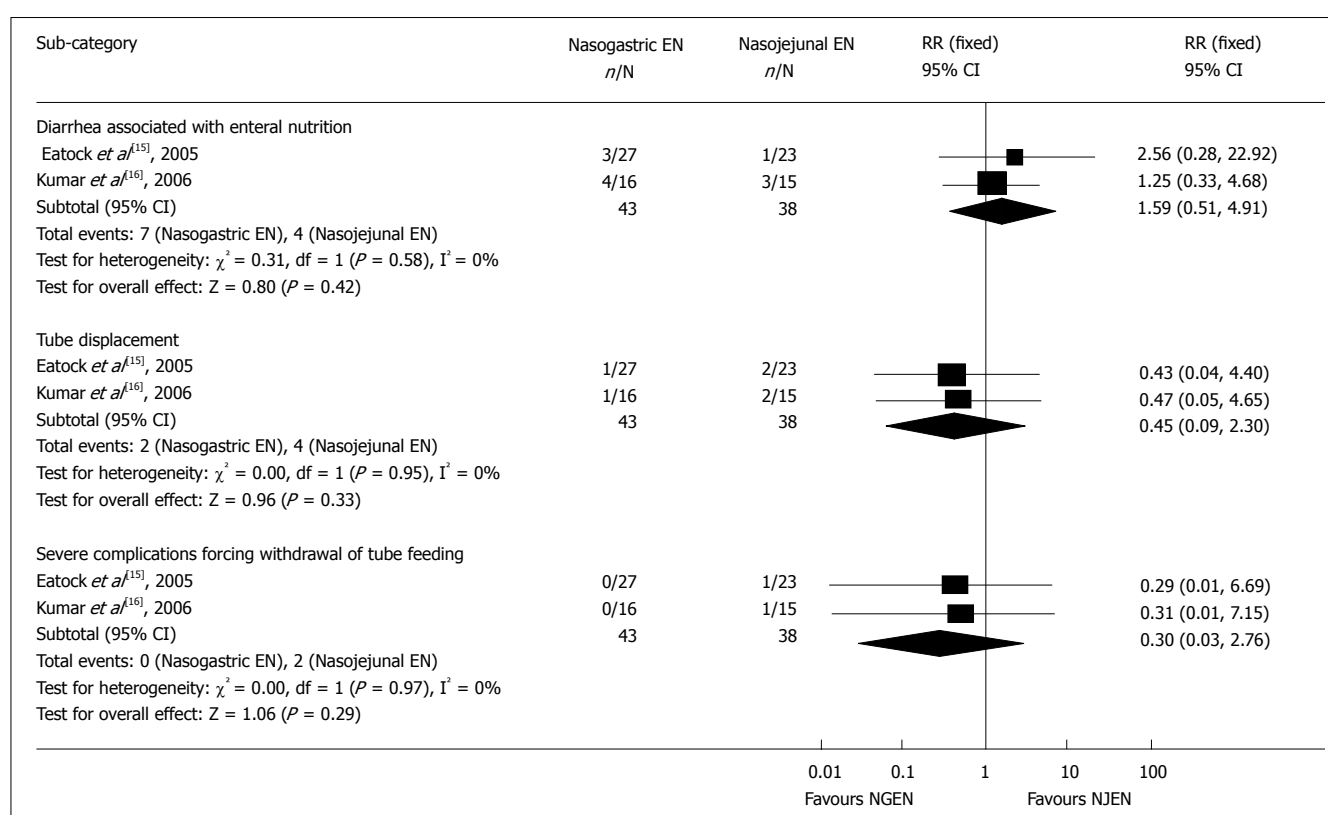

Figure 6 Comparison of nutrition associated adverse events between nasogastric and nasojejunal enteral nutrition (NJEN).

but the proper time of commence needs to be further investigated. Oral re-feeding given 1 wk after onset of the disease is safe in selected MAP patients^[4], while there is no evidence that early oral re-feeding within 1 wk is a feasible management for SAP.

In conclusion, early nasogastric enteral nutritional support route is potentially feasible and safe, which does not increase the rate of mortality, complication and re-feeding pain recurrence in patients with severe acute pancreatitis, and prolong the hospital stay. No major innovations in the treatment of SAP have been introduced in recent years^[23]. It is a breakthrough in enteral nutrition management of severe acute pancreatitis, with a bright future because it is more convenient and cheaper. However, before it is applied in clinical practice, further investigation is necessary to validate its effectiveness, safety

and cost-effectiveness.

ACKNOWLEDGMENTS

The authors thank Professor Qing Xia, Department of Integrated Traditional Chinese and Western Medicine, West China Hospital, Sichuan University, China, for academic instructions, and Dr. Xin-Zu Chen, Department of General Surgery, West China Hospital, Sichuan University, Chengdu 610041, Sichuan Province, China, for substantial methodological support.

COMMENTS

Background

Nutritional management of severe acute pancreatitis is an important issue

and regarded as an indispensable approach. Total parenteral nutrition and gastrointestinal tract rest have been recommended in the management of severe acute pancreatitis (SAP) since the mid 1990s. Enteral nutrition through jejunal route has been accepted as a safe and effective approach to the management of SAP by preserving the integrity of intestinal mucosa and preventing bacterial translocation. Moreover, some studies have attempted to find the feasibility and safety of early enteral nutrition through nasogastric route.

Research frontiers

Gastrointestinal and pancreatic rest has been regarded as an important factor for management of severe acute pancreatitis. Nevertheless, nasogastric enteral nutrition disobeys this discipline. Whether nasogastric route is able to gain the similar results needs to be further investigated. If possible, serological, radiological or histological appraisal should be considered for the effectiveness and safety of early nasogastric enteral nutrition in the treatment of severe acute pancreatitis.

Innovations and breakthroughs

Early nasogastric enteral nutrition is a breakthrough in the management of severe acute pancreatitis. Previously, it was forbidden for the sake of potentially opposing to the requirement of pancreatic rest in the acute inflammation phase. However, the present systematic review of three randomized controlled trials showed that nasogastric route does not worsen the clinical outcomes compared with the conventional total parenteral or jejunal enteral routes.

Applications

Nasogastric route is much more convenient in clinical practice. Moreover, it is obviously cheaper than nasojejunal tube placement. Based on the present results, nasogastric enteral nutrition can be applied in the early management of severe acute pancreatitis. However, before its application in clinical practice, further investigation is necessary to validate its effectiveness and safety.

Terminology

Severe acute pancreatitis (SAP) is usually accompanied with pancreatic necrosis, systematic inflammatory response syndrome, or organ failure. Total parenteral nutrition (TPN) is the way to give nutrient substances intravenously, bypassing the digestive system. Nasogastric enteral nutrition (NGEN) is the way to provide nutrient substances for patients through a tube placed in the nose up to the stomach. Nasojejunal enteral nutrition (NJEN) is the way similar to NGEN, but the tube is placed up to the jejunum.

Peer review

The authors evaluated the effectiveness and safety of early nasogastric enteral nutrition (NGEN) for severe acute pancreatitis (SAP) compared with conventional nutritional routes. Based on the current studies, early NGEN appears effective and safe, but the available evidence is limited.

Abstract

AIM: To investigate the expression and localization of periostin in gastric cancer and its clinical relevance.

METHODS: Reverse transcriptase polymerase chain reaction was used to measure periostin mRNA expression. Western blotting was carried out to detect periostin protein expression. Immunohistochemistry was performed to localize and quantify the expression of periostin in benign gastric diseases and gastric cancer, and immunostaining results were correlated with gastric cancer pathological stages.

RESULTS: Periostin expression was low at both mRNA and protein levels in normal gastric tissues, but was overexpressed in gastric cancer tissues. Immunohistochemical staining revealed that periostin was overexpressed in primary gastric cancer, as well as in metastatic lymph nodes, but only faint staining was found in benign gastric ulcers. By quantitative analysis of the immunostaining results, periostin expression was increased 2.5-4-fold in gastric cancer, compared to that in benign gastric disease, and there was a trend toward increasing periostin expression with tumor stage.

CONCLUSION: This observation demonstrated that periostin was overexpressed in gastric cancer and lymph node metastasis, which suggests that periostin plays an important role in the progression and metastasis of gastric cancer.

INTRODUCTION

Gastric cancer remains the fourth most common cancer worldwide. Due to its high incidence and malignant behavior, and the lack of major advances in treatment strategy, it is still the second most frequent cause of death from malignant diseases^[1]. A variety of clinicopathological characteristics may affect the prognosis of gastric cancer, and accumulating evidence has revealed that numerous genetic markers influence the biological behavior of gastric cancer. The abnormal expression of certain genes in cancer cells is closely related to various aspects of tumor progression, including tumor growth, invasion and metastasis, and inactivation of tumor suppressor genes, particularly the p53 or adenomatous polyposis coli gene^[2].

Recently, great efforts have been made to determine the gene expression pattern differences between various types of human cancer and their corresponding normal tissues, although the alterations of a certain number of tumor suppressor genes and oncogenes have been shown to be closely associated with the progression of human cancer. Less is known about the functions of a large number of other genes whose expression patterns are also significantly changed during the tumorigenic process. Particularly interesting is the mesenchyme-specific gene family, normally associated with osteoblasts, which are highly expressed in various types of human cancer^[3,4]. One such candidate gene is that for periostin, which is overexpressed in several types of human cancer, such as breast, colon and ovarian cancer^[5-7]. Furthermore, it is supposed that, at the molecular level, periostin functions as a ligand for alpha (V), beta (3), and alpha (V) beta (5) integrins to support adhesion and migration of ovarian epithelial cells^[5], and periostin activates the Akt/PKB signaling pathway through the alpha (V) beta (3) integrins, to increase cellular survival^[7]. While integrin expression level is supposed to be related to the metastasis and relapse of gastric cancer^[8], the expression pattern of periostin in gastric cancer is still unknown. In this paper we investigated periostin expression profile in gastric cancer and its clinical relevance.

MATERIALS AND METHODS

Patients and tissue collection

Samples from 35 gastric cancers, including five metastatic lymph node samples, were obtained from 25 male and 10 female patients (median age, 56 years; range, 45-79 years) who underwent gastric resection at the University Hospital of the Affiliated Zhong-Da Hospital, Southeast University. Five benign gastric ulcer tissue samples were obtained from three male and two female patients, in whom gastrectomy was performed (median age, 55 years; range, 25-67 years). According to the TNM classification of the Union International Contre le Cancer (UICC), the 35 gastric cancers were classified as follows: five tumors were stage I, eight were stage II, 16 were stage III, and six were stage IV. The vast majority of the tumors were located in the distal part of the stomach (21 cases), and one-third were located in the proximal part of the stomach. Immediately upon surgical removal, tissue samples were either snap-frozen in liquid nitrogen and then maintained at 80°C until use (for RNA extraction), or fixed in 5% formalin and embedded in paraffin after 24 h. All studies were approved by the ethics committees of the Affiliated Zhong-Da Hospital, Southeast University.

RNA extraction and reverse transcriptase polymerase chain reaction (RT-PCR)

Total RNA from human gastric tissues was isolated either by the Trizol Reagent (TIANGEN, Beijing, China) according to the manufacturer's instructions. Potentially contaminating DNA was removed by RNase-free DNase I treatment. Primers for the genes of interest were: periostin 193 bp (5'-GCCATCACATCGGACA TA-3' and 5'-CTCCCATAATAGACTCAGAACA-3'), and β -actin 621 bp (5'-ACACTGTGCCCATCTACGAG G-3' and 5'-AGGGGCGCGACTCGTCATACT-3'). The RT-PCR conditions were: for the first strand synthesis of cDNA, 48°C for 45 min and 94°C for 2 min to denature the template; and for second strand synthesis and DNA amplification, 94°C for 30 s, 50°C for 30 s, and 72°C for 1 min, for a total of 32 cycles, followed by a single step at 68°C for 7 min.

The products were visualized on 1.5% agarose gels stained with ethidium bromide, and signals were quantified by densitometry using the MetaView analyzing system (version 4.5 Universal Imaging, West Chester, PA, USA). Periostin expression was standardized to β -actin expression assessed from the same cDNA in separate PCR reactions, and run on the same gels. The standardized mean of each triplicate PCR was then expressed relative to the levels in β -actin cDNA. The density value was analyzed by Labimage software (Halle, Germany). $P < 0.05$ was considered as statistically significant.

Protein extraction

Tissues were lysed in 0.5 mL lysis buffer containing 50 mmol/L Tris/HCl (pH 7.5), 150 mmol/L NaCl, 2 mmol/L EDTA (pH 8.0) and 1% SDS with proteinase inhibitors (one tablet/10 mL, Roche Molecular Biochemicals, USA). Protein concentration was determined by the BCA Protein Assay (Pierce, Rockford, IL, USA).

Western blot analysis

Fifty micrograms of protein was separated on SDS-polyacrylamide gels and electroblotted onto nitrocellulose membranes. Membranes were then incubated in blocking solution (5% non-fat milk in 20 mmol/L Tris/HCl, 150 mmol/L NaCl, 0.1% Tween-20; TBS-T), followed by incubation with rabbit anti-periostin antibodies (Abcam, Cambridge, MA, USA; 1:500) at 4°C overnight. The membranes were then washed in TBS-T and incubated with horseradish peroxidase-conjugated secondary antibodies (Amersham Life Sciences, Amersham, UK) for 1 h at room temperature. Antibody detection was performed with an enhanced chemiluminescence reaction (Amersham Life Sciences).

Immunohistochemistry

Immunohistochemistry was performed using the streptavidin-peroxidase technique and the DAKO EnVision System (Dako Cytomation, Hamburg, Germany). Consecutive paraffin-embedded tissue sections (4- μ m thick) were deparaffinized and rehydrated. Antigen retrieval was performed by pretreatment of the slides in citrate buffer (pH 6.0) in a microwave oven for 12 min. Thereafter, slides were cooled to room temperature in deionized water for 5 min. Endogenous peroxidase activity was quenched by incubating the slides in methanol containing 0.6% hydrogen peroxide, followed by washing in deionized water for 3 min, after which the sections were incubated for 1 h at room temperature with normal goat serum, and subsequently at room temperature for 1 h with the primary anti-periostin antibody (Abcam; 1:100). Next, the sections were rinsed with washing buffer (Tris-buffered saline with 0.1% BSA) and incubated with biotinylated goat anti-rabbit IgG and streptavidin-peroxidase complex, followed by reaction with diaminobenzidine and counterstaining with Mayer's hematoxylin. In addition, to confirm the specificity of the primary antibody and the technique used, tissue sections were incubated in the absence of the primary antibody and with negative control rabbit IgG. Under these conditions, no specific immunostaining was detected. The quantitative analysis of the immunohistochemistry staining of periostin expression in gastric tissues was performed as previously described^[9]. The staining of each tissue was analyzed to determine the mean optical density (MOD), which represents the concentration of the stain per positive pixels.

RESULTS

Periostin mRNA expression is upregulated in gastric cancer tissues

To clarify the expression of periostin in human gastric tissues, we initially examined the expression of periostin mRNA in five gastric cancer tissues (T) versus normal gastric tissues (N) obtained from the same patients. The expression of β -actin was examined as an internal control. As shown in Figure 1, periostin mRNA was expressed in all five gastric cancer tissues at different levels. In contrast, its staining was detected at a very low level in normal gastric tissues, and quantitative analysis showed that there

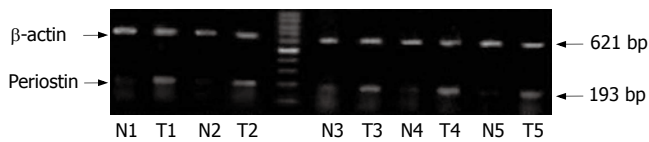

Figure 1 RT-PCR analysis of periostin mRNA expression in human gastric cancer (T) and normal gastric tissues (N). Periostin was differentially expressed in gastric cancer tissues (T) compared with normal gastric tissues (N) from the same patient. The expression of β -actin was used as an internal control.

was a significant difference in periostin expression between gastric cancer and normal tissues ($P < 0.05$, the density ratio between N and T was 0.1912 *vs* 0.8804).

Periostin protein expression in gastric cancer and normal tissues

To determine if the higher level of periostin mRNA expression revealed by RT-PCR analysis was directly linked to increased levels of periostin protein expression, we performed Western blot analysis with protein extracts from matched tissue sections (from which the mRNA samples were extracted). As shown in Figure 2A, periostin was found to be highly expressed in gastric cancer tissues from five different patients (T), whereas only faint periostin expression was found in the normal gastric tissues, with a fivefold overexpression of periostin in cancer tissues compared with normal tissues ($P < 0.05$, the density ratio was 0.8354 *vs* 4.5773) (Figure 2B). Taken together, these data demonstrate that periostin is highly expressed at both mRNA and protein levels in gastric cancer tissues.

Cellular localization of periostin in gastric tissues and its clinical relevance

To investigate the significance of periostin overexpression in gastric cancer further, immunohistochemistry was carried out on five benign gastric ulcers and 35 cases of gastric cancer, which included: five stage I tumors, eight stage II, 16 stage III, and six stage IV tumors, and five metastatic lymph nodes. As shown in Figure 3, the immunostaining indicated that high levels of periostin were present in the areas surrounding cancer cells, as well as in some cancer cells themselves. Periostin was also prominently stained in metastatic lymph nodes. In contrast, periostin expression was low in benign gastric ulcer tissues. Quantitative analysis of the periostin immunohistochemistry results indicated that the average MOD of periostin staining in the stage I-IV tumors was much higher than that in benign gastric ulcers in each group ($P < 0.05$). Furthermore, there was a trend for increasing periostin expression in stage I-IV tumors, although the difference was not statistically significant. In addition, there was no correlation between periostin expression and patient age and gender (data not shown). Taken together, these observations indicated that higher levels of periostin expression were associated with cancer progression and metastasis.

DISCUSSION

Many studies have already demonstrated that interactions

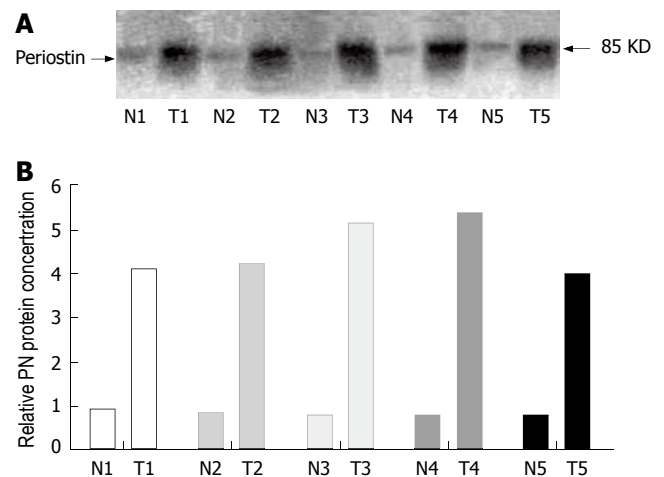

Figure 2 Periostin protein expression in normal and cancer tissue samples. Tissue extracts from normal or gastric cancer tissue samples were subjected to immunoblot analysis with a polyclonal antiperiostin antibody. The results shown in the T and N lanes are for cancer and normal tissues, respectively, from which RT-PCR was performed (A). Over fivefold more periostin was detected in gastric cancer tissues than in normal tissues from the same patient (B).

between integrins of the tumor cell surface and adhesion molecules in the extracellular matrix (ECM) microenvironment may play a critical role in tumor cell migration, survival and growth^[10-12]. The ECM-integrin interactions may also trigger intracellular signaling and activation of certain genes that leads to tumor cell proliferation during metastatic growth^[13], and the formation of blood vessels within the tumor mass^[14]. It is believed that integrins are also important in the attachment and metastasis of gastric cancer^[8]. As a mesenchymal gene, periostin was formerly called osteoblast-specific factor-2, and was originally identified as an 811-amino acid protein secreted by osteoblasts^[15]. It has structural homology with insect fasciclin I and can bind heparin and support adhesion of osteoblasts^[16], which leads to the hypothesis that it functions to recruit and attach osteoblasts to the periosteum.

Periostin is upregulated in colorectal and breast cancer, and their liver metastases, which suggests that it plays a role in promoting growth in these tumors; furthermore, anti-periostin antibodies activate apoptosis and potentiate the effects of 5-fluorouracil chemotherapy in colorectal cancer^[17,18]. Sasaki has reported^[6] that periostin serum level is elevated in breast cancer with bone metastases, and has suggested it as a tumor marker in breast cancer. Since periostin functions as a ligand for integrins, and promotes ovarian cancer cell migration and adhesion^[7], it is reasonable to investigate its role in gastric cancer.

In the present study, we found that periostin was expressed in normal gastric and gastric cancer tissues, while its expression was markedly elevated in cancer tissues. The basal mRNA and protein level of periostin in normal and benign gastric tissues suggest that it plays a role in the normal physiology of the gastrointestinal epithelium, as it was also found that periostin was expressed in normal colon tissue (data not shown). The dramatic increase in periostin in gastric cancer suggests its role in cancer progression. We found that periostin level

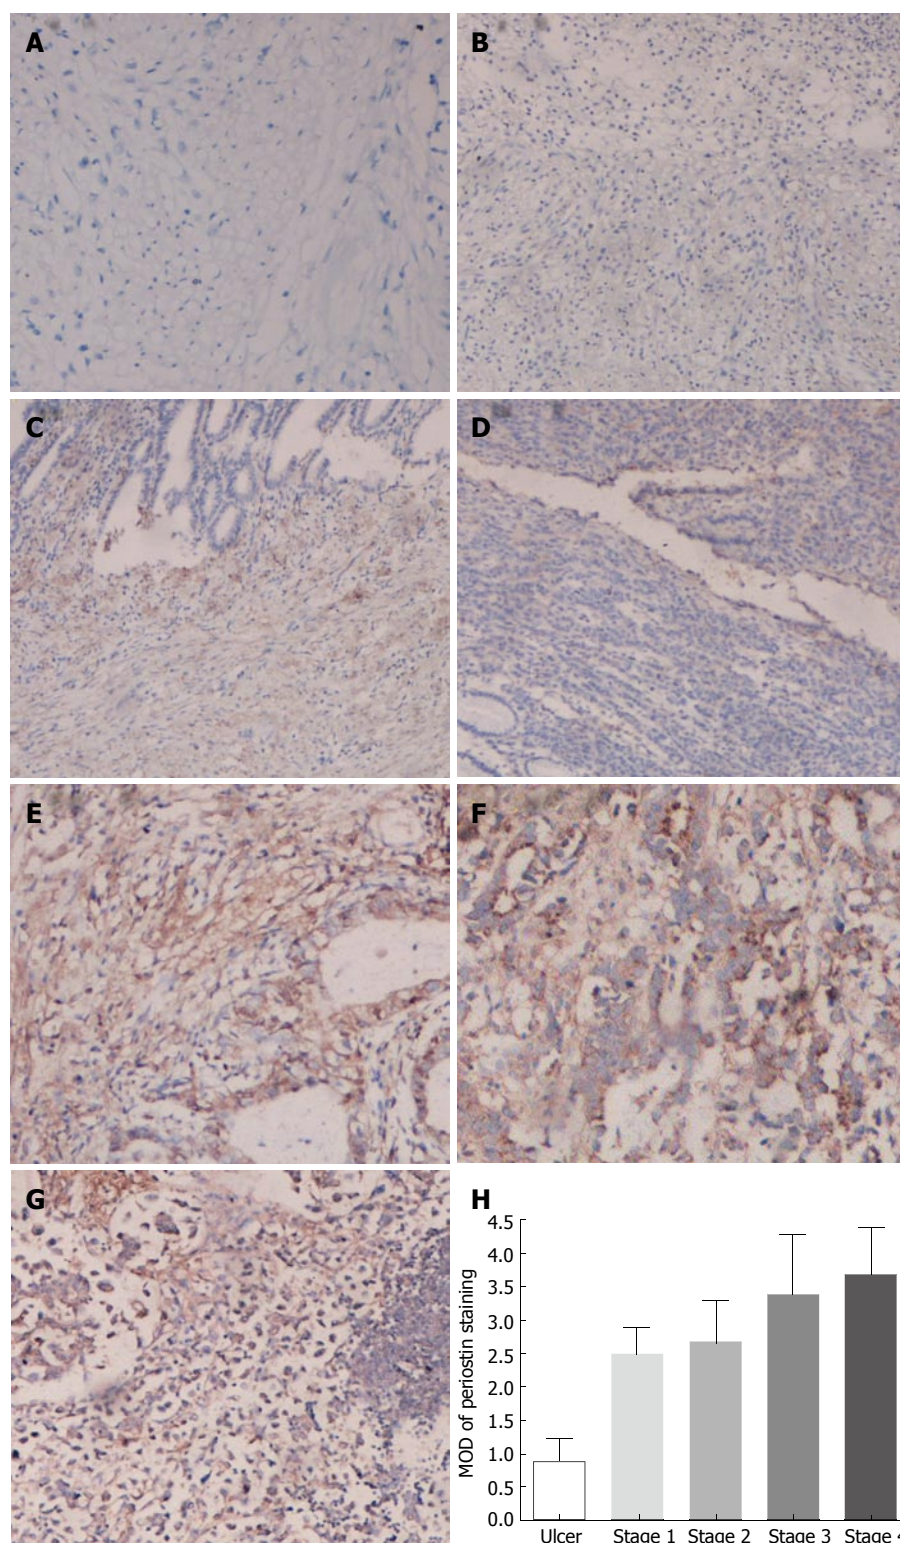

Figure 3 Immunohistochemical analysis of periostin expression in normal gastric tissues, benign gastric ulcers, gastric cancer tissues, as well as lymphoid metastasis from gastric cancer. The tissue sections were immunostained with a polyclonal antibody. The positive staining for periostin protein is shown with a brown color. All sections were counterstained with hematoxylin showing a blue color. (A) Negative control; (B) benign gastric ulcer; (C) stage I gastric cancer; (D) stage II gastric cancer; (E) stage III gastric cancer; (F) stage IV gastric cancer; (G) lymph node metastasis. The average MOD of periostin staining from stage I-IV gastric cancer was significantly higher than that from normal gastric tissues in each group (H) ($P < 0.05$).

was significantly increased in cancer tissues compared with gastric ulcers, and periostin level also increased with tumor-stage progression. As observed in other cancers, increased expression of periostin was associated with advanced stage and cell proliferation, adhesion and migration^[5,19-27], and these results demonstrate that periostin may play a role in the progression of gastric cancer.

However, it has been reported that decreased expression of periostin is associated with progression of bladder cancer in humans, and expression of periostin

mRNA is markedly reduced in a variety of human cancer cell lines^[28,29]. These results differed from our findings that showed that periostin was upregulated in gastric cancer tissues at both the mRNA and protein level. We speculate that there are several explanations for the present findings. First, the expression profile of cancer cell lines may not reflect the *in vivo* expression pattern in certain tumors; second, periostin may have different functions according to different histopathological types of cancer; and third, it is possible that periostin may function differently by

expressing alternative splicing events at the C-terminal region, as five different spliced transcripts of periostin are produced^[15].

In summary, periostin expression was greater in gastric cancer tissues and metastatic lymph nodes compared to that in normal gastric tissues and benign gastric diseases (ulcers), and this increased expression was closely correlated with the TNM stage of gastric cancer. Our results strongly suggest that periostin plays a role in the progression of gastric cancer.

We thank the Department of Pathology, Zhong-Da hospital, Southeast University for providing all the paraffin blocks.

COMMENTS

Background

The pathogenesis of gastric cancer has been extensively investigated in recent years, and the expression of many genes changes in the progression of carcinogenesis, cell invasion and metastasis. Periostin was originally identified in a mouse osteoblastic library. Its role in tumorigenesis is still unclear.

Research frontiers

Periostin has been suggested to be involved in cell adhesion and tumor formation. The human periostin gene has been shown to be overexpressed in lung cancer. Serum periostin levels are elevated in many kinds of human malignancy, and are correlated with poor prognosis. All of these observations suggest that periostin plays a role in tumorigenesis.

Innovations and breakthroughs

The expression of periostin is variable throughout the gastrointestinal tract. The basic level of this protein expression suggests that it plays a role in the normal physiology of the gastrointestinal epithelium. However, the expression of periostin mRNA differs between primary tumors and their respective cell lines. For example, periostin mRNA expression is low in colorectal cancer and head and neck squamous cell carcinoma cell lines, but higher in the primary tumors. The possibility is that stromal components play a role in stimulating periostin expression. Furthermore, opposite findings have been reported, periostin is down-regulated in bladder cancer, and invasiveness and metastasis are suppressed by periostin.

Applications

This study has implications for the future investigation of mesenchyme-specific genes in the formation of gastrointestinal cancer. Regarding the higher expression of periostin in gastric cancer, at both the mRNA and protein level, it is possible that periostin plays a role in the development of gastric cancer, and further study of this molecule in gastric cancer and its role as a biological marker is warranted.

Peer review

This is a well-written study which investigated the expression of the periostin gene. There has not been much research on this molecule in gastric cancer, and this study revealed that periostin was more highly expressed at the mRNA and protein level in gastric cancer, and the expression level was positively correlated with clinical tumor stage. Further investigation regarding the function and prognostic significance of periostin will be interesting, and this paper is a valuable addition to the literature on gastric cancer.

Abstract

AIM: To evaluate the relationship between changes in serum transforming growth factor β 1 (TGF β 1) level and curative effect of radiotherapy (RT) in patients with esophageal carcinoma.

METHODS: Ninety patients with histologically confirmed esophageal carcinoma were enrolled. Serum samples for TGF β 1 analysis were obtained before and at the end of RT. An enzyme-linked immunosorbent assay was used to measure serum TGF β 1 level. Multivariate analysis was performed to investigate the relationship between disease status and changes in serum TGF β 1 level.

RESULTS: Serum TGF β 1 level in patients with esophageal carcinoma before RT was significantly higher than that in healthy controls ($P < 0.001$). At the end of RT, serum TGF β 1 level was decreased in 67.82% (59/87) of the patients. The overall survival rate at 1, 3 and 5 years was 48.28% (42/87), 19.54% (17/87) and 12.64% (11/87), respectively. Main causes of death were local failure and regional lymph node metastasis. In patients whose serum TGF β 1 level decreased after RT, the survival rate at 1, 3 and 5 years was 61.02% (36/59), 28.81% (17/59) and 18.64% (11/59), respectively. The survival rate at 1 year was 17.86% (5/28) in patients whose serum TGF β 1 level increased after RT, and all died within 18 mo ($P < 0.01$).

CONCLUSION: Serum TGF β 1 level may be a useful marker for monitoring disease status after RT in patients with esophageal carcinoma.

INTRODUCTION

Esophageal carcinoma is one of the most common malignant diseases in China. However, for a large number of patients, treatment is only palliative. The 5-year survival rate has remained about 10% for patients treated with conventionally fractionated radiotherapy (CR) alone. The poor prognosis is the result of both loco-regional treatment failure, seen in up to 80% of cases, and early disease dissemination^[1,2]. Failure of local control remains a significant clinical problem. Therefore, local control to improve survival of patients with esophageal carcinoma patients has been focused on by most investigators. Much emphasis has been placed on the role of physical factors (e.g., total dose and dose per fraction) in improving local control and survival rate. In China, investigators have published their results on esophageal carcinoma, using a schedule named late-course hyperfractionation accelerated radiation therapy (LCHART)^[3-7]. In this way, the survival rate of patients with esophageal carcinoma has been increased from 10% to 30%. However, acute toxicity reactions, mainly esophagitis, have increased. Although physical factors are important, none of these models considers the molecular biological events that may be responsible for the observed heterogeneity in tumor tissue response.

Cytokines play a key role in regulation of cells of the immune system and have also been implicated in the pathogenesis of malignant diseases. Transforming growth factor beta-1 (TGF β 1) is a cytokine with multiple biological functions. It influences the proliferation rate of many cell types, and acts as a growth inhibitor in most but not all cases. In addition, TGF β 1 controls

the process of epithelial cell differentiation. In normal cells, TGF β 1 generally enhances adhesion through increased cell matrix production and decreased proteolysis. Resistance to the negative growth-regulating properties of TGF β 1 has been observed in epithelial and mesenchymal tumors. In addition to acting as a stimulator of angiogenesis, TGF β 1 also influences the growth of tumor cells directly or indirectly. Tumor cells can escape the inhibitory effects of TGF β 1 on normal cells at the post-transcription, receptor or post-receptor level. When tumor cells are insensitive, TGF β 1 can also promote tumor metastasis by enhancing angiogenesis, and adjusting the character of the matrix, or adjusting the body's immune response to tumor growth. Animal experiments and clinical observations have demonstrated the functions of TGF β 1 in radiation-induced injury of normal tissues^[8,9]. It has been implicated in the injury of several organs after irradiation, including the lungs and breasts, especially in radiation-induced pneumonitis (RP)^[10-13]. It also has been proposed that serial measurements of plasma TGF β 1 can be valuable for estimating the risk of RP and deciding whether additional dose-escalation can be safely applied. In recent studies, a relationship between prognosis of many tumors and this cytokine has also been found^[14-17]. These suggest that TGF β 1 may be a promising prognostic marker for some cancer patients. However, Fukai's data have suggested that an elevated systemic TGF β 1 level is not related to tumor progression in esophageal cancer^[18]. For this reason, they think that systemic inflammation or chronic disease, in addition to the tumor itself, may influence plasma TGF β 1 level. However, another study has shown a significant correlation between TGF β 1 level measured in the azygos vein and distant lymph node metastasis in esophageal cancer^[19]. Based on these findings, we hypothesized that serial blood TGF β 1 measurements can be used to identify disease status in patients with esophageal carcinoma treated with conventional doses of radiotherapy (RT), and as a potential predictive marker that may allow us to stratify patients into different treatment groups. Here, we detected serum TGF β 1 level in 90 patients with esophageal carcinoma before and at the end of RT, to investigate the relationship between changes in serum TGF β 1 level and disease status in patients with esophageal carcinoma after RT.

MATERIALS AND METHODS

Patients and pretreatment characteristics

From August 1997 to June 1998, 90 unresectable or medically inoperable patients were enrolled into our clinical trial. Only patients with histologically confirmed esophageal carcinoma were eligible. The additional criteria for eligibility were age \leq 75 years, Karnofsky performance status \geq 70, white blood cell and hemoglobin levels within the normal range, and no prior treatment. The patients' clinical characteristics are listed in Table 1. The pretreatment evaluation generally included medical history and physical examination, complete blood cell count, chest radiography and/or chest computed tomography

(CT), esophageal barium examination, and ultrasound examination of the abdomen, including the liver, kidneys, spleen and retroperitoneal lymph nodes. Based on the examinations mentioned above, patients were staged according to the TNM staging system of the 1997 American Joint Committee on Cancer staging system.

The study, including the criteria for patient eligibility, diagnostic procedures, fractionation schemes for treatment techniques, collection of blood samples, and tests, was approved by the Ethical Committee of Changhai Hospital. All patients received full information concerning the aim of the study, diagnostic and treatment procedures, medical care, and risks of acute and late sequelae before they entered the trial, and all patients voluntarily gave informed consent.

RT

All patients were given RT alone. A 10 MV X-ray linear accelerator was used for treatment. The design of the radiation fields was based on the diagnosis by CT and barium examination. For all patients, a three-field approach was administered: one anterior and two posterior oblique portals. The width of the fields was adjusted to cover gross tumors with 2-3 cm extended margins, so as to include subclinical lesions. The length of the field covered clinical tumors with a 3-5 cm extended margin at both ends of the lesion. All patients received conventional fractions, 2.0 Gy per fraction, five fractions per week. The total dose given to the tumor was 60-70 Gy/6-7 W. Lung corrections were not performed in this study.

Clinical evaluation of radiation response

At the end of RT, all patients received esophageal barium examination and the clinical radiation response was evaluated according to standard X-ray diagnosis of esophageal carcinoma after RT^[5]. A complete response (CR) was the disappearance of the mass shadow, no narrowing observed in the esophageal lumen, and none or slight

Table 2 Changes in serum TGFβ1 levels before and after RT

Groups	n	Mean value (ng/mL)	t value	P value
Control	15	9.53 ± 6.45	5.287	0.001
All patients				
Before RT	90	41.13 ± 15.41		
After RT	87	36.52 ± 19.26	1.365	0.072
Decreased group				
Before RT	59	42.93 ± 14.37		
After RT	59	25.98 ± 8.39	2.481	0.006
Increased group				
Before RT	28	40.25 ± 16.29		
After RT	28	51.61 ± 19.75	1.827	0.039

rigidity of the esophageal wall without residual ulceration. Partial response (PR) was > 50% reduction in tumor bulk, but < 100% resolution of the disease and a residual shallow ulcer with a diameter < 1.5 cm, despite the disappearance of the mass shadow. Minor response (MR) was definite improvement in the barium esophagogram, but with < 50% regression, with a large residual ulcer crater and/or narrowing of the esophageal lumen, regardless of the residual state of the mass shadow. No change (NC) was no improvement in the X-ray findings, with a deep and large residual ulcer or complete obstruction of the esophageal lumen, regardless of the residual state of the mass shadow.

The main endpoint in this analysis was the relationship between survival rate and change in serum TGFβ1 level. Death from any cause was calculated from the starting date of RT until death or the last follow-up evaluation. After treatment, follow-up included medical oncology visits at 3-mo intervals for 1 year, and then every 6 mo thereafter up to 5 years. The relationship between 1, 3 and 5-year survival rates and change in serum TGFβ1 level was observed.

Preparation of blood samples and tests for TGFβ1

Blood samples (2 mL each) were collected in EDTA tubes and stored for 1-3 h at 4°C, until the samples were centrifuged for plasma removal. Blood samples were centrifuged at 2000 g for 20 min, and only the top 0.5-1.0 mL plasma supernatant (serum) was removed to avoid platelet contamination. The serum samples were kept frozen at -70°C until assayed for TGFβ1. An enzyme-linked immunosorbent assay (ELISA) was used to determine TGFβ1 level. The TGFβ1 ELISA kit was purchased from R&D Systems (Shanghai, China). Serum samples were not subjected to acid/ethanol extraction, and active TGFβ1 was measured using the kit according to the manufacturer's recommended procedures. The control population consisted of 15 samples from normal blood donors.

Statistical analysis

The Statistical Package for Social Sciences, version 10.0. was used for statistical analysis. Serum TGFβ1 levels were expressed as means ± SD. Two sample means were statistically compared using Student's *t* test, assuming an unequal variance. Multiple comparisons between the mean TGFβ1 concentrations were performed using analysis of

Table 3 Immediate response to RT and serum TGFβ1 levels (%)

TGFβ1	n	CR	PR	MR	NC
Decrease	59	32.20 (19/59)	50.85 (30/59)	13.56 (8/59)	3.39 (2/59)
Increase	28	21.43 (6/28)	46.43 (13/28)	25.00 (7/28)	7.14 (2/28)

variance. The Kaplan-Meier model was used to estimate survival, and the differences between them were compared by the log-rank test.

RESULTS

All patients were followed until death or the time of analysis. Three patients were interrupted during RT and were removed from the statistical analysis, and five patients were lost to follow-up, who were counted as being dead at the time they disappeared. Eighty-two patients were followed for 5 years and the follow-up rate was 94.25%.

Changes in serum TGFβ1 level before and after RT

As shown in Table 2, before RT, mean serum TGFβ1 level in patients with esophageal cancer was 41.13 ± 15.41 ng/mL. This concentration was significantly higher than that in controls (9.53 ± 6.45 ng/mL) (*P* < 0.001). At the end of RT, a decreased serum TGFβ1 level was found in 67.82% (59/87) of all patients that completed the schedule. This suggested that TGFβ1 in the blood was produced by the esophageal tumor, and that its decrease may be due to the tumors being controlled by RT.

Clinical response to RT and serum TGFβ1 level

The relationship between clinical response to RT and serum TGFβ1 level is listed in Table 3. In patients with a reduced TGFβ1 level, tumor response rate to RT (CR plus PR) was 83.05% (49/59), and it was 67.86% (19/28) in those showing an increase (*P* < 0.05).

Changes in serum TGFβ1 level and disease status

It was found in stage III patients that serum TGFβ1 level was significantly decreased at the end of RT compared to that before RT. Mean serum TGFβ1 levels before and after therapy in these patients were 42.38 ± 13.65 and 34.76 ± 15.62, respectively (*P* < 0.05). Three months after RT, 11.5% (10/87) of patients had local treatment failure and regional lymph node metastasis. Among these patients, nine out of 28 (32%) patients' serum TGFβ1 levels increased, while only one out of 59 (1.7%) patients had a decreased TGFβ1 level. Comparatively, the difference between change in serum TGFβ1 level and local treatment failure and metastasis was significant (*P* < 0.001). The patterns of failure and metastasis are listed in Table 4.

Changes in serum TGFβ1 level and survival rate

Five patients were lost to follow-up between 1 and 5 years after RT, and were counted as deaths from the day that they died. The overall survival rate at 1, 3 and 5 years was 48.28% (42/87), 19.54% (17/87) and 12.64% (11/87), respectively. Main causes of death were local treatment failure and regional lymph node metastasis. In patients with

Table 4 Characteristics of ten patients

Case	Location	Stage	Response to RT	Failure or metastasis	TGFβ1 (ng/mL)	
					Before	After
1	Upper	III	NC	Lymph nodes M	30.10	42.80
2	Middle	II b	NC	Lymph nodes M	51.95	67.65
3	Upper	II a	PR	Lymph nodes M	18.60	38.20
4	Upper	III	PR	Lymph nodes and bone M	25.93	28.73
5	Middle	III	PR	Trachea M	29.45	29.55
6	Lower	II a	PR	Regional failure	23.05	27.18
7	Middle	II a	PR	Regional failure	40.68	19.88
8	Middle	II b	PR	Regional failure	30.08	62.65
9	Upper	I	CR	Regional failure	40.73	49.03
10	Upper	I	PR	Lymph nodes M	13.00	32.65

decreased serum TGFβ1 level after RT, survival rate at 1, 3 and 5 years was 61.02% (36/59), 28.81% (17/59) and 18.64% (11/59), respectively. The survival rate at 1 year was 17.86% (5/28) in patients with increased serum TGFβ1 levels after RT, and all died within 18 months ($P < 0.01$). The survival curves for patients in the three groups are shown in Figure 1.

DISCUSSION

In the present study, we investigated the relationship between changes in serum TGFβ1 level and curative effect of RT in patients with esophageal carcinoma, and the function of the cytokine TGFβ1 in treatment prognosis or disease status after RT. Data showed that average serum TGFβ1 level in patients with esophageal carcinoma before RT was significantly higher than that of healthy controls, which suggests that TGFβ1 in the blood is produced by esophageal tumors. After RT, serum TGFβ1 level was reduced in 67.82% (59/87) of patients compared to that before RT. This may be because the tumors were controlled by RT. This is believed to be the first report that there is a relationship between serum TGFβ1 level and esophageal carcinoma.

As mentioned above, much emphasis has been placed on the role of physical factors (e.g., total dose and dose per fraction) in improving local control and survival rate of esophageal carcinoma. Although physical factors are important, molecular biological events may be responsible for the observed heterogeneity in tumor tissue response between patients.

Recently, investigators have shown that changes in blood levels of certain cytokines, such as TGFβ1, may predict the risk of radiation-induced lung injury and association with disease progression^[20-22]. In a study of 73 patients receiving high-dose thoracic RT for lung cancer, Anscher *et al*^[23] found that those patients whose plasma TGFβ1 level was normal at the completion of RT were at low risk for subsequent radiation-induced lung injury, whereas the risk of symptomatic lung damage was increased in patients whose TGFβ1 level remained elevated. Subsequent analysis showed that these changes in plasma TGFβ1 correlated with the risk of pulmonary injury, independent of the volume of lung irradiated. TGFβ1 seems to affect tumor angiogenesis and play an

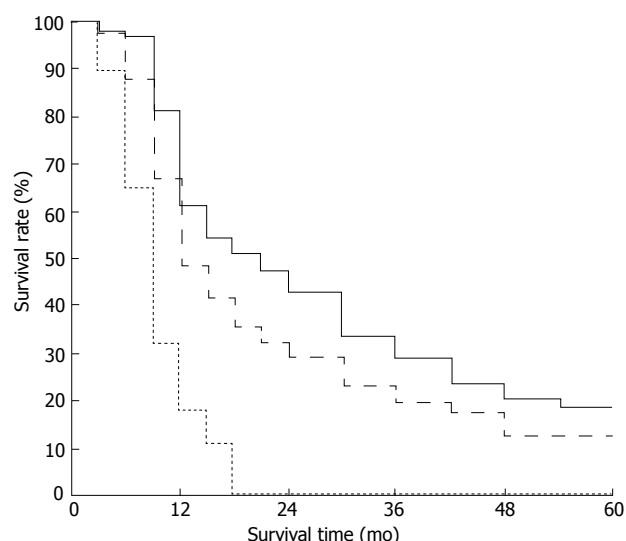

Figure 1 Survival status of all patients, and those with decreased and increased serum TGFβ1 levels. These data show statistically significant differences in the increased group compared with the decreased group and all patients ($P < 0.01$). Solid line indicates the decreased group; broken line indicates all patients; and dashed line indicates the increased group.

important role in tumor progression in non-small cell lung carcinoma. Kong *et al*^[24] measured plasma TGFβ1 concentrations before, during and after RT in 54 patients with lung cancer non-small cell lung cancer (NSCLC), to determine the kinetics of TGFβ1 expression during and after RT, and to correlate plasma TGFβ1 level with disease status after treatment. The results show that in those patients with an elevated plasma TGFβ1 level at diagnosis, monitoring this level may be useful in detecting both disease persistence and recurrence after therapy. Ivanovic *et al*^[25] examined the association between elevated plasma TGFβ1 level and disease progression in advanced breast cancer. Follow-up of six patients indicated a relationship between plasma TGFβ1 and treatment response.

In patients with cervical cancer treated with RT alone, pretreatment plasma TGFβ1 level is a significant prognostic factor for survival and local control, but not for radiation toxicity^[26]. Using concurrent chemoradiotherapy, Yang *et al*^[27] treated 42 patients with biopsy-proven squamous cell carcinoma or adenocarcinoma of the cervix, and assessed serum TGFβ1 level weekly. They have found that sudden elevation of serum TGFβ1 level after the first fraction of brachytherapy is accompanied by greater RT-related morbidity. Lower pretreatment TGFβ1 levels are associated with tumor response to chemoradiation. The conclusion is that serial changes in serum cytokines during chemoradiation may correlate with tumor regression and treatment morbidity.

In breast, gastric, colorectal, prostate, renal and liver cancers, a similar relationship to ours has been found between plasma TGFβ1 level and treatment response^[28-31]. However, in advanced head and neck cancer and NSCLC, no similar relationship between plasma TGFβ1 level and tumor burden was found, and neither to treatment response^[26]. Thus, for these cancers, it can be hypothesized that healthy tissues and the immune system are responsible for the major part of TGFβ1 production and that cancer

cells make only minor contribution to the total plasma TGFβ1 level.

Among patients with local treatment failure and regional lymph node metastasis after RT, there were nine with increased serum TGFβ1 (Table 4). There was a positive relationship between changes in serum TGFβ1 level and local treatment failure and regional lymph node metastasis. All patients with increased serum TGFβ1 died within 18 months after RT, which strongly suggests that serum TGFβ1 level can predict progression in patients with esophageal carcinoma. Our results have been confirmed by other studies on different kinds of carcinoma^[16, 24].

To the best of our knowledge, few of these studies have shown the predictive power of TGFβ1 for disease progression in patients with esophageal carcinoma after RT. The present study demonstrates that a higher serum TGFβ1 level after RT is strongly associated with residual or recurrent tumor or lymph node metastasis. These data suggest that serum TGFβ1 may be useful as a marker for monitoring tumor response to therapy and disease progression.

In conclusion, our findings provide preliminary evidence that significantly elevated serum TGFβ1 level in patients with esophageal carcinoma is associated with poor prognosis. Although the complete mechanism of action and the role of TGFβ1 in esophageal carcinoma remain to be elucidated, our results suggest that this biomarker may be useful for monitoring tumor response to therapy and diseases progression in patients with esophageal carcinoma.

COMMENTS

Background

TGFβ1 is a cytokine with multiple biological functions. In recent studies, a relationship between prognosis of many tumors and this cytokine has also been found. These suggest that TGFβ1 may be a promising prognostic marker for some cancer patients. Based on these findings, we hypothesized that serial blood TGFβ1 measurements can be used to identify disease status in patients with esophageal carcinoma treated with conventional doses of radiotherapy (RT), and as a potential predictive marker that may allow us to stratify patients into different treatment groups.

Research frontiers

A study has shown a significant correlation between TGFβ1 level measured in the azygos vein and distant lymph node metastasis in esophageal cancer. Few of studies have shown the predictive power of TGFβ1 for disease progression in patients with esophageal carcinoma after RT.

Innovations and breakthroughs

Our findings provide preliminary evidence that significantly elevated serum TGFβ1 level in patients with esophageal carcinoma is associated with poor prognosis.

Applications

TGFβ1 may be useful for monitoring tumor response to therapy and diseases progression in patients with esophageal carcinoma. It may allow us to stratify patients into different treatment groups.

Terminology

Serum TGFβ1 level in esophageal carcinoma reflects disease status. A higher serum TGFβ1 level after RT is strongly associated with residual or recurrent tumor or lymph node metastasis.

Peer review

This paper is a well done and interesting study regarding TGF-beta serum levels and response/survival to radiation therapy in patients with esophageal cancer. The science seems interesting and sound.

Abstract

AIM: To evaluate the impact of early steroid withdrawal on the incidence of rejection, tumor recurrence and complications after liver transplantation for advanced-stage hepatocellular carcinoma.

METHODS: Fifty-four patients underwent liver transplantation for advanced-stage hepatocellular carcinoma from April 2003 to June 2005. These cases were divided into a steroid-withdrawal group (group A, $n = 28$) and a steroid-maintenance group (group B, $n = 26$). In group A, steroid was withdrawn 3 mo after transplantation. In group B, steroid was continuously used postoperatively. The incidence of rejection, 6-mo and 1-year recurrence rate of carcinoma, 1-year survival rate, mean serum tacrolimus trough level, and liver and kidney function were compared between the two groups.

RESULTS: In the two groups, no statistical difference was observed in the incidence of rejection (14.3 vs 11.5% , $P > 0.05$), mean serum tacrolimus trough levels (6.9 ± 1.4 vs 7.1 ± 1.1 $\mu\text{g/L}$, $P > 0.05$), liver and kidney function after 6 mo [alanine aminotransferase (ALT): 533 ± 183 vs 617 ± 217 nka/L , $P > 0.05$; creatinine: 66 ± 18 vs 71 ± 19 $\mu\text{mol/L}$, $P > 0.05$], 6-mo recurrence rate of carcinoma (25.0 vs 42.3% , $P > 0.05$), and 1-year survival rate (64.2 vs 46.1% , $P > 0.05$). The 1-year tumor recurrence rate (39.2 vs 69.2% , $P < 0.05$), serum cholesterol level (3.9 ± 1.8 vs 5.9 ± 2.6 mmol/L , $P < 0.01$) and fasting blood sugar (5.1 ± 2.1 vs 8.9 ± 3.6 mmol/L , $P < 0.01$) were significantly different. These were lower in the steroid-withdrawal group than in the steroid-maintenance group.

CONCLUSION: Early steroid withdrawal was safe after liver transplantation in patients with advanced-stage hepatocellular carcinoma. When steroids were withdrawn 3 mo post-operation, the incidence of rejection did

not increase, and there was no demand to maintain tacrolimus at a high level. In contrast, the tumor recurrence rate and the potential of adverse effects decreased significantly. This may have led to an increase in long-term survival rate.

INTRODUCTION

Liver transplantation is well recognized as a treatment for prolonging survival in patients with advanced-stage hepatocellular carcinoma^[1]. Obviously, tumor recurrence is the main reason for the poor long-term survival after transplantation in these patients. It has been shown that long-term immunosuppression can facilitate the growth and spread of malignant cells^[2]. There is evidence that steroids play an important role in tumor recurrence after liver transplantation for hepatoma^[3], but whether steroids can be safely withdrawn remains controversial. In this study, we contrasted patients with early steroid withdrawal with those using continuous steroids, in order to establish the validity of the steroid-withdrawal regimen.

MATERIALS AND METHODS

Patients

Fifty-four patients suffering from advanced-stage hepatoma (all exceeding the Milan criterion) underwent liver transplantation between April 2003 and June 2005. There were two immunosuppressive protocols: 28 patients (group A) were given an early steroid-withdrawal protocol and 26 patients (group B) were given a steroid-maintenance protocol. Factors such as age at transplantation, stage of carcinoma, Child-Pugh score, graft cold ischemic time, anhepatic phase, operation time, and mean level of liver function before operation were noted, and these parameters were well matched in both groups (Table 1).

Table 1 Preoperative and intraoperative data for patients in the 2 groups

Parameter	Group A (n = 28)	Group B (n = 26)	P value
Sex (F/M)	1/27	0/26	0.3370
Mean age at OLT	45.7 ± 3.5	47.4 ± 6.3	0.2310
TNM stage of carcinoma			0.9914
II	1 (3.5%)	1 (3.8%)	
III A	8 (28.6%)	7 (26.9%)	
III B	5 (17.9%)	4 (15.4%)	
IV A	14 (50.0%)	14 (53.8%)	
Child-Pugh class			0.5259
A	20 (71.4%)	21 (80.8%)	
B	7 (25.0%)	5 (19.2%)	
C	1 (3.5%)	0 (0.0%)	
Liver and kidney function			
ALT (nka/L)	935.1 ± 383.3	1010.2 ± 536.8	0.5545
T-Bil (μmol/L)	23.1 ± 11.2	20.1 ± 10.8	0.3314
Creatinine (μmol/L)	67.8 ± 22.2	59.8 ± 24.3	0.2218
Graft cold ischemic time (min)	481.6 ± 97.0	462.1 ± 88.0	0.4464
Anhepatic phase (min)	51.5 ± 3.4	50.8 ± 3.1	0.4339
Operation time (min)	375.2 ± 98.1	391.5 ± 116.7	0.5799

OLT: Orthotopic liver transplantation.

Immunosuppressive regime

All the patients took tacrolimus, with a target serum trough level of 6-8 μg/L until 12 mo, and 4-6 μg/L thereafter. Mycophenolate mofetil was prescribed for 1 year at a dose of 0.5-1.0 g/d. Methylprednisolone was given at 500 mg/d intravenously for 3 d, during and after transplantation. Patients in group A received a rapid steroid reduction with the intention of withdrawing steroid by 3 mo. Patients in group B received a slow taper of steroid to prednisone 10 mg/d at 3 mo, and were maintained on this dose thereafter.

Postoperative treatment

ALT, creatinine, total cholesterol and fasting blood sugar were noted regularly after operation. Biopsies were used to establish the diagnosis of rejection on a histological basis when biochemical analysis suggested rejection. The following adjuvant chemotherapy regimen was adopted: E-ADM 40-60 mg/m² on d 1 and C-DDP 20-40 mg/m² on d 2-5, with 28 d as a cycle and 6 cycles in all. Tumor recurrence was confirmed by computed tomography or magnetic resonance imaging.

Statistical analysis

Statistical analysis was performed on preoperative and intraoperative data in the two groups, such as sex, age, stage of carcinoma, Child-Pugh score, liver and kidney function, Graft cold ischemic time, anhepatic phase and operation time. The rejection rate, tumor recurrence rate, patient survival rate and mean levels of biochemical parameters were compared between the two groups. Statistical analyses were conducted using the Statistical Package for the Social Sciences computer program (SPSS for Windows 11.5; SPSS, Chicago, IL, USA). The Student's *t* test and χ^2 test were used to determine statistical

Table 2 Rejection, tumor recurrence, and survival rate

Group <i>n</i>	Rejection rate	Tumor recurrence rate		1-yr survival rate (%)
		6-mo	1 yr	
A 28	14.3	25.0	39.2 ^a	64.2
B 26	11.5	42.3	69.2	46.1

^a*P* < 0.05 vs Group B.

significance between the groups. *P* < 0.05 was considered significant.

RESULTS

There were no significant differences between the two groups for rejection rate and 6-mo tumor recurrence rate. One-year tumor recurrence rate (39.2 vs 69.2%, *P* < 0.05) was significantly higher in the steroid-maintenance group. One-year survival rate was higher in group A than in group B, but the difference was not statistically significant (64.2 vs 46.1%, Table 2).

At 6 mo, the mean serum tacrolimus trough level was (6.9 ± 1.4) μg/L in group A and (7.1 ± 1.1) μg/L in group B, although the difference was not significant. There was no difference in liver and kidney function (ALT and creatinine) between the two groups. However, at 6 mo post operation, the mean levels of total serum cholesterol and fasting blood sugar were significantly lower in group A (Table 3).

DISCUSSION

Corticosteroids, with their multifaceted immunosuppressive properties, have long been considered as a linchpin in the prevention and treatment of transplant rejection. In addition to inhibiting the release and function of cytokines, such as interleukin-2, steroids can also regulate T- and B-lymphocyte apoptosis^[4]. However, there are well-known adverse effects that result in significant morbidity, including hypertension, diabetes, hyperlipidemia, obesity, and infectious complications. The adverse effects of long-term steroid use, even at a low dose, have stimulated interest in the feasibility of steroid-free maintenance immunosuppressive regimens.

This randomized clinical study was focused on a particular group of recipients who suffered from advanced-stage hepatocellular carcinoma before liver transplantation. In this group of patients, the high tumor-recurrence rate may cause the long-term survival rate to decrease sharply. Indisputably, the use of steroids has exacerbated this problem, either *via* a direct negative impact and/or by its adverse effects. One multicenter study has shown that when steroids were withdrawn 3-6 mo after liver transplantation, tumor recurrence was reduced to its lowest level^[2]. A retrospective study of three centers in Italy has found that the risk of hepatoma recurrence in patients with permanent use of steroids was almost fourfold when compared with patients made steroid-free not later than 6 mo after liver transplantation^[3]. Steroids may contribute to tumor recurrence. The potential

^b*P* < 0.01 *vs* Group B.

mechanism of this may be that steroids can inhibit malignant-cell apoptosis and promote migration of these cells. Yazawa *et al*^[5] have reported that glucocorticoids can inhibit human neutrophil-mediated tumor cell cytostasis. Ho *et al*^[6] have found that, in patients with hepatoma, the survival rate is higher when hepatoma cells are negative for corticosteroid receptors, compared with those that are positive. In our study, the 1-year tumor recurrence rate in the steroid-withdrawal group was lower than that in the steroid-maintenance group. This demonstrates that early steroid withdrawal can reduce tumor recurrence. The 1-year survival rate was higher in the steroid-withdrawal group. However, because of the small sample size and short time of follow-up, the difference was not statistically significant.

Early steroid-withdrawal regimens do not increase the rejection rate^[7-11]. Padbury^[12] has reported that, when steroids were withdrawn safely in 140/197 patients (71%), the acute and chronic rejection rate was 4.5 and 3.9%, respectively, and this was similar to the reported rates with steroid-containing regimens. In Jane's study^[13], 499 liver transplant recipients accepted early steroid-withdrawal immunosuppression, and only 9.8% of patients had steroid reintroduction. Stegall's study has shown that early steroid withdrawal after liver transplantation does not increase the fatality rate and the rate of chronic graft dysfunction^[14,15]. In our study, the incidence of acute rejection during the withdrawal phase did not increase, and each episode of rejection had only a modest effect and was steroid-responsive. No graft was lost to immunological causes. The tacrolimus trough levels were similar in the two groups. There was no demand to increase serum tacrolimus levels to prevent extra rejection. Thus, this early steroid-withdrawal protocol was safe in most patients.

The toxicity of steroids includes increased susceptibility to infection (particularly opportunistic organisms), hyperlipidemia, hypertension, diabetes mellitus, osteoporosis and aseptic necrosis, acne, Cushingoid facies, and growth retardation in children. The cumulative toxicity of immunosuppressive agents remains a major source of morbidity and mortality after liver transplantation, therefore, a protocol eliminating the steroid component has been a goal. Stegall's study has shown that steroid withdrawal after adult liver transplantation reduces diabetes, hypertension and hypercholesterolemia, without causing graft loss^[15]. In our study, total serum cholesterol and fasting blood sugar were significant lower in the early steroid-withdrawal group. This effect suggests that corticosteroids are a major causative agent in new-onset diabetes and hypercholesterolemia in liver transplantation recipients. Considering the adverse effects of steroid

treatment, steroid should be withdrawn earlier, except in patients who use prednisone preoperatively, such as primary biliary cirrhosis and sclerosing cholangitis^[13].

This study indicates that steroid withdrawal at 3 mo after liver transplantation is safe and necessary. Early steroid withdrawal does not lead to a high incidence of rejection or a high level of immunosuppressive drugs. In addition, steroid withdrawal may lead to a decreased incidence of tumor recurrence, new-onset diabetes and hypercholesterolemia. The decrease in tumor recurrence and adverse effects may lead to a higher survival rate for liver transplantation recipients with hepatocellular carcinoma. However, the 1-year survival rate in the steroid-withdrawal and steroid-maintenance groups was not significantly different. This result may have been due to the small sample size and short follow-up. Therefore, large long-term follow-up (several years), prospective, randomized and multicenter trials will be necessary to confirm the potential benefit of this regimen for the incidence of tumor recurrence, adverse events, and graft and patient survival.

COMMENTS

Background

Steroids have been the pillars of immunosuppression in organ transplantation for over 50 years. However, the fact that immunological graft loss is rare after liver transplantation, combined with the severe adverse effects of long-term prednisone therapy, supports steroid withdrawal in liver transplantation patients. Especially for patients suffering from advanced-stage hepatoma before liver transplantation, the long-term use of steroids may exacerbated the problem of reduced graft survival and patient survival. However, few clinical studies have focused on this group of recipients.

Research frontiers

Many clinical trials have proven the necessity of steroid withdrawal. The main findings of this study were that early withdraw of steroids was confirmed as a positive posttransplant action with a significant influence in reducing hepatoma recurrence.

Related publications

The present study was a randomized clinical trial of steroid withdrawal after liver transplantation in patients with advanced-stage hepatocellular carcinoma. We have cited several articles from other investigators that report research on steroid withdrawal after liver transplantation.

Innovations and breakthroughs

In prior studies of liver transplantation, little attention has been paid to the immunosuppression of hepatoma transplant recipients. This present clinical trial studied a steroid-withdrawal protocol for this group of recipients. We reached the conclusion that tumor recurrence can be reduced when steroids are withdrawn at 3 mo postoperatively. This protocol can be used as the guide for hepatoma transplant recipients.

Applications

In patients suffering from advanced-stage hepatocellular carcinoma, immuno-

suppression with early steroid withdrawal can reduce tumor recurrence after liver transplantation. In addition, total serum cholesterol and fasting blood sugar decrease sharply in steroid-withdrawal patients. This means that the use of steroids is one of the major causes of new-onset diabetes and hypercholesteremia after liver transplantation. Therefore, this steroid-withdrawal protocol can also be used following liver transplantation for other indications.

Terminology

Advanced-stage hepatocellular carcinoma is the end stage of a primary malignant neoplasm of the liver. Liver transplantation is the treatment for this disease. However, because of the high incidence of tumor recurrence, the outcome is poor. Steroids are a group of hormones that affect carbohydrate, fat and protein metabolism. They also possess pronounced anti-inflammatory activity. They have been used for immunosuppression for over 50 years.

Peer review

This is a brief but well-executed study which underscores what Starzl and others have been writing about for some time: the need to reduce immunosuppression in liver transplant recipients. In the authors' study, steroids were withdrawn successfully 3 mo after operation. This protocol caused a reduction in tumor recurrence and incidence of diabetes and hypercholesteremia after liver transplantation.

Abstract

Hypersensitivity reactions (HSR) to oxaliplatin in patients with colorectal cancer include facial flushing, erythema, pruritis, fever, tachycardia, dyspnea, tongue swelling, rash/hives, headache, chills, weakness, vomiting, burning sensations, dizziness, and edema. We report a patient with fever as the sole manifestation of initial HSR, review the literature and discuss the management of HSR. A 57-year-old female with T3N2M0 rectal adenocarcinoma received modified FOLFOX-6. She tolerated the first 8 cycles without any toxicities except grade 1 peripheral neuropathy and nausea. During 9th and 10th infusions, she developed fever to a maximum of 38.3°C with stable hemodynamic status despite medications. During 11th infusion, she developed grade 3 HSR consisting of symptomatic bronchospasm, hypotension, nausea, vomiting, cough, and fever. On examination, she was pale, cyanotic, with a temperature of 38.8°C, BP dropped to 95/43 mm Hg, pulse of 116/min and O₂ saturation of 88%-91%. She was hospitalized for management and recovered in 24 h. Fever alone is not a usual symptom of oxaliplatin HSR. It may be indicative that the patient may develop serious reactions subsequently, as did our patient who developed hypotension with the third challenge. Treatment and prevention consists of slowing the infusion rate, use of steroids and antagonists of Type 1 and 2 histamine receptor antagonists, whereas desensitization could help to provide the small number of patients who experience severe HSR with the ability to further receive an effective therapy for their colorectal cancer.

INTRODUCTION

Oxaliplatin (C₈H₁₄N₂O₄) (Eloxatin; Sanofi-Aventis), is an organoplatinum in which the platinum atom is complexed with diaminocyclohexane and with an oxalate ligand. It is a third generation platinum which is indicated for the first-line treatment of metastatic colorectal cancer in combination with 5-fluorouracil (5-FU) and leucovorin (LV)^[1] and for the adjuvant treatment of stage III colorectal cancer^[2]. Oxaliplatin is safely administered in the outpatient setting but hypersensitivity reactions (HSR) can occur. Hypersensitivity is defined as an unexpected reaction that can not be explained by the known toxicity profile of the chemotherapeutic agent^[3]. HSR are seen usually with the taxanes (paclitaxel), the platinum compounds, asparaginase, the epipodophyllotoxins and procarbazine^[3]. Doxorubicin and 6-mercaptopurine have also been associated with these reactions. Acute onset and delayed reactions have been described which can cause flushing, pruritis, hypotension, dyspnea, nausea, back pain and rash^[3,4].

We report a patient with fever as the sole manifestation of initial hypersensitivity reaction, who subsequently developed a serious HSR including hypotension with the third challenge.

CASE REPORT

The patient is a 57-year-old female diagnosed with T3N2M0 (Stage III/Dukes C) rectal adenocarcinoma who was treated with oxaliplatin-based regimen in the adjuvant setting. The tumor was 5.7 cm in size and six lymph nodes were positive for cancer. She was started on treatment with adjuvant chemotherapy with modified FOLFOX-6 (mFOLFOX-6; oxaliplatin 85 mg/m² with concurrent LV 400 mg/m² on d 1 followed by IV bolus 5-FU 400 mg/m² followed by a single continuous infusion of 5-FU 2400 mg/m² over 46 h every 2 wk). As per

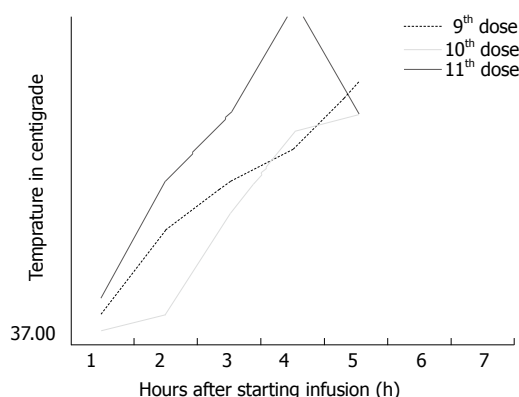

Figure 1 Fever in relation to infusion of oxaliplatin in the present case during 9th-11th cycles of modified FOLFOX-6 regimen in a patient with Stage III rectal cancer.

Table 1 Common terminology criteria for adverse events grading of hypersensitivity reactions (version 3.0)^[26]

Grade	Hypersensitivity reactions
1	Transient flushing or rash; drug fever < 38°C
2	Rash; flushing; urticaria; dyspnea; drug fever ≥ 38°C
3	Symptomatic bronchospasm, with or without urticaria; parenteral medication(s) indicated; allergy-related edema/angioedema; hypotension
4	Anaphylaxis

institutional standard premedication, she received dexamethasone 20 mg and ondansetron 16 mg intravenously. She tolerated 8 infusions without any complications. One and a half hour after starting the 9th infusion, she developed fever of 37.7°C. Other toxicities were grade 1 vomiting and grade 1 diarrhea. She was treated with promethazine (25 mg IV), hydrocortisone (100 mg IV), lorazepam (1 mg IV) and acetaminophen (650 mg PO). During this episode, her BP was 100/60 mm of Hg and pulse of 100/min. Despite the treatment, the fever continued to rise and reached a maximum of 38.8°C (Grade 2). She was discharged with the infusional 5-FU pump after observation and once fever came down to 37.8°C.

Two weeks later when she returned for the 10th infusion, she again developed fever of 37.7°C towards the end of the 2 h infusion. She also had emesis (grade 1) with nausea (grade 1) during oxaliplatin infusion. She was treated with promethazine and acetaminophen. Temperature rose to maximum of 38.4°C (Grade 2). The pulse and BP were preserved. Work-up for infectious etiology including line infection was done and ruled out. Fever defervesced and patient was discharged and returned home.

The patient was pre-medicated with promethazine before cycle 11th. She was planned to receive oxaliplatin over 2-h infusion. One and half hour into the infusion, she complained of itching for which diphenhydramine (25 mg) was given. After this she developed nausea (Grade 1) and vomiting (Grade 1) for which she received promethazine. One hour later she complained of cough and gagging sensation and on examination was found to be pale and cyanosis was visualized on the nail bed. Her temperature rose to 38.8°C (Figure 1) and soon her BP dropped to 95/43

Table 2 Incidence of HSR in pivotal studies of oxaliplatin in metastatic and adjuvant treatment of colorectal cancer

HSR: Hypersensitivity reactions.

mm Hg, pulse of 116/min and O₂ saturation of 88%-91% (Grade 3). Two liters of oxygen were administered with nasal canula and the saturations improved to 91%. She was admitted to the hospital. Fever defervesced overnight and blood and urine cultures were negative. Hypotension responded to fluids and patient was discharged the next day. Desensitization was offered but patient refused further therapy with oxaliplatin.

DISCUSSION

HSR have been reported to occur in a minority of patients (12%) who receive oxaliplatin, and as less than 0.55% of the patients develop grade 3 or 4 reactions^[5-8] (Table 1). However, the incidence of HSR to oxaliplatin is rising recently as a result of increasing clinical use both in the adjuvant and metastatic treatment of colorectal cancer. The reactions usually occur after multiple infusions (mean 2-17) cycles of therapy with variable and unpredictable clinical features^[9]. Patients can experience flushing, alterations in heart rate and blood pressure, bronchospasm, back pain, chest discomfort, fever, pruritis, erythema, nausea, and rash^[3,5]. Usually the symptoms are mild but life-threatening anaphylactic reactions can occur. For this reason the FDA and Sanofi-Aventis has included a BOX warning for such reactions^[10]. The incidence of HSR in pivotal phase III trials of oxaliplatin both in metastatic and adjuvant setting is shown in Table 2^[2,10,11].

All platinum compounds are known to cause HSR^[12-15]. Being a platinum derivative, it is not surprising that oxaliplatin can also develop HSR^[5-9]. The differences in the reactions have been summarized in the Table 3.

The pathophysiology of HSR is not well understood. Development of this reaction after multiple infusions in most patients suggests the need for sensitization. Some investigators have described these reactions as Type I (IgE-mediated) allergic reactions^[16]. Santini *et al* reported a case of an idiosyncratic reaction; the serum analysis of the patient showed elevated TNF-α and IL6. The investigator postulated it to be a T-cell mediated reaction^[17]. It was also postulated that oxaliplatin acted as a super-antigen on mononuclear cells and resulted in the release of these cytokines. Other mechanisms that have been suggested include binding of the platinum salts to different peptides of major histocompatibility complex (MHC). In fact, HLA phenotype is a significant determinant of occupational

Table 3 Characteristics of HSR with different Platinum compounds

sensitization to inhaled hapten of complex platinum salts and the strength of this association varies according to the intensity of exposure^[18]. Furthermore, the relationship between hypersensitivity reactions and HLA-haplotype has been described for other drugs^[19]. Additional factors are deemed to be necessary to the immune system for developing the reaction after several infusions.

Fever alone is not a usual symptom of oxaliplatin hypersensitivity. In another study among 39 patients who received a FOLFOX regimen in first line or beyond, the most common manifestations of an allergic reaction included: respiratory (50%), cutaneous (40%), and an anaphylactic shock (7.6%)^[20]. Ulrich-Pur *et al.*^[21] reported a case of 74-year-old man who developed fever hours after receiving the third infusion of oxaliplatin (5-FU + LV d 1 and d 5 every 28 d + mitomycin C d 1). The temperature was recorded to 39°C and lasted for 3 d. Patient had similar episodes of fever with 4th to 6th infusion. A rise in serum levels of IL 6 levels with 5th and 6th infusion corresponded to the rise in temperature. Pre-medication with dexamethasone, clarithromycin and metamizol for 3 d prior to therapy did not prevent the febrile reaction. Because the reactions occurred 1.5 to 2 h after infusion, the authors did not consider it to be hypersensitivity reactions, and thought to be definitely some kind of acquired allergic reaction because the 1st and the 2nd infusions were well-tolerated. It is to be noted that mitomycin C can also cause fever as a reaction in some cases. Thomas *et al.*^[5] reported hypersensitivity reactions in 3 patients; one of them reported fever of 39.6°C 2 h after the infusion of the 9th cycle of oxaliplatin. Fever defervesced overnight and cultures were negative. The patient again developed fever of 39.0°C with rigors and chest tightness several hours after the next cycle. Before the next cycle, the patient was pre-medicated with dexamethasone 20 mg, 6 and 12 h. Thirty minutes before the infusion the patient received solumedrol 125 mg, diphenhydramine 50 mg and cimetidine 30 mg. Despite this, the patient still developed a single spike of 38.3°C without associated symptoms^[5].

When a HSR occurs, the infusion of oxaliplatin should be immediately stopped and replaced by a saline infusion, an intravenous antihistaminic drug and a low-dose corticosteroids administration. In the case of more severe reactions (dyspnoea, sweating, bronchospasm, laryngospasm), immediately administer a high dose of steroid. The steroid dose range between 100 and 1000 mg of hydrocortisone^[9]. After the reaction disappears, the oxaliplatin infusion should not be restarted and the decision to administer the

other scheduled drugs must be taken evaluating the clinical status of the patient after the reaction, the risk of additional toxicity and the clinical utility of the chemotherapy. Mild hypersensitivity reactions to oxaliplatin and other platinum compounds can be ameliorated in some patients through the use of steroids and antihistamines before administration of subsequent cycles. However, premedication cannot prevent all hypersensitivity reactions, and mild reactions may escalate to severe reactions even when steroids and antihistamines are administered prior to oxaliplatin infusion^[22].

Over the years many protocols have been devised to desensitize patients against these life-threatening reactions so that they can benefit from Oxaliplatin. The various approaches have been summarized in the Table 4. One of the approaches is to increase the duration of the infusion. This was described in a retrospective study by Brandi *et al.*^[6] In the review of 124 patients the author reported fewer hypersensitivity reactions as the infusion time was increased from standard 2 to 6 h. In this review, 17 patients out of 124 (13.7%) developed hypersensitivity. Out of the 17 only 2 developed reactions at the end of infusion while in the rest the reaction appeared 10-15 min from start of the infusion. Six of the 17 patients were successfully re-exposed after pre-medication with steroids and antihistaminic drugs. Five patients developed hypersensitivity symptoms again and only one had no further reactions.

Another approach is desensitization to the drug. Lydia *et al.*^[23] reported a 53-year-old female with metastatic colon cancer who was treated with CAPOX (capecitabine 1000 mg/m² per day Monday to Friday with 2 weekly 85 mg/m² oxaliplatin) and bevacizumab (Avastin) 10 mg/kg. With the cycle 5th she developed diaphoresis, hypotension, hypoxia, nausea, and abdominal cramps 12 min from the start of infusion. She was immediately resuscitated with fluid bolus, oxygen, diphenylhydramine (25 mg IV) and dexamethasone (10 mg IV). The patient received cycle 5th through 7th without oxaliplatin. Because she had partial response to combination chemotherapy with oxaliplatin and she refused to take irinotecan (camptosar; Pfizer) due to toxicity profile, it was decided to desensitize her. On d 1 of desensitization, the patient was given prednisone 20 mg every 6 h for 4 doses and was hospitalized the same day. On d 2, 45 min before infusion 8 mg of ondasterone and 20 mg of dexamethasone were administered. Then 30 min before infusion, diphenylhydramine 50 mg and cimetidine 300 mg was administered. Oxaliplatin was administered over 8 h in serial dilutions from 1:10 000 to 1:1 and she

received a total dose of 140 mg. Intravenous epinephrine (1:1000) and diphenylhydramine and methylprednisolone 125 mg were placed at bedside. The patient tolerated the therapy without complications. The next infusion was given as outpatient. Thus desensitization helped this patient to receive an additional three doses. In this report 24-h pre-medication schedule with serial dilution of oxaliplatin over longer period of time was used based on reports used for desensitization of carboplatin. Lim *et al*^[24] also published his case with successful desensitization.

With carboplatin, an intradermal skin test after 6th dose is a good predictor for occurrence of this reaction. However, no intradermal test is recommended before oxaliplatin administration. An intradermal skin test for hypersensitivity to oxaliplatin has been reported in small series to be 75%-80% accurate^[25]. The investigators suggested that desensitization might be considered for patients with a mild to moderate skin reaction in whom oxaliplatin would be beneficial. The investigators also suggested that a challenge should not be attempted for patients with markedly positive skin test reactions. Garufi *et al* reported the skin test to be negative in 15 patients with no previous reactions to oxaliplatin. A positive skin-test reaction is helpful; however, negative results may be seen in some patients who experience hypersensitivity^[25]. Two of 8 patients with prior hypersensitivity reactions to oxaliplatin were reported by Meyer *et al*^[7] to have negative skin tests with oxaliplatin, as did 1 of 3 patients described by Thomas *et al*^[5].

It is expected to see a rising incidence of HSR to oxaliplatin as has been observed as a result of increasing clinical use. Siu *et al*^[11] recently reported epidemiological and clinical features of these reactions in his institution. Among 180 patients, 15% were labeled as allergic to oxaliplatin, the proportion being higher among those receiving oxaliplatin in palliative second-line or above settings (19.6%) than in adjuvant or palliative first-line settings (10.2%). Overall, 2.2% of them developed grade 3-4 reactions. Re-exposure to oxaliplatin in 14 patients resulted in 28.6% HSR with 14.3% reactions of grade 3-4 intensity.

Although the reported incidence of HSR is about 12%

of the patients who receive oxaliplatin (1%-2% grade 3 or 4 in severity), the recent rising incidence of HSR to oxaliplatin observed is the result of increasing clinical use. It is also important to remember that fever can be the sole manifestation of initial HSR in few cases akin to ours; a harbinger that this patient can subsequently develop serious HSR with continued use of oxaliplatin. Therefore, proper recognition and management can prevent a serious HSR. Few patients can be managed with pre-medication with steroids and antihistamines, but the majority of patients require intensive desensitization. Due to the desensitization regimens many patients can successfully continue to receive this agent. Reintroductions have only been reported as single case studies or small cohorts. Large scale validation on desensitization strategies are still missing. Knowledge of this rare but real toxicity of oxaliplatin is paramount since the use of this drug is wide-spread both for metastatic and adjuvant settings in the treatment of colorectal cancer-the second leading cause of cancer mortality in USA.

Abstract

Percutaneous endoscopic gastrostomy (PEG) tube complications can be serious or life threatening. Retrograde intussusception is a very rare complication of PEG tubes with only 9 cases reported in the literature. We describe a case of retrograde intussusception, associated with the use of a Foley catheter as a replacement gastrostomy tube, presenting with upper gastrointestinal bleeding. To our knowledge, this is the first reported case of PEG-related retrograde intussusception successfully managed in a non-surgical manner. Retrograde intussusception likely occurred due to migration of the replacement tube with resultant securing and invagination of the proximal jejunum when the gastrostomy tube was anchored to the abdominal wall.

INTRODUCTION

Since introduction by Gauderer in 1980, percutaneous endoscopic gastrostomy (PEG) has become the preferred procedure for establishing enteral feeding in most clinical

situations^[1]. The complication rate ranges from 3% to 14% depending on the definition used, and mortality approaches 1%^[2]. Retrograde intussusception, defined as the telescoping or invagination of a distal segment of intestine (the intussuseptum) into the receiving proximal end (the intussusipiens), is a very rare complication of gastrostomy tube migration. We report here the first case treated successfully in a non-surgical manner.

CASE REPORT

An 89-year-old female nursing home resident was hospitalized with generalized abdominal pain, coffee ground emesis and change in mental status. Past history revealed hypertension, mild dementia, coronary artery disease, transvaginal hysterectomy and percutaneous endoscopic gastrostomy (PEG) placement six months prior due to poor oral intake. Four weeks prior to admission, the patient's PEG tube was dislodged unintentionally and replaced at the bedside using a 22f Foley catheter, inflating the balloon with 10 CC of sterile water. No testing was performed to confirm intraluminal placement of the Foley at the nursing home.

Physical examination revealed a cachectic elderly woman who was somnolent but arousable. She was afebrile and normotensive. Abdominal examination revealed a distended, diffusely tender abdomen with evidence of erythema and exudate at the ostomy site and normal bowel sounds. The remainder of the physical examination was unremarkable. Pertinent laboratory studies included white blood cell count of 12.9 thousand/ μ L and hemoglobin of 10.7 gm/dL. Abdominal flat and upright radiographs revealed only fecal impaction. An upper endoscopy was performed within 24 h of hospitalization with detection of a large amount of brownish foul smelling fluid within the stomach. A twisted loop of small bowel with mucosal discoloration and sloughing was seen protruding through the pylorus into the gastric body (Figures 1 and 2). A 22 fr Foley catheter was seen tethering the loop of bowel to the body of the stomach. The pyloric channel was not visualized and the intubation of the duodenum was not attempted. A water contrast X-ray series performed immediately after endoscopy showed an antral filling defect with typical coil spring appearance of intussusception. A barium study through the PEG tube showed its tip in the proximal jejunum. The clinical diagnosis of retrograde intussusception was made at this time. A general surgery

Figure 1 Intussuscepted loop of small bowel and size 22 Fr Foley catheter tethering loop to ostomy site in the gastric body.

Figure 2 Close up view of intussuscepted small bowel.

opinion was obtained based on the endoscopic and radiologic findings, but a conservative approach was taken at the request of the patient's family. This included deflation and removal of the Foley catheter, placement of a button replacement PEG at the ostomy site, intravenous hydration, packed red blood cell transfusion and institution of broad-spectrum antibiotics.

There was no overt worsening of her clinical status after deflation/removal of the Foley catheter and button PEG replacement. Repeat upper endoscopy was performed three days after PEG tube replacement. Examination distal to the second portion of the duodenum revealed a segment of continuous mucosal necrosis and discoloration. Biopsies obtained revealed mucopurulent exudates and debris with dense inflammatory infiltrates only. Feeding through the button PEG began the day after the repeat endoscopy and was tolerated well during the remainder of her hospital stay. The patient continued to improve clinically and was discharged, on hospital d 14, initially to a skilled nursing unit for a 2 wk observation period followed by eventual return to her permanent assisted living facility.

DISCUSSION

PEG tube insertion is a simple endoscopic procedure performed worldwide. Multiple complications have been reported (major and minor) including those occurred while placing the PEG and postprocedure^[2]. Common complications include pain at the insertion site, peristomal leak and infection, tube extrusion, transient ileus and cutaneous ulceration^[2,3]. Major complications include gastric or colonic perforation, peritonitis, gastrocolic or colocutaneous fistula, peritonitis and necrotizing fascitis^[4-8]. Bleeding and aspiration are complications that have the potential of turning into serious or life threatening situations^[4]. Retrograde intussusception is very rare and can occur as a complication of gastrostomy tube migration. In the English literature on this subject, only 9 cases have been reported^[9-17]. Nearly all of these cases were secondary to distal migration of a Foley catheter gastrostomy tube lacking an external fixation device or support.

The diagnosis in these cases was made based on radiologic imaging (contrast or barium study, abdominal ultrasound or CT scan) with endoscopy used in 2 cases. All except 1 (postmortem diagnosis) required surgical

resection. The exact mechanism leading to retrograde intussusception is unknown. Oswald *et al.*^[11] suggested that migration of the gastrostomy tube is the initiating event resulting in telescoping of the mobile jejunum over the tip of an impacted gastrostomy tube into the proximal duodenum. Lamont and Rode^[12] have proposed a different mechanism with passage of an inflated Foley gastrostomy catheter migrating past the pylorus into the small bowel, resulting in balloon fixation. Retraction attempts with the balloon inflated result in invagination of the small bowel into the duodenum. Finally, Gasparri and associates^[15] suggest a 3rd potential mechanism with balloon migration resulting in increased intraluminal traction and invagination of the jejunal wall. Attempts at repositioning result in the inflated balloon acting as a lead point with retrograde telescoping of the jejunum back through the duodenum and into the gastric lumen. Following these case reports, new gastrostomy tubes are now fitted with external fixation devices or bolster to prevent distal migration.

Our case illustrates a rare but preventable complication of a gastrostomy tube with uniqueness in terms of therapeutic approach. Unlike previous cases reported in the literature, our patient did not undergo surgical exploration, making a full recovery without evidence of overt sepsis or peritonitis and was eventually discharged to her nursing home. We hypothesize that following replacement of the PEG tube with a Foley catheter, the catheter migrated into and past the C-loop of the duodenum and was pulled back by NH staff without first deflating the balloon, leading to invagination of the mobile portion of the jejunum. The tube was then likely anchored in some manner leading to mucosal ischemia and necrosis but not in a transmural fashion. After deflation of the Foley catheter balloon, blood supply was restored allowing for revascularization of the mucosa.

We recommend that intussusception should be ruled out in a patient with a PEG tube who presents with symptoms of nausea, vomiting, hematemesis or abdominal pain by direct visualization of gastric and duodenal mucosa with EGD and upper GI series with water-based contrast. If intussusception is diagnosed, surgery remains the treatment of choice. However, if identified early or patient's surrogates decline a surgical approach, rapid deflation of the Foley catheter and button PEG replacement can result in a successful conservative approach to retrograde jejuno-duodenal

intussusception with a positive outcome. Prevention of such a complication may be simply achieved by anchoring, with an external bolster, any type of replacement tube to prevent such a migration.

Abstract

Percutaneous endoscopic gastrostomy (PEG) is generally considered safe with a low rate of serious complications. However, dislocation of the PEG-tube into the duodenum can lead to serious complications. An 86-year old Japanese woman with PEG-tube feeding sometimes vomited after her family doctor replaced the PEG-tube without radiologic confirmation. At her hospitalization, she complained of severe tenderness at the epigastric region and the PEG-tube was drawn into the stomach. Imaging studies showed that the tip of PEG-tube with the inflated balloon was migrated into the second portion of the duodenum, suggesting that it might have obstructed the bile and pancreatic ducts, inducing cholangitis and pancreatitis. After the PEG-tube was replaced at the appropriate position, vomiting and abdominal tenderness improved dramatically and laboratory studies became normal immediately. Our case suggests that it is important to secure PEG-tube at the level of skin, especially after replacement.

INTRODUCTION

Percutaneous endoscopic gastrostomy (PEG) has gained

broad acceptance as an effective method for achieving enteral access in patients who need chronic nutritional support. The feeding through PEG-tube is convenient, safe, and agreeable. Most of complications of PEG-tube feeding are minor, except for those arising at tube-exchange, which is necessary for a long-term feeding because of degradation of tubes, or incidental tube-removal. It is better to exchange PEG-tubes under fluoroscope in hospital for preventing complications. However, many primary doctors perform at the bed side in patient's home through unavoidable circumstances. This is one of the reasons why serious complications occur when a long-term PEG-tube feeding is needed.

In this report, we describe a case of pancreatitis and cholangitis induced by dislocated PEG-tube, which are the very rare complications of PEG-tube feeding.

CASE REPORT

An 86-year-old Japanese woman with PEG-tube feeding was referred to our hospital for reiterated emesis. She had an attack of cerebral infarction and cerebral embolism at the age of 84 years. Since the disease caused her dysphagia and continuous consciousness disturbance, she received chronic nutritional support by PEG-tube feeding. One month before her hospitalization, a gastrostomy tube (Gastrostomy-tube, Bard Access Systems, Salt Lake City, UT, USA) with a diameter of 18 F, which is fixed by an intragastric balloon (20 mL of water) and an external disc bumper, was replaced by her family doctor in her home without radiologic confirmation, and she sometimes vomited gastric juice and bile without enteric nutrient. Her family noticed that the PEG-tube was sometimes drawn into the stomach. At her hospitalization, she complained of severe tenderness at the epigastric region and the PEG-tube was drawn into the stomach. The distance between the balloon and external disc bumper was 8 cm measured by a scale indicated on the PEG-tube. Laboratory studies revealed $10.4 \times 10^9/L$ white blood cells (normal range: $5.0-8.0 \times 10^9/L$), 97.9 mg/L C-reactive protein (normal range: < 3 mg/L), 1.24 $\mu\text{mol/L}$ total serum bilirubin (normal range: 0.49-2.16 $\mu\text{mol/L}$), 213 U/L aspartate aminotransferase (normal range: 10-34 U/L), 254 U/L alanine aminotransferase (normal range: 5-40 U/L), 553 U/L alkaline phosphatase (normal range: 100-358 U/L), 238 U/L lactate dehydrogenase (normal range: 104-224 U/L), 1191 U/L amylase (normal range: 32-112 U/L), 176 U/L gamma-glutamyltranspeptidase (normal range: 7-29 U/L). A diagnosis of acute pancreatitis and cholangitis was made based on the physical examination and laboratory findings.

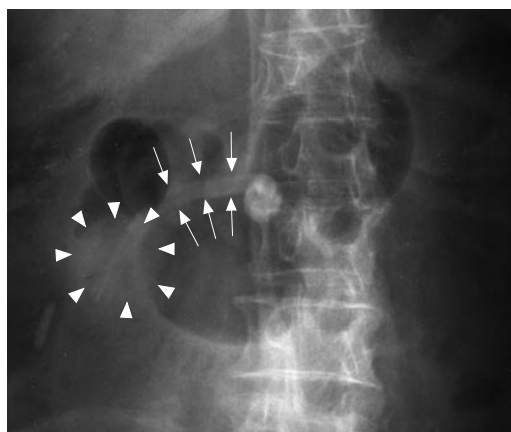

Figure 1 A plain abdominal radiograph showing collected gas in the stomach and duodenum with the tube balloon situated in the second portion of duodenum (tube: arrow, balloon: arrowhead).

Abdominal roentgenography and computed tomography (CT) showed that the tip of PEG-tube with the inflated balloon was migrated into the second portion of the duodenum (Figures 1 and 2), suggesting that it might have disturbed the flow of bile and pancreatic juice at the papilla, and thus was thought to be the cause of cholangitis and pancreatitis. No stone or tumor was found at this region in these studies.

Once the balloon was deflated and fixed at the appropriate position by the balloon re-inflation after the tube was retracted into the stomach. After the PEG-tube was replaced at the appropriate position, vomiting and abdominal tenderness improved on the next day and laboratory studies became normal after two days.

DISCUSSION

PEG has become the preferred method in patients requiring long-term enteral nutrition because of its ease and safety of placement. Previous studies reported that complications are infrequent and a procedure-related mortality is less than 1%^[1,2]. Common procedure-related complications include wound infection, aspiration, hemorrhage, pneumoperitoneum, peritonitis, and common long-term complications include leakage, granulation tissue, unintentional removal, buried bumper syndrome^[3-7]. Obstructive pancreatitis and cholangitis induced by migrated PEG-tube are the very rare complications.

Although PEG-tube feeding is generally considered safe with a low rate of serious complications, dislocation of the PEG-tube into the duodenum can lead to symptoms of obstructive pancreatitis and cholangitis. Because a balloon with PEG-tube is hard to pass through the pyloric ring, a migrated balloon may obstruct the pyloric ring and cause vomiting. In this case, the family doctor might have inserted the PEG-tube too deep into the duodenum, so the tube passed through the pyloric ring and the balloon was inflated in the duodenum. As enteral peristalsis moved the balloon up to papilla of Vater, the flow of bile and pancreatic juice might have been obstructed. These speculations were supported by the frequent PEG-tube traction

Figure 2 A plain CT scan demonstrating the PEG-tube balloon in the second portion of duodenum.

into the stomach noticed by her family, and her repeated vomiting due to small bowel obstruction by the balloon. Roentgenography could easily show the dislocation of PEG-tube which might have been noticed by checking carefully the length of PEG-tube over the skin.

Five cases of acute pancreatitis related to gastrostomy tube migration have been reported^[8-12]. Foley catheter has been used as PEG-tubes in 4 cases^[8-10,12]. This catheter is more likely to migrate because it has no external bumper which prevents dislocation of the tube. In another case using a gastrostomy tube with an external bumper, spontaneous loosening of the external bumper caused the tube migration^[11]. In this case, a technical error might have caused tube dislocation when a new tube was replaced blindly, although the tube has an external bumper.

This case demonstrates that a malpositioned PEG-tube can be an iatrogenic cause of acute pancreatitis and cholangitis. It is important to secure PEG-tube at the level of skin, especially a couple of days after its replacement.

Abstract

The etiology and pathogenesis of portal vein thrombosis are unclear. Portal venous thrombosis presentation differs in cirrhotic and tumor-related versus non-cirrhotic and non-tumoral extrahepatic portal venous obstruction (EHPVO). Non-cirrhotic and non-tumoral EHPVO patients are young and present with well tolerated bleeding. Cirrhosis and tumor-related portal vein thrombosis patients are older and have a grim prognosis. Among the 118 patients with portal vein thrombosis, 15.3% had cirrhosis, 42.4% had liver malignancy (primary or metastatic), 6% had pancreatitis (acute or chronic), 5% had hypercoagulable state and 31.3% had idiopathy, 12% had hypercoagulable state in the EHPVO group.

TO THE EDITOR

We read with great interest the article "Portal hypertension due to portal venous thrombosis: Etiology, clinical outcomes" by Harmanci *et al*^[1] in the May 14, 2007 issue of World Journal of Gastroenterology. We agree that portal vein thrombosis (PVT) should be considered under two different categories [acute or chronic PVT (noncirrhotic and nontumoral), (b) PVT due to cirrhosis and tumors], as the presentation, clinical course and prognosis are different in the two categories.

Table 1 Clinical and laboratory findings in 118 patients with portal vein thrombosis

Parameters	Extrahepatic portal vein obstruction (n = 50)	Cirrhosis and tumor-related portal vein thrombosis (n = 68)
Male:Female	33:17	51:17
Age (yr) ²	25 (9-40)	52 (23-80)
Hematemesis	36 (72%)	10 (14.7%)
Hypersplenism	30 (60%)	6 (8.8%)
Pain abdomen	18 (36%)	42 (61.8%)
Abdominal distension	8 (16%)	36 (52.9%)
Awareness of splenomegaly	6 (20%)	-
Jaundice	5 (10%)	18 (26.5%)
Cholangitis	1 (2%)	5 (7.4%)
Splenomegaly ² cm ¹	4 (2-14); (n = 35)	2 (2-4); (n = 7)
Hepatomegaly ² cm ¹	2 (1-3); (n = 8)	3 (2-6); (n = 16)
Etiology		
Hepatocellular carcinoma	-	31
Cirrhosis liver	-	18
Metastases liver	-	6
Pancreatic carcinoma	-	7
Cholangio carcinoma	-	3
Carcinoma gallbladder	-	2
Duodenal carcinoid	-	1
Esophageal Varices	35 (70%)	32 (47%)
Gastric Varices	11 (22%)	3 (4.4%)
GoVI	1	2
GoV2	8	1
IGV1	2	
Portal hypertensive gastropathy	8 (16%)	48 (70.4%)
Mild	6	40
Severe	2	8
Hemoglobin ² (gm/dL)	7.2 (1.7-14.7)	8.0 (6.0-11.6)
Total leucocyte count ² (10 ³ /mm ³)	2.9 (1.0-6.8)	6.4 (1.36-29.71)
Platelet count ² (10 ³ /mm ³)	0.49 (0.14-1.54)	1.52 (0.29-2.59)
Bilirubin ² (mg/dL)	1.0 (0.4-18.5)	1.2 (0.5-15.1)
AST ² (U/L)	38 (18-231)	79 (39-961)
ALT ² (U/L)	34 (18-254)	65 (18-1146)
SAP ² (U/L)	264 (110-2849)	348 (140-3140)
Protein/albumin ² (mg/dL)	6.8 (5-7.5)/3.8 (3-4)	6 (5.3-8)/3.3 (2-4.6)
Prothrombin time	2 (1-3)	4 (2-14)
prolongation ² (seconds)		
Portal biliopathy	4 (8%)	
Choledocholithiasis	2	
CBD stricture	2	
EVL sessions ²	3 (2-4)	-
Glue injection (n)	4	-
Superior mesenteric vein thrombosis	11 (22%)	6 (8.8%)
Inferior vena cava thrombosis	4 (8%)	3 (4.4%)
Splenic vein thrombosis	4 (8%)	4 (5.6%)
Deep vein thrombosis	-	1 (1.4%)
HBsAg	0	27 (39.7%)
Anti-HCV	0	3 (4.4%)

¹Centimeter below costal margin; ²Median (range).

Of the 118 cases of PVT admitted to our hospital over the 2-year period (from January 1, 2005 to December 31, 2006), 50 were due to extrahepatic portal vein obstruction (EHPVO) and 68 were due to cirrhosis and tumors. The clinical and laboratory characteristics of 50 patients with EHPVO are given in Table 1. The patients were young and commonly presented with features of hematemesis, hypersplenism, abdominal pain and distension. Ten patients had acute PVT and 2 had presentation as acute Budd-Chiari syndrome, 2 patients had pregnancy and delivered the fetus at term with supportive treatment. Thirty-six patients who presented with hematemesis were managed with endoscopic variceal ligation (2-4 sessions), and four patients were treated with gastric varices glue injection. These patients were maintained on beta-blockers and follow-up endoscopic surveillance. Four patients with symptomatic portal biliopathy were managed with stent placement ($n = 2$) and common bile duct (CBD) stone extraction ($n = 2$). Antithrombin-III deficiency was present in 2 patients, antiphospholipid antibody in 2 patients, factor V Leiden (FVL) mutation in 1 patient and paroxysmal nocturnal hemoglobinuria in 1 patient. All the 6 patients were started on heparin and warfarin with warfarin continued to maintain a 2-3 INR. Four (8%), 2 (4%) and 1 (2%) patients had chronic pancreatitis, acute pancreatitis and liver abscess, respectively. During the mean follow-up period of 9 mo (3-24 mo), none of the patients had symptomatic hypersplenism.

EHPVO affects young individuals who present with well-tolerated bleeding. The etiology and pathogenesis of PVT are unclear. It was initially proposed that umbilical sepsis or catheterization of umbilical veins in the neonatal period is responsible for PVT^[2]. In recent years, the presence of congenital or acquired prothrombotic conditions has been considered an interesting hypothesis for the causation of PVT. FVL mutation is known to be less common among Asians as compared to the population of European descent. Koshy *et al.*^[3,4] reported that FVL mutation has been found in 3% patients with portal vein thrombosis

and prothrombin G20210A gene in patients with portal vein thrombosis in a south Indian study. In our study, FVL mutation was present in 2% of cases.

The clinical and laboratory features of 68 patients in cirrhosis and tumor groups are given in Table 1. The clinical presentation was abdominal pain and distension and jaundice. During a mean follow-up period of 7 mo (range 1-24 mo), 48% of the patients died.

Of 118 cases of PVT admitted to our hospital, 15.3% had cirrhosis, 42.4% had liver malignancy (primary or metastatic), 6% had pancreatitis (acute or chronic), 5% had hypercoagulable state and 31.3% had idiopathy. The higher percentage in idiopathic group might be due to a low prevalence of hypercoagulable factors, abnormality and attribution of umbilical sepsis in childhood. The role of JAK2 mutation in early diagnosis of overt or silent myeloproliferative disease cannot be undermined but requires standardization^[5].

In conclusion, the presentation, etiology and prognosis in non-cirrhotic and non-tumoral EHPVO patients are different from those in cirrhosis and tumor-related portal vein thrombosis patients.

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (WJG, *World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly journal of more than 48 000 circulation, published on the 7th, 14th, 21st and 28th of every month.

Original Research, Clinical Trials, Reviews, Comments, and Case Reports in esophageal cancer, gastric cancer, colon cancer, liver cancer, viral liver diseases, etc., from all over the world are welcome on the condition that they have not been published previously and have not been submitted simultaneously elsewhere.

Indexed and abstracted in

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, *Index Medicus*, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, *Nature Clinical Practice Gastroenterology and Hepatology*, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

Published by

The WJG Press

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297 mm × 210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, acknowledgements, References, Tables, Figures and Figure Legends. Neither the editors nor the Publisher is responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part without the written permission of both the authors and the Publisher. We reserve the right to put onto our website and copy-edit accepted manuscripts. Authors should also follow the guidelines for the care and use of laboratory animals of their institution or national animal welfare committee.

Authors should retain one copy of the text, tables, photographs and illustrations, as rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for the loss or damage to photographs and illustrations in mailing process.

Online submissions

Online submissions are strongly advised. Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/index.jsp>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. Authors encountering problems with the Online Submission System may send an email you describing the problem to wjg@wjgnet.com for assistance. If you submit your manuscript online, do not make a postal contribution. A repeated online submission for the same manuscript is strictly prohibited.

Postal submission

Send 3 duplicate hard copies of the full-text manuscript typed double-spaced on A4 (297 mm × 210 mm) white paper together with any original photographs or illustrations and a 3.5 inch computer diskette or CD-ROM containing an electronic copy of the manuscript including all the figures, graphs and tables in native Microsoft Word format or *.rtf format to:

Editorial Office

World Journal of Gastroenterology

Editorial Department: Apartment 1066, Yishou Garden,
58 North Langxinzhuang Road,
PO Box 2345, Beijing 100023, China
E-mail: wjg@wjgnet.com
<http://www.wjgnet.com>
Telephone: +86-10-85381892
Fax: +86-10-85381893

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using a word-processing software. All submissions must be typed in 1.5

line spacing and in word size 12 with ample margins. The letter font is Tahoma. For authors from China, one copy of the Chinese translation of the manuscript is also required (excluding references). Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was accomplished, disclosure of any financial support for the research, and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (removing all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s) and full family name.

Abstract

An informative, structured abstract of no more than 350 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipments, and the experimental procedures should be included. RESULTS: The observatory and experimental results, including data, effects, outcome, etc. should be included. Authors should present *P* value where necessary, and the significant data should accompany. CONCLUSION: Accurate view and the value of the results should be included.

The format of structured abstracts is at: <http://www.wjgnet.com/wjg/help/11.doc>

Key words

Please list 5-10 key words that could reflect content of the study mainly from *Index Medicus*.

Text

For most article types, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include in appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both.

Illustrations

Figures should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. No detailed legend should be involved under the figures. This part should be added into the text where the figures are applicable. Digital images: black and white photographs should be scanned and saved in TIFF format at a resolution of 300 dpi; color images should be saved as CMYK (print files) but not as RGB (screen-viewing files). Place each photograph in a separate file. Print images: supply images of size no smaller than 126 mm × 85 mm printed on smooth surface paper; label the image by writing the Figure number and orientation using an arrow. Photomicrographs: indicate the original magnification and stain in the legend. Digital Drawings: supply files in EPS if created by freehand and illustrator, or TIFF from photoshops. EPS files must be accompanied by a version in native file format for editing purposes. Existing line drawings should be scanned at a resolution of 1200 dpi and as close as possible to the size where they will appear when printed. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes of atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...

Tables

Three-line tables should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each table. No detailed legend should be included under the tables. This part should be added into the text where the tables are applicable. The information should complement but not duplicate that contained in the text. Use one horizontal line under the title, a second under the column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. ^a*P*<0.05, ^b*P*<0.01 should be noted (*P*>0.05 should not be noted). If there are other series of *P* values, ^c*P*<0.05 and ^d*P*<0.01 are used. Third series of *P* values can be expressed as ^e*P*<0.05 and ^f*P*<0.01. Other notes in tables or under

illustrations should be expressed as 1F , 2F , 3F ; or some other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, etc. in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions are included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should code the references according the citation order in text in Arabic numerals, put references codes in square brackets, superscript it at the end of citation content or the author name of the citation. For those citation content as the narrate part, the coding number and square brackets should be typeset normally. For example, Crohn's disease (CD) is associated with increased intestinal permeability^[1,2]. If references are directly cited in the text, they would be put together with the text, for example, from references [19,22-24], we know that...

When the authors code the references, please ensure that the order in text is the same as in reference part and also insure the spelling accuracy of the first author's name. Do not code the same citation twice.

PMID requirement

PMID roots in the abstract serial number indexed by PubMed (<http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed>). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information of the journal citations is very important. Through reference testing system, the authors and editor could check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in ASP file so that the readers can read the abstract of the citations online immediately.

Style for journal references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). Title of the cited article and italicized journal title (Journal title should be in its abbreviation form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634]

Note: The author should test the references through reference testing system (<http://www.wjgnet.com/cgi-bin/index.pl>)

Style for book references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Morse SS. Factors in the emergence of infectious diseases. Emerg Infect Dis serial online, 1995-01-03, cited 1996-06-05; 1(1): 24 screens. Available from: URL: <http://www.cdc.gov/ncidod/EID/eid.htm>

Patent (list all authors)

- 16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those that are linked with a hyphen and the difference between the two numbers at two sides of the hyphen is more than 5. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered as inappropriate references. Authors should not cite their own unrelated published articles.

Statistical data

Present as mean \pm SD or mean \pm SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as γ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p*(B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 $24.5 \mu\text{g/L}$; CO₂ volume fraction, 50 mL/L CO₂ not 5% CO₂; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format about how to accurately write common units and quantum is at: <http://www.wjgnet.com/wjg/help/15.doc>

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further mention.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kbo I*, *Kpn I*, etc.

Biology: *H pylori*, *E coli*, etc.

SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. Author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, the final check list for authors, and responses to reviewers by a courier (such as EMS) (submission of revised manuscript by e-mail or on the *WJG* Editorial Office Online System is NOT available at present).

Language evaluation

The language of a manuscript will be graded before sending for revision.

(1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing; (4) Grade D: rejected. The revised articles should be in grade B or grade A.

Copyright assignment form

Please download CAF from <http://www.wjgnet.com/wjg/help/9.doc>.

We certify that the material contained in this manuscript:

Ms:

Title:

is original, except when appropriately referenced to other sources, and that written permission has been granted by any existing copyright holders. We agree to transfer to *WJG* all rights of our manuscript, including: (1) all copyright ownership in all print and electronic formats; (2) the right to grant permission to republish or reprint the stated material in whole or in part, with or without a fee; (3) the right to print copies for free distribution or sale; (4) the right to republish the stated material in a collection of articles or in any other format. We also agree that our article be put on the Internet.

Criteria for authorship: The *WJG* requests and publishes information about contributions of each author named to the submitted study. Authorship credit should be based on (1) direct participation in the study, including substantial contributions to conception and design of study, or acquisition of data, or analysis and interpretation of data; (2) manuscript writing, including drafting the article, or revising it critically for important intellectual content; (3) supportive work, including statistical analysis of data, or acquisition of funding, or administration, technology and materials support, or supervision, or supportive contributions. Authors should meet at least one of the three conditions. The *WJG* does not publish co-first authors and co-corresponding authors.

We hereby assign copyright transfer to *WJG* if this paper is accepted.

Author Name in full (Full names should be provided, with first name first, followed by middle names and family name at the last, eg, Eamonn MM Quigley). Handwritten names are not accepted.

Author Name in abbreviation (Family name is put first in full, followed by middle names and first name in abbreviation with first letter in capital, eg, Quigley EMM). Handwritten names are not accepted.

Final check list for authors

The format is at: <http://www.wjgnet.com/wjg/help/13.doc>

Responses to reviewers

Please revise your article according to the comments/suggestions of reviewers. The format for responses to the reviewers' comments is at: <http://www.wjgnet.com/wjg/help/10.doc>

Abstract

Therapeutic colonoscopy with electrocautery is widely used around the world. Adequate colonic cleansing is considered a crucial factor for the safety of this procedure. Colonic gas explosion, although rare, is one of the most frightening iatrogenic complications during colonoscopy with electrocautery. This complication is the result of an accumulation of colonic gases to explosive concentrations, but may be prevented by meticulous bowel preparation. The purpose of this review is to discuss the indications and the types of bowel preparations for therapeutic colonoscopy, and to contribute recommendations for the adequate bowel preparation for colonoscopy with electrocautery.

INTRODUCTION

Endoscopic polypectomy and argon plasma coagulation for hemostasis of colonic vascular lesions are considered relatively safe procedures. Among complications that have been reported, gas explosion is rare, but its nature could be dramatic, as perforation could complicate colonic explosion and urgent surgery is needed.

Three factors are necessary to trigger an explosion of colonic gases: presence of combustible gases (hydrogen, methane) produced by the fermentation of non-absorbable carbohydrates in the colon by the colonic bacteria, presence of combustive gas (oxygen), and application of a heat source (electrocautery or argon plasma coagulation)^[1-3]. Five major components of gases have been identified in colon: nitrogen (23%-80%), oxygen (0.1%-2.3%), hydrogen (0.06%-47%), methane (0%-26%), and carbon dioxide (5.1%-29%). Only hydrogen and methane are combustible^[4]. They are produced in the colonic lumen from fermentation of non absorbable (e.g, lactulose, mannitol) or incompletely absorbed (lactose, fructose, sorbitol) carbohydrates by the colonic flora^[4-6]. Concentrations of hydrogen more than 4% and/or methane more than 5% are considered potentially explosive^[7]. Almost half of the patients (42.8%) with unprepared colon have potentially explosive concentrations of hydrogen and methane^[8]. Nevertheless, an explosion with these two gases can occur only if the oxygen concentration is over 5%^[9].

Following bowel preparation with a combination of clear liquids, cathartics, and enemas, mean concentration of hydrogen (0.024% ± 0.007%) and methane (0.0023% ± 0.001%) were below of their minimal explosive concentration^[4]. Thus, safety of therapeutic colonoscopy could be in part related to the quality of preparation before the procedure. An accumulation of colonic gas to potentially explosive concentrations due to poor colon preparation is considered an initiating factor in the complication of colonic gas explosion. Therefore, quality of bowel preparation as well as type of preparation and dietary restrictions are all essential for an uneventful therapeutic colonoscopy.

INDICATIONS FOR COLONOSCOPY WITH ELECTROCAUTERY

The main indication for application of electrosurgical energy is snare colonoscopic polypectomy with blended or pure coagulation current^[10]. Argon plasma has been successfully used for hemostasis of vascular ectasias, for ablation of intestinal polyps or residual adenomatous tissue after colonic polypectomy, and for the endoscopic therapy of postradiation colitis^[11].

Electrosurgical generators

Electrosurgical generators are used to supply electrical energy to endoscopic accessories. When electrical energy is introduced to tissue, it produces excitation of molecules,

which results in generation of heat^[12]. Electrosurgical generators may supply two types of circuits, monopolar and bipolar. Electrosurgical cutting is achieved by a high voltage (> 200 V) continuous current^[10].

Argon plasma coagulation

Argon plasma coagulation is a noncontact electrocoagulation device that uses high-frequency monopolar current conducted to target tissues through ionized argon gas^[10]. Argon plasma delivered through a flexible probe passed through the accessory channel and allows treatment of a large area quickly^[13]. In general, low power and low argon flow rates are used for hemostasis with settings of 40-50 W and 0.8 to 1.2 L/mn, whereas higher settings (70-90 W and over 1.2 L/mn) are used for tissue ablation^[14].

BOWEL PREPARATION

Bowel preparation with purgatives

The selection of purgative used for colon preparation is an important factor that makes the bowel safe for therapeutic procedures. Earlier than 1980's, mannitol was considered as the reference agent for colonic preparation. Explosions during therapeutic colonoscopy have been reported after mannitol preparation and its use is now avoided as cleansing colonic solution^[1-3,5,15-17]. Use of oral mannitol increased hydrogen and methane excretion^[3,5,9,18-19]. Aspiration of colonic gas at the time of colonoscopy showed that mean intracolonic hydrogen concentration was significantly higher after mannitol than after castor oil. Moreover, potentially explosive concentrations were present in 60% of patients given mannitol compared to 0%-20% of patients given castor oil^[3,19]. Fermentation of mannitol by *E.coli* is thought to be responsible for the production of potentially explosive gas mixture after oral mannitol preparation^[20-21]. Significantly higher counts of gas-producing *E.coli* were recovered from patients prepared with mannitol alone compared with mannitol preceded by oral antimicrobials^[20]. Therefore, the use of antibiotics prior to therapeutic colonoscopy could be a measure that would lower the load of intracolonic bacteria. An alternative approach to reduce the risk of explosion of colonic gases if mannitol preparation is used before electrocautery is insufflation of an inert gas such as carbon dioxide instead of air^[3,22].

Since 1990, a major progress occurred with new agents, such as polyethylene glycol electrolyte lavage solution (PEG-ELS) and oral sodium phosphate (NaP) solutions. Several studies agree that these agents provide a climate safe for electrocautery during colonoscopy by decreasing the concentrations of combustible gases^[14,23-26]. The highest hydrogen and methane concentrations after a PEG-ELS preparation are well below the combustible level^[26]. A recent report described a case of colonic gas explosion in a patient that underwent bowel preparation with a polyethylene glycol solution containing sorbitol^[27]. Sorbitol is an important carbohydrate that is daily included in humans diet. Studies have shown that the frequency of sorbitol malabsorption may be as high as 60% in healthy subjects^[3,28]. Thus, fermentation of this malabsorbed carbohydrate by colonic bacteria could result in raised combustible gas concentrations in the colon and explain the explosion that occurred in the above mentioned case report^[27].

Partial bowel preparation by enemas

For lesions that need electrocautery and are located up to the level of sigmoid colon, a flexible sigmoidoscopy with enema preparation is the procedure of choice by the majority of gastroenterologists. However, studies have reported cases of gas explosion in patients prepared by enemas^[29-31]. In these cases, the used enema did not contain any fermentable agents and the extension of colonic preparation was thought to be the initiating factor in this complications. Due to the partial colonic preparation, presence of residual stools above the lesions could enhance gas production and explain gas explosion.

In a prospective study, sixty patients were evaluated to compare the presence of the combustible gases hydrogen and methane during colonoscopy after a PEG-ELS preparation and flexible sigmoidoscopy after phosphosoda enemas alone^[32]. During colonoscopy, the concentrations of hydrogen and methane remained below combustible levels in all patients, whereas 10% of patients had combustible levels of either hydrogen or methane during flexible sigmoidoscopy. Patients had combustible levels even after air insufflation during sigmoidoscopy and the possibility of explosion was clinically significant. Another important observation of this elegant study was that even segments of colon with excess retained stools did not have combustible levels of these two gases. It seems that insufflation of air during colonoscopy equalizes the distribution of combustible gases, overcoming the compartmentation of the colon.

In a more recent study using argon plasma coagulation for hemorrhagic radiation proctitis, incidence of gas explosion was higher after local colon preparation (3/19 sessions) compared with oral preparation (0/53 sessions)^[31]. All three explosions after enema preparation occurred in patients with persistent solid stool above the coagulated lesions. Thus, the presence of stools could constitute the main risk for the colonic explosion.

REVIEW OF PUBLISHED STUDIES

A systematic review of the medical research published in English language from 1952 to October 2006 was performed, by using MEDLINE, SCOPUS, SCIRUS, and EMBASE to obtain studies published on colonic gas explosion. The search terms included were combinations of "colonic explosion" or "gas explosion" with "surgery", "electrocautery", "polypectomy", and "argon plasma coagulation".

A total of 20 cases of colonic gas explosion were identified (Figure 1). Eleven cases of gas explosion during surgery^[2,16,33-39] and 9 cases during colonoscopic procedures have been published. Argon plasma coagulation provided the initiating heat source in five of the nine colonoscopic cases^[29-31], whereas the remaining four cases were associated with endoscopic polypectomy^[1,15,17,27]. Recently, we also experienced a case of colonic explosion during an argon plasma coagulation procedure for postradiation colitis. Although seven successive, uneventful sessions of argon plasma coagulation were performed with enema preparation, gas explosion without colonic perforation occurred upon finishing the last procedure.

Nine of the 20 published cases (45%) of gas explosion

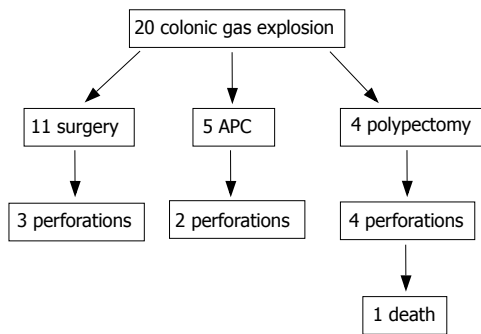

Figure 1 Flow chart of published cases with colonic gas explosion.

were complicated with colon perforation. Perforation was observed in all of the four polypectomy cases^[1,15,17,27], in two cases using argon plasma coagulation^[29,31], and in three cases during electrosurgery^[2,33-34]. One of the four perforations during polypectomy was fatal^[1].

Bowel preparation by ingestion of a mannitol solution was used in 14 cases and of a cleansing solution containing sorbitol in one case^[27]. Preparation by enemas containing no fermentable agent was used in all five cases treated with argon plasma coagulation for post-radiation colitis^[29-31].

CONCLUSION

Colonic gas explosion is a rare, but potentially serious complication during colonoscopy with electrocautery. Accumulation of colonic combustible gases at potentially explosive concentrations due to poor colon preparation is the cause of gas explosion. Cleansing purgatives (PEG, NaP) that make the bowel safe for electrocautery by decreasing the concentrations of the combustible gases are adequate for colon preparation. Argon plasma coagulation carries an increased risk of explosion during sigmoidoscopy following enemas, and it should only be performed after full bowel preparation.

In conclusion, we recommend the following to avoid colonic gas explosion during colonoscopy with electrocautery:

(1) Cleansing solution containing mannitol^[3,8,19] or other malabsorbed carbohydrates (e.g., sorbitol)^[6] should be avoided in the preparation of the colon since intracolonic concentrations of H₂ or/and CH₄ could be at combustible levels.

(2) During flexible sigmoidoscopy after standard enema preparation, concentrations of H₂ or/and CH₄ could be at explosive levels^[32].

(3) Argon plasma coagulation for post-radiation colitis should be performed only after complete bowel preparation with PEG or NaP, to avoid the risk of explosion^[31].

(4) Polypectomy with electrocautery should only be performed after full bowel preparation with PEG or NaP to prevent colonic explosion^[1,15,17,27].

Abstract

AIM: To investigate *in vitro* effects and mechanisms of silibinin on hepatocellular carcinoma (HCC) cell growth.

METHODS: Human HCC cell lines were treated with different doses of silibinin. The effects of silibinin on HCC cell growth and proliferation, apoptosis, cell cycle progression, histone acetylation, and other related signal transductions were systematically examined.

RESULTS: We demonstrated that silibinin significantly reduced the growth of HuH7, HepG2, Hep3B, and PLC/PRF/5 human hepatoma cells. Silibinin-reduced HuH7 cell growth was associated with significantly up-regulated p21/CDK4 and p27/CDK4 complexes, down-regulated Rb-phosphorylation and E2F1/DP1 complex. Silibinin promoted apoptosis of HuH7 cells that was associated with down-regulated survivin and up-regulated activated caspase-3 and -9. Silibinin's anti-angiogenic effects were indicated by down-regulated metalloproteinase-2 (MMP2) and CD34. We found that silibinin-reduced growth of HuH7 cells was associated with increased activity of phosphatase and tensin homolog deleted on chromosome ten (PTEN) and decreased p-Akt production, indicating the role of PTEN/PI3K/Akt pathway in silibinin-mediated anti-HCC effects. We also demonstrated that silibinin increased acetylation of histone H3 and H4 (AC-H3 and AC-H4), indicating a possible role of altered histone acetylation in silibinin-reduced HCC cell proliferation.

CONCLUSION: Our results defined silibinin's *in vitro* anti-HCC effects and possible mechanisms, and provided a rationale to further test silibinin for HCC chemoprevention.

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common malignancies related to a high mortality globally^[1,2]. Recent studies have noted a significant rise in the incidence of HCC in the United States in the past 2 decades^[2]. Less than 1% of HCC patients underwent a radical surgical resection in the US between 1974 and 1996^[3]. HCC's limited treatment remedies and the poor prognosis emphasize the importance in developing an effective chemoprevention for this disease.

Milk thistle (*Silybum marianum*) has been widely utilized as a folk remedy for liver diseases. It is a popular dietary supplement widely used in the United States and Europe^[4]. Silibinin is a polyphenolic flavonoid and the major biologically active compound of milk thistle^[4-6]. It is well known that milk thistle is safe and well-tolerated, and it protects the liver from drug or alcohol-related injury^[7,8]. Studies demonstrated silibinin's inhibitory effects on multiple cancer cell lines, including prostate^[9-12], colon^[13,14], skin^[15-17], bladder^[18,19] and lung cancers^[20]. Recently, we and Varghese *et al*^[21,22] reported silibinin's anti-HCC effects, but further studies are needed to define silibinin's inhibitory effects and mechanisms on human HCC cell growth.

Searching for non-invasive biomarkers is another important field of HCC chemoprevention. Plasma alpha-fetoprotein (AFP) has been used as a clinical marker for diagnosing and monitoring recurrent HCC^[23-25]. However, AFP's value in monitoring effect of HCC chemoprevention has not been tested before.

Phosphatase and tensin homolog deleted on chromosome ten (PTEN), phosphatidylinositol 3'-kinase (PI3K) and Akt (PTEN/PI3K/Akt) pathway has been associated with carcinogenesis^[26]. Activated PI3K-Akt signaling promotes carcinogenesis^[27,28]. PTEN is a negative regulator of PI3K-Akt signaling^[29] and one of the most frequently inactivated genes in malignancies^[30,31]. Akt is a downstream protein kinase of PI3K (PTEN) and is a signal transduction

protein that has been identified as one of the key elements in protecting cells from apoptosis. If unregulated, Akt promotes uncontrolled cell replication^[32,33]. It was reported that silibinin affects Akt expression in prostate cancer cells^[16], but it remains unknown whether silibinin affects HCC growth through a PTEN/PI₃K/Akt pathway in human liver cancer cells.

Histone acetylation modifies nucleosome structure that leads to DNA relaxation, reduces the affinity of histone complexes with DNA, and enhances the access of transcriptional factor to DNA^[34]. Accumulating evidence has indicated that alteration of histone acetylation plays an important role in carcinogenesis^[35,36], but it remains unknown whether it is associated with silibinin's anti-HCC effects.

In the present study, we demonstrated that silibinin significantly inhibited the growth of HuH7, HepG2, Hep3B, and PLC/PRF/5 human HCC cells that was associated with decreased Ki-67 expression, and cell cycle progression by arresting G₁-S transition, and promoted apoptosis. These effects of silibinin were associated with increased PTEN activity and decreased p-Akt production, indicating the role of PTEN/PI₃K/Akt pathway in silibinin-mediated anti-HCC effects. We also demonstrated that silibinin increased AC-H3 and AC-H4 expression, indicating that altered histone acetylation is involved in silibinin-reduced HCC cell proliferation.

MATERIALS AND METHODS

Reagents

The cell culture media were the same, as previously reported^[37,38]. Anti-activated caspase-3 antibody was purchased from Sigma Chemical Co. (St. Louis, MO). The antibodies against human Ki-67, AFP, p-Rb, E2F1, DP1, CD1, CDK4, p21 and p27, activated caspase-9, bcl-2, survivin, CD34, metalloproteinase (MMP)-2, MMP-9, phosphorylated-Akt^{Thr308}, PTEN, AC-histone3 and AC-histone4, and β -actin were purchased from Santa Cruz Biotechnology (Santa Cruz, CA). PTEN activity assay kit was from Biomol Research Laboratories, Inc (Plymouth Meeting, PA). An EIA kit for cell death detection was from Roche Applies Science (Indianapolis, IN).

Cell culture

Human HCC cell lines, HuH7, HepG2, PLC/PRF/5, and Hep3B cells^[37,38], were used in the present study. All the cells were cultured, as previously reported^[37,38]. The experiments were performed when cells reached about 80% confluence and cultured in FBS-free media for 24 h to synchronize the cell growth^[37,38].

Cell proliferation assay

Cell proliferation was determined using MTT assay, as previously reported^[37,38]. Briefly, the effects of silibinin on HCC cell growth were then determined after 24 h of incubation by optical density absorbance at 490 nm according to the manufacturer's instruction^[37,38].

Apoptosis assays

Apoptosis was determined in duplicate using an EIA kit for cell death detection, as previously reported^[37,38].

Immunoprecipitation (IP) and immunoblot (IB) assays

After 24 h of treatment with silibinin at 25% inhibitory concentration (IC₂₅) or IC₅₀ dose, the cell pellets were lysed and the supernatants were used to detect Ki-67, AFP, p-Rb, E2F1, CD1, CDK4, p21^{waf1/cip1}, p27^{kip1}, bcl-2, survivin, activated caspase-3 and caspase-9, CD34, MMP-2, MMP-9, phosphorylated-Akt^{Thr308}, PTEN, and AC-H3 and AC-H4. The IP assays were same, as previously reported^[37,38]. β -actin was used as an internal control. The relative amount of each protein was quantified by digitally scanning its hybridizing bands, as previously reported^[37,38].

PTEN activity assay

PTEN protein was immunoprecipitated with 10 μ L of rabbit anti-human antibody at 4°C overnight, followed by addition of 25 μ L of anti-rabbit IgG-conjugated agarose beads for 2 h at 4°C, washing and centrifugation. The phosphatase reaction was performed in 50 μ L of assay buffer containing 200 μ mol/L water-soluble diC₈-PIP₃ and the immunoprecipitated PTEN protein. The release of phosphate from the substrate was measured in a colorimetric assay using the Biomol Green Reagent (Plymouth Meeting, PA)^[39]. The OD absorbance at 650 nm was recorded in an ELISA plate reader^[37,38].

Statistical analysis

The descriptive statistics was provided with mean \pm SD. A repeated-measure ANOVA test was used to assess dose dependent effects of silibinin on HuH7, HepG2, Hep3B, and PLC/PRF/5 cells. An independent sample *t*-test was used to assess the effects (i.e., mean differences) of silibinin treatment on apoptosis, and IB results. A *P* value < 0.05 was considered statistically significant.

RESULTS

Potent dose-dependent anti-proliferative effects of silibinin on human HCC cells

Effects of silibinin were initially assessed in HuH7 cells by MTT assay. As shown in Figure 1A, silibinin resulted in a dose-dependent inhibition of HuH7 cell growth. Compared to the control, there was a dose-dependent inhibitory which became significant at the dose greater than 180 μ mol/L (*P* < 0.05). As shown in Figure 1B, silibinin also significantly inhibited the growth of HepG2, Hep3B, and PLC/PRF/5 human HCC cell lines, indicating a wide spectrum of silibinin's inhibitory effects on human HCC cell growth, as previously reported^[21,22]. Because the HuH7 cell line is one of the most commonly used human HCC lines^[37,38], it was then used to further determine silibinin's anti-HCC effects and mechanisms. For further characterization of dose-related mechanistic effect of silibinin, approximate IC₂₅ (i.e., 120 μ mol/L) and IC₅₀ (i.e., 240 μ mol/L) concentration were subsequently used for the remainder of the study.

Ki-67 is a commonly used biomarker for cell proliferation^[40]. Consistent with the data derived from MTT assay, silibinin treatment resulted in a significantly dose-dependent decrease in Ki-67 expression, as shown in Figure 2B (*P* < 0.05). These data further demonstrated

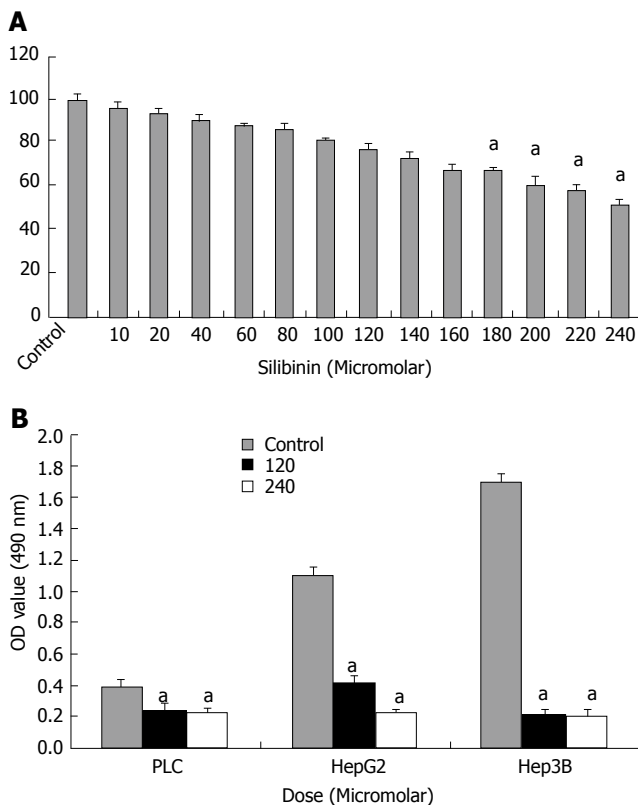

Figure 1 Silibinin's effects on growth of human hepatoma cells. **A:** MTT assay showed silibinin's dose dependent anti-proliferative effects on HuH7 cells. A significant decrease in proliferation compared to control was noted from silibinin $\geq 180 \mu\text{mol/L}$. The IC_{25} is determined to be $120 \mu\text{mol/L}$ and the IC_{50} is determined to be $240 \mu\text{mol/L}$; **B:** Silibinin's effects on other human HCC cell growth. PLC/PRF/5, HepG2, and Hep3B HCC cells were treated with silibinin at IC_{25} and IC_{50} doses for HuH7 cells. Silibinin significantly reduced growth of all three HCC cells in different rates. ^a $P < 0.05$ vs control.

silibinin's significant dose-dependent anti-proliferative effects on human HCC cells.

Effects of silibinin on cell cycle progression

Uncontrolled progression of the cell cycle promotes growth of cancer cells^[41]. A major activity of the CD1/CDK4 complex is to initiate phosphorylation of retinoblastoma (Rb) that then fails to maintain its binding to E2F1, and thus releases the transcription factor to promote cell cycle progression^[42]. Previous studies on other cancer cell lines showed a significant inhibitory effect of silibinin on the cell cycle progression^[11-13]. In the present study, we found that silibinin resulted in a significant dose-dependent inhibition of CD1/CDK4 complex that was associated with reduced Rb phosphorylation and, E2F1/DP1 complex in HuH7 cells ($P < 0.01$), as shown in Figure 2C-E.

By binding to the cyclin/CDK complexes, cyclin dependent kinase inhibitors (CDKIs), such as p21 and p27, halt uncontrolled cell proliferation^[43]. As noted in previous studies on other cancer cell lines^[12-14], we demonstrated that silibinin not only significantly increased p21 and p27 expression ($P < 0.01$), but also increased formation of p21/CDK4 and p27/CDK4 complexes (Figure 2F-I) in a dose-dependent fashion. Thus, our results demonstrate

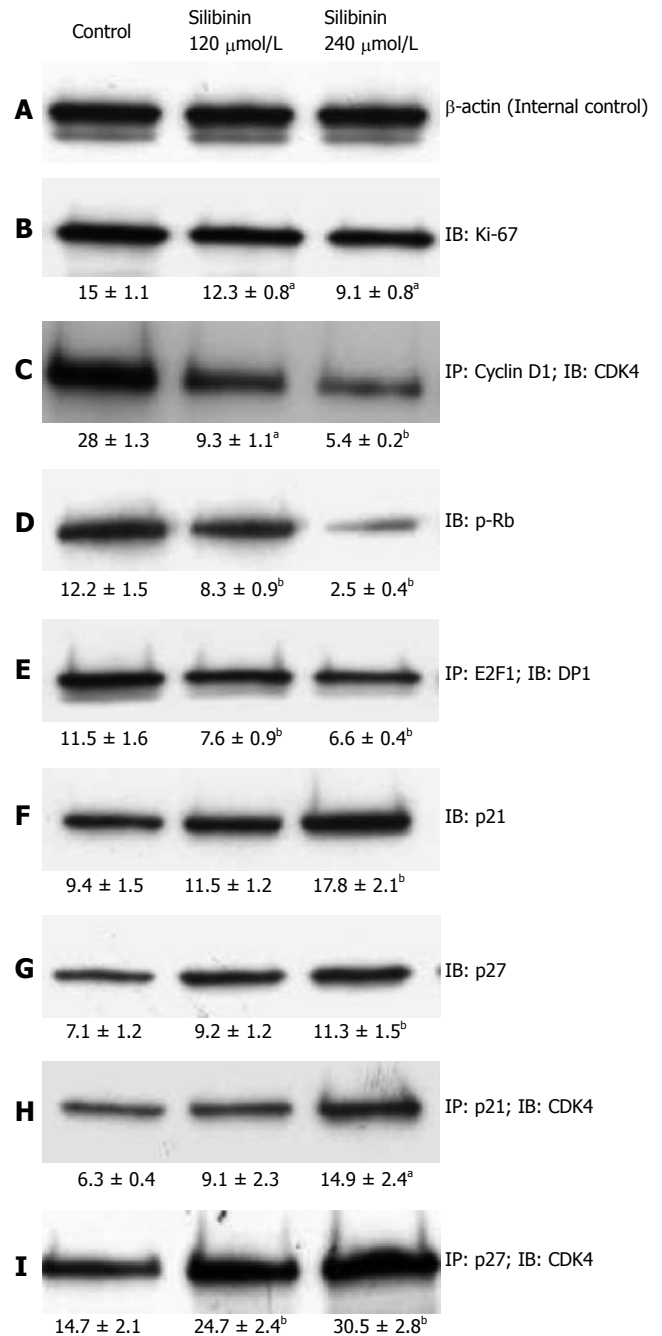

Figure 2 Silibinin's effects on proliferation of HCC cells. After HuH7 cells were treated with silibinin at IC_{25} and IC_{50} doses, immunoprecipitation (IP) and immunoblots (IB) were performed in triplicate for each specimen. A mean densitometer reading was expressed in the respective box and used for statistical analysis. **A:** β -actin for internal control; **B:** Ki-67; **C:** CD1/CDK4 complex; **D:** p-Rb; **E:** E2F1-DP1 complex; **F:** p21^{Waf1/Cip1}; **G:** p27^{Kip1}; **H:** p21^{Waf1/Cip1}/CDK4 complex; **I:** p27^{Kip1}/CDK4 complex. ^a $P < 0.05$, ^b $P < 0.01$, vs control.

silibinin inhibits the growth of human hepatoma cells through inhibiting CDK activity.

Effects of silibinin on AFP production and secretion from HuH7 cells

As shown in Figure 3B, compared to untreated HuH7 cells, silibinin at the dose of $120 \mu\text{mol/L}$ resulted in a significant decrease in AFP production in HuH7 cells ($P < 0.05$) that was associated with a reduced AFP level in the culture medium (Figure 3C, $P < 0.05$).

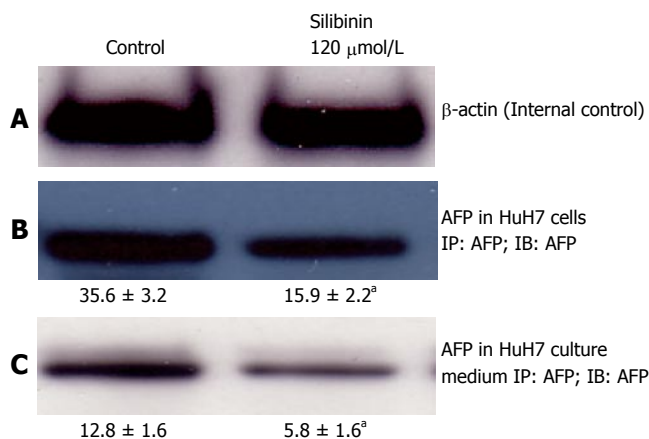

Figure 3 Silibinin's effects on AFP production and secretion from HuH7 cells. **A:** β -actin for internal control; **B:** Silibinin at IC₂₅ dose decreased AFP production in HuH7 cells; **C:** Silibinin at IC₂₅ dose decreased AFP secretion from HuH7 cells. ^a $P < 0.05$ vs control.

Effects of Silibinin on Apoptosis

Apoptosis is another important regulatory step in controlling cancer cell proliferation^[4]. Studies indicated that silibinin induces apoptosis in several malignant cell lines^[13,14,18], but such effects have not been tested in human hepatoma cells. We demonstrated silibinin dose-dependently increases of apoptosis in HuH7 cells, as shown in Figure 4A ($P < 0.01$). To understand the mechanisms of silibinin-induced apoptosis, we examined the expression of Bcl-2, survivin, and activated caspase-3 and 9. Our results showed that silibinin-induced apoptosis did not alter bcl-2 expression (data not shown), but resulted in a dose-dependent inhibition of survivin expression (Figure 4C, $P < 0.01$) that was associated with increased levels of activated caspases-3 and -9 (Figure 4D and E, $P < 0.01$).

Possible effects of silibinin on angiogenesis

In previous studies, silibinin has been reported to inhibit angiogenesis in non-HCC cancer cell lines^[13]. To evaluate whether silibinin affects angiogenesis in human HCC cells, we measured the expression of CD34, a transmembrane glycoprotein on vascular cells associated with angiogenesis^[44], and MMP-2 and MMP-9, which are markers associated with angiogenesis as well as metastatic invasion^[45]. As shown in Figure 5B, silibinin at IC₅₀, but not IC₂₅ dose decreased the expression of CD34 ($P < 0.01$). At the higher dose, Silibinin also resulted in decrease of MMP-2 (Figure 5C, $P < 0.01$), but not MMP-9 (data not shown) in HuH7 cells.

Effects of silibinin on PTEN/PI3K/Akt pathway

It has been reported that the PTEN/PI3K/Akt pathway is involved in cancer growth^[16,46]. As shown in Figure 6B, silibinin-reduced HuH7 cell proliferation was associated with a dose-dependent decrease in p-Akt ($P < 0.01$) in these cells. PTEN is an upstream negative regulator of Akt. It was reported that altered PTEN expression or activity is associated with the pathogenesis of HCC^[47-49]. In the present study, we found that silibinin at IC₅₀ dose did not significantly change PTEN expression (data not shown), but significantly increased PTEN activity (Figure 6E). These results suggested that the PTEN/PI3K/Akt pathway is involved in silibinin-reduced growth of human HCC cells.

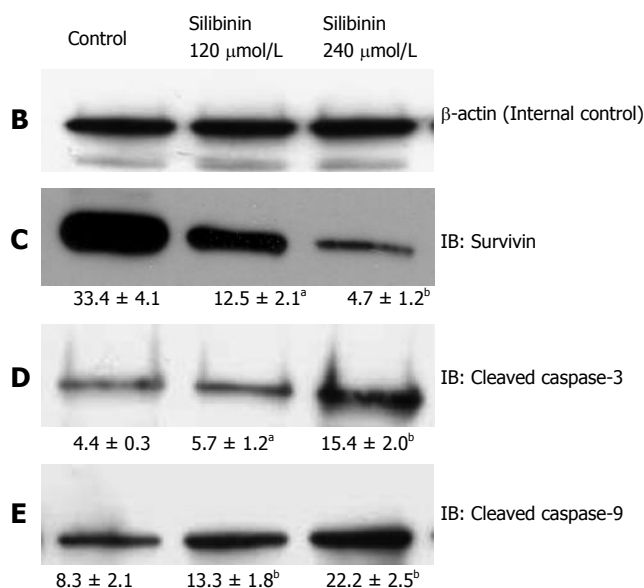

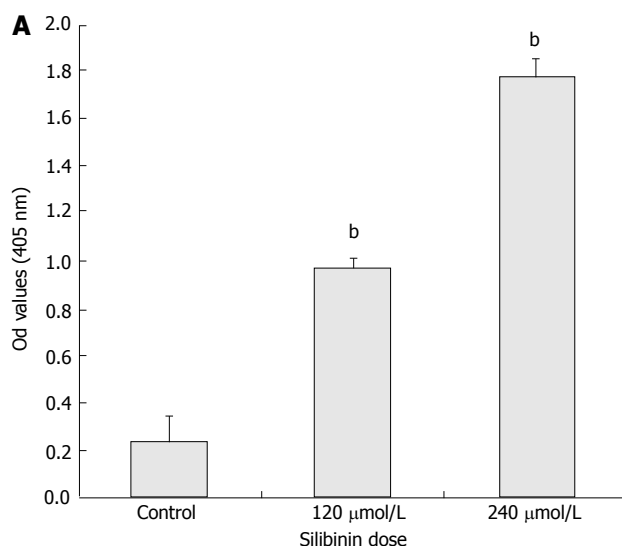

Figure 4 Silibinin's effects on apoptosis in HuH7 cells. **A:** Silibinin at IC₂₅ and IC₅₀ doses significantly promoted apoptosis of HuH7 cells; **B:** β -actin for internal control. Silibinin at IC₂₅ and IC₅₀ doses decreased survivin expression (**C**), but increased activated caspase-3 (**D**), and activated caspase-9 (**E**). ^a $P < 0.05$, ^b $P < 0.01$, vs control.

Effects of silibinin on AC-H3 and AC-H4 expression

We then examined the association of AC-H3 and AC-H4 expression with silibinin-reduced HCC cell growth. Our results demonstrated that silibinin-reduced HuH7 cell growth was associated with increased AC-H3 and AC-H4 expression (Figure 6 C and D, $P < 0.05$). These results suggest that increased AC-H3 and AC-H4 expression may play an important role in silibinin-reduced HCC growth.

DISCUSSION

Searching for an effective chemoprevention of HCC has been an active field of research. Silibinin is a polyphenolic flavonoid and the major biologically active compound of milk thistle. It is well known that milk thistle is safe and well tolerated, and it protects the liver from drug or alcohol-related injury^[7,8]. Recent demonstration of silibinin's anti-HCC

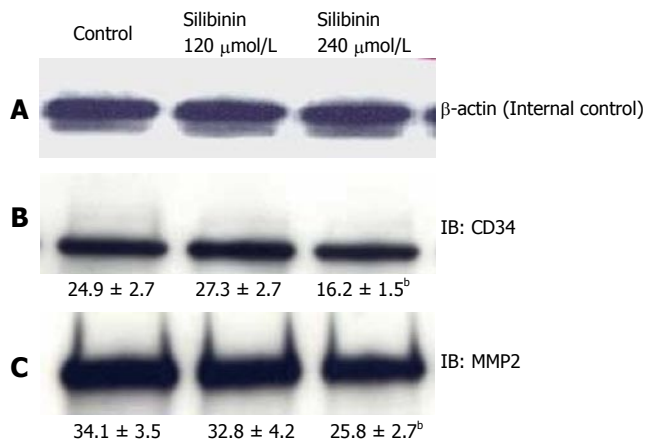

Figure 5 Silibinin's effects on angiogenesis in HuH7 cells. **A:** β-actin for internal control. Silibinin decreased CD34 (**B**), and MMP-2 (**C**). ^b*P* < 0.01 vs control.

effects^[21,22] provided us with a rationale to further define the related effects and mechanisms of HCC chemoprevention. In the present study, we examined the effects and mechanisms of silibinin on growth of human HCC cells.

Using MTT assay^[37,38], we demonstrated that silibinin treatment resulted in a potent inhibition of four different human HCC cell lines, indicating its broad spectrum of anti-HCC effects. We also revealed silibinin's linear dose-dependent inhibition of HuH7 cell growth. Silibinin at IC₂₅ and IC₅₀ doses for HuH7 cells also resulted in reduced growth of HepG2, Hep3B, and PLC/PRF/5 cells, confirming the previous reports^[21,22]. These results promote us to further test silibinin for HCC chemoprevention.

Both PCNA and Ki-67 are biomarkers for cell proliferation^[40]. Singh *et al*^[11] reported silibinin significantly decreases PCNA and Ki-67 expression in nude mice bearing xenografts of human prostate cancer. Consistent with this, we have demonstrated that silibinin significantly reduced Ki-67 expression in HuH7 cells in a dose-dependent fashion. These suggest that silibinin reduces growth of human HCC cells by down regulating their proliferation.

AFP is associated with HCC differentiation and has been widely used for diagnosing HCC and assessing treatment effects or recurrence of HCC in humans^[24,25]. Our results showed that silibinin treatment resulted in significant decrease in AFP production and secretion that was well correlated with growth inhibition of HuH7 cells. These findings suggest silibinin may promote HCC cell differentiation, and AFP may serve as a non-invasive biomarker to determine silibinin's *in vivo* anti-HCC effects.

An uncontrolled G₁-S progression results in continued proliferation with potential malignant transformation and carcinogenesis. Increased CDK4/CD1 complex enhances Rb phosphorylation that results in release of E2F1 from p-Rb/E2F1 complex and promotes E2F1/DP1 complex formation and stimulates cell cycle progression^[42]. Tyagi *et al*^[10] reported that silibinin causes a significant decrease in p-Rb in human prostate cancer cells. Our results indicate that silibinin-inhibited CDK4/CD1 complex formation is one of the important steps that inhibit Rb phosphorylation, followed by reduction of E2F1/DP1 complex formation.

CDKs are important regulators of the activity of the CD1/CDK4 complex. By binding to the cyclin/CDK

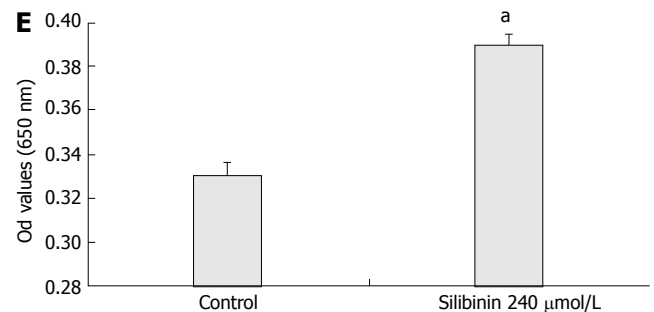

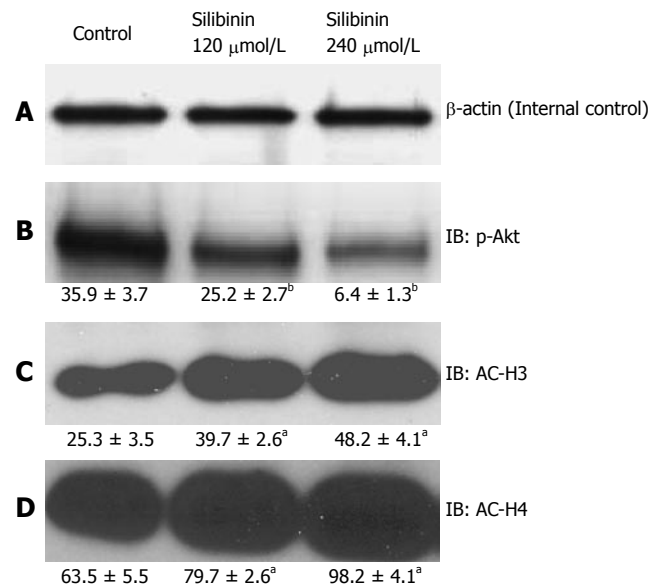

Figure 6 Silibinin's Effects on PTEN, p-Akt, AC-H3 and AC-H4 in HuH7 Cells (**A**). β-actin for internal control. Silibinin significantly decreased p-Akt (**B**); increased AC-H3 (**C**); AC-H4 (**D**). Silibinin at 240 μmol/L significantly increased PTEN activity in HuH7 cells (**E**). ^a*P* < 0.05, ^b*P* < 0.01, vs control.

complexes, two very important CDKs, p21 and p27, inhibit their activities. Varghese, *et al*^[22] reported that silibinin increases levels of p27 in human hepatoma cells. Silibinin was also reported increasing expression of p21 in several non-HCC cancer cells^[14]. In the present study, we demonstrated that silibinin resulted in a significantly dose-dependent increase in both p21 and p27, which was well correlated with their respective binding to CDK4, the bioactive forms of these CDKs. Taken together, our data demonstrated that silibinin reduces cell cycle progression in human hepatoma cells by arresting G₁-S transition that involves a comprehensive signaling of cell cycle modulators.

Previous data on other cancer cell lines have demonstrated that silibinin has effects on the apoptotic control^[10,14,21]. We demonstrated that silibinin causes a significant increase in apoptosis of HuH7 cells which was associated with decreased survivin expression and increased activated caspase-3 and -9. Because survivin can bind with caspases^[19,50,51], our results suggest that silibinin-induced apoptosis of HuH7 cells is mediated by decreased survivin that results in increased caspase-3 and 9 activation.

Angiogenesis is an important aspect of cancer invasion and survival. CD34 is a valuable marker to demonstrate this issue^[44]. A previous study demonstrated that silibinin decreases angiogenesis in colon cancer cells^[15]. In the present study, we revealed that silibinin at IC₅₀ decreased CD34

protein expression. MMP-2 and MMP-9 have been used as markers for angiogenesis and malignant invasion^[45]. It was reported that silibinin resulted in a significant decrease in MMP-2, but not MMP-9 levels in human lung cancer cells^[20]. In the present study, we found that silibinin also resulted in a dose-dependent and significant decrease in MMP-2, but not MMP-9 expression. Although our data suggest that silibinin may reduce angiogenesis in human HCC cells, further *in vivo* studies with quantification of microvessel density^[52] will be needed to validate these findings.

There is growing evidence of PTEN/PI3K/Akt pathway in hepatocarcinogenesis^[27,32,47-49]. PTEN is a tumor suppressor gene and the deletion or inactivation of this gene has been described in a variety of cancer cell lines^[30,33,53]. As a result, the tumor suppressive properties of PTEN relates in part to its ability to down-regulate the Akt pathway and thus inhibit cell proliferation^[32,33]. Paramio *et al*^[54] showed that PTEN decreases p-Rb and resulted in down-regulation of CD1. Furthermore, Weng *et al*^[55] demonstrated through the use of breast cancer cells that PTEN also up-regulates p27 and down-regulates CD1. However, it remains to be determined whether PTEN/PI3K/Akt pathway is involved in silibinin-reduced growth of cancers. In the present study, we found that silibinin significantly increased PTEN activity in association with decreased p-Akt in HuH7 cells. Since silibinin treatment also resulted in significant decrease of p-Rb and proliferation in these cells, it is evident that silibinin alters PTEN activity to assist in cellular growth control through downstream regulation of Akt and also possibly in promoting the up-regulation of p27 and the down-regulation of both p-Rb and CD1 as suggested by previous studies^[54]. It was also reported that overexpression of PTEN reduces survivin expression^[56]. We found that silibinin-mediated increase in PTEN activity and decrease in p-Akt was associated with decreased survivin expression and enhanced apoptosis in HuH7 cells. These data support the notion that PTEN/PI3K/Akt pathway may mediate cancer cell apoptosis by modulating surviving expression, and silibinin may play an important role in this interaction. Additional studies will be needed to further detail the role of PTEN/PI3K/Akt signaling in silibinin-reduced growth of human HCC cells.

Histone acetylation alters chromatin conformation by making promoter regions more accessible to transcription factors and permissive to transcriptional activation^[34]. Studies have reported that histone acetylation is involved in cell proliferation, differentiation, and cell cycle regulation^[34]. Decrease in acetylation status in the cell is associated with carcinogenesis^[35,36]. Our results demonstrated that silibinin-reduced HuH7 cell growth was significantly associated with increased AC-H3 and AC-H4 expression, suggesting that increased histone acetylation may mediate silibinin-reduced HCC growth. Our findings not only indicate silibinin's novel anti-cancer mechanisms, but also provide additional targets for searching new agents for HCC chemoprevention.

Abstract

AIM: To investigate the expression of survivin during the early stages of hepatocellular carcinoma (HCC).

METHODS: Immunohistochemical expression of survivin in liver tumor and non-tumor tissue specimens taken from 17 patients was compared. In addition, to determine the survivin expression in response to anti-cancer drugs in early stage HCC, the survivin expression was determined after the treatment of the HCC cells with anti-cancer drugs under hypoxic culture conditions.

RESULTS: Survivin proteins were expressed in 64.7% of cells in early HCC specimens. A correlation between the survivin expression rate in the peritumoral hepatocytes and the rate of expression in the HCC specimens (low-rate group vs high-rate group) was observed. The survivin protein concentration in HCC cells was increased by the combination of hypoxia and anti-cancer drugs.

CONCLUSION: This study suggests that survivin could be used as a therapeutic target in early HCC.

INTRODUCTION

Hepatocellular carcinoma (HCC) is a major health problem worldwide. There are more than 500 000 new cases diagnosed each year, with an age-adjusted incidence of 5.5-14.9 per 100 000 people^[1]. In some areas of Asia and the Middle East, HCC ranks as the most frequent cancer-related cause of death^[2]. The incidence of HCC is also increasing in Europe and the United States^[3]. A more effective therapy thus needs to be developed from early stages.

Survivin is a member of a family of inhibitors of apoptosis protein (IAP), which has been implicated in both the control of cell division and the inhibition of apoptosis. Specifically, its anti-apoptotic function is associated with the ability to directly or indirectly inhibit caspases. By inhibiting apoptosis and promoting mitosis, survivin facilitates cancer cell survival and growth^[4-8]. Survivin is selectively expressed in the most common human neoplasms and appears to be involved in tumor cell resistance to some anticancer agents and ionizing radiation^[9].

Several preclinical studies have demonstrated that the down-regulation of survivin expression/function by the use of anti-sense oligonucleotide, dominant negative mutants, ribozymes, small interfering RNAs and cyclin-dependent kinase inhibitors increased the rate of apoptosis, reduced tumor growth potential and sensitized tumor cells to various chemotherapeutic drugs and γ -irradiation in *in vitro* and *in vivo* models of various types of human tumors^[9]. Moreover, YM155 is the first agent designed to inhibit survivin. Some early phase clinical studies demonstrated that this novel anticancer agent was well tolerated and shrank tumors in some patients with non-Hodgkin lymphoma and hormone-refractory prostate cancer that recurred after conventional chemotherapy. In addition, interim reports indicate that there are few side effects.

These results suggest the possible efficacy of the survivin inhibitor on HCC. It may be effective for patients with early stages of HCC. Survivin is expressed in HCC^[10]. However, the expression during the early stages of HCC has not been characterized pathologically. In addition, previous results have shown that survivin gene transcription is increased in hypoxic tumor cells^[11]. The well-differentiated HCC has portal blood flow and is not hypervascular^[12]. In order to compare the expression of

survivin and the efficacy of anti-cancer drugs, HCC cells were cultured in a hypoxic environment.

MATERIALS AND METHODS

Patients

The study population included 17 patients (11 men and 6 women; median age 68 years, range 56-81 years) who underwent a tumor biopsy between January 2004 and December 2005 in the Jikei University Daisan Hospital, Tokyo, Japan (Table 1). All patients underwent biopsies to confirm the diagnosis of HCC. These tissue specimens were examined retrospectively. This study was approved by the Jikei University Ethics Committee Institutional Review Board.

Pathologic specimens

Tumor specimens were obtained by tumor biopsies with a 21-G fine-needle aspiration kit. Non-tumorous liver tissue specimens were concurrently obtained by an 18-20-G needle liver biopsy. Formalin-fixed, paraffin-embedded specimens of liver tumor and non-tumor tissues were processed for conventional histological assessment by hematoxylin and eosin (H&E) staining. The tumors were histologically graded as well or moderately differentiated.

Immunohistochemical analysis

For the immunohistochemical analysis, formalin-fixed, paraffin-embedded specimens were used after deparaffinization. A rabbit anti-human survivin polyclonal antibody (Diagnostic BioSystems, USA) was used at dilution of 1:2000 as the primary antibody, which was detected with ENVISION + Rabbit/HRP (Dako, Japan). The specimens were heated in a microwave oven containing antigen retrieval solution (10 mmol/L citrate buffer, pH 6.4) at 121°C for 15 min for the retrieval of the antigens and then cooled to room temperature. 3, 3-Diaminobenzidine and hematoxylin were used for color development and counterstaining, respectively. Cells with brown-colored nuclei were regarded as positive. The mean percentage of survivin-positive HCC cells was determined in three areas at 100 × magnification with the nuclear labeling index (labeled nuclei/500 nuclei). The same method was performed for hepatocytes in non-tumorous biopsy specimens.

HCC cell line cultured in the combination of hypoxia and anti-cancer drugs environment

Human hepatocellular carcinoma cell line FLC-7 was cultured with RPMI-1640 (Invitrogen, Carlsbad, CA) medium supplemented with 100 mL/L heat-inactivated fetal bovine serum (FBS) under conventional conditions at 37°C in a humidified atmosphere containing 50 mL/L CO₂^[13] until the cells were 70%-80% confluent. Cells were then used for culture under hypoxic conditions employing the AnaeroPack for cell (Mitsubishi Gas Chemical Co., Tokyo, Japan) packaging device. The cells were sealed tightly and incubated at 37°C for either 6 or 96 h. In addition, for the anti-cancer drug therapy, the cells were cultured continuously with 0.1 μmol/L farfomycin (EPI)

Table 1 Characteristics of the patients undergoing tumor biopsies (*n* = 17)

Features	Values
Age, yr	68 (56-81)
Sex (Male/Female)	11/6
AFP (ng/mL)	21 (3-444)
HBsAg/HCVAb	3/14
Tumor size (mm)	15 (8-23)
Cirrhosis (positive/negative)	5/12
Differentiation (well/moderate)	11/6

Data are expressed as the medians with ranges in parentheses unless indicated otherwise. HBsAg: Anti-hepatitis B surface antigen; HCVAb: Anti-hepatitis C antibody; Well: Well-differentiated HCC; Moderate: Moderate-differentiated HCC; Normal ranges: AFP (alpha-feto protein) > 20 ng/mL.

Table 2 PCR primer sequences

Name	Forward sequence (5'-3')	Reverse sequence (5'-3')
Survivin	GCCAGTGTTCTCTCT GCTT	GCACITTCITCGCAGT TTCC
β-actin	AGCCATGTACGTAGC CATCC	AAGTGGTGGTGTGCGAC TCTC

containing growth medium for 6 or 96 h. The cytotoxicity (IC₅₀) with EPI of FLC-7 cells determined the medication concentration (Normoxia cultured for 96 h, data not shown).

Reverse transcription-polymerase chain reaction (RT-PCR)

Total RNA was extracted from the cells using the RNeasy kit (Qiagen, Hilden, Germany). The mRNA was reverse transcribed into cDNA using the Prime script (TAKARA BIO INC, Shiga, Japan). The specific cDNA target sequences for survivin were amplified by a PCR reaction mixture consisting of 1 μL cDNA template, 10 μmol/L each primer (Primer sequences are listed in Table 2), PCR Master Mix (Go taq, Promega, Madison, WI, USA). The PCR conditions were: initial pre-denaturation at 95°C for 5 min; 30 amplification cycles of denaturation at 95°C for 30 s, primer annealing at 55°C for 30 s, and elongation at 72°C for 60 s; and a final extension at 72°C for 5 min. PCR products were analyzed on a 20 g/L agarose/TBE gel electrophoresis and compared to the expression of β-actin as a housekeeping gene.

Western blotting

The harvested cells cultured in either a normal or hypoxic environment for 96 h with or without 0.1 μmol/L of EPI were washed with ice-cold PBS and lysed in ice-cold 5 mL/L Triton X-100 containing 10 mmol/L EDTA. The cell lysate was centrifuged at 15000 *g* for 5 min and the supernatant was used for Western blotting. Thirty micrograms of protein was separated on 150 g/L polyacrylamide gels and transferred onto 0.2-μm nitrocellulose membranes by wet blotting (20 mA for 60 min). Membranes were blocked with blocking buffer (1 × TBS, 1 g/L Tween-20, 1 g/L casein gelatin) for 0.5 h at 37°C and stained with the specific antibody for survivin

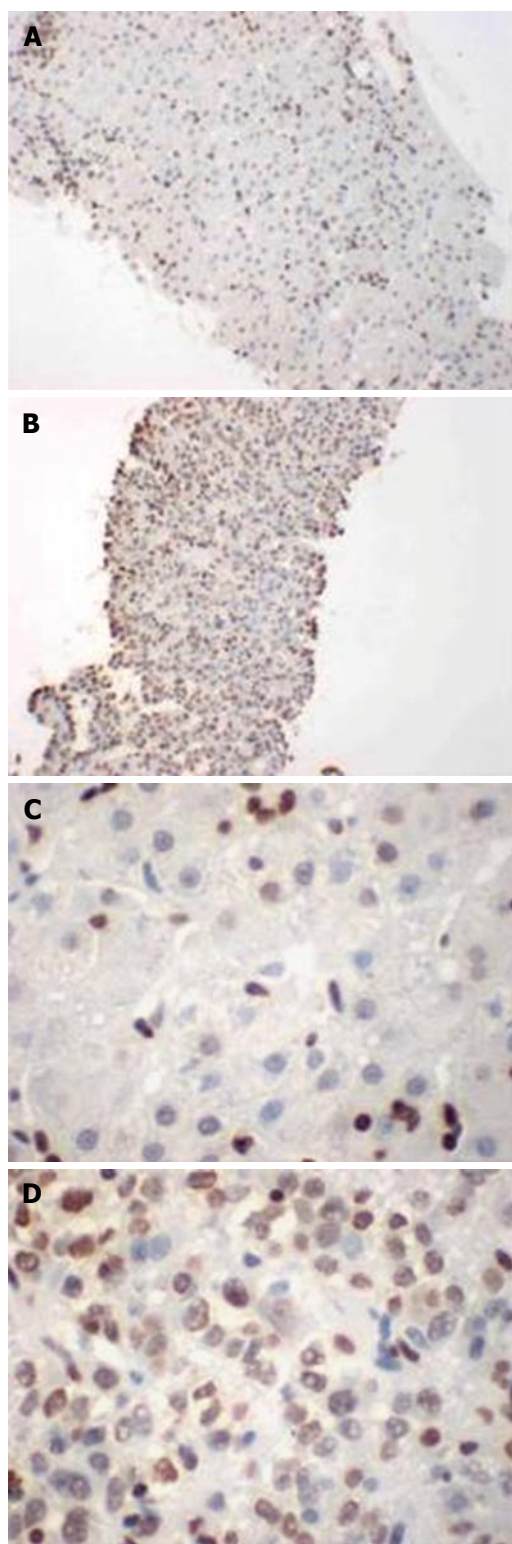

Figure 1 Immunopathological staining of survivin in HCC and peritumoral biopsy tissues. A: Non-tumor biopsy (x 100); B: Tumor biopsy (x 100); C: Non-tumor biopsy (x 400); D: Tumor biopsy (x 400).

(1:1000; Novus Biologicals, Littleton, USA). The complex of antigen with the primary antibody was completely labeled with the secondary antibody, anti-rabbit IgG alkaline phosphatase conjugate (1:2000; Sigma-Aldrich Japan, Tokyo, Japan). The survivin band was visualized with 5-bromo-4-chloro-3-indolyl-phosphate/nitro blue tetrazolium (Sigma-Aldrich Japan, Tokyo, Japan).

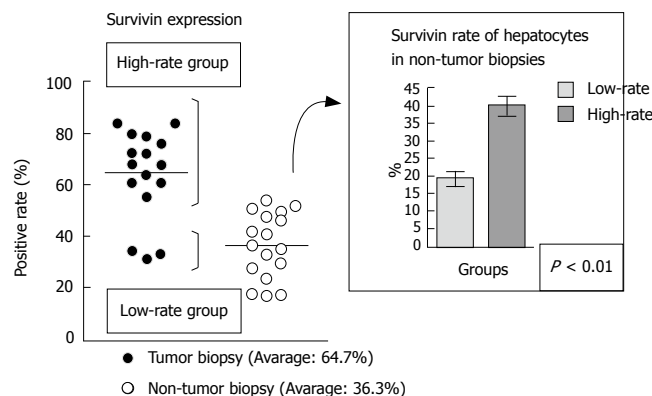

Figure 2 Nuclear survivin expression rates in HCC biopsies and non-tumor biopsies samples. In tumor biopsies, > 500 survivin-expressing HCC cells were counted in three areas at 100 x magnification using the nuclear labeling index. In non-tumor biopsies, > 500 survivin-expressing hepatocyte cell were counted in three areas at 100 x magnification using the nuclear labeling index.

Protein determination

Protein concentration was assayed by a Bio-Rad protein assay kit (Bio-Rad Lab., Tokyo, Japan) using BSA as the standard.

Statistical analysis

Statistical analyses were performed using the Wilcoxon-Mann-Whitney two-sample rank-sum test. A P value less than 0.05 was considered statistically significant.

RESULTS

Rates of survivin expression in early HCC and in non-tumorous liver tissues

In HCC tissues, the rate of survivin expression was determined by counting survivin-positive cancer cells (Figure 1). The average survivin expression rate was 64.7% (median). The samples with a survivin expression rate over 50% were regarded as high-rate group, while the three samples with a survivin expression rate under 50% were regarded as low-rate group (Figure 2). In early-stage HCC with a tumor size > 10 mm ($n = 3$), the expression rate ranged from 67.7% to 83.7%. The expression rate of survivin in HCC had no significant correlation to the level of differentiation of HCC. In non-tumorous liver tissues, survivin expression rates were counted in all hepatocytes. The average of survivin expression was 36.3% (median, Figure 2). A correlation between the survivin expression rate in peritumoral cells and the rate of expression in the HCC specimens (low-rate group vs high-rate group) was observed. A significant difference in survivin expression in the hepatocyte was observed between the high-rate group and low-rate group ($P < 0.01$, Figure 2).

Survivin expression of HCC cells in hypoxic conditions and post-treatment with anti-cancer drugs

The hypoxic environment increased the survivin mRNA expression in both short-term and long-term cultures (Figure 3). Under both normoxia and hypoxia, the survivin mRNA concentrations increased in the presence of anti-cancer drugs in the short-term culture.

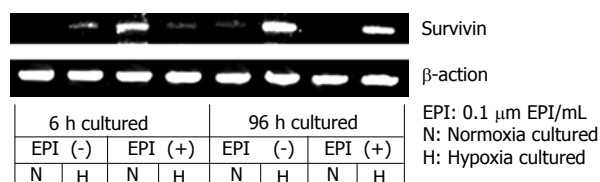

Figure 3 Expression of survivin mRNA in a hypoxic and anti-cancer drug-containing medium. The survivin mRNA expression increased under hypoxia, by anti-cancer drug treatment, and in presence of the both conditions in the 6-h culture. The survivin mRNA expression increased under hypoxia and in the combined conditions of hypoxia and anti-cancer drug in the 96-h culture.

Nevertheless, the survivin mRNA concentrations only increased in the combination of hypoxic culture and anti-cancer drugs in the long-term culture (Figure 3). No survivin protein expression was observed in the hypoxia culture (Figure 4). In contrast, the survivin protein concentration increased with the anti-cancer drug concentrations. Moreover, the survivin protein concentrations increased when cultured in a combination of hypoxia and anti-cancer drugs (Figure 4).

DISCUSSION

The suppression of apoptosis is thought to contribute to carcinogenesis due to several mechanisms, including unusually prolonging the cellular lifespan, facilitating the accumulation of gene mutations and permitting growth factor-independent cell survival^[14]. In addition, since the host's immune system normally eliminates cancer cells by induction of apoptosis, inhibition of this process is critical for cancer cells survival. Several proteins, including the bcl-2 family and the IAP family, are involved in the inhibition of apoptotic signaling^[15-16]. Survivin, a novel member of the IAP family, inhibits the activation of caspase-3 and -7, which are downstream effectors of apoptosis, in cells exposed to apoptotic stimuli^[17-20]. Previous studies have shown that survivin is expressed at a high level in 60%-100% of the most common human tumor types, including colon, pancreas, breast, lung, liver, brain, lymphoma, melanoma and prostate cancers^[21-24]. The elevated expression of survivin is associated with poor patient survival^[25-28]. In the present study, positive nuclear survivin expression was observed in all tumor biopsy samples. It is possible that this result was based on dyeing conditions and the nuclear labeling index. The differential nuclear and cytoplasmic localization of survivin has been shown to be due to differences in the amino-acid sequence of its carboxy-terminal domain^[29]. In HCC, the predominant function of survivin is its cell cycle nuclear distribution, and not the cytoplasmic caspase-3-dependent anti-apoptotic effect^[30]. So in HCC, the prognostic significance of survivin immunostain relates to the cell cycle in nuclei, and not to its cytoplasmic anti-apoptotic effect^[31]. These reports suggest that most cytoplasm in the early HCC samples might be stained moderately under the conditions employed in this study.

In the present study, nuclear survivin is expressed in 64.7% of cells (median) from early-stage HCC specimens.

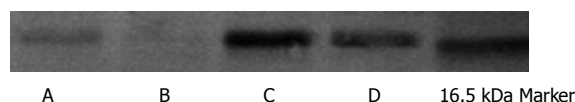

Figure 4 Western blotting showing the expression of survivin protein in the combined conditions of hypoxia and anti-cancer drugs in the 96-h culture. Survivin expression increased under anti-cancer drug-containing medium. Moreover, survivin further increased after the administration of a combination of hypoxia and anti-cancer drug. A: Normoxia; B: Hypoxia; C: Normoxia + 0.1 μ mol/L EPI; D: Hypoxia + 0.1 μ mol/L EPI.

Moreover, in all early HCCs of tumor size > 10 mm ($n = 3$), survivin expression was always above the median average. These data indicate that survivin could be an effective target of gene therapy for HCC, even at an early stage. Moreover, a previous study reported that in surgically removed tissues, the expression of survivin had no correlation with the patient's age, gender, tumor size and differentiation level of HCC^[11]. This is consistent with the rate of nuclear expression in the small biopsy samples from early-stage HCC observed in the present study. However, a recent report showed that alpha-feto protein (AFP) blocked the X-linked inhibitor of apoptosis protein-mediated inhibition of endogenous active caspases in the cytosolic lysates of tumor cells^[32]. Further immunohistological analyses of other proteins of the IAP family must be compared to the clinical parameters in early-stage HCC.

In this study, the survivin expression in HCC samples could be divided into two groups: a high-rate group (rate > 50%) and low-rate group (rate < 50%). Ikeguchi *et al.*^[33,34] detected survivin mRNA over-expression in 21 of 51 (41%) of HCC biopsies, and suggested that this could be useful as a prognostic factor for patients with HCC. From the early stages, the level of nuclear survivin expression may correlate with the prognosis of HCC.

HBV X and HCV core proteins activate NF- κ B and/or STAT-3, which regulate the gene expression for cell survival factors such as the anti-apoptosis proteins, including survivin^[35,36]. A resulting up-regulation of anti-apoptosis factors during HCV or HBV infection may contribute to hepatocarcinogenesis^[35,36]. A previous report demonstrated that HBx promotes the upregulation of survivin expression in hepatoma and normal liver cells, regardless of apoptosis. These findings suggest that survivin and HBx may play important roles in the carcinogenesis of HCC^[37]. Other studies have shown that HCV NS5A protein can stimulate survivin protein expression, and this may result from induced survivin gene transcription^[38]. In the present study, the average nuclear survivin expression was 36.3% in hepatocyte of non-tumor specimens. This result may indicate that the hepatitis virus is associated with survivin expression in peritumoral cells. The expression of survivin has been detected in a variety of pre-neoplastic and/or benign lesions, including polyps of the colon, breast adenomas, Bowen's disease and hypertrophic actinic keratosis^[39], suggesting that expression of survivin may occur during early malignant transformation or following a disturbance in the balance between cell proliferation and death^[9]. The same process may also occur in viral hepatitis.

A previous study reported that inhibition of apoptosis by survivin plays a pivotal role in the metastasis of HCC, and it has some correlation with tumorigenesis. The expression of survivin in the primary lesion can be an indicator of metastasis and the prognosis of HCC^[10]. In this study, a correlation between the survivin expression rate in the non-tumor cells and that in the HCC specimens of the high-rate group (rate > 50%) and low-rate group (rate < 50%) was observed. A significant difference in the survivin expression in the peritumoral hepatocyte was observed between the high-rate group and the low-rate group ($P < 0.01$). The survivin expression of peritumoral cells may, therefore, also be a prognostic factor for patients with HCC. Interestingly, we observed that when the amount of survivin expression was low in the adjacent non-tumor tissues, the corresponding tumor tissues also showed low expression. So in the future, when taking the target therapy of survivin into consideration, a curative effect may be possible if the amount of survivin expression with non-tumorous tissue is evaluated with liver biopsies.

Saitoh *et al*^[40] demonstrated that the portal blood flow is lost before the increase in arterial flow develops in well-differentiated HCC. When the well-differentiated HCC has portal blood flow and is not hypervascular, it shows slow growth^[12]. Yamaguchi *et al*^[41] suggested that this phenomenon is related to hypoxia, because the well-differentiated HCC would be in a transitional stage from the portal blood supply to the arterial blood supply, but the reduction in portal flow appears prior to the increase in arterial flow. Therefore, the current research indicates that the impairment of the normal liver blood system probably causes local hypoxic regions at an early stage of hepatocarcinogenesis and eventually induces angiogenesis^[12]. Recent studies have shown that human solid tumors, even those less than 1 cm in diameter, may have substantial hypoxic fractions^[42-43]. Hence tumor growth is restricted by limited oxygen and nutrients when they are too distant from nearby vessels^[12]. Therefore, to observe the expression of survivin in early-stage HCC, HCC cells were cultured in a hypoxic environment. Previous studies have shown that survivin gene transcription is increased in hypoxic tumor cells^[11]. In the current study, the hypoxic environment increased the survivin mRNA expression in both the short-term and long-term cultures. Moreover, the appearance of survivin protein is thought to control the survivin mRNA levels in the presence of anti-cancer drugs. On the contrary, in the present study, the survivin protein concentrations increased when both hypoxia and anti-cancer drugs were combined. These data suggest that survivin inhibition could therefore potentially be as effective as interventional therapy for the treatment of early HCC.

In conclusion, survivin is expressed at a rate of 64.7% (median) in early HCC. Moreover, survivin protein concentration of HCC cells increases when cultured with anti-cancer drugs under hypoxic conditions. These data suggest that survivin inhibition for early HCC could therefore be potentially useful as an effective interventional radiological treatment modality.

COMMENTS

Background

Several preclinical studies have demonstrated that the down-regulation of survivin expression/function increases the rate of apoptosis, reduces the tumor-growth potential and sensitizes tumor cells to various chemotherapeutic drugs and γ -irradiation in both *in vitro* and *in vivo* models of various types of human tumors.

Research frontiers

Previous reports have shown survivin to be expressed in post-operative HCC tissues. However, it has not yet been fully elucidated regarding whether survivin can be used as a therapeutic target in early HCC.

Innovations and breakthrough

We studied biopsy tissue specimens to confirm the diagnosis of HCC. In all early HCCs of tumor size > 10 mm, survivin expression was always above the median average (64.7%). Moreover, the survivin protein concentrations increased when cultured in a combination of hypoxia and anti-cancer drugs.

Applications

These data suggest that survivin inhibition for early HCC could therefore be potentially useful as an effective interventional radiological treatment modality, such as transcatheter arterial chemoembolization (TACE), etc.

Terminology

In this study, a hypoxia model of cultured HCC cells was employed using an AnaeroPack for cell culture. The Anaeropack is a gas concentration-controlling reagent yielding a hypoxic atmosphere. The principal ingredient of this reagent is sodium ascorbate, which absorbs oxygen and generates carbon dioxide by oxidative degradation. The culture dishes were placed into an airtight jar with the Anaeropack and then the lid was closed. The jar was then incubated at 37°C for 2 h. The concentration of oxygen decreased to less than 1% within 1 h and the carbon dioxide concentration was maintained at about 5% as reported previously.

Peer review

This paper investigated survivin expression in early-stage, small HCC and the results are interesting. The methods and results were clearly written, and the authors gave thoughtful discussions on this topic and their findings. This is an interesting paper that is generally well written.

Abstract

AIM: To inhibit the expression of vascular endothelial growth factor (VEGF) in colon cancer cell line by RNA interference (RNAi).

METHODS: Followed the service of E-RNAi, we designed and constructed two kinds of shRNA expression vectors aiming at the VEGF gene, then transfected them into colon cancer HT29 cells by lipofectamine™ 2000. The level of VEGF mRNA was investigated by RT-PCR and Northern blotting. The protein expression of VEGF was observed by immunofluorescence staining and Western blotting.

RESULTS: We got two kinds of VEGF specific shRNA expression vectors which could efficiently inhibit the expression of VEGF in HT29 cells. RT-PCR, Northern blotting, immunofluorescence staining and Western blotting showed that inhibition rate for VEGF expression was up to 42%, 89%, 73% and 82%, respectively.

CONCLUSION: The expression of VEGF can be inhibited by RNA interference in HT29 cells.

Key words: RNA interference; Vascular endothelial growth factor; Colon cancer; Northern blotting; Western blotting

INTRODUCTION

Angiogenesis is a common process that is essential for tumor growth beyond 2 mm^[1]. Although numerous growth factors are involved, vascular endothelial growth factor (VEGF), particularly VEGF-A, has been shown to play an important role in tumor angiogenesis^[2]. VEGF, a 45 kDa heparin-binding growth factor, is induced by hypoxia-inducible factor-1a. Binding of VEGF-A to tyrosine kinase receptors, especially VEGFR-2, mediates many key components of angiogenesis, including endothelial cell proliferation, invasion, migration, survival, as well as vessel permeability. VEGF is secreted by most tumors, including tumors of the lung, gastrointestinal tract, kidney, thyroid, bladder, ovary, and cervix, and the level of VEGF is correlated with tumor progression, invasion^[3].

RNAi is the sequence-specific, posttranscriptional gene silencing method initiated by double-stranded RNAs, which are homologous to the suppressed gene. Double-stranded RNAs are processed by Dicer, a cellular RNase III, to generate duplexes of about 21nt with 3'-overhang small interfering RNA (siRNA), which mediate sequence-specific mRNA degradation. RNAi technology is not only an extremely powerful instrument for functional genomic analysis but also a potentially useful method to develop highly specific gene silencing therapeutics^[4-9]. In this study, we constructed vector-based expression systems in which sense and antisense strands of short VEGF sequences were transcribed into the hairpin structure under control of the U6 promoter.

A number of studies are available on VEGF in the treatment of tumors, such as colon cancer and liver cancer^[10-15]. However, due to the "off-target" of RNAi, experiments have to be done to verify the more effective sequence of VEGF before it is used in clinical practice. This study was to find a better VEGF specific RNAi for colon cancer.

MATERIALS AND METHODS

Construction of RNAi vectors

RNAi vectors pShRNA-V1 and pShRNA-V2 were constructed as previously described^[16-19]. In brief,

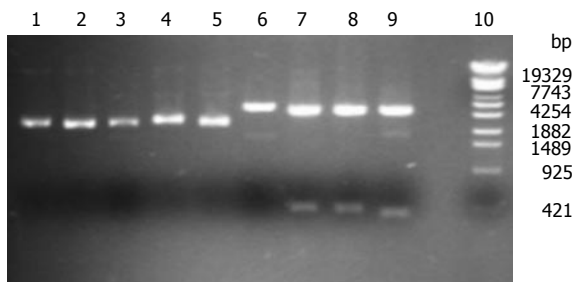

Figure 1 Restriction map of recombinant plasmid pShRNA. Lanes 1-2: pShRNA undigested; Lane 3: undigested null vector pTZU6+1; Lanes 4-5: pShRNA digested by sal I; Lane 6: pTZU6+1 digested by sal I; Lanes 7-8: pShRNA digested by Hind III and EcoR I (2800 + 395 bp); Lane 9: pTZU6+1 digested by Hind III and EcoR I (2800 + 352 bp); Lane 10: λ T14 DNA Marker.

21-nucleotide-long inverted repeats (separated by a 4-nucleotide linker, ttcg) were inserted downstream of the U6 promoter. The transcribed RNA thus comprised a 21-base pair of double-stranded RNAs. Five thymidines were inserted downstream the antisense strand to provide a stop signal for the RNA polymerase. The sense strand of hairpin was homologous to a 21-nucleotide region in the target mRNA. The target sequences were selected following the advice of E-RNAi services (<http://e-rnai.dkfz.de/>). The sequence of V1 and V2 is 5'-TGAAGTT CATGGATGTCTATC-3' and 5'-ACATCACCATGCAG ATTATGC-3', respectively. An irrelevant RNAi control plasmid was constructed for green fluorescent protein (GFP) gene, pShRNA-GFP. The sequence (5'-AGCTG ACCCTGAAGTTCATCT-3') was designed to target the nucleotides 126-144 of the GFP coding region.

Cell culture and transfection

Human colon cancer cells were maintained in RPMI 1640 medium supplemented with 10% fetal calf serum (FCS), 100 μ g/mL streptomycin, and 100-units/mL ampicillin. The cells were plated in 24- or 6- well plates at 50%-70% confluence 24 h prior to transfection. Transfection of cells was carried out with LipofectamineTM 2000 reagent (Invitrogen, Carlsbad, CA).

Real-time polymerase chain reaction for VEGF

Total RNA was isolated from cultured cells and real-time polymerase chain reaction (RT-PCR) was performed using the RNeasy and one step RT-PCR kit from Qiagen Corp. RT-PCR of hGAPDH, a housekeeping gene served as a control. The sequences used for primers are 5' ctacctccaccatgccagt-3' (sense) and 5'-aatgtctttctcgcgtctga-3' (antisense) for VEGF (411 bp), 5'-GGCTCTCCAGAACATCAT-3'(sense) and 5'-CACCTGGTGCTCAGTGTA-3' (antisense) for hGAPDH (240 bp). For RT-PCR, two pairs of primers were added into a reaction tube, the program consisted of an initial reverse transcription at 50°C for 30 min, denaturation at 95°C for 10 min, followed by 24 cycles of amplification (denaturation at 95°C for 30 s, annealing at 55°C for 1 min, and extension at 68°C for 1 min) and a final extension at 68°C for 10 min. The products were then separated by electrophoresis on 1.5% agarose gel, the bands were visualized using UV light and analyzed by Genetools software.

Northern blotting analysis

Total RNA was extracted from transfected cells on d 3 post-transfection, and purified using the RNeasy Mini Kit (Qiagen). Twenty micrograms of total RNA was separated on 1.2% agarose-formaldehyde gels and transferred onto a positively charged nylon membrane (Amersham). The presence of VEGF mRNA was probed with 32P-labeled VEGF DNA, which was generated with a random-primed labeling kit (Amersham).

Immunofluorescence staining

Cells were harvested on d 2 post-transfection for analysis, washed once with PBS and fixed with 4% paraformaldehyde in PBS for 20 min at 4°C. After blocked with goat serum, the cells were incubated with monoclonal mouse anti-VEGF for 2 h at 37°C. After three washes, the cells were incubated with Cy3-conjugated rabbit anti-mouse secondary antibodies for 1 h at 37°C and washed three times with PBS. The stained cells were mounted and analyzed under fluorescence microscope.

Western blotting

Cells were harvested on d 3 post-transfection, washed twice with 10 mL of PBS, lysed with SDS buffer, boiled for 5 min, separated by 10% SDS-PAGE gel electrophoresis, transferred onto a nitrocellulose membrane, incubated with VEGF antibodies at a dilution of 1/400 and HRP-conjugated rabbit anti-mouse antibody at a dilution of 1/4000. The HRP substrate was observed on the NC membrane. After three washes, the NC membrane was incubated with actin antibody and HRP-conjugated second antibody. The HRP substrate was observed again.

RESULTS

Identification of recombinant plasmid pShRNA and sequencing

Recombinant plasmid pShRNAs could not be digested by Sal I due to the loss of Sal I site. However, the blank plasmid pTZU6+1 could be lined by sal I. When digested by Hind III and EcoR I, pShRNAs could be separated into two parts (2800 and 395 bp), and pTZU6+1 into 2800 bp and 352 bp. The correct recombinant plasmids were shown in gel electrophoresis and verified by DNA sequencing (Figure 1).

Gel electrophoresis of VEGF

The size of VEGF was 411 bp, and consisted of the Marker in gel electrophoresis. After cloned into T vector, its sequence was verified by DNA sequencing (Figure 2).

VEGF mRNA inhibition in HT29 cells by RT-PCR

The inhibition rate of pShRNA-V1 and pShRNA-V2 was 42% and 40% respectively in HT29 cells compared with the control plasmid pShRNA-GFP (Figure 3A and B).

VEGF mRNA inhibition in HT29 cells by Northern blotting

The inhibition rate of pShRNA-V1 and pShRNA-V2 was 87% and 89% respectively in HT29 cells compared with the control plasmid pShRNA-GFP (Figure 4A and B).

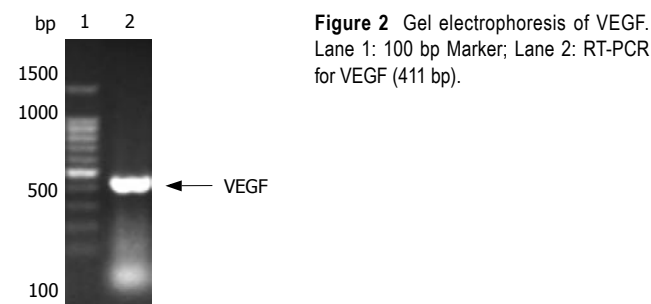

Figure 2 Gel electrophoresis of VEGF. Lane 1: 100 bp Marker; Lane 2: RT-PCR for VEGF (411 bp).

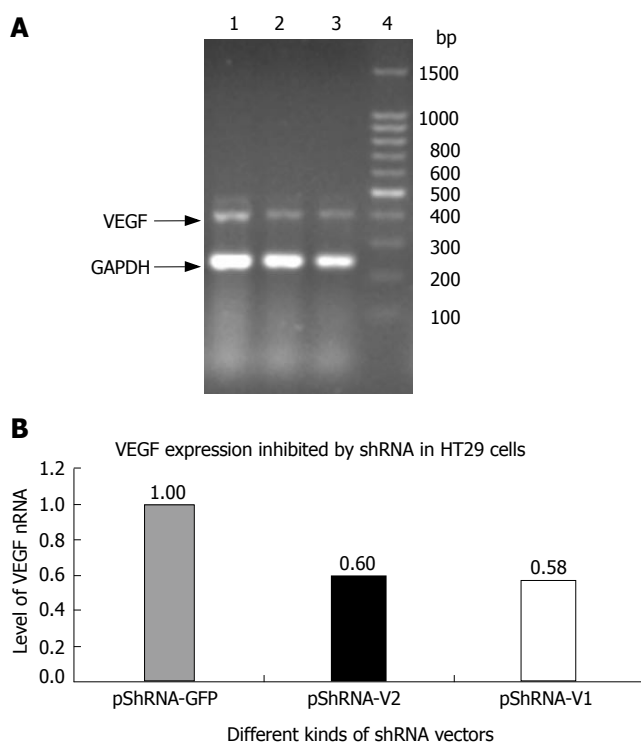

Figure 3 VEGF gene expression inhibited by shRNAs (A) and the inhibition rate of pShRNA-V1 and pShRNA-V2 (B) in HT29 cells. Lane 1: pShRNA-GFP; Lane 2: pShRNA-V2; Lane 3: pShRNA-V1; Lane 4: 100 bp Marker.

VEGF protein inhibition in HT29 cells by immunofluorescence staining

The inhibition rate of pShRNA-V1 and pShRNA-V2 was 63% and 73% respectively in HT29 cells compared with the control plasmid pShRNA-GFP and pTZU6+1 (Figure 5A and B). VEGF was stained red and located in plasma of cells.

VEGF protein inhibition in HT29 cells by Western blotting

The inhibition rate of pShRNA-V1 and pShRNA-V2 was 69% and 82% respectively in HT29 cells compared with the control plasmid pShRNA-GFP and pTZU6+1 (Figure 6A and B).

DISCUSSION

Angiogenesis is a process of generating new capillaries from pre-existing blood vessels, which involves multiple gene products expressed by various cell types. This uncontrolled process of new blood vessel growth from the

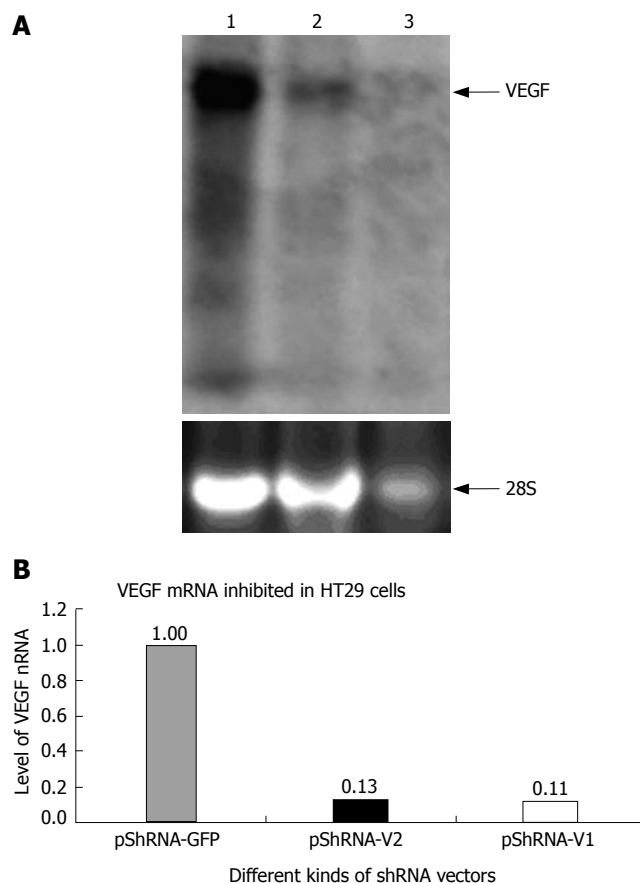

Figure 4 VEGF mRNA inhibited in HT29 cells by Northern blotting analysis (A) and the inhibition rate of pShRNA-V1 and pShRNA-V2 (B). Lane 1: pShRNA-GFP; Lane 2: pShRNA-V1; Lane 3: pShRNA-V2.

preexisting circulation network is an important pathogenic cause of tumor growth^[20-24]. Although several proteins such as hepatocyte growth factor, tumor necrosis factor- α , and fibroblast growth factor 2 (FGF2) have been identified as stimulators of angiogenesis in various settings, the most important angiogenic growth factor is VEGF, which is over-expressed in many human cancers. VEGF expression in tumors can be induced by more than one mechanism. Hypoxia, which is found in most tumors, has long been known to be a potent inducer of VEGF^[25-28].

In this study, shRNAs targeting VEGF efficiently reduced the transcript levels of VEGF mRNAs, and ultimately resulted in the reduction in VEGF protein levels. Furthermore, this inhibition was shown to be highly selective and sequence-specific, since control siRNAs had almost no inhibitory effect on the expression and transcription of VEGF.

There has been a considerable interest in treating a wide range of diseases with RNAi therapeutics^[29,30]. In this study, in addition to the above-reported target sites in the VEGF genome, the specific 21-bp siRNAs targeting VEGF could efficiently and specifically inhibit VEGF expression, suggesting that it is a good method to inhibit the expression of VEGF.

The results of this study demonstrated that the constructed shRNA could efficiently reduce the level of VEGF transcripts and expression, suggest that shRNA-

Abstract

AIM: To assess the safety and efficacy of antioxidant therapy for patients with chronic hepatitis C virus (HCV) infection.

METHODS: One hundred chronic HCV infection patients failed in interferon treatment were enrolled and randomly assigned to receive combined intravenous and oral antioxidants or placebo, or oral treatment alone. Primary end points were liver enzymes, HCV-RNA levels and histology.

RESULTS: Combined oral and intravenous antioxidant therapy was associated with a significant decline in ALT levels in 52% of patients who received antioxidant therapy vs 20% of patients who received placebo ($P = 0.05$). Histology activity index (HAI) score at the end of treatment was reduced in 48% of patients who received antioxidant therapy vs 26% of patients who received placebo ($P = 0.21$). HCV-RNA levels decreased by 1-log or more in 28% of patients who received antioxidant therapy vs 12% who received placebo ($P = \text{NS}$). In part II of the trial, oral administration of antioxidants was not associated with significant alterations in any of the end points.

CONCLUSION: Antioxidant therapy has a mild beneficial effect on the inflammatory response of chronic HCV infection patients who are non-responders to interferon. Combined antiviral and antioxidant therapy may be beneficial for these patients.

INTRODUCTION

The pathogenesis of hepatitis C virus (HCV) infection involves a complex interaction between viral factors and host immune responses. A major component of the latter involves oxidative stress^[1]. Oxidative stress has been attributed to both host inflammatory processes and induction by viral proteins, with the two mechanisms possibly acting in synergy. HCV non-structural proteins have been shown to induce activation of STAT-3 *via* oxidative stress and Ca^{2+} signaling^[2]. This induction is influenced by the activation of cellular kinases, including p38 mitogen-activated protein kinase, JNK, JAK-2 and Src, and inhibited *in vitro* in the presence of antioxidant 3. It was reported that HCV core protein increases radical oxygen species (ROS) as well as lipid peroxidation products and antioxidant gene expression^[3]. Increased intrahepatic lipid peroxidation products have been observed in HCV transgenic mice, following exposure to carbon tetrachloride^[4]. These processes may contribute to fibrosis and carcinogenesis in chronic HCV^[5]. Analysis of HCV-sub genomic RNA replicon cell lines has shown a drastic reduction in cellular glutathione peroxidase, increasing cellular susceptibility to oxidative stress^[6]. Based on these data, a rationale for antioxidant treatment of chronic hepatitis C was suggested. Currently, the mainstay of treatment of chronic hepatitis C is a combination of pegylated interferons and ribavirin^[7]. However, the overall response rate of its pharmacological efficacy and adverse effects is approximately 55% in genotype I patients^[8].

The use of complimentary and alternative medicine is common in patients with chronic liver disease. In a recent study, 41% of patients reported use of these modalities,

with 20% reporting use of herbal medicine, including silymarin (12%), licorice root (glycyrrhizin) and St. John's wort^[9]. In a review of medicinal herbs for HCV infection, the authors concluded that some of these agents may have an effect on liver enzymes but there is no firm evidence that supports their efficacy on chronic HCV^[10].

In a recently published phase-I, open label clinical trial, 50 patients with chronic HCV infection were treated orally with a combination of seven antioxidative oral preparations (glycyrrhizin, schisandra, silymarin, ascorbic acid, lipoic acid, L-glutathione, and alpha-tocopherol) on a daily basis for 20 wk, along with four different intravenous preparations (glycyrrhizin, ascorbic acid, L-glutathione, B-complex) twice weekly for the first 10 wk^[11]. Normalization of liver enzymes occurred in 44% of patients who had elevated pretreatment ALT levels. A decrease in viral load by one log or more was observed in 25% of the patients. Histological improvement, with two-point reduction in the HAI score, was noted in 36.1% of the patients. The SF-36 quality of life score improved in 26 of 45 patients (58%) throughout the trial. No major adverse reactions were noted. These findings suggest that antioxidant therapy may have a beneficial effect on necro-inflammatory variables in these patients.

The aim of the present trial was to determine the effect of a mixture of antioxidants on the inflammatory response of chronic HCV infection patients who were non-responders to interferon, in a double-blind placebo controlled trial. Two different treatment regimens were studied and compared. The data suggest that combined intravenous and oral antioxidant therapy mildly alleviates the inflammatory response in these patients.

MATERIALS AND METHODS

Subjects

A total of 100 chronic HCV infection patients were enrolled in a double-blind, placebo controlled single-center trial. The study focused on 2 treatment options, with 50 patients in each section. Part I looked at administration of intravenous and oral antioxidant preparations *versus* placebo. Part II tested administration of oral preparations only *versus* placebo. Patients were randomly assigned to treatment or placebo groups, 25 patients in each group. Antioxidants were administered as described below. All experiments were carried out in accordance with the guidelines of the Hebrew University-Hadassah Institutional Committee for Human Clinical Trials. The Israel Ministry of Health Committee for Human Trials approved all experiments.

Inclusion criteria: Eligible participants were male and female chronic HCV infection patients at the age of 18-75 years. All patients were required to display positive HCV RNA on two tests for at least 6 mo prior to enrollment. Diagnosis of chronic HCV infection was based on positive HCV RNA levels with liver biopsy (within 1 year of initiation of study) with or without elevated liver enzymes. Informed consent was obtained from patients prior to participation in the trial. Patients screened for the trial included those in whom treatment with interferon had previously failed, or was contra-indicated. Both partial

responders and non-responders were enrolled. Abstinence from any alternative medications or vitamin supplements for 6 mo prior to initiation of therapy was stipulated.

Exclusion criteria: Patients excluded from the trial included those with decompensated liver disease as evidenced by Child's B or C status; those with creatinine levels above 150 $\mu\text{mol/L}$, hemoglobin levels below 100 mg/L, white blood cell count below $3 \times 10^9/\text{L}$, or platelet count below $1 \times 10^{11}/\text{L}$; those with a history of varices, ascites, or encephalopathy. Also ineligible were patients who exhibited irreversible neurologic deficit or active co-infection with HBV, HAV, HDV, or HIV. Those treated with interferon or pegylated interferon or ribavirin less than 6 mo prior to enrollment or with a history of having received any systemic anti-neoplastic or immune modulatory treatment 6 mo prior to the first dose of study medication were excluded. Evidence of other causes of liver disease or other severe debilitating diseases precluded the patient from participating in this study. Patients who used alcohol or anti-viral medication during the trial, pregnancy or breast-feeding, and had a history of hepatic, renal, or other major organ transplantation were also exclude from the study.

In part I, 50 patients (30 males and 20 females) with a mean age of 56.1 (range, 22-75) years were enrolled in the trial. Sixty-four percent of patients ($n = 32$) had elevated liver enzymes on screening, and 36% ($n = 18$) had normal liver enzymes despite viremia and active inflammation on biopsy. All other markers for additional causes of liver disease were negative. HCV genotype 1, genotype 1a, and genotype 1b were found in 33, 5, and 28 patients, respectively. HCV genotype 2, genotype 3, and genotype 4 were found in 8, 6 and 3 patients, respectively.

In part II, 50 patients (34 males and 16 females) were randomly assigned to treatment ($n = 25$) and placebo ($n = 25$) groups. Their mean age was 57.4 (range 24-75) years. Thirty-five patients had genotype 1 (31 had genotype 1b and 4 had genotype 1a). Two patients had genotype 2a2c, two had genotype 3a, and one had genotype 4c.

Drug administration

Patients in the treatment group received a combination of seven different anti-oxidants orally at the appropriate dose (glycyrrhiza capsules, 500 mg, bid; schizandra capsules, 500 mg, tid; ascorbate capsules, 2000 mg, tid; L-glutathione capsules, 150 mg, bid; silymarin capsules, 250 mg, tid; lipoic Acid capsules, 150 mg, bid; d-alpha tocopherol, 800 IU/d) prepared by Vital Nutrients Middletown (CT, USA), once daily for 24 wk. In addition, all patients in part I of the trial received intravenously a combination of four different preparations (120 mg glycyrrhiza, 10 g ascorbate, 750 mg L-glutathione, 1 mL B-complex) at the appropriate dose, twice a week for the first 10 wk of the study. Medications were prepared by GY&N Nutriment Pharmacology, Unique Pharmaceuticals Company, Palmdale, CA, USA. Dosages were determined based on previous trials in humans. Products for intravenous injection were added to 400 mL of normal saline for infusion. Patients were followed up for an additional 24 wk following completion of the treatment as described below. Patients in the placebo group received identical pills and normal saline intravenously.

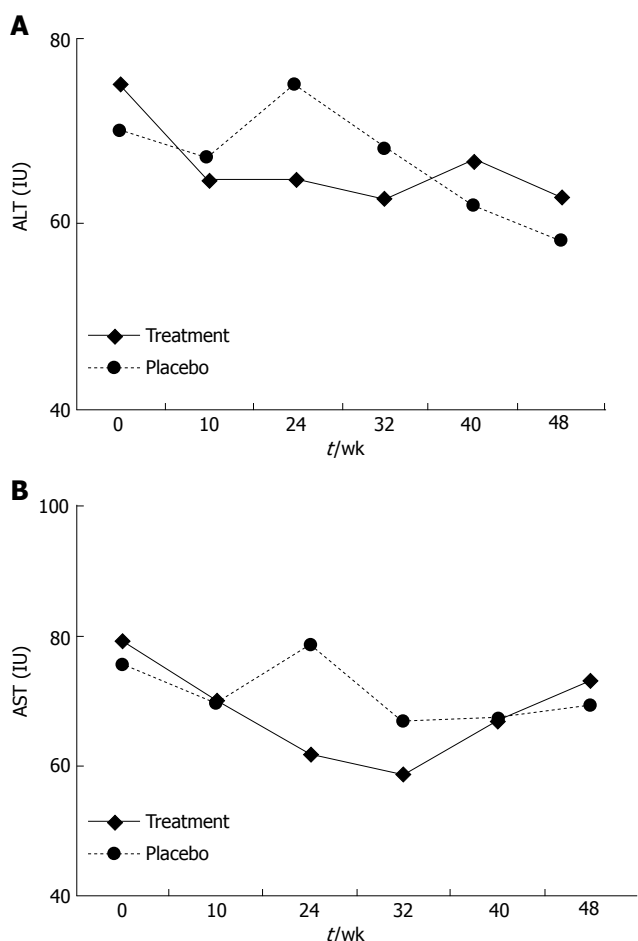

Figure 1 Effect of antioxidant treatment on ALT (A) and AST (B) serum levels in part I with treatment group in solid lines and placebo in dashed lines.

Follow-up parameters

Patients were followed up for clinical, biochemical, virological, and histological parameters. Patients underwent a bi-weekly physical examination throughout the treatment period, and every 4 wk during the follow-up period. Serum bilirubin and liver enzymes, kidney function, prothrombin time, and complete blood counts were checked bi-weekly during the treatment period and every 4 wk during follow-up. HCV RNA was detected every 4 wk throughout the study by standard assays (Roche Diagnostics Systems Inc., Branchburg, NJ). The lower limit of detection for this assay was 100 copies/L. All patients underwent a liver biopsy within 2 years prior to treatment. A repeat biopsy was performed 2 to 6 wk following completion of the antioxidant therapy. Intra-hepatic inflammatory score was evaluated by two blinded pathologists using the standard histological activity index (HAI). Evaluation of the effect of treatment on quality of life was performed using the eighth paradigm (self assessment of general health) of the SF-36 quality of life questionnaire. The questionnaire was completed 2 wk before and within 4 wk after the study.

Primary and secondary variables

The objectives of the study were: (1) evaluation of the safety and tolerability of intravenous and oral administration of glycyrrhizin, antioxidants, and vitamins

in patients with chronic HCV infection; (2) evaluation of the effect of glycyrrhizin, antioxidants, and vitamins on inflammatory indices and HCV viral load. The two primary variables were: (1) safety and tolerability of intravenous and oral administration of glycyrrhizin, antioxidants, and vitamins in patients with chronic HCV infection; (2) amelioration of inflammation and existing liver damage, and reduction in viral load.

Statistical analysis

Data were analyzed using Fisher's exact test. $P < 0.05$ was considered statistically significant.

RESULTS

Safety and adverse effects

In part I, no major adverse effects related to treatment were noted. Side effects possibly related to the mineral corticoid effect of glycyrrhizin treatment included hypokalemia in 6 patients of the treatment group (24%), in 5 patients of the placebo group (20%), and mild exacerbation of hypertension in 1 patient of the treatment group. All cases were mild and treated symptomatically. Two patients in the treatment group developed pedal edema and a sense of bloating. One patient in the treatment group was hospitalized twice due to fever during the trial period which was considered unrelated to treatment.

In part II, One patient in the treatment group had exacerbation of hypertension at wk 6 of treatment, requiring treatment with enalapril and lercanidipine. Subsequent blood pressure during treatment was normal. Six patients in the treatment group had hypokalemia of 2.9 to 3.3 and one patient in the placebo group had hypokalemia of 3.4. One patient in the treatment group had a high systolic blood pressure (up to 190 mmHg) on the day of his second biopsy, and resolved after administration of oral oxazepam. One patient in the treatment group had a weight loss of 5.5 kg during treatment, but regained three kg by wk 32. One patient in the placebo group reported weakness, upper abdominal pain and arthralgia.

Effect of antioxidative treatment on liver enzymes

In part I, at the end of 24 wk of treatment a decline in ALT and AST levels was observed in the treatment group compared to the placebo group. The ALT level at this point was 64.8 IU in the treatment group and 75.04 IU in the placebo group ($P = 0.42$, Figure 1A), the AST level at this point was 61.72 IU in the treatment group and 78 IU in the placebo group ($P = 0.1$, Figure 1B). This effect diminished during the follow-up period. At wk 48, the ALT level was 63 IU in the treatment group and 58.27 IU in the placebo group ($P = 0.68$), the AST level was 73.13 IU in the treatment group and 69.33 IU in the placebo group ($P = 0.75$). At the end of the treatment period, the ALT level improved in 54% of treated patients and in 20% of patients receiving the placebo ($P = 0.05$, Figure 2A), the AST level declined in 50% of treated patients and 20% of patients receiving placebo ($P = 0.02$, Figure 2B). At

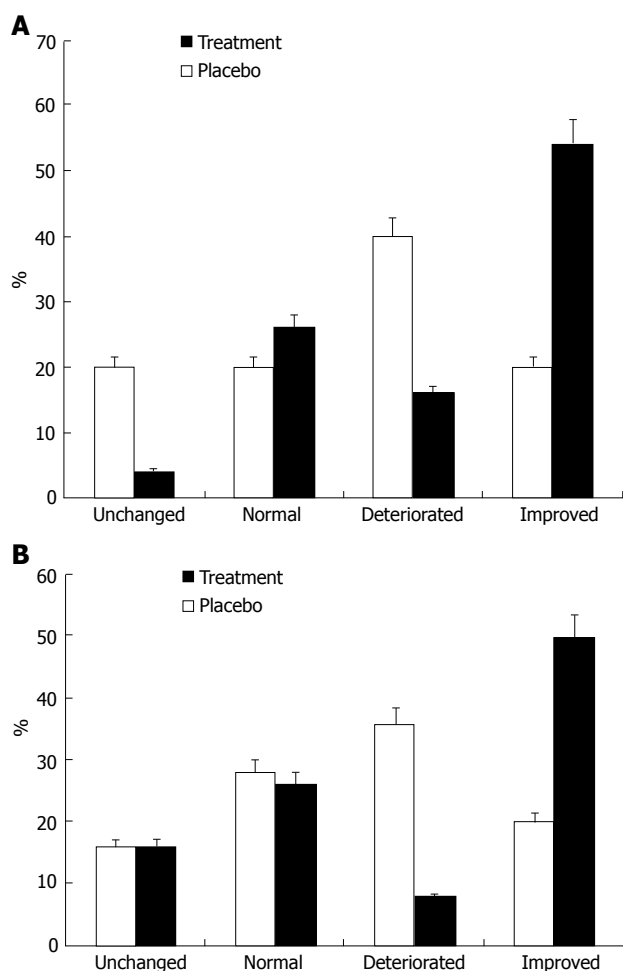

Figure 2 Proportions of patients with improvement in ALT (A) and AST (B).

the end of the follow-up period (at wk 48), the ALT level improved in 46% of patients in the treatment group and in 45% of patients in the placebo group, the AST level improved in 35% of patients in the treatment group and 34% of patients in the placebo group compared to their baseline.

In part II, a minor non-significant decline in liver enzyme levels was noted after 24 wk of treatment. The ALT level at this point was 63.5 IU in the treatment group and 81.81 IU in the placebo group ($P = 0.35$, Figure 3A), the AST level was 65.71 IU in the treatment group and 81.82 IU in the placebo group ($P = 0.24$, Figure 3B). This effect disappeared during the follow-up period. At wk 48, the ALT level was 61.75 IU in the placebo group and 83.94 IU in the treatment group ($P = 0.24$, Figure 3A), the AST level was 69.5 IU in the placebo group and 92.66 IU in the treatment group ($P = 0.39$, Figure 3B).

Effect of antioxidant treatment on biopsy scores

In part I, the HAI reduced from 8.87 before to 8.13 after treatment in the treatment group and from 7.85 to 7.4 in the placebo group ($P = 0.42$). Compared to the pre-treatment score, the total biopsy HAI score at the end of treatment reduced in 48% of patients in the treatment group and 27% of patients in the placebo group, and

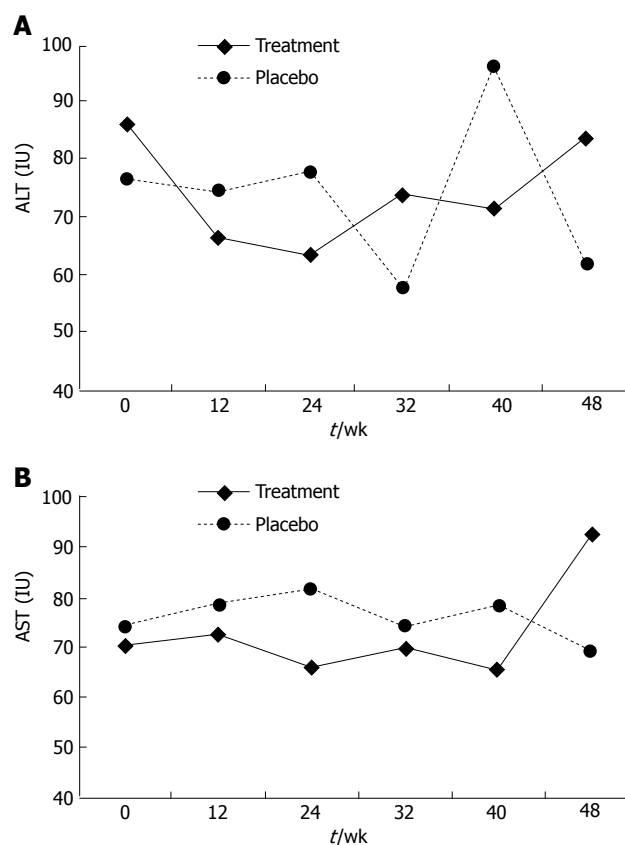

Figure 3 Effect of antioxidant treatment on ALT (A) and AST (B) serum levels in part II with treatment group in solid lines and placebo in dashed lines.

unchanged in 26% of patients in the treatment group and 49% of patients in the placebo group ($P = 0.21$).

In part II, the HAI scores increased from 7.619 to 8.36 in the treatment group, and from 8.53 to 9 in the placebo group ($P = 0.42$).

Effect of antioxidant treatment on HCV RNA serum levels

In part I, antioxidant treatment had no effect on diminishing viral load, and the average log of HCV RNA at wk 24 was 5.08 for the treatment group and 5.04 for the placebo group (Figure 4A).

In part II, similarly, no effect of treatment on viral load was observed. The average log of HCV RNA at wk 24 was 5.36 for the treatment group and 5.28 for the placebo group (Figure 4B).

Effect of antioxidant treatment on quality of life

In part I, data were available from thirty-eight patients. The average baseline quality of life in the treatment group was 52.88 out of a maximum of 100, and the post-treatment value was 52.12 ($P = \text{NS}$). The value in the placebo group was 48.5 before and 47.25 after treatment ($P = \text{NS}$).

In part II, data were available from thirty-seven patients. The average baseline quality of life in the treatment group was 53.1 out of a maximum of 100, and the post-treatment value was 48.8 ($P = 0.50$). The value in the placebo group was 43.44 before and 50.31 after treatment ($P = 0.38$).

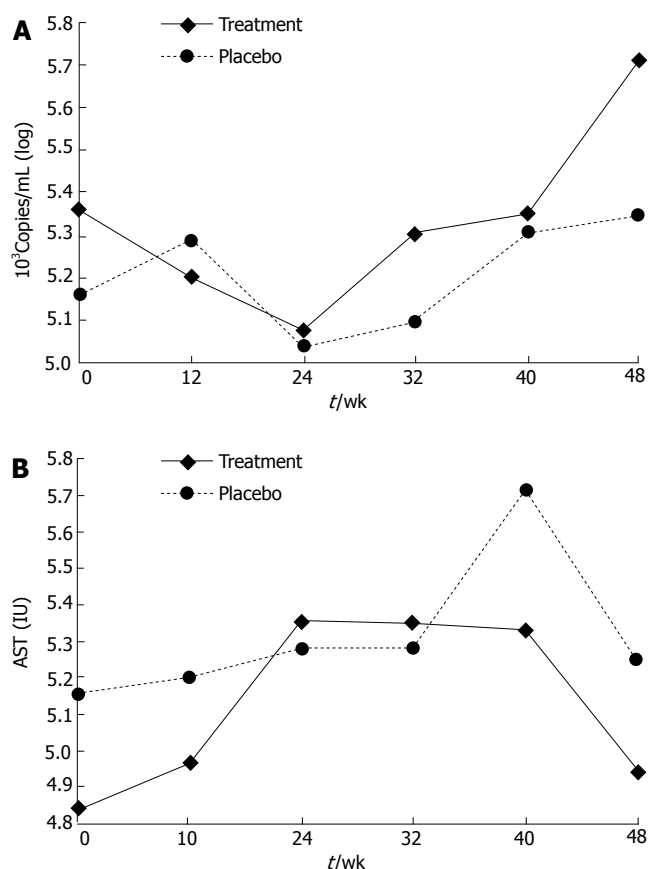

Figure 4 Effect of antioxidant therapy on viral RNA serum levels in part I (A) and part II (B).

DISCUSSION

A combination of intravenous and oral antioxidants could mildly alleviate the intra-hepatic inflammatory response in chronic HCV infection patients who non-responders to interferon therapy. This was manifested as a significant decrease in ALT and AST serum levels, along with improvement in the biopsy inflammatory scores. No effect was noted when oral antioxidants were used alone. The rationale for treatment of chronic HCV infection patients with antioxidants is based on the role of oxidative stress in the pathogenesis of disease progression in animal models and humans. Results of uncontrolled trials suggest that this treatment may have a beneficial effect on inflammatory indices such as liver enzymes and biopsy HAI scores, as well as quality of life^[11]. Intravenous glycyrrhizin was previously tested in patients with chronic HCV infection, and lowered ALT levels (26% *vs* 6% with placebo) within 4 wk were noted. The effect disappears after cessation of therapy^[12]. A retrospective study examining the effects of stronger neo-minophagen C (SNMC), which contains glycyrrhizin as an active component, revealed that treatment with this agent reduces the long term relative risk of developing hepatocellular carcinoma by a factor of 2.49^[13]. When SNMC is used in combination with interferon, a higher rate of improvement in liver enzymes and viral clearance can be observed with no statistical significance^[14]. It was reported that a combination therapy of interferon (IFN) with glycyrrhizin

induces normalization of serum ALT levels in 64.3% of non-responders with serum HVC RNA disappeared in 38.5%^[13]. The efficacy of glycyrrhizin in European studies was less than that reported on Japanese subjects, which can be explained by the genetic polymorphism in drug metabolism^[15].

Silybum marianum (milk thistle) is a herbal medicine commonly used in treatment of liver disease. Its active component, silybinin, has been shown to have anti-fibrotic and antioxidant properties, and hepatoprotective effects in animal models of acetaminophen-induced liver damage^[16]. It was reported that silymarin protects liver cells from other toxins (including ethanol, carbon tetra-chloride, and D-galactosamine) and ischemic injury, radiation, iron toxicity, and viral hepatitis^[17,18]. A combination of three potent anti-oxidants [alpha-lipoic acid (thioctic acid), silymarin, and selenium] induces marked clinical, laboratory, and histological improvements in chronic HCV infection patients^[19,20]. However, a Cochrane systematic review of trials of medicinal herbs in HCV, reported that silybin is significantly reduced in serum AST and GGT levels in only one trial, with no firm evidence for the use of herbal medicines in this condition^[21]. Schizandrae chinensis, a potent anti-oxidant, lowers ALT levels in patients with chronic viral hepatitis^[22]. Administration of glutathione to patients with chronic hepatitis significantly decreases GSH-Px activity of catalase (CAT), and increases superoxide dismutase (SOD) activity^[23,24]. N-acetyl-cysteine, sodium selenite and vitamin E have also been studied as supplementation to interferon therapy for patients with chronic HCV infection^[25]. Vitamin E supplementation increases the chance for a complete response^[25]. A randomized double-blind trial of thioctic acid (alpha-lipoic acid) in chronic hepatitis patients showed that 55% patients have significant improvements in mean ALT levels, and 77% patients have histological improvements on liver biopsy^[26,27]. The results of the present study showed a modest reduction in liver enzymes at the end of 24 wk of treatment in patients receiving the combined intravenous and oral protocol. The proportion of patients on the combination therapy with improvements, was statistically significant, the difference in absolute values did reach significance. In both parts of the trial, the beneficial effect on enzymes did not sustain throughout the follow-up period, which is consistent with some of the previous published data^[13]. The lack of significant improvement on liver biopsy seems to reflect the relatively transient nature of the anti-inflammatory effect of antioxidants in this setting. No significant effect on viral load was noted in either part of the trial. This finding was not surprising given the lack of known direct anti-viral effects of antioxidants. A study reported that induction of gastrointestinal glutathione oxidase (which counteracts oxidative stress) by all trans retinoic acids, down-regulates HCV replicon in cell lines^[6]. Adverse events that are attributable to therapy such as exacerbation of hypertension, pedal edema, and hypokalemia, are mostly related to pseudoaldosteronism associated with the 11-hydroxy-steroid dehydrogenase inhibitory activity of glycyrrhiza and L-glutathione. The excess endogenous cortisol produced by both agents, reacts with the renal

mineral corticoid receptor, promoting an aldosterone-like action. Similar adverse events have also been described^[11]. These findings suggest that it is important to have a close follow-up of patients' blood pressure and serum potassium levels throughout antioxidant therapy.

In the present study, the use of antioxidants had no significant effect on quality of life (QOL) as measured in the general health paradigm of the SF-36 questionnaire which is in contrast with uncontrolled trials, suggesting that antioxidants may exert a beneficial effect on quality of life in chronic HCV infection patients^[11]. The combined intravenous and oral antioxidants had a better effect than oral combination alone, further supporting the potential of the intravenous antioxidants, specifically of glycyrrhiza, as a possible basis for the beneficial anti-inflammatory effect noted. Although not directly tested in the present study, the use of a combination of multiple antioxidants administered both intravenously and orally, may have enhanced the anti-oxidative effect, thus contributing to the observed effect.

The data of the present study support the role of oxidative stress in the pathogenesis of HCV-induced inflammation. The modest effect noted should be viewed in light of the fact that patients enrolled in the trial were non-responders to anti-viral therapy. Therefore, they represent a relatively "hard to treat" subset of chronic HCV infection patients. Treatment in the present study was lasted for a relatively short period of time, less than that of the current treatment with anti-viral drugs. If the main effect of antioxidants is anti-inflammatory, it would be expected that a combination of antioxidants with current anti-viral treatment may be of benefit for these patients. Indeed, previous reports suggest an added value for antioxidants in interferon-treated chronic HCV infection patients. It has been demonstrated that vitamin E-treated patients have a 2.4 times higher chance of obtaining a complete response and a more significant reduction in viral load than patients not treated with vitamin E^[28].

In conclusion, a combination of intravenous and oral antioxidants can reduce intra-hepatic inflammatory response in chronic HCV infection patients who are non-responders to interferon. It is plausible to examine whether such a treatment in combination with anti-viral therapy may be useful.

COMMENTS

Background

The pathogenesis of hepatitis C virus (HCV) infection involves a complex interaction between viral factors and host immune responses. A major component of the latter involves oxidative stress^[1].

Research frontiers

The aim of the present trial was to determine the effect of a mixture of antioxidants on the inflammatory response of chronic HCV infection patients who were non-responders to interferon, in a double blind placebo controlled trial. Two different treatment regimens were studied and compared. The data suggest that the combined use of intravenous and oral antioxidants mildly alleviates the inflammatory response in these patients.

M, Ohana H, Zabrecky G, Cohen R, Ilan Y. Treatment of chronic hepatitis C virus infection via antioxidants: Results of a phase I clinical trial. *J Clin Gastroenterol* 2005; 39: 737-342.

Innovations and breakthroughs

Antioxidant therapy has a mild beneficial effect on the inflammatory response in chronic HCV infection patients who are non-responders to interferon. A combination of antiviral and antioxidant therapy may be beneficial for these patients.

Applications

It is plausible to examine whether such a treatment in combination with anti-viral therapy may be useful.

Peer review

This is the first double blind trial using a combination of several anti oxidants in patients with chronic hepatitis C who failed in interferon therapy. The study was designed well and the results were summarized and discussed appropriately.

Abstract

AIM: To establish a rapid and convenient animal model with hepatitis B virus (HBV) replication.

METHODS: A naked DNA solution of HBV-replication-competent plasmid was transferred to BALB/C mice *via* the tail vein, using a hydrodynamic *in vivo* transfection procedure. After injection, these mice were sacrificed on d 1, 3, 4, 5, 7 and 10. HBV DNA replication intermediates in the liver were analyzed by Southern blot hybridization. The expression of hepatitis B core antigen (HBcAg) and hepatitis B surface antigen (HBsAg) in the liver was checked by immunohistochemistry. Serum HBsAg and hepatitis B e antigen (HBeAg) was detected by enzyme-linked immunosorbent assay (ELISA). Inhibition of HBV replication was compared in HBV replication model mice treated intraperitoneally with polyinosinic-polytidylin acid (polyIC) or phosphate-buffered saline (PBS).

RESULTS: After hydrodynamic *in vivo* transfection, HBV DNA replication intermediates in the mouse liver were detectable on d 1 and abundant on d 3 and 4, the levels were slightly decreased and remained relatively stable between d 5 and 7, and were almost undetectable on d 10. The expression patterns of HBcAg and HBsAg were similar to that of HBV replication intermediate DNA, except that they reached a peak on d 1 after injection. No obvious differences in HBV DNA replication

INTRODUCTION

Hepatitis B virus (HBV) infection is a major health problem with more than 350 million chronic carriers worldwide, who are at high risk for developing liver cirrhosis and hepatocellular carcinoma^[1,2]. Because the pathogenic mechanisms of HBV remain unclear, molecular-biological studies are required. Until recently, most *in vivo* studies on the mechanism by which HBV causes liver diseases, and the mechanism of anti-HBV drugs, have been performed by using HBV transgenic mice^[3]. However, the acquisition of transgenic mice is very time-consuming and laborious, because expensive microinjection equipment and complicated technology is needed. We have reported previously that high-level expression of HBV surface antigen (HBsAg) in mouse hepatocytes is achieved after injection of an HBsAg expression plasmid *via* the tail vein using a hydrodynamic method^[4]. In this study, we developed a mouse model for HBV replication by using a hydrodynamic procedure that provides a simple, convenient and useful tool for molecular-biological studies on HBV, and for selection of antiviral drugs to treat HBV infection.

MATERIALS AND METHODS

Preparation of plasmid DNA

The HBV replication-competent plasmid used in this study was pHBV4.1, which contains 1.3 copies of the HBV genome (subtype *aym*). This construct has been proven to be able to initiate replication of HBV efficiently after being transfected into human hepatoma HepG2 cell lines^[5,6]. The plasmid DNA was prepared by using a plasmid-purifying Kit (QIAGEN TIP-500) according to the manufacturer's instructions.

Injection of naked plasmid DNA

Male BALB/C mice at specific-pathogen-free (SPF) level, weighing 18–20 g, were provided by the Huaxi Laboratory Animal Center of Sichuan University. Mice were injected *via* the tail vein with plasmid DNA at different doses in 1.8 mL saline within 5–8 s (hydrodynamic *in vivo* transfection)^[7]. The animals were sacrificed at different time points after injection, and the serum and liver were collected. The serum was stored at -20°C. The liver tissue was separated into two parts: one was fixed in 40 g/L neutral-buffered formalin, and the other was snap frozen in liquid nitrogen and stored at -70°C for subsequent analysis of HBV DNA replication intermediates.

Polyinosinic-polytidylin acid (polyIC) treatment

Twenty-four hours after hydrodynamic injection with pHBV4.1, the HBV replication-competent mice were matched by body weight, age and serum levels of hepatitis B e antigen (HBeAg), and were divided into two groups of five mice each. The mice in the experimental group were injected intraperitoneally with 200 µg polyIC (P-0913; Sigma) in 200 µL phosphate-buffered saline (PBS), three times at 24-h intervals, while the control group mice received only 200 µL PBS. The mice were sacrificed 4–6 h after the final injection of polyIC. Liver tissue was frozen in liquid nitrogen and stored at -70°C for DNA extraction and analysis.

Detection of HBV DNA replication intermediates

Frozen liver tissue was mechanically pulverized in liquid nitrogen and HBV DNA replicative intermediates were isolated as described previously, with some modifications^[8]. One hundred and twenty micrograms of liver tissue powder was lysed in 0.6 mL 100 mmol/L Tris hydrochloride (pH 8.0) and 2 mL/L NP40. The lysate was centrifuged for 1 min at 14000 rpm in a microcentrifuge. The supernatant was adjusted to 6.75 mmol/L magnesium acetate plus 200 µg DNaseI/mL, and incubated for 1 h at 37°C. The supernatant was readjusted to 10 mmol/L ethylenediaminetetraacetic acid EDTA, 8 g/L sodium lauryl sulfate, 100 mmol/L NaCl and 1.6 mg pronase/mL, and was incubated for an additional 1 h at 37°C. The supernatant was extracted twice with phenol/chloroform, precipitated with 0.7 volume of isopropanol, and resuspended in 30 µL 10 mmol/L Tris hydrochloride (pH 8.0) and 1 mmol/L EDTA. DNA Southern blot hybridization analysis was performed with 30 µL viral replication intermediates, as previously described^[7]. HBV DNA probe was labeled by

using DIG Luminescent Detection Kit (Roche Applied Science). A digoxigenin-labeled, full-length HBV DNA probe was used for Southern filter hybridization analysis.

Detection of liver HBsAg and HBeAg by immunohistochemistry

The number and location of cells in the liver that expressed HBV core antigen (HBeAg) or HBsAg were assessed by immunohistochemical staining. Liver tissue fixed in formalin was embedded with paraffin and sectioned (3 µm thick). The paraffin-embedded sections in PBS were treated for 15 min at 37°C with 30 g/L hydrogen peroxide, and washed with PBS. After the sections were blocked with normal goat serum for 20 min at 37°C, rabbit anti-HBsAg (Bioscience) or rabbit anti-HBe (NEOMARKERS) primary antibody was applied at 1:100 or 1:150 dilution for 60 min at 37°C, or overnight at 4°C, respectively. After washing with PBS, the secondary antiserum consisting of Polymer-HRP Anti-Rabbit (Zhongshan, Beijing) was applied at 1:350 dilution for 50 min at 37°C, according to the manufacturer's instructions. The antibody-coated sections were washed with PBS, stained with 3', 3'-diaminobenzidine tetrahydrochloride (DAB), and counterstained with hematoxylin, before being mounted.

Serological analysis for HBV antigen

HBeAg and HBsAg analysis was performed with 50 µL mouse serum by using enzyme-linked immunosorbent assay (ELISA). The HBeAg and HBsAg Detection Kits (Shanghai Shiye Kehua Company, China) were used respectively.

RESULTS

Assessment of the appropriate amount of pHBV4.1 plasmid DNA for hydrodynamic injection

To determine an appropriate amount of pHBV4.1 DNA for establishing the mouse model for HBV replication, mice were divided into different groups (two in each group) and injected with various amount of plasmid DNA (5, 10 and 25 µg per mouse). HBV DNA replicative intermediates were examined on d 4 after injection. The results of three independent experiments showed that a significant level of HBV DNA replicative intermediates was detected in mouse liver when the amount of plasmid DNA injected was as low as 5 µg per mouse. The level of HBV replicative intermediates increased when the amount of plasmid DNA was increased to 10 µg per mouse. A further increase in the amount of plasmid DNA to 25 µg per mouse did not result in a significant increase in HBV replicative intermediates in mouse liver. Therefore, we used 10 µg per mouse as the appropriate dose of pHBV4.1 to develop an HBV-replication-competent mouse model (Figure 1).

Establishment of a mouse model with HBV replication

Thirty mice were injected with pHBV4.1 plasmid DNA at 10 µg per mouse using a hydrodynamic procedure. These mice were sacrificed on d 1, 3, 4, 5, 7 and 10 after injection (*n* = 5 at each time point). The level of HBV replication and expression were analyzed.

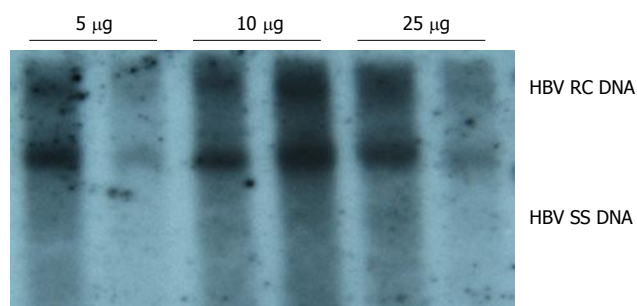

Figure 1 DNA-dose-dependent HBV replication. Various amount of pHBV4.1 in 1.8 mL saline were injected into BALB/c mice within 5-8 s. Mice were sacrificed on d 4 after injection, and HBV DNA intermediates were detected by Southern blotting.

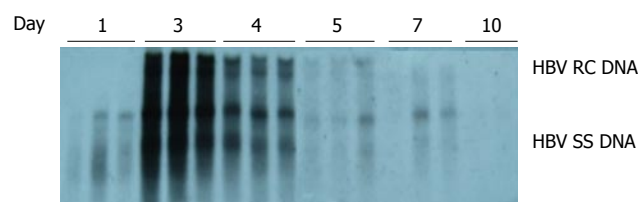

Figure 2 Time-dependent viral replication after hydrodynamic *in vivo* transfection with pHBV4.1. Mice were injected hydrodynamically with 10 µg pHBV4.1 and were sacrificed at different time points after injection. HBV DNA intermediates were detected by Southern blotting.

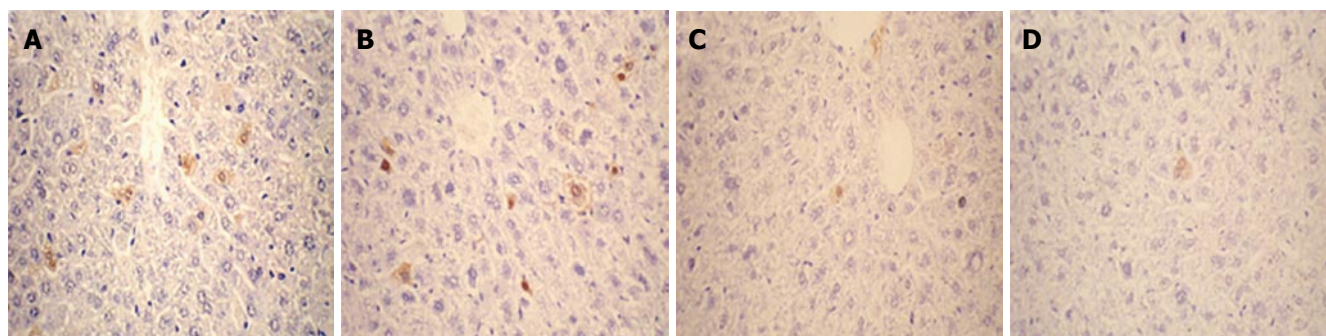

Figure 3 Detection of HBCAg expression in the liver by immunohistochemical staining (DAB, × 40). Mice were injected hydrodynamically with 10 µg pHBV4.1 and were sacrificed at different time points after injection and HBCAg in mouse liver was detected. **A:** 1 d after transfection; **B:** 4 d after transfection; **C:** 7 d after transfection; **D:** 10 d after transfection.

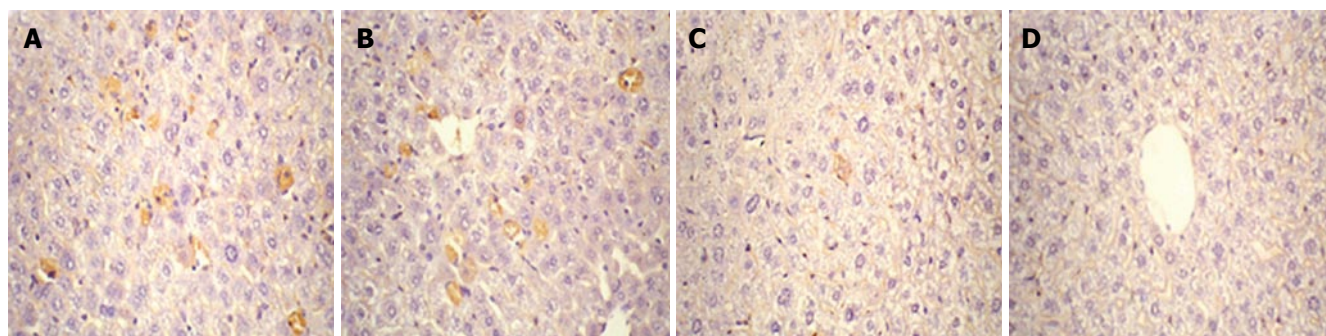

Figure 4 Detection of HBsAg expression in liver by immunohistochemical staining (DAB, × 40). Mice were injected hydrodynamically with 10 µg pHBV4.1 and were sacrificed at different time points after injection and HBsAg in mouse liver was detected. **A:** 1 d after transfection; **B:** 4 d after transfection; **C:** 7 d after transfection; **D:** 10 d after transfection.

HBV replication intermediates

As shown in Figure 2, HBV DNA replication intermediates were detected on d 1 [but without the relaxed circular DNA (RC DNA) form], and were abundant on d 3 and 4. By d 5, the number of HBV replication intermediates decreased, and were eventually undetectable by d 10. These results suggested that HBV could replicate in the liver of the mice, and that the level of HBV replication reached a peak on d 3 and 4 after hydrodynamic transfection.

Expression of HBCAg and HBsAg in mouse liver

Expression of HBCAg and HBsAg in the liver collected on d 1, 4, 7 and 10 after injection was detected by immuno-

histochemistry. As shown in Figures 3 and 4, HBCAg- and HBsAg-positive hepatocytes were randomly distributed throughout the liver lobules, with a tendency for localization in the centrilobular area. HBCAg was present in the nuclei and cytoplasm of the hepatocytes, with most expression in the nuclei. HBsAg staining was only seen in the cytoplasm. The expression of both antigens exhibited a similar time-dependent expression pattern that reached a maximum level on d 1, and remained steady until d 4 after injection, followed by a sharp decline. There were only a few HBCAg- and HBsAg-positive cells in whole liver sections by d 7 and 10.

Serum from mice sacrificed on d 1, 3, 4, 5, 7 and 10

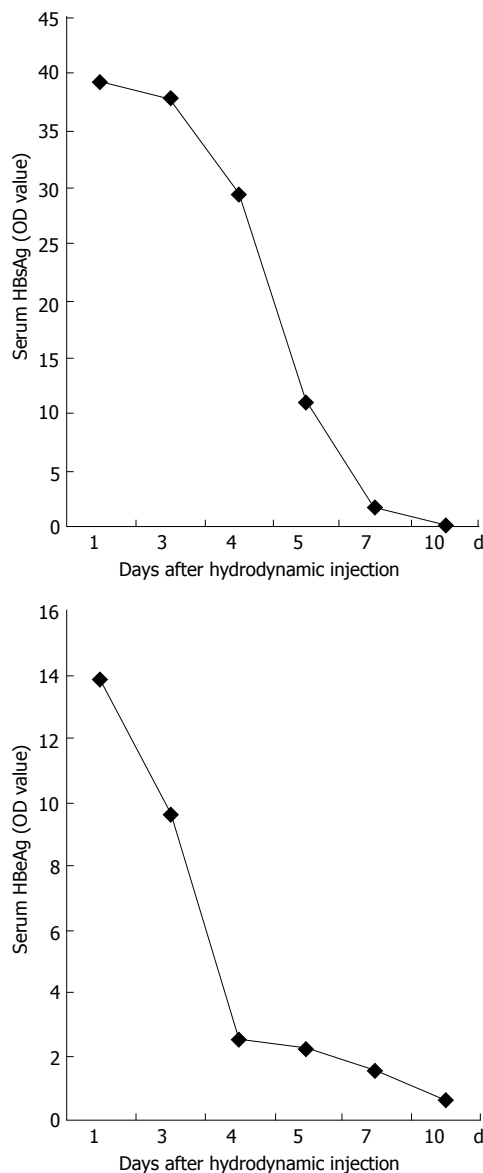

Figure 5 Time-dependent HBV antigen expression in serum after hydrodynamic transfection. Mice were injected with 10 μ g pHBV4.1. At different time points, HBsAg and HBeAg in the serum were measured by ELISA.

after injection was measured by ELISA for the level of HBeAg and HBsAg (OD₄₅₀). Samples were considered positive at OD₄₅₀ \geq 2.1. The mean level of HBeAg or HBsAg expression at each point was derived from five mice. Figure 5 shows that the expression of HBeAg and HBsAg in the serum was detected on d 1, 3, 4 and 5, reached a peak on d 1 after injection, and decreased thereafter. All samples from mice on d 7 and 10 after injection were negative for HBeAg and HBsAg.

HBV replication levels in different parts of mouse liver

To investigate whether the levels of HBV replication in different parts of the liver are similar, mice were injected with 10 μ g pHBV4.1 plasmid DNA and sacrificed 3 d later. The liver of each mouse was divided into three parts: left, right and middle lobules. The level of HBV DNA replication intermediates in each part was analyzed and compared. We found that the level of HBV replication in

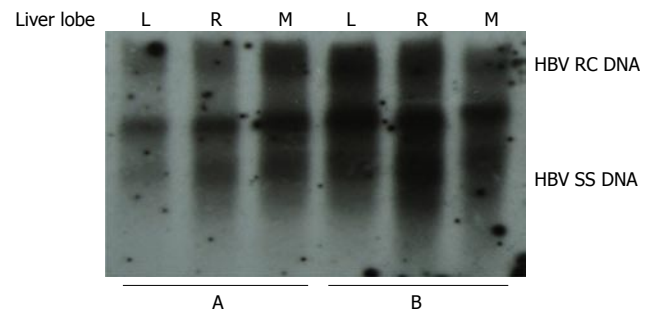

Figure 6 Viral replication in different parts of the mouse liver after hydrodynamic transfection. The results from two mice (A and B) are shown. L: left lobe; R: right lobe; M: middle lobe.

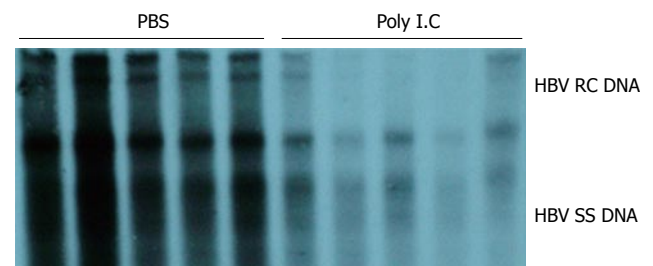

Figure 7 Effect of polyIC on HBV replication in mice. After matched by body weight, age and serum HBeAg, mice were treated with PBS or polyIC. HBV replication levels in the liver of the two groups of mice were compared.

the left, right and middle lobules in each mouse was similar (Figure 6).

Effect of polyIC injection on HBV replication

To investigate whether the mouse model established in this study can be used for the study of HBV, we used it to evaluate the effect of polyIC on HBV replication. As shown in Figure 7, compared with the control animals that were injected with PBS only, HBV DNA replicative intermediates dramatically decreased in the liver from mice injected with polyIC. This result suggested that repetitive polyIC injection decreased the level of viral replication in the liver.

DISCUSSION

HBV is a member of the hepadnavirus family, which contains a group of closely related hepatotropic DNA viruses that infect their respective animal hosts, such as HBV, woodchuck hepatitis virus (WHV)^[9] and duck hepatitis B virus (DHBV)^[10]. HBV naturally infects human and certain non-human primates such as chimpanzees. However, experiments with chimpanzees are limited by cost, availability and ethical considerations. Also, the ability of HBV to infect tupia and the significance of tupia as an HBV animal model remain controversial. Therefore, much current understanding about HBV is derived from studies of WHV and DHBV infection in their natural host^[11]. In addition to their use for the selection of anti-HBV drugs^[12,13], they are also used to study the mechanism of HBV replication by reverse transcription^[14].

and pathogenesis of HBV-related hepatocellular carcinoma^[15-17]. However, these two hepadnaviruses have some differences to HBV in terms of genome structure and transcriptional and replicative regulation; therefore, they cannot serve as a substitute for research into HBV^[18]. Recently, much attention has been paid to HBV transgenic mice, especially HBV-replication-competent transgenic mice with 1.3 copies of the genome of HBV. It is one of the most widely-used animal models in studies on the mechanism of HBV replication^[19-21], the pathogenesis of HBV-related liver diseases^[22-24], and the selection of anti-HBV drugs^[25-27]. However, the production of transgenic mice is very laborious and time-consuming. Therefore, it is necessary to develop a convenient, rapid and useful animal model for HBV-related studies. Hydrodynamic *in vivo* transfection is an efficient, rapid and convenient gene-delivery method, invented in 1999^[7]. We have reported previously that with the hydrodynamic injection of plasmid DNA encoding HBsAg *via* the tail vein into mice, efficient expression of HBsAg was detected mainly in the mouse liver, which persisted for about 10 d. In this study, by taking advantage of this hydrodynamic *in vivo* transfection method, an HBV-replication mouse model was developed by using the HBV-replication-competent plasmid pHBV4.1. The replication of HBV was confirmed by the presence of HBV-replication-intermediate DNA, HBcAg and HBsAg in the mouse liver, and the sera of mice were positive for HBeAg and HBsAg.

For different plasmid DNA, the doses needed for hydrodynamic injection are presumably different; therefore, we first determined the appropriate amount of pHBV4.1 for hydrodynamic transfection. The results of three independent experiments demonstrated that the level of HBV replication was significant and reached a steady-state level when the amount of plasmid DNA injected was as low as 10 µg per mouse. To keep the replication at a high level and also save the plasmid, we used 10 µg per mouse as the appropriate amount of pHBV4.1 to establish an HBV-replication-competent mouse model.

HBV is an enveloped virus containing a 3.2-kb partially double-stranded DNA genome within its nucleocapsids^[28,29]. Upon HBV infection of the hepatocyte, the viral genome is converted to covalently closed circular DNA (cccDNA) in the nucleus. The cccDNA serves as the template for transcription by the host RNA polymerase II, which generates the 3.5-, 2.4-, 2.1- and 0.7-kb viral transcriptions that encode the HBV core (HBcAg and HBeAg) and polymerase polypeptide, the large surface antigen polypeptide, the middle and major surface antigen polypeptides (HBsAg)^[30-32] and the HBx polypeptide^[33]. Besides encoding for the HBV core polypeptide and HBV DNA polymerase that compose the viral capsid, the greater-than-genome-length 3.5-kb pregenomic RNA (pgRNA) is encapsulated and serves as the template for reverse transcription to synthesize HBV replication intermediates^[34-36]. The time-course of the results of our experiments provided the characteristics of HBV replication in the mouse model: within 24 h after transfection, the input DNA apparently reached the nuclei of the hepatocytes, in which it was transcribed and translated to produce HBV-related antigens, and these

antigens were soon secreted into the serum. The time at which HBV antigen expression peaked was on d 1 after transfection. The expression level of viral antigen in mouse liver was stable, but the titer of HBeAg and HBsAg in the serum decreased from d 1 to 4 accordingly. The reason for this difference is unclear at present. Viral replication was not robust on d 1, although the presence of small amounts of single-stranded DNA, the earliest replicative DNA intermediates, indicated that viral replication had begun. By d 3 and 4, viral replication reached its peak level and decreased substantially until d 10, which is the time that HBV replication intermediates could not be detected. All these findings suggest that it probably requires about 2 d for 3.5-kb mRNA to produce HBV replication intermediates by reverse transcription abundantly.

The basic mechanism of the hydrodynamic transfection procedure is that when a large volume of DNA solution is injected rapidly *via* the tail vein, a high hydrostatic pressure develops in the inferior vena cava and causes heart failure, which forces a rapid flow of DNA solution to the liver tissue and DNA molecules into liver cells^[7,37-39]. In this way, digestion of the input DNA by DNAase in the blood is greatly reduced.

To assess whether the levels of gene expression in different liver lobes are different, we compared the level of HBV replication in left, right and middle liver lobes from the same mouse. The results suggested that, for a given mouse, the level of HBV-DNA-replicative intermediates was similar in all parts of the liver. This also suggests that the experimental results were not influenced by the use of different liver tissue parts. As shown in Figures 1 and 2, however, there was some variation in HBV replication between different mice, even under similar experimental conditions. This suggests that if this animal model is to be used for selecting anti-HBV drugs or for other research in which HBV replication levels need to be compared, it is necessary to match the HBV-DNA-replication levels by checking serum HBeAg before treatment, and that repeated experiments are needed to guarantee the reliability and accuracy of the test findings.

As a strong inducer of alpha/beta interferon, polyIC has been widely used in HBV transgenic mice and exerts an inhibitory effect on HBV replication^[40-42]. Therefore, we applied polyIC treatment to the HBV replication mouse model established in this study to investigate whether this model can be used for studies of HBV. We found that polyIC could inhibit HBV replication, which suggests that the mouse model developed in our study can be used for future research on HBV.

To understand the mechanisms of HBV transcription, replication and pathogenesis, it is usually necessary to mutate the HBV genome, and then measure the transcription, replication and expression levels of viral mutants; in this way, the function of various HBV genome sequences can be understood. If HBV transgenic mice are used, it is necessary for every mutated HBV genome to be transferred into mouse fertilized eggs, and then transgenic mice can be cultivated, but that is very time-consuming, costly and laborious. In contrast, by using the HBV-replication-competent mouse model developed in this study, no surgical techniques or special equipment

are needed, which suggests that this model is very simple, convenient, rapid and economical. As a result, this model affords new opportunities for studying HBV; in particular, it is useful for investigating HBV genomic function, especially its role and mechanism in HBV replication through mutation of the HBV genome.

In conclusion, we developed a rapid and convenient mouse model with a high level of HBV replication, and applied it to detecting the inhibitory effect of polyIC on HBV. This provides a very useful tool for functional studies on HBV replication and selection of anti-HBV drugs.

COMMENTS

Background

Hepatitis B Virus (HBV) infection is a worldwide health problem. Because the pathogenic mechanisms of HBV remain unclear, molecular-biological studies for HBV are required. Until recently, most *in vivo* studies about HBV have been performed by using HBV transgenic mice. However, the acquisition of transgenic mice is very time-consuming and laborious. Therefore, it is necessary to develop a convenient, rapid and useful animal model.

Research frontiers

HBV mouse model developed by using the hydrodynamic *in vivo* transfection method is convenient and useful for HBV-related studies. If the mouse genetic background or plasmid backbone are changed, many different HBV mouse models can be developed for different purposes. By using immunodeficient mice or using AAV as backbone of transferred plasmid, chronic HBV carrier mouse models were established.

Innovations and breakthroughs

In this study, we established a mouse model with HBV replication with naked HBV plasmid through a hydrodynamic procedure and found that for a certain mouse, the levels of HBV DNA replication are similar in left, right, and middle parts of liver tissue. Non-isotope labeled probe and chemiluminescent detection system was used to detect hepatitis B virus replication levels *in vivo* by southern hybridization.

Applications

This mouse model can be used for functional study of HBV genome, for studies about HBV replication mechanism and for selection of anti-HBV drugs.

Peer review

This paper describes the establishment of a mouse model with hepatitis B virus replication, with the aim to provide a tool for selection of antiviral drugs to inhibit HBV replication. The work is well developed, and shows promising results.

Abstract

AIM: To study the value of biochemical and ultrasonographic parameters in prediction of presence and size of esophageal varices.

METHODS: The study includes selected cirrhotic patients who underwent a complete biochemical workup, upper digestive endoscopic and ultrasonographic examinations. Albumin/right liver lobe diameter and platelet count/spleen diameter ratios were calculated. The correlation between calculated ratio and the presence and degree of esophageal varices was evaluated.

RESULTS: Ninety-four subjects (62 males, 32 females), with a mean age of 52.32 ± 13.60 years, were studied. Child-Pugh class A accounted for 42.6%, class B 37.2%, whereas class C 20.2%. Esophageal varices (OE) were not demonstrated by upper digestive endoscopy in 24.5%, while OE grade I was found in 22.3% patients, grade II in 33.0%, grade III in 16.0%, and grade IV in 4.3%. The mean value of right liver lobe diameter/albumin ratio was 5.51 ± 1.82 (range from 2.76 to 11.44), while the mean platelet count/spleen diameter ratio was 1017.75 ± 729.36 (range from 117.39 to 3362.50), respectively. Statistically significant correlation was proved by Spearman's test between OE grade and calculated ratios. The *P* values were 0.481 and -0.686, respectively.

CONCLUSION: The right liver lobe diameter/albumin and platelet count/spleen diameter ratios are non-invasive parameters providing accurate information pertinent to determination of presence of esophageal varices, and their grading in patients with liver cirrhosis.

INTRODUCTION

Esophageal varices development is among the major complications of liver cirrhosis, with an estimated prevalence of approximately 50%. The risk of bleeding from varices is 25%-35% with majority of the initial bleeding occurring within 1 year from varices detection^[1]. The mortality from each episode of variceal bleeding is 17%-57%^[2-4]. Bleeding episodes can be predicted by the presence of red signs ("red cherry spots") on the varices, and by the variceal size^[5,6]. The incidence of bleeding can be reduced with nonselective beta-blockers^[7,8]. It is also suggested that prophylactic endoscopic variceal ligation can decrease the incidence of first variceal bleeding and mortality in patients with liver cirrhosis who have large varices^[9,10]. Therefore, annual endoscopic screening is highly recommended for patients with small esophageal varices while the procedure should be conducted once every two years for patients suffering from liver cirrhosis without diagnosed varices^[11,12]. Nevertheless, repeated endoscopic examinations are unpleasant for patients, and have cost impact on health care insurance, while only half of cirrhotic patients have esophageal varices, and up to 30% have large varices. Therefore, the sensitivity and specificity of numerous non-invasive parameters have been investigated for assessment of presence and size of esophageal varices, and risk prediction for bleeding.

We aim to identify non-invasive parameters based on ultrasonographic measurement and laboratory test that have a potential in assessment of presence and size of esophageal varices in patients with liver cirrhosis.

MATERIALS AND METHODS

This study includes 94 patients treated for liver cirrhosis in Clinic for Gastroenterology and Hepatology, Clinical Centre of Serbia in 2006. The diagnosis of cirrhosis

Table 1 Clinical characteristics of patients

Sex (M/F)	62/32
Age (yr; mean \pm SD)	52.32 \pm 13.60
Age range (yr)	17-79
Aetiology of liver disease (alcoholic/infective/autoimmune/other)	43/19/17/15
Child-Pugh class (A/B/C)	40/35/19
Mean size of the right liver lobe (mean \pm SD)	157.71 \pm 23.37
Mean size of the spleen (mean \pm SD)	148.05 \pm 33.73
Mean albumin concentration (g/L; mean \pm SD)	30.79 \pm 7.97
Mean thrombocyte number (mean \pm SD)	134 632.98 \pm 75 937.83
Oesophageal varices grade (0/ I / II / III / IV)	23/21/31/15/4

Table 2 Calculated ratios and varice size

Varices	Right lobe/albumin ratio		Platelet count/spleen ratio	
	mean \pm SD	Range	mean \pm SD	Range
Grade 0	4.19 \pm 1.36	2.76-8.19	1822.53 \pm 804.06	608.70-3362.50
Grade I	5.43 \pm 1.58	3.25-9.44	1072.86 \pm 493.49	366.67-2021.05
Grade II	5.84 \pm 1.25	3.40-8.48	696.46 \pm 439.43	150.00-2283.33
Grade III	6.57 \pm 2.42	4.07-10.00	549.14 \pm 289.90	127.27-1275.00
Grade IV	6.68 \pm 2.52	4.07-11.44	348.19 \pm 231.86	117.39-633.33

was based on clinical features, laboratory test, imaging diagnostics, and liver histology whenever possible.

The following information was collected for each patient: age, gender, etiology of cirrhosis, biochemical parameters (aspartate aminotransferase, alanine aminotransferase, total bilirubin, serum albumin, prothrombin activity, and platelet count), presence and degree of esophageal varices and degree of liver function impairment by Child-Pugh classes. Cirrhosis etiology was determined as viral if hepatitis B surface antigen or hepatitis C serum markers were positive. If viral markers were negative, and the history obtained indicated alcohol consumption of at least 50 g per day in the past five years, liver cirrhosis was considered as alcoholic. Positive immunological markers were characteristic for immunological liver disease. The other studied cases had liver cirrhosis of different etiology (Wilson's disease, α 1 antitrypsin deficiency, hemochromatosis, *etc.*).

All studied subjects underwent ultrasonographic examination of the upper abdomen. The right lobe diameter in the medioclavicular line, as well as the spleen bipolar diameter were measured for three times and the mean value was recorded. One investigator performed all measurements (TA) in order to reduce the inter- and intra-observer errors in assessing the diameters.

Using the laboratory and ultrasonographic values, we calculated two ratios: right lobe diameter/serum albumin concentration and platelet count/spleen diameter.

An experienced endoscopist (SD) who used the grade I-IV classification^[13] did the endoscopies. Varices in the level of mucosa were recognized as grade I, those smaller than 5 mm fulfilling less than 1/3 of the esophageal lumen were recognized as grade II, grade III were varices larger than 5 mm fulfilling more than 1/3 of the esophageal, while grade IV varices occupied more than 2/3 of esophageal lumen. Patients with previous variceal

bleeding, porto-systemic shunts and those taking beta-blockers medications and patients with coexistent illness or infection that could influence the liver and spleen size, were excluded.

Child-Pugh score was calculated using five variables (ascites, encephalopathy, bilirubin, albumin, and prothrombin time). Values 1, 2 or 3 were assigned to each of these variables due to increasing abnormality, and the score calculated as sum of the five variables for each patient. A Child-Pugh score less than 7 was considered as class A, from 7 to 9 as class B, while any score greater than 9 was as class C^[14]. Laboratory test and ultrasonographic and endoscopic examinations were performed within one week.

The Ethic Committee of our institution approved the study and all patients gave an informed consent prior to inclusion into this investigation.

All collected data were analyzed and correlated. Statistical analysis was performed using the Statistical Package for Social Sciences (SPSS, version 10.0). Basic descriptive statistics included means, standard deviations, ranges and percentages. For correlation analysis, we used Spearman's test. Differences were considered statistically significant if the two-tailed *P* value was less than 0.05. Sensitivity and specificity, as well as the best cut-off value for the diagnosis of varices were calculated using ROC curves.

RESULTS

Clinical characteristics of the patients are presented in Table 1.

The mean value of the ratio of the platelet count/spleen size was 1017.75 \pm 729.36 (range 117.39-3362.50). The mean value of the ratio of the right liver lobe size/serum albumin concentration was 5.51 \pm 1.82 (range 2.76-11.44).

These ratios were correlated with the presence and size of esophageal varices (Table 2, Figure 1A and B). Spearman's test for nonparametric correlation showed that, the platelet count/spleen size ratio significantly correlated with the presence (*P* = 0.585, *P* < 0.01) and size (*P* = 0.686, *P* < 0.01) of esophageal varices, so does the right liver lobe/serum albumin concentration ratio (*P* = 0.488, *P* < 0.01 and *P* = 0.481, *P* < 0.01 respectively). We also studied the correlation with Child-Pugh score of liver function impairment (Table 3, Figure 2A and B). These ratios had a highly significant correlation (*P* < 0.01) with Child Pugh score. For the platelet count/spleen size ratio, *P* = -0.585, while for the right liver lobe/serum albumin concentration ratio, *P* = 0.491.

We counted the best cut-off value of the right liver lobe/serum albumin concentration ratio for diagnosis of varices. For the value of 4.425, the sensitivity was 83.1% and the specificity was 73.9% (Figure 3).

DISCUSSION

Incidence of esophageal varices in patients with liver cirrhosis is approximately 90%, but only 9%-35% have been described^[15-17]. Variceal bleeding in cirrhotic

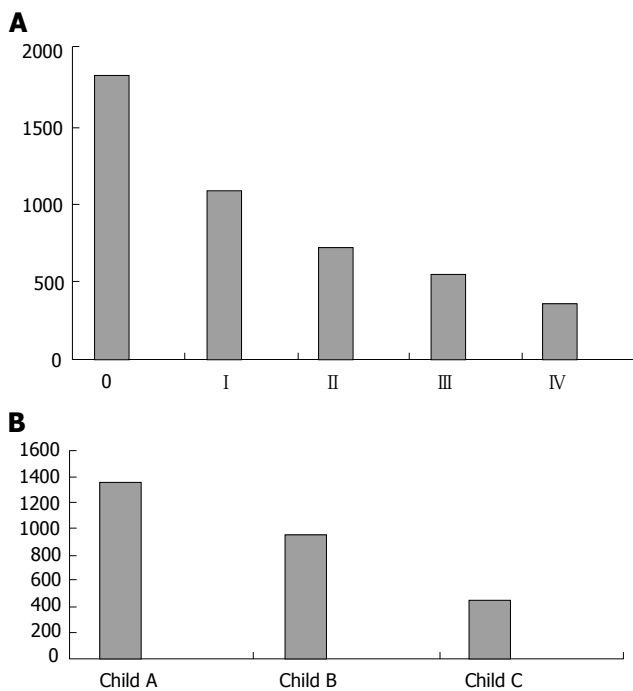

Figure 1 A: Platelet count/spleen ratio in correlation to varice size; B: Platelet count/spleen ratio in correlation to Child-Pugh score.

Table 3 Calculated ratios and Child score for hepatic insufficiency

Child-Pugh score	Right lobe/albumin ratio		Platelet count/spleen ratio	
	mean \pm SD	Range	mean \pm SD	Range
A	4.59 \pm 1.38	2.76-8.19	1355.34 \pm 796.62	365.52-3362.50
B	5.92 \pm 1.60	3.25-9.44	946.67 \pm 612.48	127.27-2975.00
C	6.68 \pm 2.12	4.07-11.44	437.97 \pm 215.99	117.39-900.00

patients is associated mainly with fatal outcome. Portal hypertension is an essential element of survival in cirrhotic patients^[5]. Therefore, regular control and evaluation of esophageal varices with timely introduction of nonselective beta-blockers and variceal ligation play an important role in prevention of bleeding. Endoscopy is an invasive and costly diagnostic procedure. Therefore, introduction of non-invasive parameters for assessment of presence and size of esophageal varices is a major goal of numerous studies.

Platelet count and spleen size were the most frequently explored non-invasive parameters in recent studies. Zaman^[15] reported that patients with platelet counts of less than 88 000/mm³ have five times greater likelihood of having large esophageal or gastric varices as compared with the patients with higher platelet counts. Ng^[16] identified correlation between presence of ascites, thrombocytopenia, hyperbilirubinemia and larger varices in the Chinese population. Similarly, Chalasani^[11] concluded that large esophageal varices are predictable in thrombocytopenic patients who have enlarged spleen, while platelet count of less than 88 000/mm³ indicates a higher risk for esophageal bleeding. The same study also demonstrated that endoscopy is incrementally cost-effective. Madhura reported that platelet count less than 68 000/mm³ have a

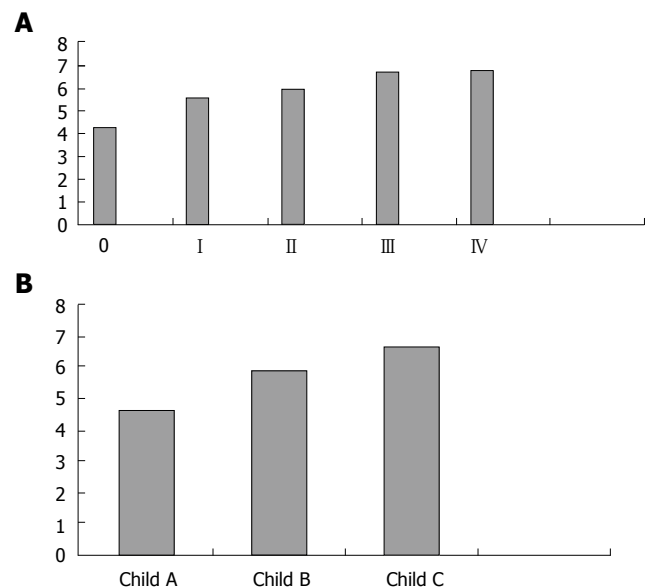

Figure 2 A: Right lobe/albumin ratio in correlation to varice size; B: Right lobe/albumin ratio in correlation to Child-Pugh score.

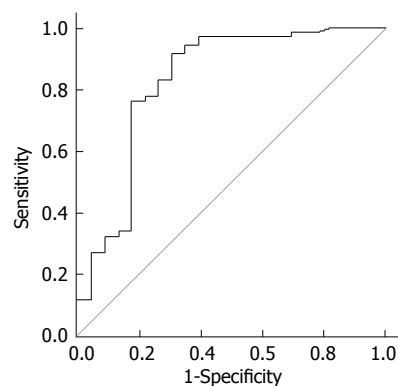

Figure 3 ROC curve for diagnosis of esophageal varices using right lobe/albumin ratio.

larger discriminatory value^[12].

Splenomegaly and hypersplenism are prevalent in patients with liver cirrhosis and portal hypertension^[11]. Thrombocytopenia is a common and highly specific manifestation of hypersplenism, but with low sensitivity for presence of portal hypertension^[18]. It is suggested that the main mechanism of thrombocytopenia is splenic sequestration and pooling^[19], and other mechanisms are also involved. Madhura and co-authors reported that 32% of patients had platelet count less than 68 000/mm³ without detectable splenomegaly, which might be explained by insufficient synthesis of thrombopoietin. It is also indicated that platelet count and thrombopoietin level are returning to referent values following liver transplantation^[20]. Other potential explanations for this phenomenon are presence of antithrombotic antibodies and thrombocyte associated immunoglobulin, which can be found in the sera of patients with liver diseases^[21].

Some investigators reported that the use of non-invasive indicators is invalid for avoiding the endoscopic screening in patients with primary biliary cirrhosis and

sclerosing cholangitis. The probability of esophageal varices presence is lower in these patients if they have platelet count less than $200\,000/\text{mm}^3$, possibly due to the fact that thrombopoietin production is preserved in primary biliary cirrhosis and sclerosing cholangitis^[22].

It is well documented that the spleen size is correlated with severity of esophageal varices^[23-25]. Watanabe^[25] calculated the splenic ratio (length \times width \times height of the spleen size on computed tomography) and showed that patients having a ratio greater than 963 cm^3 have esophageal varices, and that a high ratio may predict esophageal bleeding in patients with liver cirrhosis. It is concluded that ultrasonographic measurement of splenic cranio-caudal diameter results in lower inter- and intra-observer variability unlike Doppler sonographic assessment of hepatic flow^[26,27]. The value of Doppler sonographic assessment of portal hypertension is controversial. It is indicated that congestive ratio (counted from the cross section area and mean velocity of portal flow)^[26,28,29], as well as resistance ratio of the hepatic artery^[30] and splenic artery^[24] are correlated with portal hypertension. Portal hemodynamic parameters (mean and maximum portal vein velocity) seem to be weak in assessment of portal hypertension^[31]. In addition, it is important to keep in mind that performing Doppler sonographic examination requires sophisticated skills and equipment.

The pathophysiologic mechanisms are combined based on the integration of two non-invasive parameters, i.e., platelet count and spleen size into one ratio. Calculation of this ratio is very easy for routine clinical practice. Gianinni and co-authors^[32,33] reported the results of a retrospective and prospective study and concluded that this ratio is sensitive for prediction of presence and size of esophageal varices. The same study group suggests as especially important, the use of non-invasive parameters in the diagnostic algorithm for identifying patients without esophageal varices. A cut-off value of 909 has been proposed for platelet count/spleen size ratio^[34]. Patient having the ratio greater than cut-off value should not receive nonselective beta-blockers prophylactic therapy because they are less likely to develop esophageal varices. These patients should less frequently undergo endoscopy.

Taking into account the results of previous studies in the field, we also combined laboratory and ultrasonographic parameters and counted an original ratio. For the first time we reported the value of the right liver lobe/serum albumin concentration in assessment of portal hypertension^[35]. We used serum albumin concentration as a parameter of liver function in combination with right liver lobe size.

Previously published studies reported that platelet count/spleen size ratios are good predictors of esophageal varices. Despite a good correlation between these ratios and esophageal varices grade, it is unlikely that these ratios could be used to exclude patients from initial endoscopic screening. Nevertheless, these ratios may serve for selection of patients who need more frequent endoscopies. These ratios will help identify patients at higher risks for development of esophageal varices. It will provide insight into the relationship between clinical, biochemical,

hematological and imaging abnormalities and development of clinically significant esophageal varices. The right liver lobe diameter/albumin, as well as platelet count/spleen diameter ratios are non-invasive parameters that can provide accurate information pertinent to determination of the presence and grade of esophageal varices in patients with liver cirrhosis. Further validation of the results will be achieved through long-term follow-up of the patients and a larger number of studied subjects.

COMMENTS

Background

Esophageal varices are frequent in patients with liver cirrhosis. There is an increasing mortality rate of cirrhotic patients due to high risk of bleeding. The correlation of varices size and risk of bleeding is well-known, yet non-invasive techniques for variceal size estimation have not been intensively studied.

Research frontiers

Valuable laboratory tests and clinical examination may help predict the risk of esophageal varices bleeding. This study shows that excellent correlation exists between platelet count/spleen size and size of esophageal varices, so does the right liver lobe/serum albumin concentration ratio. In addition, the authors suggest that the use of non-invasive and less expensive methods may be of benefit for patients and consumers.

Innovations and breakthroughs

Accumulated literature shows that it is necessary to investigate non-invasive parameters in liver cirrhosis for prediction of the size of esophageal varices. Development of these methods may decrease the exposure of cirrhotic patients to repeated endoscopic procedures.

Applications

This can be used for non-invasive estimation of esophageal varice size in cirrhotic patients.

Peer review

The manuscript reports the results from an investigation of non-invasive parameters in estimation of variceal size and risk for bleeding. The authors conclude that combination of laboratory and ultrasonographic parameters such as right liver lobe/serum albumin concentration may be useful in assessment of portal hypertension. The appropriate figures and tables are supporting the results.

Abstract

AIM: To study liver biopsy practice over two decades in a district general hospital in the United Kingdom.

METHODS: We identified all patients who had at least one liver biopsy between 1986 and 2006 from the databases of the radiology and gastroenterology departments. Subjects with incomplete clinical data were excluded from the study.

RESULTS: A total of 103 liver biopsies were performed. Clinical data was available for 88 patients, with 95 biopsies. Between 1986 and 1996, 18 (95%) out of the 19 liver biopsies performed were blind and 6 (33%) were for primary biliary cirrhosis. Between 1996 and 2006, 14 (18%) out of 76 biopsies were blind; and the indications were abnormal liver tests (33%), hepatitis C (12%) and targeted-biopsies (11%). Liver biopsies were unhelpful in 5 (5%) subjects. Pain was the most common complication of liver biopsy (5%). No biopsy-related mortality was reported. There was a trend towards more technical failures and complications with the blind biopsy technique.

CONCLUSION: Liver biopsies performed in small district hospitals are safe and useful for diagnostic and staging purposes. Abnormal liver tests, non-alcoholic fatty liver disease and targeted biopsies are increasingly common indications. Ultrasound-guided liver biopsies are now the preferred method and are associated with fewer complications.

INTRODUCTION

Since the first reported percutaneous liver biopsy in 1923, the liver biopsy has become widely used in the investigation of liver disease and is currently the gold standard for confirming the diagnosis and for staging of liver disease^[1]. However, it remains an invasive procedure, with a mortality risk ranging between 0.01% and 0.17%^[2]. Studies have shown that less than one-third of the biopsies altered the treatment^[3]; hence biopsies should only be performed in patients who would benefit from this procedure.

Over the last few decades, there has been a significant improvement in diagnostic and imaging techniques, as well as in the drug therapy of liver disease^[1]. These have led to changes in our management of liver diseases. At the same time, changes in socio-economic status and life-style, have resulted in increased prevalence of obesity^[4,5] and rising incidence of non-insulin diabetes mellitus^[6,7]. Non-alcoholic steatohepatitis (NASH), the hepatic manifestation of the metabolic syndrome or insulin-resistant state^[8], is now one of the most common indications for liver transplantation in the USA^[9]. Consequently, the indications for liver biopsies in the UK will be expected to evolve over time.

We reviewed all liver biopsies performed in a single district general hospital (DGH) in the UK over two decades. We examined the indications, findings and complications of liver biopsy and explored the changes in our practice over the last two decades.

MATERIALS AND METHODS

Patients

All patients who had a liver biopsy were identified from the databases of the radiology and gastroenterology departments. Relevant clinical and laboratory information was collected retrospectively. Patients whose clinical information was incomplete were excluded from the analysis.

Table 1 Patient demographics and clinical features

	Median values (range)	Normal values
Age (yr)	57 (25-86)	
Sex (F/M)	51:37	
Liver biochemistry		
ALT (U/L)	66.5 (11-1103)	10-31
Bilirubin ($\mu\text{mol/L}$)	13 (5-430)	1-17
GGT (U/L)	221 (20-1394)	0-50
ALP (U/L)	145 (44-994)	45-145
Platelets ($\times 10^9/\text{L}$)	239 (93-813)	150-500
Indications for biopsy:		
Acute hepatitis	5	
Chronic hepatitis/Chronic elevated liver tests/Staging of disease	75	
Abnormal imaging	8	
Disease follow-up	3	
Routes of biopsy:		
Blind	32 (3 ¹)	
USS guided	60 (1 ¹)	
TJB	2	
Laparoscopic	1	

ALT: Alanine aminotransferase; GGT: Gamma glutamyltransferase; ALP: Alkaline phosphatase; USS: Ultrasonography; TJB: Transjugular liver biopsy.
¹Failed.

Liver biopsy protocol

In the absence of any contraindications, liver biopsies were performed when clinically indicated, as determined by the supervising clinician. The clinician performing the biopsy obtained an informed consent.

A full blood count (FBC) and clotting profile were obtained one day prior to the biopsy to ensure that the platelet counts were $> 80\,000/\text{mm}^3$ and the international normalized ratio (INR) was < 1.3 ^[1,2,10]. Appropriate platelet and clotting factors were given as necessary. An abdominal ultrasound of the liver was performed within six months of biopsy to ensure that there were no anatomical variants, biliary dilatation or focal or cystic lesions that may require a targeted biopsy^[1,11]. The presence of moderate to severe ascites was considered a contraindication to percutaneous biopsy^[1]. If considered safe and feasible, patients with massive ascites underwent paracentesis until completely dry, prior to the liver biopsy.

All liver biopsies were performed either as a 'blind' procedure or under ultrasound (USS)-guidance, depending on the personal preference of the clinician or the availability of a radiologist. Patients were discharged after six hours if the procedure was uncomplicated, and if the patient was clinically stable and pain free. A transjugular liver biopsy (TJB) was performed in patients with contraindications to a percutaneous biopsy.

Liver biochemistry, serology and immunology

All patients had liver biochemistry (serum bilirubin, alanine aminotransferase (ALT), alkaline phosphatase (ALP), gamma glutamyltransferase (GGT)) taken at the time of the initial clinical assessment. The normal ranges of these tests were: INR, 1; platelets $150\text{--}500 \times 10^9/\text{L}$; bilirubin, $1\text{--}17 \mu\text{mol/L}$; ALT, $10\text{--}31 \text{ U/L}$; ALP, $45\text{--}145 \text{ U/L}$; GGT

$0\text{--}50 \text{ U/L}$. Serum aspartate transaminase (AST) is not part of the routine liver panel at our centre. A liver screen comprising of immunological tests (anti-nuclear antibodies, anti-mitochondrial antibodies, anti-smooth muscle antibodies) for autoimmune diseases, serological tests for hepatitis B and C viruses (hepatitis B surface antigen, anti-hepatitis C antibodies) and serum levels for metabolic disease (ceruloplasmin, alpha-1 antitrypsin, ferritin) was performed in all patients with abnormal liver biochemistry or abnormal USS. Patients with elevated ferritin levels had additional blood samples taken for haemochromatosis gene (C282Y/H63D) mutation analysis.

Usefulness of liver biopsy

In the present study, the usefulness of a liver biopsy was determined qualitatively by a) the success in establishing the diagnosis and/or b) any change (s) in the management based on the results of the liver biopsy

RESULTS

Patient population

A total of 103 liver biopsies were obtained between 1986 and 2006. Clinical data was available on 88 patients who had 95 biopsies. The number of successful liver biopsies was 91; 88 had one biopsy, 7 (4 failed 1st attempt; 3 follow-up biopsies) had two biopsies, while none of the subjects had > 2 biopsies. The median age of the patients was 57 (range, 25-86) years; 51 patients were female. 5 patients had acute hepatitis and 8 patients had focal lesions in the liver on abdominal imaging. The remaining patients underwent staging biopsies or diagnostic biopsies for chronic hepatitis or chronic elevations in liver function tests.

Liver function tests, platelets and clotting profile

The median INR was 1 (range 0.9-1.6). All patients had platelet levels $> 80\,000/\text{mm}^3$ (median 239; range 93-813). The median values of the liver tests were as follows: ALT 66.5 (range 11-1103) U/L, ALP 145 (range 44-994) U/L, GGT 221 (range 20-1394) U/L and bilirubin 13 (range 5-430) $\mu\text{mol/L}$ (Table 1).

Liver biopsy

Between 1986 and 1996: Number of patients and approach used: Eighteen patients underwent 19 biopsies. One biopsy was USS-guided and 18 were 'blind' biopsies (94.7%). One patient needed a repeat biopsy because of inadequate sample (blind) at the first attempt. The median size of liver biopsies was 1.5 cm (range: 0.5-2.5) (Table 2).

Liver biopsy findings: One-third of biopsies were performed for primary biliary cirrhosis (PBC). Two patients had elevated serum ferritin levels but only one was homozygous for the C282Y haemochromatosis mutation. Liver biopsy of the second patient showed features of porphyria cutanea tarda that was confirmed on faecal and plasma porphyrin tests.

Between 1996 and 2006: Number of patients and approach used: A total of 70 patients underwent 76 liver

Table 2 Liver biopsies between 1986 and 1995

Number of successful liver biopsies	Diagnosis pre-biopsy	History	Abnormal liver tests	Viral serology	Autoimmune / Immunoglobulins	Imaging	Others	Final Diagnosis
6	PBC	Y	Y	N	Y	Normal	n/a	PBC
3	AIH	N	Y	N	Y	Normal	n/a	AIH: 3 (staging)
1	LKM	N	Y	N	Y	Spleen +	n/a	Possible overlap AIH/PBC
3	ALD	Y	Y	N	N	Normal/Spleen +	n/a	ALD: 3 (cirrhosis in 1)
3	Abnormal Liver tests	N	Y	N	N	Echogenic liver	Elevated ferritin	NAFLD (simple steatosis): 3
1	ALD/Iron overload	Y	Y	N	N	Normal	Elevated ferritin	Porphyria cutanea tarda (plasma porphyrin 618, faecal porphyrin +)
1	Iron overload	N	Y	N	N	Normal	Elevated ferritin and homozygous C282Y	Primary haemochromatosis

Total number of biopsies performed: 19; Failed biopsies: 1; Successful biopsies: 18. Y: Present; N: Negative or not present; n/a: Not applicable; PBC: Primary biliary cirrhosis; AIH: Autoimmune hepatitis; ALD: Alcoholic liver disease; NAFLD: Non-alcoholic fatty liver disease; LKM: Liver, kidney, microsomal antibody; AMA: Anti-mitochondrial antibody.

biopsies; 59 biopsies were USS-guided and 14 (18.4%) were 'blind' procedures. Two patients had contraindications to a percutaneous biopsy (one had large volume ascites with raised INR and one had elevated INR), and underwent TJB. Laparoscopic liver biopsy was performed in one patient during laparoscopy performed for abdominal pain. Three patients needed a second biopsy after a failed initial attempt (2 blind, 1 USS-guided) while a further 3 had follow-up biopsies. The median size of liver biopsies was 1.7 (range, 0.1-3) cm (Table 3).

Liver biopsy findings: One-third of the biopsies were performed for undiagnosed elevation in the liver function tests and 12% were for staging of hepatitis C infection. Out of 59 USS-guided biopsies, 8 were performed in patients with focal lesions seen on abdominal imaging. Seven out of eight patients were found to have metastatic lesions while one patient had macrovesicular steatosis.

Changes in indications and/or findings over two decades

Between 1996 and 2006, 26% of patients were diagnosed with non-alcoholic fatty liver disease (NAFLD) (including non-alcoholic steatohepatitis), compared with 16.7% between 1986 and 1995. In the last ten years, targeted biopsies were also more common (11%; Table 3) but only one patient underwent biopsy for PBC.

Usefulness of liver biopsy

Diagnosis: In patients with elevated liver function tests but non-specific liver screen, liver biopsy confirmed the diagnoses in 25 out of 27 patients. It provided histological confirmation of metastases in 7 patients and was useful in confirming the overlap syndrome (autoimmune hepatitis/PBC) in 3 patients. Non-specific features were seen in 5 patients (5%).

Staging disease and treatment: Biopsy findings were used to stage autoimmune hepatitis, haemochromatosis, hepatitis B, hepatitis C, alcoholic liver disease and NAFLD.

Those with moderate to severe fibrosis and cirrhosis at liver histology were placed on six-monthly hepatocellular carcinoma USS screening programme and had an upper gastrointestinal endoscopy to assess the presence and size of varices. Six patients with NASH were followed on a regimen of exercise and dietary changes, with tight glycaemic and blood pressure control. Nine patients with hepatitis C infections were treated with pegylated interferon and ribavirin.

Complications: Five patients experienced severe pain, requiring hospital admission and treatment with opiates. One patient developed a sub-capsular haematoma (blind biopsy); one patient developed pneumothorax (blind biopsy) that was managed conservatively; and another patient had an intra-abdominal bleed during TJB, requiring admission to the intensive care unit. There was no biopsy-related mortality.

DISCUSSION

In the present study, we observed an increasing number of liver biopsies being performed for elevated liver function tests. NAFLD was the most common diagnosis (70%) in these patients. When all the biopsies were taken in account, NAFLD accounted for nearly 30% of biopsies in our study population. These findings are consistent with the results of previous studies^[12-14], and likely reflect that an increasing proportion of our population suffers from obesity^[15-18] and non-insulin dependent diabetes mellitus^[19,20]. Although the diagnosis of NAFLD can often be made clinically in patients with a combination of elevated liver tests, negative liver screen, 'bright' liver on abdominal USS and the presence of metabolic risk factors such as hypertension, non-insulin dependent diabetes mellitus, hyperlipidaemia and obesity^[16,21,22], the distinction between simple steatosis and steatohepatitis can only be made by liver biopsy^[23,24]. This is important because simple steatosis is considered a benign condition, while steatohepatitis can progress to

Table 3 Liver biopsies between 1996 and 2006

Number of successful liver biopsies	Diagnosis pre-biopsy	History	Abnormal liver tests	Viral serology	Autoimmune/Immunoglobulins	Imaging	Others	Final Diagnosis
24	Abnormal liver tests	Non-specific Abdominal pains in 2	Y	N	SMA in 1 IgG in 1	Normal/ Echogenic	n/a	Simple steatosis: 12 NASH: 4 Autoimmune (including overlap): 2 Drug-related: 2 Microhamartomas: 1 (laparoscopy) Non-specific: 2 Venous congestion: 1

Total number of biopsies: 76; Failed biopsies: 3; Number of successful biopsies: 73. Y: Present; N: negative or not present; n/a: Not applicable. PBC: Primary biliary cirrhosis; PUO: Pyrexia of unknown origin; AIH: Autoimmune hepatitis; ALD: Alcoholic liver disease; NAFLD: Non-alcoholic fatty liver disease. NASH: Non-alcoholic steatohepatitis; LKM: Liver, kidney, microsomal antibody; SMA: Smooth muscle antibody. ANA: Anti-nuclear antibody; AMA: Anti-mitochondrial antibody; IgG: Immunoglobulin G; IgA: Immunoglobulin A; IgM: Immunoglobulin M; US: Ultrasound; CT: Computed tomography.

cirrhosis^[25]. Aggressive control of metabolic risk factors has been shown to improve the liver function tests and liver histology^[26-31]. Although it is not feasible to biopsy all patients with possible NAFLD, this should be considered

in patients who are older (over 40 years), obese or have non-insulin dependent diabetes^[18,32].

With improvements in chemo-radiotherapy regimens, many patients with metastatic diseases are offered neo-

Table 4 Liver biopsies for acute hepatitis

Acute hepatitis	Pre-biopsy diagnosis	Final diagnosis
1	Cause unknown	Likely drug-induced; prednisolone started
2	Cause unknown	Mild steatohepatitis
3	Pyrexia of unknown origin	Tuberculosis excluded
4	Cause unknown	No specific features
5	Cause unknown	Microhamartomas with cholestatic hepatitis

adjuvant and adjuvant therapy. Hepatic resection for colorectal metastases limited to the liver, has become the standard of care^[33,34]. Imaging guided biopsy of liver lesions is being performed increasingly to confirm metastases and to determine the primary tumor. By contrast, a liver biopsy is no longer necessary to make a diagnosis of PBC. A persistently elevated E2AMA strongly suggests PBC, even in asymptomatic patients^[35]. Moreover, Cox-regression analyses have shown that the main prognostic marker in PBC is serum bilirubin^[36]; thus indicating that the presence of fibrosis or cirrhosis in PBC is of limited prognostic use.

Liver biopsies are currently recommended in patients with chronic hepatitis C before treatment to stage and grade the disease^[37,38]. Six patients with genotype 1 disease and three with genotype 3 disease received combination treatment with pegylated interferon and ribavirin. Since over 75% of patients infected with genotype 3 hepatitis C have a sustained virologic response after six months of combination treatment with pegylated interferon and ribavirin^[39], a liver biopsy may be unnecessary in some of these patients. In the future, non-invasive fibrosis markers are likely to play a bigger role in staging liver disease. We found that in patients with isolated autoantibodies or complex clinical and laboratory features, a liver biopsy was able to confirm the disease processes. For example, in a patient with excessive alcohol consumption who also had elevated immunoglobulin levels, liver biopsy indicated a diagnosis of autoimmune hepatitis instead of alcoholic hepatitis.

Liver biopsies from five patients showed non-specific features (5%). It has been suggested that for evaluation of diffuse liver disease, a core of at least 1.5cm is required^[40] as it provides at least 6 to 8 portal tracts for adequate histological assessment. Although the median biopsy size in the study was 1.5 cm, many samples were inadequate, with the smallest recorded size being 0.1 cm. Three of these patients had biopsy fragments measuring less than 1cm in size, which may account for the non-specific findings. Liver biopsies are generally not required in patients with acute hepatitis^[1]. We however, found it helpful in three patients (Table 4).

The most common complication of liver biopsy is abdominal discomfort. Hospitalization is needed in up to 3% of patients for pain and hypotension^[41,42], but major complications are rare^[43]. At our centre, five patients (5.6% of patients, 5.2% of biopsies) were admitted for severe pain while another patient developed clinically significant intraperitoneal bleed after a TJB and required intensive care treatment. Consistent with published reports^[44,45],

we found a trend towards greater technical failures and complications with the 'blind' biopsy technique. Three out of four patients who needed a second liver biopsy had their initial biopsies performed 'blind'; two other patients, one with a pneumothorax and the second with sub-capsular haematoma also had 'blind' biopsies. In the last decade, nearly 78% of all biopsies in our unit were USS-guided. This increase is likely to be related to the increasing availability and safety of USS-guided liver biopsy^[46,47].

Although our study population was small, it is reflective of the current DGH practice in the UK. Post-liver transplant, protocol liver biopsies are performed at the tertiary transplant units, hence the absence such data in the present study.

In conclusion, our findings confirm that liver biopsies in the DGH are safe and useful in the evaluation and staging of liver diseases. USS-guided rather than 'blind' liver biopsies are likely to be the preferred technique by patients and clinicians. NAFLD rather than PBC or viral hepatitis, will increasingly constitute the majority share of the liver biopsy workload.

COMMENTS

Background

Liver biopsy is a widely used tool in the investigation of liver diseases. However, it is an invasive procedure and studies have shown that less than one-third of the biopsies actually alter the management of patients. A liver biopsy should therefore only be performed in those patients who would benefit from such a procedure. Over the last two decades, changes in the socio-economic status and life-style have led to alterations in disease profiles. There is an increasing burden of obesity, type II diabetes mellitus and non-alcoholic steatohepatitis. Non-alcoholic steatohepatitis is now one of the most common causes of chronic liver disease and indications for liver transplantation in the USA. Concurrently, there have been rapid improvements in diagnostic and treatment options for patients with liver disease. With such changes, we expect that indications for liver biopsy will also evolve over time.

Research frontiers

Between 1986 and 1996, liver biopsies were performed mainly in patients with primary biliary cirrhosis as part of the staging process. With the development of reliable immunological markers designed to confirm the diagnosis, and prognostic markers to predict outcome of primary biliary cirrhosis, liver biopsy is no longer necessary. Between 1996 and 2006, the majority of biopsies (> 40%) were performed for raised liver function tests and hepatitis C staging. Non-alcoholic fatty liver disease was also found to be more common. In the present study, only 5% of biopsies showed non-specific features and were therefore unhelpful in patient management. The rest of the biopsies confirmed the diagnoses of the primary liver disease or the presence of metastasis. Patients with end-stage liver disease were placed on regular surveillance and those with treatable diseases were managed according to the treatment protocols. The complication rates after a liver biopsy in a district general hospital were found to be similar to the published rates. Between 5% and 6% of patients were admitted for severe pain. There was a trend towards increasing technical failures and complications with blind liver biopsy. In the last decade, ultrasound-guided biopsies were obtained more frequently than blind biopsies.

Innovations and breakthroughs

This study confirms that a liver biopsy is safe and useful in evaluating and staging of liver disease, even in district general hospitals. The risks from a biopsy remains small, but ultrasound-guided biopsies should be the preferred technique. In the future, non-alcoholic fatty liver disease will account for the vast share of the biopsy workload.

Applications

Useful for practicing clinicians in smaller hospitals as it confirms the safety and

utility of a liver biopsy. Ultrasound-guidance may be safer. Non-alcoholic fatty liver disease is increasingly common.

Peer review

This is a very nice review that describes the historical changes in liver biopsy methodology over the past 20 years. The data presented is clear and concise and has been described clearly in the text.

Abstract

AIM: To assess whether a 24-wk course of interferon (IFN) could prevent hepatocellular carcinoma (HCC) recurrence and worsening of liver function in patients with hepatitis C virus (HCV)-infected patients after receiving curative treatment for primary HCC.

METHODS: Outcomes in 42 patients with HCV infection treated with IFN- α , after curative treatment for primary HCC (IFN group), were compared with 42 matched curatively treated historical controls not given IFN (non-IFN group).

RESULTS: Although the rate of initial recurrence did not differ significantly between IFN group and non-IFN group (0%, 44%, 61%, and 67% vs 4.8%, 53%, 81%, and 87% at 1, 3, 5, and 7 years, $P = 0.153$, respectively), IFN group showed a lower rate than the non-IFN group for second recurrence (0%, 10.4%, 28%, and 35% vs 0%, 30%, 59%, and 66% at 1, 3, 5 and 7 years, $P = 0.022$, respectively). Among the IFN group, patients with sustained virologic response (SVR) were less likely to have a second HCC recurrence than IFN patients without an SVR, or non-IFN patients. Multivariate analysis identified the lack of SVR as the only independent risk factor for a second recurrence, while SVR and Child-Pugh class A independently favored overall survival.

CONCLUSION: Most intrahepatic recurrences of HCV-

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common malignant neoplasms worldwide. Chronic infection with hepatitis C virus (HCV) has been causally associated with HCC^[1-3]. Recent advances in imaging and treatment have brought about some improvement in prognosis of patients with HCV-related HCC, but outcomes are still unsatisfactory. The 5-year survival rate is only 50%-70%, even after curative treatment such as hepatic resection or local ablation^[4]. Reasons for this unfavorable prognosis are considered to include high intrahepatic tumor recurrence rates and sustained hepatic damage, both resulting from HCV infection^[5].

Even after curative hepatic resection for HCV-related HCC, the rate of intrahepatic tumor recurrence within 1 year is 20%-40%, rising to about 80% by 5 years^[4,6-8]. Intrahepatic recurrence of HCC may result from intrahepatic metastasis originating from the primary HCC, or from ongoing multicentric carcinogenesis related to chronic HCV infection. Underlying HCV-related hepatic damage may also compromise hepatic functional reserve, and worsen clinical outcome. Thus prevention of HCC recurrence and preservation of liver function are both high priorities for improving prognosis of patients with HCV-

related HCC.

Interferon (IFN) therapy for patients with HCV infection is effective in reducing serum alanine transaminase (ALT) activity and in eradicating HCV^[9,10], and thus IFN could have value in minimizing hepatic necrosis, inflammation and fibrosis, as well as reducing the incidence of HCC. Several recent studies have reported that IFN therapy, even after curative treatment for HCV-related HCC, could prevent HCC recurrence and improve survival^[11-17]. Unfortunately, since these studies are characterized by differing IFN regimens, definitions of IFN responses, and background characteristics of patients, results have varied and no standard IFN regimen has been established for after curative treatment of HCV-related HCC. As well, the mechanisms by which IFN suppresses HCC recurrence, including possible direct anti-tumor and anti-inflammatory effects, remain uncertain.

In the present study, recurrence and survival outcomes in matched historical controls were compared with those in patients receiving a 24-wk course of IFN- α therapy after receiving curative treatment for HCC.

MATERIALS AND METHODS

Patients

We retrospectively reviewed 495 consecutive patients treated for primary HCC associated with HCV infection at Hiroshima University Hospital from March 1992 to March 2004. Of these, 384 with HCC initially underwent therapeutic intervention with curative intent. Curative treatment was defined as complete tumor eradication, with no residual tumor visible by computed tomography, or resection of all evident tumor tissue. Medical treatment included percutaneous radiofrequency ablation (RFA), ethanol injection, and microwave coagulation therapy (MCT). Surgical treatment included hepatic resection and ablation during laparotomy.

Among these 384 patients, we administered IFN therapy to 42 who met the following eligibility criteria: age under 70 years; up to three tumors with none exceeding 30 mm in diameter, or a solitary tumor less than 50 mm in diameter; tumor-node-metastasis (TNM) stage I, II, or III; detectable serum HCV RNA; seronegativity for hepatitis B surface antigen; chronic hepatitis or compensated cirrhosis with a Child-Pugh class of A or B; platelet count above 70 000/ μ L; absence of local recurrence during the follow-up period; and absence of ectopic intrahepatic recurrence within 24 wk after treatment for primary HCC. We used the TNM classification system of the Liver Cancer Study Group of Japan as the staging system for HCC^[18]. Underlying liver conditions such as hepatitis or cirrhosis were confirmed by laboratory, pathologic and radiologic examinations. We classified liver function in chronic hepatitis as Child class A because chronic hepatitis is a known pre-cirrhotic condition. There were only a few chronic hepatitis cases: three in the IFN group and four in the non-IFN group.

As historical control subjects, we selected 42 patients with no IFN therapy after treatment for primary HCC (non-IFN group). These 42 patients, who met the eligibility

criteria noted above, were matched by age, gender, tumor size, TNM stage of HCC, serum albumin, platelet counts, and Child-Pugh class with patients who received IFN therapy (IFN group).

Thus, a total of 84 patients (42 in the IFN group and 42 in the non-IFN group) were enrolled. All agreed to participate in the research protocol, which was approved by the hospital research ethics board. Table 1 shows the baseline characteristics of the two groups, indicating no significant differences for age, gender, liver function, tumor characteristics, or therapeutic methods used against HCC.

IFN therapy

In the IFN group, patients received 6 MIU of natural IFN- α (human lymphoblastoid IFN, Sumiferon; Dainippon Sumitomo Pharmaceuticals, Osaka, Japan) intramuscularly every day for 2 wk, followed by three times weekly for 22 wk. IFN therapy began within 24 wk after the initial treatment for HCC. All patients were evaluated every week in an outpatient setting during IFN treatment. Qualitative detection of HCV-RNA was performed by a standardized qualitative reverse transcription-polymerase chain reaction (RT-PCR) assay at every 4 wk during and after IFN treatment.

Among the patients who received IFN therapy, 28 were of HCV genotype 1 and 14 were of HCV genotype 2. These 42 patients had various pretreatment viral loads. Twenty patients (genotype 1, $n = 11$; genotype 2, $n = 9$) had high viral loads (≥ 100 kIU/mL by PCR), and 22 (genotype 1, $n = 17$; genotype 2, $n = 5$) had low viral loads (≤ 100 kIU/mL by PCR). The 42 patients were divided into two subgroups according to virologic response, i.e., patients with vs without a sustained virologic response (SVR). SVR was defined as the sustained absence of serum HCV RNA for more than 24 wk after completion of IFN treatment. Absence of SVR included both persistent viremia (no response) and transient viral disappearance (transient response) during or after IFN therapy. Biochemical response was defined as ALT activity declining to a value within the normal reference range in the presence of viremia.

Follow-up

After curative treatment for primary HCC, all patients studied underwent liver function tests, serum tumor marker assays, such as those for α -fetoprotein (AFP) and protein induced by vitamin K absence or antagonist II (PIVKA-II) every month, abdominal ultrasonography every 3 mo, and dynamic computed tomography (CT) every 6 mo. If recurrence of HCC was suspected, additional examinations including CT during arteriography or tumor biopsy were performed. Recurrence of HCC was defined as any new nodules indicated by CT as hyperattenuation during hepatic arteriography or by hypoattenuation in CT performed during arteriportography. Hypovascular HCC was confirmed histopathologically after fine-needle aspiration biopsy. Patients with recurrent HCC were treated medically or surgically, with curative intent if possible.

In IFN patients, including those with or without SVR, and in the non-IFN group, we compared both the rate of HCC recurrence and the survival rate. We also sought to identify significant prognostic indicators for survival and recurrence after curative treatment of primary HCC.

Statistical analysis

Chi-squared and Fisher exact tests were used for categorical variables, while Student's *t* test and the Mann-Whitney *U* test were used for continuous and ordinal variables, as appropriate. The Kaplan-Meier method was used to assess cumulative survival and recurrence rates, calculated from the date of diagnosis to the date of disease recurrence or death. Surviving patients and those who died of causes unrelated to the liver were defined as censored cases, while patients who died of causes related to the liver were defined as non-censored cases. The log-rank test was used to compare survival and recurrence curves. Univariate and multivariate predictors of survival or recurrence time were determined using the Cox proportional hazard model. Hazard ratios and their 95% confidence intervals (95% CI) were computed. $P < 0.05$ was considered to indicate statistical significance. The JMP version 5.1 statistical software package (SAS Institute, Cary, NC, USA) was used for analysis of data.

RESULTS

Virologic and biochemical responses to IFN therapy and side effects

The 42 patients receiving IFN therapy included 29 in the SVR group and 13 in the group without SVR (10 transient virological responders, 3 with no virological response). In the group without SVR, 7 biochemical responders who had a normalized ALT included 5 with transient virological responses and 2 with no virological response. Although there was no significant difference in the population of patients with HCV genotype 1 between the SVR and non-SVR group, patients in the former had significantly lower pre-IFN viral loads than patients in the latter group. In the SVR group, 24 patients received full-dose IFN therapy without dose reduction, while five patients received a reduced dose of IFN until completion

of treatment. In the group without SVR, one patient with no response discontinued IFN treatment at 16 wk because of a recurrence of HCC, while three patients with a transient response discontinued treatment because of generalized fatigue. The remainder of the group without SVR received the full course of IFN therapy. Thus, most patients were able to complete the 24-wk course.

Recurrence of HCC

In the IFN group, first recurrences of HCC developed in 20 patients after the initial treatment for HCC during a median follow-up period of 32 mo. Of these recurrences, 10 were in patients with SVR (10/29) and 10 in patients without SVR (10/13), including 7 transient virological responders and 3 with no virological response. For the 7 biochemical responders without SVR, HCC recurred in 6 patients, including 5 transient virological responders and 1 with no virological response. Of these 20 patients with recurrence, 18 were treated with local ablation therapy or surgical resection without leaving any residual tumor. The remaining 2 patients developed uncontrolled multiple HCC and were excluded from the subsequent study concerning the next recurrence. One died of HCC, while the other was treated repeatedly with hepatic arterial infusion, and has survived. Three patients in the SVR group and 7 in the group without SVR (5 transient virological responders and 2 with no virological response) had a second recurrence of HCC. Of these 10 patients with a second recurrence, 3 (2 transient virological responders and one with no virological response) developed uncontrolled HCC, while others were treated curatively with hepatic resection or local ablation therapy. In the non-IFN group, a first recurrence of HCC occurred in 30 patients during a median follow-up period of 31 mo. HCC recurred in 11 of the 17 who had a normal ALT level. Among the 30 patients with recurrent HCC, 25 were treated with local ablation therapy or surgical treatment, with no residual tumor. The remaining 5 patients who did not undergo curative therapy were treated repeatedly with transarterial chemoembolization. A second recurrence developed in 15 of the 25 patients who had curative treatment for a first recurrence. Among these 15 patients, 10 were treated curatively (9 with local ablation and 1 with hepatic resection). The remaining 5 patients had uncontrolled multiple HCC as their second recurrence.

Overall cumulative rates for first and second recurrence of HCC were compared between the groups. The 1-, 3-, 5- and 7-year rates for first recurrence in the IFN and non-IFN group were 0% *vs* 4.8%, 44% *vs* 53%, 61% *vs* 81%, and 67% *vs* 87%, respectively (Figure 1A, $P = 0.153$; no significant difference between groups). However, the 1-, 3-, 5-, and 7-year rates for second recurrence in the IFN and non-IFN group were 0% *vs* 0%, 10.4% *vs* 30%, 28% *vs* 59%, and 35% *vs* 66%, respectively (Figure 1B, $P = 0.022$). Thus, the second-recurrence rate was significantly lower in the IFN group than in the non-IFN group.

Next, the recurrence rates of HCC were compared between the SVR group, the non-SVR group and the non-IFN group. The rate of first recurrence was significantly lower in the SVR group than in the non-SVR and non-IFN group (Figure 2A). The rate of second recurrence in the

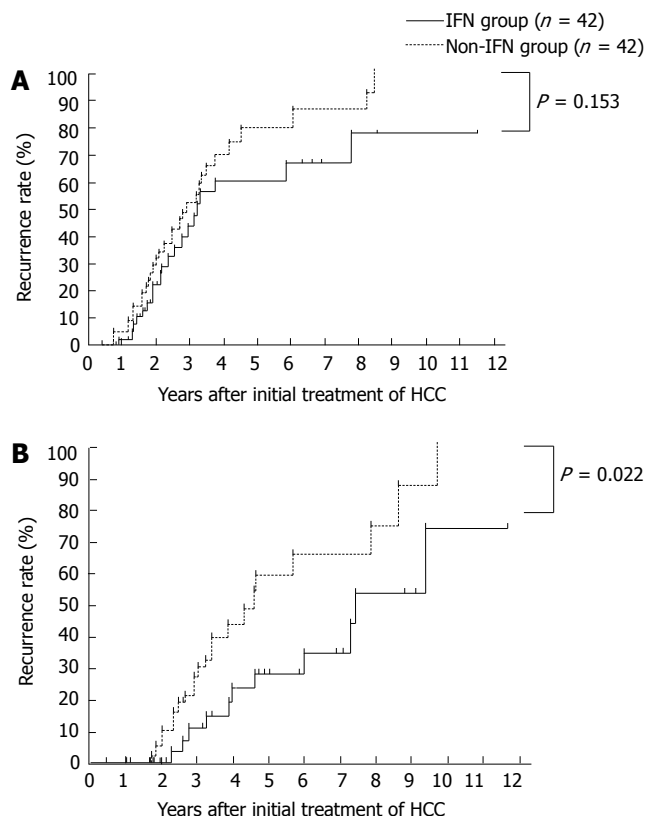

Figure 1 Cumulative recurrence rates after curative treatment of HCC. **A:** Rates of first recurrence compared between IFN and non-IFN groups, showed no significant difference ($P = 0.153$); **B:** Rates of second recurrence compared between IFN and non-IFN groups. The second recurrence rate for the IFN group was lower than that for the non-IFN group ($P = 0.022$).

SVR group was also lower than that in the non-SVR and non-IFN groups; this decrease was significantly greater than that for the rate of first recurrence (Figure 2B). No significant difference was seen in cumulative rates for first or second recurrence between the non-SVR and non-IFN groups. We also confirmed that biochemical responders in the non-SVR and non-IFN groups showed similar Kaplan-Meier curves for cumulative recurrence (data not shown). Recurrence curves were similar between the non-SVR group, including biochemical responders, and the non-IFN group, therefore, we defined these two groups as "non-SVR status" for statistical analysis. Factors found to be significantly associated with first recurrence by univariate analysis were tumor size (≥ 20 mm) and non-SVR status ($P = 0.019$, $P = 0.0067$, respectively). Multivariate analysis showed that no independent risk factor was associated with the first recurrence of HCC (data not shown), although non-SVR status tended to be associated with first recurrence ($P = 0.0657$). As shown in Table 2, univariate analysis indicated that non-SVR status, low platelet count ($< 100\,000$) and high indocyanine green retention ($\geq 20\%$) were significantly associated with second recurrence. Multivariate analysis identified only SVR status as a significant independent inhibiting factor for second recurrence of HCC.

Survival of patients

During the observation period, 13 of the total patients

studied died of liver disease. Nine died of HCC and 4 of liver failure. When we compared cumulative survival rates between the IFN and the non-IFN groups (Figure 3A), the respective rates were 100% *vs* 95% at 3 years, 100% *vs* 72% at 5 years, and 86% *vs* 63% at 7 years. The cumulative survival rate was significantly higher in the IFN group than in the non-IFN group ($P = 0.039$). Median survival time following the first treatment of HCC was 52.3 mo (range, 12-158) in the IFN group and 51.8 mo (range, 11-126) in the non-IFN group. In the IFN group, 2 patients died of advanced HCC, 1 with an SVR and the other without. No patients in the IFN group died of hepatic failure. In the non-IFN group, 7 patients died of HCC and four of hepatic failure.

Figure 3B shows cumulative survival curves for the SVR, non-SVR and non-IFN groups. The rate of survival in the SVR group was significantly better than that in the non-IFN group ($P = 0.029$), while no significant difference was evident between the non-SVR and non-IFN group ($P = 0.248$).

Pretreatment factors found to be significantly associated with survival by univariate analysis subsequently were evaluated by Cox regression analysis to determine independent factors. Multivariate analysis showed that SVR status and Child-Pugh class A were independent factors favorably associated with long survival (Table 3).

Liver function

Compared with the non-IFN group, patients who received IFN therapy were less likely to have worsening of hepatic dysfunction. For the SVR, non-SVR and non-IFN groups, we compared the average score for Child-Pugh classification at initial treatment of HCC with that at the time of data analysis. Median observation time was 59.8 mo in the SVR group, 45 mo in the non-SVR group, and 51.8 mo in the non-IFN group. There were no significant differences in the Child-Pugh classification score among these three groups at the time of initial treatment of HCC; however, at the time of data analysis, scores in the non-IFN group were significantly worse than in the SVR group ($P = 0.003$). No significant difference was seen between the non-SVR and non-IFN groups (Figure 4).

DISCUSSION

The present study compared historical control subjects with no IFN treatment with other subjects who were treated with IFN. Background characteristics showed no significant difference between the groups. IFN and non-IFN group did not differ significantly in their rate of first recurrence, but did differ significantly in their rate of second recurrence. According to IFN response, the recurrence rate in the SVR group was significantly lower than that in the non-SVR and non-IFN group, while recurrence rates in the non-SVR and non-IFN group did not differ significantly. Thus, SVR (i.e., HCV eradication) was the most important, and only, inhibiting factor for decreasing risk of HCC recurrence, associated with a 24-wk course of IFN- α therapy following HCC treatment.

Although several recent studies have reported the

Table 2 Factors associated with second recurrence

Variables	Univariate analysis			Multivariate analysis		
	Hazard ratio	95% CI	P	Hazard ratio	95% CI	P

Cox's proportional hazards model was used.

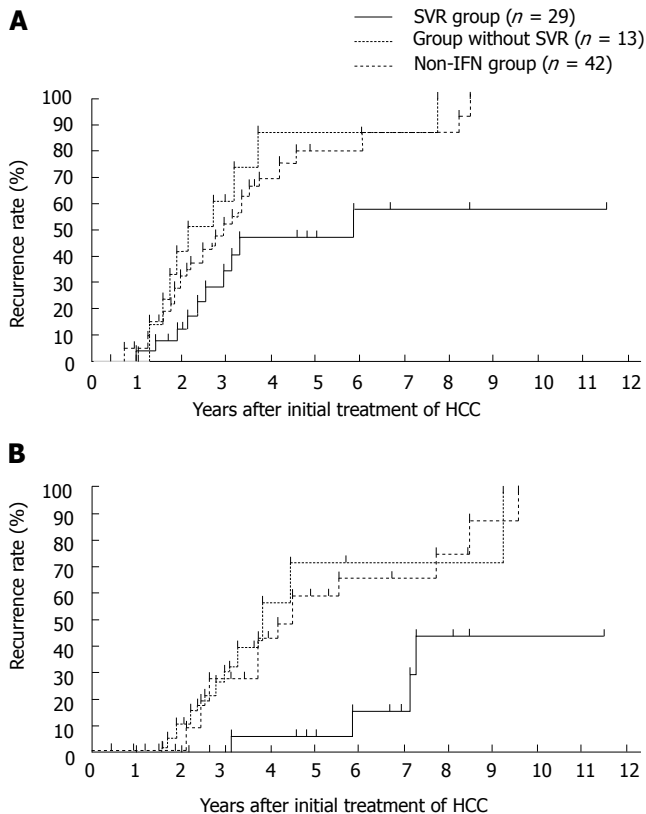

Figure 2 Cumulative recurrence rates according to SVR to IFN therapy after curative treatment of HCC. **A:** Rates of first recurrence compared among SVR, non-SVR and non-IFN groups. The rate of first recurrence of HCC in the SVR group was significantly lower than in the non-SVR and non-IFN groups ($P = 0.002$, $P = 0.016$, respectively). No significant difference in first recurrence rate was seen between the non-SVR and non-IFN groups ($P = 0.381$); **B:** Rates of second recurrence compared among the three groups. Second recurrence of HCC was suppressed in the SVR group compared with the non-SVR and non-IFN groups ($P = 0.0037$, $P = 0.0019$, respectively), and to a more pronounced degree than for the first recurrence rate. No significant difference in second recurrence rate was seen between the non-SVR and non-IFN groups ($P = 0.90$).

efficacy of chemoprevention with IFN after treatment of HCV-related HCC, the basis of this benefit has not been determined, since IFN has a variety of biologic effects, including antiviral, antiproliferative, immunomodulatory^[19-22] and anti-fibrogenic^[23,24] activities; growth inhibition through changes in signal transduction^[19,25,26]; and activation of natural killer cells^[27] and T cells^[28,29]. Through these various effects, IFN therapy is thought to suppress tumor recurrence directly and/or indirectly.

Sakaguchi *et al.*^[15] have reported that low-dose, long-term, intermittent IFN- α therapy can, by a direct anti-cancer effect, inhibit intrahepatic metastasis but not

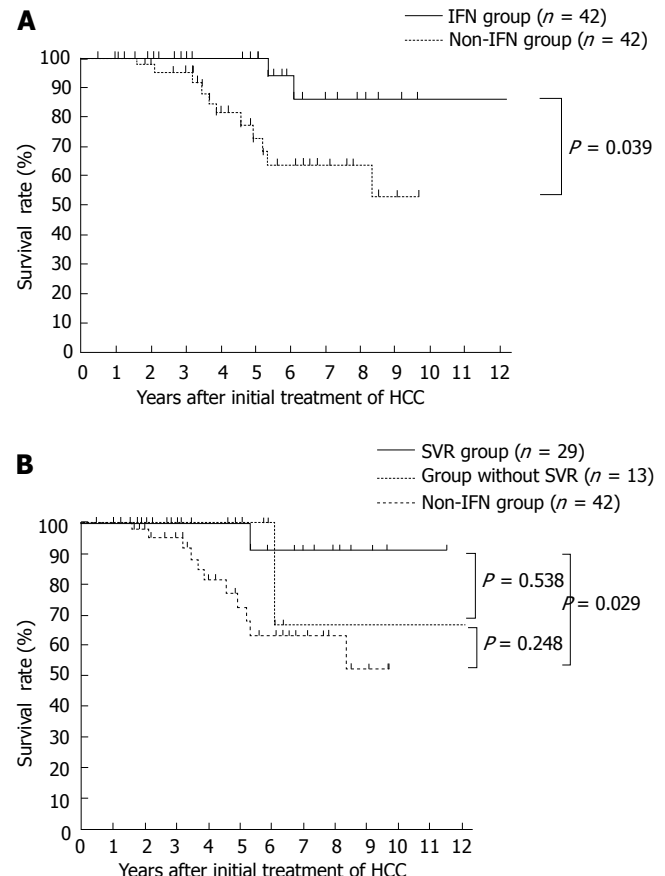

Figure 3 Cumulative survival rates after curative treatment of HCC. **A:** Comparison of cumulative survival rates in the IFN and non-IFN groups. The cumulative survival rate was significantly higher in the IFN group than in the non-IFN group ($P = 0.039$); **B:** Comparison of cumulative survival rates in the SVR, non-SVR and non-IFN groups. Although no significant overall difference was found between the SVR and non-SVR groups ($P = 0.538$), the SVR group had a particularly high survival rate compared with the non-IFN group ($P = 0.029$).

multicentric occurrences. Lai *et al.*^[29] have reported that IFN- α therapy is effective in advanced HCC. Several experimental studies have shown that IFN inhibits the growth of a human hepatoma cell line^[11,15]. In partial disagreement, however, Nishiguchi *et al.*^[12,14], Suou *et al.*^[16] and Shiratori *et al.*^[17] have reported that the rate of HCC recurrence was not different between IFN and non-IFN group during the first few years, but later became significantly lower in the IFN group. They suggested that IFN reduced HCC recurrence in the later period of observation by suppressing multicentric occurrence, as an indirect anti-tumor effect that was related to sustained hepatic inflammation. Although the present study did not have a randomized controlled design, and details of the

Table 3 Factors associated with survival

Variables	Univariate analysis			Multivariate analysis		
	Hazard ratio	95% CI	P	Hazard ratio	95% CI	P

Cox's proportional hazards model was used.

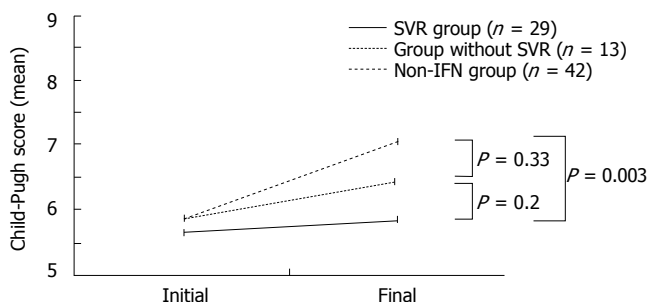

Figure 4 Influence of IFN therapy after curative treatment of HCC on Child-Pugh scores. IFN-treated patients were less likely to show deterioration of hepatic function. In particular, liver function scores in the SVR group were significantly better preserved than in the non-IFN group ($P = 0.003$). Median observation time was 59.8 mo in the SVR group, 45 mo in the non-SVR group, and 51.8 mo in the non-IFN group.

IFN protocol differed from those of others, the long-term results appear to be similar among studies. Recurrence during the first few years might involve undetectable intrahepatic metastasis, or a potential malignant tumor already existing at the time of treatment of the primary HCC; afterward, HCC might recur as multicentric new liver tumor, accompanied by sustained hepatic necrosis and inflammation. Although a direct anti-cancer effect of IFN might to some extent have directly inhibited HCC recurrence, our IFN doses were insufficient to suppress intrahepatic metastatic tumors because there was only a 24-wk treatment. Therefore, in our study, we believe that IFN therapy suppressed HCC recurrence less by a direct anti-tumor effect than by an indirect effect through inhibition of the chronic inflammation associated with HCV infection in the later period of observation.

Several studies have reported that recurrence was suppressed not only in virologic responders to IFN, but also in biochemical responders, even though HCV was not eradicated^[12-14]. However, the recurrence rates in our study did not differ significantly between biochemical responders and the non-IFN group. HCV eradication appeared to stand alone as an IFN effect capable of inhibiting recurrence, with eradication having a stronger influence against second recurrence than the first. The differences between the results of the various studies might be due to several reasons. In most previous studies, IFN therapy was given for more than 48 wk, compared with our 24 wk. Differences may also have been present in underlying hepatic inflammatory conditions such as chronic hepatitis and cirrhosis. Although such differences introduce some uncertainty to the conclusions, several recent studies suggest that HCV core protein might directly participate in hepatocarcinogenesis^[28,29], which supports the importance

of virus eradication.

Although some other recent studies have reported that IFN therapy following HCC treatment also improves liver function and survival of patients with HCV-related HCC, which of the specific IFN actions is important for these benefits remains unknown. We found that overall survival rate and preservation of liver function were significantly better in the SVR group than in the other groups, even including biochemical responders, with all subgroups without SVR resembling non-IFN patients. Favorable independent factors associated with survival by multivariate analysis were SVR and Child-Pugh class A. Thus, with a 24-wk course of IFN- α therapy, HCV eradication appears necessary for prolonging survival, suppressing HCC recurrence, and preserving liver function.

As stated above, effective management of HCV infection is needed, as well as direct treatment of the primary HCC. Although our study had limitations, such as the use of historical controls and a small number of patients, we could demonstrate a clear requirement for HCV eradication to improve survival after a short-course IFN- α therapy. Ribavirin combination or pegylated IFN therapy are considered more effective in HCV eradication than conventional IFN monotherapy^[32-34]. Several studies have indicated that pegylated IFN therapy is superior to conventional IFN when administered for 48 wk^[34-41]. Pegylated IFN therapy, with or without ribavirin, may improve prognosis in selected patients with no sustained initial response to conventional IFN. For patients who cannot undergo standard-dose IFN therapy because of limited hepatic reserve or thrombocytopenia, low-dose IFN therapy for a longer course might be effective. Nonetheless, further studies with larger controlled groups and long-term follow-up need to be performed to establish what constitutes optimal management of HCV infection after HCC treatment.

COMMENTS

Background

Risk of multicentric recurrence of hepatocellular carcinoma (HCC) and liver function deterioration remains high in hepatitis C virus (HCV)-infected patients even after receiving curative treatment for primary HCC. Most intrahepatic recurrences occurred during persistent viral infection. Although several recent studies have reported the efficacy of chemoprevention with interferon (IFN) therapy after treatment of HCV-related HCC, there was no standard IFN regimen. We investigated whether 24-week course of IFN- α therapy following curative treatment for primary HCC associated with HCV infection could suppress HCC recurrence and improve prognosis.

Research frontiers

To obtain sustained virological response (SVR) was important for suppression of HCC recurrence and for long-term survival in a 24-week course of IFN- α therapy.

Innovations and breakthroughs

Our study demonstrated that only SVR status by a 24-wk IFN- α therapy was the most important factor for decreasing risk of HCC recurrence in the later period of observation including second recurrence.

Applications

This study demonstrated that compared with non-IFN and non-SVR group, SVR group decreased the rate of recurrence, preserved liver function, and prolonged survival time in a 24-wk course of IFN- α therapy.

Peer review

This is a matched historical case controlled study concerning about the effect of 24-week short course IFN- α therapy after receiving curative treatment for primary HCC. The paper is well written and the results show that the most important factor associated with the improvement of prognosis is the SVR status.

Received: June 30, 2007 Revised: August 9, 2007

Abstract

AIM: The purpose of this study is to find a better operative technique by comparing interrupted stitches with continuous stitches for the outer layer of the pancreaticojejunostomy, i.e., the stitches between the stump parenchyma of the pancreas and the jejunal seromuscular layer, and other risk factors for the incidence of pancreatic leakage.

METHODS: During the period January 1997 to October 2004, 133 patients have undergone the end-to-side and duct-to-mucosa pancreaticojejunostomy reconstruction after pancreaticoduodenectomy with interrupted suture for outer layer of the pancreaticojejunostomy and 170 patients with a continuous suture at our institution by one surgeon.

RESULTS: There were no significant differences between the two groups in the diagnosis, texture of the pancreas, use of octreotide and pathologic stage. Pancreatic fistula occurred in 14 patients (11%) among the interrupted suture cases and in 10 (6%) among the continuous suture cases ($P = 0.102$). Major pancreatic leakage developed in three interrupted suture patients (2%) and zero continuous suture patients ($P = 0.026$). In multivariate analysis, soft pancreatic consistency (odds ratio, 5.5; 95% confidence interval 2.3-13.1) and common bile duct cancer (odds ratio, 3.7; 95% CI 1.6-8.5) were predictive of pancreatic leakage.

CONCLUSION: Pancreatic texture and pathology are the most important factors in determining the fate of pancreaticojejunal anastomosis and our continuous suture method was performed with significantly decreased occurrence of major pancreatic fistula. In conclusion, the continuous suture method is more feasible and safer in performing duct-to-mucosa pancreaticojejunostomy.

INTRODUCTION

Despite improvement of the operative technique, materials and instruments, pancreatic fistula after pancreaticoduodenectomy is the most common and serious complication. Recent large series have reported that the failure rate of the pancreaticoenteric anastomosis is 9%-18%^[1-6], a complication rate not far improved from Dr. Whipple's report of a 19.5% fistula rate more than 50 years ago^[7]. A number of methods for reducing the incidence of pancreatic fistula have been proposed and tested. Many of these involve technical aspects of the anastomosis, including the site of reconstruction (pancreaticogastrostomy versus pancreaticojejunostomy)^[8,9], the anastomotic technique (duct-to-mucosa anastomosis versus stump invagination)^[10,11], the use of biologic adhesive^[12,13] and the use of intraoperative transanastomotic stents^[14]. In addition, in order to determine how to prevent pancreatic fistula, the risk

factors for pancreatic fistula have been extensively studied. They include the patient's comorbid illness^[8], age^[15], texture of the pancreas^[4], pancreatic duct size^[16], intraoperative blood loss^[15] and the surgeon's experience^[15].

The present study tested the hypothesis that using continuous stitches for the outer layer of the pancreaticojejunostomy (i.e., the stitches between the stump parenchyma of the pancreas and the jejunal seromuscular layer) is a better operative technique than using interrupted stitches in terms of safety and efficiency.

MATERIALS AND METHODS

During the period from January 1997 to October 2004, 133 patients underwent duct-to-mucosa pancreaticojejunostomy reconstruction after pancreaticoduodenectomy with the interrupted suture method for the outer layer of the pancreaticojejunostomy and 170 patients underwent the procedure with the continuous suture method at our institution. From 1997 to 2000, the interrupted suture method was performed, and from 2001 to 2004, the continuous suture method was performed. The operations were performed by one surgeon who had experienced more than 500 cases of pancreaticoduodenectomy before this study.

We retrospectively reviewed the medical records of the patients who underwent duct-to-mucosa pancreaticojejunostomy after pancreaticoduodenectomy noting parameters such as the existence of pancreatic fistula, age, sex, preoperative symptoms, preoperative laboratory tests results, amount of intraoperative bleeding, and postoperative octreotide usage. Postoperative octreotide was given subcutaneously (dose 100 mg every 8 hours) for the patients considered high risk for pancreatic fistula based on gland texture and duct size.

Pancreaticoduodenectomy was performed with conventional pancreaticoduodenectomy or pylorus-preserving pancreaticoduodenectomy (PPPD). Anastomosis for the remnant pancreas was performed between the pancreas and jejunum by a two layer pancreaticojejunostomy. The outer layer consisted of the remnant pancreatic parenchyma and the seromuscular layer of jejunum and interrupted suture or continuous suture between these two was performed with 5-0 polypropylene (Prolene[®], Ethicon, Somerville, NJ). The inner layer consisted of the pancreatic duct and mucosa of the jejunum, and interrupted suture for duct-to-mucosa was performed with 5-0 polydioxanone (PDS[™] II, Ethicon, Somerville, NJ). A silastic polyethylene tube was inserted into the pancreatic duct as a stent for all patients, and external drainage was done (Figure 1).

Two or three drains were routinely placed anterior and posterior to the pancreatico-jejunal anastomosis and exteriorized through the lateral abdominal wall.

A pancreatic fistula was defined as the drainage of more than 30 mL of fluid with an amylase level higher than 600 U/dL on or after postoperative week 1^[17]. Also, three grades of fistula severity (A, B, C) were classified according to the International Study Group for Pancreatic Fistulas (ISGPF) clinical criteria^[18] as follows: Grade A

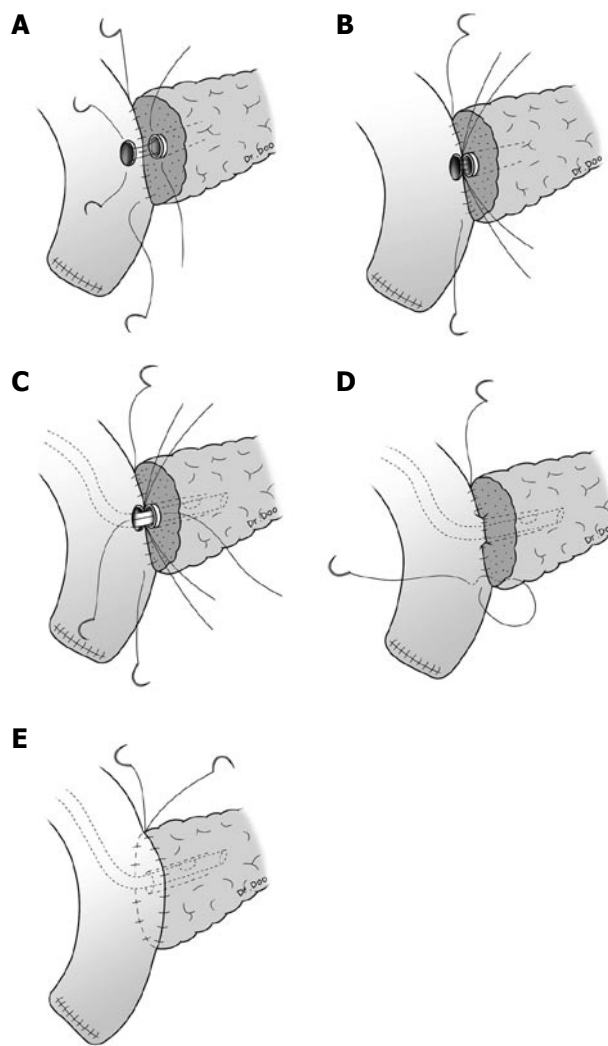

Figure 1 Continuous suture method for the outer layer of pancreaticojejunostomy. **A:** The posterior outer layer consisted of the remnant pancreatic parenchyma and the seromuscular layer of jejunum and continuous suture between these two was performed with 5-0 polypropylene (Prolene[®], Ethicon, Somerville, NJ); **B:** The posterior inner layer consisted of the pancreatic duct and mucosa of the jejunum, and interrupted suture for duct-to-mucosa was performed with 5-0 polydioxanone (PDS[™] II, Ethicon, Somerville, NJ); **C:** A silastic polyethylene tube was inserted into the pancreatic duct and external drainage was done; **D:** For anterior inner layer consisted of the pancreatic duct and mucosa of the jejunum, interrupted suture was performed; **E:** Continuous suture for anterior outer layer was performed.

fistulas are transient, asymptomatic fistulas, with only elevated drain amylase levels and treatments or deviation in clinical management are not required. Grade B fistulas are symptomatic, clinically apparent fistulas that require diagnostic evaluation and therapeutic management. Grade C fistulas are severe, clinically significant fistulas that require major deviations in clinical management and aggressive therapeutic interventions are unquestionably warranted. Major pancreatic leakage was defined as the drainage of more than 200 mL of fluid or the development of an intra-abdominal abscess.

Pancreatic fistulas, according to the operative methods and clinicopathologic factors causing pancreatic fistula, were analyzed.

Table 1 Comparison of clinical characteristics between the interrupted suture group and the continuous suture group *n* (%)

	Interrupted suture group (<i>n</i> = 133)	Continuous suture group (<i>n</i> = 170)	<i>P</i> value
Age (yr)	58.2 ± 12.4	60.4 ± 10.9	0.072
Male:Female	1.8:1	1.5:1	0.484
Pancreas texture			0.893
Hard	35 (26)	52 (31)	
Firm	86 (65)	76 (45)	
Soft	12 (9)	42 (24)	
Use of prophylactic octreotide	83 (62)	122 (72)	0.072
Jaundice	59 (44)	69 (41)	0.643
Diabetes mellitus	21 (16)	33 (19)	0.544
Diagnosis			0.433
Ampulla of Vater cancer	35 (26)	45 (26)	
Common bile duct cancer	38 (29)	46 (27)	
Pancreatic cancer	34 (25)	57 (34)	
Duodenal cancer	6 (5)	6 (4)	
Etc.	20 (15)	16 (9)	

Etc.: Ampulla of Vater adenoma, choledochal cyst, chronic pancreatitis, duodenal GIST, gallbladder cancer, intraductal papillary mucinous tumor, islet cell tumor of pancreas, peripancreatic neurilemmoma, pseudocyst, serous cystic adenoma.

Data comparisons between the two groups were made using the χ^2 test for qualitative parameters, a Student's *t*-test for quantitative parameters and logistic regression for determining the effect of multiple risk factors on pancreatic leakage. A value of *P* < 0.05 was accepted as significant.

RESULTS

There were no significant differences in mean age, sex, prophylactic use of octreotide, pancreas texture, stage, and indication for pancreaticoduodenectomy between the two groups (Table 1).

Although there was no significant difference in the mean total operation time between the interrupted suture and continuous suture groups, there was a statistically significant difference in the mean operation time of the outer layer anastomosis of pancreaticojejunostomy. The mean operation time of the interrupted suture method for the outer layer anastomosis of pancreaticojejunostomy was 35.4 ± 4.8 minutes, and the mean operation time of the continuous suture method was 29.1 ± 3.9 min (*P* < 0.001).

Pancreatic fistula occurred in 14 patients (11%) of the 133 patients who underwent interrupted suture for the outer layer and in 10 patients (6%) of the 170 patients who underwent continuous suture (*P* = 0.102). There were 5 grade A fistulas, 6 grade B fistulas, and 3 grade C fistulas in the interrupted suture group. There were 4 grade A fistulas, 5 grade B fistulas, and no grade C fistula in the continuous suture group. There was no significant difference between the two groups (*P* = 0.085). Major pancreatic leakage occurred in three patients (2%) in the interrupted suture group and zero patients in the continuous suture group (*P* = 0.026). For one patient of the interrupted suture group

Table 2 Comparison of postoperative complications and mortality between the interrupted suture group and the continuous suture group *n* (%)

	Number of patients		<i>P</i> value
	Interrupted suture group (<i>n</i> = 133)	Continuous suture group (<i>n</i> = 170)	
Pancreatic fistula	14 (10.5)	10 (5.9)	0.102
ISGPF grade			0.085
Grade A	5 (3.8)	4 (2.4)	
Grade B	6 (4.5)	6 (3.5)	
Grade C	3 (2.3)	0	
Major pancreatic fistula	3 (2.3)	0	0.026
Disruption	1 (0.8)	0	
Daily drainage > 200 cc	0	0	
Intra-abdominal abscess	2 (1.5)	0	
Pseudoaneurysm	0	2	0.128
Reoperation for pancreatic fistula	1 (0.8)	0	0.199
Hospital mortality	0	0	

who experienced pancreaticojejunal anastomotic rupture, externalization of the pancreatic duct was performed at the 10th postoperative day. For the other two patients of the interrupted suture group with major pancreatic leakage, percutaneous drainage was added.

Two patients of the continuous suture group with distal common bile duct (CBD) cancer developed pseudoaneurysm with preceding pancreatic fistula. They were successfully managed by radiologic intervention. There was no postoperative hospital mortality in the two groups (Table 2).

Of the total of 303 patients, 24 patients (8%) developed postoperative pancreatic fistula. There were no significant differences in age, sex, preoperative bilirubin and albumin levels, operation methods, amount of intraoperative bleeding, total operation time, postoperative prophylactic octreotide usage, and stage between the pancreatic fistula group and the non-pancreatic fistula group. There was a significant difference in pathologic features between the pancreatic fistula group and the non-pancreatic fistula group (*P* = 0.039). When the pathologic features were divided into CBD cancer and non-CBD cancer, there was a significant difference (*P* = 0.004). The consistency of the remnant pancreas correlates strongly with subsequent postoperative fistula rates. In the non-pancreatic fistula group, 43 (15%) were classified as soft and 85 as hard. In the pancreatic fistula group, 11 (46%) were classified as soft and 2 as hard (*P* < 0.001) (Table 3). In multivariate analysis, soft pancreatic consistency (odds ratio, 5.5; 95% confidence interval 2.3-13.1) and CBD cancer (odds ratio, 3.7; 95% confidence interval 1.6-8.5) were predictive of pancreatic leakage.

DISCUSSION

Recently, pancreaticoduodenectomy has become popularized as the standard treatment for various benign and malignant diseases of the periampullary region, including the pancreas head. Although the mortality rate has markedly decreased, the incidence of pancreatic fistula, the most catastrophic complication, remains high

Table 3 Perioperative risk factors for pancreatic fistula

after pancreaticoduodenectomy. After the first successful pancreaticoduodenectomy was performed by the German surgeon Kausch in 1912^[19], the risk factors for pancreatic anastomotic leakage and methods aimed at prevention of pancreatic anastomotic leakage have been extensively studied.

Several factors related to pancreatic anastomotic leakage have been described in the literature. They can be conveniently divided into disease factors (pancreatic texture^[4], pancreatic pathology^[8], pancreatic duct size^[16], pancreatic juice output^[8]), procedure-related factors (intraoperative blood loss^[15], operative techniques^[15]) and patient factors (age^[15], sex^[8], comorbid illness^[8], jaundice^[8]). Still, it is very difficult to predict the relationship of the risk factors and pancreatic fistula, and many studies have revealed heterogeneous results. In our study, two risk factors, common bile duct cancer and soft pancreatic texture were correlated with increased incidence of pancreatic fistula. The relative proportion of bile duct and ampulla of Vater cancers is much larger in Korea than in Western countries. The reason is not clear. The high incidence of hepatolithiasis, choledocholithiasis, choledochal cyst, and clonorchiasis in Korea is a possible explanation, at least in a proportion of cases. Unlike in the Johns Hopkins series^[8], the leakage rate was lower in cases of ampulla of Vater cancer (5%, 4/80) than in others (9%, 20/223). Patients with ampulla of Vater cancer are diagnosed early, and their general condition is

relatively good. More importantly, most of the patients have a dilated pancreatic duct and a firm pancreas, which facilitates the anastomosis and its healing. On the other hand, most of the patients with common bile duct cancer have a non-dilated pancreatic duct and a soft pancreas. The increased fistula rates with soft pancreatic texture may be interpreted by three explanations. First, most soft pancreases have no pancreatic duct dilatation, which makes secure duct-to-mucosa anastomosis difficult^[20,21]. Second, a soft pancreas is more easily injured directly or *via* ischemia by stitches placed between the pancreas parenchyma and the seromuscular layer of the jejunum^[20]. Third, a soft pancreas has a good exocrine function, secreting more pancreatic juices rich in proteolytic enzymes^[20-22].

Prophylactic use of octreotide is expected theoretically to reduce the incidence rate of the pancreatic fistula through decreasing pancreatic juice secretion. However, randomized trials from Europe and United states showed opposite results^[23-26]. In our study, there was no significant difference in the incidence rate of pancreatic fistula between postoperative prophylactic octreotide usage group and no usage group ($P = 0.347$). To prove the effect of octreotide in reducing the amount of postoperative pancreatic fistula, more organized randomized controlled studies are needed.

Various techniques for managing the pancreatic remnant have been studied with the aim of reducing the anastomotic leakage rate, including varying the site of the jejunum for pancreaticojejunostomy (end *vs* side), varying the type of anastomosis (duct-to-mucosa *vs* invagination)^[10,11], comparing the difference between pancreaticogastrostomy and pancreaticojejunostomy^[8,9], use of fibrin glue^[12,13] and pancreatic duct stenting^[14]. Unfortunately, randomized trials on these technical measures are scarce^[11]. As a result, there is no universal agreement on which operative technique is safer and less prone to pancreatic leakage^[11].

Because our study is not a prospective randomized controlled study, there is potential for a beta error. However, it could be thought as a periodic randomized study. The operations were performed by one surgeon who had experienced more than 500 cases of pancreaticoduodenectomy before this study, and the improved results are unlikely associated with a learning curve by doing more procedures.

Although there was no significant difference between the interrupted suture and continuous suture methods for preventing pancreatic fistula in our study, the incidence of major pancreatic fistula decreased significantly in the continuous suture group ($P = 0.026$). Theoretically, the continuous suture method has many advantages over the interrupted suture method^[27-32]. First of all, a more even distribution of tension is possible in the continuous suture between the pancreatic parenchyma and jejunum^[27]. Due to the coiled spring effect, the continuous suture method provides a reduction in the likelihood of focal tissue ischemia^[27], an increase in tensile strength^[27], and a reduction of the risk of pancreaticojejunal rupture. A continuous suture provides an enhanced air and watertight seal^[28,29]. As our study shows, a continuous suture reduces anastomosis time^[30,31]. A continuous suture is technically

easier^[30,31] and costs less^[31,32]. For continuous sutures, we use one polypropylene (Prolene*, Ethicon, Somerville, NJ) thread, and the thread costs 5.7 dollars. However, for interrupted sutures, we use 16 polypropylene sutures and it costs 86 dollars more than continuous suture.

The study of two methods for approximating the pancreatic parenchyma to the jejunal seromuscular layer in duct-to-mucosa pancreaticojejunostomy revealed that the incidence of major pancreatic fistula decreased significantly and operation time is reduced significantly in the continuous suture group. In conclusion, the continuous suture method is more feasible and safe to use in performing pancreaticojejunostomy.

COMMENTS

Background

Leakage of the pancreaticojejunal anastomosis has been a major complication after pancreaticoduodenectomy. Over the past decades, various measures directed towards prevention of pancreatic leakage have been studied.

Research frontiers

The purpose of this study is to find better operative technique as comparing the interrupted stitches with the continuous stitches for the outer layer of the pancreaticojejunostomy, ie. the stitches between the stump parenchyma of the pancreas and the jejunal seromuscular layer, and other risk factors for the incidence of pancreatic leakage.

Innovations and breakthroughs

Soft pancreatic consistency (odds ratio, 5.5; 95% confidence interval 2.3-13.1) and CBD cancer (odds ratio, 3.7; 95% confidence interval 1.6-8.5) were predictive of pancreatic leakage and our continuous suture method performed with significantly decreasing major pancreatic fistula.

Applications

The study of two methods for approximating the pancreatic parenchyma to the jejunal seromuscular layer in duct-to-mucosa pancreaticojejunostomy revealed that the incidence of major pancreatic fistula decreased significantly and operation time is reduced significantly in the continuous suture group. In conclusion, the continuous suture method is more feasible and safe to use in performing pancreaticojejunostomy.

Terminology

A pancreatic fistula was defined as the drainage of more than 30 mL of fluid with an amylase level higher than 600 U/dL on or after postoperative week 1. Also, three grades of fistula severity (A, B, C) were classified according to ISGPF clinical criteria as follows: Grade A fistulas are transient, asymptomatic fistulas, with only elevated drain amylase levels and treatments or deviations in clinical management are not required. Grade B fistulas are symptomatic, clinically apparent fistulas that require diagnostic evaluation and therapeutic management. Grade C fistulas are severe, clinically significant fistulas that require major deviations in clinical management and aggressive therapeutic interventions are unquestionably warranted. Major pancreatic leakage was defined as the drainage of more than 200 mL of fluid or the development of an intra-abdominal abscess.

Peer review

As this was a retrospective, non-randomized study in which the continuous suture was used after experience with 133 patients in whom an interrupted suture technique was used, the "better" results with the continuous suturing may simply be a learning curve.

Abstract

AIM: To prospectively investigate serum CA 19-9 levels in type 2 diabetic patients in comparison with age- and gender-matched control subjects.

METHODS: We recorded duration of diabetes and examined fasting glucose levels, HbA1c levels and serum CA 19-9 levels in 76 type 2 diabetic patients and 76 controls. Abdominal CT was performed in order to eliminate abdominal malignancy in the diabetic and control groups.

RESULTS: The average CA 19-9 level was 46.0 ± 22.4 U/mL for diabetic patients whereas it was 9.97 ± 7.1 U/mL for the control group ($P < 0.001$). Regression analysis showed a positive correlation between diabetes and CA 19-9 independent from age, gender, glucose level and HbA1c level ($t = 8.8$, $P < 0.001$). Two of the diabetic patients were excluded from the study because of abdominal malignancy shown by CT at the initial evaluation. For all patients, abdominal CT showed no pancreatic abnormalities.

CONCLUSION: CA 19-9 is a tumor-associated antigen, which is elevated in pancreatic, upper gastrointestinal tract, ovarian hepatocellular, and colorectal cancers, as well as in inflammatory conditions of the hepatobiliary system, biliary obstruction and in thyroid diseases. Diabetes has been claimed to be a risk factor for pancreatic cancer, which is increasing its incidence and has one of the lowest survival rates of all cancers. CA 19-9 is used in the diagnosis of pancreatic cancer but is also a marker of pancreatic tissue damage that might

INTRODUCTION

CA 19-9 is a tumor-associated antigen that was originally defined by a monoclonal antibody produced by a hybridoma prepared from murine spleen cells immunized with a human colorectal cancer cell line. CA 19-9 is elevated in pancreatic cancers, in cancers of the upper gastrointestinal tract, in ovarian cancer, hepatocellular cancer, colorectal cancer, as well as in inflammatory conditions of the hepatobiliary system and in thyroid diseases^[1]. It may also be elevated in malignant and benign cases of biliary obstruction^[2].

Diabetes has been claimed to be a risk factor for pancreatic cancer, which is increasing its incidence and has one of the lowest survival rates of all cancers^[3].

The association between diabetes and pancreatic cancer remains controversial. A meta-analysis of 20 studies found a two-fold increased risk of pancreatic cancer among diabetic patients of 5 years duration, suggesting that diabetes is a risk factor for the tumor^[4]. Other studies have concluded that cancer preceded and caused diabetes^[5]. There are even some studies suggesting that diabetes protects against pancreatic cancer^[6].

CA 19-9 is used in the diagnosis of pancreatic cancer but is also a marker of pancreatic tissue damage that might be caused by diabetes. Therefore it is necessary to define the normal range of CA 19-9 in type 2 diabetic patients in order to eliminate additional interventional approaches. In this study, we prospectively evaluated serum CA 19-9 levels in type 2 diabetic patients in comparison with age- and gender-matched control subjects.

MATERIALS AND METHODS

76 consecutive, type 2 diabetic patients and 76 age- and gender-matched healthy controls comprised the study groups. We recorded duration of diabetes and examined fasting glucose levels, HbA1c and serum CA 19-9 levels. CA 19-9 was measured with a chemiluminescence immunoassay (Roche Diagnostics E 170 analyser). The normal range of CA 19-9 was defined as less than 27 U/mL. Abdominal CT was performed in order to eliminate abdominal malignities for the diabetic and control groups.

RESULTS

Characteristic features of the control and study groups are shown in Table 1. Two of the diabetic patients were excluded from the study because of abdominal malignancy found with CT at the initial evaluation (one had an adrenal mass and the other prostatic carcinoma).

Average CA 19-9 levels were 46.0 ± 22.4 U/mL in diabetic patients whereas it was found to be 9.97 ± 7.1 U/mL in the control group ($P < 0.001$). Regression analysis showed a positive correlation between diabetes and CA 19-9, independent from age, gender, glucose level and HbA1c level ($t = 8.8$, $P < 0.001$) (Figure 1). For all patients, abdominal CT showed no pancreatic abnormalities.

DISCUSSION

Diabetes mellitus is a chronic inflammatory disease of the pancreas. The mechanisms of glucose intolerance include insulin resistance and destruction of islet beta cells. Most of these conditions damage exocrine tissue and islet cells and both of these systems are anatomically and functionally related. There are no capsules or basement membranes around islets and there are cell-to-cell contacts between exocrine and endocrine cells. There are direct connections between the capillaries of islets and acini that underlie the regulatory connections between islet hormones and exocrine pancreatic secretion, or in other words the relation between parenchymal disease and beta-cell dysfunction^[3].

Insulinitis is a progressive phenomenon in diabetes mellitus. The United Kingdom Prospective Diabetes Study evaluated beta cell function in diabetes using the homeostasis model assessment and found that beta cell function was already reduced by 50% at diagnosis and that there was subsequent deterioration regardless of therapy^[7]. Diabetes can even be described as the last step of chronic pancreatitis with the new developing concepts of pathogenesis^[8].

On the other hand, patients with chronic pancreatitis often suffer from endocrine pancreatic dysfunction, which leads to a secondary form of diabetes. This form of diabetes accounts for $< 1\%$ of all diabetic cases^[8]. Eighty percent of patients with chronic pancreatitis develop an overt diabetes mellitus in the long run and diabetes mellitus is an independent risk factor for mortality in patients with chronic pancreatitis^[9,10]. Chronic pancreatitis is a risk factor for pancreatic cancer^[11] and the same is also true for diabetes^[3]. Therefore diabetic patients have to be followed up for pancreatic cancer.

CA 19-9 is a tumor marker used for the diagnosis of

Table 1 Sex distribution and mean age of patients

	Sex		Mean age (yr)
	Male	Female	
Type II DM	19	55	53.3
Control	17	59	52.5

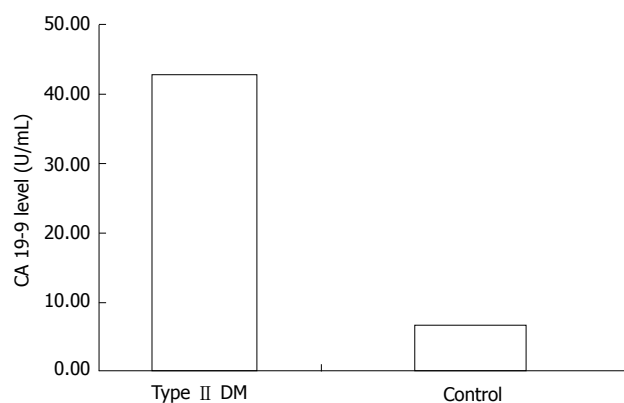

Figure 1 Mean CA 19-9 levels in Type II DM and Control groups.

pancreatic cancer with a sensitivity of 70%-90% and a specificity of 68%-91%^[12]. The main limitation of CA 19-9 is that it can also be elevated in patients with nonmalignant obstructive jaundice, thyroid disease and ovarian diseases resulting in impaired specificity of the marker. The solution to this problem was found with the use of higher cut-off values and a combination of tumor markers in differential diagnosis of gastrointestinal cancers. Lewis blood group status is also important for the interpretation of CA 19-9 because 10% of the Caucasian population who are Lewis genotype negative are unable to express CA 19-9^[13]. Diabetes is also associated with an increased risk of hepatocellular carcinoma^[14].

Taking the close relation between exocrine and endocrine pancreatic function into consideration, the use of CA 19-9 in diabetics is controversial. The relationship between diabetes mellitus and CA 19-9 has been studied by Benhamou *et al*^[15] and they investigated the relationship between CA 19-9 and metabolic control of diabetes in 51 adult patients. They concluded that CA 19-9 in diabetic patients is raised in acute metabolic situations, which correlated very well with blood glucose concentration.

In contrast to Benhamou *et al*, 64 diabetic patients examined by Banfi *et al*^[16] showed no correlation between CA 19-9 and biochemical markers of metabolic compensation in diabetes. In our study we also found that CA 19-9 levels were higher in diabetic patients in comparison to controls ($P < 0.001$). The elevation of CA 19-9 in diabetics was less than twice of the normal range. Regression analysis showed a positive correlation between diabetes and CA 19-9 independent from age, gender, glucose level and HbA1c level ($t = 8.8$, $P < 0.001$). We could not identify any pancreatic or gastrointestinal cancer in the diabetic patients with a high level of CA 19-9, which is consistent with the concept of exocrine pancreatic dysfunction in diabetes.

We propose that a higher cut-off value for CA 19-9

should be used for diabetics to differentiate benign and malignant pancreatic disease, and subtle elevations of CA 19-9 in diabetics should be considered as an indication of exocrine pancreatic dysfunction.

COMMENTS

Background

Ca 19-9 is a widely used antigen in the diagnosis of pancreatic and gastrointestinal cancers but its elevation might also be due to some nonspecific causes. Chronic inflammation such as diabetes mellitus can lead to pancreatic tissue damage and to a nonmalignant cause of high Ca 19-9 levels. Therefore the "normal" interval of Ca19-9 should be defined in type 2 diabetic patients.

Research frontiers

Insulinitis is a progressive phenomenon in type 2 diabetes and United Kingdom Prospective Diabetes Study confirmed this entity. Chronic pancreatitis is a risk factor for diabetes and also for pancreatic cancer. The studies by Benhamou and Banfi found controversial data regarding the correlation between Ca 19-9 and diabetes.

Innovations and breakthroughs

Elevation of Ca 19-9 in type 2 diabetics has been associated with bad metabolic control in previous studies and no morphological studies was done. We performed abdominal CT in all the patients in order to exclude any pancreatic malignancy and found out that Ca 19-9 was elevated in all the diabetic patients.

Applications

We have to define a new cut-off value for Ca 19-9 level in type 2 diabetics in order to eliminate unnecessary investigations for pancreatic cancer in this subgroup. This article can lead to further study the effect of insulinitis and chronic pancreatitis on Ca 19-9 expression in experimental and morphological studies.

Terminology

Ca 19-9 is a tumor-associated antigen which is originally defined by a monoclonal antibody that has been produced by a hybridoma prepared from murine spleen cells immunized with a human colorectal cancer cell line.

Peer review

This study has interesting scientific and innovative contents, and good readability.

Abstract

AIM: To evaluate the effectiveness of a holistic acupuncture approach on nausea, pain, bloating and electrogastrogram (EGG) parameters in patients with intractable symptoms.

METHODS: Twelve patients with no or mild nausea (those without nausea had bloating or pain) and 10 with a history of moderate to severe nausea were referred for acupuncture. All underwent an EGG and were treated at acupuncture points PC6, SP4 and DU20. Visual analog scales (VAS) assessing severity of nausea, pain and bloating were obtained before and after acupuncture treatment. Nineteen patients received three and three patients received two treatments.

RESULTS: VAS scores for nausea reflected the clinical assessment and differed significantly between mild and moderate/severe nausea groups. Acupuncture significantly improved severity of nausea in both groups with improved pre-treatment nausea between the first and third treatments in the moderate/severe nausea group. Pain scores improved with acupuncture in the mild nausea group only and bloating improved only with the first treatment in this group. Patients with bloating with VAS scores greater than 35 pre-treatment improved with acupuncture and over all VAS scores for pain improved with treatment. Acupuncture increased the power in the 2.7 to 3.5 cpm range in the EGG.

CONCLUSION: In this uncontrolled clinical study, a holistic acupuncture approach significantly improved nausea in patients with refractory symptoms and increased the power in the 2.7-3.5 cpm component of the electrogastrogram. Bloating and pain VAS scores improved acutely with treatment. This study suggests that acupuncture may be effective in this refractory group of patients and further study using appropriate controls is warranted.

INTRODUCTION

Nausea is a debilitating symptom that severely impacts on quality of life. Surveys of patients with functional dyspepsia (chronic or recurrent abdominal pain without an anatomic or inflammatory cause) and patients undergoing chemotherapy, identify nausea as one of the symptoms with the greatest negative impact on quality of life^[1,2]. It is a complicated symptom to study and treat because it is often a co-morbid symptom and multiple factors impact on its etiology and severity.

Nausea is a prominent symptom in approximately 20% of patients recruited to dyspepsia studies in whom pain is the major complaint^[1]. Patients who present with chronic or recurrent nausea in whom no biochemical, anatomic or inflammatory abnormalities can be found, are diagnosed as having functional nausea^[3]. Efforts to determine a single pathophysiologic process in patients with functional nausea have been unsuccessful. Some patients have gastroparesis, or delayed emptying of solid foods from the stomach, either related to other medical conditions such as diabetes mellitus or without any obvious underlying systemic disorder. Others have normal gastric emptying despite severe nausea. Even when a condition such as gastroparesis is identified, it is unclear whether the symptom of nausea can be directly ascribed to that condition^[4]. Symptoms of nausea can vary in severity over time despite persistent delayed gastric emptying, suggesting that gastroparesis alone does not explain the severity of nausea. Medications for treatment of nausea are limited to those that increase gastric or duodenal contractile activity, the prokinetic agents, and those affecting the chemoreceptor trigger zone^[3]. Many prokinetic and centrally acting medications have significant side effects. Psychological factors are often important. Even following chemotherapy, a condition where nausea is known to be a direct effect of medications, the severity of nausea is impacted by psychological stress from family

relations^[5]. Psychotropic agents may be helpful in the treatment of nausea, but many have side effects that may be counterproductive to gastric function, such as the anticholinergic action of tricyclic antidepressants.

The complexity of the processes contributing to nausea does not lend itself to the usual "modern" medical approach to disease, which includes treating each abnormal condition with separate medications. In contrast, the ancient Chinese paradigm of medicine involves a holistic approach that uses a paradigm of deviation from balance in energy or "Qi" and accepts the concept that many conditions that would appear to involve disparate organ systems may be intertwined resulting in "imbalance". Improvement in symptoms requires the treatment of multiple conditions to restore balance^[6].

Acupuncture has been used since antiquity to treat patients with nausea⁷ and has been subjected to clinical study. It has been used with moderate success in patients with chemotherapy induced nausea and post-operative nausea^[7,8,9]. A search of the literature revealed no reports of its use in treating functional nausea.

The aims of this study were to examine the effect of acupuncture, using a holistic approach, in patients referred for nausea and/or abdominal pain, refractory to routine medical treatment. We examined the effect on the symptoms of nausea, bloating, and pain and on gastric motor activity, as assessed by electrogastrography. The holistic approach included acupuncture therapy at three points, PC6, SP4 and DU20. These are described in detail in the methods section.

MATERIALS AND METHODS

Subjects and treatment

Charts were reviewed of 22 patients (3 male, 19 female. Mean 44.1 ± 2.7 years, range 17-66) who were treated with acupuncture between June 2003 and December 2005. Patients were referred to Hershey Medical Center for care and treatment with prokinetic agents and usual therapy had failed. All patients were interested in pursuing alternative medical therapy. All patients had undergone the same treatment plan. Charts were reviewed for the history of the severity and duration of nausea, abdominal pain and bloating and prior gastric emptying studies. Fourteen of the patients had a documented diagnosis of depression on their chart. The other patients had no documentation of psychiatric disorders but no documentation stated specifically that there were no psychological issues. From the chart narrative, patients were determined to have either no nausea or mild nausea (those with no nausea complained primarily of abdominal bloating and pain) or moderate to severe nausea. The severity of each symptom was also assessed before and after each acupuncture treatment using a visual analog scale (VAS) with 0 for no symptoms and 100 for the worst symptom during the first three treatments. The assessment by the physician in clinic was not known to the subject who completed the VAS score and was based on patients' history of the complaint. EGGs were also performed on all patients^[10]. During the treatment sessions, the acupuncture points P6, SP4 bilaterally and DU20 were needled for 30 min, while the EGG was recorded. A

VAS was completed for each of the symptoms of nausea, pain and bloating before and after each acupuncture treatment. Patients returned for at least one or two additional treatments. Nineteen patients had three treatment and three patients underwent two treatments. The average duration between treatments was 15 ± 1.9 d (mean \pm SE), range 7-33 d. The study was approved by the Institutional Review Board of the Hershey Medical Center (November 8, 2006).

Electrogastrogram (EGG) recording and analysis

All patients underwent a clinical EGG following our standard protocol^[10]. Patients fasted overnight. On the day of treatment, each patient consumed a standard 200 Kcal snack of 8oz of apple juice and two slices of toast. Each subject then fasted for an additional two hours after which time EGG recordings were obtained. On the first treatment day, a water load test was performed after 15 min of baseline EGG. EGG recording was then continued during the 30 min of acupuncture treatment. Signals were passed through 0.016 Hz high-pass filter and a 0.25 Hz low-pass filter. The EGG signal was reviewed to remove areas of artifact and the resulting EGG signal was digitized for computer analysis and subjected to fast Fourier transform to extract the frequency information present in the EGG signal. A running spectral analysis of the component wave form was followed over time. The percent power in the frequency ranges of 1.0-2.5 cpm, 2.5-3.7 cpm and 3.7 to 10 cpm were recorded.

Water load test

A water load test was performed at the first treatment session. After a 15 min baseline EGG was recorded, the patients ingested water "until full" within five minutes. The water was non-carbonated spring water at room temperature (23°C). The volume (mL) of water drunk was recorded^[10].

Visual analog scale (VAS) for symptoms

A visual analog scale (VAS) with a score from 0-100 points was utilized to assess the intensity of each of the following visceral sensations: nausea, pain, bloating, with 0 being none and 100 being unbearable. Each subject completed a VAS score prior to the study and before and after each acupuncture treatment.

Acupuncture points

Acupuncture points P6, SP4 and DU20 were selected for this treatment regimen^[7]. The point PC6 (Neiguan) is on the pericardium meridian of hand-jueyin. It is located 2 cm above the transverse crease of the wrist, between the tendons of *muscularis palmaris longus* and the *flexor radialis*. The traditional indications for needling of the PC6 point are stomach ache, nausea, vomiting, hiccough, mental disorders, epilepsy, insomnia, febrile disease, irritability, and malaria. The point SP4 (Gong sun) lies on the Spleen meridian of the foot-taiyin. It is located in the depression distal and inferior to the base of the first metatarsal bone. The traditional indications for treatment of the SP4 point relate to the gastrointestinal (GI) or central nervous system and are abdominal pain and distension, diarrhea, dysentery,

Table 1 Demographics and clinical characteristics of patients in the mild or severe nausea groups

	Mild nausea (<i>n</i> = 12) symptom score 0 or 1	Severe nausea (<i>n</i> = 10) symptom score 2 or 3	<i>P</i>
Gender	10F:1M	9F:1M	NS
Age (yr ± SE)	47.5 ± 2.9	40 ± 4.6	NS
Weight (lbs ± SE)	143 ± 7	150.8 ± 10.4	NS
Diabetes	1/12	1/10	
Severity of nausea ¹	0.25 ± 0.04	2.6 ± 0.15	<i>P</i> < 0.0001
Severity of pain ¹	2 ± 0.3	1.1 ± 0.37	NS
Severity of bloating ¹	2.3 ± 0.37	1.2 ± 0.5	NS
Duration of symptoms in months (mean ± SE)	24.9 ± 5 Range 7-60	15.3 ± 3.4 Range 4-36	NS ²

¹Symptom key: 0-none, 1-mild, 2-moderate, 3-severe (based on narrative and complaint in patient chart). ²Using Mann-Whitney test for non-parametric data.

borborygmus, nausea, vomiting, hiccough, and insomnia. The point DU20 (Baihui or GV 20) lies on the Governor vessel. It is located in the midline of the head, at the intersection of the line connecting the apices of both ears and a line that lies in the midline in the sagittal orientation on the head. The traditional indications for using the DU20 point are vertigo, headache, tinnitus, nasal obstruction, aphasia by apoplexy, coma, mental disorders, prolapse of the rectum and the uterus. It was felt that this combination of points would treat specific nausea symptoms and gastrointestinal complaints as well as depression, which was felt to be a common problem for many patients with refractory nausea.

Statistical analysis

The charts were reviewed for age, weight, gender, and assessment of the severity of the symptoms of nausea, vomiting, bloating and pain at the clinic visit. As the degree of nausea was variable patients were analyzed in two groups based on the severity of nausea determined by history at the initial clinic assessment-either in a "none to mild" nausea group or a "moderate to severe" nausea group. Separation of patients into the two groups was based on clinical assessment of the chart and was determined prior to any knowledge of the outcome of treatment.

The effect of acupuncture before and after treatment in the different groups and its effect on the parameters of VAS scores for nausea, bloating and pain and power of EGG in the different frequencies was analyzed using ANOVA. If a significance level of *P* < 0.05 was determined, direct comparisons between specific parameters was performed using a student *t* test (two-tailed) for parametric data or Mann-Whitney test for non-parametric data. Data are presented as mean ± SE.

RESULTS

Patients were primarily analyzed as two groups, based on

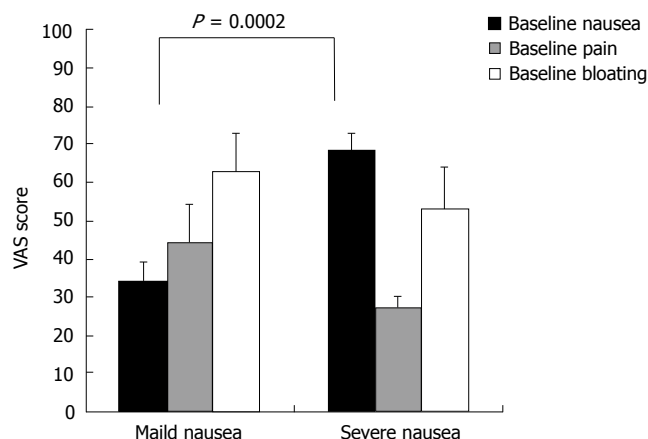

Figure 1 VAS score for symptoms of nausea, abdominal pain and bloating at baseline for patients in either the mild or severe nausea groups. A significant difference was seen in the VAS score for nausea between the groups (*P* = 0.0002).

an assessment of the severity of nausea as determined by obtaining a history from patients at their initial clinic visit. Those with no or mild nausea were grouped in the mild nausea group (*n* = 12), those with moderate or severe nausea were grouped in the severe nausea group (*n* = 10). The demographics and clinical features are shown in Table 1. In the group who complained of mild to no nausea, nine patients did not complain of nausea, but complained more of pain and/or bloating. The frequency of nausea (25% vs 100%) and the severity of nausea was significantly different between the groups (*P* < 0.05). There was no difference in either the prevalence of abdominal pain or bloating or severity of these symptoms between the two groups. The duration of nausea when present was between seven months and five years in the mild nausea group and between four months and three years in the severe nausea group (not significant [NS]). Only one out of each group was diabetic.

At the first visit for acupuncture treatment, the VAS scores for nausea were significantly greater in the severe nausea group than the mild nausea group (68.2 ± 4.4 vs 33.3 ± 5.8 , *P* < 0.0002, Figure 1) and these subjects tolerated the water load test more poorly than did the mild nausea group (429 ± 33.9 vs 642 ± 22 mL, *P* < 0.0001). There was no significant difference in VAS scores for bloating or pain at baseline between the two groups. Bloating was the predominant symptom in the mild nausea group while both nausea and bloating were equally prominent in the severe nausea group.

Effect of acupuncture on symptoms

Acupuncture significantly improved the VAS score for nausea in both the mild nausea and severe nausea groups (Figure 2A). There was improvement in the pre-acupuncture nausea score between the first and third treatment in the severe nausea group (*P* < 0.03) suggesting a persistent effect between treatments. In the mild nausea group, there was no significant difference in the baseline score between the first and third treatment.

Acupuncture was less effective for the symptoms of pain or bloating (Figure 2B and C). Pain scores were significantly improved during acupuncture in the mild nausea

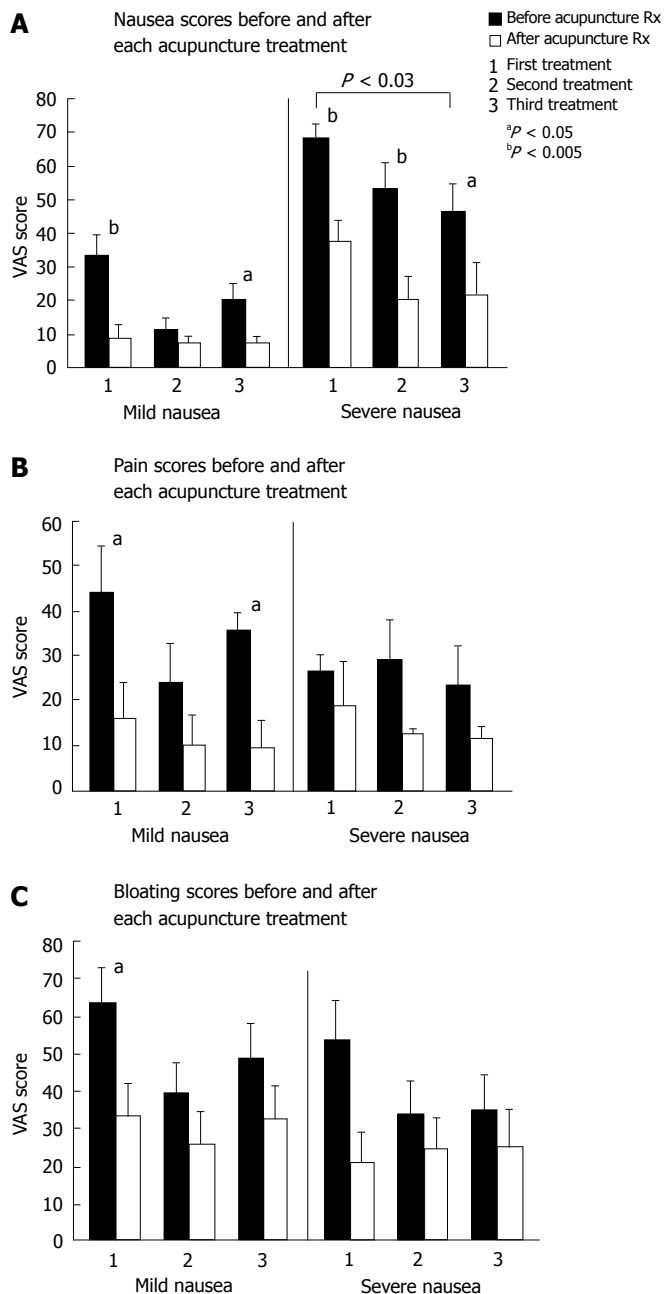

Figure 2 Effect of acupuncture on the symptoms of nausea (A), abdominal pain (B) and bloating (C) in the patients with mild or severe nausea. The response to each acupuncture treatment is shown.

group. No significant improvement was seen in the severe nausea group although the trend was towards improvement. Although bloating improved during the first acupuncture treatment in the mild nausea group, no significant improvement was seen in the severe nausea group.

Additional categorization of patients examined the response of bloating and pain to acupuncture by the pre-treatment VAS score, as the examining physician did not score the symptoms of pain and bloating clinically. The VAS for bloating improved with the first acupuncture treatment ($n = 22$) from 56.2 ± 7.7 to 30.4 ± 5.4 ($P < 0.01$). The overall pain score for all patients decreased from 35.9 ± 7.8 to 17.8 ± 0.8 ($P = 0.08$) with the first treatment. We also compared responses to acupuncture in patients with mild vs moderate/severe symptoms of bloating or pain.

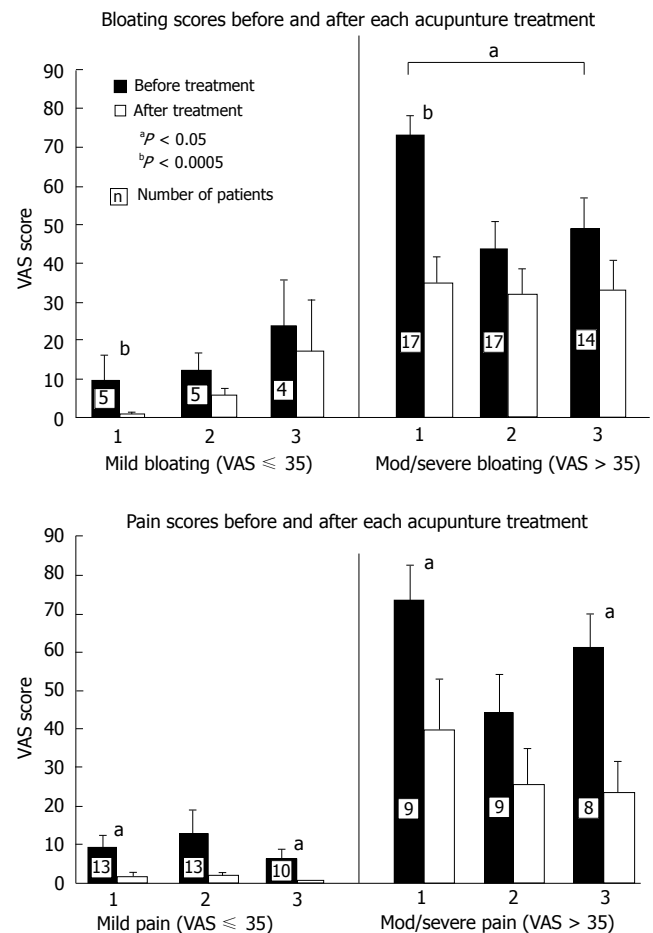

Figure 3 Effect of acupuncture on the symptoms of bloating and pain. Response of patients with a baseline pre-treatment VAS of > 35 (moderate/severe) or ≤ 35 (mild) are shown. The numbers of patients in each group are shown for each treatment session. A significant improvement was seen with acupuncture at the first treatment only for bloating although there was a significant decrease in pre-treatment bloating between the first and third treatment. Acupuncture improved pain with most treatments but the improvement was not sustained.

We chose an arbitrary cut off of an initial VAS score of 35 out of 100 to differentiate patients with mild bloating or pain from those with moderate or severe bloating or pain (Figure 3). The VAS for bloating improved with initial treatment in those with a baseline VAS score of greater than 35. While there was no acute improvement with subsequent treatments, there was a significant improvement in the pre-treatment VAS for bloating over the three treatments (Figure 3). Acupuncture treatment resulted in improvement of the VAS score for pain in both those with severe/moderate pain and mild pain after the acute acupuncture treatment (Figure 3). However, there was no significant improvement in pre-treatment pain between the first and third treatments.

Effect of acupuncture on EGG

Acupuncture resulted in a significant improvement in the percent of power in the normal frequency. At baseline, there was no difference in overall EGG diagnosis between the severe and mild nausea groups. When comparing the power in the different frequency components before and after acupuncture, there was a significant improvement in the power in the 2.5-3.7 cpm between the pre-acupuncture

and post-acupuncture EGG following the first and second treatments in the severe nausea patients. The percent power in this range improved from 23.4 ± 7.5 to 30.8 ± 10 following the first treatment ($P < 0.05$) and from 19.35 ± 10 to 31.2 ± 10.8 with the second treatment ($P < 0.03$). The third treatment increased the percent power in this frequency range from 28.1 ± 11.3 to 37.3 ± 15 (NS). In the mild nausea group, the percent power in this normal frequency range also improved comparing pre- and post-acupuncture treatment but did not reach statistical significance. There was no correlation between the percent power in the 2.5-3.7 cpm range and the symptoms of bloating or pain.

DISCUSSION

We report the results of our experience with the use of acupuncture in patients with functional dyspepsia and nausea. A significant improvement in the level of nausea was seen following acupuncture in patients with none to mild nausea (mild nausea group) and those who complained of moderate to severe nausea (severe nausea group). A significant response was seen in both, suggesting that acupuncture given in the holistic method was effective for both mild to severe nausea. Only one patient in each group was diabetic and most had failed other treatment modalities. A review of Pubmed using the search term "acupuncture and nausea" revealed no prior reports of the use of acupuncture for functional dyspepsia or nausea, other than one study of 15 patients with diabetes and symptoms suggestive of gastric dysmotility^[11]. There was a significant improvement in the VAS score for pain in the mild nausea group and the first treatment only improved bloating in the mild nausea group. This difference in response between complaints of nausea and the other complaints of pain and bloating suggest that the response seen was not purely placebo. This is also the first reported study in which acupuncture was given in a holistic approach for nausea.

Multiple studies report the use of acupuncture in the treatment of chemotherapy induced nausea, post-operative nausea and nausea in pregnancy. Acupuncture is effective in most studies without controls, but its effectiveness is less noticeable if compared to a placebo or sham treatment^[7-9]. Controlled studies of acupuncture in the treatment of chemotherapy induced nausea and vomiting suggest a moderate effect with less acute vomiting episodes and an improvement in the mean worst nausea severity in patients treated by acupressure and concurrent anti-emetics^[8]. Following elective gynecological surgery, a greater percentage of patients treated with acupressure of PC6 point (also known as P6 point) reported no nausea or vomiting compared to sham treated patients^[9]. Several studies suggest effectiveness of acupuncture/acupressure in treating nausea of pregnancy. A randomized controlled trial of acupressure at P6 *vs* placebo showed improvement of symptoms of nausea over time in both groups with nausea symptoms being less severe in the acupressure treated group^[12]. Others report an improvement in duration but not intensity of nausea in pregnancy compared to placebo treatment^[13]. Although well-conducted placebo controlled studies failed to show a difference compared to

sham treatment, acupuncture may prove to be as effective as medications^[13,14].

Comparison between studies is difficult because the criteria for recruitment of subjects and presence of potentially confounding factors, such as depression, are often not discussed. Most of the trials involve acupuncture at one or two acupuncture points only, mainly P6, and are therefore different from the usual clinical holistic approach when using acupuncture to treat a patient. A review of several studies suggests that these studies may be underpowered and a true difference between placebo and sham may be missed^[15].

Our treatment included acupuncture at three points, two related to the GI tract and one at a point recommended for psychological complaints. These points were chosen based on clinical experience and training and our observation that many of the subjects with nausea have psychological distress. We did not formally test for any psychiatric diagnosis, as this was a clinical treatment approach. The results suggest that acupuncture at the points chosen for this study may be effective in treating nausea and less for pain or bloating when patients are grouped by degree of nausea. When the subjects are grouped into moderate/severe or mild bloating or pain by their first pre-treatment VAS score, an improvement in VAS score was seen in bloating and pain. It is unclear if this can be extrapolated to treatment of functional bloating or pain as the degree of symptom was assessed by the pre-treatment VAS score and it is unknown if this correlates with the degree of chronic symptom complaint. There was an increase in the power of gastric myoelectric activity in the normal range, 2.5-3.7 cpm, as assessed by EGG. Whether this is a primary effect of acupuncture or secondary to a central nervous system response cannot be determined in this study. These data support further study using a placebo-controlled approach.

The mechanism of the action of acupuncture is unknown. There are few studies in patients examining the effect in nausea in humans. Hu *et al*^[16] demonstrated that acupressure at the PC6 point decreased symptoms of nausea and decreased the gastric dysrhythmia induced byvection in an optokinetic drum. An increase in the percent of normal frequency in the EGG has been reported in diabetic patients with symptoms suggesting an action of acupuncture on gastric motor function^[17]. In these subjects, the ST36 points and electrical stimulation of needles was used. In humans, acupuncture and manipulation at the PC6 point in healthy volunteers selectively activated regions of the superior frontal gyrus, anterior cingulate gyrus and dorsomedial nucleus of the thalamus as well as areas of the cerebellum^[17]. The subjects did experience more unpleasantness with active acupuncture than with sham treatment which may explain the cerebral cortical findings. The cerebellar findings may be more specific to the action of acupuncture at PC6, as activation of this brain area is probably unrelated to the pain of needle placement.

In animals, acupuncture of the PC6 and ST36 points results in an increased rate of gastric emptying and an increase in the percent of time that the dominant frequency is within the normal range^[18]. Based on the effect of acupuncture on the heart rate variability, it was concluded that this effect was associated with increased vagal activity. A

central effect of electroacupuncture has also been suggested by Tatewaki *et al*^[19] who demonstrated that electroacupuncture at PC6 reduced the number of retching and vomiting episodes following vasopressin injection in dogs, an anti-emetic effect which was abolished by pretreatment with naloxone. Whether this proves to be similar for humans is unknown. The effect of acupuncture is complex in animals, with studies showing that in the rat, electrical stimulation of the ST36 point can induce either excitatory or inhibitory effects on gastric contraction^[20]. Multiple variables are possible to explain differences in animals: the site of stimulation and the intensity and type of stimulation. These effects in animals support a true physiologic response to stimulation of acupuncture points.

In humans, additional variables are present. These include co-morbid conditions, particularly other pain or psychological conditions. The effect may be influenced by belief in the treatment that may contribute to a placebo effect, or may be associated with central nervous system biological responses that may impact on response to acupuncture *via* a non-placebo mechanism. For example, a study by Pariente *et al*^[21] demonstrated that real acupuncture stimulated activity in the brain, as assessed by fMRI, to a greater extent than placebo and that belief in acupuncture affected the response at other areas of the brain. Our clinical study was not designed to test the effect of placebo or belief in the response. However, the differential effect of acupuncture on the symptoms of nausea compared to pain and bloating in the same subjects suggests that the effect on nausea may not be entirely placebo. These results would support the value of a rigorously designed study to examine the effects of acupuncture on the symptoms of patients with functional nausea.

ACKNOWLEDGMENTS

The efforts of Dr. Xu were supported in part by a grant from the American College of Gastroenterology.

COMMENTS

Nausea is a common and debilitating symptom complaint. In many patients the underlying pathophysiology is unknown and likely represents a combination of gastric pathophysiology and psychological issues. There are few medications available, many of which have significant side effects. The traditional approach of acupuncture allows several likely underlying conditions to be treated at the same time.

Research frontiers

While acupuncture has been studied in treatment of nausea of chemotherapy, postoperatively and during pregnancy, no studies have been published on its use in functional nausea. Most published studies also use acupuncture and one site, which is a different approach to the general clinical acupuncture approach. Based on experience and the finding that 14/22 subjects had documented history of depression, a holistic approach which treated multiple clinical conditions was used. The same acupuncture points were used in all patients.

Innovations and breakthroughs

The study showed a significant improvement in degree of nausea in subjects who presented with moderate/severe nausea. The degree of nausea improved over the three treatment visits suggesting a lasting effect. Both bloating and pain were improved by acute treatment with acupuncture, but it is unclear whether the pre-treatment VAS score accurately reflects the severity of chronic complaints by the patients. The main innovation in this study was the holistic approach to treat both gastrointestinal and psychological conditions concurrently.

Applications

Data from this study would support the need for a controlled study to examine the effect of treatment and to control for factors such as concurrent psychological conditions and belief in acupuncture as a treatment.

Terminology

Functional nausea-symptom of nausea in the absence of anatomic or biochemical abnormalities, such as pregnancy, ulcer disease, obstruction *etc.* Dyspepsia-chronic upper abdominal pain. The symptom may be associated with ulcer, but functional dyspepsia is a condition with similar symptoms but in the absence of identifiable pathology in the stomach.

Peer review

It is an interesting paper integrating Traditional Chinese Medicine (acupuncture) with Western Medicine. The author has included a lot of thought provoking factors in this paper, such as the causes of nausea, the Chinese medical theory of imbalance, the conducted placebo controlled studies failed to show a difference compared to sham treatment, activation of brain region related to needle stimulation, and that acupuncture affected the response, and so on.

Abstract

AIM: To define the sub site distribution of upper gastrointestinal cancers in three provinces of Iran.

METHODS: The study was carried out in three provinces in Iran: Ardabil, Golestan, and Tehran. In Ardabil and Golestan, the data was collected from the sole referral center for gastrointestinal cancers and the local cancer registry. For Tehran province, data from two major private hospitals were used. All gastric and esophageal cancer patients diagnosed during the period from September 2000 and April 2002 were included in the study.

RESULTS: A total of 761 patients with upper gastrointestinal cancers were identified, 314 from Ardabil, 261 from Golestan, and 186 from Tehran. In Tehran, the relative rate of cancer increased from the upper esophagus to the distal stomach. In Golestan, the reverse pattern was observed. In Ardabil, the mid portion (distal esophagus and proximal stomach) was involved most frequently.

CONCLUSION: There were considerable variations in the sub site of upper gastrointestinal cancers in the three provinces studied. We cannot provide any explanation for this variation. Further research aimed at explaining the discrepancies in sub site distribution of upper gastrointestinal cancers may help identify important risk factors.

INTRODUCTION

Gastric cancer is the third most common malignancy worldwide^[1]. According to a recent report by Iran's ministry of health, cancer is the third most common cause of mortality, constituting 14% of all deaths in Iran. Upper gastrointestinal (GI) cancers cause 55% of all cancer-related deaths in Iran, with gastric cancer being the most common. Gastric cancer accounts for nearly 50% of all GI cancers^[2]. The incidence of squamous cell carcinoma of the esophagus and cancer of the stomach are very high as compared to their incidence in western countries^[3,4].

A major problem in classifying upper GI cancers is the lack of a universally accepted and clearly reproducible anatomic landmark separating the gastric cardia from the distal esophagus. Even when the landmarks are defined, cancer frequently destroys the anatomy to the extent that the landmarks become unrecognizable. Therefore, misclassification of gastric cancer occurs frequently^[5,6].

Recently, several studies have indicated an increase in the incidence of adenocarcinoma of the distal esophagus compared to cancer of the gastric cardia in western countries. These studies postulate that a significant proportion of adenocarcinomas of the distal esophagus may have been misclassified as cancer of gastric cardia, leading to the apparent increase in cardia cancer^[6,7].

In view of recent recognition of the importance of the sub site involvement in upper GI cancers, we aimed to examine the sub sites of upper GI cancers in Tehran and two provinces in north Iran.

MATERIALS AND METHODS

Subjects

The study was carried out in three provinces: Golestan, Ardabil, and Tehran. Golestan, located in the south-east of the Caspian Sea, is distinguished from other Caspian littoral provinces by an ethnic composition that has 40% Turkmen ethnicity. This province is located on longitude 51°-56° E, and latitude 36°-38° N, with an altitude of 50-500 meters above sea level.

Ardabil is situated near the south-western border of the Caspian Sea on 48°-49° E, 38°-39° N, and altitude of 3010 m. In this mountainous land, 98% of the population is of Azeri ethnicity.

Tehran is the most densely populated province of Iran and is located between the other two provinces (51°-52° E, 35°-36° N, altitude 1100-1700 m). Tehran has a diverse ethnicity which is representative of the entire Iranian population. Western lifestyle is prevalent in Tehran. By contrast; traditional lifestyle is still dominant in Golestan and Ardabil.

Methods

The data was collected from three different sources. The first source was Atrak clinic located in Gonbad, the main Turkmen-resident city of Golestan. Atrak clinic is the sole referral center for gastroesophageal cancers in the region and it also hosts an active cancer surveillance program. We estimate that over 95% of cancers in the region are registered in this center.

The second source was Aras clinic established in Ardabil for the management of gastroesophageal cancers. This clinic is also the sole referral center for such cancers in the Ardabil province and is a host to another active cancer surveillance program registering over 95% of cancers in the region.

The third source was two private general hospitals in Tehran. These two hospitals together are the primary referral centers for nearly 2 million upper socioeconomic class residents of Tehran.

All patients with gastric and esophageal cancer diagnosed during the period from September 2000 to April 2002, were included in the study. An essential inclusion criterion was that the subjects were born in the specified provinces and had been residing there for at least the last 10 years.

Endoscopic and pathologic tests were performed by the same team, according to the study protocol in the regions^[8]. Uniform endoscopic, surgical, and histologic criteria were used to define the tumor sub site.

The sub-site of esophageal tumors was recorded as upper, middle, or lower based on the endoscopy or surgery report. If the location of the main tumor bulk was not obvious, the cancer was recorded as "esophageal".

Non-cardia gastric cancers were defined as those where the center of the tumor was located over 2 cm distal to the gastro-esophageal junction. The gastro-esophageal junction was defined as the most proximal site of the gastric folds. Non-cardia gastric cancers were further divided into antrum, body, and fundus, according to the location of the main bulk of tumor. If the main bulk was

Table 1 The demographic characteristics of patients in the study

	Ardabil	Golestan	Tehran	Total
Patients No.	314	261	186	761
Age, yr (SD)	63 (10.8)	64.4 (11.8)	60.1 (12.7)	62.8 (11.7)
Male/Female	224/90	161/100	123/63	508/253
Urban/Rural residents	97/217	85/176	186/0	368/393

not obvious, the cancer was recorded as "gastric".

Adenocarcinomas of the gastro-esophageal junction area were classified according to the WHO/IARC guidelines as a tumor which crosses the gastro-esophageal junction regardless of the main site of the tumor bulk. Adenocarcinoma of esophagus was located entirely above the gastro-esophageal junction, and adenocarcinoma of gastric cardia was located below the gastro-esophageal junction and was centered within 2 cm from the junction.

Statistical analysis

Statistical analysis was performed using SPSS for windows, version 11.5. Analysis of variance was applied for comparison between normal numeric variables and chi-square for categorical variables.

RESULTS

A total of 761 patients with a confirmed diagnosis of gastric and esophageal cancer were identified. Of the patients included, 41.3% were from Ardabil, 34.3% from Golestan, and 24.4% from Tehran. The demographic characteristics are shown in Table 1.

The mean age of the subjects was 63 years (SD 12, range 18-96). There was no difference with respect to the age of the subjects in the three provinces (ANOVA, $F = 2.7$, $P = 0.64$). The male to female ratio was 2.0; there was no difference in the sex ratios between the three provinces ($\chi^2 = 9.16$, $P = 0.10$).

None of the subjects from Tehran resided in rural regions. This observation is in agreement with the fact that 87% of Tehran's population resides in urban areas. In Ardabil and Golestan provinces this ratio was 43.1%, and 54.5% respectively.

In 54 (7%) cases, the location of the tumor sub site was determined by review of the surgical report. Endoscopic data was used in the remaining subjects. Localization to a specific sub site was not possible in 5.2% of gastric cancers and 2% of esophageal cancers. The details of the anatomic distribution of cancers are shown in Table 2.

DISCUSSION

We observed distinct patterns of sub site involvement of upper GI cancers in the three geographic regions of Ardabil, Gonbad and Tehran. Tehran province had a higher rate of antral cancer compared to esophageal or junctional cancers. By contrast, in Ardabil and Golestan provinces, junctional and esophageal cancers were more common respectively, compared to antral cancers.

Table 2 The distribution of upper gastrointestinal cancers in three provinces of Iran *n* (%)

	Ardabil	Golestan	Tehran	Total
Stomach	178 (56.7)	93 (35.6)	137 (73.7)	408 (53.6)
Antrum	49 (15.6)	18 (6.9)	64 (34.4)	131 (17.2)
Body	47 (15.0)	32 (12.3)	29 (15.6)	108 (14.2)
Fundus	0 (0)	1 (0.4)	3 (1.6)	4 (0.5)
Cardia	82 (26.1)	41 (15.7)	21 (11.3)	144 (18.9)
Unspecified	0 (0)	1 (0.4)	20 (10.8)	21 (2.8)
Junction	24 (7.6)	13 (5.0)	13 (7.0)	50 (6.6)
Esophagus	112 (35.7)	155 (59.4)	36 (19.4)	303 (39.8)

Unspecified	0 (0)	3 (1.1)	3 (1.6)	6 (0.8)
Total	314	261	186	761

SCC: Squamous cell carcinoma; ADC: Adenocarcinoma.

The disparity in the relative frequencies of upper GI cancers in different regions could be explained by variations in the environmental and genetic factors. There are several reports that dietary, behavioral, life style and environmental factors may play a causative role in high-risk populations^[9].

HP infection is a well recognized factor involved in the pathogenesis of gastric cancer^[10,11]. All the three provinces studied have *HP* prevalence rates of nearly 90%^[12,13]. Therefore, in the present study, *HP* infection is unlikely to have accounted for the observed disparity in the sub-site prevalence of cancer.

Gastro-esophageal reflux (GER) is another risk factor associated with lower esophageal and cardia cancers^[14]. The prevalence of GER, defined as having reflux symptoms at least once a week, has been found to be 21.2% in Tehran^[15] and 30% in Golestan^[16,17]. The endoscopic prevalence of erosive GER in Ardabil was 34.7%^[12]. The progressive increase in the prevalence rate of GER from Tehran to Golestan to Ardabil correlates with the increase in the rate of cancer of gastric cardia in these provinces, from 11.3% in Tehran to 15.7% in Golestan and 26.1% in Ardabil (Table 2). It is possible that the prevalence of GER may explain the differences in cancer rate, especially that of cardia cancer. However, other explanations are required to determine the basis of the other cancer variations in the present study.

In the west, adenocarcinoma of the distal stomach (non-cardia cancer) has shown a decreasing incidence over the last 50 years^[9]. By contrast, adenocarcinoma of the cardia of the stomach and the adjacent gastro-esophageal junction has increased over the past 25 years. This increase is occurring at rate that exceeds that of any other cancer^[18-21]. The opposite trends in the incidence may indicate distinct etiologies for the cancer at these two sub sites of the stomach. Moreover, cancers at these sub sites differ with respect to the underlying gastric phenotype. Non-cardia gastric cancers occur in patients with *HP*-induced atrophic gastritis and accompanying hypochlorhydria. These patients usually have elevated

serum gastrin and low serum pepsinogen levels^[10,22]. On the other hand, cancer of the cardia and gastro-esophageal junction occur in subjects with normal acid secretion and is generally not associated with *HP* infection^[10,23].

Although the distinctive patterns observed in gastric cardia and non-cardia cancers have received much attention in explaining the underlying etiology of cancer, junctional cancers have not excited much interest.

One type of cancer pattern is observed in western countries where the incidence of junctional cancer is increasing while that of non-junctional esophageal cancer (SCC) is decreasing. The other pattern is observed in high incidence regions such as Linxian in China and North Iran. In these areas, an increase in junctional cancer is accompanied by high rates of esophageal SCC (not only of the lower esophagus), which is in sharp contrast to the pattern in the west where esophageal SCC is uncommon^[8,12]. As with the case of cardia *vs* non-cardia gastric cancers, it is possible that distinct etiologies are involved in the pathogenesis of junctional cancers such that junctional cancers associated with high rates of esophageal SCC may have different etiologies than those not associated with high rates of high esophageal SCC.

In summary, the present study represents the largest report from Iran identifying sub site involvement of upper GI cancers. We observed distinct pattern of cancers in the three provinces of Tehran, Ardabil, and Golestan. There is no clear explanation for this disparity, although we postulate that different etiologic factors are likely to be involved.

COMMENTS

Background

Gastric cancer is the world's third most common malignancy. Defining the exact origin of gastric cancers is sometimes difficult especially when the gastro-esophageal junction is involved. This difficulty often leads to misclassification of cancers, especially those arising from the gastric cardia and the lower esophagus.

Research frontiers

The incidence of cancer of the gastric cardia and the lower esophagus has shown a rapid change in several areas of the world. This rapid change offers a unique opportunity to study the etiology of these cancers. Many scientists are working on the epidemiologic characteristics of these changes in order to identify the etiologic factors. Thus, the exact determination of the sub site of origin of cancers and their epidemiology is very important.

Innovations and breakthroughs

The decreased prevalence of *H. pylori* infection in some areas is believed to have resulted in a decrease in the incidence of gastric cancers. On the other hand, the increase in prevalence of gastro-esophageal reflux disease is believed to have lead to an increase in lower esophageal cancer.

Applications

We observed different patterns of sub site involvement in different parts of Iran. This difference could indicate different etiologies. Further epidemiologic studies aimed at identifying the probable etiologic factors are required.

Terminology

Gastric cardia is the most proximal 2 cm of stomach located distal to the gastro-esophageal junction.

Peer review

In this prospective study, the authors studied the sub site distribution of upper

gastrointestinal cancers in three provinces of Iran and they found that there are considerable variations in the sub site of upper gastrointestinal cancers in the three provinces studied.

Abstract

AIM: To assess Magnetic resonance colonography with fat enema as a method for detection of colorectal neoplasm.

METHODS: Consecutive twenty-two patients underwent MR colonography with fat enema before colonoscopy. T1-weighted three-dimensional fast spoiled gradient-echo with inversion recovery sequence was acquired with the patient in the supine position before and 75 s after Gadopentetate Dimelumine administration. Where by, pre and post MR coronal images were obtained with a single breath hold for about 20 s to cover the entire colon. The quality of MR colonographs and patients' tolerance to fat contrast medium was investigated. Colorectal neoplasms identified by MR colonography were compared with those identified on colonoscopy and sensitivity of detecting the lesions was calculated accordingly.

RESULTS: MR colonography with fat enema was well tolerated without sedation and analgesia. 120 out of 132 (90.9%) colonic segments were well distended and only 1 (0.8%) colonic segment was poor distension. After contrast enhancement scan, mean contrast-to-noise ratio (CNR) value between the normal colonic wall and lumen was 18.5 ± 2.9 while mean CNR value between colorectal neoplasm and lumen was 20.2 ± 3.1 . By Magnetic resonance colonography, 26 of 35 neoplasms (sensitivity 74.3%) were detected. However, sensitivity of MRC was 95.5% (21 of 22) for neoplasm larger than 10 mm and 55.6% (5 of 9) for 5-10 mm neoplasm.

CONCLUSION: MR colonography with fat enema and T1-weighted three-dimensional fast spoiled gradient-

INTRODUCTION

Conventional colonoscopy, with its ability to visualize the mucosa directly, is the standard procedure for evaluating the colon^[1]. But poor patients' acceptance and high cost limit the utility of the technique for colorectal screening^[2]. This catalyzes the investigation for non-invasive methods to visualize the colon. A great number of studies about computed tomography (CT) colonography have been reported in the United States and Europe^[3-6]. But CT colonography has its intrinsic limitation of exposing patients to ionizing radiation and magnetic resonance colonography (MRC) has theoretic capacity for originating soft-tissue contrast 10-1000 times greater than that on CT^[7,8]. So the future of colorectal screening has shifted to MRC.

To date, most of the MRC research needs administration of a rectal enema containing paramagnetic contrast medium and the acquisition of three-dimensional (3D) gradient-echo pulse sequence^[9-12]. This approach directly demonstrates the lumen but not the bowel wall and requires an effective breath hold of up to 30 s. In addition, enema containing paramagnetic contrast medium needs to be compounded by staff themselves and has high cost. These factors may limit its widespread application in the symptomatic and screening population.

Recently, several MRC studies used air, carbon dioxide and water as intraluminal contrast medium which provides negative contrast within bowel lumen and have a high accuracy in diagnosing colorectal neoplasm^[13-16]. But there are few patients in the MRC studies with air enema and the data required from MRC with water enema could not provide the magnetic resonance virtual endoscopy (MRVE) mode.

In this paper, we evaluated the feasibility of detection of colorectal neoplasm with fat enema in MRC using T1-weighted 3D fast spoiled gradient-echo with inversion recovery sequence.

MATERIALS AND METHODS

Materials

The study was approved by the Ethics Committee of the Fudan University Cancer Hospital. All patients who participated in the study were requested to review and sign a written informed consent. No patient has a history of severe arrhythmia and glaucoma. MRC was performed in consecutive 22 patients (9 men, 13 women) aged 46-86 (mean age 58.6) years. Owing to rectal bleeding, positive fecal occult blood test or altered bowel habits, these patients had been referred for conventional colonoscopy.

Exclusion criteria included contraindications to magnetic resonance imaging, such as the presence of a pacemaker, metallic implants in the central nervous system, as well as claustrophobia.

Methods

Following a standard bowel preparation (oral ingestion of 0.5 L of 20% mannite and 1 L of 5% glucose sodium chloride solution), MRC was performed with a 1.5T MR system (Signa twinspeed with excite; GE medical system, Milwaukee, Wis). No sedative or analgesic agents were administered. An eight-channel body coil was used for signal transmission and reception to permit coverage of the entire colon. To minimize bowel peristalsis, 20 mg of raceanisodamine hydrochloride (No.1 Biochem & Pharm, Shanghai, China) were injected intramuscularly.

Following placement of a rectal enema tube (202-26, Shuangling Medical Device, China), fat contrast medium (Kangque; Atai medical system, Inner Mongolia, China) were gently insufflated into the colon at up to 1 m of hydrostatic pressure with the patient lying in the prone position. Fat insufflation was stopped when the patient began to feel uncomfortable. Reinsufflation was not a routine procedure. The administered volume was 1200-1500 mL.

MRC was performed using T1-weighted three-dimensional fast spoiled gradient-echo with inversion recovery sequence. Coronal images were obtained in the supine position with a single breath hold that lasted about 20 s to cover the entire colon. Imaging parameters included: repetition time 4 ms, echo time 2 ms, flip angle 14°, field of view 38-42 cm, matrix 256 × 256 and section thickness 5 mm. Zero interpolation was applied in coronal plane, rendering an effective section thickness of 2.5 mm and a matrix of 512 × 512. About 68 sections were required. Subsequently, using an automatic injector (Optistar, Mallinckrodt; Tyco, Missouri, USA), gadopentetate dimelumine (Magnevist; Schering, Berlin, Germany) was intravenously administered by the basilic vein. Injection parameters included a dosage of 0.2 mmol/kg and a flow rate of 2.0 mL/s, followed by rapid injection of 10 mL of normal saline at the same rate. After a delay of 75 s, 3D acquisition was repeated with identical imaging parameters with the patient in the supine position.

The 3D data sets were transferred to a post processing

workstation (Advantage 4.0; GE Medical System) and evaluated by two radiologists who were blinded to the colonoscopic data. All the data sets were assessed in the multiplanar reformation and MRVE mode. For the purpose of analysis, the entire colon was divided into six segments: cecum, ascending colon, transverse colon, descending colon, sigmoid colon, and rectum. The colonic distension was classified by scores as follows: score 1 = well distension; score 2 = moderate distension, if it was distended enough to visualize the mucosa and fat interface; and score 3 = poor distension, if it was collapsed. For quantitative assessment, region of interest (ROI) was placed in the lumen, all the colonic neoplasm and the adjacent healthy colonic walls. Image noise, defined as the standard deviation of signal intensities (SI) measured in a ROI placed outside the body, were determined^[14]. On the basis of these measurements, contrast-to-noise ratio (CNR) values were calculated: $CNR = [SI(\text{colonic wall}/\text{colonic lesion}) - SI(\text{lumen})]/\text{noise}$.

Localization and size of all detected colonic neoplasm was recorded. Colorectal neoplasm was classified based on size: (a) < 5 mm; (b) 5-10 mm; (c) > 10 mm in diameter. Extracolonic lesions, including hepatic metastasis, were also recorded as additional findings. Colonoscopic findings were considered as the standard of reference.

RESULTS

All patients completed the MRC without any complication, but 4 patients did not complete colonoscopy for obvious stenosis of colon. Of the 132 colonic segments examined, distensions were documented as follows: 120 (90.9%) had a score of 1, 11 (8.3%) had a score of 2, and 1 (0.8%) had a score of 3. Distinct motion artefacts affecting diagnosis were not found.

Mean CNR values were documented as follows: between the normal colonic wall and lumen, pre contrast enhancement scan 8.4 ± 2.1 , post contrast enhancement scan 18.5 ± 2.9 ; between colorectal neoplasm and lumen, post contrast enhancement scan 20.2 ± 3.1 .

MRC revealed 26 neoplasms including an inflammatory neoplasm (Figure 1), 16 carcinomas (Figure 2) and 9 polyps in 22 patients. The size of five polyps (Figure 3) was between 5 mm and 10 mm and the size of the other 21 neoplasm (Figure 4) was larger than 10 mm in diameter. In patients, there were no false positive MR findings. However, four polyps less than 5 mm, four 5-10 mm polyps and one 20 mm polyp were not found by MRC but by colonoscopy. The 20 mm polyp was a flat polyp. On MRC, neoplasm larger than 10 mm had a higher sensitivity and neoplasm less than 10 mm had a lower sensitivity. The sensitivity for neoplasm of a diameter of < 5 mm, 5-10 mm, and > 10 mm was 0% (0/4), 55.5% (5/9), and 95.5% (21/22). The overall sensitivity was 74.3% (26/35).

MRC permitted assessment of extracolonic organs. Hepatic metastases were discovered in two patients. Hepatic and/or renal cysts were seen in three patients.

DISCUSSION

MRC is a promising, less intrusive imaging technique that can image the entire colon. The potential advantages of

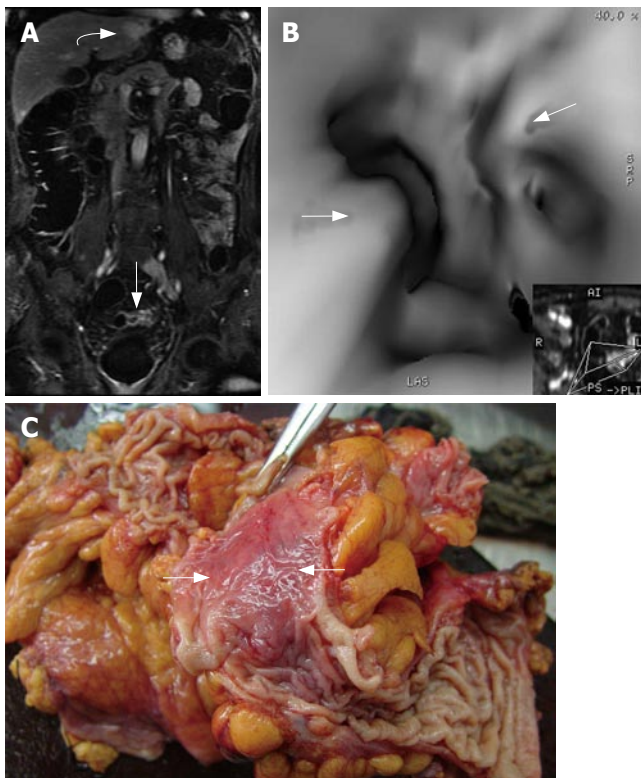

Figure 1 74-year-old man with history of altered bowel habits. **A:** The thickened and increased-contrast-uptake bowel wall of sigmoid colon is seen (white arrow) in the coronal gadolinium enhanced T1-weighted image. In liver, an obvious high-intensity neoplasm is discovered (white curved arrow). Subsequent MR scan confirms the diagnosis of a hepatic angioma; **B:** MR virtual endoscopic rendering confirms stenosis of sigmoid colon (white arrows); **C:** Post-operation pathology confirms the condition of an inflammatory neoplasm. Specimen shows inflammatory mucosa change (white arrows).

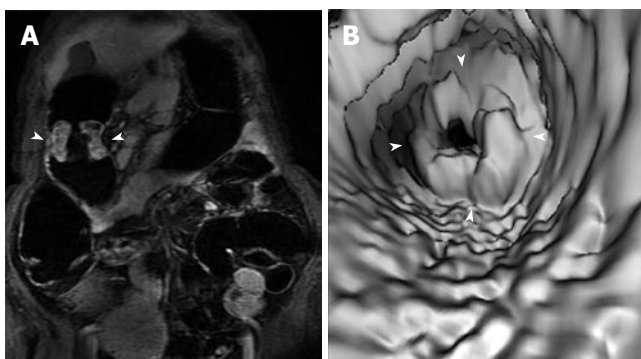

Figure 2 79-year-old woman with history of right upper quadrant pain. **A:** Coronal gadolinium enhanced T1-weighted image shows an obviously enhanced 6 cm carcinoma (white arrowheads) in the transverse colon; **B:** Virtual endoscopic rendering confirms the carcinoma (white arrowheads).

MRC over CT colonography include powerful multi-planar data acquisition, superior contrast resolution and absence of ionizing radiation^[8].

To date, most MRC techniques require a water enema containing paramagnetic contrast material gadolinium at 10 mmol/L concentration^[9,11,12]. Despite Luboldt *et al*^[9] reporting promising results, the gadolinium enema may limit extensive use of MRC. Given 10 mmol/L as optimal concentration of gadolinium, 1.5 L enema would need 30 mL of 0.5 mol/L gadopentetate dimeglumine. The

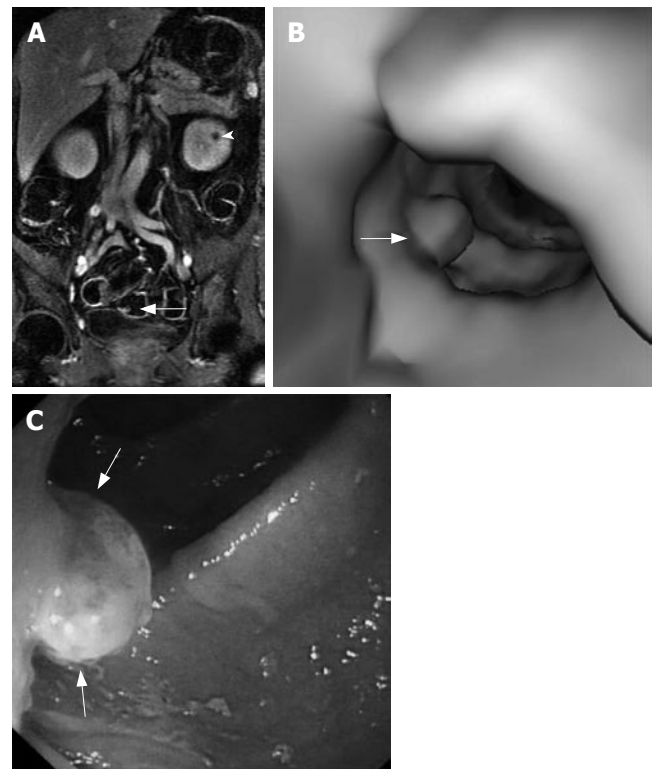

Figure 3 54-year-old man with positive results of FOBT. **A:** Coronal gadolinium enhanced T1-weighted image shows a 7 mm polyp (white arrow) in the sigmoid colon and a cyst (white arrowhead) in the left kidney; **B:** Virtual endoscopic rendering shows a well-defined filling defect (white arrow) in the sigmoid colon; **C:** Endoscopy confirms the polyp (white arrows).

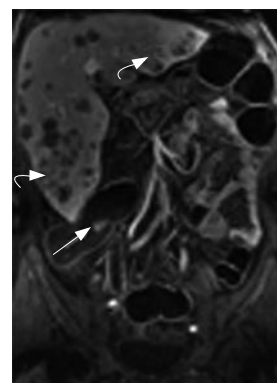

Figure 4 66-year-old man with history of right lower quadrant pain. Coronal gadolinium enhanced T1-weighted image shows a 1.1 cm polyp (white arrow) covered by residual water in the ascending colon and multiple hepatic metastases (white curved arrows).

cost of dilute gadolinium enema would be considered as big setback to MRC. In addition, a 3D gradient echo sequence method that is designed to generate maximal signal from interior of the lumen and depress all the other tissue including the luminal wall was performed. Colorectal neoplasms were identified solely on filling defects in the bright colonic lumen. Hence the differentiation between polyps or carcinomas and residual fecal materials or air bubbles proved to be difficult and sometimes even impossible. So the MRC technique needs to be further amplified by the acquisition of 2D gradient echo sequence datasets. And to compensate for the residual air in the lumen, the MRC requires data acquisition both in the supine and the prone patient positions, which results in the complicated examination and longer examination time.

Recently, MRC has been used with air or carbon

dioxide insufflation and Susceptibility artefacts which thought to be a big obstacle had been minimized by using a half-Fourier single-shot fast spin-echo (SE) sequence or a short echo time (TE) multi-slice half-Fourier acquisition single-shot turbo spin-echo (HASTE) sequence^[14,17,18]. Although air is cheap and abundant, HASTE sequence acquires two or more breath hold acquisitions to cover the entire colon, and can not afford virtual endoscopic observation. In addition, the MRC with air or carbon dioxide insufflation analysis had shortage of clinical cases.

The fat contrast medium that we used in MRC mainly contains salad oil, acacia, menthol and distilled water. It is not absorbed by gastrointestinal tract and has no obvious side-effects. The estimated price of 500 mL of fat contrast medium is \$1.25. It is cheaper than paramagnetic contrasts such as gadolinium and less sensitive to susceptibility artefacts than air. It could provide negative contrast within the bowel lumen with a fat-depression sequence. On T1WI, the intensity of fat contrast medium was slightly lower compared to pericolic fat; however it was too low to visualize air-fat interface when the fat-depression sequence was used. But the intensity of residual water in colon on T1-weighted three-dimensional fast spoiled gradient-echo with inversion recovery sequence was higher than that of fat, which led to distinction of fat-water interface. At the same time, residual water blurred colonic wall and neoplasm, even resulting in neoplasm being missed in diagnosis. But after gadolinium administration, the intensity of colonic wall and neoplasm increased considerably, and the intensity difference between colonic wall, neoplasm and water became distinct. Thus the diagnosis of neoplasm obscured by residual water could be done without a need to change patients' position.

Residual fecal materials can not take up paramagnetic contrast, so it is easy to differentiate between residual fecal materials and neoplasm. This form of direct visualization of the colonic wall and colorectal pathologies stemming from it can reduce the possibility of false positive findings that might mimic neoplasm in MRC with gadolinium solution.

T1-weighted three-dimensional fast spoiled gradient-echo with inversion recovery sequence is a 3D SPGR acquisition that automatically uses a Partial K spatial filling technique and a segmented special technique. Thus T1-weighted three-dimensional fast spoiled gradient-echo with inversion recovery sequence allows shortening of acquisition time, enlargement of spectrum of scan, optimization of fat saturation, and boosting spatial resolution. However, it is essential that the patients maintain the breath-hold position throughout the data acquisition. Minor movements can lead to significant motion artefacts. After being trained, all patients can hold their breath for approximately 25 s. The mean acquisition time of 20 s for covering entire colon can be tolerated by the patients. And thus T1-weighted three-dimensional fast spoiled gradient-echo with inversion recovery sequence is able to accomplish MRC.

In terms of lesion detection, the sensitivity of barium enema in detecting polyps of 10 mm or larger has been reported to be varied between 39% and 56%^[19]. For CT colonography, the sensitivities of detecting > 9 mm, 6-9

mm and < 6 mm polyps were 85%, 70% and 48% and specificities of detecting > 9 mm, 6-9 mm and < 6 mm polyps were 97%, 93% and 92%, respectively^[20]. Using a water enema containing paramagnetic contrast material as a contrast medium, MRC of colorectal neoplasm larger than 10 mm has been reported to have a sensitivity of 93%, specificity of 99%, positive predictive value of 92%, and negative predictive value of 98%^[9]. While using water as a contrast medium, sensitivity was 93% and specificity was 100% for colonic neoplasm exceeding 5 mm^[15]. However, colorectal neoplasm less than 5 mm are often missed in diagnosis^[9,15,16,21]. In contrast, MRC using air has shortcomings of low sensitivity, limited coverage and signal drop-off at the borders of the field of view as well as needs further large-scale studies^[14,22]. Although the number of patients in our study was small, our results suggest that MRC with fat enema could correctly detect neoplasm larger than 10 mm and neoplasm less than 5 mm would most likely were missed.

This technique can be helpful in patients with colonic carcinoma. It can demonstrate the entire colon and exclude synchronous colorectal neoplasm, as well as detect extra-colonic involvement, such as hepatic metastases.

But there are three limitations of this study. The first is the relatively large slice thickness, 5 mm slice thickness. It may be a reason for missing colorectal neoplasm less than 5 mm in diameter. With technical advancements, it is more likely that colorectal neoplasm less than 5 mm would be identified on MRC with fat enema. The second is that patients required a standard bowel preparation, which results in the limitation of patient acceptance for the technique. Recent studies have shown that fecal tagging technique which does not need a cleansed colon can improve patient acceptance, evaluate the majority of colonic segments inaccessible with conventional colonoscopy and depict polyps exceeding 5 mm in size^[23-25]. The third is the small number of the patients and almost all patients with colorectal carcinoma that have large neoplasm. It could be a reason for high sensitivity.

In summary, the present data indicates that MRC with fat enema is a promising alternative to colonoscopy for the detection of colorectal neoplasm larger than 10 mm. Fat contrast medium distention seems to be well tolerated by patients. In the future, advancements in technique together with large-scale clinical cases analysis might improve the sensitivity of the method and hence reliability of its results.

COMMENTS

Background

MR colonography (MRC) is an effective diagnostic tool for colorectal lesions. Currently two techniques were introduced for MRC based on the signal in the colorectal lumen: "bright lumen" and "dark lumen". Usually, bowel cleansing is essential for two techniques. Bright lumen MRC can be performed by fast T1 weighted 3D gradient-echo acquisitions within the conforms of a single breath hold and requires a rectal enema containing paramagnetic contrast. Dark lumen MRC is based on contrast generated between an enhancing colorectal wall and a homogeneously dark colonic lumen. The technique requires intravenous administration of paramagnetic contrast and administration of a water or air enema.

Research frontiers

Recently, several studies laid emphasis on dark lumen MRC. Compared with bright lumen MRC, dark lumen MRC has considerable advantages including reduced examination and post-processing time, good differentiation between polyps and stool, direct analysis of the bowel wall and comprehensive assessment of parenchymal abdominal organs within the field of view. However, bowel cleansing is not well accepted by more than half of patients. To assure high patient acceptance of MRC, fecal tagging has been introduced. It is based on the principle of altering the signal intensity of fecal material by adding contrast compounds to regular meals. For fecal tagging, a paramagnetic MR contrast medium and a highly concentrated barium sulphate containing contrast are administered for bright lumen MRC and dark lumen MRC, respectively.

Innovations and breakthroughs

MRC with fat enema is a technique that could generate a dark colonic lumen with a fat-depression sequence. So it has almost all of the advantages of dark lumen MRC. The data sets required could render an endoluminal virtual view through post-processing. In addition, fat contrast medium is cheaper than paramagnetic contrasts such as gadolinium and less sensitive to susceptibility artefacts than air.

Applications

MRC with fat enema is a promising alternative to colonoscopy for the detection of colorectal neoplasms larger than 10 mm. Moreover, it could depict the infiltration of extra-colonic fat and evaluate other abdominal organs.

Terminology

MRC is based on 3D datasets required from cross sectional images. Compared with a conventional colonography, MRC is not limited to endoscopic viewing. Multiplanar reformation analysis can not only depict the colonic lumen and colonic wall, but also assess parenchymal abdominal organs.

Peer review

The authors assessed Magnetic resonance colonography with fat enema as a method for detection of colorectal neoplasms. Colorectal neoplasms identified by MR colonography were compared with those identified on colonoscopy and sensitivity of detecting the lesions was calculated accordingly. They concluded that MR colonography with fat enema and T1-weighted three-dimensional fast spoiled gradient-echo with inversion recovery sequence is feasible in detecting colorectal neoplasms larger than 10 mm.

Abstract

AIM: To investigate and evaluate the technical feasibility and clinical effectiveness of fluoroscopically guided peroral uncovered expandable metal stent placement to treat gastric outlet and duodenal obstructions.

METHODS: Fifteen consecutive patients underwent peroral placement of Wallstent™ Enteral Endoprosthesis to treat gastric outlet and duodenal obstructions (14 malignant, 1 benign). All procedures were completed under fluoroscopic guidance without endoscopic assistance. Follow-up was completed until the patients died or were lost, and the clinical outcomes were analyzed.

RESULTS: The technique success rate was 100%, and the oral intake was maintained in 12 of 14 patients varying from 7 d to 270 d. Two patients remained unable to resume oral intake, although their stents were proven to be patent with the barium study. One patient with acute necrotizing pancreatitis underwent enteral stenting to treat intestinal obstruction, and nausea and vomiting disappeared. Ten patients died during the follow-up period, and their mean oral intake time was 50 d. No procedure-related complications occurred. Stent migration to the gastric antrum occurred in one patient 1 year after the procedure, a tumor grew at the proximal end of the stent in another patient 38 d post-stent insertion.

CONCLUSION: Fluoroscopically guided peroral metal stent implantation is a safe and effective method to treat malignant gastrointestinal obstructions, and complications can be ignored based on our short-term study. Indications for this procedure should be discreetly considered because a few patients may not benefit from gastrointestinal insertion, but some benign gastrointestinal obstructions can be treated using this procedure.

INTRODUCTION

Gastroduodenal obstruction is usually a preterminal event in patients with advanced malignancies of the stomach, pancreas, and duodenum. Surgery is associated with a high complication rate, and relatively high morbidity and mortality rates, due to poor nutrition and general status or progressing tumor infiltration in these patients^[1-8]. Fluoroscopically guided peroral placement of self-expandable metal stents to treat gastric and duodenal obstructions have been demonstrated to be an effective alternative to surgical bypass with lower morbidity and mortality rates, shorter hospitalization, and a lower cost of the overall treatment^[1,3,5,6,8-10]. Various stents including vascular stents have been used to treat gastric and duodenal obstructions before the design of special duodenal stents^[1]. Here, we report our experience in the treatment of gastric and duodenal obstructions using uncovered Wallstent Enteral Endoprosthesis in recent years. There have been few reports on enteral stenting for benign gastrointestinal obstructions^[2,11,12]. Here, we discuss our methods used for intestinal stenting for one patient with acute necrotizing pancreatitis. We also discuss our opinions on the placement technique, indications, complications, and follow-up results.

MATERIALS AND METHODS

Subjects

A total of 15 consecutive patients underwent fluoroscopically guided peroral placement of Wallstent Enteral Endoprosthesis to treat gastroduodenal obstructions from June 2004 to December 2006, in our department. There were 11 men and 4 women with an average age of 62.4 years (age range, 32-87 years). The underlying causes of

Table 1 Patient information

Case	Sex/age (yr)	Underlying disease	Stent size (diameter × length, mm)	Duration of oral intake after stenting	Follow-up time	Outcome

13	M/48	Pancreatic cancer	20 × 90	0 d	6 d	Dead
14	M/32	Colon cancer	20 × 60	At least 7 d	7 d	
15	M/53	Esophageal cancer	20 × 60	0 d	40 d	Dead

obstructions were pancreatic carcinoma ($n = 6$), ampullary carcinoma ($n = 2$), colon carcinoma ($n = 2$), gastric cancer ($n = 1$), duodenal cancer ($n = 1$), gallbladder cancer ($n = 1$), esophageal carcinoma ($n = 1$), and acute necrotizing pancreatitis ($n = 1$) (Table 1). The diagnosis was established by means of CT ($n = 7$), endoscopy ($n = 2$) or after surgery ($n = 6$). Gastrointestinal obstructions were confirmed by a barium study ($n = 11$), endoscopy ($n = 2$), and CT ($n = 2$). The sites of obstructions were the gastric antrum ($n = 1$), pylorus ($n = 1$), gastrointestinal anastomotic stoma ($n = 1$), duodenum ($n = 12$, including duodenal metastasis from colon carcinoma in two patients). Fourteen patients with malignant obstructions were considered inoperative because of the risk of recurrence after surgery, extensive tumor growth, metastatic cancer or the presence of peritoneal seeding or distant metastasis. They all presented with severe nausea and recurrent vomiting. The patient with acute necrotizing pancreatitis developed severe intestinal obstruction following surgery. Although jejunostomy had been performed, nausea and vomiting persisted in this patient, and duodenal obstruction was finally detected. There was no amelioration in conditions after 4 months, so we decided to insert a metal stent in order to relieve the obstructive syndrome.

Methods

The Wallstent Enteral Endoprosthesis (Boston Scientific Medi-Tech, USA) was used in all patients. The sizes of the stents were as follows: 20 mm (diameter) × 60 mm (length), 22 mm × 60 mm, 20 mm × 90 mm, and 22 mm × 90 mm. Informed consent was obtained from all patients before all procedures. Stent placement procedures were performed according to a standard technique as described in the literature^[1,13,14]. More than 2 d before the stent placement, a barium study was performed to evaluate the site, length, and severity of the obstruction. A nasogastric tube was placed overnight to empty the stomach, and was removed just before the stent insertion. All procedures were performed using a digital angiographic unit with the patient in the supine position. Pharyngeal

anesthesia was usually performed using lidocaine aerosol spray ($n = 13$), but basal anesthesia ($n = 1$) or intravenous general anesthesia ($n = 1$) was also offered depending on the patients' or their relatives' demands. A catheter and guiding wire were inserted perorally into the esophagus under fluoroscopic guidance, and were advanced into the stomach. A small amount of contrast medium was injected through the catheter to identify the gastric outlet or the site of obstruction. The guiding wire and catheter were carefully manipulated to cross the obstruction using a standard catheter technique. After the catheter and guiding wire were located distal to the obstruction and the length of the obstruction was measured, the wire was exchanged for a 260-cm super-stiff guide wire to provide better support for the stent insertion. The Wallstent Enteral Endoprosthesis was then performed under fluoroscopic monitoring to ensure the perfect position of the stent. A stent 4 cm longer than the obstruction length was routinely chosen to completely overlap the affected region. Balloon dilation was performed when the stent assembly could not pass the stenosis. We also performed balloon dilation after stent deployment in 2 of our patients, which was a different procedure from the literature^[1].

The patients were monitored hourly for at least 8 hours after the procedure. If they did not complain of abdominal pain and the hemoglobin level was normal, they were allowed to resume oral intake of liquids. Their diet progressed to soft or solid foods when they could tolerate liquids well. A barium study or endoscopy was performed to verify the position and patency of the stent in cases of bad tolerance of foods or recurrence of nausea and vomiting.

Follow-up was continued by phone calls after patient discharge, and a further barium study or endoscopy was suggested only when symptoms recurred.

RESULTS

Peroral stent deployment was successfully completed under fluoroscopic guidance in our 15 patients, indicating

a technique success rate of 100%. No procedure-related complication occurred. Two stents were needed in 2 patients, and three stents were needed in one due to the lengths of the obstructions. Therefore, a total of 19 stents were used in our 15 patients. The follow-up period was 6 d to 365 d (mean = 80.5 d). Stent migration to the gastric antrum occurred in one patient 1 year after the procedure, and tumor ingrowth at the proximal end of the stent was detected in another patient 38 d after stent insertion. Oral intake was maintained in 12 of 14 patients (85.7%) varying from 7 d to 270 d. Two patients were still unable to resume oral intake, although their stents were proven to be patent with the barium study. The patient with acute necrotizing pancreatitis (benign gastrointestinal obstruction) underwent enteral stenting in order to treat the intestinal obstruction, and nausea and vomiting disappeared after the procedure. Ten patients died during the follow-up period, and their mean oral intake time was 50 d (0 d to 270 d). The time between their death and the stent insertion varied from 6 d to 300 d (mean = 68.5 d).

Percutaneous transhepatic biliary drainage (PTBD) and/or bile duct stent embedding were performed before enteral stenting in 13 patients, 4 of whom further underwent biliary interventional procedures as jaundice recurred after the procedure. The times between the relapse of jaundice and the enteral stent procedure were 7 d, 14 d, 15 d, and 130 d for these 4 patients, respectively. No evidence showed that jaundice recurred because of enteral stenting.

Three of the 14 patients (malignant gastrointestinal obstructions) underwent transcatheter arterial chemotherapy (TAC), and their nutritional status improved after the procedure. Their survival time seemed to be longer than that of the others. However, we did not analyze the influence of TAC considering the small number of patients.

DISCUSSION

A malignant gastrointestinal obstruction is usually a preterminal event in patients with pancreatobiliary, stomach or duodenum malignancies. Such patients often cannot undergo curative resections because of the inoperability or unresectability of their tumors. Palliative surgery is associated with a high complication rate, and relatively high morbidity and mortality rates, due to poor nutritional and general status or progressing tumor infiltration in such patients^[1-8]. Fluoroscopically guided peroral placement of self-expandable metal stents to treat gastric and duodenal obstructions have been demonstrated to be an effective alternative to surgical bypass with lower morbidity and mortality rates, shorter hospitalization, and a lower cost of the overall treatment^[1,3,5,6,8-10]. Various stents including vascular stents have been used for the treatment of gastric and duodenal obstructions before the availability of specially designed duodenal stents^[13]. However, only expandable metal stents have been approved by the Food and Drug Administration for the treatment of gastrointestinal obstructions due to cancer risks^[5,15]. We chose the Wallstent Enteral Endoprosthesis (Boston Scientific Medi-Tech, USA) because of its flexibility and safety. Covered stents have been used to prevent tumor

ingrowth or overgrowth^[4,6,10,12,16-19]. Because we thought the expected survival time of these patients was limited, and tumor ingrowth or overgrowth did not need to be considered^[19], we chose to use uncovered metal stents to obviate migration. In fact, only one case of tumor ingrowth was identified in our 15 patients 38 d after stent insertion, with an ingrowth rate of 6.67%. Additionally, the implantation of peroral uncovered stents is technically easier than covered stents^[1,6,8,16-18].

According to the literature, fluoroscopic stent placement for duodenal obstructions is a technically more difficult procedure than for gastric outlet obstructions, not only because of a loop formation of the stent delivery system in the distended stomach, but also because of the curved configuration of the duodenal C loop^[1,16,17,20]. Endoscopic assistance and gastrostomy have been used after guide wire navigation to advance past the duodenal obstructions^[1,3,16]. In our series, the site of obstruction was located in the duodenum in 12 patients, but no endoscopic assistance or gastrostomy was required in any of them because of the flexibility of the endoprosthesis system and the patience of the interventional radiologists. PTBD before enteral stenting is considered to be necessary by some authors, but there are different opinions^[1,18]. Thirteen patients in our series developed jaundice and underwent PTBD or biliary stenting before gastrointestinal obstructions occurred, and enteral stenting was scheduled. Three of them underwent a second biliary intervention after the enteral stenting, but there was no evidence showing that enteral stenting caused recurrence of jaundice.

TAC was performed in three patients who showed a relatively longer survival time than those who could not tolerate TAC. Considering the small number of patients, we did not analyze the influence of TAC on survival time. Further studies are required to elucidate this relationship.

Nausea and vomiting disappeared or mitigated, and oral intake was maintained in 12 of 14 (85.7%) patients with malignant gastrointestinal obstructions ranging from 7 d to 270 d (mean = 54.7 d). Two patients were still unable to resume oral intake while nausea and vomiting continued after the procedure, although their stents were proven to be patent according to the barium study. A clinical success rate of 85.7% is acceptable because many factors may contribute to the symptoms in malignant gastrointestinal obstructions^[21]. Further studies on the indications of enteral stenting for malignant gastric and duodenal obstructions are warranted.

The patient with acute necrotizing pancreatitis (benign gastrointestinal obstruction) underwent enteral stenting to treat the intestinal obstruction, and nausea and vomiting disappeared after the procedure. His symptoms of nausea and vomiting continued for over 4 mo even after jejunostomy had been performed. Therefore, we decided to perform enteral stenting after discussion with his surgeons. The convention has been that stent placement is rarely indicated for benign gastrointestinal strictures^[12,14], and further studies are needed to elucidate such issues. No procedure-related complication occurred, and only two complications were observed during the follow-up period. Stent migration to the gastric antrum happened in one

patient 1 year after the procedure, and a gastric ulcer with hemorrhage was found around the proximal end of the stent by endoscopy. The patient refused further treatment, and left. Tumor ingrowth at the proximal end of the stent was detected by the barium study in another patient 38 d after stent insertion. Due to progressing tumor infiltration and a hepatic abscess leading to deterioration, a second stent implantation could not be performed, and the patient died 36 d later.

In conclusion, fluoroscopic peroral placement of self-expandable metal stents is a safe and effective treatment for malignant gastric outlet and duodenal obstructions. The technique success rate is high, and complications can be ignored due to the short survival time of the patients in our study. However, indications should be carefully considered before the procedure because a minority of patients may not benefit from gastrointestinal insertion, while some benign gastrointestinal obstructions can also be treated with this procedure.

COMMENTS

Background

Gastroduodenal obstruction is usually a preterminal event in patients with advanced malignant diseases. It can lead to severe malnutrition and even death in the patients. Many studies have reported that enteral stents can be used to achieve gastroduodenal patency, and the effects have been satisfactory.

Research frontiers

Stents have been widely used in interventional procedures. A research hotspot has been to modify the craft of stents to obtain more flexible and durable materials. Various covered stents have been studied to improve effectiveness and reduce adverse reactions.

Innovations and breakthroughs

In previous applications of stents to treat gastroduodenal obstructions, it was found that tumor ingrowth or overgrowth could cause restenosis in uncovered stents, while migration might happen in covered stents. Endoscopic assistance or gastrostomy has been used after guide wire navigation to advance past the duodenal obstructions. Here, we proved that fluoroscopic peroral placement of uncovered metal stents can be safe and effective for most cases.

Applications

The study results suggest that fluoroscopic peroral placement of uncovered metal stents is safe and effective to treat gastroduodenal obstructions. However, indications should be discreetly considered before the procedure.

Peer review

This is a clinical study in which authors investigate and evaluate the technique feasibility and clinical effectiveness of fluoroscopically guided peroral uncovered expandable metal stent placement to treat gastric outlet and duodenal obstructions.

Abstract

AIM: To elucidate the influences of *H pylori* infection on oral iron treatment for iron deficiency anemia (IDA).

METHODS: A total of 86 patients were divided into two groups: group A, receiving ferrous succinate combined with triple therapy for *H pylori* eradication, and group B (control), treated with ferrous succinate only. During treatment of IDA, dynamic changes in hemoglobin (Hb) level, mean corpuscular volume (MCV), mean corpuscular hemoglobin (MCH), serum iron (SI), and serum ferritin (SF) were compared between the groups.

RESULTS: Hb was slightly higher in group A at d 14 after the start of triple therapy for *H pylori* eradication ($P > 0.05$). After the therapy, the increase of Hb in group A became significantly faster than that in group B ($P < 0.05$). At d 56, the mean Hb in group A returned to the normal level, however, in group B, it was lower than that in group A ($P < 0.05$) although it had also increased compared with that before oral iron treatment. The MCV and MCH in group A recovered to the normal level, and were much higher than those in group B ($P < 0.05$) at d 21. In Group B, the MCV and MCH remained at lower than normal levels until d 42 after the start of therapy. And then, they reached a plateau in both groups and the differences disappeared ($P > 0.05$). The SF in group A was higher than that in group B ($P < 0.05$) 28 d after the treatment and its improvement was quicker in group A ($P < 0.05$), and the difference between the two groups was even more significant ($P < 0.01$) at d 56. The SI in group A was higher than that in group B ($P < 0.05$) at d 14 and this persisted until d 56 when the follow-up of this research was finished.

CONCLUSION: Treatment of *H pylori* can enhance the

INTRODUCTION

Spontaneous iron excretion in adults is minimal and iron deficiency anemia (IDA) is generally attributed to abnormal blood loss^[1]. IDA is often caused by gastrointestinal bleeding due to peptic ulcer and chronic gastritis, or in women of reproductive age by increased menstrual flow and the greater requirements of pregnancy. Recently, several seroepidemiological studies have suggested a link between IDA and *H pylori* infection^[2,3]. A high percentage of *H pylori*-positive IDA patients exhibit atrophic changes in the gastric body, and the remainders have chronic superficial gastritis extending to the fundic mucosa.

H pylori infection has even been implicated as a cause of IDA refractory to oral iron treatment^[4,5]. Some patients with refractory IDA have no gastrointestinal symptoms but *H pylori* gastritis, as the only cause of their anemia^[6]. Most dietary iron is in the non-hemic ferric form, and an acidic intragastric pH is needed to reduce it to the ferrous form for absorption. This reaction is promoted by gastric acidity and ascorbic acid (AA), which is thus considered the most potent regulator of iron absorption^[7]. Patients with *H pylori* gastritis showed an increase in intragastric pH with a median of > 3 , a pH that is known to be critical in the process of iron absorption. Moreover, AA is actively secreted from plasma to the gastric juice^[8], but the concentration of AA in the gastric juice of patients with *H pylori* gastritis and IDA is clearly reduced in comparison with both healthy and non-anemic *H pylori*-positive controls^[9-11].

The availability of convenient, non-invasive methods for identifying *H pylori* gastritis has greatly facilitated the recognition of infected patients, resulting in progressive

awareness of its influences and possible role in the causation of IDA^[12]. Therefore, we first examined the prevalence of *H. pylori* infection and serum markers of iron deficiency. We then evaluated the effects of subsequent *H. pylori* eradication on the response to oral iron therapy, which could provide valuable information for further clinical applications.

MATERIALS AND METHODS

Patients

From January 2002 to December 2005, 86 IDA adult patients with *H. pylori*-positive chronic gastritis were enrolled. The participants comprised 36 women and 50 men; median age 53 years, range 18-76. According to Sydney System, the patients were diagnosed as having atrophy, intestinal metaplasia, or antral versus body gastritis, in 34, 27, and 25 cases, respectively. According to the criteria^[13], IDA was defined as hemoglobin (Hb) concentration < 120 g/L in the men and < 110 g/L in the women, serum ferritin (SF) < 12 µg/L, mean corpuscular hemoglobin (MCH) < 27 pg, and mean corpuscular volume (MCV) < 80 fL. Obvious causes of blood loss, such as active gastrointestinal hemorrhage, menometorrhagia or heavy menstrual loss, and any other non-gastrointestinal disease likely to cause IDA, were exclusion criteria for this study. Also excluded from the study protocol were patients with previous gastric surgery, and those who received anti-*H. pylori* treatment or anti-secretory drugs before. Patients who were lactating or pregnant and those with malnutrition or cancer were also excluded.

Methods

The ¹⁴C-urease breath test was performed as described previously^[14]. Briefly, the patients fasted overnight and were then given urea labeled with 37 kBq of ¹⁴C dissolved in water. Breath samples were collected before and 15 min after ingestion, when enzymolysis of labeled urea occurred and ¹⁴CO₂ had been released into the peripheral circulation. The ¹⁴CO₂ in these samples was trapped in 1 mmol/L of hyamine hydroxide in ethanol and transferred into scintillation liquid. The ¹⁴C content was measured in Bq mode using a liquid β-scintillation counter (Headway, China). Samples with < 3.33 Bq were considered negative for *H. pylori*, while samples with > 3.33 Bq were considered positive. The peripheral hemogram including MCH and MCV was measured with a Sysmex automated analyzer (Kobe, Japan). Biochemical assays for serum iron (SI) and Hb were performed as routine. SF was determined with a chemiluminescent immunometric analyzer and kit from Bayer Co. (Germany).

The 86 patients were randomly divided into two groups of equal size. Group A comprised 43 cases and received oral iron treatment combined with triple therapy for *H. pylori* eradication, while the 43 cases in group B received oral iron treatment only as controls. Oral iron treatment comprised ferrous succinate (with an Fe²⁺ content of 34%-36%) 200 mg supplemented with ascorbic acid 100 mg three times daily. Treatment was given until the SF recovered to normal. Triple therapy for *H. pylori* eradication included deuterio-bismuth citrate 240 mg × 2/d, amoxicillin 500 mg × 2/d, and metronidazole 400 mg × 2/d for 2 wk; in all cases, *H. pylori* was eradicated.

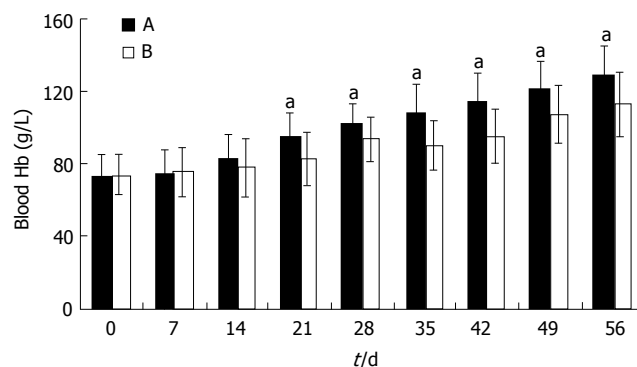

Figure 1 Blood Hb during iron treatment (mean ± SD, *n* = 43; ^a*P* < 0.05 vs group B).

Follow-up

The mean Hb, MCH, and MCV in the peripheral blood of the two groups were recorded before and at d 0, 7, 14, 21, 28, 35, 42, 49, and 56 after iron treatment. SI and SF were compared before and at d 0, 14, 28, 42, and 56.

Statistical analysis

Each assay was made at least three times and data were expressed as the mean ± SD. The differences between groups were determined using *t* test for paired analysis. *P* < 0.05 was considered statistically significant.

RESULTS

Influence of *H. pylori* on Hb

Hb was slightly higher in group A at d 14 after the start of triple therapy for *H. pylori* eradication, but the difference was not significant (*P* > 0.05). After the complete course of triple therapy, the increase of Hb in group A became significantly faster than that in group B (*P* < 0.05). At d 56, the mean Hb in group A returned to the normal level referred to the criteria. In group B, the mean Hb had also increased compared with that before oral iron treatment, but it was still lower than that in group A (*P* < 0.05, Figure 1).

Influence of *H. pylori* on MCV and MCH

Similar to the trend seen for Hb, the increase of MCV and MCH in group A was not significantly greater than that in group B (*P* > 0.05). At d 21, the MCV and MCH in group A became normal, and were much higher than those in group B (*P* < 0.05). In group B, the MCV and MCH remained at lower than normal levels until 42 d after the start of therapy. At this time, the MCV and MCH reached a plateau in both groups and the differences disappeared (*P* > 0.05, Figures 2 and 3).

Influence of *H. pylori* on iron status

There were no significant differences in parameters of iron status between the two groups at the start of treatment (*P* > 0.05), but after 28 d the SF in group A was higher than that in group B (*P* < 0.05). Thereafter, the improvement of SF was much quicker in group A, and at d 56 the difference between the two groups was even more significant (*P* < 0.01). At d 14, the SI in group A was higher than in group B (*P* < 0.05) and this persisted until 56 d after the start of oral iron treatment, when the follow-up of this research was finished (Table 1).

DISCUSSION

H. pylori infection has been reported to have various manifestations in adolescents and adults, including IDA. A double-blind, placebo-controlled trial performed in adolescents with IDA and *H. pylori* infection suggested that SF was significantly lower in the *H. pylori*-infected group and that *H. pylori* eradication led to resolution of iron deficiency^[15,16]. A large serosurvey of *H. pylori* in adults also found that SF was significantly lower in adults positive for *H. pylori* IgG than that in non-infected controls^[17,18]. Based on our medical records of adult patients with chronic gastritis, we found that IDA occurred more frequently in *H. pylori*-positive cases. The coexistence of *H. pylori* gastritis in the 86 IDA adult patients enrolled in this study was determined by endoscopy and the urease breath test. To avoid influences from other clinical factors, the subjects were selected according to strict criteria.

It has recently been shown that extension of gastritis to the corporal mucosa occurs in a higher percentage of patients with *H. pylori* infection and IDA compared with non-anemic *H. pylori*-infected controls^[19]. The blood loss in chronic gastritis, and bleeding from duodenal or gastric ulcers related to *H. pylori* infection, plays an important role in the development of iron deficiency in adults. In response to *H. pylori* chronic gastric inflammation, the epithelial cells in the mucosa are damaged, leading to detachment and apoptosis. In the absence of bleeding lesions, the possible mechanisms by which *H. pylori* is involved in the development of IDA remain unclear. Preliminary studies suggest that the growth and proliferation of *H. pylori* requires iron from the host and that some *H. pylori* strains have a specific ability to interfere with iron metabolism by binding iron to their outer membrane proteins^[20]. However, other studies have demonstrated that neither virulence factors such as Cag-A4 nor mutations in the bacterial genes involved in iron uptake are associated with IDA. Given the high prevalence of *H. pylori* infection, this hypothesis cannot explain why not all patients with *H. pylori* gastritis develop IDA^[21].

Besides the occult gastrointestinal bleeding and competition for dietary iron, *H. pylori* infection can affect the gastric body and initiate the development of atrophic body gastritis that can in turn cause decreased gastric acid secretion and increased intragastric pH^[5,22]. *H. pylori* infection adversely influences the composition of the gastric juice; for example, in terms of its acidity and ascorbate content, both of which are critical for normal iron absorption^[23]. These findings suggest that the physiological mechanisms that are necessary for the absorption of alimentary iron in the duodenal mucosa are impaired in patients with *H. pylori* gastritis and IDA. Thus, we planned to determine the relationship between *H. pylori* infection status and indices of IDA such as the peripheral hemogram and SI. These indices were compared between group A, which received triple therapy combined with oral iron treatment, and group B, which received oral iron treatment only.

Before the completion of *H. pylori* eradication, there were no significant differences in parameters reflecting iron status between the two groups, though the indices were slightly higher in group A. After the 2 wk triple therapy was finished, our observations indicate that the response to oral iron treatment was significantly greater in group A than in group B. Since supplementation with ascorbic acid has been commonly shown to reduce the pH of gastric juice thereby increasing iron absorption, its influence was not evaluated in this research. It has been clearly demonstrated in previous studies that *H. pylori* eradication can reverse the negative effect of *H. pylori* infection on iron absorption and lead to improvement of IDA in case series and in clinical trials in both children and adults^[4,15,16]. Successful *H. pylori* eradication resulted first in a significant post-treatment decrease of serum gastrin and *H. pylori* IgG antibody titers, and then an increase in the peripheral hemogram and SI. This normalization of iron metabolism in *H. pylori*-positive patients increased the MCV and MCH to a plateau similar to the normal level.

The *H. pylori* gastritis is increasingly considered a pos-

sible cause of IDA refractory to oral iron treatment, and eradication of *H pylori* may be followed by an improved response to oral iron in previously refractory IDA patients^[4,5]. In this study, *H pylori* infection slowed the trend of recovery from IDA recovery, but the indices in group B still reached normal levels. In our opinion, *H pylori* eradication is necessary for the resolution of IDA with a lower risk of recurrence. Patients with *H pylori* infection and IDA should receive oral iron and triple therapy simultaneously.

COMMENTS

Background

Iron deficiency anemia (IDA) is often caused by gastrointestinal bleeding due to peptic ulcer and chronic gastritis. *H pylori* infection, which has been proved to play the main role in peptic ulcer and chronic gastritis, has been implicated as a cause of IDA refractory to oral iron treatment. The role of *H pylori* and its eradication in IDA in patients with *H pylori*-positive gastritis has been unclear.

Research frontiers

In some cases, refractory IDA is not sensitive to oral iron treatment, especially in patients with *H pylori*-positive gastritis. It is important to elucidate the relation of IDA to *H pylori* infection and the effect of *H pylori* eradication on the treatment of IDA.

Related publications

Related publications are rare.

Innovations and breakthroughs

This study showed that the *H pylori* infection could slow the trend of recovery from IDA and that *H pylori* eradication is necessary for the resolution of IDA with a lower risk of recurrence. The efficacy of simultaneous oral iron and triple therapy was evaluated.

Applications

For the treatment of IDA in patients with *H pylori*-positive chronic gastritis, it is effective and necessary to eradicate *H pylori* infection, which can lead to satisfactory recovery of this category of IDA.

Terminology

H pylori infection: *H pylori* infection is the main cause of peptic ulcer and chronic gastritis. IDA: iron deficiency anemia is generally attributed to abnormal blood loss, which is often caused by gastrointestinal bleeding due to peptic ulcer and chronic gastritis, or in women of reproductive age by increased menstrual flow and the greater requirements of pregnancy.

Peer review

This is a good review on an interesting topic with an appropriate number of patients. The major point greatly enhances the conclusions.

Received: March 28, 2007 Revised: August 12, 2007

Abstract

AIM: To investigate the potential protective effect of HO-1 on cirrhotic liver cells in rats.

METHODS: Male Wistar rats included in the current study were randomly divided into 5 groups as follows: normal (N) group; liver cirrhotic (LC) group; sham (S) group; I/R group and I/R + hemin group. The model for inducing liver cirrhosis in rats was established according to a previously published protocol. Following this the segmental hepatic ischemia reperfusion operation was carried out. The rats were treated with 30 μ mol/kg hemin (HO-1 inducer, ferric protoporphyrin IX chloride) i.p. or 0.9% NaCl (control) 24 h and 12 h before hepatic ischemia for 30 min or sham laparotomy. Blood was collected for serum enzymatic measurement 6 and 12 h after reperfusion or sham laparotomy. HO-1, NF- κ B and caspase-3 expressions were assessed by immunohistochemical analysis.

RESULTS: The expressions of proteins are inversely correlated to the gray values. HO-1 expression in the I/R + hemin group was increased significantly than I/R group at 6 h and 12 h after hepatic I/R (6 h: 112.0 ± 8.3 vs 125.1 ± 5.7 , $P < 0.01$; 12 h: 120.8 ± 11.0 vs 132.4 ± 6.2 , $P < 0.01$). Hemin improved serum manganese superoxide dismutase (MnSOD) (6 h: 131.3 ± 17.6 vs 107.0 ± 13.9 , $P < 0.01$; 12 h: 141.4 ± 12.5 vs 118.3 ± 10.2 , $P < 0.01$), lessened liver cell injury, decreased caspase-3 (6 h: 166.7 ± 8.1 vs 145.5 ± 14.6 , $P < 0.01$; 12 h: 172.8 ± 3.8 vs 148.0 ± 6.5 , $P < 0.01$) and NF- κ B expression (6 h: 150.2 ± 8.6 vs 139.7 ± 6.0 , $P < 0.01$; 12 h: 151.1 ± 5.9 vs 148.1 ± 5.3 , $P > 0.05$) and serum alanine aminotransferase (ALT) (6 h: 413.3 ± 104.1 vs 626.8 ± 208.2 , $P < 0.01$; 12 h: 322.2 ± 98.8 vs 425.8 ± 115.4 , $P < 0.05$), aspartate aminotransferase (AST) (6 h: 665.2 ± 70.1 vs 864.3 ± 70.4 , $P < 0.01$; 12 h: 531.1 ± 98.6 vs 664.4 ± 115.6 , $P < 0.01$), malondialdehyde

(MDA) levels (6 h: 11.1 ± 2.17 vs 13.5 ± 2.01 , $P < 0.01$; 12 h: 9.36 ± 1.10 vs 10.8 ± 1.62 , $P < 0.05$) in the I/R + hemin group when compared with the I/R group.

CONCLUSION: These results suggest that HO-1 plays an important role in protecting liver cells from hepatic I/R injury in cirrhotic rats by decreasing oxidative stress, apoptosis and inflammation.

INTRODUCTION

Gastrointestinal bleeding, liver surgery and liver transplantation may lead to hepatic ischemia/reperfusion (I/R) injury. Previous studies have shown that pro-inflammatory, apoptosis, oxidative stress and microcirculation dysfunction are strongly correlated with hepatic I/R^[1,2]. Many patients presenting with hepatic ischemia have liver cirrhosis disease. Some studies have shown that cells from a cirrhotic liver are more fragile than the cells from a normal liver. Similarly, other studies have found that the anti-oxidative capacity during stress decreases in patients with hepatic decompensated cirrhosis^[3,4], and further, the tolerance time of ischemia is shorter in cirrhotic rats than in normal rats^[5].

Heme oxygenases (HOs), the rate-limiting enzymes in heme catabolism, catalyzes the oxidative degradation of heme into carbon monoxide (CO), free iron, and biliverdin. Three isoforms of the enzyme have been identified: The inducible HO-1, also known as heat shock protein 32, the constitutive HO-2, and a not fully defined HO-3. It has been found that HO-1 serves as a protective gene by virtue of anti-inflammatory, anti-apoptotic and anti-oxidative actions and improves microcirculation in many cell types^[6,7].

Amersi *et al*^[8] reported that up-regulation of HO-1 protects genetically fat Zucker rat livers from I/R injury.

Some researchers have demonstrated that HO-1 has potent protecting effects against I/R injury in various organ systems^[9,10]. Kaizu *et al.*^[11] reported that prior induction of the HO-1 protein may lead to anti-inflammatory and anti-apoptotic effects on warm renal I/R injury.

HO-1 has been shown to protect liver cells from I/R injury^[12,13]. However, there are few reports regarding the protective effect of HO-1 on liver cells affected by the pathological condition of cirrhosis. Investigations into the role of HO-1 in protecting liver cells from hepatic I/R injury in cirrhotic rats and the mechanism by which it achieves this protective effect have great significance. Thus, the objective of the present study was to investigate whether upregulating HO-1 would result in reduced damage to liver cells as a result of hepatic I/R in a liver cirrhotic rat model. Secondly, we investigated the possible mechanism/s by which HO-1 exerts its protective effect.

MATERIALS AND METHODS

Rat cirrhosis and grouping

Adult male Wistar rats (weighting 200–250 g) were obtained from the experimental Animal Center of Xi'an Jiaotong University. Ethical approval for this study was obtained from the Ethical Committee on Animal Experiments at the Medical College of Xi'an Jiaotong University. The rats had free access to food and water, were kept in an air-conditioned room at 23°C, with a 12 h/12 h light/dark cycle, and were handled humanely. Liver cirrhosis was induced by subcutaneous injection of 400 mL/L CCl₄-olive oil solution twice a week at an initial dose of 5 mL/kg. Subsequent doses were adjusted to body mass changes at a dose of 3 mL/kg for 11 wk as described previously^[14,15]. The rats in the normal group received the same dose of pure olive oil only. The I/R operation was carried out in wk 12.

All 91 animals were randomly divided into 5 groups as follows: Normal (N) group; liver cirrhotic (LC) group; sham (S) group (cirrhotic group operated); I/R group and I/R + hemin group. The last three groups were divided into two subgroups for sampling at different time-points. The I/R + hemin group was administered 30 µmol/kg hemin^[16] (HO-1 inducer, Sigma chemical Co., USA) 24 h and 12 h before hepatic I/R. Hemin solution was prepared under subdued lighting by dissolving the compound in 1 mL of 0.2 mol/L NaOH, adjusting the pH to 7.4 with 1 mol/L HCl, and diluting the solution with 9 g/L NaCl^[11]. The stock concentration was 5 g/L. The solution was kept in the dark and used within 1 h. The concentration dose of hemin used in the present study was selected according to previous reports.

Hepatic I/R model

Rats were anaesthetized using ketamine hydrochloride (800 mg/kg) intraperitoneally. The laparotomy was performed through a midline abdominal incision. Partial (70%) hepatic ischemia of the median and the left lobes was induced by placing non-crushing microvascular clamps around the appropriate branches of the portal vein and hepatic artery for 30 min. The portal branches to the right

and caudate lobes were left open to prevent mesenteric venous congestion^[17]. Reperfusion was initiated by removal of the clamps. Hepatic I/R injury was induced by 30 min of ischemia followed by 6 h and 12 h of reperfusion. After 30 min of ischemia, the clamps were removed allowing the liver to reperfuse, and the wound was closed with 3-0 silk. Sham operated rats underwent isolation of the portal vein and hepatic artery without occlusions. At the indicated time after the start of reperfusion, rats were anesthetized and sacrificed. Blood was collected from the portal vein and liver samples were taken from the left lobe. The blood samples were centrifuged to obtain the serum for the biochemical analyses, and the left lobe liver tissue samples (0.8 cm × 0.4 cm × 0.4 cm) were fixed in 40 g/L paraformaldehyde for immunohistochemical analysis.

Immunohistochemical analysis of HO-1, NF-κB and caspase-3 expression

Serial 5 µmol/L sections were prepared after the samples had been dehydrated in graded ethanol solutions, cleared in chloroform and embedded in paraffin. Immunohistochemical staining was performed to detect expression of NF-κB (diluted 1:300; Boster, China), caspase-3 (diluted 1:100; Boster, China), and HO-1 (diluted 1:100; Boster, China) using the MaxVision™ kit-5004 (Maxin Biotechnology Co., Fujian, China). Sections were boiled in 0.01 mol/L citrate buffer (pH 6.0) to retrieve the antigens. Endogenous peroxidases were inactivated by immersing the sections in 30 mL/L hydrogen peroxide for 20 min. The sections were then incubated overnight at 4°C with the relevant primary rabbit anti-rat polyclonal antibodies. After washing, the sections were overlaid with peroxidase-conjugated goat anti-rabbit secondary antibodies (MaxVision™ kit-5004, Maxin Biotechnology Co., Fujian, China) for 15 min. The chromogenic reaction was developed with diaminobenzidine. Some sections were counterstained with hematoxylin. The immunohistochemical signal was analyzed using an image acquiring and analysis system (QWin500CW, Leica, Germany). At least four random fields of each section were examined at a magnification of × 400, and analyzed using a computer image analysis system (Image-Pro Plus, Media Cybernetics, Silver Spring, MD). The expressions of proteins are inversely correlated to the gray values.

Serum enzyme analysis

For the assessment of hepatic injury, serum levels of aspartate transaminase (AST) and alanine transaminase (ALT) activities were measured using an automatic biochemical analyzer (Vitros 250, Johnson & Johnson Co., USA). Serum Malondialdehyde (MDA) and superoxide dismutase (SOD) activity were measured with a commercially available kit (Nanjing Jiancheng Bioengineering Institute, China, NJBI). Total SOD and Cu/Zn-SOD activities were measured. Mn-SOD activity was calculated as the difference between total SOD and Cu/Zn-SOD activity.

Statistical analysis

All results were expressed as mean ± SD. The statistical analysis was performed using a one-way analysis of variance. The results were considered statistically significant if $P < 0.05$.

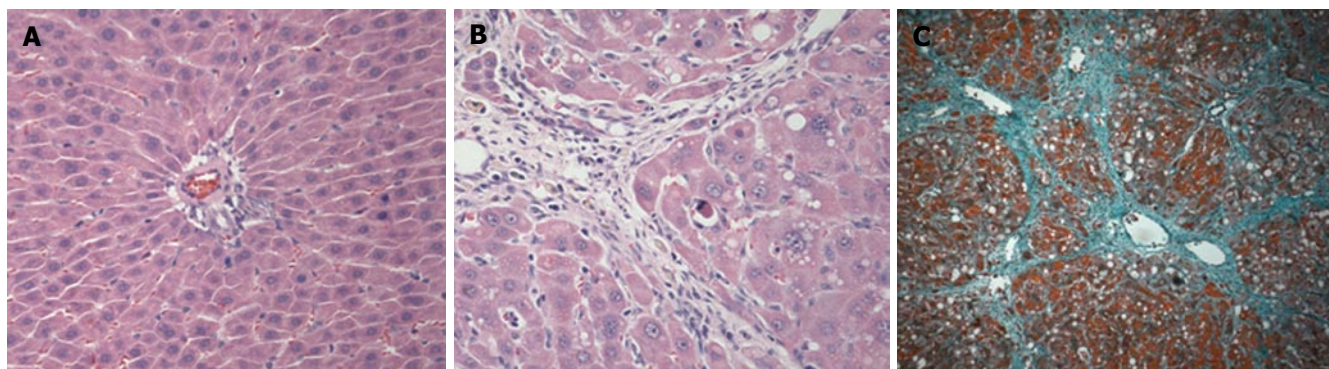

Figure 1 A: No evidence of collagen deposition was observed in the liver of the normal group (HE, × 400); B: The collagens deposited in portal areas of liver cirrhosis group (HE, × 400); C: Severe fibrosis with regenerating nodules was observed in liver cirrhosis group (Masson, × 100).

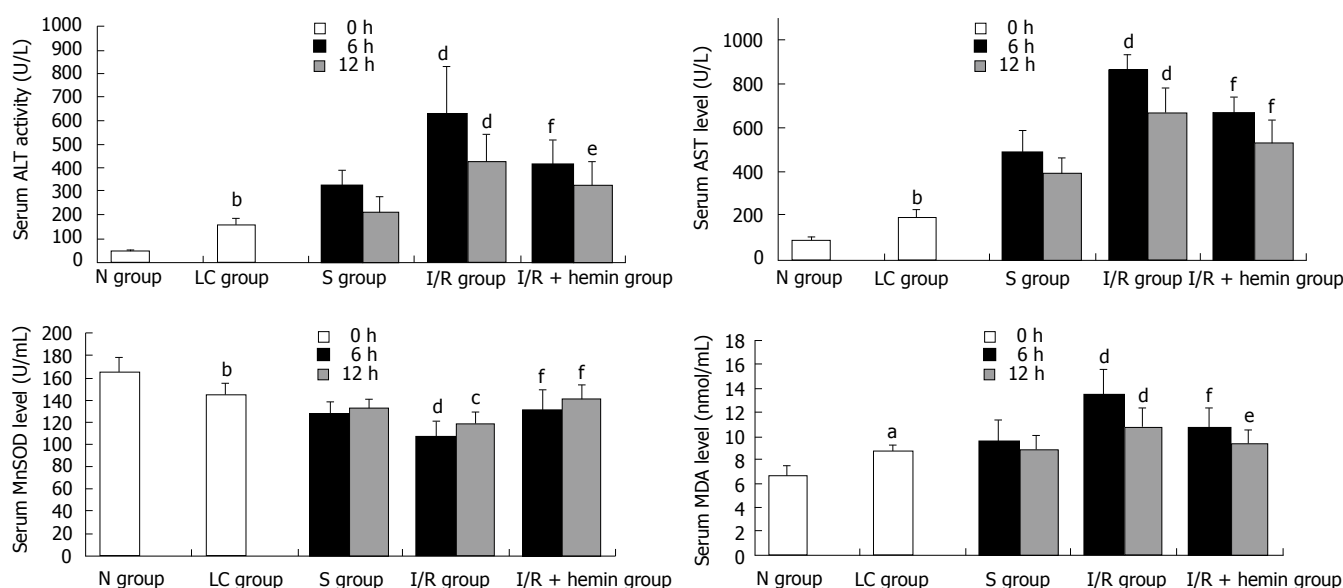

Figure 2 Serum ALT, AST activity, MnSOD and MDA levels of each group. N group: normal group; LC group: liver cirrhosis group; S group: sham group; I/R group: the rats underwent hepatic ischemia/reperfusion operation; I/R + hemin group: the rats were administered with 30 μ mol/kg hemin before hepatic ischemia/reperfusion operation. 6 h: 6 h after reperfusion. 12 h: 12 h after reperfusion. After hepatic ischemia/reperfusion, the ALT, AST and MDA levels were increased and the levels were all decreased after hemin administration. The level of MnSOD was low in I/R group, and after giving hemin, its level in I/R + hemin group was higher than I/R group. Values are mean \pm SD. ^b $P < 0.01$ vs N group, ^c $P < 0.05$ vs N group, ^d $P < 0.01$ vs S group, ^e $P < 0.05$ vs S group, ^f $P < 0.01$ vs I/R group, ^g $P < 0.05$ vs I/R group.

Table 1 Gray values of caspase-3, NF- κ B and HO-1 of rats (mean \pm SD)

Group	n	NF- κ B	Caspase-3	HO-1

^b $P < 0.01$ vs N group; ^c $P > 0.05$ vs I/R group; ^d $P < 0.01$ vs I/R group.

RESULTS

Changes in the CCl₄ induced liver cirrhotic rats

To confirm the occurrence of liver cirrhosis, the liver tissues were examined following hematoxylin and eosin

staining (HE staining) and Masson's trichrome staining (Figure 1). Biochemical analyses of the serum and immunohistochemical analysis of the liver samples were also performed. The levels of serum ALT and AST activities are markers for hepatic injury, MDA and MnSOD reflect the anti-oxidative ability. Following the administration of CCl₄ for 11 wk, the activities of ALT, AST and MDA in the LC group were increased when compared with those observed in the N group. The MnSOD in the LC group was decreased when compared with the N group (Figure 2).

Hemin induced HO-1 high expression in liver tissue

Animals in the I/R + Hemin group were given hemin prior to the induction of I/R. We examined the changes in HO-1 expression in liver tissues after I/R using the gray value method. HO-1 expression in the I/R + hemin group was increased significantly, especially 6 h after reperfusion (Table 1 and Figure 3). Hepatic I/R resulted in an increase in serum ALT, AST and MDA levels in the I/R group

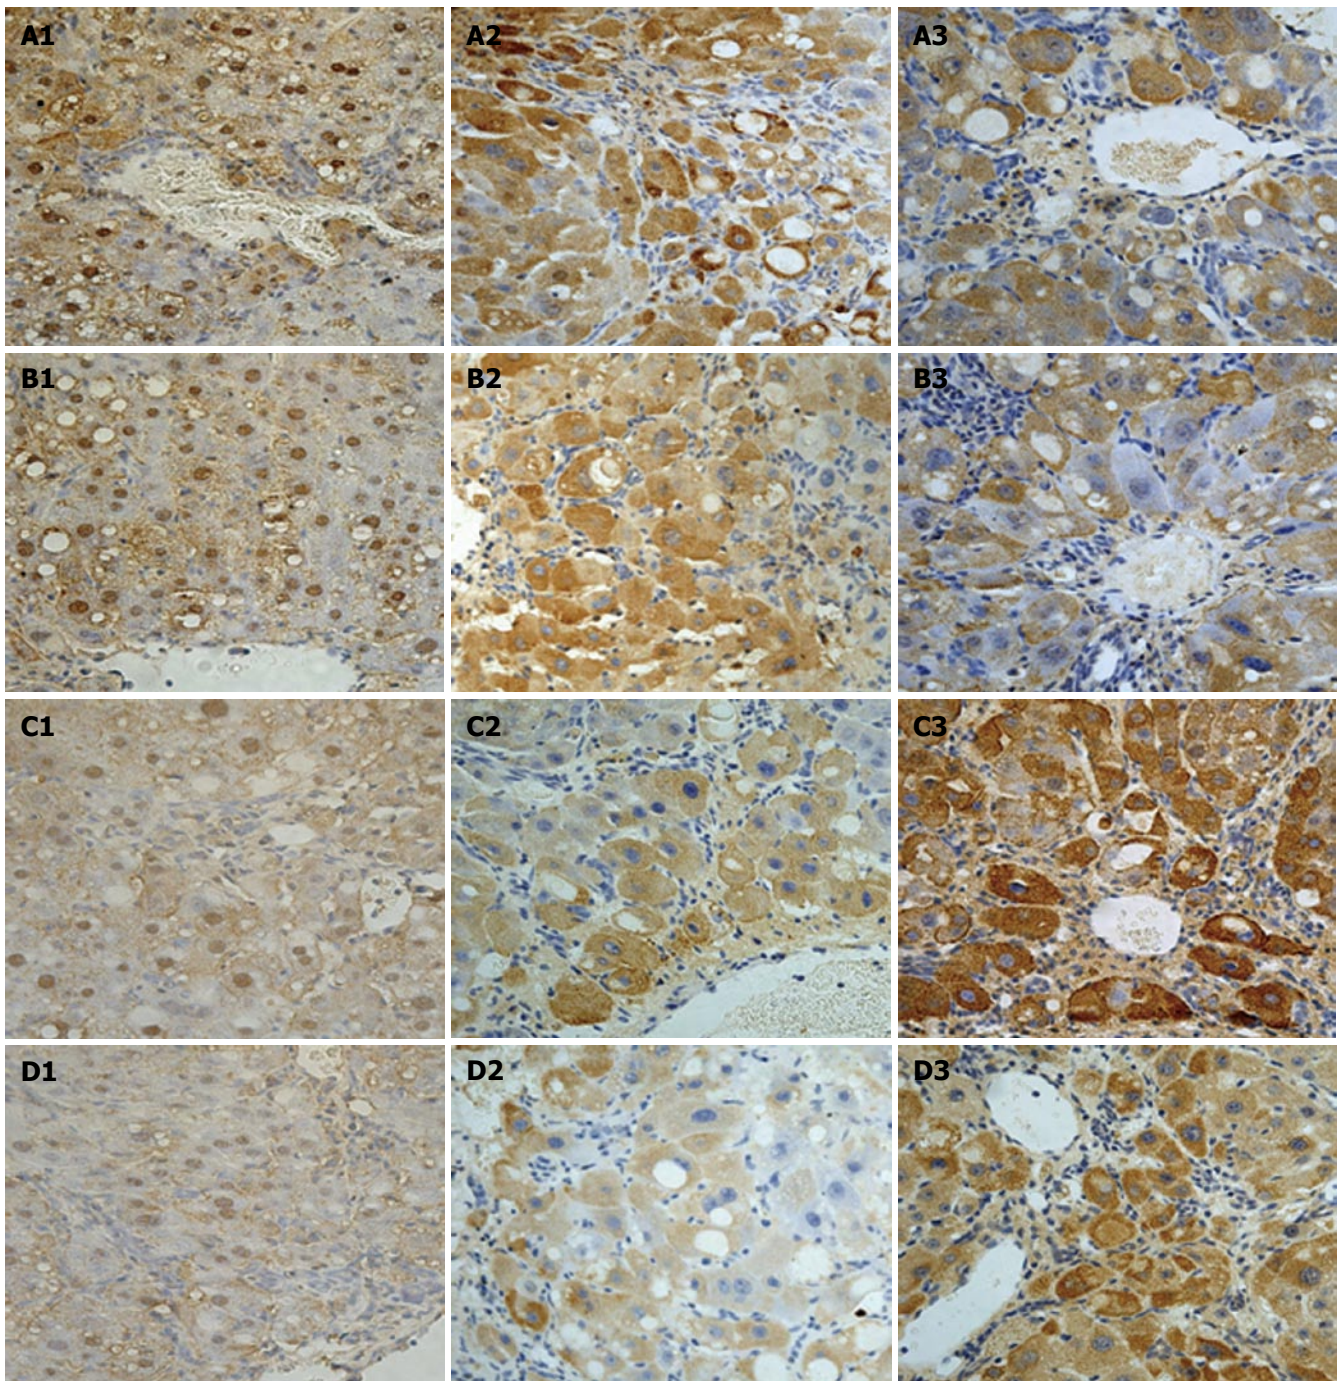

Figure 3 Immunohistochemistry of NF- κ B, caspase-3 and HO-1 at 6 h and 12 h after hepatic ischemia/reperfusion in cirrhotic rats. **A:** I/R group, 6 h after reperfusion; **B:** I/R group, 12 h after reperfusion; **C:** I/R + hemin group, 6 h after reperfusion; **D:** I/R + hemin group, 12 h after reperfusion; 1: NF- κ B: Most positive NF- κ B expression was in the nuclear of liver cells. After giving hemin to induce HO-1, the positive expression of NF- κ B in I/R + hemin group was decreased compared with I/R group at 6 h after reperfusion ($P < 0.01$). There is no difference between I/R group and I/R + hemin group at 12 h after reperfusion ($P > 0.05$) (Figure A1-D1); 2: Caspase-3: The positive caspase-3 expression was in the cytoplasm of hepatic cells. After hemin administration, the caspase-3 expression was decreased at 6 h and 12 h after reperfusion when compared with I/R group ($P < 0.01$) (Figure A2-D2); 3: HO-1: The positive HO-1 expression was in the plasma of hepatic cells. After hepatic ischemia/reperfusion, the expression of HO-1 was increased in I/R group, and through giving hemin, the expression of HO-1 was higher than I/R group at 6 h and 12 h after reperfusion ($P < 0.01$) (Figure A3-D3).

compared with the S group, especially at 6 h after reperfusion. In contrast, the I/R + hemin group had significantly lower serum ALT, AST and MDA levels at both time-points relative to the I/R group (Figure 2). MnSOD levels were markedly decreased in the I/R group at 6 h and 12 h after hepatic I/R compared with that of the S group. However, hemin administration increased MnSOD levels in the I/R+hemin group at both time-points (Figure 2).

Caspase-3 and NF- κ B immunohistochemical staining

To examine the protective effects of elevated HO-1 expression on apoptosis and inflammation in the liver following hepatic I/R, caspase-3 and NF- κ B expression in the liver were assessed by immunohistochemical staining. Most positive NF- κ B expression was observed in the nucleus of liver cells, while caspase-3 expression was localized in the cytoplasm of hepatocytes. After hepatic I/R, the expres-

sion of NF- κ B and caspase-3 was significantly stronger with a lower gray value in the I/R group compared with the S group ($P < 0.01$). After giving hemin to upregulate HO-1, caspase-3 expression in the I/R + hemin group was decreased 6 h and 12 h after reperfusion and the gray values were increased ($P < 0.01$). Following upregulation of HO-1, the expression of NF- κ B in the I/R + hemin group was lower 6 h after reperfusion than in the I/R group ($P < 0.01$), but there was no difference 12 h after reperfusion between the two groups ($P > 0.05$, Figure 3).

DISCUSSION

In this study, we have shown that HO-1 upregulation following hemin administration protects cirrhotic rats from hepatic I/R injury. Hepatic injury induced by I/R has been proposed as a key clinical problem associated with liver upper gastrointestinal bleeding, liver surgery or liver transplantation. There are two distinct phases of liver injury after I/R. The initial phase (< 2 h after reperfusion) is characterized by oxidant stress, where production and release of reactive oxygen species (ROS) appears to directly result in hepatocellular injury. The late phase of liver injury, from 6 h to 48 h after hepatic reperfusion, is an inflammatory disorder mediated by recruited neutrophils^[18-20]. Our results regarding the mechanism leading to I/R injury will undoubtedly provide important clues for developing an approach to decreasing liver cell damage caused by I/R. Protection against hepatic I/R injury is, clinically, one of the most critical problems in liver cirrhotic patients.

Recently, it was demonstrated that HO-1 upregulation ameliorates hepatic I/R injury^[12,13]. In addition, Coito *et al*^[21] reported that HO-1 gene transfer inhibits inducible nitric oxide synthase expression and protects genetically fat Zucker rat livers from I/R injury. In the present study, our data support the hypothesis that HO-1 provides a protective effect against I/R injury in cirrhotic rats via anti-oxidative, anti-apoptotic and anti-inflammatory actions. Our results also highlight that administration of hemin may be an important new therapy for the treatment of hepatic I/R. Although these mechanisms are complicated and largely unknown, our findings suggest the possibility that upregulation of HO-1 may reduce the potential risk in hepatocellular I/R complicated with liver cirrhosis.

HO-1 is one of the most critical of the cytoprotective mechanisms activated during cellular stress, exerting anti-oxidative and anti-inflammatory functions, modulating the cell cycle, and maintaining the microcirculation. The up-regulation of HO-1 is thought to be a protective response from cellular stress following ischemia, inflammation and radiation. Given the multi-factorial cytoprotective properties of HO-1, it is used as a novel strategy to prevent I/R injury^[22]. In line with this, we have found that hemin administration significantly protects the cells in the hepatic I/R as compared with control treatment.

The role of SOD in hepatic I/R has received more attention. There are three isoforms of SOD. The Cu/Zn-SOD is located in the cytosol, the MnSOD is primarily a mitochondrial enzyme, and extracellular SOD is usually found on the outside of the plasma membrane interacting with matrix component. Marczin *et al*^[23] reported that, by

utilizing adenoviral gene transfer, overexpression of Mn-SOD may reduce the extent of *in vivo* regional I/R injury in the rat heart. Similarly, in the current study we found that MnSOD levels were increased, and the injury due to I/R was lessened, after giving hemin to induce HO-1 expression. Based on this, we suggest that HO-1 has an anti-oxidant function during hepatic I/R.

MDA is the main product of lipid peroxidation, and is reactive with thiobarbituric acid (TBA). MDA concentration is therefore generally presented as the total level of lipid peroxidation products^[24]. As the end product of lipid peroxidation MDA can produce ozone, which reacts rapidly with cellular structures, generates hydrogen peroxide and other active oxygen species and causes peroxidation and denaturation of membranes^[25]. Our findings suggest that HO-1, induced by hemin administration, decreases the serum MDA level after hepatic I/R. Therefore, we speculate that high HO-1 expression induced by hemin may decrease the lipid peroxidation and play an anti-oxidative role in hepatic I/R.

Apoptosis plays a vital role in lethal hepatic I/R injury as indicated by many studies in various animal models^[2,26]. There are two major pathways of apoptosis, and caspase-3 is the final executor of apoptosis^[27]. Although the TUNEL assay is a very sensitive and widely used method^[28,29], data is also available suggesting that caspase-3 immunohistochemistry is an easy, sensitive, and reliable method for detecting and qualifying apoptosis in tissue sections^[30]. In the present study, to determine the effect of HO-1 on apoptosis, we carried out an immunohistochemical analysis of caspase-3. The expression of caspase-3 was elevated following hepatic I/R. However, caspase-3 expression was lower in the I/R + hemin group than in the I/R group. These data suggest that the increase in HO-1 following treatment with hemin results in a decrease in apoptosis during hepatic I/R in liver cirrhotic rats. Our findings in this regard are consistent with other studies^[31].

NF- κ B is activated during I/R of the liver, and plays an important and complex role in the gene expression of proinflammatory cytokines (TNF- α and IL-1), chemokines and adhesion molecules (ICAM-1 and VCAM-1), which will lead to the tissue injury^[32]. In the present study, the level of NF- κ B at 6 h after reperfusion was decreased in the I/R + hemin group compared with the I/R group. However, there was no statistical difference 12 h after reperfusion between the I/R group and the I/R + hemin group. We believe that high levels of HO-1 expression may decrease NF- κ B expression to lessen the inflammatory reaction at 6 h after reperfusion.

Hepatic I/R injury may cause more severe tissue damage in cirrhotic liver than in normal livers. Our data show that HO-1 overexpression, induced by hemin, plays a crucial role in protecting liver cells from hepatic I/R injury in cirrhotic rats. Our results also raise the possibility of a new treatment for reducing hepatic I/R injury in the pathological condition of cirrhosis.

COMMENTS

Background

Gastrointestinal bleeding, liver surgery and liver transplantation may lead to

hepatic ischemia/reperfusion (I/R) injury. Previous studies have shown that pro-inflammatory, apoptosis, oxidative stress and microcirculation dysfunction are strongly correlated with hepatic I/R. Many patients presenting with hepatic ischemia have liver cirrhosis disease. Some studies have shown that cells from a cirrhotic liver are more fragile than the cells from a normal liver. Similarly, other studies have found that the anti-oxidative capacity during stress decreases in patients with hepatic decompensated cirrhosis, and further, the tolerance time of ischemia is shorter in cirrhotic rats than in normal rats.

Research frontiers

Three isoforms of the Heme oxygenases (HOs) have been identified: The inducible HO-1, also known as heat shock protein 32, the constitutive HO-2, and a not fully defined HO-3. It has been found that HO-1 serves as a protective gene by virtue of anti-inflammatory, anti-apoptotic and anti-oxidative actions and improves microcirculation in many cell types.

Related publications

Researchers have demonstrated that HO-1 has potent protecting effects against I/R injury in various organ systems. It has also been reported that upregulation of HO-1 protects genetically fat Zucker rat livers from I/R injury and that prior induction of the HO-1 protein may lead to anti-inflammatory and anti-apoptotic effects on warm renal I/R injury. HO-1 has been shown to protect liver cells from I/R injury. Investigations into the role of HO-1 in protecting liver cells from hepatic I/R injury in cirrhotic rats and the mechanism by which it achieves this protective effect have great significance.

Innovations and breakthroughs

There are few reports regarding the protective effect of HO-1 on liver cells affected by the pathological condition of cirrhosis. The objective of the present study was to investigate whether upregulation of HO-1 would lessen the liver cell damage caused by hepatic I/R in a liver cirrhotic rat model and, secondly, to study the possible mechanisms for its protective effect. Our data support the hypothesis that HO-1 has a protective effect from I/R injury in cirrhotic rats. Our data further suggest that this effect is mediated by the anti-oxidative, anti-apoptotic and anti-inflammatory actions of HO-1, and highlight that administration of hemin may be an important new therapy method in hepatic I/R. Although many of these mechanisms are still unknown, our findings suggest the possibility that upregulation of HO-1 may reduce the potential risk in hepatocellular I/R complicated with liver cirrhosis.

Applications

Hepatic I/R injury may cause more severe tissue damage in a cirrhotic liver than in a normal liver. Our data have shown that HO-1 over-expression, induced by hemin, plays a crucial role in protecting liver cells from hepatic I/R injury in cirrhotic rats, and raises the possibility of a new treatment in hepatic I/R injury in the pathological condition of cirrhosis.

Terminology

Heme oxygenases (HOs): Heme oxygenases (HOs) are the rate-limiting enzymes in heme catabolism. HOs catalyse the oxidative degradation of heme into carbon monoxide (CO), free iron, and biliverdin. Three isoforms of the enzyme have been identified: HO-1, HO-2 and HO-3. Superoxide dismutase (SOD): Superoxide dismutase (SOD) is a ubiquitous enzyme with an essential function in protecting cells against oxidative stress by catalytic removal of superoxide radicals and conversion to H₂O₂ by the dismutation reaction.

Peer review

In this manuscript, Hui Xu *et al* have analyzed the beneficial effects of hemin-dependent induction of hepatic heme-oxygenase-1 expression in cirrhotic livers after ischemia/reperfusion which is an interesting paper.

Abstract

Small bowel obstructions (SBOs) are primarily caused by adhesions, hernias, neoplasms, or inflammatory strictures. Intraluminal strictures are an uncommon cause of SBO. This report describes our findings in a unique case of sequential, stenotic intraluminal strictures of the small intestine, discusses the differential diagnosis of intraluminal intestinal strictures, and reviews the literature regarding intraluminal pathology.

INTRODUCTION

Small bowel obstructions (SBOs) are most commonly caused by adhesions, hernias, neoplasms, or inflammatory strictures^[1], with most caused by extraluminal adhesions due to postoperative inflammatory changes^[2]. Intraluminal strictures are less common and are primarily caused by congenital defects, inflammation, ischemia, neoplasms, or radiation. We present an unusual case of sequential, stenotic strictures of the small intestine with no clearly defined etiology.

CASE REPORT

A 43-year-old Hispanic female presented to a surgical service for evaluation of SBO. Four days prior to presentation she developed nausea and mid-epigastric, cramping abdominal pain. She had not been able to tolerate liquids or solids for 2 d.

She had a 22-year history of chronic abdominal pain. An outpatient work-up involving an abdominal computed tomography (CT) scan the previous year revealed dilated loops of small intestine, with areas of diffuse thickening of the intestinal wall, but no evidence of obstruction. An esophagogastroduodenoscopy revealed gastritis but no major pathology. Stool cultures sent for *Clostridium difficile* toxin, ova, and parasites (Iodine and trichrome staining for worms (i.e., *Ascaris*, *Necator*, *Enterobius*, *Taenia*), amoeba (i.e., *Entamoeba*), flagellates (i.e., *Giardia*), cryptosporidium, and others) were negative. Her surgical history included bilateral tubal ligation, open appendectomy, and laparoscopic cholecystectomy. She had no personal or family history of trauma, cancer, or inflammatory bowel disease.

The patient was awake and alert with stable vital signs. Her abdomen was soft and mildly distended, with mid-epigastric tenderness upon palpation. She had no peritoneal signs. Her laboratory test values were all within normal limits.

A CT scan of the abdomen revealed a proximal SBO with dilated loops of small intestine and a transition point in the mid jejunum. Distal to the transition point, the intestine was thickened for several centimeters (Figure 1). Distal to the thickened portion, the intestine was normal in appearance. The terminal ileum and colon were normal, and no retroperitoneal lymphadenopathy was present.

On exploratory laparotomy, we found a thickened, dilated proximal small intestine with a clear transition point to the decompressed distal jejunum. The intestine was pink and viable. No extraluminal bands, adhesions or hernias were present. The duodenum and ligament of trietz appeared normal. Distal to the duodenum, the jejunum became thickened and dilated. We found deposits of mesenteric fat on the serosal edge of the intestine every 5-10 cm. Associated with these areas of mesenteric fat were palpable intraluminal stenoses. The rest of the intestine was normal in appearance. There were no intestinal or mesenteric masses. Strong pulses were palpated in all of the mesenteric vessels. We resected the thickened portion of jejunum and mesentery, and performed a jejunojejunum anastomosis.

Figure 1 CT scan of the abdomen. A CT scan of the abdomen revealed an SBO with dilation of small-intestinal loops, and a transition point in the mid-jejunum. A distended small was observed anteriorly of the air fluid level, and distal to this, a dilated loop and cross section was filled with feces, the so-called small bowel feces sign, which is indicative of SBO. Distal to the obstruction, there was a clear transition point in the mid-jejunum.

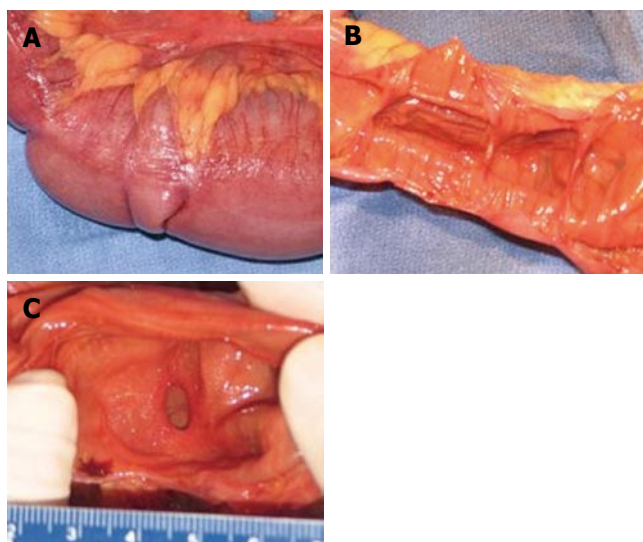

Figure 2 Gross specimens. Seventy-six centimeter segment of small intestine. On gross examination, fat surrounded the serosal surface of the intestine at irregular intervals, at the mesenteric border (A). Associated with these deposits of fat were 14 areas of mucosal stricture. In the normal intestine, the luminal diameter ranged from 4.7 to 9.5 cm. In the areas of luminal constriction, the diameter was 0.7 to 1.0 cm (B, C).

A 76-cm segment of small intestine was resected. On gross examination, fat was seen surrounding the serosal surface of the intestine at irregular intervals at the mesenteric border (Figure 2A). Associated with these deposits of fat were 14 areas of mucosal stricture causing luminal constriction (Figure 2B and C). The lumen between the constrictions was dilated and showed mucosal thinning. In the mesentery, four benign reactive perienteric lymph nodes were present.

On microscopic examination, the intestinal strictures contained mucosa and submucosa. Muscularis propria was not present within the webs (Figure 3). There was no evidence of inflammatory bowel disease, malignancy, or pathologic inflammation of the bowel or mesentery.

Postoperatively, bowel function was slow to return to

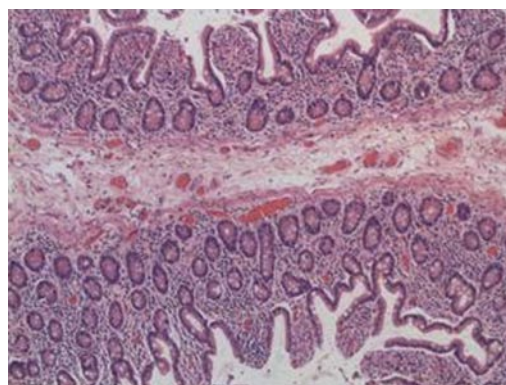

Figure 3 Microscopic image. On microscopic examination, the intestinal webs contained mucosa and submucosa. Muscularis propria was not present within the webs. There was no evidence of inflammatory bowel disease, malignancy, or pathologic inflammation of the bowel or mesentery.

normal. The patient had minimal bowel sounds and did not pass flatus until postoperative day (POD) 8. After POD 8, the patient progressed quickly; first, she tolerated a clear liquid diet and then a regular diet. On POD 10, the patient had an upper gastrointestinal barium study with a small intestine follow through, which showed normal motility, prompt emptying through the anastomosis, and barium reached the cecum within an hour. She was discharged on POD 10 and had no postoperative complications.

DISCUSSION

SBOs are most commonly caused by adhesions, hernias, neoplasms, or inflammatory strictures^[1], with most caused by extraluminal adhesions due to postoperative inflammatory changes^[2]. Although our patient had a history of abdominal surgery, she had no evidence of adhesions or extraluminal pathology. Her SBO was secondary to intraluminal strictures.

Intraluminal strictures are primarily caused by congenital defects, inflammation, ischemia, neoplasms or radiation. Congenital atresia is a common cause of neonatal intestinal obstruction. Jejunoileal atresia primarily results from intrauterine vascular events and tends to present early in life^[3]. Late presentation of jejunal atresia has been reported; however, this is associated with other abnormalities^[4]. It is unlikely that our patient had such a condition that had remained undiagnosed since birth.

Inflammatory bowel diseases, such as Crohn's disease, may also cause intestinal strictures. Crohn's disease presents with full thickness inflammation of the intestinal wall. Obstruction occurs through either acute inflammation leading to occlusion, or through chronic inflammation leading to strictures. Our patient had no clinical or pathologic evidence of acute or chronic inflammatory bowel disease. Chronic inflammatory bowel disease strictures also tend to be longitudinal and localized to the ileum^[5,6]; whereas our patient's strictures were distinct, concentric jejunal bands. Intestinal ischemia may also cause intestinal strictures and usually occurs in the presence of trauma, drug use, or vascular disease. The patient had no history of vascular disease or abdominal

trauma, and reported no history of postprandial abdominal pain or fecal blood, which might indicate chronic intestinal ischemia. Cases of intestinal ischemia usually reveal some degree of mucosal ulceration and necrosis, with associated intestinal fibrosis and vascular disease^[7]. A Medline search revealed no previous cases of sequential, stenotic strictures of the small intestine.

Intraoperatively, the intestine was viable and the mesenteric vessels had strong pulses. On pathologic examination, the patient had no evidence of mucosal irritation, intestinal fibrosis, or vascular pathology.

Malignancies may be another cause of intraluminal strictures. Benign tumors are the most common (i.e., leiomyomas); however, malignant lesions are more likely to have a symptomatic presentation. Melanoma is the most common metastatic malignancy of the small intestine and adenocarcinoma is the most common primary malignancy^[8]. Additionally, radiation therapy used to treat intraabdominal masses may cause intestinal webs or scarring^[9]. However, the patient had no history of malignancy or radiation therapy, and the pathology revealed no evidence of malignancy.

Chronic nonsteroidal anti-inflammatory (NSAID) usage may also cause intraluminal pathology^[10]. With newer imaging modalities such as capsule endoscopy, the small intestine is increasingly being recognized as a site of NSAID-induced toxicity. Mucosal damage is primarily mediated by a cyclooxygenase-independent mechanism, but may also be caused by cyclooxygenase-dependent mechanisms^[10]. NSAID usage may cause either longitudinal or concentric strictures; however, our patient had no history of chronic NSAID usage, and there was no pathologic evidence of mucosal ulceration or inflammation.

Other possible sources of intestinal stricture are parasites (e.g., *Ascaris*) or bacteria (e.g., *Mycobacterium tuberculosis*); however, the patient had no evidence of bacterial or parasitic infection.

In conclusion, in this report, we describe our finding

of sequential, stenotic intraluminal strictures of the small intestine, which led to SBO. The unusual sequential, concentric nature of the strictures, along with the lack of evidence of inflammatory bowel disease, vascular disease, or malignancy is believed to be unique. This lack of a clearly defined etiology of the patient's strictures made this an intriguing case.

CASE REPORT

Occasional finding of mesenteric lipodystrophy during laparoscopy: A difficult diagnosis

Abstract

Mesenteric lipodystrophy is a rare pathological condition affecting the mesentery. Its initial presentation is typically asymptomatic. Pathological characteristics are unspecific, and generally attributed to inflammation, unless the diagnosis is suspected. Laparoscopy done for other reasons has been, as in this case, unsuccessful in providing evidence for the correct diagnosis, thus requiring laparotomy due to lack of diagnostic tissue. After 6 mo no further medical therapy is required, as the patient remains asymptomatic. Discussion of this case and a brief review of the literature are presented in the following paragraphs.

INTRODUCTION

Mesenteric lipodystrophy is an uncommon diagnosis with few, if any, symptoms at presentation. Only 200 cases have been reported in the world literature^[1]. These cases mirror the presentation and symptoms of this case. Therefore, the diagnosis requires the astute clinical

suspicion of the surgeon, radiologist, and pathologist, as it may resemble other diseases which require different therapeutic approaches. Diagnosis is usually achieved through laparotomy performed for a mesenteric mass with lipomatous characteristics. The first report is attributed to Jura^[2], an Italian surgeon, who described a condition of "retractile sclerosing mesenteritis" in 1924. The term was reprinted by Durst^[3], who reviews 68 cases previously described in the literature and defines it as a benign disease. Today most articles describe the pathologic condition as "sclerosing mesenteritis", and divide it into three major phases, each regarding a progressively worsening state. The pathologic findings begin with fat necrosis and end with regenerative fibrosis. Within this progress of disease state, fat necrosis predominates in the first step, therefore called mesenteric lipodystrophy. This is then followed by mesenteric panniculitis, characterized by intense inflammatory reaction, and lastly by retractile mesenteritis, when fibrosis becomes the main feature.

CASE REPORT

An obese (body mass index = 41), 56-year old Caucasian man underwent laparoscopy for the repair of an umbilical hernia (> 3 cm). On exploration chylous ascites was noted in the pouch of Douglas and taken for examination. Because of the patient's obesity no mass or other abnormalities were noted, with the exception of cerulean stains on the surface of the mesentery, at first attributed to an unknown previous pancreatitis. A laparoscopic repair was performed, using a polytetrafluoroethylene (PTFE) mesh. The recovery was uneventful with dismissal on post operative day five. The patient did have chylous drainage in the first two days which then ceased by dismissal. Cytological and chemical examination of the fluid was negative for malignant cells, even though mononuclear inflammatory cells with enlarged cytoplasm were noted. Abdominal ultrasound and blood chemistry were normal, comprising amylase, lipase, lipidic asset, carcino-embryonal antigen (CEA) and Ca 19-9. After a month, a follow-up computed tomography (CT) scan (Figure 1) revealed hyperdensity of mesenteric fat, with regular margins, and radiological characteristics of a mesenteric lipoma (8 cm wide). Exploratory laparotomy was then performed to exclude definitely any malignancy. The mass was biopsied, however a complete removal was impossible due to its encasement of the superior mesenteric vessels

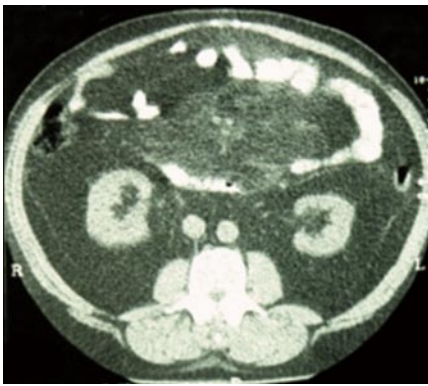

Figure 1 CT scan visualizing a mesenteric lipoma-like mass.

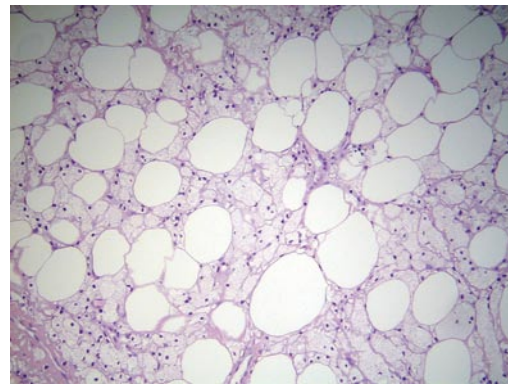

Figure 3 Mesenteric adipose tissue showing lipid necrosis and foamy macrophages (HE, x 10).

Figure 2 Intraoperative view of pseudonodular thickening of the mesentery.

(Figure 2). The ileum showed chronic ischemic condition with scars on the serosal surface. Macro-biopsies were performed which excluded neoplastic origin and diagnosed fatty necrosis, with scarce fibrotic component, adipose cells with foamy cytoplasm, infiltration of lipid-laden macrophages and foreign body giant cells (Figure 3). The patient was asymptomatic in the next six months, without any medical therapy, and did not complain of any digestive discomfort. The follow-up CT after three months was unchanged, except for a minimal reduction in the diameter of the mesenteric enlargement.

DISCUSSION

A nosological classification has been recently proposed^[4] for this rare pathology with unknown origin, defining under the word of "sclerosing mesenteritis", a disease previously described as mesenteric panniculitis, retractile mesenteritis, isolated lipodystrophy, mesenteric lipogranuloma, mesenteric manifestation of Weber-Christian disease, *etc.* Only three large series have been collected in Literature, one by Durst^[3], one by Kipfer^[5] and one more recently by Emory^[4] of 68, 53 and 42 cases, respectively. Still this disease is largely unknown to many surgeons and pathologists. It usually affects males (2-3:1), in the fifth or sixth decade of life (age range 20-80 years), and might take on different clinical aspects. In almost half of the cases (as in our patient) the mass is incidentally

discovered during abdominal surgery (i.e., during cholecystectomy). The remaining patients might complain of various degrees of intestinal obstruction, from post-prandial discomfort to acute occlusion. Other uncommon clinical findings may be fever, protein, losing enteropathy or abdominal mass. The biochemistry is mostly unhelpful in diagnosis. CT scan appearance varies from increased attenuation ("misty mesentery") to solid soft-tissue mass, which might envelope the mesenteric vessels preserving a fatty area around ("fat ring sign")^[6,7]. Other tumors of the mesentery may show a similar radiologic appearance, like lipoma, lymphoma, carcinoid tumor, carcinomatosis or tuberculosis, mesothelioma, edema or hematoma (from cirrhosis, trauma, hypoalbuminemia, heart failure or vasculitis)^[8]. Percutaneous needle aspiration or biopsy can give a hint to diagnosis, but generally laparotomy and surgical biopsy is required. More recently laparoscopic biopsy has been described^[9,10], but a pre-operation suspicion is mandatory, given, for example, by a CT scan. In our case, obesity (hiding the diffuse thickness of the mesentery) and the peritoneal aspect (mimicking that of a pancreatitis) misled laparoscopic diagnosis. A CT scan, performed after dismissal, led to laparotomy, in order to obtain a radical excision of the described mass. Intraoperative findings might be a diffuse thickening of the mesentery, a single tumor, multiple tumors or also a various mix of the nodular and hypertrophic components. Also the mesocolon may be involved, as well as, rarely, mesoappendix, peripancreatic area, omentum and pelvis. Its gross appearance explains how easy it is to mimic many other intra-abdominal neoplastic diseases. Histology displays different grades of involvement. Lipodystrophy is characterized by mesenteric infiltration by lipid-filled macrophages in the narrow septa inside the adipose tissue, as inflammation increases (panniculitis) lymphocytic infiltrate and lipid cystic necrosis can be noted. The last stage is distinguished by a diffuse presence of necrosis and fibrosis that contribute to tissue retraction as seen in retractile mesenteritis. Also calcifications and giant multinucleated cells have been seen in some cases. In the case presented, macrophage infiltration was the main feature, even if a component of fatty necrosis and fibrosis was evidenced. Haematoxylin and eosin stain

is generally enough to provide a correct diagnosis, but also immunochemistry might prove useful in some cases (between antibodies' panel nuclear beta-catenin has proved interesting)^[11]. The differential diagnosis comprises foreign body reaction (more fibrosis and fewer lipid laden macrophages) and Weber-Christian disease (predominantly localized in the subcutaneous tissue and with enhanced lymphocytic infiltrate)^[12]. Lipomatosis, lymphoma and retroperitoneal fibrosis have quite different microscopic features, and no fatty necrosis^[13]. Although the aetiology remains obscure, association with other diseases has been described. AIDS^[14], non-Hodgkin lymphoma^[15], tuberculosis^[1], cholesterol ester storage disease^[16] have been found together with sclerosing mesenteritis. Drug therapy is not standardized, and should be based on the stage of the disease. In the first stage, when fat necrosis is predominant, authors agree not to treat the disease as it can regress spontaneously. Chronic inflammation requires therapy based on corticosteroids and various types of immunosuppressants. Good results are reported with cyclophosphamide, colchicine, azathioprine and also with oral progesterone^[17]. As intense fibrosis appears, bowel obstruction may occur. Intestinal resections, bypasses or neostomy might be required^[18,19].

In summary, diagnosis of this unspecific, benign inflammatory disease is a challenge, both for the radiologist, surgeon and pathologist. Some authors^[20] suggest that this condition might be more common than reported. In fact, as Poniachik *et al*^[21] has supposed, the suspect of sclerosing mesenteritis has to be arisen in order to prevent such conditions to be catalogued as "unspecific inflammatory process". Since we also met the difficulty in diagnosis by laparoscopic means, especially for large masses in obese patients, we acknowledge that laparotomy is required to achieve complete removal or at least a macro-biopsy of the mass, as pathologic examination on frozen section might be incomplete, and radiology is unhelpful.

Abstract

Endoscopic biliary stent insertion is a well-established procedure. It is especially successful in treating postoperative biliary leaks, and may prevent surgical intervention. A routine change of endoprosthesis after 3 mo is a common practice but this can be prolonged to 6 mo. We reported a colonic perforation due to biliary stent dislocation and migration to the rectosigmoid colon, and reviewed the literature.

INTRODUCTION

Endoscopic biliary stent insertion is a well-established treatment for hepatic, biliary or pancreatic disorders (e.g., chronic pancreatitis or pancreatic carcinoma). It is especially successful in treating postoperative biliary leaks, and may prevent surgical intervention^[1,2]. Stenting of the biliary duct can be performed with a variety of prosthesis that can

differ by size, design and material^[3,4].

The available biliary endoprosthesis can be classified by material into two categories: plastic (i.e., polyethylene, polyurethane and "Teflon") and metallic stents. Plastic endoprosthesis are less expensive but have a higher risk of clogging and dislocation^[5]. On the other hand, they are easier to remove or to change.

A routine change of an endoprosthesis after 3 mo is common practice, but this can be prolonged to 6 mo^[6]. To avoid stent migration, the biliary stent should be placed across the sphincter of Oddi^[7]. Distal stent migration is an infrequent late complication, but occurs in up to 6% of cases^[3,8]. The majority of biliary endoprosthesis pass through the intestine without any problems. Infrequently, however, stents get stuck in the bowel, leading to complications.

Endoscopic retrieval is often possible and surgical intervention is rarely necessary^[9,10]. The most common site of a migrated biliary stent is the duodenum^[11-17], whereas complications in the rest of the small intestine^[18,19] or colon^[20-30] are rare.

CASE REPORT

A 65-year-old female patient presented with 4 d of persistent diffuse colicky abdominal pain and localized peritonitis in the supra-symphysial area. Normal leukocytes, elevated C-reactive protein (14.5 mg/dL; normal value < 0.5) and simultaneous cystitis (6500 bacteria/ μ L; normal value < 600) were found. Three months previously, the patient had undergone a laparoscopic cholecystectomy 4 wk after acute cholangitis with choledocholithiasis. The intraoperatively placed easy-flow drainage showed early postoperative biliary secretion. Endoscopic retrograde cholangiography was performed and showed a small peripheral leakage from the liver. A residual bile duct stone that was causing partial obstruction was removed. A 12 French 10 cm plastic stent was placed in the common bile duct without sphincterotomy. Biliary drainage stopped concurrently. The patient was discharged on the ninth postoperative day. A biliary stent extraction was advised at 4-6 wk later, but this was not carried out because of the patient's non-compliance.

A computed tomography (CT) scan was performed because of extensive pain. A biliary stent dislocation and migration to the rectosigmoid colon was detected. The CT scan showed rectal perforation, and the stent was found in

the rectal mesentery (Figure 1). A rectal resection was performed. After an uncomplicated postoperative recuperation, the patient was discharged on the seventh postoperative day.

DISCUSSION

The incidence of postoperative biliary fistula is elevated in settings of acute or chronic inflammation^[32-34]. Treatment options are surgical biliary leak repair, percutaneous biliary drainage, and endoscopic biliary drainage.

Endoscopic placement of a biliary endoprosthesis is a well-established procedure for treatment of biliary outflow obstruction. The most frequent complication associated with bile duct stents is early occlusion caused by clogging, with resultant cholangitis, or by tumor over-growth. Stent dislocation and proximal or distal migration are uncommon, with an overall incidence of up to 6%^[3]. Several complications of stent migration have been reported and can be classified into categories of penetration, intestinal perforation, and obstruction. Other organs are usually unaffected^[9,10].

Most ingested foreign bodies pass through the intestine without major problems. Neither size nor shape of the stent predicts the likelihood of successful conservative management. In all patients, a close follow-up after biliary stent placement is mandatory. Patients with diverticular disease, hernia or intra-abdominal adhesions, are

especially at risk. Intestinal-wall weakness and increased resistance during bowel movement can produce localized complications^[26,39].

Lesions of the intestinal wall due to biliary-stent migration have been reported in the duodenum, and are related to retroperitoneal fixation of this intestinal segment. Penetration requires adherence between the perforated and the penetrated organ, and does not induce intra-abdominal contamination, but eventually causes fistulae (i.e., interenteric or biliocolic^[36], colovaginal^[25] or colovesicular^[27]).

Downstream migration is more frequent in benign than in malignant biliary duct strictures^[9,35]. Benign stenoses are not as tight because of regression of inflammatory reactions after placement of the stent. By contrast, tumor growth can anchor a stent in malignant stenoses.

In the case of intestinal perforation, surgical stent removal and drainage of consecutive intra-abdominal or retroperitoneal abscesses is mandatory. A pelvic abscess^[28], and colovesicular^[27] or colocutaneous^[29] fistula are typical consequences (Table 1). A case of necrotizing fasciitis due to colonic perforation has also been reported^[31].

A review of the literature published to January 2007 has revealed 11 cases of colonic perforation due to biliary stent migration, with the majority being straight plastic endoprostheses^[10,17,26,27,29,38,40].

In conclusion, endoscopic insertion of biliary stents is a useful and powerful procedure for short-term decompression of the biliary system. In the case of long-term therapy, stent-migration-associated complications have to be considered as a differential diagnosis that may lead to life-threatening situations. A correct diagnosis is sometimes difficult to make because of the absence of typical symptoms.

A migrated biliary stent, symptomatic or not, should be removed immediately^[19]. In cases of intestinal perforation, immediate surgical therapy is required. In cases of benign lesions of the bile duct, the stent should be either removed early to decrease the risk of secondary complications, or replaced regularly to prevent stent obstruction, infection or migration.

Caution should be exercised when straight plastic stents are inserted, and these should be closely followed-up.

Abstract

We present a female patient with sigmoid colon endometriosis who was diagnosed correctly preoperatively and underwent minimally invasive surgery. She was admitted to our hospital with rectal bleeding and constipation. We performed several workups. Colonoscopy and endoscopic ultrasonography showed sigmoid colon stenosis caused by submucosal tumor, and magnetic resonance imaging revealed a sigmoid colon tumor displaying signal hypointensity on both T1- and T2-weighted imaging. However, colonoscopic ultrasonography-assisted needle aspiration biopsy could not specify tumor characteristics. From these examinations, the lesion was diagnosed as sigmoid colon endometriosis and laparoscopy-assisted sigmoidectomy was performed. Pathological diagnosis from the resected specimen was identical to preoperative diagnosis, i.e., colonic endometriosis. Since differential diagnosis of intestinal endometriosis seems difficult, a cautious preoperative diagnosis is required to select treatments including minimally invasive surgery.

INTRODUCTION

Endometriosis is a common benign disease among women of reproductive age, and affects the intestinal tract in 15%-37% of all patients with pelvic endometriosis^[1]. The disease is thus comparatively common, but preoperative diagnosis is reportedly difficult^[2-4]. Herein, we report a case of sigmoid colon endometriosis that was diagnosed preoperatively using magnetic resonance imaging (MRI) and then treated by minimally invasive surgery.

CASE REPORT

A 43-year-old woman was admitted to our hospital with chronic constipation and decreased stool caliber for 3 mo before admission. Rectal bleeding was also reported, but was not associated with her menstrual cycle. She did not have any other symptoms, including abdominal pain. She was 14-years-old at first menstruation and her cycle was irregular at every 27-50 d, lasting 7-12 d. The patient was nulliparous and had not had an abortion.

Physical examination revealed no specific findings, including abdominal pain or palpable masses in the abdomen.

Laboratory examination showed an elevation of cancer antigen (CA) 125 level to 90.5 IU/mL, but other values were within normal limits.

Gynecological examination revealed a normal vagina, uterus and uterine cervix. Transvaginal ultrasonography revealed multiple myomas with diameters of 1-2 cm in the uterine wall, but no abnormality in either ovary.

Barium enema showed stenosis of the sigmoid colon caused by tumor, but the mucous membrane was smooth (Figure 1).

Colonoscopy also revealed sigmoidal stenosis with a smooth mucosal surface. Endoscopic ultrasonography was performed at the same time and revealed an iso- to high-echoic lesion in the 3rd echoic layer (submucosal layer) (Figure 2). In addition, endoscopic ultrasonography-guided fine needle aspiration biopsy (EUS-FNAB) was attempted, but sufficient specimens could not be obtained due to severe stenosis of the sigmoid colon.

MRI was performed for evaluation and differential

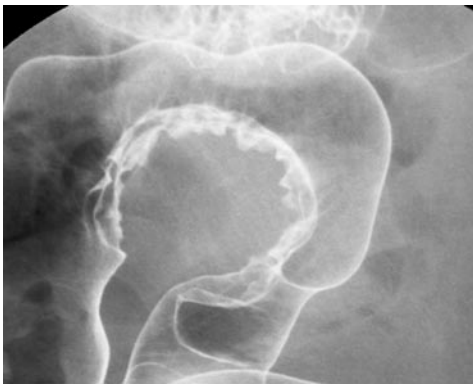

Figure 1 Barium enema shows sigmoidal stenosis with smooth inner lumen.

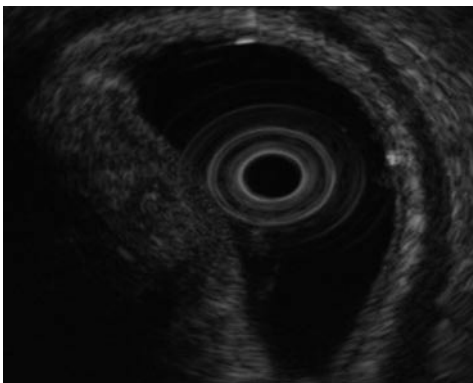

Figure 2 EUS shows iso to high echoic submucosal tumor in the 3rd echoic layer.

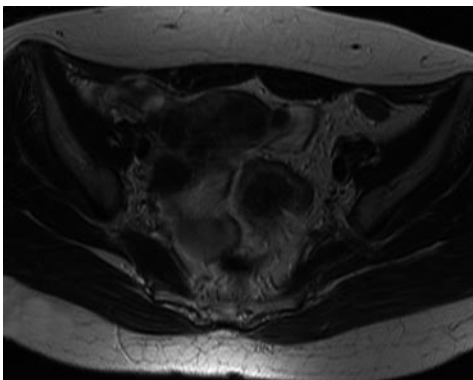

Figure 3 MRI (T2 weighted image) shows a sigmoidal tumor lesion with low signal intensity.

diagnosis of the submucosal tumor, revealing a tumor 3 cm in diameter in the sigmoid colon with signal hypointensity on both T1- and T2-weighted imaging (Figure 3; T2-weighted image only). Several small myomas were also seen in the uterus.

The sigmoid tumor was diagnosed as intestinal endometriosis from these examinations, for the following reasons: (1) the patient was a woman of reproductive age; (2) tumor was located in the sigmoid colon; (3) a submucosal tumor containing muscle and/or fibrous components was detected on MRI. As stenosis of the colon was severe and the patient wanted to have children

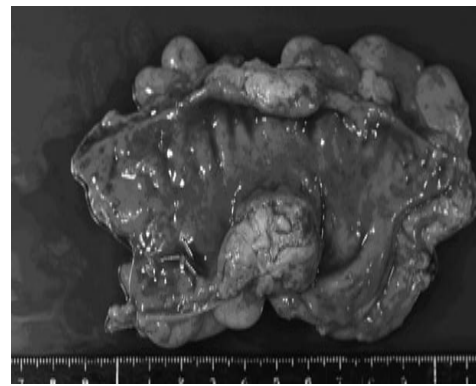

Figure 4 Gross examination of the resected specimen.

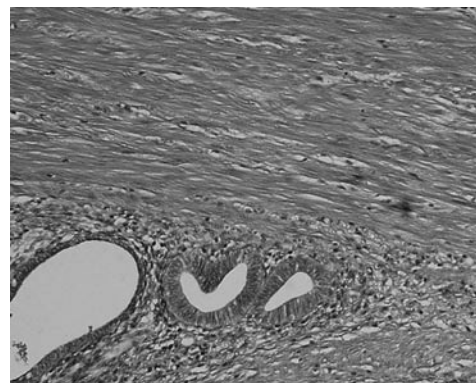

Figure 5 Tumor comprising endometrial-like glands and smooth muscle cells (× 200).

in the near future, we selected sigmoid resection by laparoscopy-assisted sigmoidectomy with a minimal skin incision to prevent postoperative abdominal adhesions. Surgery was performed after informed consent was obtained from the patient.

Three trocars, including a 5-mm laparoscope, were introduced and a 4-cm minilaparotomy was performed in the left lower abdomen to retrieve the resected specimen and anastomose the colon. The operation was successful and she was discharged uneventfully 7 d after surgery.

Gross examination of the resected specimen revealed a 30 mm × 20 mm × 15 mm hard submucosal mass, and the serous membrane of this site was indented to the tumor (Figure 4). No abnormality in the mucosal surface was identified.

Histological examination revealed a mixture of smooth muscle cells and endometrial glands, without atypical cells and goblet cells, so the diagnosis of sigmoid endometriosis was confirmed (Figure 5).

DISCUSSION

Endometriosis is histologically defined as the presence of endometrial-like tissue outside the uterus^[5]. This condition is thought to affect the intestinal tract in 15%-37% of patients with pelvic endometriosis^[1]. The disease is not particularly rare among women of childbearing age, but many authors have reported that correct preoperative

diagnosis is difficult^[2-4]. This is because the symptoms such as abdominal pain, hemostool and decreased stool caliber are not specific for this disease, and hemostool or rectal bleeding are thought to result from mucosal injury during passage of stools through the narrowed intestinal lumen^[2]. Some patients reportedly display symptoms associated with the menstrual cycle^[2,4], but these patients represent only about 40% of all patients with endometriosis^[6]. In addition, some reports have described aggravation of inflammatory bowel disease and irritable bowel syndrome during menstruation^[7]. Symptoms alone are thus not helpful for differential diagnosis, and a similar situation is seen for laboratory examination of the blood. Mol *et al*^[8] reported a systematic review of the diagnosis of endometriosis, and concluded that serum CA125 level may be elevated in endometriosis, but this measurement had no value as a diagnostic tool compared to laparoscopy.

Imaging examination is thus essential for the preoperative diagnosis of intestinal endometriosis, but some reports have described preoperative confusion between this disease and cancer according to colonoscopy and CT with barium enema, particularly in patients with lesions involving the mucosal surface^[3,4]. In such patients, MRI is helpful for differential diagnosis. In a typical endometrial lesion, MRI showed signal hyperintensity on T1-weighted imaging and signal hypointensity on T2-weighted imaging^[9]. However, smooth muscle components are reportedly recognized frequently in endometrial lesions^[10]. In such lesions, as seen in the present case, MRI indicates signal hypointensity on both T1- and T2-weighted imaging, and differential diagnosis from other diseases such as cancer and gastrointestinal stromal tumor is thus difficult. In fact, Chapron *et al*^[11] reported that MRI specificity for deeply infiltrating endometriosis was 97.9%, but sensitivity was only 76.5%.

Endoscopic ultrasonography is also a useful and noninvasive examination for the diagnosis of intestinal endometriosis. Sensitivity and specificity are reportedly about 97% for the diagnosis of rectal involvement in patients with known pelvic endometriosis^[12]. In addition, EUS-FNAB provides accurate tissue and may be the only procedure for correct preoperative diagnosis of intestinal endometriosis, but the overall specificity, sensitivity and accuracy of EUS-FNA for neoplasms of the gastrointestinal tract are reportedly 88%, 89% and 89%, respectively^[13].

Biscaldi *et al*^[14] reported the usefulness of multislice CT combined with distention of the colon by rectal enteroclysis for intestinal endometriosis. The sensitivity was 98.7% and specificity was 100% in identifying women with intestinal endometriosis. This method is thought to be very helpful for diagnosing intestinal endometriosis, but requires bowel preparation, such as the need for a low-residue diet for 3 d, drinking of 4-6 doses of a granular powder dissolved in 500 mL of water per dose and intravenous administration of iodinated contrast medium. This technique is thus inappropriate for patients with obstructive symptoms or

allergy to iodinated contrast medium.

Among these examinations, we consider MRI and EUS (and/or EUS-FNAB) are the most useful examinations for intestinal endometriosis. However, it is important to perform valuable examinations for diagnosis of intestinal endometriosis, including radiological, histological and etiological examinations, as the condition basically involves a benign lesion requiring minimally invasive treatment. This disease should also be considered in the differential diagnosis for women of childbearing age presenting with gastrointestinal tract symptoms.

Abstract

A case of a 53-year-old female patient with reactive lymphoid hyperplasia (RLH), clinically designated as pseudolymphoma of the liver is described in this article. The patient was admitted to our hospital for further evaluation of hepatic tumors incidentally discovered at another hospital. Various diagnostic methods, including ultrasonography (US), computerized tomography (CT), magnetic resonance imaging (MRI) and hepatic angiography displayed three small lesions in the liver with outstanding findings consistent with hepatocellular carcinoma (HCC). Surgical resection was performed and the three lesions were microscopically diagnosed as RLH of the liver. The lesions comprised a massive infiltration of lymphoid cells with follicles and hyalinized inter-follicular spaces. Immunohistochemical examination revealed that infiltrating lymphocytes had no prominent nuclear atypia and polyclonality. RLH of the liver is a very rare condition and only twelve cases have been reported in the English literature. Majority of the reported cases were middle-aged women and about half of them had some immunologic abnormalities such as autoimmune thyroiditis, Sjogren's syndrome, primary immunodeficiency, primary biliary cirrhosis. Since they are often clinically misdiagnosed as HCC, surgery is the choice of treatment for these patients. Although their pathology resembles malignant lymphoma, the clinical course is completely benign. The authors propose that RLH of the liver can be discriminated from HCC by its clinical features.

INTRODUCTION

Reactive lymphoid hyperplasia (RLH) is a benign nodular lesion, histopathologically characterized by marked proliferation of non-neoplastic, polyclonal lymphocytes forming follicles with an active germinal center. The lesion is encountered in various organs such as the orbit^[1], lung^[2], skin^[3,4] and gastrointestinal tract^[5-7]. However, disease of the liver is quite rare, with only 12 cases reported in the English literature. We have recently encountered a patient with 3 RLH lesions occurred in the liver. In this paper, the clinicopathological and radiographic characteristics of this unique disorder are discussed. Problems in differential diagnosis from malignant diseases, including malignant lymphoma and hepatocellular carcinoma, are also discussed.

CASE REPORT

A 53-year-old Japanese woman with a history of autoimmune thyroiditis was admitted to our hospital for further evaluation of hepatic lesions incidentally discovered on abdominal ultrasonography. The patient was asymptomatic on admission and her condition was generally good. Physical examination revealed no abnormalities. Relevant laboratory tests disclosed slightly elevated lactate dehydrogenase activity (547 IU/L; normal range: 120-245 IU/L), thymol turbidity (7.2 U/L; normal range: 0.0-4.0 U/L) and zinc sulfate turbidity (13.0 U/L; normal range: 4.0-12.0 U/L), although other hepatic function tests including serum aspartate aminotransferase, serum alanine aminotransferase and total bilirubin were within normal range. Levels of serum thyroid-stimulating hormone (10.22 μ U/mL; normal range: 0.35-3.73 μ U/mL) and antinuclear antibody (80 \times ; normal range: $< 40 \times$) were elevated due to autoimmune thyroiditis. Both hepatitis B surface antigen and anti-hepatitis C virus antibody were negative. Tumor markers including alpha-fetoprotein and protein induced by vitamin K antagonist-II were negative.

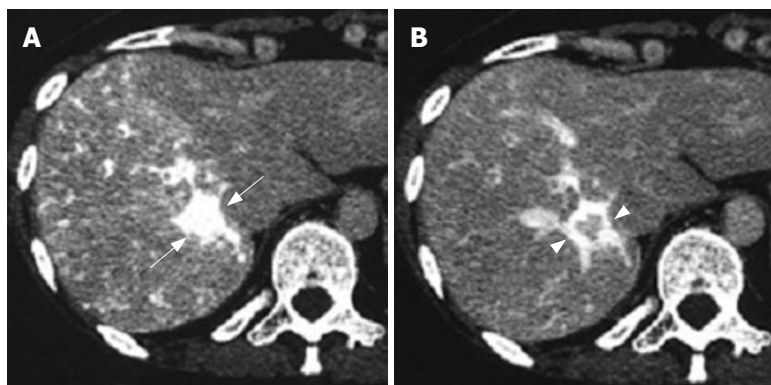

Figure 1 CT angiography showing the conspicuously enhanced lesion in segment 7 through the early phase (arrows) (A) and intensified tumor rim enhancement through the delayed phase along with radial enhancement (arrowheads) (B).

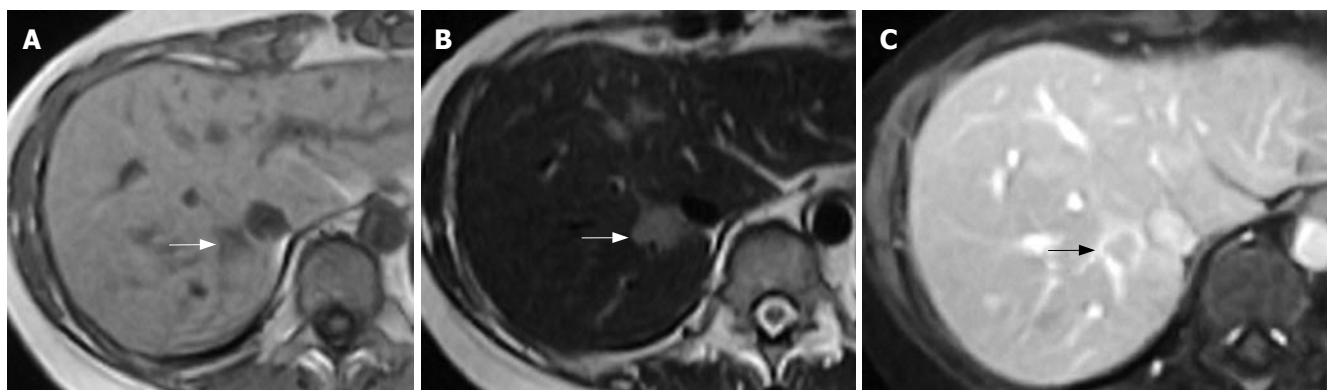

Figure 2 MRI displaying a hypointense signal on T1-weighted imaging (arrow) (A), a hyperintense signal on T2-weighted imaging of the lesion (arrow) (B), and enhanced tumor rim in the delayed phase of MRI (arrow) (C).

Figure 3 Macroscopy of tumor in segment 7 demonstrating the lesion as a well-circumscribed, white-yellowish nodule on the cut surface.

Precise US examination disclosed 2 hypoechoic nodules in the posterior segment and 1 nodule in the medial segment of the liver (13, 11 and 8 mm in diameter) respectively. Dynamic CT performed in the planes of lesions demonstrated a slight hyperdensity in the arterial phase followed by hypodense areas with pronounced enhancement along the tumor rims in the portal phase. The lesion in segment 7 was conspicuously enhanced through the early phase on CT angiography (Figure 1A). The tumor rim was continually intensified through the delayed phase, and radial enhancement toward surrounding liver parenchyma was also recognized (Figure 1B). The lesion was identified as a portal flow defect on CT with arterial portography. On MRI, tumor gave a hypointense signal on T1-weighted imaging (Figure 2A) and a hyperintense signal on T2-weighted imaging (Figure 2B). The tumor rim

was underscored as an annular enhancement in the delayed phase, similar to dynamic CT (Figure 2C). Other lesions within segments 4 and 6 showed equivalent hemodynamics to the tumor in segment 7. Hepatic angiography of the 3 lesions also demonstrated distinct tumor staining in the arterial phase, following dense staining along tumor rims in the parenchymal-venous phase. As all images suggested hepatocellular carcinoma, posterior segmentectomy and partial resection of the medial segment of the liver were performed.

The resected liver displayed smooth surfaces and normal appearance. On the cut section, lesions were well-circumscribed, but not encapsulated white-yellowish nodules with irregular shapes (Figure 3). The 3 nodules exhibited similar microscopic findings, comprising a massive infiltration of lymphoid cells with follicles and hyalinized interfollicular spaces at low magnification (Figure 4A). Lymph follicles varied in size and shape with germinal centers composed of small or large lymphoid cells and tingible body macrophages. Interfollicular areas mostly comprised mature lymphocytes with no prominent nuclear atypia and a small amount of infiltrated plasma cells and histiocytes (Figure 4B). Strands of amorphous, somewhat-dense hyalinized material accompanied with capillaries were observed in interfollicular areas (Figure 4C). In some parts, fibrous materials aggregated as nodular structures of various sizes. Bile ductule proliferation was seen along the lesion edges. Portal areas apart from nodules showed irregular expansion with infiltration of small mature lymphocytes (Figure 4D). Immunohistochemical studies on

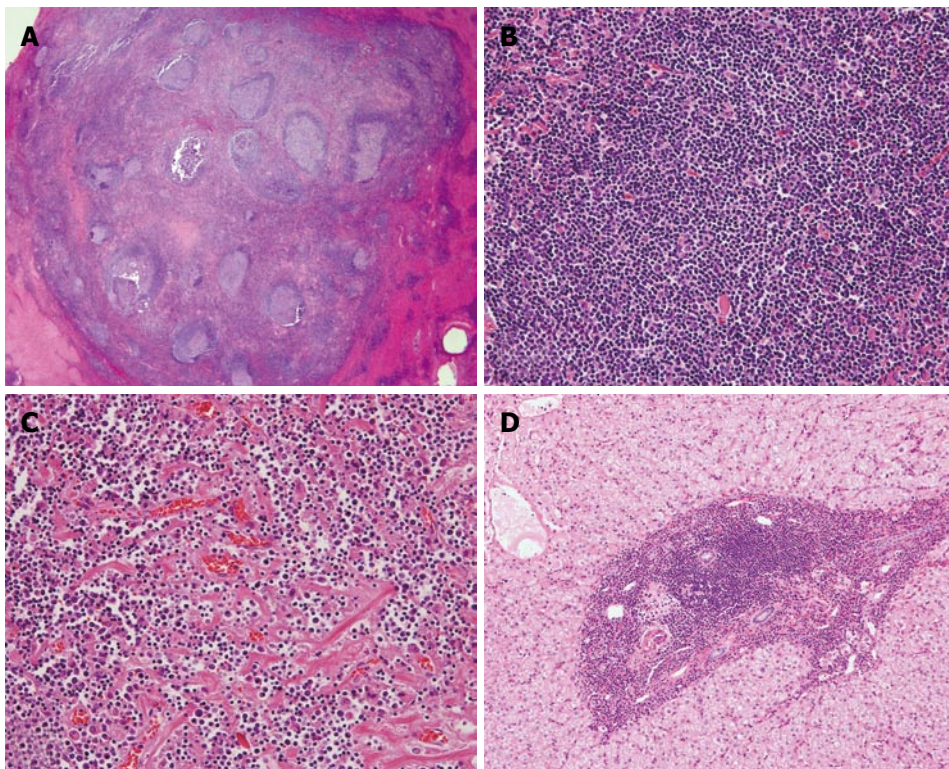

Figure 4 Microscopy revealing lesions comprising massive lymphoid cell infiltration with prominent follicles and hyalinized interfollicular spaces at low magnification (HE, X 2.5) (A), interfollicular areas mainly comprising mature lymphocytes with no nuclear atypia (HE, X 50) (B), strands of amorphous hyalinized material accompanying capillaries in interfollicular areas (HE, X 50) (C), and portal areas apart from the nodules with irregular expansion of infiltration of small mature lymphocytes (HE, X 25) (D).

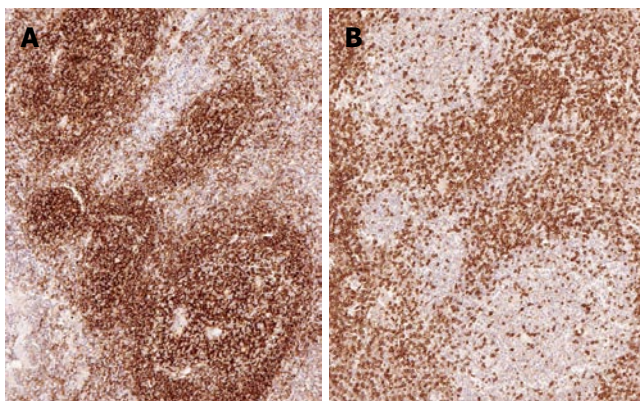

Figure 5 Immunohistochemistry discovering follicles mainly comprising CD20-positive lymphocytes (X 50) (A), and interfollicularly and circumferentially distributed CD3-positive cells compared to follicles (X 50) (B).

paraffin-embedded tissue sections for CD3, CD5, CD10, CD20, bcl-2 and both κ and λ immunoglobulin light chains were undertaken using the avidin-biotin-peroxidase complex technique. Follicles mainly comprised CD20-positive lymphocytes, while CD3-positive cells were distributed interfollicularly and circumferentially around follicles (Figure 5). Distributions were similar to that seen in reactive hyperplasia of lymph nodes. Lymphoid cells in follicles showed ordinary immunoreactivity, while cells in the mantle zone were positive for CD5 and cells in the germinal center were positive for CD10. Bcl-2 reacted only to lymphocytes in marginal or circumferential areas of follicles, but not in central regions. Scattered plasma cells were positive for both κ and λ light chains at an equal frequency. These immunohistochemical results indicate that lymph follicles were of reactive origin, but not of neoplastic, and

that the lesion was composed of polyclonal lymphocytes and plasma cells. A genetic investigation of clonality in the immunoglobulin heavy chains (IgH) using a previously reported polymerase chain reaction method^[6] with DNA from paraffin-embedded tissue was also performed. No clonal IgH gene rearrangement was detected with satisfactory negative and positive controls. The 3 lesions were thus pathologically diagnosed as RLH of the liver.

Postoperative course was relatively good and the patient experienced no signs of recurrence for 22 mo.

DISCUSSION

Although RLH can be found in various organs, including the gastrointestinal tract^[5-7], orbit^[1], lung^[2] and skin^[3,4], its occurrence in the liver is rare. To the best of our knowledge, only 14 lesions in 12 other cases of hepatic RLH of the liver have been reported in the English literature since the first case report by Snover *et al*^[9] in 1981, with this case representing the thirteenth (Table 1). RLH occurs predominantly in middle-aged women, with a mean age of 54.1 years (range 15-72 years, Table 1). Although the pathogenesis remains unknown, an association between development of hepatic RLH and systemic or local immunological abnormalities has been suggested in earlier reports^[10,11]. In fact, 6 of 13 patients, including the present, have displayed some immunological complications, such as autoimmune thyroiditis^[10], Sjogren's syndrome^[11], primary immunodeficiency (PI)^[9], and primary biliary cirrhosis (PBC)^[12] (Table 1). Two cases have been reported in association with hepatitis B (HB) virus or hepatitis C (HC) virus infection^[13,14] (Table 1). The patient with hepatitis B was treated with interferon (IFN)- α ^[13]. Whether hepatitis viral infection is involved in hepatic RLH remains unclear. However,

Table 1 Reported cases of RLH of the liver

the findings in these patients indicate that continuous stimulation from cytokines such as IFN- α or hepatitis viruses may cause RLH of the liver.

Saltzstein *et al*^[15] has defined RLH as propagation of lymph-follicles constructed with lymphoid cells without cytological atypia, accompanied with a conspicuous, reactive germinal center. Katayanagi *et al*^[16] and Tanizawa *et al*^[17] have also proposed RLH as a localized lesion well-demarcated from the surrounding tissues and characterized by the presence of hyperplastic lymphoid follicles with polymorphic and polyclonal cell populations composed of small mature lymphocytes, mature plasma cells, macrophages and stromal fibrosis. The nodular lesion described herein seems to satisfy these histological criteria.

When RLH is diagnosed, malignant lymphoma must be excluded from the differential diagnosis. In the present case, immunohistochemical examination was performed to rule out malignant lymphoma. Germinal centers were considered non-neoplastic, based on negative results for bcl-2. In addition, lymphoid cells, including plasma cells, proliferating in the interfollicular area displayed polyclonal immunophenotypes. The results of a genetic investigation pertaining to IgH clonality also supported the histological findings. A diagnosis of RLH of the liver thus seems justified.

The lesion has been often misdiagnosed as a malignant tumor, since features are shared with hepatocellular carcinoma on various imaging modalities, namely detection as a hypoechoic mass on US, low density on CT with or without enhancement, low intensity on T1-weighted imaging and high intensity on T2-weighted imaging with magnetic resonance imaging, and tumor staining on hepatic angiography. Distinguishing RLH from hepatocellular carcinoma (HCC) is thus extremely difficult. Hepatectomy has therefore been performed for many patients^[10-14,16-19] (Table 1). In the present case, the tumor rim displayed a sustained intensity accompanied with radial enhancement in addition to intratumoral hyperintensity on various imaging modalities. This prominent finding may represent increased capillaries within the nodule and massive infiltration of lymphocytes into portal areas around the lesion. Needle biopsy was indicated for only 4 patients in past reports^[9,11,16,18] (Table 1), but it is not helpful for a confident diagnosis of this disease.

In conclusion, accumulation of reported cases with this

benign lesion, including our patient, reveals some knowledge concerning the characteristics of this rare condition, such as female predominance, small tumor size, coexistent immunological disorder, and imaging features resembling HCC. The authors would like to emphasize that RLH should be included in the differential diagnosis of small hepatic lesions, particularly in middle-aged women with suspected HCC.

Abstract

We report a case of acute hepatotoxicity in a 42-year-old woman after administration of clindamycin for a dental infection. After 6 d of treatment, she had fatigue, nausea, vomiting, anorexia, pruritus and jaundice. Her laboratory analysis showed alanine aminotransferase (ALT), 1795 IU/L (normal range 0-40); aspartate aminotransferase (AST), 1337 IU/L (normal range 5-34); alkaline phosphatase (ALP), 339 IU/L (normal range 40-150); γ -glutamyl transpeptidase (GGT), 148 IU/L (normal range 9-64 IU/L); total bilirubin, 4.1 mg/dL; direct bilirubin, 2.9 mg/dL and prothrombin time (PT), 13.5 s, with international normalized ratio (INR), 1.04. She was hospitalized, with immediate drug discontinuation. Her liver biopsy specimen showed mixed-type (both hepatocellular and cholestatic) hepatic injury, compatible with a diagnosis of drug-induced hepatitis. An objective causality assessment using the Naranjo probability scale suggested that clindamycin was the probable cause of the acute hepatitis. In susceptible individuals, clindamycin use may lead to acute mixed-type liver toxicity. Complete recovery may be possible if the drug is discontinued before severe liver injury is established.

INTRODUCTION

Liver injury may be caused by various drugs and chemicals. The severity of injury may vary from minor non-specific changes in hepatic structure and function to fulminant

hepatic failure, cirrhosis and even hepatocellular cancer. The term drug-induced liver disease should be confined to cases in which the nature of the liver injury has been characterized histologically, because biochemical parameters used to detect liver injury may also be elevated as an adaptive response to drugs.

The lincosamide antibiotics seem to be most useful against the bacteria classified as Gram-positive cocci. In addition, they are helpful against protozoa, such as *Toxoplasma* and *Mycoplasma*, as well as many anaerobic bacteria^[1]. Clindamycin (7-chlorolincomycin), a semisynthetic derivate of lincomycin, has been extensively used in the therapy of obstetric, gynecologic and oral infections for over 20 years. It is more active than erythromycin or clarithromycin against anaerobic bacteria. In humans, absorption of clindamycin is rapid and virtually complete (90%) following oral administration, and is widely distributed throughout the body^[2]. We describe herein a case of acute hepatitis following clindamycin use for dental infection.

CASE REPORT

A 42-year-old woman was admitted to hospital for pruritus, jaundice and asthenia. Her medical history included recurrent gingival infections treated with clindamycin on several previous occasions. Six days after the initiation of the last clindamycin (150 mg PO qid) treatment, the patient had fatigue, nausea, vomiting, anorexia, pruritus and jaundice. Emergency laboratory analysis showed the following results: Alanine aminotransferase (ALT), 1795 IU/L (normal range 0-40); aspartate aminotransferase (AST), 1337 IU/L (normal range 5-34); alkaline phosphatase (ALP), 339 IU/L (normal range 40-150); γ -glutamyl transpeptidase (GGT), 148 IU/L (normal range 9-64); total bilirubin, 4.1 mg/dL; direct bilirubin, 2.9 mg/dL and prothrombin time (PT), 13.5 s, with international normalized ratio (INR), 1.04. Blood tests for glucose, blood urea nitrogen (BUN), serum creatinine, total protein, albumin, uric acid, total cholesterol and triglycerides were within normal limits. There was no peripheral eosinophilia. The patient was hospitalized and clindamycin treatment was discontinued. Additional test results for hepatitis A, B and C viruses, cytomegalovirus, and Epstein-Barr virus were negative. Ferritin and ceruloplasmin levels were within normal limits. Autoantibodies (antinuclear, antimitochondrial, anti-smooth-muscle, anti-liver-kidney microsomal enzymes and anti-soluble liver antigen) were also negative. Hepatobiliary imaging with ultrasonography was normal. She denied taking any other medications,

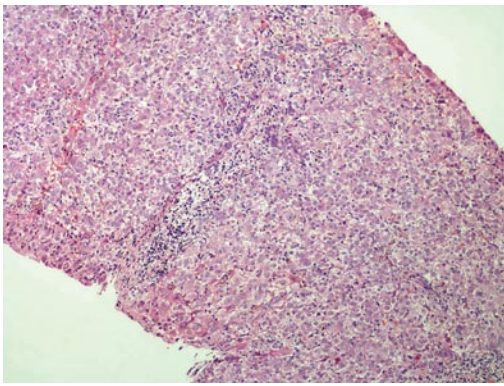

Figure 1 Extensive hepatocellular injury showing centrilobular and portal cholestatic hepatitis with inflammatory infiltration (HE, × 40).

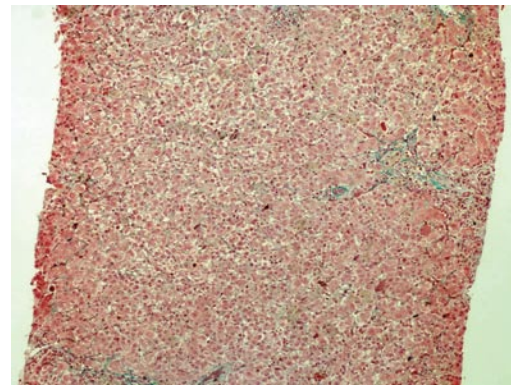

Figure 2 Intense inflammatory reaction in liver without evidence of fibrosis (Mason's Trichrome, × 40).

or using alcohol or any herbal or folk remedies at any time. There were no known contributing environmental issues. One week after hospitalization, her liver function tests were as follows: ALT, 1579 IU/L; AST, 1031 IU/L; ALP, 345 IU/L; GGT, 112 IU/L; total bilirubin, 3.34 mg/dL; and direct bilirubin, 2.4 mg/dL. Her medical history and laboratory results suggested severe acute hepatitis of mixed-type, with hepatocellular and cholestatic hepatic injury, and liver biopsy was performed. The histopathological samples revealed centrilobular and portal cholestatic hepatitis, without fibrosis or necrosis, highly suggestive of drug-related hepatotoxicity (Figures 1 and 2). Within 3 wk of hospitalization, the patient had significant subjective improvement, and showed improvement of liver function tests (ALT, 754 IU/L; AST, 429 IU/L; ALP, 175 IU/L; GGT, 82 IU/L; total bilirubin, 1.8 mg/dL; and direct bilirubin, 1.26 mg/dL). After 8 wk hospitalization, her liver function test results were within normal limits (ALT, 28 IU/L; AST, 23 IU/L; and total bilirubin, 0.74 mg/dL). The patient was discharged in good condition. The probability that the symptoms of hepatotoxicity that occurred after clindamycin treatment were an adverse drug reaction (ADR) was assessed using the Naranjo ADR probability scale. The total Naranjo score for the patient was 7, which is in the "probable" range^[3].

DISCUSSION

Six days after the start of treatment with clindamycin, our 42-year-old female patient experienced signs of hepatotoxicity with jaundice and asthenia. Laboratory testing showed marked elevations in serum ALT, AST, ALP, GGT and total bilirubin concentrations. Her symptoms, as well as the liver tests, resolved on discontinuation of the drug treatment. The subtype of the hepatotoxicity observed in the patient was considered as mixed hepatocellular and cholestatic. The diagnosis of severe clindamycin-induced hepatotoxicity in our case was suggested by: (1) symptoms such as fatigue, nausea, vomiting, anorexia, pruritis and jaundice 6 d after clindamycin initiation; (2) the chronology between clindamycin introduction and liver test abnormalities; (3) histological findings that were highly suggestive of a toxic mechanism; (4) absence of any other clear etiology;

and (5) recovery after clindamycin withdrawal.

Cholestasis with hepatitis is a frequent type of hepatic drug reaction and it is characterized by conspicuous cholestasis with hepatocellular injury. Histological lesions may show lobular and portal tract inflammation, often with neutrophils, eosinophils or mononuclear cells^[4]. The clinical spectrum of cholestatic hepatitis was indicated in our case by pruritis and jaundice. It was also reflected by the markedly elevated liver tests, with increased serum bilirubin, GGT and ALP. Cases of mixed cholestasis and hepatitis are considered highly suggestive of a drug reaction^[5].

To exclude dilation of large bile ducts produced by biliary obstruction, and hepatic or pancreatic masses, hepatobiliary imaging is essential. Ultrasound is the most preferred method to rule out possible bile duct obstruction. Endoscopic retrograde cholangiopancreatography, percutaneous transhepatic cholangiography or computed tomography may be necessary in difficult cases. In the absence of the symptoms mentioned earlier, drug-induced cholestasis is more likely, and a liver biopsy is often advisable. Certain histological findings, such as lobular and portal tract inflammation, suggest a hepatic drug reaction, whereas others such as edema of the portal tracts suggest biliary obstruction. When the temporal relationship to drug ingestion indicates a high probability of a drug reaction, particularly when the agent is known to be potentially hepatotoxic, it is appropriate to discontinue the incriminated drug and observe whether improvement occurs. Recovery may be seen rapidly if the drug is discontinued before severe liver injury is established^[6].

Hepatocytes, because of their capability to metabolize drugs, form minute amounts of drug-protein adducts, for which the immune system normally shows tolerance. Hypersensitivity reactions occur when this tolerance is impaired. Additional signals, such as a concomitant inflammatory reaction, may eventually be needed to break this tolerance. The allergic hepatitis induced by drugs is generally a type IV hypersensitivity reaction involving CD4+, CD8+ cytotoxic lymphocytes, as well as natural killer cells. Antibodies directed to the drug are much less common. Antibodies against cellular components may, however, occur when the sensitization process evolves towards an autoimmune reaction^[7,8]. In our patient, autoantibodies were negative and several features, such as the absence of

predictable dose-dependent toxicity of clindamycin and pruritis (hypersensitivity manifestations), were consistent with a metabolic type of idiosyncratic toxicity.

Clindamycin is a widely used antibiotic that is available in many countries. Previously, another case of hepatotoxicity associated with use of clindamycin has been reported, in which the clinicopathological spectrum encompassed cholestatic liver disease with portal inflammation, bile duct injury and bile duct paucity (ductopenia). In the same patient, a second biopsy after clinical recovery showed resolution of cholestasis but persistence of duct paucity, whereupon the authors concluded that early onset hepatic injury with cholestasis and duct paucity may occur after clindamycin use, and long term duct paucity may persist on repeat biopsy^[9]. Bile duct paucity as a biopsy finding was not significant in our patient.

In summary, with this report, we presented a case of hepatotoxicity after 6 d of oral clindamycin treatment for dental infection. The toxicity appeared to be associated with drug use. In conclusion, although rare, mixed-type (hepatocellular and cholestatic) hepatic injury might be associated with clindamycin use in some cases. Patients may present with fatigue, nausea, vomiting, anorexia, pruritis and jaundice. Complete recovery may be possible if the drug is discontinued before critical liver injury is established.

Received: June 7, 2007 Revised: July 23, 2007

Abstract

Adverse effects associated with peginterferon and ribavirin during hepatitis C treatment are well known. Sudden hearing loss has rarely been reported. Possible mechanisms involved include direct ototoxicity of interferon, autoimmunity, and hematological changes. Hearing loss is frequently fully resolved after discontinuation of antiviral therapy. We report a 47-year-old man with chronic hepatitis C, genotype 2 ac who developed sudden hearing loss 22 wk after starting therapy with peginterferon alpha 2a at a dose of 180 µg per week and ribavirin 800 mg per day. Since symptoms did not worsen, antiviral therapy was continued for 2 wk, according to the patient's wish. Hearing loss resolved within 2 wk after the end of treatment. Serum liver alanine aminotransferase remained normal during and after the end of antiviral therapy. HCV RNA was undetectable at the end of therapy and remained negative 24 wk later. Thus, patients should be aware that hearing loss may occur with peginterferon therapy, but the decision whether to continue or to stop the treatment is based on the clinical judgment of the physician and the wishes of the patient.

Elloumi H, Houissa F, Hadj NB, Gargouri D, Romani M, Kharrat J, Ghorbel A. Sudden hearing loss associated with peginterferon and ribavirin combination therapy during hepatitis C treatment. *World J Gastroenterol* 2007; 13(40): 5411-5412

<http://www.wjgnet.com/1007-9327/13/5411.asp>

INTRODUCTION

Chronic hepatitis C affects 250-300 million people worldwide, and in Tunisia, the prevalence is estimated to be 0.4%-1.6% of the general population^[1-3]. The higher prevalence is in the north which corresponds to the south side of the Mediterranean basin. The most frequent genotype in Tunisia is 1b^[4].

Treatment of hepatitis C virus infection with the combination of peginterferon alpha (2a or 2b) and ribavirin therapy is now recommended^[5,6]. Both peginterferon and ribavirin are well known to be associated with significant adverse effects^[7]. Hearing loss has been reported as a consequence of therapy with pegylated and non-pegylated interferon^[8-10]. However, we still pay little attention to auditory acuity. Moreover, contrary to standard interferon, hearing loss seems to not be fully resolved after discontinuation of peginterferon treatment^[8,10].

We report a case of sudden hearing loss in a patient with HCV infection treated with a combination of peginterferon and ribavirin. The interesting aspect of our case is that peginterferon therapy was continued during the last month and hearing loss was fully resolved after the end of treatment.

CASE REPORT

A 47-year-old Tunisian man with chronic hepatitis C, with 10⁶ UI/L HCV RNA and genotype 2a/2c, attended the Gastroenterology Department for follow-up. He did not have any pathological history and he had not taken any drugs prior to his visit. His initial physical and neurological examinations were normal. Serum levels of glucose, urea, creatinine, lipids, electrolytes, alkaline phosphatase, bilirubin, gammaglutamyl transferase, blood cell count, ferritin and cryoglobulin were within normal limits. Alanine aminotransferase (ALT) was 62 UI/L (upper limit of normal < 45), aspartate aminotransferase (AST) was 39 UI/L (upper limit of normal < 45 UI/L). Antinuclear, smooth muscle, anti-liver-kidney microsome 1 and anti-mitochondrial antibodies were negative. He was treated with peginterferon alpha 2a (180 µg/wk) and ribavirin (800 mg/d) for a predetermined period of 24 wk. Twenty-two weeks after beginning therapy, he developed otalgia and sudden onset of left-sided hearing loss. He was seen in consultation by an otolaryngologist who reported that ear examination was normal. Since

symptoms did not worsen, and in accord with the patient's wishes, antiviral therapy was continued for 2 wk. Hearing loss resolved within 2 wk after the end of treatment. Serum liver ALT remained normal during and after the end of antiviral therapy, and no sign of thrombocytopenia was detected during blood cell count monitoring. HCV RNA was undetectable at the end of therapy and remained negative 24 wk later.

DISCUSSION

This is another report on sudden hearing loss after treatment with peginterferon alpha, which adds to the observations made in patients treated with peginterferon and standard interferon for chronic hepatitis C^[8-11]. Such hearing loss is mostly unilateral and sensorineural^[12]. In one prospective study of 73 patients receiving interferon, hearing impairment (tinnitus and/or hearing loss) occurred in 32 patients (43.8%), among whom audiometry documented hearing loss in 27 cases (36.9%)^[13].

Several factors may cause sensorineural hearing loss in patients treated with interferon. First, the drug itself may be directly toxic to the auditory nerve hairy cells^[9]. Also, an indirect effect of interferon due to its immunoregulatory and antiviral activity can explain this sensorineural pathology. Cadoni has detected anti-endothelial-cell antibodies in an HCV patient with sudden hearing loss during interferon therapy^[11]. The finding of these antibodies suggests microvascular damage during therapy for vasculitis. In addition, interferon-induced thrombocytopenia may cause a microvascular accident in the inner ear.

Some authors have reported that hearing loss fully resolves 5 d to 1 mo after discontinuation of antiviral therapy with interferon^[9,14]; whereas others have demonstrated that hearing impairment does not completely recover after cessation of peginterferon, and worsens with continued treatment^[8,10].

In the case reported here, hearing loss fully resolved after the end of treatment with peginterferon. Auditory disability frequently develops in the later stages of treatment^[15]; in our case, it developed 2 wk before the end of the treatment (i.e., after 22 wk).

The average cumulative dose until development of auditory disability is about 176.9 mV^[13]. In a recent study, hearing loss was detected in nine of 27 patients after 7 d, and the degree of hearing loss increased until 21 d of treatment^[14]. Therefore, it is recommended that patients on interferon therapy should be monitored during treatment for changes in hearing perception. It remains possible that those who develop hearing loss can continue with inter-

feron therapy. The decision whether to continue or to stop the treatment when signs of ototoxicity appear is based on the clinical judgement of the treating physician and the wishes of the patient.

INTRODUCTION

Recurrence and metastasis are the major obstacles to further improve the prognosis of hepatocellular carcinoma (HCC). Tumor recurrence is common after hepatic resection of huge HCC greater than 10 cm in diameter. The overall 1- and 3-year survival rates are 66% and 44%, respectively. The overall 5-year survival ranges from 11% to 76%, with a median around 30% after hepatectomy^[1]. Extrahepatic recurrence occurs in 30% of the patients. Resection of isolated extrahepatic HCC metastasis has been advocated to obtain a possibility of long-term survival^[2,3]. Accurate re-staging plays the most important role in making a decision on extrahepatic metastasis resection. Nowadays, PET/CT is more and more widely available, and its application with 18F-FDG in oncology has become one of the standard imaging modalities in diagnosing, staging and re-staging HCC^[4]. We present here a patient with huge HCC resected six years ago and a new omental lymph node metastasis recently identified by 18 F-FDG PET/CT. Long-term survival was achieved in this patient after resection of the omental lymph node metastasis.

CASE REPORT

A 60-year old woman with a medical history of HBV infection and no cirrhosis was referred to our hospital for a liver tumor found by coincidence. The AFP level was 13.4 ng/mL. HCC was suspected (Figure 1) and a left hemihepatectomy was performed in December 2000. Histology showed a HCC (Edmondson-Steiner's grade I) with a diameter of 13.0 cm with central necrosis. No microscopic vascular invasion was found. After partial liver resection, AFP values returned to normal. The patient accepted transcatheter arterial chemo-embolization (TACE) treatment 1 mo after hepatectomy and no special change was found during angiography. After 78 mo of follow-up, her AFP increased to 597.8 ng/mL. Conventional chest and abdominal CT did not find any evidence of intrahepatic recurrence and extrahepatic metastasis. To find out the reason for AFP increasing, the patient was referred to our center for a whole body PET/CT examination. 18F-FDG PET/CT detected a high metabolic lymph node in the omental position (Figure 2). Due to the maximum stan-

Abstract

Hepatocellular carcinoma (HCC) is one of the most common primary cancers in the world. Surgery is the gold standard for treatment of patients with HCC. Recurrence and metastasis are the major obstacles to further improve the prognosis of HCC. Most recurrences are intrahepatic. However, 30% of the recurrences are extrahepatic. The role of resection in intrahepatic recurrences is widely accepted. The role of resection in extrahepatic HCC recurrence and metastasis is not well established. 18F fluorodeoxyglucose (18F-FDG) positron emission tomography/computer tomography (PET/CT) is useful in detecting distant metastasis from a variety of malignancies and shows superior accuracy to conventional imaging modalities in identification of intrahepatic and extrahepatic metastasis. We present one patient with one new isolated omental lymph node metastasis, who had a history of huge HCC resected six years ago. The metastatic focus was identified with 18 F-FDG PET/CT and resected. The follow-up revealed good prognosis with a long-term survival potential after resection of the omental lymphatic metastasis.

Sun L, Guan YS, Pan WM, Chen GB, Luo ZM, Wu H. Positron emission tomography/computer tomography in guidance of extrahepatic hepatocellular carcinoma metastasis management. *World J Gastroenterol* 2007; 13(40): 5413-5415

Figure 1 Contrast CT demonstrating a huge lesion at the left lobe of liver (black arrows, portal phase).

standard uptake value (SUVmax), lymph node metastasis was considered. The high metabolic lymph node was excised. Histopathological examination of the resected nodule revealed a metastatic hepatocellular carcinoma. After excision of the tumor, her AFP level decreased to normal. Ten months after resection of the extrahepatic metastasis and 88 mo after partial liver resection, the patient was in good condition with no recurrence at the time when we wrote this paper.

DISCUSSION

HCC over 10 cm in diameter is found in a number of patients undergoing hepatic resection. A large HCC has its specific clinicopathological features. Multiple tumor nodules, venous invasion and impaired liver function are factors associated with its recurrence^[5]. Hepatic resection of HCC with a diameter ≥ 10 cm at stage II or III is safe and effective for selected patients without liver cirrhosis. The overall incidence of postoperative complications is 39%. The 3-, 5- and 9-year overall survival rates after hepatic resection are 32%, 27%, and 17%, respectively^[6]. Appropriate selection of candidates for partial hepatectomy based on the above prognostic factors may play an important role in decreasing the high mortality rate and poor long-term survival of such patients^[7].

Approximately 50% of patients with resected HCC may have tumor recurrence. The overall 1-, 3- and 5-year disease-free survival rates are reported to be 43%, 26% and 20%, respectively^[1]. Thus, it is of importance to predict its relapse and treat it with other modalities^[8]. The role of resection in case of intrahepatic recurrences is widely accepted. If the distribution and localization of extrahepatic metastasis are fully confirmed, these lesions may be resected. In our case, conventional CT did not find any intrahepatic and extrahepatic metastasis. However, the whole body PET/CT detected isolated extrahepatic metastasis which we treated with surgery. 18F-FDG PET/CT is not only a useful tool for preoperative staging, but also a follow-up means better than conventional diagnostic modalities, especially for staging and re-staging after hepatectomy.

In case of an AFP producing HCC, unexplained rise of serum AFP after treatment is an early indicator of tu-

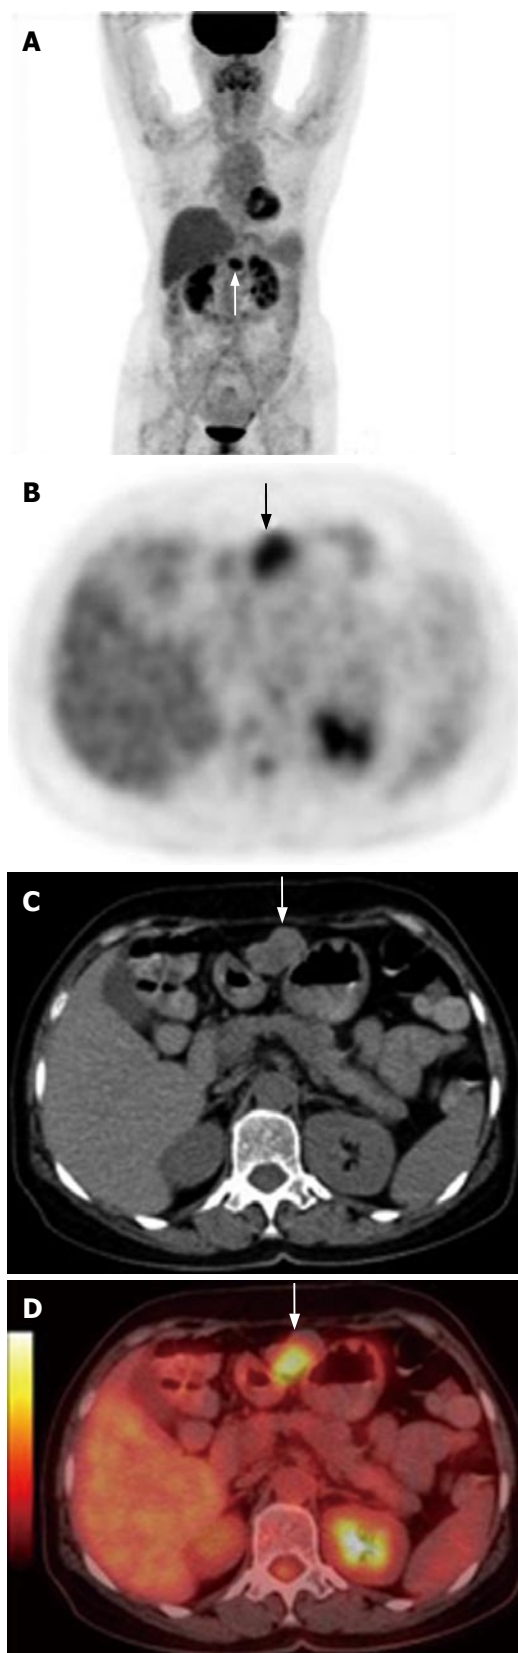

Figure 2 Whole body PET showing an isolated highly metabolic focus in the upper abdomen (white arrow) (A), non-enhanced CT (C) detecting a median density lesion in the omentum (white arrow), ¹⁸F-FDG PET (B) and fused imaging of PET/CT (D) revealing a highly metabolic lesion at the same position.

mor recurrence or extrahepatic metastasis. However, the sensitivity of conventional imaging techniques is limited in detecting recurrent diseases in such patients^[9]. 18F-FDG

PET/CT has proved to be an effective whole-body imaging technique that detects metabolic changes preceding structural findings. It was reported that tumor restaging with PET/CT can detect and localize disease recurrence among patients with no or mild symptoms and an elevated tumor marker level^[10]. PET/CT also can provide information about whether the detected disease is resectable. 18F-FDG PET/CT provides fused images that demonstrate the complementary role of functional and anatomic assessments in the diagnosis of cancer recurrence through the precise localization of suspected 18F-FDG uptake foci and their characterization as malignant or benign^[11].

TACE is a procedure involving injection of chemotherapeutic agents into the hepatic artery supplying the tumor, followed by embolization with lipiodol or gelfoam pieces. It appears that postoperative adjuvant hepatic arterial chemotherapy is more likely beneficial for preventing recurrence than preoperative TACE. To date, convincing evidence supporting the effectiveness of adjuvant therapy in preventing HCC recurrence is lacking. Validated information in the literature is limited in a paucity of randomized studies. It was reported that meaningful meta-analysis is impossible because of different therapeutic regimens used and the lack of stratification of patients according to the risk of recurrence^[12]. Better understanding of biological characteristics of HCC can lead to better outcomes of adjuvant surgical treatment^[13]. For example, if patients at a high risk of HCC recurrence could be identified before the resection, they would benefit from additional treatment modalities, such as neoadjuvant therapy, adjuvant therapy and biotherapy. It is not necessary for patients at a low risk of tumor recurrence to receive the above therapies^[14]. Molecular imaging in oncology is the noninvasive imaging of the key molecules and molecule-based events characterized by the genotype and phenotype of human cancer. Tumors with increased 18F-FDG uptake are more metabolically active and biologically aggressive. PET/CT with 18F-FDG would play a key role in evaluating recurrence risk of HCC before hepatectomy^[15]. Further research is warranted because of the limited number of reports and the absence of randomized trials.

Aggressive management with combined resection of isolated extrahepatic recurrence and re-resection or local therapy for intrahepatic recurrence may offer long-term survival in selected HCC patients. Our case demonstrates that 18F-FDG PET/CT provides the most significant additional information related to the accurate detection of extrahepatic spread of tumors and additional important information in patients with presumed resectable extrahepatic metastases. This test should be used for patients at a high risk of extrahepatic disease and should be evaluated prospectively for all patients under consideration for intra-

hepatic recurrence and extrahepatic metastasis resection.

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (WJG, *World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly journal of more than 48 000 circulation, published on the 7th, 14th, 21st and 28th of every month.

Original Research, Clinical Trials, Reviews, Comments, and Case Reports in esophageal cancer, gastric cancer, colon cancer, liver cancer, viral liver diseases, etc., from all over the world are welcome on the condition that they have not been published previously and have not been submitted simultaneously elsewhere.

Indexed and abstracted in

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, *Index Medicus*, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, *Nature Clinical Practice Gastroenterology and Hepatology*, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

WJG

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297 mm × 210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, acknowledgements, References, Tables, Figures and Figure Legends. Neither the editors nor the Publisher is responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of WJG, and may not be reproduced by any means, in whole or in part without the written permission of both the authors and the Publisher. We reserve the right to put onto our website and copy-edit accepted manuscripts. Authors should also follow the guidelines for the care and use of laboratory animals of their institution or national animal welfare committee.

Authors should retain one copy of the text, tables, photographs and illustrations, as rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for the loss or damage to photographs and illustrations in mailing process.

Online submission

Online submission is strongly advised. Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/index.jsp>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. Authors encountering problems with the Online Submission System may send an email you describing the problem to wjg@wjgnet.com for assistance. If you submit your manuscript online, do not make a postal contribution. A repeated online submission for the same manuscript is strictly prohibited.

Postal submission

Send 3 duplicate hard copies of the full-text manuscript typed double-spaced on A4 (297 mm × 210 mm) white paper together with any original photographs or illustrations and a 3.5 inch computer diskette or CD-ROM containing an electronic copy of the manuscript including all the figures, graphs and tables in native Microsoft Word format or *.rtf format to:

Editorial Office

World Journal of Gastroenterology

<http://www.wjgnet.com>
Telephone: +86-10-85381892
Fax: +86-10-85381893

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using a word-processing software. All submissions must be typed in 1.5

line spacing and in word size 12 with ample margins. The letter font is Tahoma. For authors from China, one copy of the Chinese translation of the manuscript is also required (excluding references). Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was accomplished, disclosure of any financial support for the research, and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (removing all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s) and full family name.

Abstract

An informative, structured abstract of no more than 350 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipments, and the experimental procedures should be included. RESULTS: The observatory and experimental results, including data, effects, outcome, etc. should be included. Authors should present *P* value where necessary, and the significant data should accompany. CONCLUSION: Accurate view and the value of the results should be included.

The format of structured abstracts is at: <http://www.wjgnet.com/wjg/help/11.doc>

Key words

Please list 5-10 key words that could reflect content of the study mainly from *Index Medicus*.

Text

For most article types, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include in appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both.

Illustrations

Figures should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. No detailed legend should be involved under the figures. This part should be added into the text where the figures are applicable. Digital images: black and white photographs should be scanned and saved in TIFF format at a resolution of 300 dpi; color images should be saved as CMYK (print files) but not as RGB (screen-viewing files). Place each photograph in a separate file. Print images: supply images of size no smaller than 126 mm × 85 mm printed on smooth surface paper; label the image by writing the Figure number and orientation using an arrow. Photomicrographs: indicate the original magnification and stain in the legend. Digital Drawings: supply files in EPS if created by freehand and illustrator, or TIFF from photoshops. EPS files must be accompanied by a version in native file format for editing purposes. Existing line drawings should be scanned at a resolution of 1200 dpi and as close as possible to the size where they will appear when printed. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes of atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...

Tables

Three-line tables should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each table. No detailed legend should be included under the tables. This part should be added into the text where the tables are applicable. The information should complement but not duplicate that contained in the text. Use one horizontal line under the title, a second under the column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. ^a*P*<0.05, ^b*P*<0.01 should be noted (*P*>0.05 should not be noted). If there are other series of *P* values, ^c*P*<0.05 and ^d*P*<0.01 are used. Third series of *P* values can be expressed as ^e*P*<0.05 and ^f*P*<0.01. Other notes in tables or under

illustrations should be expressed as 1F , 2F , 3F ; or some other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, etc. in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions are included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should code the references according the citation order in text in Arabic numerals, put references codes in square brackets, superscript it at the end of citation content or the author name of the citation. For those citation content as the narrate part, the coding number and square brackets should be typeset normally. For example, Crohn's disease (CD) is associated with increased intestinal permeability^[1,2]. If references are directly cited in the text, they would be put together with the text, for example, from references [19,22-24], we know that...

When the authors code the references, please ensure that the order in text is the same as in reference part and also insure the spelling accuracy of the first author's name. Do not code the same citation twice.

PMID requirement

PMID roots in the abstract serial number indexed by PubMed (<http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed>). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information of the journal citations is very important. Through reference testing system, the authors and editor could check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in ASP file so that the readers can read the abstract of the citations online immediately.

Style for journal references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). Title of the cited article and italicized journal title (Journal title should be in its abbreviation form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634]

Note: The author should test the references through reference testing system (<http://www.wjgnet.com/cgi-bin/index.pl>)

Style for book references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Morse SS. Factors in the emergence of infectious diseases. Emerg Infect Dis serial online, 1995-01-03, cited 1996-06-05; 1(1): 24 screens. Available from: URL: <http://www.cdc.gov/ncidod/EID/eid.htm>

Patent (list all authors)

- 16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those that are linked with a hyphen and the difference between the two numbers at two sides of the hyphen is more than 5. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered as inappropriate references. Authors should not cite their own unrelated published articles.

Statistical data

Present as mean \pm SD or mean \pm SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as γ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p*(B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4 \pm 2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5 μ g/L; CO₂ volume fraction, 50 mL/L CO₂ not 5% CO₂; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format about how to accurately write common units and quantum is at: <http://www.wjgnet.com/wjg/help/15.doc>

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further mention.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kbo I*, *Kpn I*, etc.

Biology: *H pylori*, *E coli*, etc.

SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. Author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, the final check list for authors, and responses to reviewers by a courier (such as EMS) (submission of revised manuscript by e-mail or on the *WJG* Editorial Office Online System is NOT available at present).

Language evaluation

The language of a manuscript will be graded before sending for revision.

(1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing; (4) Grade D: rejected. The revised articles should be in grade B or grade A.

Copyright assignment form

Please download CAF from <http://www.wjgnet.com/wjg/help/9.doc>.

We certify that the material contained in this manuscript:

Ms:

Title:

is original, except when appropriately referenced to other sources, and that written permission has been granted by any existing copyright holders. We agree to transfer to *WJG* all rights of our manuscript, including: (1) all copyright ownership in all print and electronic formats; (2) the right to grant permission to republish or reprint the stated material in whole or in part, with or without a fee; (3) the right to print copies for free distribution or sale; (4) the right to republish the stated material in a collection of articles or in any other format. We also agree that our article be put on the Internet.

Criteria for authorship: The *WJG* requests and publishes information about contributions of each author named to the submitted study. Authorship credit should be based on (1) direct participation in the study, including substantial contributions to conception and design of study, or acquisition of data, or analysis and interpretation of data; (2) manuscript writing, including drafting the article, or revising it critically for important intellectual content; (3) supportive work, including statistical analysis of data, or acquisition of funding, or administration, technology and materials support, or supervision, or supportive contributions. Authors should meet at least one of the three conditions. The *WJG* does not publish co-first authors and co-corresponding authors.

We hereby assign copyright transfer to *WJG* if this paper is accepted.

Author Name in full (Full names should be provided, with first name first, followed by middle names and family name at the last, eg, Eamonn MM Quigley). Handwritten names are not accepted.

Author Name in abbreviation (Family name is put first in full, followed by middle names and first name in abbreviation with first letter in capital, eg, Quigley EMM). Handwritten names are not accepted.

Final check list for authors

The format is at: <http://www.wjgnet.com/wjg/help/13.doc>

Responses to reviewers

Please revise your article according to the comments/suggestions of reviewers. The format for responses to the reviewers' comments is at: <http://www.wjgnet.com/wjg/help/10.doc>

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Publication fee

Authors of accepted articles must pay publication fee.

EDITORIAL and LETTERS TO THE EDITOR are free of charge.
