## Abstract

**AIM:** To assess the incidence of infantile colic and its association with variable predictors in infants born in a community maternity hospital, Tehran, Iran.

**METHODS:** In this prospective cohort study, mothers who gave birth to live newborns between February 21 and March 20, 2003 at the hospital were invited to join to the study. For every infant-mother dyad data were collected on infant gender, type of delivery, gestational age at birth, birth weight, birth order, and mother's reproductive history. Then mothers were given a diary to document the duration of crying/fussiness behaviors of their infants for the next 12 wk. We scheduled home visits at the time the infants were 3 mo of age to collect the completed diaries and obtain additional information on infants' nutritional sources and identify if medications were used for colic relief. Cases of colic were identified by applying Wessel criteria to recorded data. Chi-square and Mann-whitney *U* tests were used to compare proportions for non-parametric and parametric variables, respectively.

**RESULTS:** From 413 infants, follow-up was completed for 321 infants. In total, 65 infants (20.24%) satisfied the Wessel criteria for infantile colic. No statistical significance was found between colicky and non-colicky infants according to gender, gestational age at birth, birth weight, type of delivery, and, infant's feeding pattern. However, firstborn infants had higher rate for developing colic ( $P = 0.03$ ).

**CONCLUSION:** Colic incidence was 20% in this popu-

lation of Iranian infants. Except for birth order status, no other variable was significantly associated with infantile colic.

## INTRODUCTION

Infantile colic refers to a behavioral syndrome occurring during the first 3 mo of life. Crying is the core symptom, but clinicians differ on what other behaviors constitute the syndrome. By far the most widely used quantitative definition of colic is the one proposed by Wessel & his colleagues known as the "rule of threes"<sup>[1]</sup>.

Infants are considered to have colic if they cry for more than 3 h a day, for more than 3 d a week, and for more than 3 wk. It is usually self-limiting, without long term adverse consequences, but caring for an infant with colic can be distressing and frustrating for parents<sup>[2]</sup>. Estimates of cumulative incidence have varied from 10% to 40%<sup>[3-7]</sup>. This wide range may reflect differences in definitions, methods of data gathering, and study design<sup>[3,8]</sup> but also it may be related to a true difference in the occurrence rate of infantile colic among different communities. Notably, most studies are from western societies and many reviews only use data from selected populations<sup>[9-13]</sup>. While, due to the possible contribution of psychosocial factors to colic incidence<sup>[14-17]</sup>, it is unclear whether the data from developed countries can be applied to others, there are scarce reports on colic incidence from developing countries. On December 1, 2007 we performed a Medline search (1966-2007) using "colic"

as a text free word. The search was limited to "humans" and "infants (age up to 23 mo)". No other limitation was made in order to contain the search sensitivity. The Medline search revealed 795 citations. No study was found to evaluate the occurrence rate of infantile colic in the Middle East countries. We conducted this study in an effort to contribute new data from Iran as well as to identify risk factors for developing infantile colic.

## MATERIALS AND METHODS

### **Study setting and subjects**

This prospective cohort study was performed in Shahid Akbar Abadi maternity hospital, a high volume maternity hospital that serves as a major facility for a non-selected population of pregnant women in the southern part of Tehran, Iran; the majority of them having no medical problem. Anticipating the prevalence of colic in infants less than 3 mo to be 25% and absolute precision to be 5% ( $d = 0.05$ ), the chance of which should be at least 95%; a sample size of 289 was required. Considering the average hospital census of about 500 live births per month, and predicting a drop-out rate of up to 40% for nonparticipation or follow-up losses, we chose to consecutively include all live births at the hospital throughout a month period. Accordingly, between February 21 and March 20, 2003, all mothers of newborn babies at the hospital were invited to join the study.

### **Data collection**

Upon agreement to enter to the study, for every infant-mother dyad data were extracted from hospital files on infant gender, type of delivery, gestational age at birth, birth weight, birth order, and mother's reproductive history. Whenever the data were obscure or insufficient in charts, clarification was made by direct interviews with mothers. Within 3 d of delivery and before leaving the hospital, participating mothers received a 12 sheet diary leaflet, for the coming 12 wk. The diary format was based on a design introduced by Canivet *et al* elsewhere<sup>[18]</sup>. Briefly, it included a detailed form with squares for every 5 min period of 24 h for one predetermined day (Wednesday) of each week. Parents noted "crying" and "fussiness" separately and recorded them at their earliest convenience with letter symbols in relevant blocks on Wednesdays. The selection of 1 d out of a week, was a compromise to improve parents compliance in filling the forms and, therefore, to improve the diagnostic quality of estimating crying duration. As to the other 6 d of the week, parents made an estimation of crying and fussing time. Mothers were told not to register episodes of crying that were without any doubt related to hunger, fatigue or diaper changing. The crying thus had to cease instantly when the baby was fed, had fallen asleep, or when the diaper change was completed, and in no case continue for more than 5 min.

### **Follow-up**

When the children assessed in the perinatal study were 3 mo old, a home visit was made in order to obtain ad-

ditional information on whether medication had been required to manage crying/fussing lasted 1 wk or more, whether feeding formula had been added to or substituted for breast milk by the age of 2 mo and finally to collect the diaries. Arrangement was made to set the date of home visit not to exceed a time frame of  $\pm 3$  d from the exact age of 3 mo for any individual infant. Cases of colic were identified by applying Wessel criteria to recorded data. Crying and fussiness both were accounted for colic identification. We also accepted colic when crying/fussing continued for 3 h per day on 3 d for at least 1 wk and needed drug intervention to be controlled. This has been known as Wessel medication subcriterion<sup>[18]</sup>. We excluded cases if the diary questionnaire was returned incomplete or could not be reached, or if the infant was not alive by the age of 3 mo.

### **Statistical analysis**

The statistical analysis was performed using SPSS 11 for Windows. Chi-square was used for comparison of proportions. For reporting of results only variables with a *P* value less than or equal to 0.05 was considered significant.

## RESULTS

### **Baseline and follow-up data**

During the enrollment period a total of 442 infants were born from 437 mothers; 29 infants were not included in the study as their mothers chose not to be enrolled ( $n = 18$ ) or could not reliably fill in the diaries as they were illiterate ( $n = 11$ ). As a result 413 infants were initially entered to this study. At the follow-up visit 90 infants were excluded from the study-as parents could not be reached at home either due to nonattendance or moving to another address ( $n = 49$ ) or their diaries returned incomplete ( $n = 41$ ). We also excluded 2 premature infants who died early in their neonatal period. The rate of overall drop-out after enrolling to the study was 22%. Of 316 successful home visits, we gathered complete data for 321 infants (312 were singletons, 3 twins, and 1 triplet). Subsequent analyses were performed on these 321 infants who completed the study protocol. Of them, 168 cases (52.3%) were male and 153 (47.7%) were female. The range of birth orders was from 1 to 8; with the most frequent one was the first order which comprised 169 infants (52.6%). According to gestational age at birth, 229 infants (71.3%) were born full-term, 85 (26.5%) pre-term and 7 (2.2%) post-term. Type of delivery was vaginal delivery in 198 cases (61.7%) and cesarean section in 123 cases (38.3%). The mean  $\pm$  SD of birth weights was  $3072 \pm 580$  g (range: 1200-5000 g). In total, 57 infants (17.7%) had a low birth weight (< 2500 g). By 2 mo of age, the frequencies of exclusive breast-fed, exclusive formula-fed, and complementary-fed infants were 273 (85%), 17 (5.3%), and 31 (9.7%), respectively.

### **Colic incidence and risk factors**

In total, 65 infants fulfilled the Wessel criteria for infantile colic; all had cry/fuss behaviors of at least 3 h a day on

**Table 1 Comparison of potential predictors of infantile colic in colicky and non-colicky subgroups**

Factor	Colicky group (n = 65)	Non-colicky group (n = 256)	P
Gender			
Male	31	137	
Female	34	119	
Ratio	0.91	1.15	0.40
Mode of delivery			
Vaginal	42	156	
Cesarean	23	100	
Ratio	1.82	1.56	0.58
Gestational age at birth			
≥ 37 wk	45	191	
< 37 wk	20	65	
Ratio	2.25	2.93	0.38
Birth weight			
≥ 2500 g	50	214	
< 2500 g	15	42	
Ratio	3.33	5.09	0.21
Birth order			
First born	42	127	
Later born	23	129	
Ratio	1.82	92	0.03
Mode of feeding			
Exclusive breastfed	54	219	
Non-exclusive breastfed	11	37	
Ratio	4.90	4.76	0.24

3 d per week, lasting for 3 wk or more. No infant met the Wessel medication subcriterion i.e. their symptoms resolved after 1 wk by taking medication. Overall, the cumulative incidence rate of colic was found to be 20% in this study.

The frequency of selected potential risk factors for infantile colic in colicky and non-colicky subgroups has been demonstrated in Table 1.

Being the firstborn infant was more probable in colicky population ( $P = 0.03$ ), but no significant difference for other variables including gender, mode of delivery, gestational age at birth, birth weight, and mode of feeding was found between the two subgroups.

## DISCUSSION

The cumulative incidence rate of colic in the first 3 mo of infancy was 20% in this study. This rate is in concert with most reports from developed countries<sup>[3]</sup>. We enrolled all the infants whose mothers consented to participate in the study if they were literate enough to reliably fill in the diary. We did not exclude the infants born prematurely and/or needed special care at neonatal care unit. The only two infants who died over the study period (both within 2 wk after enrollment) were excluded from the study, as there was no chance to detect colic.

It has been claimed that surveys recruiting cases from well baby clinics reported lower occurrence rates compared to recruitment from birth-registered hospitals<sup>[3]</sup>. Hence, according to the non-selective design of our inclusion criteria and the site of the study which was a maternity hospital, the rate of 20% for infantile colic may be considered an overestimate if the figure

is to be extrapolated to the reference community. Nonetheless, in urban areas in Iran, the vast majority of all births occur in hospitals. In such settings, the results of prevalence studies on newborns in hospital settings could be considered representative of general population.

It has been suggested that the vast majority of infants with colic are presented by the age of 6 wk. Collection of cry/fuss data at this time point was expected to capture most cases of colic because the sixth week of life represents the peak of infant crying<sup>[19]</sup>. Colic is widely believed to remit by 3 mo of age<sup>[1,2]</sup>. Therefore it would be improbable that we missed significant number of colics by following the infants for 90 d.

We defined the occurrence of colic using the criteria proposed by Wessel, which are the criteria for diagnosis of colic in infants, which has gained most acceptance<sup>[19]</sup>. Although we also adopted Wessel medication subcriterion for colic definition, not even a single case required to be enrolled only by this definition. The popularity of colic definition in this study would make our results more comparable with the counterpart studies from western societies.

The reported occurrence rates of infantile colic vary within a wide range up to 40%. There is a tendency to attribute the different results to inconsistencies in case definitions and study protocols<sup>[3]</sup>. Little attention has been paid to the possibility of true epidemiological differences, probably due to paucity of qualified data from non-Western societies. Different diet and care taking activities, both of potential relevance to colic incidence<sup>[3]</sup> between developed and developing countries make comparative studies more plausible. Two retrospective studies published from India and Brazil revealed colic prevalence of 16% and 16.3%, respectively<sup>[12,20]</sup>. In a prospective study of 160 Korean infants, no case of infantile colic was found<sup>[21]</sup>. Interestingly, the latter survey was adequate according to the quality criteria in this study as the researchers use a 24 h diary and a definition of infantile colic that included a time criteria<sup>[3]</sup>.

The only variable showed to be predictive of colic development in this study was the birth order. Other factors including gender, weight at birth, type of delivery, mode of feeding and prematurity were not associated with the development of colic. The literature is very controversial in defining the risk factors for colic. Some methodological issues have been blamed to be responsible. Those include inconsistent definitions for colic, the failure to control covariates, and potentially biased assessments of exposure and/or outcome variables because of non-prospective study designs<sup>[19]</sup>.

Our study showing no difference regarding gender for colic presentation is in accordance with most other reports<sup>[3,22-25]</sup>. In a systematic review only one study reported a significantly higher proportion of boys crying more than 3 h per day<sup>[3,22]</sup>. Mode of delivery was not associated with colic in our study, which is in agreement with a report by Hogdall *et al*<sup>[24]</sup>. Like our study, no association between colic and low birth weight was

found in Lucassen's review<sup>[3]</sup>. That is contradicting with Crowcroft's study<sup>[2]</sup>.

We were unable to demonstrate a protective role of exclusive breastfeeding on the development of colic. Among surveys compared breast fed and formula fed infants: four found no difference<sup>[17,18,26,27]</sup>, in three studies the occurrence rates among breast fed infants were slightly higher<sup>[2,28,29]</sup>, and in one it was slightly lower<sup>[22]</sup>. When analyzing the presence of association between breastfeeding and the development of colic, reverse causality is an important distorting factor, since the mother of crying children may stop breastfeeding because they relate the condition to feeding or believe that their milk is insufficient or weak. In order to prevent this deviation we used the same definition used by Saavedra *et al* in their cohort study, i.e. children were considered exclusively breastfed if they were receiving only their mother's milk at the onset of colic<sup>[28]</sup>.

Despite observing some trend toward less colic in breast fed subgroup we were not able to reproduce the results of the latter study. Our smaller sample size might have caused the inability to detect meaningful differences in subgroups, but methodological differences could be the reason. Data were collected retrospectively in that study applying a questionnaire by the time the infants were 3 mo of age. In our study data gathering was performed prospectively by using diaries. It seems further prospective studies are needed to resolve this issue.

Being first borne was the single predicting factor for colic in our study. Surprisingly, this association has been evaluated in very few studies. Crowcroft *et al* published similar result but Lucassen *et al* and Saavedra *et al* reported contradicting finding<sup>[2,3,28]</sup>, the latter although benefited from a large sample size, was a retrospective study.

To evaluate the incidence and risk factors of infantile colic, we took the primary advantage of cohort studies for being not susceptible to reverse causality distortions<sup>[28]</sup>. Furthermore, we used diaries to collect data on cry/fuss behaviors. The prospective design of the study yields more reliable estimates of occurrence rates than retrospective studies, as the latter are prone to recall bias<sup>[3]</sup>.

Our study had two main limitations. Firstly, this was a single-center study and accordingly prone to selection bias distorting the application of the results to the reference community. Admittedly, because of differences in referral pattern in community and private hospitals, we can not exclude this potential source for selection bias. Nevertheless, the site in which our study was performed is located in the southern part of Tehran, where a minority of births occurs in private hospitals. Secondly, we lost 22% of cases initially enrolled to the study. This may raise the possibility of selection bias in the results. Higher rates for drop-out, however, are usual in other prospective studies. Moreover, the part of case loss which might be more important to selection bias was the subgroup who excluded for having incomplete

diaries. This subgroup consisted of 41 infants (10%) out of 331 infants initially recruited, a figure which was reasonably low.

In summary, this was a rare prospective cohort study conducted in a developing country to detect the occurrence rate of colic. The cumulative incidence rate for colic was defined 20% in the study group. The only significant predictor for developing colic was being the first live-born infant. According to this study, similar to Western societies, infantile colic is a common condition in Iranian infants.

## COMMENTS

### Background

Published data from developing countries on the incidence and/or risk factors of infantile colic are scarce. The possible contribution of cultural, nutritional, and socioeconomical factors to colic development make it prudent to conduct more studies in developing countries.

### Research frontiers

There is consensus in the literature on the complexity of the nature and heterogeneity of the risk factors associated with infantile colic. Most data on this issue has been obtained from the studies conducted in Western societies, especially in North America and Scandinavian countries. Those populations differ in the frequency of many infantile colic risk factors from developing countries.

### Innovations and breakthroughs

Our study is one of the rare prospective studies which have ever performed in developing countries to define the infantile colic incidence and its associated risk factors. During 3 mo follow-up of a population of Iranian infants, around 20% met the Wessel criteria for infantile colic which is in concert with most reports from developed countries. We also found firstborn infants were at higher risk to develop colic.

### Applications

Despite difference in many demographical, social and cultural factors between developed and developing countries, we demonstrated a comparable incidence of infantile colic in our study population. Although further studies are needed to define colic incidence in developing countries, our results may suggest colic occurrence is not tightly related to social or cultural variables.

### Peer review

It's a well-written paper. The study showed that colic incidence was 20% in this population of Iranian infants. Except for birth order status, no other variable was significantly associated with infantile colic.

## INTRODUCTION

The internal anal sphincter (IAS) is the specialized continuation of the circular smooth muscle layer of the rectum. It is innervated by autonomic nerve system and plays an important role in anorectal physiology. Prominent nonadrenergic noncholinergic (NANC) innervations of IAS have been demonstrated<sup>[1-3]</sup>. *In vivo* and *in vitro* studies showed that the NANC neurons caused relaxation of the IAS<sup>[4-6]</sup>. The tonic resting pressure of IAS is called “anal resting pressure”. The IAS pressure has been found to display an overshoot phenomenon in the patients with chronic anal fissure<sup>[7,8]</sup>.

A number of drugs and chemicals were studied to decrease basal and precontracted tonus of IAS *in vitro*<sup>[9-14]</sup>. It has been shown that some drugs such as glyceryl trinitrate (GTN) and isosorbide dinitrate (ISDN) as nitric oxide (NO) donor might be used in treatment of chronic anal fissure<sup>[15,16]</sup>. However, prolonged exposure to high levels of nitroglycerine and other organic nitroesters is known to induce tolerance in the cardiovascular system drug both in humans and in experimental animals<sup>[17-20]</sup>. The same type of tolerance was also shown in rabbit penile tissue against relaxant effect of ISDN<sup>[21,22]</sup>.

It would be reasonable to expect that a similar type of tolerance may develop in internal anal sphincter smooth muscle against the relaxant effect of NO donating drugs. The present study is conducted to test this hypothesis, in rabbit IAS strips smooth muscle using ISDN as a tolerance-inducing agent.

## Abstract

**AIM:** To investigate the tolerance development against the relaxant effect of nitric oxide donating drug isosorbide dinitrate (ISDN) and sodium nitroprusside (SNP) in internal anal sphincter (IAS) smooth muscle.

**METHODS:** Relaxation responses of ISDN, and electrical field stimulation (EFS) were obtained before and after tolerance induction by ISDN incubation.

**RESULTS:** ISDN ( $10^{-7}$ - $10^{-4}$  mol/L) and SNP ( $10^{-8}$ - $10^{-4}$  mol/L) caused a concentration-dependent relaxation on the basal tonus of the isolated rabbit IAS strips. After a period of 2 h incubation of the  $6 \times 10^{-4}$  mol/L ISDN the relaxation effects of ISDN and SNP did not change compared to control strips. EFS evoked frequency-dependent relaxation in internal anal sphincter smooth muscle and  $E_{max}$  obtained from control strips were not changed in ISDN tolerance-inducing condition. In this study nitrate tolerance was not observed in rabbit IAS smooth muscle.

**CONCLUSION:** This result shows that nitric oxide donating drugs relaxes the internal anal sphincter of the rabbits without the development of tolerance.

## MATERIALS AND METHODS

### **Isolation of rabbit internal anal sphincter**

Twelve white New Zealand rabbit weighing between 2.5-3 kg were used in this study. Rabbits were sacrificed by cervical dislocation after sodium pentobarbital (40 mg/kg per body weight) anesthesia. The entire anal canal was isolated in continuation with a part of the rectum and transferred to oxygenated (95% O<sub>2</sub> and 5% CO<sub>2</sub>) Krebs' solution of following composition (mmol/L): NaCl, 118; KCl, 4.7; CaCl<sub>2</sub>, 2.5; NaHCO<sub>3</sub>, 25; MgSO<sub>4</sub>, 1.2; KH<sub>2</sub>PO<sub>4</sub>, 1.2, glucose, 11. The anal canal was carefully freed of all extraneous tissues. It was opened along its anterior wall, rinsed quickly, and pinned on a wax block containing oxygenated Krebs' solution, at its *in vivo* length as mucosa facing up. The mucosa was removed by sharp dissection under magnification. Distal 2 mm of the anal canal was used for preparation of 2 mm width and 1 cm long IAS smooth muscle strips. Each end of the IAS strips was tied with fine silk ligatures.

### **Measurement of isometric tension**

IAS strips transferred to 10 mL tissue baths containing oxygenated (95% O<sub>2</sub> and 5% CO<sub>2</sub>) Krebs' solution maintained at 37°C. One end of each strip was anchored to the bottom of the tissue bath, and other end was anchored to force transducer (model FT03 Grass Instruments Co., Quincy, MA) under an initial load of 2 g for the measurement of isometric tension on a pen polygraph recorder (model 79E Grass Instruments Co., Quincy, MA). After equilibration, relaxation responds of ISDN, SNP and Papaverine were obtained in different concentrations by adding these agents to the bath in a cumulative manner. Maximum relaxations induced by ISDN and SNP were expressed as the percentage of relaxation induced by papaverine.

### **Induction of ISDN tolerance**

After obtaining pre-incubation concentration-response curves with relaxant agents, IAS muscle strips were incubated by ISDN at a concentration of  $6 \times 10^{-4}$  mol/L for 2 h in different experiments in order to induce the tolerance. After exposure to the tolerance-inducing condition, strips were washed repeatedly with Krebs' solution for 15 min and then exposed cumulative concentrations of SNP, ISDN and papaverine again and post-incubation-response curves were obtained.

### **Electrical field stimulation (EFS)**

In another series of experiments, rabbit IAS muscle strips were electrically stimulated. Stimulation was provided *via* two parallel platinum electrodes. It was conducted at sequential frequencies of 2 Hz, 4 Hz, 8 Hz, 16 Hz as square-wave pulses of 50 V (0.8 ms) delivered by a current amplifier and a stimulator (S 88, Grass). Muscle strips were allowed to return to the base-line of normal basal tonus before each new frequency was delivered during EFS. In all studies, the duration of the electrical stimulation was 10 s. In order to eliminate adrenergic

and cholinergic components of nerve stimulation and to study relaxation responses to the non adrenergic, non-cholinergic nerves all experiments were performed in presence of atropine ( $10^{-5}$  mol/L) (muscarinic nerve blocker) and guanethidine ( $10^{-6}$  mol/L) (adrenergic nerve blocker). The application of the nitric oxide synthase inhibitor L-NAME [N (G)-nitro-L-arginine of methyl ester], a potent inhibitor of NO synthase, inhibited the relaxation responses, which were restored by application of L-arginine, and it has been concluded that the relaxation responses elicited by EFS were nitrergic-mediated activation. After the EFS relaxation was obtained, the same procedure was repeated in the presence of ISDN tolerance-induced conditions.

### **Drugs**

Guanethidine sulphate, atropine sulphate, sodium nitroprusside, L Name, L arginine, and papaverine hydrochloride were dissolved in distilled water. ISDN was dissolved in dimethylsulphoxide and dilutions were made in distilled water. All drugs were purchased from Sigma Chemical Company.

### **Statistical analysis**

All data are expressed as mean  $\pm$  SE. Tissue relaxant responses were expressed as percentage of papaverine-induced relaxation. In order to evaluate the effect of agonists; maximum responses (E<sub>max</sub>) and pD<sub>2</sub> values were calculated. The concentration-response data obtained in each individual experiment were plotted as the response/concentration (y) against the response (x). This produced a straight-line relationship in each experiment as predicted from the Scathard equation for drug-receptor interaction: Response/Concentration = -1/EC<sub>50</sub> × Response + Maximum response/EC<sub>50</sub>.

The pD<sub>2</sub> value was expressed as the negative logarithm of the EC<sub>50</sub> value. Inter-group differences were tested by Wilcoxon test. P value of less than 0.05 was considered to be statistically significant.

## RESULTS

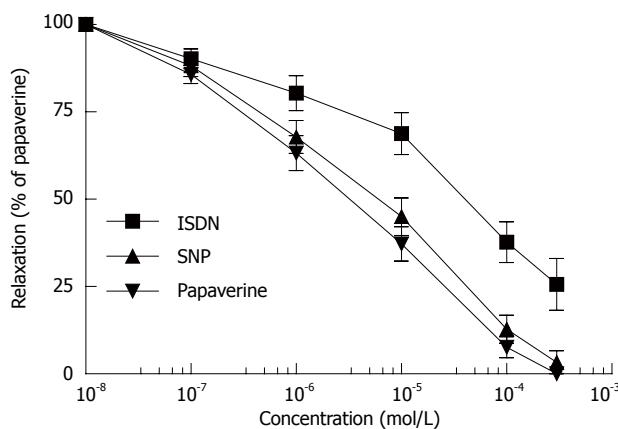

The IAS muscle strips developed spontaneous basal tonus several minutes after equilibration. ISDN ( $10^{-7}$ - $10^{-4}$  mol/L) caused a concentration-dependent relaxation on the basal tonus of the isolated rabbit IAS muscle strips. The maximum relaxation caused by ISDN was  $74.4 \pm 7.2$  percent of the relaxation caused by papaverine (Table 1, Figure 1). pD<sub>2</sub> value (negative logarithm of the EC<sub>50</sub> value) was  $5.48 \pm 0.05$  (Table 1). After a period of 2 h incubation by  $6 \times 10^{-4}$  mol/L ISDN, the relaxation effect induced by ISDN was not change compared to control strips (Figure 2A). pD<sub>2</sub> value of ISDN was not changed either by the attempt to induce tolerance with ISDN incubation. When we compared the concentration-response curves of the strips incubating by ISDN and control, there was no statistically significant difference in E<sub>max</sub> values between groups (Table 1).

SNP ( $10^{-8}$ - $10^{-4}$  mol/L) caused a concentration-dependent relaxation on the basal tonus of the isolated

**Table 1 Maximum relaxation responses ( $E_{max}$ ) and pD2 values to agonists in strips of internal anal sphincter smooth muscle from two groups of rabbits ( $n = 6$  each experiments)**

	Control	ISDN-induced tolerance
ISDN	$E_{max}$ 5.48 ± 0.05	74.4 ± 7.2 5.40 ± 0.06
SNP	$E_{max}$ 5.48 ± 0.05	96.7 ± 3.3 5.57 ± 0.05
EFS	$E_{max}$	72.5 ± 7.4 78.1 ± 6.3

$E_{max}$ : The maximum relaxation response (percentage of papaverine induced relaxations); pD2: Negative logarithm of the  $EC_{50}$  value.

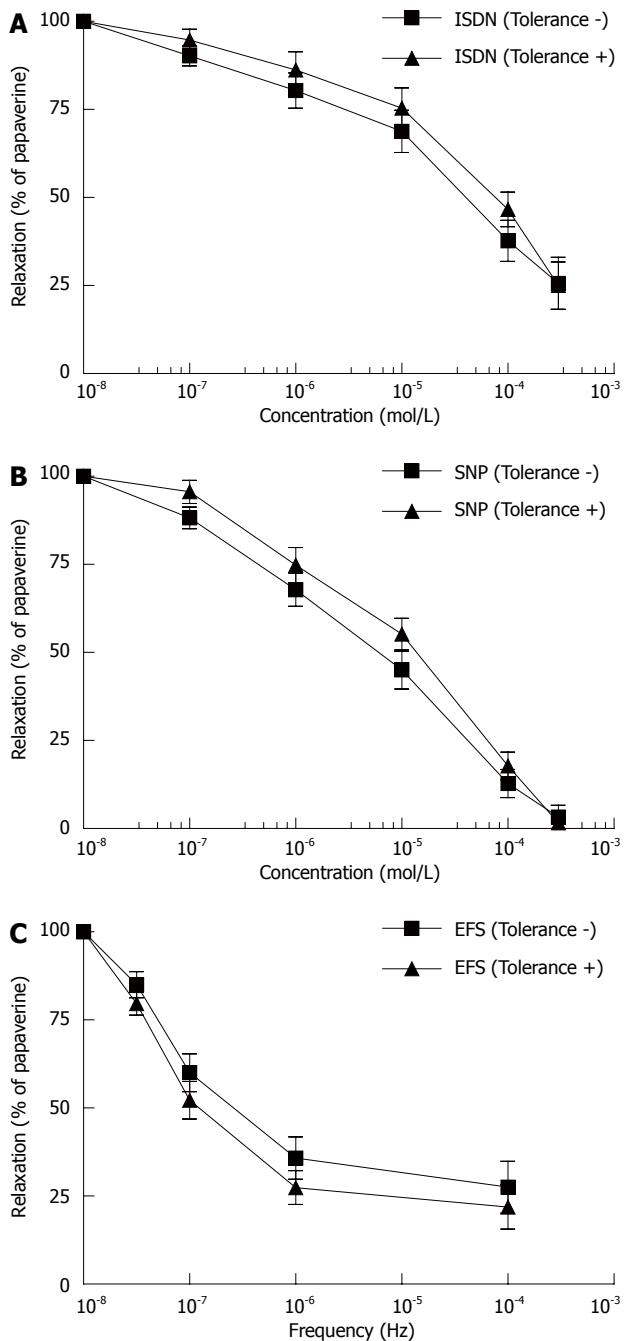

**Figure 1** The relaxant effects of ISDN, SNP and papaverine, in isolated rabbit internal anal sphincter smooth muscle strips. Papaverine induced relaxation was accepted as 100%. Maximum relaxations of ISDN and SNP were expressed as percentage of relaxation induced by papaverine. Each curve represents the mean ± SE for 6 experiments.

rabbit IAS muscle strips the maximum relaxation induced by SNP was  $96.7 \pm 3.3$  percent of the relaxation induced by papaverine (Figure 1). The attempt to induce tolerance with ISDN incubation had no significant effect on these responses and there was no change in  $E_{max}$  values of drug (Table 1, Figure 2B). pD2 values of SNP in basal tonus and ISDN-induced condition were  $5.60 \pm 0.04$  and  $5.57 \pm 0.05$ , respectively.

EFS evoked frequency-dependent relaxation of IAS smooth muscle strips in the presence of  $5 \times 10^{-5}$  mol/L guanethidine and  $10^{-6}$  mol/L atropine.  $E_{max}$  ( $72.5 \pm 7.4$ ) obtained from vehicle incubated control strips was not significantly changed in ISDN tolerance-inducing condition ( $78.1 \pm 6.3$ , Table 1, Figure 2C).

## DISCUSSION

Traditionally, lateral internal sphincterotomy was the gold standard treatment for chronic anal fissures. However this procedure is associated with a risk of incontinence to some degree in 30% of patients<sup>[23]</sup>. Recent studies have suggested that NO release as an important mediator from enteric inhibitory neurons and causes the relaxation of the IAS muscle<sup>[24,25]</sup>. In a similar way, NO donating agents lead to IAS relaxation via a non-adrenergic non-cholinergic pathway<sup>[26]</sup>. This effect of NO donating agents such as

**Figure 2** The influence of *in vitro* isosorbide dinitrate (ISDN)-induced tolerance on relaxant effects of ISDN (A), relaxant effects of sodium nitroprusside (SNP) (B) and relaxant effects of electric field stimulation (C) compared with control values in isolated strips of internal anal sphincter smooth muscle. Each curve represents the mean ± SE for 6 experiments.

ISDN and GTN can produce beneficial clinical effects in the healing of anal fissures by relaxing of IAS. Topical application of GTN and ISDN seems to promote the healing process of chronic anal fissures<sup>[16,27-30]</sup>.

In this study, the organic nitrates ISDN and SNP caused concentration-dependent relaxation in rabbit IAS muscle strips. The maximum relaxation effects induced by ISDN and SNP in basal tonus were 74% and approximately 100% respectively as compared to papaverine response.

Organic nitrates have long been used in treating

cardiovascular diseases due to their potent relaxation effects on the vascular smooth muscle. This relaxant effect is generated by *in vivo* metabolic conversion of these compounds to nitric oxide (NO), which then stimulates vascular relaxation by producing of cyclic GMP<sup>[31,32]</sup>.

One of the major drawbacks of NO donating agent therapy in cardiovascular diseases is the rapid development of pharmacological tolerance. It develops shortly after the beginning of treatment and occurs both *in vitro* and *in vivo* conditions<sup>[32,33]</sup>. Both human and experimental studies showed that prolonged exposure to high levels of nitroglycerin and other organic nitroesters induce tolerance against the cardiovascular effects of the drugs<sup>[17-20]</sup>.

So far, only one study has been reported about NO donating drug tolerance in anorectal smooth muscle<sup>[34]</sup>. Wang *et al* showed that GTN caused significant and sustained relaxation of anorectal smooth muscle in the anaesthetized rat without evidence of tolerance development<sup>[34]</sup>. In this study the relaxation response induced by NTG was not diminished in the anorectum in conditions that produced vascular tolerance.

The mechanisms of nitrate tolerance are complex and multi-factorial, including processes such as decreased tissue sulphhydryl availability, reduced bioactivation of the parent drug, physiological compensation and tissue oxidative stress<sup>[32,33,35]</sup>. Some investigators suggested that tolerance may arise from one or more steps involving the biotransformation process of organic nitrates prior to the formation of NO<sup>[21,22]</sup>. The action of nitrates is dependent on the liberation of from their molecule which subsequently activating guanilate cyclase<sup>[36]</sup>. The production of cGMP (the alleged mediator of nitrate-induced vascular smooth muscle relaxation) is reduced in tissues, which develop tolerance<sup>[37]</sup>. cGMP accumulation, was significantly decreased after NTG pre-incubation in the rat aorta but not in the rat anorectal smooth muscle and anal sphincter<sup>[34]</sup>.

Prolonged exposure of rabbit IAS muscle strips to high concentration of ISDN did not change the relaxant effect of the NO donating agents. As far as we know this result is the first *in vitro* evidence showing that rabbit IAS smooth muscle is spared from the tolerance induced by organic nitrates.

In conclusion, the main finding of the current study is that nitrate tolerance is not developing in isolated rabbit internal anal sphincter smooth muscle.

## COMMENTS

### Background

The internal anal sphincter pressure has been found to display an overshoot phenomenon in the patients with chronic anal fissure. It has been showed that some drugs such as glyceril trinitrate (GTN) and isosorbide dinitrate (ISDN) as nitric oxide (NO) donor might be used in treatment of chronic anal fissure. Prolonged exposure to high levels of nitroglycerin and other organic nitroesters is known to induce tolerance in the cardiovascular system and penile tissue both in humans and in experimental animals.

### Research frontiers

In this study, the organic nitrates ISDN and SNP caused concentration-

dependent relaxation in rabbit IAS muscle strips. The main finding is that nitrate tolerance is not developing in isolated rabbit internal anal sphincter smooth muscle.

### Innovations and breakthroughs

Our study is the first *in vitro* evidence showing that rabbit IAS smooth muscle is spared from the tolerance induced by organic nitrates. Only one *in vivo* study has been reported about NO donating drug tolerance in anorectal smooth muscle before.

### Applications

Although animal findings cannot be assumed to apply to human beings and *in vitro* experimentation should not lead straight to clinic conclusions, topical use of NO donating drugs should be continued for the treatment of anal fissure disease without a fear of tolerance development. In the future, this result may be verified in human studies.

### Peer review

The paper deals nicely with an interest subject. The main finding of the current study is that nitrate tolerance is not developing in isolated rabbit internal anal sphincter smooth muscle. Topical use of NO donating drugs should be continued for the treatment of anal fissure disease without a fear of tolerance development.

**CONCLUSION:** We report concordance between ATP7B mutation and WD phenotype within each family with > 1 member affected with WD. Homozygous ATP7B mutation was present in 3 of the 4 families studied. Our report supports allelic dominance as a determinant of WD phenotype. However, in one family with compound heterozygous mutation, there was a similar WD phenotype which suggests that there may be other factors determining the phenotype.

Santhosh S, Shaji RV, Eapen CE, Jayanthi V, Malathi S, Finny P, Thomas N, Chandy M, Kurian G, Chandy GM. Genotype phenotype correlation in Wilson's disease within families-a report on four south Indian families. *World J Gastroenterol* 2008; 14(29): 4672-4676 Available from: URL: <http://www.wjgnet.com/1007-9327/14/4672.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.4672>

### Abstract

**AIM:** To study the genotype phenotype correlation in Wilson's disease (WD) patients within families.

**METHODS:** We report four unrelated families from South India with nine members affected with WD. Phenotype was classified as per international consensus phenotypic classification of WD. DNA was extracted from peripheral blood and 21 exons of ATP7B gene and flanking introns were amplified by polymerase chain reaction (PCR). The PCR products were screened for mutations and the aberrant products noted on screening were sequenced.

**RESULTS:** Four separate ATP7B mutations were found in the four families. ATP7B mutations were identical amongst affected members within each family. Three families had homozygous mutations of ATP7B gene while one family had compound heterozygous mutation, of which only one mutation was identified. We noted concordance between ATP7B gene mutation and Wilson's disease phenotype amongst members within each family. The age of onset of symptoms or of detection of asymptomatic disease, baseline serum ceruloplasmin and baseline urinary copper levels were also similar in affected members of each family. Minor differences in phenotype and baseline serum ceruloplasmin level were noted in one family.

### INTRODUCTION

Wilson's disease (WD) is an autosomal recessive disorder characterized by excess hepatic copper accumulation and impaired biliary copper excretion. In 1993, the gene encoding WD protein (ATP7B) was cloned and was found to encode a copper transporting P-type ATPase required for biliary copper excretion. However, although the characterization of the molecular genetic basis of this disease has provided insight into the mechanisms of copper homeostasis, clinical studies of specific patients have not been useful in elucidating the mechanism of hepatic copper metabolism<sup>[1]</sup>. One intriguing question in WD is how closely the genotype determines the phenotype. While over 300 mutations of ATP7B gene have been reported in WD, over one-half of these occur rarely in any given population. Most patients are compound heterozygotes, possessing alleles with two different mutations. This degree of allelic heterogeneity has been a major hindrance in studying genotype phenotype correlation in WD<sup>[2,3]</sup>.

In such a situation, one approach is to study the

phenotypes of a single predominant genotype in a population. The results of this approach have shown poor genotype phenotype correlation in the different populations studied<sup>[4-6]</sup>. Another approach is to compare genotype and phenotype in WD occurring within members of a family. In a report of two Japanese families, the affected family members had similar compound heterozygous mutations of ATP7B gene but had different phenotypes and different ages of onset of disease suggesting allelic dominance as a factor determining the phenotype<sup>[7]</sup>. We report four families wherein the affected members within each family had identical mutations of ATP7B. We compared the phenotypes within these families to see if the phenotypes were true to the index case.

## MATERIALS AND METHODS

### Subjects

We report four unrelated families from the states of Tamil Nadu and Andhra Pradesh in South India with nine documented cases of WD. The basis of the diagnosis of WD was the presence of Kayser Fleischer rings in the cornea on slit lamp examination and the presence of a low serum ceruloplasmin level (measured by copper oxidase method). Further investigations were carried out as clinically indicated. WD phenotype was classified as per the international consensus classification<sup>[8]</sup>. Neurological involvement was determined by clinical examination, while liver involvement was assessed by liver function tests, ultrasonography and liver biopsy, if indicated, in addition to clinical examination.

### Genetic studies

Peripheral blood was collected from the patients after obtaining an informed consent. The genomic DNA was extracted from white blood cells by standard phenol-chloroform method. The 21 exons of ATP7B gene and their flanking intronic sequences were amplified by polymerase chain reaction (PCR) using primers described earlier<sup>[5]</sup>. PCR amplified products were subjected to conformation sensitive gel electrophoresis (CSGE) for mutation screening<sup>[9]</sup>; those exhibiting aberrant patterns in CSGE were sequenced using automated sequencer (ABI 310, Applied Biosystems, CA).

### Genotype phenotype correlation

Mutations of ATP7B gene and WD phenotype in each of the affected family member was compared with other affected members within that family. Similarly, other indices like age of onset of symptoms/age of detection of asymptomatic disease, baseline serum ceruloplasmin and baseline urinary copper levels were also compared within symptomatic members of each family.

## RESULTS

All the nine patients had Kayser Fleischer rings and low serum ceruloplasmin levels. Three of the nine patients

were asymptomatic and were detected to have WD on family screening, after the index patient was diagnosed within the family. All nine patients had abnormal liver function tests and/or abnormal liver on ultrasound. Only one patient (family 4, Table 1) underwent liver biopsy, which showed cirrhosis of liver. The affected members in families 1 to 3 had identical homozygous mutations of ATP7B gene within each family (Table 1). These three mutations of ATP7B gene are novel mutations. The ATP7B gene mutations identified were A2623G (Arg-Gly) in family 1, G4021A intronic mutation in family 2, and a point mutation A3029G (Lys-Arg) in family 3. The two siblings in family 4 were compound heterozygotes, in whom the only mutation identified, G3282A (Phe1094Leu), was identical in both the siblings. This mutation has been recently reported from Brazil<sup>[10]</sup>.

In addition to the mutations, 2-5 polymorphisms of ATP7B gene were also identified in each of the nine patients studied. Similar to the mutations, the polymorphisms of ATP7B gene were also identical in members within the same family (Table 1). In Family 1, 4 of 6 children born to partners in a consanguineous marriage, had WD. DNA was available for mutation analysis from three of the four affected children. While all three had hepatic involvement, the elder brother also had arthritis involving the right knee (Table 1). In Family 2, of the 4 children-products of a consanguineous marriage-one son and one daughter had neurological and neuro-psychiatric involvement respectively. In Family 3, (non-consanguineous marriage), the father presented at age 45 years with WD accompanied with a metabolic bone disorder and renal tubular acidosis. On screening the family, his son was detected to have WD (diagnosed on the basis of low serum ceruloplasmin level and KF rings on slit lamp examination). He also had elevated urinary copper level. However, his liver function tests were normal and the liver appeared normal on ultrasonography. A liver biopsy was refused. Since this subject did not have neurological involvement, it was assumed that he had sub-clinical liver disease. Unlike the father, the son did not have renal tubular acidosis. The mother and daughter did not have WD. In family 4, four children (4 sons) were born to parents in a consanguineous marriage. One son died of liver disease (age of onset of symptoms: 13 years), however he had not been evaluated for WD. Another son aged 17 years, who was healthy, had no clinical, biochemical, and radiological signs of liver disease. Of the two affected sons who were alive, one had overt and the other had asymptomatic hepatic involvement.

The WD phenotype, age of onset of symptoms/age of detection of WD, baseline serum ceruloplasmin and baseline urinary copper levels were similar among members of a family, except for some differences in family 3 (Table 1). In family 3, there were marked differences in the age of onset of symptoms/age of detection of WD and baseline serum ceruloplasmin levels (difference of 50 U/L) between the father and

son. In addition, renal tubular acidosis was present only in the father.

## DISCUSSION

The present study, examined the genotype phenotype correlation in WD occurring within members of each family, whereas previous studies examined the question with respect to a single common mutation in a given population. While the previous studies gave answers related to that particular mutation, we investigated the impact of four different mutations in members of four unrelated families with more than one member affected with WD. Although the number of subjects studied was small, our report highlights some aspects of interest in genotype phenotype correlation in WD. In the present report, the affected members of each family shared identical mutations of ATP7B gene within each family (homozygous mutations in three families and compound heterozygous mutation in one family). We found strong genotype phenotype concordance in members of each family. The two minor differences in phenotype within members of a family were the following: in the first family, one sibling had monoarticular arthritis; a known association with WD, which was not present in the other two siblings, while in family number 3, the father had renal tubular acidosis and metabolic bone disease where as the son did not have these abnormalities.

The three additional phenotypic indices studied (age of onset of symptoms or age at detection of asymptomatic disease, baseline serum ceruloplasmin and baseline urine copper levels) were similar in members of each family, except for family 3 (Table 1). While the father in family 3 became symptomatic with disabling metabolic bone disease and liver involvement only at the age of 45, WD was detected at an early asymptomatic stage by screening in the son at the age

of 16. It is possible that some of the differences in phenotype between father and son in this family could be due to longstanding untreated copper overload state in the father. Defining disease onset accurately in WD is difficult and this could be a confounding factor in genotype phenotype correlation in WD<sup>[11]</sup>.

In summary, we found genotype phenotype concordance in four families with different types of ATP7B mutations in each family: homozygous exonic mutation in two families, homozygous intronic mutation (Family 3) and compound heterozygous mutation (Family 4). It is of interest that such a concordance of genotype and phenotype was seen in different phenotypic manifestations, including neurological involvement in childhood in family 2, an uncommon presentation of WD.

The occurrence of identical homozygous mutations within members of a family could reflect genetic inbreeding in the population perpetuated by consanguineous marriages. Consanguineous marriages are common in South India (28% in one study)<sup>[12]</sup>. Analysis of data from the 1992-1993 National Family Health Survey to assess trends in consanguinity in the South Indian states of Andhra Pradesh, Karnataka, Kerala and Tamil Nadu showed that in Kerala the frequency of consanguineous marriages was very low and one type of preferred marriage of the Dravidian marriage system-uncle niece marriage-was conspicuously absent, whereas in the other states of South India, consanguinity and the coefficient of inbreeding were high<sup>[13]</sup>. In a study of 407 infants and children in Karnataka, of a total of 35 genetic diseases detected, autosomal recessive disorders formed the largest single disease category diagnosed<sup>[14]</sup>.

Differences in phenotypic classification used in different studies could affect the interpretation of results of genotype phenotype correlation in WD. Although

the Japanese used a phenotypic classification different from the international consensus classification which we have applied in our report, the distinction between hepatic versus neuropsychiatric phenotypes in both the classification systems appears to be similar<sup>[7]</sup>. While the Japanese study of two families showed that within each family, members with different mutations of ATP7B gene had different WD phenotypes; we report four families wherein affected members of each family had identical mutations of ATP7B gene and similar phenotypes. Thus, both these studies suggest that within families, a particular ATP7B genotype is associated with a particular WD phenotype thereby supporting the concept of allelic dominance as a significant determinant of WD phenotype.

In a previous report, we did not find symptomatic WD in >1 member in each family. On studying the phenotype of presumed WD in deceased siblings of index patients with WD, we found concordance of WD phenotype within each family in 6 of 8 families studied. The WD phenotype in these 6 families with concordant phenotype within each family was hepatic (4 families), hepatic and neurological (1 family) and neuro-psychiatric (1 family)<sup>[15]</sup>.

By contrast, studies on WD patients with a common mutation in a given population have not shown this degree of concordance between genotype and phenotype. In a study on patients mainly from Austria, neurological presentation was significantly more common than hepatic presentation in H1069Q homozygotes compared to H1069Q compound heterozygotes or H1069Q negative patients<sup>[11]</sup>. However, these findings were not borne out by studies from other parts of Europe and North America<sup>[4,16]</sup>. Some studies have reported later age of onset of symptoms in H1069Q homozygotes compared to H1069Q compound heterozygotes<sup>[4,17]</sup>.

Apolipoprotein E genotype, intestinal metallothionein inducibility and the individual's capacity to withstand "copper stress" by utilizing glutathione, superoxide dismutase and heat shock proteins are some epigenetic factors that may affect the WD phenotype<sup>[11,18]</sup>. It is possible that common epigenetic or environmental factors within families accentuate the genotype phenotype concordance seen in family members affected with WD.

Further studies of WD within families in different populations are needed to assess whether the concept of allelic dominance determining the phenotype holds true. It would also be important to see if the phenotypes associated with a particular mutation of ATP7B gene in WD within families are the same as in WD patients with the same mutations, but in a different family or a different population<sup>[19]</sup>. Application of a standard phenotypic classification like the international consensus phenotypic classification for WD<sup>[8]</sup> in future studies will enable valid comparison of the results.

In conclusion, we report 4 families with WD wherein affected members had identical mutations of the ATP7B gene and showed genotype phenotype concordance amongst members within each family. This finding

supports allelic dominance as a determinant of WD phenotype and is at variance with previous studies of WD conducted in a given population. Further studies of genotype phenotype correlation in WD occurring in families are needed.

## ACKNOWLEDGMENTS

We thank for Dr. Peter Ferenci for critical appraisal of the manuscript. The institutional ethics committee of Christian Medical College, Vellore approved this study under the R.C Number: 5613 dated 19-04-2005.

oxidative damage precedes that of systemic oxidative imbalance. Predominant metabolic features of the increased lipid peroxidation further suggest a close association of the oxidative imbalance and the dyslipidemia with functional deterioration of the steatotic liver. The findings need to be further evaluated, especially in human studies.

## Abstract

**AIM:** To investigate oxidative stress and lipid peroxidation in hepatic steatosis and the underlying implications in pathological mechanisms of non-alcoholic fatty liver disease (NAFLD).

**METHODS:** F<sub>2</sub>-isoprostanes (iPF<sub>2α</sub>-III) in blood and liver samples from steatotic ( $n = 9$ ) and control ( $n = 7$ ) rats were measured as *in vivo* marker of lipid peroxidation by a mass spectrometric approach. The lipid profile and endogenous antioxidant status (SOD and CAT) in the rats were also analyzed.

**RESULTS:** Significantly higher levels of iPF<sub>2α</sub>-III (mean 3.47 vs 2.40 pmol/mg tissue,  $P = 0.004$ ) and lower activities of SOD (mean 1.26 U vs 1.40 U,  $P < 0.001$ ) and CAT (mean 1026.36 U/mg vs 1149.68 U/mg protein, without significance) were observed in the livers of steatotic rats. Plasma total iPF<sub>2α</sub>-III was significantly correlated with the abnormalities of blood lipids as well as alanine aminotransferase (ALT) levels in the rats with simple steatosis, whereas no similar tendencies were observed in the control rats.

**CONCLUSION:** Enhancement of hepatic oxidative imbalance occurring at the steatotic stage of NAFLD suggests a possibility that manifestation of the local

## INTRODUCTION

Non-alcoholic fatty liver disease (NAFLD), in the absence of alcohol abuse, represents a pathological spectrum of fatty liver disorders including simple steatosis and non-alcoholic steatohepatitis (NASH)<sup>[1]</sup>. The cause of the disease progression remains elusive. The “two hits” hypothesis addresses a requirement of one or more “second hits”, in addition to the excessive hepatic fat deposition (the “first hit”), for presumed transition of simple steatosis to NASH<sup>[1,2]</sup>. Despite the involvement of many other proinflammatory mediators, lipid peroxidation is one hypothesis as the “second hit” to explain the development of the disorder in humans<sup>[1,3-8]</sup>.

Lipid peroxidation as an important mechanism of NAFLD has been a field of intense research but is not yet fully understood. Majority of previous researches were conducted mainly in NASH in both human subjects and animals. Only a few studies have focused on the effects of lipid peroxidation in simple steatosis, an earlier stage of NAFLD<sup>[9,10]</sup>. Given that ectopic lipids

accumulation in the liver is primarily linked to hepatic mitochondrial dysfunction and insulin resistance<sup>[1]</sup>, the steatosis stage of the disease might be of real importance in evaluating the cause-effect association of lipid peroxidation with the disease progress, thus providing clues for earlier pharmacological interventions against the development of NASH. Furthermore, malondialdehyde (MDA), a widely used index of lipid peroxidation, has been considered neither the sole end product of fatty peroxide formation and decomposition nor a substance generated exclusively through lipid peroxidation<sup>[11]</sup>. It remains uncertain if MDA in blood or tissues reflexes oxidative stress status associated with biological changes observed.

$\text{F}_2$ -isoprostanes, also referred to as iPF<sub>2 $\alpha$</sub> -III, are a group of prostaglandin-like isomers produced by free radical-catalyzed peroxidation of arachidonic acid<sup>[12]</sup>. Results from the Biomarkers of Oxidative Stress Study (BOSS) suggested that the most accurate marker to assess lipid peroxidation *in vivo* is the plasma or urinary iPF<sub>2 $\alpha$</sub> -III<sup>[13]</sup>. Elevated plasma or urinary levels of iPF<sub>2 $\alpha$</sub> -III have been reported in patients<sup>[14,15]</sup> and in animals with NASH<sup>[16]</sup>. Information in the literatures with regard to iPF<sub>2 $\alpha$</sub> -III formation related to hepatic steatosis, however, is limited. Tong *et al*<sup>[17]</sup> found elevated iPF<sub>2 $\alpha$</sub> -III in plasma and liver of the rats with valproic acid-triggered liver injury.

The present study was conducted to investigate the oxidative imbalance by measuring local and circulating iPF<sub>2 $\alpha$</sub> -III and enzymatic antioxidant status in the rats with high-fat diet induced hepatic steatosis. The measures of the lipid peroxidation were then correlated with metabolic risk factors such as lipid profile, which are believed to be greatly involved in the pathogenesis of NAFLD among the steatotic rats.

## MATERIALS AND METHODS

### Animals

Adult male Sprague-Dawley rats were obtained from the Slac Animal Center (Shanghai, China), and maintained with a 12 h light/dark cycle under constant temperature and humidity. The rats were chosen according to their lipid levels and then randomly assigned into a defined lard-based high-fat (HF) diet ( $n = 9$ ) and standard laboratory chow ( $n = 7$ ) groups (45% *vs* 10% kcal as fat, respectively). Both diets were made based on the ingredients of products D12451 and D12450B (Research Diets, New Brunswick, NJ, USA), respectively, and supplied by Double Lion Ltd. (Suzhou, China). Animals were fed ad libitum water and their corresponding diet for up to 16 wk. At the end of the study, two rats from each group were chosen randomly for the identification of hepatic steatosis. All rats were anesthetized and killed. Their fasting plasma samples were kept at -70°C, and the liver samples were thoroughly rinsed with ice-cold saline and frozen in liquid nitrogen and then stored at -70°C. The study was approved by the Animal Ethics Committee and all procedures complied

**Table 1 Body weight and biochemical parameters of HF rats and control**

Parameter	HF ( $n = 9$ )	Control ( $n = 7$ )	P

with international standards of humane care in animal experimentation.

### Biochemical measurements

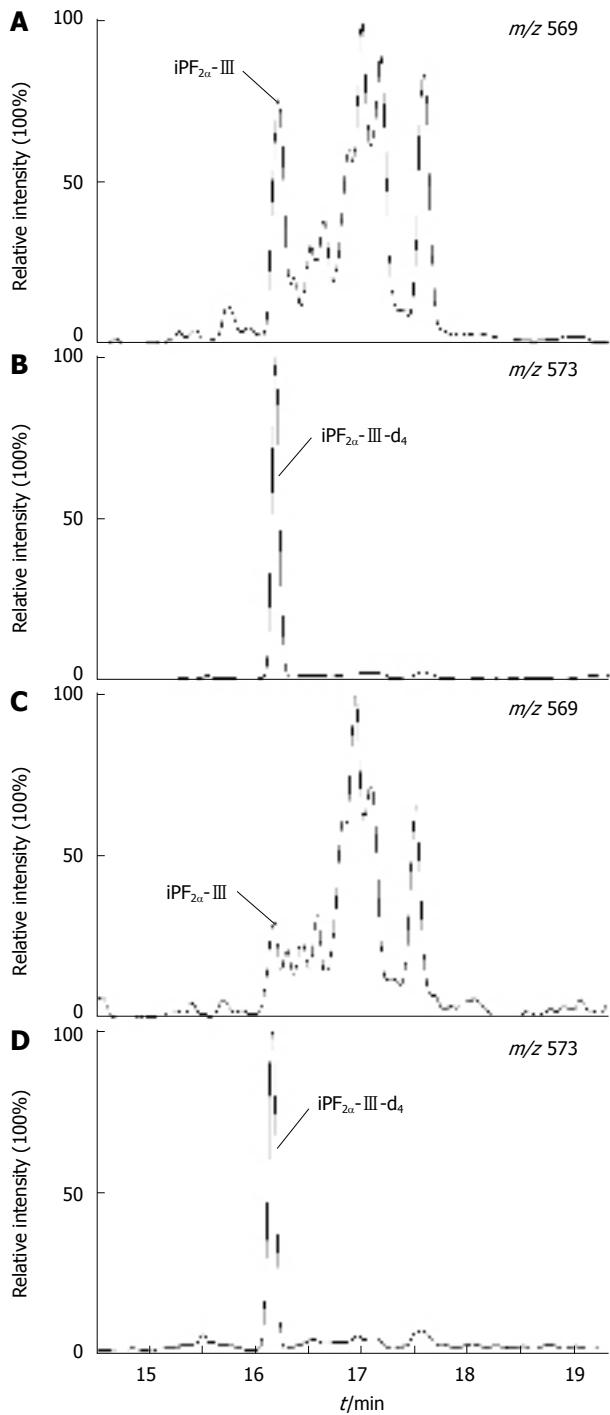

Fasting plasma glucose (GLU), total cholesterol (TC), low-density lipoprotein cholesterol (LDL-C), high-density lipoprotein cholesterol (HDL-C), triglycerides (TG), alanine aminotransferase (ALT) and aspartate aminotransferase (AST) were determined using a 7020 biochemical analyzer (Hitachi, Japan). The hepatic TC and TG were also determined in the same manner. The biochemical data for the control and HF rats are listed in Table 1.

### Histological examinations

Fragments of liver tissues were fixed in 10% formalin, embedded in paraffin, and sectioned (5 mm in thickness). The sections were mounted on the charged microscopic slides (Okando, USA). Hematoxylin-eosin (HE) staining was performed on all slides. The slides were then examined and pictured using a DM4000B fluorescent microscopy (Leica, Switzerland).

### Hydrolysis and solid-phase extraction of liver and plasma iPF<sub>2 $\alpha$</sub> -III

The purification of iPF<sub>2 $\alpha$</sub> -III from the liver and plasma were performed as described<sup>[18,19]</sup> with modifications. Briefly, the tissue sample (50–100 mg) was homogenized in 4 mL ice-cold chloroform:methanol (2:1, v/v). For plasma, the aliquots (500  $\mu$ L) were transferred to Eppendorf tubes. The internal standard iPF<sub>2 $\alpha$</sub> -III-d<sub>4</sub> (50 ng for liver and 5 ng for plasma) was added. For the liver sample, the homogenate was mixed at 4°C for 1 h, 1.6 mL of 0.9% NaCl was added to the sample followed by centrifuging at 2000  $\times g$  for 10 min. The residual was dried under nitrogen. One mol/L KOH (1 mL for the liver residual and 500  $\mu$ L for the plasma) was added to the tubes containing the samples. Both liver and plasma samples were hydrolyzed at 40°C for 45 min. One mol/L HCl (1 mL for the liver sample and 500  $\mu$ L for the plasma sample) and 1 mL of 10 mmol/L formate buffer (pH 3.0) were then

**Figure 1** GC-NICI-MS SIM chromatograms of (A) plasma total iPF<sub>2α</sub>-III and (C) hepatic iPF<sub>2α</sub>-III isolated from a rat with simple steatosis, and (B) and (D) the internal standard iPF<sub>2α</sub>-III-d<sub>4</sub> in the plasma and tissue samples, respectively.

added. The sample was centrifuged at 12 000 × g for 20 min; the supernatant was removed and applied to an Oasis HLB extraction cartridge<sup>[19]</sup>. The extraction steps were programmed into an ASPEC XL SPE System (Gilson S.A.S., France) and run automatically.

#### Derivatization and GC-MS analysis of liver and plasma iPF<sub>2α</sub>-III

The iPF<sub>2α</sub>-III extracts were analyzed using gas chromatography-negative ion chemical ionization-mass spectrometry (GC-NICI-MS) as described<sup>[19]</sup>. After

derivatizations with pentafluorobenzyl bromide (PFB) and N,O-bis-(trimethylsilyl)trifluoroacetamide (BSTFA), the PFB-TMS derivatives of iPF<sub>2α</sub>-III were analyzed on a TRACE DSQ gas chromatograph-mass spectrometer (ThermoFisher Scientific, USA). Selected ion monitoring (SIM) was performed to monitor the carboxylate anion (M-181) at *m/z* 569 for the iPF<sub>2α</sub>-III and *m/z* 573 for iPF<sub>2α</sub>-III-d<sub>4</sub>. The representative GC-NICI-MS chromatograms of hepatic and plasma F<sub>2</sub>-isoprostanes are shown in Figure 1.

#### Determination of activities of liver and erythrocyte superoxide dismutase (SOD) and blood catalase (CAT)

Liver and erythrocyte SOD activities were measured with a SOD Assay Kit-WST (Dojindo Laboratories, Japan), and liver and blood CAT activities and the protein levels of the samples were determined using the Catalase Assay Kit and the BCA Protein Assay Kit (Beyotime Institute of Biotechnology, Jiangsu, China), using the protocols provided by the manufacturers, respectively.

#### Statistical analysis

Data were expressed as the mean ± SE. The differences between the mean values of two groups were determined by paired *t* test. Associations between the different variables were examined by Pearson correlation analysis. Statistical significance was set at *P* < 0.05.

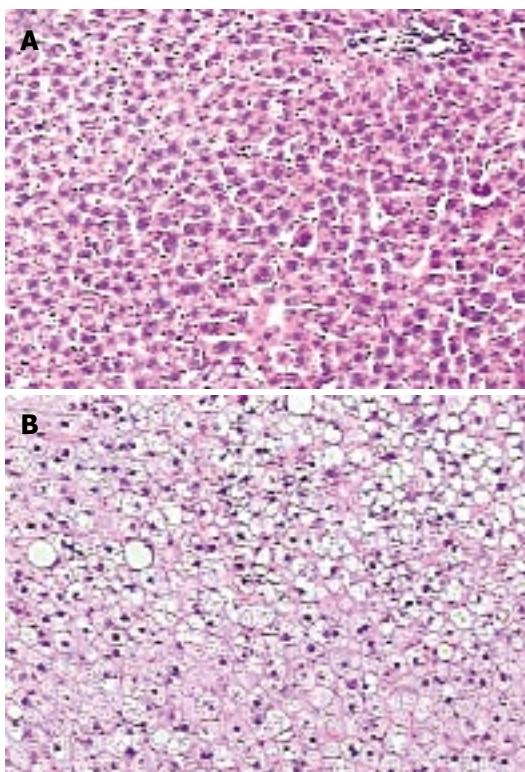

## RESULTS

#### Effects of high-fat diet on body weight, metabolic indices and occurrence of hepatic steatosis

Prolonged feeding with the high-fat diet led to significant increases in body weight (*P* < 0.001) and fasting plasma glucose levels (*P* < 0.005) in HF rats compared to the control rats. Plasma LDL-C (*P* = 0.001) and TG (*P* < 0.001) were significantly higher in HF rats than those in the controls, whereas no difference in TC and HDL-C levels was found between the groups. Notably, feeding with high-fat diet increased the hepatic TG levels (*P* = 0.023), and typically resulted in steatosis in approximately 40% of hepatic lobules in the liver section examined (Figure 2). The hepatic steatosis was further supported by a significant increase in plasma ALT in HF rats (*P* = 0.019) (Table 1). No development of NASH was found in the rats.

#### Liver and plasma iPF<sub>2α</sub>-III as indices of oxidative imbalance in vivo in rats with hepatic steatosis

Hepatic and plasma total iPF<sub>2α</sub>-III levels and the activities of antioxidant enzymes were examined (Figure 3). While no significant difference appeared in circulating total iPF<sub>2α</sub>-III, an elevated hepatic iPF<sub>2α</sub>-III was observed in HF rats as compared to the control rats (mean 3.47 pmol/mg vs 2.40 pmol/mg tissue, *P* = 0.004) (Figure 3). Analysis of the endogenous antioxidant capacity revealed that the SOD activities in the liver, but not in circulation, were significantly reduced in the rats with steatosis as compared with that in the control (mean 1.26 U vs 1.40 U, *P* < 0.001) (Figure 3). Similar changes were also found

**Figure 2** Enhanced lipid accumulation in the liver of rat by high-fat diet. (A) Control, and (B) Steatotic liver (HE, magnification  $\times 100$ ).

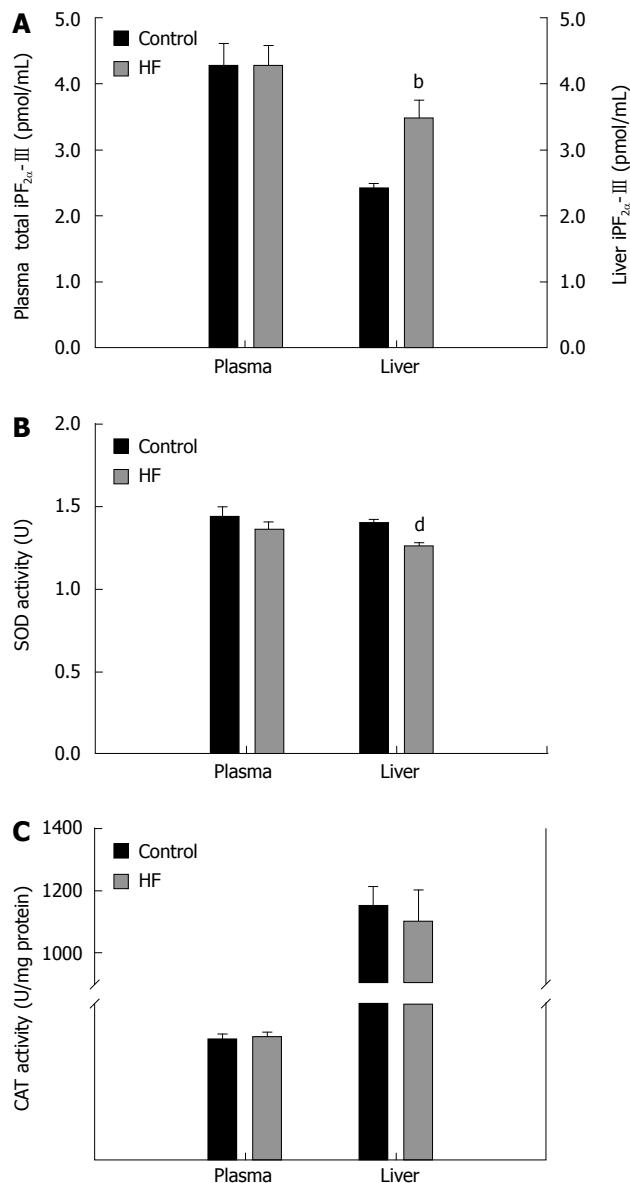

for the liver CAT activities, however, the difference did not reach statistical significance.

#### **Relationship between oxidative imbalance and metabolic risk factors in rats with hepatic steatosis**

Pearson correlation analysis was performed between iPF<sub>2α</sub>-III and the metabolic risk factors, e.g. the abnormal lipid status, in HF rats. There were no significant associations of plasma total iPF<sub>2α</sub>-III with either erythrocyte SOD and blood CAT activities or fasting plasma glucose among HF rats. The significant associations were found between the plasma iPF<sub>2α</sub>-III concentrations and the plasma TC ( $r = 0.799$ ,  $P = 0.005$ ) as well as TG ( $r = 0.624$ ,  $P = 0.036$ ) in the HF rats (Figure 4A and B). A similar correlation but without significance was also found in the plasma LDL-C levels ( $r = 0.578$ ,  $P = 0.052$ ). Furthermore, there was a strong relationship between the iPF<sub>2α</sub>-III levels and the plasma ALT concentrations ( $r = 0.629$ ,  $P = 0.035$ ) (Figure 4C). In the liver, however, there were no relationships of iPF<sub>2α</sub>-III with either TC and TG or SOD and CAT in HF rats.

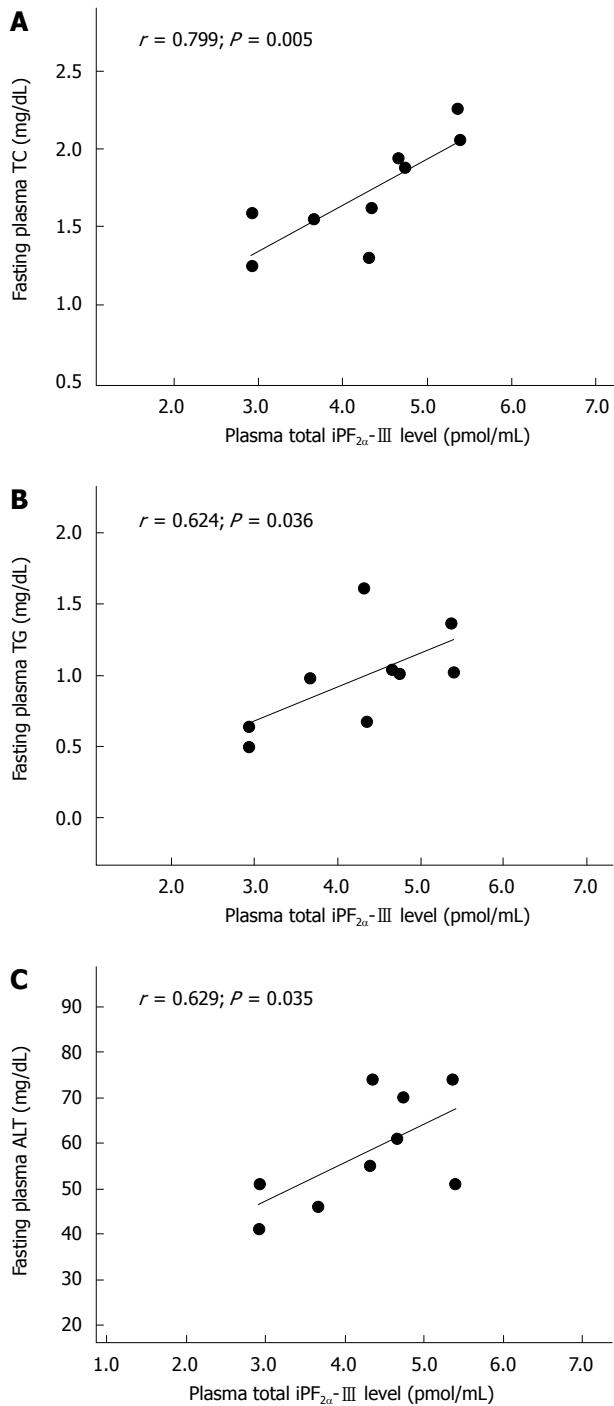

## **DISCUSSION**

In the present study, a Sprague-Dawley rat model with simple steatosis was established by feeding the rats for up to 16 wk with a high-fat diet. The purpose of using such dietary regimen in the normal rats was, by resembling a common fat-rich diet in humans (60% kcal of fat) without toxin ingestion and alimentary deficiency,

**Figure 3** Plasma and hepatic levels of iPF<sub>2α</sub>-III and antioxidant enzymes in rats. (A) Significant differences in iPF<sub>2α</sub>-III levels were found in the liver, but not in plasma between HF rats and control; (B) Significant decreases in SOD activity were found in the liver, but not in erythrocytes of HF rats compared to that in control, and (C) Reducing tendency of CAT activities was observed in liver, but not in blood of HF rats. <sup>b</sup> $P < 0.01$  and <sup>d</sup> $P < 0.001$ .

to naturally reproduce typical features of metabolic abnormalities at the simple steatotic stage of NAFLD seen in humans<sup>[20,21]</sup>. As shown in Table 1, hepatic TG in the HF rats were elevated significantly, indicating an occurrence of lipotoxicity due to the imbalance between TG synthesis and degradation in the liver. The enhanced plasma ALT activity also suggested the lipotoxicity-induced impairment in the liver function. A recent cross-sectional and observational study in 257 Italians also showed that elevation of TG and ALT levels is the most predictive condition for hepatic steatosis<sup>[22]</sup>. In the present study, the presence of hepatic steatosis in HF rats was further confirmed histologically, showing mild to moderate macrovesicular fat accumulation in the liver samples observed (Figure 2). Despite of being

**Figure 4** The formation of plasma total iPF<sub>2α</sub>-III was significantly correlated with the levels of fasting plasma TC (A), TG (B) and ALT (C) in HF rats.

multifactorial in nature in the onset of steatosis<sup>[23]</sup>, these data clearly demonstrate that prolonged treatment with the high-fat diet can successfully cause liver steatosis in the experimental rats. Our results are supportive to the previous publications<sup>[20,24]</sup>. Given that NAFLD is an important hepatic manifestation of metabolic syndrome<sup>[25]</sup>, as expected, the steatotic rats in the present study were also featured with a spectrum of metabolic risk factors (Table 1), suggesting a close association of hepatic steatosis with obesity and insulin resistance, as commonly seen in humans<sup>[26]</sup>.

With the rat model established, we investigated

the oxidative imbalance status specifically at the earlier steatotic stage of NAFLD. The hepatic and blood iPF<sub>2α</sub>-III and enzymatic antioxidants (SOD and CAT) were measured to characterize the effects of oxidative imbalance on the underlying pathogenesis of NAFLD. The main finding is that hepatic iPF<sub>2α</sub>-III concentrations were significantly higher in HF rats than that in the control rats ( $P = 0.004$ ). Associated with this marked elevation in iPF<sub>2α</sub>-III, hepatic activities of SOD ( $P < 0.001$ ) and CAT ( $P = 0.068$ ) of the HF rats were declined as compared to the control, though the decrease of CAT activity did not show statistical significance. In contrast, circulating levels of iPF<sub>2α</sub>-III as well as the activities of SOD and CAT were not different between two groups of rats (Figure 3). The results demonstrate that there was a local but possibly not systemic enhancement of oxidative imbalance in the rats with steatosis. It has been postulated that abnormal hepatic accumulation of TG has implication as the “first hit” in the formation of steatosis<sup>[2]</sup>. This accumulation is believed to be mediated, not exclusively, by alteration in intracellular fatty acid trafficking and the decrease in mitochondrial fatty acid β-oxidation<sup>[27]</sup>. All of these mediators can trigger oxidative imbalance by excessive production of free oxygen radicals capable of inducing lipid peroxidation of hepatocyte membranes. In this regard, while being consistent with those postulations, increased iPF<sub>2α</sub>-III in the steatotic livers observed in the present study is also compatible with the F<sub>2</sub>-isoprostanes results<sup>[17]</sup> and the MDA results<sup>[9]</sup> derived from the animals with simple steatosis. Taking together with these observations, our data also demonstrate enhanced oxidative imbalance mechanisms especially at the steatotic stage of NAFLD. The discrepancy in circulating status of oxidative stress exists between our study and others in steatotic animal models<sup>[17]</sup>. One explanation for the disagreement could be the way to induce steatosis used in the present study is different from that of Tong *et al*<sup>[17]</sup>, possibly resulting in two distinct pathways towards different biochemical and physiological manifestations of systemic oxidative stress. In addition, in the study by Tong *et al*, the local as well as systemic antioxidant status was not characterized as to whether the valproic acid treatment would also parallelly lead to significant damages in antioxidative capacities of the rats with liver injury is unclear. Given that in the present study the circulating SOD and CAT activities were not changed among the experimental rats, it should make sense to postulate that the absence of increase in plasma iPF<sub>2α</sub>-III in HF rats may simply reflect an apparent systemic balance between oxidative stress and antioxidant defense existing temporally in simple steatosis before NASH develops. Indeed, as in the NASH mice fed with a choline-deficient diet, Yoshida *et al*<sup>[16]</sup> reported a more prominent elevation of iPF<sub>2α</sub>-III in the liver than that in plasma. Machado *et al*<sup>[28]</sup> also observed that there was no significant difference in plasma concentrations of 8-OHdG, a DNA oxidation marker, and 4-HNE, a toxic lipid peroxidation product, between patients with NASH and the control. These findings from both animals and human studies suggest a

possibility that manifestation of oxidative imbalance in the local might precede that in circulation in the steatotic stage of NAFLD. This possibility certainly needs to be validated further.

In agreement with the present observation, there have also been increasingly concerns as to whether circulating oxidative stress status can accurately be a reflection of hepatic oxidative damage in NAFLD<sup>[29]</sup>. Despite of the absence of increased circulating iPF<sub>2α</sub>-III in HF rats, the present study found that plasma iPF<sub>2α</sub>-III concentrations were strongly correlated not only with plasma TC and TG (and LDL, but without significance) but also with plasma ALT in rats with steatosis (Figure 4), whereas such a correlation was not found in the control rats. Thus, the abnormal lipid profile could be, at least in part, important contributors to oxidation imbalance related to the high-fat induced steatosis, whereas systemic relationship of lipid peroxidation with lipid status could be an important reflection of the functional decline of steatotic liver. While it might be expected that enhanced lipid peroxidation in NAFLD would be dependent, at least partially, on some lipidemic measures, there was little published support for such a correlation to date. Konishi *et al*<sup>[30]</sup> found no significant associations of plasma iPF<sub>2α</sub>-III with TC and TG in patients with NAFLD. In addition, Madan *et al*<sup>[31]</sup> failed to find relationship between oxidant stress and ALT levels in either NAFLD patients or diseased controls. Nevertheless, the present data suggest that oxidative imbalance and lipid peroxidation play a significant role in pathogenesis of NAFLD, especially at the steatotic stage. The results may indicate a potential value of measuring circulating total iPF<sub>2α</sub>-III to assess the extent of hepatic lipotoxicity during *in vivo* oxidative imbalance and its relevance to the progression of simple steatosis to NASH. This might further provide the rationale for interventions to slow the steatosis in human studies.

In summary, the present study demonstrates an enhanced oxidative imbalance at the steatotic stage of NAFLD. Such oxidative imbalance was not observed in the circulation, suggesting a possibility that manifestation of the local oxidative damage precedes that of systemic oxidative imbalance. The association analysis shows predominant metabolic features of the increased lipid peroxidation and also suggests a close association of the oxidative imbalance and the dyslipidemia with functional deterioration of the steatotic liver. Although there is no confirmatory conclusion in terms of the cause-effect relationship between oxidative stress and occurrence of steatosis from the present study, the results suggest that the steatotic stage of NAFLD might be a valuable model for evaluating the roles of oxidative imbalance in pathogenesis of NAFLD and for providing clues for earlier interventions against the development of NASH in human studies.

## COMMENTS

### Background

Oxidative imbalance as an important mechanism of non-alcoholic fatty liver

disease (NAFLD) has been a field of intense research but is not yet fully understood. While majority of previous researches were conducted mainly in NASH, only a few studies have focused on the effects of lipid peroxidation in simple steatosis, an earlier stage of NAFLD. As ectopic lipids accumulation in the liver is primarily linked to hepatic mitochondrial dysfunction and insulin resistance, it is reasonable to postulate that the steatotic stage of NAFLD might be of real importance in evaluating the cause-effect association of lipid peroxidation with the disease progression, thus providing clues for earlier pharmacological interventions against the development of NASH.

### Research frontiers

This study utilized the quantitative assay of F<sub>2</sub>-isoprostanes (i.e. iPF<sub>2α</sub>-III), which has been considered to be the most accurate *in vivo* lipid peroxidation marker, along with endogenous enzymatic antioxidants SOD and CAT to characterize hepatic as well as peripheral oxidative imbalance and its metabolic relevance in a rat model with simple steatosis.

### Innovations and breakthroughs

F<sub>2</sub>-isoprostanes, also referred to as iPF<sub>2α</sub>-III, are a group of prostaglandin F<sub>2</sub>-like isomers produced by free radical-catalyzed peroxidation of arachidonic acid. Increased plasma or urinary levels of iPF<sub>2α</sub>-III have been reported both in humans and animal models with NASH. Information in the literatures with regard to iPF<sub>2α</sub>-III production related to hepatic steatosis, however, is limited. The basic findings of the study are (1) significantly higher levels of iPF<sub>2α</sub>-III and lower activities of SOD and CAT were observed in the steatotic livers as compared with the control rats, while no such oxidative imbalance was found in the circulation; and (2) the formation of iPF<sub>2α</sub>-III in the circulation was significantly correlated with the abnormalities of blood lipids as well as ALT levels in the rats with simple steatosis, whereas no similar tendencies were evident in the control rats.

### Applications

The findings of the present study suggest an enhanced oxidative imbalance at the steatotic stage of NAFLD prior to the appearance of NASH, and it may further suggest a possibility that manifestation of the local oxidative damage precedes that of systemic oxidative imbalance. Furthermore, the results reveal not only a predominant metabolic feature of the increased lipid peroxidation, but also a close association of the oxidative imbalance and the dyslipidemia with functional deterioration of the steatotic liver in the rats with simple steatosis. We believe that these findings do provide supports to the postulation mentioned above.

### Peer review

This study performed a fine measurement of iPF-III using GC-MS to show a strong evidence for oxidative imbalance in the steatotic liver. It demonstrated in this paper that F<sub>2</sub>-isoprostanes (iPF<sub>2</sub>-III) in the liver increased when steatosis was induced in rats by treatment of high fat diet. This result together with decreased in SOD and catalase levels led to the conclusion that oxidative imbalance proceeds in early stages of NAFLD.

### Abstract

**AIM:** To investigate the inhibitory effects of hepatitis B virus (HBV) replication and expression by transfecting artificial microRNA (amiRNA) into HepG2.2.15 cells.

**METHODS:** Three amiRNA-HBV plasmids were constructed and transfected into HepG2.2.15 cells. HBV antigen secretion was detected in the cells with transient and stable transfection by time-resolved fluoroimmunoassays (TRFIA). HBV DNA replication was examined by fluorescence quantitative PCR, and the level of HBV S mRNA was measured by semi-quantitative RT-PCR.

**RESULTS:** The efficiency of transient transfection of the vectors into 2.2.15 cells was 55%-60%. All the vectors had significant inhibition effects on HBsAg and HBeAg at 72 h and 96 h after transfection ( $P < 0.01$  for all). The secretion of HBsAg and HBeAg into the supernatant was inhibited by  $49.8\% \pm 4.7\%$  and  $39.9\% \pm 6.7\%$ , respectively, at 72 h in amiRNA-HBV-S608 plasmid transfection group. The copy of HBV DNA within culture supernatant was also significantly decreased at 72 h and 96 h after transfection ( $P <$

0.01 for all). In the cells with stable transfection, the secretion of HBsAg and HBeAg into the supernatant was significantly inhibited in all three transfection groups ( $P < 0.01$  for all, vs negative control). The copies of HBV DNA were inhibited by  $33.4\% \pm 3.0\%$ ,  $60.8\% \pm 2.3\%$  and  $70.1\% \pm 3.3\%$ , respectively.

**CONCLUSION:** In HepG2.2.15 cells, HBV replication and expression could be inhibited by artificial microRNA targeting the HBV S coding region. Vector-based artificial microRNA could be a promising therapeutic approach for chronic HBV infection.

### INTRODUCTION

RNA interference (RNAi) has become a new promising approach to develop effective antiviral drugs in recent years, including hepatitis C virus (HCV), human immunodeficiency virus (HIV), poliovirus and hepatitis B virus (HBV)<sup>[1-3]</sup>. For HBV, RNAi was shown to have impressive inhibitory effects against viral gene transcription and expression<sup>[4-7]</sup>. One recent study further demonstrated the viral clearance from the liver of transgenic mice by RNAi targeted HBV<sup>[8]</sup>, which sheds light on the use of RNAi in HBV gene therapy.

HBV replication and gene expression can be strongly inhibited with virus specific siRNA treatment. However, the high sequence specificity of siRNAs, combined with prolonged treatment, promoted the emergence of siRNA-resistant virus variants. Selection of RNAi

escape mutants has been reported *in vitro* for HIV, HCV and HBV<sup>[9-11]</sup>. These findings indicate that the antiviral properties of specific siRNAs targeted virus are not as effective as expected.

RNAi can be triggered by small RNA molecules such as siRNA and microRNAs (miRNAs). MiRNAs endogenously expressed small ssRNA sequences of about 22 nucleotides in length, which naturally direct gene silencing through components shared with the RNAi pathway<sup>[12]</sup>. The mature miRNAs regulate gene expression by mRNA cleavage or translational repression<sup>[13,14]</sup>. Compared with siRNA, miRNA still can play a translational repression role when miRNAs partially complement with the target gene. Because of the flexibility of miRNA in binding with partially complementary mRNA targets, miRNA can serve as an anti-virus drug or vaccine to achieve a breakthrough in the treatment of virus mutation. Moreover, since miRNAs are single-stranded molecules insensitive to interferon systems, the utilization of this Pol-II-mediated miRNA generation can be safe both *in vitro* and *in vivo* without the cytotoxic effects of dsRNAs and siRNAs<sup>[15]</sup>. These findings indicate that miRNA mediated RNAi can be used as a tool for gene-specific therapeutics against viral infections.

In this study, we applied the recently developed artificial miRNA (amiRNA) expression vector based on the murine miR-155 sequence<sup>[16]</sup>, to observe whether amiRNA could efficiently suppress the expression and replication of HBV *in vitro*.

## MATERIALS AND METHODS

### Design of amiRNA and plasmid construction

The pcDNA™6.2-GW/± EmGFP-miR plasmid (Invitrogen, Carlsbad, CA, USA), driving the expression of amiRNA with polymerase II and containing a spectinomycin resistance gene, was used in this study. The engineered pre-miRNA sequence structure is based on the murine miR-155. According to the sequences of conserved region in HBV genome, we designed three target sequences against the S region of the HBV genome using Invitrogen's RNAi design algorithm at <https://rnaidesigner.invitrogen.com/rnaiexpress/>. The BLAST algorithm was also used to ensure the designed sequences would not target other gene transcripts to avoid off-target effects. These oligonucleotides (Table 1) were annealed and ligated into pcDNA6.2-GW/EmGFP-miR vector. The pcDNA6.2-GW/EmGFP-miR-negative control plasmid contains an insert that can form a hairpin structure which is processed into mature miRNA, but is predicted not to target any known vertebrate gene. Thus, this plasmid serves as a suitable negative control. Control cells were mock transfected with Lipofectamine 2000 alone.

### Cell culture and transfection

The HepG2.2.15 cells were cultured in Dulbecco's modified Eagle's medium (Invitrogen) supplemented with 10% fetal bovine serum (FBS, Gibco), 380 mg/L

antibiotic G-418 sulfate (Promega, USA), and 100 IU/mL penicillin and streptomycin, and 1% L-glutamine, at 37°C in the atmosphere of 5% CO<sub>2</sub>. Transfections were performed using Lipofectamine 2000 reagent (Invitrogen) according to the manufacturer's instructions. Briefly, cells were trypsinized and plated in 12-well plates at a density of 5.0 × 10<sup>4</sup> cells/mL (1 mL/well) for 24 h before transfection. Four μL of lipofectamine was diluted dropwise into Opti-MEM I (Gibco, USA) for a final volume of 100 μL and incubated at room temperature for 5 min. Then 1.6 μg of amiRNA expression vector was added to the diluted lipofectamine and incubated for another 20 min. The normal HepG 2.2.15 cells and the cell transfection with negative control plasmid containing scrambled miRNA were used as the negative control. Each plasmid was repeated in three wells. After transfection, the medium was partly removed for analysis every 24 h and the cells were replenished with fresh medium. The cell culture supernatant was collected for detection of HBsAg, HBeAg and HBV-DNA.

Stable transfection was carried out at 24 h after transfection, the cells were passaged at a 1:10 dilution into fresh growth medium and selection was performed with 10 mg/L Blasticidin 30 h later. The Blasticidin resistant colonies were picked with 200 μL pipet tip and cultured with medium containing 10 mg/L Blasticidin to establish individual clone lines. Successfully transfected cellclones were obtained by a long-term culture in a selected medium containing 6 mg/L Blasticidin.

### Detection of HBV-DNA in cell culture medium by real-time PCR

After transfection, 50 μL of the supernatant were mixed with an equal volume of the DNA extractant. Samples were incubated at 94°C for 10 min and then centrifuged at 10000 × g for 5 min. The supernatant was used as template for real-time PCR. The forward primer of HBV-DNA is 5'-GGAGTATGGATTTCGCACTCCTC-3', the reverse primer is 5'-TTGTTGTTGTAGGGGACCTG CCT-3', the fluorescent probe 5'-ACTTCCGGAAAC TACTGTTAGACGA-3', and the quenching probe 5'-GTAGTTCCCGAAGT-3'. PCR amplification and analysis were performed using the ABI 7500 real-time PCR detector (ABI). Assays were repeated in triplicate and average threshold cycle values were used to determine the concentration of HBV-DNA. The inhibitory rate was calculated using the follow formula: inhibitory rate (%) = (C control-C tester)/C control × 100%. Control represents HBV-DNA copies in HepG2.2.15 cells transfected with Lipofectamine alone, C tester represents HBV-DNA copies in cells transfected with amiRNA.

### HBsAg and HBeAg assay

To assess the effect of amiRNAs on HBV at the protein level, the viral proteins of hepatitis B surface antigen (HBsAg) and e antigen (HBeAg) of the culture supernatant from transfected cells at various times were measured with time-resolved fluoroimmunoassays kit (TRFIA) according to the supplier's instructions. The inhibitory rates were calculated according to the

**Table 1** Three pairs of two single-stranded DNA oligonucleotides

Plasmid	Top oligo strand	Bottom oligo strand
amiRNA-HBV-S89 (89-109 nt)	5'-TGCTGTCCCCACCACGAGTCTAGACTCTGTTGGCC ACTGACTGACAGAGTCACTCGTGGTGA -3'	5'-CCTGTCCACCACGAGTAGACTCTGTCAGTCAGT GGCCAAAACAGAGTCTAGACTCGTGGTGA -3'
amiRNA-HBV-S367 (367-387nt)	5'-TGCTGTGAGCAGTAGTCATGCAGGTGTTGGCC ACTGACTGACACCTGCATCTACTGCTCAA -3'	5'-CCTGTGAGCAGTAGATGCAGGTGTCAGTCAGT GGCCAAAACACCTGCATGACTACTGCTCAAC -3'
amiRNA-HBV-S608 (608-628nt)	5'-TGCTGTCAGATGCTGTACAGACTTGGTGGCC ACTGACTGACCAAGTCTGCAGCATCTGAC -3'	5'-CCTGTCAAGATGCTGTCAGACTTGGTCAGTCAGT GGCCAAAACCAAGTCTGTACAGCATCTGAC -3'

following formula: inhibitory rate (%) = (C control-C tester)/C control × 100%. Assays were performed in triplicate, and the average inhibitory rate was expressed as a mean ± SD.

#### Semiquantitative RT-PCR analysis of HBS mRNA

Total RNA was isolated by Trizol Reagent (Invitrogen) following the manufacturer's instructions. The quantity of total RNA was first determined by  $A_{260}$  measurement, and the quality of total RNA was estimated by 1.5% agarose gel electrophoresis. cDNA was synthesized from total RNA using the Reverse Transcription System (Promega) according to the manufacturer's protocol. The first-strand cDNA product was used for semi-quantitative PCR. PCR reaction was performed in a single reaction of 25  $\mu$ L volume. The forward (fp) and reverse (rp) primers used were: HBVS-FP: 5'-TAGACTCGTG-GTGGACTTC-3', HBVS-RP: 5'-ATTGGTAACAGC-GGTAAA-3', GAPDH-FP: 5'-ACCACAGTCCATGC-CATCAC-3', GAPDH-RP: 5'-TCCACCACCTGTT-GCTGTA-3'. The schedule consisted of incubation for 5 min at 94°C followed by 30 cycles of 94°C for 30 s, 55°C for 30 s and 72°C for 30 s, with a final cycle for 5 min at 72°C. PCR products were run on a 1% agarose gel and visualized by ethidium bromide staining, and the intensities were then measured by scanning the gel with JIEDA 801 (JIEDA, Nanjing, China). The products were quantified by densitometry and normalized with respect to GAPDH as internal control.

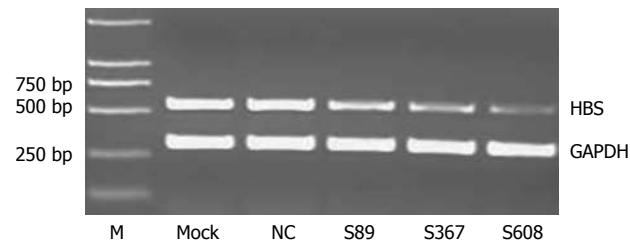

#### Statistical analysis

The data were expressed as mean ± SD. Statistical analysis was performed using Student's *t* test, with *P* value less than 0.05 being considered statistically significant. All statistical analyses were performed using SPSS software.

## RESULTS

#### Identification of recombinant plasmid amiRNA-HBV

RNAi was performed using the BLOCK-iT™ Pol II RNAi expression vector kit as recommended by the manufacturer (Invitrogen). Three plasmids containing pre-miRNA sequences were constructed and designated as amiRNA-HBV-S89, amiRNA-HBV-S367, and amiRNA-HBV-S608, respectively. In order to identify successful construction of recombinant plasmids, the miRNA forward sequencing primer 5'-GGCATGGACGAGCTGTACAA-3' and miRNA reverse sequencing primer 5'-CTCTAGATCAACCA

**Figure 1** Effect of amiRNA-HBV with stable transfection on HBV S mRNA levels, compared with negative control, all three plasmids had significant inhibitory effect on HBV S mRNA (*P* = 0.00094, 0.000047 and 0.000011, respectively).

CTTGTG-3', (Invitrogen) were used to perform PCR. And the PCR products, which contained the miRNA insert fragments, were verified by DNA sequencing. The mutant in these inserted oligonucleotides was excluded from this experiment.

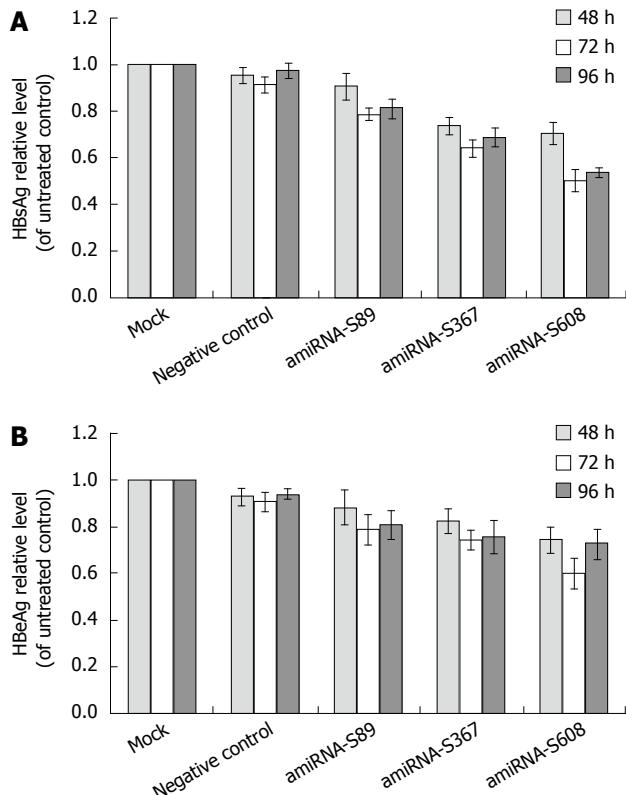

#### Inhibition of HBS mRNA expression by amiRNA

Once the recombinant plasmids were transfected into HepG2.2.15 cells, the expression of Emerald green fluorescent protein (EmGFP) could be detected directly under fluorescence microscopy. By this way, we found that the transfection efficiency of these vectors into HepG2.2.15 cells was 55%-60% in the current study. At 72 h after transfection, compared with mock and negative control vector, amiRNA-mediated RNAi resulted in a significantly reduced level of HBS mRNA in three plasmids transfected cells (*P* = 0.008, 0.0015 and 0.00074, respectively). Among them, amiR-HBV-S367 and amiRNA-HBV-S608 were more efficient with 38.7% and 47.4% average inhibitory rate in viral mRNA (Figure not shown).

For cell clones with stable transfection, amiRNA-mediated RNAi resulted in a higher decrease degree of HBS mRNA in three plasmid transfected groups than the cells with transient transfection. Among them, compared with negative control vector, the inhibitory rate of HBV S mRNA was 40.6% ± 3.8% in amiRNA-HBV-S89 group (*P* = 0.00094). amiR-HBV-S367 and amiRNA-HBV-S608 was much more efficient with an inhibitory rate of 63.4% ± 2.5% and 83.0% ± 4.3% in HBV S mRNA (*P* = 0.000047 and 0.000011, respectively; Figure 1).

#### Inhibition of HBeAg and HBsAg secretion by amiRNA

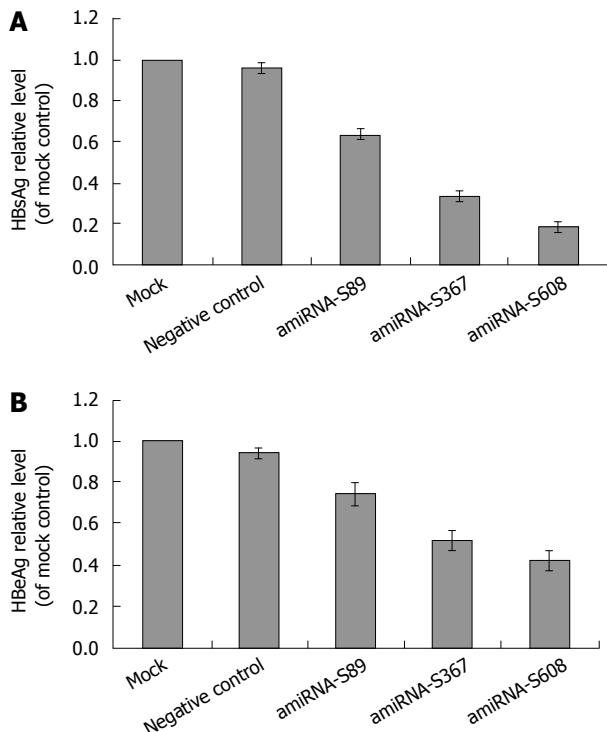

The concentrations of HBsAg and HBeAg in the culture supernatant were measured at 48 h, 72 h and 96 h, which were stable after transfection using TRFIA. As shown in Figure 2, our results demonstrated that three amiRNAs

**Figure 2.** A: Effect of amiRNA-HBV on HBsAg levels; B: Effect of amiRNA-HBV on HBeAg levels. HBsAg and HBeAg levels are expressed as mean  $\pm$  SD. Compared with negative control, all three plasmids had significant inhibitory effect on HBsAg and HBeAg at 72 h and 96 h after transfection (HBsAg:  $P = 0.00039$  and  $0.0012$  for S89 group,  $P = 0.000011$  and  $0.00021$  for S367 group,  $P = 0.000016$  and  $0.000056$  for S608 group; HBeAg:  $P = 0.02$  and  $0.035$  for S89 group,  $P = 0.0093$  and  $0.0032$  for S367 group,  $P = 0.007$  and  $0.0025$  for S608 group).

had distinct inhibition effects on HBsAg and HBeAg at 72 h and 96 h after transfection (HBsAg:  $P = 0.00039$  and  $0.0012$  for S89 group,  $P = 0.000011$  and  $0.00021$  for S367 group,  $P = 0.000016$  and  $0.000056$  for S608 group; HBeAg:  $P = 0.02$  and  $0.035$  for S89 group,  $P = 0.0093$  and  $0.0032$  for S367 group,  $P = 0.007$  and  $0.0025$  for S608 group). No significant reduction was measured when transfected with negative control vector, compared with mock control ( $P > 0.05$ ). Transfection with amiRNA-HBV-S608 vector had the greatest reduction of HBsAg and HBeAg compared with the negative vector control. At 48 h, 72 h and 96 h after amiRNA-HBV-S608 transfection compared with negative control, the inhibitory rates of HBsAg secretion were  $29.5\% \pm 5.0\%$ ,  $49.8\% \pm 4.7\%$  and  $39.9\% \pm 6.7\%$ , and the inhibitory rates of HBeAg secretion were  $25.5\% \pm 5.6\%$ ,  $39.9\% \pm 6.7\%$  and  $37.4\% \pm 6.7\%$ , respectively.

HBsAg and HBeAg in the culture medium of stably transfected cells were also assayed. The HBsAg and HBeAg levels of all the three cell lines integrated with the pCDNA6.2-HBV-amiRNA vector were significantly reduced compared with negative control of transfected HepG2.2.15 cells, (HBsAg:  $P = 0.00019$ ,  $0.000035$  and  $0.000012$ , respectively; HBeAg:  $P = 0.003$ ,  $0.0002$  and  $0.000024$ , respectively). The greatest reduction of HBsAg in amiRNA-S608 was  $81.5\% \pm 2.2\%$  ( $P = 0.000012$ ,

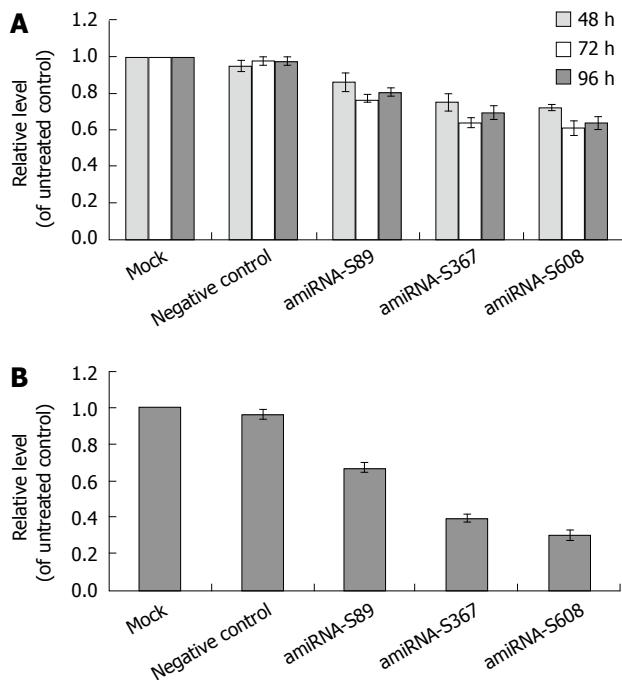

**Figure 3.** A: Effect of amiRNA-HBV with stable transfection on HBsAg levels; B: Effect of amiRNA-HBV with stable transfection on HBeAg levels. HBsAg and HBeAg levels are expressed as mean  $\pm$  SD. Compared with negative control, all three plasmids had significant inhibitory effect on HBsAg and HBeAg (HBsAg:  $P = 0.00019$ ,  $0.000035$  and  $0.000012$ , respectively; HBeAg:  $P = 0.003$ ,  $0.0002$  and  $0.000024$ , respectively).

Figure 3A), while the greatest reduction of HBeAg in amiRNA-S608 was  $58.1\% \pm 5.2\%$  ( $P = 0.000024$ , Figure 3B). No significant reduction was measured on the cells stably transfected with negative control plasmid compared with HepG2.2.15 cells ( $P > 0.05$ ).

#### Inhibition of HBV DNA replication by amiRNA

Real-time fluorescence quantitative PCR was performed to determine whether transfection with amiRNA-HBV-S vector would result in reduction of HBV DNA level. Quantitative assay revealed that HBV DNA levels of all three plasmid transfection groups decreased at 48 h, 72 h and 96 h after transfection, compared with negative control ( $P = 0.049$ ,  $0.000021$  and  $0.0011$  for S89 group;  $P = 0.0002$ ,  $0.000016$  and  $0.0012$  for S367 group;  $P = 0.0003$ ,  $0.00006$  and  $0.00016$  for S608 group). The greatest reduction was found in the amiRNA-HBV-S608 transfected group. The copies of HBV DNA in cells treated with amiRNA-HBV-S608 were reduced by  $39.0\% \pm 4.5\%$  at 72 h ( $P = 0.00006$ , vs negative control; Figure 4A). In the cell clones with stable transfection, compared with negative control vector, amiRNA-mediated RNAi resulted in a higher reduction level of HBV DNA in three plasmids transfected cells than those with transient transfection (Figure 4B). Among them, the HBV DNA level of amiRNA-HBV-S89 group decreased by  $33.4\% \pm 3.0\%$  ( $P = 0.00009$ ); amiRNA-HBV-S367 and amiRNA-HBV-S608 was much more efficient with inhibitory rates of  $60.8\% \pm 2.3\%$  and  $70.1\% \pm 3.3\%$ , respectively ( $P = 0.000007$  and  $0.000006$ , respectively).

**Figure 4.** A: Effect of amiRNA-HBV with transient transfection on HBV DNA levels; B: Effect of amiRNA-HBV with stable transfection on HBV DNA levels. The amounts of HBV DNA are expressed as mean  $\pm$  SD. Compared with negative control, all three plasmids had significant inhibitory effect on HBsAg and HBeAg at 48 h, 72 h and 96 h after transfection ( $P = 0.049$ ,  $0.000021$  and  $0.0011$  for S89 group;  $P = 0.0002$ ,  $0.000016$  and  $0.0012$  for S367 group;  $P = 0.0003$ ,  $0.00006$  and  $0.00016$  for S608 group). All three plasmids had significant inhibitory effect on HBV DNA in stably transfected groups, ( $P = 0.00009$ ,  $0.000007$  and  $0.000006$ , respectively).

## DISCUSSION

MicroRNA-induced RNA silencing has become a commonly used tool for the analysis of gene function<sup>[17,18]</sup>. The artificial microRNAs (amiRNAs) technology exploits endogenous miRNA precursors to generate sRNAs that direct gene silencing in either plants or animals<sup>[15,18-20]</sup>. AmiRNAs were first generated and used in human cell lines<sup>[15]</sup> and later in *Arabidopsis*<sup>[18]</sup>, where they were shown to effectively interfere with reporter gene expression. Subsequently, it was demonstrated that not only reporter genes but also endogenous genes can be targeted with amiRNAs (also called synthetic miRNAs). A few tumor genes have been successfully targeted with artificial synthetic miRNAs<sup>[21-23]</sup>.

In this paper, microRNA-induced RNA silencing was utilized to suppress HBV replication and expression. Three different miR-155 based vectors targeting HBV S gene were constructed. The three different plasmids all proved effective, but were not to the same extent at all three times. Among the three amiRNAs, amiRNA-HBV-S608 is the most potent in inhibiting HBV replication and expression in the transient transfection group. We found that HBsAg and HBeAg in the supernatant were inhibited by  $49.8\% \pm 4.7\%$  and  $39.9\% \pm 6.7\%$  at 72 h after transfection with amiRNA-HBV-S608 plasmid. The HBV DNA levels were also found to be decreased similarly. In view of transfection efficiency of 55%-60%, we concluded that actual antigen

inhibition rate of amiRNA-HBV-S608 vector was above 80%. To further confirm the effect of amiRNA-HBV, we performed stable transfection of amiRNA-HBV plasmid to exclude the effect of transfection efficiency. In the stably transfected cells with amiRNA-S608 plasmid, amiRNA-mediated RNAi resulted in a higher reduction level of both HBV antigen and DNA than with transiently transfected cells. The greatest reduction of HBsAg and HBeAg in stably transfected cells with amiRNA-HBV-S608 was  $81.5\% \pm 2.2\%$  and  $58.1\% \pm 5.2\%$ , respectively in stably transfected cells. The copies of HBV DNA in cells with stable transfection of amiRNA-HBV-S608 were reduced by  $70.1\% \pm 3.3\%$  compared to negative controls. These data provided a strong indication that continuous expression of amiRNA could provoke stable and sequence-specific silencing of target genes of HBV.

The HepG2.2.15 cells can produce replicative viral DNA intermediates, mature Dane particles and high level of viral antigens constitutively, which may be similar to the behavior in HBV-infected human being. But the inhibitory effect of amiRNA-mediated RNAi in HepG2.2.15 cells is lower than that in other hepatocytes and mice using co-transfection method<sup>[24,25]</sup>. We believed that all the HepG2.2.15 cells contained HBV genome and could secrete HBV proteins and DNA, but only approximately 55%-60% of the cells received the amiRNA-HBV vector. So the low transfection efficiency on HepG2.2.15 cells resulted in the reduction of inhibition effect. When stable transfection was performed in our experiment with the same vectors, all of these vectors acted with a similar effect as against other cotransfection methods.

Our results showed that artificial miRNA-mediated RNAi could inhibit HBV protein expression and HBV DNA replication in HepG2.2.15 cells *in vitro*. Similar to the siRNA mediated RNAi, microRNA mediated RNAi was sufficient to disrupt the viral life cycle and inhibited HBV DNA replication. The inhibition was sequence-specific, because the transfection with the negative control had no such effects. This is the first time to our knowledge that a marked reduction of HBV replication induced by artificial miRNA has been noted.

In summary, we constructed three artificially expressed miRNA plasmids and used them as a tool to inhibit HBV replication. We systematically evaluated the effects of amiRNA-based RNAi on HBV expression and replication in HepG2.2.15 cells. The data from our experiments suggested that amiRNA mediated RNAi might represent an alternative approach for the treatment of chronic HBV infection, which can enhance the anti-HBV efficacy and overcome the drawbacks of current therapies.

## COMMENTS

### Background

MicroRNAs (miRNAs) endogenously expressed small ssRNA sequences with

about 22 nucleotide, which naturally direct gene silencing through components shared with the RNAi pathway.

### Research frontiers

Recently, it has been described how artificial miRNAs (amiRNAs) designed to target one or several genes of interest could provide a new and highly specific approach for effective post-transcriptional gene silencing.

### Innovations and breakthroughs

The results of our study suggest that amiRNA-expressing vectors can be used as RNAi-based anti-HBV therapeutics. amiRNA mediated RNAi is more advantageous for treating chronic HBV infection, which is easy to mutate *in vivo*.

### Applications

Vector-based amiRNA could be a promising approach for the treatment of chronic HBV infection.

### Peer review

AmiRNA is a hot topic and the papers dealing with it is scarce. The importance of this strategy as a therapeutic tool of HBV infection could be outstanding.

Reddy VB, Aslanian H, Suh N, Longo WE. Asymptomatic ileal adenocarcinoma in the setting of undiagnosed Crohn's disease. *World J Gastroenterol* 2008; 14(29): 4690-4693 Available from: URL: <http://www.wjgnet.com/1007-9327/14/4690.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.4690>

## INTRODUCTION

The incidence of inflammatory bowel disease (IBD) is increasing with rates of around 6/100 000 for Crohn's disease with a marked rise in the age group between twenty to forty years<sup>[1]</sup>. Small bowel carcinomas are uncommon representing less than 5% of all gastrointestinal malignancies<sup>[2-7]</sup>. Prognosis is unfavorable with 1 and 2 year survival of 30%-60%, depending on the stage of the cancer<sup>[8-12]</sup>. Crohn's disease has been associated with an elevated risk for the development of small bowel adenocarcinoma<sup>[9,13-20]</sup> and chronic inflammation is implicated in this neoplastic progression<sup>[21]</sup>. Although most adenocarcinomas arise in the duodenum, those associated with Crohn's disease generally occur in the ileum 20 years or more after the onset of Crohn's disease<sup>[9,11,12]</sup>. In most cases, detection of small bowel carcinoma associated with Crohn's disease is at operation for other reasons or due to obstructive symptoms<sup>[22-25]</sup>.

Neither the risk factors nor screening for early diagnosis of small bowel adenocarcinoma in patients with Crohn's disease have been established. Here we report on an asymptomatic patient who on routine screening colonoscopy was diagnosed with adenocarcinoma of the terminal ileum which eventually led to the establishment of his Crohn's disease.

## CASE REPORT

A 53-year old man presented for evaluation of a small bowel mass found on a screening colonoscopy. He denied any episodes of abdominal pain or diarrhea. He noted that his father had been diagnosed with Crohn's disease at the time of his death. He subsequently underwent a computed tomography (CT) examination

## Abstract

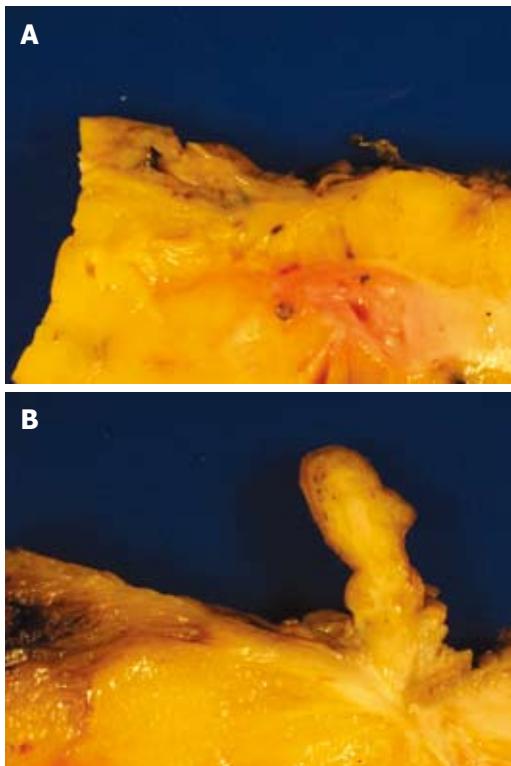

A 53-year old previously healthy male underwent a screening colonoscopy for detection of a potential colorectal neoplasm. The terminal ileum was intubated and a mass was noted. Examination of the colon was normal. The biopsy of the ileal mass was consistent with an adenocarcinoma arising from the terminal ileum. His father who had never been previously ill from gastrointestinal disease died of natural causes, but was found to have Crohn's disease postmortem. The patient underwent exploratory laparotomy and a right hemicolectomy with a 30 cm section of terminal ileum in continuity. Findings were consistent with ileal adenocarcinoma in the setting of Crohn's disease. The patient made an uneventful recovery. The pathology was stage 1 adenocarcinoma. This is a unique case in that on a screening colonoscopy, a favorable ileal adenocarcinoma was discovered in the setting of asymptomatic, undiagnosed ileal Crohn's disease in a patient whose father had Crohn's disease diagnosed postmortem.

**Key words:** Ileal adenocarcinoma; Crohn's disease; Colonoscopy

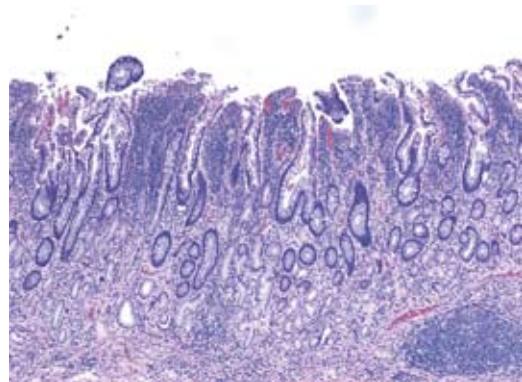

**Figure 1** CT scan of the abdomen showing thickened and spiculated ileal wall.

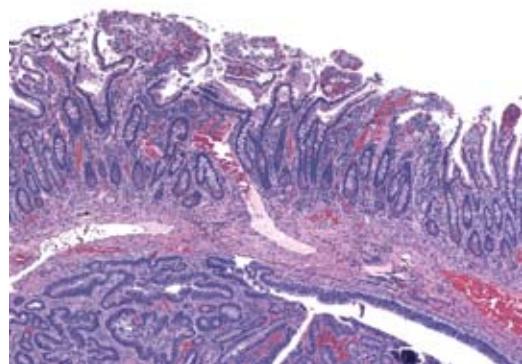

**Figure 2** A: Stricture adjacent to the ileocecal valve; B: 3 cm polyp, sections of which revealed a white spiculated area extending into the underlying fat.

of his abdomen and pelvis with both oral and intravenous contrast which revealed a thickened and spiculated wall of the terminal ileum with fistulization from the terminal ileum to the cecum (Figure 1). Given these findings, he was taken to the operating room for exploration.

On exploration, he was found to have a dense inflammatory mass in the right lower quadrant with multiple adhesions to the abdominal wall and bladder. Further exploration revealed a mass in the terminal ileum with dense adhesions involving the terminal ileum and cecum. Given these findings, a right hemicolectomy with a concomitant terminal ileal resection was performed. The surgical specimen consisted of a 20 cm segment of the cecum and a 53 cm segment of the terminal ileum with pericolic fat averaging 9 cm in diameter.

**Figure 3** Crohn's changes in the terminal ileum (HE, x 400).

**Figure 4** Adenocarcinoma invading the muscularis propria (HE, x 400).

Macroscopic examination revealed Crohn's disease involving the distal most segment of the terminal ileum with a stricture adjacent to the ileocecal valve (Figure 2A). Adjacent to the stricture was a 3 cm polyp, sections of which revealed a white spiculated area that extended into the underlying fat (Figure 2B).

Histopathological examination in the area of the stricture revealed areas of chronic inflammatory change with marked architectural distortion and extensive pseudo-pyloric metaplasia in the mucosa. Extensive transmural lymphoid aggregates, muscular hypertrophy, neural hyperplasia, and submucosal fibrosis, compatible with Crohn's disease were also noted (Figure 3). In many areas, the mucosa was sitting directly in contact with the muscularis propria without any intervening submucosa. In the background of this inflammation, areas of low and high grade dysplasia were identified. Scattered glands were seen infiltrating into the markedly hypertrophic and disorganized muscularis mucosa. Isolated tumor glands were also seen in the submucosa and as discussed above, in some areas, there were hardly any intervening submucosa with the tumor glands infiltrating the muscularis propria (Figure 4). The size of the tumor was difficult to estimate, as grossly no obvious mass was identified. However, from microscopic sections, it was estimated that the intramucosal carcinoma extended over a 2.0 cm area. The staging of this tumor was also difficult due to complex architecture and histological changes in the bowel wall. However, due to the presence

of occasional tumor glands in the muscularis propria, it was staged as pT2. Twenty-nine lymph nodes were harvested and all were negative for carcinoma. The patient recovered well from surgery.

## DISCUSSION

A thorough search of the worldwide literature has revealed that the case presented here is the first ever of a patient with ileal adenocarcinoma as the first manifestation of Crohn's disease in an otherwise asymptomatic patient. There are, however, other reports of ileal adenocarcinoma as the first manifestation of Crohn's disease in patients with vague abdominal complaints<sup>[26,27]</sup>.

In 1956, Ginzburg *et al* first described carcinoma as a rare complication of small bowel Crohn's disease<sup>[28]</sup>. To date, several cases of small bowel carcinoma in Crohn's disease have been reported<sup>[29]</sup>. The most common small bowel carcinoma is adenocarcinoma, and risk factors include long-standing disease, surgically bypassed loops, male sex, onset of disease before the age of 30 years, and associated chronic active disease with strictures and fistulas<sup>[11,30-32]</sup>.

Munkholm *et al* reported an incidence of 0.54% of small bowel cancer in Crohn's disease compared to an expected rate of 0.04% ( $P = 0.0001$ )<sup>[30]</sup>. In a later study, the same group reported a more than 60-fold increased risk of small bowel adenocarcinoma independent of age and sex in patients with Crohn's disease<sup>[33]</sup>. The lifetime prevalence of small bowel adenocarcinoma in patients with Crohn's disease is 1%-3%<sup>[34]</sup>. The combination of genetic susceptibility, mechanical irritation and surgery has been suggested as possible etiologies for this elevated risk in Crohn's disease. Small bowel carcinomas are also mostly localized to strictures<sup>[22,35,36]</sup>. Immunosuppression has also been implicated<sup>[32]</sup>.

These occult carcinomas pose a challenge to conventional diagnostic investigations such as upper or lower gastrointestinal endoscopy and small bowel series. CT has now emerged as the imaging modality of choice<sup>[37-40]</sup>. Magnetic resonance imaging (MRI)<sup>[41]</sup>, double-contrast enteroclysis<sup>[42]</sup>, and video wireless capsule endoscopy<sup>[43,44]</sup> have also been promising.

Survival rates for small bowel malignancies are much worse than for large bowel cancers with a mean survival of 6 mo as compared to 65 mo for the latter<sup>[9]</sup>. Mortality rates range from 30%-60% depending on the stage of the carcinoma<sup>[8-12]</sup>. Poor prognostic factors include positive resection margins, extramural venous spread, lymph node metastases, poor tumor differentiation, depth of tumor, and a history of Crohn's disease<sup>[45]</sup>.

Only small studies have evaluated adjuvant therapy for small bowel adenocarcinoma<sup>[46,47]</sup>. These studies are not in patients with Crohn's disease and randomized controlled trials are definitely needed.

We report a patient with ileal adenocarcinoma as the first manifestation of Crohn's disease. The patient had no symptoms of Crohn's disease and had only a family history of Crohn's disease. This case report, as well as others discussed above, highlight the need for a higher

index of suspicion in screening for Crohn's disease and initiating a regular follow-up with ileocolonoscopy.

### Abstract

Lymphoepithelioma is a particular form of undifferentiated carcinoma, characterized by a prominent lymphoid stroma, originally described in the nasopharynx. Lymphoid stroma-rich carcinomas arising in other organs have been termed lymphoepithelioma-like carcinoma (LELC). In the liver, primary LELCs are very rare, and the majority has been identified as cholangiocarcinomas. Here a rare case of lymphoepithelioma-like hepatocellular carcinoma (HCC) is described. A 47-year old woman presented with abdominal pain. Ultrasoundography revealed a liver nodule, 2.2 cm in diameter, localized in the right lobe, adjacent to the gallbladder. Viral markers for hepatic B virus (HBV), hepatic C virus (HCV) and Epstein-Barr virus (EBV) were negative. The nodule was hypoechoic. The patient underwent surgery, with resection of the nodule. Histology showed hepatocellular carcinoma, characterized by a prominent lymphoid infiltrate. At immunocytochemistry, tumor cells were reactive for Hep Par1 and glypican 3. Immunophenotyping of tumor infiltrating lymphocytes evidenced the predominance of CD8+ cytotoxic suppressor T cells. The postoperative clinical outcome was favorable and the patient was recurrence-free 15 mo after resection. This case, to the best of our knowl-

edge, is the first reported non EBV and non cirrhosis-associated lymphoepithelioma-like hepatocellular carcinoma. The association between the lack of EBV infection, the absence of cirrhosis, a "cytotoxic profile" of the inflammatory infiltrate and a good prognosis could identify a variant of lymphoepithelioma-like HCC with a favorable clinical outcome.

### INTRODUCTION

Lymphoepithelioma is a particular form of undifferentiated carcinoma, characterized by a prominent lymphoid stroma, primarily described in the 1920's by Regaud and Schminke in the head and neck region of Asian subjects<sup>[1]</sup>. Subsequently, histologically similar carcinomas have been described in other organs, such as salivary glands<sup>[2]</sup>, lung<sup>[3]</sup>, stomach<sup>[4]</sup>, colon<sup>[5]</sup>, thymus<sup>[6]</sup>, uterus<sup>[7]</sup>, bladder<sup>[8,9]</sup> and urinary tract<sup>[10]</sup>. Lymphoid stroma-rich carcinomas in these locations have been termed Lymphoepithelioma-like carcinoma (LELC). The similarities among these neoplasms arising in diverse sites are not limited to the histological picture, i.e. to the presence of a heavy lymphocytic intratumoral infiltrate. The majority of these tumors, particularly those originating from the nasopharynx<sup>[11]</sup>, salivary glands<sup>[2]</sup>, thymus<sup>[12]</sup>, lung and stomach<sup>[13]</sup>, show relevant pathogenetic similarities: a close etiopathogenetic linkage with Epstein-Barr virus (EBV) infection. At the immunohistochemical level, EBV expression in these tumors has been associated

**Figure 1** Histological picture characterized by a strong lymphoid intratumoral infiltrate (HE, x 250) (A), vast majority of neoplastic cells showing intense granular cytoplasmic reactivity for Hep Par 1 (x 250) (B), scattered atypical tumor cells showing cytoplasmic immunoreactivity for Glycocalyx 3 (x 400) (C), and a large atypical tumor cell surrounded by CD34-positive newly formed capillaries (x 400) (D).

with p53 over expression in the nuclei of EBV-infected tumor cells<sup>[14]</sup> and hyperreactivity of tumor cells for bcl-2 and proliferating cell nuclear antigen (PCNA)<sup>[15]</sup>.

Although it has been suggested by many authors that lymphoepithelioma-like carcinomas have a better prognosis than conventional carcinomas with a less marked lymphocytic infiltrate<sup>[10]</sup>, given the few studies on the clinical course of lymphoepithelioma-like carcinomas in the literature to date, this topic needs further investigation.

In the liver, lymphoepithelioma-like primitive carcinomas are extremely rare. To the best of our knowledge, only nine cases of cholangiocarcinomas have been reported, and the majority was associated with EBV infection<sup>[16]</sup>. Here we report a rare case of hepatocellular carcinoma (HCC) characterized by a prominent lymphoid stroma, indistinguishable on morphological grounds from tumors called lymphoepithelioma-like carcinomas with a discussion on their histological, immunohistochemical and clinical findings.

## CASE REPORT

A 47-year-old woman presented with acute abdominal pain, localized in the right liver lobe. Ultrasonography evidenced a hypoechoic liver mass, 2.2 cm in diameter, adjacent to the gallbladder. At CT-scan, the nodule showed signs of a recent intranodular hemorrhage. Laboratory tests showed negativity for HBV (serum HBsAg, HbeAg, anti-HbcAg and HBV DNA), HCV, and EBV markers. Molecular analyses for detecting EBV DNA, performed in tumor samples by PCR and Southern blot hybridization, were negative. The patient underwent surgery, with resection of the liver nodule. Histological examination

showed proliferation of atypical large cells, characterized by an eosinophilic cytoplasm, with large nuclei and prominent nucleoli. Epithelial cells were surrounded by a dense lymphoid stroma, extending inside the tumor (Figure 1A). At immunocytochemistry, tumor cells were diffusely Hep Par1-positive (Figure 1B) and focally immunoreactive for glycocalyx 3 (Figure 1C). No reactivity for cytokeratins 7, 19 and 20 was observed. CD34 showed diffuse capillarization of intratumoral sinusoids (Figure 1D). The clinical outcome was favorable and the patient was recurrence-free after a 15-mo follow-up.

## DISCUSSION

The case reported here is, to the best of our knowledge, the fourth reported case of Lymphoepithelioma-like HCC. The first case described in 2000 by Emile *et al* and defined as HCC with lymphoid stroma<sup>[17]</sup>, was characterized by a good prognosis after liver transplant and negativity for EBV infection<sup>[18]</sup>. Subsequently, in a letter to the Journal, Szekely E. argued that the tumor was indistinguishable from LELC described in other organs, suggesting the final diagnosis of lymphoepithelioma-like HCC<sup>[19]</sup>. The second case of hepatocellular LELC, described in 2004 by Si MW and coworkers<sup>[20]</sup>, showed some similarities and marked differences as compared with the first one. Both patients affected by end stage chronic liver disease underwent liver transplant. The patient described by Si was younger and infected with HCV and EBV, which was detected in tumor samples. The clinical course was precipitous, multiple recurrences appeared 3 mo after liver transplant and the patient expired within a few weeks. The third case of hepatocellular LELC was recently reported by Chen *et al*<sup>[21]</sup> in a 56-year old male patient with cirrhosis related

to HCV infection and negative EBV markers. The case reported here shows some peculiarities as compared with the previous 3 cases. It is the first case of hepatocellular LELC arising in a non cirrhotic liver. Moreover, the risk factor for Lymphoepithelioma-like HCC in our case was unknown since EBV, HBV and HCV markers were negative. The absence of EBV infection was associated with a favorable clinical outcome, as in two previously reported cases of EBV-negative lymphoepithelioma-like HCC<sup>[17,21]</sup>, contrasting with the aggressive course of one case of EBV-positive hepatocellular LELC<sup>[20]</sup>. These data show that, even in LELCs arising in the liver, and in spite of a striking similarity of the histological picture of all tumors, the clinical aggressivity of HCC in a single case may be extremely variable. In our case, we observed the predominance of CD8+ cytotoxic T cells, in the inflammatory intratumoral infiltrate, suggestive of an effective immune response to the tumor<sup>[22]</sup>.

Finally, this case is the first case of non EBV and non cirrhosis-associated lymphoepithelioma-like HCC. The association between the lack of EBV infection, the absence of cirrhosis, a CD8+/cytotoxic profile of the inflammatory infiltrate and a good prognosis could identify a variant of lymphoepithelioma-like HCC with a favorable clinical course.

Vanishing bile duct and Stevens-Johnson syndrome associated with ciprofloxacin treated with tacrolimus. *World J Gastroenterol* 2008; 14(29): 4697-4700 Available from: URL: <http://www.wjgnet.com/1007-9327/14/4697.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.4697>

## INTRODUCTION

Stevens-Johnson syndrome (SJS), a rare but severe dermatological condition<sup>[1]</sup>, is considered a severe type of erythema exsudativum multiforme<sup>[2]</sup>, characterized by erythema with bullous and eroded lesions of skin and mucous membranes. It typically occurs after ingestion of medications such as nonsteroidal drugs, antibiotics, and anticonvulsants<sup>[1,2]</sup>. Extracutaneous manifestations of the syndrome may involve the conjunctiva, trachea, buccal mucosa, gastrointestinal tract, and genitourinary tract<sup>[2,3]</sup>. Cholestatic liver disease, which may precede the cutaneous manifestations of SJS, occurs in a very limited number of patients with SJS. In the present case, SJS and acute vanishing bile duct syndrome (VBDS), the most severe cholestatic liver diseases, were identified.

## CASE REPORT

A 26-year-old woman presented to the emergency department of our hospital, complaining of dysphagia, dysuria, fever and rashes on her body. Two weeks prior to eruption, 500 mg ciprofloxacin, twice daily, was started for acute bronchitis by a pulmonologist. Her medical history was unremarkable. Physical examination revealed macular erythematous eruption on her face, back, arms and erosions on the lips, buccal and genital mucous membranes. She was febrile (39°C), her conjunctivae were icteric and injected. Laboratory investigations showed 4.07 mg/dL total bilirubin (< 1.2 mg/dL), 3.58 mg/dL conjugated bilirubin (< 0.2 mg/dL), 326 IU/L alanine transaminase (ALT, < 31 IU/L), 280 IU/L gamma-glutamyl-transpeptidase (GGT, < 36 IU/L), 229 IU/L alkaline phosphatase (ALP, < 104 IU/L), and 107 mm/h erythrocyte sedimentation rate (ESR). Serologic tests were negative for viral hepatitis A-C, E, Epstein Barr virus, cytomegalovirus, Herpes simplex virus, Mycobacteria and Mycoplasma pneumonia. Abdominal ultrasound showed that liver

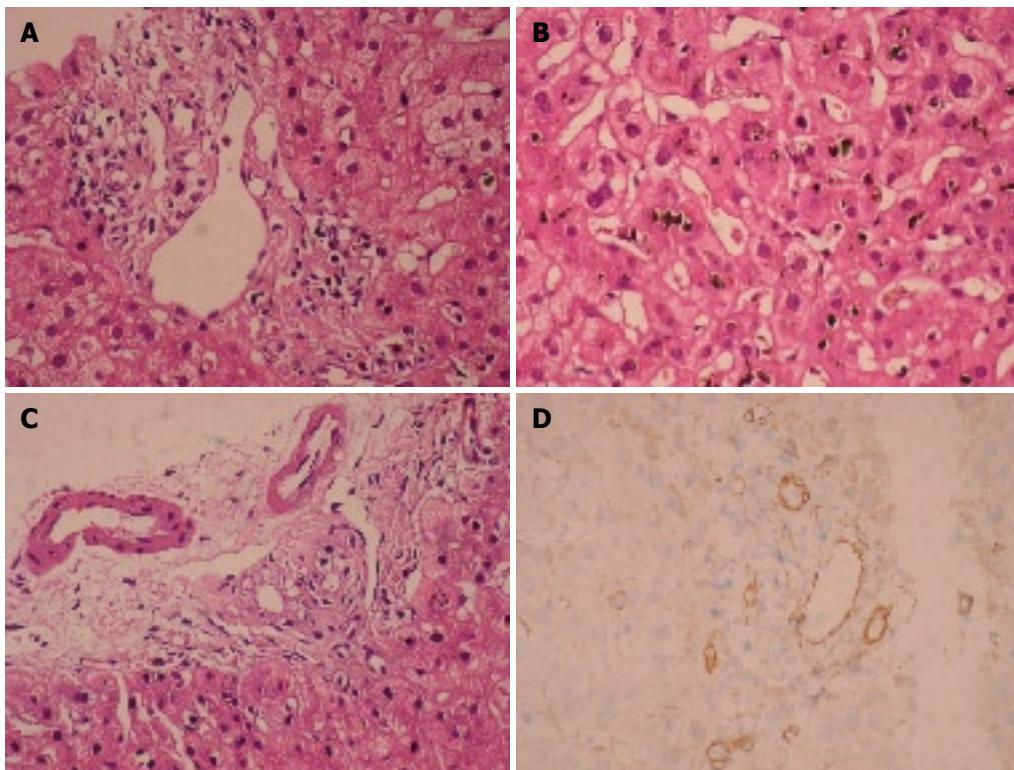

## Abstract

Stevens-Johnson syndrome (SJS) is a serious and potentially life-threatening disease. Vanishing bile duct syndrome (VBDS) is a rare cause of progressive cholestasis. Both syndromes are mostly related with drugs. We report a case of a patient with ciprofloxacin-induced SJS and acute onset of VBDS, and reviewed the related literature. It is the first case of ciprofloxacin-induced VBDS successfully treated with tacrolimus. This case reminds physicians of the importance of drug reactions, their severity, techniques for diagnosis and methods of management.

Tricomi, Palermo 90127, Italy

**Figure 1** Moderate predominantly lymphocytic mixed portal infiltration and absence of interlobular bile duct destruction (HE,  $\times 400$ ) (A), intralobular severe canalicular cholestasis (HE,  $\times 400$ ) (B), marked cytoplasmic vacuolization in cholangiolar epithelium (HE,  $\times 400$ ) (C), and absence of bile ducts by cytokeratin 19 immunohistochemical staining (IHC,  $\times 400$ ) (D), observed in our patient.

**Figure 2** ALT and ALP (A) and total bilirubin (B) levels during and after treatment in our case.

had homogeneous texture with normal bile ducts and gallbladder. Skin biopsy from the neck showed subepidermal vesiculation and epidermal necrosis, which was consistent with SJS. Skin eruptions resolved after supportive care. However, cholestatic picture persisted. Ursodeoxycholic acid treatment (15 mg/kg per day) did not alleviate the symptoms. Antinuclear antibody, anti-neutrophil cytoplasmic antibody, anti-liver/kidney microsomal antibody and antismooth muscle antibody titers turned out to be negative. Magnetic resonance cholangiopancreatography showed no abnormality in bile ducts. Percutaneous liver biopsy 30 d after the diagnosis showed cholestasis, along with a decreased number of bile ducts and mild portal inflammation, which was consistent with VBDS (Figure 1). Prednisone (40 mg/d) was added to the treatment with ursodeoxycholic acid

and discontinued after 4 wk because of lack of efficacy and iatrogenic Cushing's syndrome. Cholestasis persisted and bilirubin level exceeded 30 mg/dL (Figure 2). After long medical discussions and repetitive literature reviews, she was put on treatment with tacrolimus (0.15 mg/kg per day in two divided doses). Significant clinical and biochemical improvements were observed 3 mo after treatment. She took tacrolimus for 3 mo, ursodeoxycholic acid (15 mg/kg per day) for 7 mo. She had a normal physical status with normal liver synthetic functions and was instructed to avoid ciprofloxacin in the future.

## DISCUSSION

SJS is a serious and potentially life-threatening disease,

mainly caused by drugs. More than 100 different medications have been implicated<sup>[1]</sup>. The syndrome usually begins within 1-14 d of ingestion of the offending agent but may not manifest itself for up to three to 6 wk after ingestion<sup>[3]</sup>. In our case, the interval was 3 wk. Anticonvulsants, sulfonamides, penicillins, allopurinol, nonsteroidal anti-inflammatory drugs are the most common culprit medications while ciprofloxacin and cephalosporin are rarely reported as the causative agents of SJS<sup>[1,3,4]</sup>.

SJS is a well-recognized immune complex-mediated hypersensitivity reaction that affects all age groups<sup>[5-7]</sup>. It has classic systemic, mucosal and dermatologic manifestations<sup>[5]</sup>. VBDS, a rare cause of progressive cholestasis, is mostly related with drugs. Drugs act as a hapten and produce autoantibodies against cytokeratin which is in the bile duct, skin, conjunctival epithelium and orogenital mucosa<sup>[5]</sup>. Autoantibodies destroy biliary apparatus and as a result, with resultant disappearance of intrahepatic bile duct<sup>[8]</sup>.

The mechanism of biliary epithelial cell injury and interlobular duct loss in the VBDS has not been fully understood yet<sup>[5]</sup>. Toxic, idiosyncratic, metabolic, and immune etiologies have been suggested<sup>[5,7]</sup>. The latest evidence supports the importance of the immune system in the pathogenesis and suggests mechanisms common to both SJS and VBDS<sup>[5]</sup>. In SJS, there are immune complex formation and deposition, followed by a cytokine- and cell-mediated response<sup>[5,7]</sup>. Many drugs associated with VBDS are also associated with SJS like antibiotics, non-steroidal anti-inflammatory drugs and carbamazepine.

In the literature, there are less than ten reported cases of SJS and VBDS co-occurrence<sup>[1,5,7]</sup>. So it is great deal to have a standardized approach to these patients. There is no proven effective therapy for VBDS and SJS, but authors mostly agree that treatment modalities for both VBDS and SJS include withdrawal of the offending agent, supportive care, and usage of immunosuppressants<sup>[9,10]</sup>. Steroids, choleretic agents and immunosuppressants have been tried<sup>[1,2,10]</sup>. Acute onset of VBDS may be unresponsive to these modalities and progress to biliary cirrhosis, thus liver transplantation may be needed<sup>[5]</sup>. Because of the paucity of cases, there are no available success and failure rates, frequency of complication and percentage of liver transplantation need. Case-based literature just gives us some clinical clues for treatment approaches.

In our case, VBDS was refractory to steroid and ursodeoxycholic acid therapies. The clinical and biochemical improvements were obtained by immune suppression with tacrolimus therapy in our patient. In the literature, it is the first case of ciprofloxacin-induced VBDS successfully treated with tacrolimus.

Tumor necrosis factor-alpha (TNF- $\alpha$ ) has been shown to be strongly expressed in SJS lesions by an Italian group<sup>[11]</sup>. Authors suggest that IFN-gamma may play an important role in SJS. IL-2, IL-5 and IL-13 may contribute to the cutaneous immunoinflammation in this disease. Since immune complex-mediated reaction is very

important in these drug-induced syndromes, anti-TNF- $\alpha$  antibodies may be a promising therapy in the future<sup>[12,13]</sup>. However, it is not available in clinical practice, and there is no reported SJS or VBDS case treated with anti-TNF- $\alpha$  yet in literature.

Several recent studies have reported strong genetic associations between HLA alleles and susceptibility to drug hypersensitivity<sup>[14]</sup>. The genetic associations can be drug specific, such as HLA-B1502 being associated with carbamazepine-induced SJS, HLA-B5701 with abacavir hypersensitivity and HLA-B5801 with allopurinol-induced severe cutaneous adverse reactions<sup>[15,16]</sup>. The high sensitivity and specificity of some markers provide a plausible basis for developing tests to identify individuals at risk for drug hypersensitivity. Drug specific genetic screening tests may prevent those catastrophic diseases. Prescribing medication, according to history and genetic tests, will decrease the prevalence of both diseases in the future.

Our case reminds physicians of the importance of drug reactions, their severity, techniques for diagnosis and ways of management. Prescribing any drug with ultimate care, early diagnosis and treatment of both syndromes will improve the outcome.

H, Kinjo F. An autopsy case of a primary aortoenteric fistula: A pitfall of the endoscopic diagnosis. *World J Gastroenterol* 2008; 14(29): 4701-4704 Available from: URL: <http://www.wjgnet.com/1007-9327/14/4701.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.4701>

## INTRODUCTION

A primary aortoenteric fistula (PAEF) is a rare but often life-threatening cause of massive gastrointestinal bleeding<sup>[1-5]</sup>. PAEFs have a mortality rate of nearly 100% in the absence of surgical intervention, and diagnosis is not established preoperatively<sup>[2-5]</sup>. Diagnostic procedures are often non confirmatory and can sometimes impede urgently needed surgical intervention<sup>[3,4,6]</sup>. Although it is infrequent, gastrointestinal endoscopy may be a double-edged sword when PAEFs coexist with multiple bleeding sites<sup>[7]</sup>. Here, we report such a case in which the cause of death was massive gastrointestinal bleeding due to a PAEF after leaving the hospital.

## CASE REPORT

A 68-year-old man went to a hospital after suffering from melena for several days. He was conscious but looked pale. He had a blood pressure of 120/60 mmHg. His hemoglobin level was 5.7 g/dL and his hematocrit was 19.8%. An abdominal examination appeared normal, and no abdominal mass was observed. An emergency gastrointestinal endoscopy revealed a bleeding ulcer in the second part of the duodenum (Figure 1A). Other potential sources of acute bleeding were excluded. The patient was diagnosed with a probable duodenal ulcer, which was the presumed source of his bleeding. Endoscopic hemoclipping was performed (Figure 1B), and the patient received a blood transfusion and hemostatic agents. Following these procedures, the patient had no signs of hemorrhaging and recovered from anemia. After a follow-up endoscopy on the 13th d (Figure 1C), the patient was discharged from the hospital. However, the following day, the patient complained of lumbago and abdominal distension. In the middle of the night, he suddenly entered into a state of shock, experienced a cardiac arrest, and was taken to the hospital. In the emergency room, a nasogastric tube was inserted and

## Abstract

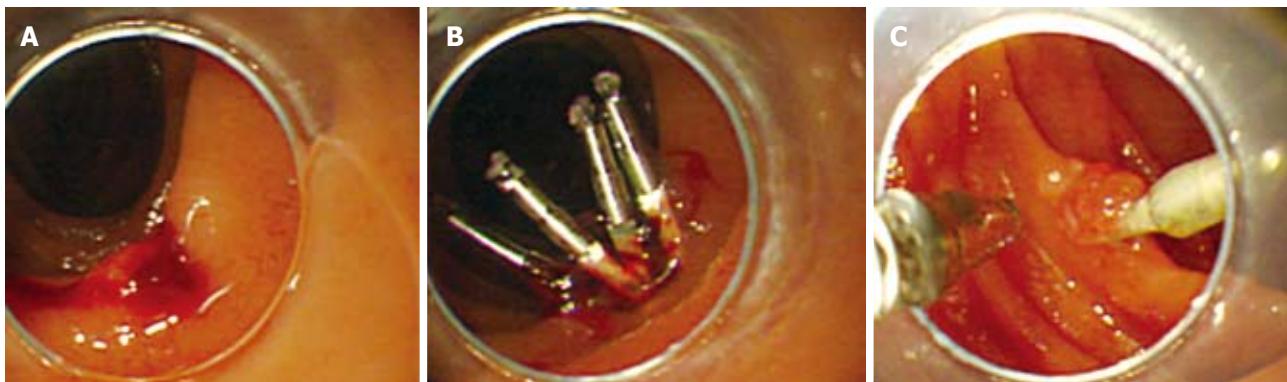

A primary aortoenteric fistula (PAEF), defined as a communication between the native aorta and the gastrointestinal tract, is a rare cause of gastrointestinal bleeding. The preoperative diagnosis of PAEF is extremely difficult. Consequently, PAEF may cause sudden and unexpected death. We present an autopsy case of a 68-year-old man who died of massive gastrointestinal bleeding due to a PAEF. Autopsy revealed a pinhole rupture located on the third part of the duodenal mucosa and fistulized into the adjacent abdominal aortic aneurysm (AAA). Our case indicates that the aortoenteric fistula can result in fatal gastrointestinal bleeding. Consequently, a PAEF should be included in the differential diagnosis of gastrointestinal bleeding.

**Figure 1** Endoscopic image showing a bleeding ulcer in the second part of the duodenum (A), the endoscopic clipping procedure revealing no other bleeding site detected by upper and lower gastrointestinal endoscopy (B), and follow-up gastrointestinal endoscopic view 12 d after hemostatic procedure (C). Only one hemoclip remained on the scar of the duodenal ulcer.

**Figure 2** The presence of a firm adhesion between the AAA and the digestive duodenal wall located on the third part of duodenum (A), and magnification of the firm adhesion between the anterior site of the abdominal aorta and the posterior serosa of the duodenum (B).

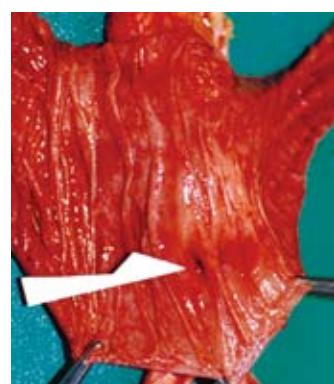

nasogastric aspiration was performed producing 880 mL of blood.

#### Autopsy findings

The patient measured 162 cm in height and weighed 58 kg. Postmortem hypostasis on the back was very slight. No petechiae were observed in the palpebral conjunctivae. External examination revealed no injuries except for those caused by clinical procedures performed in the emergency room. Internal examination revealed that the gastrointestinal tract was dilated and contained 2200 mL of clotted blood between the stomach and jejunum. No abdominal organ injury and blood were found in the abdominal cavity. An abdominal aortic aneurysm (AAA) was located above the bifurcation of the aorta and resembled a fusiform swelling, 4 cm in diameter and 5 cm in length. An AAA with atherosclerosis thrust forward, adhering firmly to the digestive duodenal wall (Figure 2). The inferior mesenteric artery was hardly identified due to fibrous adhesion. The internal surface of the AAA had highly calcified atheromatous ulcers covered with mural thrombus (Figure 3). A pinhole rupture was located on the third part of the duodenal mucosa (Figure 4) and fistulized into the adjacent AAA. A scarred ulcer with a hemoclip was observed on the second part of duodenal mucosa

**Figure 3** The AAA has severe atherosclerosis with calcification and clotted blood on the aneurysm inside the aortic lumen.

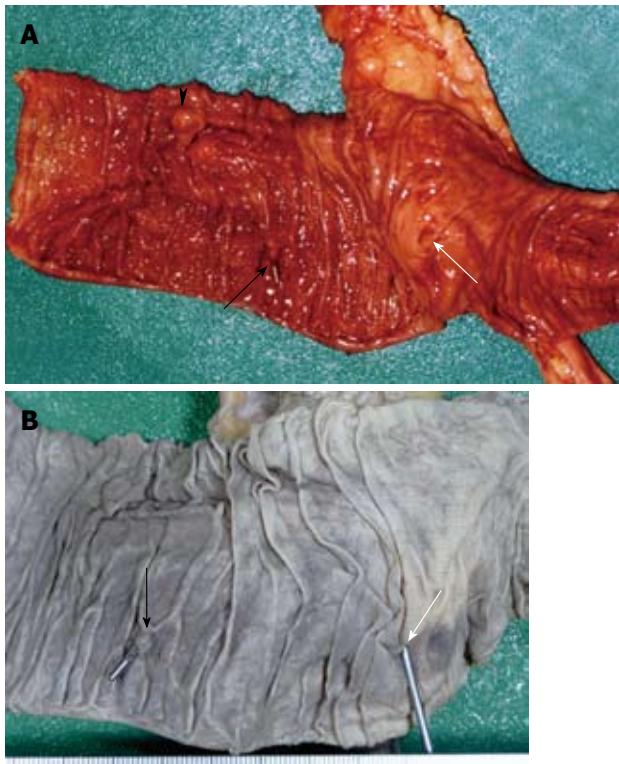

**Figure 4** A rupture and the size of a pinhole with no degeneration or inflammation of the third part of the duodenal mucosa as indicated by the white arrow.

(Figure 5). No other origin of bleeding was found in the gastrointestinal tract.

#### Microscopic investigations

Histological examination revealed a fibrous adhesion between the aorta and duodenal serosa. The aneurysm contained atheromatous degeneration covered by a mural thrombus with a layer of fibrin. The internal and external elastic membranes were destroyed and the media of the artery was thinned under the most advanced plaque. Fibroblast proliferation and granulation tissue were revealed in the adventitia of the aorta and perivascular tissue. Inflammation of the duodenum was more serious at the serosa, but there were no signs of inflammation of the duodenal mucosa (Figure 6). Because repair reaction of the aorta was broader than that of

**Figure 5** A scar on the clipped ulcer indicated by the black arrow, papilla Vater indicated by the black triangle, and a rupture on the third part of duodenal mucosa located in front of the firm adhesion indicated by the white arrow in the duodenal mucosa specimen (A), and a postclipping scar indicated by the black arrow and a rupture indicated by the white arrow in the formalin-fixed specimen of the duodenal mucosa (B). The rupture was located approximately 6 cm from the anal side of the postclipping scar.

the duodenum, inflammation may originate out of the aorta.

## DISCUSSION

A PAEF, defined as a communication between the native aorta and gastrointestinal tract, is a rare cause of gastrointestinal bleeding<sup>[2,3,8,9]</sup>. A large autopsy series reported an incidence of PAEF of 0.04%-0.07%<sup>[1,2,7]</sup>. A fistula most commonly originates from an AAA, of which 85% are atherosclerotic. AAA is a common disease among middle-aged and older subjects, and its clinical consequences depend on its location and size. The major complications of AAA include rupture into the peritoneal cavity, occlusion of a branch vessel and embolism from atheroma or mural thrombus. PAEF is the rarest complication of AAA. The most frequent site of a fistula is the third part of the duodenum, as in the current case<sup>[1,4,10]</sup>. The literature reports that PAEFs are often fatal, with a total mortality rate of 80%-100% and a perioperative mortality rate of 18%-63%<sup>[1-3,7,9-11]</sup>. However, the actual incidence and mortality rates are not known because many patients die of PAEFs before they have been correctly diagnosed<sup>[1,8]</sup>.

The classical triad of symptoms, i.e. gastrointestinal bleeding, abdominal pain, and a pulsating abdominal mass is overemphasized<sup>[1,3,4]</sup>, as it occurs in less than 25% of PAEF cases<sup>[6]</sup>. The diagnosis of a PAEF is difficult because of its nonspecific and subtle clinical presenta-

**Figure 6** Formalin-fixed duodenum and aorta specimen demonstrating a sonde inserted from the rupture on the duodenal mucosa to the inside of the aortic lumen (A), horizontal cross sections showing a firm adhesion between the aorta and its wall as well as a rupture (black arrow) on the third part of the duodenum (B); and a microphotograph of a horizontal cross section showing an adhesion between the duodenum and the aorta with atherosclerosis-contained clotted blood (C). The histology of the duodenal appears normal (HE,  $\times 5$ ).

tion<sup>[2,4]</sup>. However, PAEFs usually present with a herald bleeding prior to exsanguination<sup>[1-4,9]</sup>. Herald bleeding is usually minor and self-limiting, and it is probably due to a spasm of the intestinal wall musculature in response to sudden distention<sup>[1,3]</sup>. Bleeding can be further limited by hypotension and thrombus formation<sup>[1-3]</sup>. Consequently, excessive volume therapy and endoscopy may promote fatal exsanguination<sup>[1,12]</sup>. The time interval between a herald bleeding and exsanguination is known to range from hours to months<sup>[1-4,9]</sup>. The interval was about 2 wk in the current patient. When the patient dies of fatal exsanguination after going to the hospital due to a herald bleeding, his family may suspect an error in medical treatment.

Frequently, the choice of a diagnostic procedure is based on the clinical condition<sup>[1,3,5]</sup>. Diagnostic imaging techniques, such as contrast-enhanced computed tomography (CT) and angiography, are useful investigation modalities for identifying PAEFs<sup>[1-4]</sup>. Even if there is limited bleeding at the examination, CT might reveal the size, location, and degree of calcification of an AAA. Fibrous adhesion between the aorta and duodenum might facilitate PAEF identification. In a hemodynamically stable patient with gastrointestinal bleeding, endoscopy is the preferred primary procedure which provides valuable information<sup>[1-3,7]</sup>. However, endoscopy rarely reveals confirmatory evidence of a PAEF because stable patients do not often have an active bleeding<sup>[1,2,11,13]</sup>. Additionally, endoscopic visualization of a fistula that is present

lower than the third part of the duodenum, which is the most common site of PAEF occurrence, is extremely difficult<sup>[2,4,14]</sup>. In the clinical setting, the absence of identifiable bleeding lesions with initial gastrointestinal endoscopy is regarded by some as a strong indicator for laparotomy<sup>[3,13]</sup>. Recently, since the introduction of capsule endoscopy for clinical use, small bowel bleeding from the ampulla of Vater into the terminal ileum can be easily visualized and defined<sup>[15]</sup>. Capsule endoscopy, which non-invasively captures images of the gastrointestinal mucosa without any pressure load, might be the best strategy for identifying a PAEF. However, if upper endoscopy or colonoscopy detects other coexisting bleeding sites in PAEF patients, the findings may be misleading<sup>[3,4,6,7,13]</sup>. Furthermore, concomitant gastrointestinal lesions are occasionally found in PAEF patients, and this incidence is 25% as indicated in previous series<sup>[5,7,13,16]</sup>. In the current patient, a bleeding ulcer was identified as the source of the gastrointestinal bleeding. Hence, the possibility of a PAEF might have been overlooked. Ultimately, the key to early diagnosis of PAEF is an endoscopist's heightened index of suspicion<sup>[4,5,13]</sup>. Endoscopists need to recognize PAEFs as a potential cause of gastrointestinal bleeding.

## Abstract

Tubulovillous adenomas are common in the colon and rectum, but are rare in the common bile duct. Biliary adenomas may produce obstructive jaundice, which can be easily confused with a malignant neoplasm or stone. We report a case of a carcinoma *in situ* arising in a tubulovillous adenoma of the distal common bile duct causing obstructive jaundice. A 55-year-old male presented with a 10-d history of pruritus and progressive jaundice. Abdominal sonography and computed tomography showed a mass in the distal common bile duct. Endoscopic retrograde cholangiopancreatography showed luminal narrowing of the bile duct due to a polypoid mass. Positron emission tomography demonstrated no abnormal uptake. It was thought that this mass was a malignant tumor, thus a pylorus-preserving pancreaticoduodenectomy was performed. The final pathology showed a tubulovillous adenoma with carcinoma *in situ* of the distal common bile duct. At follow-up 8 mo later, endoscopy showed multiple polyps in the rectum, colon and stomach. The polyps were removed by endoscopic mucosal resection and shown to be tubular adenomas with high grade dysplasia. Biliary adenomas require careful follow-up for early detection of recurrence and malignant transformation.

## INTRODUCTION

Biliary adenomas are very rare tumors, which may pose diagnostic dilemmas preoperatively. Due to recent advances in diagnostic techniques and early diagnosis, biliary adenomas are often detected as high grade dysplasias or carcinomas *in situ*. The optimal therapeutic strategy for adenomas of the distal common bile duct (CBD) or ampillary region has not been established. We report herein a case of a bile duct tubulovillous adenoma with carcinoma *in situ* presenting painless jaundice in a man who was treated with a pylorus-preserving pancreaticoduodenectomy (PPPD) and presented 8 mo later with a tubular adenoma in the gastrointestinal tract with high grade dysplasia. Our patient did not exhibit any clinical signs of familial adenomatous polyposis<sup>[1]</sup> or Gardner's syndrome<sup>[2]</sup>. We also reviewed the literature about the common bile duct adenoma found in the English literature<sup>[3-22]</sup> (Table 1).

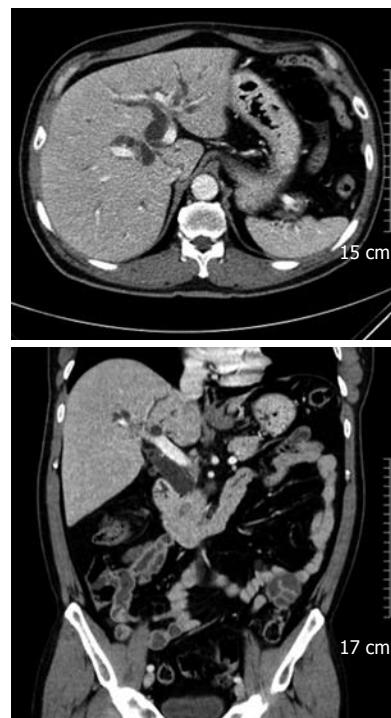

## CASE REPORT

A 55-year-old man was admitted to our hospital with a 10-d history of painless obstructive jaundice and pruritus. He had diabetes mellitus which had been controlled by an oral hypoglycemic agent. He had no family history of colorectal cancer or polyposis. On physical examination, he had icteric sclerae. Abdominal examination revealed no palpable mass or tenderness. Laboratory tests showed elevations of total bilirubin (8.2 mg/dL), direct bilirubin (6.3 mg/dL), alkaline phosphatase (302 IU/L), alanine transaminase (27 IU/L) and gamma glutamyl transpeptidase (110 IU/L). Endoscopic retrograde cholangiopancreatography (ERCP) showed a 10-mm polypoid mass in the distal CBD. Endoscopic mucosal resection (EMR) was performed and the specimen was sent for histopathological examination. The final pathology showed a tubulovillous adenoma with carcinoma *in situ* of the distal common bile duct. At follow-up 8 months later, endoscopy showed multiple polyps in the rectum, colon and stomach. The polyps were removed by endoscopic mucosal resection and shown to be tubular adenomas with high grade dysplasia.

PPPD: Pylorus-preserving pancreaticoduodenectomy.

**Figure 1** Ultrasound examination reveals a 2 cm sized non-shadowing mass and a dilated common bile duct (arrow).**Figure 2** Computed tomography shows a diffuse dilatation of the common bile duct with an intraluminal mass in the distal common bile duct.

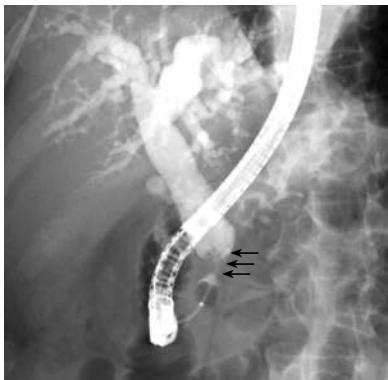

tidase (321 IU/L). The serum amylase was within the normal range. The carbohydrate antigen 19-9 level was 131.6 U/mL (normal range,  $\leq 27$  U/mL) and the carcinoembryonic antigen level was 1.5 ng/mL (normal range, 5 ng/mL). The hepatitis serologic markers were all negative. On abdominal ultrasonography, the CBD was dilated with a distal non-shadowing polypoid mass, however, there was no pancreatic duct dilatation (Figure 1). The CT findings were similar to the ultrasonographic findings and therefore a distal CBD tumor was suspected (Figure 2). Endoscopic retrograde cholangiopancreatography showed a 2cm polypoid mass and stricture in the distal CBD (Figure 3). Bile cytology revealed no malignancy. Positron emission tomography (PET) showed no hypermetabolic lesions. Based on the preoperative diagnosis of a distal tumor, a PPPD was performed.

The resected specimen revealed a 2 cm  $\times$  1.5 cm polypoid mass in the distal CBD (Figure 4). The final pathology showed a tubulovillous adenoma with carcinoma *in situ* in the distal CBD (Figure 5). There was no lymph node metastasis. The patient recovered

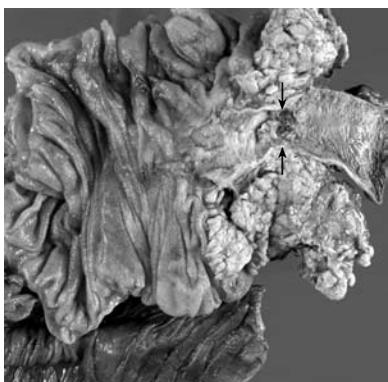

uneventfully. Eight months later, he developed multiple polyps (two in rectum, three in the colon and two in the stomach). An endoscopic mucosal resection was performed, which revealed a tubular adenoma with high grade dysplasia.

## DISCUSSION

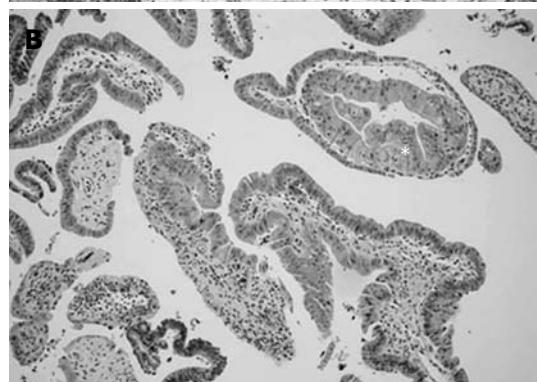

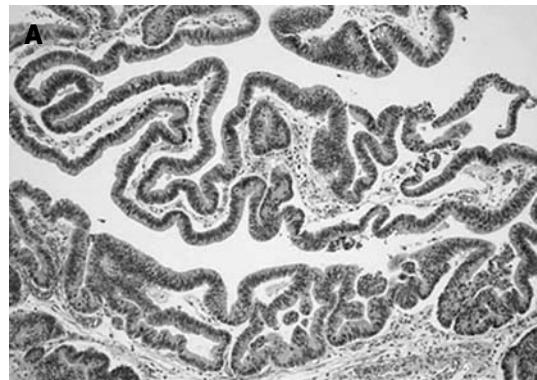

Tubulovillous adenomas are usually encountered in the gastrointestinal tract, but as a primary site, the CBD is

**Figure 3** Endoscopic retrograde cholangiopancreatography shows a 2 cm round lobulated filling defect in the distal common bile duct (arrows).

**Figure 4** A photograph of the pylorus-preserving pancreaticoduodenectomy specimen shows a polypoid mass in the distal common bile duct, 2 cm x 1.5 cm x 1.5 cm size (arrows).

**Figure 5** Microscopic features of the tubulovillous adenoma. Hematoxylin-eosin stain. **A:** The elongated and pseudostratification of nuclei are stained ( $\times 40$ ); **B:** Higher magnification on this slide demonstrates carcinoma *in situ* (asterisk;  $\times 100$ ).

rare. Adenomas arising from the CBD are summarized in Table 1. Saxe *et al*<sup>[5]</sup> was first to report a case of a villous adenoma in the CBD. The clinical manifestations of a biliary adenoma include jaundice, right upper quadrant abdominal pain, dyspepsia, nausea and vomiting in a fashion similar to ampullary tumors. Villous adenomas are benign tumors, but are considered to be premalignant. It is possible that the adenoma-to-carcinoma sequence occurs in biliary tumors<sup>[23-26]</sup>. Considering the similarity of the histologic and biologic characteristics of adenomas in the other segments of the GI tract, such an adenoma-to-carcinoma carcinogenic process involving the rectum, ampulla, gallbladder, and biliary duct occurs within the biliary tract<sup>[27,28]</sup>. Therefore, complete resection of the lesion makes it possible to avoid development of carcinoma<sup>[29]</sup>. It is difficult to differentiate biliary adenomas from other malignant lesions with radiologic imaging<sup>[23]</sup>. Predicting the presence of malignant foci preoperatively is difficult. However, suspicion of malignancy could be made by an experienced biliary endoscopist.

Appropriate management of these lesions in the distal CBD has not been clearly defined. In 1992, Sturgis *et al*<sup>[7]</sup> first reported that high-risk patients with tubulovillous adenomas of the CBD were best treated by endoscopic resection but the risk of recurrence is high. Other treatment options, such as local resection, are performed in high-risk patients thought preoperatively to have benign tumors<sup>[10]</sup>. Ariche *et al*<sup>[10]</sup> proposed that resection with free margins of the CBD with lymph node dissection of the hepatoduodenal ligament for tumors in the mid part of the CBD is an appropriate treatment option. If the remaining duct length is inadequate, local resection is impossible and

PD should be considered mandatory in cases involving cancer of the distal CBD. If malignancy is suspected or the size is larger than approximately 2 cm, radical resection is needed. We considered the other treatment option, duodenum preserving pancreatic head resection(DPPHR) which was first introduced by Beger *et al*<sup>[27]</sup> for chronic pancreatitis and has been increasingly used in neoplastic lesions, cystadenoma, borderline lesions, and carcinoma *in situ*<sup>[28-30]</sup>. However, we suspected that this tumor would be malignant and performed PPPD considering the size, site and clinical findings. Compared to Whipple-type resection, duodenum preserving pancreatic head resection has benefits in regard to postoperative morbidity and mortality, maintenance of glucose metabolism, absence of delay of gastric emptying, shorter hospital stay offers better quality of life of patients. However, duodenum preserving pancreatic resection has two major problems, incomplete lymph node dissection and ischemia of duodenum and has not been used yet as a surgical option of adenoma of common bile duct. Maeda *et al*<sup>[31]</sup> reported that duodenum preserving pancreatic resection in the treatment of pancreatic metastasis from renal cell carcinoma should be considered as radical lymph node dissection is not necessary. And then, if the nature and extent of common bile duct adenoma is suggestive of benign tumor and lymph node enlargement is absent, preoperatively, DPPHR should be considered in the treatment of common bile duct adenoma.

In this case, colonoscopy has not been performed and gastroscopy revealed no tumors in the stomach and

duodenum preoperatively. At the time of follow-up 8 mo postoperatively, colonoscopy and gastroscopy revealed multiple polyps in the rectum, sigmoid colon, and stomach. They were removed by endoscopic mucosal resection and confirmed as tubular adenomas with high grade dysplasia. In view of the risk of recurrence of adenomas, careful follow-up is in order.

Järvinen *et al*<sup>[32]</sup> have reported biliary involvement in familial adenomatous coli patients. The present report is the first case of a tubulovillous adenoma with carcinoma *in situ* of the distal CBD and several tubular adenomas with high grade dysplasia of the GI tract confirmed 8 mo apart. We think that although adenoma of the biliary tract and GI tract did not exist concurrently, tubulovillous adenoma of the distal CBD may have developed by a similar mechanism to that of the GI tract. In conclusion, this case suggests that adenomas arising from the distal CBD can transform into carcinoma and support the existence of an adenoma-to-carcinoma sequence given that carcinoma *in situ* with an adenomatous lesion of the distal CBD and tubular adenoma of the GI tract adenoma ultimately developed.

## Abstract

Small cell neuroendocrine carcinoma of the ampulla of Vater is extremely rare and different from the common ampullary adenocarcinoma. The ampillary adenoma is also a rare neoplasm and has the potential to develop an adenocarcinoma. Their coexistence has been rarely reported in the literature. We herein describe an unusual case of a small cell neuroendocrine carcinoma associated with a villous adenoma in the ampulla of Vater with emphasis on computed tomography (CT) and histopathological findings. We also discuss their clinical, histopathological and radiological features as well as possible histogenesis.

Coexistence of small cell neuroendocrine carcinoma and villous adenoma in the ampulla of Vater. *World J Gastroenterol* 2008; 14(29): 4709-4712 Available from: URL: <http://www.wjgnet.com/1007-9327/14/4709.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.4709>

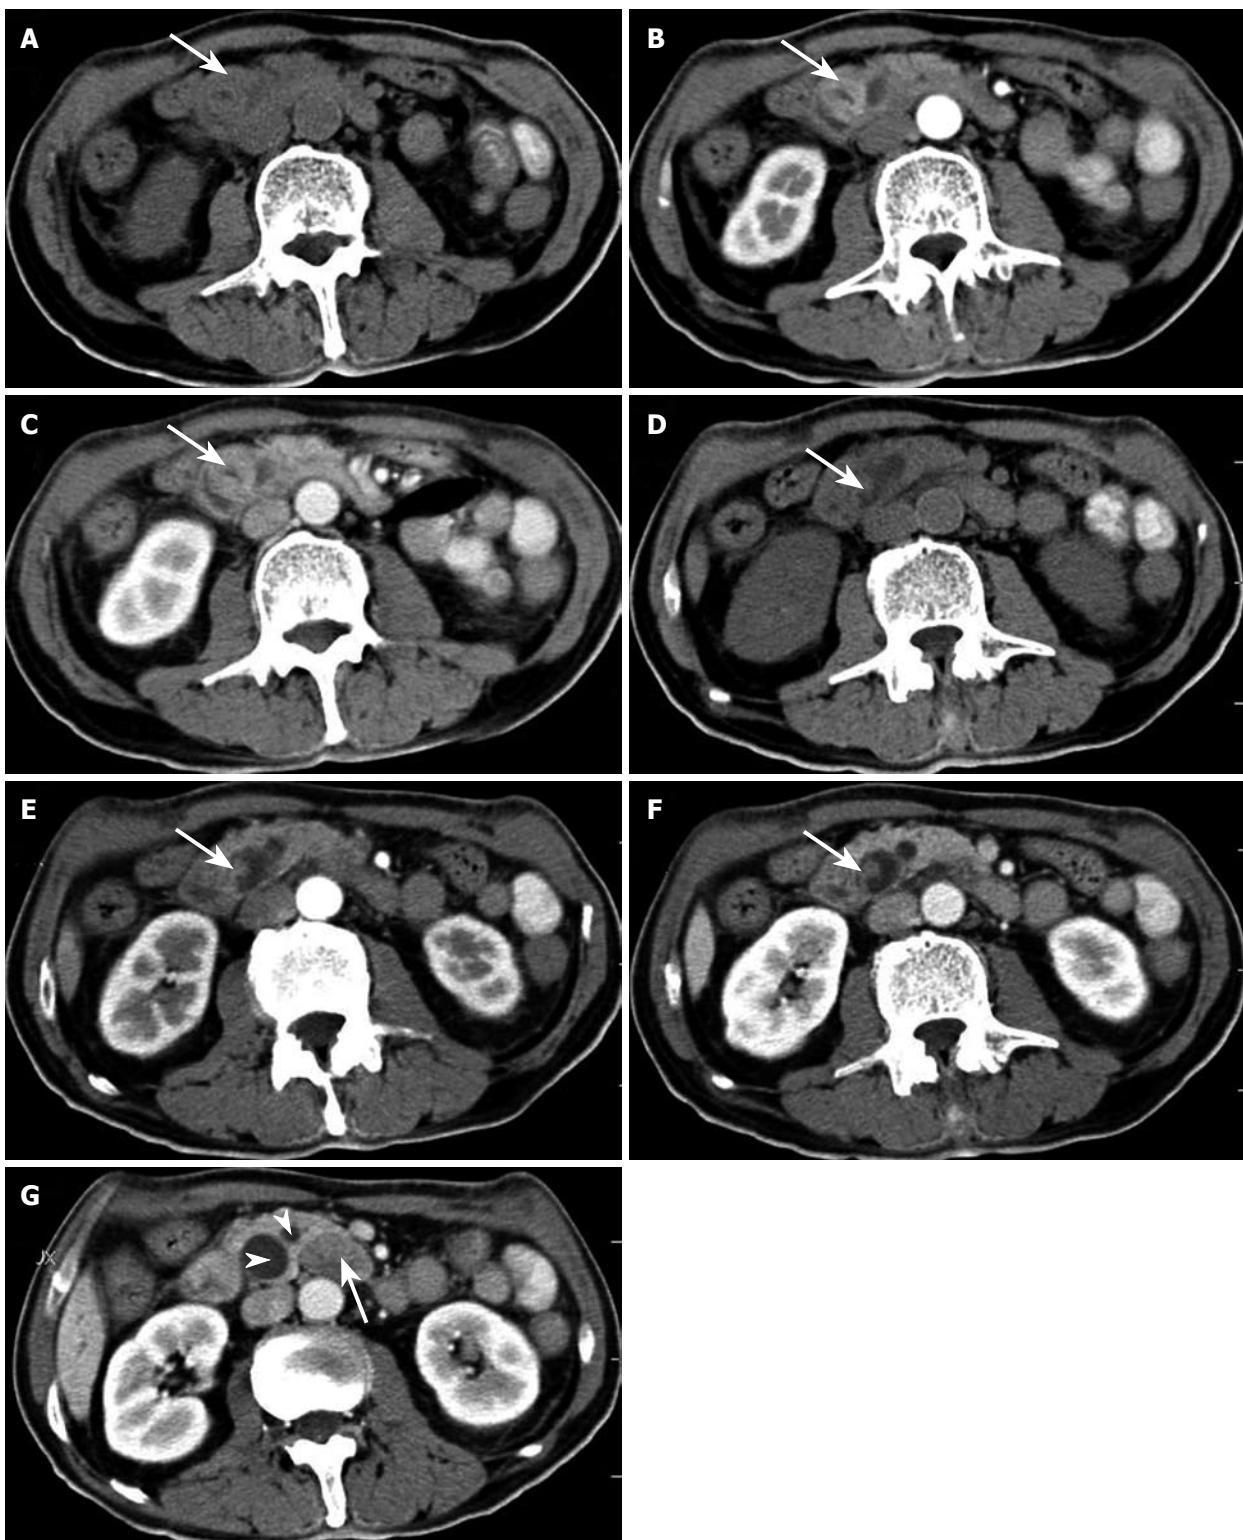

## INTRODUCTION

Primary extrapulmonary small cell neuroendocrine carcinoma is rare, occurring in only 4% of all patients with small cell carcinomas<sup>[1]</sup>. Small cell neuroendocrine carcinoma presents 0.1%-1% of all gastrointestinal malignant tumors with varying incidence in different organs<sup>[2]</sup>. Small cell neuroendocrine carcinoma of the ampulla of Vater is extremely rare and different from the common ampullary adenocarcinoma<sup>[3]</sup>. The ampillary adenoma is also a rare neoplasm and has the potential to develop an adenocarcinoma<sup>[4]</sup>. Only two cases of a small cell neuroendocrine carcinoma associated with an adenoma have been described by Nassar *et al*<sup>[5]</sup>. To our knowledge, there has been no report describing the imaging features of these coexisting tumors of the ampillary region. Here we report the computed tomography (CT) and magnetic resonance (MR) findings of an unusual case of a small cell neuroendocrine carcinoma associated with a villous adenoma in the ampulla of Vater, and review their clinical and histopathologic features.

## CASE REPORT

A 74-year-old man presented with a 3-wk history of abdominal discomfort and jaundice. Physical examination showed icterus and a palpable gall bladder. Laboratory findings were: total bilirubin, 11.19 mg/dL (normal 0.3-1.5); direct bilirubin, 6.91 mg/dL (normal 0.01-0.35); serum albumin, 3.14 g/dL (normal 3.5-5.0); alanine aminotransferase, 209 U/L (normal 0-50); aspartate aminotransferase, 197 U/L (normal 0-40); γ-glutamyl transpeptidase, 1610 U/L (normal 0-40); alkaline phosphatase, 1419 IU/L (normal 30-140); and carbohydrate antigen 19-9, 657.4 U/mL (normal < 37).

Gastroduodenal endoscopy showed a swollen duodenal papilla with the intact mucosal surface. Abdominal ultrasonography revealed a heterogeneous hypoechoic mass in the ampulla of Vater and markedly dilated bile ducts over the neoplasm. Abdominal CT showed two well-defined masses, dilated bile ducts and peripancreatic lymphadenopathy (Figure 1). On precontrast CT scanning, the two masses were isoattenuated to the surrounding pancreatic parenchyma (Figure 1A and D). On arterial and portal phase images after contrast enhancement, the larger oval mass was slightly hyperattenuated to the surrounding pancreas and showed the stenosis of the ampulla of

**Figure 1** Abdominal CT reveals two well-defined masses in the ampulla of Vater. On precontrast CT scanning, the two masses (arrow) show isoattenuation to the surrounding pancreatic parenchyma (A and D). On arterial and portal phase images after contrast enhancement, the larger oval mass (arrow) shows slightly higher attenuation than the surrounding pancreas (B and C). The smaller polypous mass (arrow) with a long pedicle and stalk shows slightly lower attenuation than the surrounding pancreas (E and F). Contrast-enhanced CT scan (G) shows peripancreatic lymphadenopathy (arrow) and dilatation of the common bile duct and the pancreatic duct (arrowheads).

Vater in its central portion (Figure 1B and C). The smaller polypous mass with a pedicle was slightly hypoattenuated to the surrounding pancreas (Figure 1E and F). MR cholangiopancreatography (MRCP) showed the dilated biliary tree up to the level of the ampulla, where the

common bile duct ended abruptly (Figure 2). The low-signal intensity mass was demonstrated immediately inferiorly to the level of the obstruction. The pancreatic duct was moderately dilated.

The patient underwent Whipple's operation with

**Figure 2** MRCP demonstrates dilatation of intrahepatic and extrahepatic bile ducts and the pancreatic duct as well as the low signal intensity mass (arrow) in the ampulla of Vater.

local lymph node dissection. At operation there was a 1.5 cm × 2 cm yellowish gray tumor located mainly in the submucous layer of the ampulla. A polyp with a 6 mm × 6 mm spherical head and a relatively long pedicle and stalk was found in the vicinity of the tumor and extended to the distal common bile duct. Histologically, the tumor proliferated in a nesting pattern. Patchy necrosis was present. The tumor was composed predominantly of small to medium-sized, round or oval cells with a high nucleus-to-cytoplasm ratio, finely dispersed chromatin, inconspicuous nucleoli, and high mitotic activity (more than 10 per 10 high power microscopic fields) (Figure 3A). Lymphatic permeation was seen, but no obvious venous involvement was identified. Immunohistochemically, neoplastic cells were positive for synaptophysin and low-molecular-weight cytokeratin (Figure 3B and C). Ki-67 immunostaining revealed a proliferation index of more than 80%. The associated adenomatous polyp with villous structures as well as foci of areas of moderate and severe dysplasia was seen in the ampillary mucosa (Figure 3D). The dysplastic epithelium of the adenoma was in continuity with the invasive tumor (Figure 3E). Unfortunately, the patient died of pneumonia 3 mo after the operation.

## DISCUSSION

Ampullary small cell neuroendocrine carcinoma is extremely rare and has only been documented in few case reports and retrospective studies<sup>[2,5]</sup>. The patients with ampullary small cell neuroendocrine carcinoma usually presented after the age of 60 years (mean age, 63.5 years), and a male predilection was observed<sup>[6]</sup>. The tumor is a poorly differentiated, high-grade neuroendocrine carcinoma and resembles its counterpart originating from the tracheobronchial tree in its aggressive behavior and high propensity for early lymph node metastases and distant metastases<sup>[2,3,5]</sup>.

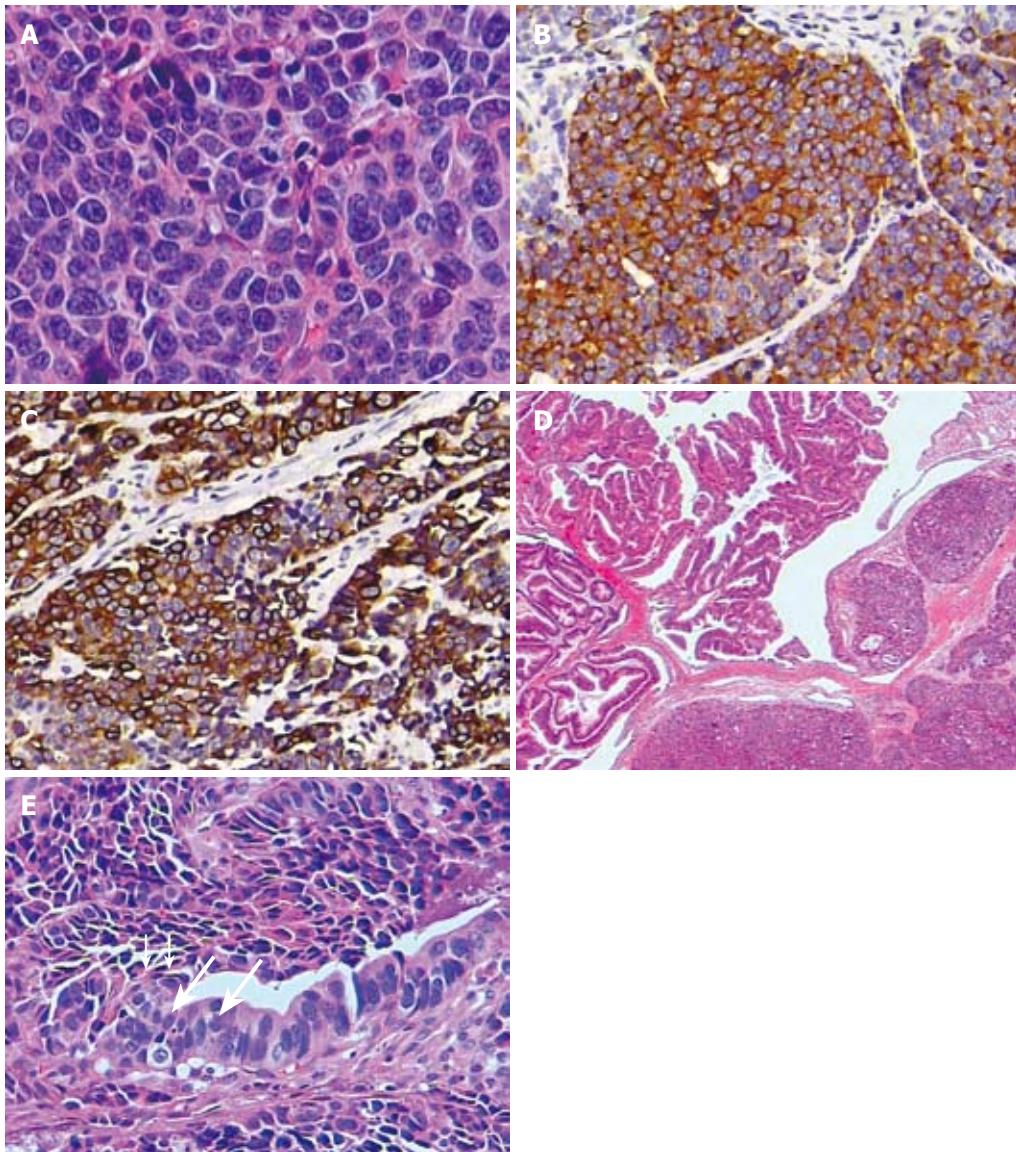

Pancreatoduodenectomy with local lymph node dissection is currently the standard surgical treatment for the ampullary cancer<sup>[7]</sup>. No effective postoperative chemotherapies for ampullary small cell neuroendocrine carcinoma have been established. Chemotherapy or

radiation has been reported to be effective for some cases of the tumor of the gastrointestinal tract and the biliary system<sup>[2,8]</sup>. The prognosis of these patients with small cell neuroendocrine carcinoma was poor, the survival period even after operation usually being less than a year<sup>[2,6,9]</sup>.

Ampullary adenoma and adenocarcinoma are tumors that originate in the glandular epithelium of the ampulla of Vater. The progression from adenoma to carcinoma in the ampulla of Vater is similar to that in colon<sup>[10]</sup>. Some cases of ampullary small cell neuroendocrine carcinoma associated with or mixed with adenoma, adenocarcinoma and squamous cell carcinoma have been reported<sup>[5,11]</sup>. These associations suggest a common origin of small cell neuroendocrine carcinoma and adenoma at this site. It is likely that the two neoplasms originate from non-neoplastic multipotent stem cells that terminally differentiate into all kinds of epithelial cells including ciliated cells, mucous cells and endocrine cells. However, the molecular data suggest that there are significant differences in the pathogenesis of the various types of tumors of the ampulla.

Ampullary small cell neuroendocrine carcinomas have histologic appearance similar to their pulmonary counterparts<sup>[6]</sup>. They are usually comprised of solid sheets of pleomorphic cells with small round-to-oval hyperchromatic nuclei, inconspicuous nucleoli, a high nuclear-to-cytoplasmic ratio. On immunohistochemical examination, the diagnosis of neuroendocrine tumors must be confirmed by positive immunohistochemical staining for at least 1 neuroendocrine marker, such as chromogranin or synaptophysin<sup>[12]</sup>. In our case, the diagnosis of small cell neuroendocrine carcinoma was based on typical morphological and immunohistochemical findings. In addition, neoplastic cells exhibited cytoplasmic immunostaining for cytokeratin and nuclear Ki-67 positivity (a proliferation index of more than 80%). We postulate that this neoplastic histogenesis was from epithelial stem cells with both epithelial and neuroendocrine characteristics.

The preoperative diagnosis of these rare tumors in the ampulla is potentially problematic. In most cases with ampullary tumors, endoscopic retrograde cholangiopancreatography (ERCP) with biopsy is valuable for making a definitive preoperative diagnosis in patients with ampullary tumors. However, it is very difficult to diagnose intramural ampullary neoplasm at endoscopy because the papilla is covered with normal duodenal mucosa. Although MRCP and CT can show obstruction of the ampulla of Vater, CT is known to be more accurate for demonstrating the location and extent of the involved biliary duct than MRCP and ERCP<sup>[13]</sup>. In our case, CT revealed two well-defined masses in the ampulla of Vater. The radiological finding of a polypous mass with a long pedicle was helpful to diagnose an adenoma. The ampullary small cell neuroendocrine carcinoma presented as a well-enhancing mass with local lymphadenopathy and differentiating it from ampullary adenocarcinoma may not be possible. Thus, small cell neuroendocrine carcinoma should be included in the differential diagnosis of ampullary masses especially when the patient is an elderly man.

**Figure 3** Histopathological findings. **A:** The tumor cells are composed predominantly of small to medium-sized, round or oval cells with hyperchromatic nuclei, inconspicuous nucleoli and scanty cytoplasm (HE,  $\times 400$ ); Immunohistochemically, the tumor cells are positive for synaptophysin (**B**) and low-molecular-weight cytokeratin (**C**) ( $\times 200$ ). **D:** Light microscopy shows the coexistence of villous adenoma and small cell neuroendocrine carcinoma (HE,  $\times 20$ ); **E:** The epithelium of the adenoma (long arrows) is in continuity with the small cell neuroendocrine carcinoma (short arrows) (HE,  $\times 200$ ).

## INTRODUCTION

Interferon-alpha (IFN- $\alpha$ ) is now widely used in the treatment of chronic hepatitis B and C. Systemic side effects of IFN- $\alpha$  therapy can affect numerous organ systems. These adverse reactions include flu-like syndrome, hematological abnormalities, cardiovascular and central nervous symptoms, gastrointestinal symptoms, pulmonary dysfunction, depression and retinopathy. Besides, IFN- $\alpha$  has been shown to be related to the development of a variety of autoimmune diseases, including systemic lupus erythematosus (SLE), rheumatoid arthritis (RA) and autoimmune thyroid diseases (AITDs). However, the development of type 1 diabetes mellitus (DM) is relatively rare and few patients with positive islet cell autoantibody (ICAb) or glutamic acid decarboxylase autoantibody (GADAb) have been reported<sup>[1-3]</sup>. Here, we report the first case of a patient suffering from chronic hepatitis B who had an unexpected onset of type 1 DM during IFN- $\alpha$  2b therapy in China.

## CASE REPORT

A 33-year-old woman with a body mass index (BMI) of 22.49 kg/m<sup>2</sup> was treated with recombinant human IFN- $\alpha$  2b at a dosage of 3 million units (MU) once every other day from April 2006 because of hepatitis B. Ten months after IFN- $\alpha$  2b treatment, both hepatitis B e antigen (HBeAg) and HBV DNA became negative, and serum aminotransferases returned to normal. However, 13 mo after initiation of IFN- $\alpha$  2b treatment (reaching 585 MU of total dose in May 2007), the patient complained of weakness, polydipsia, polyuria and a rapid weight loss (5 kg within 10 d). She was then admitted to our hospital. Her clinical data on admission are shown in Table 1. Urinalysis showed glucosuria and ketonuria.

## Abstract

We describe a case of a 33-year-old female patient with chronic hepatitis B who developed type 1 diabetes mellitus (DM) after a 13-mo period of treatment with recombinant human interferon-alpha (IFN- $\alpha$ ) 2b. The patient presented with polydipsia, polyuria, hyperglycemia, diabetic ketoacidosis, combined with C-peptide secretion deficiency and positive islet cell autoantibody (ICAb). IFN- $\alpha$  2b treatment was terminated and instead insulin treatment was initiated. Five months after cessation of the recombinant human IFN- $\alpha$  2b therapy, the patient remained insulin-dependent. Her serum HBV DNA became negative and serum transaminase returned to the normal level after a 10-mo period of IFN therapy. Type 1 DM induced by IFN- $\alpha$  is relatively rare in patients with chronic hepatitis B. We should pay more attention to patients on IFN- $\alpha$  therapy to avoid destruction of pancreatic beta cells. This is the first case report from China.

Fasting plasma glucose and glycosylated hemoglobin (HbA1c) were 31.7 mmol/L (570.6 mg/dL) and 10.0%, respectively. Arterial blood gas analysis showed metabolic acidosis. Serum aspartate aminotransferase (AST) and alanine aminotransferase (ALT) were within normal range. Hepatitis B surface antigen (HBsAg) and anti-HB core antibody (HBcAb) in serum were positive. The fasting plasma C-peptide level was low. The curve of C-peptide response to 75 g glucose load was flat (Table 2). The serum ICAb was positive (Figure 1). The patient had no family history of type 1 DM or other autoimmune disorders. She had no symptoms of other autoimmune diseases. Other autoantibodies including thyroid peroxidase antibody (TPOAb), thyroglobulin antibody (TgAb), antinuclear antibody (ANA), anti-dsDNA antibody, anti-RNP, anti-SSA, anti-SSB, and rheumatoid factor (RF) were all negative. Taken together, clinical and laboratory data confirmed the diagnosis of type 1 DM with ketoacidosis. Administration of IFN was immediately terminated. Her clinical condition improved with diet

**Table 2** Results of oral glucose tolerance test (75 g)

Time (min)	Blood glucose (mmol/L)	C-peptide (pmol/mL)
0	7.5	0.29
30	10.8	0.40
60	15.0	0.61
120	18.3	0.77
180	14.1	0.78

therapy, intravenous fluids and insulin therapy (isophane protamine biosynthetic human insulin, Novolin® R, Novo Nordisk, Denmark). Ketonuria disappeared after 12 h insulin therapy for. Following normalization of the acute metabolic disturbances, intensive insulin therapy was recommended with four daily doses of subcutaneous insulin: each before every meal and last at bedtime. Four days later, fasting plasma glucose decreased to 5.6 mmol/L (100 mg/dL). Five months after cessation of IFN- $\alpha$  2b therapy, the patient remained insulin dependent with a daily requirement of 20 units Novolin® 30R. The plasma C-peptide level was still low. Serum HbA1c level was 6.5%. Serum aminotransferase was normal, and serum HBV DNA remained undetectable.

## DISCUSSION

IFN- $\alpha$  has different biologic effects (antiviral, antiproliferative, immunomodulatory), and has been used in treatment of chronic viral hepatitis for nearly 20 years<sup>[4]</sup>. IFN- $\alpha$  acts on many target cells and organs. The thyroid represents the main target for autoimmunity associated with IFN- $\alpha$  therapy. Although several reports indicate a beneficial effect on glucose metabolism<sup>[5-7]</sup>, IFN- $\alpha$  has been considered to have a variety of effects on pancreatic beta cells<sup>[1-3,8,9]</sup>. In 1992, Fabris *et al*<sup>[10]</sup> reported the first case of type 1 DM in a chronic hepatitis C patient treated with IFN- $\alpha$  and concluded that IFN could trigger autoimmune destruction of pancreatic beta cells.

IFN- $\alpha$  therapy-induced autoimmunity of pancreatic beta cells has been evaluated in some studies<sup>[11-14]</sup>. The prevalence of ICAb, GADAb, insulin autoantibody (IAA), and/or tyrosine-like phosphatase autoantibody

(IA2Ab) is not generally increased in patients with chronic viral infection prior to IFN- $\alpha$  therapy compared with normal control subjects. In 50% of the previously reported patients, markers of pancreatic autoimmunity predated treatment, the majority of cases having a genetic predisposition (HLA-DR3/-DR4 was positive)<sup>[15]</sup>. However, after IFN- $\alpha$  treatment, the prevalence of pancreatic autoantibodies may increase from 3% to 7% with type 1 DM developed in a few cases. Therefore, IFN- $\alpha$  therapy may induce type 1 DM in genetically and immunologically predisposed individuals.

The exact mechanism underlying the development of type 1 DM in chronic viral hepatitis patients treated with IFN- $\alpha$  is unclear. A variety of mechanisms may account for the effect of IFN- $\alpha$  on pancreatic beta cell dysfunction<sup>[14]</sup>. First, IFN- $\alpha$  activates the oligoadenylyate synthase-RnaseL pathway and the protein kinase R pathway, thus inducing apoptosis of pancreatic beta cells. Second, IFN- $\alpha$  may stimulate a counter regulatory hormone secretion (growth hormone, glucagon, etc.), thus resulting in impaired glucose tolerance. Third, regarding type 1 DM, IFN- $\alpha$  may favor the development of Th1 immune reaction and thereby contribute to the development of autoimmune disease by activating CD4 lymphocytes secreting IL-2, IFN- $\gamma$ , and tumor necrosis factor. IFN- $\alpha$  is also associated with over-expression of MHC class I antigens in human islets of pancreas. In addition to IFN- $\alpha$ , HCV infection can increase the frequency of pancreatic autoimmunity. That is why IFN- $\alpha$ -induced type 1 DM is relatively rare in chronic hepatitis B patients.

Transient insulin dependency was observed in some cases and permanent insulin administration was required in the other reported cases. These data demonstrate that in some cases the autoimmune attack is at least partially reversible with interruption of interferon therapy<sup>[15]</sup>.

In conclusion, development of type 1 DM should be considered as one of the risk consequences after IFN- $\alpha$  therapy. In order to avoid it, administration of IFN- $\alpha$  in special patients should be evaluated, weighing the risk of diabetes and the benefit of the treatment. We conclude that patients having positive islet autoantibodies, HLA-DR3/-DR4, impaired glucose regulation, or positive family history of diabetes mellitus, should be considered to have a higher risk of developing type 1 DM following IFN- $\alpha$  treatment<sup>[13]</sup>. Physicians should be cautious of the use of IFN therapy.

## Meetings

### Events Calendar 2008-2009

#### FALK SYMPOSIA 2008

January 24-25, Frankfurt, Germany  
Falk Workshop: Perspectives in Liver Transplantation

#### International Gastroenterological Congresses 2008

February 14-16, Paris, France  
EASL-AASLD-APASL-ALEH-IASL Conference Hepatitis B and C virus resistance to antiviral therapies  
[www.easl.ch/hepatitis-conference](http://www.easl.ch/hepatitis-conference)

February 14-17, Berlin, Germany  
8<sup>th</sup> International Conference on New Trends in Immunosuppression and Immunotherapy  
[www.kenes.com/immuno](http://www.kenes.com/immuno)

February 28, Lyon, France  
3<sup>rd</sup> Congress of ECCO - the European Crohn's and Colitis Organisation Inflammatory Bowel Diseases 2008  
[www.ecco-ibd.eu](http://www.ecco-ibd.eu)

February 29, Québec, Canada  
Canadian Association of Gastroenterology  
E-mail: general@cag-acg.org

March 10-13, Birmingham, UK  
British Society of Gastroenterology Annual Meeting  
E-mail: BSG@mailbox.ulcc.ac.uk

March 14-15, HangZhou, China  
Falk Symposium 163: Chronic Inflammation of Liver and Gut

March 23-26, Seoul, Korea  
Asian Pacific Association for the Study of the Liver  
18<sup>th</sup> Conference of APASL: New Horizons in Hepatology  
[www.apaslseoul2008.org](http://www.apaslseoul2008.org)

March 29-April 1, Shanghai, China  
Shanghai-Hong Kong International Liver Congress  
[www.livercongress.org](http://www.livercongress.org)

April 05-09, Monte-Carlo (Grimaldi Forum), Monaco  
OESO 9<sup>th</sup> World Congress, The Gastro-esophageal Reflux Disease: from Reflux to Mucosal Inflammation-Management of Adeno-carcinomas  
E-mail: robert.giuli@oeso.org

April 9-12, Los Angeles, USA  
SAGES 2008 Annual Meeting - part of Surgical Spring Week  
[www.sages.org/08program/html/](http://www.sages.org/08program/html/)

April 18-22, Buenos Aires, Argentina  
9<sup>th</sup> World Congress of the International Hepato-Pancreato Biliary Association  
Association for the Study of the Liver  
[www.ca-ihpba.com.ar](http://www.ca-ihpba.com.ar)

April 23-27, Milan, Italy  
43<sup>rd</sup> Annual Meeting of the European Association for the Study of the Liver  
[www.easl.ch](http://www.easl.ch)

May 2-3, Budapest, Hungary

Falk Symposium 164: Intestinal Disorders

May 18-21, San Diego, California, USA  
Digestive Disease Week 2008

May 21-22, California, USA  
ASGE Annual Postgraduate Course  
Endoscopic Practice 2008: At the Interface of Evidence and Expert Opinion  
E-mail: education@sgo.org

June 4-7, Helsinki, Finland  
The 39<sup>th</sup> Nordic Meeting of Gastroenterology  
[www.congrex.com/ngc2008](http://www.congrex.com/ngc2008)

June 5-8, Sitges (Barcelona), Spain  
Semana de las Enfermedades Digestivas  
E-mail: sepd@sepde.es

June 6-8, Prague, Czech Republic  
3<sup>rd</sup> Annual European Meeting: Perspectives in Inflammatory Bowel Diseases  
E-mail: meetings@imedex.com

June 10-13, Istanbul, Turkey  
ESGAR 2008 19<sup>th</sup> Annual Meeting and Postgraduate Course  
E-mail: fca@netvisao.pt

June 11-13, Stockholm, Sweden  
16<sup>th</sup> International Congress of the European Association for Endoscopic Surgery  
E-mail: info@aes-eur.org

June 13-14, Amsterdam, Netherlands  
Falk Symposium 165: XX International Bile Acid Meeting. Bile Acid Biology and Therapeutic Actions

June 13-14, Prague, Czech Republic  
Central and Eastern European Conference on Colorectal "Cancer" Screening, Prevention and Management  
E-mail: idca2008@guarant.cz

June 25-28, Barcelona, Spain  
10<sup>th</sup> World Congress on Gastrointestinal Cancer  
Imedex and ESMO  
E-mail: meetings@imedex.com

June 25-28, Lodz, Poland  
Joint Meeting of the European Pancreatic Club (EPC) and the International Association of Pancreatology (IAP)  
E-mail: office@epc-iap2008.org  
[www.e-p-c.org](http://www.e-p-c.org)  
[www.pancreatology.org](http://www.pancreatology.org)

June 26-28, Bratislava, Slovakia  
5<sup>th</sup> Central European Gastroenterology Meeting  
[www.ceurgem2008.cz](http://www.ceurgem2008.cz)

July 9-12, Paris, France  
ILTS 14<sup>th</sup> Annual International Congress  
[www.ilts.org](http://www.ilts.org)

September 10-13, Budapest, Hungary  
11<sup>th</sup> World Congress of the International Society for Diseases of the Esophagus  
E-mail: isde@isde.net

September 13-16, New Delhi, India  
Asia Pacific Digestive Week  
E-mail: apdw@apdw2008.net

III FALK GASTRO-CONFERENCE  
September 17, Mainz, Germany

Falk Workshop: Strategies of Cancer Prevention in Gastroenterology

September 18-19, Mainz, Germany  
Falk Symposium 166: GI Endoscopy - Standards & Innovations

September 18-20, Prague, Czech Republic  
Prague Hepatology Meeting 2008  
[www.czech-hepatology.cz/phm2008](http://www.czech-hepatology.cz/phm2008)

September 20-21, Mainz, Germany  
Falk Symposium 167: Liver Under Constant Attack - From Fat to Viruses

September 24-27, Nantes, France  
Third Annual Meeting  
European Society of Coloproctology  
[www.escp.eu.com](http://www.escp.eu.com)

October 8-11, Istanbul, Turkey  
18<sup>th</sup> World Congress of the International Association of Surgeons,  
Gastroenterologists and Oncologists  
E-mail: orkun.sahin@serenash.com.tr

October 18-22, Vienna, Austria  
16<sup>th</sup> United European Gastroenterology Week  
[www.negf.org](http://www.negf.org)  
[www.acv.at](http://www.acv.at)

October 22-25, Minnesota, USA  
Anstralian Gastroenterology Week 2008  
E-mail: gesa@gesa.org.au

October 22-25, Brisbane, Australia  
71<sup>st</sup> Annual Colon and Rectal Surgery Conference  
E-mail: info@colonrectalcourse.org

October 31-November 4, Moscone West Convention Center, San Francisco, CA  
59<sup>th</sup> AASLD Annual Meeting and Postgraduate Course  
The Liver Meeting  
Information: [www.aasld.org](http://www.aasld.org)

November 6-9, Lucerne, Switzerland  
Neurogastroenterology & Motility Joint International Meeting 2008  
E-mail: ngm2008@mci-group.com  
[www.ngm2008.com](http://www.ngm2008.com)

November 12, Santiago de Chile, Chile  
Falk Workshop: Digestive Diseases: State of the Art and Daily Practice

November 28-29, Cairo, Egypt  
1<sup>st</sup> Hepatology and Gastroenterology Post Graduate Course  
[www.egyptgastrohep.com](http://www.egyptgastrohep.com)

December 7-9, Seoul, Korea  
6<sup>th</sup> International Meeting Hepatocellular Carcinoma: Eastern and Western Experiences  
E-mail: sglee@amc.seoul.kr

Digestive Disease Week 2009

November 21-25, London, UK  
Gastro 2009 UEGW/World Congress of Gastroenterology  
[www.gastro2009.org](http://www.gastro2009.org)

#### Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London, The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (*World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly open access peer-reviewed journal supported by an editorial board consisting of 1208 experts in gastroenterology and hepatology from 60 countries. The aim of the journal is to deliver the most clinically relevant original and commentary articles to readers, and to make the full text publicly available to all clinicians, scientists, patients and biomedical students on an unrestricted platform, so that they can access and learn about the most recent key advances in the field.

In addition to the open access nature, another key characteristic of *WJG* is its reading guidance for each article which includes background, research frontier, related reports, breakthroughs, applications, terminology, and comments of peer reviewers for the general readers.

*WJG* publishes articles on esophageal, gastrointestinal, hepatobiliary and pancreatic tumors, and other esophageal, gastrointestinal, hepatic-biliary and pancreatic diseases in relation to epidemiology, immunology, microbiology, motility & nerve-gut interaction, endocrinology, nutrition & obesity, endoscopy, imaging and advanced hi-technology.

The main goal of *WJG* is to publish high quality commentary articles contributed by leading experts in gastroenterology and hepatology and original articles that combine the clinical practice and advanced basic research, to provide an interactive platform for clinicians and researchers in internal medicine, surgery, infectious diseases, traditional Chinese medicine, oncology, integrated Chinese and Western medicine, imaging, endoscopy, interventional therapy, pathology and other basic medical specialties, and thus eventually improving the clinical practice and healthcare for patients.

#### Indexed and abstracted in

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, Index Medicus, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, *Nature Clinical Practice Gastroenterology* and *Hepatology*, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

The WJG Press

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

#### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://wjg.wjnet.com>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjnet.com/wjg/help/instructions.jsp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [submission@wjnet.com](mailto:submission@wjnet.com), or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was carried out; author contributions; disclosure of any financial support for the research; and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (remove all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s), and full family name.

**Author contributions:** The format of this section should be like this: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed research; Wang CL, Zou CC, Hong F and Wu XM performed research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed data; and Wang CL, Liang L and Fu JF wrote the paper.

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

#### Abstract

An informative, structured abstract of no more than 350 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipment, and the experimental procedures should be included. RESULTS: The observed and experimental results, including data, effects, outcome, etc. should be included. Authors should present *P* value where necessary, and also include any significant data. CONCLUSION: Accurate view and the value of the results should be included.

The format for structured abstracts can be found at: <http://www.wjnet.com/wjg/help/11.doc>.

#### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

#### Text

For articles of these sections, original articles, rapid communication

and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, should be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

### Illustrations

Figures should be numbered as 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...etc. It is our principle to publish high resolution-figures for the printed and E-versions.

### Tables

Three-line tables should be numbered 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P* < 0.05 and <sup>d</sup>*P* < 0.01 are used. A third series of *P* values can be expressed as <sup>e</sup>*P* < 0.05 and <sup>f</sup>*P* < 0.01. Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, □, ▲, △, etc., in a certain sequence.

### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

### PMID requirement

PMID roots in the abstract serial number indexed by PubMed (<http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed>). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information for journal citations is very important. Using the reference testing system, the authors and editor should check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in an ASP file so that the readers can immediately access the abstract of the citations online.

### DOI requirement

A CrossRef DOI® (Digital Object Identifier) name is a unique string created to identify a piece of scholarly content in the online environment. The author should supply the DOIs for journal citation(doi:10.3748/wjg.13.6458). This link (<http://www.crossref.org/SimpleTextQuery/>) allows you to retrieve Digital Object Identifiers (DOIs) for journal articles, books, and chapters by simply cutting and pasting the reference list into the box. You may use the form with any reference style, although the tool works most reliably if references are formatted in a standard style such as shown in this example: Assimakopoulos SF, Scopa CD, Vagianos CE. Pathophysiology of increased intestinal permeability in obstructive jaundice. *World J Gastroenterol* 2007; 13(48): 6458-6464

The accuracy of the information of journal citations is very important. We will interlink all references with DOI in ASP file so that readers can access the abstracts of cited articles online immediately.

### Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

### Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

## Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those linked with a hyphen when the difference between the two numbers is greater than five. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered inappropriate references. Authors should not cite their own unrelated published articles.

## Statistical data

Write as mean  $\pm$  SD or mean  $\pm$  SE.

## Statistical expression

Express  $t$  test as  $t$  (in italics),  $F$  test as  $F$  (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as  $r$  (in italics), degree of freedom as  $v$  (in Greek), sample number as  $n$  (in italics), and probability as  $P$  (in italics).

## Units

Use SI units. For example: body mass,  $m$  (B) = 78 kg; blood pressure,  $p$  (B) = 16.2/12.3 kPa; incubation time,  $t$  (incubation) = 96 h, blood glucose concentration,  $c$  (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA mass concentration,  $p$  (CEA) = 8.6 24.5  $\mu$ g/L;  $CO_2$  volume fraction, 50 mL/L  $CO_2$ , not 5%  $CO_2$ ; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: <http://www.wjgnet.com/wjg/help/15.doc>.

## Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of

Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

## Italics

Quantities:  $t$  time or temperature,  $c$  concentration,  $A$  area,  $l$  length,  $m$  mass,  $V$  volume.

Genotypes:  $gyrA$ ,  $arg\ 1$ ,  $c\ myc$ ,  $c\ fos$ , etc.

Restriction enzymes:  $EcoRI$ ,  $HindII$ ,  $BamHI$ ,  $KhoI$ ,  $KpnI$ , etc.

Biology:  $H\ pylori$ ,  $E\ coli$ , etc.

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

## Editorial Office

### World Journal of Gastroenterology

Editorial Department: Room 903

Ocean International Center, Building D

No. 62 Dongsihuan Zhonglu

Chaoyang District, Beijing 100025, China

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

Telephone: +86-10-59080039

Fax: +86-10-85381893

## Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

## Copyright assignment form

Please download a Copyright assignment form from <http://www.wjgnet.com/wjg/help/9.doc>.

## Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/wjg/help/10.doc>.

## Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

## Links to documents related to the manuscript

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

## Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

## Publication fee

Authors of accepted articles must pay a publication fee. EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

### INTRODUCTION

Chemokines and their receptors, such as CXCR4, induce chemotaxis of diverse immune cells [CD4<sup>+</sup> cells, CD8<sup>+</sup> cells, macrophages, and dendritic cells (DC)] into areas of inflammation<sup>[1]</sup>. CXCR4 and CCR5 were initially reported to represent co-receptors for human immunodeficiency virus (HIV) infection in man. Gp120 binds CXCR4 and CCR5, mediating fusion of HIV with the host cell membrane. Therefore, CXCR4 was previously termed *Fusin*. However, after viral binding to the chemokine receptor CXCR4, HIV induces an immunologic T helper (Th) cell response, called a Th1 to Th2 switch, which clearly supports the immune evasion of HIV-infected lymphocytes<sup>[2,3]</sup>. In addition, *in vitro* studies on HIV revealed that the chemokine receptor CXCR4 ligand SDF-1 $\alpha$  induced apoptosis of CD8<sup>+</sup> cells, again inhibiting strong immune defence mechanisms<sup>[4]</sup>. In HIV therapy, much attention has been paid to CXCR4, to which the fusion-mediating and migration-inducing chemokine SDF-1 $\alpha$  binds selectively. However, the sole blockade of this receptor, which is expressed on CD4<sup>+</sup> cells, CD8<sup>+</sup> cells, and APC, does not lead to a sufficient inhibition of the fusion and, therefore, to a persisting HIV infection of lymphocytes.

During the last 5 years, diverse human cancers were reported to express high levels of CXCR4 multiplying the metastasis process *via* their aggressive-invasive and migratory phenotypes<sup>[5,6]</sup>. We and others recently reported that gastrointestinal cancers co-express CXCR4 and its ligand SDF-1 $\alpha$  in an autocrine and paracrine fashion, thereby increasing tumor cell dissemination<sup>[7-9]</sup>.

### IMMUNOLOGICAL RELEVANCE OF THE CXCR4/SDF-1 AXIS

The CXCR4/SDF-1 pathway has been reported to impact the progression of various malignomas. However, the influence on the immune system was only analyzed at a basic level, so far. Moreover, only brief investigations have focused on the influence of SDF-1 $\alpha$  in comparison

### Abstract

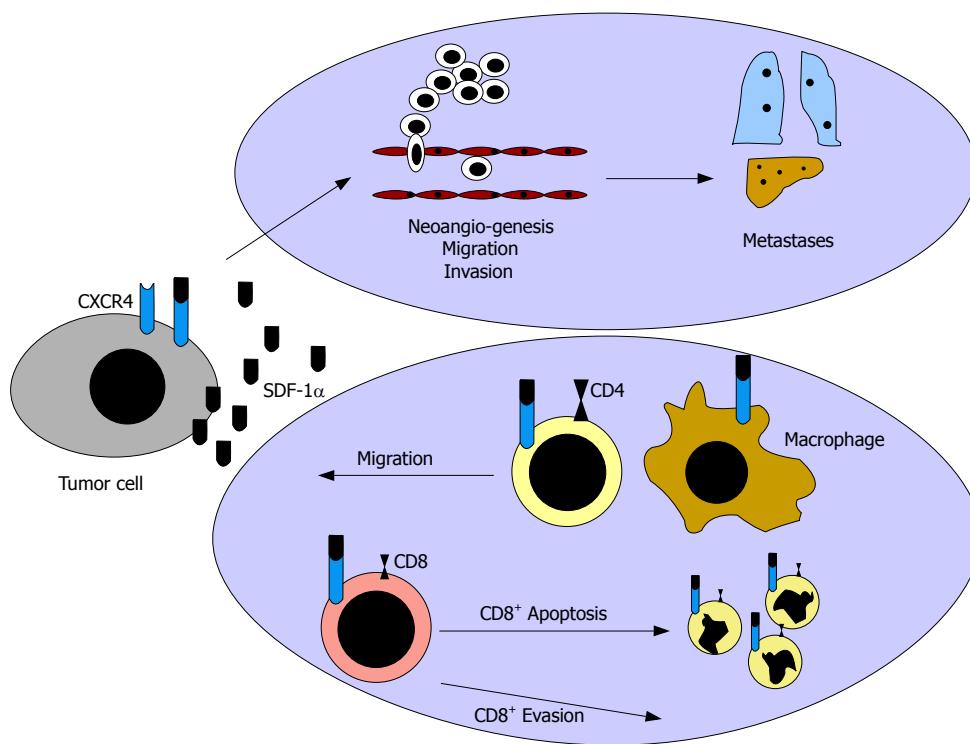

To review the implication of CXCR4 for gastrointestinal cancer, a "Pubmed" analysis was performed in order to evaluate the relevance of CXCR4 and its ligands for gastrointestinal cancers. Search terms applied were "cancer, malignoma, esophageal, gastric, colon, colorectal, hepatic, pancreatic, CXCR4, SDF-1 $\alpha$ , and SDF-1 $\beta$ ". CXCR4 expression correlated with dissemination of diverse gastrointestinal malignomas. The CXCR4 ligand SDF-1 $\alpha$  might act as "chemorepellent" while SDF-1 $\beta$  might act as "chemorepellent" for CTLs, inducing tumor rejection. The paracrine expression of SDF-1 $\alpha$  was furthermore closely associated with neoangiogenesis. CXCR4 and its ligands influence the dissemination, immune rejection, and neoangiogenesis of human gastrointestinal cancers. Inhibition of CXCR4 might be an interesting therapeutic option.

Schimanski CC, Galle PR, Moehler M. Chemokine receptor CXCR4-prognostic factor for gastrointestinal tumors. *World J Gastroenterol* 2008; 14(30): 4721-4724

**Figure 1** CXCR4 mediates tumor dissemination via induction of tumor cell migration and invasion and via stimulation of neoangiogenesis. The CXCR4 ligand SDF-1 $\alpha$  might act as "chemorepellent" preventing tumor rejection.

to the splicing variant SDF-1 $\beta$  on "immune escape" mechanisms (Figure 1). SDF-1 is the only known ligand of CXCR4 and exists in several splicing variants<sup>[10]</sup>. Its expression is restricted to some cell types, as endothelial cells, epithelial thymus cells, bone marrow cells, mucosal epithelial cells, and tumor cells<sup>[11-13]</sup>. Increased expression occurs, especially in areas of inflammation and neoangiogenesis, and thus leads to a fulminate chemotaxis of CXCR4 expressing immune cells, such as CD4 $^{+}$  cells and DC along the SDF-1 gradient<sup>[14]</sup>.

Interestingly, SDF-1 $\alpha$  exposition of anti-CD3-activated CD4 $^{+}$  cells induced Th1-(IFN- $\gamma$ ) as well as Th2 (IL-4 and IL-10)-specific cytokine expression<sup>[15]</sup>. A SDF-1 $\alpha$  exposition of activated T cells inhibited CD4 $^{+}$  cell apoptosis by reduction of BCC-2 and activation of PI3-K and MAPK<sup>[16]</sup>. However, this effect was linked to the SDF-1 $\alpha$  concentration and the activation state of the CD4 $^{+}$  cells, as a higher concentration of SDF-1 $\alpha$  induced apoptosis of CD4 $^{+}$  Jurkat cells by up-regulation of CD95 and CD95 ligands<sup>[17]</sup>.

Moreover, SDF-1 $\alpha$  induced CD8 $^{+}$  apoptosis after up-regulation of membrane-bound TNF- $\alpha$  on APC and TNF- $\alpha$  receptor II on CD8 $^{+}$  cells and a consecutive interaction of the ligand with the receptor<sup>[4]</sup>.

Further results implied that SDF-1 $\alpha$  expressing tumor cells may protect themselves from a cytotoxic immune reaction, as SDF-1 $\alpha$  promotes apoptosis in cytotoxic T cells and might induce a local Th1 → Th2 shift in the tumor bed. This theory is supported by data reporting that SDF-1 $\alpha$  induces a chemorepulsion of CTL supporting an immune evasion in melanoma<sup>[18]</sup>. In contrast, SDF-1 $\beta$  acts as chemoattractant for CTLs, inducing tumor rejection<sup>[19]</sup>. Interestingly, CXCR4 blockade not only inhibited dissemination but also sensitized tumor cells for immune therapy<sup>[20]</sup>. However,

the influence on the immune system and differences between the splicing variants SDF-1 $\alpha$  and SDF-1 $\beta$  have been analysed only marginally.

## ONCOLOGICAL ASPECTS OF THE CXCR4/SDF-1 $\alpha$ / $\beta$ AXIS

The presence of different chemokine/cytokine receptors and their ligands, such as IL-8, IP10, Rantes, or SDF-1 $\alpha$  could be confirmed in the tumor bed of diverse malignancies<sup>[7]</sup>. Current investigations reveal an expression by tumor cells, but also by endothelial cells<sup>[7,14]</sup>. Thus, these findings suggest that both tumor-expressed CXCR4 and SDF-1 $\alpha$  play important roles in local progression, dissemination, and immune evasion of tumor cells.

SDF-1 $\alpha$  binding to the second extracellular loop of CXCR4 induces activation of classical G-protein-coupled PI3-K/AKT/mTOR and RAF/MEK/ERK signalling pathways in the respective cells<sup>[7,21]</sup>. Proliferation, adhesion, migration, and invasion are the most relevant consequences. In addition, current publications report that CXCR4 activation induces EGFR1, HER2neu, and VEGFR transactivation. Most interestingly, CXCR4 upregulation was observed after EGFR/Her2neu activation, implying a compensatory pathway possibly inducing resistance to tyrosine-kinase inhibition<sup>[11]</sup>.

Autocrine SDF-1 $\alpha$  expression has initially been described in breast cancer and glioblastoma cell lines, where it has been correlated with an increased migratory and invasive potential of the tumor cells<sup>[7-9]</sup>. These effects are closely associated with the receptor affinity of SDF-1 $\alpha$ , since a SDF-1 $\alpha$  gene polymorphism, which is associated with an increased SDF-1 $\alpha$  receptor affinity

occurring in 5% of the general population<sup>[22]</sup>, can be frequently observed in patients with breast cancer and HIV-associated non-Hodgkin lymphoma<sup>[23,24]</sup>.

The paracrine expression of SDF-1 $\alpha$  is also closely associated with neoangiogenesis. On the one side, SDF-1 $\alpha$  and VEGFB attract endothelial precursor cells towards the tumor. On the other side, hemangiocytes (VEGFR1 $^+$ , CXCR4 $^+$ ) are released in the bone marrow by VEGFA and directed towards the tumor by a SDF-1 $\alpha$  gradient, where they might differentiate to pericytes stabilizing the neo-vasculature<sup>[25,26]</sup>.

In contrast to benign tissues, tumors often reveal a significant up-regulation of CXCR4. A key investigation concerning the relevance of chemokine receptors links CXCR4 expression with the localization of metastases in breast cancer<sup>[27]</sup>. In a variety of human tumor entities, an increased CXCR4 expression correlated with hematogenous and lymphogenic metastasis and reduced survival times<sup>[5,6,28]</sup>. *In vitro*, the activation of this receptor was associated with increased proliferation, migration, and invasion. These properties could be efficiently inhibited by CXCR4 blockade in tumor models<sup>[29,30]</sup>. The important role of CXCR4 for dissemination of tumor cells was confirmed in animal models. AMD3100, a recently developed CXCR4-inhibiting “small molecule”, blocked CXCR4 in a glioblastoma model with high receptor affinity and induced a massive tumor regression *in vivo*<sup>[31]</sup>. T22, another CXCR4 antagonist, strongly inhibited pulmonary metastasis in a murine B16 melanoma model<sup>[32]</sup>.

## INFLUENCE OF SDF-1 $\alpha$ /CXCR4 ON THE CLINICAL OUTCOME OF GASTROINTESTINAL TUMORS

The relevance of CXCR4 expression for tumor progression has been described in various gastrointestinal malignancies.

Over-expression of CXCR4 in colorectal cancer was significantly associated with advanced UICC tumor stages III/IV and with lymphatic or haemotogenous metastasis, respectively<sup>[28]</sup>. Moreover, the CXCR4 ligand SDF-1 $\alpha$  stimulated migration and invasion in the CXCR4-expressing colon carcinoma cells SW480 and SW620 *in vitro*<sup>[28]</sup>.

In esophageal cancer, the median overall survival of patients with CXCR4 expressing tumors was 20 months compared to 76 months for CXCR4 negative cases. CXCR4 expression was furthermore significantly associated with increased lymph node and bone marrow involvement. In multivariable analysis, CXCR4 expression was an independent variable and strongly associated with reduced disease-specific survival and overall survival. In another publication, which discriminated squamous cell from adenocarcinoma, a strong CXCR4 expression revealed a poorer long-term prognosis following curative esophagectomy for both histological subtypes, though with lack of statistical significance<sup>[33]</sup>.

In gastric cancer, CXCR4 expressing primary gastric

carcinomas significantly correlated with the development of peritoneal carcinomatosis and malignant ascites which contained high concentrations of CXCL12<sup>[34]</sup>.

In pancreatic cancer, an over-expression of CXCR4 correlated with advanced UICC stages III/IV and revealed a trend for hematogenous metastasis and progressed local tumor stages without affecting survival<sup>[35]</sup>.

In hepatocellular cancer, a high expression of CXCR4 or CCR7 was associated with locally advanced primary tumors and lymphogenic metastasis<sup>[36]</sup>. Moreover, high expression of CXCR4 led to a significant increase in haematogenic metastasis and to a decreased 3-year survival<sup>[36]</sup>. In Huh7 hepatoma cells, SDF-1 $\alpha$  exposition induced receptor internalization and perinuclear localization as well as an increase of proliferation and invasion. As a result of a CXCR4 receptor defect, these phenomena did not occur in HepG2 cells. While Hep3B and Huh7 showed high levels of autocrine and paracrine SDF-1 $\alpha$  expression, this effect could barely be observed in HepG2 cells.

In summary, CXCR4 increases the metastatic phenotype for diverse gastrointestinal malignancies. Current analyses are investigating whether CXCR4 expression might be valuable predictor for tumor recurrence.

## HISTORY OF THE DISCOVERY OF HEPATITIS G VIRUS

GBV-C, or hepatitis G virus (HGV), was discovered by two independent groups of investigators in the study of cases of hepatitis non-A, non-B, non-E<sup>[1,2]</sup>. The discovery of a new viral agent associated with liver diseases has attracted considerable attention due to the fact that there are hepatides of unknown etiology. This determined the urgency of investigations aimed at comprehensively studying the properties of the virus, its association with liver disease and infection rates in different countries of the world.

In 1966, the 34-year-old surgeon G. Barker (GB) fell ill with acute hepatitis of moderate enzymatic activity and three-week icteric period. Patient blood taken on icteric day 3 was used for intravenous inoculation of nonhuman primates (bare-faced marmosets, the Callithricidae family). Hepatitis was recorded in all animals when four monkey-to-monkey passages were performed. The findings suggested that the cause of this hepatitis was a yet unidentified viral agent that was named GBV.

Investigations of the GB agent recommenced 25 years later when new methods for qualitative viral analysis and recognition evolved. Serum taken in the acute stage of hepatitis from infected marmosets was found to contain two viral genomes: GBV-A and GBV-B belonging to closely-related viruses of the Flaviviridae family. Both viruses were able to replicate in the marmosets, but only GBV-B caused hepatitis. Attempts to detect GBV-A or GBV-B in human beings failed. A third virus GBV-C was soon isolated from patient material by means of specially designed primers to the conserved part of the NS3 region of the viruses GBV-A, GBV-B and HCV. GBV-C was assigned to the GBV group as it was slightly similar to GBV-B protein in immunoassays and largely identical to GBV-A in nucleotide sequence. GBV-C proved to be genetically related to another independent isolate that had been originally called HGV. They are virtually indistinguishable in the routine diagnosis by polymerase chain reaction (PCR). Since the signs of GBV-C/HGV became more commonly detected in patients with hepatitis and persons at risk for parenteral hepatitis, hepatitis G was considered

## Abstract

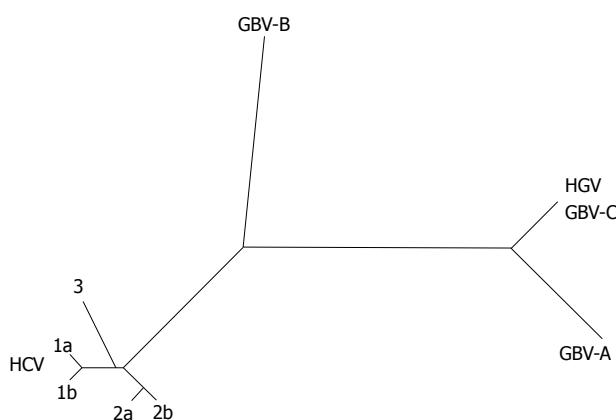

A number of new hepatitis viruses (G, TT, SEN) were discovered late in the past century. We review the data available in the literature and our own findings suggesting that the new hepatitis G virus (HGV), disclosed in the late 1990s, has been rather well studied. Analysis of many studies dealing with HGV mainly suggests the lymphotropicity of this virus. HGV or GBV-C has been ascertained to influence course and prognosis in the HIV-infected patient. Until now, the frequent presence of GBV-C in coinfections, hematological diseases, and biliary pathology gives no grounds to determine it as an "accidental tourist" that is of no significance. The similarity in properties of GBV-C and hepatitis C virus (HCV) offers the possibility of using HGV, and its induced experimental infection, as a model to study hepatitis C and to develop a hepatitis C vaccine.

to be an independent hepatotropic entity.

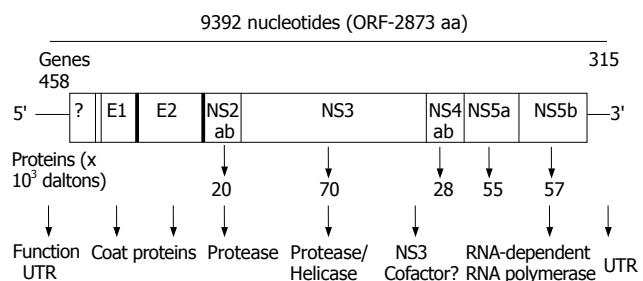

Experiments infecting chimpanzees with the GBV-C RNA-containing plasma taken from patients with chronic hepatitis G (CHG) yielded rather unexpected results. All the infected animals developed persistent and continuing (as long as 20 mo) viremia. However, no case showed a rise in the levels of indicator enzymes or detectable abnormal liver tissue changes in liver biopsy specimens taken weekly throughout the follow-up. Javan macaques were also observed to have viremia without signs of liver damage. By contrast, signs of hepatitis in the form of hyperenzymaemia and necrotic and inflammatory changes in the liver appeared by day 30 after inoculation of the marmosets that had received the same GBV-C-containing materials<sup>[3]</sup>.

Further serological screening-based investigations have indicated that the GBV-C isolate is of widespread occurrence; however, there is no evidence for an association of viremia with the development of some known diseases, such as hepatitis<sup>[4]</sup>.

## TAXONOMY AND GENOTYPIC VARIETY OF GBV-C

GBV-C virus, like GBV-A, GBV-B, and HCV, belongs to the Flaviviridae family. Comparison of the genomes of GBV-C, GBV-A, GBV-B, and HCV has demonstrated that their RNA does not bear a more than 32% similarity, thereby supporting the hypothesis that these viruses are independent (Figure 1)<sup>[5]</sup>.

Five HGV genomes (the divergence between them was 12%) have been described<sup>[6,7]</sup>. Investigations dealing with the classification of GBV-C were conducted by measuring restriction fragment length polymorphisms. The isolates from West Africa are referred to as genotype 1 wherein 2 subtypes: 1a and 1b are identified. Genotypes 2a and 2b are more frequently detected in North America and Europe; genotypes 3, 4 and 5 are more common in Asia, South-Eastern Asia, and South Africa, respectively. Phylogenetic analysis of genomic nucleotide sequences of the 5' and NS5 regions made by Novikov in 2000<sup>[8]</sup> has established that the GBV-C

**Figure 2** Schematic representation of GBV-C RNA structure, coded proteins, and their functions (from Kim JP, Frey KE)<sup>[14]</sup>.

isolate belonging to viral genotype 2 circulates in Russia, Kazakhstan, Kyrgyzstan, and Turkmenistan. Analysis of GBV-C 5'-untranslated region sequences revealed a new sixth genotype of virus in Indonesia<sup>[9]</sup>. In addition to genomic variability in different GBV-C isolates, some authors propose GBV-C genomic variability within one isolate, i.e. they suggest that there are quasispecies, thereby emphasizing their similarity with HCV<sup>[10]</sup>. But, the opponents of this theory argue that based on the absence of a hypervariable region in the E2 gene, the presence of quasispecies is impossible<sup>[11,12]</sup>.

## GBV-C STRUCTURE

The genome of the virus is represented by single-chain RNA with positive polarity<sup>[13]</sup>. The GBV-C genome is similar to hepatitis C virus (HCV) RNA in its organization, i.e. the structural genes are located at the genomic 5' region and non-structural genes are at the 3' end (Figure 2)<sup>[14]</sup>. The untranslated region at the 5' end may serve as an internal ribosomal embarkation site, which ensures translation of a RNA coding region<sup>[15]</sup>. The extent of the genome in different viral isolates ranges from 9103 to 9392 nucleotides<sup>[16,17]</sup>. An open reading frame carries information on the virus-specific polypeptide consisting of 2873-2910 amino acid residues. GBV-C RNA codes for two structural proteins (E1 and E2) which are envelope proteins. Unlike HCV, the proportion of glycosylated E2 is much lower in GBV-C. It has a total of three potential N-glycosylation sites as compared with HCV E2, which has eleven sites. The complete structure of viral nucleocapsid is still to be determined as the genomic region coding for core proteins has not been identified yet<sup>[18]</sup>.

Five non-structural proteins: NS2, NS3, NS4b, NS5a, and NS5b with molecular weights of 20, 70, 28, 55, and 57 kDa, respectively, have been found<sup>[19,20]</sup>. These proteins perform the function of protease, helicase, and RNA-dependent RNA-polymerase. The sequencing of the E1 and E2 regions has shown that they are not hypervariable unlike the respective regions of HCV<sup>[12]</sup>. Of interest are the data obtained while studying the buoyant density of GBV-C particles in a sucrose gradient before and after treatment with the nonionic detergent Tween-80. These data suggest that there is a lipid envelope in the virus whose association with lipids reduces antibody formation.

## MARKERS OF GBV-C

The basic marker used to diagnose GBV-C is RNA that is detectable by the amplification technique with a preliminary stage of reverse transcription in which cDNA is synthesized [reverse-transcriptase polymerase chain reaction (RT-PCR)]. Data on the sequence of the RNA region coding for helicase (NS3) and the NS5A region are used to synthesize oligonucleotide primers. This choice is made due to the high (83%-99%) stability of this region in various viral isolates (the sensitivity was as high as 200 copies/mL).

Further investigations indicated that there might be false negative results in the testing of some samples despite the fact that the latter contained the virus. By taking this into account, primers with the information coded in the 5'-untranslated region (the sensitivity was as high as 100 copies/mL) came into additional use for the designing of diagnostic kits<sup>[10]</sup>. The above primer kits had a high sensitivity, but also a rather high level of errors due to the incomplete conservatism of respective viral RNA regions.

An alternate primer kit for the region coding for E2 has been developed. These primers had 100% specificity for this RNA region; however, their sensitivity was not greater than 76.6%. Recent investigations propose the use of the two different primer kits (for viral RNA NS3, NS5A, 5'UTR, or E2 regions) for the accurate diagnosis of GBV-C RN<sup>[21]</sup>.

GBV-C RNA has been detected in hepatocytes<sup>[19,20,22]</sup>, peripheral blood lymphocytes and monocytes<sup>[23,24]</sup>, vascular endothelial cells<sup>[25]</sup>, and other tissues<sup>[7]</sup>. GBV-C viremia may persist for a few years. The infection is accompanied by the formation of specific antibodies against the envelope protein E2 (anti-E2). These antibodies have a long survival and may prevent the body from reinfection.

An enzyme immunoassay has been developed to detect serum GBV-C antibodies. The envelope E2 antigen (glycoprotein) was used as a viral antigen. Analysis of the sera from healthy individuals and patients with hepatitis demonstrated that most anti-E2-positive sera were GBV-C RNA negative, which enabled anti-E2 to be regarded as a marker of previous infection<sup>[8,26-28]</sup>. As a rule, GBV-C antibodies and RNA are not simultaneously encountered in a patient despite the fact that HCV, the nearest relation of GBV-C, is

**Table 2** Detection rate of anti-E2 in blood donors

Authors, year, country	Anti-E2 (%)
Jarvis et al, 1996, United Kingdom <sup>[33]</sup>	3.0
Masuko et al, 1996, Japan <sup>[38]</sup>	4.9
Bouchardieu et al, 2000, France <sup>[45]</sup>	42.1

Grabarczyk et al, 2006, Poland <sup>[41]</sup>	23.6

typified by this an inverse correlation between anti-E2 and viremia. The presence of serum viral RNA is also indicative of continuing infection so is that of E2 protein antibodies for clearance of viral particles from the patient's body. It has been shown that the production of GBV-C antibodies and the cessation of viremia in most (60%-75%) immunocompetent patients occur spontaneously and they are followed by the generation of antibodies to the envelope protein E2<sup>[29,30]</sup>. Two markers (RNA and anti-E2) of GBV-C have been concurrently detected in single studies (in 5% of cases)<sup>[8]</sup>. The highest detection rates of GBV-C antibodies are observed in individuals aged above 50 years<sup>[31,32]</sup>.

## EPIDEMIOLOGY OF GBV-C

Infection with HGV is common in the world. The detection rate of GBV-C in the population averages 1.7%. GBV-C, like other parenteral hepatitis viruses, occurs universally, but nonuniformly (Table 1)<sup>[8,11,33-41]</sup>. GBV-C is detectable in all ethnic groups. Analysis of the results of examining 13 610 blood donors described in 30 reports revealed viral RNA in 649 (4.8%) of cases. These included Caucasians (4.5%), Asians (3.4%), and Africans (17.2%)<sup>[42]</sup>. The authors propose to test blood samples due to the high risk of infection with GBV-C<sup>[42,43]</sup>.

An investigation of the prevalence of HGV among north-eastern Thai blood donors carrying HBsAg and anti-HCV revealed the high frequency of GBV-C RNA (10% and 11%, respectively) in the co-infected as compared with the controls (0%)<sup>[44]</sup>.

The development of an anti-E2 detection method has promoted a complete definition of the prevalence of GBV-C. E2 antibodies are several times more frequently detectable than RNA in blood donors (Table 2)<sup>[8,33,38,40,41,45]</sup>.

GBV-C is a parenterally transmitted infection<sup>[28-30]</sup>. The first verification of this fact were the experiments dealing with inoculation of primates with the blood of the surgeon who fell ill in 1966<sup>[2]</sup>. Cases of acute posttransfusion hepatitis along with the enhanced activity of serum aminotransferases and the detection of blood GBV-C RNA in the absence of other markers of viral hepatitis has been documented<sup>[3,31,32]</sup>. Indirect evidence that HGB is parenterally transmitted lies in its more frequent detection in the groups at higher risk for infection with hepatitis viruses by similar routes of transmission (Table 3)<sup>[8,11,34,36,38,41,46-51]</sup>, as well as the increased risk for infection in patients treated with multiple hemodialysis procedures and higher units of transfused blood products<sup>[33-35]</sup>.

The use of infected blood and its products promotes the prevalence of HGV. In the USA, 18%-20% of all blood preparations are infected with GBV-C, of them plasma being in 33%-84%<sup>[33]</sup>. In the United Kingdom, 94%-100% of coagulation factor VIII-IX preparations are infected with this virus<sup>[34]</sup>. Despite the fact that this persistent infection is present in a considerable number of healthy blood donors and in more than 35% of the human immunodeficiency virus (HIV)-infected, the world food and drug administration considers it unnecessary to recommend donor blood to be tested for serum GBV-C RNA.

There may be a sexual transmission in hepatitis G, as in hepatitis B and C. This is evidenced by the high detection rate of GBV-C RNA in homosexuals and prostitutes: 13.4%-63.0%<sup>[48,52]</sup> and 13.9%-24.8%<sup>[48,53]</sup>, respectively. Yeo *et al*<sup>[54]</sup> studied sexual transmission risk in 161 hemophilic patients. 21% of the females in sexual contact with them were found to be GBV-C RNA seropositive. The more frequent detection of markers of GBV-C in persons at increased risk for sexually transmitted diseases is also indirect evidence for its sexual transmission. Wachtler *et al*<sup>[31]</sup> revealed HGV RNA in 27% and anti-E2 in 35% of the HIV-infected, while in the control group these were 2% and 6%, respectively.

The vertical transmission of GBV-C from infected mother to infant may now be considered proven<sup>[36,55-57]</sup>. There may be intranatal infection of a baby at delivery by the maternal passage, as confirmed by the data on a significant reduction in the infection rates of neonates after cesarean section of their mothers<sup>[55]</sup>. There is also postnatal GBV-C infection. On examining 288 mothers, Lefrere *et al* revealed that 89% of the GBV-C-positive babies were infected at 3 mo after birth<sup>[36]</sup>.

The level of viremia is a factor that is of importance in the transmission of the virus. By following up 24 babies born to mothers with a GBV-C RNA level of more than  $10^6$  copies/mL, Ohto *et al* revealed GBV-C in 23 (96%) of them. The viremia index in the mothers whose babies proved to be infected was significantly higher than that in those whose babies were seronegative ( $P < 0.001$ ). Most

babies had no clinical or biochemical signs of liver disease despite one-year HGV persistence<sup>[58]</sup>. In the opinion of Wejstal *et al*, the vertical transmission of GBV-C amounts to 75%-80% of cases and that of HCV is 2.8%-4.2% ( $P < 0.001$ )<sup>[56]</sup>. The frequent maternal-infant transmission of GBV-C may account for the high prevalence of the virus among the adult population at low risk of parenteral and sexual transmissions. The detection of GBV-C increases with age. HGV was detectable in 9% and 28.6% of the children under 15 years and above 16 years of age, respectively<sup>[59]</sup>.

## GBV-C TROPISM

GBV-C predominantly replicates in peripheral blood mononuclear cells, mainly in B and T (CD4+ and CD8+) lymphocytes and bone marrow<sup>[23-25,60]</sup>. The mechanism responsible for the development of GBV-C-induced hepatitis is not clear so far. Despite the described cases of acute and chronic hepatitis G, its hepatotropism remains controversial. Table 4<sup>[11,27,28,61-74]</sup> shows data that both confirm and rule out viral tropism to liver tissue.

Viral hepatotropism is supported by the detection of GBV-C RNA in hepatocytes and by the development of acute and fulminant hepatitis following the transfusion of infected blood and its products. Lang *et al* reported interesting data on the immunohistochemical detection of GBV-C NS5 Ag in the liver biopsy specimens taken from patients with various liver diseases<sup>[68]</sup>. Like RNA-containing HCV, GBV-C does not integrate into the genome of an infected cell, but it is located in its cytoplasm and the "positive" cells are diffusely arranged. The indirect evidence for the liver tissue GBV-C replication is a considerable reduction in the serum content of viral RNA after liver transplantation ( $12.4 \pm 3.9 \times 10^7$  copies/mL vs  $2.8 \pm 0.7 \times 10^7$  copies/mL)<sup>[69]</sup>.

Primary replication of HGV in the hepatocytes has been questioned. Thus, the level of GBV-C RNA in the serum was higher than that in the liver tissue (there is an inverse correlation for HCV). In a third of serum-positive patients, RNA was undetectable in

**Table 4 Data on the hepatotropicity of GBV-C**

Hepatotropicity	No hepatotropicity
Detection of GBV-C RNA in the sera of patients with acute hepatitis non-A-non-E <sup>[61,66]</sup>	The equal detection rate of GBV-C RNA in donors with normal and increased alanine aminotransferase activities (1.7 and 1.5%, respectively) <sup>[70]</sup>
Histological pattern of hepatitis in GBV-C infection <sup>[27,28,66,67]</sup>	Normal aminotransferase activity values in the presence of GBV-C RNA <sup>[11,71]</sup>
Detection of GBV-C RNA and NS5 Ag in the liver tissue <sup>[68]</sup>	No correlation between the level of GBV-C RNA and the activity of alanine aminotransferase <sup>[72]</sup>
A significant reduction in the serum level of GBV-C RNA after liver transplantation <sup>[69]</sup>	The level of GBV-C RNA in the liver tissue is lower than that in the serum <sup>[73,74]</sup>

the hepatocytes despite the fact that tissue had been repeatedly taken from different lobes of the liver<sup>[73]</sup>. A study of liver biopsy specimens from 12 GBV-C-positive patients revealed no RNA “minus” strand responsible for replication and a RNA “plus” strand only in half the patients with low titers, which may be indicative of GBV-C contamination from blood. Laskus *et al* reported similar results investigating liver tissue and sera from 10 patients co-infected with HCV and GBV-C<sup>[74]</sup>.

After establishing that the hepatotropicity of GBV-C was low, the next stage of elucidating the pathogenicity of the virus was to study its tropism to other tissues. Handa *et al* determined the presence of a RNA “minus” strand in the vascular endotheliocytes<sup>[25]</sup>. In the authors’ opinion, isolation of GBV-C RNA from a liver biopsy specimen may reflect viral replication in the endothelium of the vessels located in the liver<sup>[25]</sup>. Tucker *et al* reported the detection of RNA “plus” strands in all 23 study organs taken for analysis from GBV-C-infected patients who had suddenly died<sup>[7]</sup>. However, both RNA strands were found only in the spleen and bone marrow.

The comparison of nucleotide sequences in the E2-region and the lack of occurrence of mutant viral forms during antiviral therapy with interferons suggested that the mechanisms that are responsible for persistent infection are different from those for HCV. Thus, during 2-year follow-up, the average amino acid sequence replacement in the E2-region was 100 times lower in GBV-C than in HCV<sup>[75]</sup>. Investigations indicated that viremia in GBV-C-infected patients was low and equal to  $10^3\text{-}10^4$  copies/mL<sup>[76]</sup>. It has been suggested that the viral particles that are present in the blood use low-density lipoprotein receptors for penetration into the target cell and generate lipid complexes similar to those seen for HCV particles. An experiment was made on cultured peripheral blood mononuclear cells (PBMC)<sup>[60,77]</sup>.

GBV-C may replicate in PBMC and interferon-resistant Daudi cells<sup>[60]</sup>. Experiments were carried out to inoculate human PBMC lines and hepatocytes with GBV-C RNA *in vitro*. The same lines were infected with HCV as a control. These experiments demonstrated that GBV-C replicates only in CD4+ cells<sup>[60,78]</sup>. Studies of cells from different organs of GBV-C-infected patients were conducted in parallel. They also detected traces of RNA “minus” strand virus. Thus, the *in vitro* and *in vivo* studies provide evidence that PBMC are the primary site of GBV-C replication.

The contribution of not only the immune system,

but also genetic predisposition to prolonged viral circulation is suggested. HLA typing in GBV-C-infected patients with hemophilia showed that 22% of the RNA-positive patients and 72% of the anti-E2-positive patients had HLA DQ7, HLA DR15 and HLA DR8. There is also evidence for low content of CD4+ and the high level of CD8+ lymphocytes in anti-E2-positive patients, which makes it possible to predict GBV-C clearance<sup>[79]</sup>.

HGV replication in peripheral blood monocytes and lymphocytes, and the spleen and bone marrow, combined with long viral persistence suggest that GBV-C replicates predominantly in the hematopoietic system. On examining 44 patients with non-Hodgkin’s lymphoma, African *et al* revealed markers of HCV infection in 5% of cases<sup>[80]</sup>. None of them was found to have HGV RNA. However, meta-analysis of 178 cases of non-Hodgkin’s lymphoma and 355 healthy volunteers indicated GBV-C RNA in 8.4% (15/176) and 0.8% (3/355) of the examinees, respectively, which points to the high risk of HGV in patients with lymphoma<sup>[81]</sup>. There is evidence for the frequent detection of GBV-C RNA in patients with leukemia as compared to those with myeloproliferative diseases<sup>[82]</sup>. Crespo *et al* reported the development of aplastic anemia in a 24-year-old male patient with acute hepatitis G<sup>[83]</sup>. Frequent transfusions in these patients may be one of the causes of HGV infection.

There are higher detection rates of GBV-C RNA (11%) and anti-E2 (17%) in autoimmune hepatitis than in the control group (2%)<sup>[84]</sup>. Heringlake *et al* revealed serum GBV-C RNA in 6.7%, 10.0% and 12.5% of the patients with types I, II and III autoimmune hepatitis, respectively<sup>[85]</sup>. GBV-C is typified by a long-term (as long as 16 years) persistence in human blood<sup>[86]</sup>.

## CLINICAL MANIFESTATIONS OF GBV-C

The clinical picture of GBV-C infection is commonly similar to that of the subclinical and anicteric types of hepatitis with normal or low aminotransferase activities<sup>[87]</sup>. GBV-C-associated hepatitis runs with normal biochemical parameters in 75% of patients<sup>[80]</sup>. There are reports on the occurrence of acute (Table 5)<sup>[62-65,88,89]</sup>, fulminant<sup>[61,90,91]</sup> and chronic (mild and moderate)<sup>[32,76,92,93]</sup> hepatitis and hepatic fibrosis<sup>[27,86]</sup>. Some author’s note the younger age of the GBV-C-infected<sup>[28,37,93]</sup>. The incubation period of acute viral

**Table 5 Detection rate of GBV-C RNA in acute nonA-nonE hepatitis**

Authors, year, country	Number of patients	GBV-C RNA (%)
Alter <i>et al</i> , 1997, United Kingdom <sup>[62]</sup>	45	9.0
Romano <i>et al</i> , 2000, Italy <sup>[63]</sup>	98	3.1
Chu <i>et al</i> , 1999, Taiwan, China <sup>[64]</sup>	53	3.0
Parana <i>et al</i> , 1999, Brazilia <sup>[65]</sup>	25	16
Yashina <i>et al</i> , 1997, USA <sup>[88]</sup>	28	3.6
Uchaikin <i>et al</i> , 2000, Russia <sup>[89]</sup>	35	5.7

hepatitis G averages 14-20 d. The outcome of acute hepatitis may be: (1) recovery with the disappearance of serum GBV-C RNA and the emergence of anti-E2; (2) development of chronic hepatitis (CH) with serum GBV-C RNA being persistently detectable; (3) presence of GBV-C RNA without biochemical or histological signs of liver disease.

The alanine aminotransferase (ALT) activity in GBV-C unlike HCV, does not correspond to the degree of viremia and the severity of hepatic histological changes. By examining 1075 patients with isolated hypertransaminasemia for 6 mo, Berasain *et al* revealed GBV-C RNA in 74 (6.9%) patients<sup>[94]</sup>. Only one (0.09%) patient was monoinfected. There is also evidence for two-fold increases in the activity of alkaline phosphatase (AP) and  $\gamma$ -glutamyl transpeptidase ( $\gamma$ -GTP) in GBV-C positive patients<sup>[95]</sup>.

## HISTOLOGICAL CHANGES

Fibrosis of the portal tract without lymphoid-cell infiltration<sup>[96]</sup>, steatosis and insignificant inflammatory infiltration of the portal tract<sup>[67,97,98]</sup> were detectable in isolated persistent GBV-C infection. The histological activity index in patients infected with GBV-C alone was observed to be much lower than that in patients with HCV+GBV-C or HCV<sup>[37,99,100]</sup>. In GBV-C monoinfected patients, moderate or mild focal portal hepatitis was prevalent with slight periportal infiltration and lobular components being found in single cases. The bile tract displayed epithelial fragmentary swelling and flattening and no nuclei in some epitheliocytes. Some bile ducts demonstrated partially desquamated epithelium in the case of higher activities<sup>[99,101]</sup>.

Intraoperative biopsies from GBV-C positive patients with cholelithiasis who were monoinfected with GBV-C, indicated that they had mild chronic hepatitis and, in some cases, viral RNA in the liver tissue and gallbladder mucosa. It is suggested that GBV-C may play a role in the production of lithogenic bile and in the development of cholelithiasis<sup>[102]</sup>.

Coinfection of HGV with hepatitis B, C, and D viruses is significantly more frequently detected than mono-infection<sup>[103]</sup>. In patients with acute viral hepatitis A (HAV), -B (HBV), -C (HCV), the detection rate of GBV-C RNA was 2.9%-25%, 19%-32%, and 20%-48.3%, respectively<sup>[88,89]</sup>. GBV-C RNA was detectable in 8%-16% of patients with chronic hepatitis (CH) B<sup>[30,77,100]</sup>, 5.6%-21% of CH C<sup>[30,77,100]</sup>, and 58% of

CH B+D<sup>[98]</sup>. No differences were found in the clinical manifestations (including those in the chronic pattern and outcome) of the disease, biochemical parameters, or the severity of hepatic histological changes in patients with HBV and/or HCV as compared in those with HBV+GBV-C and/or HCV+GBV-C<sup>[104-106]</sup>. Patients with CHC alone and in combination with HGV have been meticulously examined. By examining 420 patients, Tanaka *et al* revealed a higher ALT activity in the group of patients coinfected with HCV and GBV-C than in those infected with HCV<sup>[107]</sup>.

By comparing histological changes in the liver tissue of patients with HCV and HCV + GBV-C, Moriyama *et al* detected more significant bile duct damages, perivenular and pericellular fibrosis in the latter group<sup>[108]</sup>. These data were supported by the examination of 312 patients with CH<sup>[99]</sup>. Of them 28 (9%) patients were found to have RNA for HCV and GBV-C. Complaints and clinical symptoms did not differ in the groups of patients with HCV and HCV+GBV-C. There was no evidence for the impact of HGV on the clinical manifestations and the course of concomitant HCV infection. However, analysis of liver tissue morphological changes in patients coinfected with HCV and GBV-C revealed slightly more frequent epithelial damage in the bile duct (89%) than in those infected with HCV (67%), which manifested itself as lysis of the epitheliocytic nuclei, as well as flattening, destruction, and swelling of the epithelium and its lymphocytic infiltration.

Whether GBV-C influences the course of CHC and whether therapy with interferon is effective are currently being discussed. Most studies demonstrate no differences in the clinical course of the disease, biochemical parameters, or the magnitude of hepatic histological changes in both HCV alone and in combination with GBV-C<sup>[109-111]</sup>. A study for the therapy of HGV is based on the evaluation of interferon treatment in patients coinfected with HCV+GBV-C. HGV was ascertained to be sensitive to interferon. Administration of  $\alpha$ -interferon ( $\alpha$ -IFN) to patients at a dose of 3 000 000 IU thrice weekly for 6 mo resulted in ALT activity normalization and serum GBV-C RNA clearance in 18%-40% of the patients treated with  $\alpha$ -IFN<sup>[112,113]</sup>. Six months after termination of a course of therapy, there were persistent biochemical and virological responses in 55%-57% of patients<sup>[114]</sup>. The therapeutic efficiency was observed to depend on baseline GBV-C RNA levels. The patients who had a low RNA titer (mean,  $3.3 \times 10^5$  copies/mL) more frequently responded to the therapy than those who had a higher one (mean,  $3.5 \times 10^8$  copies/mL)<sup>[104,109]</sup>. There is now a prevailing opinion that GBV-C has no impact on the efficiency of  $\alpha$ -interferon treatment for chronic hepatitis C<sup>[114,115]</sup>. At the same time some investigations suggest that the therapy causes more frequent adverse reactions in patients with HCV+GGV-C and that after its termination, this group of patients has a higher histological activity index<sup>[116,117]</sup>.

The implications of HGV for the development of chronic liver diseases has not been appraised to date.

As for GBV-C infection, investigators could not trace the clinical stages characteristic of HBV and HCV: acute hepatitis-chronic hepatitis-liver cirrhosis (LC)-hepatocellular carcinoma (HCC). A long-term (less than 16 years) follow-up of patients permitted discussion only of the likelihood of development of chronic hepatitis. GBV-C RNA was detectable in 8%-25.4% of patients with chronic hepatitis non-A-non-E<sup>[118]</sup>, 6%-15% of patients with cryptogenic liver cirrhosis<sup>[119,120]</sup>, and 3.1%-8.3% with HCC<sup>[121,122]</sup>.

The similarity of the properties of GBV-C and HCV offers a possibility of using HGV and its induced experimental infection as a model to study hepatitis C. Unlike hepatitis C, hepatitis G infection may be modeled in nonhuman primates, which considerably reduces the cost these studies that are in great demand for the designing of hepatitis C vaccine.

Unexpected results were obtained while studying the impact of GBV-C on the course of HIV infection<sup>[123,124]</sup>. Co-infection with GBV-C in the HIV-infected was established to cause a reduction in mortality rates and better clinical parameters of infection. Furthermore, the efficiency of high-activity antiretroviral therapy significantly increased. The positive effect of GBV-C is accounted for by the fact that the envelope proteins of this virus bind CD81+ on T cells and induce dose-dependent secretion of RANTES (regulated on activation, normal T-cell expressed and secreted), the natural ligand that binds CCR5 on the target cell, thereby blocking the penetration of HIV<sup>[21,125]</sup>. *In vitro* studies showed an increase in the expression of the chemokines-RANTES, macrophage inflammatory proteins (MIP-1 $\alpha$ , MIP-1 $\beta$ ), and stromal-cell derived factor (SDF-1) in the blood of patients. There was also a reduction in the expression of CCR5 onto the surface of GBV-C-infected cells. All these factors may provide indirect evidence for the diminished sensitivity of GBV-C-infected cells to HIV<sup>[125-127]</sup>.

A review of available data in the literature and the authors' own data suggest that the new HGV discovered in the late 1990s has been rather well studied. The structure of the virus is almost completely known; its genotypes have been ascertained; its prevalence (epidemiology) shown and the clinical picture of the disease, routes of viral transmission, and the types of coinfection described. The predominant site of replication of the virus in the blood mononuclear cells, spleen, and bone marrow has been indicated. The lack of hepatotropism of virus G (which is rarely detected in the liver), its frequent detection in the body and tissues of a patient without any clinical signs of hepatitis, and clinical improvement in the HIV-infected patients coinfected with GBV-C cast doubt on the appropriateness of the concept "viral hepatitis G". The interest shown in HGV is likely to be associated with the similarity of its properties to those of HCV.

## Abstract

Acute pancreatitis (AP) causes release of platelet-activating factor (PAF), which induces systemic effects that contribute to circulatory disturbances and multiple organ failure. PAF is a cell surface secretion of bioactive lipid, which could produce physiological and pathological effects by binding to its cell surface receptor called platelet-activating factor receptor (PAF-R). Studies showed that PAF participates in the occurrence and development of AP and administration of platelet-activating factor receptor antagonists (PAF-RAs) could significantly reduce local and systemic events after AP. PAF has also been implicated as a key mediator in the progression of severe AP, which can lead to complications and unacceptably high mortality rates. Several classes of PAF-RAs show PAF-RAs significant local and systemic effects on reducing inflammatory changes. As a preventive treatment, PAF-RAs could block a series of PAF-mediated inflammatory injury and thus improve the prognosis of AP. This review introduces the important role of PAF-RAs in the treatment of AP.

## INTRODUCTION

Acute pancreatitis (AP) is a kind of inflammatory disease that can develop into severe acute pancreatitis (SAP). SAP refers to AP associated with organ failure and/or local complications such as necrosis, pseudocyst or abscess<sup>[1]</sup>. The overall mortality of SAP has decreased in recent years to around 15%-20%<sup>[2]</sup>. A variety of inflammatory mediators play a crucial role in AP. Synthesis of platelet-activating factor (PAF) is sensitive to biologically active mediators seen in many inflammatory processes, which could produce physiological and pathological effects by binding to its cell surface receptor called platelet-activating factor receptor (PAF-RA). PAF significantly potentiates pancreatic tissue damage and increases serum amylase and lipase levels, causes scattered haemorrhages and may serve as a primary mediator of inflammation. Many identified PAF-RAs exhibit varied structures, and interact with the PAF-RA in different ways. It has been postulated that these differences could be due to conformation changes in the receptor protein itself, by G-protein coupling or changes on the cell membrane. Several classes of PAF-RAs show significant local and systemic effects on reducing inflammatory changes. PAF-RAs used as a preventive treatment can block a series of inflammatory injury caused by PAF, thereby improving AP prognosis<sup>[3]</sup>. Research on such as a potential therapy has helped to elucidate the role of PAF in AP<sup>[4]</sup>. Progress in treatment of AP with PAF-RAs is summarized below.

## BIOLOGICAL ACTIVITY OF PAF

PAF released by various cells including endothelial,

polymorphonuclear, gastrointestinal epithelial cells and macrophages, is a potent proinflammatory phospholipid mediator that belongs to a family of biologically active, structurally related alkyl phosphoglycerides with diverse pathological and physiological effects. These bioactive phospholipids mediate such diverse processes as wound healing, physiological inflammation, angiogenesis, apoptosis, reproduction, long-term potentiation and immunoregulatory role<sup>[5]</sup>. The data suggest that PAF enhances PAF-R expression<sup>[6,7]</sup>. PAF activates multiple intracellular signaling pathways by binding to PAF-R. In the inflammatory process, the primary function of PAF is to activate the interleukin system in endothelial cells to surface rolling, adhesion and through endothelial cells to stroma cells. PAF has neurological toxicity<sup>[8]</sup>. It is also involved in etiopathogenesis of type-1 diabetes<sup>[9]</sup> and liver tissue repair post-acetaminophen treatment<sup>[10]</sup>.

## RELATIONS BETWEEN PAF AND AP

In the development of AP, the pancreas and its surrounding tissues secrete digestive enzymes to digest their own components, causing acute inflammation. AP is divided into acute edema and acute hemorrhagic pancreatitis according to its histology and clinical manifestations. Acute hemorrhagic pancreatitis is also called as severe acute pancreatitis (SAP). Studies found that SAP is closely related to neutrophil excessive activation and cytokines-mediated cascade of systemic inflammatory response syndrome (SIRS)<sup>[11]</sup>. The considerable release of PAF and direct or indirect systemic response facilitates formation of SIRS and causes circulation dysfunction, resulting in multiple organ dysfunction syndrome (MODS)<sup>[4]</sup>. *In vitro* experiments showed that PAF can stimulate a large number of trypsin release<sup>[12]</sup>, while *in vivo* experiments showed that PAF could induce and aggravate AP through injection into pancreatic arteries<sup>[13]</sup>. PAF is increased in pancreas, ascites, immune complexes, cerulein and AP induced by cows iodine acid salt.

## PAF-RA

PAF-RA can successfully repress the effect mediated by PAF in AP. PAF-RAs are divided into five categories according to their chemical structure and properties: nitrogen heterocyclic compounds (such as WEB2086, WEB2170, etc), PAF analogues (such as CV3988, SDZ63072, etc), dihydropyridines (such as PCV4233, PVA4248, etc), natural medicines (such as BN52021, Kadsurenone, etc), and others (such as 52770 RP, TCV309, etc).

PAF-RAs exert their effects by inhibiting the activity of neutrophils and depressing pulp peroxidase, competing targets with PAF and inhibiting the activity of PAF<sup>[14]</sup>, inhibiting increasing PAF in AP, reducing vascular permeability and improving microcirculation of blood flow velocity, reducing plasma cytokines and inflammatory mediators, enzyme activity and the role of self-digestion of pancreatic tissue. At present, there are

several compounds with obvious antagonism of PAF, their chemical codes are BN52021, WEB2170, TCV309, WEB2086 and BB882 (*lexipafant*), which can reduce the inflammatory response and significantly affect local and systemic status in AP.

### WEB2170

WEB2170 is a nitrogen heterocyclic compound. Nitrogen binds to the receptor through the hydrogen bond, facilitating the activity of PAF-RAs, thus reducing the NO production by liver cells in pancreatitis. PAF is likely to be the main contributing factor for endotoxin effect. WEB2170 can significantly reduce intestinal necrosis mediated by lipopolysaccharide (LPS)<sup>[15]</sup> and WEB2170 does not affect the TNF levels<sup>[16]</sup>. WEB2170 can reduce vascular permeability and infiltration of neutrophils and macrophages.

WEB2086 (Apafant) can inhibit angiogenesis in atherosclerotic plaque<sup>[17]</sup>. Oral WEB2086 can elevate low blood pressure induced by PAF.

### TCV309

TCV309 is an important PAF antagonist, which can inhibit the biological activity of PAF both *in vivo* and *in vitro*. Oral TCV309 can significantly reduce the concentration of neutrophil chemokine, but does not lead to significant changes in amylase<sup>[18]</sup>. TCV309 has more advantages than PAF analogues in avoiding hemolysis and vascular injury when the inhibitory activity of PAF binding to its receptor is higher. In addition to injection, TCV309 can be taken orally.

### Lexipafant

Lexipafant has entered clinical trials. Lexipafant is a molecule specifically designed to bind to PAF-R<sup>[4]</sup> and an imidazole derivative of heterocyclic sp<sup>2</sup> nitrogen compounds and has been shown to be considerably more potent than other PAF receptor antagonists with a much greater affinity than PAF itself for its binding to human platelet PAF-R.

Lexipafant can prevent liver ischemia/reperfusion injury<sup>[19]</sup> and reduce the severity of inflammatory response to liver injury induced by bile duct ligation in rats<sup>[20]</sup>, leading to impairment of AP endothelial barrier function, leukocyte accumulation and IL-1 level in the pancreas<sup>[21]</sup>. Treatment of pancreatitis with lexipafant reduces the severity of pancreatitis-associated intestinal dysfunction, systemic IL-1 concentration and local leukocyte recruitment<sup>[22]</sup>.

Animal experiments showed that lexipafant improves inflammation of AP<sup>[23]</sup>. Lexipafant treatment can improve acute necrotizing pancreatitis caused by bacteria shift<sup>[24]</sup>. In clinical trials, it was shown that lexipafant could reduce the morbidity and mortality of acute pancreatitis, but may not reduce the morbidity and mortality of severe acute pancreatitis. Further investigation is expected about the effect of lexipafant<sup>[25]</sup>.

Vincent *et al*<sup>[26]</sup> also claimed that there is no difference in survival, hemodynamics, respiratory function and MOF score between treatment with lexipafant and

placebo. Johnson *et al*<sup>[27]</sup> used lexipafant intervention therapy to study 290 cases of AP patients and found that the organ failure scores of AP are significantly reduced, suggesting that lexipafant cannot change the SAP organ failure process in patients. Further study is needed to observe the effect of lexipafant.

### BN52021

BN52021 is a terpenoid extracted from *Ginkgo biloba* leaves. In 1988, Jancar found that treatment of AP in immune-complex-induced mouse model with BN52021 could significantly relieve edema of pancreas<sup>[28]</sup>. Since BN52021 competitively inhibits the binding to PAF and its platelet receptor, PAF cannot activate phospholipase C through G-protein transduction, adenosine cyclase and tyrosine protein kinase, thereby blocking the PAF receptor signal transduction and the biological effects of PAF. BN52021 exerts its biological effects by competitively inhibiting the expression of PAF and PAF-R rather than by decreasing the expression of PAF receptor in pancreatic tissues<sup>[29]</sup>. BN52021 is a non-competitive GABA receptor antagonist<sup>[30]</sup> and inhibits gene transcription of adrenal peripheral benzodiazepine receptor and synthesis of steroids<sup>[31]</sup>.

BN52021, a most promising PAF-R antagonist, can effectively inhibit PAF-induced neutrophil chemotaxis, adhesion, aggregation and other inflammatory factors, thus reducing inflammation injury. BN52021 significantly reduces the mortality of AP, prolongs the average survival time, maintains a lower serum amylase activity, reduces pancreatic injury as well as Ca<sup>2+</sup> content and malondialdehyde (MDA) level and superoxide dismutase (SOD) activity in pancreatic tissue. Bedirli *et al*<sup>[32]</sup> reported that BN52021 can inhibit intestinal bacterial shift to the pancreas. BN52021 protects the stability of macrophage membrane against lysis<sup>[33]</sup>. PAF may play an important role in liver injury and regeneration. Ginkgolide B attenuates liver damage, thus improving liver function following acetaminophen intoxication<sup>[34]</sup>.

To sum up, BN52021 has a wide range of pharmacological effects. Currently, pharmacology of BN52021 mainly focuses on the PAF-R antagonists. Whether other mechanisms of BN52021 exert effects through different pathways is worthy of further study.

### CONCLUSION

Progress has been made in research about the therapy for AP, especially for SAP, with PAF-RA. However, there is still a long way to go. Further study is needed to confirm the encouraging results obtained from animal experiments and find other key inflammatory mediators in the pathogenesis of AP.

## Abstract

**AIM:** To detect the nuclear factor kappa B (NF- $\kappa$ B) condition in human stage IV gastric carcinoma patients and to explore the correlation between NF- $\kappa$ B activation and survival of these patients after chemotherapy.

**METHODS:** Expression of NF- $\kappa$ B-p65 was determined by immunohistochemical analysis. Activity of NF- $\kappa$ B DNA-binding in carcinoma tissue was detected by electrophoretic mobility shift assay. Kaplan-Meier survival analysis was performed to show the relation between NF- $\kappa$ B and progression-free survival (PFS) or overall survival (OS) of the patients.

**RESULTS:** The positive expression rate of NF- $\kappa$ B-p65 in 60 gastric cancer tissue samples was 76.7% (46/60). The expression of NF- $\kappa$ B-p65 was reduced in adjacent carcinoma and normal tissue samples. Electrophoretic mobility shift assay (EMSA) analysis showed a strong activation of NF- $\kappa$ B in cancer tissue samples. A survival difference was found in NF- $\kappa$ B-p65 positive and negative patients. NF- $\kappa$ B-p65 expression was negative in cancer tissue samples ( $n = 14$ ). PFS was  $191.40 \pm 59.88$  d and  $152.93 \pm 16.99$  d, respectively, in patients with positive NF- $\kappa$ B-p65 expression ( $n = 46$ ) ( $P = 0.4028$ ). The

survival time of patients with negative and positive NF- $\kappa$ B-p65 expression was  $425.16 \pm 61.61$  d and  $418.85 \pm 42.98$  d, respectively ( $P = 0.7303$ ). Kaplan-Meier analysis showed no significant difference in PFS or OS. The 46 patient tissue which positive NF- $\kappa$ B-p65 expression was found in the tissue samples from the 46 patients whose PFS and OS were  $564.89 \pm 75.94$  d and  $352.37 \pm 41.32$  d, respectively ( $P = 0.0165$ ).

**CONCLUSION:** NF- $\kappa$ B is activated in gastric carcinoma tissue, which is related to the OS after chemotherapy.

## INTRODUCTION

Nuclear factor kappa B (NF- $\kappa$ B) contributes to cell differentiation, proliferation, and death, as well as plays a prominent role in the immune response of mammals<sup>[1]</sup>. It consists of homodimers or heterodimers of the Rel family members: NF- $\kappa$ B1 (p50), NF- $\kappa$ B2 (p52), c-Rel, RelA (p65), and RelB<sup>[2]</sup>. The ability of NF- $\kappa$ B to suppress apoptosis and regulate cell-cycle transition indicates that NF- $\kappa$ B may participate in oncogenesis<sup>[3]</sup>.

There is evidence that NF- $\kappa$ B level is higher in gastric carcinoma cells than in normal adjacent epithelial cells, and activation of NF- $\kappa$ B in gastric carcinoma is related to lymphatic invasion<sup>[4]</sup>. It was reported that patients with high NF- $\kappa$ B activation in carcinoma tissue would not survive as long as those with low NF- $\kappa$ B activation<sup>[5]</sup>, and p65, but not NF- $\kappa$ B, is a prognostic indicator of gastric carcinoma<sup>[5]</sup>. It was also reported that NF- $\kappa$ B is frequently activated in the early-stage gastric carcinoma, and negatively associated with lymphatic invasion, but

significantly associated with a better prognosis<sup>[6]</sup>.

Although NF-κB is activated in human gastric carcinoma tissue, there is no evidence that NF-κB activation is associated with the clinicopathological features of cancer<sup>[6]</sup>. Our present study was to detect whether NF-κB is activated in human stage IV gastric carcinoma and explore the correlation between its activation with the survival of gastric cancer patients after chemotherapy.

## MATERIALS AND METHODS

### Materials

The criteria for inclusion of patients in this study were (1) those with histologically or cytologically proved gastric cancer, (2) those with stage IV gastric cancer diagnosed according to the 2002 American Joint Committee on Cancer (AJCC) modified staging criteria, (3) those treated in our hospital with follow-up data, (4) those not receive chemotherapy prior to admission to our hospital, (5) those who received treatment with chemotherapeutics FOLFOX or paclitaxel/LV5Fu2 (PLF), (6) those with their therapeutic effect divided into complete remission (CR), partial remission (PR) and progression of disease (PD). The exclusion criteria for patients from this study were those with less than two cycles of treatment with FOLFOX or PLF, those with their therapeutic effect not estimate after two cycles of treatment with FOLFOX or PLF, those with stable effect of chemotherapeutics after several cycles of treatment, those having received two cycles of chemotherapy with FOLFOX and PLF. The response evaluation criteria used were the WHO and UICC criteria. We collected 60 gastric carcinoma samples from the First Affiliated Hospital of Sun Yat-Sen University in November 1999-June 2005. The data obtained from patients are shown in Table 1.

### Immunohistochemistry for NF-κB-p65 detection

All samples were fixed with 100 mL/L formalin and embedded in paraffin. Each paraffin block was cut into 5-μm thick sections. Streptavidin-Biotin Complex (SABC) Immunohistochemistry was performed according to the manufacturers' instructions to detect the expression of NF-κB-p65. Briefly, the tissue sections were deparaffinized in xylene at 37°C for 20 min. Endogenous peroxide was blocked by incubating the sections with 30 mL/L H<sub>2</sub>O<sub>2</sub> for 10 min at 37°C. The sections were incubated with primary antibodies to NF-κB-p65 at 4°C overnight. Staining was visualized with diaminobenzidine (DAB) for 10 min at room temperature. Finally, the sections were counterstained for nuclei with hematoxylin solution. Each section was observed microscopically in eight visual fields ( $\times 400$  magnification) and at least 100 cells were counted in each field. Positive staining for NF-κB-p65 appeared as buffy grains in the nuclei and cytoplasm. A semi-quantitative method was adopted to judge the results as previously described<sup>[7]</sup>. Immunohistochemistry score was calculated by combining an estimate of the percentage of immunoreactive cells (quantity score) with

**Table 1 Data obtained from patients in the two treatment groups**

an estimate of the staining intensity (staining intensity score) as follows: no staining as 0, 1%-10% of cells stained as 1, 11%-50% cells stained as 2, 51%-80% cells stained as 3, and 81%-100% cells stained as 4. Staining intensity was rated on a scale of 0-3, with 0 = negative, 1 = weak, 2 = moderate, and 3 = strong. The staining was evaluated by color intensity and density of grade products as follows: 0-3 = negative (-), > 3 = positive (+). All specimens were evaluated by two pathologists without any knowledge about the clinical data obtained from the patients. Negative control was designed using PBS instead of primary antibody. Adjacent glandular epithelium served as an internal positive control of NF-κB-p65 protein expression.

### Electrophoretic mobility shift assay (EMSA) of NF-κB

Activity of NF-κB DNA-binding was detected by EMSA as previously described<sup>[8]</sup> with certain modifications. Double-stranded oligonucleotide sequence of 5'-AG TTGAGGGGACTTCCCCAGGC-3', 5'-GCCTGGG AAAGTCCCCTCACT-3', which corresponds to the NF-κB binding site, was end-labeled with [ $\gamma$ -32P] ATP by T4 polynucleotide kinase (Promega). Labeled probes were purified and detected with Whatman DE81 (> 5000 r/min). Nuclear extract (15 μg) was mixed with 5 × 2 μL binding buffer at room temperature for 10 min, then labeled probe (0.0175 pmol) was incubated at room temperature for 20 min. The mixture was then subjected to electrophoresis on 4% polyacrylamide gel at 150 V in 0.5 × TBE buffer for 40 min at 4°C. After drying, the gel was exposed to an imaging system of FX P screen (Bio-Rad, America) for 24 h. The result was analyzed with software Bandscan 4.0 (denary logarithm of total gray value).

### Follow-up methods

All patients were followed up in out-patient clinic, or by

**Figure 1** Immunohistochemical staining for NF- $\kappa$ B-p65 showing p65 expression in cancer tissue samples but not in adjacent non-neoplastic tissue samples (SABC,  $\times$  100) (A), in gastric adenocarcinoma epithelial tissue samples (SABC,  $\times$  200) (B), in intestinal metaplasia samples (SABC,  $\times$  200) (C), in nuclei of cancer cells (SABC,  $\times$  200) (D), and very weak expression of NF- $\kappa$ B-p65 in gastric mucosa samples (SABC,  $\times$  200) (E), and in negative control (SABC,  $\times$  200) (F).

telephone or letters, two times each year, until June 4, 2006. We calculated progression-free survival (PFS) and overall survival (OS) rates from the day of treatment. Life-table methods were used to estimate PFS and OS<sup>[9]</sup>. For OS, deaths, irrespective of cause, were coded as events. For PFS, an event was defined as relapse, progression, or death during the period of active follow-up. Kaplan-Meier curves for PFS and OS were calculated for the subgroups with positive or negative NF- $\kappa$ B-p65 staining. In addition, other sets of Kaplan-Meier curves were derived to determine the PFS and OS of patients after FOLFOX and PLF therapy when NF- $\kappa$ B-p65 staining was positive. To assess variables influencing PFS and OS, univariate analysis using log-rank tests and proportional hazards models was performed. This study was approved by the local human investigation committee.

#### Statistical analysis

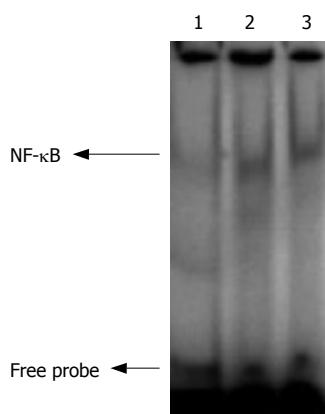

Statistical analysis was performed using SPSS 10.0

software. Significant differences were compared using one-way ANOVA test. Chi square test was performed for numerical data. Survival analysis was carried out using the Kaplan-Meier product-limit method, and survival curves were plotted. Differences were evaluated by the log rank test.  $P < 0.05$  was considered statistically significant.

## RESULTS

### NF- $\kappa$ B-p65 expression by SABC

The positive expression rate of NF- $\kappa$ B-p65 in 60 gastric cancer tissue samples was 76.7% (46/60). Most positive expression of NF- $\kappa$ B-p65 showed brown-stained signals in cell cytoplasm or membrane (Figure 1A-C). Only a small amount of expression was found in the nuclei (Figure 1D). The immunohistochemistry score was  $7.18 \pm 2.72$ . The expression of NF- $\kappa$ B-p65 was reduced in the carcinoma tissue samples and the expression rate

**Figure 2** Images of EMSA. Lanes 1-3: NF- $\kappa$ B activity in normal, moderately- and poorly-differentiated gastric carcinoma tissue samples.

was 26.7% (16/60, Figure 1C). Weak expression of NF- $\kappa$ B-p65 was observed in normal tissue samples (Figure 1E). The immunohistochemistry score was  $1.85 \pm 1.29$  and  $0.17 \pm 0.38$ , for carcinoma and normal tissue samples, respectively ( $P < 0.00001$ ). No stained signal was detectable in negative control (Figure 1F).

#### EMSA for NF- $\kappa$ B

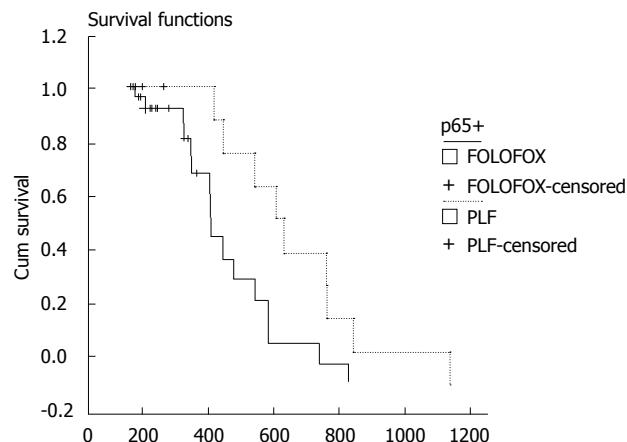

Nuclear extracts from normal, moderately- and poorly-differentiated gastric carcinoma tissue samples were analyzed by EMSA, which showed a strong activation of NF- $\kappa$ B in cancer tissue samples (Figure 2).

#### Different survival time of positive and negative NF- $\kappa$ B-p65 patients

We analyzed PFS and OS using the Kaplan-Meier method. The results showed that the expression of NF- $\kappa$ B-p65 was negative in cancer tissue samples (immunohistochemistry score ranged from 1 to 3 scores,  $n = 14$ ) and PFS was  $191.40 \pm 59.88$  d (95% CI = 74.04 - 308.76), while it was positive in adjacent and normal tissue samples (immunohistochemistry score  $> 3$ ,  $n = 46$ ) and PFS was  $152.93 \pm 16.99$  d (95% CI = 119.62 - 186.24). The survival time of patients with negative and positive expression of NF- $\kappa$ B-p65 was  $425.16 \pm 61.61$  d (95% CI = 304.41 - 545.92) and  $418.85 \pm 42.98$  d (95% CI = 334.62 - 503.08), respectively.

#### Different survival time of patients after treatment with FOLFOX and PLF

Kaplan-Meier analysis showed that the PFS time of patients after treatment with PLF and FOLFOX was  $135.79 \pm 15.09$  d (95% CI = 106.22 - 165.35) and  $183.08 \pm 30.97$  d (95% CI = 122.37 - 243.78), respectively. The OS time of patients after treatment with PLF and FOLFOX was  $539.51 \pm 69.82$  d (95% CI = 402.66 - 676.35) and  $363.12 \pm 35.70$  d (95% CI = 293.15 - 433.09), respectively. There was no significant difference in PFS or OS time of patients after treatment with FOLFOX and PLF ( $P = 0.2931$  and  $P = 0.0548$ , respectively). The NF- $\kappa$ B-p65 expression was positive in the tissue samples from 46 patients. PFS time of patients with positive p65 expression was  $132.60 \pm 16.62$  d (95% CI = 100.03 - 165.17) and  $163.64 \pm 23.99$  d (95% CI = 116.62 - 210.65), respectively, after treatment with

**Figure 3** Survival cures for OS time of patients after treatment with PLF and FOLFOX.

PLF and FOLFOX ( $P = 0.2407$ ). However, the OS time of patients with negative p65 expression was  $564.89 \pm 75.94$  d (95% CI = 416.04 - 713.74) and  $352.37 \pm 41.32$  d (95% CI = 271.38 - 433.36), respectively, after treatment with PLF and FOLFOX ( $P = 0.0165$ ). Their survival cure is shown in Figure 3.

## DISCUSSION

NF- $\kappa$ B plays a role in oncogenic transformation. v-Rel, a highly oncogenic retroviral homologue of c-Rel, causes carcinogenesis in avian lymphoid cells<sup>[3,10]</sup>. Inhibition of NF- $\kappa$ B, by over expression of a degradation-resistant I $\kappa$ B, delays the development of T-cell lymphomas and prolongs the survival of v-Rel transgenic mice<sup>[3,10]</sup>. Chromosomal alterations in NF- $\kappa$ B family genes provide additional evidence for the role of NF- $\kappa$ B in oncogenesis. It has been demonstrated that genes encoding c-Rel, NF- $\kappa$ B2 (p100/p52), p65/RelA, and Bcl-3 proteins are all located within breakpoint regions of the genome involving oncogenic rearrangements or amplifications<sup>[3,11]</sup>. Indeed, increased NF- $\kappa$ B activity is evident in a number of human cancers, including breast cancer, non-small cell lung carcinoma, thyroid cancer, T- or B- lymphocyte leukemia, melanoma, colon cancer, bladder cancer, and several virus-induced tumors<sup>[12]</sup>.

It was reported that NF- $\kappa$ B is constitutively activated in gastric carcinoma tissue<sup>[4-6,13,14]</sup>. The expression rate of NF- $\kappa$ B-p65 in gastric carcinoma is 18%-78.3%, which is higher than in normal adjacent epithelial cells. Sasaki *et al*<sup>[4]</sup> hold that increased NF- $\kappa$ B expression is correlated to the clinicopathological features of tumor aggression (especially its invasive ability) of gastric carcinoma. In the present study, NF- $\kappa$ B-p65 expression was mainly observed in gastric carcinoma cytoplasm with an expression rate of 77.6% (46/60), which is consistent with the previously reported data<sup>[4,14]</sup>. Some representative tumor specimens showed that p65 staining was increased in nuclei (Figure 1D), suggesting that subunit of NF- $\kappa$ B is translocated from cytoplasm to nuclei. We also determined p65 expression in samples from normal gastric glands and

intestinal metaplasia except in cancer tissue samples. Weaker staining was found in such tissue samples, suggesting that NF-κB activation is associated with cell proliferation. EMSA showed that the increased nuclear translocation of NF-κB-p65 showed a higher NF-κB DNA-binding activity in differently differentiated tumor tissue samples than in adjacent normal tissue samples (Figure 2). The NF-κB-p65 expression rate is not consistent with the previously reported rate<sup>[6]</sup>. The discrepancy might be due to the following reasons. (1) The classification reference for positively-stained cells might have decreased the expression rate of NF-κB-p65. Lee *et al*<sup>[6]</sup> reported that cells showing p65 nuclear staining irrespective of cytoplasmic staining display constitutive NF-κB activation. (2) Carcinoma stage was different. In our study, the 60 patients had stage IV gastric cancer compared with 15.5% reported in the study of Lee *et al*<sup>[6]</sup>, who found that NF-κB activation is more prominent in early-stage pTNM tumors than in late-stage tumors.

Sasaki *et al*<sup>[4]</sup> analyzed the relation between NF-κB activation and traditional clinicopathological parameters, showing that NF-κB activation is correlated with tumor size and lymphatic invasion. However, Lee *et al*<sup>[6]</sup> showed that NF-κB activation, as a prognostic factor, is not correlated with the prognosis of patients after curative resection of their tumors, but significantly associated with a better prognosis of early-stage gastric carcinoma patients, suggesting that NF-κB activity is less reliable than TNM criteria as a prognostic biomarker of gastric cancer<sup>[6]</sup>. In the present study, we selected specimens from stage IV gastric cancer patients to discriminate p65 positive and negative expression. Sixty samples were divided into positive p65 expression group ( $n = 46$ ) and negative p65 expression group ( $n = 14$ ). When no significant difference in age, sex, accumulative organs and pathologic classification was found between the two groups, we analyzed the PFS and OS time of the patients in the two groups. The PFS time and OS time were longer in the group with positive p65 expression than in the group with negative p65 expression ( $P > 0.05$ ), which is not consistent with previous reports<sup>[5,6]</sup>. We speculate that this discrepancy is caused by (1) the different carcinoma stages, (2) different treatment modalities, and (3) the number of tumor cases not taken into account.

In the present study, the 60 patients were treated with PLF ( $n = 16$ ) and FOLFOX ( $n = 44$ ), respectively (Table 1). Their PFS time and OS time had no statistical significance ( $P > 0.05$ ). However, when we divided the 46 patients into a PLF treatment group ( $n = 12$ ) and a FOLFOX treatment group ( $n = 12$ ) with positive p65 expression ( $n = 34$ ), the OS time of the patients in the two groups was  $564.89 \pm 75.94$  d (95% CI = 416.04 - 713.74) and  $352.37 \pm 41.32$  d (95% CI = 271.38 - 433.36), respectively ( $P = 0.0165$ ), suggesting that NF-κB activation is associated with the prognosis of gastric cancer patients.

In conclusion, NF-κB-p65 is constitutively activated in late-stage gastric carcinoma patients and NF-κB

activation is correlated to the survival time of gastric cancer patients after chemotherapy.

## COMMENTS

### Background

Nuclear factor kappa B (NF-κB) contributes to cell differentiation, proliferation, and death. There is experimental evidence that NF-κB plays a major role in the development and progression of various human cancers including gastric carcinoma. The effect of anti-cancer drugs is related to NF-κB in cancer cells.

### Research frontiers

As it is known, there is evidence that NF-κB plays a major role in the development and progression of various human cancers including gastric carcinoma. On the other hand, NF-κB can suppress tumor growth by promoting apoptotic signals in response to certain cancer therapeutic agents. However, the molecular mechanism of NF-κB underlying cancer development remains to be elucidated.

### Innovations and breakthroughs

NF-κB was found to be a biomarker of gastric cancer. Further study is needed to prove it.

### Applications

NF-κB activation is correlated to the survival of gastric cancer patients after chemotherapy and may affect treatment of choice for late human gastric carcinoma.

### Peer review

In the present work, the authors revealed the differential expression of NF-κB p65 in normal and gastric carcinoma tissue samples, and the potential importance of p65 up-regulations was underscored in chemotherapy for human gastric carcinoma. Their findings support the theory that p65 functions as a tumor promoter in human gastric carcinoma. Therefore, identification of the functional and phenotypic characteristics of p65 is essential for designing a rational anti-cancer therapy, as suggested by the authors. The study is well designed, and the data are reliable.

### Abstract

**AIM:** To re-evaluate the diagnostic criteria of insulin resistance hepatic iron overload based on clinical, biochemical and histopathological findings.

**METHODS:** We studied 81 patients with hepatic iron overload not explained by known genetic and acquired causes. The metabolic syndrome (MS) was defined according to ATPIII criteria. Iron overload was assessed by liver biopsy. Liver histology was evaluated by Ishak's score and iron accumulation by Deugnier's score; steatosis was diagnosed when present in  $\geq 5\%$  of hepatocytes.

**RESULTS:** According to transferrin saturation levels, we observed significant differences in the amount of hepatic iron overload and iron distribution, as well as the number of metabolic abnormalities. Using Receiving Operating Curve analysis, we found that the presence of two components of the MS differentiated

two groups with a statistically significant different hepatic iron overload ( $P < 0.0001$ ). Patients with  $\geq 2$  metabolic alterations and steatosis had lower amount of hepatic iron, lower transferrin saturation and higher sinusoidal iron than patients with  $< 2$  MS components and absence of steatosis.

**CONCLUSION:** In our patients, the presence of  $\geq 2$  alterations of the MS and hepatic steatosis was associated with a moderate form of iron overload with a prevalent sinusoidal distribution and a normal transferrin saturation, suggesting the existence of a peculiar pathogenetic mechanism of iron accumulation. These patients may have the typical dysmetabolic iron overload syndrome. By contrast, patients with transferrin saturation  $\geq 60\%$  had more severe iron overload, few or no metabolic abnormalities and a hemochromatosis-like pattern of iron overload.

### INTRODUCTION

Iron overload includes a wide spectrum of conditions from mild to marked tissue iron accumulation and iron-related organ dysfunctions<sup>[1-3]</sup>. Apart from the known hereditary and acquired conditions of iron overload<sup>[4]</sup>, there are other conditions in which iron overload cannot be explained and the pathophysiology of iron accumulation is still obscure. Increased hepatic iron

deposits have been frequently described in association with overweight and alterations of lipid or glucose metabolism. These abnormalities are part of the metabolic syndrome (MS) that is closely linked to insulin resistance, affecting a large number of adults in Western countries, and is associated with non-alcoholic fatty liver disease (NAFLD), now considered the hepatic manifestation of MS<sup>[5]</sup>. This form of iron overload has been variably named dysmetabolic or insulin resistance hepatic iron overload syndrome (IR-HIO)<sup>[6]</sup>. However, the etiopathogenetic mechanisms that link metabolic abnormalities, insulin resistance and/or NAFLD to iron accumulation are still undefined. The fact that only a proportion of subjects with metabolic abnormalities are at risk for iron overload<sup>[7]</sup> suggests that other factors may be involved. In addition, the original definition of IR-HIO<sup>[6]</sup> includes hyperferritinemia with normal or high transferrin saturation, presence or absence of NAFLD, and even a single metabolic alteration among the following: body mass index (BMI) > 25 kg/m<sup>2</sup>, dyslipidemia and abnormal glucose metabolism. These criteria are generous compared with those more recently established to define the presence of MS<sup>[8,9]</sup>.

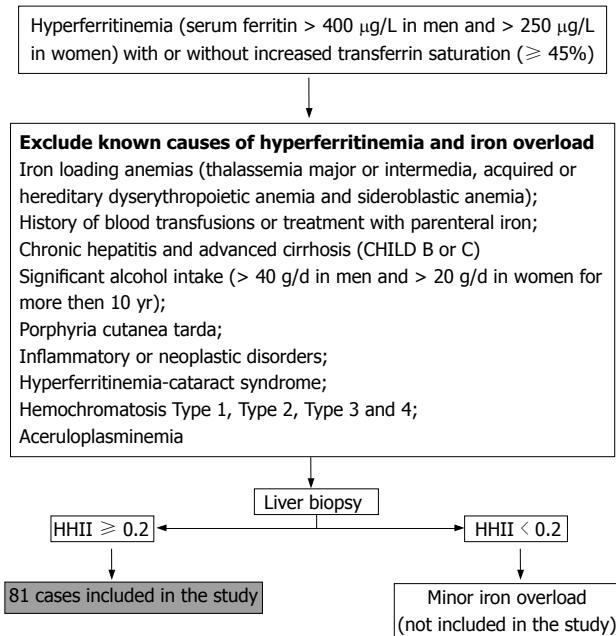

In the present study, we evaluated patients with alterations of serum iron indices and hepatic iron overload not explained by mutations in iron related genes or by acquired factors that can lead to iron overload through known pathogenetic mechanisms<sup>[3]</sup>. We defined this condition as hepatic iron overload (HIO) irrespective of the presence of metabolic alterations. Our aims were to obtain information in order to differentiate the variegated phenotypes in patients with HIO and to better characterize the dysmetabolic iron overload syndrome.

To this end, we carried out the following: (1) Analyzed iron status either at biochemical and histological levels. We hypothesized that the level of transferrin saturation and the cellular distribution of iron deposits in the liver might give insight into the mechanism leading to iron accumulation<sup>[3,10]</sup>; (2) Determined the frequency of abnormalities that are part of the MS (according to the more recent criteria), the frequency and severity of hepatic steatosis and their relation with iron indices. We hypothesized that the presence and the number of metabolic alterations might be associated with a peculiar iron phenotype; (3) Studied a control group of patients with HFE-related hemochromatosis (HFE-HH), taken as the model of primary iron overload, in order to compare hepatic iron distribution, the frequency of metabolic alterations and hepatic steatosis with those found in the group of patients with HIO.

## MATERIALS AND METHODS

### Materials

We studied 81 Italian unrelated adult patients (67 males and 14 females) with HIO. They were consecutively selected, since 1998, from outpatients who were referred to us for abnormalities of serum iron indices. Selection

**Figure 1** Selection criteria of the 81 patients included in the study. HHII: Histological Hepatic Iron Index [Total iron score/Age (years)].

criteria are reported in Figure 1.

To compare patients' data we also selected from our own database 57 patients affected by HFE-HH (51 were C282Y homozygotes, two were compound heterozygous for C282Y/E168X and four for C282Y/H63D). Criteria for selection of HFE controls were: availability of liver biopsy, semiquantitative iron grading and metabolic indices. All patients gave their written consent to liver biopsy, which was done for diagnostic and/or prognostic evaluation according to international guidelines<sup>[11]</sup>.

### Methods

All data were recorded at the time of diagnosis. All patients with HIO and HFE-HH underwent liver biopsy. Liver sections were stained with standard methods for histological evaluation and with Perl's stain for iron grading and assessed by an independent observer (G.B.).

### Biochemical and metabolic data

The following data were collected: glucose and insulin, total cholesterol, HDL, triglycerides, serum alanine and aspartate-aminotransferases, and  $\gamma$ -glutamyl transferase, which were measured using commercial kits, BMI, waist circumference and blood pressure. Overweight was defined by BMI > 25 kg/m<sup>2</sup> and < 30 kg/m<sup>2</sup> and obesity by BMI  $\geq$  30 kg/m<sup>2</sup><sup>[12]</sup>. Diagnoses of arterial hypertension, diabetes mellitus and glucose intolerance were based on the ESH/ESC and American guidelines, respectively<sup>[13,14]</sup>. The presence of dyslipidemia and MS was based on NCEP-ATP III criteria<sup>[8]</sup>. HOMA index was available in 68 patients (84%)<sup>[15]</sup>. A HOMA index of 2.77 was chosen to distinguish insulin resistant and insulin sensitive patients according to Bonora *et al*<sup>[16]</sup>.

### Iron status

Serum iron indices were determined using standard

**Table 1** Main clinical, biochemical and histological data of the HIO patients (as a whole and according to gender) and HFE controls

	HIO (n = 81)	P	HFE-HH (n = 57)	Men (n = 67)	P	Women (n = 14)
Age (yr)	52 (28-76)	> 0.05	50 (26-71)	54 (28-76)	> 0.05	51 (29-70)
Transferrin saturation (%)	39 (21-118)	< 0.0001	76 (29-100)	38 (21-118)	0.02	56 (28-99)
Serum ferritin ( $\mu\text{g/L}$ )	982 (413-5050)	> 0.05	1100 (274-10990)	964 (413-5050)	> 0.05	1286 (520-3987)
AST (U/L)	27 (12-174)	> 0.05	27 (17-87)	27 (12-174)	> 0.05	28 (13-65)
ALT (U/L)	38 (11-271)	> 0.05	43 (11-114)	38 (14-271)	> 0.05	36 (11-118)
Total Iron Score	19 (12-46)	0.0071	24 (8-49)	18 (12-40)	0.0006	32 (12-46)
Hepatocytic iron score	15 (6-27)	0.001	18 (3-27)	12 (6-27)	0.0022	21 (9-27)
Sinusoidal iron score	5 (3-8)	< 0.0001	3 (0-10)	5 (3-7)	> 0.05	6 (3-8)
Portal iron score	0 (0-12)	0.0002	2 (0-12)	0 (0-8)	< 0.0001	3.5 (0-12)
SIS/TIS	0.25 (0.09-0.5)	< 0.0001	0.13 (0-0.63)	0.25 (0.10-0.5)	0.001	0.16 (0.09-0.29)
HH II	0.38 (0.20-1.21)	0.0012	0.53 (0.15-0.97)	0.36 (0.20-1.08)	0.004	0.64 (0.23-1.21)
Hepatic fibrosis (Ishak's score)	34 (42)	> 0.05	33 (57.8)	26 (38.8)	> 0.05	8 (57.1)
Hepatic cirrhosis (Ishak's score)	7 (8.6)	0.027	13 (22.8)	3 (4.5)	0.015	4 (28.6)
Patients with hepatic steatosis	47 (58)	0.015	20 (36.3)	41 (61.2)	> 0.05	6 (42.9)
Patients with moderate-severe hepatic steatosis	35 (43.2)	< 0.0001	6 (10.5)	31 (46.3)	> 0.05	4 (28.6)
Metabolic syndrome	20 (24.7)	> 0.05	9 <sup>1</sup> (16.1)	19 (28.4)	> 0.05	1 (7.1)

Data are reported as median (range) or number (%). Hepatic steatosis: > 5% of hepatocytes involved by steatosis; Moderate-severe steatosis: ≥ 33% of hepatocytes involved by steatosis. <sup>1</sup>Not available in one HFE-control. SIS/TIS: Sinusoidal/total iron score; HHII: Histological hepatic iron index (ratio of TIS to age).

methods. Transferrin saturation was calculated as follows: serum iron/(serum transferrin  $\times$  1.4)  $\times$  100<sup>[17]</sup>. A semi-quantitative evaluation of hepatic iron was done according to Deugnier *et al*<sup>[18]</sup>. Iron deposits were assessed according to size, cellular and lobular locations in Rappaport's acinus, leading to three different scores: hepatocytic (HIS; range, 0-36), sinusoidal (SIS; range, 0 to 12) and portal iron scores (PIS; range, 0-12). The sum of these scores defined the total iron score (TIS; range, 0-60). Previous studies have shown that age-related histological hepatic iron index (the ratio of TIS to age, HHII) is an accurate means of predicting the genetic status of HH patients (heterozygotes *vs* homozygotes)<sup>[19]</sup>. Accordingly, all the patients with HIO and HFE-HH had a histological hepatic iron index in the range of homozygous HH.

### Hepatic fibrosis and steatosis

Hepatic fibrosis was graded according to Ishak *et al*<sup>[20]</sup>. Hepatic steatosis was diagnosed when at least 5% of hepatocytes were involved and steatosis was graded as follows: absence ( $\leq 5\%$  of hepatocytes), mild ( $> 5\% \leq 33\%$ ), moderate ( $> 33\% \text{ and } \leq 66\%$ ), severe ( $> 66\%$ )<sup>[21]</sup>.

### Statistical analysis

Data were expressed as median and range due to the non-Gaussian distribution of iron indices. The Student's *t* test was used for quantitative variables with a normal distribution. All the comparisons involving hepatic iron distribution according to Deugnier *et al*<sup>[18]</sup> and variables with non-skewed distributions were performed on medians by non-parametric methods (Mann-Whitney or Kruskall-Wallis when more than two groups were involved). The Fisher's exact test or the Chi-square test was used for qualitative data. Correlations between variables were evaluated by the Spearman's test. The

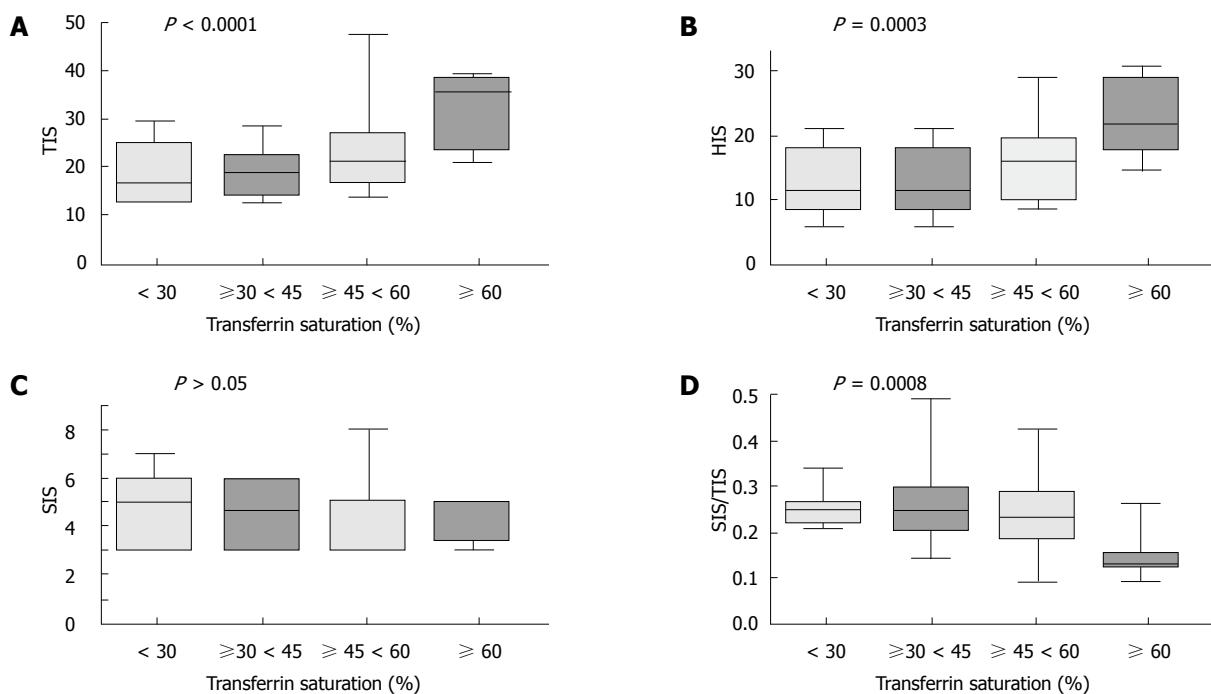

receiving operating curve (ROC) was used to evaluate if a threshold number of MS components was associated with different hepatic iron overload as defined by the HHII. We compared the Area under the curve (AUC) of the ROCs relative to 1, 2, 3, 4 and 5 components of the MS according to HHII. The influence of age, gender, alcohol intake, BMI, serum iron indices and hepatic iron distribution (HIS, SIS and PIS) on hepatic fibrosis, was evaluated by a logistic regression model. All tests were two-sided and with a significance level of  $P \leq 0.05$ .

## RESULTS

### Iron status

Seven patients (8.6%) were heterozygous the C282Y and 27 (33.3%) the H63D mutation. Table 1 shows the main clinical, biochemical and histological data of patients with HIO (as a whole and according to gender) and with HFE-HH.

Thirty patients (37%) had transferrin saturation repeatedly  $\geq 45\%$  and 39 patients (48%) had serum ferritin  $> 1000 \mu\text{g/L}$ . All patients showed homogeneous hemosiderin deposits in the hepatic lobules and a decreasing hepatocytic iron gradient from Rappaport I to III. In this series, females had more iron overload and a higher frequency of cirrhosis, lower BMI ( $P = 0.0007$ ) and a number of MS components more than males. TIS correlated with age in males ( $r = 0.4$ ,  $P = 0.0007$ ), but not in females. TIS significantly correlated with several indices, as reported in Table 2, showing an inverse correlation with metabolic indices. At linear regression analysis, gender ( $P = 0.0005$ ), grade of fibrosis ( $P = 0.0005$ ), transferrin saturation ( $P < 0.0001$ ) and severity of steatosis ( $P < 0.0001$ ) retained statistical significance with TIS.

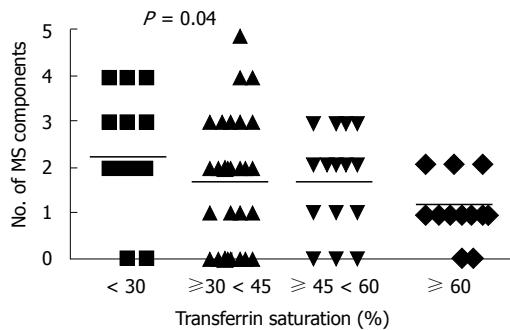

**Figure 2** Total iron score (TIS,  $P < 0.0001$ ), hepatocytic iron score (HIS,  $P = 0.0003$ ), sinusoidal iron score (SIS,  $P > 0.05$ ) and sinusoidal to total iron score ratio (SIS/TIS,  $P = 0.0008$ ) according to transferrin saturation. The box includes all the observations between the first and the third quartile, the horizontal bar represents the median. Whiskers extend from the edges of the box to the extreme values.

**Table 2 Correlation between total iron score (TIS) and several parameters in HIO patients**

	<i>r</i>	<i>P</i>
Hepatocytic iron score	0.94	< 0.0001
Sinusoidal iron score	0.54	< 0.0001
Portal iron score	0.58	< 0.0001
Serum ferritin ( $\mu\text{g/L}$ )	0.53	< 0.0001
Transferrin saturation (%)	0.43	< 0.0001
Age (yr)	0.23	0.04
Hepatic fibrosis	0.28	0.012
Body mass index ( $\text{kg}/\text{m}^2$ )	-0.48	< 0.0001
Degree of hepatic steatosis	-0.53	< 0.0001
No. of components of MS	-0.33	0.0026
HOMA index	-0.3	0.0125

Degree of hepatic steatosis refers to the percentage of hepatocytes involved by steatosis. Hepatic fibrosis refers to Ishak's score.

Dividing HIO patients according to transferrin saturation, we observed that TIS, HIS and PIS significantly increased with the increasing transferrin saturation. By contrast, SIS did not change, whereas the SIS to TIS ratio significantly decreased (Figure 2). We observed that the higher the transferrin saturation level, the lower was the number of MS components (Figure 3). Patients with transferrin saturation  $< 45\%$  ( $n = 51$ ) had lower amount of iron overload in hepatocytic ( $P = 0.0004$ ) and portal ( $P = 0.0007$ ) compartments than patients with increased transferrin saturation but with a proportionally greater amount of iron in sinusoidal compartment (SIS/TIS:  $0.25 \pm 0.07$  vs  $0.2 \pm 0.08$ ,  $P = 0.003$ ). These patients also had a lower prevalence of fibrosis (Ishak's score  $\geq 1$ :  $16/51$  vs  $18/30$ ,  $P = 0.019$ ). Patients with the highest levels of transferrin saturation

**Figure 3** Number of MS components by transferrin saturation ( $P = 0.04$ ).

( $\geq 60\%$ ) had a SIS to TIS ratio (median, 0.15; range, 0.1-0.25) not different than that observed in HFE-HH (median, 0.13; range, 0-0.63). They also had a prevalence of hepatic steatosis and hepatic fibrosis comparable to that observed in patients with HFE-HH (data not shown) but without MS.

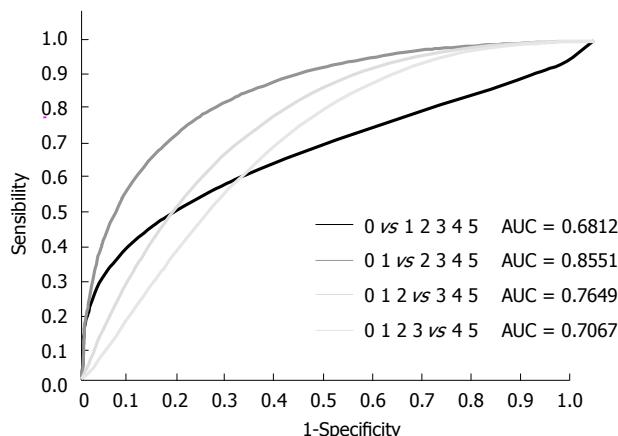

#### Metabolic alterations

One patient (1.2%) had all five components of MS, five (6.2%) had four components, 14 (17.2%) had three, 27 (33.3%) had two, 17 (20.9%) had one and 17 (20.9%) had none. The frequency and severity of hepatic steatosis and MS prevalence in HIO are reported in Table 1 and are compared with those observed in HFE-HH patients. Thirty-one patients with HIO (45.6%) were insulin resistant. Steatosis was more common in Rappaport zones 2 and 3 and more prevalent in HIO patients with MS than in those without (90% vs 47.5%,  $P = 0.0007$ ). The number of MS components correlated positively with age, severity of steatosis and

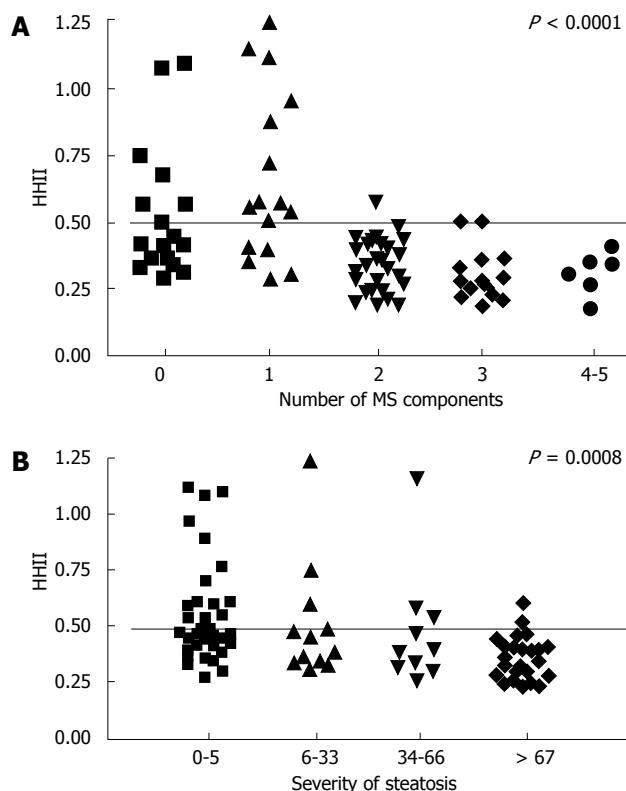

**Table 3** Correlation between number of MS components and several parameters in HIO patients

	<i>r</i>	<i>P</i>
Age (yr)	0.3	0.0055
Degree of hepatic steatosis (%)	0.57	< 0.0001
HOMA index	0.59	< 0.0001
Transferrin saturation (%)	-0.25	0.0293
Total iron score	-0.33	0.0053
Histological hepatic iron index	-0.53	< 0.0001
Sinusoidal iron score/Total iron score	0.13	> 0.05

Degree of hepatic steatosis refers to the percentage of hepatocytes involved by steatosis.

**Figure 4** Receiving operating curve relative to 1, 2, 3, 4 and 5 components of the MS.

**Figure 5** Distribution of HHII (histological hepatic iron index) according to number of MS components (A) and the degree of hepatic steatosis (B).

**Table 4** Iron indices in patients according to the presence of  $\geq 2$  components of MS or steatosis

	Number of MS components		Hepatic steatosis			
	0-1 ( <i>n</i> = 34)	<i>P</i>	$\geq 2$ ( <i>n</i> = 47)	Absent ( <i>n</i> = 34)	<i>P</i>	Present ( <i>n</i> = 47)
Transferrin saturation (%)	44 (28-118)	0.0058	36 (21-99)	39 (23-118)	> 0.05	39 (21-76)
Total Iron Score	24 (12-46)	0.0008	17 (12-39)	24.5 (12-46)	< 0.0001	16 (12-39)
HHII	0.51 (0.3-1.21)	< 0.0001	0.33 (0.2-0.57)	0.43 (0.23-1.1)	0.0004	0.34 (0.19-1.2)
SIS/TIS	0.21 (0.1-0.5)	0.0185	0.25 (0.11-0.4)	0.22 (0.1-0.5)	0.032	0.25 (0.09-0.4)
MS components $\geq 2$	-	-	-	11 (32)	< 0.0001	36 (77)
Degree of hepatic steatosis (%)	0 (0-80)	< 0.0001	40 (0-98)	-	-	-

Data are reported as median (range) or number (%). HHII: Histological hepatic iron index (ratio of TIS to age); SIS/TIS: Sinusoidal/total iron score. Hepatic steatosis, absent when  $\leq 5\%$  of hepatocytes are involved; present when at least 5% of hepatocytes are involved.

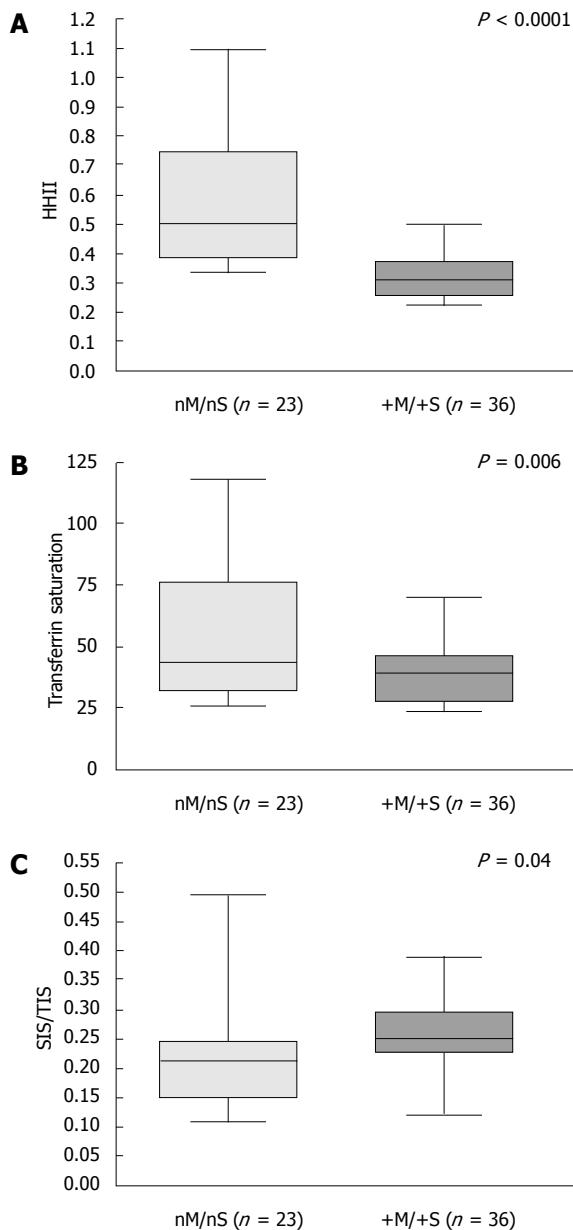

HOMA index, and inversely with transferrin saturation and hepatic iron indices, but not with serum ferritin (Table 3).

By the ROC analysis (Figure 4), we found that the presence of two MS alterations best differentiates HIO patients according to HHII ( $P < 0.0001$ ). Patients with 0-1 MS components showed a wide range of HHII from low to very high, whereas in patients with two or more MS features the HHII was  $\leq 0.50$  in all but one (Figure 5A). Similar findings were observed when patients were divided according to the presence of steatosis (Figure 5B). In addition, the percentage of hepatocytes involved by steatosis inversely correlated with HIS ( $r = -0.52$ ,  $P < 0.0001$ ) and with the amount of iron removed by phlebotomies ( $r = -0.45$ ,  $P = 0.0019$ ).

Table 4 compares iron indices, in patients according to the presence of  $\geq 2$  components of MS or steatosis. Figure 6 compares the same data in two subgroups: patients with a “metabolic phenotype” (+M/+S, patients with  $\geq 2$  MS alterations and hepatic steatosis) and patients without (nM/nS, patients with 0-1 MS components and absence of hepatic steatosis).

#### Hepatic damage in HIO patients

Data on hepatic damage in HIO patients are summarized in Table 1. TIS correlated with fibrosis ( $r = 0.28$ ,  $P = 0.01$ ), but PIS showed the highest correlation ( $r = 0.51$ ,  $P < 0.0001$ ) and SIS none. Logistic regression modelling indicated that PIS, age, HOMA index and presence of steatosis independently correlated with hepatic fibrosis

**Figure 6** Distribution of HHII (histological hepatic iron index), transferrin saturation and Sinusoidal/Total Iron Score (SIS/TIS) in patients with 0-1 MS components and absence of steatosis (nM/nS) and patients with 2 MS alterations and steatosis (+M/+S).

( $P < 0.0001$ ,  $P = 0.004$ ,  $P < 0.0001$  and  $P = 0.04$ , respectively).

## DISCUSSION

In the present study, we evaluated 81 patients with hepatic iron overload not explained by known genetic or acquired disorders. HIO as expected, patients showed a wide range of variability in the biochemical iron status, in hepatic iron deposits and lobular iron distribution, and had a variable number of metabolic alterations that are part of the MS, with or without NAFLD. There was an inverse relationship between transferrin saturation and sinusoidal iron. Patients with transferrin saturation  $< 45\%$  had a lower amount of iron overload in the hepatocytic and portal compartments than

patients with increased transferrin saturation, but have a proportionally greater amount of iron in sinusoidal compartment as shown by the higher SIS to TIS ratio. Accordingly, when compared to HFE-controls, patients with transferrin saturation  $< 45\%$  had higher SIS and SIS to TIS ratios (data not shown). These findings indicate that, in HIO patients with normal transferrin saturation, the mechanism of hepatic iron accumulation is different than that of the classical HH<sup>[1,2]</sup> and suggest the existence of macrophage iron retention and an iron recycling defect. By contrast, in patients with increased transferrin saturation, hepatic iron distribution was comparable to that observed in HFE-HH, thus supporting the idea that the pathogenetic mechanism of iron overload was due to increased iron absorption<sup>[22]</sup>. The strongest identity with HFE-HH was observed in patients with the highest transferrin saturation ( $\geq 60\%$ ), suggesting that between 45% and 60% there is a grey zone that includes mixed conditions. In addition, patients with transferrin saturation  $\geq 60\%$  had the same prevalence of hepatic steatosis and of organ damage as HFE-HH, however, none had MS. Thus, transferrin saturation can distinguish, among HIO patients, two main subgroups with likely different pathogenetic mechanisms of iron overload.

Another part of the study concerns the metabolic aspects and their relation with serum and hepatic iron indices. First, in agreement with the theory that NAFLD is the hepatic manifestation of the MS, we found that the number of MS components correlated with the severity of hepatic steatosis and hyperinsulinemia and that 90% of the patients with the MS had NAFLD<sup>[5]</sup>. Second, we found that the presence of metabolic abnormalities and/or NAFLD was associated with a peculiar iron phenotype characterised by a lower hepatic iron overload, a more prevalent iron in the sinusoidal compartment and a lower transferrin saturation that corresponds to the more typical features of IR-HIO<sup>[6]</sup>. We demonstrated that this phenotype was common in patients presenting at least two of the MS features and in the subgroup with  $\geq 2$  MS abnormalities and NAFLD.

An inverse relation between steatosis and hepatic iron has been previously observed and variably explained<sup>[23-25]</sup>. The significant inverse correlation that we found between the degree of steatosis and the amount of iron removed by phlebotomies provides the strongest evidence that the higher the percentage of hepatocytes involved by steatosis, the lower the amount of iron accumulation. Recent studies in severely obese patients<sup>[26]</sup> and in an animal model of insulin resistance<sup>[27]</sup> suggest that obesity or hyperinsulinemia favour the development of iron deficiency. Increased adipocyte hepcidin production has been reported in morbid obesity that could result in reduced intestinal iron absorption, macrophage iron release and eventually in low iron stores<sup>[26]</sup>. Although these findings need to be further elucidated and confirmed, they support the hypothesis that metabolic abnormalities associated with insulin resistance and MS might protect from iron overload. Accordingly, in C282Y homozygous patients, obesity (in

females)<sup>[28]</sup> and hepatic steatosis<sup>[29]</sup> were associated with a decreased transferrin saturation<sup>[28]</sup> and hepatic iron concentration<sup>[28,29]</sup>. It was suggested that the overweight-related chronic inflammatory state may increase hepcidin production (likely at extrahepatic sites) and partially compensates for the defect of hepcidin synthesis due to the HFE mutation<sup>[7,28]</sup>. We recently found that urinary hepcidin levels, although inappropriate for the iron overload, were indeed significantly higher in patients with dysmetabolic iron overload than in controls<sup>[30]</sup>. Overall, these findings seem to contradict the hypothesis that iron overload and metabolic abnormalities are linked by a common pathogenetic mechanism in IR-HIO, unless a hepcidin-resistance state is hypothesized. Another possible explanation is that IR-HIO is a multifactorial disease that results from the association of a mild-moderate, maybe polygenic, defect of hepcidin production and insulin resistance or MS. This may explain some of the features of the disease: late-onset and mild-moderate iron overload tending to a plateau<sup>[31]</sup>. As observed in subjects carrying the low expressing C282Y/H63D HFE genotype<sup>[32]</sup>, these patients may retain some ability to increase hepcidin production in response to iron load that possibly explains their slight phenotype. In patients with dysmetabolic iron overload, NAFLD and MS might foster hepcidin production leading to the typical IR-HIO phenotype. Further studies are needed to clarify this issue and the role of dysmetabolisms in dysregulating iron regulatory pathways. This is not unimportant considering that the dysmetabolic iron overload syndrome is currently the most prevalent iron overload disorder in the adult population.

Based on our findings and in the absence of a clear pathogenetic explanation of IR-HIO, we suggest a more strict clinical definition of this syndrome characterised by the presence of two or more components of the MS, hepatic steatosis and normal transferrin saturation. Liver biopsy should confirm the presence of steatosis and iron overload with typical involvement of sinusoidal compartment. In fact, in agreement with other studies<sup>[23,24,33]</sup>, we showed that serum ferritin is not a reliable index of iron overload in patients with metabolic abnormalities and might overestimate the true amount of hepatic iron overload due to NAFLD-related hepatocellular damage, local cytokine activation or higher mesenchymal iron retention<sup>[7]</sup>. Noninvasive methodologies, such as magnetic resonance (MR) for iron quantification, can be an alternative option when liver biopsy is not feasible, provided the MR apparatus is calibrated and validated<sup>[34]</sup>.

Finally, we showed that a number of HIO patients presented a classical hemochromatosis phenotype (high transferrin saturation and prevalent hepatocytic iron overload). Some of them, including a few young women, had a severe iron overload that lead to clinical complications. We had no etiopathogenetic explanation for this form of iron overload, which may represent the severe boundary of a complex trait due to gene-gene and gene-environmental interactions, or the result

of a still undefined major locus defect. Studies aimed to clarify the genetic background and the complex pathways causing these forms of unexplained iron overload are needed to improve the diagnostic setting of iron overload disorders.

## COMMENTS

### Background

Hepatic iron overload includes a wide spectrum of conditions from mild to marked tissue iron accumulation. In some cases the pathophysiology of iron accumulation is still obscure. The association of hepatic iron overload and metabolic alterations and/or non-alcoholic fatty liver is common in Western population. A new syndrome, named Dysmetabolic Hepatic Iron Overload or Insulin Resistance Hepatic Iron Overload was described in 1999, based on the presence of hepatic iron overload in association with even a single metabolic abnormality. These criteria were generous compared to those more recently established for the metabolic syndrome. In addition, the pathogenetic mechanisms that link insulin resistance and/or steatosis to iron overload are still undefined.

### Research frontiers

To characterize clinical, biochemical and histological features of hepatic iron overload not explained by known genetic or acquired disorders, including the form associated to metabolic alterations. To understand the pathogenetic mechanisms of hepatic iron accumulation. To characterize the phenotype of the dysmetabolic iron overload syndrome, according to the more recent criteria defining the metabolic syndrome, and the presence of fatty liver disease.

### Innovations and breakthroughs

We demonstrated that patients with hepatic iron overload, not explained by known genetic or acquired disorders, need a systematic diagnostic approach, including the evaluation of hepatic iron overload and cellular iron distribution. We suggested the existence of two main different pathogenetic mechanisms leading to forms of unexplained iron overload: an iron recycling defect and an increased intestinal iron absorption. We suggested a new, updated definition of the dysmetabolic iron overload syndrome. We speculated on the pathogenesis of the iron overload syndrome based on our results and current knowledge of iron metabolism.

### Applications

This study may improve the diagnostic approach in patients with unexplained forms of iron overload including the dysmetabolic iron overload syndrome. This is not trivial considering that the latter disorder is currently the most prevalent iron overload disease in adult population. In addition, our findings indicate simple and valid criteria to better classify these forms of iron overload. This will be useful: (a) to better understand the etiopathogenesis of these disorders and the dysregulation of iron homeostasis in future studies; (b) to better address therapeutic strategies, e.g. iron depletion vs treatment of metabolic abnormalities and hepatic steatosis.

### Peer review

In this manuscript authors give a different angle to a problem that has interested the scientific world recently. The study is well conducted.

## Abstract

**AIM:** To evaluate the ability of *Curcuma longa* (CL) and *Tinospora cordifolia* (TC) formulation to prevent anti-tuberculosis (TB) treatment (ATT) induced hepatotoxicity.

**METHODS:** Patients with active TB diagnosis were randomized to a drug control group and a trial group on drugs plus an herbal formulation. Isoniazid, rifampicin, pyrazinamide and ethambutol for first 2 mo followed by continuation phase therapy excluding Pyrazinamide for 4 mo comprised the anti-tuberculous treatment. Curcumin enriched (25%) CL and a hydro-ethanolic extract enriched (50%) TC 1 g each divided in two doses comprised the herbal adjuvant. Hemogram, bilirubin and liver enzymes were tested initially and monthly till the end of study to evaluate the result.

**RESULTS:** Incidence and severity of hepatotoxicity was significantly lower in trial group (incidence: 27/192 vs 2/316,  $P < 0.0001$ ). Mean aspartate transaminase (AST) ( $195.93 \pm 108.74$  vs  $85 \pm 4.24$ ,  $P < 0.0001$ ), alanine transaminase (ALT) ( $75.74 \pm 26.54$  vs  $41 \pm 1.41$ ,  $P < 0.0001$ ) and serum bilirubin ( $5.4 \pm 3.38$  vs  $1.5 \pm 0.42$ ,  $P < 0.0001$ ). A lesser sputum positivity ratio at the end of 4 wk (10/67 vs 4/137,  $P = 0.0068$ ) and decreased incidence of poorly resolved parenchymal lesion at the end of the treatment (9/152 vs 2/278,  $P$

= 0.0037) was observed. Improved patient compliance was indicated by nil drop-out in trial vs 10/192 in control group ( $P < 0.0001$ ).

**CONCLUSION:** The herbal formulation prevented hepatotoxicity significantly and improved the disease outcome as well as patient compliance without any toxicity or side effects.

Adhvaryu MR, Reddy MN, Vakharia BC. Prevention of hepatotoxicity due to anti tuberculosis treatment: A novel integrative approach. *World J Gastroenterol* 2008; 14(30): 4753-4762 Available from: URL: <http://www.wjgnet.com/1007-9327/14/4753.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.4753>

## INTRODUCTION

During the first few years of introduction of Isoniazid (INH), it was considered so safe that in 1963, The American Thoracic Society recommended for all tuberculin-positive persons to receive a year of INH chemoprophylaxis regardless of age or duration of the tuberculin positivity<sup>[1]</sup>. A retrospective study reported a 1% incidence of clinical hepatitis and a 0.1 % death in patients taking INH chemoprophylaxis<sup>[2]</sup>. A large multicenter prospective surveillance study by United States Public Health Service revealed a 1% incidence of hepatitis and 0.06% deaths from hepatitis due to INH<sup>[3]</sup>. After introduction of Rifampicin (RMP), several reports suggested that hepatitis was more frequent and severe in patients receiving both INH and RMP than in those receiving INH alone<sup>[4]</sup>. For preventing acquired

resistance and a successful treatment; it is recommended to start with a combination chemotherapy containing INH, RMP, and Pyrazinamide (PZA)-one more hepatotoxic agent- with or without ethambutol for the initial 2 mo followed by a continuation phase of 4-6 mo of INH + RMP<sup>[5]</sup>. It is well known that drug induced hepatotoxicity is a potentially serious adverse effect of anti-tuberculosis treatment (ATT) containing INH, RMP and PZA<sup>[6]</sup>. Preventive therapy of latent TB with 2-mo course of RMP and PZA has been associated with fatal and severe hepatotoxicity more often than does 6 mo of INH therapy or curative treatment of clinical TB<sup>[7-9]</sup>. Similar high risk was observed with PZA and ethambutol or a fluoroquinolone when given to contacts of multi-drug resistant TB patients<sup>[10]</sup>. Now integrating these observations with the fact that about one third of the world's population has latent TB and roughly 9 million cases of active TB emerge annually resulting in 2-3 million deaths<sup>[11]</sup>, exemplifies the magnitude and importance of the problem, especially when most new cases occur in the most populated nations like India and China<sup>[12]</sup>. Also, a higher risk of hepatotoxicity has been reported in Indian patients (up to 11.5%) than in their western counterpart (up to 4.3%)<sup>[4]</sup>. In a study of European patients, the incidence of ATT induced hepatotoxicity was found to be 18.2% in group having risk factors like, old age, extensive TB, malnutrition, alcoholism, HIV and chronic viral hepatitis B and C infections, as against 5.8% in group without risk factors indicating the significance of risk factors<sup>[13]</sup>.

The only measure available for managing ATT induced hepatotoxicity in clinical cases is stopping the offending agents, once there is an evidence of liver damage and reintroducing the same after normalization of liver enzymes<sup>[14,15]</sup>. To reduce the incidence of hepatotoxicity in latent TB patients, recommendations for drugs and patient selection criteria have been revised several times by organizations like Center for Disease Control, American Thoracic Society, Joint Tuberculosis Committee of British Thoracic Society, and Hong Kong Tuberculosis Service *etc.*, but until today no drug has been developed for prevention of hepatotoxicity.

The pathogenesis of hepatotoxicity is not entirely clear, but INH and RMP induced damage may involve oxidative stress<sup>[16]</sup>, lipid peroxidation<sup>[17]</sup>, choline deficiency leading to lowering of phospholipids protein synthesis with alteration in cell wall configuration<sup>[18]</sup>, reduced glutathione level<sup>[19]</sup> and activation of CYP2E1<sup>[20]</sup>. It is well known that some non-toxic herbs are having opposite activities in the form of membrane stabilizing, anti-oxidative and CYP2E1 inhibitory effects<sup>[21]</sup>. A review of available literature suggests that reduction in lipid peroxide content in tissue and increase in superoxide dismutase, catalase, glutathione, glutathione-s-transferase and glutathione peroxidase activities should help to maintain liver cell integrity and control the increase in level of liver enzymes.

In a previous preclinical study we found *Curcuma longa* (CL) and *Tinospora cordifolia* (TC) to offer protection in guinea pig model of ATT induced

hepatotoxicity<sup>[22]</sup>. Both these herbs have an excellent safe toxicological profile<sup>[23,24]</sup>. Phase-I clinical trials on curcumin showed that it is safe to humans up to 12000 mg/d when taken orally<sup>[25,26]</sup>. Several animal experiments for various activities of TC did not reveal any toxicity at dosage as high as 400 mg/kg while no adverse reactions have been noted in international adverse reaction database in spite of several clinical trials and wide spread usage in Ayurvedic system of medicine<sup>[27]</sup>. So it was logical and ethical to conduct a randomized controlled clinical trial to evaluate the efficacy of CL and TC to control the hepatotoxic episodes in patients diagnosed to have TB and undergoing ATT. The primary aim of the present study was to estimate to what extent CL and TC addition in the standard regime affects hepatotoxicity profile and the secondary being whether the well known immunomodulatory and tonic activity of these herbs have any impact on the outcome of TB itself. To the best of our knowledge, such a clinical trial using hepatoprotective herbs as an adjuvant medicine to prevent ATT induced hepatotoxicity has not been performed anywhere.

## MATERIALS AND METHODS

### **Study population**

All the cases between the ages of 15 to 85 years having evidence of pulmonary or extra-pulmonary TB requiring a full curative course of ATT and coming to the clinic run by Shree Gurudev Sarvajanik Charitable Trust (SGSCT) from April 2005 to March 2007 were screened for enrollment in the trial with reservations as shown in Table 1. As the six centers of the mobile clinic were attending patients on a weekly basis for any illness, catering more than 200 villages of the District Surat and adjoining state Maharashtra, the local primary care agencies were advised and allowed to give routine treatment for inter-current illnesses and patients were advised to inform about the episodes and treatment given.

As shown in Figure 1, out of 578 patients screened 528 were found eligible. Periodic review was done by an independent review committee at 48, 100, 148 and 200 patients' recruitment in each group. The interim analysis of first 400 patients performed in October, 2006 revealed zero incidence of hepatotoxicity in the trial as against 22 patients with any grade of hepatotoxicity and 16 patients with no improvement in functional status in control group. The trial was granted with an intention to treat and as the criteria for outcome assessment were objective and as the sample size exceeded the WHO criteria for adequacy of sample size with power > 80%, the control arm was truncated on ethical ground and later all the patients were recruited in trial arm till March, 2007; only to find out whether any case of hepatotoxicity was encountered.

During their baseline visit, patients underwent a review of symptoms that included history of nausea, vomiting, jaundice, abdominal pain, weight loss, arthralgia, headache and neuropathy.

**Table 1** Protocol for selection of patients for recruitment

Protocol for selection of patients for recruitment	
Criteria for selection	
Evidence of active pulmonary or extra-pulmonary tuberculosis	
Age between 15 and 85 years	
Readiness to comply with randomization, treatment and follow-up protocols	
Patients giving written informed consent	
Absence of diseases warranting treatment with systemic steroids, antimetabolites or warfarin	
Concomitant conditions allowed	
Patients with relapse, multiple relapse, treatment failure of DOTS regimen	
Patients with hypertension, diabetes mellitus, COPD (chronic obstructive pulmonary disease) with continuation of required medications	
Patients with asthma on inhalational steroid	
Skin conditions requiring topical small area steroid application	
Patients with HIV positivity but without symptoms suggestive of AIDS	
Hepatitis B/C virus carrier	
Criteria for rejection	
Presumptive diagnosis or lack of evidence of active tuberculosis	
Age < 15 or > 85	
Patients taking other alternative therapies for tuberculosis	
Patients declining to give consent or comply with protocol	
Pregnant females	
Heavy alcoholism history, > 80 g of alcohol/d for males and > 20 g of alcohol/d for females <sup>[50]</sup>	
Concomitant conditions not allowed	
Preexisting liver disease with AST, ALT raised > twice upper normal, evidence of portal hypertension.	
Preexisting renal disease with S. Creatinine raised > twice upper normal	
Sickle cell disease with history of crisis, anemia and jaundice	
History of gout	
Recent drop-outs from other TB centers due to complications and side effects	
Patients on steroid and/or antimetabolite for other collagen, autoimmune or neoplastic diseases	

**Table 2** Chemical constituents of formulation

Chemical constituents of formulation with active principles	
Chemical constituents of <i>curcuma longa</i> with active principles	
Curcuminoids	Desmethoxycurcumin Bisdesmethoxycurcumin Curcumin
Turmerones	Ar-turmerone $\alpha$ -turmerone $\beta$ -turmerone
Curcumenes	$\gamma$ -Curcumene, ar-Curcumene, Dehydrocurcumene zingiberene $\beta$ -bisabolene $\beta$ -sesquiphellandrene
Miscellaneous	Terpinolene, P-Cymene, 1-8-Cineole, Currone
Chemical constituents of <i>Tinospora cordifolia</i> with active principles	
Alkaloids	Berberine, Palmatine,Tembatarine, Magnoflorine, Choline,Tinosporin, Isocolumbin, Tetrahydropalmatine
Glycosides	18-norclerodane glycoside, Furanoid diterpene glucoside, Tinocordiside,Tinocordifolioside, Syringin, Syringin-apiosylglycoside, Palmatosides C, PalmatosidesP Cordifolioside A, Cordifolioside B Cordifolioside- A, -B, -C, -D and -E Furanolactone, Clerodane derivatives,
Diterpenoid	
Lactones	Tinosporon, Tinosporides, Jateorine, Columbin
Steroids	$\beta$ -sitosterol, $\delta$ -sitosterol, 20 $\beta$ -hydroxyecdysone Ecdysterone, Makisterone A, Giloinsterol.
Sesquiterpenoid	Tinocordifolin
Aliphatic compounds	Octacosanol, Heptacosanol, Nonacosan-15-one
Miscellaneous compounds	3, ( $\alpha$ , 4-dihydroxy-3-methoxy-benzyl)-4-(4-hydroxy-3-methoxy-benzyl)- tetrahydrofuran, Jatrorrhizine, Tinosporidine, cordifol, cordifelone N-trans-feruloyl tyramine as diacetate, Giloin, Giloinin

### Herbal formulation

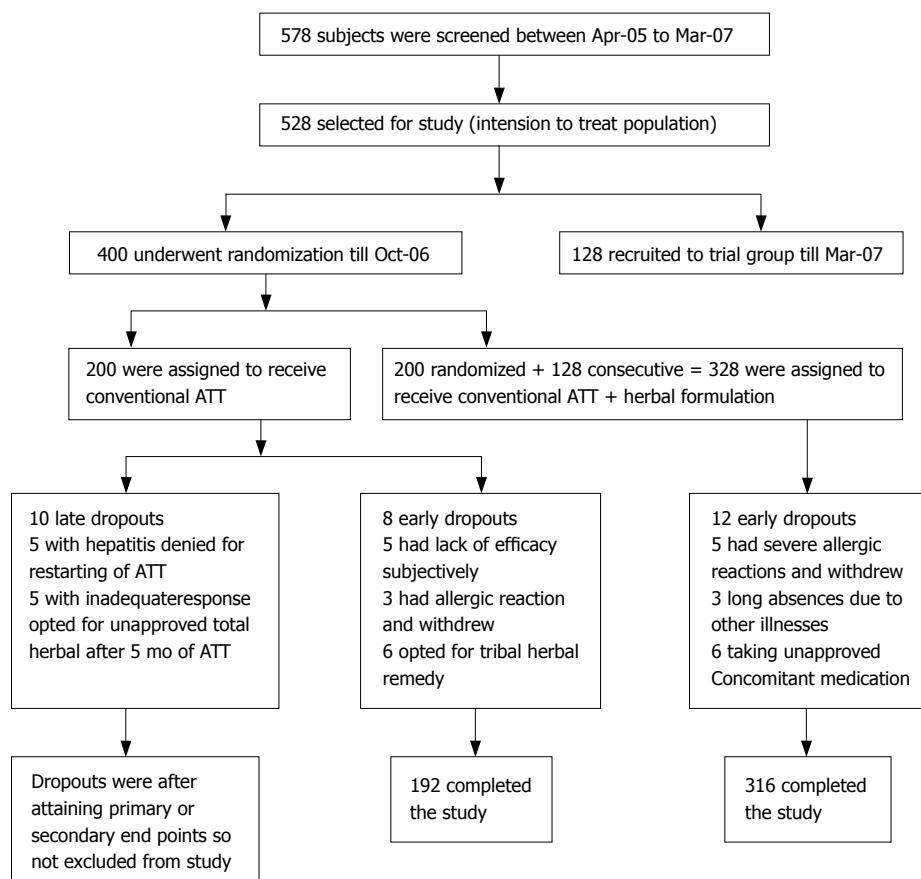

By high performance thin layer chromatography (HPTLC) analysis of different samples, we found that Salem types of turmeric powder contained highest 4% of curcuminoids that are the main active molecules. In Ayurvedic literature, the dose for turmeric has been described to be 6-12 g/d<sup>[28]</sup>. Our patient population being malnourished with an average wt of 38 kg, we preferred equivalent of 6 g/d by enriching the turmeric powder curcumin content to 25% so that 1 g dose would suffice. The dose of *Tinospora cordifolia* is also described to be 6-12 g/d<sup>[29]</sup> and again we preferred to make 1 g/d equivalent of 6 g/d by enriching the crude *Tinospora cordifolia* with 10:1 strength hydro-ethanolic extract to 50%. The phytochemical groups with active principles of both the herbs are shown in Table 2<sup>[30-32]</sup> and HPTLC fingerprinting of the formulations used were done for standardization purpose and have been shown in Figure 2.

### Study design

Ninety percent of all the patients were tribal, either working as laborers or owner of small piece of

agricultural land, while 10% were belonging to suburban area and belonging to other casts and occupations. Hence patients were explained in their local language about the protocol and those agreeing to comply were assigned the group by permuted block randomization for a balanced distribution. Because the evaluation criteria were fully objective and as the biochemical assessments were done in laboratories at a distance by unknown technicians, patients were not blinded conventionally about the therapy. Being a joint project it was approved by both the institutional ethical committee and informed consents were obtained from all the patients.

All of the eligible patients in the control group were started with an intensive phase ATT comprising of INH 300 mg/d, RMP 450 mg/d and PZA 20 mg/kg body wt to the closest 250 mg in two divided doses and Ethambutol 800 mg HS for initial 2 mo and than three drugs excluding PZA for 4 mo. Similar ATT medications supplemented with curcumin enriched (25%) CL and a hydro-ethanolic extract enriched (50%) TC 1 g/d each in two divided doses started from day one in trial group. Other supplemental medications like vitamins, iron, H2 blockers, proton pump inhibitors, anti-emetics,

**Figure 1** Study design and enrollment and follow-up of patients.

gut motility enhancers and calcium were also being given on an individual basis to patients in any group as deemed necessary by the physician. Two weeks quota of medications was given for self administration and patients were advised to return to the clinic every two weeks or earlier if any troublesome symptoms mentioned earlier were experienced. Blood sample for liver enzymes and bilirubin were taken every alternate visit and a pre-filled requisition form was given with the instruction to get it done at nearby center having pathology laboratory facility if patient could not come at time of appearance of symptoms. At each visit the patients were evaluated for signs and symptoms of adverse events by trained staff and adherence to treatment schedule was confirmed for both the groups. Sputum examination was repeated at fourth week in all sputum AFB positive cases.

Hepatotoxicity gradation was based on the WHO classification and defined by liver enzyme level, however, aspartate transaminase (AST) level was preferred instead of alanine transaminase (ALT) level as it is well known that AST/ALT ratio > 2 is one important criteria for differential diagnosis between drug or chemical and viral hepatitis<sup>[33]</sup>. Grade I for any AST level of 51-125 U/L; grade II for any AST level of 126-250 U/L; Grade III for AST level of 251-500 U/L and grade IV for any level greater than 500 U/L or more than 250 U/L with symptoms of fulminant hepatitis. In case of grade I or II liver injury ATT was continued for 2 wk and enzymes were repeated. In grade III and IV

hepatitis ATT was stopped till enzyme level came to normal. AST was checked weekly, once its rise beyond 2 fold was confirmed after initial 2 wk follow-up till it came to normal level. Patients were called for monthly follow-up visits after completion of scheduled treatment for 3 mo in both the groups.

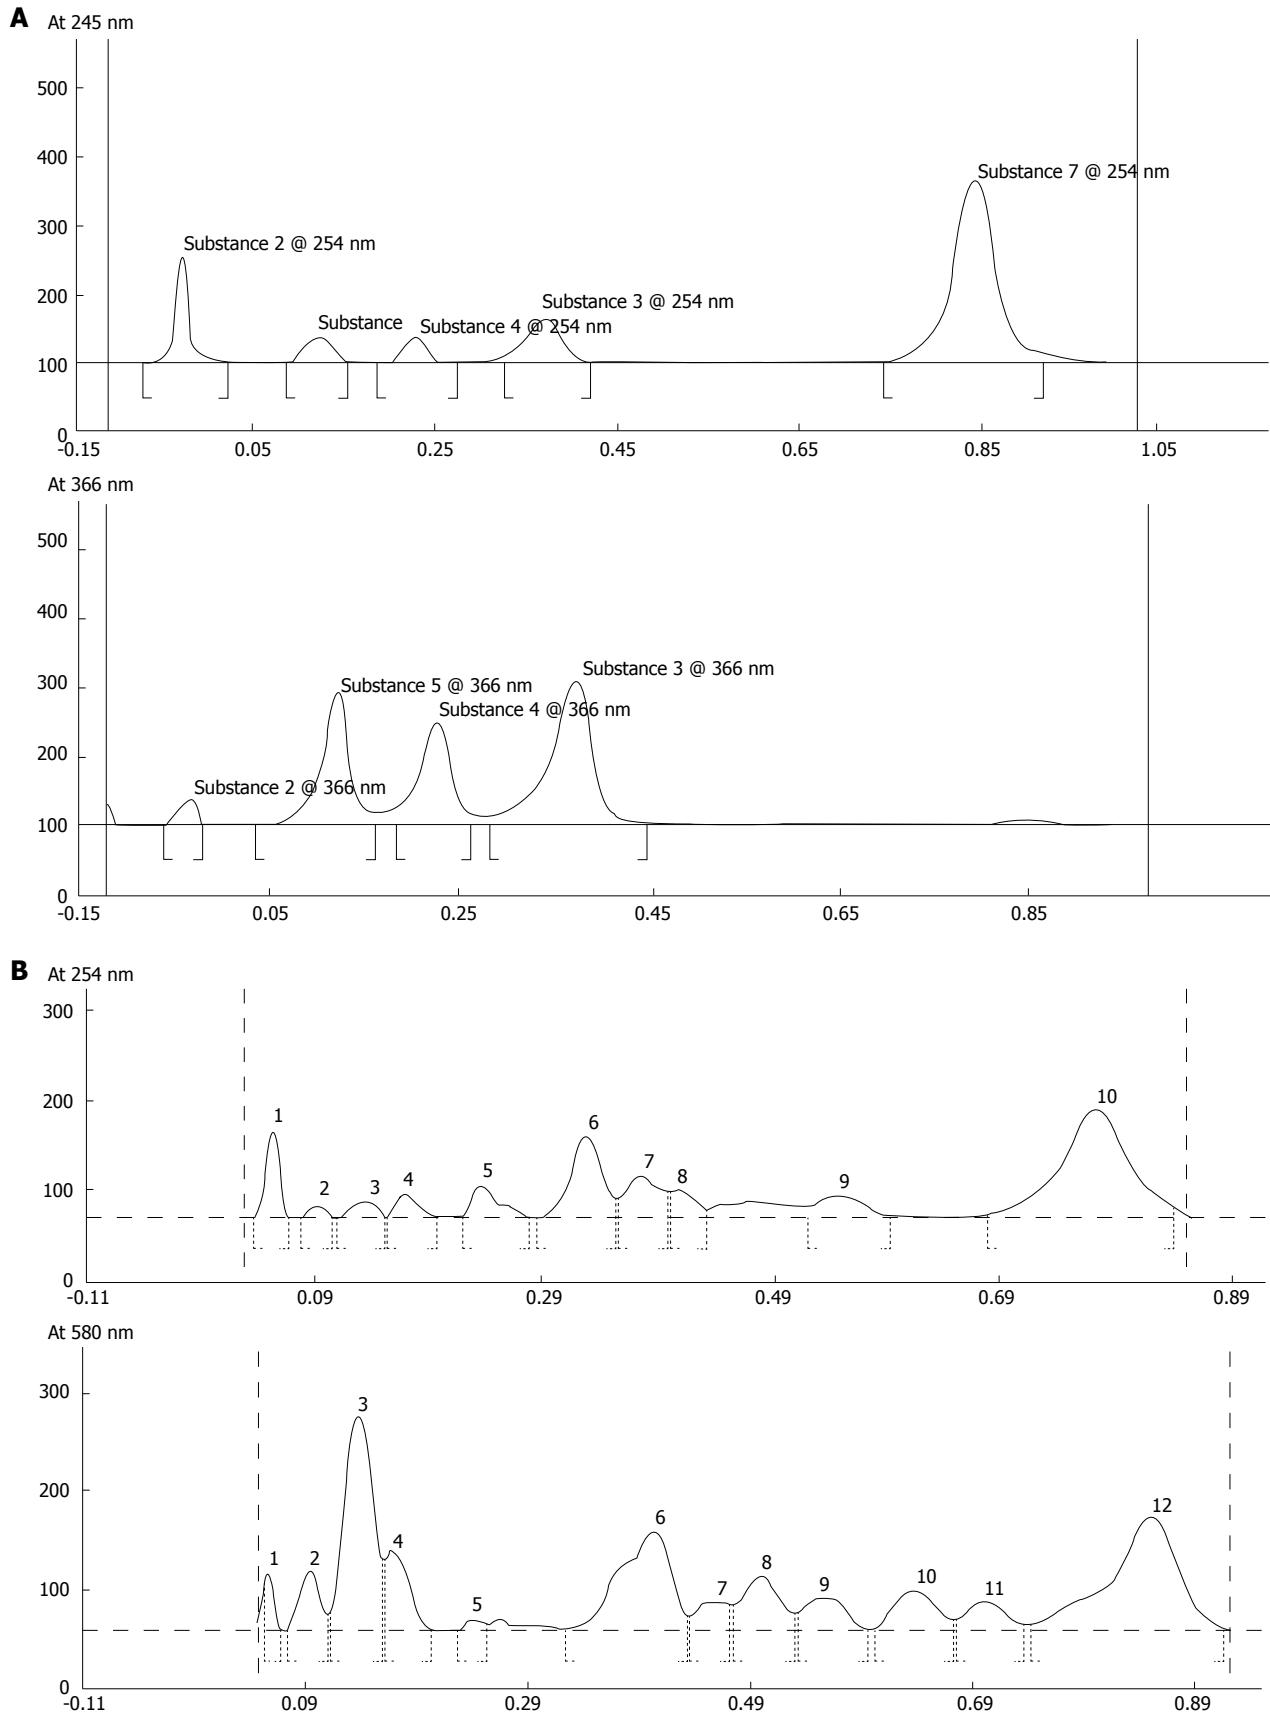

### Outcomes

Primary endpoints were to observe the development of hepatotoxicity in both the groups with assessment of severity by biochemical parameters and liver function tests if the hepatotoxicity exceeded Grade III parameters. Secondary outcome was to assess the impact of adjuvant medicine on the outcome of TB itself as defined by follow-up investigations, clinical cure and functional improvement<sup>[34]</sup> by the end of scheduled ATT and follow-up period. Completion of the regimen was defined as taking > 80% of scheduled medication for both the groups. Occasional breaks of one or two weeks due to some tribal festivals or an episodes of minor illness were not considered to be a break in the treatment.

### Statistical analysis

A sample of approximately 500 patients would provide 99% power in two sided tests with an  $\alpha$  value of 0.05 to detect a decrease in expected incidence of hepatotoxicity of any grade from 15% in control to < 3% in trial group.

Nominal and ordinal data in patient characteristics were described with percentage, median and inter

**Figure 2** A: HPTLC finger print of formulation of *Curcuma longa*. Sample was extracted in MeOH and Solvent system for Mobile phase used was Chloroform: MeOH (99.5: 0.5). Note: Before loading the material on TLC plate, it was impregnated with di NaHPO<sub>4</sub> (anhydrous)-1.25 g dissolved in 25 mL double distilled water (DDW). quartile range (IQR) between 25% and 75%, while measurement data by mean  $\pm$  SD. Significance for each

characteristic was tested to ensure basic homogeneity of both the groups. Normality test was performed as the patients were representative of a tribal ethnicity and belonged to a disease that may have specific propensity for a subgroup, so the distribution may not be Gaussian despite a large sample. Those parameters failing the normality test were further analyzed by Wilcoxon's rank sum test and those passing it were tested by unpaired *T* test with Welch's modification where variance was unequal. Student's *T* test and  $\chi^2$  test with Yate's correction were done as needed.  $P \leq 0.05$  was considered significant. Number needed to treat (NNT) was decided for the adjuvant as test therapy. Finally more common outcomes including completion of treatment and response to treatment were analyzed by Fisher Exact test. Analyses were done by using KyPlot Version 2 beta 15, GraphPad InStat Version 3.06 and GraphPad StatMate 2 version 2.00.

## RESULTS

### Clinical and demographic characteristics at baseline

As shown in Figure 1, 528 patients were enrolled at six centers of SGSCT mobile clinic. A high proportion of patients were of tribal ethnicity from Chaudhari, Gamit, Vasava and Bhil community known to carry sickle cell trait in up to 30% of population<sup>[35]</sup> and disease in 1.5%<sup>[36]</sup>, as reported by different governmental agencies. Eight patients from control and 12 patients from trial group were excluded from study due to violation of the protocol, hence control had 192 and trial had 316 patients for final analysis. As seen in Table 3 the median age and IQR for both the groups were quite similar. Also the two groups were similar in sex, body weight, habits, disease profile, baseline hematologic means and liver function except that trial group contained significantly higher number of patients with Cavitary Koch's than the control group.

### Hepatotoxicity

Tables 4 and 5 depict the effects of herbal adjuvant on primary outcome in the form of significantly decreased incidence of hepatotoxicity (2/316 vs 27/192) in the trial group as compared to control group. Mean onset of asymptomatic hepatitis was delayed in trial group and none in the trial group suffered from symptomatic hepatitis as against 63% of control group hepatitis patients. Grades II and III hepatotoxicity were observed in control group only. Serum AST, ALT and bilirubin level were raised in control group much significantly when compared with trial group hepatotoxicity cases.

### Disease outcome

As shown in Table 6, the number of sputum-positive cases after 1 mo of treatment in the trial group (2.9%) was significantly lower than control group (14.93%). Incidence of poorly resolved parenchymal lesion by roentgenogram and failure to improve functional status by ECOG score<sup>[34]</sup> being significantly lower and treatment dropouts nil in the trial group proved the efficacy of herbal adjuvant formulation.

**Table 3 Baseline demographic and disease characteristics in the intention-to-treat population**

Characteristics of patients	Control	Trial	P
Sex			
Male (%)	104 (54)	169 (53)	0.934
Female (%)	88 (46)	147 (47)	0.927
Age-yr median(IQR 25th & 5th)	35 (23.75-45)	35 (27-45)	0.229
Weight (kg, mean $\pm$ SD)	37.61 $\pm$ 5.94	38.32 $\pm$ 6.08	0.199
Ethnicity (%) <sup>1</sup>

Hematology			
Hb (%)	8.84 $\pm$ 1.93	8.95 $\pm$ 1.95	0.808
Total leucocyte count/mm <sup>3</sup>	10 179 $\pm$ 4 680	9575 $\pm$ 4075	0.478
ESR	66.79 $\pm$ 30.64	70.49 $\pm$ 27.91	0.517
Liver Function (mean, 95%CI)			
Serum bilirubin	1.07 (0.7-1.3)	1.09 (0.8-1.4)	0.952
AST	34.35 (17-63)	32.4 (11-61)	0.658
ALT	27.45 (9-57)	31.15 (6-52)	0.655
ALP	100 (50-260)	107 (50-260)	0.092

Unless stated otherwise, P values were calculated with the use of a two sided *t*-test with Welch's modification (when unequal variance) for continuous data and a  $\chi^2$  test for categorical data. <sup>1</sup>Ethnic group was assessed by investigation on screening. Tribal consists of Chaudhari, Gamit, Vasava, Bhil, Valvi, Nayka and Halpati. <sup>2</sup>Patients may belong to more than one category. ALP: Alkaline phosphatase.

### Weight and hematologic outcome

As seen in Table 3 and Table 6, the mean weight in control increased to  $39.17 \pm 5.5$  kg from  $37.61 \pm 5.94$  kg before ATT ( $P = 0.0063$ ) and in trial group mean weight was  $40.65 \pm 6.22$  kg from  $38.32 \pm 6.08$  kg before ATT and herb treatment ( $P < 0.0001$ ). While comparing the weight gain, trial group showed significantly higher weight gain than control group. Mean Hb of control and trial groups increased significantly after therapy; however, the inter group difference was nonsignificant. Erythrocyte sedimentation rate (ESR) in both groups decreased significantly compared from start to end of the treatment period; however, inter group comparison

**Table 4** Effects of herbal formulation on incidence, onset, duration and severity of hepatitis

ATT induced hepatitis outcome (Table 2)	Control (n = 192)	Trial (n = 316)	P
Patients with raised AST (%)	27 (14)	2 (0.63)	< 0.0001
Patients with raised S bilirubin (%)	17/27 (63)	0	< 0.0001

ESR mm in 1st hour	45.96 ± 18.52	38.84 ± 22.37	0.0001

P calculated by  $\chi^2$  (categorical data) and two-sided Student's t-test with Welch's procedure (continuous data with unequal variance).

that was nonsignificant at the start showed a significantly more decrease in trial group at completion.

#### Non-hepatotoxic adverse events (data not shown)

Non-hepatotoxic adverse events occurred occasionally in both the groups and included nausea, vomiting, skin rash, epigastric pain and discomfort, malaise, dizziness,

arthralgia, peripheral neuropathy, anorexia and insomnia and sickle crisis. They were treated symptomatically with appropriate medications by the physician. Early dropouts occurred in both groups due to allergic reactions to ATT and they were excluded from the analysis as shown in Figure 1.

## DISCUSSION

The present clinical trial was based on unpublished results of previous preclinical studies at our center. As the conventional ATT has been well established and the Ayurvedic herbs have excellent safety profile as described previously, a phase I trial omission was granted. As the efficacy of the herbs was shown in concurrent administration design in an animal model of ATT induced hepatotoxicity<sup>[22]</sup>, it was considered scientific, as well as ethical, to try a similar model for a human clinical trial, hence herb treatment was started along with ATT at the same time and continued until completion of ATT.

Curcumin has anti-inflammatory, free radical scavenging and hepatoprotective activities tested *in vitro*. It suppresses production of superoxide by macrophages, exerts potent anti-inflammatory action that inhibits production of tumor necrosis factor alpha (TNF- $\alpha$ ), interleukin (IL) 1- $\beta$  and the activation of NF- $\kappa$ B in human monocytic derived cells<sup>[37,38]</sup>. Also, it has a strong antioxidant property and it inhibits lipid peroxidation in rat liver microsomes, erythrocyte membranes and brain homogenates, by maintaining the activity of SOD, catalase and glutathione peroxidase at a higher level<sup>[39]</sup>. These properties clearly explain the hepatoprotective activity of CL in preclinical studies and present trial as well. Curcumin has antiviral, antiprotozoal, antibacterial, anti inflammatory, and antioxidant actions, in addition to its hepatoprotective activity, making it a suitable adjuvant agent that actually enhanced efficacy of ATT in present study.

In preclinical studies, TC has been shown to induce enzymes of drug metabolism and antioxidant system and to inhibit lipid peroxidation in mice. Cytochrome P450, NADP-Cytochrome (P sub 450) reductase, glutathione-s-transferase, DT diaphorase, SOD and catalase are enhanced. These effects improve liver function, protect against toxic assaults and increase protein synthesis by liver<sup>[40]</sup>. These activities can account for its hepatoprotective potential. It is a known immunostimulant enhancing cell mediated as well as humoral immune response in mice. Treatment of mice with dried stem crude extract prevented cyclophosphamide induced myelosuppression as well as immunosuppression<sup>[41]</sup>. Improved humoral immunity, enhanced macrophage and Kupffer cell function, enhanced neutrophil function, antioxidant activity and excellent hepatoprotective potential might explain the result of present clinical trial. Since many years the concept of classical phytotherapy using herbal drug combinations with superior efficacy and lesser side effects in comparison with single isolated constituents

of plant extracts has been repeatedly assessed clinically as well as pharmacologically. The exact mechanisms of action underlying these synergy effects are unknown. It could be explained by a multitarget action of compounds on a molecular level or partly by an improved resorption rate and a change of pharmacokinetics<sup>[42]</sup>. Hence, a formulation of CL and TC was used with an idea to enhance the potency due to synergistic action that was backed by promising results of a small preclinical pilot study (unpublished). As such, many standard Ayurvedic preparations also contain both of these herbs, albeit in a lower dose along with other multiple herbs.

Regarding the design of the trial, the strength lied in the base line characteristics which were remarkable similar and all the parameters for hepatotoxicity were objective and being tested by laboratory technicians at different places and totally unaware about the trial or outcome, so there could not be any chance for a bias in the detection and gradation of hepatotoxicity. In many complex clinical situations adaptive random allocation methods are implemented to maintain balance between stratification variables<sup>[43]</sup>; however, periodic evaluation revealed acceptably similar distribution among groups even with permuted block randomization. When one treatment or an intervention is expected to be superior; a Bayesian adaptive randomization (BAR) method is considered desirable to conventional randomization because it utilizes the accruing data in a "learn-as-you-go" fashion that arguably makes more sense than ignoring the trial's data until it is completed<sup>[44]</sup>. BAR would allocate more numbers of patients to the potentially advantageous group without compromising the randomization, but making the trial design very complicated. Instead the control arm was truncated for ethical reasons with caution at periodic evaluations so that no dissimilarity in favor of the trial group should occur.

Though sickle cell disease patients were excluded from the study, persons having sickle cell traits are prone to have anemia, repeated chest infection and theoretically sickle cell crisis in extremes of situations with dehydration and acidosis. In the present trial two events of sickle cell crisis occurred in the control group. They might have phenotypic sickle cell disease<sup>[45]</sup>.

The average weight of the study population was around 38 kg in both the groups confirming malnutrition in addition to effect of TB alone. The significance of this characteristic could not be overemphasized because a low weight would culminate in to a higher per kg dosage of the hepatotoxic ATT. Considering the average weight to be 38 kg, the per kg dose of INH, RFM, PZA and EMB would come to 7.9, 11.84, 26.31 and 21 mg, respectively. Comparing this dose with a previous study<sup>[46]</sup> in which the per kg doses for INH, RFM and PZA were 5, 10 and 25-30 mg, respectively, and the period for observation was 59 d with reported hepatotoxicity to be 11%; it is apparent that the chances of developing hepatotoxicity would be definitely more for the patients in present study. In addition to malnutrition as a known risk factor, a higher per kg dose could also play some role.

With all these background, the results of present trial carried utmost importance that hepatotoxicity did not occur in the trial group despite a slightly unfavorable profile in the form of significantly higher number of patients with Cavitary pulmonary TB. Only two instances of raised AST were detected during monthly surveillance of liver enzymes and ATT was not stopped as it was asymptomatic grade I hepatotoxicity. Extensive disease, relapse cases, multiple relapse cases, miliary TB cases and cases with malnutrition, HIV carrier, and hepatitis B and C carrier, sickle cell trait, other back ground illnesses like COPD, hyper-eosinophilic syndrome, MB leprosy, diabetes mellitus, asthma, rheumatoid arthritis were all recruited in the control as well as the trial group and yet no incidence of clinically significant hepatotoxicity occurred in trial group, suggesting that regular administration of adjuvant herbs had taken care of all the known, hypothesized and unknown risk factors predisposing to ATT induced hepatotoxicity in clinical cases of TB.

Though with a power of 99% and highly significant out-come, this was a pilot study and much has remained to be done to exploit the full potential of the hepatoprotective ability of these herbs in cost-effective manner with defined recommendation for different subclasses of patients including latent TB cases and different high risk groups of clinical cases. A separate study with a low risk control, a high risk control and a high risk trial would serve both the purposes of testing the efficacy of herbs in high risk group as well as the validity of the hypothesis that low risk group has lower incidence of hepatotoxicity in the same population having similar ethnicity. The answer to the question whether low risk patients should be subjected to adjuvant medication or not, could also be answered from the results of study with such a design.

As latent TB cases on different preventive regimes have been shown to be at a greater risk for developing hepatotoxicity<sup>[7-9]</sup>, a separate well-designed trial for this class of patients could not be over-emphasized. The efficacy of these herbs may also be tested in patients showing liver enzyme increase detected by surveillance to decide whether ATT could be continued without risk of it to progress to higher grade hepatotoxicity as it is observed that sooner the detection, lesser the risk and later the appearance of hepatitis, greater the chances of fulminant failure<sup>[47]</sup>.

The NNT analysis of the study with a single outcome of hepatoprotection would come to eight. This is because the herbs were given to all as an adjuvant medicine where the possibility of developing hepatitis itself was expected to be between 11% and 15%. Looking to the result on disease profile it is clear that the sputum conversion to negativity was significantly superior in herb treated group despite an unfavorable sample, resolution of parenchymal lesion was significantly higher, failure to improve functional status was significantly lower and dropout rate came to nil. If these treatment factors are added then NNT would surely come lower.

Weight and hemoglobin both increased and ESR reduced significantly on intra group pre- and post-treatment comparison in both the groups proving the efficacy of conventional ATT alone too. The inter group comparison post treatment showed a significant advantage in weight gain and reduction in ESR, but not in hemoglobin level in trial group suggesting the superiority of ATT plus adjuvant herbs over ATT alone. It is apparent that iron and vitamin supplements were being given to anemic patients as per diagnosis and role of ATT must be supportive only in rising the Hb. Tumor necrosis factor alpha (TNF) has been shown to cause hypoferremia and reduced intestinal iron absorption in mice and Curcumin inhibits TNF thereby having the potential to enhance iron absorption and help alleviate anemia<sup>[48,49]</sup>. Rise in Hb was not a direct function of both modalities and effects of curcumin on iron absorption in humans has not yet been tested; so the only valid comment would be that the theoretical advantage of CL was not observed practically in present study.

In conclusion CL and TC given as an adjuvant to standard ATT to any kind of TB patients prevented hepatotoxicity very significantly in terms of incidence, duration and severity and also helped improve outcome in terms of quicker and more efficient achievement of sputum negativity in open, potentially infectious cases; better response in parenchymal lesion resolution and helped improve patient compliance. Treated cases had better weight gain and significantly more reduction in ESR. A prospective trial for latent TB and MDR TB contacts can further exemplify its usefulness. Post-treatment design on detection of hepatotoxicity and concurrent administration design for different subgroups may clarify its efficacy in different clinical situations and provide a basis for evidence based recommendation for different sub groups of TB patients.

## ACKNOWLEDGMENTS

Dr. Manish Patel, Dr. Jyoti Patel, of Shivjyoti Hospital for helping in selection and follow-up studies of the patients. Dr. Pragna Kalarthi, Dr. Ramiben Chaudhari, Dr. Nilesh Nayak for helping at various stages of clinical trial in patient assessment and follow-up. All the peripheral centers that co-operated for bio-chemical tests, roentgenogram and hemogram on no-profit basis.

## COMMENTS

### Background

Isoniazid, rifampicin and pyrazinamide, three major drugs of intensive phase of conventional anti-tuberculosis (TB) treatment (ATT), are hepatotoxic and the incidence varies between 4%-11%. Healthy contacts of TB patients (latent TB cases) are more prone to develop hepatotoxicity by presently recommended regimens. There is no established drug therapy to cure or prevent hepatotoxicity except stopping the treatment for a while and restoring it gradually at a later date when liver enzymes come to a normal level. Stopping the therapy may increase morbidity or prolong disability, while shifting to suboptimal non-hepatotoxic regime for time being poses the risk of emergence of resistant strains.

### Research frontiers

Search for non-toxic and highly effective new compounds for treating

tuberculosis or an effective vaccine conferring sustained protective immunity have largely failed. In literature there are many published preclinical studies showing herbs to prevent CCl<sub>4</sub>, and paracetamol induced liver damage in rodents. Recently, four Ayurvedic herbs were shown to prevent ATT induced hepato-toxicity and immunosuppression in Guinea pigs. (<http://www.wjgnet.com/1007-9327/13/3199.asp>). But no clinical trial of hepatoprotective compound has ever been carried out in patients taking conventional ATT.

### Innovations and breakthroughs

The present study is the first of its kind and the results are encouraging for the prevention of hepato-toxicity and improving the disease outcome by greater sputum clearance in Cavitary lesions and better resolution of parenchymal lesions. Thus, addition of two simple herbs makes the conventional ATT much safer and efficacious.

### Applications

Incorporation of such a formulation in current conventional ATT at a mass level may contribute a lot to minimize the risk of liver injury, improve patient compliance and disease outcome that might ultimately help to control emergence of MDR strains of AFB. If similar protection is observed in latent tuberculosis by a prospective trial, it would be a boon for the latent TB cases subjected to a serious risk by preventive ATT.

### Peer review

The manuscript is well written. This is an interesting trial. The study is nicely designed and the analytical data appear to be technically and scientifically sound. The outcome is remarkable and clearly shows beneficial effect of the herbal formulation in hepatic injury by ATT.

## Abstract

**AIM:** To evaluate the effect of propolis administration on the healing of colon anastomosis with light and transmission electron microscopes.

**METHODS:** Forty-eight Wistar-Albino female rats were divided into two groups and had colon resection and anastomosis. In group I, rats were fed with standard rat chow pre- and postoperatively. The rats in group II were fed with standard rat chow and began receiving oral supplementation of propolis 100 mg/kg per day beginning 7 d before the operation and continued until they were sacrificed. Rats were sacrificed 1, 3, 7 and 14 d after operation, and anastomotic bursting pressures measured. After the resection of anastomotic segments, histopathological examination was performed with light and transmission electron microscopes by two blinded histologists and photographed.

**RESULTS:** The colonic bursting pressures of the propolis group were statistically significantly better than the control group. Ultrastructural histopathological analysis of the colon anastomosis revealed that propolis accelerated the phases of the healing process and stimulated mature granulation tissue formation and collagen synthesis of fibroblasts.

**CONCLUSION:** Bursting pressure measurements and ultra structural histopathological evaluation showed

## INTRODUCTION

Despite the use of optimal surgical techniques and medical treatments, the integrity of intestinal anastomosis may be compromised, resulting in wound dehiscence<sup>[1]</sup>. The frequency of this complication, which carries a high morbidity and mortality rate, increases if surgery has to be performed in the presence of high-risk situations, such as surgeries performed in emergency settings, on infected and necrotic stumps, in unsafe anatomical areas (rectum, esophagus), or in patients with metabolic derangements<sup>[2,3]</sup>. If we consider these high-risk situations annihilated, there are several factors in the etiology of colon anastomotic leakage. These factors can be separated into two groups, as systemic (advanced age, malignancy, malnutrition, anemia, hypovolemia, hypoproteinemia) and local (colonic perfusion disorders, septic colonic contents, perfusion impairment at anastomotic line, anastomotic tension, haematoma, inadequate surgical technique, type of preparation prior to surgery and primary colonic pathology)<sup>[4,5]</sup>. Many studies focused on the detrimental effects of these local and systemic factors. However, in the last century researchers have drawn attention to the cellular mechanisms of the healing and suggested many agents to decrease anastomotic insufficiency and leakage. This

experimental study was performed to investigate the cellular ultrastructure of the anastomotic healing process besides to examine the effects of propolis.

Propolis is a resinous material collected by bees from various plants. Bees use material actively secreted by plants or exuded from wounds. Once collected, this material is enriched with salivary and enzymatic secretions of bees. Propolis is used by bees to cover hive walls, fill cracks or gaps, and embalm killed invader insects<sup>[6]</sup>. It also found its way into a wide spectrum of applications from scolicidal efficacy to cosmetic products such as face creams, ointments, lotions, and solutions<sup>[7]</sup>. Propolis contains a variety of flavonoids, phenols, alcohols, terpenes, sterols, vitamins, and amino acids<sup>[8]</sup>. Chemical composition of propolis samples was detected by gas chromatography mass spectrometry (GC-MS) and high-performance liquid chromatography (HPLC)<sup>[9]</sup>. Antimicrobial properties of propolis seem attributable mainly to the flavonoids, pinocembrin, galangin, and pinobanksin. Pinocembrin also exhibits antifungal properties. Other active compounds are esters of coumaric and caffeic acids. Prenylated p-coumaric and diterpenic acids possess antibacterial and cytotoxic activities. Caffeoylquinic acid derivates show immunomodulatory and hepatoprotective actions and furofuran lignans inhibit the growth of some bacteria. It also has antioxidative, immunostimulative and regenerative properties<sup>[6]</sup>.

According to these properties, we planned to use propolis for determining the effects on the healing of colonic anastomoses in the rats after colonic resection and anastomosis.

## MATERIALS AND METHODS

### **Animals**

Forty-eight Wistar-Albino female rats, weighing  $225 \pm 25$  g were included in this study. Twelve hours before anesthesia, animals were deprived of food, and had free access to water until two hours before anesthesia. No enteral or parenteral antibiotics were administered at all. Rats were housed under constant room temperature ( $21 \pm 2^\circ\text{C}$ ) individually in wire cages with a 12-h light-dark cycle. The rats, which died during the experimental period, were excluded from the study and were not replaced with new rats. Additionally, 6 sham-operated rats (no surgery performed on colons) were used to measure basal bursting pressure. The procedures in this experimental study were performed in accordance with the National Guidelines for the Use and Care of Laboratory Animals and approved by the Animal Ethics Committee of Ankara Research and Training Hospital.

### **Study groups**

Rats were randomly divided into two groups each including 24 animals. Colon resection and anastomosis were performed on all animals. In group I, rats were fed with standard rat chow pre- and postoperatively. The rats in group II were fed with standard rat chow and began receiving oral supplementation of propolis

100 mg/kg per day beginning 7 d before the operation and continued until they were sacrificed. Propolis was given by nasogastric tube everyday at 8 am.

### **Surgical procedure**

Animals were anesthetized by intramuscular injection of 30 mg/kg ketamine hydrochloride (Ketalar®; Parke-Davis, Istanbul, Turkey) and 5 mg/kg xylazine (Rompun®; Bayer, Istanbul, Turkey). Under sterile conditions, midline laparotomy was performed. The left colon was transected 3 cm proximal to the peritoneal reflection and a 1 cm-long colon segment was resected. End-to-end anastomosis was performed by one-layer, inverted, interrupted sutures by using 6-0 polydioxanone (PDS, Ethicon, UK). The same surgeon, who was unaware of the grouping of each rat, performed all anastomoses. The fascia and skin layers of the abdomen were closed separately with continuous 3-0 silk sutures. Animals had free access to food after the operation. The rats were sacrificed on postoperative day 1, 3, 7, and 14 by high-dose diethyl ether inhalation. The abdominal cavity was inspected through a U-shaped incision.

### **Measurement of bursting pressure**

The anastomotic segment was separated from the surrounding organs. The tissues that adhered to the anastomosis too tightly were not forced away. A colon segment including the anastomosis with 2.5 cm proximal and distal parts was removed. One end of the segment was tied by a 3-0 silk suture. The cannula was inserted into the proximal colonic segment. A catheter was inserted into the other end and tied by 3-0 silk suture to avoid air leaks; it was connected to an infusion pump and to the computer for pressure readings (Logger computer program). Air was pumped into the colon segment at a constant rate of 8 mL/min. The maximum pressure reading before the pressure declined suddenly was recorded as the bursting pressure.

### **Histological examination**

The histopathological analysis of this study was carried out in the Histology and Embryology Department of Ankara University Faculty of Medicine. For light microscopic analyses, a colonic anastomosis-site segment was removed from each rat and the specimens were fixed in 10% neutral buffered formalin solution for 2 d. Tissues were washed in flowing water and dehydrated with increasing concentrations of ethanol (50%, 75%, 96%, and 100%). After dehydration, specimens were put into xylene to obtain transparency and then infiltrated with and embedded in paraffin. Embedded tissues were cut into sections of 5-μm thickness using a Leica RM 2125 RT. Systematically randomly selected sections were stained with hematoxylin and eosin and mallory-azan dyes. Histopathological examinations were performed by two histologists blinded to the study design and photographed with a Nikon eclipse E 600.

For the transmission electron microscope (TEM) analyses, samples were fixed with phosphate buffered (pH 7.3) 2.5% glutaraldehyde and a 2% PFA mixture

**Table 1** The colonic bursting pressures

Time	Sham group	Control group	Propolis group	Sham vs Control	Sham vs Propolis	Control vs Propolis
1st day	214.7 ± 5.50	33.8 ± 2.99	43.3 ± 1.51	P = 0.002	P = 0.002	P = 0.002
3rd day		43.7 ± 1.86	52.7 ± 3.33	P = 0.002	P = 0.002	P = 0.002
7th day		146.5 ± 6.53	179.8 ± 6.71	P < 0.001	P < 0.001	P < 0.001
14th day		176.7 ± 4.41	200.8 ± 7.19	P < 0.001	P = 0.002	P < 0.001

solution for 2 h at room temperature. They were washed with phosphate-buffered saline solution (PBS, pH 7.3) and fixed with 1% osmium tetroxide for 2 hours as the secondary fixative. After washing, they were embedded in Araldite 6005 and cut with a Leica EM FCS (Vienna-Austria) ultramicrotome. One micrometer semi-thin sections were stained by toluidine blue-Azur II to select the region of interest for the following procedures. Sixty-seventy nm thin sections were stained with uranyl acetate and lead citrate. The sections were examined and photographed using a LEO 906 E TEM (80 kV, Oberkochen, Germany) microscope.

### Statistical analysis

Data analysis was performed using the SPSS (Statistical Package for Social Science, version 11.5) software package. Whether the bursting pressure measurements were normally distributed or not was determined by using the Shapiro Wilk test. Descriptive statistics were shown as mean ± standard deviation (SD). The differences among groups and days were evaluated by one-way ANOVA post-hoc Tukey test or Kruskal Wallis test, where appropriate. When the P-value from the Kruskal-Wallis test statistics was statistically significant, Bonferroni adjusted Mann Whitney U test was used to know which groups or days differ from which others. Bonferroni correction was applied for all possible within group or day comparisons. A P value less than 0.05 was considered statistically significant.

## RESULTS

### Surgical results

The rats were sacrificed on postoperative day 1, 3, 7, and 14. One rat from each group died in the early postoperative period, probably due to anesthesia. On gross evaluation, no signs of anastomotic leakage, intraabdominal abscess, peritonitis, or ileus were detected.

Anastomotic wound healing was evaluated by means of bursting pressure and histopathological assessment. The biggest P value among the P values as P < 0.001 was found as 5.6E-6. To obtain a standardized projection the notation was preferred as P < 0.001 for most of the P values. The colonic bursting pressures of the propolis group were significantly better than the control group (Table 1).

### Histopathological results

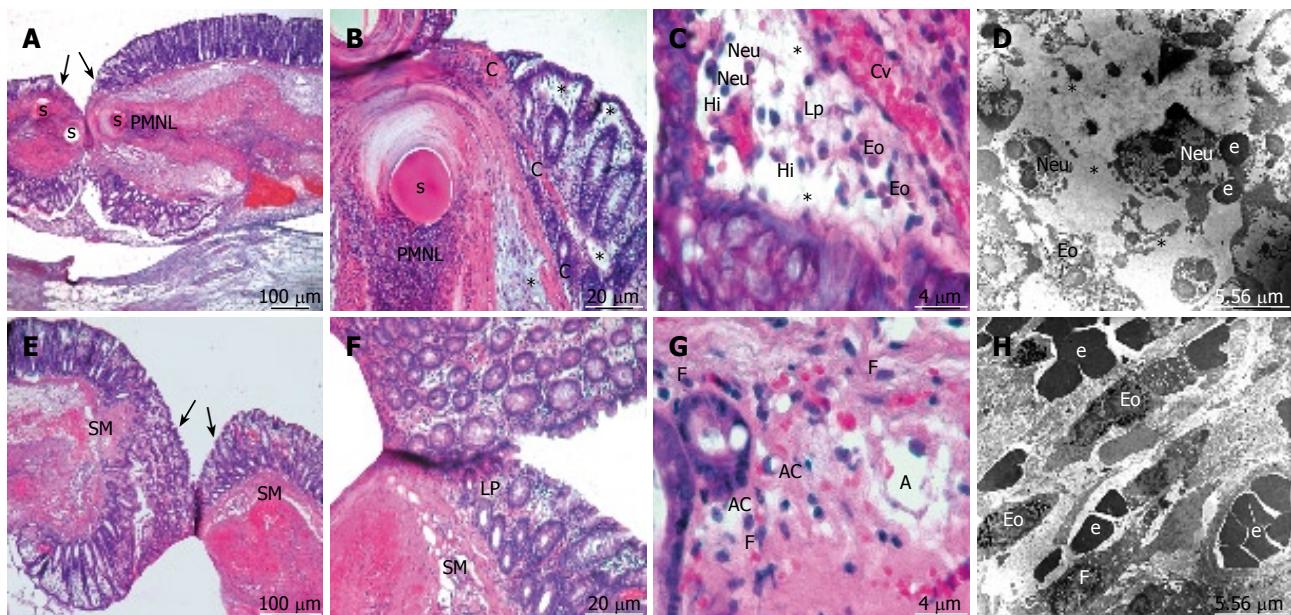

On the first postoperative day of the control group, healing began with a strong influx of polymorphonuclear

leucocytes (PMNL), most prominent in the anastomotic line. There was a massive infiltration of neutrophils, eosinophils, and histiocytes in the lamina propria, submucosa, and the area surrounding the suture material. The subepithelial region of the mucosal layer and the submucosa were highly congested and edematous. The subepithelial edema was expanded to the wide adjacent area of the anastomotic line (Figure 1A-D). In the propolis group, the subepithelial edema was not striking and not expanded very far from the anastomotic line. Congestion and infiltration of PMNL was also present; additionally the fibroblasts' migration became apparent in the wound edges and around the suture material. The thing to note was that angiogenesis became visible in focal areas of the submucosa (Figure 1E-H).

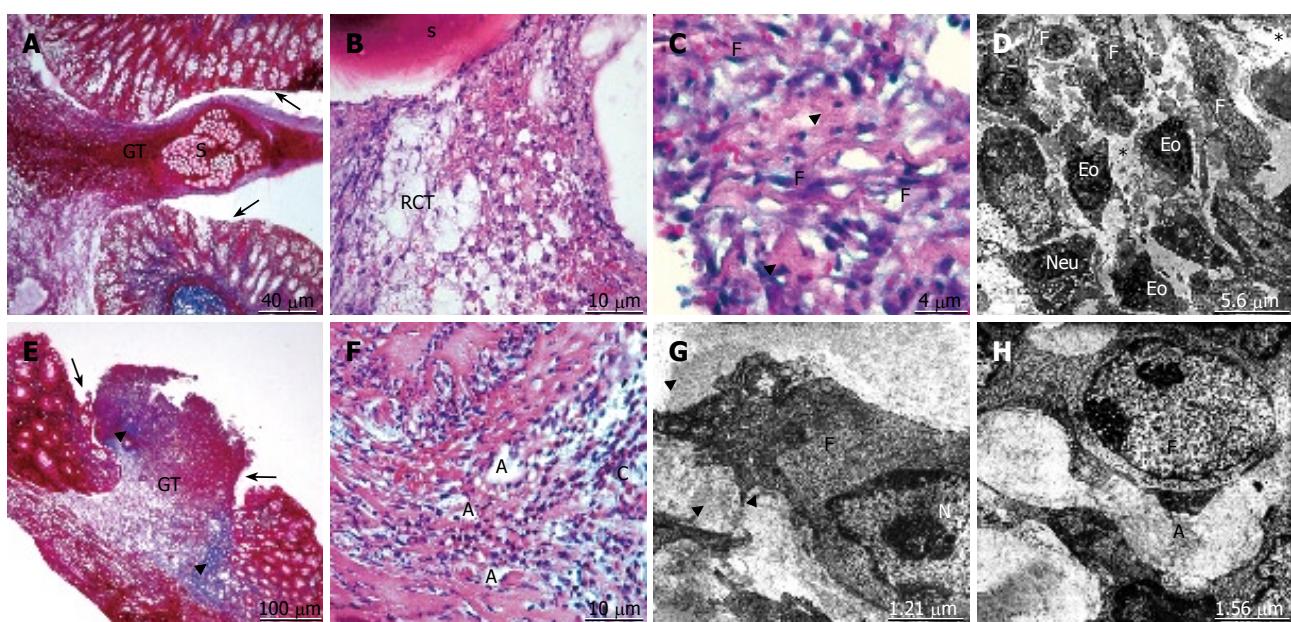

On the third postoperative day, edema of the control group was persistent. The existence of PMNL and a slight increase in the lymphocyte infiltration was seen. The hemorrhage, inflammation and the intensity of eosinophils in the lamina propria were recognizable. The granulation tissue formation and the resorption of the suture material were observed. The reticular connective tissue formation by fibroblasts and the wrapping of this tissue around the suture line were evident (Figure 2A-D). In the propolis group, the edema and the swelling of the tissue ends regressed. The fibroblastic activity and the synthesis of new collagen were observed. Angiogenesis, a component of granulation tissue formation, was prominent. The spatial arrangement of collagen fibers in the submucosal layer and inclining towards the anastomotic line to form bridging of the gap was recognizable (Figure 2E-H).

On the seventh postoperative day, edema of the control group had almost disappeared. The granulation tissue was well organized and wrapped around the suture material particles. The collagen formation with increased fibroblastic activity was present but irregular. The macrophage infiltration removing the debris was observed (Figure 3A-D). In the propolis group, a very small tissue defect was still visible in the mucosal layer. Many bands of collagen fibers and well-developed capillary vessels were distinguished. The collagen bundles were well arranged to form the bridging between mucosal and submucosal layers. The macrophage cells clearing off the debris and the mature cells of the connective tissue as fibrocytes were easily viewed (Figure 3E-H).

On the fourteenth postoperative day for the control group, the mucosal integrity was still not gained. There was a very small (< 1 mm) tissue defect between the anastomotic ends. The regeneration of the epithelium

and the mucosa only partially covered by simple squamous and cuboidal epithelium was observed. The apoptotic cells and the macrophages clearing the debris were still remarkable. The granulation tissue and the epithelium of the anastomotic ends were very close (Figure 4A-D). In the propolis group, the mucosa had completely healed. The regeneration of epithelium was with glandular columnar epithelium. The lamina propria of the anastomotic line under the restored epithelium was cleaned out from the debris. There was

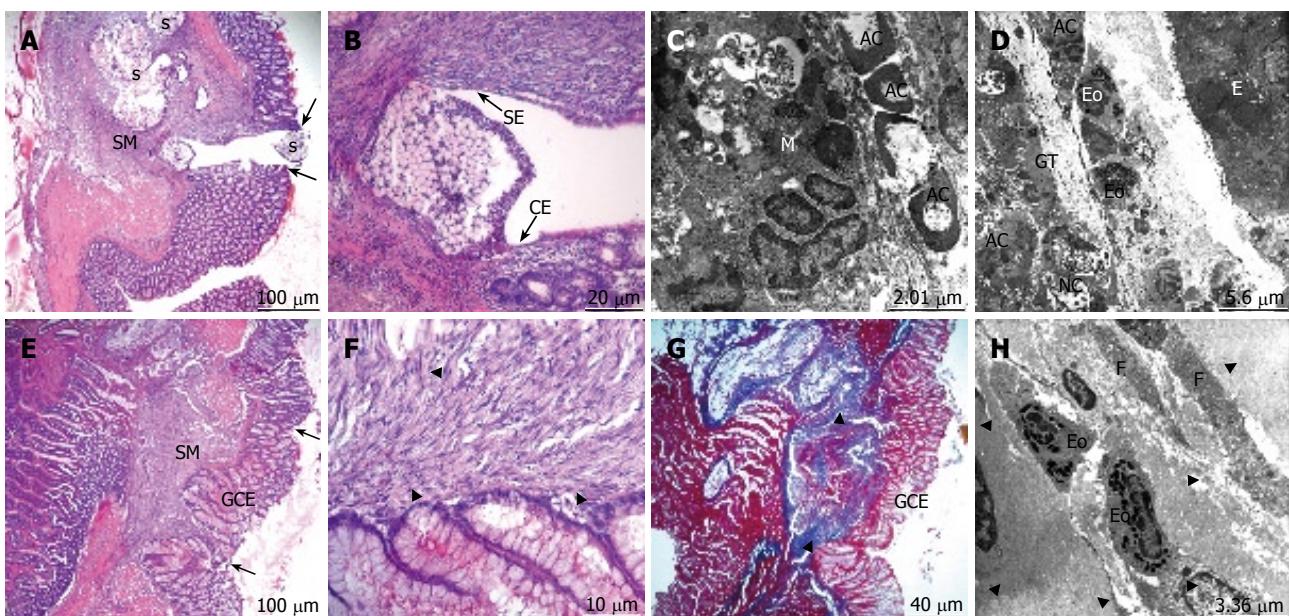

a dense collagen deposition in the submucosal layer. The collagen bundles were regular and harmoniously organized (Figure 4E-H).

## DISCUSSION

Leakage of anastomoses is a very serious and severe complication in gastrointestinal surgery. Morbidity and mortality rates are still high despite advances in operative techniques and suture materials. Therefore, basic

research on the mechanisms of intestinal healing and the factors affecting it is very crucial<sup>[10]</sup>. Even though wound healing is a complex and dynamic process, it can be divided into three distinct, but at the same time overlapping phases of (1) hemostasis and inflammation, (2) proliferation, and (3) maturation and remodeling<sup>[2]</sup>. Intestinal anastomotic healing differs slightly from the general healing process, as it is a controlled full-thickness injury, followed by reconstitution of luminal integrity with artificial sutures. During this period, an organized

and complex cascade of cellular and biochemical events take place, and many disturbances in any phase of this healing process may result in complications<sup>[11]</sup>.

The first phase of the healing, described as the inflammatory phase is seen on the first 3 d of the healing process. As Steed and Portera *et al* reported, this is the essential phase in which the polymorphonuclear leucocytes (PMNL) migrate from the circulation to the wound<sup>[12,13]</sup>. It is really an essential phase because of the large microorganism content of the colonic

lumen. During the first three-day period, we found the regressive effect of propolis on edema might be by decreasing the level of IL-5 as Leticia *et al* reported<sup>[14]</sup>. The cellular content on the first day were supporting the regression of edema with the rare number of eosinophils. Marcucci and later Krol *et al* studied the antiinflammatory activity of propolis and 19 phenolic compounds<sup>[15,16]</sup>. Also supporting these observations, we found in our study that, while in the control group the PMNLs were leading on the first and third postoperative days, in the propolis group proliferation of fibroblasts began immediately following the decrease in the amount of PMNLs.

Extensive bacterial invasion was well known to impair healing at anastomotic sites. This is most likely secondary to increased PMNLs invasion and activation by microorganisms. Granulocyte collagenase activity of PMNLs' has been implicated at increasing collagen breakdown and delaying the anastomotic healing process. The potential protective effect of propolis may be suggested by our findings of early decreased number of PMNLs and less inflammatory reaction at the anastomotic line and further away during first and third day<sup>[17,18]</sup>.

Propolis has a constructive antibacterial effect besides antiinflammatory properties on bacterial invasion, which plays a crucial role in the healing process. There are a number of studies documenting the antimicrobial functions of propolis, its extracts, and constituents. This is a broad-spectrum activity against Gram-positive and Gram-negative rods and cocci, and viruses<sup>[19]</sup>. Park *et al* tested antimicrobial activity on oral microorganisms<sup>[20]</sup>; and Sosa *et al* observed that propolis samples inhibited the growth of some gram-positive bacteria and *Candida albicans*<sup>[21]</sup>. Kujumgiev *et al* further examined the antibacterial, antifungal, and antiviral activity of propolis from different geographical origins. All the propolis samples were active against the fungal and gram-positive bacterial test strains, and most showed antiviral activity. The antibacterial activities of these samples were very similar, despite differences in their chemical composition<sup>[22]</sup>. We had also shown its protective effect on ileal mucosa and reduced bacterial translocation in an experimental obstructive jaundice model in our previous researches<sup>[23]</sup>. Although the chemical composition of propolis varies depending on the site of its collection, antimicrobial properties seem attributable mainly to the flavonoids pinocembrin, galangin, and pinobanksin<sup>[24]</sup>. Other active compounds are esters of coumaric acid and caffeic acids. Phenylated p-coumaric and diterpenic acids possess antibacterial and cytotoxic activities. Caffeoylquinic acid derivatives show immunomodulatory and hepatoprotective actions and furofuran lignans inhibit the growth of some bacteria<sup>[25]</sup>.

Propolis has been used in the treatment of cutaneous lesions such as burns, wounds, and ulcers. Morales *et al*<sup>[26]</sup> used a hypoallergic formula of propolis and obtained a very satisfactory evolution and cicatrization in cases of wounds with and without infection. A fast cure, shorter treatment period, and less septic complications were

also obtained. The cicatrization was evident between the 4th and 5th day by the early formation of granulation tissue. The antimicrobial capacity was evident with a fast regression of the septic component of the suppurated wound. Claus *et al* reported that, propolis also exhibits immunostimulatory and immunomodulatory effects *in vitro* on macrophages<sup>[27]</sup>, while Kimoto *et al* reported it increases the ratio of CD4/CD8 T cells *in vivo* in mice<sup>[28]</sup>. An intact cellular immune response, particularly of T lymphocytes, is not necessary for the initial phase of wound healing but seems to be essential for a normal outcome of tissue repair. In our study, the propolis group indicated that lymphocytes appear earlier in contrast with the control group. Propolis exerts a wound healing effect by minimizing acute inflammatory exudate and stimulating macrophage and CD4 T lymphocyte activity.

In this study, angiogenesis was remarkable in the propolis group beginning on the third postoperative day; unfortunately, the capillaries were poor in the control group. We know that oxygen is critical for anastomotic wound healing<sup>[2]</sup>. The exact cellular and molecular mechanisms caused by hypoxia, which results in impaired anastomotic healing, are not well understood. While hypoxia may act as an early stimulus for neovascularization, it is unlikely to sustain it. The process of angiogenesis, whereby new capillaries are formed from pre-existing blood vessels, is essential for wound healing<sup>[29]</sup>. At the molecular level of angiogenesis, vascular endothelial growth factor (VEFG) and nitric oxide (NO) are the two key factors that are relevant<sup>[30]</sup>. Tan-no *et al* reported the anti-inflammatory effect of propolis through inhibition of nitric oxide production<sup>[31]</sup> and also Attard *et al* reported the expression of both VEGF and inducible nitric oxide synthase (iNOS) significantly increased at the anastomotic site exposed to a hypoxic environment but the healing was not enhanced<sup>[32]</sup>. These two hypotheses above warrant further evaluation. The molecular mechanisms of angiogenesis and the reflection of it to the healing process are not clearly understood yet; however, we definitely observed new capillary formation in the early period of the propolis group.

Propolis mostly contains flavonoids and phenolic compounds, which have been reported to have antioxidative properties. Due to its antioxidative effects, propolis may protect humans from deleterious oxidative processes. Several groups of authors thus studied the antioxidative properties of propolis and their active constituents<sup>[33-35]</sup>. Propolis may also act as a scavenger against oxygen radicals. Recent studies indicate that propolis is able to inhibit the formation of superoxide anion, which is produced during autoxidation of  $\beta$ -mercaptoethanol<sup>[25]</sup>.

In the healing process, the first phase of inflammation is followed by the second phase, fibroblastic proliferation. Fibroblasts are normally found in the later phases of normal wound healing. They are responsible for the production of collagen and for establishing the structural extracellular matrix. Although

the healing process can be divided into phases as we mentioned before, they are overlapping. The maturation and remodeling phase following the fibroblastic proliferation are very close to each other. Because remodeling of tissue requires the deposition of adequate amounts of extracellular matrix components, particularly collagen fibers, in the wound area. As comprehended, fibroblasts have a key position. Graham *et al* reported, in contrast to dermal tissue, both smooth muscle cells and fibroblasts manufacture collagen in the gastrointestinal tract<sup>[36]</sup>. We know that the bulk of collagen within the intestinal tract is contained within the submucosa since intestinal smooth muscle cells in the lamina propria produce and maintain intestinal collagen. As a result, most of the strength of the intestine is found in the submucosal layer. Furthermore, it is responsible for anchoring the sutures that hold anastomosed bowel ends together<sup>[11]</sup>.

Simpson and Ross reported that, as early as 3 d after wounding, immature fibroblasts could be identified within the wound exudate<sup>[37]</sup>. We observed the fibroblasts on the third postoperative day of the control group, but interestingly, they were present on the first postoperative day of the propolis group. On the first day, possibly they were immature fibroblasts, but on the third day as these cells matured, they acquired the characteristic ultrastructural features of actively synthetic fibroblasts. By day 5, small collagen fibers were observable by electron microscopy within the extracellular spaces; the collagen fibers were distinguishable on the third postoperative day of the propolis group. The collagen fibers were in a spatial arrangement and inclining towards the anastomotic line.

Although healing in the gastrointestinal tract essentially follows the same phases as skin wound healing, our understanding of these events is much more limited. Just as with dermal reepithelialization, if the mucosa is the only injured layer, it can be reformed by migration and proliferation. Full-thickness injury provokes a fibroblastic response resulting in scar formation<sup>[38]</sup>. During the first few postoperative days, anastomotic strength is low, as collagen is degraded secondary to collagenase activity at the site of the injury. Early anastomotic strength is therefore dependent on the suture-holding capacity of existing collagen until large amounts of new collagen can be synthesized by both fibroblasts and smooth muscle cells. The final phase of healing involves maturation of newly formed anastomosis by the transformation of collagen into thick bundles and contractile units<sup>[39]</sup>. In the propolis group, the proliferation, activation, and synthesis capacity of fibroblasts were much better than the control group. As expected, the bridging of the gap between the anastomotic edges as the means of remodeling was completed.

All of the bee products, especially honey, have had a valued place in traditional medicine for centuries. In the last century, researchers rediscovered this old remedy and honey has been of proven value in many pathologies and also in the surgical wound. Honey is

a supersaturated sugar solution which the half of its content is fructose and glucose with other chemical compounds in small quantities like flavonoids and phenolics. Consequently as a bee product, propolis (100 mg/kg per day) is recommended in this study because it is more effective than the same doses of honey (10 g/kg per day)<sup>[7,40]</sup>.

In conclusion, the results of this study clearly demonstrate that, according to the histopathological parameters, administration of propolis, as an additional strategy to surgical excision, accelerated the healing of colon anastomosis. Propolis, a beehive product, possesses a broad spectrum of biological activities including hepatoprotective, antitumour, antioxidative, antimicrobial, and antiinflammatory effects. Current opinion is that the use of standardized preparations of propolis is safe and less toxic than many synthetic products. Our results suggest that propolis enhances not only the early phase of colon anastomotic healing by inhibiting the inflammatory response, but also stimulates the collagen synthesis of fibroblasts. The exact mechanisms of improved anastomotic wound healing by propolis administration are not known, although increase of neoangiogenesis, mononuclear cell infiltration, and the stimulation of collagen synthesis are all involved. These findings may provide insight into potential therapeutic approaches to improve and promote healing of colonic anastomosis and to minimize the morbidity and mortality associated with anastomotic leaks. We conclude that propolis should be further investigated for its capacity to enhance anastomotic healing and to reduce the incidence of the anastomotic dehiscence.

## COMMENTS

### Background

Inadequate healing of colon anastomosis may still be a cause of postoperative morbidity and mortality despite the use of optimal surgical techniques.

### Research frontiers

This study was to evaluate the effect of propolis administration on the healing of colon anastomosis with light and transmission electron microscopes.

### Innovations and breakthroughs

The achievement of this article is to show the stages of anastomotic healing with clear light and electron micrographs without any doubt and draw attention to the cellular mechanisms of the healing. The breakthrough of our experience from the present study is that: propolis which is a natural, cheap and easily obtained material can be used safely in colonic anastomosis.

### Applications

Administration of propolis, as an additional strategy to surgical excision, might be used to accelerate the healing of colon anastomosis and to prevent the anastomotic leakage, in clinical settings.

### Peer review

Our results suggest that propolis enhances not only the early inflammatory phase of colon anastomotic healing but also stimulates the collagen synthesis of fibroblasts. These findings may provide a new insight into potential therapeutic approaches to improve and promote healing of colonic anastomosis.

## Abstract

**AIM:** To evaluate the prevalence of metabolic syndrome (MS), obesity and type 2 diabetes mellitus (T2DM) in a group of Mexican Mestizo patients with cryptogenic cirrhosis (CC) and to compare this group with patients with cirrhosis secondary to other causes (disease controls).

**METHODS:** Patients with CC, diagnosed between January, 1990 and April, 2005, were included in a retrospective study. Patients with cirrhosis caused by chronic hepatitis C, alcohol abuse or autoimmune hepatitis (AIH) served as disease controls.

**RESULTS:** A total of 134 patients with CC were analyzed. Disease controls consisted of 81 patients with chronic hepatitis C, 33 with alcohol abuse and 20 with AIH. The median age of patients with CC was 57 years (range, 16-87); 83 (61.9%) patients were female; 53 (39.6%) were Child A, 65 (48.5%) Child B, and 16 (11.9%) were Child C cirrhosis. The prevalence of MS (29.1% vs 6%;  $P < 0.001$ ), obesity (16.4% vs 8.2%;  $P = 0.04$ ) and T2DM (40% vs 22.4%;  $P = 0.013$ ) was higher in CC patients than in disease controls. There were no differences in sex, age or liver function tests between the two groups.

**CONCLUSION:** The prevalence of MS, obesity

and T2DM were higher in patients with CC than in patients with cirrhosis secondary to others causes. Our findings support the hypothesis that non-alcoholic steatohepatitis (NASH) plays an under-recognized role in CC.

Prevalence of metabolic syndrome, obesity and diabetes type 2 in cryptogenic cirrhosis. *World J Gastroenterol* 2008; 14(30): 4771-4775 Available from: URL: <http://www.wjgnet.com/1007-9327/14/4771.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.4771>

## INTRODUCTION

The diagnosis of "cryptogenic" cirrhosis is made after an extensive evaluation has excluded recognizable etiologies<sup>[1]</sup>. The prevalence of cryptogenic cirrhosis (CC) ranges from 5% to 30% in cirrhotic patients<sup>[1]</sup>. In Mexico, the etiology of cirrhosis remains unclear in 10% patients despite an extensive evaluation<sup>[2]</sup>. Several etiological possibilities are offered in such patients. These include occult alcohol abuse, silent autoimmune hepatitis (AIH), occult viral (non-B, non-C) hepatitis, and progression of nonalcoholic steatohepatitis (NASH)<sup>[3]</sup>.

The prevalence of clinically silent autoimmune hepatitis in patients with CC is unknown; however, several studies have suggested that a significant number of patients with CC may have burnt-out AIH<sup>[4-6]</sup>. Occult virus disease (Non-B, non-C hepatitis) is considered to account for about 15% of post-transfusion hepatitis<sup>[7]</sup> and may exist in a silent form for several years<sup>[8]</sup>. Obesity and non-insulin dependent diabetes mellitus are the

two most common conditions associated with NASH<sup>[9]</sup>, which is frequently asymptomatic<sup>[10]</sup> and can progress silently to cirrhosis with definitive histological features<sup>[10]</sup>.

The aim of the present study was to characterize the metabolic disturbances [prevalence of metabolic syndrome (MS), obesity and type 2 diabetes mellitus (T2DM)] in a group of Mexican Mestizo patients with CC. In particular, we compared the prevalence of metabolic disturbances in the cryptogenic group with patients with cirrhosis due to other causes: hepatitis C without prior alcoholism, alcohol abuse and AIH.

## MATERIALS AND METHODS

In a retrospective manner, we examined the medical records (paper and electronic-based records) of all patients with CC diagnosed from January, 1990 to April, 2005. We also included in a random fashion, disease controls consisting of patients with cirrhosis caused by chronic hepatitis C, alcohol abuse and AIH.

Diagnosis of CC was made after an exhaustive evaluation failed to provide a specific etiology. The data collected included the hepatologic diagnosis, comorbid conditions, complications of portal hypertension if present, and major forms of treatment. Additional information was obtained from clinical charts, hospital records, the clinic and hospital laboratory databases, and by personal or telephone interview. Patients were included in the study if sufficient data was available and if the diagnosis was confirmed on review of all the available information.

The diagnosis of cirrhosis was made on the basis of clinical, laboratory and imaging data. In addition, histological findings were available in 56 (42%) CC patients. Biopsy was not performed in 78 patients, either because of refusal by the patient or their in-charge physician. Data collected included gender, age at diagnosis of cirrhosis, presenting symptoms, potential occupational exposure to hepatotoxins, family history of liver disease, and family or personal history of autoimmune diseases. Risk assessment for viral hepatitis included history of exposure to intravenous drugs, blood transfusions, tattoos, other known percutaneous needle exposures, and high-risk sexual behavior. All patients underwent extensive serological testing including hepatitis B and C screening [hepatitis B surface antibody, surface antigen, and anticore antibody, and hepatitis C enzyme-linked immunosorbent assay (Abbott Laboratories, Abbott Park, IL)], iron studies (ferritin, iron, iron binding capacity, and tissue assessment if the diagnosis was questionable), ceruloplasmin, antinuclear antibody (ANA), antimitochondrial antibody, and  $\alpha$ 1-antitrypsin. Quantitative immunoglobulin levels (IgG, IgM, IgA) were obtained in all patients. Assessment of  $\alpha$ 1-antitrypsin level was performed using isoelectric focusing (pH range, 4.0-5.0).

Patients with CC who had a positive antinuclear antibody (positive > 1:80) test, an index of autoimmune hepatitis, were evaluated by the International Autoimmune Hepatitis (IAH) score, based on clinical

and laboratory parameters as previously described<sup>[11]</sup>. None of the patients received steroid therapy, and thus the IAH score was calculated using the Minimal Required Parameters, wherein a score of 10 to 15 is suggestive of autoimmune hepatitis, and a score of greater than 15 is considered definitive. The term overweight was defined as body mass index (BMI) greater than 25, while obesity was defined as a BMI greater than 30. BMI was calculated by dividing the patients' body weight by the square of their height expressed as kg/m<sup>2</sup>. BMI was calculated using the average adult weight reported by the patient and the patient's height. In all cases, type 2 DM was diagnosed by the presence of recurrent fasting hyperglycemia ( $\geq 126$  mg/dL), requiring treatment with dietary management, oral hypoglycemic agents, or insulin therapy. Dyslipidemia was considered in the presence of high serum triglycerides ( $> 150$  mg/dL) and/or low high-density lipoproteins ( $< 50$  mg/dL in women and  $< 40$  mg/dL in men). The diagnosis of MS was made according to the NCEP (ATP) III consensus<sup>[12,13]</sup>.

The absolute and relative frequencies were used for summary. The data is presented as mean  $\pm$  SD. The one-way ANOVA test or Kruskal-Wallis was used to compare parametric or nonparametric variables, respectively. The  $\chi^2$  test was used for categorical variables. A *P* value ( $\alpha$ ) of  $< 0.05$  was considered significant. Bonferroni correction for *P*-value was applied for multiple comparisons, calculated as  $\alpha/n$ . For multiple comparisons a *P* value of  $< 0.016$  was considered significant. All statistical analyses were conducted using the statistics program SPSS/PC version 12.0 (Chicago, IL, USA).

## RESULTS

After careful review of the medical records, 50 patients who were originally classified as CC in the hospital registry were found to have other causes of liver disease. The main reason for this discrepancy was incomplete investigation or erroneous interpretation of the test results when the patients were referred to our center. These patients were initially listed as CC, but the diagnosis was not corrected in the registry when the new information became available. Other less common reasons for patient exclusion were incomplete medical information and indeterminate test results. For the final analysis, a total of 134 patients with CC were included in the study. In addition, EIGHTY ONE patients with chronic hepatitis C, thirty-three with alcohol abuse and twenty with AIH were evaluated as disease controls. The demographic, clinical, and laboratory characteristics of the study subjects are summarized in Table 1. In patients with CC, the median age was 57 years (range 16-87); 83 (61.9%) were female; and 53 (39.6%) had Child A cirrhosis, 65 (48.5%) were Child B and 16 (11.9%) were Child C.

Five patients were determined to have moderate alcohol consumption (< 2 drinks/d), but this was not considered to be the cause of their liver disease, either by the hepatologist or their primary care physician. None of the patients had a history of intravenous drug

**Table 1 Demographic, clinical and laboratory parameters of patients with cryptogenic cirrhosis and non-cryptogenic cirrhosis**

Variable	Cryptogenic (n = 134, %)	Non-cryptogenic (n = 134, %)	P
Sex (female)	83 (62)	75 (56)	0.32
DM	53 (40)	30 (22.4)	0.013
HBP	24 (18)	14 (10.4)	0.08
Hyperuricemia	13 (10)	2 (1.5)	0.003
Dyslipidemia	72 (54)	8 (6)	< 0.001
Overweight (BMI > 25)	103 (77)	106 (79)	0.65
Obesity (BMI > 30)	22 (16.4)	11 (8.2)	0.04
MS	39 (29.1)	8 (6)	< 0.001
Age (yr, mean ± SD)	54.6 ± 14.3	56.8 ± 11.4	0.15
BMI (mean ± SD)	27 ± 4.6	26 ± 4	0.22
ALT (U/L, mean ± SD)	52.5 ± 59	57.5 ± 33	0.72
AST (U/L, mean ± SD)	67.1 ± 60	77.8 ± 46	0.19

DM: Diabetes mellitus; HBP: High blood pressure; BMI: Body mass index (calculated as patient's body weight divided by the square of the height expressed in kg/m<sup>2</sup>); MS: Metabolic syndrome.

use. Seven patients had a history of blood transfusions, but none of them had hepatitis C or hepatitis B virus infections. Seven patients had a positive family history of liver disease. A positive antinuclear antibody test was present in 13 patients (10%), but a definite score for autoimmune hepatitis was not present in any patient. Serum α1-antitrypsin deficiency was assessed in 6 patients. However, none of the patients had biochemical or histological evidence of α1-antitrypsin deficiency. Serum ferritin and iron saturation tests were measured in all patients and were within normal/non-diagnostic limits. Genetic testing for hemochromatosis was not performed, and thus carriage of abnormal alleles cannot be excluded. There was no difference in the liver function tests or the Child Pugh score between patients with CC who had a liver biopsy (n = 56, 42%) and those did not (n = 78, 58%). However, patients without liver tissue examination had higher prevalence of metabolic disturbances (Table 2).

The prevalence of MS, obesity and T2DM were greater in CC patients compared to patients without CC (Table 1). When patients without CC were classified by etiology (hepatitis C, alcohol, and AIH), significant differences in MS prevalence were observed: 6.2% in hepatitis C, 6% in patients with alcohol abuse, and 5% in AIH vs 29.1% in CC patients (P < 0.001). The differences in the prevalence of T2DM persisted, but when Bonferroni correction for multiple-comparison was used, only obesity showed a statistical trend (Table 3). The prevalence of the different components of MS were analyzed separately; Dyslipidemia (P < 0.001) and abnormal glucose (P = 0.01) were more common in CC patients than in disease controls, while high blood pressure (HBP) showed a trend towards significance (P = 0.08). Hyperuricemia was more frequent in CC patients (10% vs 1.5%, P = 0.003).

## DISCUSSION

The present study shows a high prevalence of MS,

**Table 2 Comparison of patients with cryptogenic cirrhosis with and without liver tissue examination**

Variable	Liver biopsy (n = 56, %)	No liver biopsy (n = 78, %)	P
Sex (female)	37 (66)	46 (59)	0.47
DM	13 (23)	40 (51)	0.001

DM: Diabetes mellitus; HBP: High blood pressure; BMI: Body mass index (calculated as patient's body weight divided by the square of the height expressed in kg/m<sup>2</sup>); MS: Metabolic syndrome.

obesity, and T2DM in Mexican Mestizo population with CC. The relationship between T2DM, obesity, and cirrhosis has been much debated<sup>[14-17]</sup>. To our knowledge, this is the first study that shows an association between MS and CC. There is less controversy regarding an association between MS, obesity, T2DM, and NASH<sup>[18]</sup>, and several previous studies have shown a relationship between components of MS and NASH as well as the severity of liver fibrosis<sup>[19-21]</sup>. MS is a worldwide problem with a high prevalence rate<sup>[22]</sup>, and in agreement with our data this abnormality, along with some of its components, is more frequent in CC than in patients with cirrhosis caused by other etiologies. This finding is very important because it provides further evidence to support the theory that NAFLD/NASH can progress to cirrhosis in some patients.

The prevalence of MS was 500% higher in patients with CC compared to patients without CC. When the prevalence of each of the MS components in patients with and without CC was analyzed, only abnormal glucose values and Dyslipidemia showed statistically significant differences between the two groups (Table 1). There was no difference between the two groups with respect to the prevalence of HBP and being overweight. This may be related to the hemodynamic changes and malnutrition, seen commonly in cirrhotic patients. The mean ± SD of HDL and triglyceride levels in CC patients were similar in women (43.4 ± 10.9 mg/dL and 92.4 ± 49 mg/dL) and men (39.5 ± 8.5 mg/dL and 111.3 ± 59 mg/dL). Both of these test values were abnormal when the NCEP guidelines were taken into consideration (abnormal HDL serum levels < 50 mg/dL for women and < 40 mg/dL for men); prevalence of low HDL levels was seen in 76.7% women and 41.5% men. An observation not previously reported is the finding of higher prevalence (statistically significant) of hyperuricemia in CC compared to disease controls. Hyperuricemia is not accepted as

CHC: Cirrhosis by hepatitis C virus; AIH: Autoimmune hepatitis; DM: Diabetes mellitus; HBP: High blood pressure; BMI: Body mass index (calculated as patients' body weight divided by the square of the height expressed in kg/m<sup>2</sup>); MS: Metabolic syndrome.

a criterion of MS; however, it is a common metabolic disturbance in this group of patients. We believe that the higher prevalence of hyperuricemia in CC may be another piece in the puzzle in the relationship between MS, NASH and cirrhosis.

In 1999, Caldwell *et al*<sup>[17]</sup> described the prevalence of obesity and T2DM in 70 patients with CC, and compared the findings with three patient groups: NASH, cirrhosis with hepatitis C, and primary biliary cirrhosis (PBC). The prevalence of these risk factors (obesity and T2DM) were similar between patients with NASH and patients with CC, both of which had a higher prevalence compared to patients with hepatitis C and PBC. In another study by Poonawala *et al*<sup>[16]</sup>, the prevalence of obesity and T2DM in patients with CC was compared with the prevalence in control patients. The various causes of cirrhosis in the control group were alcohol, chronic viral hepatitis, AIH, PBC and primary sclerosing cholangitis. Similar to the findings by Caldwell *et al*<sup>[17]</sup>, the prevalence of obesity (55% vs 24%) and T2DM (47% vs 22%) were significantly higher in patients with CC compared with disease controls. Both authors concluded that their data supported the hypothesis that NASH may be an etiological factor in some of the patients with CC<sup>[16,17]</sup>. We obtained similar results, but in a different population (Mexican Mestizo) and with a bigger sample size. When we classified the patients as CC vs no CC, important differences in the prevalence of obesity and T2DM were observed (16.4% vs 8.2% and 40% vs 22.4%, respectively). However, when patients without CC were classified by etiology, only the prevalence of T2DM was statistically significant (Table 3). With respect to obesity, the prevalence between CC and patients with cirrhosis secondary to alcohol abuse was similar, and both showed a higher frequency than patients with cirrhosis due to hepatitis C and AIH.

An interesting finding in the present study was that patients with CC without a liver biopsy had greater prevalence of MS, obesity and T2DM compared with patients with CC who had a liver biopsy, despite similar liver function tests. This finding may be related to the

presence of metabolic disturbances, suggesting to the physician the diagnosis of CC secondary to NASH; thus creating a different situation from patients with CC without metabolic disturbances.

The present study suffered from some limitations. First, the study design. Second, we did not record the waist circumference for the diagnosis of MS, but used BMI as a substitute for waist circumference. The use of BMI may have had a small impact on the number of cases diagnosed with MS, since there is a strong correlation between these parameters ( $r = 0.8$ )<sup>[23,24]</sup>. We recognize that this may have resulted in underestimating the number of cases that fulfilled the NCEP definition.

In conclusion, the prevalence of MS, obesity and T2DM in patients with CC is higher than that seen in patients with cirrhosis secondary to others causes. Moreover, the prevalence of hyperuricemia was higher in patients with CC compared to patients with cirrhosis secondary to others causes, a finding not reported previously. Our results support the hypothesis that NASH plays an under-recognized role in some patients with CC.

## COMMENTS

### Background

Nonalcoholic steatohepatitis (NASH) is the main etiology suspected in patients with Cryptogenic Cirrhosis (CC). The association of NASH with Metabolic Syndrome (MS) is well-known; however, the association of CC with MS has not been well examined.

### Research frontiers

The possible association of MS and CC remains unknown.

### Innovations and breakthroughs

This study shows an association between MS with CC, and raises the possibility of an under-recognized role of NASH in CC.

### Applications

Further prospective studies may clarify the association between MS and CC.

### Peer review

The findings in the present study imply that non-alcoholic steatohepatitis is frequently associated with cryptogenic cirrhosis. This paper is well written and the results suggest an under-recognized role of NASH in patients with cryptogenic cirrhosis.

Modification of end-loop ileostomy for the treatment of ischemic or radiation enteritis. *World J Gastroenterol* 2008; 14(30): 4776-4778 Available from: URL: <http://www.wjgnet.com/1007-9327/14/4776.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.4776>

### INTRODUCTION

Fecal diversion by colostomy or ileostomy represents an important treatment in colorectal surgery. Fecal diversion may be either temporary for decompression, or permanent for palliation. The indications for fecal diversion include inflammatory bowel diseases, familial adenomatous polyposis, colorectal carcinoma, nongastrointestinal obstructing tumors, pelvic sepsis, trauma, diverticulitis, fistulas, ischemic bowel disease, radiation enteritis, pseudomembranous enterocolitis, fecal incontinence and paraplegia<sup>[1]</sup>.

An ileostomy may be performed as an end stoma, or as a loop stoma constructed either for decompression of the gastrointestinal tract or for the protection of a distal colonic anastomosis. The majority of loop ileostomies are performed as a temporary treatment, except for those performed for palliation (i.e. non-respectable tumors in patients with low expected survival)<sup>[2-5]</sup>. Occasionally, a small bowel stoma is required in patients with high risk of small intestinal anastomosis.

In this report, we present a new technique of ileal anastomotic stoma, following small bowel resection, in patients in whom the anastomosis is anticipated to have borderline margins with dubious viability. These include patients with mesenteric ischemia, radiation induced stenosis or fistulas, bowel necrosis due to hernias or adhesions, intestinal trauma and necrotizing enterocolitis in children<sup>[6]</sup>.

### MATERIALS AND METHODS

Five patients underwent enterectomy and partially anastomosed end-loop ileostomy at the University

### Abstract

**AIM:** To evaluate a new technique of temporary ileal anastomotic stoma, following small bowel resection, in patients where the anastomosis is anticipated to have borderline margins with dubious viability.

**METHODS:** Five patients underwent enterectomy and partially anastomosed end-loop ileostomy at the University Hospital of Larissa between 2000 and 2006. Enterectomy was performed because of conditions such as mesenteric vascular occlusive disease, radiation enteritis and small bowel injury.

**RESULTS:** Postoperatively, none of the patients developed any stoma-related or anastomotic complications. There were no major complications. All patients were discharged between the 8th and 15th day after the procedure, and the stoma was closed 3 wk to 4 wk later.

**CONCLUSION:** We believe that our proposed modification of end-loop ileostomy is a simple, quick and safe technique with minimal stoma-related morbidity, and with simple and safe reversion. This technique can be considered as a useful option in the treatment of ischemic or radiation-induced enteritis, and in the management of severe intestinal trauma.

**Key words:** Anastomotic stoma; Loop ileostomy; Ischemic enteritis; Radiation enteritis

**Table 1** Clinical characteristics of the study patients

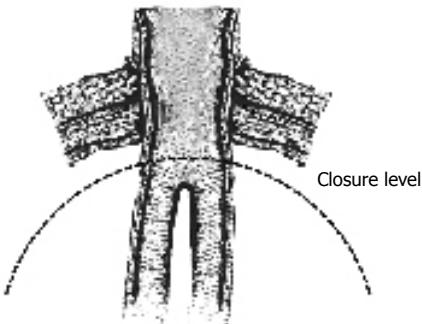

Patient	Age/Sex	Diagnosis	Procedure	Time of stoma closure (wk)
1	65/F	Radiation enteritis ileal obstruction	50 cm small bowel resection	4
2	71/F	Radiation enteritis ileal obstruction	60 cm small bowel resection	4
3	74/F	Intestinal ischemia	60 cm small bowel resection	3
4	72/M	Intestinal ischemia	80 cm small bowel resection	4
5	52/M	Blunt abdominal injury, ileal rupture	50 cm small bowel resection	3

**Figure 1** Afferent and efferent limbs brought out together.**Figure 2** Side-to-side anastomosis performed, with the blind end forming a stoma.

Hospital of Larissa between 2000 and 2006. The patient's mean age at stoma formation was 66 years (range, 52-74 years). There were three female and two male patients, and all were Caucasian. Enterectomy was performed secondary to mesenteric vascular occlusive disease, radiation enteritis and small bowel injury. The clinical characteristics of patients are shown in Table 1.

Following resection of the diseased intestinal segment, the afferent and efferent limbs were anastomosed side-to-side using a GIA 100-38 linear stapler (Autosuture, Norwalk, Connecticut, USA; Figure 1). The common blind end remained open and was brought out as a stoma (Figure 2). Using this technique the integrity and the viability of both limbs could be inspected and both the proximal and distal bowel loops were vented.

Closure of the enterostomy is a simple procedure that can be performed under local anesthesia and sedation. The common blind end-stoma was mobilized from the skin, subcutaneous tissue and fascia and was closed just below the fascia level using a TA-55 stapler (Autosuture, Norwalk, Connecticut, USA).

**Figure 3** Closure of the blind end stoma results in a patent side-to-side anastomosis.

The short amputation of the common limb (4-5 cm) enabled side-to-side anastomosis to restore anatomic continuity without sacrificing any length of the intestines (Figure 3).

Closure of the stoma was accomplished in 3 wk to 4 wk. Direct inspection of both limbs of the already fashioned side-to-side anastomosis was possible during that period.

## RESULTS

Postoperatively, none of the patients developed any stoma-related or anastomotic complication. There were no major complications. Two of the five patients developed a mild wound infection which was managed conservatively with local measures. All patients were discharged between the 8th and 15th day after the procedure and the stoma was closed 3 wk to 4 wk later.

## DISCUSSION

Small bowel enterostomies are occasionally required following emergent small bowel resection in conditions such as bowel ischemic, and inflammatory or traumatic disorders. The clinical setting of these patients requires a quick and safe procedure preserving as much of the intestinal length as possible. A small intestinal diverting stoma, however, carries significant morbidity, mostly due to fluid, electrolyte and nutrient imbalance. Furthermore, the restoration of intestinal continuity usually requires meticulous dissection of the afferent and efferent segments and the formation of a new anastomosis, usually under general anesthesia.

Even a loop or "end loop" stoma requires an anastomosis for its closure, as well as peritoneal breaching for the intraabdominal position of the anastomotic segment.

Because of the aforementioned reasons, closure itself is associated with complications such as small bowel obstruction (0%-15%), anastomotic leak (0%-8%), fistula formation (0%-7%), wound infection (up to 18%) and development of hernia at the stoma site (1%-12%)<sup>[7,8]</sup>.

Finally, morbidity related to general anesthesia should also be taken into consideration, because the majority of these patients have poor general health and nutritional status secondary to the underlying medical disorders<sup>[9]</sup>.

A special variant of ileal stoma was first described by Bishop, in 1957, for the treatment of meconium ileus, and shortly afterwards by Santuli, in 1961, for the treatment of congenital atresia of the intestines in pediatric patients. After resection of the diseased bowel, either the distal (Bishop) or the proximal (Santuli) limb is brought out as a stoma, while the remaining limb is anastomosed end-to-side to the former, a few centimeters below the abdominal wall, in order to avoid creating a blind loop. These stomas provide satisfactory decompression of the proximal bowel, along with the passage of some amounts of intestinal content into the distal limb. Although the construction of such stomas is rather demanding, they have the advantage of easy closure, even under local anesthesia.

However, the presence of an intrabdominal anastomosis carries several risks such as obstruction, breakdown, leakage and sepsis. Nevertheless, the Santuli enterostomy, the mirror image of the Bishop procedure, has been reported to be efficacious in adult patients as well, in conditions such as mesenteric ischemia, bowel necrosis due to an incarcerated hernia and trauma<sup>[10-12]</sup>.

In the present study, we modified the anastomotic stoma, a "partially anastomosed end-loop ileostomy" for the treatment of adult patients, who presented with conditions such as small intestinal necrosis due to extended mesenteric vascular occlusive disease, radiation-induced stenosis, and intestinal trauma with macroscopically borderline margins with respect to the viability of the intestinal wall after extended bowel resection. In order to preserve as much length of the small intestine as possible, and also to protect the terminal ileum, we constructed a side-to-side anastomosis between the remaining bowel limbs and fastened the common blind end as a stoma. Thus, spontaneous decompression was achieved along with the ability to easily inspect the bowel integrity through the stoma. Furthermore, both limbs were vented, and the distal limb received bowel contents within 48 h, minimizing massive intestinal fluid loss. Thus, we created a low output ileo-cutaneous fistula. The formation of the anastomosis in a side-to-side fashion provides richer blood supply, augmenting the viability of its intrabdominal portion. Moreover, the procedure requires less time than an end-to-side anastomosis. The formation of such a stoma was simple and quick, with no risk of stenosis or kinking. We believe that the short duration of our technique is an important advantage since operative time is a critical factor in the survival of these patients (urgent cases, unstable patients, "damage control" in trauma)<sup>[6]</sup>.

In addition, closure of the stoma can be performed easily and quickly under local anesthesia, by mobilizing the common limb from the abdominal wall and stapling it just below the fascia without entering the abdominal cavity. Moreover, it can be performed within 4 wk, since the integrity of the intestine can be assured by direct inspection of both limbs.

We believe that our proposed modification of end-loop ileostomy is a simple, fast and safe technique

with minimal stoma-related morbidity, and with simple and safe reversion. It should be considered as a useful treatment option in patients with ischemic and radiation-induced enteritis, and in the management of severe intestinal trauma.

## COMMENTS

### Background

Enterostomies are usually high output stomas, that often result in fluid and electrolyte depletion.

### Research frontiers

A variety of techniques have been proposed for the formation of a low morbidity ileostomy.

### Innovations and breakthroughs

Our technique is a combination of a low output stoma and an anastomosis with minimal risk of rupture.

### Applications

This technique should be taken into consideration in patients who are at a high risk of small bowel resection such as those with ischemic and radiation enteritis. We believe that our technique provides a fast, simple and safe surgical treatment of patients with small bowel necrosis.

### Peer review

Our proposed modification of end-loop ileostomy appears to be simple, fast and safe technique with minimal stoma-related morbidity, and with simple and safe reversion. It should be considered as a useful option in the treatment of ischemic and radiation-induced enteritis, and in the management of severe intestinal trauma.

### Abstract

**AIM:** To determine whether thalidomide prevents microvascular injury in acute radiation proctitis in white rats.

**METHODS:** Fourteen female Wistar rats were used: six in the radiation group, six in the thalidomide group, and two in normal controls. The radiation and thalidomide groups were irradiated at the pelvic area using a single 30 Gy exposure. The thalidomide (150 mg/kg) was injected into the peritoneum for 7 d from the day of irradiation. All animals were sacrificed and the rectums were removed on day 8 after irradiation. The microvessels of resected specimens were immunohistochemically stained with thrombomodulin (TM), von Willebrand Factor (vWF), and vascular endothelial growth factor (VEGF).

**RESULTS:** The microscopic scores did not differ significantly between the radiation and thalidomide groups, but both were higher than in the control group. Expression of TM was significantly lower in

the endothelial cells (EC) of the radiation group than in the control and thalidomide groups ( $P < 0.001$ ). The number of capillaries expressing vWF in the EC was higher in the radiation group ( $15.3 \pm 6.8$ ) than in the control group ( $3.7 \pm 1.7$ ), and the number of capillaries expressing vWF was attenuated by thalidomide ( $10.8 \pm 3.5$ ,  $P < 0.001$ ). The intensity of VEGF expression in capillaries was greater in the radiation group than in the control group and was also attenuated by thalidomide ( $P = 0.003$ ).

**CONCLUSION:** The mechanisms of acute radiation-induced proctitis in the rats are related to endothelial cell injury of microvessel, which may be attenuated with thalidomide.

### INTRODUCTION

Radiation therapy is performed widely in the suppression of the growth of malignant tumors, but it is occasionally accompanied by acute or late complications. Acute radiation injury to the intestine induces mucosal inflammation and damage to the endothelial cells (EC) of microvessels<sup>[1,2]</sup>. In radiation enteropathy, there may be a causal relationship between EC apoptosis and crypt cell apoptosis<sup>[3]</sup>. In addition to EC damage, increased chemotaxis and thrombogenesis of damaged vessels are the main mechanisms causing radiation enteropathy<sup>[1,3-6]</sup>. These events are related to complex molecular mechanisms involving many kinds of cytokines in the coagulation system, including thrombomodulin

(TM)<sup>[1,3,4]</sup>. In inflammatory bowel disease (IBD), microvascular inflammation also plays a crucial role in the pathogenesis<sup>[7]</sup>.

In studies of IBD, thalidomide has been used to treat both animal models of colitis and human refractory Crohn's disease. Thalidomide suppresses the production of many kinds of cytokines including tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ) and it also suppresses angiogenesis<sup>[8-12]</sup>. Angiogenesis, or new vessel formation, is considered a novel target of therapy for IBD<sup>[7,13-15]</sup>. The factors promoting angiogenesis in IBD are tissue hypoxia and many kinds of cytokines secreted by infiltrating inflammatory cells<sup>[13]</sup>. We investigated the expression of von Willebrand factor (vWF), TM and vascular endothelial growth factor (VEGF) in acute radiation-induced proctitis and the response to thalidomide treatment.

## MATERIALS AND METHODS

### **Experimental animals**

Fourteen 10-wk-old female Wistar rats (body weight, 220-300 g) were used as the experiment subjects. White rats were purchased from Charles River Japan (Kanagawa, Japan), maintained in a standard steel net cage for 7 d (12-h light and dark cycle) at 24°C, and fed with standard animal feed and water. Three groups were assigned randomly: six animals were assigned to the radiation group, six animals to the thalidomide group, and two animals to the control group. Both the radiation group and thalidomide group were irradiated in the pelvic area with 30 Gy as a single dose. For the thalidomide group, thalidomide was dissolved in dimethyl sulfoxide at 10 mmol/L, and 150 mg/kg thalidomide was injected intraperitoneally for 7 d from the day of irradiation. On day 8 after irradiation, all animals were killed under anesthesia by injecting pentobarbital (40 mg/kg) and the rectum was removed from each animal.

### **Microscopic examination**

The rectum was resected and examined macroscopically and then fixed in 10% formalin. The sample was dehydrated with ethanol, 7  $\mu$ m-thick paraffin sections were cut, paraffin removed with xylene, and the sections stained with hematoxylin-eosin and examined. For microscopic examination, the hematoxylin-eosin-stained samples were evaluated by a pathologist who was unaware of the groups or treatment. Each sample was scored into one of five stages<sup>[16]</sup> as 0 = normal; 1 = slight radiation damage, mild inflammation or slight crypt change; 2 = mild damage, more significant inflammation, or crypt change; 3 = moderate damage, loss of epithelium, degree of inflammation variable; and 4 = severe damage (ulcers, necrosis).

### **Immunohistochemical staining**

Tissue samples were immunohistochemically stained according to the manufacturer's protocols for TM using a polyclonal antibody (1:100; Santa Cruz, CA, USA), for vWF using a polyclonal antibody (1:600; Abcam PLC, Cambridge, UK), and for VEGF using a rabbit

polyclonal IgG (1:300; Santa Cruz, CA). The intensity of VEGF and TM expression in endothelial cells of microvessels was measured separately at the mucosa and submucosa, and it was scored into one of four grades (none, weak, moderate, strong). Expression of vWF was measured quantitatively by observing five random areas of stained microvessels under the light microscope in both the mucosa and the submucosa, and is presented as the mean  $\pm$  SD<sup>[17,18]</sup>.

### **Statistical analysis**

Parametric data were analyzed by Student's unpaired *t* test, and nonparametric data were analyzed by *F* test. *P* value less than 0.05 was considered significant.

## RESULTS

### **Histological findings**

All rats in the radiation and thalidomide groups showed grade 2-3 pathology, and this differed noticeably from the control group. The pathology (i.e. the change of crypt, the level of mucosal inflammation, and the infiltration of inflammatory cells) was more severe in the radiation and thalidomide groups than in the control group. The scores of the microscopic findings did not differ significantly between the radiation group ( $2.3 \pm 0.5$ ) and the thalidomide group ( $2.5 \pm 0.4$ ).

### **TM expression**

The EC of normal controls showed only strong (3/4) and moderate (1/4) expression of TM. In the radiation group, there was weak (58%, 7/12) or no (42%, 5/12) TM expression with no samples of strong or moderate TM expression. The thalidomide-treated group showed moderate TM expression in 50% (6/12) of samples and strong expression in 50% (6/12) of samples. TM expression was significantly greater in the control and thalidomide groups than in the radiation group (*P* < 0.001, Table 1, Figure 1).

### **Intensity of vWF expression**

The mean number of capillaries expressing vWF in both the mucosa and submucosa was  $3.7 \pm 1.7$  in the control group,  $15.3 \pm 6.8$  in the radiation group, and  $10.8 \pm 3.5$  in the thalidomide group (*P* < 0.001). The radiation-induced capillary damage was significantly greater in the radiation group than in the control group, and the damage was reduced by thalidomide treatment (Figure 2).

### **Intensity of VEGF expression**

VEGF expression was weak in all capillaries (4/4, 100%) of the control group. Most capillaries of the radiation group (11/12, 92%) had moderate expression except one severe case. Capillaries of the thalidomide group had weak (7/12, 58%) or moderate expression (5/12, 42%, *P* = 0.003; Table 1, Figure 3).

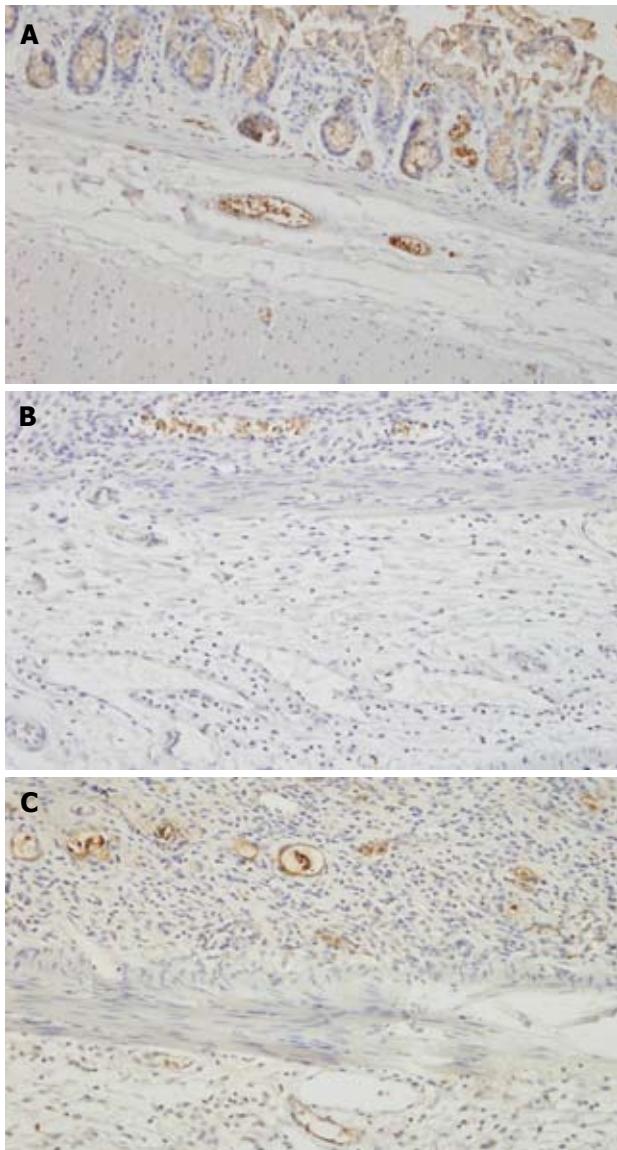

## DISCUSSION

Acute radiation injury induced histological changes

**Table 1** The intensity of TM and VEGF expression in EC in the mucosa and submucosa

	Control group				Radiation group				Thalidomide group				<i>P</i>
	0	+	++	+++	0	+	++	+++	0	+	++	+++	
TM	0	0	1	3	5	7	0	0	0	0	7	5	< 0.001
VEGF	0	4	0	0	0	0	11	1	0	7	5	0	0.003

0: None; +: Weak; ++: Moderate; +++: Strong expression.

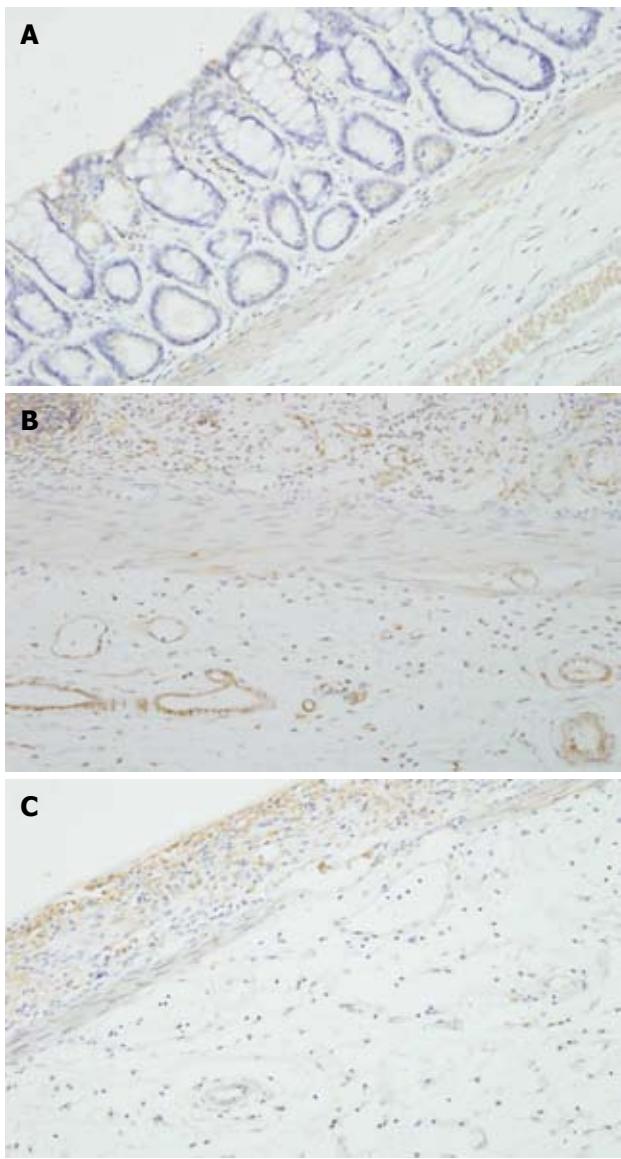

**Figure 1** Immunohistochemical staining of TM (thrombomodulin) expression in the endothelial cells of the mucosa and submucosa. The intensity of TM expression in capillaries is significantly higher in the control group (A) and thalidomide group (C) than in the radiation group (B) ( $\times 200$ ).

including edema, hyperemia, crypt abscess, ulcers, and necrosis of the intestine. It is thought that both acute and chronic radiation injury results from tissue ischemia secondary to thrombogenesis induced by thrombin formation in microvessels<sup>[1,6]</sup>. This loss of endothelial thromboresistance in radiation enteropathy may be related to the actions of many kinds of molecular markers such as tissue factor, vWF, platelet activating factor, TM, and prostacyclin 1<sup>[1,3-6]</sup>.

**Figure 2** Immunohistochemical staining of vWF expression in the endothelial cells of the mucosa and submucosa. Both the total number of microvessels and the number of vWF expressing microvessels are markedly higher in the radiation group (B) than in the control group (A), which are attenuated in the thalidomide group (C) ( $\times 200$ ).

In this study, the expression of TM in the EC was significantly lower in the radiation group than in the control group. These findings are consistent with previous studies suggesting that the mechanism of radiation-induced injury is related to endothelial thrombogenesis<sup>[1,6,19,20]</sup>. This reduced expression of TM in radiation group was restored by treatment with thalidomide. It is known that thalidomide treatment

**Figure 3** Immunohistochemical staining of VEGF expression in the endothelial cells of the mucosa and submucosa. The number of VEGF-positive microvessels and the intensity of VEGF expression were significantly higher in the radiation group (**B**) than in the control (**A**) and thalidomide (**C**) groups ( $\times 200$ ).

suppresses the increase in myeloperoxidase activity and production of TNF- $\alpha$ , interleukin-1 $\beta$ , and intercellular adhesion molecule-1 in an animal model of dinitrobenzene sulphonic acid-induced colitis and *in vitro* model via nuclear factor- $\kappa$ B signaling<sup>[10,12,21,22]</sup>. We found here that thalidomide treatment increased the TM expression in the EC of acute radiation proctitis. This finding might be due to the suppression of inflammatory cytokines including TNF- $\alpha$  by thalidomide. However, thalidomide may rarely cause thrombogenesis as a side effect when used in the treatment of multiple myeloma, although the underlying mechanism is not clear<sup>[23-26]</sup>. In our study, thalidomide seemed to contribute to thromboresistance rather than to thrombogenesis. If thalidomide is used to prevent radiation injury in the future, the clinician should consider that it can unintentionally cause aggravated enteropathy.

Because increased vWF expression in the EC is

regarded as a marker of endothelial damage<sup>[27,28]</sup>, we counted the number of vessels expressing vWF in the mucosa and submucosa of rats with radiation-induced proctitis. The number of vWF-expressing vessels was much higher in the radiation group than in the control group, but was reduced by thalidomide treatment. In the normal EC, the expression of vWF is low because high TM levels on EC surface degrade coagulation factor V and vWF<sup>[5]</sup>. Also in our study, some decrease of vWF expression in the EC of the thalidomide group might be explained by degradation of vWF by elevated TM.

We also found greater VEGF expression in the EC from the radiation group compared with the control group. It is thought that two factors induced by radiation injury contribute to elevated VEGF expression in EC. First, radiation-induced thrombus formation and ischemia of microvessels contribute to the increased production of angiogenic factors such as VEGF<sup>[29-32]</sup>. Secondly, inflammatory cytokines induce angiogenesis, and this may contribute to increased VEGF expression, as in other forms of IBD. This suggests that VEGF expression might be a candidate marker of radiation injury in radiation enteropathy, as in other IBD<sup>[13,15,33]</sup>. The effect of thalidomide on VEGF expression in the EC may be related to either direct inhibition of the EC, as shown in a study of human EC lines, or to inhibition by inflammatory cytokines of colitis, as in another colitis model<sup>[12,13]</sup>. In addition, it is thought that thalidomide might contribute to decreased VEGF expression by inhibiting thrombus formation by elevating TM production, as shown in our data. In other words, thalidomide may enhance the endothelial thromboresistance in radiation enteropathy, suggesting that thalidomide may help prevent radiation injury. We found no histological differences between the radiation and thalidomide groups, probably because of the near-complete denudation of all crypts in both the radiation and thalidomide groups. It is likely that the radiation dosage (30 Gy) was too high for thalidomide to salvage the radiation toxicity.

## COMMENTS

### Background

Tissue hypoxia or ischemia secondary to the microvessel damage and coagulopathy has been considered as a main mechanism of radiation injury in various organs including intestine. Thalidomide as anti-angiogenic or anti-TNF- $\alpha$  agent, has been used for the treatment of malignant disease and inflammatory bowel disease (IBD). Several studies about thalidomide therapy support that it might be useful to prevent radiation-induced enteropathy.

### Research frontiers

Recently, a few studies have been reported about both tissue hypoxia and microvessel injury in radiation injury of the intestine with related molecular markers such as vascular endothelial growth factor (VEGF).

### Innovations and breakthroughs

To evaluate the effect of thalidomide for prevention of radiation-induced proctitis, the markers related to radiation-induced vascular damage were investigated. Our results show that thalidomide has beneficial effects in these markers in spite of no salvation of microscopic damage.

### Applications

By applying the markers of microvascular injury (von Willebrand Factor (vWF),

VEGF and thrombomodulin (TM)] in radiation-induced proctitis, we provide scientific basis for the thalidomide therapy in the prevention of acute radiation-induced proctitis. In the future, it could be useful as a preventive agent for the prevention of radiation-induced proctitis although thalidomide has some vascular side effects.

#### Peer review

The manuscript describes that irradiation to the rectum induces vWF and VEGF in vascular endothelial cells and inhibits TM expression as a marker of thromboresistance. Thalidomide treatment attenuates the effects of the radiation injury in endothelial cells.

## Abstract

**AIM:** To investigate the mucosal protective effect and the mechanisms of action of the anti-ulcer drug irsogladine maleate in gastric injury induced by indomethacin in rats.

**METHODS:** Gastric mucosal injury was induced in male Hos:Donryu rats by oral administration of indomethacin at a dose of 48 mg/kg. One hour before indomethacin treatment, animals were orally pretreated with irsogladine maleate at doses of 1 mg/kg, 3 mg/kg or 10 mg/kg. Four hours after indomethacin administration, the animals were sacrificed and their stomachs were rapidly removed and processed for the evaluation of gastric mucosal damage and the determination of the concentrations of tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ), interleukin-1 $\beta$  (IL-1 $\beta$ ), IL-8 and myeloperoxidase (MPO) in mucosal tissues.

**RESULTS:** Linear hemorrhagic mucosal lesions were observed primarily in the glandular stomach 4 h after oral administration of indomethacin. Pretreatment with irsogladine maleate markedly reduced the number and severity of these lesions in a dose-dependent manner. The mucosal concentrations of proinflammatory cytokines (TNF- $\alpha$ , IL-1 $\beta$ , and IL-8) and MPO, which indicates the degree of mucosal infiltration by neutrophils, increased concomitantly with the occurrence of gastric injury in the indomethacin-treated rats. Pretreatment with irsogladine maleate significantly decreased the levels of these inflammatory factors in gastric tissue elicited by indomethacin.

## INTRODUCTION

Nonsteroidal anti-inflammatory drugs (NSAIDs), such as indomethacin and aspirin, are widely prescribed in clinical practice because they exhibit excellent efficacy in the management of pain, fever and inflammation through their suppression of the synthesis of prostaglandins (PGs) from arachidonic acids resulting from their inhibition of cyclooxygenase (COX)<sup>[1]</sup>. However, the use of NSAIDs is associated with significant risks of adverse gastrointestinal events, such as gastric mucosal erosion, ulceration, bleeding, and perforation<sup>[2,3]</sup>. Such side effects considerably limit the use of these drugs. In addition to the decrease in

the intrinsic production of PGs in the gastric mucosa, other processes, such as increased mucosal production of proinflammatory cytokines, increased production of reactive oxygen species, and increased lipid peroxidation as well as increased mucosal infiltration of neutrophils, are closely associated with NSAID-induced gastric mucosal injury<sup>[4-6]</sup>.

Although the anti-ulcer drug irsogladine maleate has been shown in animals to exhibit potent mucosal protective effects on various experimental gastrointestinal injuries induced by a variety of stimuli, including indomethacin<sup>[7-10]</sup>, the exact mechanisms underlying the gastroprotective effect of irsogladine maleate remains to be fully elucidated. We have recently found that irsogladine maleate increases the intracellular levels of the second messenger cyclic adenosine monophosphate (cAMP) in rat glandular stomach and in human neutrophils through its previously unreported ability to inhibit cyclic nucleotide phosphodiesterase 4 (PDE4), and this inhibitory activity is probably involved in the antiulcer effects of the drug<sup>[11-13]</sup>. PDE4 inhibitors have been demonstrated to have multiple anti-inflammatory effects mediated by the suppression of proinflammatory cytokines such as tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ), interleukin-1 $\beta$  (IL-1 $\beta$ ) and IL-8, as well as by inhibiting neutrophil infiltration by suppressing the expression of adhesion molecules<sup>[14-16]</sup>.

Paying particular attention to the novel inhibitory action of irsogladine maleate on PDE4, in the present study we investigated the mucosal protective effect of irsogladine maleate and its underlying mechanisms of action by using a rat model of gastric injury elicited by indomethacin, focusing on the effect of the drug on cytokine production and neutrophil infiltration in the gastric mucosa. We found that irsogladine maleate markedly reduced gastric injury in indomethacin-treated rats with a concomitant decrease in levels of TNF- $\alpha$ , IL-1 $\beta$ , IL-8 and myeloperoxidase (MPO) in gastric mucosal tissue. The possible contribution of PDE4 inhibitory activity to the mucosal protective effect of irsogladine maleate was also discussed.

## MATERIALS AND METHODS

### Animals

Male Hos: Donryu rats (Japan SLC, Hamamatsu, Japan) at 6 weeks of age were used following quarantine and acclimation for a week after delivery to the laboratory. The rats were housed in rooms at 20-26°C with a relative humidity of 35%-75% in a 12 h light-dark cycle (lights on, 8:00-20:00) and a ventilation frequency of at least 15 times per hour. The rats were fed standard laboratory chow (F-2; Funabashi Farm, Funabashi, Chiba, Japan) with free access to tap water. All the animals were fasted for 18 h before the experiments. However, free access to tap water was allowed 1 h before the experiments. All experimental procedures were approved by the Committee for the Institutional Care and Use of Animals of Nippon Shinyaku Co.

### Preparation of drugs

Irsogladine maleate, synthesized at Nippon Shinyaku Co., was suspended in 5 g/L methylcellulose solution. Indomethacin, purchased from Sigma Chemicals (St. Louis, MO, USA), was dissolved in 50 g/L NaHCO<sub>3</sub> solution.

### Production of indomethacin-induced gastric mucosal injury in rats

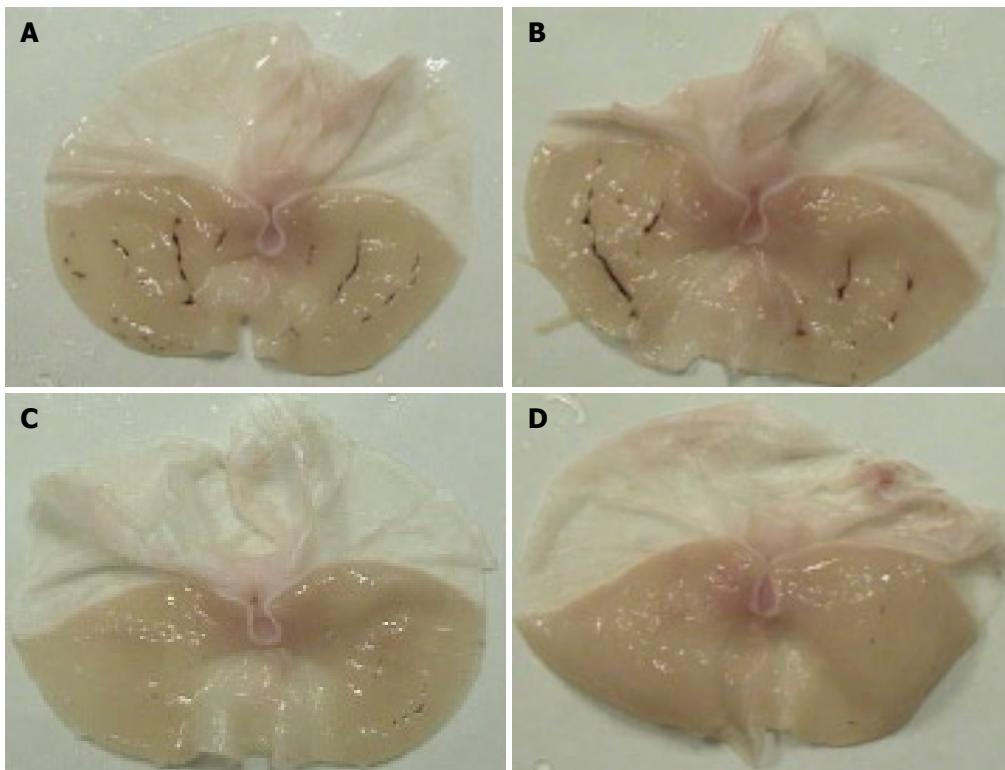

Gastric mucosal injury was produced by intragastric gavage of indomethacin at a dose of 48 mg/kg. Irsogladine maleate was given orally 1 h before indomethacin treatment. Four hours after indomethacin treatment, the animals were sacrificed with an overdose of diethyl ether and their stomachs were rapidly removed and processed for the evaluation of gastric mucosal damage and determination of TNF- $\alpha$ , IL-1 $\beta$ , IL-8 and MPO in the mucosal tissues.

### Evaluation of gastric mucosal injury

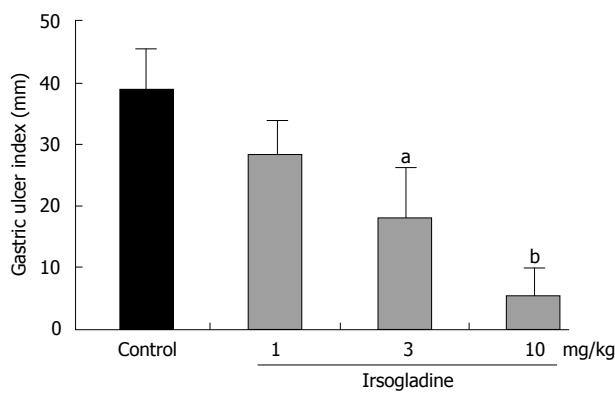

The stomach was distended with 10 mL of 8 g/L formaldehyde and immersed in the formaldehyde solution for 10 min. The lightly fixed stomach was then opened along the line of the greater curvature and spread out on a board. The hemorrhagic lesions in the mucosal layer were examined under a dissecting microscope (Olympus SZ40, Olympus Optical Co., Tokyo, Japan) at  $\times 10$  magnification by an observer who was unaware of the treatments. The gastric ulcer index was calculated for each rat as the sum of the lengths in millimeters of the hemorrhagic lesions (seen as red streaks).

### Determination of the concentrations of TNF- $\alpha$ , IL-1 $\beta$ and IL-8 in gastric mucosa

To evaluate the effect of irsogladine maleate on the mucosal production of cytokines elicited by treatment with indomethacin, the concentrations of TNF- $\alpha$ , IL-1 $\beta$ , and IL-8 in gastric mucosa were determined. Briefly, the gastric mucosa was rapidly scraped from the gastric wall of each rat and immediately frozen on dry ice and kept at -70°C until analysis. Mucosal samples were homogenized with a Phycotron NS-310E mechanical microhomogenizer (Niti-on, Tokyo, Japan) in 1 mL of PBS containing complete protease inhibitor cocktail (Roche, Indianapolis, IN, USA). The homogenate was centrifuged for 30 min at 15 000 r/min (4°C) in a Hitachi Himac CF 15D2 centrifuge (Hitachi High-Technologies, Tokyo, Japan) and the supernatant was retained for determination of proinflammatory cytokines. TNF- $\alpha$  and IL-1 $\beta$  were determined by enzyme-linked immunosorbent assay (ELISA) with commercial kits from R&D Systems (Minneapolis, MN, USA). IL-8 was determined with a commercial ELISA kit from Panapharm Laboratories (Kumamoto, Japan). The total protein in the supernatant was determined with the Bio-Rad protein assay kit (Bio-Rad Laboratories, Hercules, CA, USA), and the concentrations of TNF- $\alpha$ , IL-1 $\beta$  and IL-8 were expressed as ng per gram of total protein.

**Figure 1** Protective effect of irsogladine maleate on gastric mucosal lesions induced by indomethacin in rats. Stomachs from rats not pretreated with irsogladine maleate (A) and pretreated with irsogladine maleate at the doses of 1 mg/kg (B), 3 mg/kg (C) or 10 mg/kg (D), respectively, 1 h before administration of indomethacin. Nine rats were used in each group.

**Figure 2** Protective effect of irsogladine maleate on gastric mucosal lesions induced by indomethacin in rats. Each value represents the mean  $\pm$  SE for 9 rats. <sup>a</sup> $P < 0.05$  and <sup>b</sup> $P < 0.01$  vs control group.

#### Measurement of mucosal MPO levels

To estimate the degree of mucosal infiltration by neutrophils elicited by treatment with indomethacin, the MPO levels were measured in the gastric mucosa. Briefly, gastric mucosal samples were homogenized with a microhomogenizer in 1 mL of 10 mmol/L Tris (pH 7.4) containing 200 mmol/L NaCl, 5 mmol/L EDTA, 100 mL/L glycine, 1 mmol/L phenylmethanesufonyl fluoride, 1  $\mu$ g/mL leupeptin, and 28  $\mu$ g/mL aprotinin. The homogenate was centrifuged and the supernatant was retained for determination of MPO with an ELISA kit from Hycult Biotechnology (Uden, Netherlands) according to the manufacturer's instructions. The total protein in the supernatant was also determined as described above and the concentration of MPO was expressed as ng per gram of total protein.

#### Statistical analysis

The results are presented as mean  $\pm$  standard error of the mean (SE). The statistical significance of differences between normal and control groups was evaluated by the Aspin-Welch test, and the statistical significance of differences among the control and irsogladine maleate-treated groups was evaluated by the Williams test.  $P < 0.05$  was considered statistically significant. All tests were two-tailed, and performed with SAS version 8.2 (SAS Institute, Cary, NC, USA).

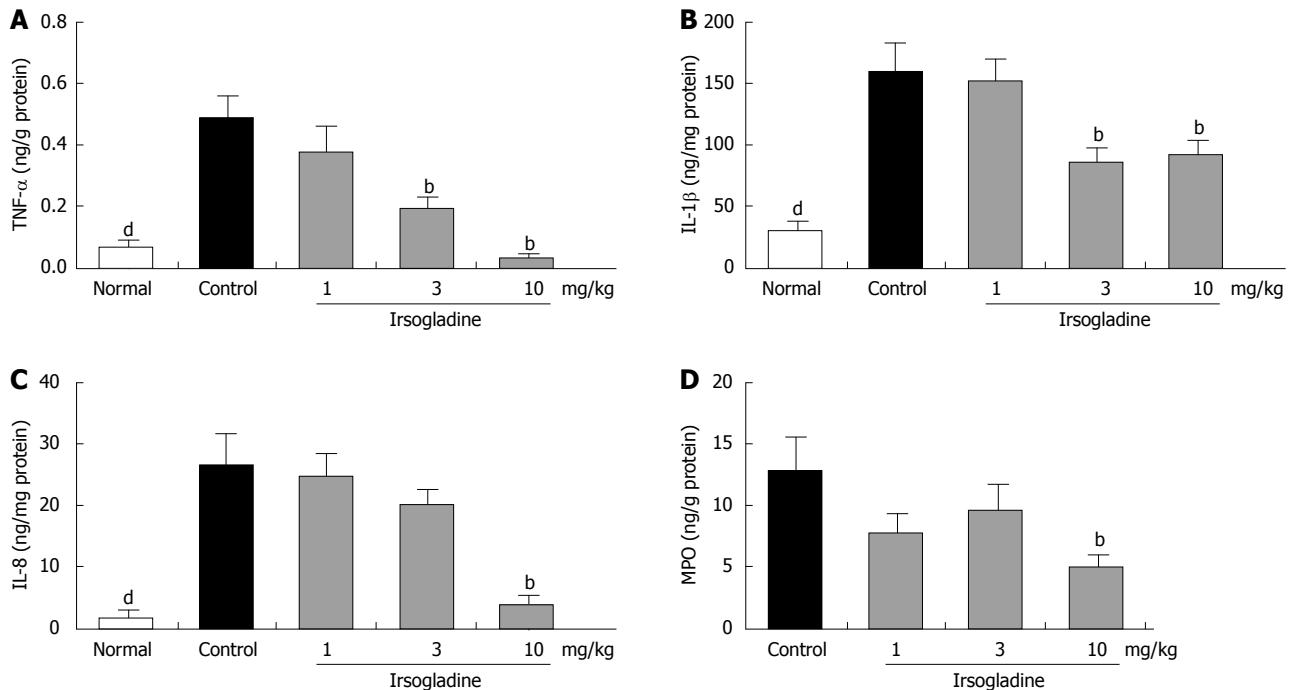

## RESULTS

#### Effect of irsogladine maleate on gastric mucosal injury induced by indomethacin

Four hours after oral administration of indomethacin, at a dose 48 mg/kg, gross linear hemorrhagic mucosal lesions were clearly observed in the glandular mucosa, and pretreatment with irsogladine maleate markedly reduced the number and severity of these lesions (Figure 1). Gastric mucosal injury was quantified under a dissecting microscope, and a gastric ulcer index of  $39.1 \pm 7.7$  mm was calculated (Figure 2). Pretreatment with irsogladine maleate reduced the gastric ulcer index in a dose-dependent manner to  $27.1 \pm 6.2$  mm at the dose of 1 mg/kg,  $18.3 \pm 7.2$  mm at the dose 3 mg/kg, and  $5.7 \pm 4.0$  mm at the dose of 10 mg/kg. In particular, irsogladine maleate at the dose of 3 mg/kg or 10 mg/kg significantly reduced the gastric ulcer index.

#### Effect of irsogladine maleate on TNF- $\alpha$ levels in gastric mucosa

Intragastric administration of indomethacin induced a marked increase in mucosal TNF- $\alpha$  concentrations. The

**Figure 3** Effect of irsogladine maleate on gastric mucosal TNF- $\alpha$  (A), IL-1 $\beta$  (B), IL-8 (C) and MPO (D) induced by indomethacin in rats. Each value represents the mean  $\pm$  SE for 9 rats,  $^bP < 0.01$  vs control group,  $^dP < 0.01$  vs normal group.

TNF- $\alpha$  level in the gastric mucosa of normal animals was  $0.070 \pm 0.014$  ng/g protein, which was significantly increased to  $0.490 \pm 0.072$  ng/g protein after intragastric administration of indomethacin (Figure 3A). Pretreatment with irsogladine maleate reduced the concentration of mucosal TNF- $\alpha$  in a dose-dependent manner to  $0.354 \pm 0.086$  ng/g protein at the dose of 1 mg/kg,  $0.186 \pm 0.042$  ng/g protein at the dose of 3 mg/kg, and  $0.045 \pm 0.005$  ng/g protein at the dose of 10 mg/kg, respectively. In particular, irsogladine maleate at the dose of 3 mg/kg or more significantly reduced the TNF- $\alpha$  levels in gastric mucosa.

#### **Effect of irsogladine maleate on IL-1 $\beta$ levels in gastric mucosa**

Intragastric administration of indomethacin induced a marked increase in mucosal IL-1 $\beta$  concentrations. The IL-1 $\beta$  level in the gastric mucosa of normal animals was  $36.1 \pm 8.1$  ng/g protein, which was significantly increased to  $160.2 \pm 19.8$  ng/g protein after intragastric administration of indomethacin (Figure 3B). Pretreatment with irsogladine maleate reduced the concentration of mucosal IL-1 $\beta$  to  $154.0 \pm 15.7$  ng/g protein at the dose of 1 mg/kg,  $85.4 \pm 15.4$  ng/g protein at the dose of 3 mg/kg, and  $93.0 \pm 17.4$  ng/g protein at the dose of 10 mg/kg, respectively. In particular, irsogladine maleate at the dose of 3 mg/kg or more significantly reduced the IL-1 $\beta$  levels in gastric mucosa.

#### **Effect of irsogladine maleate on IL-8 levels in gastric mucosa**

Intragastric administration of indomethacin induced a marked increase in mucosal IL-8 concentrations. The

IL-8 level in gastric mucosa of normal animals was  $1.1 \pm 0.5$  ng/g protein, which was significantly increased to  $27.0 \pm 6.6$  ng/g protein after intragastric administration of indomethacin (Figure 3C). Pretreatment with irsogladine maleate reduced the concentration of mucosal IL-8 in a dose-dependent manner to  $24.8 \pm 6.0$  ng/g protein at the dose of 1 mg/kg,  $19.9 \pm 5.9$  ng/g protein at the dose of 3 mg/kg, and  $2.8 \pm 0.6$  ng/g protein at the dose of 10 mg/kg, respectively. In particular, irsogladine maleate at the dose of 10 mg/kg significantly reduced the IL-8 levels in gastric mucosa.

#### **Effect of irsogladine maleate on MPO levels in gastric mucosa**

The MPO level in the gastric mucosa of indomethacin-treated animals was  $12.7 \pm 4.3$  ng/g protein (Figure 3D). Pretreatment with irsogladine maleate reduced the MPO concentration in gastric mucosa to  $7.0 \pm 1.6$  ng/g at the dose of 1 mg/kg,  $9.1 \pm 2.2$  ng/g at the dose of 3 mg/kg and  $4.9 \pm 0.8$  ng/g at the dose of 10 mg/kg, respectively. In particular, irsogladine maleate at the dose of 10 mg/kg significantly reduced the MPO levels in gastric mucosa.

## **DISCUSSION**

Though several studies have been published on the mechanisms underlying the mucosal protective effects of irsogladine maleate, an anti-ulcer drug often prescribed in Japan, on various gastrointestinal mucosal injuries<sup>[9-13]</sup>, the exact mechanisms by which this drug exerts its mucosal protective effects are not completely clear. In the present study, we investigated

the mechanisms underlying the gastroprotective effect of irsogladine maleate by using a rat experimental model of gastric injury elicited by indomethacin, focusing on the involvement of mucosal proinflammatory cytokine production and neutrophil infiltration into the gastric mucosa. We found that the concentrations of TNF- $\alpha$ , IL-1 $\beta$ , IL-8 and MPO in gastric mucosa of the rats increased concomitantly with the occurrence of gastric injury induced by a single intragastric dose of indomethacin. Pretreatment with irsogladine maleate markedly reduced the gastric injury with a concomitant decrease in the levels of these inflammatory factors.

Although the mechanisms of NSAID-induced gastric injury are not well understood, it is well accepted that both COX-dependent and independent mechanisms are involved in the pathogenesis of indomethacin-induced gastric injury. Mucosal proinflammatory cytokines, such as TNF- $\alpha$ , IL-1 $\beta$  and IL-8, are considered key inducers of gastric injury induced by NSAIDs like indomethacin<sup>[5,13]</sup>. For example, it is recognized that TNF- $\alpha$  may strongly promote inflammation and subsequent tissue destruction by recruiting leukocytes, particularly neutrophils and monocytes, through the induction of adhesion molecules on both leukocytes and vascular endothelial cells<sup>[17,18]</sup>. It is also known that TNF- $\alpha$  can induce the production of superoxide and proinflammatory cytokines by inflammatory cells<sup>[18,19]</sup>. In addition, intravenous administration of TNF- $\alpha$  induces gastric injury characterized by marked neutrophil infiltration into the gastric mucosa of rats<sup>[20]</sup>, while TNF- $\alpha$  levels in the gastric mucosa correlate well with the severity of gastric injury in rats<sup>[21-23]</sup>. It was reported that IL-1 $\beta$  and IL-8, as well as TNF- $\alpha$ , can promote inflammatory response and are involved in NSAID-induced gastric mucosal injury in humans and animals<sup>[17,24-26]</sup>.

In an attempt to clarify the mechanisms underlying the protective effects of irsogladine maleate on gastric mucosa, we evaluated its effects on the production of TNF- $\alpha$ , IL-1 $\beta$ , and IL-8 in gastric mucosa. We found that these cytokines were involved in the inflammatory response in a rat gastric mucosal injury model induced by indomethacin, and the concentrations of TNF- $\alpha$ , IL-1 $\beta$  and IL-8 in gastric mucosa increased concomitantly with the occurrence of gastric mucosal lesions, suggesting that the increased levels of these cytokines are closely associated with the occurrence and development of gastric mucosal lesions. Irsogladine maleate suppressed gastric mucosal injury at the dose of 3 mg/kg or higher. The doses of irsogladine maleate showing effective mucosal protection in this study are similar to those showing protection in previous studies of a variety of animal models of gastric injury<sup>[7-9,13]</sup>. Irsogladine maleate also significantly suppressed the increased levels of TNF- $\alpha$ , IL-1 $\beta$  and IL-8 in gastric mucosa, indicating that the suppression of proinflammatory cytokine production in gastric mucosa by irsogladine maleate significantly contributes to its protective effect on gastric mucosa.

In addition to proinflammatory cytokines, the

accumulation and activation of neutrophils, which may lead to microcirculation disturbance and production of free radicals in gastric mucosa, are also important events in gastric injury induced by NSAIDs<sup>[6,27]</sup>. Studies on experimental models of gastric injury induced by NSAIDs have demonstrated that infiltration of neutrophils into the injured mucosa occurs in rats as early as 15-30 min after indomethacin administration<sup>[28]</sup>, and gastric injury can be ameliorated in animals by eliminating the neutrophils through the administration of antineutrophil antibodies<sup>[6]</sup>. Neutrophil infiltration into gastric mucosa is, therefore, considered a critical step in the development of gastric injury induced by NSAIDs. In the present study, irsogladine maleate significantly reduced the MPO levels in gastric mucosa, indicating a reduction in mucosal infiltration by neutrophils. The suppression of neutrophil infiltration into the gastric mucosa may, therefore, contribute to the protective effect of irsogladine maleate on gastric mucosa.

PDE4 inhibitors may exert their anti-inflammatory action on various inflammatory diseases by suppressing the production of proinflammatory cytokines and the expression of adhesion molecules by increasing the levels of intracellular cAMP<sup>[14-16]</sup>. In addition, the PDE4 inhibitor rolipram can ameliorate indomethacin-induced gastric injury in rats by inhibiting the production of TNF- $\alpha$ <sup>[29]</sup>. We and others have recently reported that irsogladine maleate prevents ischemia-reperfusion-induced gastric injury and indomethacin-induced small intestinal lesions in rats, probably by inhibiting PDE4<sup>[10,13]</sup>. It is, therefore, likely that irsogladine maleate exerts its protective effect on indomethacin-induced gastric injury by suppressing mucosal TNF- $\alpha$ , IL-1 $\beta$  and IL-8 production by neutrophils and/or macrophages through its inhibition of PDE4 in these inflammatory cells. The suppression of these proinflammatory cytokines by irsogladine maleate may in turn decrease the expression of adhesion molecules in both vascular endothelial cells and neutrophils, resulting in a reduction in mucosal infiltration by neutrophils with consequent prevention of tissue destruction. Irsogladine maleate also inhibits the *in vitro* production and release of superoxide from human neutrophils by inhibiting PDE4<sup>[12]</sup>. Therefore, it is likely that the protective effects of irsogladine maleate on gastric mucosa arise not only from its suppression of neutrophil infiltration through its inhibition of proinflammatory cytokine production and adhesion-molecule expression, but also from its direct suppression of neutrophil activation through its inhibition of PDE4.

In conclusion, irsogladine maleate exerts its mucosal protective effects on gastric injury by suppressing the acute inflammatory response and subsequent tissue destruction in gastric mucosa through its suppression of mucosal proinflammatory cytokine production and neutrophil infiltration as well as by directly inhibiting neutrophil activation. It is also likely that the suppression of proinflammatory cytokines or neutrophils by irsogladine maleate arises from its ability to inhibit PDE4.

## ACKNOWLEDGMENTS

The authors thank Dr. Gerald E. Smyth for his careful reading of the manuscript and Mr. Masaru Tamura for his assistance with the statistical analysis of the data.

## COMMENTS

### Background

Nonsteroidal anti-inflammatory drugs (NSAIDs) are widely prescribed for their efficacy in the management of pain, fever and inflammation. However, NSAIDs are associated with significant risks of adverse gastrointestinal events, which considerably limit the use of these drugs. Although irsogladine maleate exhibits potent mucosal protective effects against indomethacin-induced gastrointestinal injuries in animals, its mechanisms of action are not fully understood.

### Research frontiers

We investigated the mechanisms underlying the protective effect of irsogladine maleate on gastric mucosa by using a rat experimental model of gastric injury elicited by indomethacin, focusing on the involvement of mucosal proinflammatory cytokine production and neutrophil infiltration into the gastric mucosa.

### Innovations and breakthroughs

The present study reported the effect of irsogladine maleate on mucosal proinflammatory cytokine production and neutrophil infiltration into the gastric mucosa in indomethacin-induced gastric injury.

### Applications

A single intragastric dose of irsogladine maleate could markedly reduce gastric injury with a concomitant decrease in the levels of inflammatory factors in indomethacin-treated rats, suggesting that irsogladine maleate can be applied to the treatment of patients with NSAID-induced gastric injury.

### Peer review

In this study, the authors examined the effects of irsogladine maleate on gastric mucosal injury and proinflammatory cytokine production and neutrophil infiltration (measured by MPO) using a rat model of gastric injury elicited by indomethacin. The authors found that irsogladine maleate could markedly reduce gastric injury in indomethacin-treated rats with a concomitant decrease in the gastric mucosal levels of tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ), interleukin-1 $\beta$  (IL-1 $\beta$ ), IL-8 and myeloperoxidase (MPO). The results of these straightforward experiments demonstrate that the protective effects of irsogladine are mediated by reducing neutrophil induction and inhibition of mucosal cytokine expression. This paper is well written and the data are novel.

## INTRODUCTION

Anorectal fistula is the chronic phase of anorectal infection and is characterized by chronic purulent drainage or cyclical pain associated with abscess reaccumulation followed by intermittent spontaneous decompression<sup>[1]</sup>. The goals of surgery for fistulainano are permanent healing and preservation of anal continence. Traditional surgical techniques, namely fistulotomy and seton technique, sever the internal anal sphincters and may damage the external anal sphincters. The recurrent rate of “lay-open” fistulotomy was reported to be 2%-9% with functional impairment ranging from 0%-17%<sup>[2-4]</sup>. The use of a seton has a recurrence rate of 0%-8%. Minor and major incontinence is 34%-64% and 2%-26%, respectively<sup>[5-10]</sup>.

Many different methods for treating anorectal fistulæ, particularly fistulæ in which fistulotomy are contraindicated, have been reported in recent years. Other alternative approaches are the application of fibrin glue and fistula plug. Since 1999, several studies on fibrin glue treatment of anal fistula have been published. The healing rate after debridement and fibrin glue injection is 14%-60%<sup>[11-13]</sup>. Incontinence may not be affected. Fistula plug, the latest technique for complex fistula-in-ano repair, has a reported failure rate of 13%. A success rate of 83% with a median follow-up of 12 mo is reported for high cryptoglandular anal fistulas, and the method has also been reported for a smaller group of Crohn fistulas<sup>[14,15]</sup>.

Our institution began repairing anorectal fistulæ using acellular extracellular matrix (AEM) in the past 1 yr. In our study, 30 patients with anorectal fistula were treated using acellular extracellular matrix. All of the 30 patients had successful closure of their fistula after a 7-14 d follow-up, giving an overall successful closure rate of 100% (30 of 30 patients). It can reduce pain, shorten disease course and protect anal function.

## Abstract

**AIM:** To investigate a new technique of the anorectal fistula treatment with acellular extracellular matrix (AEM).

**METHODS:** Thirty patients with anorectal fistula were treated with AEM. All fistula tracts and primary openings were identified using conventional fistula probe. All tracts were curetted with curet and irrigated with hydrogen peroxide and metronidazole. The AEM was pulled into the fistula tract from secondary to primary opening. The material was secured at the level of the primary opening. The excess AEM was trimmed at skin level at the secondary opening.

**RESULTS:** All of the 30 patients had successful closure of their fistula after a 7-14 d follow-up. The healing rate of anal fistula in treatment group was 100%. The ache time, healing time and anal deformation of treatment group were obviously superior to traditional surgical methods.

**CONCLUSION:** Using AEM anal fistula plug in treatment that causes the anorectal fistula is safe and successful in 100% of patients. It can reduce pain, shorten disease course and protect anal function.

## MATERIALS AND METHODS

### **Patients**

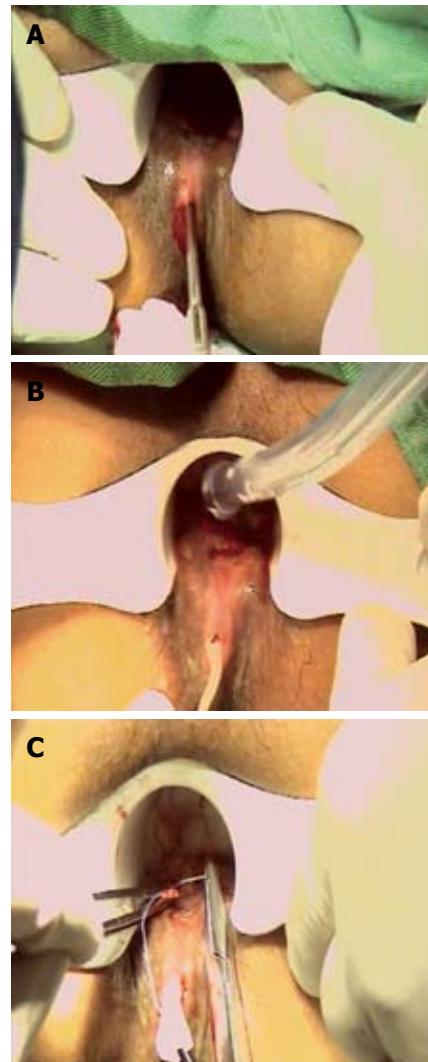

From January, 2007 to August, 2007, 30 patients with anorectal fistula were selected from ChaoYang Hospital of Capital Medicine University. They were treated with AEM (19 males, 11 females). All the patients had low anorectal fistula. Twenty-eight patients had simple anorectal fistula cases, and 2 patients had complicated anorectal fistula. their age was 18-72 years (mean, 38 years). All patients underwent mechanical bowel preparation the day before surgery, followed by 2 g of metronidazole by mouth the same evening. A broad-spectrum parenteral antibiotic was given to induce anesthesia. All procedures were performed under general anesthesia at a prone jackknife position.

### **Anal fistula acellular dermal matrix technique**

All operations were performed in the operating room. The primary and secondary fistula tract openings were identified. The fistula tract was then thoroughly cleaned with a blunt curette or gauze strip that was threaded through the tract (Figure 1A). All fistula tracts and primary openings were identified using a conventional fistula probe and/or hydrogen peroxide instillation<sup>[16,17]</sup>. All tracts were irrigated with hydrogen peroxide and metronidazole (Figure 1B). The AEM was cut out with a pair of scissors for three or four strips (Figure 2). Each primary opening was occluded by using a AEM anal fistula plug. The AEM was pulled into the fistula tract from secondary to primary the plug fitted snuggly into the tract (Figure 1C). The AEM material was secured at the level of the primary opening opening using a 2-0 vicryl, which was inserted deep to the internal sphincter muscle. The excess AEM was trimmed at skin level at the secondary opening. Care was taken to avoid complete closure of the secondary opening to allow drainage of material and to avoid a closed system. At the end of the procedure, the plug was completely buried within the fistula tract (Figure 1C). In the two cases of multiple separate fistules, the plug was cut into multiple strips to fit multiple fistula tracts. All patients were instructed to have a clear liquid diet for 48 h, avoid any strenuous activity; a broad-spectrum parenteral antibiotic was given. The status of fistula was determined at final follow-up. Success criteria were defined: closure of all secondary openings, absence of fistula drainage and abscess formation.

## RESULTS

Thirty patients were prospectively studied during an eight-month period. Twenty-seven patients had successful closure of their fistula tracts after a 7-14 d follow-up, but 3 patients had successful closure of their fistula tracts after 30 d follow-up. The mean healing time was 10.0 d (range, 7-14 d, 27/30). The mean operative time was 20 min (range, 15-25 min). All 28

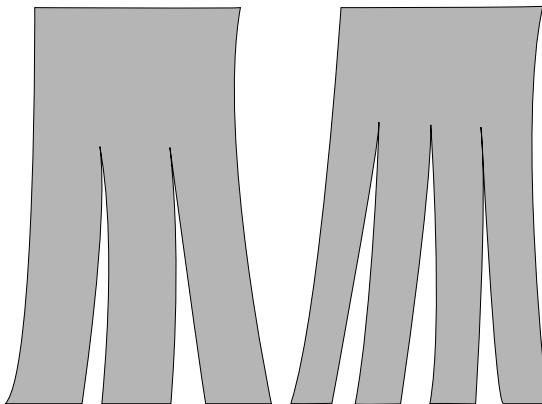

**Figure 1** Fistula tract thoroughly cleaned using a blunt curette (A), irrigated with hydrogen peroxide and etronidazole (B), pulled into the primary fistula opening until resistance(C). The AEM is secured at the level of the primary opening opening using a 2-0 vicryl. The excess of the AEM is trimmed at the level of the secondary opening. Care is taken to avoid complete closure of the secondary opening to allow free drainage of fluid and avoid a closed system.

patients with single fistula tracts had successful closure of their fistula tracts. These 2 patients with multiple tracts had successful closure of their fistula tracts too. The healing rate of anal fistula treatment group was 100%. There was no change of the continence status in all patients. There was no major post operative complication. Successful closure was not significantly associated with single fistula tracts or multiple fistula tracts.

## DISCUSSION

Traditional surgical techniques for anorectal fistula, include fistulotomy and seton techniques. Fistulotomy has been performed since ancient times. The outcome is generally acceptable. However, fistulotomy causes various degrees of anal sphincter injury<sup>[6,17-21]</sup>. The incontinence status is underestimated. The seton technique is to minimize incontinence, but only with

**Figure 2** AEM cut out with a knife for three or four strips.

moderate success. Recently, many techniques have been developed, such as endorectal advancement flap, anoderm island flap, excision and closure of internal opening, fibrin glue, and fistula plug. These techniques have less risk of anal incontinence, despite some recurrences. Several studies on fibrin glue treatment of anal fistula have been published since 1999, but, the healing rate after debridement and fibrin glue injection is 14%-60%<sup>[22-26]</sup>. Use of anal fistula plug for complex fistula-in-ano repair<sup>[27,28]</sup> has a reported success rate of 83%. The method has also been reported for a smaller group of Crohn fistulas<sup>[14,15]</sup>.

We used fibrin glue and fistula plug during the past year. Our institution began repairing all types of anorectal fistulae using the AEM to drain materials from human or animal skin tissue and to remove the composition of immunogenicity. This technique has been used in the field of burn and plastic surgery, stomatological surgery, tumor repaired surgery and urinology for a long time, and clinical results. In our study, the AEM was only used in low anorectal fistula, but could not be used in fistulas of cryptoglandular origin, fistules caused by Crohn's disease, recurrent fistules, and high anorectal fistules. Thirty patients with fistulae in ano were treated, 27 of them had successful closure of their fistula tracts after a 7-14 d follow-up. All the 28 patients with single fistula tracts had successful closure of their fistula tracts. Of them, 2 patients with multiple tracts had successful closure of their fistula tracts too. Giving an overall successful closure rate of 100% (30 of 30 patients), complications and recurrent case were encountered during the postoperative course, immune response and extensive fibrosis were not found in this study, suggesting that treatment of fistula with AEM can reduce pain, shorten disease course, protect anal function. The ache time, and healing time of the treatment group were obviously shorter compared with those achieved by using traditional surgical techniques<sup>[29]</sup>.

The AEM technique is based on sound principles. It is a new, simple, safe, less invasive and effective technique for closing anorectal fistules, and for avoiding the risks of anorectal incontinence. The early results are satisfactory.

## COMMENTS

### Background

Anorectal fistula is the chronic phase of anorectal infection. Traditional surgical techniques may damage the external anal sphincters. Many different methods for treating anorectal fistula have been reported in recent years. Other alternative approaches are the application of fibrin glue and fistula plug. However, the result of these approaches is uncertain.

### Research frontiers

The use of acellular extracellular matrix (AEM) in the anorectal fistula treatment was first study in the world.

### Innovations and breakthroughs

It is a new technique that is simple, safe, minimally invasive for closing anorectal fistules, and for avoiding the risks of anorectal incontinence. The early results are satisfactory.

### Applications

This technique can, reduce pain, shorten healing time, protect anal function. Therefore, it can be used in the treatment of fistulae.

### Peer review

This paper describes a new technique for the treatment of fistulae, which is of certain importance in clinical treatment of fistulae.

## Abstract

**AIM:** To investigate the effects of a ghrelin receptor agonist GHRP-6 on delayed gastrointestinal transit in alloxan-induced diabetic mice.

**METHODS:** A diabetic mouse model was established by intraperitoneal injection with alloxan. Mice were randomized into two main groups: normal mice and diabetic mice treated with GHRP-6 at doses of 0, 20, 50, 100 and 200 µg/kg ip. Gastric emptying (GE), intestinal transit (IT), and colonic transit (CT) were studied in mice after they had a phenol red meal following injection of GHRP-6. Based on the most effective GHRP-6 dosage, atropine was given at 1 mg/kg for 15 min before the GHRP-6 injection for each measurement. The mice in each group were sacrificed 20 min later and the percentages of GE, IT, and CT were calculated.

**RESULTS:** Percentages of GE, IT, and CT were significantly decreased in diabetic mice as compared to control mice. In the diabetic mice, GHRP-6 improved both GE and IT, but not CT. The most effective dose of GHRP-6 was 200 µg/kg and atropine blocked the prokinetic effects of GHRP-6 on GE and IT.

**CONCLUSION:** GHRP-6 accelerates delayed GE and IT, but has no effect on CT in diabetic mice. GHRP-6 may exert its prokinetic effects via the cholinergic pathway in the enteric nervous system, and therefore, has therapeutic potential for diabetic patients with delayed upper gastrointestinal transit.

## INTRODUCTION

Ghrelin is a peptide synthesized by endocrine cells of the gastric mucosa, initially identified in rodents<sup>[1]</sup>. The major actions of this recently discovered peptide include stimulation of growth hormone (GH) release<sup>[1-3]</sup>, regulation of appetite and nutrient ingestion<sup>[4-6]</sup>, and improvement of digestive motility<sup>[7-9]</sup>. When injected into mice<sup>[7,10]</sup>, rats<sup>[8]</sup>, human<sup>[9]</sup>, or dogs<sup>[11]</sup>, ghrelin accelerates gastric emptying of a liquid or solid meal.

Delayed gastrointestinal transit is a well-known diabetic complication, and may lead to uncomfortable gastrointestinal symptoms, such as frequent vomiting, emaciation, and unpredictable changes in blood glucose, all of which impair the quality of life of diabetic patients<sup>[12,13]</sup>. Gastrointestinal transit of solid or nutrient liquid meals is abnormally slow in approximately 50% of diabetic patients<sup>[12]</sup>. Delayed gastrointestinal transit may be associated with cardiac autonomic neuropathy, blood glucose concentration, and gastrointestinal symptoms<sup>[12]</sup>.

GHRP-6 is a peptide ghrelin receptor agonist, which has previously been reported to increase gastric emptying in normal rats<sup>[14]</sup>. Ghrelin has been shown to accelerate gastric emptying in animal models of postoperative ileus<sup>[15]</sup>, septic ileus<sup>[10]</sup>, burn-induced slow gastrointestinal transit<sup>[16]</sup> and diabetes mellitus<sup>[17,18]</sup>. In the present study, the prokinetic effect of GHRP-6 was investigated in a mouse model of diabetes mellitus.

## MATERIALS AND METHODS

### Chemicals

GHRP-6 was obtained from Tocris Cookson (Bristol, UK). Atropine sulphate, phenol red, and alloxan were purchased from Sigma (St Louis, MO).

### Diabetic mouse model

C57 mice (18–22 g) were provided by the Experimental Animal Center of Shanghai Academia Sinica. All procedures for the animal experiments were approved by the Medical Ethical Committee of Shanghai Jiaotong University. The mice were housed in stainless steel cages at a controlled temperature ( $22 \pm 2^\circ\text{C}$ ) with a 60%–65% relative humidity in a normal 12-h light and dark cycle. After exposure to a high-fat diet for 3 wk, the mice were fasted overnight with free access to water and injected intraperitoneally with alloxan (0.2 g/kg body weight) dissolved in a sterile normal saline solution. Seventy-two hours later, the fasting blood glucose level in the mice was determined using the glucose oxidase method with a glucose analyzer. Mice with a blood glucose level higher than 11.1 mmol/L were classified as diabetic mice (DB mice). The DB mice were continuously fed without control of blood glucose for 4 wk, and a model of DB mice was established for further investigations.

### Animal grouping for gastrointestinal transit studies

Gastric emptying, intestinal and colonic transit studies were then performed. For each study, mice were divided into two groups: a normal (control) group and a diabetic group. Mice in the diabetic group were treated with different doses of GHRP-6 (0, 20, 50, 100 and 200  $\mu\text{g}/\text{kg}$ ) given in a random order, with a total of six mice in each subgroup. A dose-response curve for GHRP-6 was obtained for the experiment. Based on the most effective dose of GHRP-6, another group of 6 mice were given atropine (1 mg/kg) injections 15 min before GHRP-6 injection.

### Gastric emptying

After a 12 h fast, the diabetic mice were injected with different doses of GHRP-6 (0, 20, 50, 100 and 200  $\mu\text{g}/\text{kg}$ ). After GHRP-6 injection, the mice received a gavage feeding (5 mg/kg body weight) of a phenol red test meal (0.5 g/L in 0.9% NaCl with 1.5% methylcellulose). Twenty minutes later, the mice were sacrificed. Their stomachs were clamped with a string above the lower oesophageal sphincter and a string beneath the pylorus to prevent leakage of phenol red. Gastric emptying was determined spectrophotometrically, according to the method previously described with certain slight modifications. The stomach of each individual mouse was resected just above the lower oesophageal sphincter and pyloric sphincter. Phenol red remained partly in the lumen of the stomach. The stomach and its contents were put into 5 mL of 0.1 mol/L NaOH. The stomach was minced. The samples containing the total amount of phenol red present in the stomach were further

diluted to 10 mL with 0.1 mol/L NaOH and left at room temperature for 1 h. Five milliliters of the supernatant was then centrifuged at 800 g for 20 min. The absorbance was read at a wavelength of 546 nm on a spectrophotometer (Shanghai Yixian Company, China), and the phenol red content in the stomach was calculated. Percentage of gastric emptying of the phenol red was calculated as [(infusion amount – remains)/infusion amount]  $\times 100\%$ .

### Intestinal and colonic transit

After an overnight fast, mice were given general anesthesia (2%–3% isoflurane inhalation) and underwent abdominal surgery. A small polyethylene tube was placed in the duodenum (or colon) *via* the stomach (or cecum), 0.5 cm distal to the pylorus (or ileocolic junction), fixed with sutures to the gut wall, and then tunneled through the abdominal wall subcutaneously to exit from the skin at the nape of the neck. Midline incisions were sutured, and mice were left to recover in separate cages. Food and water were provided abundantly. Three days later, after a 12 h fast, the mice were given different doses of GHRP-6 (0, 20, 50, 100 and 200  $\mu\text{g}/\text{kg}$ ) intraperitoneally. After GHRP-6 injection, a phenol red test meal at 5 mg/kg (0.5 g/L in 0.9% NaCl with 1.5% methylcellulose) was injected into the duodenum (or colon) *via* the implanted polyethylene tube. After 20 min, the mice were sacrificed. The distance of phenol red transit and the full length of the intestine or colon were calculated. Small intestine or colonic transit was assessed using the percentage ratio of phenol red transit over the full intestinal or colonic length.

### Statistical analysis

Statistical analysis of the data was conducted using one-way ANOVA for multiple comparisons. Data are expressed as mean  $\pm$  SE.  $P < 0.05$  was considered statistically significant.

## RESULTS

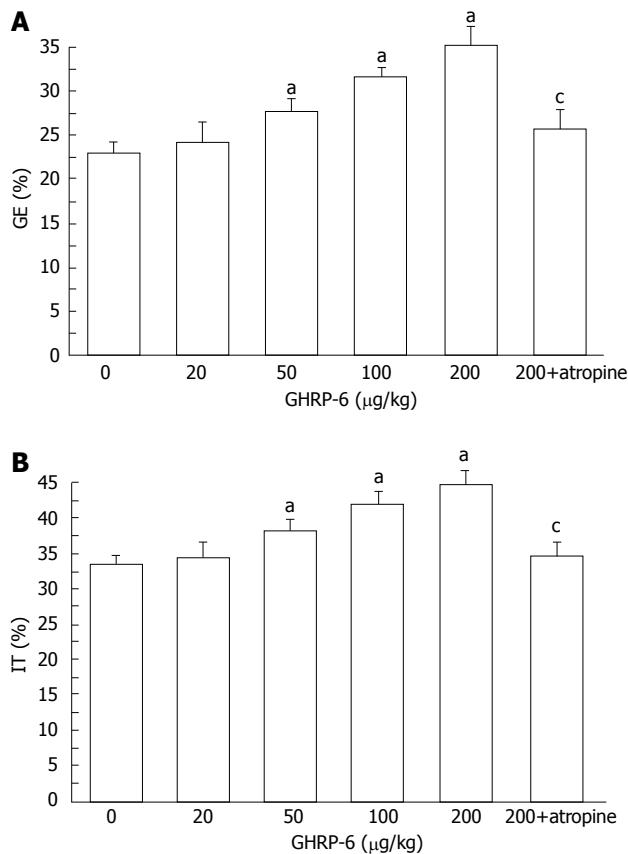

### Gastric emptying and intestinal and colonic transit in diabetic mice

Significantly delayed gastric emptying, intestinal and colonic transits were found in diabetic mice. Gastric emptying was significantly decreased in diabetic mice compared to normal mice ( $22.9\% \pm 1.4\% \text{ vs } 28.1\% \pm 1.3\%, P = 0.0216$ ).

Also, intestinal transit was significantly decreased in diabetic mice compared to normal mice ( $33.5\% \pm 1.2\% \text{ vs } 43.2\% \pm 1.9\%, P = 0.0132$ ). In addition, colonic transit was decreased in diabetic mice compared to normal mice ( $29.5\% \pm 1.9\% \text{ vs } 36.3\% \pm 1.6\%, P = 0.0148$ ).

### Effect of GHRP-6 on delayed gastric emptying in diabetic mice

GHRP-6 significantly accelerated gastric emptying in diabetic mice. The percentage of gastric emptying was

**Figure 1** GHRP-6 significantly increases gastric emptying (A) and intestinal transit (B) in diabetic mice. \* $P < 0.05$  vs control;  $^{\circ}P < 0.05$  vs 200 µg/kg GHRP-6 dose.

23.6%  $\pm$  1.9%, 26.9%  $\pm$  1.3%, 31.3%  $\pm$  0.9%, and 34.6%  $\pm$  1.5%, respectively, in the mice treated with 20, 50, 100, and 200 µg/kg GHRP-6. Except for the lowest dose, all of these doses normalized the rate of gastric emptying in diabetic mice ( $P = 0.0421$ ,  $P = 0.0324$  and  $P = 0.0103$ , respectively; Figure 1). We considered that the dosage of 200 µg/kg could most effectively increase the rate of gastric emptying.

#### Effect of GHRP-6 on delayed small intestinal transit in diabetic mice

GHRP-6 significantly accelerated intestinal transit in diabetic mice. The percentage of intestinal transit was 34.2%  $\pm$  1.9%, 39.1%  $\pm$  1.5%, 42.6%  $\pm$  1.7%, and 44.5%  $\pm$  1.8%, respectively, in the mice treated with 20, 50, 100, and 200 µg/kg GHRP-6. All of these doses, except for 20 µg/kg, normalized the delayed intestinal transit ( $P = 0.0321$ ,  $P = 0.0289$  and  $P = 0.0184$ , respectively; Figure 1). As above, the 200 µg/kg GHRP-6 dose was considered most effective in accelerating intestinal transit.

#### Effect of GHRP-6 on delayed colonic transit in diabetic mice

GHRP-6 had no effect on delayed colonic transit. The percentage of colonic transit was 30.8%  $\pm$  1.4%, 29.5%  $\pm$  1.7%, 30.3%  $\pm$  1.9%, and 31.2%  $\pm$  2.3%, respectively, in the mice treated with 20, 50, 100, and 200 µg/kg

GHRP-6. None of these doses was able to accelerate intestinal transit.

#### Effect of atropine on delayed gastric emptying and intestinal transit in diabetic mice

Atropine blocked the positive effects of 200 µg/kg GHRP-6 on gastric emptying and intestinal transit. The percentage of gastric emptying was significantly decreased from 34.6%  $\pm$  1.5% to 24.6%  $\pm$  1.8% ( $P = 0.0131$ , Figure 1). The small intestine transit was significantly decreased from 44.5%  $\pm$  1.8% to 35.4%  $\pm$  1.8% ( $P = 0.0145$ , Figure 1).

## DISCUSSION

In the present study, gastric emptying, intestinal and colonic transit were significantly delayed in the mice with alloxan-induced diabetes, which is consistent with previously reported findings<sup>[19,20]</sup>. Gastrointestinal motility disturbances including esophageal motor dysfunction, gastroparesis, constipation and diarrhea, are common in patients with diabetes mellitus. It has been reported that gastrointestinal transit is significantly slower in the diabetic animal model of human diabetes<sup>[21-23]</sup>. Inhibition of gastrointestinal motility has also been reported in humans with diabetes mellitus<sup>[24,25]</sup>. The pathogenesis of slow gastrointestinal transit in diabetes mellitus patients is not clear, but several mechanisms have been proposed<sup>[12]</sup>. Among them, autonomic neuropathy, a complication of long-standing diabetes mellitus, has been widely accepted as the culprit. This may lead to the absence of postprandial gastrointestinal response, a reflex that should present in healthy people<sup>[24]</sup>. Recent studies have shown that an acute change in blood glucose concentration also has a major effect on gastrointestinal motor function in healthy subjects<sup>[25]</sup>. In particular, acute hyperglycemia inhibits both the gastrointestinal and ascending components of peristaltic reflex. Poor glycemic control has the potential to cause delayed gastrointestinal transit in diabetic patients<sup>[26]</sup>. In our study, different doses of GHRP-6 were able to accelerate gastric emptying and intestinal transit in the diabetic mice, but had no effect on colonic transit, which is consistent with the results seen in animal models of postoperative ileus<sup>[15]</sup> and in burn-induced gastrointestinal delayed transit<sup>[16]</sup>. We believe that this result might be related to the distribution of ghrelin receptors in the gut<sup>[27,28]</sup>. The most effective dose of GHRP-6 for accelerating upper gastrointestinal transit was 200 µg/kg per mouse. Atropine blocked the GHRP-6 effect on gastric emptying and intestinal transit.

GHRP-6, possessing prokinetic characteristics, increases gastric emptying in healthy mice<sup>[29]</sup>. The mechanisms underlying the action of GHRP-6 seem to be neuron-dependent. *In vitro*, isolated strips of muscle fail to contract significantly when exposed to GHRP-6. *In vivo* the gastrokinetic effect of GHRP-6 in rats is abolished by atropine or vagotomy<sup>[14,29]</sup>. In our study, atropine blocked the effect of 200 µg/kg GHRP-6 on gastric emptying and intestinal transit, suggesting that

the prokinetic effect of GHRP-6 is mediated *via* the cholinergic pathway in the enteric nervous system.

It is reasonable to assume that GHRP-6 can be used as a potential drug for the treatment of diabetic patients with delayed gastrointestinal transit. Clinically, improvement in gastrointestinal transit facilitates enteral resuscitation, corrects blood glucose concentrations and reduces gastrointestinal symptoms in diabetic patients. In conclusion, GHRP-6 accelerates gastric emptying and intestinal transit in diabetic mice, an action that may be mediated *via* the cholinergic pathway in the enteric nerve system. GHRP-6 may have a therapeutic potential for diabetic patients with delayed upper gastrointestinal transit. The physiological role of GHRP-6 in the gastrointestinal tract remains to be identified, and its pharmacotherapeutic potential deserves to be further explored in diabetic patients suffering from delayed upper gastrointestinal transit.

## COMMENTS

### Background

Delayed gastrointestinal transit is common in patients with chronic diabetes and is always associated with impairments in quality of life and diabetic control. GHRP-6 is a potent prokinetic peptide. The effect of GHRP-6 on delayed gastrointestinal transit was studied in diabetic mice.

### Research frontiers

The effects of ghrelin on gastrointestinal motor activity and roles in motility regulation have been extensively studied. This study is the first to investigate the effects of ghrelin agonist GHRP-6 on diabetic mice with delayed gastrointestinal transit.

### Innovations and breakthroughs

GHRP-6 has been shown to accelerate gastric activity in postoperative and septic ileus animal models. However, it has not been studied in a diabetic animal model.

### Applications

According to animal experiments, GHRP-6 may be used as a potential therapeutic agent for the treatment of delayed gastrointestinal transit in diabetes.

### Peer review

This paper shows that GHRP-6 has an effect on gastric emptying and intestinal transit in diabetic mice, which may be mediated through the cholinergic pathways in the enteric nerve system. These results show that GHRP-6 can be used as a potential therapeutic drug for the treatment of delayed gastrointestinal transit in diabetes.

OB glue paste technique for establishing nude mouse human gastric cancer orthotopic transplantation models. *World J Gastroenterol* 2008; 14(30): 4800-4804 Available from: URL: <http://www.wjg-net.com/1007-9327/14/4800.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.4800>

### Abstract

**AIM:** To establish nude mouse human gastric cancer orthotopic transplantation models using OB glue paste technique.

**METHODS:** Using OB glue paste technique, orthotopic transplantation models were established by implanting SGC-7901 and MKN-45 human gastric cancer cell strains into the gastric wall of nude mice. Biological features, growth of the implanted tumors, the success rate of transplantation and the rate of auto-metastasis of the two models were observed.

**RESULTS:** The success rates of orthotopic transplantation of the two models were 94.20% and 96%. The rates of hepatic metastasis, pulmonary metastasis, peritoneal metastasis, lymphocytic metastasis and splenic metastasis were 42.13% and 94.20%, 48.43% and 57.97%, 30.83% and 36.96%, 67.30% and 84.06%, and 59.75% and 10.53%, respectively. The occurrence of ascites was 47.80% and 36.96%.

**CONCLUSION:** OB glue paste technique is easy to follow. The biological behaviors of the nude mouse human gastric cancer orthotopic transplantation models established with this technique are similar to the natural processes of growth and metastasis of human gastric cancer, and, therefore, can be used as an ideal model for experimental research of proliferative metastasis of tumors.

### INTRODUCTION

Establishment of human gastric cancer nude mouse transplantation models has undergone three representative stages<sup>[1-5]</sup>: subcutaneous transplantation of cell suspension<sup>[6]</sup>, gastric wall seeding of cell suspension<sup>[7-12]</sup>, and intra-gastric wall transplantation of histologically intact tissues<sup>[13-17]</sup>, of which the fresh tissue orthotopic transplantation model has two types in method: the “suture method”<sup>[18]</sup> and the “gastric bursa method”<sup>[19]</sup>. Enlightened by surgical use of OB glue, the present study used OB glue paste technique to implant SGC-7901 and MKN-45 human gastric cancer cell strains to the gastric wall of nude mice in an attempt to examine the biological features of proliferative metastasis of gastric cancer cells.

### MATERIALS AND METHODS

#### Animals

The study included 314 6-week BALB/C nude mice of both sexes weighing 18-20 g provided by Shanghai Experimental Animal Center of the Chinese Academy of Sciences (qualification No.: SCXK, Shanghai, 2004-0003). In this study, 166 cases of models for SGC-7901 and 148 cases for MKN-45 were established. The animals were raised in the said center in SPF experimental animal rooms (approval No.: SYXK, Shanghai, 2004-0011) with free access to water.

### Cell strains

SGC-7901 and MKN-45 cell strains were kind gifts from the laboratory of experimental pathology of Shanghai Institute of Tumor Research, CAS. Cancer cells were cultured in RPMI-1640 solution containing 10% bovine serum in a CO<sub>2</sub> thermostatic incubator and passaged routinely.

### Establishment and passage of subcutaneously transplanted tumor in nude mice

*In vitro* cancer cells were collected to the content of  $1 \times 10^7$ /mL. Each nude mouse was injected with 0.2 mL cancer cells under the cervical skin. When the implanted tumor grew to about 1cm diameter, it was removed out of the mouse. The tumor was cut into 1 mm × 1 mm × 2 mm pieces after scraping off the surrounding fibrous capsule, and implanted directly into the cervical skin of the nude mice. Each inter-mouse passage used two mice. The third generation subcutaneously transplanted tumor was used as the source of orthotopic transplantation in this study.

### Establishment of orthotopic transplantation models

The mice were purchased two days ahead of the experiment for environmental adaptation. The animals were fasted 12 h before operation and anesthetized with 0.4% pentobarbital sodium (60 mg/kg) intraperitoneally. The skin was sterilized routinely and a 1 cm incision was made along the left paramedian line to expose the peritoneum and gastric wall meticulously. The serous layer of the greater curvature of stomach where there are abundant blood vessels, was carefully ruptured with an injection needle until bleeding was visible, into which the tumor tissue was implanted. One to 2 drops of medical OB glue (Cyanoacrylate, medical OB 508 series for anastomosis, Guangzhou Bai Yun Medical Glue Co., Ltd., Batch No. 030703) were applied to seal the rupture. After the glue coagulated for about 10 s, the peritoneum was closed with No. 3 suture and the skin was closed with No. 1 suture.

### Sacrifice of animals and observation of metastasis of the transplanted tumor

When the mice were seen developing failing signs such as leanness, limited activity and listlessness, they were sacrificed by cervical dislocation and anatomized for comprehensive exploration of the chest and abdominal cavities and macroscopic observation of any transplanted tumor with regard to local growth, ascites, adjacent lymph nodes and distal organ metastasis. The transplanted tumor, enlarged lymph nodes, liver, spleen, pancreas and lungs were excised, and the specimens were fixed, sliced and stained for histopathologic observation under light and electron microscope. The tumor was weighed with an analytical balance and recorded. Four mice which died during the study were treated in the same manner without including into statistics, but for reference and later causative analysis.

### Preparation of chromosomal specimens of human gastric cancer cells

Part of the transplanted tumor tissues was sheared with aseptic technique and placed in serum-free 1640 medium for primary culture. When the cells grew vigorously and formed a single layer, the first generation passage was done, for which chromosomal specimens were prepared. The specimens were observed under an  $\times 40$  light microscope and photographed for chromosomal metakinesis of one cell with a microscopic camera.

## RESULTS

### Growth of the orthotopically transplanted tumor

One mouse died from excessive bleeding during establishment of the SGC-7901 orthotopic transplantation model. The skin suture fell off at about day 5 and the wound healed completely in a week. At week 3-4, 4 mm nodules were palpable in the upper abdomen, which grew large gradually by week 5-6 and became markedly large by week 8-10. At week 10 some of the tumors were even visible through the wall and as large as 10-20 mm in diameter. The surfaces of these tumors were nodular and hard in consistency. From week 11 on, the animals began presenting failing signs such as leanness, limited activity, listlessness and hypoactivity. One animal died. At week 12 the failing signs were more evident and severe, and tumors in some mice subcutaneously projected out, or the abdomens were bulky looking like a frog abdomen. The animals were sacrificed by cervical dislocation.

One animal in the MKN-45 orthotopic transplantation model died on the second day because of suture failure due to mutual fierce biting of the animals. The situation of the remaining animals was much the same as that of the SGC-7901 model. The only difference in the MKN-45 model was that the tumors grew faster in fewer days. By week 2, hard nodules about 4mm were palpable in both right and left upper abdomen; the tumors became large gradually by week 3-4 and grew to 10-15 mm in diameter by week 5-6; 3 animals died by week 6-7; and the failing signs became worse by week 8 when giant tumors of 15-20 mm in diameter were palpable. The animals were sacrificed by cervical dislocation.

### Invasion of the orthotopically transplanted tumor

A total of 164 cases of models with SGC-7901 were established in this study, including 159 cases of SGC-7901 orthotopic transplantation with a success rate of 97% (159/164). Gross anatomy revealed: the body of stomach was enlarged and the fundus was dilated; grayish fish meat like tumors were seen on the gastric wall; the tumor tissue was parenchymatous with vague margins and round or oval in shape. There were nodular processes on the surface, which infiltrated into the surrounding tissues and adhered with the mesentery, liver, spleen and peritoneum in varying degrees. There

**Figure 1** Macroscopic observation of orthotopically transplanted MKN-45 tumor.

was bloody ascites in some mice. The tumor sections were grayish, looking like fish meat and homogenous in consistency, on which there were abundant capillaries. In some large tumors, there were small necrotic patches in the center. The mean weight of the tumors was  $2.31 \pm 0.75$  g.

A total of 144 cases of models with MKN-45 were established, including 138 cases of orthotopic transplantation, with a success rate of 96% (138/144). Gross anatomic findings were much the same as those of the SGC-7901 model. The tumors were oval in shape, uneven and hard in consistency. There was a serous necrotic area in the center. The mean weight of the tumors was  $2.53 \pm 0.84$  g (Figure 1).

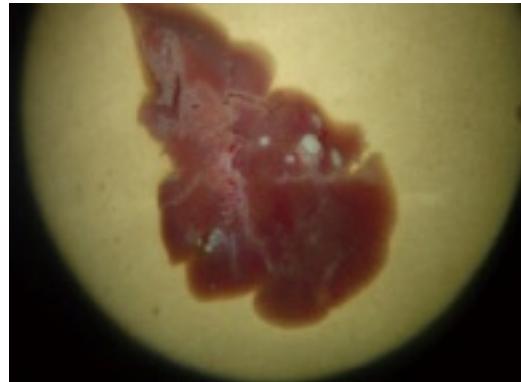

#### **Metastasis of the orthotopically transplanted tumor**

Intraperitoneal lymph nodes were enlarged in most mice of the SGC-7901 model. Involvement of the tumors was various. Several small grayish miliary nodules were seen in the liver of most tumor-bearing mice, which went into the hepatic parenchyma and were difficult to separate. Pyloric obstruction and bloody ascites were seen in some tumor-bearing mice, and pulmonary, splenic and peritoneal metastases were seen in other animals. The metastasis rates of the liver, lungs, peritoneum, lymph node and spleen were 42.02% (67/159), 48.43% (77/159), 30.82% (49/159), 67.30% (107/159) and 59.75% (95/159), respectively. The prevalence of ascites was 47.80% (76/159).

The situation in the MKN-45 model was similar to that of the SGC-7901 model, where the hepatic focus of metastasis was 2-3 mm (Figure 2). The lung surface was congested in some animals and transparent nodules about 1mm were visible. The metastasis rates of the liver, lungs, peritoneum, lymph node and spleen were 94.20% (130/138), 57.97% (80/138), 36.96% (51/138), 84.06% (116/138) and 10.86% (15/138), respectively. The prevalence of ascites was 31.88% (44/138).

#### **Histopathologic findings of the orthotopical transplantation models**

SGC-7901 gastric cancer tissue was adenocarcinoma of low differentiation. The tumor cells present as oval shape with large malformed nuclei, most of which were of pathologic mitosis with clear and multiple nucleoli.

**Figure 2** Hepatic metastatic focus of orthotopically transplanted MKN-45 tumor.

They were deranged like a nestle with rich sinusoids, in which filtration of lymphocytes was seen.

Histological sections of MKN-45 tumor body was also characterized by poorly differentiated adenocarcinoma, where cells were in patchy, nestle or streaky arrangement and shaped round, oval or irregular. Cell differentiation was poor, with large deep stained nuclei and a large nuclear-cytoplasmic ratio, where karyokinetic phase was seen. Fibrous connective tissue was seen in the mesenchyma, and infiltrative growth of the tumor tissue was seen in the gastric wall (Figure 3A).

The histological structure of the tumor metastatic foci in the liver and lungs was consistent with that of the orthotopic gastric tumor, mostly distributing around blood vessels of the lung parenchyma and hepatic sinusoid and growing infiltratively to the surrounding tissues. Large numbers of cancer cells were seen in the enlarged lymph nodes; they arranged closely, destroying almost all lymphatic structure. Cytohistological morphology of ascites smear was similar to that of the orthotopic tumor.

#### **Identification of cell chromosome of the orthotopically transplanted tumor**

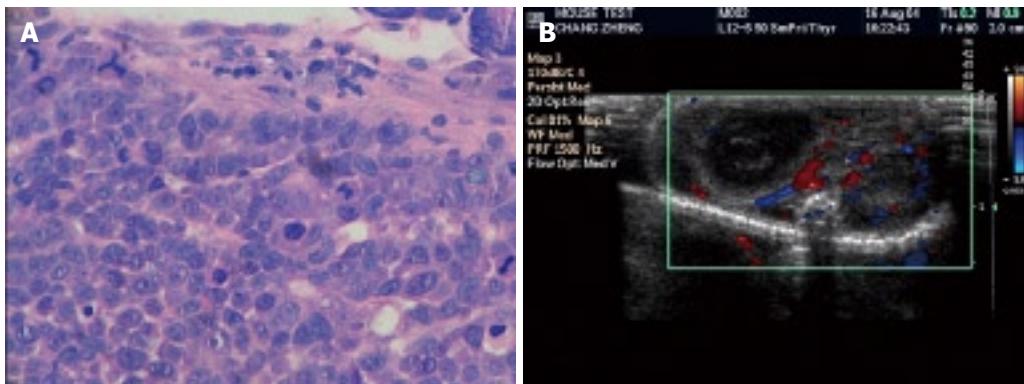

Under  $\times 40$  light microscope, no single chromosome in the metaphase was seen as a telocentric chromosome, indicating that it was a human chromosome. Distribution of the chromosomes was more than 46, indicating that they were malignant tumor cells.

#### **Color doppler imaging of the orthotopically transplanted tumor**

B-ultrasound detected low echo masses in the upper abdomen of the nude mice, which grew into the abdominal cavity (Figure 3B). Most blood flow of the tumors was in the periphery, or mixed blood flow was seen both inside and around the tumor. The course of vessels was irregular and the vessels were various in size and deranged, forming winding, fork-like and net-like blood flows. Blood flow was more abundant and faster in the periphery than in the center of the tumor (Figure 3B).

## **DISCUSSION**

Human gastric cancer fresh tissue orthotopic transplantation is the main means of model establishment. The

**Figure 3** A: Histological findings of orthotopically transplanted MKN-45 tumor; B: Ultrasound findings of orthotopically transplanted SGC-7901 tumor.

site of transplantation is usually between the serous layer and seromuscular layer of the greater curvature of stomach. The “suture method”<sup>[20]</sup> or the “gastric bursa method”<sup>[21-22]</sup> has many practical difficulties and disadvantages in establishing the model of transplantation, for example, the tumor tissue is easy to fall off postoperatively; manipulation is complex and needs relatively high skills; and there may be great blood loss during suturing, and mortality is relatively high. OB glue is biologic glue and has been used widely in surgery owing to its secure wound adhesion. We have had two-years experience with the use of “OB glue paste technique” to establish the human gastric cancer nude mouse orthotopic transplantation model since 2003, when the technique was first attempted in our department<sup>[23-30]</sup>. The present study used OB glue paste technique to establish two tumor strain orthotopic transplantation models. Observations showed that although different tumor strains grew at different rates, infiltrative growth and multi-organ metastases are common features of the two models, and these features are similar to the clinical presentation of invasive metastasis. Chromosomal identification also demonstrated that both orthotopic and metastatic tumors came from the human gastric cancer implanted. This technique is an ideal means of model establishment owing to its easier manipulation, shorter operating time, less blood loss, quicker postoperative recovery, and higher survival of experimental animals and avoidance of tumor falling off.

The success rate was not 100% in both cases. Anatomy of the mice that failed to bear tumors showed that there was local organ adhesion arising from manipulation, and part of the transplanted tumor tissues stop growing. With our experience, the following points are worthy of mention with regard to factors affecting the success rate: (1) The amount of glue should be appropriate, 1-2 drops are enough, too much glue would envelope the implant, halting its growth; (2) It is best to wait for 10 seconds or so before closing the abdomen so that the glue can coagulate sufficiently; or it may cause extensive adhesion of the surrounding tissues; (3) It is preferable to use the seromuscular layer near the antrum of the greater curvature, because rich blood flow there facilitates tumor growth and metastasis; (4) Rupture of

the seromuscular layer should not be too superficial, and bleeding is the hallmark. In addition, the tumor tissue to be implanted should be placed into the ruptured site before dropping OB glue. Smooth forceps can be used to push the rupture inward to form a denture before implanting the tumor tissues, if necessary; and (5) It is not preferable to leave too much suture outside the abdomen to avoid suturing failure due to fierce biting between animals.

## COMMENTS

### Background

Establishment of human gastric cancer nude mouse transplantation models has undergone three representative stages: subcutaneous transplantation of cell suspension, gastric wall seeding of cell suspension, and intra-gastric wall transplantation of histologically intact tissues. The fresh tissue orthotopic transplantation model has two types in method: the “suture method” and the “gastric bursa method”.

### Research frontiers

Human gastric cancer fresh tissue orthotopic transplantation is the main means of model establishment. But the “suture method” or the “gastric bursa method” transplantation has many practical difficulties and disadvantages in establishing the model. The “OB glue paste technique” was attempted to establish the human gastric cancer nude mouse orthotopic transplantation model.

### Innovations and breakthroughs

Observations showed that the “OB glue paste technique” is an ideal means of model establishment owing to its easier manipulation, shorter operating time, less blood loss, quicker postoperative recovery, higher survival of experimental animals and avoidance of tumor falling off.

### Applications

OB glue paste technique is easy to follow and can be used as an ideal model for experimental research of proliferative metastasis of tumors.

### Peer review

Shi et al established the nude mouse human gastric orthopedic transplantation model using OB glue paste technique. This is an interesting paper. However, several points should be addressed. If possible, the success rate of orthotopic transplantation of SGC-7901 and MKN-45 models should be indicated without using OB glue. If additional effect of OB glue was clarified, this paper would be more convincing.

**Published online:** August 14, 2008

tumor infiltration ( $\chi^2 = 5.052, P = 0.168$ ), depth of tumor invasion ( $\chi^2 = 4.588, P = 0.101$ ), lymph node metastases ( $\chi^2 = 3.688, P = 0.055$ ) and TNM staging system ( $\chi^2 = 3.765, P = 0.152$ ). The local recurrence rate of middle and lower rectal carcinoma was 33.3% (4/12) in patients with positive circumferential resection margin and 6.8% (3/44) in those with negative circumferential resection margin. There was a significant difference between the two groups ( $\chi^2 = 6.061, P = 0.014$ ). Local recurrence of rectal carcinoma occurred in 6 of 36 patients (16.7%) with mesorectal metastasis, and in 1 of 20 patients (5.0%) without mesorectal metastasis. However, there was no significant difference between the two groups ( $\chi^2 = 1.600, P = 0.206$ ).

**CONCLUSION:** Family history, high CEA level, cancerous perforation, tumor differentiation, vessel cancerous emboli and circumferential resection margin status are the significant risk factors for local recurrence of middle and lower rectal carcinoma after curative resection. Local recurrence may be more frequent in patients with mesorectal metastasis than in patients without mesorectal metastasis.

Risk factors for local recurrence of middle and lower rectal carcinoma after curative resection. *World J Gastroenterol* 2008; 14(30): 4805-4809 Available from: URL: <http://www.wjgnet.com/1007-9327/14/4805.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.4805>

## INTRODUCTION

It is well known that local recurrence is of rectal carcinoma plays an important role in its prognosis<sup>[1-3]</sup>. However, local recurrence of rectal carcinoma occurs in about 4%-50% of patients even after radical resection of primary tumors and lymph nodes<sup>[4-8]</sup>. The risk factors

for local recurrence of rectal carcinoma remain unclear. Therefore, the aim of the current study was to explore the risk factors for local recurrence of middle and lower rectal carcinoma after curative resection. Specimens of middle and lower rectal carcinoma from 56 patients who underwent total mesorectal excision (TME) at the Department of General Surgery, Guangdong Provincial People's Hospital, from November, 2001 to July, 2003, were studied. A large slice technique was used to detect mesorectal metastasis and evaluate circumferential resection margin status. The relationship between mesorectal metastasis, local recurrence and circumferential resection margin status of rectal carcinoma was observed. The clinicopathologic characteristics of middle and lower rectal carcinoma were also evaluated.

## MATERIALS AND METHODS

### **Patients and specimens**

Specimens of middle and lower rectal carcinoma from 56 patients who underwent TME at the Department of General Surgery, Guangdong Provincial People's Hospital, from November, 2001 to July, 2003, were studied. There were 37 men and 19 women, ranging in age from 30 to 86 years, with a mean age of 60.5 years. None of these patients received preoperative chemotherapy or radiotherapy. Twenty-six patients had lower rectal carcinoma and 30 had middle rectal carcinoma. Tumors  $\geq 5$  cm and in  $< 5$  cm diameter were found in 18 and 38 patients, respectively. Low anterior resection was performed in 40 patients and abdominoperineal resection in 16 patients. TNM stages were as follows: stage I in 5 patients, stage II in 22 patients, and stage III in 29 patients. Poorly-differentiated carcinoma was observed in 14 patients, moderately-differentiated carcinoma in 37 patients, and well-differentiated carcinoma in 5 patients, respectively. A large slice technique was used to detect mesorectal metastasis and evaluate circumferential resection margin status. Two pathologists who were blinded to the clinicopathological data observed the specimens independently. If tumor cells were detected within 1 mm of circumferential margin, they were classified to have a positive circumferential resection margin as previously described<sup>[9-11]</sup>.

### **Statistical analysis**

Statistical analysis was performed by the Pearson  $\chi^2$  test to examine the association between local recurrence, circumferential resection margin status and mesorectal metastasis of rectal carcinoma. Clinicopathologic characteristics of the patients with middle and lower rectal carcinoma were also analyzed.  $P < 0.05$  was considered statistically significant.

## RESULTS

### **Correlation between local recurrence and clinicopathologic characteristics of patients with middle and lower rectal carcinoma**

Local recurrence of middle and lower rectal carcinoma

after curative resection was found in 7 of 56 patients (12.5%), which was significantly related with family history ( $\chi^2 = 3.929, P = 0.047$ ), high CEA level ( $\chi^2 = 4.964, P = 0.026$ ), cancerous perforation ( $\chi^2 = 8.503, P = 0.004$ ), tumor differentiation ( $\chi^2 = 9.315, P = 0.009$ ) and vessel cancerous emboli ( $\chi^2 = 11.879, P = 0.001$ ). In contrast, no significant correlation was found between local recurrence and other variables such as age ( $\chi^2 = 0.506, P = 0.477$ ) and gender ( $\chi^2 = 0.102, P = 0.749$ ), tumor diameter ( $\chi^2 = 0.421, P = 0.516$ ), tumor infiltration ( $\chi^2 = 5.052, P = 0.168$ ), depth of tumor invasion ( $\chi^2 = 4.588, P = 0.101$ ), lymph node metastases ( $\chi^2 = 3.688, P = 0.055$ ) and TNM staging system ( $\chi^2 = 3.765, P = 0.152$ ) (Table 1).

### **Correlation between circumferential resection margin status and local recurrence of middle and lower rectal carcinoma**

A positive circumferential resection margin of middle and lower rectal carcinoma was observed in 12 of 56 patients (21.4%). Local recurrence of middle and lower rectal carcinoma was found in 4 of 12 patients (33.3%) with a positive circumferential resection margin and in 3 of 44 patients (6.8%) with a negative circumferential resection margin. There was a significant difference between the two groups ( $\chi^2 = 6.061, P = 0.014$ ) (Table 1).

### **Correlation between mesorectal metastasis and local recurrence of middle and lower rectal carcinoma**

Mesorectal metastasis of middle and lower rectal carcinoma was detected in 36 of 56 patients (64.3%). The local recurrence rate of mesorectal metastasis was 16.7% (6 of 36 patients) and 5.0% (1 of 20 patients), respectively. However, there was no significant difference between the two groups ( $\chi^2 = 1.600, P = 0.206$ ) (Table 1).

## DISCUSSION

It is well known that middle and lower rectal carcinoma is one of the most common carcinomas in China. Local recurrence of middle and lower rectal carcinoma after curative resection has significant morbidity and mortality<sup>[4,12-15]</sup> and its recurrence rate varies from less than 4% to greater than 50%. Since TME was adopted as the standard treatment of patients with rectal carcinoma, a significant decrease in local recurrence and a trend to improve relative survival have been reported<sup>[16-18]</sup>. In our study, local recurrence of middle and lower rectal carcinoma occurred in 7 of 56 patients (12.5%) after TME, indicating that TME can significantly reduce the local recurrence rate of middle and lower rectal carcinomas.

The correlation between circumferential resection margin status and local recurrence of rectal carcinoma is still controversial<sup>[10,11,19-21]</sup>. Wibe *et al*<sup>[10]</sup> reported that a positive circumferential resection margin has a significant and major prognostic impact on the local recurrence rate of rectal carcinoma after TME. However, Luna-Perez *et al*<sup>[19]</sup> reported that circumferential resection margin involvement is not correlated significantly with

local recurrence of rectal adenocarcinoma ( $P = 0.33$ ). Hall *et al*<sup>[11]</sup> reported that the local recurrence rate of rectal carcinoma with a positive circumferential resection margin is 15% and 11% in those with a negative circumferential resection margin. The difference between the two groups was not significant. Our results demonstrate that circumferential resection margin involvement had a significant correlation with local recurrence of middle and low rectal carcinoma. Local recurrence was more frequently observed in rectal carcinomas with a positive circumferential resection margin (4 of 12 patients, 33.3%) than in those with a negative circumferential resection margin

(3 of 44 patients, 6.8%) ( $P = 0.014$ ), suggesting that circumferential resection margin status is an important predictor for the local recurrence of middle and low rectal carcinoma. It has been shown that residual mesorectal metastasis observed in rectal surgery may be the most important factor for local recurrence of rectal carcinoma<sup>[22,23]</sup>. In the current study, the local recurrence of rectal carcinoma was more frequent in patients with mesorectal metastasis than in those without mesorectal metastasis (16.7% vs 5.0%). However, there was no significant difference between the two groups ( $P = 0.206$ ). TME may be also a plausible explanation for the observation.

Sugihara *et al*<sup>[24]</sup> investigated the correlation between local recurrence and clinicopathologic characteristics of rectal carcinoma by multivariate analysis, and found that local recurrence of lower rectal cancer is significantly associated lymph node metastasis. It has been demonstrated that pathologic stages T and N are the significant predictors for the local recurrence of rectal carcinoma<sup>[25]</sup>. In the present study, local recurrence of poorly- and moderately- differentiated rectal carcinomas was found in 5 of 34 patients (35.7%) and in 2 of 37 patients (5.4%), respectively ( $P = 0.009$ ), while no local recurrence of well-differentiated rectal carcinoma was observed in any patients, suggesting that local recurrence of rectal carcinoma is significantly correlated with tumor differentiation. We also found that the local recurrence rate of rectal carcinoma was also correlated with the depth of tumor invasion. Local recurrence of  $T_3$  and  $T_2$  tumors was observed in 6 of 27 patients (22.2%) and in 1 of 23 patients (4.3%), respectively, while no local recurrence of  $T_1$  tumors was observed ( $P = 0.101$ ). Local recurrence of rectal carcinoma developed in 6 (20.7%) of the 29 patients with lymph node metastasis and in 1 (3.7%) of 27 patients without lymph node metastasis ( $P = 0.055$ ). These observations may be explained by the fact that the number of patients in our study was comparatively small. Further study with a larger sample size is needed.

Park *et al*<sup>[26]</sup> reported that change in perioperative serum CEA is a useful prognostic predictor for the occurrence of stage III rectal cancer and the survival of such patients. Oh *et al*<sup>[27]</sup> reported that vascular invasion is significantly associated with local recurrence of rectal cancer. Our results also demonstrate that local recurrence of rectal carcinoma had a significant correlation with high CEA level ( $P = 0.026$ ) and vessel cancerous emboli ( $P = 0.001$ ). We also found that family history and cancerous perforation were significantly correlated with local recurrence of rectal carcinoma ( $P < 0.05$ ).

In conclusion, extensive mesorectal excision and postoperative adjuvant chemotherapy should be used in the treatment of middle and lower rectal carcinoma.

## COMMENTS

### Background

It is well known that local recurrence is the most important prognostic factor for rectal carcinoma. However, local recurrence of rectal carcinoma occurs in about 4%-50% of patients even after radical resection of primary tumors and lymph nodes. The risk factors for local recurrence of rectal carcinoma remain unclear.

### Research frontiers

Since total mesorectal excision (TME) was adopted as the standard treatment of rectal carcinoma, a significant decrease in its local recurrence and a trend to improve the relative survival of rectal carcinoma patients have been reported. However, the local recurrence rate of rectal carcinoma is still high. The correlation between circumferential resection margin status and local recurrence of rectal carcinoma is still controversial.

### Innovations and breakthroughs

The aim of the current study was to explore the risk factors for local recurrence of middle and lower rectal carcinoma after curative resection. A large slice technique was used to detect its mesorectal metastasis and evaluate its circumferential resection margin status. The relationship between mesorectal

metastasis and circumferential resection margin status with local recurrence was identified. The clinicopathological characteristics of rectal carcinoma were described.

### Applications

Family history, high CEA level, cancerous perforation, tumor differentiation, vessel cancerous emboli and circumferential resection margin status are the significant risk factors of local recurrence of middle and lower rectal carcinoma after curative resection. Local recurrence of middle and lower rectal carcinoma may be more frequent observed in patients with mesorectal metastasis than in those without mesorectal metastasis.

### Terminology

Local recurrence of middle and lower rectal carcinoma was defined as any recurrence diagnosed or suspected in the pelvis (tumor bed, pelvic nodes, anastomosis, drain site, or perineum).

### Peer review

The authors explored the risk factors for local recurrence of middle and lower rectal carcinoma after curative resection, demonstrating that family history, high CEA level, cancerous perforation, tumor differentiation, vessel cancerous emboli and circumferential resection margin status are the significant risk factors for the local recurrence of middle and lower rectal carcinoma. The study was well designed. The data provided in the paper are interesting and valuable.

## Abstract

**AIM:** To explore the effect of trichostatin A (TSA) on apoptosis and acetylated histone H3 levels in gastric cancer cell lines BGC-823 and SGC-7901.

**METHODS:** The effect of TSA on growth inhibition and apoptosis was examined by MTT, fluorescence microscopy and PI single-labeled flow cytometry. The acetylated histone H3 level was detected by Western blot.

**RESULTS:** TSA induced apoptosis in gastric cancer cell lines BGC-823 and SGC-7901 was in a dose and time-dependent manner. Apoptotic cells varied significantly between TSA treated groups (37.5 ng/mL 72 h for BGC-823 cell line and 75 ng/mL 72 h for SGC-7901 cell line) and control group ( $0.85 \pm 0.14$  vs  $1.14 \pm 0.07$ ,  $P = 0.02$ ;  $0.94 \pm 0.07$  vs  $1.15 \pm 0.06$ ,  $P = 0.02$ ). Morphologic changes of apoptosis, including nuclear chromatin condensation and fluorescence strength, were observed under fluorescence microscopy. TSA treatment in BGC-823 and SGC-7901 cell lines obviously induced cell apoptosis, which was demonstrated by the increased percentage of sub-G1 phase cells, the reduction of G1-phase cells and the increase of apoptosis rates in flow cytometric analysis. The result of Western blot showed that the expression of acetylated histone H3 increased in BGC-823 and SGC-7901 TSA treatment groups as compared with the control group.

## INTRODUCTION

Gastric cancer is the second most common cancer worldwide<sup>[1]</sup>. It is often not detected until an advanced stage; consequently, the 5-year survival rates are low (10%-20%). Owing to local invasion and metastasis, radiation therapy or chemotherapy does not significantly increase the length or improve the quality of life of patients with advanced gastric cancer. Therefore, there is growing interest in the development of novel neoadjuvant and adjuvant treatment modalities.

It is widely accepted that histone acetylation is essential to establish a transcriptional competent state of chromatin<sup>[2-4]</sup>. The reversible (de)acetylation of the N-terminal histone tails by specific histone acetylases and deacetylases (HDAC) is involved in the regulation of gene expression. Dysfunction of histone acetylases and HDACs are associated with different types of cancer<sup>[5-8]</sup>. Various HDAC inhibitors (HDACIs) have been described to induce cell cycle arrest, differentiation, and apoptosis in cell lines<sup>[9-12]</sup>. Many of these have potent antitumor activities *in vivo*<sup>[13]</sup>. One of the most effective and best studied HDAC inhibitors is trichostatin A (TSA). The crystallographic analysis of TSA and a histone deacetylase homologue indicates that TSA interacts reversibly with the HDAC catalytic site preventing binding of the substrate<sup>[13]</sup>. Considering that HDAC inhibitors are able to induce apoptosis in different cell types<sup>[14-16]</sup>, we intend to know their potential

to induce apoptosis in gastric cancer cell lines BGC-823 and SGC-7901. We also studied the effect of TSA-induced acetylated histone H3 level on these cell lines.

## MATERIALS AND METHODS

### Reagents and antibodies

Stock solutions of TSA (Sigma-Aldrich, USA) in ethanol were stored at -20°C. Dimethylthiazole diphenyl tetrazolium bromide (MTT), propidium iodide (PI, Beijing Zhongshan Golden Bridge Biotechnology, China) and Hoechst 33342 (Sigma-Aldrich) were used. Antibody against GAPDH was purchased from Santa Cruz Biotechnology (Santa Cruz Biotechnology, USA). Anti-acetyl-histone H3 (rabbit polyclonal IgG) and Goat Anti-Rabbit IgG, HRP-conjugate were purchased from Upstate Biotechnology (Upstate Biotechnology, USA).

### Cell culture and treatment

Human gastric epithelial cell lines BGC-823 and SGC-7901 were obtained from Institute of Tumor Research of Heilongjiang. BGC-823 cells and SGC-7901 cells were cultured and maintained in RPMI 1640, supplemented with fetal bovine serum 10% (v/v), penicillin 100 IU/mL, and streptomycin 100 µg/mL in a humidified atmosphere of 5% CO<sub>2</sub> in air at 37°C.

### MTT assay

MTT assay was used to obtain the number of living cells in the sample. Cells were seeded on 96-well plates at a predetermined optimal cell density to ensure exponential growth in the duration of the assay. After a 24 h preincubation, growth medium was replaced with experimental medium containing the appropriate drug or control. Six duplicate wells were set up for each sample, and cells untreated with drug served as control. Treatment was conducted at 12, 24, 48 and 72 h with final TSA concentrations of 37.5, 75, 150, 300 and 600 ng/mL, respectively. After incubation, 10 µL MTT (6 g/L, Sigma) was added to each well and the incubation was continued for 4 h at 37°C. After removal of the medium, MTT stabilization solution (dimethylsulphoxide: ethanol = 1:1) was added to each well, and shaken for 10 min until all crystals were dissolved. Then, optical density was detected in a microplate reader at 550 nm wavelength using an ELISA reader. The negative control well without cells was used as zero point of absorbance. Each assay was performed in triplicate.

### Detection of chromatin condensation

Chromatin condensation was detected by nuclear staining with Hoechst 33342. BGC-823 and SGC-7901 cells were collected by centrifugation (500 × g for 5 min at 4°C) and washed twice with PBS. Cells were fixed in 10% formaldehyde and stored at 4°C. For analysis, cells were washed in PBS, then Hoechst 33342 (5 mg/L) was directly added to the medium by gently shaking at 4°C for 5 min. Stained nuclei were visualized under a Zeiss Axiophot fluorescence microscope at

400 × magnification with an excitation wavelength of 355-366 nm and an emission wavelength of 465-480 nm. Four independent replicates were used. In this way, apoptotic BGC-823 and SGC-7901 cells were stained brightly blue because of their chromatin condensation, while normal BGC-823 and SGC-7901 cells were evenly stained slightly blue.

### Cell cycle and apoptosis assays

BGC-823 and SGC-7901 cells were treated as indicated. Floating and adherent cells were collected by centrifugation (500 × g for 5 min at 4°C) and washed twice with PBS. Cells were fixed in 90% ethanol and stored at -20°C. For analysis, cells were washed in PBS and stained by suspension in PI (50 mg/L) containing RNase A (2 mg/L) for 30 min at 4°C. Stained cells were analyzed on a FACSscan (Becton-Dickinson, Heidelberg, Germany).

### Western blotting

Cells treated as indicated were harvested in 5 mL of medium, pelleted by centrifugation (1000 × g for 5 min at 4°C), then washed twice with ice-cold PBS and lysed in ice-cold HEPES buffer [HEPES (pH 7.5) 50 mmol/L, NaCl 10 mmol/L, MgCl<sub>2</sub> 5 mmol/L, EDTA 1 mmol/L, glycerol 110% (v/v), Triton X-100 1% (v/v), a cocktail of protease inhibitors, and 1 mg/L TSA on ice for 30 min. The lysates were clarified by centrifugation (15000 × g for 10 min at 4°C) and the supernatants then either analyzed immediately or stored at -80°C. Equivalent amounts of protein (50 µg) from total cell lysates were resolved by SDS-PAGE using precast 12% Bis-Tris gradient gels and transferred onto polyvinylidene difluoride (PVDF) membranes. Membranes were blocked overnight at 4°C in blocking buffer [nonfat dried milk 5% (v/v), NaCl 150 mmol/L, Tris (pH 8.0) 10 mmol/L and 0.05% Tween 20 (v/v)]. Proteins were detected by incubation with primary antibodies at appropriate dilutions in blocking buffer overnight at 4°C. Unbound antibody was removed by washing with Tris-buffered saline (pH 7.2) containing 0.5% Tween 20 (TBS-T). The membrane was then incubated at room temperature with horseradish peroxidase-conjugated secondary antibody. After extensive washing with TBS-T, bands were visualized by enhanced chemiluminescence followed by exposure to autoradiography.

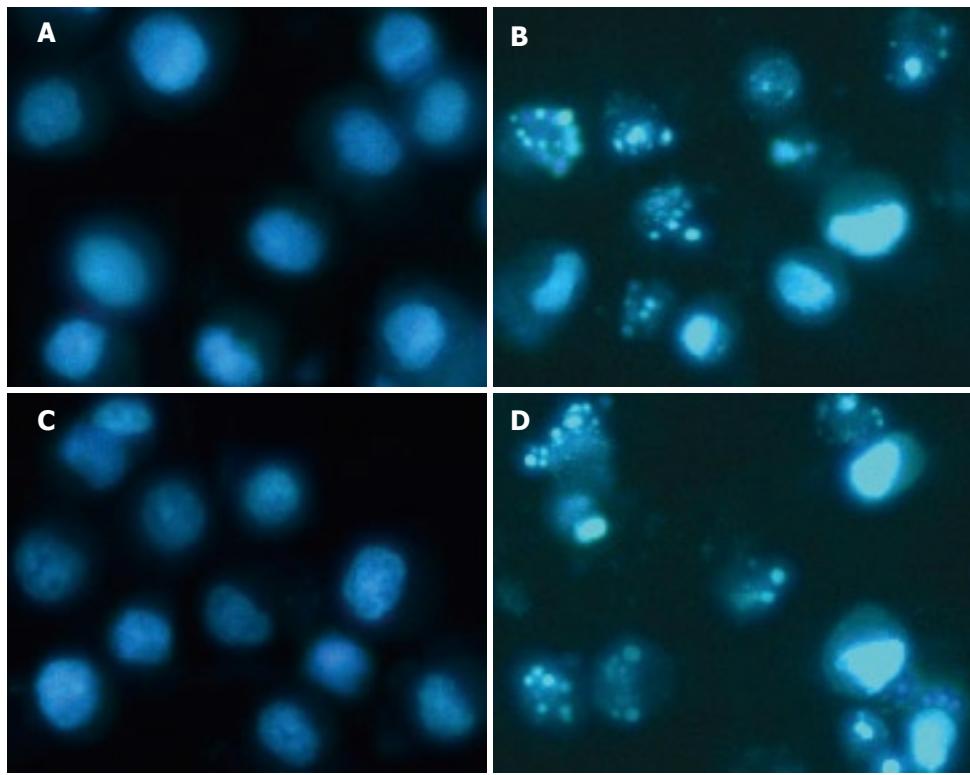

## RESULTS

### TSA inhibited the proliferation of BGC-823 and SGC-7901 cells

TSA inhibited cellular proliferation and survival in BGC-823 and SGC-7901 cell lines. It resulted in a significant decrease in the cell population of BGC-823 and SGC-7901 compared with control, following treatment with TSA. Inhibition of TSA was dependent on the dose and incubation time (Tables 1 and 2).

### TSA induced apoptosis of BGC-823 and SGC-7901 cells

To investigate the effects of TSA induced cytotoxicity,

**Figure 1** TSA (37.5 ng/mL per 72 h in BGC-823 cells and 75 ng/mL per 72 h in SGC-7901 cells) induced apoptosis (Hoechst 33342 staining,  $\times 400$ ). **A:** No typical apoptotic BGC-823 cells were observed in control group; **B:** BGC-823 cells treated with TSA (37.5 ng/mL per 72 h) showed the typical apoptotic nuclear morphology; **C:** No typical apoptotic SGC-7901 cells were observed in control group; **D:** SGC-7901 cells treated with TSA (75 ng/mL for 72 h) showed the typical apoptotic nuclear morphology.

**Table 1 Cell proliferation of BGC-823 and SGC-7901 cells incubated with various concentrations of TSA for 72 h (mean  $\pm$  SD)**

TSA	1	2	3	4	5	Control
BGC-823	$0.81 \pm 0.09^1$	$0.75 \pm 0.14^1$	$0.71 \pm 0.10^1$	$0.14 \pm 0.02^2$	$0.14 \pm 0.03^2$	$1.12 \pm 0.06$
SGC-7901	$1.11 \pm 0.04$	$0.87 \pm 0.04^1$	$0.58 \pm 0.09^1$	$0.23 \pm 0.06^2$	$0.21 \pm 0.04^2$	$1.16 \pm 0.07$

<sup>1</sup>P = 0.02 vs control; <sup>2</sup>P = 0.005 vs control. 1: 37.5 ng/mL; 2: 75 ng/mL; 3: 150 ng/mL; 4: 300 ng/mL; 5: 600 ng/mL.

**Table 2 Cell proliferation of BGC-823 (37.5 ng/mL) and SGC-7901 cells (75 ng/mL) for 12, 24, 48 and 72 h (mean  $\pm$  SD)**

TSA	12	24	48	72	Control
BGC-823	$1.13 \pm 0.12$	$1.13 \pm 0.04$	$1.11 \pm 0.02$	$0.85 \pm 0.14^1$	$1.14 \pm 0.07$
SGC-7901	$1.14 \pm 0.21$	$1.07 \pm 0.07$	$1.01 \pm 0.17$	$0.94 \pm 0.07^1$	$1.15 \pm 0.06$

<sup>1</sup>P = 0.02 vs control.

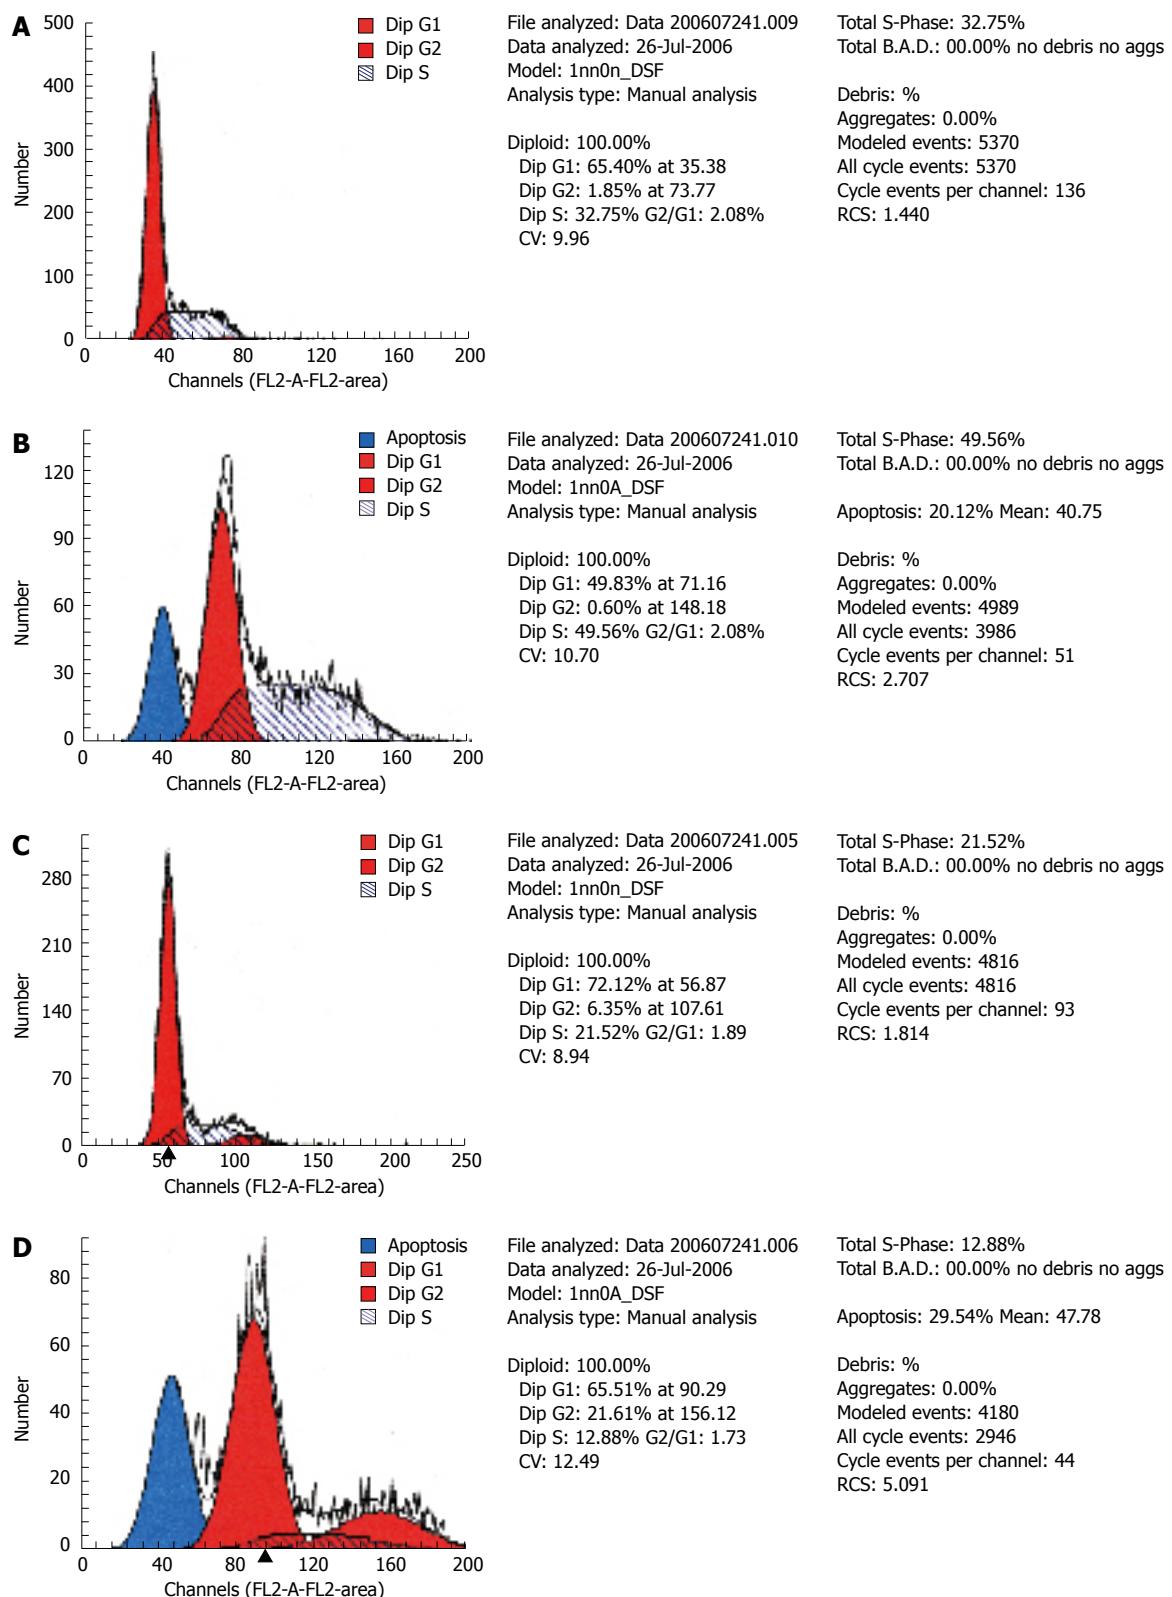

morphologic changes of apoptosis were observed under fluorescence microscope. At 72 h, cells treated with or without TSA (37.5 ng/mL in BGC-823 and 75 ng/mL in SGC-7901) were stained by Hoechst 33342, a classical way of identifying apoptotic cells, to observe nuclei morphology. The result indicated that nuclei of most BGC-823 and SGC-7901 cells treated with TSA were stained highly condensed, bright nucleus; while the cells in control group were stained average slightly blue (Figure 1).

TSA treatment (37.5 ng/mL per 72 h) sensitively induced apoptosis of BGC-823 cells, which was

demonstrated by the raised percentage of sub-G1 phase cells, the increase of apoptosis rates (20.12%) in flow cytometry (Figure 2). Cell cycle effects were examined by FACS analysis. The reduction of G1-phase cells (65.40%-49.83%) and the increment of S-phase cells (32.75%-49.56%) were observed in BGC-823 cells (Figure 2A, B). TSA induced apoptosis in SGC-7901 cells. Upon treatment with TSA (75 ng/mL) for 72 h in SGC-7901 cells, the reduction of G1-phase cells (72.12%-65.51%), S-phase cells (21.52%-12.88%) and the increment of G2-phase cells (6.35%-21.61%), and apoptosis rates (29.54%) were observed by FACS analysis (Figure 2C, D).

#### **TSA regulated the level of acetylated histone H3 in BGC-823 and SGC-7901 cell lines**

Western blot analysis was used to detect the level of acetylated histone H3 of BGC-823 cells and SGC-7901 cells treated with TSA (37.5 ng/mL per 48 h in BGC-823 cells and 75 ng/mL per 48 h in SGC-7901 cells). It was

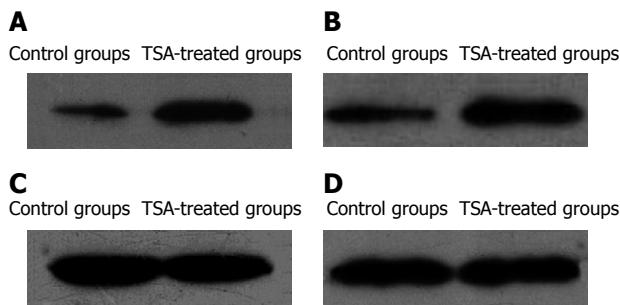

**Figure 2** Effect of TSA on the cell cycle and apoptosis as analyzed by FACS. **A:** Control of BGC-823 cells; **B:** Treatment with 37.5 ng/mL TSA for 72 h in BGC-823 cells; **C:** Control of SGC-7901 cells; **D:** Treatment with 75 ng/mL TSA for 72 h in SGC-7901 cells.

shown that there was an increase of acetylated histone H3 level in TSA treated cells (Figure 3).

## DISCUSSION

Histones are small-sized and basic-charged proteins

essential for chromatin folding. Posttranslational modifications such as acetylation, methylation, and phosphorylation have been suggested to be involved in the regulation of gene expression, cell division, nucleosome assembly, and DNA repair processes *via* alterations in the nucleosome architecture<sup>[17]</sup>. To

**Figure 3** Cell lysates were analyzed by Western blots using anti-GAPDH and anti-acetyl-histone H3 antibody. **A:** BGC-823 cells acetylated histone H3 (17 kDa); **B:** SGC-7901 cell acetylated histone H3 (17 kDa); **C:** BGC-823 cells GAPDH (loading control, 37 kDa); **D:** SGC-7901 cells GAPDH (loading control, 37 kDa).

date, acetylation is the best understood among these modifications. Chromatin structure and, thereby, transcription is controlled by the level of acetylation of histones, which is determined by the balance between histone acetyl transferase (HAT) activity and histone deacetylase (HDAC) activity. While proteins with HAT activity have been demonstrated to function as transcriptional coactivators, proteins with HDAC activity induce transcriptional repression<sup>[18]</sup>. Therefore, acetylation of histones seems to be predominantly implicated in the regulation of gene transcription due to nucleosome remodeling. The aberrant utilization of HDACs is believed to be a contributing factor in carcinogenesis.

HDAC inhibitors are members of a new class of agents able to regulate gene expression by modulating chromatin structure. HDAC inhibitors have been known to induce differentiation, growth arrest, and apoptosis in cancer cells<sup>[15,19,20]</sup>. TSA, an antifungal antibiotic with cytostatic and differentiating properties in mammalian cell culture, is a potent and specific inhibitor of HDAC activity. X-ray crystallographic studies showed that TSA has a tubular structure with a zinc atom at its base and TSA fits into this structure with the hydroxamic moiety of the inhibitor binding to the zinc. Numerous studies have reported that TSA can induce apoptosis in cancer cells<sup>[21-23]</sup>.

Moderately and poorly differentiated gastric adenocarcinomas are the main types of gastric cancer in China. The rate of each was 71.0% and 58.7% in early gastric cancer and advanced gastric cancer, respectively. The cell lines BGC-823 and SGC-7901 were derived from human gastric adenocarcinoma. The stem cells in tumor tissue have infinite proliferating ability, and can form colonies *in vitro*. The BGC-823 cell line is a poorly-differentiated human gastric adenocarcinoma cell line. SGC-7901 cell was a moderately-differentiated human stomach adenocarcinoma cell line with mutant p53. Here, we examined the effect of TSA on BGC-823 and SGC-7901 cells.

We found that low concentrations of TSA can significantly reduce the growth of BGC-823 and SGC-7901 cells, and the effects of TSA on BGC-823 and SGC-7901 cells are dose and time-dependent. The

mechanism leading to these effects remained unknown. Accumulating evidence suggests that inhibition of HDAC activity leads to relaxation of the structure of chromatin associated with a specific set of programmed genes. The relaxed chromatin structure allows these genes to be expressed, which, in turn, arrests tumor cell growth<sup>[13,24]</sup>. This suggests that induction of histone hyperacetylation by HDAC inhibitors is responsible for the antiproliferative activity through selective induction of genes that play important roles in the cell cycle and cell morphology<sup>[25]</sup>. It has been shown that reversible acetylation of lysine on histone H3 plays an important role in regulating gene transcription<sup>[26]</sup>. Our findings indicate that acetylated histone H3 expression levels increased in BGC-823 and SGC-7901 cells following TSA treatment. Increased acetylated histone H3 expression levels in BGC-823 and SGC-7901 cells may be an important event in mediating the apoptosis of BGC-823 and SGC-7901 cells induced by TSA. These findings generate the necessity to investigate the mechanism of TSA in the treatment of BGC-823 and SGC-7901 cells. Therefore, we suppose that HDAC inhibitors cause acetylated histones to accumulate in tumor tissues, and this accumulation can be used as a trigger of the biologic activity of the HDAC inhibitors.

In summary, in this study we showed that TSA can induce apoptosis in gastric cancer cell lines BGC-823 and SGC-7901. We demonstrated that the expression of acetylated histone H3 might be correlated with apoptosis. Further work will be necessary to explore additional mechanisms that lead to induction of apoptosis.

## COMMENTS

### Background

Histones are small-sized and basic-charged proteins essential for chromatin folding. The acetylation state of histones is reversibly regulated by histone acetyltransferase (HAT) and deacetylase (HDAC). An imbalance of this reaction leads to an aberrant behavior of the cells in morphology, cell cycle, differentiation, and carcinogenesis. HDAC is especially known to play an important role in carcinogenesis.

### Research frontiers

There is increasing evidence that HDAC inhibitors are effective therapeutic agents in the treatment of a variety of cancers refractory to conventional anticancer agents. Several structurally diverse HDAC inhibitors, such as trichostatin A (TSA), amicropic acid, or butyrate, have been identified and their *in vitro* activity in transformed cells makes them promising agents for cancer therapy. Although extensive studies have been done, roles of HDAC inhibitor in gastric cancer are still unclear.

### Innovations and breakthroughs

This study investigates the effects of the HDAC inhibitor TSA on gastric cancer cell lines BGC-823 and SGC-7901. The results demonstrate that low concentrations of TSA can significantly reduce the growth of BGC-823 and SGC-7901 cells and the effects of TSA on BGC-823 and SGC-7901 cells are dose and time-dependent. These findings indicate that acetylated histone H3 expression levels increased in BGC-823 and SGC-7901 cells following TSA treatment.

### Applications

It can be seen from this paper that the HDAC inhibitor, TSA, can induce apoptosis of BGC-823 and SGC-7901 cells. It suggests that HDAC is a promising target for the development of anticancer drugs for gastric cancer.

### Peer review

This paper examined the role of TSA in gastric cancer cell lines BGC-823

and SGC-7901. The results show that TSA can induce apoptosis of BGC-823 and SGC-7901 cells. And the expression of acetylated histone H3 might be correlated with apoptosis. It suggests that TSA has a potential against gastric cancer.

### Abstract

**AIM:** To obtain evidence for selection of antigens used in genetically engineered vaccine against *Helicobacter pylori* (*H pylori*).

**METHODS:** Enzyme linked immunoabsorbent assay (ELISA) was established on the basis of recombinant protein antigens rUreB, rHpaA, rVacA, rCagA1, rNapA, rFlaA and rFlaB of *H pylori* to detect expression rates of the antigens in bacterial isolates as well as positive rates of the antibodies in sera from *H pylori*-infected patients. PCR was applied to the detection of carrying rates of the genes encoding antigens in the isolates.

**RESULTS:** The outputs of rUreB, rHpaA, rVacA, rCagA1, rNapA, rFlaA and rFlaB were approximately 35%, 32%, 15%, 23%, 56%, 25% and 20% of the total bacterial proteins, respectively. One hundred and fifty-one strains of *H pylori* were isolated from 347 biopsy specimens of chronic gastritis, peptic ulcer or gastric adenocarcinoma, with a positive rate of 43.5%. All of the isolates expressed UreB, HpaA, FlaA and FlaB while 52.3%, 92.1% and 93.4% of the isolates expressed VacA, CagA and NapA, respectively. In the sera of 151 *H pylori*-infected patients, the positive rates

### INTRODUCTION

In 1983, for the first time, Barry J. Marshall and J. Robin Warren successfully isolated *Helicobacter pylori* (*H pylori*) from the gastric mucosa of patients with chronic active gastritis or peptic ulcer<sup>[1,2]</sup>, for which they were awarded the Nobel Prize in Physiology or Medicine in 2005. Thereafter, lots of findings have confirmed that *H pylori* is strongly associated with chronic gastritis, peptic ulcer<sup>[3-5]</sup>, gastric adenocarcinoma, mucosa-associated lymphoid tissue (MALT) lymphoma and primary gastric non-Hodgkin's lymphoma<sup>[6,7]</sup>. Vaccination is by far the most effective and economical method in infection prevention, though the vaccine against *H pylori* is scarcely touched up to date, which is probably due to the culture of *H pylori* characterized by enriched media, slow growth and incubation in a microaerophilic environment, plus difficulty in storage, etc. Thus, it may be a cost-effective strategy in developing a genetically engineered vaccine against *H pylori*.

The selection for antigenic targets is critical in the design of a genetically engineered vaccine against *H pylori*. The best ascertained antigens out of the outer membrane protein antigens are UreB and HpaA followed by VacA, CagA, NapA, FlaA and FlaB<sup>[8-13]</sup>. Tomb reported all the genomic sequences of *H pylori* in 1997<sup>[14]</sup>, and in our previous study, these genomic prokaryotic expression systems were constructed.

The expression rates of outer membrane protein antigens are known to be diverse in the same bacterial isolates from various area, and so are the levels of immune response to different protein antigens, all of which will ultimately affect the selection of vaccine antigens. In order to develop effective genetically engineered vaccines, the encoding gene of the antigen should be widely located at the genome of clinical strains. The gene sequence should be conservative, the natural expression rate should also be high, and the immunogenicity of expression products should be potent. Our research focused on the carrying rates and expression level of 7 genes of *H pylori* from the clinical *H pylori* in China, including rUreB, rHpaA, rVacA, rCagA1, rNapA, rFlaA and rFlaB. Meanwhile, the levels of specific antibodies against the 7 antigens in serum were measured. This research will further our understanding of the diversity of carrying rates of the encoding genes, the expression levels and immunogenicity of the antigens, and provide evidence for the selection of antigens employed in genetically engineered vaccines against *H pylori*.

## MATERIALS AND METHODS

### Materials

Three hundred and forty-seven biopsy specimens and serum samples were collected gastroscopically from patients with chronic gastritis, peptic ulcer or gastric adenocarcinoma in hospitals between January, 2005 and December, 2006, and 35 serum samples were collected from healthy children. All the patients were not treated with antibiotics, anti-inflammatory agents or antacids within a month prior to the sample collections. *H pylori* NCTC11637 strain, 10 clinical strains of *Bacillus coli* and 10 *Staphylococcus aureus* strains were offered by Department of Pathogenic Biology, Zhejiang University School of Medicine. Urease test kit was from Sanqiang BioChem Co., Ltd., Fujian Province, China. Oxidase test kit was from Hangzhou Tianhe Microorganism Reagent Co., Ltd., Zhejiang Province, China. Gel image analysis system was from Bio-Rad, and Ni-NTA affinity column was from BioColor. Rabbit anti-*H pylori* antibody was from DAKO. HRP-labeling goat anti-rabbit IgG and HRP-labeling goat anti-human IgG were from Jackson ImmunoResearch. The primer and PCR SuperMix High Fidelity were from TaKaRa Biotechnology, Dalian, China.

### Isolation and identification of bacteria

Each biopsied specimen from the patients was divided

into two parts. One was detected by urease test to check whether the urease test is positive. If it was positive, the other was then used to isolate *H pylori* as previously described<sup>[15]</sup>. Biopsy specimens were homogenized with a tissue grinder and inoculated onto Columbia agar plates supplemented with 8% defibrinated sheep blood, 5 mg/L TMP, 10 mg/L vancomycin, 2500 U/L bacilliosporin B and 2.5 mg/L amphotericin B. The plates were incubated at 37°C under microaerophilic conditions (5% O<sub>2</sub>, 10% CO<sub>2</sub>, 85% N<sub>2</sub>) for 3-5 d. Isolates were identified as *H pylori* with Gram-staining. The positive strains were stored in Brucella broth at -70°C.

### Expression, purification and identification of recombinant protein antigens

The gene clones of ureB, hpaA, vacA, cagA, napA, flaA and flaB were from *H pylori* NCTC11637 strain. The plasmids pET32a or pET42a and an *Escherichia coli* (*E.coli*) BL21DE3 (presented by the Department of Pathogenic Biology, Zhejiang University School of Medicine) were used as the expression system and host cells, respectively. The expression system of recombinant antigens was inoculated in LB medium with 0.5 mmol/L IPTG and shaken at 250 r/min and cultured at 30°C for 4-5 h. The expression of rUreB (569 aa, about 63 kDa), rHpaA (260 aa, about 29 kDa), rVacA (747 aa, about 82 kDa), rCagA1 (716 aa, about 79 kDa), rNapA (144 aa, about 16 kDa), rFlaA (510 aa, about 56 kDa) and rFlaB (514 aa, about 57 kDa) were detected with SDS-PAGE and gel image analysis system. These recombinant protein antigens were purified by Ni-NTA affinity column. The purity quotient of recombinant protein antigens was detected with SDS-PAGE. The recombinant antigens were identified by Western blot. Rabbit anti-*H pylori* were used as the first antibody and HRP-labeling goat anti-rabbit IgG as the second antibody. The density of extracted proteins was determined by ultraviolet spectrophotometry<sup>[16]</sup>.

### Preparation of recombinant protein antiserum

Each of these recombinant proteins was respectively mixed with Freund's complete adjuvant, and thereafter administered into the New Zealand rabbits for immunization with multiple dorsal ID, four times, once every two weeks. Rabbit serum was collected by cardiac puncture two weeks after the final immunization. The titer of antiserum was determined by double immunodiffusion.

### Detection of specific serum antibodies

The purified rUreB, rHpaA, rVacA, rCagA1, rNapA, rFlaA and rFlaB were diluted to 20 µg/mL with carbonic acid buffer (pH 9.6), coated in a 96-well plate with 0.1 mL of the dilution per well overnight. Based on the result of the preliminary experiment, serum samples from patients with chronic gastritis, peptic ulcer or gastric adenocarcinoma, and those from healthy people (1:200 dilution in both) were used as the first antibody, and HRP-labeling goat anti-human IgG (1:4000 dilution)

**Table 1 Major information relative to PCR for amplifying 7 genes of *H pylori***

Target genes	Primer sequences (5'-3')	Reference	Tm (°C)	Products (bp)
<i>ureB</i>	F: CGTCGGCAATAGCTGCCATAGT R: GTAGGTCTGCTACTGAAGCCTTA	[18]	55	463
<i>hpaA</i>	F: CTTTAGGTGCGAGCGTGGTG R: AATTCTTGGCGTCTTTGATAA	[19]	54	716

as the second antibody. The ELISA result of the serum sample from a patient was considered positive if the optical density at 490 nm ( $A_{490}$ ) was over the mean  $\pm$  3SD of negative serum sample<sup>[17]</sup>.

#### Expression levels of target proteins on clinical strains

*H pylori* NCTC11637 strain, clinical strains of *H pylori*, 10 *Bacillus coli* strains and 10 *Staphylococcus aureus* strains were ultrasonically broken up and centrifuged at 1000 r/min to obtain supernatant, which was later determined by ultraviolet spectrophotometry<sup>[16]</sup>. The proteins of *H pylori*, *Bacillus coli* and *Staphylococcus aureus* were diluted to 50 µg/mL with carbonic acid buffer (pH 9.6), coated in a 96-well plate with 0.1 mL of the dilution per well overnight. Based on the result of the preliminary experiment, the self-prepared rabbit antiserum against the recombinant protein (1:200 or 1:400 dilution) was used as the first antibody, and HRP-labeling goat antiserum against rabbit IgG (1:3000 dilution) as the second antibody, respectively. The ELISA result of an ultrasonic supernatant sample of *H pylori* was considered positive if the  $A_{490}$  value was over the mean  $\pm$  SD of 20 ultrasonic supernatant samples at the same protein concentration of *Bacillus coli* and *Staphylococcus aureus*<sup>[17]</sup>.

#### Detection of target genes

The genes of clinical *H pylori* *ureB*, *hpaA*, *vacA*, *cagA*, *napA*, *flaA* and *flaB* were detected by PCR. Each reaction volume was 50 µL with an amplification of 35 cycles. Both the upstream and downstream primer concentrations were 20 pmol. Primer sequences, main reaction values and the product are shown in Table 1<sup>[13,18-22]</sup>. The PCR products were identified with 2% agarose gel staining using the fluorescent dye ethidium bromide.

#### Comparison of positive target gene rates and their products with serum antibodies

The positive rates of target genes and their products of clinical *H pylori*, as well as specific antibodies against target antigens in patients' sera were compared, which

would benefit the comprehension of the diversity of positive rates of target genes, the expression levels and immunogenicity of their antigens.

#### Comparison of positive *H pylori* infection rates with expression rates of virulent factors in different gastric diseases

*HpaA*, *FlaA* and *FlaB* are structural proteins essential to the outer membrane of *H pylori*, while *UreB*, *VacA*, *CagA* and *NapA* are virulent factors of functional proteins. Accordingly, the positive *H pylori* infection rates were compared with the expression rates of virulent factors and the severity of gastric diseases.

#### Statistical analysis

Data were analyzed with SPSS10.0 statistical software. The positive ratio was performed by chi square test.  $P < 0.05$  was considered statistically significant.

## RESULTS

#### Positive *H pylori* infection rates

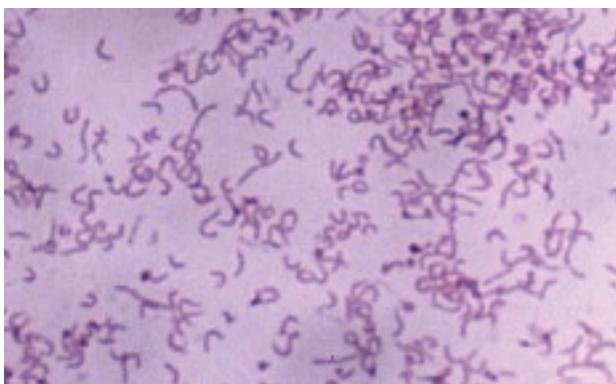

One hundred and fifty-one strains of *H pylori* were successfully isolated from 347 biopsy specimens of chronic gastritis, peptic ulcer or gastric adenocarcinoma with a positive rate of 43.5% (Figure 1). Of the 151 *H pylori*-infected patients, 102 were diagnosed to have chronic gastritis (38 with superficial gastritis, 52 with active gastritis and 12 with atrophic gastritis), and 43 patients were diagnosed to have peptic ulceration (16 with gastrectosis, 18 with duodenobulbar ulcer and 9 with complex ulcer), and 6 patients with gastric adenocarcinoma.

#### Expression of target recombinant proteins and detection of purified recombinant proteins and their antigens

The expression rate of *rUreB*, *rHpaA*, *rVacA*, *rCagA1*, *rNapA*, *rFlaA* and *rFlaB* was approximately 35%, 32%, 15%, 23%, 56%, 25% and 20%, respectively. The purified recombinant proteins were shown as a single band detected by SDS-PAGE (Figure 2). The recombinant protein antigens could be recognized specifically by the rabbit antiserum against the whole cells of *H pylori*, and the results were shown to be positive by Western Blot analysis (Figure 3).

**Table 2** Comparison between positive rates of 7 genes and their products of *H pylori* and serum antibodies

Target gene (positive/negative)	Positive rate (%)	Target antigen (positive/negative)	Positive rate (%)	Target antibody (positive/negative)	Positive rate (%)
<i>ureB</i> (151/0)	100	UreB (151/0)	100	Anti-UreB (151/0)	100
<i>hpaA</i> (151/0)	100	HpaA (151/0)	100	Anti-HpaA (132/19)	87.4
<i>vacA</i> (151/0)	100	VacA (79/72)	52.3	Anti-VacA (65/86)	43.0
<i>CagA</i> (146/5)	96.7	CagA (139/12)	92.1	Anti-CagA (108/43)	71.5
<i>napA</i> (148/3)	98.0	NapA (141/10)	93.4	Anti-NapA (135/16)	89.4
<i>flaA</i> (151/0)	100	FlaA (151/0)	100	Anti-FlaA (128/23)	84.8
<i>flaB</i> (151/0)	100	FlaB (151/0)	100	Anti-FlaB (120/31)	79.5

Figure 1 *H pylori* isolated from a patients' biopsy (Gram-staining,  $\times 1000$ ).

### Titer of rabbit antiserum against target recombinant proteins

All the rUreB, rHpaA, rVacA, rCagA1, rNapA, rFlaA and rFlaB could efficiently induce the rabbits to produce specific antibodies, and the titer of antisera was 1:8, 1:8, 1:4, 1:4, 1:8, 1:4 and 1:4, respectively.

### Positive rates of specific serum antibodies

The  $A_{490}$  (mean  $\pm$  SD) of the negative control sera from the 35 healthy children was  $0.23 \pm 0.05$ , and the  $A_{490}$  of the positive standard was 0.38. In the sera from 151 *H pylori*-infected patients, the positive rate of IgG antibodies against UreB, HpaA, VacA, CagA, NapA, FlaA and FlaB was 100% (151/151), 87.4% (132/151), 43% (65/151), 71.5% (108/151), 89.4% (135/151), 84.8% (128/151) and 79.5% (120/151), respectively. The total range of the  $A_{490}$  was 0.27-2.05.

### Positive rates of target protein antigens of clinical *H pylori* strains

The  $A_{490}$  (mean  $\pm$  SD) of the negative control proteins from 10 *Bacillus coli* strains and 10 *Staphylococcus aureus* strains was  $0.21 \pm 0.03$ , and the  $A_{490}$  of the positive standard was 0.30. UreB, HpaA, FlaA and FlaB were expressed in 100% of the isolates (151/151), while VacA, CagA and NapA were expressed in 52.3% (79/151), 92.1% (139/151) and 93.4% (141/151) of the isolates. The total range of the  $A_{490}$  was 0.33-1.97.

### Positive rates of target genes of clinical *H pylori* strains

In the 151 clinical *H pylori* strains, the PCR products showed that the positive rate of ureB, hpaA, vacA, flaA

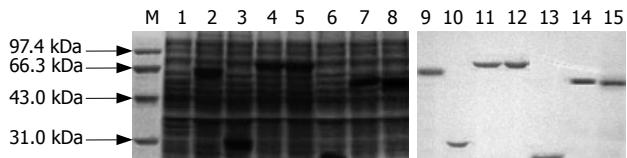

Figure 2 Expression and purification of target recombinant proteins. M: Marker (BioColor); Lane 1: Blank expression vector; Lanes 2-8 and 9-15: rUreB, rHpaA, rVacA, rCagA1, rNapA, rFlaA and rFlaB, respectively.

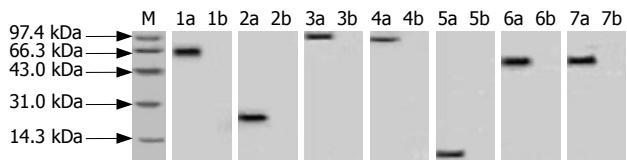

Figure 3 Detection results of target recombinant proteins by Western blot assay. M: Marker (BioColor); Lanes 1a-7a: rUreB, rHpaA, rVacA, rCagA1, rNapA, rFlaA, rFlaB, respectively; Lanes 1b-7b: blank controls.

and flaB genes was 100%, respectively, while the positive rate of CagA and napA genes was 96.7% (146/151) and 98% (148/151), respectively. The representative amplified product of each gene is shown in Figure 4.

### Positive rates of target genes, expression products and specific antibodies

In the 151 clinical strains of *H pylori*, the positive rates of ureB, hpaA, vacA, cagA, napA, flaA and flaB genes and their expression products as well as the specific corresponding antibodies are listed in Table 2. The positive rate of ureB gene and its expression product was completely coincident with that of the antibody. The positive rate of antibody against CagA was obviously lower than the positive rate and expression rate of cagA. The expression rate of vacA gene and the positive rate of corresponding antibody were obviously lower than the positive rate of vacA gene. There was a sequential decrease in the positive rate of the remaining genes, expression products and specific antibodies.

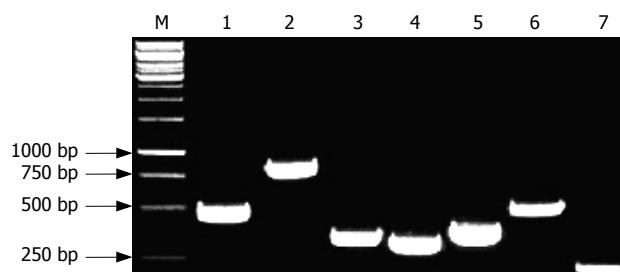

### Correlation between positive *H pylori* infection rates and expression rates of virulent factors in different gastric diseases

There was no statistically significant difference in the positive rates of *H pylori* isolated from the specimens of different gastric diseases. The expression rate of VacA

**Table 3** Correlation between positive *H pylori* infection rates and virulent factor expression in different gastric diseases

Disease	Patient	Positive number/rate of bacteria, n/%	Positive number/rate of virulence factor, n/%

<sup>a</sup>P < 0.05 vs peptic ulcer, <sup>c</sup>P < 0.05 vs active gastritis, <sup>d</sup>P < 0.01 vs atrophic gastritis.

**Figure 4** PCR products of 7 genes of *H pylori*. M: Marker (BioColor); Lanes 1-7: ureB, hpaA, vacA, CagA, napA, flaA and flaB genes of *H pylori* NCTC 11637, respectively.

gene in *H pylori* isolated from specimens of chronic gastritis was lower than that isolated from specimens of peptic ulcer ( $\chi^2 = 5.55$ ,  $P = 0.019$ ). The expression rate of VacA gene in superficial and atrophic gastritis was lower than that in active gastritis ( $\chi^2 = 5.76$ ,  $P = 0.016$ ). The expression rate of NapA gene in *H pylori* isolated from atrophic gastritis (66.7%) was lower than that in *H pylori* isolated from superficial and active gastritis (94.7%, 96.2%;  $\chi^2 = 6.81$ ,  $P = 0.009$ ;  $\chi^2 = 9.98$ ,  $P = 0.002$ ). There was no statistically significant difference in the expression rate of UreB and CagA genes and in their virulence factors in the specimens from different gastric diseases (Table 3).

## DISCUSSION

It was reported that there are many protective antigens against *H pylori*, such as UreB, HpaA, VacA, CagA, NapA, FlaA, FlaB and heat shock protein (HSP)<sup>[8-13,23]</sup>. Due to cross-antigens against HSP in different sibling bacteria<sup>[23]</sup>, 7 kinds of protective antigens of *H pylori* except for HSP were selected in our research. In order to develop effective genetically engineered vaccines, the encoding gene of the antigen should be widely located at the genome of clinical strains. The gene sequence should be conservative, the natural expression rate should also be high, and the immunogenicity of expression products should be potent. In addition, the high expression rate of recombinant proteins is also one of the most important problems to be solved in preparing a genetically engineered vaccine. Thus, it is essential

to understand the above-mentioned characteristics of protein antigens of *H pylori*.

The biological characteristics of bacteria and other microbes exhibit an obvious diversity in different regions, mainly manifested as different dominant serological types or genotypes according to their different antigenicity, toxicity and drug resistance. So far, the gene orders of ureB, hpaA, napA, flaA and flaB have been confirmed as highly conservative, while the gene order of vacA can mutate moderately between signal peptide zone (S) and intermedial zone (M), and the mutations of CagA gene order are mainly located at the 3' terminal repeat<sup>[8,9,12,13,15]</sup>. Our research focused on the carrying rates and expression level of the 7 kinds of genes of *H pylori* from the clinical *H pylori* in China. The PCR products showed the carrying rate of ureB, hpaA, vacA, flaA and flaB genes was 100%, respectively, while the carrying rate of cagA and napA genes was 96.7% and 98%, respectively. However, the expression rates of these genes were significantly different. As shown above, all the strains (100%) could express UreB, HpaA, FlaA and FlaB, and more than 90% strains (92.1% and 93.4%) could express CagA and NapA, but the expression rate of VacA was only 52.3%. While the unique epitoxin of *H pylori*, VacA, has always been the selective antigen against gene vaccine<sup>[11,24]</sup>, our study demonstrated that VacA was not the ideal antigen on the grounds that the carrying rate (100%) was not consistent with the expression rate (approximately 50%) of the gene. It was reported that the activity of vacuolus toxin is high if the vacA genotype is s1/m1, and moderate or low if the vacA genotype is s1/m2<sup>[25]</sup>. The expression rate of vacA gene was low in our study, which is relevant to the vacA genotype s1a/m2, because the vacA genotype of 55.1% *H pylori* strains is a low virulent s1a/m2 in China<sup>[15]</sup>. Almost 100% of the *H pylori* strains could carry napA gene, while the expression rate of NapA is only 60%<sup>[12]</sup>. In our research, the expression rate of napA gene was high (98%), which might be related to the protein expression of diverse epidemic strains in different regions.

In vaccination, antibodies mainly play their preventive function, while cell-mediated immunity generally eliminates the pathogenic microorganisms which invade

the human body. Because of their high level and long duration in all antibodies, IgG antibodies are regarded as the most important antibodies, thus IgG antibodies against UreB, HpaA, VacA, CagA, NapA, FlaA and FlaB in serum samples were detected in our study. The results show that the positive rate of IgG antibodies against UreB, NapA, HpaA and FlaA was 100%, 89.4%, 87.4% and 84.8%, respectively, while the positive rate of IgG antibodies against FlaB, CagA and VacA was 79.5%, 71.5% and 43%, respectively. The positive rate of IgG antibodies against HpaA, CagA, FlaA and FlaB was 71.5%-87.4%, while the carrying rate (96.7%-100%) and expression rate (92.1%-100%) of these genes were higher. This discrepancy might be related to the weak antigenicity and low natural expression of these proteins, presumably due to the insufficient exposure of these proteins to the surface of bacteria. For example, HpaA is usually called an adhesin of *H pylori*, and in fact, it is a tunica vaginalis protein expressed in the flagellae of *H pylori*<sup>[9]</sup>. FlaA and FlaB expressed in the flagella are subunits of flagellin<sup>[13]</sup>. As an intein of *H pylori*, CagA is a non-exocrine protein and only when *H pylori* has contact with host cells, does it act on the target cells through type III secretory system<sup>[10,11]</sup>. However, the high expression rate of rNapA, rUreB and rHpaA and the low expression rate of the other 4 kinds of proteins would consequently affect the selection of genetically engineered vaccines against *H pylori*.

Moreover, the relationship between the infection rate of *H pylori*, virulence factors and various gastropathies was also taken into account in our research. As mentioned above, VacA and NapA are the most important virulence factors. The former can induce vacuolar degeneration of target cells, while the latter can activate leukocytes to evoke inflammatory reactions. Urease (Ure) is the key colonization factor for *H pylori*, which is considered closely related to the virulence for its resistance to the acid environment. CagA is not directly cytotoxic, though it is the most important component of cag pathogenicity island (CPI), and thus also regarded as a reference index to bacterial virulence<sup>[26]</sup>. No statistically significant difference in the positive rate of *H pylori* isolated the specimens of different gastric diseases was found in our study. All of the strains could express UreB, and the expression rate of cagA gene was not statistically significant in the specimens of different gastric diseases. However, the expression rate of vacA gene in *H pylori* isolated from specimens of chronic gastritis was lower than that isolated from specimens of peptic ulcer ( $P = 0.019$ ), and its expression rate in superficial and atrophic gastritis was lower than that in active gastritis ( $P = 0.016$ ). The expression rate of NapA gene in *H pylori* isolated from specimens of atrophic gastritis was lower than that in *H pylori* isolated from specimens of superficial gastritis and active gastritis ( $P < 0.0001$ ). These results suggest that different gastritis might not be related to the infection rate of *H pylori* but related to the virulence of VacA and NapA.

In conclusion, according to the expression rate of the 7 kinds of genes, the positive rates of

serum antibodies, quantities of the recombinant proteins, UreB is the top option for antigens in developing genetically engineered vaccines against *H pylori* followed by NapA and HpaA.

## COMMENTS

### Background

Lots of findings have confirmed that *Helicobacter pylori* (*H pylori*) is strongly associated with chronic gastritis, peptic ulcer, gastric adenocarcinoma, mucosa-associated lymphoid tissue (MALT) lymphoma and primary gastric non-Hodgkin's lymphoma. Vaccination is by far the most effective and economical method in infection prevention, though the vaccine against *H pylori* is scarcely touched up to date. So, it is a very important task to search the vaccine against *H pylori* nowadays.

### Research frontiers

The vaccine against *H pylori* is scarcely touched nowadays, probably due to the culture of *H pylori* characterized by enriched media, slow growth and incubation in a microaerophilic environment, plus difficulty in storage, etc. Thus, it may be a cost-effective strategy in developing a genetically engineered vaccine against *H pylori*. The selection of antigenic targets is critical in the design of a genetically engineered vaccine against *H pylori*.

### Innovations and breakthroughs

In this study, the expression rate of antigens in bacterial isolates and the positive rate of antigenic antibodies in sera from *H pylori*-infected patients were detected by ELISA according to the recombinant protein antigens rUreB, rHpaA, rVacA, rCagA1, rNapA, rFlaA and rFlaB of *H pylori*. Meanwhile, PCR was performed to detect the carrying rate of genes encoding antigens in the isolates. Our research focused on the carrying rate and expression level of 7 kinds of genes of *H pylori* from the clinical *H pylori* in China.

### Applications

The experimental results of this study indicate that UreB is the first choice of the 7 kinds of recombinant protein antigens in developing a genetically engineered vaccine against *H pylori* followed by NapA or HpaA. Our results also indicate that different diseases are no correlated to the *H pylori* infection rate but to the virulence of *H pylori* strains. These results provide additional evidence for selection of antigens used in genetically engineered vaccines against *H pylori*.

### Peer review

It is an interesting paper with almost novel findings which may help develop *H pylori* vaccines.

## INTRODUCTION

Biliary rhabdomyosarcoma (BRMS) is an uncommon cause of recurrent jaundice and conjugated hyperbilirubinemia in children. Because its presentation may mimic that of a choledochal cyst, the correct diagnosis is frequently made intraoperatively at a planned choledochal cystectomy. However, identification of this entity prior to surgery is important because early surgery may carry excess morbidity and mortality. We present a patient with BRMS in whom therapeutic endoscopy was used successfully as an adjunct to chemotherapy and radiotherapy.

## CASE REPORT

A 3-year-old African American boy was referred to our center with a 1-wk history of scleral icterus, pruritus and light-colored diarrhea. His medical history included a self-limited episode of scleral icterus accompanied by diarrhea 1 mo earlier. His family history was unremarkable. Examination revealed a well-developed, healthy-appearing child. His abdomen was non-distended, the liver was soft and palpable 6 cm beneath the right costal margin without splenomegaly.

Laboratory investigations showed serum aspartate aminotransferase (AST) 391 U/L (20-60 U/L), alanine aminotransferase (ALT) 269 U/L (5-45 U/L), alkaline phosphatase (AP) 2 759 U/L (145-320 U/L), gamma-glutamyl transferase (GGT) 704 U/L (6-19 U/L), unconjugated bilirubin (UCB) 0.5 mg/dL (< 1 mg/dL), conjugated bilirubin (CB) 1.3 mg/dL (< 0.35 mg/dL) and international normalized ratio (INR) 0.9 (0.9-1.1). Hepatitis A, B and C serologies and stool studies were negative; amylase and lipase were normal.

Abdominal ultrasound revealed dilated intrahepatic and extrahepatic bile ducts and a dilated gallbladder without stones, which was suspicious for a choledochal cyst. Abdominal magnetic resonance imaging (MRI) showed an enhancing soft-tissue mass (5.8 cm × 2 cm × 1.5 cm) within the common bile duct (CBD)

## Abstract

Biliary rhabdomyosarcoma (BRMS) is an uncommon childhood malignancy which has been managed surgically. We present a case of a 3-year-old boy with BRMS, in whom endoscopic retrograde cholangiopancreatography (ERCP) was successfully used both diagnostically and therapeutically, thus obviating the need for surgery and its attendant risks of morbidity and mortality. We conclude that ERCP is an effective alternative to surgery for BRMS in some patients.

suggestive of BRMS (Figure 1). No intra-abdominal lymphadenopathy was present. The patient underwent (ERCP) to obtain tissue for diagnostic confirmation and for placement of a biliary stent. Filling defects were present on opacification of the biliary tree (Figure 2A) and sphincterotomy of the boggy ampulla revealed a protuberant fleshy mass (Figure 2B). Histology showed poorly differentiated round to stellate-shaped neoplastic cells in a myxoid stroma consistent with rhabdomyosarcoma of the botryoid subtype (Figure 3). Immunohistochemical stains for myogenin (Figure 4) and MyoD1 were positive. Chest computed tomography, whole body bone scan and bone marrow examination were unremarkable and a venous access device was

**Figure 3** A few rhabdomyosarcoma cells have eosinophilic cytoplasm suggesting skeletal muscle differentiation but most are very undifferentiated in a myxoid stroma (HE, x 400).

**Figure 4** Immunostain for myogenin reveals almost 100% positivity in neoplastic cell nuclei. The growth of this tumor beneath biliary epithelium (top) is typical of botryoid rhabdomyosarcoma (x 250).

placed to commence chemotherapy with vincristine, actinomycin-D and cyclophosphamide.

After 12 wk of chemotherapy the patient was anicteric and the tumor was undetectable by MRI, so the biliary stent was removed. At this endoscopy a repeat biopsy was obtained at the tumor bed which was histologically consistent with BRMS. Based on persistent disease, a radiation dose of 50.4 Gy was subsequently delivered to the tumor bed. The patient has completed therapy without significant complications.

## DISCUSSION

Although it is the most common biliary tumor in children, BRMS comprises only about 1% of all rhabdomyosarcomas<sup>[1-3]</sup>. BRMS usually arises in the CBD, but may originate from anywhere along the biliary tree. Positive regional lymph nodes or distant metastases were present at diagnosis in nearly 25% of children in one series<sup>[4]</sup>; and hepatic, pulmonary, peritoneal and bone metastases have been described.

Median age at presentation is 3 years and males are affected more often than females<sup>[1]</sup>. Presenting signs and symptoms include jaundice, scleral icterus, pruritus, acholic stools and abdominal pain or distention. Fever,

vomiting, diarrhea, malaise and anorexia occur less frequently.

Laboratory evaluation of patients reveals AP and gamma glutamyl-transferase elevation out of proportion to transaminases and a variable increase in CB depending on the extent of biliary obstruction. As in our patient, imaging shows a dilated biliary tree and may demonstrate an obstructive soft-tissue density.

Treatment protocols developed by the Soft Tissue Sarcoma Committee of the Children's Oncology Group, formerly the Intergroup Rhabdomyosarcoma Study Group (IRSG), stratify patients according to the site and size of the tumor, histologic subtype, degree of surgical resection and presence or absence of nodal disease or distant metastases. Although early case series advocated primary surgical resection together with chemotherapy and radiotherapy, a review by Spunt and colleagues<sup>[4]</sup> described the clinical features and outcomes of 25 children with BRMS and questioned the necessity of aggressive surgical excision for patients with tumors in this primary site. In their series, only six patients underwent gross tumor resections, of which, only two resulted in negative margins. In spite of residual tumor burden, however, 92% of patients who survived post-operatively remained disease-free. Moreover, they found that complications were more frequent in patients who underwent primary resection, these included ascending cholangitis, peritonitis, small bowel obstruction and peptic ulcer disease. The estimated five-year survival for

all patients with BRMS in this study was 66%; patients with local/regional disease fared better with 78% survival at five years<sup>[4]</sup>.

BRMS is a rare malignancy of childhood that presents with clinical and radiographic evidence that can mimic choledochal cysts. With highly effective chemotherapy, ERCP is an important diagnostic and therapeutic modality that may obviate the need for early and aggressive surgery in patients with BRMS.

### Abstract

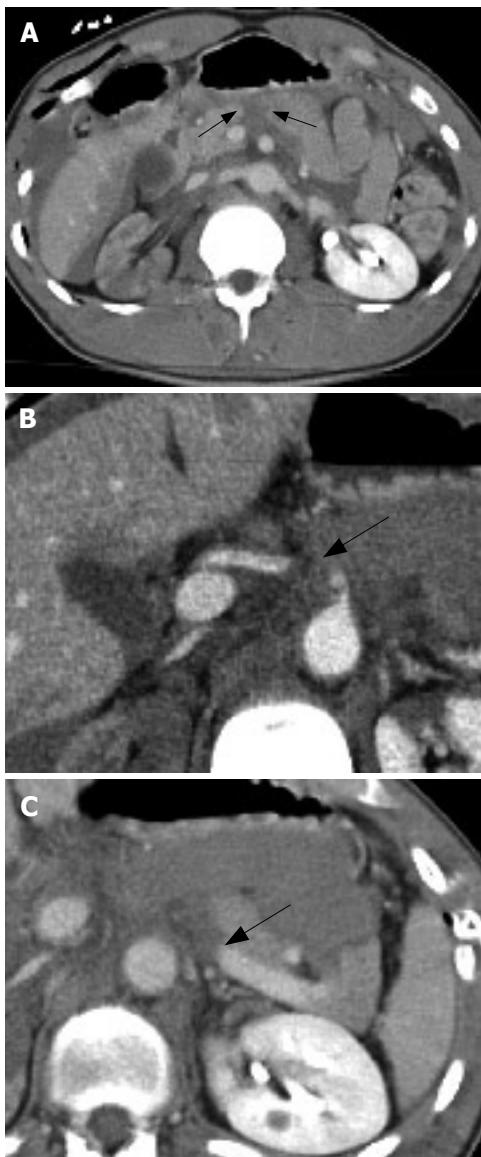

Major injuries of the pancreas may result in considerable morbidity and mortality when associated with vascular and visceral injuries. In such cases, a right diagnosis and a prompt surgical intervention are necessary to give a chance to the patient. We herein describe a case of blunt abdominal trauma in a 29-year-old man whose pancreatic rupture was associated with hepatic artery, splenic vein and extrahepatic bile duct damage. Immediate surgery was performed after computer tomography (CT), the haemorrhagic lesions dictate the emergency transfer to the operating room. Spleno-pancreatic resection was done with reconstruction of the hepatic artery, ligation of the splenic vein and a Roux-en-Y bilio-jejunial diversion. The early post-operative course was complicated by stenosis of the arterial reconstruction, which was treated by endovascular angioplasty followed by percutaneous drainage of symptomatic pseudocyst, rest and antibiotics. Finally, the patient was discharged and was alive without clinical problems at the time when we wrote this case report. The present case underlines the clinical relevance of vascular and visceral injuries associated with pancreatic trauma and the problems arising in the diagnostic evaluation and the surgical strategy of complex multiple visceral and vascular lesions in blunt abdominal trauma.

### INTRODUCTION

Isolated pancreatic injury occurs in less than 5% of major blunt abdominal traumas due to its retroperitoneal location<sup>[1]</sup>. In the majority of patients, pancreatic trauma is associated with major thoraco-abdominal lesions, which are the main factors influencing its clinical evolution in the acute phase. On the contrary, in the subsequent period, its mortality is related to septic complications and subsequent pancreatic or biliary disruption.

Few retrospective series of blunt pancreatic trauma, including more than 30 patients, have been published<sup>[2-6]</sup>. Its postoperative morbidity ranges from 42%<sup>[3]</sup> to 62%<sup>[2]</sup>, and its mortality is as high as 18.1%<sup>[6]</sup>. Age, severity of injury, amylase level, abdominal pain, injury severity score (ISS), presence of associated lesions, duration of shock, unrecognised diagnosis, delay in treatment and postoperative sepsis are the factors that significantly influence its outcome. Cases of multiple visceral and vascular lesions in the pancreatic area are not reported in the literature, presumably because the gravity of such situations does not allow the patient to survive.

We herein describe a case of blunt abdominal trauma causing pancreatic rupture associated with multiple arterial, venous, and biliary lesions, and discussed the diagnostic and therapeutic approach to such a rare case of multiple severe traumatic lesions.

**Figure 1** CT scan shows pancreatic transection between the head and body (A), thrombosis of the hepatic artery at its origin from the celiac trunk (B) and rupture/thrombosis of the splenic vein (C).

## CASE REPORT

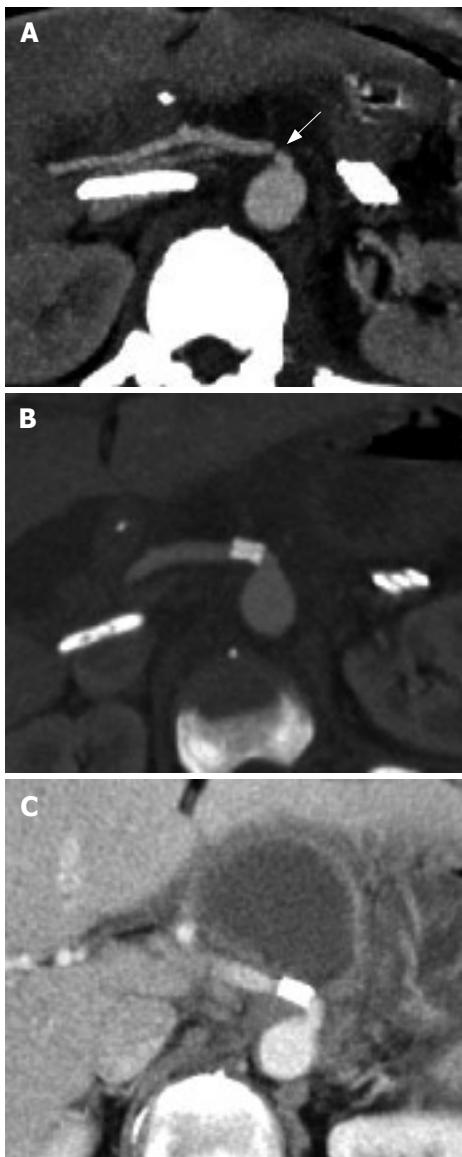

A 29-year-old male sustained a blunt abdominal trauma crushed by a carriage at work. At first observation he was in stable hemodynamic conditions, but complained of abdominal and back pain. Initial radiologic evaluation (chest and pelvis X-ray, and abdominal US) detected a right pneumothorax, bilateral rib fractures and a small amount of free blood in the abdominal cavity. Thoraco-abdominal computer tomography (CT) scan confirmed the presence of hemoperitoneum and revealed hepatic and spleen contusions, pancreatic transection at the junction between head and body (Figure 1A), thrombosis of the hepatic artery at its origin from the celiac trunk (Figure 1B), and thrombosis of the splenic vein (Figure 1C), as well as contusion of the right renal artery with no renal perfusion and fracture of D12 and L1. ISS was 34<sup>[7]</sup>. An immediate laparotomy was performed with free blood and bile found in the peritoneal cavity. After

the gastro-colic ligament was cut open, the pancreatic transaction and contusion of the common hepatic artery at its origin were confirmed with their continuity maintained by adventitia, while intima and media layers were partitioned with consequent occlusion of the artery. Splenic vein was completely transected at its confluence with the mesenterico-portal axis. Removal of the retropancreatic hematoma induced bleeding, stopped at first by digital compression and then by clamping the splenic vein and tangentially suturing the spleno-portal confluence. A complete interruption of the choledocus was demonstrated, his distal stump was ligated and the proximal one was clamped. The intra operative Doppler evaluation demonstrated that the right kidney was perfused with normal flow in the renal artery. The arterial blood supply to the liver was maintained by the inverted flow into the gastro-duodenal artery, but no pulsation could be appreciated at porta hepatis. Thus, a distal spleno-pancreatectomy was performed. After a short resection of the dissected tract, the common hepatic artery was reconstructed by end-to-end direct anastomosis to the celiac artery. Cholecystectomy and hepatico-jejunal anastomosis completed the operation. In the first postoperative period, ALT abd AST increased up to 154 U/L and 121 U/L, respectively. Postoperative CT scan showed stenosis of the celiac-hepatic anastomosis (Figure 2A), requiring operative angiography with stenting of the hepatic origin. A further CT control demonstrated the good results of the procedure (Figure 2B). Prophylactic octreotide acetate, 300 mg/d, was given after the intervention, as previously described<sup>[8]</sup>, and serum lipases were in the normal range. The patient was finally discharged on day 27 after operation.

Three months later, the patient complained of abdominal pain and dyspepsia, fever and leucocytosis. Abdominal US and CT scan showed a pancreatic pseudocyst (8 cm in diameter) in the epigastric region, between the residual pancreas, the posterior part of the stomach and the hepatic artery (Figure 2C), requiring percutaneous drainage, rest and antibiotic therapy. A significant reduction in size of the pseudocyst was achieved and the patient was discharged. At the 3-year control, the patient had normal quality of life, laboratory tests and abdominal US.

## DISCUSSION

Blunt pancreatic trauma is frequently combined with other organ injuries, which may cause early death of the patient<sup>[2-6]</sup>. The case reported in the present paper is of particular significance for the presence of multiple severe lesions involving vital structures in the pancreatic region, as a consequence of a violent trauma focused in this area, substantially sparing the rest of the patient's body. In our knowledge, this is the first reported case of contemporary traumatic disruption of the pancreatic neck, choledocus, spleno-portal confluence and common hepatic artery, probably because a patient so severely damaged is unlikely to survive to the required diagnostic

**Figure 2** CT scan 12 h after operation showing severe stenosis of hepatic artery-ceeliac reconstruction (**A**), good result of the procedure confirmed by CT after endovascular treatment (**B**), and a symptomatic pseudocyst in the epigastric region three months later (**C**) which was successfully treated by percutaneous drainage, rest and antibiotics.

and therapeutic time. In a paper analysing over 300 cases of traumatic vascular injury, the overall mortality was 54%, increasing up to 73% when 3 vessels were involved and 100% when 4 vessels were involved<sup>[9]</sup>. Patients affected by associated vascular and pancreatic injuries were even more rarely described (only 3 out of 101 cases analysed by Bradley and Coll)<sup>[6]</sup>.

The good outcome of the presented case is in our opinion due to the spontaneous partial haemostasis, but also to the prompt intervention, whose indication was dictated by the contrast-enhanced CT scan. The limits of this examination in defining the presence and gravity of pancreas trauma are well known. It was reported that the sensitivity of pancreatic rupture is 42.9%<sup>[6,10,11]</sup> and its low accuracy is particularly critical in defining the damage of the main pancreatic duct, the single most important factor both for surgical indication and choice

of the best surgical strategy<sup>[12-14]</sup>. In our case, CT allowed to exclude thoracic lesions and to focus on the pancreatic region, demonstrating the pancreatic body fracture and the presence of associated vascular damage. At the same time, choledochus fracture was not demonstrated, a wrong diagnosis of right renal artery thrombosis was suggested and also the hepatic artery and the splenic vein thrombosis were not clearly evaluated. This is in agreement with the literature, which reported that the mean injury grade resulting from CT is significantly lower than that resulting from surgical exploration<sup>[11]</sup>.

To avoid this limit of CT, endoscopic retrograde cholangio-pancreatography has been proposed to allow a more accurate identification of the biliary and Wirsung duct discontinuity, the superiority of which over CT scan in the evaluation of such structures is well documented<sup>[5]</sup>. However, in emergency situations, endoscopic examination is rarely considered since it requires a significant loss of time and is uselessly invasive, particularly if a surgical intervention has already proved to be necessary. In the reported case, the demonstrated vascular lesions dictated the necessity of immediate laparotomy, due to either the haemorrhagic risk or the ischemic damage to the liver. Thus, CT scan, even though it may be considered not completely accurate, is very useful for the correct management of this case.

These considerations shift the problem of complete diagnostic evaluation to the operating table, namely surgical exploration must be meticulous and systematic to demonstrate, define and treat the lesions associated with a pancreatic rupture. Undervaluation of the associated lesions is the most important negative prognostic factor for pancreatic trauma. By sectioning the gastrocolic ligament and the lesser omentum and completely mobilizing the right colon with the hepatic flexure and the right part of the transverse colon, or by performing a wide Kocher manoeuvre, a complete control of the structures potentially involved in pancreatic trauma is obtained. Surgical exploration can be completed by intraoperative instrumental evaluations such as cholangiography, endoscopy and doppler ultrasound, especially in cases in which preoperative imaging has been lacking or not exhaustive. In the presented case, the only employed intraoperative diagnostic tool was Doppler spectral analysis of the hepatic and portal flow. Evident lesions of the choledochus and pancreatic duct could be observed at inspection and irrigation. A vascular lesion may be really difficult to ascertain by simple exploration. However, after a complete transection, the haemorrhage can spontaneously stop and a complete thrombosis may be undiagnosed by a simple palpation. Intraoperative Doppler scan finally allows evaluation of the flow dynamics of suspected vascular lesions. In our case, it enabled us to demonstrate the preservation of a normal mesenterico-portal flow, the absence of residual stenosis of the mesenterico-portal axis after its suture and to document the collateral arterial flow at the hepatic hilum maintained by the gastroduodenal artery in presence of a contusion with short dissection occluding

the common hepatic artery. In case of a post-traumatic hepatic artery thrombosis, in the context of a complex trauma, reconstruction of this artery can be considered not necessary if a compensating inverted gastroduodenal artery flow is demonstrated. Reconstruction of a damaged hepatic artery is difficult, time-consuming and not rarely ineffective. However, when a bilio-digestive anastomosis has to be performed, a normal arterial flow is needed for the optimal perfusion of the biliary anastomotic stump. Intraoperative evaluation of the arterial collateral liver vascularisation may be misleading, lacking of quantitative determination. For these reasons, we did prefer to reconstruct the celiac-hepatic artery continuity by an end-to-end direct anastomosis, that later has proved to be technically imperfect and to require a post-operative percutaneous angioplasty with stenting. Our effort to maintain the continuity of the hepatic artery was justified by the transitory post-operative rise of hepatic enzymes, which returned to the normal range after stenting of the anastomosis. Moreover, a case of unrecognised hepatic artery dissection, having as a consequence a fatal fulminate hepatic failure, was recently reported<sup>[15]</sup>. Alternative techniques of revascularization by means of a prosthetic conduit should be avoided if possible, because septic complications are frequent in the postoperative course.

With regard to the biliary reconstruction, hepatico-jejunal anastomosis is preferable to a direct end-to-end reconstruction, as it allows a wide resection of the contused choledocus and anastomosis on a healthy tissue without tension<sup>[16]</sup>.

For the treatment of pancreatic transection, a number of techniques have been proposed, as an alternative to the distal pancreatectomy, accounting for 30% of the operations for pancreatic injuries<sup>[17]</sup>. With the aim to preserve endocrine pancreatic function, the distal pancreas can be anatomised to a Roux-en-Y jejunal loop, or to the stomach<sup>[18]</sup>. In presence of multiple lesions associated with the pancreatic injury, the strategy should be guided by the principle of obtaining repair of the lesions by a more simple and safe technical solution, reducing the risk of postoperative complications. Distal pancreatectomy with splenectomy, or whenever possible with splenic preservation, has a complication rate of 22.2%, lower than that of distal pancreas preserving procedures<sup>[2]</sup>. Moreover, postoperative exocrine and endocrine insufficiency is quite rare when the cephalic portion of the gland is preserved. The risk of developing proximal pancreatic stump fistula, with eventual pseudocyst formation, is independent of the treatment of the distal portion of the pancreas.

Our case demonstrates that if the haemorrhage can be spontaneously and temporarily controlled, giving to the surgeon the time strictly necessary to obtain the basilar diagnostic indications and to perform laparotomy, a systematic exploration and a surgical strategy inspired

by the principle of doing all but just what is necessary to save the patient, allow to obtain both immediate survival and long-term good quality of life.

### INTRODUCTION

Hepatocellular adenomas (HCAs) are found as unique or multiple entities. The term adenomatosis is used<sup>[1]</sup>, if the number of HCAs is greater than ten; specific etiological factors, including glycogenosis or patients taking male hormones, were initially excluded from the definition<sup>[1]</sup>, as well as women that previously were but are no longer taking oral contraceptives<sup>[2]</sup>. Adenomatosis is suspected if multiple nodules are observed on ultrasound performed in various circumstances: pain, discomfort, mass, shock related to bleeding, hepatocellular carcinoma (HCC), or by chance<sup>[3]</sup>.

HCAs belong to various categories, as shown by molecular testing of hepatocyte nuclear factor 1 $\alpha$  (HNF1 $\alpha$ )<sup>[4-6]</sup>, and  $\beta$ -catenin<sup>[5,6]</sup>, and by the expression of members of the acute phase inflammatory response [serum amyloid A (SAA), and C-reactive protein (CRP)] at both the mRNA and protein levels<sup>[7]</sup>. We used genotype/phenotype classification to identify four groups of HCA: HNF1 $\alpha$ -mutated,  $\beta$ -catenin-mutated, inflammatory HCA and HCA without known mutation. Some inflammatory adenomas are also  $\beta$ -catenin-mutated. This classification also applies to adenomatosis. However, the number of cases of adenomatosis studied in the series used for classification is less than the number of cases of single or multiple HCA.

We report two cases in which the diagnosis of adenomatosis was unexpected, based on radiological and clinical grounds, and for whom molecular and immunohistochemistry testing revealed HNF1 $\alpha$ -mutations.

### CASE REPORT

#### Case one

A 54-year-old woman was admitted to our surgical department in September, 2004, due to the discovery of hyperechoic infracentimetric nodules, within the context

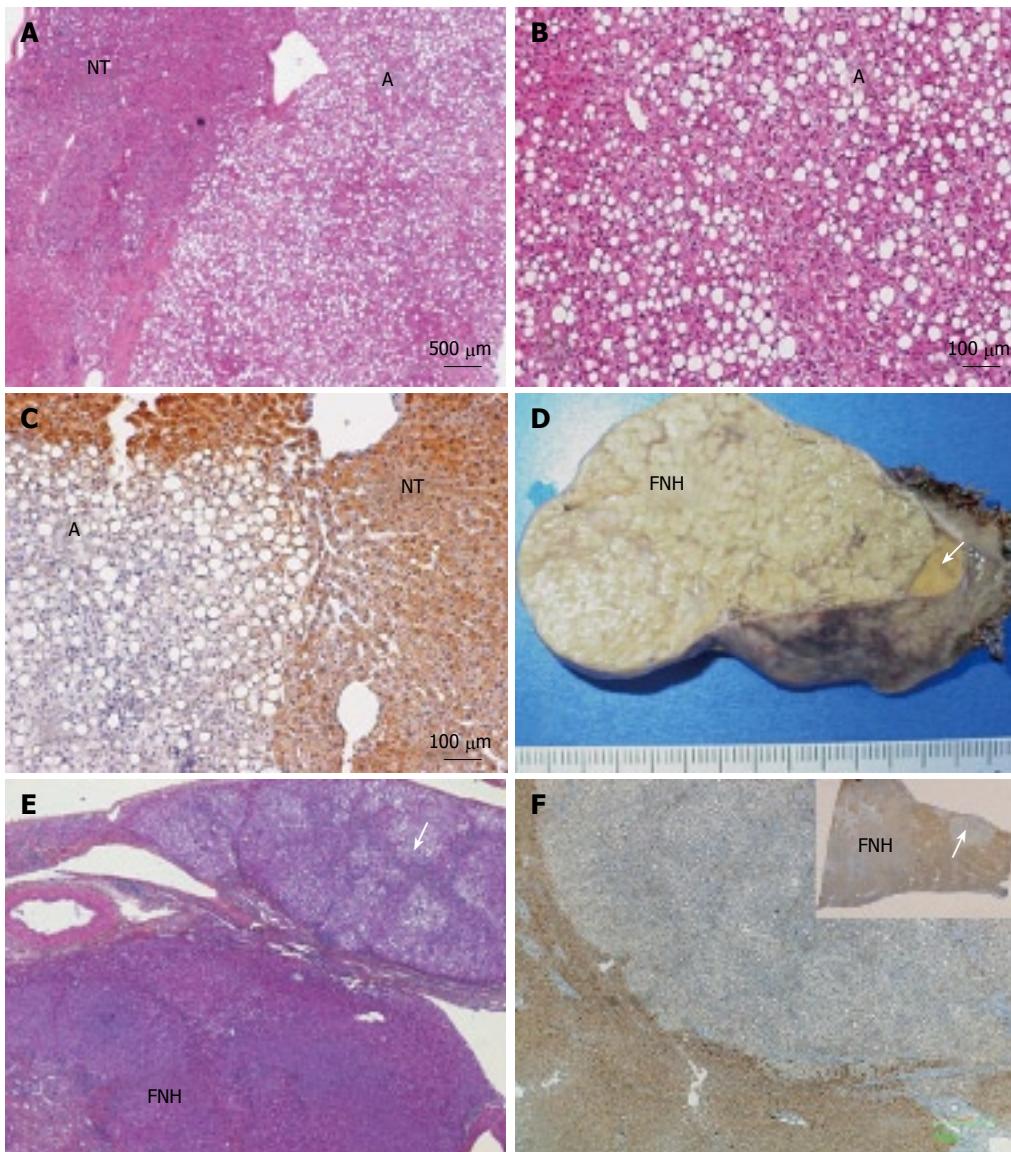

### Abstract

We present 2 cases of hepatocyte nuclear factor 1 $\alpha$  (HNF1 $\alpha$ )-mutated adenomatosis, discovered for reasons unrelated to this disease, and identified using immunohistochemical methods. These new tools may further our understanding of the link between adenomas/adenomatosis subtypes and their complications, and their association with other abnormalities.

**Figure 1** Case 1- HE staining for steatotic adenoma showing non-encapsulated nodule (A, B) and non-tumoral liver (NT) (A), LFABP immunostaining for steatotic or non steatotic tumoral hepatocytes showing no expression of LFABP (C); Case 2- a small yellowish nodule (arrow) adjacent to a typical focal nodular hyperplasia (FNH) (D), HE staining for the small nodule showing a steatotic adenoma adjacent to the FNH (E) and another small steatotic microadenoma (arrows) in the non-tumoral liver (F).

of malignancy. Her past history was remarkable: she had a haemangioma of the bulbar area for over 20 years, a cerebellar meningioma discovered later and surgically removed in June, 1999, and a choroidal melanoma treated with proton therapy in February, 2004. At the time of those diagnoses, liver nodules were not visible on ultrasound. She had 2 children and took the pill for a very short period of time (less than 1 year prior to consulting our clinic). She weighed 70 kg and was 163 cm high. Physical examination revealed a cerebellar syndrome. Several punctiform angiomas were present on the thorax and limbs. Liver function tests were normal, with the exception of 39 IU/L GGT (normal < 34 IU/L). Her blood glucose was 7.1 mmol/L (normal < 6.1 mmol/L). She had a family history of non-insulin-dependant diabetes (father and mother of the father). Magnetic resonance imaging confirmed the presence of several infra-centimetric liver nodules, but the results

were inconclusive in relation to their nature. A liver biopsy was proposed under laparoscopic guidance to confirm the suspected diagnosis of melanoma metastasis. Multiple tan nodules were observed on the surface of the liver by the surgeon. A surgical biopsy (1.5 cm × 0.8 cm) containing two yellowish nodules (0.8 mm), and a histological examination of the tissue ruled out melanoma metastasis.

Both small liver nodules were non-encapsulated and showed a benign steatotic hepatocytic proliferation, intermingled with thin-walled isolated arteries and veins (Figure 1A and B). Cytokeratin (CK) 19 was negative and very few progenitor-like cells were visible on CK7 immunostaining (not shown). Therefore, the most probable diagnosis of these small nodules was HCA. Also, a complete absence of liver fatty acid-binding protein (LFABP), in contrast to normal expression detected in hepatocytes of the surrounding liver, favoured

a diagnosis of HNF1 $\alpha$ -mutated HCA (Figure 1C). The non-tumoral liver was limited to a thin band of tissue containing mildly enlarged fibrotic portal tracts.

### Case two

A 34-year-old woman visited our surgical clinic in February, 2004, for consultation. Two liver nodules were discovered by chance (one in segment III: 40 mm  $\times$  35 mm and one in segment VI: 20 mm  $\times$  20 mm) and there were at least two additional infracentimetric nodules. The two larger nodules were described as characteristic focal nodular hyperplasia (FNH), but no final diagnosis of the smaller nodules was made. The patient had been taking oral contraceptives for 12 years. However, she was no longer taking them in the last 2 years prior to consultation at our clinic. Her family history was complex (two maternal uncles had a cerebral vascular accident at a young age, with at least one of their children having an aneurysm resulting in a death, another uncle died after cardiac surgery, her mother and two maternal aunts also had breast cancer). Blood tests, including liver function tests, were normal. An operation was ruled out, and instead the patient was monitored. She came back 6 mo later complaining of epigastric pain. The size of the largest nodule increased (60 mm  $\times$  40 mm). Segmentectomy III and VI were performed under coelioscope. The surgeon observed multiple tan nodules on the surface of the liver. The two large nodules were macro and microscopically typical FNH. Three other small nodules were also clearly visible on the resected specimen, one of which was adjacent to the FNH (Figure 1D).

Routine examination of the nodules (cases 1 and 2) consisted of HE, Masson's trichrome, and reticulin stains, as well as CK7, CK19, and a smooth muscle actin (SMA), LFABP, serum amyloid A, glutamine synthetase (GS) and  $\beta$ -catenin immunostains<sup>[7]</sup>.

All the three small nodules were steatotic, with mild ductular reaction and inflammation, as well as a few entrapped portal tracts at the periphery. It was, thus, not possible to distinguish clearly between small, incomplete, so-called FNH-like or pre-FNH<sup>[8,9]</sup> and adenomas (Figure 1E). In case 1, the complete absence of LFABP in the nodule favoured a diagnosis of HNF1 $\alpha$ -mutated HCA, whereas the LFABP immunostaining was normal both in non-tumoral livers and in adjacent FNH (Figure 1F).

SAA, GS and  $\beta$ -catenin immunostaining were negative in both cases (data not shown).

## DISCUSSION

The above two cases lead to several comments.

Such cases of adenomatosis would have been totally ignored, if for specific reasons (fear of metastasis in case 1, and surgery for a growing and painful FNH in case 2) the surface of the liver had not been observed. This is indeed true for any benign lesion without clinical or biological manifestations, including FNH,

HCA, haemangioma, etc. Thus, the true prevalence of adenomatosis is impossible to calculate, as long as we do not have the tools to recognize clinically-, biologically- and radiologically-silent HCA, particularly microadenomas. We usually ignore the outcome of such cases, but it is likely that such small nodules will remain silent, particularly in patients that are no longer on oral contraception, which was the case in our two patients.

One can argue that the presence of multiple nodules on surface of the liver does not definitely prove that all nodules are microadenomas, this is particularly true for case 2, a case associated with FNH. The possibility of multiple FNH associated with occasional adenomas cannot be excluded. However, in our experience we have never observed such a case, whereas the presence of FNH is not a rare event in adenomatosis<sup>[10]</sup>.

As a result of advances made in molecular biology and immunohistochemistry, there has been much progress in the field of HCA. In particular with genotype/phenotype correlations, it is now possible, on routine pathological examinations, to identify typical cases of HNF1 $\alpha$ -mutated or inflammatory adenomas with a greater certainty. HNF1 $\alpha$  HCA is characterized by their fat distribution<sup>[6]</sup>.

We can easily and rapidly classify 80% of adenomas with the use of immunohistochemistry, including SAA, LFABP, GS and  $\beta$ -catenin, the results of which correlate well with molecular studies<sup>[6]</sup>. The genotype/phenotype classification of HCA using immunohistochemical methods, particularly  $\beta$ -catenin immunostaining coupled to GS, is particularly important for detecting patients at risk of developing HCC, as recently reported<sup>[4,6,7,11]</sup>. Immunostains are also important for identifying atypical nodules and small sized-resected nodules and have also been particularly used to differentiate micro adenomas from other types of nodules, especially pre-FNH<sup>[8,10,12]</sup> if fibrosis or some bile ductules are present.

The next step is to validate immunohistochemical methods on liver biopsy. To better interpret the results, it is mandatory to compare the data obtained in the non tumoral liver. Non tumoral livers express LFABP, but not SAA. GS is expressed only around hepatic veins.

The term adenomatosis has frequently been used in cases with more than 10 nodules<sup>[11]</sup>. If nodules are visible on surface of the liver, the diagnosis is usually easy, irrespective of the number of larger nodules detected by imaging techniques. Adenomatosis may also be suspected, if microadenomas are present on the resected specimen containing one or several HCAs from the non-tumoral liver<sup>[13]</sup>. In our opinion, the term adenomatosis has been used incorrectly, if defined on the basis of there being more than 3 lesions on imaging<sup>[13]</sup>, without the presence of nodules visible on the liver surface or microadenomas discovered by the pathologist on the resected specimen from the non-tumoral liver. In our experience, adenomatosis is associated with HNF1 $\alpha$ -mutations (90% being somatic) in most cases<sup>[7]</sup>.

Patients with adenomas/adenomatosis may have other organ abnormalities or diseases that may or may not be related to the pathogenesis of adenomas. In

1989, Wanless *et al*<sup>[14]</sup> noticed that patients with diseases, including meningioma, astrocytoma, telangiectasia of the brain, berry aneurysm, had what he called "telangiectatic FNH" more often (TFNH). Genotype/phenotype analysis<sup>[4,6,7]</sup> has revealed that TFNH are indeed inflammatory/telangiectatic adenomas<sup>[15,16]</sup>. Curiously enough in case 1, meningioma and telangiectasia of the brain were not associated with inflammatory/telangiectatic adenomatosis, but with HNF1 $\alpha$ -mutated adenomatosis.

With this new HCA classification at hand and the knowledge that adenomas/adenomatosis can be associated with various factors, including FNH<sup>[10]</sup>, diabetes with or without familial form of adenomas/adenomatosis<sup>[17-20]</sup>, polycystic ovaries<sup>[21]</sup>, and obesity/NASH<sup>[2,22]</sup>, it is of interest to collect clinical, biological and radiological data, which should not only be related to the liver but also be related to other organs (such as the brain, skin, thyroid, ovaries, kidneys, pancreas *etc*) to understand if there is a link or not between these various types of abnormalities.

### Abstract

A cerebral lipiodol embolism is an extremely rare complication of transcatheter arterial chemoembolization for hepatocellular carcinoma. We present a case of cerebral lipiodol embolism that occurred after the third arterial chemoembolization, report the clinical and radiological findings, and review the medical literature.

### INTRODUCTION

Hepatocellular carcinoma (HCC) is a common malignancy in Asia<sup>[1,2]</sup>. Many patients with HCC present with advanced stage disease when first diagnosed. There are a variety of different therapeutic modalities used to treat advanced HCC. Transcatheter arterial chemoembolization (TACE) is used to confine tumors to the liver, in addition to shrinking their size, limiting the progression to vascular invasion, and decreasing the risk that viable tumor will embolize systemically, during hepatic manipulation at transplant hepatectomy<sup>[3-5]</sup>. Although TACE is an invasive procedure associated with several potential complications, it is a procedure that has been adopted worldwide and is the mainstay of treatment of patients with advanced HCC<sup>[6]</sup>.

To date, the literature on embolic injury to the brain, associated with iodized oil after TACE, includes only four reports<sup>[7-10]</sup>. Here we report our experience with a patient who had HCC and a cerebral lipiodol embolism (CLE) after TACE and review the previous literature.

### CASE REPORT

A 62-year-old woman with advanced HCC was admitted to the hospital for her third course of TACE. Six months previously, she was diagnosed with HCC. A 15 cm × 12 cm, well demarcated and exophytic growing tumor, at the right hepatic lobe without portal invasion, was initially identified. The exophytic HCC growth was contiguous to the diaphragm (Figure 1). Although serum alpha-fetoprotein (4514 ng/mL) was very elevated, metastatic evidence to the regional lymph nodes and bone marrow was not detected. The patient was initially treated with TACE and had a second course six months later.

On physical examination, a non-tender smooth surfaced mass was palpated at the right upper abdomen. Laboratory data (normal values in parentheses) on admission revealed a white blood cell count of  $5.95 \times 10^9/L$  (normal,  $4 \times 10^9-10 \times 10^9$ ), a platelet count of  $292 \times 10^9/L$  (normal,  $150 \times 10^9-450 \times 10^9$ ), and hypoalbuminemia, 3.6 g/dL (normal, 3.8-5.1). The hemoglobin was low, 10.0 g/dL (normal, 12.0-18.0). The coagulation time, liver function studies and renal function

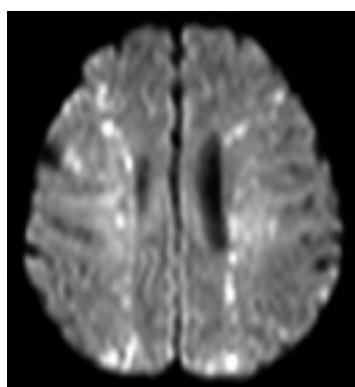

**Figure 1** Enhanced abdominal CT scan obtained after second chemoembolization shows a 15 cm × 12 cm capsulated HCC with necrotic change occupying the right hepatic lobe. The right dome of mass revealed heterogenous enhancement adjacent to the diaphragm, suggesting a viable portion (arrow).

**Figure 2** A brain CT scan without contrast obtained 7 h after chemoembolization shows multiple increased attenuated lesions in both cerebral hemisphere, consistent with deposition of iodized oil.

**Figure 3** A chest CT scan obtained 7 h after chemoembolization shows lipiodol oil dense depositions (arrow) at right basal lungs.

**Figure 4** Diffusion-weighted MR images obtained 48 h after TACE shows multiple hyperattenuating and hypertensive punctate-patchy lesions in both cerebral hemispheres.

were within normal range. Serological studies for hepatitis B were positive for HBsAg and HBeAb. The serum DNA level of hepatitis B virus was 64 400 copies/mL.

There was no evidence of cirrhosis. The distal subtraction angiography (DSA) revealed the HCC was supplied from the right inferior phrenic artery and right hepatic artery. A third course of TACE was performed via two arteries using a mixture of 50 mg adriamycin and 30 mL lipiodol as well as gelatin sponge particles (Gelform; Upjohn, MI, USA).

During the procedure, patient had no complaints, and the vital signs remained stable. Immediately after the procedure, the patients' level of consciousness deteriorated; in addition, she had breathing difficulty. The arterial blood gas analysis showed a PaO<sub>2</sub> of 55.7 mmHg, consistent with hypoxemia. A computed tomography (CT) scan of the brain, without contrast, 7 h after the TACE procedure revealed multiple lesions of increased attenuation in the cerebral cortex, basal ganglia, thalamus, and cerebellum (Figure 2).

At the same time, a CT of the chest revealed hyperattenuated images at the right lung base (Figure 3). Forty-eight hours after the procedure, magnetic resonance imaging (MRI) of the brain was performed. Diffusion-weighted (DW) images demonstrated disseminated hyperattenuated and hyper-intense punctate-patchy lesions in the cerebrum and cerebellum (Figure 4). The laboratory data was not remarkable except for a

leukocytosis. The chest X-ray showed a right pleural effusion and diffuse parenchymal infiltration one day post TACE. Echocardiography revealed no atrial septal defect or other intracardiac shunt. Three weeks later, a follow up brain CT scan revealed complete resolution of the lesions. The patients' level of consciousness gradually had improved. The neurological symptoms recovered completely by discharge 6 wk later.

## DISCUSSION

TACE is an invasive procedure associated with several potential complications, including the postembolization syndrome, septicemia, hepatic insufficiency, liver abscess formation, intrahepatic biloma, embolization of extrahepatic organs, cholecystitis, tumor rupture, multiple intrahepatic aneurysms, gastrointestinal mucosal lesions, variceal bleeding, and iatrogenic dissection or perforation of the vessel<sup>[11]</sup>. However, a CLE, following TACE in patients with HCC, is an extremely rare complication<sup>[7-10]</sup>.

The symptoms associated with CLE are variable and include visual loss, headache, motor dysfunction, and mental status changes; the severity of such symptoms varies with the site of lipiodol deposition. Occasionally, patients present with disorientation and hypoxia when the lungs are involved in lipiodol embolization (Table 1).

It is known that CLE is associated with a right-to-left shunt, and infusion of a large dose of lipiodol<sup>[12,13]</sup>. Right-to-left shunt is often undetectable on routine examination, including chest or abdominal CT, DSA,

**Table 1 Clinical characteristics of seven patients with CLE at initial presentation**

ND: Not described.

and routine echocardiography. Evidence of a shunt has not been reported in previous studies (Table 2). It is not necessary to routinely examine for detection of shunt prior to the TACE. But, if a condition is present that increases the risk of a shunt<sup>[14]</sup>, further evaluation to detect the shunt is indicated.

In most prior cases of CLE including present case, the HCC was a large tumor<sup>[7,9,10]</sup>. Determination of the optimal dose of lipiodol is of critical importance. The lipiodol dose is determined by a variety of factors including the blood supply of the tumor, the tumor size, the patients' condition, procedure tolerance, catheter position, and liver function reserve<sup>[15,16]</sup>. Generally, it is known that lipiodol dose should not exceed 15 mL to 20 mL in order to prevent the risk of an extrahepatic embolism<sup>[13]</sup>. However, there were prior reported cases of CLE that had appropriate doses of lipiodol<sup>[8-10]</sup>. Moreover, there was a study that recommended the use of a high dose iodized oil (more than 20 mL) TACE for patients with large HCC<sup>[17]</sup>. Therefore, all procedures must be individualized.

Another risk factor of a CLE is the communication between inferior phrenic artery (IPA) and the pulmonary artery; this might occur with adhesive pleura or tumor invasion<sup>[10,11]</sup>. In the previous reports, including present case, the vessels used for the lipiodol infusion described for four of seven cases. Among the four cases, there were three where lipiodol was infused into the right IPA<sup>[7,9]</sup>. In addition, in one of the four cases, where the IPA was not used, the lipiodol was infused into the right renal capsular artery (RCA), which might have

**Table 2 Outcomes and associated risk factors for TACE in the patients with CLE**

ND: Not described; RCA: Renal capsular artery; RHA: Right hepatic artery; MHA: Middle hepatic artery; RIPA: Right inferior phrenic artery; RMA: Right mammary artery.

been anastomosed to the IPA. Evidence of pulmonary embolism was noted in six of seven cases.

Therefore, we think that right IPA to pulmonary artery shunt is also a potential route for right-to-left shunt.

In the present case, because we performed echocardiography and DSA, we confirmed the absence of intracardiac and intratumoral shunts. The communication between IPA and pulmonary vessels occurred via adherent pleura and tumor recurrence. Moreover, a large dose of lipiodol was used and, therefore, the patient had a greater risk for a CLE.

As previous reports recommended<sup>[10]</sup>, the total dose of lipiodol should not exceed 20 mL and injection of lipiodol via the IPA should be used with caution during TACE procedure.

To prevent a CLE, an individualized plan of therapy including the lipiodol dose, evaluation for a shunt and choice of the vessels used for the lipiodol infusion prior to TACE are important considerations.

## INTRODUCTION

Inflammatory myoglandular polyp (IMGP) is characterized by inflammatory granulation tissue in the lamina propria<sup>[1]</sup>, proliferation of smooth muscle<sup>[2]</sup>, and hyperplastic glands with variable cystic change<sup>[3-7]</sup>. Only a small number of cases have been reported, and its pathogenesis and natural history remain unclear<sup>[8-12]</sup>. Herein, we describe a relatively rare case of lobulated-type IMGP in the ascending colon causing hematochezia. We also report the magnifying endoscopy findings of this IMGP.

## Abstract

The patient was a 33-year-old man with hematochezia. Colonoscopy revealed a lobulated peduncular polyp with bleeding, about 40 mm in diameter, in the ascending colon. The polyp had both red and white components and a mosaic pattern. Magnifying observation revealed a red rugged surface component, and smooth white nodules with enlarged round or oval crypt openings. Endoscopic polypectomy was performed. Histological examination of the specimen revealed inflammatory granulation tissue in the lamina propria, proliferation of smooth muscle, and hyperplastic glands with cystic change. This polyp was diagnosed as inflammatory myoglandular polyp (IMGP). Lobulated-type IMGP in the ascending colon is rare.

## CASE REPORT

A 33-year-old man presented with the symptom of hematochezia. He was diagnosed with chronic renal failure and underwent hemodialysis 5 years ago. His body temperature was 36.7°C, blood pressure was 148/82 mmHg, and radial pulse rate was 70 beats/min and regular. He had anemia. Laboratory tests showed hemoglobin concentration of 8.0 g/dL [normal range (NR): 12-16 g/dL], a red blood cell count of  $325 \times 10^4/\mu\text{L}$  (NR:  $380-500 \times 10^4/\mu\text{L}$ ), a white blood cell count of 8400/ $\mu\text{L}$ , and a platelet count of  $28.8 \times 10^4/\mu\text{L}$ . The levels of hepatic and biliary enzymes, such as aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphatase (ALP),  $\gamma$ -glutamyltranspeptidase ( $\gamma$ -GTP), and lactate dehydrogenase (LDH), were normal. On renal function tests, the blood urea nitrogen and creatinine levels were 44.9 mg/dL (NR: 8-20 mg/dL) and 14.1 (NR: 0.5-1.3 mg/dL), respectively. Colonoscopy revealed a lobulated peduncular polyp with bleeding, about 40 mm in diameter, in the ascending colon (Figure 1A1). The polyp had both red and white components and a mosaic pattern (Figure 1A2). Magnifying observation (EC-450ZH, Fujinon Toshiba ES Systems) revealed a red, slightly rugged surface component without normal mucosal structure (Figure 1B), and smooth white nodules with enlarged round or oval crypt openings (Figure 1C). We speculated that this polyp was non-neoplastic. It was suspected to

**Figure 1** Endoscopy showing a lobulated, peduncular polyp with bleeding, about 40 mm in diameter, in the ascending colon with both red and white components and a mosaic pattern observed in the polyp (A), magnifying endoscopy revealing a rugged surface of red component without normal mucosal structure ( $\times 50$ ) (B), and aggregated smooth nodules with enlarged round or oval crypt openings in the white component ( $\times 50$ ) (C).

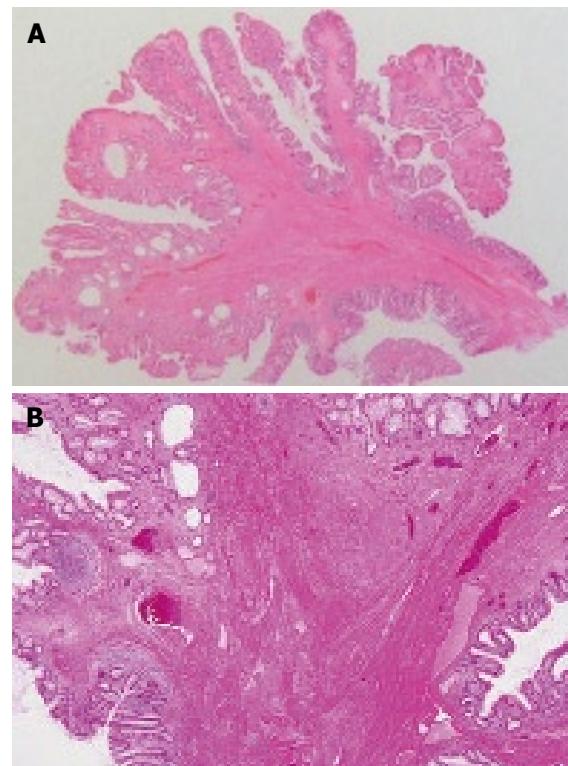

**Figure 2** Double-contrast radiograph of the ascending colon showing an about 40 mm lobulated peduncular polyp (arrow).

be an inflammatory polyp from endoscopic findings. An air contrast barium enema also revealed a pedunculated, lobulated polyp in the ascending colon (Figure 2). Endoscopic polypectomy was performed. Histological examination of the specimen revealed inflammatory granulation tissue in the lamina propria, proliferation of smooth muscle, and hyperplastic glands with cystic change (Figure 3). The lesion was diagnosed as IMGP. After endoscopic polypectomy, the symptom of hematochezia was resolved.

## DISCUSSION

IMGP is a non-neoplastic colorectal polyp, first described by Nakamura *et al*<sup>[1]</sup>. IMGP is solitary,

**Figure 3** Microscopy of the polypectomy specimen showing a stalked polyp containing numerous cystically dilated glands on the cross section under lower-power view (HE,  $\times 4$ ) (A) and inflammatory granulation tissue in the lamina propria mucosae and proliferation of smooth muscle (HE,  $\times 50$ ) (B).

pedunculated and rarely covered by a fibrin cap, and

follows a benign course. Also, IMGP has no association with inflammatory bowel diseases and is located not only in the rectosigmoid, but also in the descending and transverse colon<sup>[5]</sup>.

Only a small number of IMGP cases have been reported. According to Fujino *et al*<sup>[8]</sup>, a review of the literature revealed 48 cases of IMGP in the large intestine up to 2001. However, recent advances in diagnostic techniques have enabled us to identify small and asymptomatic polyps, and reports on IMGP of the colon have been increasing<sup>[9,10]</sup>. Fujino *et al*<sup>[8]</sup> described that the macroscopic appearance was the pedunculated type in 83.3% of cases. In that report, the sites of IMGP in the large intestine were studied and 47 of 48 cases (97.9%) had lesions in the rectum to transverse colon. Thus, IMGPs of the large intestine are predominantly in the distal colon<sup>[8,9]</sup>.

IMGPs in the colon are usually asymptomatic and often detected incidentally on barium enema or endoscopy<sup>[8-10]</sup>. Another review of the literature revealed that the main clinical feature of colorectal IMGPs is hematochezia<sup>[10,11]</sup>. Endoscopic characteristic findings are as follows: (1) pedunculated or semipedunculated, (2) red and (3) smooth, spherical and hyperemic surface with patchy mucous exudation and erosion<sup>[8,9]</sup>. IMGPs should be distinguished from other colorectal polyps such as inflammatory fibroid polyps (IFP)<sup>[10,13]</sup>, Peutz-Jegher-type polyps or juvenile polyps<sup>[10,11]</sup>. However, the correct endoscopic diagnosis of colorectal IMGP can seldom be made. Endoscopic findings of IMGP are similar to those of IFP and juvenile polyp. The final diagnosis of colonic IMGP depends on the pathological findings of endoscopic mucosal resection (EMR) or endoscopic polypectomy specimens. Harada *et al*<sup>[7]</sup> reviewed the literature and described that 4 of 40 IMGPs (10%) were lobulated. The present case was rare because IMGP located in the ascending colon and the radiographic and endoscopic findings of the polyp were the lobulated type.

Moriyama *et al*<sup>[9]</sup> reported magnifying endoscopic findings of 5 IMGPs in 2003. They described that magnifying observation revealed a slightly rugged surface consisting of aggregated smooth nodules with enlarged round or oval crypt openings. In the present case, magnifying endoscopic findings were the same as Moriyama's description. However, this polyp was unique because the lesion had red and white components and a mosaic pattern. There have been few reports on magnifying endoscopic findings of IMGP. To clarify the characteristic magnifying endoscopic findings of IMGP, we should accumulate and analyze many cases of IMGP.

As to therapy, IMGP of the large intestine can best be removed endoscopically, because it is thought to be clinically and histologically benign. Most Japanese cases are treated with polypectomy or EMR<sup>[5,7-10]</sup>. Endoscopic or surgical treatment is necessary if gastrointestinal bleeding<sup>[9]</sup> or colonic intussusception occurs. Local excision of the polyp is curative. Kayhan *et al*<sup>[12]</sup> reported a case of large IMGP (> 6 cm in diameter), which was too large for endoscopic removal, and treated with surgical resection. We consider that the percentage of

colonic IMGP patients who undergo surgical resection will decrease and endoscopic resection will increase in the future because of advances in diagnostic techniques such as improved endoscopic images and the discovery of asymptomatic small IMGPs.

In conclusion, we reported a case of IMGP in the ascending colon causing hematochezia. IMGP should generally be taken into consideration as a differential diagnosis of peduncular polyp of the colon. IMGP of the large intestine is not fatal and patients remain asymptomatic in their daily lives except for gastrointestinal bleeding or bowel obstruction. Therefore, it is likely that there will be many latent patients with IMGP in the future. Endoscopists should be aware of IMGP endoscopic characteristics, although lobulated type-IMGP in the ascending colon is rare. Further studies on the magnifying endoscopy findings of IMGP are certainly required.

### INTRODUCTION

Pancreatic pseudocysts (PPs), common sequelae of acute or chronic pancreatitis and trauma, are fluid collections arising in or adjacent to the pancreas enclosed by a wall of fibrous granulation tissue, but lacking a true epithelial lining. Interventions indicated for symptomatic, large ( $> 6$  cm in diameter), complicated and persistent ( $> 6$  wk) PP<sup>[1]</sup>, include percutaneous, endoscopic or surgical approaches<sup>[2]</sup>. With the advent of minimally invasive techniques such as cystogastrostomy, cystojejunostomy and cystoduodenostomy<sup>[3]</sup>, laparoscopy plays a great role in the management of PP. Moreover, laparoscopic cystogastrostomy has been described as a safe and efficacious alternative to open drainage of PP in adults<sup>[1,2]</sup>.

We report, in this paper, a case of a patient with a pancreatic pseudocyst caused by acute pancreatitis, who underwent intragastric laparoscopic cystogastrostomy.

### CASE REPORT

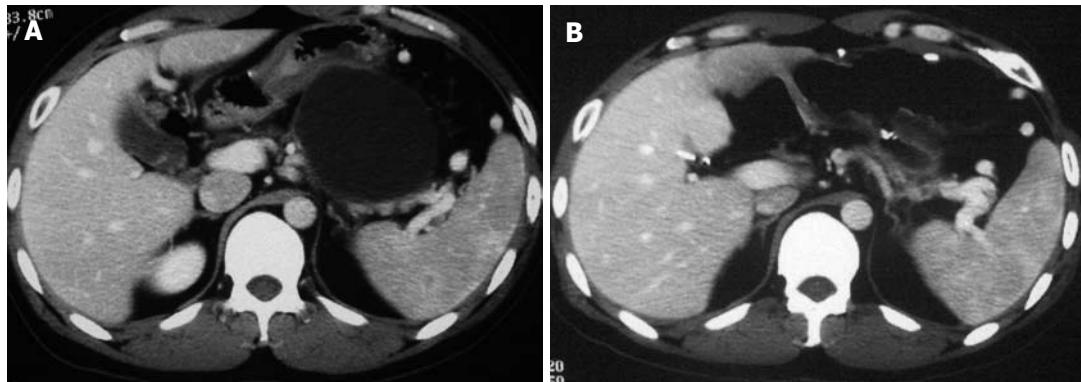

A 30-year-old male patient, complaining of epigastric pain and postprandial distension, was admitted to our hospital. He developed acute pancreatitis 10 mo ago. Regular B type ultrasound and computed tomography (CT) showed a pseudocyst at the body of the pancreas. A recent CT scan (Figure 1) demonstrated a 7.5 cm × 6.0 cm mass with its anterior wall closely contacted with the posterior wall of the stomach, as well as splenic vein compression and splenomegaly.

### Abstract

Pancreatic pseudocysts (PPs) are collections of pancreatic secretions that are lined by fibrous tissues and may contain necrotic debris or blood. The interventions including percutaneous, endoscopic or surgical approaches are based on the size, location, symptoms and complications of a pseudocyst. With the availability of advanced imaging systems and cameras, better hemostatic equipments and excellent laparoscopic techniques, most pseudocysts can be found and managed by laparoscopy. We describe a case of a 30-year-old male patient with a pancreatic pseudocyst amenable to laparoscopic cystogastrostomy. An incision was made through the anterior gastric wall to expose the posterior gastric wall in close contact with the pseudocyst using an ultrasonically activated scalpel. Then, another incision was made for cystogastrostomy to obtain complete and unobstructed drainage. The patient recovered well after operation and was symptom-free during a 6-mo follow-up, suggesting that laparoscopic cystogastrostomy is a safe and effective alternative to open cystogastrostomy for minimally invasive management of PP.

**Key words:** Pancreatic pseudocyst; Laparoscopic

**Figure 1** **A:** Pre-operative CT scan shows a 7.5 cm X 6.0 cm pseudocyst, is in close contact with the posterior wall of the stomach. In addition, splenic vein compression and splenomegaly are also observed. **B:** Post-operative CT scan reveals effective drainage of the pseudocyst and dramatic relief of splenic vein compression.

The patient underwent laparoscopic cystogastrostomy. In brief, after general anesthesia, a 10-mm port was placed subumbilically for laparoscopy, two 5-mm working ports were placed in the left subcostal area and a 5-mm port was placed in the subxiphoid. Laparoscopic ultrasound showed that a pseudocyst was firmly adhered to the posterior wall of the stomach. An ultrasonically activated scalpel was used to create a 5 cm anterior gastrostomy at the maximal displacement site of the stomach. A laparoscopic needle was introduced to confirm the location of the pseudocyst and to sample fluid. Then, the scalpel was used to create a cystogastrostomy opening approximately 4 cm in size between the adherent posterior and anterior gastric walls of the pseudocyst. After the needle entered the pseudocyst, more than 500 mL of fluid contents was aspirated. Electrocautery diathermy and titanium clips were used to achieve hemostasis at the bleeding sites in the cystogastrostomy. The anterior gastrostomy was closed using a linear stapler. A nasojejunal tube was left in place at the end of the procedure which took 150 min. Histologic analysis revealed a typical pancreatic pseudocyst.

After the operation, the patient was given parenteral nutrition and enteral nutrition *via* a nasojejunal tube, and recovered well without complications. The nasojejunal tube was removed on the 8th postoperative day and the patient was discharged on the 11th postoperative day. A repeat CT scan (Figure 1B) before discharge revealed effective drainage of the pseudocyst and dramatic relief of splenic vein compression. The patient was free of symptoms and signs of recurrent pseudocyst during a 6-mo follow-up.

## DISCUSSION

Pancreatic pseudocysts occur in 2%-10% of patients after acute pancreatitis and in about 10%-30% of patients after chronic pancreatitis<sup>[4]</sup>, and can be treated with different procedures. In general, spontaneous regression of small asymptomatic PPs may be observed in 30%-60% of acute pancreatitis patients<sup>[5]</sup>. Conservative management with bowel rest and parenteral

nutrition increases the likelihood of spontaneous regression<sup>[6]</sup>. However, a large number of patients with PPs need interventions. Factors determining the route and time of intervention include (1) location, size and persistence of the cyst, (2) maturity of the cyst wall when the patient presents with symptoms, (3) presence or absence of complications, (4) availability of local expertise and experience<sup>[2]</sup>. Generally, indications for intervention of PPs include > 6 cm in diameter, > 6 wk in persistence, symptoms (including epigastric pain, nausea, vomiting, biliary obstruction, and duodenal obstruction), complications (including infection, hemorrhage, rupture) and matured wall<sup>[1,2,7]</sup>.

Intervention options for treatment include percutaneous, endoscopic, and surgical procedures. Percutaneous drainage of PPs is a procedure of choice for infected and obstructed pseudocysts with an immature wall. It is also used in situations where definitive internal drainage could not be done<sup>[2]</sup>. However, this procedure seems to have a high risk of recurrence or development of pancreatic percutaneous fistula<sup>[8]</sup>. Furthermore, percutaneous drainage is inadequate in many cases because of thick viscous contents, which may cause luminal obstruction of drainage catheters<sup>[9]</sup>. Endoscopic drainage in the presence of endoscopic ultrasound (EUS) is an important procedure in the management of pseudocysts, especially cysts indenting the stomach or duodenum and in the absence of necrotic tissue<sup>[2]</sup>. However, endoscopic drainage is associated with a high rate of technical failure, cyst recurrence, infection, bleeding, stent blockage, and inadequate drainage. Aljarabah *et al*<sup>[1]</sup> hold that endoscopic drainage is more suitable for chronic PPs within the head and body of the gland, whereas acute PPs, particularly those that complicate necrotizing pancreatitis, are best managed with laparoscopic surgery where expertise is available. Laparoscopic drainage of mature PPs is minimally invasive and offers definitive drainage. Over the past years, laparoscopic surgery of the pancreas has increasingly emerged as a procedure in the treatment of PPs<sup>[3]</sup>. Laparoscopic procedures for pancreatic pseudocysts include pancreatic cystogastrostomy, cystoduodenostomy, and cystojejunostomy. Barragan *et al*<sup>[10]</sup> compared the laparoscopic procedures by analyzing their advantages and

disadvantages, and concluded that when the pancreatic cyst is located in close contact with the posterior wall of the stomach, it is best drained with the anterior procedure.

According to the history of acute pancreatitis and the location, size, and persistence of the pseudocyst in our case, percutaneous procedure and EUS-guided drainage were not suitable, and laparoscopic cystogastrostomy was performed via the anterior procedure. Laparoscopy was carried out using a 4-port technique. Because the pseudocyst shared a common wall, a cystogastrostomy, 4 cm in size, was created directly using an ultrasonic scalpel. The superior visualization provided by laparoscopy afforded the ability to obtain hemostasis efficiently, and the adequate incision helped establish effective drainage, thus preventing recurrence of the pseudocyst. The patient recovered well after the operation and was free of symptoms after 6 mo of follow-up.

Laparoscopic drainage, a minimally invasive technique, can definitively drain mature PPs. Our patient was treated with laparoscopic procedures without any untoward effects. Although our experience is limited, our minimally invasive procedure appears to be safe and effective. Laparoscopic cystogastrostomy should be considered a choice of treatment in the management of PPs.

## Meetings

### Events Calendar 2008-2009

FALK SYMPOSIA 2008  
January 24-25, Frankfurt, Germany  
Falk Workshop: Perspectives in Liver Transplantation

International Gastroenterological Congresses 2008  
February 14-16, Paris, France  
EASL-AASLD-APASL-ALEH-IASL Conference Hepatitis B and C virus resistance to antiviral therapies  
[www.easl.ch/hepatitis-conference](http://www.easl.ch/hepatitis-conference)

February 14-17, Berlin, Germany  
8<sup>th</sup> International Conference on New Trends in Immunosuppression and Immunotherapy  
[www.kenes.com/immuno](http://www.kenes.com/immuno)

February 28, Lyon, France  
3<sup>rd</sup> Congress of ECCO - the European Crohn's and Colitis Organisation Inflammatory Bowel Diseases 2008  
[www.ecco-ibd.eu](http://www.ecco-ibd.eu)

February 29, Québec, Canada  
Canadian Association of Gastroenterology  
E-mail: general@cag-acg.org

March 10-13, Birmingham, UK  
British Society of Gastroenterology Annual Meeting  
E-mail: BSG@mailbox.ulcc.ac.uk

March 14-15, HangZhou, China  
Falk Symposium 163: Chronic Inflammation of Liver and Gut

March 23-26, Seoul, Korea  
Asian Pacific Association for the Study of the Liver  
18<sup>th</sup> Conference of APASL: New Horizons in Hepatology  
[www.apaslseoul2008.org](http://www.apaslseoul2008.org)

March 29-April 1, Shanghai, China  
Shanghai-Hong Kong International Liver Congress  
[www.livercongress.org](http://www.livercongress.org)

April 05-09, Monte-Carlo (Grimaldi Forum), Monaco  
OESO 9<sup>th</sup> World Congress, The Gastro-esophageal Reflux Disease: from Reflux to Mucosal Inflammation-Management of Adeno-carcinomas  
E-mail: robert.giuli@oeso.org

April 9-12, Los Angeles, USA  
SAGES 2008 Annual Meeting - part of Surgical Spring Week  
[www.sages.org/08program/html/](http://www.sages.org/08program/html/)

April 18-22, Buenos Aires, Argentina  
9<sup>th</sup> World Congress of the International Hepato-Pancreato Biliary Association  
Association for the Study of the Liver  
[www.ca-ihpba.com.ar](http://www.ca-ihpba.com.ar)

April 23-27, Milan, Italy  
43<sup>rd</sup> Annual Meeting of the European Association for the Study of the Liver  
[www.easl.ch](http://www.easl.ch)

May 2-3, Budapest, Hungary  
Falk Symposium 164: Intestinal

### Disorders

May 18-21, San Diego, California, USA  
Digestive Disease Week 2008

May 21-22, California, USA  
ASGE Annual Postgraduate Course Endoscopic Practice 2008: At the Interface of Evidence and Expert Opinion  
E-mail: education@sgo.org

June 4-7, Helsinki, Finland  
The 39<sup>th</sup> Nordic Meeting of Gastroenterology  
[www.congrex.com/ngc2008](http://www.congrex.com/ngc2008)

June 5-8, Sitges (Barcelona), Spain  
Semana de las Enfermedades Digestivas  
E-mail: sepd@sepdi.es

June 6-8, Prague, Czech Republic  
3<sup>rd</sup> Annual European Meeting: Perspectives in Inflammatory Bowel Diseases  
E-mail: meetings@imedex.com

June 10-13, Istanbul, Turkey  
ESGAR 2008 19<sup>th</sup> Annual Meeting and Postgraduate Course  
E-mail: fca@netvisao.pt

June 11-13, Stockholm, Sweden  
16<sup>th</sup> International Congress of the European Association for Endoscopic Surgery  
E-mail: info@aes-eur.org

June 13-14, Amsterdam, Netherlands  
Falk Symposium 165: XX International Bile Acid Meeting, Bile Acid Biology and Therapeutic Actions

June 13-14, Prague, Czech Republic  
Central and Eastern European Conference on Colorectal "Cancer" Screening, Prevention and Management  
E-mail: idca2008@guantar.cz

June 25-28, Barcelona, Spain  
10<sup>th</sup> World Congress on Gastrointestinal Cancer  
Imedex and ESMO  
E-mail: meetings@imedex.com

June 25-28, Lodz, Poland  
Joint Meeting of the European Pancreatic Club (EPC) and the International Association of Pancreatology (IAP)  
E-mail: office@epc-iap2008.org  
[www.e-p-c.org](http://www.e-p-c.org)  
[www.pancreatology.org](http://www.pancreatology.org)

June 26-28, Bratislava, Slovakia  
5<sup>th</sup> Central European Gastroenterology Meeting  
[www.ceurgem2008.cz](http://www.ceurgem2008.cz)

July 9-12, Paris, France  
ILTS 14<sup>th</sup> Annual International Congress  
[www.ilts.org](http://www.ilts.org)

September 10-13, Budapest, Hungary  
11<sup>th</sup> World Congress of the International Society for Diseases of the Esophagus  
E-mail: isde@isde.net

September 13-16, New Delhi, India  
Asia Pacific Digestive Week  
E-mail: apdw@apdw2008.net

APDW 2008  
September 13-16, New Delhi, Indian Organized: Indian Society of Gastroenterology

III FALK GASTRO-CONFERENCE

September 17, Mainz, Germany  
Falk Workshop: Strategies of Cancer Prevention in Gastroenterology

September 18-19, Mainz, Germany  
Falk Symposium 166: GI Endoscopy - Standards & Innovations

September 18-20, Prague, Czech Republic  
Prague Hepatology Meeting 2008  
[www.czech-hepatology.cz/phm2008](http://www.czech-hepatology.cz/phm2008)

September 20-21, Mainz, Germany  
Falk Symposium 167: Liver Under Constant Attack - From Fat to Viruses

September 24-27, Nantes, France  
Third Annual Meeting  
European Society of Coloproctology  
[www.escp.eu.com](http://www.escp.eu.com)

October 8-11, Istanbul, Turkey  
18<sup>th</sup> World Congress of the International Association of Surgeons, Gastroenterologists and Oncologists  
E-mail: orkun.sahin@serenas.com.tr

October 18-22, Vienna, Austria  
16<sup>th</sup> United European Gastroenterology Week  
[www.negf.org](http://www.negf.org)  
[www.acv.at](http://www.acv.at)

October 22-25, Minnesota, USA  
Anstralian Gastroenterology Week 2008  
E-mail: gesa@gesa.org.au

October 22-25, Brisbane, Australia  
71<sup>st</sup> Annual Colon and Rectal Surgery Conference  
E-mail: info@colonrectalcourse.org

October 31-November 4, Moscone West Convention Center, San Francisco, CA  
59<sup>th</sup> AASLD Annual Meeting and Postgraduate Course  
The Liver Meeting Information: [www.aasld.org](http://www.aasld.org)

November 6-9, Lucerne, Switzerland  
Neurogastroenterology & Motility Joint International Meeting 2008  
E-mail: ngm2008@mci-group.com  
[www.ngm2008.com](http://www.ngm2008.com)

November 12, Santiago de Chile, Chile  
Falk Workshop: Digestive Diseases: State of the Art and Daily Practice

November 28-29, Cairo, Egypt  
1<sup>st</sup> Hepatology and Gastroenterology Post Graduate Course  
[www.egyptgastrohep.com](http://www.egyptgastrohep.com)

December 7-9, Seoul, Korea  
6<sup>th</sup> International Meeting Hepatocellular Carcinoma: Eastern and Western Experiences  
E-mail: sglee@amc.seoul.kr

INFORMATION FOR ALL  
FALK FOUNDATION e.V.  
E-mail: [symposia@falkfoundation.de](mailto:symposia@falkfoundation.de)  
[www.falkfoundation.de](http://www.falkfoundation.de)

Advanced Courses - European

Institute of Telesurgery EITS - 2008 Strasbourg, France  
January 18-19, March 28-29, June 6-7, October 3-4

N.O.T.E.S  
April 3-5, November 27-29  
Laparoscopic Digestive Surgery

June 27-28, November 7-8  
Laparoscopic Colorectal Surgery

July 3-5  
Interventional GI Endoscopy Techniques  
Contact address for all courses:  
E-mail: [info@eits.fr](mailto:info@eits.fr)

International Gastroenterological Congresses 2009  
March 23-26, Glasgow, Scotland  
Meeting of the British Society of Gastroenterology (BSG)  
E-mail: [bsg@mailbox.ulcc.ac.uk](mailto:bsg@mailbox.ulcc.ac.uk)

May 17-20, Denver, Colorado, USA  
Digestive Disease Week 2009

November 21-25, London, UK  
Gastro 2009 UEGW/World Congress of Gastroenterology  
[www.gastro2009.org](http://www.gastro2009.org)

### Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London, The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (*World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly open access peer-reviewed journal supported by an editorial board consisting of 1208 experts in gastroenterology and hepatology from 60 countries. The aim of the journal is to deliver the most clinically relevant original and commentary articles to readers, and to make the full text publicly available to all clinicians, scientists, patients and biomedical students on an unrestricted platform, so that they can access and learn about the most recent key advances in the field.

In addition to the open access nature, another key characteristic of *WJG* is its reading guidance for each article which includes background, research frontier, related reports, breakthroughs, applications, terminology, and comments of peer reviewers for the general readers.

*WJG* publishes articles on esophageal, gastrointestinal, hepatobiliary and pancreatic tumors, and other esophageal, gastrointestinal, hepatic-biliary and pancreatic diseases in relation to epidemiology, immunology, microbiology, motility & nerve-gut interaction, endocrinology, nutrition & obesity, endoscopy, imaging and advanced hi-technology.

The main goal of *WJG* is to publish high quality commentary articles contributed by leading experts in gastroenterology and hepatology and original articles that combine the clinical practice and advanced basic research, to provide an interactive platform for clinicians and researchers in internal medicine, surgery, infectious diseases, traditional Chinese medicine, oncology, integrated Chinese and Western medicine, imaging, endoscopy, interventional therapy, pathology and other basic medical specialties, and thus eventually improving the clinical practice and healthcare for patients.

#### Indexed and abstracted in

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, Index Medicus, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, *Nature Clinical Practice Gastroenterology* and *Hepatology*, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

#### Published by

The WJG Press

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

#### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://wjg.wjnet.com>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjnet.com/wjg/help/instructions.jsp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [submission@wjnet.com](mailto:submission@wjnet.com), or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was carried out; author contributions; disclosure of any financial support for the research; and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (remove all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s), and full family name.

**Author contributions:** The format of this section should be like this: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed research; Wang CL, Zou CC, Hong F and Wu XM performed research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed data; and Wang CL, Liang L and Fu JF wrote the paper.

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

#### Abstract

An informative, structured abstract of no more than 350 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipment, and the experimental procedures should be included. RESULTS: The observed and experimental results, including data, effects, outcome, etc. should be included. Authors should present *P* value where necessary, and also include any significant data. CONCLUSION: Accurate view and the value of the results should be included.

The format for structured abstracts can be found at: <http://www.wjnet.com/wjg/help/11.doc>.

#### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

#### Text

For articles of these sections, original articles, rapid communication

and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, should be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

### Illustrations

Figures should be numbered as 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...etc. It is our principle to publish high resolution-figures for the printed and E-versions.

### Tables

Three-line tables should be numbered 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P* < 0.05 and <sup>d</sup>*P* < 0.01 are used. A third series of *P* values can be expressed as <sup>e</sup>*P* < 0.05 and <sup>f</sup>*P* < 0.01. Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, □, ▲, △, etc., in a certain sequence.

### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

### PMID requirement

PMID roots in the abstract serial number indexed by PubMed (<http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed>). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information for journal citations is very important. Using the reference testing system, the authors and editor should check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in an ASP file so that the readers can immediately access the abstract of the citations online.

### DOI requirement

A CrossRef DOI® (Digital Object Identifier) name is a unique string created to identify a piece of scholarly content in the online environment. The author should supply the DOIs for journal citation(doi:10.3748/wjg.13.6458). This link (<http://www.crossref.org/SimpleTextQuery/>) allows you to retrieve Digital Object Identifiers (DOIs) for journal articles, books, and chapters by simply cutting and pasting the reference list into the box. You may use the form with any reference style, although the tool works most reliably if references are formatted in a standard style such as shown in this example: Assimakopoulos SF, Scopa CD, Vagianos CE. Pathophysiology of increased intestinal permeability in obstructive jaundice. *World J Gastroenterol* 2007; 13(48): 6458-6464

The accuracy of the information of journal citations is very important. We will interlink all references with DOI in ASP file so that readers can access the abstracts of cited articles online immediately.

### Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

### Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

## Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those linked with a hyphen when the difference between the two numbers is greater than five. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered inappropriate references. Authors should not cite their own unrelated published articles.

## Statistical data

Write as mean  $\pm$  SD or mean  $\pm$  SE.

## Statistical expression

Express  $t$  test as  $t$  (in italics),  $F$  test as  $F$  (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as  $r$  (in italics), degree of freedom as  $v$  (in Greek), sample number as  $n$  (in italics), and probability as  $P$  (in italics).

## Units

Use SI units. For example: body mass,  $m$  (B) = 78 kg; blood pressure,  $p$  (B) = 16.2/12.3 kPa; incubation time,  $t$  (incubation) = 96 h, blood glucose concentration,  $c$  (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA mass concentration,  $p$  (CEA) = 8.6 24.5  $\mu$ g/L;  $CO_2$  volume fraction, 50 mL/L  $CO_2$ , not 5%  $CO_2$ ; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: <http://www.wjgnet.com/wjg/help/15.doc>.

## Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of

Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

## Italics

Quantities:  $t$  time or temperature,  $c$  concentration,  $A$  area,  $l$  length,  $m$  mass,  $V$  volume.

Genotypes:  $gyrA$ ,  $arg\ 1$ ,  $c\ myc$ ,  $c\ fos$ , etc.

Restriction enzymes:  $EcoRI$ ,  $HindII$ ,  $BamHI$ ,  $KhoI$ ,  $KpnI$ , etc.

Biology:  $H\ pylori$ ,  $E\ coli$ , etc.

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

## Editorial Office

### World Journal of Gastroenterology

Editorial Department: Room 903

Ocean International Center, Building D

No. 62 Dongsihuan Zhonglu

Chaoyang District, Beijing 100025, China

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

Telephone: +86-10-59080039

Fax: +86-10-85381893

## Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

## Copyright assignment form

Please download a Copyright assignment form from <http://www.wjgnet.com/wjg/help/9.doc>.

## Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/wjg/help/10.doc>.

## Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

## Links to documents related to the manuscript

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

## Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

## Publication fee

Authors of accepted articles must pay a publication fee. EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

## Abstract

Cytomegalovirus (CMV) is a common viral pathogen that influences the outcome of liver transplantation. In addition to the direct effects of CMV syndrome and tissue-invasive diseases, CMV is associated with an increased predisposition to acute and chronic allograft rejection, accelerated hepatitis C recurrence, and other opportunistic infections, as well as reduced overall patient and allograft survival. Risk factors for CMV disease are often interrelated, and include CMV D+/R-serostatus, acute rejection, female gender, age, use of high-dose mycophenolate mofetil and prednisone, and the overall state of immunity. In addition to the role of CMV-specific CD4+ and CD8+ T lymphocytes, there are data to suggest that functionality of the innate immune system contributes to CMV disease pathogenesis. In one study, liver transplant recipients with a specific polymorphism in innate immune molecules known as Toll-like receptors were more likely to develop higher levels of CMV replication and clinical disease. Because of the direct and indirect adverse effects of CMV disease, its prevention, whether through antiviral prophylaxis or preemptive therapy, is an essential component in improving the outcome of liver transplantation. In the majority of transplant centers, antiviral prophylaxis is the preferred strategy over preemptive therapy for the prevention of CMV disease in CMV-seronegative recipients of liver allografts from CMV-seropositive donors (D+/R-). However, the major drawback of antiviral prophylaxis is the occurrence of delayed-onset primary CMV disease. In several prospective and retrospective studies, the incidence of delayed-onset primary CMV disease ranged from 16% to 47% of CMV D+/R- liver transplant recipients.

Current data suggests that delayed-onset CMV disease is associated with increased mortality after liver transplantation. Therefore, optimized strategies for prevention and novel drugs with unique modes of action are needed. Currently, a randomized controlled clinical trial is being performed comparing the efficacy and safety of maribavir, a novel benzimidazole riboside, and oral ganciclovir as prophylaxis against primary CMV disease in liver transplant recipients. The treatment of CMV disease consists mainly of intravenous (IV) ganciclovir, and if feasible, a reduction in the degree of immunosuppression. A recent controlled clinical trial demonstrated that valganciclovir is as effective and safe as IV ganciclovir for the treatment of CMV disease in solid organ (including liver) transplant recipients. In this article, the author reviews the current state and the future perspectives of prevention and treatment of CMV disease after liver transplantation.

## INTRODUCTION

Throughout the four decades that have elapsed since the first successful liver transplantation in 1967, cytomegalovirus (CMV) has remained the single most common viral pathogen influencing the outcome of this procedure. Infection with CMV is not only a very common complication after liver transplantation but it also contributes significantly to the morbidity and mortality, both by direct and indirect mechanisms<sup>[1,2]</sup>.

CMV is a ubiquitous herpes virus that infects 60%-100% of humans<sup>[1,2]</sup>, with primary CMV infection occurring most commonly during the first 2 decades of life. If immunocompetent, the infected individuals are mostly asymptomatic or may present with a benign febrile infectious mononucleosis-like illness. However, in individuals with compromised immunity, such as liver transplant recipients, clinical disease with high morbidity may develop and, in some cases, may lead to death<sup>[1,2]</sup>.

Facilitated by its ability to evade the immune system, infection with CMV results in a state of latency in several host cells<sup>[1,2]</sup>. Consequently, these cellular sites of viral latency become reservoirs of reactivation during periods of stress and cytokine release, and serve as vehicles for transmission to susceptible hosts. Both these scenarios are operational in liver transplant recipients, wherein the pharmacologic-induced impairment of immune response to "endogenously reactivated" or "allograft-transmitted" CMV leads to febrile and tissue-invasive diseases<sup>[1,2]</sup>. Because of the lack of a pre-existing CMV-specific immunity, CMV-seronegative recipients of liver allografts from CMV-seropositive donors (CMV D+/R-) are at the highest risk of CMV disease and its complications<sup>[3-5]</sup>.

This article reviews the current concepts and challenges in the management of CMV after liver transplantation. Historical aspects of the disease are discussed to emphasize the remarkable improvements that have been achieved over the past several years. Conversely, ongoing issues of delayed-onset and drug-resistant CMV disease are discussed in detail, to highlight future perspectives in terms of CMV disease prevention and treatment.

## CLINICAL IMPACT OF CMV IN LIVER TRANSPLANTATION

### Direct CMV effects

The clinical illness caused by CMV commonly manifests as fever, bone marrow suppression, and organ-invasive diseases (Table 1)<sup>[1]</sup>. These direct clinical effects are traditionally classified as CMV syndrome (fever with myelosuppression) and tissue-invasive CMV disease, which most often involves the gastrointestinal tract (in the form of CMV gastritis, esophagitis, enteritis, and colitis), although virtually any organ system may be involved<sup>[6]</sup>. Infection of the liver (i.e., CMV hepatitis) is especially common in liver transplant recipients (compared to other solid organ transplant recipients), and this may manifest with symptoms indistinguishable from acute allograft rejection<sup>[7]</sup>. The availability of sensitive tests for the rapid detection of CMV in the blood may obviate the need for liver biopsy to differentiate the CMV infection from rejection. However, in many cases, a liver biopsy is needed to differentiate or to demonstrate the co-existence of CMV disease and allograft rejection.

In the absence of effective antiviral prophylaxis, the

**Table 1 Direct and indirect clinical effects of CMV after solid organ transplantation**

Direct effects	Indirect effects
CMV syndrome	Acute allograft rejection
Fever	
Myelosuppression	
Malaise	
Tissue-invasive CMV disease <sup>1</sup>	Chronic allograft rejection
Gastrointestinal disease (colitis, esophagitis, gastritis, enteritis)	Vanishing bile duct syndrome
Hepatitis	
Pneumonitis	Chronic ductopenic rejection
CNS disease	Hepatitis C virus recurrence
Retinitis	Allograft hepatitis, fibrosis and allograft failure
	Opportunistic and other infections
Mortality	Fungal superinfection
	Nocardiosis
	Bacterial superinfection
	Epstein-Barr virus and PTLD
	HHV-6 and HHV-7 infections
	Vascular thrombosis
	Mortality

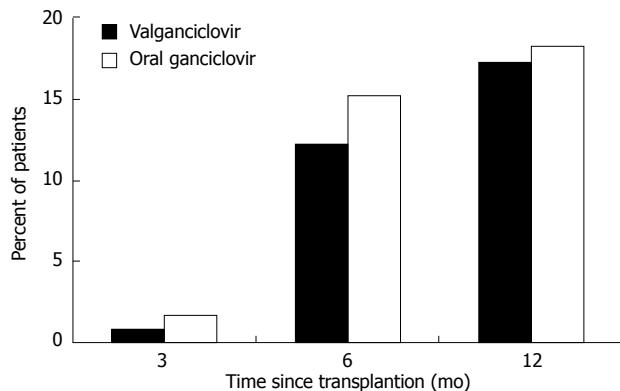

<sup>1</sup>Any organ system may be affected by CMV.

**Table 2 Estimated incidence of CMV disease during the first 12 mo after liver transplantation**

	Use of anti-CMV prophylaxis	
	Yes <sup>1</sup>	No
CMV D+/R-	12%-30%	44%-65%
CMV D+/R+	2.7%	18.2%
CMV D-/R+	3.9%	7.9%
CMV D-/R-	0	0
All patients	4.8%	18%-29%

D: Donor; R: Recipient. <sup>1</sup>Most cases occur as delayed-onset CMV disease. CMV disease occurs rarely during prophylaxis with oral valganciclovir. Data adapted from<sup>[4,5,7]</sup>.

direct effects of CMV occur most commonly during the first 3 mo after liver transplantation<sup>[6]</sup>. Overall, it is estimated that 18%-29% of all liver transplant recipients will develop CMV disease (Table 2)<sup>[4,5,8-10]</sup>. However, this incidence varies widely depending upon donor and recipient CMV serologic status; it may be as high as 44%-65% in CMV D+/R-, or as low as 8%-19% in CMV-seropositive liver transplant recipients (CMV R+)<sup>[4,8,10]</sup>. The incidence is markedly reduced in liver transplant recipients who receive prophylaxis with 3 mo of valganciclovir and oral ganciclovir. Recent studies have reported CMV disease rates of 12%-30% in high-risk CMV D+/R-, and < 10% in CMV R+ liver transplant recipients who received 3 mo of antiviral prophylaxis<sup>[3,4,8,10-12]</sup>. In individuals who received antiviral prophylaxis, CMV disease occurred 3 mo to 6 mo after completing antiviral prophylaxis; hence, the term "delayed-onset (also termed late-onset) CMV disease" (Figure 1)<sup>[3]</sup>.

**Figure 1** Time to the onset of CMV disease in solid organ transplant recipients who received 3 mo of oral ganciclovir or valganciclovir prophylaxis. Data obtained from the study by Paya et al<sup>[3]</sup>.

### Indirect CMV effects

The clinical impact of CMV extends beyond the direct effect of the virus. Numerous indirect outcomes, believed to be mediated by the ability of the virus to modulate the immune system have been reported (Table 1)<sup>[1,2]</sup>. CMV is known to be a potent up-regulator of alloantigens, thereby increasing the risk of acute rejection and chronic allograft dysfunction<sup>[13]</sup>. CMV is associated with vanishing bile duct syndrome and ductopenic rejection, leading to chronic cholestasis and eventually allograft failure<sup>[14-16]</sup>. Several studies have reported a higher incidence of vascular and hepatic artery thrombosis in liver transplant recipients with CMV disease, an effect that is believed to result from CMV infection of the vascular endothelial cells<sup>[17,18]</sup>. The immunomodulatory effects of CMV have also been blamed for the higher predisposition to other opportunistic infections including fungi, other viruses, and bacteria such as *Nocardia* sp.<sup>[19,20]</sup>. CMV-infected transplant recipients are more likely to develop Epstein-Barr virus-associated post transplant lymphoproliferative disorders (PTLDs), or develop co-infections with other viruses such as human herpes virus (HHV)-6 and HHV-7<sup>[19,21]</sup>. A well-described interaction between members of the beta-herpes group of viruses has been described, exemplified by the observation that reactivation of HHV-6 and HHV-7 is associated with an increased predisposition to CMV disease after liver transplantation<sup>[22-24]</sup>. In a similar manner, there is a significant association between CMV and hepatitis C virus<sup>[25-30]</sup>, manifested by an accelerated course of HCV recurrence in patients who develop CMV infection after liver transplantation. In our analysis of 92 HCV-infected liver transplant recipients, there was a four-fold higher risk of allograft failure and mortality in patients with CMV infection and disease<sup>[28,30]</sup>. Three years after liver transplantation, 48% patients who developed CMV disease had allograft loss or had died, compared to 35% patients with asymptomatic CMV infection, and 17% in those who did not develop CMV infection<sup>[28,30]</sup>.

### Impact on mortality

CMV infection is an independent predictor of mortality

**Table 3** Selected traditional and novel factors associated with the increased risk of CMV disease after liver transplantation

Traditional factors	Recently identified factors
CMV D+/R- > CMV R+	Toll-like receptor gene polymorphism
Allograft rejection	Mannose binding lectin deficiency
High viral replication	Chemokine and cytokine defects (IL-10, MCP-1, CCR5)
Mycophenolate mofetil	Deficiency in CMV-specific CD4+ T cells
Muromonab-CD3	Deficiency in CMV-specific CD8+ T cells
Anti-thymocyte globulin	Expression of immune evasion genes
Alemtuzumab	Programmed cell death 1 expression
HHV-6	
HHV-7	
Renal insufficiency	
Others <sup>1</sup>	

<sup>1</sup>Others factors include re-transplantation, volume of blood transfusion, sepsis and factors associated with high tumor necrosis factor- $\alpha$  secretion<sup>[14,11,13,21,39-42,77,89-93]</sup>.

after solid organ transplantation, by mechanisms which may be direct, indirect or immunomodulatory<sup>[19,31,32]</sup>. CMV was a major cause of mortality after liver transplantation prior to the availability of intravenous (IV) and oral ganciclovir. Several recent meta-analyses have demonstrated that the use of anti-CMV drugs, either through antiviral prophylaxis or preemptive therapy, have led to significant reduction in the overall mortality after solid organ transplantation<sup>[19,33-35]</sup>. However, despite much improvement in outcome, there is emerging data to suggest that even in the contemporary era, with widespread use of antiviral prophylaxis, development of delayed onset CMV disease remains a common problem, and importantly, is associated with significantly increased risk of mortality after liver transplantation<sup>[32]</sup>. An analysis of 437 liver transplant recipients demonstrated that CMV disease occurred in 37 patients (8.5%), and its occurrence was independently associated with a 5-fold increased risk of all-cause mortality, and an 11-fold increased risk of infection-related mortality after liver transplantation<sup>[32]</sup>. The other significant and independent predictors of mortality in this study included the need for pre-liver transplant hemodialysis, a higher model for end-stage liver disease (MELD) score, and post-transplant occurrence of bacterial and fungal infections<sup>[32]</sup>.

## RISK FACTORS FOR CMV DISEASE AFTER LIVER TRANSPLANTATION

### Lack of pre-existing CMV-specific immunity

The most common predisposing factor for the occurrence of CMV disease after liver transplantation is the lack of an effective CMV-specific immunity<sup>[4,19]</sup>. As a result, CMV D+/R- are at the highest risk of CMV disease<sup>[4,19]</sup>, while CMV R+ patients have a modest risk and CMV D-/R- have the lowest risk of CMV disease after liver transplantation (Table 3).

### Drug-induced immunodeficiency

The use of highly potent pharmacologic immuno-

suppression severely impairs the ability of liver transplant recipients to mount an effective immune response against reactivating CMV, thereby predisposing to increased risk of CMV disease<sup>[4,19]</sup>. The severity of immune dysfunction is particularly intense with lymphocyte-depleting drugs such as muromonab-CD3 (OKT3) and anti-thymocyte globulin<sup>[36,37]</sup>. More recently, the use of alemtuzumab has been found to be associated with higher risk of CMV disease<sup>[38]</sup>. Drugs used for maintenance immunosuppression have also been associated with CMV disease, particularly high doses of mycophenolate mofetil<sup>[30,39]</sup>. It is very likely that immunosuppressive drugs not only predispose to CMV disease, but the net state of combined pharmacologic immunosuppression increases the risk of CMV disease after liver transplantation<sup>[1,2,19]</sup>.

### **Defects in innate and CMV-specific cell-mediated immunity**

The appreciation of the role of the immune system in controlling CMV led to recent observations that inherent defects in immunity, such as mutations in the innate immunity-associated genes, increased the risk of CMV disease after liver transplantation (Table 3). In a study of 92 liver transplant recipients, a genetic polymorphism in the Toll-like receptor (TLR)-2 gene, which resulted from the substitution of arginine to glutamine at position 753 in the protein-receptor, was significantly associated with a higher degree of CMV replication and a higher incidence of CMV disease<sup>[40]</sup>. TLR2 is a pattern recognition receptor expressed in innate immune cells, and its function is to sense the glycoprotein B of CMV, thereby signaling the immune cells to produce antiviral peptides and other cytokines<sup>[40]</sup>. Our *in vitro* data suggests that this specific genetic polymorphism causes an impairment of cellular recognition of CMV by TLR2-expressing cells<sup>[40]</sup>.

Likewise, the CMV-specific T cell compartment is necessary for adequate control of CMV after liver transplantation<sup>[41]</sup>, although a recent study indicated that CMV-specific T cells may not necessarily predict the risk after liver transplantation<sup>[41]</sup>. There are ongoing studies in this field that may further clarify the prognostic role of CMV-specific T cell assays in stratifying CMV disease risk after liver transplantation.

Other immune measures, such as programmed death-1 expression<sup>[42]</sup> and immune evasion genes<sup>[43]</sup> have also been assessed as prognostic indicators of CMV disease after liver transplantation. In one study, programmed death-1 receptor up-regulation was significantly associated with incipient and overt CMV disease and with CMV viremia<sup>[42]</sup>.

### **Allograft rejection**

Allograft rejection *per se* is one of the most potent inducers of CMV reactivation, and thus considered a significant risk factor for CMV disease after liver transplantation<sup>[12]</sup>. Cytokines released during acute rejection, particularly tumor necrosis factor- $\alpha$ <sup>[44]</sup>, are

potent transactivators of latent CMV<sup>[45]</sup>, as demonstrated in animal models<sup>[46]</sup>. Moreover, therapy for allograft rejection with the intensification of immunosuppressive regimen further increases the risk of CMV disease both by enhancing its reactivation and by impairing the ability to generate effective cell-mediated immunity against replicating CMV<sup>[47]</sup>. Conversely, CMV induces allo-stimulation and increases the risk of allograft rejection, thereby creating a bidirectional relationship between CMV and allograft rejection<sup>[13]</sup>.

### **Virus-to-virus interactions**

Virus-virus interaction may influence the risk of CMV disease after liver transplantation<sup>[21,22,26-30]</sup>. Reactivation of HHV-6 has been shown to predispose to an increased incidence of CMV disease after liver transplantation<sup>[21,22,24]</sup>. In a study on 247 patients, HHV-6 seroconversion was an independent marker of CMV disease after liver transplantation. Likewise, HCV-infected liver transplant recipients also have a higher incidence of CMV disease<sup>[48]</sup>, although our data in the era of valganciclovir prophylaxis has refuted this observation<sup>[25]</sup>.

### **Degree of viral replication**

The risk of CMV disease after liver transplantation is associated, in direct proportion, with the degree of CMV replication, which is partly a function of over-immunosuppression<sup>[8,23,49,50]</sup>. In one study, a viral load of 1-2860 CMV copies/ $10^6$  peripheral blood mononuclear cells (PBMC) increased CMV disease risk by nine-fold, while viral loads  $> 2860/10^6$  PBMC increased the risk by 50-fold<sup>[8]</sup>.

### **Other factors**

Other factors associated with CMV disease after transplantation include cold ischemia time, bacterial and fungal infections and sepsis, the amount of blood loss, fulminant hepatic failure as the indication for transplantation, age, female gender, Hispanic race, and renal insufficiency<sup>[2,3,19,51]</sup>. It is likely that other factors that have not yet been identified may also be influence the risk of CMV disease after liver transplantation.

## **PREVENTION OF CMV DISEASE AFTER LIVER TRANSPLANTATION**

Because of the adverse effects of CMV on transplant outcome, its prevention is key to management of such patients<sup>[19]</sup>. Over the years, the pharmacologic agents used for CMV prevention have evolved, from the use of acyclovir<sup>[52]</sup> and immunoglobulins<sup>[53]</sup> to IV and oral ganciclovir<sup>[4]</sup> and more recently, valganciclovir<sup>[5]</sup>. There are two major strategies for CMV disease prevention after liver transplantation: (1) preemptive therapy (wherein CMV reactivation is aggressively monitored by sensitive assays and upon detection, antiviral therapy is administered preemptively to prevent its progression to clinical disease); and (2) antiviral prophylaxis (wherein

antiviral drugs such as ganciclovir and valganciclovir are administered to patients at risk of CMV disease after liver transplantation<sup>[19]</sup>. Both strategies are highly effective in preventing CMV disease after liver transplantation<sup>[4,5,54-57]</sup>. However, antiviral prophylaxis is generally regarded as a more efficient approach and is used by the majority of transplant centers in preventing primary CMV disease in high-risk CMV D+/R- liver transplant recipients<sup>[4,8,54]</sup>. Indeed, the current American Society of Transplantation recommendation is to use antiviral prophylaxis in all CMV D+/R- liver (and other solid organ transplant) recipients<sup>[58]</sup>. Moreover, primary antiviral prophylaxis has the added benefit of reduction in bacterial and fungal opportunistic infections and mortality<sup>[33,34]</sup>.

### **Preemptive therapy**

The basic principle of preemptive therapy is to detect the presence of CMV reactivation prior to the onset of clinical symptoms, so that antiviral drugs are administered early in order to halt the progression of asymptomatic infection to full-blown clinical disease<sup>[50,54,55,57,59]</sup>. The success of this approach relies on patient compliance with CMV surveillance<sup>[60]</sup>, availability of highly sensitive CMV assay that predicts the risk of disease<sup>[61]</sup>, and early administration of antiviral drugs such as IV ganciclovir and oral valganciclovir<sup>[9,55,59]</sup>. With the advance in molecular diagnostic microbiology, including the availability of polymerase chain reaction (PCR), it is now possible to employ successfully preemptive therapy in liver transplant recipients (reviewed in<sup>[61]</sup>). Several studies have reported the success of IV or oral ganciclovir and valganciclovir in the preemptive treatment of CMV reactivation in liver transplant recipients, including high-risk CMV D+/R-patients<sup>[56,59]</sup>. However, some studies have indicated that preemptive therapy may not be completely effective in CMV D+/R- liver transplant recipients since the replication kinetics of CMV in immune-deficient individuals is so rapid<sup>[49]</sup> that it may result in clinical illness prior to CMV detection with once a week PCR assay<sup>[8,54]</sup>. Indeed, in our clinical experience, nearly 25% of CMV D+/R- liver transplant recipients who developed CMV disease were not identified early by a protocol-based weekly CMV PCR assay<sup>[8,54]</sup>. Accordingly, the current guideline from the AST does not recommend preemptive approach in CMV D+/R- liver transplant recipients<sup>[58]</sup>. However, this approach is recommended, and is highly effective, in CMV-seropositive liver transplant recipients. Reassuringly, clinical trials have demonstrated the efficacy of preemptive therapy in CMV disease prevention<sup>[54-56,59]</sup>. Three meta-analyses that collectively analyzed data from prospective clinical trials confirmed the efficacy and benefits of preemptive therapy in the prevention of CMV disease<sup>[34,35,62]</sup>. When conducted properly, preemptive therapy, with the use of oral ganciclovir, IV ganciclovir, or valganciclovir resulted in reduction of CMV disease by about 70%<sup>[34,35,62]</sup>. Moreover, preemptive therapy is not associated with late onset CMV disease (unlike with antiviral prophylaxis,

as discussed below)<sup>[55,59]</sup>. Currently, valganciclovir is the most commonly used drug for preemptive therapy, and in one study, was demonstrated to be as effective in terms of clinical and virologic response, when compared with IV ganciclovir<sup>[55,59]</sup>. In addition, preemptive therapy may be beneficial in reducing the indirect effects of CMV. In one study, the incidence of major opportunistic infections, bacteremia, bacterial infection, HCV recurrence, and rejection were not significantly different between liver transplant patients who received preemptive therapy and those who did not have CMV reactivation<sup>[63]</sup>.

### **Antiviral prophylaxis**

Several clinical trials have demonstrated that antiviral prophylaxis is highly effective in preventing the direct, and possibly the indirect effects of CMV after liver transplantation<sup>[4,5]</sup>. Recent meta-analyses have highlighted the clinical benefits<sup>[34,35,62]</sup>. Compared to placebo or no treatment, patients who received antiviral prophylaxis had lower incidence of CMV disease (58%-80% reduction) and CMV infection (about 40% reduction)<sup>[62]</sup>. In one meta-analysis, a 25% reduction in the incidence of acute allograft rejection was also observed<sup>[34]</sup>. In two studies, a reduction in all-cause mortality was also observed<sup>[34,62]</sup>, mainly due to a decline in CMV-related death<sup>[62]</sup>. A reduction in the incidence of other herpes viruses, bacterial, and protozoal infections was also observed<sup>[62]</sup>. Indeed, a survey of several transplant centers showed a general preference for antiviral prophylaxis over preemptive therapy in the prevention of CMV disease in CMV D+/R- and R+ liver transplant recipients.

### **Acyclovir prophylaxis**

The use of acyclovir as anti-CMV prophylaxis after liver transplantation has been supplanted by ganciclovir (and valganciclovir) because of the superior efficacy of the latter drugs in CMV disease prevention. In a study on 143 liver transplant recipients, CMV infection developed in 61% patients who received 3 mo of high-dose oral acyclovir compared to 24% patients who received 14 d of IV ganciclovir followed by 3 mo of acyclovir ( $P < 0.001$ )<sup>[64]</sup>. In a second study, 57% and 23% patients in the acyclovir group compared to 37% and 11% patients in the ganciclovir-acyclovir group developed CMV infection and disease, respectively<sup>[52]</sup>. In a third randomized controlled trial on 250 liver transplant recipients, CMV infection and disease occurred in 38% and 10% of patients in the acyclovir group, respectively, compared to 5% and 1% in the ganciclovir group, respectively<sup>[65]</sup>.

### **Ganciclovir prophylaxis**

The current data indicates that ganciclovir-based regimen is more effective (compared to acyclovir and immunoglobulins) in reducing the incidence of CMV after liver transplantation. In one study, the administration of IV ganciclovir for 90-100 d reduced the incidence of CMV disease in CMV D+/R- liver

transplant recipients to 5.4% (compared to 40% in patients who received < 7 wk of prophylaxis)<sup>[65]</sup>. The major drawback to IV ganciclovir was the need for long-term IV access and the risk of thrombosis, phlebitis, and line-associated infections<sup>[37,66]</sup>. Subsequently, oral ganciclovir became available, and in a landmark randomized trial that compared the drug with placebo, oral ganciclovir for 98 d reduced significantly the 6-mo incidence of CMV infection (51.5% vs 24.5%;  $P < 0.001$ ), and CMV disease (19% vs 5%;  $P < 0.001$ ) in liver transplant recipients<sup>[4]</sup>, including CMV D+/R-patients (44% vs 15%,  $P = 0.02$ ) and patients who received antilymphocyte antibodies (33% vs 5%;  $P = 0.002$ )<sup>[4]</sup>. Among CMV R+ liver transplant recipients, oral ganciclovir for 12 wk reduced the incidence of CMV disease to 1% (compared to 7% in patients who received acyclovir)<sup>[67]</sup>. These studies were in support of the United States FDA approval of oral ganciclovir prophylaxis for the prevention of CMV disease in liver transplant recipients. Oral ganciclovir, however, is poorly absorbed, and its oral administration results in low systemic ganciclovir levels<sup>[68]</sup>. This factor has been implicated in the emergence of ganciclovir-resistant CMV in certain clinical settings<sup>[69,70]</sup>, such as high-risk CMV D+/R- patients, and those receiving potent immunosuppressive regimens.

### **Valganciclovir prophylaxis**

Valganciclovir, a valine ester of ganciclovir, which results in enhanced absorption, resulting in systemic drug levels that are comparable to IV ganciclovir<sup>[68,71]</sup>. Pharmacokinetic studies indicate that a 900 mg dose of valganciclovir achieves a similar daily area under the concentration time curve (AUC<sub>24</sub>) as an IV dose of 5 mg/kg of ganciclovir<sup>[68]</sup>. The role of valganciclovir in the prevention of CMV disease after liver transplantation was evaluated in a multicenter randomized non-inferiority clinical trial that compared it with oral ganciclovir in a cohort of 364 CMV D+/R- solid organ transplant (including liver) recipients (Figure 1)<sup>[5]</sup>. Overall, the 6-mo incidence of CMV disease was 12% and 15% in the valganciclovir and oral ganciclovir groups, respectively<sup>[5]</sup>. Follow-up at one year, demonstrated that the incidence of protocol-defined CMV disease in all patients was 17.2% and 18.4% with valganciclovir and oral ganciclovir, respectively<sup>[5]</sup> (Notably, the incidence of investigator-determined CMV disease cases was about 28% and 30%, respectively).

However, in 177 liver transplant recipients who participated in the clinical trial, the incidence of CMV disease was 19% in the valganciclovir group as opposed to only 12% in the ganciclovir group<sup>[5]</sup>. There was also a higher incidence of tissue-invasive CMV disease in the valganciclovir group. While the clinical trial was not designed to determine differences between the transplanted organs, these results raised skepticism about the efficacy of valganciclovir prophylaxis after liver transplantation. As a result of these findings, valganciclovir prophylaxis did not gain approval from the US-FDA for prophylaxis against CMV disease after

liver transplantation (valganciclovir received approval for prevention of CMV disease in heart, kidney, and pancreas recipients). Although not FDA-approved for prophylaxis in liver transplant recipients, valganciclovir is the most widely used drug for the prevention of CMV disease after liver transplantation<sup>[72]</sup>.

The efficacy of valganciclovir (and oral ganciclovir) prophylaxis is undermined by the emergence of late-onset CMV disease (Figure 1). In a retrospective study on 203 liver transplant recipients who received valganciclovir 900 mg daily for 3 to 6 mo, the overall incidence of CMV disease was 14%<sup>[73]</sup>. The incidence varied among the different CMV serogroups (16% in D+/R+ group; 7% in D-/R+ group; and 26% in D+/R-group)<sup>[73]</sup>. These findings illustrate that the burden of delayed-onset CMV disease remains high particularly in the CMV D+/R- group<sup>[5]</sup>. In our analysis of 67 CMV D+/R- liver transplant recipients who received 3 mo of oral ganciclovir and valganciclovir prophylaxis, the two year incidence of CMV disease was 29%<sup>[3]</sup>. The incidence of delayed-onset CMV disease was not significantly different between patients who received oral ganciclovir or valganciclovir (22% vs 28%;  $P = 0.63$ )<sup>[3]</sup>.

### **Maribavir prophylaxis (investigational)**

The search for anti-CMV strategies continues to evolve with the recent entry of maribavir into clinical trials. Maribavir, a novel benzimidazole riboside compound that inhibits viral DNA assembly and egress of viral capsids<sup>[74]</sup>, is now undergoing clinical trials for the prevention of primary CMV disease after liver transplantation<sup>[75,76]</sup>. Because it has a unique mechanism of action that is distinct from ganciclovir, foscarnet, and cidofovir (all of which act to inhibit CMV DNA polymerase), maribavir is expected to expand the therapeutic armamentarium against CMV<sup>[75]</sup>. So far, it does not show cross-resistance with the currently available drugs. Therefore, it has a good potential as an alternative drug for the treatment of ganciclovir-resistant CMV. In addition, maribavir provides a more favorable toxicity profile compared to foscarnet and cidofovir, both of which are highly nephrotoxic. In preliminary studies conducted in allogeneic bone marrow transplant recipients, maribavir was found to be safe and did not have myelosuppressive effects. In terms of efficacy, when compared with placebo, maribavir showed significant reduction in CMV viremia<sup>[76]</sup>. The ongoing comparative multicenter trial of maribavir and oral ganciclovir in liver transplant recipients will likely complete enrollment in 2009. In this multi-center international randomized trial, the incidence of CMV disease will be compared between patients randomized to oral maribavir, and the currently approved standard oral ganciclovir.

### **The challenge of delayed- and late-onset CMV disease**

With the success of a 3-mo anti-CMV prophylaxis program (in terms of the almost complete elimination of CMV disease in individuals who are actively taking antiviral drugs), the challenge of delayed- and late-onset CMV disease has emerged. Indeed, in many

high-risk CMV D+/R- individuals, the use of antiviral prophylaxis has only delayed the onset of CMV disease to 3-6 mo after liver transplantation<sup>[3-5,12]</sup>. In one of these retrospective studies, CMV disease occurred in 14 of 54 (26%) CMV D+/R- liver transplant recipients who received valganciclovir for at least 3 mo<sup>[73]</sup>. Our clinical data suggests that, while no breakthrough CMV disease occurred during the 3 mo of oral ganciclovir or valganciclovir prophylaxis, 29% of CMV D+/R- liver transplant recipients developed delayed-onset primary CMV disease<sup>[3]</sup>. Thus, one out of every four CMV D+/R-liver transplant recipients will develop CMV disease after cessation of antiviral prophylaxis<sup>[3]</sup>. Delayed-onset CMV disease commonly presents as CMV syndrome, with fever and bone marrow suppression<sup>[3]</sup>. In less than half of the patients, CMV manifested as tissue-invasive disease, and frequently affected the gastrointestinal tract<sup>[3]</sup>. Factors such as age<sup>[3]</sup>, female gender<sup>[3,77]</sup>, renal dysfunction<sup>[77]</sup>, and allograft rejection<sup>[12]</sup> predisposed to the development of delayed-onset primary CMV disease<sup>[3,12,77,78]</sup>. Delayed-onset CMV disease appears to be clinically less severe, although it is associated with significant mortality after liver transplantation<sup>[32]</sup>. Therefore, a better method for CMV prevention is needed among CMV D+/R- liver transplant recipients.

Currently, there is an ongoing effort (in kidney transplant recipients only) to assess the efficacy and safety of 3 mo *vs* 6 mo of valganciclovir prophylaxis. Foreshadowing what may be expected from this trial, a recent single center study on 68 CMV D+/R- kidney transplant recipients demonstrated a significantly lower incidence of CMV disease in patients who received 24 wk compared to 12 wk of oral ganciclovir prophylaxis (7% *vs* 31%, respectively)<sup>[79]</sup>. If this practice is proven safe and effective, it may eventually be adopted in the liver transplant field. There are concerns regarding ganciclovir resistance, drug toxicity, and cost with such a prolonged prophylactic approach. In addition, the long-term drug toxicity of ganciclovir-based regimen is not known. In animal studies, ganciclovir has been shown to be mutagenic, teratogenic, carcinogenic, and has caused aspermatogenesis, although the clinical relevance of these findings in humans is unclear<sup>[68]</sup>.

Another strategy that is gaining interest is an aggressive effort to minimize immunosuppression, including the use of prednisone-free regimens. In one Kidney and Pancreas Transplant Program, the incidence of CMV disease was markedly reduced in patients receiving a steroid-free immunosuppressive regimen<sup>[80]</sup>. Many liver transplant programs (including ours) have adapted this approach, and have minimized immunosuppression gradually so that patients are maintained on tacrolimus monotherapy beyond the 4th mo after liver transplantation. In a retrospective analysis, we observed a higher incidence of CMV disease among transplant recipients who were still receiving mycophenolate mofetil and prednisone at the time they discontinue antiviral prophylaxis. The major consequence of this approach, however, is the risk of allograft rejection when the level of immunosuppression

is reduced to levels lower than necessary for the prevention of allo-stimulation<sup>[13]</sup>.

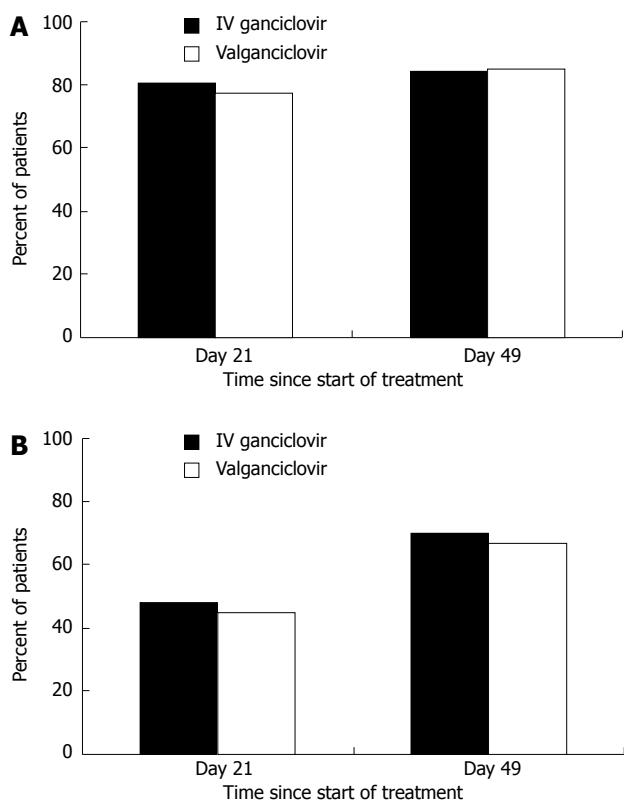

## TREATMENT OF CMV DISEASE AFTER LIVER TRANSPLANTATION

The current recommendation for antiviral treatment of CMV disease after liver transplantation is IV ganciclovir<sup>[58,66,81]</sup>. Equally important is the reduction in the degree of pharmacologic immunosuppression<sup>[19]</sup>. Oral ganciclovir should not be used for the treatment of active CMV disease because of its poor bioavailability<sup>[19]</sup>. Valganciclovir, a prodrug of ganciclovir that provides high systemic ganciclovir concentrations<sup>[71]</sup>, has now made it possible for oral treatment of CMV disease<sup>[68,81]</sup>. Indeed, in AIDS patients, valganciclovir is approved as induction and maintenance treatment of CMV retinitis<sup>[82]</sup>. There is good clinical data to support the use of valganciclovir for the treatment of CMV after solid organ transplantation<sup>[81]</sup>. Viral kinetic studies showed comparable viral decay between IV ganciclovir and valganciclovir<sup>[50]</sup>. In a recent study, 321 solid organ (including liver) transplant recipients with non-severe CMV disease were randomized to valganciclovir or IV ganciclovir for a fixed 21-d course, followed by valganciclovir maintenance treatment for 4 wk; the proportion of patients with viral eradication at 21 and 49 d were comparable in the IV ganciclovir and valganciclovir groups (Figure 2)<sup>[81]</sup>. The overall time to viral eradication was 21 d with valganciclovir and 19 d with IV ganciclovir<sup>[81]</sup>. The calculated viral decay was 11.5 d with valganciclovir and 10.4 d with IV ganciclovir<sup>[81]</sup>. Likewise, clinical resolution was not different between the two groups. It was noted that patients enrolled in this trial were mostly CMV-seropositive, the majority were kidney recipients, and patients with severe CMV disease were excluded. Despite these limitations, this pivotal trial now supports the use of valganciclovir for oral treatment of CMV disease, at least in selected transplant patients<sup>[81]</sup>. In many instances, valganciclovir is used as a step-down treatment when the clinical symptoms have resolved after an initial induction treatment with IV ganciclovir.

The duration of treatment of CMV disease should be individualized<sup>[58,83]</sup>. The persistence of the virus at the end of therapy (by polymerase chain reaction [PCR] or pp65 antigenemia) is associated with a higher risk of clinical relapse<sup>[84]</sup>. It is now generally accepted that multiple (at least two) weekly negative CMV PCR results should be obtained before antiviral therapy is discontinued. Although this may be true for non-tissue invasive CMV syndromes, the utility of such an approach may not necessarily apply to tissue-invasive disease, which may manifest as “compartmentalized disease”<sup>[19]</sup>.

### ***The challenge of treating compartmentalized CMV disease***

Compartmentalized CMV disease refers to clinical

**Figure 2** The proportion of solid organ transplant patients with resolution of clinical symptoms (A) and viremia eradication (B) at day 21 and 49 following the start of valganciclovir or IV ganciclovir treatment of CMV disease. Data obtained from the study by Asberg *et al*<sup>[81]</sup>.

syndromes wherein the virus is detected in the affected tissues but is minimally detectable or undetectable in the blood<sup>[19]</sup>. In the current era, gastrointestinal CMV disease (in the form of gastritis, esophagitis, enteritis, colitis) constitutes the vast majority of tissue-invasive patients<sup>[3,19]</sup>, and in a number of cases, this type of CMV disease is “compartmentalized.” Such a clinical presentation is reminiscent of CMV retinitis, a very rare manifestation of tissue-invasive CMV disease after transplantation, that is often not accompanied by viremia<sup>[82,85]</sup>. This dilemma brings to the forefront the limitation of viral load monitoring in assessing duration of treatment. In our clinical practice, it is not uncommon to have negative blood PCR assay even when there is histologic evidence of tissue invasion. Accordingly, it has become a more common practice to perform colonoscopy or upper endoscopy to document clearance of gastrointestinal CMV disease prior to discontinuation of therapy. Our anecdotal experience however indicates that this may not be necessary in mild to moderate disease as long as sufficient therapy is provided.

### The challenge of treating ganciclovir-resistant CMV disease

Ganciclovir-resistant CMV is now emerging as an important complication of prolonged antiviral drug use after transplantation<sup>[2,19,70]</sup>. Currently, ganciclovir-resistant CMV is very rarely seen in liver transplant recipients (it is more common after kidney-pancreas and

lung transplantation). Unlike lung and kidney-pancreas transplant recipients who have rates as high as 9% and 13%, respectively, the estimated incidence of ganciclovir resistant CMV after liver transplantation is < 0.5%<sup>[70,86]</sup>. Several studies have identified risk factors for ganciclovir-resistant CMV<sup>[2,19,70]</sup>, including CMV D+/R- status, high levels of viral replication, potent immunosuppressive therapy, and suboptimal ganciclovir levels. The vast majority of drug-resistant cases involve the selection of viral strains with UL97 (kinase) mutation<sup>[2,19,70,75,87]</sup>. UL97 mutation generally confers resistance to ganciclovir, although in some cases, a concomitant UL54 mutation (CMV DNA polymerase) is also observed, in which case, cross-resistance with cidofovir and/or foscarnet is likely. As noted, no cross-resistance has been observed with the investigational drug, maribavir.

Drug-resistant CMV is associated with significant morbidity and mortality, and there is a very limited number of antiviral drugs (which are often toxic) available for treatment<sup>[86]</sup>. Drug-resistant CMV should be suspected when viral load or antigenemia rises or does not decline to undetectable levels despite IV ganciclovir treatment. The diagnosis is confirmed by genetic analysis to demonstrate mutational changes in UL97 and UL54 genes encoding for kinase and polymerase, respectively<sup>[70,86]</sup>. In our retrospective study of 225 CMV D+/R- solid organ transplant recipients who received 3 mo of valganciclovir prophylaxis, CMV disease occurred in 65 patients (29%), including four (8%) caused by drug-resistant CMV, judged by the failure of the viral load to decline to undetectable levels while on IV ganciclovir treatment<sup>[70,88]</sup>. In our cohort, one liver transplant recipient was clinically suspected to have ganciclovir-resistant strain, although the genotypic assay failed to document any mutations<sup>[88]</sup>. The treatment of ganciclovir-resistant CMV should be guided by genotypic analysis. In patients where foscarnet or cidofovir was used, nephrotoxicity was a major adverse effect<sup>[88]</sup>. Other potential drugs for the treatment of multi-drug resistant CMV include the off-label use of immunoglobulins and leflunomide, although data supporting their use are only anecdotal<sup>[19]</sup>. The potential clinical utility of maribavir in the treatment of resistant CMV is highly anticipated<sup>[74-76,87]</sup>.

### CONCLUSION

Remarkable advances in molecular diagnostics and therapeutics has led to marked reduction in the incidence and severity of CMV disease after liver transplantation, and a parallel decline in the associated morbidity and mortality. However, despite these improvements, CMV remains a common infectious complication and continues to negatively influence the outcome of liver transplantation. In addition to viral factors and pharmacologic immunosuppression, the role of innate and adaptive immune deficiencies is being recognized in the pathogenesis of CMV disease after liver transplantation. Such novel findings should provide additional avenues and opportunities for

improving our management strategies. Prevention of CMV with antiviral prophylaxis and preemptive therapy is effective, although a well-controlled trial assessing these two strategies in a head-to-head comparison is yet to be conducted after liver transplantation. Currently, valganciclovir prophylaxis is the most common approach for the prevention of CMV disease in CMV D+/R- and R+ liver transplant recipients. The availability of predictive diagnostic tests has paved the way for the successful use of preemptive therapy in preventing the progression of CMV reactivation to clinical disease even in high-risk liver transplant patients. IV ganciclovir remains the standard of treatment for established CMV disease, although valganciclovir has now been shown to be equally effective in the treatment of mild to moderate CMV diseases. The duration of treatment should be individualized, depending upon clinical and laboratory parameters such as the decline of CMV load in the blood as measured by rapid and sensitive molecular testing. In this context, it is generally recommended that treatment should be continued until all evidence of active infection, such as positive CMV viral load, has resolved. Ganciclovir-resistant CMV and compartmentalized tissue-invasive disease (most commonly with gastrointestinal CMV disease) are emerging challenges to the management of CMV after liver transplantation. These, together with the common occurrence of late-onset CMV disease in high-risk patients, should serve as catalysts to the ongoing search for the optimal preventive strategy for CMV disease after liver transplantation.

### Abstract

Peritoneal adhesions are a near inevitable occurrence after laparotomy and a major cause of both patient and physician misery. To date, clinical attempts at their amelioration have concentrated on manipulating the physical factors that affect their development despite a wealth of experimental data elucidating the molecular mechanisms that underlie their initiation, development and maturation. However, the advent of targeted, specific anti-cytokine agents as directed therapy for inflammatory and neoplastic conditions raises the prospect of a new era for anti-adhesion strategies. To harness this potential will require considerable cross-disciplinary collaboration and that surgeon-scientists propel themselves to the forefront of this emerging field.

### INTRODUCTION

Post-operative peritoneal adhesion formation remains a considerable source of patient and physician frustration and a significant burden on hospital resources<sup>[1]</sup>. As the commonest cause of small bowel obstruction in patients who have previously undergone laparotomy, adhesions account for 40% of all cases of intestinal obstruction and 60%-70% of those affecting the small bowel. After a first such clinical episode, 53% of patients will go on to develop a second relapse, and 83% of these will have chronic symptoms<sup>[2]</sup>. Some 14% of those who manifest overt adhesive intestinal obstruction do so within 2 years of their initial surgery, with 2.6% requiring operative adhesiolysis for its relief<sup>[3]</sup>. Furthermore, approximately 20% of patients developing adhesional bowel obstruction do so at a remove of more than ten years after their index operation<sup>[4]</sup>. Post-operative adhesions are also a common cofactor in female infertility in those with prior laparotomy<sup>[5,6]</sup> and they add markedly to the technical complexity of any repeat abdominal operation. By doing so, they give rise to considerable surgeon frustration<sup>[7]</sup> and a heightened risk of patient morbidity<sup>[8]</sup>.

For all these reasons, this iatrogenic complication weighs heavily on the balance books of health care providers. Indeed, in overall costs, the financial cost due to adhesion-related morbidity approximates the expenditure required for the surgical management of gastric or rectal cancer<sup>[9]</sup> and this is then further compounded by the cost of medicolegal claims and settlements. Finally, the considerable number of bed-days consumed by the sequelae and treatment of post-operative adhesions (indeed in Finland, adhesion-related admissions exceeds the number of bed-days appropriated to varicose vein surgery) also reinforces the urgency for developing effective means of adhesion abrogation.

Unfortunately, however, clinical strategies and therapies aimed at controlling or alleviating adhesion formation have been largely inadequate in their address of both ongoing human suffering<sup>[10]</sup> and economic cost<sup>[11]</sup>. To date these attempts have mostly concentrated on employing physical means to align<sup>[12-14]</sup> or separate<sup>[15]</sup> adjacent loops of bowel in the early post-operative period (so that any configuration of interloop bands is either organised or hindered respectively) or have focused on manipulating peritoneal fibrinolytic mechanisms<sup>[16-18]</sup>.

## CYTOKINE ORCHESTRATION IN POST-OPERATIVE ADHESION FORMATION

Adhesions however represent a form of secondary wound healing. Therefore the mesothelial tissue response to injury (occurring either directly due to handling and dissection or indirectly due to desiccation, cooling or relative ischaemia at sites both adjacent to and distant from the actual operative site) is initiated locally and thence both propagated and orchestrated by cytokine signaling. Although systemic<sup>[19]</sup> and genetic elements<sup>[20]</sup> may also influence the severity of the cascade and factors such as bacterial contamination can potentiate it<sup>[21]</sup>, interruption or manipulation of key cellular processes early in the response cascade would seem likely to markedly diminish all downstream events including the ultimate fibrotic endpoint. Furthermore, the increasing sophistication of anti-cytokine therapies now allows single components of complex cellular processes to be specifically targeted. In addition, potentially efficacious agents have already been proved both safe and useful in the management of anti-neoplastic<sup>[22]</sup> and anti-inflammatory conditions<sup>[23]</sup>. Therefore a new era in the approach to adhesion amelioration may be in the offing.

## SPECIFIC TARGETTING OF SELECTED CYTOKINES

There has of course been a vast array of cytokines and chemokines implicated in the initiation, development and maturation of abdominal adhesions after laparotomy (Table 1) and therefore it may initially appear forbidding to try and narrow the therapeutic target most likely to lead to unopposed benefit. Tumor necrosis factor was one of the earliest cytokines investigated and certainly seems to represent one important factor. However its recent elucidation as a key mediator of the bacterial response to infection seems to mitigate against using monoclonal antibodies (already commercially available) to abrogate this cytokine early after intestinal operation<sup>[24]</sup>. Equally, the variability of action depending on the relative proportions of its isoforms and the central role it plays in wound healing would also seem to deter use of directed therapy against transforming growth factor-beta. Of the remaining candidate targets the majority only really have a slender evidence base to support their selection from out of the general post-operative molecular milieu. The one exception, at present, would seem to be vascular endothelial growth factor (VEGF).

Although this important signaling protein is best known as a potent angiogenic cytokine (and indeed may be proposed as having a role in the process of adhesion growth through the induction of new blood vessels into areas of operative tissue injury<sup>[25]</sup>), VEGF is now also well established as being directly involved in restorative tissue processes, including early inflammatory responses, as well as wound repair and remodeling *via* effecting fibroblast function<sup>[26]</sup>. Furthermore, the central role of VEGF in facilitating increased vascular permeability

(essential for the early proinflammatory response to injury) as well as the subsequent deposition of the fibrin-rich matrix necessary for subsequent cellular migration and proliferation<sup>[27,28]</sup> would seem to make it a prime putative agent in the formation of peritoneal adhesions. It is not surprising therefore that VEGF has been consistently positively implicated (albeit non-selectively) in this process<sup>[29]</sup>. The realization that peritoneal mast cells both constitutively and inducibly express this cytokine<sup>[30,31]</sup> further suggests an intriguing link given that these cells are known also to be central to adhesion formation<sup>[32]</sup>. However, it may well be that rather than through direct secretion, mast cells effect the threshold concentration of this cytokine by exciting the egress of neutrophils and monocytes from the circulation into the peritoneum and that it is these cells that instead then contribute most to regional VEGF levels.

Regardless of its exact cellular origin, VEGF seems to represent an ideal target as its levels correlate with adhesion formation in animal models with its regulation (either positively<sup>[19]</sup> or negatively<sup>[32]</sup>) affecting the degree to which they form after peritoneal operations. The clinical success and safety of VEGF neutralization by a specific monoclonal antibody in the treatment of malignant diseases<sup>[33]</sup> adds further impetus to the need to try its pharmacological manipulation as an anti-adhesion strategy particularly as selective therapeutic targeting of the cytokine does not seem to disrupt operative wound healing in a clinically important fashion<sup>[34]</sup>.

## DETERMINATION OF CLINICAL EFFICACY

Clinical evidence of efficacy of anti-adhesion therapies is notoriously difficult to attain as second look-laparotomy to assess distribution and intensity of peritoneal reaction is not ethically justifiable (although may be possible in the case of certain gynecological procedures<sup>[35]</sup>). Additionally, the mere presence of adhesions, even if extensive, does not necessarily correlate with the incidence and severity of subsequent symptomatic episodes and long-term follow-up is required to determine the full-extent of the problems arising. These challenges are not however insurmountable as have been shown by those who advance the cause of bioactive substances<sup>[36,37]</sup> and the difficulties that would be encountered in establishing a progressing and adequately powered multi coated blinded study would be markedly outweighed by the huge benefit to patients of many differing specialties. With regard to monoclonal antibody therapies in particular, there now exists the opportunity to piggy-back on the human safety testing performed on this class of drug in alternative settings. While pursuit of molecular mechanisms for adhesion amelioration will undoubtedly still be expensive<sup>[38]</sup>, the cost incurred by the management of adhesion-related morbidity<sup>[39,40]</sup> economically justifies considerable investment in any potential means of their attenuation.

## CONCLUSION

There have long been a multitude of groups proposing

**Table 1** Overview of literature to date regarding cytokine orchestration in postoperative adhesion formation. Included in the list are cytokines, chemokines, and proteases as well as trigger enzymes

Cytokine <sup>Ref</sup>	Mechanism investigated	In vitro/vivo	Species	Experimental model	Effect on adhesion formation
Heparin-binding growth factor <sup>[41]</sup>	Macrophage and neutrophil omental migration	In vivo	Mouse	(1) Partial hepatectomy (2) Omental adherence	Exacerbated by Midkine- omental inflammation reduced
HGF <sup>[42]</sup>	Mesothelial cell proliferation and migration	Both	Rat	Cecal abrasion	Exacerbated by local HGF gene transfer
IFN-γ, HGF <sup>[43]</sup>	Natural killer T cell activity	Both	Mouse	Cecal cauterization	Attenuated by HGF
IL-1 <sup>[44]</sup>	Nonspecific inflammation	In vivo	Rat	Cecal abrasion	Exacerbated by IL-1
IL-1, TNF <sup>[45]</sup>	Proinflammatory markers	In vivo	Human	Adhesion samples	IL-1 & TNF-α associated with adhesion
IL-1, IL-6, TNF-α <sup>[46]</sup>	Cellular mediation	In vitro	Human	Peritoneal fluid sampling	Adhesions associated with IL-6 and IL-1
IL-10 <sup>[47]</sup>	Natural antiinflammatory	In vivo	Mouse	Peritoneal injury	Attenuated by IL-10 but no effect with IL-10 mAb. No association with IL-10 levels
IL-10 <sup>[48]</sup>	Immunosuppression	In vivo	Mouse	Peritoneal injury	Attenuated by IL-10
IL-1b, TNF-α, TGF-β1, IL-10, IFNg, GM-CSF <sup>[49]</sup>	Inflammatory	In vitro	Human	Peritoneal fluid sampling	Only IFN-γ and TGF-β1 associated with adhesion formation. No association found with other cytokines.
IL-6 <sup>[50]</sup>	Early proinflammatory effects	In vivo	Rat	Cecal abrasion with C <sub>2</sub> H <sub>5</sub> OH	Exacerbated by IL-6, attenuated by monoclonal Ab to IL-6
PAF <sup>[51]</sup>	Early inflammatory mediators	In vivo	Rat	Uterine horn abrasion	Adhesions and IL-6 levels attenuated by Lexipafant (PAF antagonist)
Substance P <sup>[52]</sup>	Substance P mediation	In vivo	Rat	Peritoneal ischaemic buttons	Substance P and TGF-β1 as well as ICAM-1 and VCAM-1 increased
TGF <sup>[53]</sup>	TGF isoforms	In vivo	Mouse	Serosal abrasion and apposition	Exacerbated by TGF-β3, attenuated by combined TGF-β1 and TGF-β2 mAB
TGF-β <sup>[54]</sup>	TGF-β regulation of extracellular matrix	In vitro	Human	Human fibroblast culture	Dichloroacetic acid inhibited fibronectin and collagen type III expression
TGF-β <sup>[55]</sup>	Chemoattraction	In vitro	Rat	Cecal abrasion	TGF-β mRNA increased by trauma
TGF-β <sup>[56]</sup>	Mast cells	In vivo	Hamster	Uterine horn abrasion	Exacerbated by chymase inhibitor
TGF-β <sup>[57]</sup>	Chemoattraction	In vivo	Rat	Uterine horn abrasion	Exacerbated by TGF-β
TGF-β <sup>[58]</sup>	Mast cells	In vitro	Human	Cell culture	TGF-β and tryptase increased collagen
TGF-β <sup>[59]</sup>	Peritoneal repair	In vivo	Rat	Uterine horn abrasion	No antiadhesion effect of anti-TGF mAb
TGF-β <sup>[60]</sup>	Immunosuppression	In vivo	Rat	Small bowel transplant	Adhesions attenuated by tacrolimus
TGF-β <sup>[61]</sup>	Mast cells	In vivo	Rat	Uterus scraping	TGF-β increased by trauma, adhesions attenuated by chymase inhibition
TGF-β <sup>[62]</sup>	Cellular effects of Tisseel	In vitro	Human	Cell culture	Fibroblasts TGF-β reduced
TGF-β, MMP-9, TIMP-1 <sup>[63]</sup>	Matrix factors	In vivo	Human	Sampled peritoneal fluid	Adhesion assor with reduced MMP-9 but elevated MMP-9/TIMP-1 ratio
TGF-β/MDF <sup>[64]</sup>	Carboxymethylcellulose sponge	In vivo	Rat	Cecal denudation & apposition	Effect of sponge independent to cytokine release (barrier function)
TGF-β1 <sup>[65]</sup>	Chemoattraction	In vitro	Human	Cell culture	TGF-β1 increased in scar tissue
TGF-β1 <sup>[66]</sup>	Extracellular matrix	In vivo	Mouse	Cecal abrasion	Exacerbated by haploid insufficiency
TGF-β1 <sup>[67]</sup>	Fibrinolysis	In vitro	Human	Biopsy sampling	Attenuated by TGF-β1 overexpression
TGF-β1 <sup>[68]</sup>	Peritonitis	In vivo	Rat	Cecal ligation and puncture	Peritonitis upregulates TGF-β1 expression
TGF-β1 <sup>[69]</sup>	Mitogenicity of macrophages & fibroblasts	In vivo	Rat	Small Bowel transection and re-anastomosis	Adhesions and TGF-1 levels attenuated by ACE inhibition
TGF-β1, MMP1&2, TPA, TIMP-1 <sup>[70]</sup>	Cellular effects of seprafilm	In vitro	Human	Human fibroblast & mesothelial cell culture	No cytokine effect induced by Seprafilm (barrier effect important)
TGF-β1, TGF-β2 <sup>[71]</sup>	Basal expression	In vitro	Human	Biopsy sampling	Sit-specific TGF-β1 & TGF-β3 expression
TGF-β1 <sup>[72]</sup>	Cellular effects of changtong	In vivo	Rat/rabbit	Cecal abrasion	TGF-β reduced in rats
TNF, IL-1, IL-6 <sup>[73]</sup>	Effects of gloves and powders	In vivo	Rat	Cecal abrasion	Adhesions increased by glove powder
TNF-α <sup>[74]</sup>	Proinflammatory effects of TNF-α	In vivo	Rat	Cecal abrasion	Adhesion formation attenuated by infliximab but no histological effect
TNF-α, IL-1 <sup>[75]</sup>	Proinflammatory markers	In vivo	Rat	Cecal abrasion or small bowel resection	TNF-α appears a good biological marker for adhesion formation
TNF-α, IL-1 <sup>[76]</sup>	Immunosuppression	In vivo	Rat	Cecal abrasion	Adhesion formation attenuated by mAbs to IL1 and IL-1/TNF-α
TNF-α, IL-6 <sup>[77]</sup>	Proinflammatory mediators	In vitro	Mouse	Murine macrophages	Adhesion formation attenuated by hyaluronic acid and dexamethasone
TNF-α, MMP <sup>[78]</sup>	Mesothelium reaction to peritoneal injury	In vivo	Rat	Peritoneal wounding	No effect of MMP & TACE inhibition, TNF-α may not be adhesiogenic
TNF-α, TGF-β1 <sup>[79]</sup>	PROACT to injured peritoneum	In vivo	Human	Tissue sampling	TNF-α and TGF-β reduced by heating
VEGF <sup>[80]</sup>	Angiogenesis	In vivo	Rat	Uterus-peritoneal scrub	Associated by angiogenesis
VEGF <sup>[29,32]</sup>	Vascular permeability	In vivo	Mouse	Peritoneal injury	Adhesions attenuated by Antiserum and monoclonal antibody
VEGF, basic-FGF <sup>[25]</sup>	Fibrovascular band formation	In vivo	Human	Adhesion samples	VEGF in endothelial cells associated with adhesion formation

VEGF, IL-6 <sup>[21]</sup>	Bacterial Translocation	Both	Mouse	Caecal abrasion & suture	Adhesions attenuated by rBPI
VEGF, PIGF <sup>[81]</sup>	Pnenumoperitoneum	In vivo	Mouse	Lap. uterine horn model	Exacerbated by VEGF and CO <sub>2</sub>
CCL 1-CCR 8 <sup>[83]</sup>	Specific recruitment of peritoneal macrophages	Both	Mouse	Peritoneal ischaemic button & colitis-associated peritoneal adhesions	Unaffected by CCR8 gene deficiency and antiCCL1-neutralizing antibody
CD 28 T cell costimulatory pathway <sup>[84]</sup>	CD28 T cell costimulatory pathway/Inhibitor programmed death-1 pathway	Both	Mouse	Caecal abrasion	Exacerbated by CD28 T Cell costimulatory pathway but unaffected by death-1 pathway
Interferon-inducible protein-10 <sup>[85]</sup>	Regulates influxing neutrophils, monocytes and lymphocytes	In vivo	Mouse	Peritoneal side wall injury	
Broad spectrum of chemokines <sup>[86]</sup>	Broad spectrum chemokine inhibitor NR58-3.14.3	In vivo	Mouse	Peritoneal traumatization	Adhesions significantly attenuated
MCP-1 <sup>[87]</sup>	Fibroblast and mononuclear cell chemotaxis	In vivo	Mouse	Peritoneal injury	Attenuated by MCP-1 antibody
MCP-1 <sup>[88]</sup>	Fibroblast and mononuclear cell chemotaxis	In vivo	Human	Cell culture	
MCP-1 <sup>[89]</sup>	Fibroblast and mononuclear cell chemotaxis	In vivo	Human	Cell culture	
T cells, IL-17, CXC MPI-2/ CXCL8, CXCL1 <sup>[90]</sup>	CD4+ T cells	In vivo	Mouse	Caecal abrasion	Unaffected by anti-IL-17 antibodies

HGF: Hepatocyte growth factor; IFN- $\gamma$ : Interferon-gamma; IL: Interleukin; TNF- $\alpha$ : Tumour necrosis factor-alpha; TGF- $\beta$ : Transforming growth factor-beta; GM-CSF: Granulocyte macrophage colony stimulating factor; PAF: Platelet activating factor; MMP: Matrix metalloproteinase; TIMP: Tissue inhibitor of metalloproteinase; MDF: Macrophage deactivating factor; TPA: Tissue plasminogen activator; VEGF: Vascular endothelial growth factor; FGF: Fibroblast growth factor; PIGF: Placental growth factor; MCP: Monocyte chemotactic protein.

novel, potential therapies for the attenuation of adhesion formation at a preclinical level- the onus now though is on leading surgeon-scientists to corral their endeavour and progress their preclinical expertise into the clinical setting. For a start, the most likely candidate cytokine must be agreed (in our mind VEGF would seem the most apposite) and the most appropriate means of affecting its activity (whether directly<sup>[52]</sup> or indirectly<sup>[21]</sup>) selected. Furthermore industry interest will need to be stimulated for its support for Phase II and III trials as well as for the subsequent manufacture and marketing processes is crucial. Above all, though it must be realized that the timing for a concerted attempt to prove that molecular manipulation of post-operative peritoneal formation has never been better.

## Abstract

Narrow-band imaging (NBI) is an innovative optical technology that modifies the center wavelength and bandwidth of an endoscope's light into narrow-band illumination of  $415 \pm 30$  nm. NBI markedly improves capillary pattern contrast and is an *in vivo* method for visualizing microvessel morphological changes in superficial neoplastic lesions. The scientific basis for NBI is that short wavelength light falls within the hemoglobin absorption band, thereby facilitating clearer visualization of vascular structures. Several studies have reported advantages and limitations of NBI colonoscopy in the colorectum. One difficulty in evaluating results, however, has been non-standardization of NBI systems (Sequential and non-sequential). Utilization of NBI technology has been increasing worldwide, but accurate pit pattern analysis and sufficient skill in magnifying colonoscopy are basic fundamentals required for proficiency in NBI diagnosis of colorectal lesions. Modern optical technology without proper image interpretation wastes resources, confuses untrained endoscopists and delays inter-institutional validation studies. Training in the principles of "optical image-enhanced endoscopy" is needed to close the gap between technological advancements and their clinical usefulness. Currently available evidence indicates that NBI constitutes an effective and reliable alternative to chromocolonoscopy for

## INTRODUCTION

In 1971, Folkman proposed that all tumor growth was angiogenesis-dependent. This was the foundation for the development of angiogenic research and helped to stimulate investigation that is now being pursued by scientists in many different fields worldwide<sup>[1]</sup>. New blood vessel creation favors a transition from hyperplasia to neoplasia (i.e., the passage from a state of cellular multiplication to a state of uncontrolled proliferation characteristic of tumor cells)<sup>[2]</sup>.

An *in vivo* means for visualizing angiogenesis or microvessel morphological changes in superficial neoplasms would constitute a promising method for the diagnosis of early gastrointestinal tumors. Narrow-band imaging (NBI) is an innovative optical technology developed in Japan that modifies the center wavelength and bandwidth of an endoscope's light into a narrow-band illumination of  $415 \pm 30$  nm. By utilizing this narrow spectrum, contrast in the capillary pattern of the superficial layer is markedly improved<sup>[3]</sup>, thereby facilitating clearer visualization of vascular structures during gastrointestinal endoscopy<sup>[4]</sup>.

The first clinical study of the NBI system for the diagnosis of gastrointestinal tumors was reported by Sano *et al*<sup>[5]</sup> in 2001. Their promising observations resulted in the first pilot colorectal study in which the NBI system demonstrated better vascular pattern

visualization than conventional colonoscopy in the diagnosis of colorectal polyps<sup>[6]</sup>. These early studies opened the way for subsequently using NBI in the diagnosis of pre-malignant and malignant lesions of the hypo-pharynx, esophagus and stomach<sup>[4,7,8]</sup>.

This review focuses on the current advantages and limitations of using the NBI system in the diagnosis of colorectal lesions.

## SCIENTIFIC BASIS FOR NBI

Video endoscopes use white light from a xenon source for illumination. In order to understand the reflectance spectrum of any tissue, both the scattering process and absorption must be taken into account. Based on the Monte Carlo simulation, several investigations into the mechanism of scattering from tissue structures have determined that the penetration depth of the light depends on the wavelength. The depth of penetration into the gastrointestinal tract mucosa is superficial for the blue band, intermediate for the green band and deep for the red band (penetration depth range: 0.15 to 0.30 mm). As a result, NBI systems use optical filters for green and blue sequential illumination and narrow the bandwidth of spectral transmittance<sup>[9,10]</sup> (Figure 1).

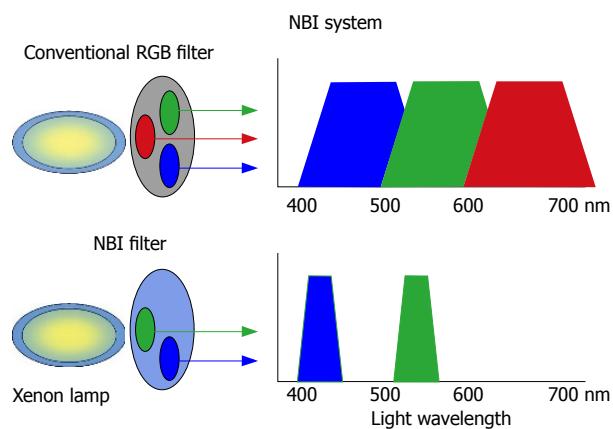

The scientific basis for the NBI system is that light with a short wavelength falls within the hemoglobin absorption band, so that blood vessels may be more clearly seen due to sufficient contrast<sup>[6]</sup>.

## IMAGE RECONSTRUCTION FROM REFLECTED LIGHT

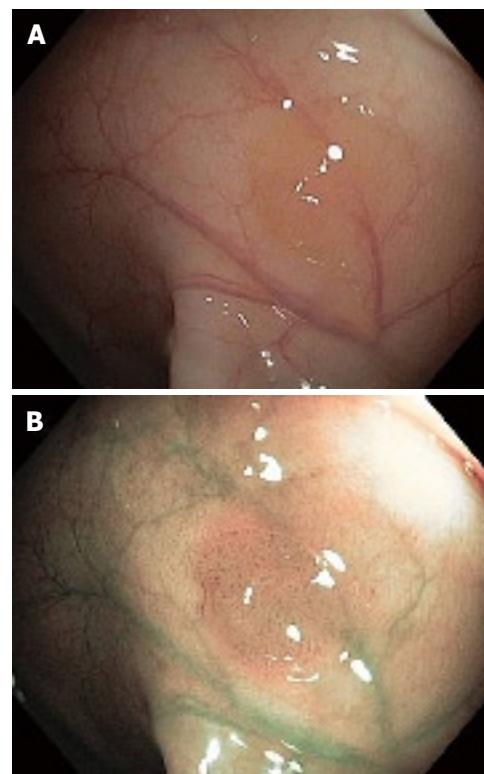

Two different types of NBI systems are used to reconstruct images from the reflected light. The non-sequential system (Exera II), also referred to as the "color chip system", uses a color charge coupled device (CCD) in which pixels are selectively assigned to specific wavelength ranges. The CCD captures the full range of the white light and transfers it in a single step to the processor in order to reconstruct natural color on the video monitor (Figure 2).

In contrast, the sequential system (Lucera Spectrum) uses a monochrome CCD in which pixels are not selectively attributed to specific colors, but transferred sequentially in the RGB bands to the processor. A rotating RGB interference filter is interposed after the white light source and the mucosa is illuminated alternately in each of the three RGB bands<sup>[11]</sup> (Figure 3).

Although the concept and basic design is the same for both the NBI sequential and non-sequential systems, a difference in color images exists due to differences in the color spectral characteristics of the RGB rotary filters used in the Lucera Spectrum and the color CCD used in the Exera II. There is considerable potential for further development, however, by improving NBI technology in the non-sequential endoscopic video system.

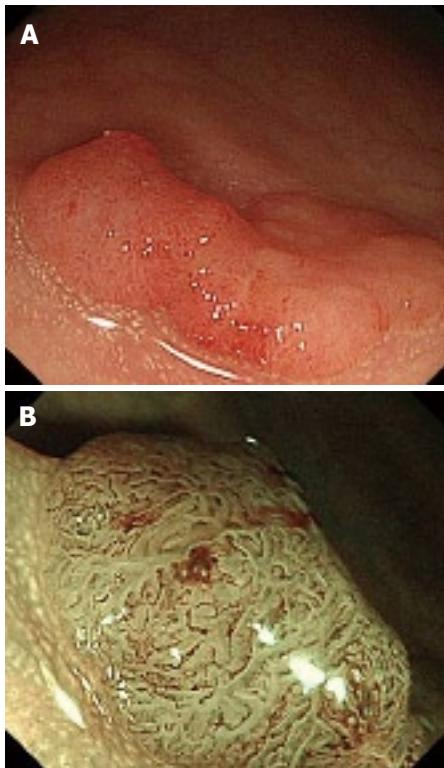

**Figure 1** NBI system. Different from the conventional RGB filter, the NBI filter consists of two narrow bands ( $415 \pm 30$  nm and  $540 \pm 30$  nm, respectively) that make it possible to observe clearly superficial vascular patterns for clinical evaluation.

**Figure 2** NBI colonoscopy image with non-sequential system. **A:** Conventional view of an I<sub>s</sub> polyp, 12 mm in diameter located in the sigmoid colon; **B:** NBI view clearly showing the superficial meshed vascular pattern on the polyp's surface indicating an adenomatous polyp.

## ARE YIELDS OF SMALL AND FLAT ADENOMAS HIGHER WITH NBI?

An interesting Japanese study involving 48 patients in which conventional white light colonoscopy was first performed followed later by blind NBI colonoscopy on the same patients found that the total number of neoplastic lesions detected by NBI was significantly higher than the total number of neoplastic lesions detected using conventional colonoscopy ( $P = 0.02$ ). Based on macroscopic appearance, location and tumor

**Figure 3** NBI colonoscopy image with sequential system. **A:** Conventional view of an IIa polyp, 20 mm in diameter located in the rectum; **B:** Meshed capillary vessels are clearly seen using magnifying NBI as dark brown areas diagnosing an intramucosal cancer.

size, flat lesions < 5 mm located in the right colon in particular were more frequently diagnosed using NBI<sup>[12]</sup>.

Although no Western study has as yet validated those Japanese results, a recent report indicated that adenomas were detected more frequently in the NBI group (23%) than in the control group (17%), but the difference was not statistically significant ( $P = 0.129$ )<sup>[13]</sup>. In contrast, it has also been recently reported that NBI did not result in better detection of adenomas. In that particular study, a colonoscopist with a known high detection rate using white light colonoscopy conducted patient examinations with high-definition colonoscopes using either white light or NBI<sup>[14]</sup>.

The fact that differences still exist between Japan and Western countries demonstrates that prospective studies are needed to determine which of these early reports are valid.

## NBI FOR NON-NEOPLASTIC AND NEOPLASTIC LESIONS

For lesions < 10 mm, it is generally accepted that hyperplastic polyps and other non-neoplastic colorectal lesions do not require endoscopic treatment because they are benign and have no malignant potential<sup>[15,16]</sup>. In contrast, adenomatous polyps should be removed to prevent progression of the adenoma-carcinoma sequence<sup>[17]</sup>.

Magnified chromocolonoscopy (MCC) has been

presented as the best means for *in vivo* selective management of colorectal polyps<sup>[18,19]</sup> and it is suggested that colorectal polyps should not be treated only on the basis of polyp size, but also with respect to the underlying histological characteristics observed during MCC<sup>[20]</sup>. The NBI system has been proposed for optical image-enhanced endoscopy because it features a simple one-touch button for changing from white light to NBI and does not require indigo carmine dye spraying.

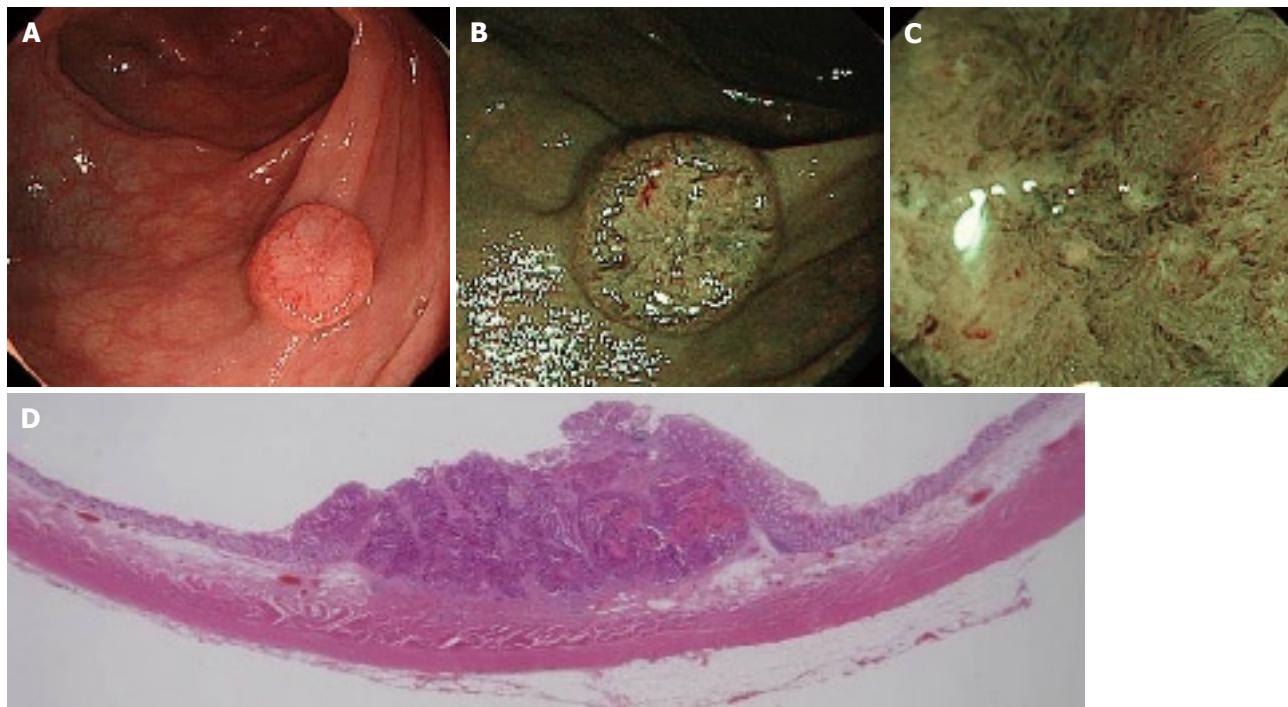

An early study of an NBI prototype used for differentiating non-neoplastic from neoplastic lesions in 34 patients with 43 lesions reported better visualization of the mucosal vascular network and lesion compared to conventional endoscopy. Chromocolonoscopy and NBI both had a sensitivity of 100% and a specificity of 75%<sup>[6]</sup>. Thereafter, the effectiveness of conventional colonoscopy, chromoendoscopy and the NBI system in distinguishing between non-neoplastic and neoplastic colonic polyps was assessed in 78 patients with 110 lesions. No significant difference existed between the NBI system and chromoendoscopy, but the sensitivity, specificity and accuracy of conventional colonoscopy were significantly lower (82.9%, 80.0% and 81.8%, respectively) compared to both chromoendoscopy and the NBI system (95.7%, 87.5% and 92.7%, respectively)<sup>[21]</sup>.

More recently, a classification of colorectal polyps based on the presence or absence of superficial meshed capillary vessels and their diameter, observed under NBI (CP type I - III) was proposed in Japan by Sano *et al*<sup>[22]</sup>. Although a promising and exciting alternative to differentiate the nature of colorectal polyps, Western prospective studies, however, are needed for its standardization worldwide.

## NBI FOR INVASIVE AND NON-INVASIVE COLORECTAL CANCER

There is growing evidence to support the theory that lesions with submucosal (sm) invasion < 1000 µm (sm1) without lympho-vascular invasion or a poorly differentiated component do not involve lymph node metastases<sup>[23]</sup>. In Japan, analysis of the pit pattern types proposed by Kudo *et al*<sup>[24]</sup> has been proven effective in predicting the level of sm invasion. In practice, however, limitations have been reported using the V<sub>1</sub> pit pattern to discriminate between mucosal (m), slight submucosal (sm1) and, deep submucosal (sm2) or deeper invasion<sup>[25]</sup>. The invasive pattern proposed by Fujii *et al*<sup>[26-28]</sup> (distorted and irregular crypts and a demarcated area) has also been reported to be effective in predicting sm2.

One promising area for NBI is in the accurate estimation of invasive depth for early colorectal cancers. Hirata *et al*<sup>[29]</sup> analyzed 148 colorectal lesions and recently reported a high degree of correspondence between pit pattern analysis by NBI and chromoendoscopy although the correspondence between MCC and NBI in evaluating the V<sub>1</sub> pit pattern of 48 early carcinomas

**Figure 4** NBI image of colorectal cancer. **A:** Conventional view of an IIa + IIc lesion, 12 mm in size, located in the transverse colon; **B:** NBI view shows a well demarcated area and meshed capillary vessels clearly visible characterized by thick diameter, branching and curtal irregularity; **C:** Magnifying NBI view additionally shows the presence of a nearly avascular or loose microvascular area due to histological desmoplastic changes in the stromal tissue, suggesting deep submucosal invasion; **D:** Histopathological analysis revealed an adenocarcinoma invading deeply into the submucosa (2500  $\mu$ m) with lymphovascular invasion.

was only 78%. Diagnosis using the type V pit pattern was possible by also evaluating various capillary features including vessel diameter, irregularity and the capillary network observed during NBI and not by relying solely on the pit pattern.

Two other promising studies on predicting the depth of invasion of early colorectal cancer by analyzing the microvascular architecture were published recently. Using NBI with magnification, Fukuzawa *et al*<sup>[30]</sup> observed several microvascular architecture characteristics in 61 early colorectal lesions (m-sm1: 37; sm2-3: 24). Univariate analysis showed that wide caliber, irregular caliber, tortuosity, irregularity, short length and non-dense arrangement were significantly more frequent in sm2-3 lesions compared to m-sm1 lesions ( $P < 0.001$ ). Multivariate analysis, however, revealed that irregularity and non-dense arrangement were the remaining independent factors<sup>[30]</sup> (Figure 4). Horimatsu *et al*<sup>[31]</sup> analyzed the presence of “meshed brown capillary vessels” in 27 colorectal lesions (m-sm1: 12; sm2: 15) also using NBI colonoscopy with magnification. The overall diagnostic accuracy, sensitivity, and specificity of microvessel density and the lack of uniformity in microvessel diameters for distinguishing between sm1 and sm2 lesions was 82.4% (14/17), 93.3% (14/15) and 75.0% (9/12), respectively<sup>[31]</sup> (Figure 4).

## DETECTION OF DYSPLASTIC AREAS IN ULCERATIVE COLITIS

Although patients with longstanding ulcerative

colitis are at increased risk of developing colorectal cancer, endoscopic detection of early neoplasia is difficult because these lesions can be subtle and even macroscopically invisible at times. A laborious protocol has been proposed involving not only target biopsies from suspicious lesions, but also two to four random biopsies taken every 10 cm of the colon<sup>[32]</sup>. MCC has emerged as the best method currently available for identifying dysplastic lesions in an inflammatory bowel disease setting<sup>[33,34]</sup>.

In terms of NBI research, the limitations of the first NBI prototype were recently shown in a prospective randomized crossover study of 42 patients with longstanding ulcerative colitis. In that study, the sensitivity of NBI for the detection of neoplasia was merely comparable to conventional colonoscopy although a larger number of suspicious lesions were found during NBI colonoscopy<sup>[35]</sup>. A more positive report on the effectiveness of a third generation NBI prototype plus magnification indicated that just as NBI reveals fine superficial blood vessels whose diameters and densities are increased in neoplastic lesions compared with normal mucosa, dysplastic lesions observed using NBI also have a darker capillary vascular pattern compared with normal mucosa<sup>[36]</sup>.

## WILL CONVENTIONAL CHROMOCOLONOSCOPY BE REPLACED BY NBI?

It is still too early to answer this question. In Japan,

chromocolonoscopy has demonstrated its effectiveness in the differentiation between adenomatous and hyperplastic polyps and is a promising method for distinguishing superficial from deep submucosal cancers, but it is regarded as an inconvenient and difficult procedure in Western countries<sup>[37]</sup>. Indigo carmine dye spraying is inexpensive and differs in practice from the NBI system in that it does not target superficial vascular patterns, but instead accentuates lesion contours and highlights the pit pattern of colonic crypts<sup>[25]</sup>. It is interesting to note that indigo carmine dye spraying is not recommended before an NBI examination because it might obscure blood vessel visualization.

In contrast, NBI even without magnification when using the non-sequential system provides accurate definition of vascular vessels throughout the entire colonic mucosa and more clearly defines the borders of a lesion without the necessity of using dye spraying. The recently developed NBI system requires an expensive new processor, however, so the cost-benefit issue requires further analysis<sup>[38]</sup>. In addition, the diagnostic accuracy of NBI is affected by the learning curve associated with this new methodology and extra time may be needed to perform the examination.

## USELESS TECHNOLOGY IN UNQUALIFIED HANDS

The acquisition and use of NBI technology is increasing in many countries, but it should be emphasized that accurate analysis of the pit pattern types and familiarity with MCC are basic fundamentals necessary to become proficient in NBI diagnosis of colorectal lesions. Modern optical technology without proper image interpretation wastes valuable resources, can cause confusion for inadequately trained endoscopists and may result in the delay of inter-institutional validation studies. Training general endoscopists in the principles and applications of optical image-enhanced endoscopy as practiced in Japan (i.e., stereomicroscopy, conventional chromoendoscopy, magnifying endoscopy and pit pattern analysis)<sup>[20,24-26]</sup> in approved centers by qualified experts will be required to narrow and, hopefully, close the existing gap between the latest advancements in optical technology and their clinical usefulness.

## CONCLUSION

Several studies have previously reported on the advantages and limitations of NBI optical image-enhanced colonoscopy in the diagnosis of colorectal diseases. One difficulty in evaluating the results, however, has been non-standardization of the NBI systems and prototypes used in the research. Despite this shortcoming, there seems to be considerable potential for further development by improving NBI technology in the non-sequential endoscopic video system by modifying the characteristics of the interference filters.

In practice, the latest technological advancements

incorporated into third generation NBI prototypes appear to offer a clear advantage over conventional chromocolonoscopy. Additional validation studies are needed, however, to confirm the effectiveness of NBI for screening colonoscopy, identification of adenomatous polyps, determining depth of invasion of early colorectal cancers, evaluating free margins after endoscopic resection and detection of dysplastic lesion in an inflammatory bowel disease setting.

A number of other questions remain unsolved that deserve additional examinations including whether NBI is less time-consuming, its cost effectiveness, whether magnification is absolutely required and whether the NBI system should completely replace chromocolonoscopy. Further studies assessing these issues are ongoing at various medical centers worldwide.

At the present time, NBI constitutes an effective and reliable alternative to chromocolonoscopy for *in vivo* visualization of vascular structures. Due to widespread incorporation of NBI technology outside Japan, however, there is an increasing need to train general endoscopists in the basic principles and applications of advanced optical image-enhanced endoscopy.

## ACKNOWLEDGMENTS

We are grateful to Dr. Kazuhiro Gono (Olympus Corp, Tokyo, Japan) for his contribution to the revision of the "Scientific Basis for NBI" section and to Christopher Dix for his assistance in the editing of this manuscript.

Several new proteins appeared after US irradiation and were up or down regulated more than 2 times. Some heat shock proteins (HSPs) were found to be associated with the signal process simulating the apoptosis of cells.

**CONCLUSION:** Low intensity US could induce apoptosis in human gastric carcinoma cells. US-induced apoptosis is related to US intensity/culture time. US-induced apoptosis may be caspases-dependent and endoplasmic reticulum (ER) stress-triggered apoptosis may also contribute to it. Proteomic experimental system is useful in finding the protein alteration in carcinoma cells after US irradiation, helping to develop a new cancer therapy.

## INTRODUCTION

Gastric carcinoma is the second commonest cause of cancer-related deaths worldwide. Although surgical removal of the stomach is the only curative treatment in clinical practice, more studies revealed that chemotherapy and radiation therapy given after surgery could improve the chance of a cure for many patients. To improve the survival rate, new therapeutic methods should be developed.

In non-surgical cancer treatment, induction of

apoptosis is a preferred mode of killing cancer cells<sup>[1,2]</sup>. Several investigators have reported that US irradiation could induce apoptosis in human leukemia cell lines<sup>[3-7]</sup>, including K562, HL-60, Nalm-6 and U937. It was also reported that apoptosis of some solid carcinoma cells, such as human ovarian carcinomas cells<sup>[8]</sup>, SMMC-7721 cells (data not shown) and Walker 256 carcinosarcoma cells<sup>[9]</sup>, are triggered by US irradiation. Different from high intensity focused ultrasound (HIFU) which can thermally ablate tissues *via* hyperthermia in different carcinomas<sup>[10-12]</sup>, low intensity ultrasound (US) defined as therapeutic US, with a relatively lower intensity than HIFU, has a great potential in apoptosis therapy for cancer and can be relatively easily applied<sup>[8,13]</sup>. So it is suggested that low intensity US-induced apoptosis in tumor cells could probably offer a new approach to elimination of cancer<sup>[4]</sup>. To our knowledge, US-induced apoptosis in gastric carcinoma has not yet been reported. Compared with human leukemia cell lines, low intensity US-induced apoptosis in solid carcinoma cells or tissues is still in the process of investigation. The mechanism has also not yet been elucidated.

The aim of this study was to prove low-intensity US-induced apoptosis in human SGC-7901 gastric carcinoma cells and investigate the effects of US intensity and culture time after US irradiation on US-induced apoptosis. Comparative proteomic analysis was performed to examine the alteration in protein profile of gastric carcinoma cells induced by US irradiation. The potential molecular mechanism was suggested *via* the protein functional analysis.

## MATERIALS AND METHODS

### Chemicals and materials

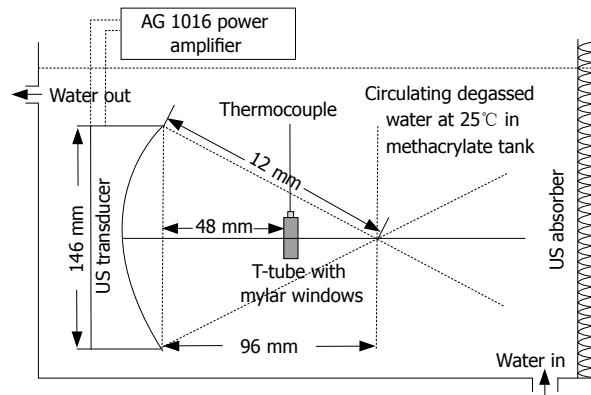

Fluorescein isothiocyanate (FITC)-Annexin V/propidium iodide (PI) kit was purchased from Jingmei Biotechnology Company, China. Immobilized pH gradient (IPG) strips (pH3-10, nonlinear, 13 cm) and IPG buffer (pH3-10, nonlinear) were purchased from Pharmacia, Amersham Biotech. Dithiothreitol (DTT), PMSF and CHAPS were purchased from Sigma Company (USA). All the buffers were made using high purity MilliQ water. Elite ESP flow cytometer was purchased from Coulter Electronics Hialeah, FL. IPGphor isoelectric focusing equipment, Hoefer SE 600 vertical chambers, electrophoresis apparatus, Image Master 2D Elite 4.01 software were purchased from Pharmacia, Amersham Biotech. Voyager-DE MALDI-TOF MS was a product from Applied Biosystems (USA).

### SGC-7901 cell line cultures

SGC-7901 human gastric carcinoma cells (Center of Laboratory Animals of the Forth Military Medical University) were cultured in RPMI 1640 culture medium in a water-saturated atmosphere with 50 mL/L CO<sub>2</sub> at 37°C.

### US irradiation set

The US irradiation system is shown in Figure 1. It consists

**Figure 1** US irradiation system.

of a AWG 2021 arbitrary waveform generator (Sony Tektronix Co., Tokyo, Japan), a AG 1016 power amplifier (T&C Power conversion, Inc., Rochester, NY, USA) and a transducer designed as a semispherical ring with an aperture 146 mm and a radius of curvature 120 mm (Imasonic, Besancon, France), a 750 mm × 750 mm × 500 mm polymethyl methacrylate tank filled with degassed water with 10-cm high water above the transducer. The central frequency is 1.2 MHz. Temperature of water in the tank was controlled at 25°C by circulating. Cell samples were carried in a specially designed inverted "T" tube as previously described<sup>[6,9]</sup>.

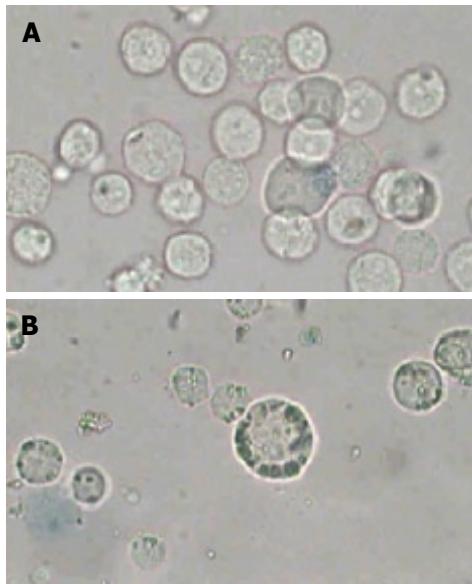

### US treatment and sample collection

The cell samples were divided into ten groups and each treatment was given in three replicates. The first group was used as the control that imitated the whole process with no irradiation. The 2-5 groups were irradiated for 10 min at the intensity of 3.0 W/cm<sup>2</sup>, 6.0 W/cm<sup>2</sup>, 9.0 W/cm<sup>2</sup> and 12.0 W/cm<sup>2</sup> ( $I_{SPT,A}$ ), respectively, and then incubated at 37°C in a humidified air containing 50 mL/L CO<sub>2</sub>. Apoptosis detection and microscopy observation were performed in each sample. Remained cells were washed 3 times with cold PBS, centrifuged at 1500 × g for 10 min to get cell pellets, then frozen quickly in liquid nitrogen and stored in a -80°C ultra low temperature freezer (LegaciTM Refregeration system, REVCO Technologies) for subsequent 2D PAGE analysis. The whole process was performed in sterile condition.

To investigate the relationship between culture time after US irradiation and cell apoptosis, the 6-10 groups were irradiated at the intensity of 12.0 W/cm<sup>2</sup> and incubated at 37°C in a humidified air containing 50 mL/L CO<sub>2</sub> for 0, 6, 12, 18 and 24 h, respectively. The following morphologic observation and apoptosis detection were performed as described above.

### Morphological observation and flow cytometry (FCM) examination

The morphologic changes in apoptotic and necrosis cells could be examined under microscope and detected by analysis of a light scatter signal by FCM<sup>[14]</sup>.

**Figure 2** Morphologic characteristics of SGC-7901 cells before and after US irradiation.

SGC-7901 cells were stained with trypan blue and then observed under microscope (Olympus BX40) to detect their structure change after US irradiation. Furthermore, the cells were analyzed with FCM to detect phosphatidylserine (PS) exposure on the cell membrane as a typical marker of early apoptosis.

#### Two-dimensional electrophoresis (2DE) analysis

Proteins were extracted from control and irradiated cells, respectively, with the freeze-thaw lysis method. Then, the protein solution (containing 200 µg proteins) was loaded to perform isoelectric focusing and second dimension separation as previously described<sup>[15]</sup>. Gels were silver stained.

2D gel images of control and irradiated cells were acquired using a Sharp JX-330 scanner, compared and matched *via* Image Master 2D Elite software. New protein spots and proteins expressing 2 times higher or lower were selected for the following identification based on MALDI-TOF-MS.

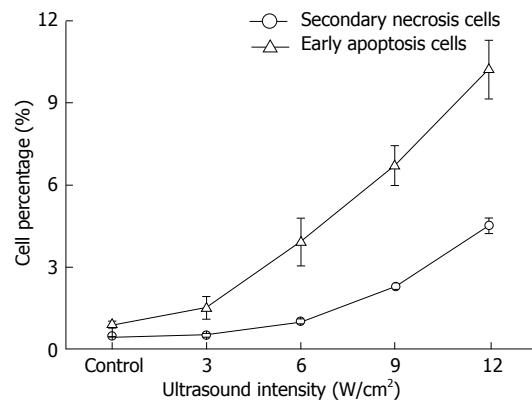

#### Identification of proteins using MALDI-TOF-MS

The selected protein spots were excised from the gel and in-gel digestion with trypsin was performed. The extracted enzymolyzed peptides were identified by peptide mass fingerprinting based on MALDI-TOF-MS (Voyager-DETM), analyzed using data explore, and matched in ProFound-peptide mapping and SWISS-PROT.

## RESULTS

#### Morphologic observation

The morphologic observations showed that the distinct morphologic characteristics of apoptotic cells, such as condensation of nucleus, chromatin margination (Figure 2B) were found after the cells were irradiated at 12.0 W/cm<sup>2</sup> for 10 min and incubated for 12 h

**Figure 3** Percentage of early apoptotic cells and secondary necrosis cells in control and US-irradiated SGC-7901 cells at different US intensities.

after irradiation. Simultaneously, the characteristics of apoptotic cells were not observed in the control samples incubated at 37°C in a humidified air containing 50 mL/L CO<sub>2</sub> (Figure 2A). However, the morphologic observation could not unambiguously give the quantity information about the proportion of cells in different physiological states, such as viable cells, apoptotic cells and secondary necrotic cells. So a further analysis was performed for the detection of functional characteristics such as exclusion of PI or plasma membrane integrity or such dyes as Annexin V-FITC.

#### Apoptosis assay

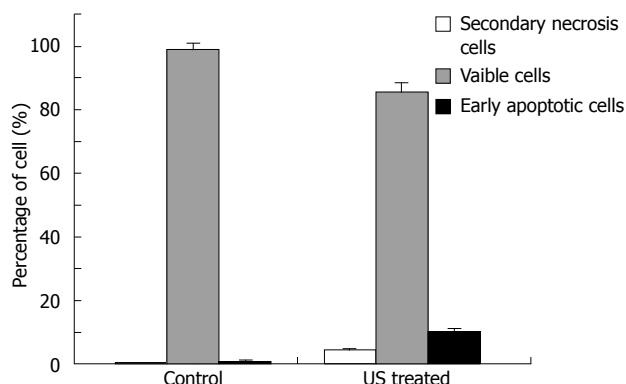

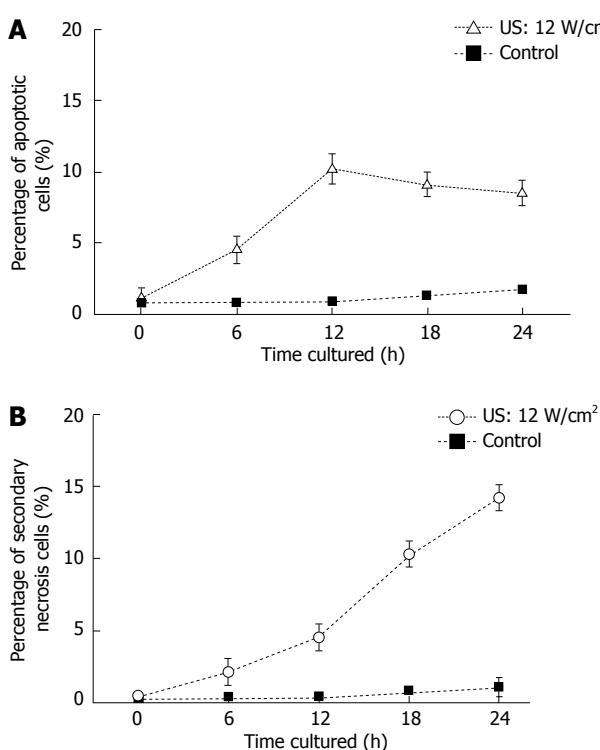

FCM with double staining of FITC-Annexin V/PI was performed to detect PS expression on the cell membrane as an end point of early apoptosis<sup>[16]</sup>, showing the exact percentage of cells in different styles, including viable cells (Annexin V/PI), early apoptotic cells (Annexin V<sup>+</sup>/PI), and secondary necrosis (Annexin V<sup>+</sup>/PI<sup>+</sup>).

The relationship between cell apoptosis and US intensity/culture time after US irradiation was investigated. The results show that the percentage of early apoptosis and secondary necrosis in the US irradiated cells increased with the increased US intensity (Figure 3). In the mean time, the percentage of viable cells decreased after US irradiation. The percentage of early apoptosis (incubated for 12 h after irradiation at the intensity of 12.0 W/cm<sup>2</sup> ( $I_{SPTA}$ ) for 10 min) increased more than 10% compared with the control cells cultured at 37°C in a humidified air containing 50 mL/L CO<sub>2</sub> (Figure 4), suggesting that apoptosis of cells can be induced by US.

US induced early apoptosis (Figure 5A) and secondary necrosis (Figure 5B) as a function of culture time after US irradiation, are determined by FCM with double staining of FITC-Annexin V/PI. Human SGC-7901 gastric carcinoma cells were irradiated by US at the intensity of 12.0 W/cm<sup>2</sup> for 10 min in this study. Apoptotic cells increased with the increased culture time after US irradiation and reached its maximum at 12 h. Then, the percentage of apoptotic cells gradually decreased. However, the secondary necrosis cells kept increasing. The percentage of viable cells kept decreasing after US irradiation.

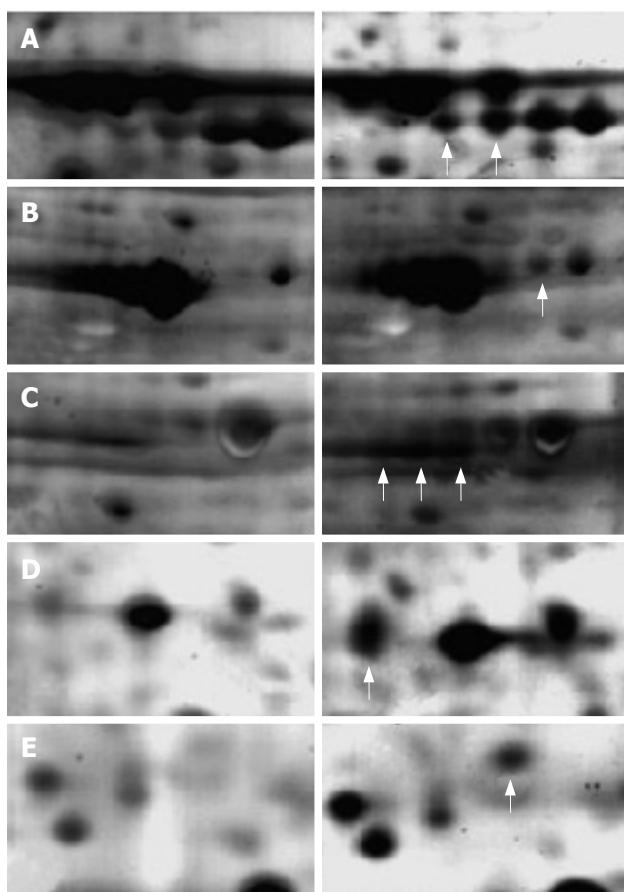

**Table 1** Identified information about proteins related to US-induced apoptosis

Swiss-Prot No.	Protein name	Theo. pI/Mw	Exp. pI/Mw	Protein function
P11021	GRP78, Bip	5.2/71.0	5.1/74.4	ER-stress associated
P38646	HSP70 (Heat shock 70 kDa protein)	5.9/73.7	5.8/72.1	Activation of pre-caspase 3
P10809	CH60 (60 kDa HSP)	5.7/61.2	5.5/58.9	Tumor suppressor and pro-apoptotic protein
P27797	Calreticulin precursor	4.3/48.2	4.5/52.8	ER-stress triggered apoptosis
P35232	Prohibitin	5.6/29.9	5.4/31.3	Inhibit the tumor cell growth

**Figure 4** Percentage of viable cells, early apoptotic cells and secondary necrosis cells in the control and US-irradiated SGC-7901 cells.**Figure 5** US-induced early apoptosis (A) and secondary necrosis (B) as a function of culture time after US irradiation, determined by FCM.

## 2DE analysis

A total of 1137 protein spots were successfully separated from the human gastric carcinoma SGC-7901 cells, 798 of which had a good match with the proteins in the 2D map of US irradiated cells. The unmatched protein spots amounted to 339. Some of the matched proteins had obviously different expressing characteristics (more than 2 times), indicating that they are obviously up-regulated or down-regulated after US irradiation. The protein expression between control cells (left) and US irradiated cells (right) is also shown in Figure 6.

**Figure 6** Magnified features of protein spots with different expressing characteristics after US irradiation. Arrow points to the differently expressed protein spots. A: Bip; B: HSP70; C: CH60; D: Calreticulin; E: Prohibitin.

or down-regulated after US irradiation. The protein expression between control cells (left) and US irradiated cells (right) is also shown in Figure 6.

## Identification of proteins by MALDI-TOF-MS

Proteins were identified by peptide mass fingerprinting based on MALDI-TOF-MS. The identified information about the proteins shown in Figure 6 is summarized in Table 1. The expression of these proteins increased more than 2 times after US irradiation. However, 4 proteins were unmatched although with good spectra. Further identification of them is needed via the tandem MS/MS.

## DISCUSSION

In the present study, we first demonstrated that low intensity US could induce early apoptosis and secondary

necrosis in gastric carcinoma cells. US irradiation could trigger apoptosis in both carcinoma and normal cells. However, a series of investigations showed that malignant cells are much more susceptible to US exposure and more prone to being killed than normal cells<sup>[17,18]</sup>. Lagneaux *et al*<sup>[4]</sup> also demonstrated that carcinoma cells are sensitive to ultrasonic treatment with a high percentage of apoptotic cells observed 5 h after treatment, whereas ultrasonic treatment has no effect on normal cells isolated from leukemic patients. This characteristic of carcinoma cells gives the chance to develop US irradiation as a new therapeutic approach to cancer treatment. Furthermore, during the US irradiation, focused US oriented by targeted multi-functional US contrast agents (UCA), could aim at the targeted region, decreasing side-effects on normal tissues around it. In addition, Gene regulation of target cells may be utilized in modifying cellular response to US treatment, thus increasing the sensitivity of diseased cells while making normal cells resistant to the side effects<sup>[19]</sup>. Therefore, US-induced apoptosis, as a novel cancer therapy, is of practical importance.

Low intensity US-induced apoptosis in gastric carcinoma cells may be an early event that increased with time in this study. The culture time for apoptotic cells to reach their maximum apoptosis is 12 h. Another study on US-induced apoptosis of human hepatocarcinoma cells performed in our laboratory (data not shown) showed that the culture time is 6 h after treatment. This discrepancy may be due to the different sensitivities of carcinoma cells to apoptosis-inducing factors. Similar results have also been reported by other investigators<sup>[5,20]</sup>, suggesting that the sensitivity of carcinoma cells to US irradiation is related to the time when apoptotic cells reach their maximum.

Apoptosis is always a special cellular response to stress stimuli, such as exposure to chemotherapeutic drugs, oxidative stress, free radicals, X-rays, ultraviolet radiation and shear stress. US irradiation belongs to the physical stress factor. Ashush *et al*<sup>[3]</sup> first reported that apoptosis is induced by high-intensity pulsed US in human leukemia cell lines, Lagneaux and Meulenaer demonstrated that low intensity US could also trigger apoptosis in human leukemia cell lines and low intensity US-induced apoptosis in tumor cells could probably offer a new approach to the elimination of cancer<sup>[4]</sup>. Feril *et al*<sup>[6]</sup> also pointed out that US without increasing its temperature and time can increase hyperthermia-induced apoptosis. It was reported that early apoptosis and necrosis induced by US are mainly caused by inertial cavitation<sup>[5-7]</sup>. During US cavitation, collapsing bubbles could create drastic conditions in an extremely short time, with a temperature of 2000 to 5000 K and a pressure up to 1800 atm inside it. Shear forces, jets and shock waves are also produced outside the bubbles. The inertial cavitation also induces free radical formation *via* the thermal dissociation of water into ·OH and ·H radicals. Any kind of these stress factors from US cavitation might cause apoptosis of tumor

cells. Apoptosis may be triggered as a response to cell membrane and DNA damage induced by inertial cavitation or *via* the action of residual hydrogen peroxide<sup>[21,22]</sup>. It is further proved when introduction of dissolved gases or UCA, Optison™ and YM454 to the system enhanced the US-induced cell killing *in vitro*<sup>[5,7]</sup>. Moreover, intracellular ROS generated from mitochondria rather than from extracellular ROS (directly produced by inertial cavitation in the medium), are involved in the regulation of apoptosis induced by US<sup>[23]</sup>. However, Lagneaux and Meulenaer claimed that US-induced apoptosis is probably related to the oxidative stress<sup>[4]</sup>.

To investigate the molecular mechanism of US-induced apoptosis in carcinoma cells, comparative proteomic analysis is a novel method that was introduced in this study. Because the biologic processes are directly executed by proteins that are dynamically modified and processed at multiple levels during or after sonication, the alteration in protein profile can reflect the status of differentiation and physiological conditions of cells. Protein functional analysis can also help reveal the molecular signal processes triggered by US irradiation in tumor cells or tissues.

Apoptosis is well-known to require the activation of caspases, a group of enzymes involved in apoptotic cascade events<sup>[24]</sup>. Apoptotic stimulus can activate apoptosis-related proteins to enter mitochondria, then induce mitochondria membrane to form pores to release molecules into cytosol, such as cytochrome C (CytC). The released molecules can activate caspase-9, which cleaves procaspase-3 to caspase-3, finally inducing apoptosis<sup>[25,26]</sup>. The activity of different caspases was not detected in this study, but some proteins, such as CH60, related to the activation of caspases were up-regulated in the cells after sonication. CH60 is regarded as a protective protein induced by the response process of mammalian cells under stress, which promotes apoptosis by helping maturation of pro-caspase-3<sup>[27,28]</sup>. Pro-caspase-3 is the key enzyme involved in the caspases-dependent apoptotic process, indicating that the US-induced apoptosis may be caspases-dependent. It is known that members of the heat shock protein (HSP) family function at multiple points in the apoptotic signal pathway. Sometimes, due to their cytoprotective role, they inhibit the apoptotic response by inhibiting the key steps in the apoptotic process. However, in other times, they serve as chaperones of a key signaling protein or directly promote apoptosis. Vykhodtseva reported that focused US sonication close to the thermal threshold exposures could induce apoptosis, suggesting that the mechanism leading to apoptosis is the production of HSPs<sup>[29]</sup>. In this study, CH60, HSP70 and Bip were found belonging to the HSP family. They participate in the apoptosis induced *via* different ways. Bip and calreticulin participate in the press-induced reactions on the endoplasmic reticulum (ER), both of them are pivotal molecules mediating ER-initiated apoptosis involved in ER stress. Prohibitin is an antiproliferative

protein and functions as a tumor suppressor. Commonly, it is involved in blocking DNA synthesis and negative regulation of cell proliferation. In US-induced apoptosis of tumor cells, the increased expression of prohibitin would help inhibit the growth of tumor cells.

In summary, low intensity US can induce apoptosis in human gastric carcinoma cells. The percentage of early apoptosis and secondary necrosis in the US-irradiated cells are increased with increased US intensity; Moreover, apoptotic cells increase with increased culture time after US irradiation and reach their maximum at about 12 h. Group of HSPs participates in the US-induced apoptosis. US-induced apoptosis is caspases-dependent, and ER stress-triggered apoptosis may also contribute to it. Moreover, experimental system can also be introduced into the research of bio-effects caused by other physical and chemical factors on tumor cells, which would be significant in investigating tumor cell apoptotic mechanism and cancer therapy.

## COMMENTS

### Background

Low intensity ultrasound (US) irradiation could trigger apoptosis in carcinoma cells, and therefore has distinct potential as a technique for cancer therapy. To investigate US-induced apoptosis in different carcinoma cells is significant to better understand its mechanism and develop a new therapeutic approach.

### Research frontiers

The present study demonstrated low intensity US-induced apoptosis in gastric carcinoma cells. Based on protein functional analysis, the molecular mechanism of US-induced apoptosis is suggested.

### Innovations and breakthroughs

Some previous studies have proved that US can induce apoptosis in human leukemia cells and solid carcinoma cells. The present study first demonstrated that low intensity US could induce early apoptosis and secondary necrosis in gastric carcinoma cells. The effects of US intensity and culture time after treatment on US-induced apoptosis are revealed. The potential molecular mechanism of US-induced apoptosis is suggested via comparative proteomic analysis.

### Applications

The present study would help to make better analysis of US-induced apoptosis in gastric carcinoma cells, and promote new therapeutic schemes. Further investigation of its mechanism would supply more useful information about US-induced apoptosis in solid carcinoma cells.

### Peer review

The authors demonstrated that low intensity US could induce early apoptosis and secondary necrosis in gastric cell line SGC-7901. As suggested by the authors, low intensity US irradiation may help to develop new cancer therapies. Therefore, this study may provide important information about gastric cancer.

Published online: August 21, 2008

**RESULTS:** Immunohistochemical analysis revealed that BAMBI expression was observed in 148 (80.8%), and strong BAMBI expression was observed in 46% of the CRCs. Strong BAMBI expression was positively correlated with histological type, depth of invasion, lymph node metastases, and tumor node metastasis (TNM) stage ( $P < 0.05$ ). Clear associations were found between BAMBI and  $\beta$ -catenin ( $P = 0.035$ ) and p53 ( $P = 0.049$ ) expression. In curatively resected CRC, 5-year recurrence-free survival was 51.9% ( $P = 0.037$ ) for strong BAMBI expression compared to 79.8% for weak BAMBI expression. In the Cox's multivariate analysis, lymph node metastases (RR 6.685;  $P < 0.001$ ) and depth of invasion (RR 14.0;  $P = 0.013$ ) were significant indicators for recurrence, and strong BAMBI expression (RR 2.26;  $P = 0.057$ ) tended to be significant.

**CONCLUSION:** BAMBI was linked to a potentially aggressive tumor phenotype and predicted tumor recurrence and cancer-related death in CRC. BAMBI expression might be applicable in the routine clinical setting of CRC.

Prognostic significance of BMP and activin membrane-bound inhibitor in colorectal cancer. *World J Gastroenterol* 2008; 14(31): 4880-4888 Available from: URL: <http://www.wjnet.com/1007-9327/14/4880.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.4880>

## INTRODUCTION

Activation of the Wnt/ $\beta$ -catenin pathway is a critical process in the malignant transformation of colonic

## Abstract

**AIM:** To investigate the clinical significance of BMP and activin membrane-bound inhibitor (BAMBI) which is a pseudoreceptor of transforming growth factor-beta (TGF- $\beta$ ) type I receptors and acts as a negative regulator of TGF- $\beta$  signaling and expression aberrantly elevated in colorectal cancers (CRCs). We studied BAMBI expression in CRCs.

**METHODS:** We studied BAMBI expression in 183 surgically resected CRCs by immunochemical and immunoblotting analyses using a generated monoclonal anti-BAMBI antibody. Commercially available anti- $\beta$ -catenin and anti-p53 antibodies were also applied for immunochemical analyses as a comparison control.

epithelium<sup>[1-5]</sup>. Wnt signaling promotes the stabilization and accumulation of β-catenin, which in turn interacts with the T cell factor/lymphoid enhancer factor (TCF/LEF) family of transcription factors and activates the transcription of downstream genes such as *c-Myc*, *cyclin D1*, and *Axin2*<sup>[6-10]</sup>. Constitutive activation of β-catenin-TCF-mediated transcription is believed to be a critical step in the tumorigenesis of various cancers<sup>[11-13]</sup>. Conversely, the transforming growth factor-beta (TGF-β) pathway participates in tumor suppressor activities such as growth inhibition and apoptosis, and this negative regulation is lost during colorectal carcinogenesis, with mutations in the type II receptor, SMAD2, and SMAD4<sup>[14-17]</sup>. TGF-β also mediates tumor-promoting effects such as growth stimulation, as well as increases in motility, invasion, and metastasis through either differential effects on tumor and stromal cells or a fundamental alteration in the TGF-β responsiveness of the tumor cells themselves<sup>[18-20]</sup>.

The TGF-β and Wnt/β-catenin signaling pathways cross talk to regulate tumor biology<sup>[20]</sup>. Axin, a negative regulator of the Wnt pathway, activates TGF-β signaling through Smad3 binding<sup>[21]</sup>, while TCF/LEF interacts directly with Smad3 to regulate the expression of their target genes<sup>[22]</sup>. It is also known that β-catenin and TCF/LEF both interact directly with Smad4 to regulate target genes during development<sup>[23]</sup>.

BMP and activin membrane-bound inhibitor (BAMBI) is a transmembrane glycoprotein induced by BMP signaling<sup>[24]</sup> that is related to TGF-β-type I receptors, but lacks an intracellular kinase domain<sup>[25]</sup>. BAMBI inhibits TGF-β signaling by forming a heterodimer with TGF-β-type II receptors<sup>[25]</sup>. Previously, we found that both Wnt/β-catenin signaling and TGF-β signaling activate transcription of *BAMBI* and that *BAMBI* expression is aberrantly elevated in most colorectal cancers (CRCs)<sup>[26]</sup>. To analyze the clinical significance of BAMBI, we studied its expression in CRC using immunohistochemical staining. We show that BAMBI overexpression is correlated with aggressive tumor phenotypes and predicts tumor recurrence and cancer-related death in CRC. BAMBI may be usable as a target for diagnostic and antibody medicine.

## MATERIALS AND METHODS

### Materials

Colorectal tumor tissues were obtained from 183 consecutive patients who underwent to surgical resection between January 1995 and July 2006 at Gunma University Hospital. All of the patients underwent to radical colorectal resection intended to obtain clear pathological margins and regional lymphadenectomy, even in Stage IV. The clinicopathological features of the patients are shown in Table 1. The subjects were 115 males and 68 females with a mean age of 66 years (range 27-95). Of these, 113 were colon and 70 were rectal cancers. The tumor tissues were staged pathologically according to the American Joint Committee on Cancer

Tumor-Node-Metastasis (TNM) classification. The tumors were categorized according to the World Health Organization (WHO) classification as well differentiated (G1; 51 cases, 27.9%), moderate (G2; 116 cases, 63.4%), and poor (G3; 16 cases, 8.7%).

Anti-BAMBI antibodies were generated by immunizing mice with a fragment comprising either amino acids 45-147 or 177-241. Known methods were used to prepare the anti-BAMBI antibody, collect antibody-producing cells, obtain cell fusion, select and clone hybridomas, collect and purify monoclonal antibodies<sup>[26]</sup>. Twenty-six mouse monoclonal anti-BAMBI antibodies were generated at the first screening. To check the utility of immunostaining for paraffin sections, these monoclonal antibodies were further screened using various immunochemistry methods, using formalin-fixed and paraffin-embedded colon cancers. Finally, one monoclonal antibody was selected and its specificity was confirmed in an absorbed test using excess GST-BAMBI protein and in the immunoblotting analysis<sup>[26]</sup>.

### Methods

Frozen samples (25 CRCs and 5 tubular adenomas were picked at random) kept at -80°C were thawed, cut into small pieces, and homogenized in SDS lysis buffer (Sigma-Aldrich, St. Louis, MO). The homogenate was then centrifuged at 10 000 g for 15 min at 4°C, and the protein concentration of the supernatant was estimated using the BCA protein assay kit (Pierce, Rockford, IL).

**Figure 1** Immunoblotting analysis using anti-BAMBI monoclonal antibody detected BAMBI as a 30 kDa protein in all of the CRC and tubular adenoma specimens. No. 1 to 3 and 6: Strong expression; No. 4, 5, 7 and 8: Weak expression. The levels of BAMBI expression in CRCs were higher than those in tubular adenomas (lanes No. 9 to 12). The quantitative analysis using densitometry of the bands of BAMBI protein revealed that the band intensity in the weak and strong expression groups in CRCs were about two and three times higher than that in tubular adenomas, respectively.

Twenty micrograms of protein from each supernatant was electrophoresed on 7.5% SDS polyacrylamide gel under reducing conditions and electrotransferred onto a polyvinylidene difluoride membrane (Millipore, Bedford, MA). After treatment with blocking solution, the membrane was incubated with anti-BAMBI antibody (dilution 1:1000) overnight at 4°C. The membrane was then treated with goat anti-mouse IgG conjugated with horseradish peroxidase (Dako, Carpinteria, CA, dilution 1:200 000) for 1 h at room temperature, and the enhanced chemiluminescence kit (ECL Advance detection kit, Amersham, Piscataway, NJ) was used for development according to the manufacturer's instructions. The luminescence image was captured and digitized using Lumi Analyst 3.0v (Boehringer Mannheim GmbH, Germany), and the integrated densities of each band were quantified using densitometry software (ImageJ 1.37v, National Institutes of Health, Bethesda, MD). To examine the equality of protein loading, the total amount of protein loaded in each lane was examined by staining with Coomassie blue.

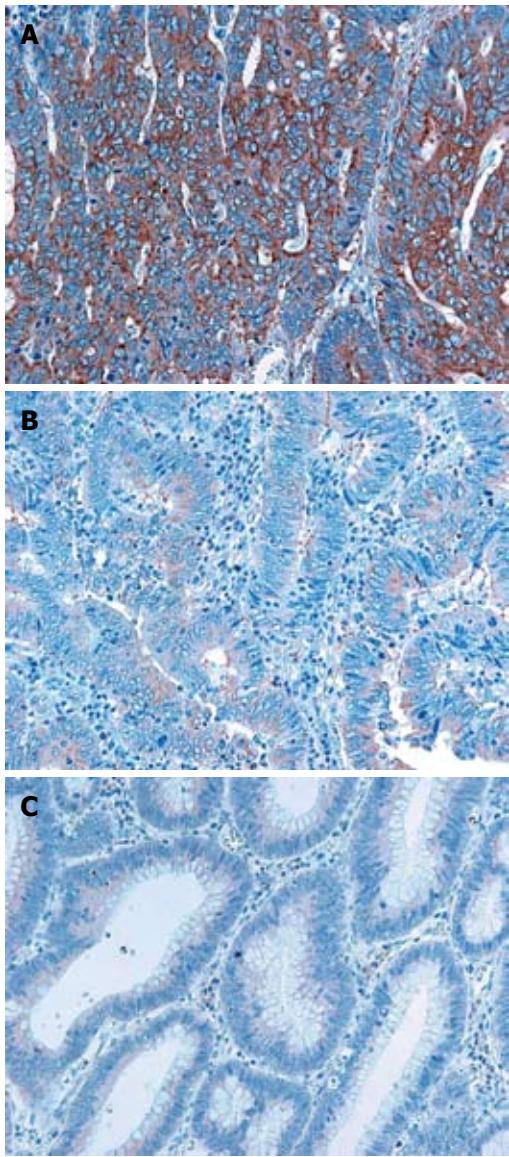

For the immunohistochemical study, 3 μm thick sections were cut from formalin-fixed, paraffin-embedded tissue blocks containing representative tumor histology. The sections were de-waxed in xylene, rehydrated with graded ethanol, and subjected to an antigen retrieval step. For antigen retrieval, the slides for β-catenin and p53 were placed in 0.01 mol/L citrate buffer, 20% ZnSO<sub>4</sub> solution, and heated in a microwave processor (Energy Beam Science, East Granby, CT) at

95°C for 20 min. They were then cooled and rinsed in 0.01 mol/L phosphate-buffered saline (PBS), pH 7.4. The antigen retrieval was not performed on the immunohistochemistry for BAMBI. The slides were then reduced with nonspecific antibody binding by incubating the sections with 10% normal serum in PBS for 30 min at room temperature. After decanting the excess serum, the sections were incubated overnight at 4°C with each monoclonal antibody for BAMBI (1:2000 dilution), β-catenin (1:1600 dilution), and p53 (1:50 dilution) in humidified chambers. After washing thoroughly with PBS, the sections were set in a Ventana Nexus Automated Stainer (Ventana Medical Systems, Tucson, AZ) for immunostaining. The automated protocol was performed according to the manufacturer's instructions, which were based on the labeled streptavidin–biotin method and used the I-VIEW DAB universal kit (Ventana Medical Systems); the kit included a universal biotinylated IgG secondary antibody (anti-mouse), avidin horseradish peroxidase, DAB, 0.03% H<sub>2</sub>O<sub>2</sub>, and 0.5% CuSO<sub>4</sub>. After immunostaining, the sections were lightly counterstained with hematoxylin, and then mounted in a carousel inside the staining module and run to completion. To standardize and confirm the immunohistochemical evaluation of BAMBI, 26 samples of colon carcinoma with tubular adenoma were collected and were tentatively subjected to immunohistochemistry using paraffin sections. Immunohistochemical staining intensity was categorized blindly by two pathologists (T.N, S.S.). Most tubular adenomas showed weak immunoreactivity compared to the cancer component.

Therefore, diffuse BAMBI immunoreactivity, which was observed in the cytoplasm and cell membrane, but not in the nucleus, was evaluated as weak expression if the positivity was similar to that of tubular adenomas. If the BAMBI immunoreactivity was far stronger than that of tubular adenomas, it was evaluated as strong expression (Figures 1 and 2). No BAMBI immunoreactivity was evaluated as negative.

The intensity of nuclear β-catenin immunostaining was graded semiquantitatively into four categories: negative, weakly positive, moderately positive, and strongly positive<sup>[27]</sup>. This evaluation was grouped into two categories: low expression (negative and weakly positive) and high expression (moderately to strongly positive). To evaluate the p53 immunostaining, the nuclear immunoreactivity for p53 was counted in five random tumor areas at high magnification ( $\times 400$ ), and the average percentage of these positive cells was calculated. The p53 immunoreactivity was evaluated as negative or positive expression if the percentage of nuclear positivity was less than or more than 70%, respectively<sup>[28]</sup>.

Statistical analysis was performed using SPSS 11.5 software (SPSS Japan, Tokyo, Japan). The Mann-Whitney U-test, Kruskal-Wallis test, and Spearman's coefficient of rank correlation were used to examine the correlation of BAMBI with other protein and pathological factors. Recurrence-free and overall survival curves were generated using the Kaplan-Meier method,

**Figure 2** Examples of the immunostaining of BAMBI at strong expression (A), weak expression (B) levels, and expression of adenoma (C) ( $\times 200$ ). The immunohistochemical expression level correctly reflected the expression level of BAMBI protein in CRC tissues.

and the log-rank test was used to compare the curves. Deaths without recurrence were included as censored observations. The relative risk and confidence limits were estimated for each variable using the Cox univariate model, using the most suitable prognostic category as the referent group. A multivariate Cox proportional hazard model was also developed using stepwise regression (forward selection) with predictive variables. The limits for entry and removal were both  $P < 0.5$ . Statistical significance was set at  $P < 0.05$ .

## RESULTS

### Immunoblotting analysis

Immunoblotting analysis using anti-BAMBI monoclonal antibody detected BAMBI as a 30-kDa protein in all of the CRC and tubular adenoma specimens. The levels of BAMBI expression in CRCs were higher than those

in tubular adenomas (Figure 1). By contrast, no specific band was detected in normal colonic epithelium (data not shown). The quantitative analysis of the bands revealed that the band intensity was divided into two groups: strong expression and weak expression was three and two times higher than that of tubular adenoma, respectively (Figure 1). Furthermore, CRC tissues with strong expression in immunoblotting were strongly positive for BAMBI immunohistochemistry, whereas other CRC tissues with weak expression revealed weak immunoreactivity to BAMBI (Figure 2). These results indicate that the immunohistochemical expression level correctly reflected the level of BAMBI protein expressed in CRC tissues.

Immunohistochemically, no BAMBI expression was detected in normal colonic epithelium. In contrast, diffuse BAMBI immunoreactivity was observed in the cytoplasm and cell membrane of tubular adenoma and CRC cells (Figure 3). We observed BAMBI immunoreactivity in 148 (80.8%) of 183 CRC tissues, and weak and strong BAMBI expression was observed in 80 (54.1%) and 68 (45.9%) CRCs, respectively.

Nuclear  $\beta$ -catenin immunostaining was not observed in normal colonic mucosa. Nuclear  $\beta$ -catenin immunoreactivity was observed in 154 (84.1%) of 183 CRCs. Nuclear accumulation of p53 was observed in 74 (40.4%) of 183 CRCs (data not shown).

### Relationship between BAMBI expression and clinicopathological factors

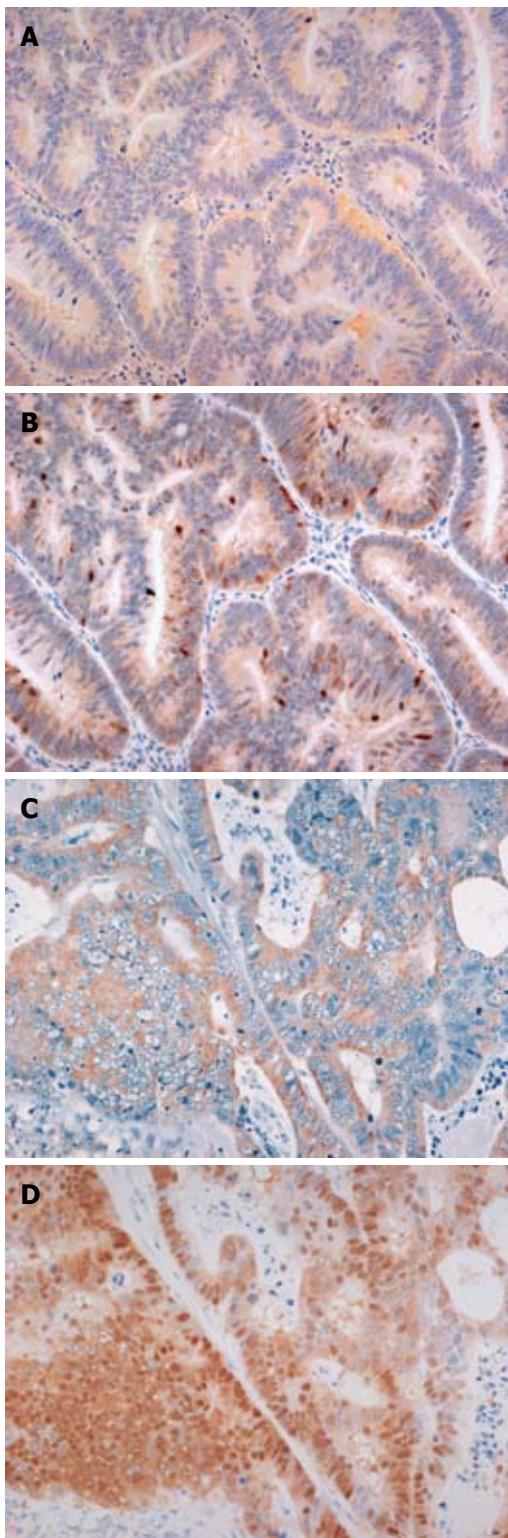

Strong immunohistochemical expression of BAMBI was positively correlated with histological type ( $P = 0.023$ ), depth of invasion ( $P = 0.021$ ), the presence or absence of lymph node metastases ( $P = 0.035$ ), and TNM staging ( $P < 0.001$ ), whereas no correlations were found with gender, age, location, or tumor size (data not shown).

### Correlation between BAMBI and $\beta$ -catenin/p53 expression

We evaluated the correlation of immunohistochemical BAMBI expression with immunohistochemical  $\beta$ -catenin and p53 expression. Strong expression of BAMBI was significantly associated with  $\beta$ -catenin ( $P = 0.035$ ) and p53 ( $P = 0.049$ ) expression (Table 2).

### Recurrence-free and overall survival according to BAMBI expression

The Stage IV patients who underwent to macroscopic resection of metastasis with no residual disease were excluded from the recurrence-free and overall survival groups and multivariate analysis. The patients who died from non-cancer-related causes were excluded from the recurrence-free survival and overall survival groups. In all, 157 of 183 patients were analyzed with a mean follow-up period of 33.7 mo (range, 2-137). In the background analysis, histological type ( $P = 0.043$ ) and TNM staging ( $P = 0.035$ ) were significant in strong BAMBI expression compared to weak BAMBI expression. The tumor depth ( $P = 0.054$ ) tended to be

**Figure 3** BAMBI and  $\beta$ -catenin expression in adenoma and cancer ( $\times 200$ ). Adjacent sections of an adenoma showing weak BAMBI expression in the cytoplasm and cell membrane (A) and weak nuclear localization of  $\beta$ -catenin (B); adjacent sections of a tumor showing strong BAMBI expression in the cytoplasm and cell membrane (C) and strong nuclear localization of  $\beta$ -catenin (D).

significant in strong BAMBI expression (Table 3). The cancer recurred in 30 patients, and 20 patients died of cancer-related causes.

No significant differences were observed in the recurrence-free and overall survival at each stage

according to the BAMBI expression level. However, the 5-year recurrence-free survival rate differed significantly ( $P = 0.037$ ); it was 51.9% with strong BAMBI expression compared to 79.8% for weak BAMBI expression (Figure 4A). The 5-year overall survival rate was 61.0% for strong BAMBI expression and 75.0% for weak BAMBI expression ( $P = 0.495$ ). No significant differences were detected in recurrence-free survival according to  $\beta$ -catenin (low vs high: 77.2% vs 65.9%,  $P = 0.109$ ) and p53 (negative vs positive: 75.8% vs 61.1%,  $P = 0.109$ ).

**Figure 4** **A:** The 5-year recurrence-free survival rate differed significantly ( $P = 0.037$ ) and was 51.9% for strong BAMBI expression compared to 79.8% for weak BAMBI expression; **B:** The impact of the coexpression of BAMBI and  $\beta$ -catenin on the recurrence-free survival with high  $\beta$ -catenin expression, the 5-year recurrence-free survival was 46.9% for strong BAMBI expression compared to 80.8% for weak BAMBI expression ( $P = 0.035$ ); **C:** The impact of the coexpression of BAMBI and p53 on the recurrence-free survival with positive p53 expression, the 5-year recurrence-free survival rate was 43.4% for strong BAMBI expression compared to 78.2% for weak BAMBI expression ( $P = 0.049$ ).

0.417) expression.

Furthermore, we evaluated the impact of the coexpression of BAMBI,  $\beta$ -catenin, and p53 on recurrence-free survival. With high  $\beta$ -catenin expression, the 5-year recurrence-free survival was 46.9% for strong BAMBI expression compared to 80.8% for

weak BAMBI expression ( $P = 0.035$ ; Figure 4B). Weak  $\beta$ -catenin expression did not affect the survival rate according to the BAMBI expression level (weak vs strong: 75.0% vs 79.2%,  $P = 0.6294$ ). With positive p53 expression, the 5-year recurrence-free survival rate was 43.4% for the strong BAMBI expression group compared to 78.2% for the weak BAMBI expression group ( $P = 0.049$ ; Figure 4C). With negative p53 expression, the 5-year recurrence-free survival rate was 62.4% with strong BAMBI expression versus 80.8% for weak BAMBI expression ( $P = 0.582$ ).

#### Cox's proportional hazards regression models

The relative risk and confidence limits for recurrence-free survival were estimated for each variable using the Cox univariate model. TNM staging (relative risk 4.63; 95% CI 2.84-7.56;  $P < 0.001$ ), presence or absence of lymph node metastases (relative risk 8.937; 95% CI 3.10-25.77;  $P < 0.001$ ), depth of invasion (relative risk 14.77; 95% CI 2.01-108.55;  $P = 0.008$ ), and strong BAMBI expression (relative risk 2.109; 95% CI 1.029-4.323;  $P = 0.041$ ) were significant. In the multivariate Cox proportional hazard model, TNM stage (relative risk 4.35; 95% CI 2.65-7.14;  $P < 0.001$ ) was the only significant indicator for recurrence. According to Spearman's coefficient of rank correlation, BAMBI expression was significantly correlated with TNM staging ( $P = 0.038$ ) and the nuclear expression of  $\beta$ -catenin ( $P = 0.01$ ). In the model excluding TNM stage and the nuclear expression of  $\beta$ -catenin, lymph node metastases (relative risk 6.685; 95% CI 2.24-19.93;  $P < 0.001$ ), depth of invasion (relative risk 14.01; 95% CI 1.74-112.69;  $P = 0.013$ ), and strong BAMBI expression (relative risk 2.26; 95% CI 0.95-5.38;  $P = 0.057$ ) were significant indicators of recurrence (Table 4).

## DISCUSSION

BAMBI was expressed in 80% of CRC tumors, and strong BAMBI expression was observed in 46% of CRC tumors. The region with BAMBI expression matched the region of  $\beta$ -catenin expression, and the expression of BAMBI and  $\beta$ -catenin were correlated, consistent with the fact that  $\beta$ -catenin is responsible for the aberrant expression of BAMBI<sup>[26]</sup>. In addition, the association of BAMBI expression and p53 expression is consistent with a previous report that p53 induces Siah-1, which mediates  $\beta$ -catenin degradation<sup>[29]</sup>. The overexpression of BAMBI inhibits the response of tumor cells to TGF- $\beta$  signaling, and interferes with TGF- $\beta$ -mediated growth arrest *in vitro*<sup>[25,26]</sup>. These results indicate that BAMBI expression is one of the critical early genetic events in CRC tumorigenesis.

Strong BAMBI expression was more frequently associated with deep tumor penetration, lymph node metastases, and advanced TNM stage. Patients with strong BAMBI expression had shorter recurrence-free and overall survival, and strong BAMBI expression was an independent factor predicting a lower recurrence-free survival in the multivariate analysis. The nuclear

**Table 4** Relative risks of prognosis according to proportional-hazards regression models

accumulation of β-catenin contributes to the transactivation of target genes, which encode regulators of differentiation and effectors supporting invasion and metastasis (CD44, laminin-52, matrix metalloproteinase MMP-7 and MT1-MMP) and angiogenesis (vascular endothelial growth factor), among others<sup>[5]</sup>. In fact, the overexpression of nuclear β-catenin is reported to be an independent predictor of short patient survival time<sup>[30-33]</sup>. Inconsistent with these reports, we showed that nuclear β-catenin accumulation alone does not affect survival and is not a prognostic factor in the univariate and multivariate analyses. However, we found that patients with both strong BAMBI expression and the overexpression of β-catenin have poorer survival compared to those without β-catenin expression. Smad activation or expression is lost in approximately 10% of CRC occurrences, and these patients have a poor prognosis because of its association with advanced disease and the presence of lymph node metastases at diagnosis<sup>[34]</sup>. BAMBI expression allows tumor cells to escape from TGF-β signaling and activate oncogenic processes such as growth stimulation, increases in motility, and invasion. Therefore, BAMBI plays an important role in the invasiveness and metastatic potential of colon cancers through cross-talk with the Wnt and TGF-β signaling pathways.

Although the available data on the correlation of p53 status and the prognosis of colorectal cancers are controversial<sup>[35]</sup>, we found that p53 expression status did not influence the recurrence-free and overall survival and was not a prognostic factor in the univariate and multivariate analyses. Nevertheless, patients with both strong BAMBI expression and p53 overexpression had lower survival compared to those without p53 expression. We speculate that target genes induced by BAMBI overexpression may complement or cooperate with those induced by p53 inactivation and thereby contribute to poorer survival.

Although CRC prognosis is stage and grade dependent, cancers with similar clinicopathological features may have major differences in outcome. A large proportion of patients with Stage II disease and some with Stage III disease can be cured by surgery alone and do not derive any benefit from adjuvant therapy<sup>[36]</sup>. Therefore, the identification of robust molecular prognostic markers to supplement conventional pathological staging systems is highly desirable. Several molecular markers are promising prognostic predictors for the outcome in CRC, including deleted in colorectal

cancer (DCC), microsatellite instability (MSI), and loss of heterozygosity at 18q<sup>[37,38]</sup>. CRC patients with strong BAMBI expression had more aggressive disease and their recurrence-free survival was markedly shorter. In contrast, patients with weak BAMBI expression had less aggressive disease and significantly longer recurrence-free survival. Strong BAMBI expression was tending to be an independent molecular predictor for survival secondary to lymph node metastasis and depth of tumor in the Cox hazard model. Therefore, strong BAMBI expression might be applicable in clinical practice to predict recurrence in addition to lymph node metastasis and depth of tumor.

In clinical scenarios, targeting the TGF-β signaling pathway for chemoprevention and the treatment of human cancers should decrease or abrogate TGF-β signaling, particularly for advanced or metastatic disease<sup>[20]</sup>. Given that the TGF-β signaling pathway has an important role in tumor-induced immunosuppression<sup>[39]</sup>, inhibitors of this pathway may be used to improve natural immunosurveillance of tumor cells or to enhance the effectiveness of active or passive immunotherapy strategies. Our findings suggest that the development of a new active monoclonal anti-BAMBI antibody may offer a great improvement in survival of CRC patients and might also serve as a diagnostic tool for CRC prognosis.

We thank Hamada K and Kawate S for providing valuable suggestions and assistance; and Hikino T, Hara F, and Saito M for their excellent technical assistance.

## COMMENTS

### Background

In generally, BMP and activin membrane-bound inhibitor (BAMBI) expression is aberrantly elevated in most colorectal cancers (CRCs). However, few studies are reported on BAMBI expression in colorectal tissue. To analyze the clinical significance of BAMBI, authors studied its expression in CRC using immunohistochemical staining. They show that BAMBI overexpression is correlated with aggressive tumor phenotypes and predicts tumor recurrence and cancer-related death in CRC. This study was to map BAMBI expression in colorectal tissue and analyze the relationship between BAMBI expression and CRC prognosis.

### Research frontiers

To analyze the clinical significance of BAMBI, authors studied its expression in CRC using immunohistochemical staining. They show that BAMBI overexpression is correlated with aggressive tumor phenotypes and predicts tumor recurrence and cancer-related death in CRC. BAMBI may be usable as a

target for diagnostic and antibody medicine.

### Innovations and breakthroughs

The results of this study show that BAMBI expression plays a role in the pathogenesis of colorectal cancer.

### Applications

The expression level of BAMBI plays an important role in the pathogenesis of colorectal cancer. The development of a new active monoclonal anti-BAMBI antibody may offer a great improvement in survival of CRC patients and might also serve as a diagnostic tool for CRC prognosis.

### Peer review

This is an extremely well written and researched paper. It discovers yet another marker of prognosis for CRC.

**Published online:** August 21, 2008

**CONCLUSION:** IBS subtypes showed different profiles in body awareness, somatic and psychological symptoms and in biochemical variables. D-IBS differed compared to the other groups by lowered body awareness, less psychological symptoms and a higher sense of coherence and elevated C-peptide values. C-IBS and A-IBS subtypes suffered more from depression and anxiety, associated with a lower quality of life. These differences may be important and will be taken into account in our treatment of these patients.

Irritable bowel syndrome subtypes differ in body awareness, psychological symptoms and biochemical stress markers. *World J Gastroenterol* 2008; 14(31): 4889-4896 Available from: URL: <http://www.wjgnet.com/1007-9327/14/4889.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.4889>

## Abstract

**AIM:** To elucidate the differences in somatic, psychological and biochemical pattern between the subtypes of irritable bowel syndrome (IBS).

**METHODS:** Eighty IBS patients, 30 diarrhoea predominant (D-IBS), 16 constipation predominant (C-IBS) and 34 alternating IBS (A-IBS) underwent physiotherapeutic examinations for dysfunctions in body movements and awareness and were compared to an apparently healthy control group (AHC). All groups answered questionnaires for gastrointestinal and psychological symptoms. Biochemical variables were analysed in blood.

**RESULTS:** The D-IBS group showed less body awareness, less psychological symptoms, a more normal sense of coherence and psychosocial rating as well as higher C-peptide values. C-IBS had a higher degree of body dysfunction and psychological symptoms, as well as the lowest sense of coherence compared to controls and D-IBS. They also demonstrated the most elevated prolactin levels. A-IBS had the lowest degree of body disturbance, deteriorated quality of life and affected biochemical pattern. All subtypes had higher pain scores compared to controls. In addition they all had significantly increased triglycerides and elevated morning cortisol levels, however, without statistical significance compared with the controls.

## INTRODUCTION

Irritable bowel syndrome (IBS) is considered to be the most common of all gastrointestinal dysfunctions<sup>[1-4]</sup>. Patients with IBS are suffering from a variety of gastrointestinal complaints, as well as associated symptoms like headache and dysuria. Furthermore, there is also a strong connection to fibromyalgia, chronic fatigue syndrome, anxiety, and depression<sup>[5,6]</sup>.

The understanding of IBS and especially the interaction between the central and enteric nervous systems has grown considerably over the last years<sup>[7]</sup>. There are several studies demonstrating abnormalities in the autonomic nervous system<sup>[8,9]</sup>, whereas the expression of different biochemical parameters has been studied with somewhat diverging results<sup>[10-14]</sup>.

The division of IBS into different subgroups is based on the fact that these patients behave in dissimilar ways. According to the Rome II criteria, building on stool and defecation patterns, IBS can be divided into diarrhoea

predominant (D-IBS), constipation predominant (C-IBS) and alternating (A-IBS) subtypes<sup>[15,16]</sup>. Although, lately questioned, the Rome II criteria are widely used in clinical practice<sup>[17]</sup>.

When comparing the various subtypes of IBS, Whitehead *et al*<sup>[18]</sup> did not find any disparity in colonic motility and psychological testing. In contrast, other authors have found differences in gender, abdominal discomfort/pain and psychological comorbidity between the IBS subtypes<sup>[19-22]</sup>. Disparities in endocrine factors between the subtypes of IBS have not been extensively studied. However, Elsenbruch *et al*<sup>[23]</sup> found a significant increase in postprandial saliva cortisol in D-IBS patients, not evident in C-IBS patients and controls. Jonsson and Theorell<sup>[24]</sup> found that plasma cortisol correlated negatively with diarrhoea symptoms and lower prolactin values were seen in patients with functional dyspepsia.

In earlier studies, we have shown that IBS could be associated with deviated tension in the body<sup>[13,25]</sup>. A physiotherapeutic approach to adjust and reduce pathological tension in the body is by the use of Body Awareness Therapy (BAT). This method is devoted to take care of, and improve, the patient's ability to become aware of his or her own capability by the use of self recruited resources to recapture a normal balance in the body<sup>[26-30]</sup>. We found that 12 wk of treatment with BAT gave symptom relief of both gastrointestinal and psychological symptoms<sup>[25]</sup>. However, patients with C-IBS were more relieved than the D-IBS and alternating types of IBS. In a second trial we treated the patients for 24 wk and satisfying effects were obtained for the entire group of IBS patients<sup>[13]</sup>.

The aim of the present study was to elucidate the differences in somatic and psychological symptoms, as well as biochemical stress markers in the IBS subtypes. The hypothesis was that these subtypes present with dissimilar symptomatic expressions.

## MATERIALS AND METHODS

### Study population

All patients with IBS as diagnosed by gastroenterologists, GI surgeons or GPs referred for Body Awareness Therapy at the Unit for Functional Gastroenterology, participated in the study. Patients with an acute psychiatric disease and patients not understanding the Swedish language were excluded from the study.

IBS patients, 73 women and 7 men (age, 21-65 years), with a BMI  $23.3 \pm 3.7$  participated in the study. According to the Rome II criteria patients were divided into 3 groups: D-IBS ( $n = 30$ , 24 women and 6 men), C-IBS ( $n = 16$ , 15 women and 1 man) and A-IBS suffering from combined symptoms ( $n = 34$ , all women). Fifty-six IBS patients had suffered from their gastrointestinal symptoms for more than 5 years (for D-IBS 67%, for C-IBS 88% and for A-IBS 65%). There were no differences in BMI between the subtypes.

A healthy control group consisting of 18 women and 3 men (age, 21-61 years) had a BMI of  $22.3 \pm 2.2$ . They

were free of gastrointestinal symptoms and without ongoing pharmacological treatment.

### Study design

The groups of IBS test patients and the AHC group underwent complete physiotherapeutic examinations in accordance to the Body Awareness Scale (BAS). They also filled in the questionnaires GIS, SCL90, SOC, PRS, and pain drawing. Blood samples were taken from an antecubital vein. The ethics committee of the University of Göteborg approved the study. All subjects gave their written consent before acceptance of inclusion into the study.

### Body examinations

BAS test is based on one hand observations by the physiotherapist of dysfunctions in defined items of basic movements (BASobs) and was carried out during video recording. In addition, standardized questions in order to measure the patients' own opinion concerning their body awareness (BASself) was performed. The variables were ranging from 0-6 where a higher score represented more symptoms<sup>[31,32]</sup>.

### Questionnaires

A modified form of Gastro Intestinal Symptom questionnaire (GIS) was used<sup>[33]</sup>. This survey evaluates 35 general gastrointestinal symptoms. A total score and scoring of specified symptoms were used. The test utilizes a seven-graded scale (0-6). A higher score means increased gastrointestinal complaints.

The Symptom Checking List questionnaire (SCL90) is a self-rating scale evaluating symptomatic behaviour of psychological state using questions related to everyday life<sup>[34]</sup>. The questionnaire includes 90 questions. The answers score in a five-graded scale (0-4) and allow subdivision into different items. A higher score reflected more symptoms.

The Sense of Coherence Scale (SOC) measures the degree to which individuals find the world around them comprehensible and manageable and thus represents a measurement of coping skills<sup>[35]</sup>. The questionnaire includes 29 questions. The answers score in a seven-graded scale (0-6) and allow subdivision into different items. A high SOC score is linked to successful coping with factors that induce stress and is consequently reflecting a higher health level/quality of life.

Psychosocial rating scale (PRS) (slightly modified from Headley Court psychosocial rating scale) has 33 items and score from 0-4 ranging from 'very severe problems' to 'no problems'<sup>[36]</sup>.

The distribution of pain was visualized on a pain-map, figuring the human body with a front and backside. When calculating the results, the body was divided into 45 sections<sup>[37]</sup>. Points were given for every section where pain was marked. The points were summed up to a score.

### Biochemistry in blood

Venous blood samples were taken under fasting condi-

Results from BASobs and BASself examination score from AHC group and D-IBS, C-IBS and A-IBS patients. The results are shown in total and as items categorised. The higher score, the more symptoms. <sup>a</sup>P < 0.05, <sup>b</sup>P < 0.01, <sup>c</sup>P < 0.001 vs AHC; <sup>d</sup>P < 0.05, <sup>e</sup>P < 0.01, <sup>f</sup>P < 0.001 vs D-IBS; <sup>g</sup>P < 0.05, <sup>h</sup>P < 0.01, C-IBS vs A-IBS. M: Mean; Md: Median; IQR: Inter quartile range.

tions from an antecubital vein in the morning for analysis of C-peptide, triglycerides, prolactin and cortisol (at 8:00 and 13:00).

### Statistical analysis

This study consisted of ordinal data (BAS and questionnaires) and quantitative data (biochemical parameters). A high value for BAS, GIS, SCL90, PRS, and pain drawing meant more symptoms. A high SOC value reflected a higher degree of sense of coherence. Median (Md), inter-quartile range (IQR), mean (M), standard deviation (SD) and percentage were used for presentation of data. Although median and IQR were optimal for ordinal data, means were presented as well for better visualization. Mann Whitney *U* test was used for ordinal and quantitative data<sup>[38]</sup>.

## RESULTS

### Study population

There was an obvious gender difference between the IBS subtypes with 20% men in the D-IBS, 6.25% in the C-IBS and 0% men in the A-IBS subgroup.

### Physiotherapeutic data

**BAS:** All subtypes of IBS patients scored higher in the BASobs than the controls. Comparing the subtypes, the A-IBS group showed less body disturbances compared to the other two groups (Table 1). In BASself the D-IBS group expressed lower score compared to the other two groups, with levels similar to the AHC group.

### Questionnaires

**Gastrointestinal symptoms:** All subtypes scored higher than the control group. There was no difference between the subtypes in total score. The A-IBS group

scored higher for constipation and flatulence and less for diarrhoea and motility compared to the D-IBS group. The C-IBS group scored more constipation, less motility and less diarrhoea compared to the D-IBS group (Table 2). Thus, the patients scored in accordance with their own subtype.

**Psychological symptoms:** The C-IBS and the A-IBS group scored higher psychological symptoms compared to the D-IBS group and all groups scored higher than the controls. Also, the C-IBS group scored more symptoms compared to the A-IBS group, especially for sensitivity, phobic anxiety, psychoticism and somatisation (Table 3).

**SOC:** The SOC questionnaire revealed that there were significant differences between the subtypes compared to the controls. The A-IBS group and the C-IBS group scored lower sense of coherence than the D-IBS group, which differed from healthy controls only in the total score and present time and external conditions (Table 4).

**PRS:** All subtypes showed lower psychosocial rating compared to the control group (Table 5). Besides, both C-IBS and A-IBS showed lower psychosocial rating/quality of life compared to the D-IBS group.

**Pain:** The subgroups of IBS showed higher scores of pain presented on the body drawings compared to the healthy controls. However, there were no differences in pain score for the different locations between the subtypes (Table 6).

**Biochemical analysis:** The D-IBS group differed from the other two subtypes and the AHC with significantly higher C-peptide values (Table 7). The C-IBS patients

**Table 7** Biochemical levels (mean ± SD, %)

Category	AHC ( <i>n</i> = 21)	D-IBS ( <i>n</i> = 30)	C-IBS ( <i>n</i> = 16)	A-IBS ( <i>n</i> = 34)
C-peptide	0.46 ± 0.14	10/10	0.62 ± 0.28 <sup>a</sup>	40/3
Triglyceride	0.7 ± 0.3	10/0	1.3 ± 0.6 <sup>c</sup>	57/3
Prolactin	264 ± 118	5/10	232 ± 94	7/23
Cortisol 8	491 ± 144	10/14	539 ± 239	10/6
Cortisol 13	316 ± 65	10/14	334 ± 157	27/30

Biochemical status presented as mean ± SD and percent (%) above/below ± 1SD for the AHC group and D-IBS, C-IBS, and A-IBS patients. Cortisol 8 and 13 equals cortisol level at 8 am, and at 1 pm, respectively. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01, <sup>c</sup>*P* < 0.001, vs AHC; <sup>a</sup>*P* < 0.01, vs D-IBS.

significance. All subgroups showed higher triglyceride levels than controls.

Looking at the variation above or below one standard deviation all subtypes had a larger variation compared to the controls. There was also a difference in the patterns of standard deviation, e.g. the prolactin values were, for the D-IBS group mostly below one standard deviation while for the C-IBS and A-IBS group the values were mostly above one standard deviation.

## DISCUSSION

In the present study our IBS population compared to healthy controls, showed overall a higher degree of dysfunctions in basic movements and awareness, as well as more psychological and gastrointestinal symptoms. They also scored a lower sense of coherence and increased pain. In addition the IBS patients had higher and more edged values of biochemical parameters.

When dividing the patients into subgroups according to their stool and defecatory patterns, i.e. D-IBS, C-IBS and alternating type of IBS the following characteristics were identified.

The D-IBS group showed a disturbed body movement pattern on BASobs in the same magnitude as the other two groups. However, on self-estimation (BASself) they rated themselves as having less dysfunction reflecting a lower sense of body awareness compared to the other two groups. They had the same amount of gastrointestinal, but less psychological symptoms compared to C-IBS and A-IBS. The D-IBS patients scored a nearly normal degree of sense of coherence and thus a good quality of life, also reflected in a slightly less distorted psychosocial rating scale compared to the other subgroups. However, they expressed a high pain score similar to the other subtypes. They also had a higher C-peptide value, not being so prominent in C-IBS and

A-IBS. All subgroups also showed higher triglyceride values compared to controls.

The C-IBS and A-IBS groups exhibited to some extent similar patterns. However, the A-IBS patients revealed less body disturbance than the C-IBS. On self-estimation (BASself) both groups rated themselves at the same level as the physiotherapist. Both subtypes suffered from more gastrointestinal and psychological symptoms, than the AHC group. However, the C-IBS patients had more psychological symptoms than the D-IBS and A-IBS groups. Both groups displayed a lowered sense of coherence, and thus a lower quality of life, also outlined in the psychosocial rating scale. Furthermore, they were afflicted with high pain scores compared to the controls. When looking at the biochemistry the C-IBS patients had elevated prolactin values compared to the other groups.

The outcome of the gastrointestinal scale (GIS) reflecting the same symptom patterns as the subtype is supportive of an initially correct subtyping of the patients prior to referral. Actually, GIS could be used as a tool to subtype the IBS patients.

From the present study it seems as the D-IBS patients differed from the other two groups. They were not aware of their dysfunctional body awareness not realising their depreciated state of health, thus coping with preserved quality of life. These patients had less psychological symptoms, and higher C-peptide values. Thus, the increased C-peptide value could be secondary to hyperinsulinemia, reflecting an altered adrenergic drive. Although, sympathetic activation normally inhibits bowel motility, one could speculate whether this tentative adrenergic abnormality may be one component of the enteric neuropathy seen in D-IBS. Overall, they revealed themselves as ambitious persons, with a higher proportion of men compared to the other subtypes and many of them in the midst of their professional careers.

The higher C-peptide and triglyceride levels may be part of a metabolic syndrome, which is known to correlate with psychosocial stress<sup>[39]</sup>. Prolactin may be important in the process of coping with stress and traumatic experience<sup>[40]</sup> and Sivik *et al*<sup>[41]</sup> reported active soldiers to have lower prolactin values. Sondergaard *et al*<sup>[42]</sup> have shown a strong correlation between prolactin and alexithymia specially the item 'difficulty to identifying feelings'. The D-IBS group in our study had both lowered prolactin values and lower body awareness.

These results are in accordance with the outcome of a study by Aggarwal *et al*<sup>[8]</sup>. When studying predominant symptoms in IBS and the correlation with autonomic nervous system abnormalities they found that the D-IBS subgroup was associated with adrenergic nervous system malfunctions. They also found that C-IBS patients were more psychologically distressed, with higher degree of depression and anxiety. Also, the C-IBS patients were found to have vagal cholinergic dysfunction in that study. This may also be in line with our results of higher prolactin values for the C-IBS group, which may correspond to increased vagal tone<sup>[43]</sup>, as well as higher SCL90 scores. The C-IBS and A-IBS patients are characterised by their psychological symptoms of anxiety and depression. Emotional strain is correlated to increased levels of prolactin and this could be one of the reasons for the prolactin increase in the C-IBS group<sup>[44]</sup>.

Also in agreement with our results, Elsenbruch *et al*<sup>[12]</sup> found in a study on postprandial autonomic and cortisol responses that D-IBS patients elicited an enhanced sympathetic drive as measured by heart rate variability compared to the C-IBS patients and controls. The D-IBS had significantly higher postprandial saliva cortisol levels, but the cortisol values at baseline were equal for these groups, which is in conformity with our results on cortisol levels. Although morning fasting cortisol levels were increased equally for all subtypes, the differences compared to controls did not turn out as statistically significant. There was also a considerable spread of the values above and below one standard deviation compared to controls. These findings were also partly true for the mid day cortisol levels.

Although the sample size of the present study is fairly modest in this context, the recruitment of subjects was from patients presenting with fairly advanced disease, with several years history of symptoms. However, since they are referred from different types of care providers they can be regarded as representing a general population of IBS patients. Thus, our results can probably be generalised for a larger IBS population.

IBS is described as a gastrointestinal functional disorder, which onset and course is affected by psychological factors. Asahina *et al*<sup>[45]</sup> suggest that treatment of psychological factors should also be considered when dealing with IBS. Moser<sup>[46]</sup> points out that functional gastrointestinal disorders are the most frequent clinical conditions seen in practice and suggests that integrated psychosomatic care should be provided i.e. the patient's psychosocial status and the demand for additional psychological care should be assessed and offered<sup>[47]</sup>. This

is supported by the results of randomised controlled studies having shown that psychotherapy is superior to conventional therapy<sup>[46]</sup>. This is also in line with the results from our studies with physical, psychological and biochemical examinations and treatment of the 'whole person' with body awareness therapy. Jones *et al*<sup>[48]</sup> showed that IBS patients had lower quality of life and less interpersonal support and greater reliance on passive coping strategies. IBS patients show in our study lower quality of life and lower body awareness which could be connected to passive coping strategies. The disparities seen in our study of the subtypes of IBS are in agreement with these studies mentioned and may be different expressions of the functional gastrointestinal disorder. With the knowledge gained from the present study body awareness therapy could be adjusted to the different manifestations encountered in the subtypes of IBS.

In conclusion, this study has shown that the D-IBS patients, with a higher proportion of men, scored less body awareness, less psychological symptoms, better sense of coherence and showed higher C-peptide values, possibly indicating an adrenergic drive representing unconscious mental stress. The C-IBS and A-IBS patients expressed higher body awareness, more depression and anxiety with impaired sense of coherence. The raised prolactin levels in C-IBS patients may reflect an increased vagal tone and emotional strain. The importance of the differences seen between the IBS subtypes in the present study and its implications for future treatment of IBS will have to be elucidated in further investigations.

## COMMENTS

### Background

Irritable Bowel Syndrome (IBS) is the most common of all gastrointestinal disorders, affecting around 15% of the population at least in the Western societies. The division of IBS into subgroups is based on the fact that these patients behave in dissimilar ways. IBS subgroups building on stool and defecation patterns can be divided into diarrhoea predominant (D-IBS), constipation predominant (C-IBS) and alternating (A-IBS) subtypes.

### Research frontiers

The understanding of IBS and especially the interaction between the central and enteric nervous systems has grown considerably over the last years. Therefore, in recent year's research has focused more and more on the psychosomatic (body and mind) aspect of the disease. IBS patients are therefore examined more comprehensible with gastrointestinal symptoms, psychological symptoms, biochemical stress markers, quality of life and body awareness. Thus, psychosomatic remedies like hypnotherapy, psychotherapy and body awareness therapy have been applied.

### Innovations and breakthroughs

Subgroups of IBS as shown in this study differ in body awareness, quality of life, psychological symptoms and biochemical stress markers.

### Applications

Treatment like Body Awareness Therapy (BAT) which is a physiotherapeutic approach, to adjust and reduce pathological tension in the body may in the future also be applied and streamlined for these subgroups in order to get a more optimal treatment.

### Peer review

This manuscript reports results of a study of differences in body awareness, pain scores, psychological symptoms and blood levels for prolactine, triglycerides and morning cortisol between healthy controls and patient diagnosed by Rome criteria with either D-IBS, C-IBS and A-IBS. The manuscript is well constructed and written.

## ACKNOWLEDGMENTS

The authors wish to express their sincere gratitude to MD, PhD Björn Öjerskog for expert technical assistance.

## INTRODUCTION

Liver cirrhosis is the terminal stage of various chronic liver diseases. Even mild but continuous injury in the liver soon results in excessive production of extracellular matrix components<sup>[1]</sup>. Deposition in the space of Disse causes capillarization of sinusoids and alterations in liver functions. This fibrotic stage ultimately progresses to cirrhosis, which is characterized by nodule formation and corruption of liver architecture.

Overproduction and accumulation of extracellular matrix proteins in the liver start usually after chronic hepatocyte injury that initiates a series of complicated cell-to-cell and cell-to-matrix interactions, eventually leading to activation of hepatic stellate cells, which are the main producers of excessive collagen during cirrhosis process<sup>[2]</sup>. Since hepatocyte injury seems to be the first and the main fibrogenic stimulus in the liver, healing of these cells could be a desirable goal in preventing progression of fibrosis.

Taurine, 2-aminoethanesulphonic acid, is an essential  $\beta$ -amino acid. It is present at high concentrations in many tissues. It plays important roles in numerous physiological functions including conjugation with bile acids, modulation of calcium levels, and maintenance of osmolarity, antioxidation and stabilization of membranes<sup>[3]</sup>. It was reported to have beneficial effects in various physiological and pathological conditions<sup>[4-7]</sup> by mainly diminishing production of reactive oxygen species (ROS). It also can prevent DNA damage at physiological concentrations<sup>[8]</sup>. Taurine has also hepatoprotective effects such as inhibition of extracellular matrix accumulation in experimental liver fibrosis<sup>[9,10]</sup> and improvement of liver function tests in fatty liver disease of children<sup>[11]</sup>. Hepatoprotective feature of taurine is attributed to its inhibitory activity on generation of ROS, which are

## Abstract

**AIM:** To search the organelle based changes in hepatocytes after taurine treatment in experimental liver fibrosis induced by CCl<sub>4</sub> administration.

**METHODS:** Thirty rats were divided into two groups. Group 1 ( $n = 15$ ) was injected with CCl<sub>4</sub> plus taurine and Group 2 ( $n = 15$ ) with CCl<sub>4</sub> plus saline for 12 wk. At the end of 12th wk, mitochondria, rough and smooth endoplasmic reticulum, and nuclei of hepatocytes were evaluated using a scoring system. The results were compared with histopathological findings, as well.

**RESULTS:** Taurine treatment reduced fibrosis scores significantly as compared to placebo. Organelle injury scores decreased significantly with taurine treatment. Ultrastructural and histopathological scores in both groups were in strong correlation ( $r = 0.931$  for CCl<sub>4</sub> plus taurine and  $r = 0.899$  for CCl<sub>4</sub> plus saline group).

**CONCLUSION:** Organelle based transmission electron microscopy findings can reflect successfully histological results as well as tissue healing in hepatocytes from hepatotoxin-induced liver fibrosis.

**Key words:** Taurine; Liver fibrosis; Hepatocyte; Ultrastructure

known to play an important role in hepatic injury both *in vitro* and *in vivo*<sup>[12,13]</sup>.

The effects of acute oxidative stress on the ultrastructure of sinusoidal endothelium, space of Disse, hepatocytes and Kuppfer cells in perfused rat liver have been studied previously by Cogger *et al*<sup>[14]</sup>. They successfully demonstrated the alterations in the mitochondria of injured hepatocytes. Recently, we have shown beneficial effects of taurine on histopathology and oxidative stress parameters in a rat model of CCl<sub>4</sub>-induced liver fibrosis<sup>[15,16]</sup> where remarkable histopathological improvement in taurine treated animals subjected to hepatotoxin was observed, and this was associated with oxidative stress reduction and hepatocellular apoptosis. In this work we report on the changes in the chronic setting, with more focusing on the multiple organelle based alterations after administration of CCl<sub>4</sub> that causes hepatic injury primarily *via* increasing ROS production in the liver<sup>[17]</sup>. We also studied the correlation of ultrastructural changes with histopathological findings.

## MATERIALS AND METHODS

The study was approved by the Institutional Animal Use and Care Committee of the Gulhane School of Medicine, Ankara, Turkey, and was performed in accordance with the National Institute of Health guidelines for the care and handling of animals. The animals were fed with free access to standard rat food and water, and housed in metabolic cages one in one at controlled temperature and 12-h light/dark cycles before and during the experiment. Electron microscopic examinations were performed at the Department of Anatomy, Hacettepe University Medical Faculty, Ankara.

### Animals and treatment strategies

Thirty male Sprague Dawley rats weighing 250-400 g were randomly divided into two groups. Group 1 (*n* = 15) was injected with CCl<sub>4</sub> (0.2 mL/100 g twice weekly; S.C) plus taurine (1000 mg/kg per day; I.P), and Group 2 (*n* = 15) with CCl<sub>4</sub> plus saline for 12 wk. At the end of 12th wk all rats were killed under anesthesia and the livers were excised. Adequate numbers of specimens from right and left lobes of each liver were collected for transmission electron microscopy and histopathological examination.

### Light microscopy analysis

For light microscopy, tissue sections were fixed in 10% neutral buffered formalin and embedded in paraffin. Paraffin sections were stained with hematoxylin-eosin, examined and scored by two pathologists who were blinded to the treatment protocol. Degree of necrosis, inflammation, fat accumulation, and fibrosis was scored as 0: Absent; 1: Slight; 2: Moderate; and 3: Severe as described elsewhere, with small modifications<sup>[18]</sup>. Histopathological evaluation was performed twice in four sections per slide from all animals in each group.

**Table 1 Ultrastructural scoring system used in experimental liver fibrosis<sup>[19-21]</sup>**

Ultrastructure Assessment	Score
Mitochondria	Normal
	Prominent cristae
	Edematous mitochondrion
	Collection of amorphous material
rER	Normal
	Dilatation
	Irregular lamellar organization
sER	Presence of focal breaks
	Normal
	Dilatation
Nucleus	Vacuolization
	Presence of large degenerated areas, myelin figures
	Normal
	Irregular chromatin distribution (margination, clumping)
	Increased heterochromatin
	Degenerated nucleus

rER: Rough endoplasmic reticulum; sER: Smooth endoplasmic reticulum.

### Ultrastructural analysis

The specimens were fixed in 2.5% glutaraldehyde for 24 h and subsequently washed in phosphate buffer (pH 7.4), post-fixed in 1% osmium tetroxide in phosphate buffer (pH 7.4) and dehydrated in increasing concentrations of alcohol. Afterwards, the tissues were washed with propylene oxide and embedded in epoxy-resin embedding media. Semi-thin sections about 3 mm in thickness were cut with a glass knife on a LKB Nova ultramicrotome (Sweden). These sections were stained with methylene blue and examined by a Nikon Optiphot (Japan) light microscope. Ultrathin sections were collected on copper grids, stained with uranyl acetate and lead citrate, and finally examined under a Jeol JEM 1200 Ex (Japan) transmission electron microscope. Twenty cells from each specimen were examined. Mitochondria, nuclei, rough endoplasmic reticulum (rER) and smooth endoplasmic reticulum (sER) of hepatocytes were evaluated by using a previously described scoring system (Table 1)<sup>[19-21]</sup>. Twenty nuclei, 50 mitochondria, 20 rERs and 20 sERs were examined for each animal.

### Statistical analysis

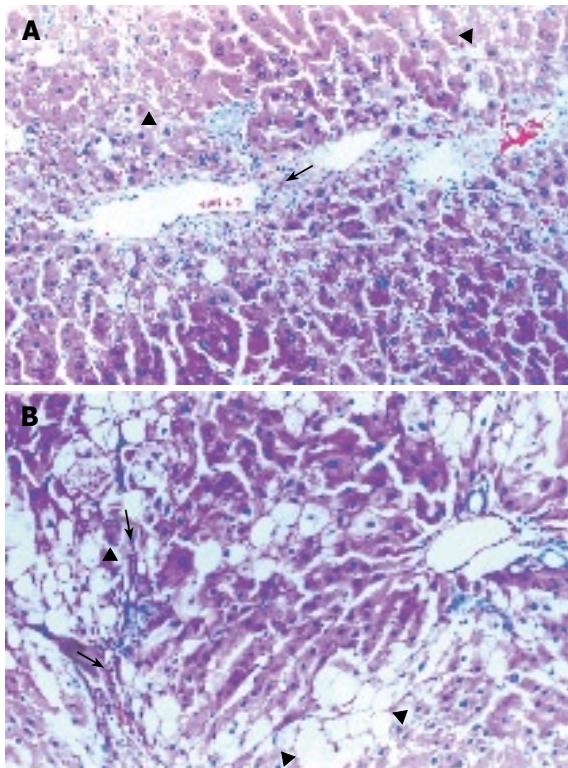

Results are expressed as mean ± SEM. Mann-Whitney U test for histopathologic scores and Student's *t*-test for ultrastructure scores were used to analyze significance of differences between groups. Correlation of histopathological and ultrastructural scores was assessed with Pearson correlation procedure. The differences were accepted as statistically significant when *P* < 0.05.

## RESULTS

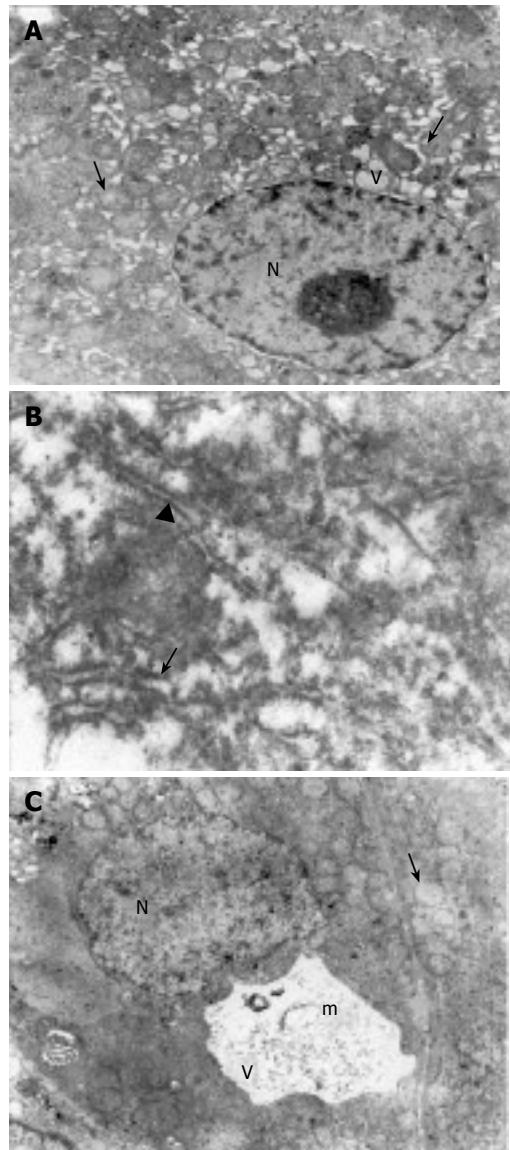

Two animals in Group 1 and four in Group 2 died before the end of experiment.

### Light microscopy

CCl<sub>4</sub> treatment produced hepatic necrosis, inflammation, fatty accumulation, and fibrosis by the 12th wk. Light

**Figure 1** **A:** Mild bile duct proliferation (arrow) and microvesicular changes (arrowheads) in Taurine treated animals (HE, x 200); **B:** Severe macro and microvesicular fatty accumulation (arrowheads) and fibrosis (arrows) in Taurine untreated group (HE, x 50).

**Figure 2** Electron micrographs. **A:** The dilatations in the rER (arrow) and sER (arrowhead), large vacuoles in the hepatocytes (V), a normal nucleus (N) and mitochondria with a prominent edema (small arrow) in  $\text{CCl}_4$  plus taurine treated group (x 4000); **B:** Large dilatations (arrow) and focal breaks (arrowhead) in the rER in  $\text{CCl}_4$  plus saline treated group (x 30 000); **C:** The vacuolizations (V) and myelin figures (m) in the sER, nucleus (N) and mitochondria with prominent edema (arrow) in  $\text{CCl}_4$  plus saline treated group (x 4000).

microscopy evaluation of liver sections from animals treated with  $\text{CCl}_4$  and taurine are shown in Figure 1, and Table 2. Necrosis, inflammation, fatty accumulation and fibrosis were significantly lower in Group 1 when compared with Group 2 (Figure 1B).

#### Transmission electron microscopy

Ultrastructural analysis of the liver sections revealed significantly lower organelle injury scores in  $\text{CCl}_4$  plus taurine treated group when compared with  $\text{CCl}_4$  plus saline treatment (Table 2). Mitochondrial edema was seen in both groups but it was more extensive in saline treated animals. Additionally, mitochondrial cristae were

much more visible in taurine treated animals (Figure 2A). While there were irregular lamellar organization and large dilatations with focal breaks in rERs of hepatocytes in  $\text{CCl}_4$  plus saline treated group in many areas (Figure 2B), only some focal slight dilatations were observed in taurine treated animals. Dilatations in taurine treated animals (Figure 2A) but vacuolization and myelin figures in saline treated group were sER findings (Figure 2C). Although there was irregular chromatin distribution in some areas, nuclei were almost normal in appearance with taurine treatment (Figure 2A). However, chromatin distribution was irregular and nuclei showed extensive margination and clumping in saline treated group. Other prominent findings were large vacuolization of hepatocyte cytoplasm in taurine treated animals and presence of active fibroblasts in some focal

**Figure 3** Correlation of histopathologic and ultrastructure scores in  $\text{CCl}_4$ . **A:** Plus Taurine treated group ( $r = 0.931$ ); **B:** Plus Saline treated group ( $r = 0.899$ ).

areas in saline treated group. Though the model was hepatotoxin-based, disruption of membranes was rarely seen; therefore, we did not modify the scoring table regarding the changes in membranes.

Ultrastructural scores in both groups highly correlated with the histopathologic scores ( $r = 0.931$  for Group 1,  $r = 0.899$  for Group 2) (Figure 3).

## DISCUSSION

The present study addresses the ultrastructural findings in hepatocytes and their correlation with histopathological scores after taurine treatment in  $\text{CCl}_4$  induced experimental liver fibrosis. As was shown previously in several studies, taurine treatment inhibits production of excess extracellular matrix in experimental liver fibrosis<sup>[8,10]</sup>. Although we did not measure tissue content of collagen in liver tissues, we found visible evidence under light microscopy that taurine decreased the degree of necrosis, inflammation, fatty accumulation and fibrosis. Antifibrotic activity of this endogenous amino acid in the liver was confirmed once more in the present study. Since  $\text{CCl}_4$  results in hepatotoxicity through its enzymatic conversion to reactive trichloromethyl free radicals<sup>[17]</sup>, antioxidant treatment is essential to be effective in reducing the degree of injury.

We analyzed mitochondria, rER, sER and nuclei according to a previously described ultrastructural scoring table<sup>[19-21]</sup> that was successfully used in experimental pancreatitis to demonstrate the level and characteristics of injury in parenchymal cells. Such a scoring system may be useful for the researchers in following the changes in ultrastructure of hepatocytes

under pathogenic stress or medications.

The most significant ultrastructural recovery with taurine treatment occurred in mitochondria and sER. Mitochondria are the energy source of the cell, as was specifically demonstrated in hepatocytes, with two membranes, one of which limits the organelle and the other of which is inside the organelle and is thrown into folds that project inward in a tubular nature called cristae mitochondria<sup>[22]</sup>. The molecules in the electron transport chain, which play the central role in ATP synthesis, are found in the cristae. It is also well known that mitochondria are both a major source of endogenous production of ROS<sup>[23]</sup>. The major mitochondrial pathology in our work was edema, the major ultrastructural sign of cellular injury, extensively invading the matrix resulting in swelling of the organelle and structural damage to cristae. Though edema was seen in both groups, it was much less in taurine treated animals. In addition, there was minimal disruption in cristae with taurine treatment and cristae integrity was preserved quite well. Swelling and loss of regular cristae structure with rupture of outer membrane, which are characteristics of deteriorated function of mitochondria<sup>[22,24,25]</sup>, decreased with taurine in our study.

Endoplasmic reticulum is normally composed of tubules, vesicles and sacs forming lamel-like shape<sup>[26]</sup>. Crucial pathways that are related to carbohydrate metabolism, biotransformation, steroid metabolism and protein processing function in the ER with integration to other organelles<sup>[27]</sup>. rER carries ribosomes on its surface different from sER, which is the place of action and storage of important cellular enzymes<sup>[28]</sup>. The proteins synthesized in rER are stored in cristae. Glycogen synthesis and detoxification of drugs are performed in sER in the liver. Severely dilated ER is representative of severely damaged hepatocytes<sup>[26]</sup>. When we examined ERs of the rats treated with saline, we found serious damage as irregular lamellar organization, large dilatations and focal breaks in rERs, and vacuolizations and myelin figures in sERs in many areas. However, only some focal and slight dilatations were observed in rERs and sERs of taurine treated animals. Besides absence of dilation that is known to be reversible when the toxic state is properly opposed or ceases<sup>[29]</sup>, intact lamellar organization and absence of vacuolization seem to be required for normal functioning of ER.

Nuclei, the hallmark of eukaryotic cells, contain DNA with its associated protein called chromatin<sup>[30]</sup>. The density of chromatin varies throughout the nucleus. Dense regions inside the nucleus are called heterochromatin and are found in parts of the chromosome where there are few or no genes. It lies next to inner side of the nuclear envelope. The genes in heterochromatin are generally inactive, that is, not transcribed. Euchromatin is found in parts of the chromosome that contain many active genes. We found alterations in chromatin distribution in the nuclei of hepatocytes from saline treated animals. Although we could not detect abundant heterochromatin, disorganization of nuclear content as margination

and clumping of chromatin in saline treated animals may be morphological evidence of injury in the nucleus. However, severely degenerated nuclei were rarely detected. Nuclear content was almost normal in appearance and organization with taurine treatment, which was previously reported to prevent DNA damage<sup>[8]</sup>. These results confirm the basic knowledge that nucleoplasmic constituents represent the structural counterpart of transcription and processing of messenger and ribosomal RNAs, and therefore constitute fine and highly sensitive indicators of cellular activity.

Electron microscope findings in hepatocytes after hepatotoxin have not been defined systematically to date. Moreover, which changes in each organelle are reversible or not is not clear. Dincer *et al*, previously reported partly the ultrastructural changes in hepatocytes after taurine treatment<sup>[31]</sup>. However, the present study not only defines the organelle changes in more detail; it also provides a better assessment and measurement of ultrastructural injury.

The change in ultrastructural scores between the two groups was nearly the same when compared with histopathological scores. This indicates that the current histopathological scoring system used to describe tissue injury in the present study successfully reflects organelle based ultrastructural changes in hepatocytes. On the other hand, the results obtained in this study should not be overwhelmed, because taurine's most significant action is directly counteracting the effect of CCl<sub>4</sub>. Protective effects of this antioxidant in clinical conditions related to other injury mechanisms in the liver might not be so strongly evident.

In conclusion, this study brought us direct view evidence of changes in morphology of hepatocyte organelles after induction of a certain hepatotoxin. Taurine preserves morphology of major organelles of hepatocytes and delays the development of fibrosis. Structural changes in hepatocyte organelles we observed in this study are likely the cause of significant histological improvements. Since transmission electron microscopy is the highest magnification tool at present, modeling new ultrastructural scoring systems including more organelles and parameters can be useful in estimating the degree of injury and outcome of alternative treatment strategies in management of chronic liver diseases.

## COMMENTS

### Background

Liver fibrosis and cirrhosis are untreatable conditions at present. Antioxidant medications including taurine have been reported to possess antifibrotic efficacy in experimental liver fibrosis. Taurine is one of the main components of energy drinks, which are widely consumed by healthy people around the world. The present study addresses organelle based changes in hepatocytes after taurine treatment in rat liver fibrosis.

### Research frontiers

Preventive effect of taurine in continuing liver injury was tested. The study design does not include treatment after establishment of liver fibrosis. Antioxidants may be taken into consideration not only for their efficacy on established liver fibrosis but also for their hepatoprotective efficacy in the long term.

### Innovations and breakthroughs

Organelle based effects of taurine in hepatocytes is to be shown for the first time on animals.

### Applications

Taurine administration was previously shown to be effective in delaying the development of fibrosis in experimental conditions. The present findings support the idea that conduct of large scale clinical studies on the efficacy of taurine in human liver fibrosis or cirrhosis should be encouraged.

### Terminology

Liver fibrosis refers to invasion of normal liver by collagen deposits in chronic liver injury leading to destruction of normal tissue architecture and functional insufficiency. Taurine is a potent antioxidant not present in the market as a drug but is included in the majority of energy drinks.

### Peer review

This paper is an experimental study in rats demonstrating that taurine protects the liver at the ultrastructural level after the administration of carbon tetrachloride. The paper is novel, well written and well organized, particularly the discussion which is comprehensive and easy to read.

Up-regulation of  $\alpha$ -catenin is associated with increased lymph node involvement in colorectal cancer. *World J Gastroenterol* 2008; 14(31): 4903-4908 Available from: URL: <http://www.wjgnet.com/1007-9327/14/4903.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.4903>

### Abstract

**AIM:** To investigate the changing pattern of  $\alpha$ -catenin expression and its relationship to clinical and pathological features of colorectal cancer (CRC) patients.

**METHODS:** Archival tumor samples were analyzed using immunohistochemistry (IHC) for  $\alpha$ -catenin in 91 patients with advanced CRC.

**RESULTS:** The values of  $\alpha$ -catenin membrane index (MI) and cytoplasmic index (CI) were significantly related to the depth of tumor invasion ( $P = 0.027$ ,  $P = 0.020$ , respectively), high indices being associated with increased depth of the primary tumor invasion (T3 and T4). Similarly, patients with high  $\alpha$ -catenin expression had a significantly increased risk of lymph node metastasis (32/39 vs 37/52 for MI and 37/45 vs 32/46 for CI) ( $P = 0.001$ ,  $P = 0.0001$ , respectively, for LNN status). An altered expression (i.e., cytoplasmic pattern) was also related ( $P = 0.047$ ) to the response to chemotherapy; patients with low CI were more responsive (CR: 7/46) than patients with high CI values (CR: 0/45). There was a marginal effect on survival in patients time with metastases (SWM) ( $P = 0.087$ ); patients with low CI showing slightly longer

### INTRODUCTION

Under normal conditions, cell-cell adhesion molecules maintain epithelial cell integrity and cellular architecture. The process of tumor invasion and metastasis is associated with alterations in the functions of several adhesion molecules. In general, tumor cells lose their capacity for normal adherence, which facilitates their detachment from their site of origin<sup>[1,2]</sup>.

Homotypic cell-cell adhesion is regulated mostly by the cadherin-catenin complex. Alterations in E-cadherin and catenins have been linked with more aggressive behavior of several human tumors<sup>[3-6]</sup>. Catenins are divided according to their molecular weight as  $\alpha$ -catenin (102 kDa),  $\beta$ -catenin (88 kDa) and  $\gamma$ -catenin (80 kDa)<sup>[7-9]</sup>.

$\alpha$ -catenin links E-cadherin to the actin cytoskeleton via its association with either  $\beta$ - or  $\gamma$ -catenin<sup>[10,11]</sup>.

Abnormal  $\alpha$ -catenin expression has been reported in many human cancers<sup>[12-15]</sup>. Reduced  $\alpha$ -catenin expression was associated with tumor invasion and metastases in colorectal cancer (CRC)<sup>[6]</sup>.

In this study, we examined  $\alpha$ -catenin expression in a series of CRC, and analyzed the relationship with clinical and pathological features of CRC patients.

## MATERIAL AND METHODS

### Study material

The material of the present study consists of a series of 91 patients with advanced CRC, enrolled among the consecutive CRC patients attending our clinic for therapeutic procedures. Of these 91 patients, 58 had metastases at diagnosis (Stage IV disease), while the remaining 33 patients (with stage II and III disease at baseline) subsequently developed a metastatic disease during the mean follow-up (FU) time of 25.1 ± 27.8 mo. All patients were treated for advanced and metastatic disease at the Department of Oncology and Radiotherapy, Turku University Hospital, according to the protocols used for CRC patients with stage II, III or IV disease at that time. These 91 patients included in the present study were enrolled into this prospective cohort between October 1998 and August 2003. All patients have been prospectively followed-up until death or when last seen alive at their clinical visit (March 2007), with the median FU-time of 27.6 mo (range 3-150 mo). The study was approved by the TUH Ethics Committee and was conducted in accordance with the Declaration of Helsinki. Samples were collected with the endorsement of the National Authority for Medico-legal Affairs.

The key clinical data of the patients are shown in Table 1. Of these 91 cases, 34 were women and 57 were men. The mean age was 61.5 years (range 24-78 years). The majority ( $n = 38$ ) of the tumors were localized in the left colon, followed in order of frequency by the right colon ( $n = 23$ ), rectum ( $n = 22$ ), and colon transversum ( $n = 7$ ). At the time of diagnosis, 14 patients had Stage II disease, 19 Stage III and 58 tumors were at Stage IV. The majority ( $n = 59$ , 64.8%) were T3 tumors, and almost half ( $n = 46$ ) had known lymph node involvement at the time of diagnosis, including the cases with Nx status. The patients were selected into the cohort on the basis of both the diagnosis and treatment received, and were assigned to one of the two treatment arms: (1) 20 were treated with irinotecan alone; and (2) 71 received a combination of irinotecan and 5-fluorouracil (5-FU) as the first line treatment.

### $\alpha$ -catenin immunostaining

Formalin-fixed, paraffin-embedded primary colorectal tumor tissue was obtained from 91 patients. Sections were cut serially at 5 µm for routine haematoxylin and eosin staining and for immunohistochemical (IHC) analysis. An experienced pathologist confirmed all histological diagnoses. IHC analysis was done using the automatic system (BenchMark XT, Ventana Medical

Systems, Inc. Tucson, Arizona, USA). This fully automated processing of bar code labeled slides included baking of the slides, solvent free deparaffinization, antigen retrieval in a cell conditioning buffer CC2 (Mild: 36 min conditioning, and standard: 60 min conditioning), incubation with the monoclonal mouse  $\alpha$ -catenin antibody (clone  $\alpha$  CAT-7A4, isotype IgG1- $\kappa$ , Zymed Laboratories, San Francisco, CA), at a dilution 1:100 (32 min, 37°C). The dilution of the primary antibody was based on dilution experiments. Application of ultraViewTM Universal DAB (a biotin-free, Multimer-based detection system for the specific and sensitive detection of mouse IgG, mouse IgM, and rabbit IgG primary antibodies). UltraView DAB includes: ultraView Universal HRP, ultraView Universal DAB Inhibitor, ultraView Universal DAB Chromogen, ultraView Universal DAB H<sub>2</sub>O<sub>2</sub>, and ultraView Universal DAB Copper. Counterstaining with haematoxylin (2021) took 4 min, and post-counterstaining with bluing reagent (2037) took 4 min as well. After staining, the sections were dehydrated in ethanol, cleared in xylene, and covered with Mountex and cover slips.

### Evaluation of $\alpha$ -catenin staining

The  $\alpha$ -catenin staining was evaluated by observers blinded to the clinical data using regular light microscopy. Membranous and cytoplasmic expression was evaluated separately. For the cell membrane staining,

four categories were used, (+++, ++, +, -), starting from equivalent to normal to entirely negative<sup>[16]</sup>. The cytoplasmic staining was also graded into four categories: (0) Negative, no detectable staining; (1) Weak, but still detectable staining; (2) Moderate, clearly positive but still weak; (3) Heavy staining, intense<sup>[17]</sup>. In calculating the staining indexes: membrane index (MI), and cytoplasmic index (CI), both the intensity of staining and the fraction of positively-stained cells were taken into account, using the following formula:  $I = 0 * f_0 + 1 * f_1 + 2 * f_2 + 3 * f_3$ , where I is the staining index,  $f_0-f_3$  are the fractions of the cells showing a defined level of staining intensity (from 0 to 3). Theoretically, the index could vary between 0 and 3n<sup>[18]</sup>. The  $\alpha$ -catenin expression was evaluated independently by two observers (AE, AB). The agreement of the evaluation of  $\alpha$ -catenin staining indices was tested between two observers, and the agreement was good as suggested by the correlation coefficient (Pearson's  $r$ : MI, CI, and NI were 0.77, 0.91, and 0.90, respectively,  $P < 0.001$ ).

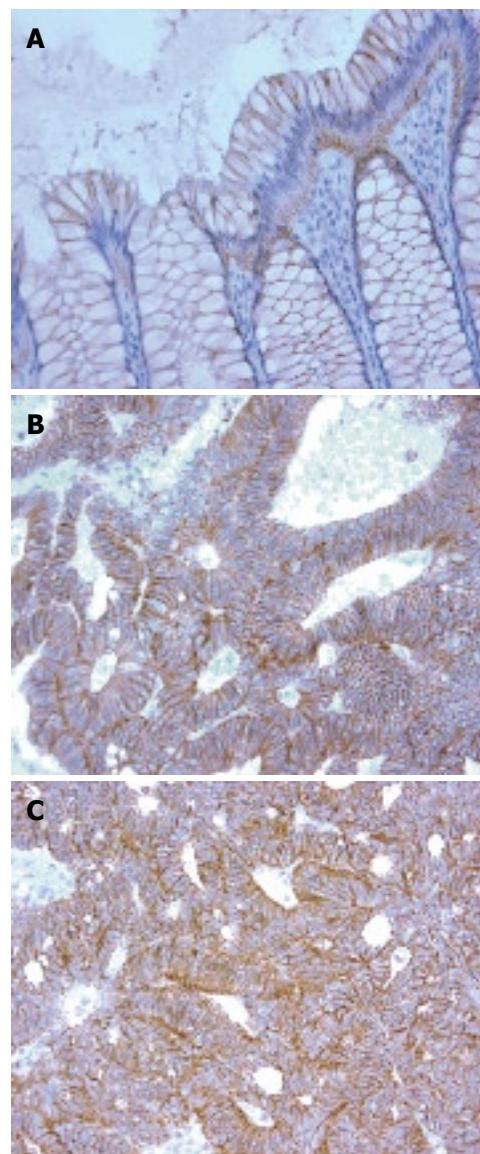

### Statistical analysis

Statistical analyses were performed using the SPSS® (SPSS, Inc., Chicago, USA) and STATA (Stata Corp., Texas, USA) software packages (SPSS for Windows, version 14.0.1 and STATA/SE 9.2). Frequency tables were analyzed using the  $\chi^2$  test, which evaluation included likelihood ratio (LR), or Fischer's exact test to assess the significance of the correlation between the categorical variables. Odds ratios and their 95% confidence intervals (95%CI) were calculated where appropriate, using the exact method. Differences in the means of continuous variables were analyzed using non-parametric tests (Mann-Whitney or Kruskal-Wallis) for 2- and K-independent samples, respectively. ANOVA (analysis of variance) was only used for deriving the mean values (and their SD) of each individual category. Univariate survival (life-table) analysis for the outcome measure (disease specific survival, DSS; disease free survival, DFS) was based on Cox's method (indices treated as continuous variables), and/or using Kaplan-Meier analysis (indices with Median as cut-off). In all tests,  $P < 0.05$  was regarded statistically significant.

## RESULTS

In normal colonic mucosa,  $\alpha$ -catenin expression was predominantly membranous but this pattern was disturbed (diffuse cytoplasmic and membranous) in the tumor tissues (Figure 1). The mean values of MI and CI were 1.3 and 1.1, respectively.

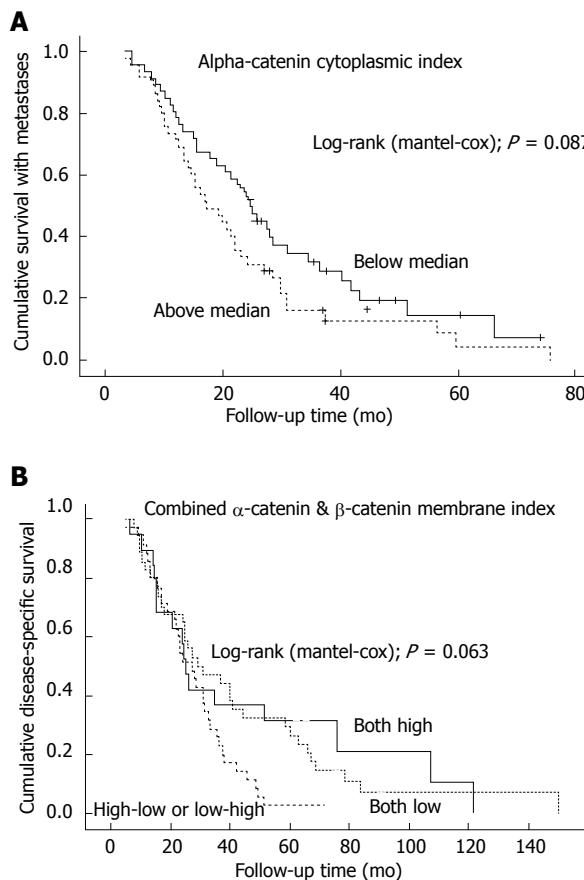

The two expression patterns of  $\alpha$ -catenin were related to all clinical and tumor variables recorded in this series. MI was significantly ( $P = 0.03$ ) related to the localization of the primary tumor, being more intense in carcinomas of the descending colon ( $n = 38$ ) and rectum ( $n = 22$ ) than in those of the ascending ( $n = 23$ ) and transverse colon ( $n = 7$ ). Both MI and CI were also correlated with the depth of the primary tumor (ANOVA;  $P = 0.027$ ,  $P = 0.020$ , respectively), higher

**Figure 1** Different immunohistochemical staining patterns of  $\alpha$ -catenin in colorectal carcinomas. **A:** In normal colonic epithelium,  $\alpha$ -catenin is predominantly expressed in the cell membrane. **B:** A medium-powered view of a colonic adenocarcinoma showing membranous expression of  $\alpha$ -catenin. **C:** This case shows both membranous and cytoplasmic expression of  $\alpha$ -catenin.

mean index values being associated with increased depth of the primary tumor invasion (i.e., T3 and T4). Interestingly, patients with high  $\alpha$ -catenin expression (MI, CI) had a significantly increased lymph node metastasis ( $32/39$  vs  $37/52$  for MI and  $37/45$  vs  $32/46$  for CI) ( $P = 0.001$ ,  $P = 0.0001$ , respectively). On the other hand, there was no correlation between  $\alpha$ -catenin expression and most of the clinical variables (e.g. age, sex, and stage). However, there was a marginal relation between MI and CI ( $P = 0.08$ ,  $P = 0.07$ , respectively) and the grade of the primary tumor.

Cytoplasmic  $\alpha$ -catenin expression was also significantly ( $P = 0.04$ ) related to the response to treatment in that the patients with low CI were more responsive (CR: 7/46) than patients with high CI values (CR: 0/45). No such association was established for the MI.

**Figure 2** A: Cytoplasmic  $\alpha$ -catenin expression and survival with metastasis in univariate (Kaplan-Meier) analysis; B: Combined  $\alpha$ -catenin and  $\beta$ -catenin (MI) expression and disease-specific overall survival in Kaplan-Meier analysis.

In univariate survival analysis, neither MI nor CI was a significant predictor of disease outcome. As to the survival with metastases, there was a marginal difference in the survival curves, patients with low CI showing slightly longer survival with metastases (SWM) (Figure 2A). Finally, when  $\alpha$ -catenin expression was analyzed jointly with  $\beta$ -catenin expression (with the combined MI and CI indices built up using the same criteria as described for  $\alpha$ -catenin), only the combined MI index was of marginal prognostic value in predicting DSS, those with high MI surviving longer (Figure 2B).

## DISCUSSION

As compared with the sub-cellular distribution of  $\alpha$ -catenin in normal colonic mucosa, neoplastic cells demonstrated a distinct shift from the membranous localization to more widespread distribution (membranous, cytoplasmic) in cancer cells. This is in line with the previous reports describing this type of altered pattern of  $\alpha$ -catenin expression in cancer cells<sup>[19,20]</sup>.

Interestingly,  $\alpha$ -catenin expression (MI) was more intense in carcinomas of the descending colon and rectum as compared with the lesions localized in the ascending and transverse colon. Similar observation was reported for  $\beta$ -catenin<sup>[21,22]</sup>, but not for  $\alpha$ -catenin. There is increasing evidence to suggest that molecular mechanisms and molecular phenotypes differ in

carcinomas arising in the proximal and distal segments of the large bowel<sup>[23]</sup>. The involvement of different molecular pathways in colorectal carcinogenesis is exemplified by the fact that cancers of “mutator” phenotypes preferentially occur in the proximal colon, whereas the adenoma-to-carcinoma sequence phenotype is characteristic of carcinomas in the distal colon and rectum<sup>[24,25]</sup>. Corresponding differences have also been demonstrated with other potential prognosticators<sup>[26]</sup>.

The correlation between  $\alpha$ -catenin expression pattern and the TNM categories is a controversial issue. Some studies report that there is no correlation between  $\alpha$ -catenin and these clinicopathological variables<sup>[3]</sup>. On the other hand, Gofuku *et al* 1999 demonstrated that reduced expression of  $\alpha$ -catenin was significantly correlated with the depth of invasion. Moreover, the frequency of lymph node metastases was significantly higher in those tumors with reduced  $\alpha$ -catenin expression<sup>[6]</sup>. Our data show that higher indices in both (MI, CI) have a correlation with increased depth of tumor invasion and to increased lymph node involvement. There are multiple reasons that could explain these inconsistent and in part discrepant results reported in these different studies<sup>[3,6]</sup>. Such potential confounding factors might include the size of tissue sample, intrinsic tumor heterogeneity, lack of standardization of the positive and negative results, and different immunohistochemical staining and grading methods, with varying degree of sensitivity. In addition, our patients represent advanced CRC, the majority of patients with stage IV disease, as compared e.g. with Gofuku’s material, in which only 24/100 patients had stage IV CRC<sup>[6]</sup>.

To our knowledge, this is the first study to investigate the relation between  $\alpha$ -catenin expression and response to treatment. Interestingly, a significant relation was observed between CI and the response to treatment. Accordingly, the patients with low CI were more responsive to treatment than patients with high CI values. The significance of these observations remains to be elucidated in a larger study, however.

As to the relation between  $\alpha$ -catenin expression pattern and clinical outcome, a marginally significant association was observed to survival with metastases. When we combined both MI and CI of  $\alpha$ -catenin and MI and CI of  $\beta$ -catenin (using 3 categories; high/high; high/low or low/high; low/low), only the combined MI index was of marginal prognostic value, high MI predicting longer DSS. Such information has not been reported previously. As shown by the data (Figure 2B), it seems feasible to speculate that patients with high MI of both  $\alpha$ - and  $\beta$ -catenin survive longer, because this is the normal expression pattern of these two adhesion molecules, and retaining this pattern could indicate a less pronounced dedifferentiation of the cancer cells.

Taken together, the present study examined the predictive and prognostic value of  $\alpha$ -catenin expression in advanced CRC. Our results substantiate the emerging evidence on different molecular events operating in CRC at different localizations, while demonstrating a

significant difference in  $\alpha$ -catenin expression between tumors of the proximal and distal sites. High  $\alpha$ -catenin expression was typical in advanced invasion of the primary tumour (i.e., T3 and T4) as well as in appearance of LNN metastases. An altered expression (i.e., cytoplasmic) pattern was also related to the response to treatment, and there was some marginal association with the SWM, but not with DFS or DSS. The latter was marginally predicted by the combined ( $\alpha$ -catenin/ $\beta$ -catenin) MI, however, patients with high MI showing longer DSS. The results implicate that  $\alpha$ -catenin expression is associated with the regulatory mechanisms leading to invasive phenotype and progressive disease in CRC. The full prognostic value of this adhesion molecule as a single marker remains to be established, however, and there is some circumstantial evidence (Figure 2B) that probably more valuable prognostic information could be obtained when  $\alpha$ -catenin is combined with the other constituents of the cell adhesion complex, e.g.  $\beta$ -catenin and the cadherins.

## COMMENTS

### Background

Process of tumor invasion and metastasis is associated with alterations in the functions of several adhesion molecules. In general, tumor cells lose their capacity for normal adherence, which facilitates their detachment from their site of origin.  $\alpha$ -catenin links E-cadherin to the actin cytoskeleton via its association with either  $\beta$ - or  $\gamma$ -catenin. Reduced  $\alpha$ -catenin expression was associated with tumor invasion and metastases in colorectal cancer (CRC). We examined  $\alpha$ -catenin expression in a series of 91 patients with advanced colorectal carcinoma, and analyzed the relationship with clinical and pathological features of CRC patients.

### Research frontiers

CRC is one of the commonest malignant tumours and has a relatively poor prognosis, where the outcome depends on the extent of local and particularly metastatic tumour spread. For example, in locally advanced disease (Dukes C), the 5-year relative survival rate is 65% but goes down to 8% in metastatic disease (Dukes D). Metastatic disease causes the majority of cancer-related deaths, either as a result of tumour involvement of critical organs or due to complications of therapy to control tumour growth and spread. This dramatic difference emphasizes the importance of delineating predictive factors capable of reliably distinguishing CRC patients at risk for developing a metastatic phenotype.

### Innovations and breakthroughs

Patients with high  $\alpha$ -catenin expression (MI, CI) had a significantly increased lymph node metastasis. There is also significant difference in  $\alpha$ -catenin expression between tumors of the proximal and distal sites. Interestingly,  $\alpha$ -catenin expression (MI) was more intense in carcinomas of the descending colon and rectum as compared with the lesions localized in the ascending and transverse colon. Similar observation was reported for  $\beta$ -catenin, but not for  $\alpha$ -catenin. There is increasing evidence to suggest that molecular mechanisms and molecular phenotypes differ in carcinomas arising in the proximal and distal segments of the large bowel. The involvement of different molecular pathways in colorectal carcinogenesis is exemplified by the fact that cancers of "mutator" phenotypes preferentially occur in the proximal colon, whereas the adenoma-to-carcinoma sequence phenotype is characteristic of carcinomas in the distal colon and rectum. Corresponding differences have also been demonstrated with other potential prognosticators. To our knowledge, this is the first study to investigate the relation between  $\alpha$ -catenin expression and response to treatment. Interestingly, a significant relation was observed between CI and the response to treatment. Accordingly, the patients with low CI were more responsive to treatment than patients with high CI values. The significance of these observations remains to be elucidated in a larger study, however.

### Applications

Valuable prognostic information could be obtained when  $\alpha$ -catenin is combined

with the other constituents of the cell adhesion complex, e.g.  $\beta$ -catenin and the cadherins.

### Peer review

The manuscript is well written and the results implicate that high  $\alpha$ -catenin expression is associated with invasive phenotype, lymph node metastases, and progressive disease in CRC. It includes interesting new data of  $\alpha$ -catenin expression in colon carcinomas of different locations. This is also the first study to investigate the relation between  $\alpha$ -catenin expression and the response to treatment.

## INTRODUCTION

The introduction of laparoscopic surgery has dramatically changed the field of surgery. With improvements in the equipment and increasing clinical experience it is now possible to perform almost any kind of procedure under laparoscopic visualization.

Although more than a century has elapsed since McBurney first performed open appendectomy<sup>[1]</sup>, this procedure remains the treatment of choice for acute appendicitis for most surgeons.

In 1983, Semm performed the first laparoscopic appendectomy<sup>[2]</sup>. Ever since then, the efficiency and superiority of laparoscopic approach compared to the open technique has been the subject of much debate<sup>[3-23]</sup>. The idea of minimal surgical trauma, resulting in significantly shorter hospital stay, less postoperative pain, faster return to daily activities, and better cosmetic outcome has made laparoscopic surgery for acute appendicitis very attractive. However, several retrospective studies<sup>[3-12]</sup>, several randomized trials<sup>[13-19]</sup> and meta-analyses<sup>[20-24]</sup> comparing laparoscopic with open appendectomy have provided conflicting results. Some of these studies have demonstrated better clinical outcomes with the laparoscopic approach<sup>[13-17]</sup>, while other studies have shown marginal or no clinical benefit<sup>[18-22]</sup> and higher surgical costs<sup>[19,23]</sup>.

At present, although there is no consensus regarding the superiority of the laparoscopic approach over the conventional technique, there is trend towards greater utilization of laparoscopic appendectomy<sup>[24,25]</sup>.

In the present study, we aim to compare the laparoscopic approach and the conventional technique in the treatment of acute appendicitis, using prospectively collected data from patients subjected to appendectomy between January 2006 and January 2008.

## Abstract

**AIM:** To compare the outcome of laparoscopic *versus* open appendectomy.

**METHODS:** Prospectively collected data from 293 consecutive patients with acute appendicitis were studied. These comprised of 165 patients who underwent conventional appendectomy and 128 patients treated laparoscopically. The two groups were compared with respect to operative time, length of hospital stay, postoperative pain, complication rate and cost.

**RESULTS:** There were no statistical differences regarding patient characteristics between the two groups. Conversion to laparotomy was necessary in 2 patients (1.5%). Laparoscopic appendectomy was associated with a shorter hospital stay (2.2 d *vs* 3.1 d,  $P = 0.04$ ), and lower incidence of wound infection (5.3% *vs* 12.8%,  $P = 0.03$ ). However, in patients with complicated disease, intra-abdominal abscess formation was more common after laparoscopic appendectomy (5.3% *vs* 2.1%,  $P = 0.002$ ). The operative time and analgesia requirements were similar in the two groups. The cost of treatment was higher by 370 € in the laparoscopic group.

**CONCLUSION:** Laparoscopic appendectomy is as safe and efficient as open appendectomy, provided surgical experience and equipment are available.

**Key words:** Laparoscopy; Appendicitis; Appendectomy; Conventional appendectomy

## MATERIALS AND METHODS

Data was collected prospectively on patients with acute appendicitis who underwent open or laparoscopic appendectomy from January 2006 to January 2008 in the surgery department of the University Teaching Hospital at Patras. The clinical data base contained information such as patient characteristics, postoperative course, length of hospital stay, postoperative morbidity and mortality, 30-d readmission and hospital charges.

All human studies were performed according to the principles of the declaration of Helsinki. The study was approved by the research and ethics committee at the University Hospital of Patras.

The diagnosis of appendicitis was made in the emergency department and was based on the presence of right lower quadrant pain, nausea or vomiting, and abdominal guarding on physical examination. In patients where a clinical diagnosis could not be established, imaging studies such as abdominal ultrasound or CT were performed. Exclusion criteria included pregnancy, hemodynamic instability, chronic medical or psychiatric illness, cirrhosis, coagulation disorders, previous laparotomy for small bowel obstruction, and ascites. In order to increase the homogeneity of the group, a total of 37 patients (11.2%), who underwent elective interval appendectomy or had incidental appendectomy in the presence of other intra-abdominal pathology were excluded from the study. The decision about the type of the operation was made according to the preference and experience of the surgical team on duty.

Prior to the surgery, all the patients received a standard regimen of intravenous antibiotics (1.5 g of Cefuroxime and 500 mg of Metronidazole). Provided purulent appendicitis was not observed at surgery, two additional doses were given. In patients with complicated appendicitis, antibiotics were not discontinued but were modified according to the culture results.

Open appendectomy was typically performed through a 3 cm McBurney muscle splitting incision in the right lower quadrant. Following appendectomy the stump was double ligated with an absorbable suture. In the presence of complicated appendicitis the abdomen was irrigated with warm saline solution and the skin incision was closed loosely.

In the laparoscopic group, pneumoperitoneum was produced by continuous pressure of 10–12 mmHg of carbon dioxide via a Verres canula, positioned in the left subcostal area. Following gas insufflation, a 12 mm trocar for the 30 degree angled laparoscope was placed in the left periumbilical area and two additional trocars, a 12 mm trocar in the suprapubic area to accommodate the stapling device and to facilitate specimen extraction, and a third 5 mm trocar in the left lower abdominal quadrant were introduced under direct visualization. The patient was placed in a Trendelenburg position, with a slight rotation to the left. The abdominal cavity was thoroughly inspected in order to exclude other intra-abdominal or pelvic pathology. After the mesoappendix was divided with bipolar forceps, the base of the

**Table 1 Patient demographics**

DM	6 (3.6)	3 (2.3)	0.14

WBC: White blood cell; CAD: Coronary artery disease; COPD: Chronic obstructive pulmonary disease; DM: Diabetes mellitus.

appendix was secured with two ligating loops, followed by dissection distal to the second loop using a curved dissector. In patients with severe inflammation, a stapling device was used for the dissection of the appendix. The specimen was placed in an endobag and was extracted through the suprapubic trocar. All specimens were sent for histopathology.

The parameters examined in this study included patient's characteristics (age, sex), operation time (from skin incision to wound closure), conversion to open procedure, and intraoperative findings (normal, gangrenous or perforated appendix). Furthermore, during the post-operative follow up, pain was assessed both by the patient's requirements for analgesia, and with a visual analog score. The length of hospital stay, complications and cost were also added to the plot. The discharge criteria were met once the patients' were afebrile, with audible bowel sounds and were able to tolerate a liquid diet.

Statistical analysis was performed using SPSS statistical software, version 12.0 (SPSS Inc., Chicago, IL). The data were expressed as mean and standard deviation. Parameters such as length of hospitalization, mortality and morbidity, and hospital cost are given as mean variable. Bivariate analyses were performed to determine the differences between laparoscopic versus open appendectomy in patient characteristics, length of hospital stay and costs using independent sample *t* tests for continuous variables and chi-square analysis for categorical variables. A *P* value of less than 0.05 was considered statistically significant.

## RESULTS

A total of 293 patients with acute appendicitis were admitted during the study period. 165 patients were subjected to open appendectomy and 128 patients to laparoscopic appendectomy. The patient characteristics are shown in Table 1. There were no significant differences with respect to gender, age, white blood cell count at presentation, and associated co-morbidities.

Out of the total 165 open procedures, 118 (71.5%) were performed for uncomplicated appendicitis and 47 (28.5%) for complicated disease including appendiceal perforation with local or widespread peritonitis.

Total morbidity (%)	10.3	7.8	0.43

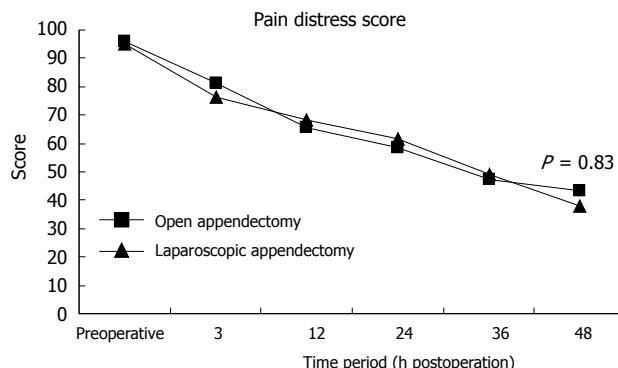

In the laparoscopic group, 90 (70.3%) procedures involved uncomplicated disease and 38 (29.7%) complicated appendicitis (Table 2). Additionally, in 16 (9.6%) open and 8 (6.2%) laparoscopic procedures, no pathology was observed in the appendix and other intra-abdominal structures (Table 2).

The actual operating room time was similar between the two groups (47 ± 19.7 min in the open group vs 44.3 ± 24 min in the laparoscopic group; P = 0.31, Table 2). Conversion to an open procedure was required in two patients (1.5%) with extensive cecal adhesions secondary to severe inflammation rendering appendiceal mobilization and visualization difficult and dangerous.

There was no mortality in either group and the overall morbidity was not significantly different (10.3% in the open group vs 7.8% in the laparoscopic group; P = 0.43, Table 3).

In patients with uncomplicated disease, the morbidity rates were low (0.8% in open appendectomy and 1.1% in laparoscopic appendectomy; P = 0.5, Table 3). One patient subjected to open appendectomy developed wound infection. The culture of pus revealed *E. coli* and the patient was successfully treated with antibiotics and wound debridement. Similarly, in one patient in the laparoscopic group, intestinal injury occurred during insertion of the visiport. The lesion was recognized intraoperatively and was successfully managed with endoscopic sutures. The end result was favorable and no further manipulations were required.

In contrast to uncomplicated disease, patients with complicated appendicitis were prone to postoperative complications (34% after open appendectomy and 23.7% after laparoscopic approach; P = 0.12, Table 3). Postop-

**Figure 1** Visual analogue score (VAS) for pain assessment.

erative bowel obstruction was observed in patients with complicated disease in both study groups (10.6% after conventional appendectomy and 7.8% after laparoscopic appendectomy; P = 0.37, Table 3). In addition, complicated appendicitis was associated postoperatively with respiratory infection in 4 patients subjected to open appendectomy, and 2 patients treated laparoscopically (P = 0.18, Table 3).

Infectious complications were seen in both study groups in patients with complicated disease. Open appendectomy was associated with a significantly higher incidence of wound infection compared with the laparoscopic group (12.8% vs 5.3%; P = 0.03, Table 3).

On the other hand, the incidence of intra-abdominal abscess formation was higher in patients with severe peritonitis who were treated laparoscopically (5.3% vs 2.1%; P = 0.002, Table 3). All patients who developed intra-abdominal abscess were treated successfully with antibiotics and CT-guided drainage of the collection, and had an uneventful recovery.

Bowel movements in the first postoperative day were observed in 92% patients subjected to laparoscopic appendectomy and 67% in the open group (P < 0.001). As a result, 78% patients in the laparoscopic group and 51% in the open group were able to tolerate a liquid diet within the first 24 postoperative hours (P < 0.001). The mean postoperative hospital stay was 2.2 d (range, 1-17 d) after laparoscopic appendectomy and 3.1 d (range, 1-18 d) after open appendectomy (P = 0.04).

Visual analogue pain scores were similar in the two groups for the first two postoperative days (Figure 1). There was a significant decline after the first 3 postoperative hours to 48 h in both groups. There was no difference between open and laparoscopic groups with respect to either overall pain level (P = 0.93) or degree of pain remission (P = 0.82). Eventually, the need for analgesic medication usage for the control of postoperative pain was similar in the two groups.

Finally, the operative costs were higher by 370 € in the laparoscopic group. In the present study, the costs were calculated based on the most cost effective materials used such as laparoscopic equipment, versatile laparoscopic instruments, endoloops and collection bags. Hospital charges regarding anesthesia were not added to the plot since there was no difference in the operative times.

## DISCUSSION

Acute appendicitis is the most common intra-abdominal condition requiring emergency surgery<sup>[26]</sup>. Although more than 20 years have elapsed since the introduction of laparoscopic appendectomy, there is no consensus on its advantages and disadvantages compared to the conventional technique.

Recent studies have shown significant advantages of laparoscopic appendectomy with respect to the length of hospital stay, postoperative pain and infectious complications<sup>[5,8,12,14,18]</sup>. These findings have been challenged by other authors who observed no significant difference in the outcome between the two procedures, and moreover noted higher costs with laparoscopic appendectomy<sup>[3,17,19,25,27]</sup>.

Bearing in mind that laparoscopic appendectomy, unlike other laparoscopic procedures, has not been found superior to open surgery for acute appendicitis, we designed the present study to determine any possible benefits of the laparoscopic approach.

Operation time remains a topic of much debate among experts. Preliminary studies<sup>[28-30]</sup> have shown significantly longer operative times for laparoscopic appendectomy. The inexperience of the surgeons with the new technique may contribute to the longer duration of the operation in the early studies. However, recent studies<sup>[16-18]</sup> have supported the initial findings. Because in these studies, most of the operations were performed by residents, the longer operation times can be attributed to the learning curve. By contrast, in the present study, the operation times were nearly similar in the two techniques, and the learning curve effect was minimal as the surgeons performing the procedures were highly experienced with a wide spectrum of laparoscopic procedures, including laparoscopic bariatric surgery and laparoscopic colectomy. This experience is reflected in our study by the relatively narrow range of operative times in the laparoscopic group ( $44.3 \pm 24$ ).

Previous studies have given conflicting results with respect to the length of hospital stay after laparoscopic appendectomy. Guller *et al*<sup>[12]</sup> in a population-based analysis using a national administrative data base showed that laparoscopic appendectomy is associated with significantly shorter hospital stay. These findings were supported by the Cochrane Collaboration large scale meta-analysis<sup>[24]</sup>. In agreement with these studies, we found that hospital stay was significantly shorter in patients subjected to laparoscopic appendectomy ( $P = 0.004$ ). In the present study, bowel movements were observed significantly earlier in patients managed laparoscopically, leading to earlier feeding and discharge from hospital.

In the present study, pain was assessed both subjectively *via* a visual analogue scale and objectively by the tabulation of analgesic use. Although some studies have reported less pain in the first 48 h after laparoscopic appendectomy<sup>[20,21,24,25,31]</sup>, in our series there was no difference between the two groups with respect to either the visual analogue scores or the use of analgesics. Our study suffered from the drawback that it

was not blinded. As a result, the perception of pain may have been influenced by the patient's enthusiasm for a novel technique.

There was no mortality in our study. This is consistent with the majority of previous publications. It has been reported that the mortality rate is 0.05% and 0.3% in laparoscopic and open appendectomy respectively<sup>[12]</sup>. The low mortality rates indicate that appendectomy, especially in the absence of complicated disease, is a safe procedure regardless of the technique used.

In the present study, the overall complication rates were 10.6% and 8.1% for open and laparoscopic appendectomy respectively. These results are in agreement with previous reports, which vary from 5.7% to 25.8% for open appendectomy and 3% to 19% for laparoscopic appendectomy<sup>[13-15,20-23]</sup>.

Complicated appendicitis was initially considered as a contraindication to laparoscopic appendectomy<sup>[32,33]</sup>. However, recent studies have shown that laparoscopic approach in complicated disease is feasible and may even be superior to the conventional approach<sup>[6,7,10]</sup>.

In our series, 28.5% patients in the open group and 29.7% in the laparoscopic group had complicated disease. These patients are considered to be at increased risk of postoperative infections such as wound infection and intra-abdominal abscess formation<sup>[34,35]</sup>. According to the Cochrane systemic review of the literature<sup>[24]</sup>, wound infection is about one-half after laparoscopic appendectomy, while intra-abdominal abscess formation is 3 times higher after laparoscopic appendectomy.

In the present study, the rate of wound infection in patients with complicated disease was significantly lower after laparoscopic appendectomy (5.3% vs 12.8%,  $P = 0.03$ ). Placement of the detached appendix into an endobag before its removal from the abdominal cavity reduces contact with the fascial surfaces and minimizes contamination.

Intra-abdominal abscess formation was more common after laparoscopic appendectomy in complicated disease (5.3% vs 2.1%,  $P = 0.002$ ). It has been suggested that carbon dioxide insufflation may promote mechanical spread of bacteria in the peritoneal cavity, especially in cases of ruptured appendix<sup>[21,36-38]</sup>. In order to decrease the bacterial load and hence the risk of abscess formation, we advocate extensive irrigation of the abdominal cavity. However, in our practice, we observed that meticulous irrigation was unnecessary and even more dangerous as it leads to contamination of the entire abdominal cavity, which is difficult to aspirate latter. That was the case in two patients with severe peritonitis where intra-abdominal abscess formation occurred. Ever since we have changed our practice to simple suctioning of the infected area, we have not observed any postoperative abscess formation, even in patients with severe peritonitis.

The higher cost of laparoscopic appendectomy compared to the conventional technique is considered as an obstacle to its greater use. However, hospital charges for laparoscopic appendectomy have reduced

dramatically over the past several years<sup>[39]</sup>. Surgical expertise and the abundance of laparoscopic equipment have significantly reduced the economical mismatch in favor of the conventional technique. In addition, Moore and coworkers, using a decision analysis model, have demonstrated an economic benefit of laparoscopic appendectomy from a social perspective, since shorter hospital stay and earlier return to daily activities is very important, especially for patients who are young and lead a productive life<sup>[40]</sup>.

In the present study, the operative costs for laparoscopic appendectomy were only 370 € higher. The greater cost of laparoscopic appendectomy observed in various studies<sup>[3,14,25]</sup> can be attributed to the use of disposable laparoscopic instruments and the longer operative time. In our series, we were able to minimize the operative costs, mainly by employing reusable laparoscopic instruments.

Although there is no consensus with regard to the advantages of the laparoscopic approach compared to the conventional technique, the use of laparoscopic appendectomy has increased significantly in the last several years. In the present study, we were able to demonstrate the superiority of the laparoscopic approach in terms of hospital stay and wound infection, with only marginally higher hospital costs. Although the incidence of intra-abdominal abscess formation was higher after laparoscopic appendectomy, all complications occurred early in our practice. Greater experience and improvements in our technique has made it possible to eradicate this catastrophic complication.

Provided that surgical experience and equipment are available, laparoscopic appendectomy is safe and equally efficient compared to the conventional technique. However, as long as there is no consensus to the best approach for appendicitis, the choice of the procedure will be based on the preference of the surgeons and patients.

## COMMENTS

### Background

Laparoscopic surgery has been available for a long time. Today, even the most complicated procedures can be performed laparoscopically. However, laparoscopic appendectomy, a relatively easy procedure, has not gained wide acceptance among surgeons, and the conventional technique remains the procedure of choice in many centres worldwide.

### Research frontiers

Intra-abdominal abscess formation is the most catastrophic complication of laparoscopic appendectomy. By simple suctioning of the infected area, rather than using widespread irrigation we were able to decrease the incidence of postoperative abscess formation.

### Innovations and breakthroughs

In the present study, we were able to demonstrate that laparoscopic appendectomy is superior to the conventional technique in terms of hospital stay and wound infection. Additionally, in expert hands, even the most serious complications such as an intra-abdominal abscess formation can be minimized. Furthermore, in the present study, we were able to decrease medical costs by employing reusable laparoscopic equipment.

### Applications

The present study has shown that laparoscopic surgery should be considered in every patient with appendicitis.

### Peer review

The authors demonstrated a prospective study of laparoscopic versus open appendectomy and concluded "Provided that surgical experience and equipment are available, laparoscopic appendectomy is safe and equally efficient alternative to conventional technique." This present study is an interesting and novel.

## Abstract

**AIM:** To elucidate the relationship between the microvessel count (MVC) by CD34 analyzed by immunohistochemical method and prognosis in hepatocellular carcinoma (HCC) patients who underwent hepatectomy based on our preliminary study.

**METHODS:** We examined relationships between MVC and clinicopathological factors in 128 HCC patients. The modified Japan Integrated Staging score (mJIS) was applied to examine subsets of HCC patients.

**RESULTS:** Median MVC was 178/mm<sup>2</sup>, which was used as a cut-off value. MVC was not significantly associated with any clinicopathologic factors or postoperative recurrent rate. Lower MVC was associated with poor disease-free and overall survivals by univariate analysis ( $P = 0.039$  and  $P = 0.087$ , respectively) and lower MVC represented an independent poor prognostic factor in disease-free survival by Cox's multivariate

analysis (risk ratio, 1.64;  $P = 0.024$ ), in addition to tumor size, vascular invasion, macroscopic finding and hepatic dysfunction. Significant differences in disease-free and overall survivals by MVC were observed in HCC patients with mJIS 2 ( $P = 0.046$  and  $P = 0.0014$ , respectively), but not in those with other scores.

**CONCLUSION:** Tumor MVC appears to offer a useful prognostic marker of HCC patient survival, particularly in HCC patients with mJIS 2.

## INTRODUCTION

Hepatic resection is a useful option for radical treatment of hepatocellular carcinoma (HCC). However, recurrence rate after resection remains high<sup>[1,2]</sup>. Patient survival thus remains unsatisfactory due to high recurrence rate even at this stage. Clinicopathological factors in HCC are related to tumor recurrence<sup>[3]</sup> and tumor biological characteristics provide useful information regarding the activity of HCC. According to previous reports, candidates for tumor biological factors and molecular markers include abnormal expression of p53<sup>[4]</sup>, nm23 (a tumor suppressor gene)<sup>[5]</sup>, tumor angiogenesis<sup>[6]</sup>, proliferative activity<sup>[7]</sup>, growth factors<sup>[8]</sup>, DNA ploidy<sup>[9]</sup> and other molecular markers<sup>[10]</sup>. Some of

these markers are related to prognosis in HCC patients. Combination of conventional clinicopathological factors and prognostic factors of tumor biology may improve prediction of prognosis after hepatectomy for HCC and may contribute to a new staging classification.

Tumor angiogenesis may be important to support tumor growth<sup>[11]</sup>, and HCC is a hypervascular tumor expressing several angiogenic factors<sup>[12]</sup>. Levels of angiogenic factors such as vascular endothelial growth factor (VEGF) or basic fibroblast growth factor (b-FGF) are increased in HCC and might affect patient survival<sup>[12,13]</sup>. Recent studies have also shown that microvessel density (MVD) in HCC or non-cancerous liver surrounding tumor correlates with tumor aggressiveness and prognosis<sup>[6,14-16]</sup>. We have previously provided a preliminary demonstration of the comprehensive analysis of various biological factors, revealing that microvessel count (MVC) using CD34 antibody was independently associated with poor prognosis in HCC patients undergoing hepatic resection by multivariate analysis<sup>[17]</sup>. However, contrary to other reports, poor patient prognosis was related to lower MVCs. We hypothesize that hypovascularity in HCC represents a factor associated with treatment-resistance such as chemoembolization, which causes poor prognosis.

The present study examined the relationship between MVC in HCC using immunohistochemical stains and conventional clinicopathological factors and prognosis in a larger number of HCC patients with longer follow-up period to clarify our hypothesis. Furthermore, we examined this relationship in subsets of patients after applying the modified Japan Integrated Staging score (mJIS).

## MATERIALS AND METHODS

### **Patients**

HCC specimens from 128 patients (104 men, 24 women) were obtained during surgery on patients admitted to the Division of Surgical Oncology at Nagasaki University Graduate School of Biomedical Sciences (NUGSBS) between 1990 and 2005. Mean age for patients at the time of surgery was  $62.9 \pm 8.2$  years (range, 28-78 yr). Prior to surgery for HCC, 36 patients (28.1%) were treated using either chemoembolization ( $n = 30$ ) or local ablation ( $n = 6$ ), including alcohol injection in 2 patients and radiofrequency ablation (RFA) in 4 patients. After surgery, 3 patients (2.3%) received adjuvant 5-fluorouracil chemotherapy by intra-arterial injection through a subcutaneously implanted reservoir. Child-Pugh classification was B in 11 patients (8.6%) and A in 117 patients. The liver damage grade by the Liver Cancer Study Group (LCSG) of Japan in 2000 was B in 26 patients and A in 102 (Table 1)<sup>[18]</sup>. The operative procedures included lobectomy or extended lobectomy ( $n = 54$ ), segmentectomy or subsegmentectomy ( $n = 43$ ) and partial resection ( $n = 31$ ). Radical hepatectomy was performed to remove hepatic tumor without leaving any residual tumor. All hepatic tumors were completely

resected without macroscopic exposure of the amputated section to the remaining liver. The present series included no in-hospital deaths and the only causes of death were cancer-related. Minimum follow-up period after hepatic resection of HCC was 24 mo.

We used the classification system of the General Rules for the Clinical and Pathological Study of Primary Liver Cancer<sup>[19]</sup>. This system provides a clinicopathological evaluation of HCC. Macroscopic classification as described by Classification of Primary Liver Cancer<sup>[19]</sup> was also applied in the study. All study protocols were approved by the Human Ethics Review Board of our institution. Informed consent for data collection was obtained from each patient during this period. Anesthetic and patient data were retrieved from the NUGSBS database.

### **Immunohistochemical staining**

Resected specimens were fixed in 10% formalin and embedded in paraffin. Thin sections (4  $\mu$ m) were deparaffinized twice using xylene and rehydrated in a series of ethanol solutions (100%, 90% and 80%). Sections were placed in 0.01 mol/L trisodium citrate dehydrate buffer (pH 6.0) and treated in a microwave oven for 10 min at 500 W. For CD34 staining<sup>[17,20]</sup>, tissue sections were digested with 0.2% trypsin in 0.01 mol/L phosphate-buffered saline (PBS) for 20 min at 37°C. In the next step, tissues were immersed in 3% H<sub>2</sub>O<sub>2</sub> with distilled water for 10 min to inactivate endogenous peroxidases. After blocking non-specific binding by normal goat serum, sections were incubated overnight at 4°C with mouse anti-monoclonal CD34 antibody (1:25; QB-END/10, Novocastra Laboratories, Newcastle, United Kingdom) as the primary antibody. This was followed by reaction with biotinylated anti-immunoglobulin and reagent using labeled streptavidin-biotin (LSAB) kit peroxidase (Dako, Carpinteria, CA). The peroxidase reaction was visualized with 0.01% H<sub>2</sub>O<sub>2</sub> and 3,3'-diaminobenzidine under light microscopy ( $\times 200$ ). For MVCs using CD34 staining, average count was determined in the 5 most-vascular areas in the HCC examined at 200  $\times$  magnification<sup>[17,20]</sup>. Two pathologists blindly assessed each slide.

**Table 2 Definition and criteria of TNM stage for HCC according to the Liver Cancer Study Group of Japan<sup>[18]</sup>**

Criteria for TNM categories	
(1) Number of tumors:	1
(2) Tumor size:	≤ 2 cm
(3) No vascular or bile duct invasion	
T category	T1: Fulfilling all three criteria T2: Fulfilling two criteria T3: Fulfilling one criterion T4: Fulfilling none of the criteria
N category	N0: Absence of lymph node metastasis N1: Presence of lymph node metastasis
M category	M0: Absence of distant metastasis M1: Presence of distant metastasis
Stage I	T1 N0 M0
Stage II	T2 N0 M0
Stage III	T3 N0 M0
Stage IV-A	T4 N0 M0 or T1-T4, N1M0
Stage IV-B	T1-4, N0 or N1, M1

TNM: tumor-node-metastasis.

### Staging criteria for the mJIS

We used the pathological tumor-node-metastasis (pTNM) classification system as defined by the Liver Cancer Study Group (LCSG) of Japan in 2000<sup>[18]</sup>. T category was determined based on 3 factors: number, size, and vascular or bile duct invasion. N category was determined as the presence of lymph node metastasis, while M category represented the presence of distant metastases. TNM staging comprises 4 stages based on the combination of T, N, and M categories (Table 2). The original Japan Integrated Staging score proposed by Kudo *et al*<sup>[21]</sup> comprised the sum of scores for the two variables of Japanese TNM classification and Child-Pugh classification. In the mJIS proposed by our institute<sup>[18,22]</sup>, Child-Pugh classification was replaced by the score for liver damage grade as defined by the LCSG of Japan (Table 3).

### Statistical analysis

Continuous data are expressed as mean ± standard deviation. Data from different groups were compared using one-way analysis of variance (ANOVA) and examined by Student's *t*-test or Dunnett's multiple comparison test. For univariate analysis, categorical data were analyzed using Fisher's exact test. Disease-free and overall survival rates were calculated according to the Kaplan-Meier method, and differences between groups were tested for significance using the log-rank test.

Multivariate analysis was performed using proportional hazards regression modeling. A two-tailed value of *P* < 0.05 was considered statistically significant. All statistical analyses were performed using SAS software (Statistical Analysis System, Cary, NC).

## RESULTS

Among the 128 patients in the present study, disease-free 1-, 3-and 5-year survival rates were 63%, 39% and 29%, respectively, and median disease-free survival was 3.5 years. Overall 1-, 3-and 5-year survival rates were 89%, 65% and 48%, respectively, and median overall survival was 5.9 years. Of 94 patients (75.0%) who displayed tumor recurrence after hepatectomy, 85 (90.4%) received chemoembolization (*n* = 81) or alcohol injection (*n* = 4).

Median MVC within the tumor area was 178/mm<sup>2</sup>, and this value was applied as a cut-off value. Table 4 shows the relationship between MVC and clinicopathological features in 128 HCC patients. However, MVC was not significantly associated with any clinicopathological factors, TNM stage or postoperative recurrence.

Figure 1 shows disease-free and overall survival after hepatectomy compared to MVC. Disease-free survival rate was significantly lower in patients with lower MVC than in patients with higher MVC (*P* = 0.039). Overall survival rates tended to be lower in patients with lower MVC than in patients with higher MVC, but this difference was not significant. Table 5 shows the results of multivariate analysis for disease-free and overall survival after hepatectomy for various factors identified as displaying significant associations on univariate analysis. Multiple tumors, vascular involvement of the tumor, liver damage grade B and lower MVC represented independent risk factors for poor disease-free survival after hepatectomy (*P* = 0.0004, 0.003, 0.007 and 0.024, respectively). Multiple tumors, vascular involvement of the tumor and macroscopic findings were identified as independent risk factors for poor overall survival after hepatectomy (*P* = 0.025, 0.014 and 0.017, respectively), whereas MVC was not associated with overall survival (*P* = 0.266).

Figure 2 shows disease-free survival by comparing MVC for each mJIS score. In HCC with mJIS 0 or 1, MVC was not associated with disease-free survival. Lower MVC was significantly associated with poor disease-free survival in HCC with mJIS 2. Lower MVC tended to be associated with poor disease-free survival in HCC with mJIS ≥ 3, but this result was not significant. Figure 3 shows overall survival by comparing MVC at each mJIS score. In HCC with mJIS 0, 1 or ≥ 3, MVC was not associated with overall survival. Lower MVC was significantly associated with poor disease-free survival in HCC with mJIS 2.

## DISCUSSION

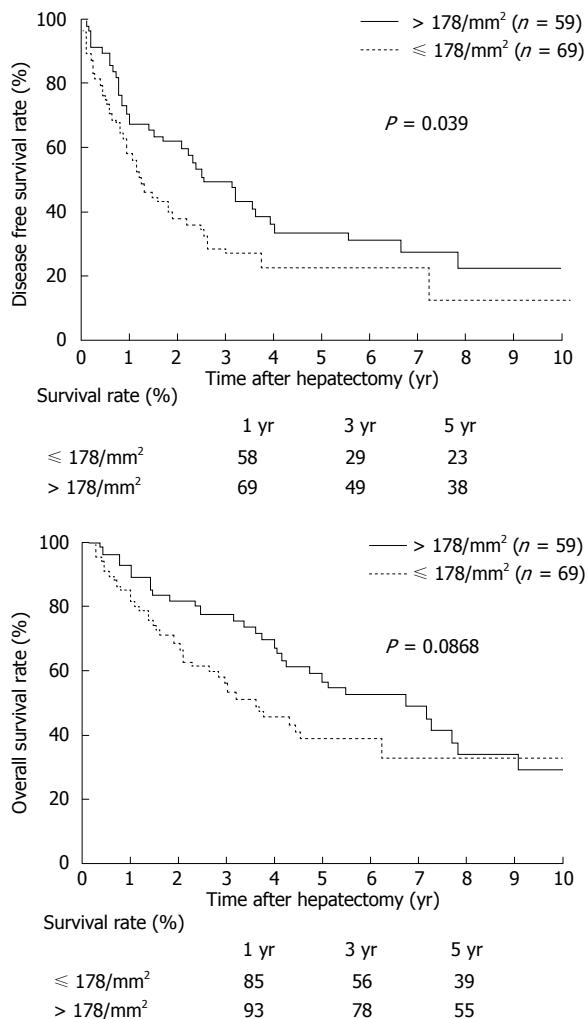

Previous studies have investigated prognostic factors in HCC for patients who underwent radical hepatectomy

<sup>1</sup>Macroscopic classification by Liver Cancer Study Group of Japan<sup>[19]</sup>; <sup>2</sup>The General Rules for the Clinical and Pathological Study of Primary Liver Cancer<sup>[18]</sup>. SN: Single nodular; SNEG: Single nodular with extranodular growth; CMN: Confluent multinodular group.

and in whom tumor stage had been determined<sup>[23,24]</sup>. The International Union against Cancer (UICC) and Japanese TNM classification systems for predicting patient prognosis in HCC did not provide good reflection of patient survival in HCC patients<sup>[25,26]</sup>. Combined staging systems with hepatic function have recently been applied<sup>[21,22,27,28]</sup>, and among these, the JIS score system was applied in Japan<sup>[21]</sup>. Child-Pugh classification was used in this system, but liver damage grade by the LCGS of Japan offers a better reflection of patient survival<sup>[18,29]</sup>. The mJIS score system thus includes liver damage grade and has been applied in a few reports<sup>[22]</sup>. The present study also applied mJIS score. In the next step, a staging system for HCC may need additional useful factors comprising tumor biological or molecular markers. The present study identified angiogenic factors of MVC

**Figure 1** Relationship between microvessel count (MVC) and disease-free and overall survival in patients with hepatocellular carcinoma (HCC) who underwent hepatic resection.

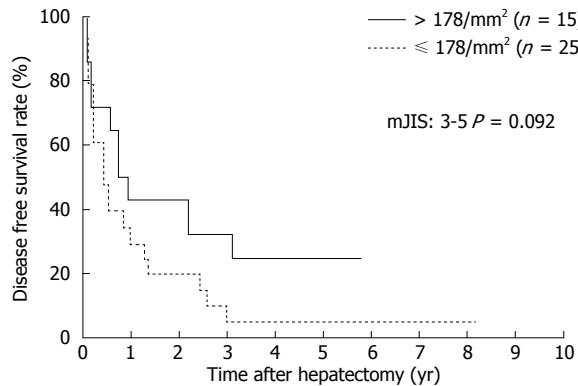

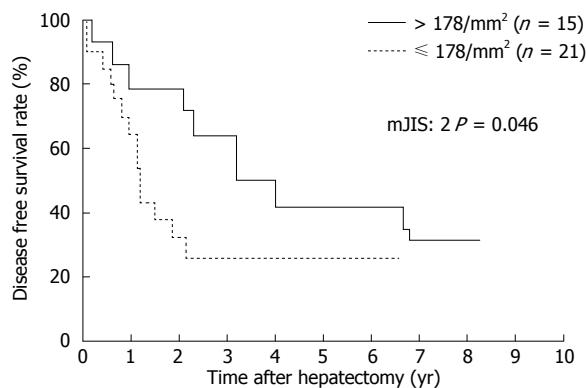

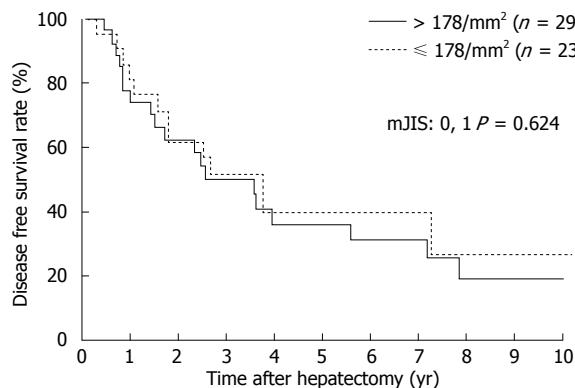

as potentially useful. In the last decade, microvessel density using CD34 as a prognostic parameter in HCC patients has been reported and appears consistently very useful<sup>[6,16,30,31]</sup>. We also performed a preliminary study of the significance of MVC for survival in HCC patients and, unlike other reports, revealed hypovascularity (i.e., lower MVC) as a poor prognostic parameter<sup>[17]</sup>.

MVC was not associated with any clinicopathological factors or recurrence rate after hepatectomy in either the present study or our pilot study<sup>[17]</sup>. In contrast to our results, El-Assal *et al*<sup>[30]</sup> and other investigators<sup>[6,14,15,30-32]</sup> have reported that microvessel density in HCC is increased in larger tumors, tumors with poor differentiation and cirrhotic patients, while higher microvessel density is associated with intra-hepatic recurrence. In the present study, however, MVC did not correlate with co-existing cirrhosis or with various etiological factors related to chronic hepatitis such as viral status. Conversely, Sun *et al*<sup>[33]</sup> found no relationship between MVC and either clinicopathological factors or patient prognosis. The relationship between tumor vascularity and clinicopathological features thus remains controversial. Increased micro-angiogenesis is definitely

**Table 5** Multivariate analysis by Cox's proportional hazard test of prognostic factors influencing disease-free survival and overall survival in HCC after hepatectomy

	Disease-free survival			Overall survival		
	Risk ratio	95% CI	P	Risk ratio	95% CI	P

**Figure 2** Relationship between MVC and disease-free survival using the modified Japan Integrated Staging score (mJIS) in HCC patients who underwent hepatic resection.

associated with carcinogenesis of HCC and development

**Figure 3** Relationship between MVC and overall survival using the mJIS in HCC patients who underwent hepatic resection.

to advanced tumor<sup>[12,32]</sup>. At the stage of smaller-sized HCC, tumor vascularity is already rich on computed

tomography or enhanced ultrasonography<sup>[34,35]</sup>. Considering the mechanisms of HCC characterized above, increased microvessel density of the tumor is a logical result. When tumor demonstrates a large tumor size or poor histologic differentiation, tumor vascularity may be decreased. Previous reports also showed that HCC tumor vascularity decreased with the progression of histopathological grade<sup>[36,37]</sup>. Our results showed that lower MVC tended to be higher in poorly differentiated HCC, but this finding was not significant. A larger sample of poorly differentiated HCCs is needed to clarify this issue, as only 6 cases were included in the present series.

With respect to disease-free and overall survival after hepatectomy<sup>[1,2,6,24]</sup>, the results from our series were favorable. Counts  $\leq 178/\text{mm}^2$  for HCC were associated with worsened prognosis in patients undergoing hepatectomy, particularly in disease-free survival by univariate and multivariate analysis in the present study. Compared to other independent risk factors, the odds ratio was lower for MVC than for other factors such as a number of tumors, vascular involvement, macroscopic findings or liver damage grade. The role of MVC for tumor relapse or progression might not be particularly strong. This result contradicts findings in other reports described above<sup>[6,14,16,30,31]</sup>. As explained above, HCC naturally acquires rich tumor vascularity in the early stages and most clinically treated HCCs represent tumor with radiological enhancement<sup>[34,35,38]</sup>. Hypervascularity is observed in the majority of HCC<sup>[36]</sup>. As tumor vascularity decreases in HCC with deterioration of histological differentiation and/or aggressive invasiveness<sup>[36,37]</sup>, the malignant potential of hypovascular HCC could increase relative to that of hypervasculary HCC, thus leading to poorer prognosis. In cases of hypervasculary HCC, initial or recurrent tumor can be observed in earlier stages under various imaging modalities, and treatments combined with chemoembolization or chemotherapy via tumor microvessels may well prove effective<sup>[39]</sup>. We speculate that hypovascular HCC is difficult to detect by conventional imaging and to treat by chemoembolization or other therapy, and treatment selection is therefore limited. Previous studies showed that tumor vascularity correlates with the response to chemotherapy, which in turn correlates with survival<sup>[40-42]</sup>. Furthermore, tumor hypervascularity, which is observed in most HCC, correlated with good response to chemoembolization, whereas hypovascular HCC did not correlate with good response to chemoembolization<sup>[40,41]</sup>. Thus, a better response to arterial chemoembolization is associated with prolonged survival<sup>[40,41]</sup>. In our series, most patients with postoperative recurrence of HCC received arterial chemoembolization and, therefore, the prognosis of these patients could have been influenced by tumor vascularity and response to chemoembolization. Although we could not provide such evidence in recurrent tumors in our follow-up study, it is possible that the vascularity of primary HCC could influence the biological characteristics of recurrent HCC. For these

reasons, the survival of patients with hypovascular HCC logically would be worse after recurrence. Our results concerning MVC are thus biologically quite feasible. Anti-angiogenic therapy is a promising treatment for HCC<sup>[43]</sup>; however, the response of hypovascular HCC to such treatment remains problematic.

In addition to tumor-associated factors, hepatic functional reserve and liver function after surgery influence postoperative prognosis<sup>[3,6,44]</sup>. In the present series, we applied mJIS score to examine subsets of HCC patients. Poon *et al*<sup>[6]</sup> also reported that the significance of MVC differed between subsets of HCC patients. Our results showed no marked differences in disease-free and overall survival according to MVC in the early stage of mJIS 0 or the advanced stage of mJIS 3-5. A significant difference in MVC was only observed for mJIS 2. Poon *et al*<sup>[6]</sup> found microvessel density by CD34 as the only significant factor predictive of disease-free survival in patients with HCC (5 cm, but no significant prognostic influence was seen for larger HCC). In early-stage HCC, tumor can be sufficiently cured by hepatic resection even in the presence of malignant potential. Conversely, in severely advanced HCC, other significant prognostic factors might exert greater influence on tumor aggressiveness and survival, such as number of tumors, vascular involvement, macroscopic findings or liver damage grade, as indicated in the present study. For mJIS 2, patient survival with hepatic resection or ablation therapy was not particularly satisfactory compared to mJIS 0 or 1 according to our recent report<sup>[45]</sup>. In this stage of mJIS 2, treatment indications need to be defined according to the appropriate prognostic factors. In cases where lower vessel count was observed at initial resection, liver transplantation following recurrence may be a good option. Our results showed that MVC did not correlate with other clinicopathological parameters and is an independent risk factor for prognosis. Thus, according to the present results, MVC would represent a useful parameter to decide treatment modality.

In conclusion, we have demonstrated that lower MVC by CD34 in HCC offers an independent predictor of disease-free and overall survival in patients with HCC, particularly in HCC with mJIS 2. As a tumor biological factor, MVC representing tumor angiogenesis offer a new candidate prognostic factor in HCC to predict tumor recurrence and patient survival in combination with traditional pathological factors. Furthermore, this marker can be applied as a predictive marker to select molecular targeting treatments in future.

## COMMENTS

### Background

Tumor biological characteristics provide useful information on the activity of hepatocellular carcinoma (HCC). The combination of conventional clinicopathological factors and prognostic factors related to tumor biology may improve prediction of prognosis of patients with HCC. HCC is a hypervasculary tumor that expresses various tumor angiogenic factors. Microvessel density (MVD) in HCC may correlate with tumor aggressiveness and prognosis.

### Research frontiers

Tumor angiogenesis may be important for tumor growth. High levels of

angiogenic factors such as vascular endothelial growth factor (VEGF) and basic fibroblast growth factor (b-FGF) have been described in HCC, and they correlate with patient survival. Microvessel counts (MVC) in HCC or non-tumorous liver tissue that surrounds HCC correlate with tumor aggressiveness and prognosis. On the other hand, it should be difficult to chemoembolize hypovascular HCC. Therefore, we hypothesized that low MVCs correlates with poor prognosis.

### Innovations and breakthroughs

Our results presented new findings that were different than studies published previously by other investigators. However, we found that a low MVC is an independent prognostic factor for tumor relapse. This was particularly significant in HCC patients with mJIS 2.

### Applications

MVC could be a potentially useful marker of prognosis in HCC by predicting tumor recurrence and patient survival, in addition to traditional pathological factors. Furthermore, MVC could help in clinical decision making with respect to the selection of treatment modality.

### Peer review

Our study identified a novel prognostic factor that can be used to predict tumor recurrence and survival of patients with HCC. This marker can be potentially used to select the most appropriate surgical treatment modality, such as a liver transplantation particularly in patients with mJIS 2.

## INTRODUCTION

Crohn's disease (CD) and ulcerative colitis (UC), the two common forms of idiopathic inflammatory bowel disease (IBD), are chronic, relapsing inflammatory disorders of the gastrointestinal tract. CD and UC are very common in developed countries with a prevalence of 0.7-11.6 per 100 000 and 2.0-14.3 per 100 000, while it is relatively uncommon in Asian countries with a prevalence of 0.08 per 100 000 and 0.5 per 100 000 in Japan<sup>[1]</sup>. However, the incidence of IBD has been increasing in some Asian countries in recent years, and China is one of the notable countries<sup>[2]</sup>.

The precise etiology of the disease is unknown, but interplay of environmental risk factors and immunologic changes will trigger the onset of the disease in a genetically susceptible host. Epidemiological studies in the past suggested a genetic susceptibility that has been confirmed by total genome scans and candidate gene studies. After the IBD1 locus in the chromosome 16 was identified as a CD locus by Hugot *et al*<sup>[3]</sup>, fine mapping of the IBD1 locus and following candidate gene approach led people to identify the *CARD15* (previously *NOD2*) as a susceptibility gene of CD. The *NOD2/CARD15* gene product is expressed in monocytes. It is involved in the binding of bacteria lipopolysaccharides and peptidoglycans so that it played an important role in activation of nuclear transcription factor kappa-B (NF-κB) in inflammatory response. Two missense mutations Arg702Trp (2104C→T), Gly908Arg (2722G→C) and one frame-shift mutation (3020insC) of the *NOD2/CARD15* gene affecting the function of binding microbial pathogens are independently associated with the development of CD<sup>[4]</sup>.

Numerous genome-wide scans and replication studies have identified IBD susceptibility loci since the initial

## Abstract

**AIM:** To investigate the single nucleotide polymorphism (SNPs) distribution of NOD2/CARD15 (R702W, G908R), OCTN1 1672C/T and OCTN2-207G/C in Chinese patients with inflammatory bowel disease (IBD).

**METHODS:** A total of 61 patients with Crohn's disease (CD), 151 patients with ulcerative colitis (UC), and 200 unrelated healthy controls were genotyped. Genotyping was performed by sequence specific primer polymerase chain reaction (PCR-SSP) or by restriction fragment length polymorphism (PCR-RFLP) analysis.

**RESULTS:** Among the subjects in our study groups, including patients with CD, UC and healthy controls, none had OCTN and CARD15 variants and very rare IBD family history was found in our patients with the percentage of 0 (0/61 with CD) and 1.3% (2/151 with UC).

**CONCLUSION:** Our results indicate that although OCTN or CARD15 variation is associated with susceptibility to IBD in Western populations, these might be rare and may not be associated with susceptibility to IBD in Chinese patients.

**Key words:** Inflammatory bowel disease; Ulcerative colitis; Crohn's disease; CARD15; Carnitine/organic cation transporter gene

study was published in 1996 by Hugot *et al*<sup>[3]</sup>. Recent studies suggested that *OCTN* (Carnitine/organic cation transporter gene) 1 and 2 in the IBD5 locus on chromosome 5 both encoded organic cation transporters and revealed significant associations with CD. The *OCTN* family is a family of transporter proteins for organic cations, and may also transport carnitine, an essential cofactor of the metabolism of lipids. *OCTNs* are therefore important in the maintenance of intracellular homeostasis and play an important role in the energy production of the cell. A C1672T substitution in exon 9 of the *OCTN1* gene and a G-207C in the *OCTN2* promoter region were indicated as functional and causative mutations to increase susceptibility to CD<sup>[5]</sup>.

The aim of the present study was to investigate the single nucleotide polymorphism (SNPs) distribution of *NOD2/CARD15* (R702W, G908R), *OCTN1* 1672C/T, *OCTN2*-207G/C and its association with IBD in Chinese patients.

## MATERIALS AND METHODS

### Study population

Blood samples from 61 patients with CD and 151 patients with UC were prospectively collected at the IBD Outpatient Clinic of the first affiliated hospital of Zhongshan University (Guangzhou, Guangdong Province, China) and Xijing Hospital of the Fourth Military Medical University (Xi'an, Shaanxi Province, China) between March 2005 and June 2006. All patients were followed up at least for one year and registered with an integrated clinical and epidemiological registry. A total of 212 healthy controls matched for age, sex and geography were healthy physical examinees in the two hospitals. All patients and healthy controls were of unrelated Chinese Han nationality. The diagnosis of either CD or UC was in accordance with previously established international criteria<sup>[6]</sup> based upon clinical, endoscopic, radiological and histopathological findings. All patients gave informed consent to participate in the study that was approved by the Ethics Committee of Zhongshan University and the Fourth Military Medical University.

### Genotyping

Genomic DNA was extracted from peripheral blood leukocytes using the spin column technique (TIANamp Blood DNA kit, Tiangen Biotech, China).

Gene polymorphisms (R702W, G908R, *OCTN1* 1672C/T, *OCTN2*-207G/C) were determined using the sequence specific primers by polymerase chain reaction (SSP-PCR). Primer sequences and methods are depicted in Table 1. The PCR cycling parameters were a denaturing step at 94°C (3 min); 5 cycles of 94°C (30 s), 70°C (45 s), 72°C (30 s); 18 cycles of 94°C (30 s), 65°C (50 s), 72°C (30 s); 10 cycles of 94°C (30 s), 55°C (1 min), 72°C (1 min); and a final elongation step of 72°C (10 min). The PCR products were electrophoresed on 2% agarose gels containing ethidium bromide and viewed under ultraviolet light.

Restriction fragment length polymorphism (RFLP)

**Table 1** Primer sequences for SSP-PCR genotyping

SNP	Primers	PCR product (bp)
<i>OCTN1</i> 1672C/T (rs1050152)	W: TCTGACTGTCTGATTGGA ATCC	Allel C: 518 bp
	S: TAGTCTGACTGCTCTGATT CGAACACT C: TTTGAGACGGAGTT TGCTTGT	Allel T: 520 bp
<i>OCTN2</i> -207G/C (rs2631367)	W: GCACGACCAGGGAAGGTTC	Allel G: 493 bp
	S: GCACGACCAGGGAAGGTTC C: TCCCAGCCTCTCTAC TAGGGTAGTT	Allel C: 493 bp
R702W 2104C/T (rs2066844)	W: CTGAGAAGGCCCTGCTCC	Allel C: 396 bp
	S: CATCTGAGAAGGCCCTGCTCT C: CAATGCCAGTAAC ACTCACTACAG	Allel T: 399 bp
G908R 2722G/C (rs2066845)	W: TGGCCTTTCAGATTCTGGG	Allel G: 308 bp
	S: TGGCCTTTCAGATTCTGGC C: TGTATCAAAACCCCTG AGAGGACAA	Allel C: 308 bp

and sequencing were performed as means of verifying the PCR results. Five samples were chosen from each allele (including homozygous wild-type, heterozygous SNP and homozygous SNP) to perform RFLP and sequencing. Sequencing was performed by AuGCT Corporation of Beijing. The primers of sequencing were the same with RFLP. RFLP was performed as follows: (1) PCR amplification: initially a denaturing step at 96°C (1 min); 25 cycles of 96°C (30 s), 70°C (40 s), 72°C (30 s); 10 cycles of 96°C (30 s), 65°C (30 s), 72°C (30 s); and a final elongation step of 72°C (10 min). (2) RFLP: 10 μL of the PCR products mixed with 2 μL 10 × buffer and 2 μL restriction enzyme, then adding water to 30 μL, incubated for 12 h at 37°C and electrophoresed on 20% non-denaturing polyacrylamide gels, finally viewed under ultraviolet light after stained with ethidium bromide solution for 30 min. Primer sequences and restriction enzymes are depicted in Table 2.

The results of gene sequence and RFLP are identical. The result of SSP-PCR about G908R and *OCTN2*-207G/C was consistent with sequence and RFLP, so we chose 30 samples to perform RFLP and obtained the same result. But the result of SSP-PCR about R702W and *OCTN1* 1672C/T was not consistent with sequence or RFLP, so we changed all samples to perform RFLP.

### Statistics analysis

Comparison between cases and controls was made using the Chi-square test for categorical data with the SPSS software ver.13.0.

## RESULTS

In this study, we first performed genotyping by SSP-PCR with less cost and time than RFLP or sequencing. But the shortage of SSP-PCR is easy to result in false positivity. So after we completed the SSP-PCR, we used

**Table 2** Primer sequences and restriction enzymes used for RFLP genotyping

SNP	Primers	Restriction enzyme	Length of restriction fragments
OCTN1 1672C/T (rs1050152)	F: CGTCATGGTAGTCTGACTGTCCGTATTGGGATC R: TCCTACTTACCATTTCACTTCTGCATCTGCTTAAGG	BamH I	Allel C: 30 + 88 bp Allel T: 118 bp

**Table 3** Demographics and phenotype of IBD patients

	CD patients (n = 61)	UC patients (n = 151)
Sex (M:F)	40:21	91:60
Median age (yr, mean ± SD)	36.9 ± 13.7	43.8 ± 13.4
Patients with relative(s) who have IBD	0	2 (1.3%)
Location of CD	Location of ulcerative colitis	
Small bowel only (%)	25 (41.0)	Rectum sigmoid colon 86 (57.0)
Colon only (%)	7 (11.5)	Left hemicolon 18 (11.9)
Small bowel & colon (%)	29 (47.5)	Extensive 47 (31.1)
Behaviour of Crohn's disease (%)		Severe criteria of ulcerative colitis
Non-stricturing, non-penetrating (%)	26 (42.6)	Mild 74 (49.0)
Penetrating (%)	15 (24.6)	Moderate 57 (37.7)
Stricturing (%)	19 (31.1)	Severe 20 (13.2)
Stricturing & penetrating (%)	1 (1.6)	

RFLP and sequencing to verify the result. The SSP-PCR results of G908R and *OCTN2*-207G/C were consistent with RFLP or sequencing so that the SSP-PCR is successful in genotyping these alleles. On the contrary, we failed to genotype alleles of R702W and *OCTN1* 1672C/T by SSP-PCR, we therefore changed to use RFLP which had been used to detect polymorphism for a long time with reliable result.

We found very rare IBD family history in our patients with the percentage of 0 (0/61 with CD) and 1.3% (2/151 with UC). The demographics and phenotype of the IBD patients are described in Table 3.

As shown in Table 4, we found that the four SNPs, *OCTN1* 1672C/T, *OCTN2*-207G/C, R702W and G908R were completely absent in the Chinese Han nation population, in either the IBD patients or the control group. These results demonstrated that *OCTN* and *CARD15* variations might be rare and may not be associated with susceptibility to IBD in Chinese patients of Han nation.

## DISCUSSION

In the present study, we found that the polymorphism of C1672T in exon 9 of *OCTN1*, G-207C in the

**Table 4** Genotype and allele results

SNP	Group	Cases	Genotype			Allele	
			C/C	C/T	T/T	C	T
<i>OCTN1</i> 1672C/T (rs1050152)	CD	61	61	0	0	122	0
	UC	151	151	0	0	302	0
	Control	200	200	0	0	400	0
<i>OCTN2</i> -207G/C (rs2631367)	CD	61	61	0	0	122	0
	UC	151	151	0	0	302	0
	Control	200	200	0	0	400	0
<i>R702W</i> 2104C/T (rs2066844)	CD	61	61	0	0	122	0
	UC	151	151	0	0	302	0
	Control	200	200	0	0	400	0
<i>G908R</i> 2722G/C (rs2066845)	CD	61	61	0	0	122	0
	UC	151	151	0	0	302	0
	Control	200	200	0	0	400	0

*OCTN2* promoter region, and 2104C/T(R702W), 2722G/C(G908R) in *CARD15* were completely absent in Chinese patients with IBD and healthy controls. The study suggested that the four SNPs might not play a role in susceptibility of IBD in Chinese patients, thereby differing from the case of Western populations, but consistent with the results in Asian population. In our study, there were 212 IBD patients (61 CD, 151 UC) and 200 healthy controls. Compared with the studies in the Chinese population before, we had the largest number of cases. In Asia, it was the first study to detect the polymorphism of *OCTN* in UC patients.

In the last ten years, there have been tremendous researches on genetic susceptibility of inflammatory bowel diseases (IBD) and over 10 chromosomal regions have been identified by genome-wide scanning. The regions on chromosomes 16, 12, 6, 14, 5, 19 and 1 have been renamed IBD 1-7, respectively<sup>[7]</sup>. Further fine mapping as well as candidate gene studies have already led to the identification of a number of susceptibility genes including *CARD15*, *DLG5*, *OCTN1* and 2, *NOD1*, *HLA*, *TLR4*, *TNF-α*, *IL-1RA*, and *ICAM-1*<sup>[8]</sup>. The *CARD15* gene is undoubtedly replicated most widely at present. The three *NOD2/CARD15* variant alleles, Arg702Trp, Gly908Arg and 3020insC were found to increase the risk of CD in Caucasians, including those from Germany, England<sup>[9]</sup>, Australia<sup>[10]</sup> and America<sup>[11]</sup>. When *OCTN1* and 2 were reported to be associated to IBD, the west-

ern countries such as Canada<sup>[5]</sup>, England<sup>[12]</sup>, German<sup>[13]</sup>, Greek<sup>[14]</sup>, Spain<sup>[15]</sup> and New Zealand<sup>[16]</sup> carried out experiments and proved that the SNPs of *OCTN1* and 2 independently or the haplotype OCTN-TC (SNPs of *OCTN1* and 2 create a two-allele risk haplotype, TC) were positively associated with IBD (with CD only in most studies). On the contrary, studies performed in Asian population differed from the case in Caucasians. The three NOD2 mutations were proved to be totally absent in the studies of Yamazaki *et al*<sup>[17]</sup> in Japan with 483 CD patients, Lee *et al*<sup>[18]</sup> in Korea with 128 CD and 47 UC by sequencing, and Leong *et al*<sup>[19]</sup> in Hong Kong with 65 CD and 63 UC, Gao *et al*<sup>[20]</sup> in Zhejiang University of China with 32 CD and 110 UC by SSP-PCR. Guo QS in Wuhan University of China found Two heterozygotes of the 3020insC mutation in 74 UC patients and one in 15 CD, and only one in healthy controls by SSP-PCR. So they concluded that the NOD2 3020insC mutation was not associated with CD or UC in Hubei Han population<sup>[21]</sup>. Similar to the *CARD* gene, Yamazaki *et al*<sup>[22]</sup> in Japan found the SNPs of *OCTN1* and 2 were completely absent with 484 CD patients and 345 healthy control by means of sequencing. The studies above showed that there was apparent genetic heterogeneity among Caucasians and Asians, so there should be a presence of ethnic differences in susceptibility to IBD in Chinese population.

In our study, familial clustering was rare in IBD patients. Although Chinese, Korean and Japanese races differ, the familial aggregation was similarly rare in IBD patients from the three countries. Does low prevalence of familial clustering and absence of NOD2/CARD15 and OCTN gene variants suggest that genetic factors may play a less important role in the development of IBD in the Asian population? The study of Kim *et al*<sup>[23]</sup> in Korea did not support this point. He found that although a positive family history [21 of 1043 (2.01%) with UC and 6 of 397 (1.51%) with CD] is much lower than that with Western patients, the population relative risk was 13.8 in first-degree relatives, indicating that a positive family history is an important risk factor for IBD in Koreans. Montgomery *et al*<sup>[24]</sup> found that young Asians who were born in Britain are at a significantly higher risk of developing IBD than the indigenous European population with relative odds of 6.1. This may reflect a greater genetic predisposition to IBD when uncovered by exposure to environmental factors. Undoubtedly, genetic susceptibility plays a most important role in the etiology of IBD. Recently, IL23R has been regarded as a milestone in unraveling etiology of CD and SNPs of IL23R was reported to be associated with CD<sup>[25]</sup>. We are recruiting more cases and controls to investigate whether SNPs of IL23R would also play a protective role in Chinese CD patients. Since there is great genetic heterogeneity between Chinese and the Caucasians, further studies including total genome-wide scans among Chinese patients are warranted to identify genes susceptible to IBD which would shed more light on the etiology of this disease in our own country.

## COMMENTS

### Background

Inflammatory bowel disease (IBD), including two clinical subtypes: Crohn's disease (CD) and ulcerative colitis (UC), has been increasing in some Asian countries in recent years, and China is one of the notable countries. Previous epidemiological studies suggested a genetic susceptibility in IBD which has been confirmed by molecular biology techniques. CARD15 (previously NOD2) was first confirmed to be a susceptible gene of CD. Two missense mutations Arg702Trp (2104C→T), Gly908Arg (2722G→C) and one frame-shift mutation (3020insC) of the NOD2/CARD15 gene affecting the function of binding microbial pathogens are independently associated with the development of CD. In recent years, A C1672T substitution in exon 9 of the *OCTN1* gene and a G-207C in the *OCTN2* promoter region were indicated as functional and causative mutations to enhance the susceptibility to IBD.

### Research frontiers

In the last ten years, there have been tremendous researches on genetic susceptibility of IBD and over 10 chromosomal regions have been identified by genome-wide scanning. Further fine mapping as well as candidate gene studies have already led to the identification of a number of susceptible genes. When CARD15 was first confirmed to be a susceptible gene of CD, its three variant alleles, Arg702Trp, Gly908Arg and 3020insC were found to increase the risk of CD in many western countries but completely different in Asian countries. Similar to the *CARD* gene, many western countries have proved that the SNPs of *OCTN1* and 2 were positively associated with IBD but absent in Japanese. These studies showed that there was apparent genetic heterogeneity between Caucasian and Asian as well as Chinese population.

### Innovations and breakthroughs

The study suggested that the four SNPs, C1672T, G-207C, 2104C/T and 2722G/C, might not play a role in susceptibility of IBD in Chinese patients, thereby differing from the case of Western populations, but consistent with the results in Asian population. Compared with the studies in the Chinese population before, we had the largest number of cases. In Asia, it was the first study to detect the polymorphism of OCTN in UC patients.

### Applications

With great genetic heterogeneity between Chinese and the Caucasian, further studies including total genome-wide scans among Chinese patients are warranted to identify genes susceptible to IBD which would shed more light on the etiology of this disease in China.

### Peer review

In this study, the authors found that of the Chinese patients with IBD as well as the healthy controls none had OCTN and CARD15 variants. These results suggest that OCTN and CARD15 are rare in the Chinese population and may not be associated with susceptibility to IBD in Chinese patients. This was an interesting study with an aim that was well justified.

totally within 6 h. The area under concentration-time profile of drug in the colon mucosa using chitosan capsules (AUCLI, 16011.2 ng·h/g) was 2.5 times and 4.4 times greater than using gelatin capsules and CMC suspension, respectively. Meanwhile, the area under concentration-time profile of drug in the plasma (AUCPL) was 1016.0 ng·h/mL for chitosan capsule, 1887.9 ng·h/mL for CMC suspension p and 2163.5 ng·h/mL for gelatin capsule. Overall, both AUCLI and AUCPL were increased when C12 was co-administrated, but the increase of AUCLI was much greater; the drug delivery index (DDI) was more than 1 compared with simple chitosan capsule group.

**CONCLUSION:** There was a regional difference in the permeability of Rebamipide across the jejunum, ileum and the colon, and passive diffusion seems to be one of the major transport mechanisms of rebamipide. Absorption enhancers can increase the permeability of rebamipide across the colon tissue significantly. In addition, chitosan capsule may be a useful carrier to deliver rebamipide to the colon specifically and the co-administration of C12 with rebamipide may also be very useful in local treatment.

## INTRODUCTION

Rebamipide (2-(4-chlorobenzoylamino)-3-[2(1H)-quinolinon-4-yl] propionic acid), a novel anti-ulcer drug, has been reported to prevent various acute

experimental gastric lesions and accelerate healing of chronic gastric ulcers<sup>[1]</sup>. This drug has been marketed in Japan since 1990 as a therapeutic agent treating gastric ulcer and acute and/or chronic gastritis. Although the characteristics of rebamipide in preclinical and clinical area<sup>[2,3]</sup>, which is one of key factors to develop its reasonable oral dosage form at the initial stage, has been investigated fully, little was known about the permeability of this drug in different gastrointestinal tissues. On the other hand, recent studies also have shown the beneficial effect of this drug on experimental colitis. It has been demonstrated that the attenuation of colitis indices induced by rebamipide was associated with its inhibition of inflammatory cytokine-mediated granulocyte (neutrophil) infiltration into the colon<sup>[4]</sup>. Other groups demonstrated that rebamipide can suppress chemically induced colitis in rodents, which appeared to be largely related with the inhibition of the production of reactive oxygen species. In clinical practice, rebamipide has been used to treat patients with proctitis<sup>[5]</sup>. Therefore, we hope to find some absorption enhancers to augment permeability of rebamipide across the colonic tissues, and in this case, this drug should be specifically localized in the large intestine by its colon-specific delivery to improve its therapeutic effect on colitis and to decrease its side-effects, as well. There are many investigations on absorption enhancers; meanwhile, it has been demonstrated previously that chitosan capsule could act as useful carriers for colon-specific delivery of peptide and anti-inflammatory drugs including insulin, calcitonin, 5-amino salicylic acid and ridogrel<sup>[6-9]</sup>. However, the effects of absorption enhancers increasing the distribution on colon and chitosan capsule on the colon-specific delivery of rebamipide ought to be established.

Therefore, we evaluated the permeability of rebamipide across different gastrointestinal membranes in the present study, analyzed potential transport mode, and investigated the effect of some absorption enhancers, such as sodium laurate (C12) and labrasol, on the permeability of rebamipide across colonic tissues. In addition, the effectiveness of chitosan capsule to the colon-specific delivery of rebamipide and the influence of rebamipide chitosan capsules with absorption enhancers on colon specific delivery were evaluated.

## MATERIALS AND METHODS

### Materials

Rebamipide was purchased from Sigma-Aldrich Chemical Co. (St. Louis, MO). HEPES (2-[4-(2-hydroxyethyl)-1-piperazinyl] ethanesulfonic acid) and HPMCP (Hydroxypropyl methylcellulose phthalate) were purchased from Wako Pure Chemical Industries Co. C12 was from Tokyo Kasei Kogyo Co. Ltd, while labrasol was from Saint-Priest, France. Chitosan capsules and gelatin capsules were obtained from Aicello Chemical Company Ltd. (Toyohashi, Japan), and the mean diameters and weight of these capsules were 3.5 mm × 1.6 mm and about 1.0 mg, respectively. All other chemicals were of analytical grade.

### Instruments

Diffusion chamber apparatus was purchased from Harvard, US. The Shimadzu LC-10A system (Japan) as high performance liquid chromatography (HPLC) instrument was used in this study. The pH measuring instrument was from DKK.TOA Corporation in Japan. NTR-6000 Dissolution Tester made in Japan was chosen to test the dissolution rate of drug dosage forms.

### Animals

Male Wistar rats (280 ± 20 g) were purchased from Laboratory Animal Center, Southern Medical University. All of the animal experiments were performed according to the guideline of Experimental Animal Ethics Committee of Southern Medical University.

### Preparation of drug solutions for the *in vitro* permeability studies

For *in vitro* permeability studies, rebamipide was dissolved in oxygenated (O<sub>2</sub>/CO<sub>2</sub>, 95/5) HEPES buffer adjusted to pH 7.4, which was prepared daily, to yield final concentration of 80 μmol/L. In certain experiments, the dosing solutions were added to labrasol (0.4, 1, 2 g/L) or C12 (0.5, 1, 2 mmol/L).

### Permeability studies

The *in vitro* transport of rebamipide across different intestinal membranes was evaluated by a diffusion chamber method using stripped rat intestine for 2 h<sup>[10,11]</sup>. Male Wistar rats, weighing 280 ± 20 g, were fasted overnight and anesthetized with sodium pentobarbital (32 mg/kg, IP). The intestine of each rat was excised and rinsed in PBS of pH 7.4 and, avoiding Peyer's patches, experimental segments were obtained. The first 5 cm of the top of small intestine was cut away, the next 10 cm was used as the jejunum and the final 10 cm was considered to be the ileum. The first 2 cm of the large intestine was removed and the next 6 cm was used as the colon. The underlying muscularis from the serosal side of the tissue was removed and the final intestinal segments were mounted in the diffusion chamber in which a surface area of 1.78 cm<sup>2</sup> was exposed and preheated to 37°C. Immediately following tissue mounting, 7 mL of HEPES buffer at pH 7.4 was added to serosal side or mucosal side, while an equal volume of the rebamipide solution with or without an absorption enhancer was added to the opposite side. Each side of the chamber was bubbled with a mixture of 95 mL/L O<sub>2</sub> and 5 mL/L CO<sub>2</sub> to maintain the viability of the membrane. The heating unit was capable of holding six cells and the temperature was kept at 37°C during the whole procedure using a circulating water bath. At predetermined time intervals, 0.4 mL of solution at receiver side was sampled and it was immediately added to an equal volume of the HEPES buffer kept at the same temperature. The concentration of rebamipide in the samples was determined by HPLC. The apparent permeability coefficient (Papp) was calculated by the equation Papp = dC/dt × (1/A C<sub>0</sub>), where Papp is expressed in cm/s, dC/dt is the slope of the linear portion of the permeation curves, A is

the diffusion area, and  $C_0$  is the initial concentration of rebamipide in the donor side.

#### **Preparation of various rebamipide dosage forms**

One mg of rebamipide or a mixture of C12 (0.05, 0.15 and 0.25 mg) with rebamipide (1 mg) was filled in one chitosan capsule. Then, the surface of the chitosan capsule was coated with hydroxypropylmethylcellulose phthalate (HPMCP) as an enteric coating material. 150 g/L HPMCP dissolved in acetone/ethanol (1/1) solvent was used in the whole procedure. In addition, 1 mg of rebamipide was filled in one gelatin capsule as one control dosage form. The procedure of preparation of this dosage form was the same as that of chitosan capsule. For another control dosage form, 4 mg/mL of rebamipide solution in 5 g/L CMC (Carboxymethylcellulose) containing 10 mmol/L NaOH was also prepared.

#### **In vitro dissolution test**

The dissolution tests of rebamipide from chitosan capsules and gelatin capsules were carried out using the Japanese Pharmacopoeia (JP) rotating basket method with some slight modifications. Liquid 1 (a model medium of an artificial gastric juice for the Japanese Pharmacopoeia disintegration test) and liquid 2 (a model medium of an artificial intestinal juice for the Japanese Pharmacopoeia disintegration test) were used as media in these experiments. The rotation speed of the baskets was 100 r/min. Samples (0.2 mL) were taken every 60 min and the amount of rebamipide released from the capsules was determined by HPLC.

#### **Establishment of rebamipide determination in rat plasma and colonic tissue using HPLC**

**HPLC conditions:** Rebamipide in colonic tissue and plasma was assayed by reversed phase HPLC system containing 5-μm Cosmosil (4.6 mm × 150 mm) particles in an analytical column from Nacalai Tesque, a Shimadzu LC-10 pump system, a Shimadzu SIL-10A autoinjector and a Shimadzu CR-6A integrator. The mobile phase was mixture of 15 mL/L HAc solution (mobile phase A) and acetonitrile containing 100 mL/L tetrahydrofuran (mobile phase B). The gradient system was programmed by linearly increasing the proportion of mobile phase B from 18% to 40% within 55 min. The ultraviolet detector was set at 240 nm.

**Preparation of colon tissue sample:** Male Wistar rats weighing 280 ± 20 g were fasted for 16 h prior to experiments but allowed water *ad libitum*. They were anesthetized with sodium pentobarbital (32 mg/kg, ip). The abdomen was opened through a midline incision and the whole colon was removed from the body. After being washed with PBS, the colon tissue was cut into small pieces. The specimens were weighed. Methanol (5 mL) was added and the specimens were homogenated at ice-water bath using a POLYTRON homogenizer. The homogenate was centrifuged at 12 000 r/min for 15 min. The supernatant was evaporated at 60°C under nitrogen flow. The residue was re-dissolved in 0.25 mL

of 5 mmol/L NaOH solution by ultrasound for 15 min. The suspension was centrifuged at 12 000 r/min for 15 min. The resulting supernatant was taken as colon tissue sample to be analyzed by HPLC.

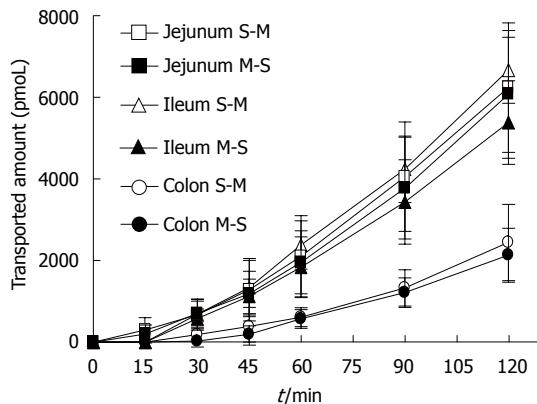

**Preparation of plasma sample:** Male Wistar rats, 280 ± 20 g, were fasted for 16 h prior to experiments but allowed water *ad libitum*. They were anesthetized with sodium pentobarbital (32 mg/kg, IP). The abdomen was opened through a midline incision and 5 mL blood was collected into heparinized syringes *via* the abdominal vein. Samples were immediately centrifuged at 10 000 r/min for 5 min to obtain plasma fraction. 5 mL methanol was added in 1 mL plasma, and the mixture was vortexed for 1 min and then centrifuged at 3600 r/min for 15 min. 4.5 mL of supernatant was evaporated at 60°C under nitrogen flow. The residue was re-dissolved in 0.25 mL 5 mmol/L NaOH solution by ultrasound for 15 min. The suspension was centrifuged at 12 000 r/min for 15 min. The resulting supernatant was taken as plasma sample to be analyzed by HPLC.

#### **In vivo absorption experiments**

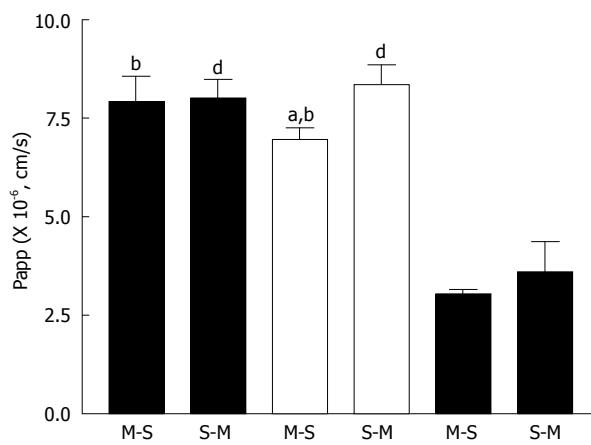

Male Wistar rats, 280 ± 20 g, were fasted for 16 h before the experiments, and then four chitosan or gelatin capsules (4 mg rebamipide) were administered orally to the stomach *via* polyethylene tubing under light ether anesthesia. One mL of distilled water was administered after that. For the CMC group, 1 mL of rebamipide CMC solution (4 mg rebamipide) was taken orally under the same conditions. At the predetermined time interval, blood samples and colonic tissue samples were prepared, and then the rebamipide contents in the samples were determined by HPLC. Drug delivery index (DDI) was calculated from the following equation: DDI = (AUC<sub>1LI</sub>/AUC<sub>2LI</sub>)/(AUC<sub>1PL</sub>/AUC<sub>2PL</sub>), where AUC<sub>1LI</sub> and AUC<sub>1PL</sub> represent the area under concentration-time profiles of rebamipide in the large intestinal mucosa and the area under the plasma concentration-time profiles of rebamipide after the oral administration of its chitosan capsules, respectively, while AUC<sub>2LI</sub> and AUC<sub>2PL</sub> represent the area under concentration-time profiles of rebamipide in the large intestinal mucosa and the area under the plasma concentration-time profiles of rebamipide, respectively, after the oral administration of its gelatin capsules or its CMC solution. The *in vivo* absorption experiments were run with C12, and then four chitosan with C12 were orally administered to the stomach, other procedures same as above, DDI = (AUC<sub>3LI</sub>/AUC<sub>1LI</sub>)/(AUC<sub>3PL</sub>/AUC<sub>1PL</sub>). AUC<sub>3LI</sub> and AUC<sub>3PL</sub> represent the area under concentration-time profiles of rebamipide in the large intestinal mucosa and the area under the plasma concentration-time profiles of rebamipide, respectively, after the oral administration of chitosan capsules with different dosage of C12.

#### **Statistical analyses**

Results were expressed as the mean ± SE and statistical significance was performed by the Student's *t*-test

**Figure 1** Time course of M-S and S-M transport of rebamipide across the different intestinal tissues. Each value represents mean  $\pm$  SE ( $n = 10$ ).

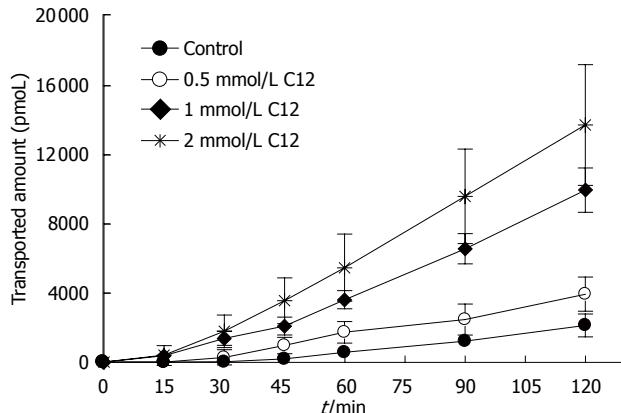

**Figure 2** The Papp of rebamipide across the different intestinal regions. Each value represents mean  $\pm$  SE ( $n = 10$ ). <sup>b</sup> $P < 0.01$  vs colon M-S, <sup>d</sup> $P < 0.01$  vs colon S-M, <sup>a</sup> $P < 0.05$  vs ileum S-M.

or Dunnett's test for multiple comparisons with the minimum levels of significance,  $P < 0.05$ .

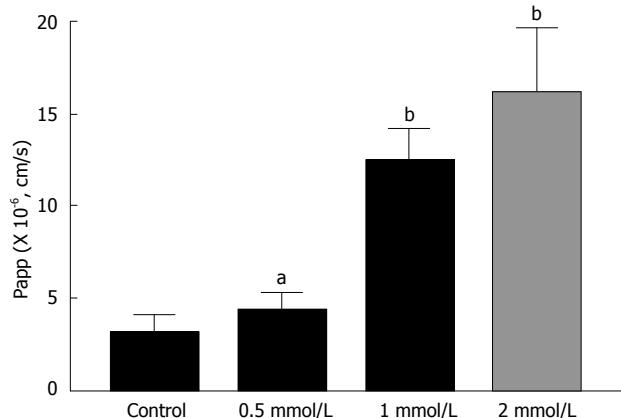

## RESULTS

### Regional differences in the permeability of rebamipide across different intestinal membranes

Figure 1 shows the time course of absorptive (mucosal to serosal, M-S) and secretory (serosal to mucosal, S-M) transport of rebamipide across the rat various intestinal membranes. As shown, there were regional differences in the *in vitro* permeability of rebamipide. The permeability of rebamipide across the jejunal or ileal membranes was higher than that across the colonic membrane. The S-M transport of rebamipide in the jejunum and colon was almost as same as its M-S transport, while the S-M transport of rebamipide across ileal tissues was slightly greater than that from M-S transport. Figure 2 summarizes the Papp of rebamipide across the different intestinal regions. As shown in Figure 2, Papp in jejunum and ileum was higher than that in colon, but no significant difference of drug permeability was observed between jejunal and ileal region. Based on the regionally different absorption studies, we selected colon as a model region to estimate the permeability of rebamipide in the presence of some

**Figure 3** Time course of transport of rebamipide across the colonic tissues in the presence of various concentrations of C12. Each value represents mean  $\pm$  SE ( $n = 10$ ).

**Figure 4** Effect of various concentrations of C12 on the Papp of rebamipide in the colonic tissues. Each value represents mean  $\pm$  SE ( $n = 10$ ). <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  vs control.

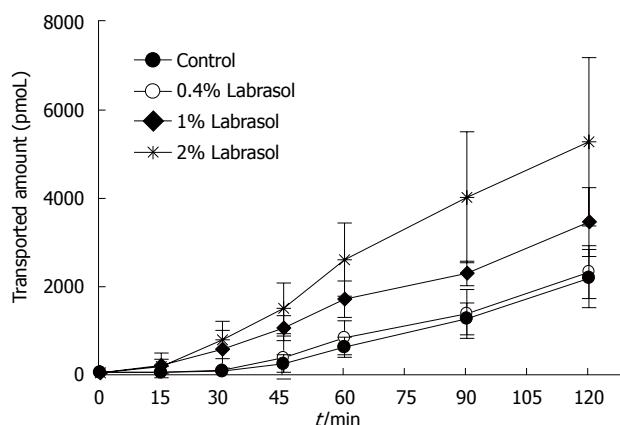

absorption enhancers in the following, because the colon is the pharmacodynamic position of rebamipide.

### Effect of C12 on the permeability of rebamipide across the colonic membranes

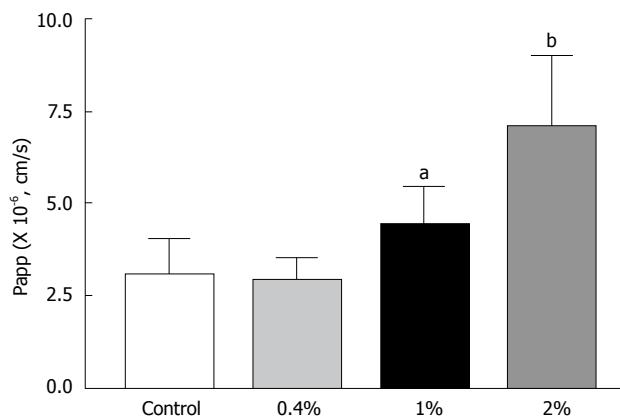

Figures 3 and 4 show the effects of different concentrations of C12 on the cumulative amount and Papp of rebamipide across the colonic region. As showed in Figures 3 and 4, the permeability of rebamipide from the colonic region was remarkably enhanced by the addition of C12. Also, there exists a concentration-dependent effect of C12 on the absorptive transport of rebamipide over the range of 0.5 to 2 mmol/L. In general, the higher concentrations of C12 gave the greater enhancement of rebamipide transport. In this experiment, we also have used 0.4% labrasol to dissolve C12, since C12 itself was not dissolved easily in the HEPES buffer. Therefore, we also investigated the influence of labrasol on the permeability of rebamipide across the colonic membranes.

### Effect of labrasol on the permeability of rebamipide across the colonic membranes

The transport of rebamipide with labrasol across

**Figure 5** Time course of transport of rebamipide across the colonic tissues in the presence of various concentrations of labrasol. Each value represents mean  $\pm$  SE ( $n = 10$ ).

**Figure 6** Effect of various concentrations of labrasol on the Papp of rebamipide in the colonic tissues. Each value represents mean  $\pm$  SE ( $n = 10$ ). <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  vs control.

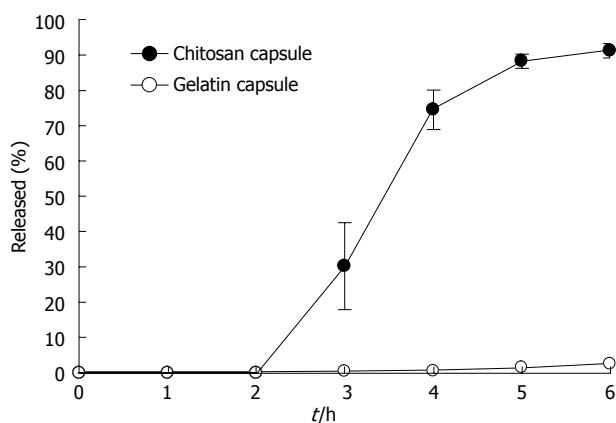

the colonic membranes was examined. We observed a concentration-dependent effect of labrasol on the cumulative amount and Papp of rebamipide across the colonic region, as indicated in Figures 5 and 6. However, there exists no effect of labrasol at lower concentration (0.4 g/L) on the transport of rebamipide. In addition, the enhancement effect of labrasol for the permeability of rebamipide was not as strong as that with C12.

#### In vitro releasing pattern of rebamipide from chitosan and gelatin capsules

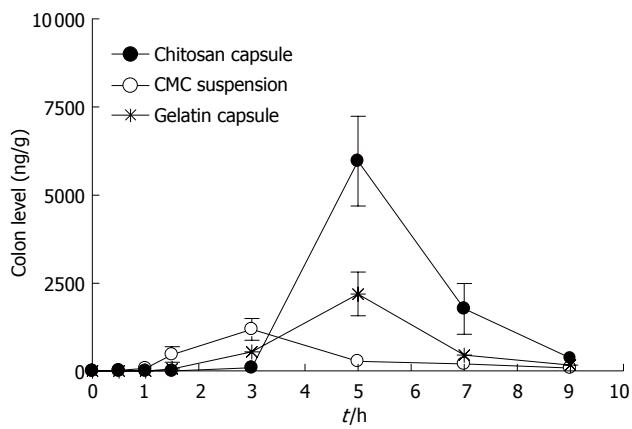

Figure 7 shows the release-time profiles of rebamipide from chitosan capsules and gelatin capsules. We studied drug release in liquid 1, an artificial gastric juice (pH 1), during the period 0–2 h after dosing, and in liquid 2, an artificial intestinal juice (pH 7) during the period 2–6 h after dosing. The release of rebamipide from the chitosan capsules in the protection of HPMCP was less than 10% totally within 6 h, while its release from the gelatin capsules reached about 100% in the same conditions.

#### Plasma concentration and colonic tissue distribution after oral administration of rebamipide in different dosage forms

Figure 8 shows the time course of rebamipide content

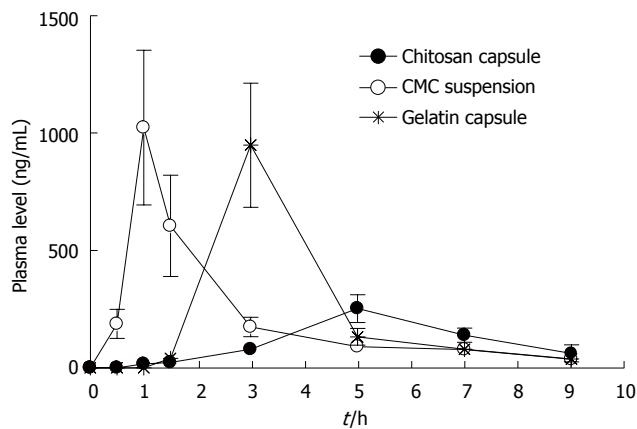

**Figure 7** Release of rebamipide from chitosan capsules or gelatin capsules by Japanese pharmacopoeia rotating basket method ( $n = 6$ ). 0–2 h: In the artificial gastric juice; 2–6 h: In the artificial small intestinal juice.

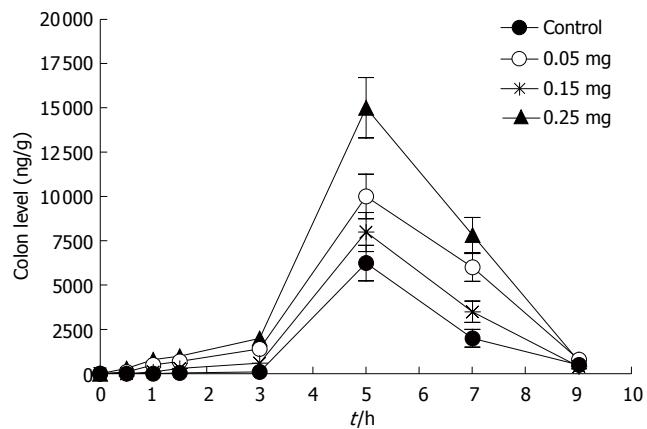

**Figure 8** Concentration-time profiles of rebamipide in the colon tissue after oral administration to rat with various dosage forms. Each value represents mean  $\pm$  SE ( $n = 3$ ).

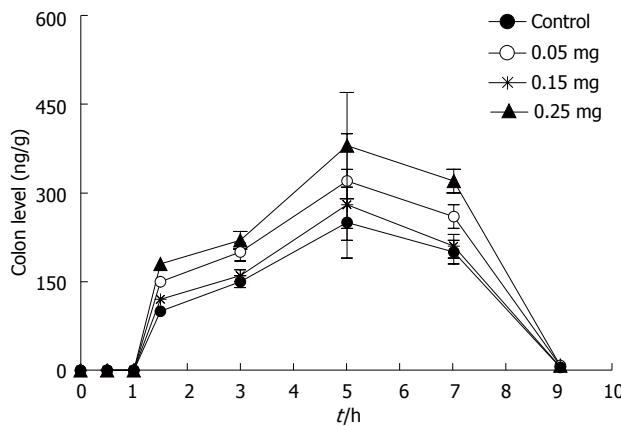

in the large intestine after the oral administration of rebamipide in different dosage forms. The area under concentration-time profile of drug in the large intestinal mucosa (AUCLLI, 16011.22 ng · h/g) after the oral administration of rebamipide using chitosan capsules was 2.5 times and 4.4 times greater than that of rebamipide using gelatin capsules and CMC solution, respectively. The target site of rebamipide is the large intestine, while the transfer amount of rebamipide to the systemic circulation after the oral administration is an index of the drug level in non-targeted sites and is related to the manifestation of adverse effects. We therefore determined the plasma concentrations of rebamipide after its oral administration with chitosan capsules and gelatin capsules as well as CMC solution. Figure 9 shows the plasma concentration-time profiles of rebamipide after the oral administration of rebamipide in different dosage forms. The area under the curve in the plasma (AUCPL) in CMC solution group was 1887.92 ng · h/mL, and AUCPL in gelatin capsule group was 2163.52 ng · h/mL. On the other hand, we observed an at least 1 h lag time in plasma concentration after the oral administration of chitosan capsules containing rebamipide. The AUCPL was 1016.02 ng · h/mL. Overall, the AUCPL value of rebamipide with chitosan capsule was lower than that seen with gelatin capsule or CMC

**Figure 9** Plasma concentration-time profiles of rebamipide after oral administration to rat with various dosage forms. Each value represents mean  $\pm$  SE ( $n = 3$ ).

**Figure 10** Concentration-time profiles of rebamipide in the colon tissue after oral administration to rat with or without C12. Each value represents mean  $\pm$  SE ( $n = 3$ ).

**Figure 11** Plasma concentration-time profiles of rebamipide after oral administration to rat with or without C12. Each value represents mean  $\pm$  SE ( $n = 3$ ).

solution. Thus the absorption of rebamipide from the gastrointestinal tract to the systemic circulation after the oral administration was inhibited by the use of chitosan capsules. In addition, the DDI, which shows the ratio of drug amount in targeted and non-targeted sites in different dosage forms, constitutes a good index for drug efficacy and safety. By using the equation indicated in Materials and Methods, the DDI of rebamipide in chitosan capsules was calculated to be 8.3 and 5.4, compared with CMC solution and gelatin capsules, respectively, and thus confirmed the effectiveness of chitosan capsules in ensuring the colon-specific delivery of rebamipide.

#### Plasma concentration and colonic tissue distribution after oral administration of rebamipide with different dosage of C12

The time course of rebamipide content in the large intestine and plasma of rebamipide after the oral administration of rebamipide with different dosage of C12 is shown in Figures 10 and 11. The area under concentration-time profile of drug in the large intestinal mucosa (AUCL) increased remarkably after the oral administration of rebamipide with C12, especially

the dosage of 0.25 mg; AUCL of chitosan capsules containing rebamipide was 38 458.2 ng · h/g. Though AUCPL (1536.1 ng · h/mL) also enhanced, the increment of AUCL was larger than AUCPL statistically. By using the three dosage of C12, the DDI of rebamipide in chitosan capsules was calculated to be 1.8, 1.4 and 1.2, respectively, compared with chitosan capsules. These indicated that absorption enhancer C12 can promote plasma concentration and colonic tissue distribution of rebamipide, but is much more profitable to colonic tissue distribution. In addition, there existed a concentration-dependent effect of C12 on the plasma concentration and colonic tissue distribution over the range of 0.05 to 0.25 mg. In general, the higher dosage of C12 gave the larger enhancement of distribution.

## DISCUSSION

Most drugs (approximately 60%) treat diseases by oral administration, which is the easiest and most useful method for drug delivery, and prediction of drug absorption is therefore very important for the design of an oral preparation. Only a few experimental *in vitro* methods have so far been established for prediction of drug absorption capability *in vivo*. Caco-2 monolayers are generally accepted to be a suitable *in vitro* model for drug transport studies as these cells have been shown to express most of the enzymatic, functional and morphological characteristics of the intestinal and morphological characteristics of the intestinal mucosa<sup>[12,13]</sup>. However, Caco-2 monolayers cannot be used to predict the regional differences in the permeability of drugs in the gastrointestinal tract. Also, the expression levels of transporters in Caco-2 cells were usually variable and were dependent on the culture condition, which is one of the major disadvantages to estimate the actual permeability of drugs, especially drugs mediated by these transporters. On the other hand, diffusion chamber technique<sup>[14-16]</sup> is one of the other effective means to predict the absorbability of drugs in humans based on rat intestinal permeability.

Recently, Watanabe *et al* investigated the correlation between the apparent permeability coefficients (Papp) of 15 water-soluble and poorly water-soluble drugs based on the diffusion chamber experiment and the fractions absorbed (Fa) in humans. A good correlation was found between Papp and Fa of the test drugs<sup>[17]</sup>. Therefore, in this study, we also investigated the permeability of rebamipide across different gastrointestinal membranes using diffusion chamber experiment.

The low solubility and low permeability of rebamipide indicate that it should be classified into Class IV in Biopharmaceutics Classification System (BCS)<sup>[18]</sup>. It has been known that many drugs categorized into BCS Class IV are P-gp substrates<sup>[19]</sup>. Also, it has also been demonstrated that the intestinal P-gp, an ATP-dependent multidrug efflux pump, can be an active secretion system or an absorption barrier by transporting some drugs from cells into intestinal lumen. Meanwhile, our results revealed that the permeability of rebamipide across the different gastrointestinal regions in M-S or S-M direction is almost equal, although S-M transport of rebamipide across the ileal tissue was slightly greater than that from M-S transport. Based on these results, it may be inferred that carrier-mediated intestinal transport was not involved in the transport of rebamipide and passive diffusion seems to be one of the major mechanisms for the intestinal transport of rebamipide. However, we have used 80 μmol/L of rebamipide in this study to avoid the limitation of detectable amount by the present HPLC method. For most of carrier-mediated intestinal transports, it has been said that there exists a saturated effect of drug concentration on the transport of drug<sup>[20]</sup>. Therefore, it is necessary to investigate the characteristics of the permeability of rebamipide across M-S or S-M direction at much lower concentration in order to elucidate the exact mechanism of its transport across the intestinal membrane in the future, as more sensitive determination of rebamipide will have to be set up. In addition, we found in this study that the Papp of rebamipide across the colonic membranes in the absorptive direction was about  $(3.06 \pm 0.07) \times 10^{-6}$  cm/s ( $n = 15$ ), while Miyake *et al*<sup>[21]</sup> reported the Papp across the same membrane was about  $(2.93 \pm 0.35) \times 10^{-6}$  cm/s. The slight difference may be result from the different experimental conditions.

As far as the discordance of the absorbability or bioavailability of rebamipide in human and its *in vitro* permeability is concerned, it can be inferred that some rebamipide metabolism or any others could be involved in human intestinal tract, as the bioavailability of rebamipide was only about 10%, while the permeabilities of rebamipide across the absorptive jejunal and ileal membranes in our study reached  $8.0 \times 10^{-6}$  cm/s and  $6.9 \times 10^{-6}$  cm/s, respectively. Consistent with our results, Walle *et al* also showed that the Papp of taxol was  $4.4 \times 10^{-6}$  cm/s in Caco-2 cells, and in general a Papp value in Caco-2 cells of  $> 1 \times 10^{-6}$  cm/s is associated with efficient intestinal absorption in humans. Therefore, it was hypothesized that the low oral bioavailability of taxol may be more dependent on presystemic metabolism in

the liver than on lack of absorption. Also, the authors pointed out that a novel development involving increased expression of CYP3A4 should be helpful to examine the potential contribution of CYP3A4 to the transport of drugs such as taxol using the Caco-2 cell system<sup>[22]</sup>. Hence, these factors also should be involved to evaluate the absorption characteristics of rebamipide in human, based on the obtained permeability parameters of rebamipide using diffusion chamber in our present study.

As the improvement of drug permeability by using an absorption enhancer has been very attractive from the aspects of biopharmaceutics, pharmacology, and economics, many researchers investigated the absorption enhancement using various adjuvants<sup>[23-25]</sup>. However, it has been very difficult to use those adjuvants for practical formulation, because they possibly cause local toxicity. Although many compounds have been reported to have absorption enhancing ability, medium-chain fatty acids and medium-chain glycerides are thought to be relatively safe because they are used as nutritional dietary supplements. Currently, only sodium caprate (C10) has been used and marketed as an absorption enhancer in ampicillin suppository marketed in Japan, Denmark, and Sweden, and in ceftizoxime suppository in Japan<sup>[26,27]</sup>. Furthermore, Miyake *et al* demonstrated that C12 was a more effective and safer adjuvant than C10 at the same concentration. Additionally, rebamipide is used to treat the proctitis in colon; therefore, we examined the effect of C12 on the permeability of rebamipide across colonic membranes in the absorptive direction, and we found that the permeability of rebamipide from the colonic region was remarkably enhanced by the addition of C12. Generally, the effects of the absorption enhancing agents are also often intestinal site-dependent. Hence, we also determined the effect of C12 on the permeability of rebamipide across the absorptive ileum membranes. We found the increased Papp ratio of rebamipide with 1 mmol/L of C12, compared with no C12 in this region was 1.92 (data was not shown in the results section), while it was 4.04 in the colon region, where Papp ratio = Papp (with C12)/Papp (without C12). It seems that using C12 as absorption enhancer to increase the absorption of rebamipide is feasible. On the other hand, C12 is not easily dissolved in the experimental HEPES buffer solution; therefore, labrasol was used to increase the solubility of C12 in this test medium. Labrasol is a surfactant that contains saturated polyglycolized C6-C14 glycerides, and its NMR characterization indicated that it is a mixture consisting of 30% mono-, di- and triglycerides of C8 and C10 fatty acids, 50% of mono- and diesters of poly (ethylene glycol) (PEG) and 20% of free PEG 400<sup>[28]</sup>. It shows high tolerance and low toxicity, and has a LD50 of 22 g/kg in rats. Labrasol has been included as a pharmaceutical excipient in European Pharmacopoeia in 1998. As a result, 0.4 g/L labrasol can make 2 mmol/L C12 dissolve in the HEPES buffer. Also, it was found that there was no influence on the permeability of rebamipide at this low concentration, though increased transport of rebamipide with 1 g/L or 2 g/L of labrasol across the colon membrane was found

and also showed concentration-dependent effect of labrasol on the permeability of rebamipide.

As the action and some mechanisms of rebamipide on treating colitis in animals and in human beings have been demonstrated, we investigated the colon specific delivery of rebamipide using chitosan capsule. Chitosan is a high molecular weight cationic polysaccharide, which can be prepared by alkaline N-deacetylation of chitin, the second most abundant natural polymer<sup>[29]</sup>. It has been known that chitosan possesses many advantages including low toxicity, with an oral LD<sub>50</sub> in mice of > 16 g/kg, moderate immunostimulating effect, and inert and biodegradable characteristics. In addition, chitosan has been widely applied as a potential formulation excipient in conventional pharmaceutical devices. This polymer also has been investigated as a potential adjuvant for orally controlled release systems<sup>[30]</sup> and colon targeting<sup>[4-7]</sup>. In addition, it was reported that chitosan had mucoadhesive properties, which probably was mediated through ionic interactions with negative charges in mucus or on cell surfaces. In this study, the chitosan material with average molecular weight of 43000 and average deacetyl degree of 83% was chosen to prepare the capsules. As results, we also have demonstrated that this kind of chitosan capsule coated with HPMCP could be a useful carrier to the colon specific delivery of rebamipide, as has been shown in that the DDI of rebamipide chitosan capsule was calculated to be 8.3 or 5.4, compared with CMC solution group or gelatin capsule group, respectively. Based on our findings, we proposed mechanisms for the colon-specific delivery of rebamipide using chitosan capsule. In the case of rebamipide CMC solution, rebamipide has been absorbed from the small intestine region. Additionally, rebamipide in the gelatin capsule also is absorbed from the small intestinal region, though HPMCP coating the surface of gelatin capsule can protect this kind of capsule from the attack of strongly acidic surroundings in the stomach. However, both HPMCP and gelatin material are easily dissolved in the small medium. Therefore, rebamipide is released and absorbed from the small region when HPMCP-coated gelatin capsule reaches this region. On the other hand, when rebamipide was orally administered using HPMCP-coated chitosan capsules, HPMCP first protected the dissolution of chitosan capsule in stomach. Then, the HPMCP is rapidly dissolved and there is little influence of the intestinal medium on the chitosan capsule when HPMCP-coated chitosan capsule enters into the small region. After that, this dosage form reaches the cecum and then the colon. The capsule was disintegrated by microorganisms richly distributed in these regions, and hence rebamipide was released and exerted its local action on colitis. Alternatively, it was reported recently that the pH may actually fall in the colon, when compared with the pH of the small intestine. This low pH, which is caused by acidification of the colonic contents by the products of bacterial fermentation, may be also related to the degradation of chitosan capsule in rat cecal contents and in colon, since chitosan is

unstable and easily degraded under acidic conditions. For one thing, rebamipide has weak acidity and can be dissolved in basic solution. Therefore, it can be dissolved in the colonic medium due to the basic property of this medium, which makes rebamipide much easier to distribute into the colon tissue and exert its local action.

Based on these mechanisms, it is also necessary to make the model drug released from the chitosan capsule easily dissolve in the colon medium by some means to insure that a large amount of drug is distributed in the tissue or absorbed into the circulation system, if we carry out the colon-specific delivery of some other model drug using chitosan capsule in the future. Since there were many experiments done to demonstrate the possibility of chitosan capsule as a specific colon delivery carrier in animals, we should pay close attention to the large scale production of drug-filled chitosan capsules and its prospects in clinical practice from now on. Further investigation should involve: (1) the difference of colon-specific delivery from other chitosan capsules with different molecular weights and degrees of deacetylation; (2) besides HPMCP, the possibility of some other enteric compounds as the coating material and the effect of the coating thickness on colon specific delivery of drugs; (3) the toxicity of cyanoacrylate adhesive used to seal the body and cap in the preparation of drug-filled chitosan capsules; (4) the evaluation of the advantages and disadvantages of chitosan capsules, compared with other colon specific delivery carriers.

Moreover, it is an important method to co-fill with some absorption enhancer in chitosan capsule to increase the drug absorption when systemic action is expected, while it is doubtful that some absorption enhancer is co-administered if the goal is to exert drug's local treatment and reduce the systemic side-effects. In our experiment, rebamipide content in the large intestine increasing notably after the oral administration of rebamipide with C12, which may indicate that absorption enhancer can enhance effect of therapeutic on colitis. On the other hand, DDI got raised, but absolutely speaking, the increasing of plasma concentration may produce adverse effects. Therefore, considering such factors, we should choose a reasonable dosage of C12, which can improve the distribution in colon of rebamipide and control the level of blood concentration; thus, rebamipide with chitosan capsule and C12 produces the best treatment outcome. In future, we will study the effects on colon absorption of rebamipide with various kinds of absorption enhancers, and the safety and toxicity of combinations of absorption enhancer and chitosan capsule.

In addition, in the case of ulcerative colitis, it is reported<sup>[31,32]</sup> that rebamipide enema treatment is useful; however, the treatment is mainly effective in local inflammation of rectum and descending colon due to the limitation of enema technique. Using chitosan capsule, rebamipide could be first distributed in the ascending colon, and then in the transverse colon and other colon. Therefore, rebamipide chitosan capsule may be more helpful in treating the extensive colitis or pancolitis.

In conclusion, we demonstrated a regional difference in the *in vitro* permeability of rebamipide across the small intestine and the colon in rats. Also, absorption enhancers such as C12 and labrasol can increase the permeability of rebamipide across the colon tissue significantly. We demonstrated that rebamipide can be specifically delivered to the colon using HPMCP-coated chitosan capsule. Meanwhile, we also confirm that rebamipide chitosan capsule, when added with C12, is more useful in treating colitis.

## COMMENTS

### Background

Rebamipide has been used to treat patients with proctitis using enema, but this treatment is inconvenient and circumscribed. It has been demonstrated previously that chitosan capsules could act as useful carriers for colon-specific delivery of peptide and anti-inflammatory drugs. However, the effects of absorption enhancement of the distribution on colon and of chitosan capsule on the colon-specific delivery of rebamipide ought to be established.

### Research frontiers

It is very important to improve therapeutic effects of rebamipide on colitis and decrease its side-effects, so it is suggested to find some absorption enhancers to augment permeability of rebamipide across the colonic tissues, and to localize specifically the drug in the large intestine by colon-specific delivery.

### Innovations and breakthroughs

Rebamipide chitosan capsule is more convenient and helpful than enema in treating colitis, especially extensive colitis or pancolitis.

### Applications

Since there were many experiments done that have demonstrated the possibility of chitosan capsule as a specific colon delivery carrier in animal, the large scale production of drug-filled chitosan capsules and its prospects in clinical practice from now on should be paid much attention. Rebamipide chitosan capsule, added with absorption enhancer, can be using in treating colitis in future.

### Terminology

The apparent permeability coefficient ( $P_{app}$ ) is the apparent parameter of permeability ( $\text{cm/s}$ ), was calculated by the equation  $P_{app} = dC/dT \times (1/A \cdot C_0)$ , where  $dC/dT$  is the slope of the linear portion of the permeation curves,  $A$  is the diffusion area, and  $C_0$  is the initial concentration of rebamipide in the donor side.

### Peer review

The authors explained rebamipide delivery using chitosan capsule. The study seems to be interesting and promising.

### Abstract

**AIM:** To investigate the feasibility of compression anastomosis clip (CAC) for gastrointestinal anastomosis proximal to the ileocecal junction.

**METHODS:** Sixty-six patients undergoing gastrointestinal anastomosis proximal to the ileocecal junction were randomized into two groups according to the anastomotic method, CAC or stapler.

**RESULTS:** The postoperative recovery of patients in CAC and stapled anastomosis groups was similar. No postoperative complication related to the anastomotic method was found in either group. Both upper gastrointestinal contrast radiography at the early postoperative course and endoscopic examination after a 6-mo follow-up showed a better healing at the compression anastomosis.

**CONCLUSION:** CAC can be used not only in colonic surgery but also in gastrointestinal anastomosis. Our result strongly suggests that CAC anastomosis is safe in various complication circumstances. However, it should be further confirmed with a larger patient sample.

### INTRODUCTION

Compression anastomosis was first reported in 1826 by Denan, who conceived a sutureless bowel anastomosis that encompassed the inverting technique proposed by Lembert<sup>[1]</sup>. The idea is to compress two bowel walls together and induce a simultaneous necrosis and healing process leading to the joining of the two lumens. In 1892, Murphy introduced a mechanical device known as "Murphy's Button", which has been used for years<sup>[2-4]</sup>.

Additional compression devices, such as magnetic ring, AKA-2 device, and biofragmentable anastomosis ring (BAR) were developed after almost 100 years<sup>[5-7]</sup>. Although animal experiments and clinical trials have reported the high efficacy and safety of these anastomotic devices, they are not widely accepted because of their narrow inner caliber and high expenses. Finally, these compression anastomotic devices were substituted by staplers which are used routinely at present<sup>[3,8]</sup>.

However, compression anastomosis with no foreign bodies left at the anastomotic site permanently, is considered an ideal anastomotic method. Many surgeons still make effort to improve this compression device. Recently, a new device, compression anastomosis clip (CAC) emerged in 2000, was approved for its use by the FDA<sup>[9]</sup>. Clinical trials performed in Israeli Medical Center have confirmed its safety and efficacy for colonic anastomosis in laparoscopic procedures<sup>[10-12]</sup>. However, its application in gastrointestinal anastomosis proximal to the ileocecal junction is limited at an experimental level<sup>[9]</sup>. This prompts us to study its clinical effects on gastrointestinal anastomosis proximal to the ileocecal junction.

### MATERIALS AND METHODS

#### Sample size and randomization

This study was approved by the institutional committee on ethics in clinical trials. Sixty-six patients at the age of 35-83 years, who underwent gastroenterostomy or enteroenterostomy in July 2005 - December 2006,

were recruited into the study. Patients with an emergency surgical history or a nickel allergy history were excluded. All participants signed an informed consent form and were randomly divided into a study group or a control group according to the anastomotic method. Randomization was based on computer-generated codes that were maintained in sequentially numbered opaque envelopes. Compression anastomosis clip (CAC) (NiTi Medical Technologies, Netanya, Israel), 30 mm in diameter, was used for anastomosis in the study group ( $n = 33$ ). In the control group, an anastomosis was performed with a stapler. Bowel preparation, consisting of oral magnesium sulphate, gentamycin, and metronidazole, was performed on the day prior to surgery in all patients except for seven patients with complete intestinal obstruction. There was no statistical difference in preoperative conditions between the two groups (Table 1). The main indication for underlying disease was gastric cancer in both groups (Table 2). One patient in the study group was complicated by postgastrectomy reflux esophagitis due to a previous radical gastrectomy and Brown's reconstruction. She complained of serious nausea and vomiting after surgery and was readmitted to our hospital for reconstruction. The afferent loop was resected and a side-to-side anastomosis to distal jejunum was performed with CAC. The distribution of anastomotic sites and operative procedures are listed in Table 3. Two anastomoses were performed for the patient who underwent total gastrectomy and Roux-en-Y reconstruction during esophagojejunostomy and jejunoojejunostomy. Only the difference in the latter was compared in both

groups based on the different anastomotic methods.

The compression anastomosis was completed with CAC which is a shape memory nitinol double ring clip. The hollow viscera to be anastomosed were parallel to each other and two 5-mm incisions were made at both sides. The CAC mounted on a deployment device was cooled in ice-cold water for 2 min before use. After the clip was opened at an angle of approximately 30°, it was inserted into the hollow viscera through the two 5-mm incisions. The device returned to its original closed shape when it was warmed by body temperature and compressed the two visceral walls firmly. Then, the scalpel incorporated in the applier created a slit through the entrapped walls to allow free passage of air and feces through the anastomosis until the healing process ended. Finally, the applier was withdrawn and the two small incisions through which the clip was inserted were sutured. The compression anastomotic procedure was completed. The postoperative parameters were followed in three aspects.

### Clinical evaluation

Vital sign, recovery of bowel function, antibiotics application, duration of nasogastric drainage, time to start oral feeding and duration of postoperative hospitalization were recorded. We also recorded the time to complete the anastomosis, intraoperative and postoperative complications in all patients, and the time to expel the ring in the study group.

### Radiological examination

Four days after surgery, patients in the CAC group received abdomen plain X-ray examination to locate the ring in body. In addition, the integrity of anastomosis was examined by upper gastrointestinal contrast radiography with dilute gastrografin 7 d after operation.

### Endoscopy

After a six-month follow-up period, endoscopy was performed to evaluate the healing of anastomosis.

### Statistical analysis

Results were expressed as mean  $\pm$  SD. Differences in means between the two groups were calculated for significance with independent-samples *t* test using SPSS 10.0.  $P < 0.05$  was considered statistically significant.

**Table 4 Recovery-related variables after operation (mean  $\pm$  SD)**

Variable	Study group (n = 33)	Control group (n = 33)	P
Gases started (d)	4.3 $\pm$ 1.24	4.7 $\pm$ 1.28	0.230
Bowel movement (d)	5.7 $\pm$ 2.36	6.2 $\pm$ 2.53	0.407
Antibiotics stopped (d)	3.8 $\pm$ 0.74	4.0 $\pm$ 0.83	0.258
Duration of nasogastric drainage (d)	2.6 $\pm$ 0.98	2.8 $\pm$ 0.64	0.314
Start of oral intake (d)	4.8 $\pm$ 1.82	5.4 $\pm$ 1.69	0.174
Postoperative hospital duration (d)	14.9 $\pm$ 6.01	15.1 $\pm$ 8.35	0.946

## RESULTS

All patients recovered from operation uneventfully. The parameters collected during their early postoperative course were similar in both groups (Table 4). No difference was observed in the duration of operation between the two groups ( $139.4 \pm 41.39$  min vs  $143.2 \pm 40.53$  min). No intraoperative and postoperative complications were found, including anastomotic leakage, bleeding, and stenosis, which were related to the anastomotic methods. However, postoperative complications unrelated to the anastomosis occurred in two patients with compression anastomosis. One patient who underwent subtotal gastrectomy and Billroth II reconstruction showed delayed emptying of the stomach. The intestinal adherence distant from the compression anastomosis was observed at the second operation. The patient recovered finally. Another gastric cancer patient with pyloric obstruction underwent a palliative gastrojejunostomy and was refed with normal diet gradually. However, the patient's condition deteriorated suddenly and the patient died on day 35 after operation because of cardiopulmonary decompensation.

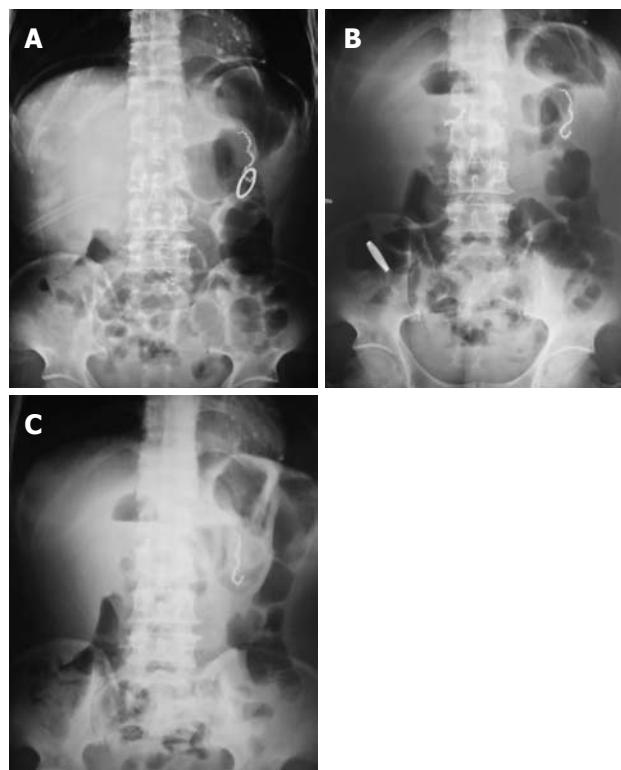

In the CAC group, all of the anastomosis clips were expelled with stool except two, and none complained of discomfort or tenesmus. The mean time of ring expulsion was  $15.1 \pm 6.04$  d (5-29 d). One patient who died 35 d after surgery did not expel the ring. The anastomotic ring in another patient with adhesive ileus was taken out by gastroscopy on the 16th postoperative day.

Using the radiological examination, we were able to locate the anastomosis ring in the patient's body dynamically (Figure 1). The upper gastrointestinal contrast radiography showed that the anastomoses in both groups were intact. No stenosis was observed in all patients, even with the CAC left at the anastomotic site (Figure 2).

After a 6-mo follow-up period, the anastomotic healing was evaluated in all patients by gastroscopy or enteroscopy. No relevant stenosis was detected in either group. All anastomoses showed good healing without scar. The mucosa of compression anastomosis was smooth (Figure 3). However, slight edema and congestion occurred in three of the stapled mucosa.

## DISCUSSION

Compression anastomosis is very close to the sutureless

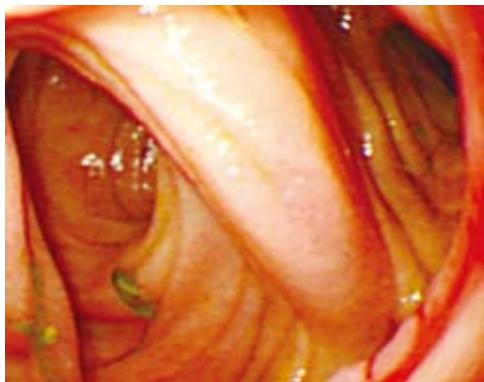

**Figure 1** Plain X-ray film showing the CAC *in situ* in abdomen of patients who underwent radical resection of gastric cancer and Billroth II reconstruction 5 d after operation (A), the ring moving to the right lower abdomen 11 d after operation (B), and expelling of the ring with stools 15 d after operation (C).

anastomosis in the absence of permanent foreign bodies at the anastomotic site<sup>[2]</sup>. Although the technique of compression anastomosis was introduced more than 180 years ago and the theoretical advantages were appreciated, the technique has not been accepted as a standard for gastrointestinal anastomosis, which could be explained by its narrow inner caliber, difficult application and assemblage, and high cost<sup>[3,8]</sup>. It seems that these barriers can be tackled well with the new device, compression anastomosis clip.

The mechanism of CAC is similar to that of Murphy's button. The walls of hollow organs are placed between coils of the ring, pressed and clamped together. Its contin-

**Figure 3** Gastroscopic examination revealing a good healing at the compression anastomosis without scar, edema or congestion six months after subtotal gastrectomy with a Billroth II reconstruction.

uous pressure creates gradual and controlled necrosis of the tissue in the area limited by the CAC coil's perimeter while the external edges of this area become sealed, forming a smooth tight homogeneous anastomosis. The device is biofragmented or detached from the anastomotic site and is excreted from the body. The innovation of CAC is the shape memory nitinol double ring that becomes flexible in cool water and resumes its programmed shape when warmed by body temperature.

Technical failure rates of a new technique must be reduced by eliminating the learning curve on a suitable animal model<sup>[13]</sup>. In our study, no intraoperative problems were observed and no additional supportive measures were needed, suggesting that the increasing experience with our previous animal experiments may significantly shorten the duration of technique learning. The learning process of this new technique is short, indicating that this technique is easy to learn and handle. We also confirmed that CAC could be used not only for colonic anastomosis but also for gastrointestinal anastomosis and enterostomy. In addition, we also performed gastrojejunostomy and enterostomy with CAC for patients with intestinal adhesion, peptic ulcer, or inflammatory bowel disease. Almost all the patients in the CAC group passed the ring without discomfort only with two exceptions. No obstruction due to anastomotic device was observed, indicating that the air and feces are able to pass through the temporary passage of anastomosis during the healing process of anastomosis. The CAC, 30 mm in diameter and 8 mm in inner caliber, could pass through the ileocecal junction successfully.

Anastomotic leakage is a serious postoperative complication of gastrointestinal anastomosis. However, surgical procedure is one of the important factors that affect the healing of anastomosis<sup>[14]</sup>. Our data are consistent with a parallel study in Israel<sup>[10-12]</sup>. No anastomotic leakage was observed in our study, which may be partially explained by a constant stress plateau, which is exerted by coils at about 400 Mpa and up to 6% perfect recoverable strain<sup>[8]</sup>. The constant pressure makes the ring detached from the anastomotic site at an appropriate time. The unique physical properties of nitinol, mostly the constancy of stress, enable the device to exert

a relatively constant pressure irrespective of the bowel wall thickness.

Ischemia, inflammation, and fibrosis due to anastomosis leakage are the factors for anastomotic stenosis<sup>[15,16]</sup>. No sign of anastomotic stenosis at compression anastomotic site was observed either in upper gastrointestinal contrast radiography early postoperatively or in the endoscopy after a long-term follow-up period. The compression anastomosis showed a smooth and intact healing. In contrast, edema and congestion occurred in three of the stapled anastomoses. These discrepancies may be explained by the following. First, the absence of foreign bodies at CAC anastomotic site may greatly decrease inflammatory stimuli and formation of fibrous tissue. Second, the compression anastomotic diameter is determined by the outer diameter of the CAC device, as opposed to staplers, which is determined by its inner diameter. Thus, the CAC is capable of creating a larger anastomosis using a small device. Finally, the raw surface at the edge of the stapler line after firing may also increase the possibility of stricture.

The mean time of expulsion of anastomosis clip was  $15.1 \pm 6.04$  d after surgery. However, significant variations were found in different individuals. Half of the patients in the CAC group expelled the anastomotic clip in about 2 wk. The patients who passed the ring within about 1 wk were always younger and more likely to have benign diseases. They recovered from surgical stress faster and started activities earlier. In contrast, the elder patients with malignant disease often had complex conditions and malnutrition before surgery. They were bedridden for a longer time after surgery and took a longer time to expel the anastomotic ring, suggesting that many factors including anastomotic healing, enterokinesia, and distance of pathway, etc, can affect the duration of the ring expelling. Therefore, we hold that the duration for the ring to detach from the anastomotic site is more important. Further study is needed to confirm our findings.

The characteristics of postoperative recovery were similar in patients with CAC or stapled anastomosis. The anastomotic device did not influence the normal diet intake. None of the patients complained of abdominal pain due to dietary. However, Thiede and colleagues conducted a multicenter prospective trial of biofragmentable anastomosis ring and found that a low fiber diet until the evacuation of ring fragments from the bowel could prevent obstruction with no discomfort<sup>[16]</sup>.

The recovery course of 7 patients with a compression anastomosis who had complete intestinal obstruction before surgery, was uneventful and similar to those without complete intestinal obstruction before operation, which might be related to the characteristics of the CAC. When a CAC anastomosis was performed, the coils were inserted into the bowel lumens that were to be anastomosed through the small incisions and the compression anastomosis was completed after closure of the incisions. However, performing a stapled anastomosis needed a relatively larger surgical field and had more chances to contaminate the abdominal cavity when the applier was withdrawn. In addition, application of

the CAC may simplify the gastrointestinal bypass operation and shorten the operative time. Therefore, surgical injury to the patient could be minimized and the bowel function could recover earlier. Moreover, previous studies demonstrated that persistent foreign bodies may be responsible for anastomotic recurrence of cancer and inflammatory bowel disease and affect radiological examination<sup>[17,18]</sup>. Although no recurrence at anastomotic site was found in our study during the 6-mo follow-up period, further study is needed.

In conclusion, CAC is an alternative method for gastrointestinal anastomosis under different disease circumstances. Further study with a larger patient sample and a longer follow-up period is needed to confirm our findings before CAC application in emergency and laparoscopic surgery.

## COMMENTS

### Background

Gastrointestinal anastomosis is a common surgical procedure in abdominal surgery. Compression anastomosis, which was first reported in 1826 by Denan, is one of the methods. Because there is no foreign body left at the anastomotic site permanently, it is considered an ideal anastomotic method. However, the compression anastomotic devices have been substituted by staplers due to their narrow inner caliber and high cost.

### Research frontiers

Recently, a new device, compression anastomosis clip (CAC), which was emerged in 2000, was approved by the FDA. The mechanism of CAC is similar to that of Murphy's button. The innovation of CAC is the shape memory nitinol double ring that becomes flexible in cool water and resumes its programmed shape when warmed by body temperature. Clinical trials performed in Israeli Medical Center confirmed the safety and efficacy of CAC for colonic anastomosis in laparoscopic procedures.

### Innovations and breakthroughs

The application of CAC in gastrointestinal anastomosis proximal to the ileocecal junction was evaluated in this study. Besides, it can also be applied in selected patients who suffered from inflammatory bowel disease, peptic ulcer disease and intestinal obstruction, etc.

### Applications

CAC can be used for gastrointestinal anastomosis proximal to the ileocecal junction.

### Peer review

This study elucidated the safety of CAC for gastrointestinal anastomosis under different disease circumstances, which may be an alternative method for abdominal surgery and decrease the anastomotic recurrence of cancer and inflammatory bowel disease. The study was well designed and the findings were reliable and significant.

## Abstract

**AIM:** To investigate the relation of expression transformation of claudin-1 with invasiveness and metastasis of gastric carcinoma.

**METHODS:** By using immunohistochemistry, expression of claudin-1 in mucosa and invasive front of 136 gastric adenocarcinoma cases and proliferative index (Ki-67) were detected and analyzed.

**RESULTS:** In mucosa, the claudin-1 over-expression rate of mucinous adenocarcinomas (including signet-ring cell carcinomas) was the highest. It was negatively related with the differentiation but positively related with the invasiveness and metastasis of gastric cancer. In invasive front, the claudin-1 over-expression rate was positively related with the differentiation, invasiveness and metastasis of gastric carcinoma. The expression transformation of claudin-1 was found in gastric carcinoma. The expression of claudin-1 in invasive front was transformed in 28/136 gastric carcinoma cases. The transformation rate in highly differentiated tubular adenocarcinomas was the highest (51.5%, 17/33). The deeper was the invasiveness, the higher was the transformation rate. The claudin-1 expression transformation rate in serosa and omenta was significantly higher (92.9%) than in tunica muscularis of invasive gastric cancer cases, as well as in patients with

## INTRODUCTION

Gastric carcinoma is one of the most frequent malignant tumors in the world. Gastric carcinoma cells with a fibroblastic pattern in which intracellular adhesion is decreased show active mobility and invasiveness, indicating that epithelial mesenchymal transition (EMT) has occurred<sup>[1]</sup>. Tight junction (TJ) proteins participate in EMT of tumors<sup>[2]</sup>. The four-time transmembrane proteins of claudin family are essential components of TJ<sup>[3]</sup>, but the role of TJ proteins in the development of malignant tumor is not clear. By using immunohistochemistry, claudin-1 expression in gastric carcinoma was investigated and its relation with biological behaviors of gastric carcinoma was discussed in this study.

## MATERIALS AND METHODS

### **Patients**

A total of 136 patients (106 males and 30 females) with primary gastric carcinoma, who underwent surgery between January and December 2007 in the First Affiliated Hospital of Fujian Medical University, were enrolled in this study. Their median age was 64 years, ranging 28-80 years. All patients did not receive radiation therapy or chemotherapy prior to operation. The histological findings, lymph node metastasis and TNM stage were evaluated based on World Health Organization Classification of Tumors<sup>[4]</sup>.

### **Immunohistochemistry**

Specimens were fixed in formalin, embedded in paraffin wax, cut into 4 μm thick sections and stained with hematoxylin and eosin.

The sections were immunostained with anti-rabbit polyclonal antibodies for claudin-1 (1:100, ZYMED) and Ki-67 (MB67, Ready, NeoMarkers) with the EnVision method. The sections were deparaffinized and heated in a microwave oven for 10 min to retrieve the antigens. After immersed in 3% hydrogen peroxide of 100% methanol for 10 min to block the endogenous peroxidase activity, the sections were incubated with primary antibodies for 60 min at room temperature, with EnVision™ for 20 min, and then immersed into a DAB solution. The sections were counterstained with haematoxylin, dehydrated and mounted. Between steps, the sections were washed three times with phosphate-buffered saline (PBS). As a negative control, PBS was used instead of primary antibody. Two independent observers without knowledge of the clinical outcomes evaluated the immunohistochemical staining of sections till a complete agreement on the classification.

### **Immunohistochemical analysis of claudin-1 and Ki-67 labeling index**

Claudin-1 was expressed in the cell membrane and/or cytoplasm (Figure 1). The intensity of staining in cell membrane and cytoplasm and the percentage of immunoreactive cells over the total tumor cells were evaluated as previously described<sup>[5]</sup>. The intensity of staining was graded as 0 when staining was not greater than negative control, 1 as light staining, and 2 as heavy staining. Immunoreactivity was scored according to the percentage of immunoreactive cells over the total tumor cells counted as 0 if < 5% cells were stained, 1 if 5%-25% cells were immunoreactive, 2 if 26%-50% cells were immunoreactive, and 3 if > 50% cells were immunoreactive. The expression of claudin-1 was finally defined according to the score obtained from the grade of intensity multiplied by the score of cell immunoreactivity, i.e. negative (-, scored 0-1), positive (+, scored 2-3), and strongly positive (++, scored 4 or above). Positive expression of Ki-67 staining was found in nuclei of carcinoma cells. Ki-67 labeling index was defined as the ratio of immunoreactive cells over 1000 tumor cells.

### **Statistical analysis**

Chi square test was used for univariable categorical analysis. All statistical analyses were performed with SPSS 10.0.  $P < 0.05$  was considered statistically significant.

## RESULTS

### **Relation between claudin-1 expression and clinicopathological parameters of gastric carcinoma**

Claudin-1 was mainly expressed in the cell membrane and/or cytoplasm of gastric carcinoma cells. The expression of claudin-1 was related with the histological type, degree of invasiveness and lymph node metastasis of gastric cancer ( $P < 0.05$ ). However, the expression of claudin-1 was not significantly related with the sex and age of gastric cancer patients (Table 1).

The claudin-1 over-expression rate was the highest in mucinous adenocarcinomas, and lower in poorly differentiated carcinomas than in well-moderately differentiated carcinomas. It was significantly higher in mucosa of patients with their tumors invaded muscularis propria and visceral peritoneum, or with lymph node metastasis than in mucosa of patients with their tumors only invaded lamina propria or submucosa, or without lymph node metastasis.

The claudin-1 expression in invasive front was different from that in the mucosa. The claudin-1 over-expression was the highest in well-moderately differentiated carcinomas and the lowest in poorly differentiated carcinomas. The deeper was the invasive depth, the higher was the claudin-1 over-expression rate. The incidence of claudin-1 over-expression rate was 50% in invasive front with tumors invaded visceral peritoneum and significantly higher in patients with lymph node metastasis. The expression of claudin-1 was not related with the proliferation index of gastric carcinoma cells.

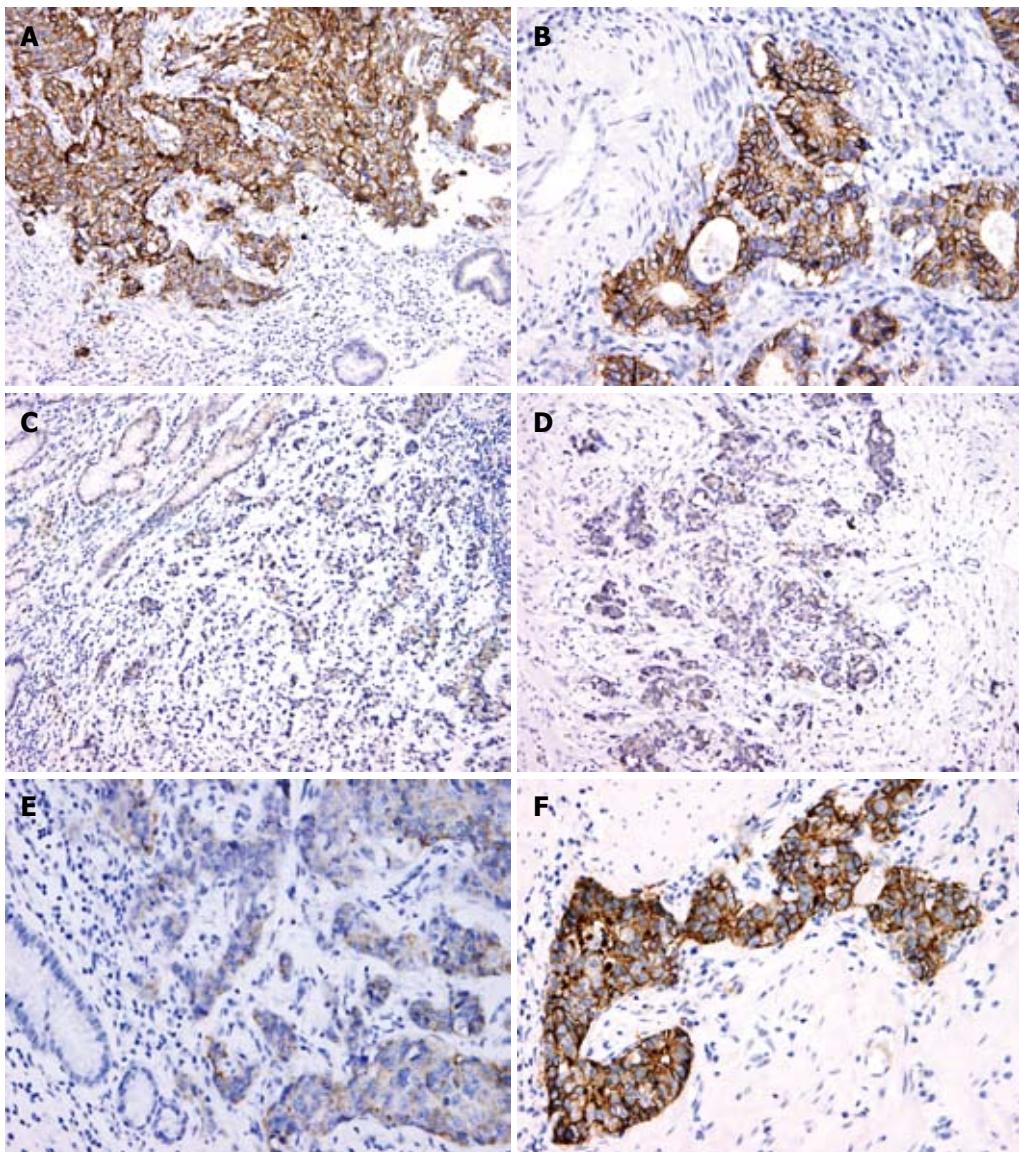

### **Relation between expression transformation of claudin-1 and biological behaviors of gastric carcinoma**

The expression of claudin-1 was transformed in mucosa and invasive front of gastric carcinoma patients, which was 26.2% (28/107) in mucosa and 49.1% (28/57) in invasive front (Table 2). The expression transformation rate of claudin-1 was 51.5% (17/33) in well-moderately differentiated carcinoma patients, 16.0% (9/57) in poorly differentiated carcinoma patients, and 11.8% (2/17) in mucinous carcinoma patients, respectively (Table 3).

The deeper was the invasiveness, the higher was the transformation rate of claudin-1 expression. The claudin-1 expression transformation was significantly higher in patients (26/28) with their tumors invaded visceral peritoneum than in those with their tumors only invaded muscularis propria ( $P < 0.05$ ), and in patients (20/61) with lymph node metastasis than in those (8/46) with no lymph node metastasis ( $P < 0.05$ ).

## DISCUSSION

TJs, adherent junctions and desmosomes form the apical

**Figure 1** Immunohistochemical staining ( $\times 200$ ) showing over-expression of claudin-1 in mucosa (A) and invasive front (B) of gastric carcinoma, low-expression in mucosa (C) and invasive front (D), and transformation of claudin-1 low-expression in mucosa (E) and over-expression in invasive front of gastric carcinoma (F).

junctional complex in epithelial cellular sheets. Adherent junctions and desmosomes are responsible for the mechanical adhesion between adjacent cells, while TJs play a mainly role in the tight sealing of cellular sheets, thus controlling the paracellular ion flux and maintaining tissue homeostasis<sup>[6]</sup>. By forming a fence that prevents lateral diffusion of membrane proteins and lipids, TJs also play a crucial role in the maintenance of cell polarity. TJs also participate in the regulation of cell proliferation and differentiation, or other cellular functions<sup>[7]</sup>.

TJs are consisted of three major integral membrane proteins: claudins, occludin and junctional adhesion molecules. The role of these proteins has not been completely elucidated. However, it is presumed that claudins form the principal chain of TJ strands. The claudin protein family is consisted of 24 members of closely correlated transmembrane proteins. A number of tissues express multiple claudin proteins and form TJ strands by interacting through homotypic and/or heterotypic fashion, though the expression pattern of claudins is tissue specific.

The histological grade of carcinomas is a significant

prognostic parameter and depends on the differentiated degree of glandular epithelium and cellular polarity. The invasiveness in high-grade and poorly-differentiated carcinoma is stronger than that in low-grade and well-differentiated carcinoma. One of the key determinants controlling cellular adhesion and polarity is the TJs<sup>[6]</sup>. Carcinoma cells frequently show deficiencies in structure and function of the TJs<sup>[8]</sup>. It was supposed that the TJs play a critical role in the progress of neoplasm through acting as a connector of extracellular environment affecting the intercellular signal pathway and cellular skeleton<sup>[9]</sup>. The changes of permeability in TJs may also permit the diffusion increase in nutrient substances and other factors for growth and survival of tumors. Otherwise, the loss of integration of TJs in the development of metastatic phenotype is also an important step.

The expression of claudin proteins may change in carcinoma cells. The expression of claudin-1 and claudin-4 in ovarian and prostatic carcinomas is increased<sup>[10-12]</sup>, claudin-4 is over-expressed in pancreatic carcinomas<sup>[13,14]</sup>, while claudin-1 expression is down-

regulated in breast and colon carcinomas<sup>[15-17]</sup>.

The three dimensional cultures of breast cancer cells showed that the reexpression of claudin-1 may increase apoptosis of cancer cells<sup>[18]</sup>. It was reported that the expression of claudin-1 in stage II colon carcinomas is related with a poor prognosis<sup>[17]</sup>. Another study showed that the expression of claudin-1 is up-regulated in colon carcinomas<sup>[19]</sup>, and the expression level of claudin-1 is negatively related with the histological grade of tumors<sup>[17]</sup>.

However, investigations on the role of claudin-1 expression in the progression of gastric carcinomas are relatively few and only two studies on the expression of claudin-1 in gastric carcinomas can be found in PubMed so far. Through tissue microarray, Resnick *et al*<sup>[20]</sup> found that claudin-1, -3, -4 and ZO-1 are expressed in non-tumor mucosa, tumor mucosa and invasive front of gastric carcinomas, the expression of caldudin-1 is higher in intestinal subtype than in diffuse subtype of adenocarcinomas. Soini *et al*<sup>[21]</sup> found that the expression of claudin-1 is significantly higher in intestinal-type gastric than in diffuse-type gastric carcinomas, indicating that claudin-1 expression is the determiner of diffuse phenotype of gastric carcinoma. Our results show that claudin-1 over-expression occurred in mucinous gastric adenocarcinomas, and was negatively related

**Table 3** Relation between the expression transformation of claudin-1 and biological behaviors of gastric carcinomas

with the differentiation degree of adenocarcinomas, but positively related with the invasiveness and metastasis of adenocarcinomas in mucosa. However, the expression of claudin-1 in invasive front was different from that in mucosa of gastric carcinoma. The claudin-1 over-expression in invasive front was positively related with the differentiated degree and the invasiveness and metastasis of gastric adenocarcinomas.

The transformation of claudin-1 expression accompanied the progression of gastric carcinomas. The expression of claudin-1 in invasive front of gastric carcinomas was transformed. The claudin-1 expression transformation percentage of well-differentiated adenocarcinomas was the highest (51.5%, 17/33). The deeper the invasiveness of gastric carcinomas was, the higher the transformation rate was. The transformation was significantly higher in patients with tumors invaded visceral peritoneum than in those with tumors only

invaded muscularis propria and in patients with lymph node metastasis than in those with no lymph node metastasis. These results suggest that transformation of claudin-1 expression participates in the progression of gastric carcinomas.

The role of TJ proteins in the development of cancer is not clear. Carcinoma cells, especially those exhibiting a higher potentiality of metastasis, frequently show loss of functional TJs, such as ZO-1, -2 and occludin is decreased in tumor and its metastasis<sup>[22,23]</sup>. The exact action of claudin on cancers is not clear. It was reported that the expression of claudin-1 is decreased in invasive duct carcinoma of breast<sup>[24]</sup> while the expression of claudin-3 and -4 is increased in some other carcinomas<sup>[25,26]</sup>. The expression of claudin-1 may promote the activation of pro-MMP-9<sup>[26-28]</sup>, suggesting that the expression of claudin-1 may involve the invasiveness and metastasis of adenocarcinoma. Caludin-1 is regarded as a target site of  $\beta$ -catenin/Tcf signals, which supports that claudin-1 down-regulates the formation of colorectal carcinomas<sup>[29]</sup>. The expression of claudin-1 mRNA is decreased in breast carcinomas<sup>[15]</sup> while the expression of claudin-23 is down-regulated in intestinal subtype of gastric carcinomas<sup>[30]</sup>. It was reported that the claudin-1 expression is frequently up-regulated in tumor tissues and its expression level is equal to or higher than in consecutive normal colon mucous membrane, suggesting that the expression of claudin-1 is related with poorly-differentiated adenocarcinoma. The loss of claudin-1 expression is a strongly predictive parameter for tumor recurrence and survival of patients. It was reported that expression of claudin-1 and -4 is increased in ovarian carcinomas and prostatic carcinomas<sup>[26,31]</sup> and over-expression of claudin-4 in pancreatic carcinomas and precancerous lesion<sup>[32]</sup> are the causative action of claudin on cellular transformation and progression of invasiveness<sup>[33]</sup>.

Usually, a low expression level of claudin may result in functional damage to TJs. However, how the over-expression of claudin promotes tumor progression remains unclear<sup>[26,31,32]</sup>. One possible mechanism is that up-regulation or abnormal expression of some claudins may facilitate tumor formation by directly altering the function of TJ. Furuse *et al*<sup>[34]</sup> reported that up-regulation of claudin-2 expression in renal cells of Madin-Darby dogs decreases the function of TJ, and Tan *et al*<sup>[35]</sup> showed that the expression and distribution of claudin-1 are related with cell dissociation in pancreatic carcinoma by activating the mitogen-activated protein kinase-2. Up-regulation of claudins may also affect cell signaling pathways by binding domains to ZO-1<sup>[36]</sup>. ZO-1 interacts with several signaling proteins related with the neoplastic process, such as ras substrate AF-6<sup>[37]</sup>, G-protein and connexin 43<sup>[38]</sup>.

In conclusion, up-regulation and transformation of claudin expression in the invasive process of gastric carcinomas are involved in the biological behavior transformation of tumors. The exact role of claudin protein in the development of malignant tumors and their prognosis remains unclear and should be further studied.

## COMMENTS

### Background

Tight junction (TJ) protein participates in the processes of epithelial-mesenchymal transformation (EMT) of carcinomas. Claudin proteins are the major members of the TJ family. In this study, the relation between the expression transformation of claudin-1 and the invasiveness and metastasis of gastric carcinoma was evaluated.

### Research frontiers

The expression of claudin-1 was found to be significantly related with the biological behavior of gastric cancers, indicating that TJ plays a role in the development of neoplasms. The mechanism of TJ underlying the progress of cancer remains to be further studied.

### Innovations and breakthroughs

This study evaluated the relation between the expression of claudin-1 and the invasiveness and metastasis of gastric carcinoma.

### Applications

The importance of TJ in tumor development has not been extensively studied. The role of the claudin family in the invasiveness and metastasis of cancers is controversial. The relation between the expression transformation of TJ proteins and MET in cancer was clarified in the present study, which contributes to the exploitation of its mechanism underlying the development and progress of gastric carcinoma.

### Terminology

TJs, adherent junctions and desmosomes form the apical junctional complex in epithelial cellular sheets. The claudin protein family is consisted of 24 members of the transmembrane proteins, such claudins1-4.

### Peer review

This study investigated the relation between the expression transformation of claudin-1 and the invasiveness and metastasis of gastric carcinomas. The results suggest that claudin-1 participates in the transformation of the biological behaviors of gastric carcinomas. The study was well designed and the findings may be valuable for the further study on mechanism of claudin-1 underlying the development and progress of gastric carcinoma.

expression ratio of Smad7 in cases with benign biliary stricture was 70.0%, higher than that in normal bile duct, but this difference is not statistically significant 70.0% vs 50%,  $P > 0.05$ ). There was a positive correlation between positive expression of TGF- $\beta_1$ , Smad4 and CTGF in cases with benign biliary stricture.  
**CONCLUSION:** The high expression of TGF- $\beta$ /Smad/CTGF signaling pathway plays an important role in the pathogenesis of benign biliary stricture.

of transforming growth factor-beta signaling pathway in  
pathogenesis of benign biliary stricture. *World J Gastroenterol*  
2008; 14(31): 4949-4954 Available from: URL: <http://www.wjgnet.com/1007-9327/14/4949.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.4949>

## Abstract

**AIM:** To characterize the expression of members of the transforming growth factor-beta (TGF- $\beta$ )/Smad/connective tissue growth factor (CTGF) signaling pathway in the tissue of benign biliary stricture, and to investigate the effect of TGF- $\beta$  signaling pathway in the pathogenesis of benign biliary stricture.

**METHODS:** Paraffin embedded materials from 23 cases of benign biliary stricture were analyzed for members of the TGF- $\beta$ /Smad/CTGF signaling pathway. TGF- $\beta_1$ , T $\beta$ R I, T $\beta$ R II, Smad4, Smad7 and CTGF protein were detected by immunohistochemical strepto-avidin-biotin complex method, and CTGF mRNA was evaluated by hybridization *in situ*, while 6 cases of normal bile duct served as controls. The percentages of positive cells were counted. The correlation between TGF- $\beta_1$ , Smad4 and CTGF was analyzed.

**RESULTS:** The positive expression ratios of TGF- $\beta_1$ , T $\beta$ R I, T $\beta$ R II, Smad4, CTGF and CTGF mRNA in 23 cases with benign biliary stricture were 91.3%, 82.6%, 87.0%, 78.3%, 82.6% and 65.2%, respectively, significantly higher than that in 6 cases of normal bile duct respectively (vs 33.3%, 16.7%, 50.0%, 33.3%, 50.0%, 16.7%, respectively,  $P < 0.05$ ). The positive

## INTRODUCTION

Benign biliary strictures are caused by a heterogeneous group of benign conditions. They are usually iatrogenic, most frequently as a result of cholecystectomy<sup>[1]</sup>. The incidence of this complication has increased with the widespread use of laparoscopic cholecystectomy (LC)<sup>[2-4]</sup>. Other causes of benign biliary strictures include hepatolithiasis, recurrent cholangitis, infection with the fluke, Mirizzi syndrome, etc<sup>[5]</sup>. Anastomotic strictures are seen following bile duct reconstruction or orthotopic liver transplant (OLT)<sup>[6,7]</sup>.

The main manifestations of benign biliary stricture are scar contracture and stenosis of bile duct, especially at the hepatic hilum or above<sup>[8]</sup>. The diagnosis and treatment of benign biliary strictures remains a clinical challenge, requiring a multidisciplinary approach. The pathogenesis of benign biliary stricture is still unclear.

It is well known that the cytokine transforming growth factor beta 1 (TGF- $\beta_1$ ) has a key role either in

the wound healing process or induction of fibrosis. The biological effect of TGF- $\beta_1$  is regulated by a special signal transduction pathway<sup>[9,10]</sup>. Following activation of the TGF- $\beta$  receptor, intracellular signal transduction is mediated by a variety of Smad proteins<sup>[11-13]</sup>. Connective tissue growth factor (CTGF), which promotes cell proliferation and deposition of extracellular matrix (ECM), is a downstream medium in the process in which TGF- $\beta_1$  produces a marked effect on connective tissue cell. The aim of the present study was to determine the expressions of various cytokines in TGF- $\beta$ /Smad/CTGF signaling pathway in tissue of benign biliary stricture, and to further investigate the role of TGF- $\beta$  signaling pathway in the pathogenesis of benign biliary stricture.

## MATERIALS AND METHODS

### **Patients and pathologic specimens**

The study population included 23 patients (10 males and 13 females; mean age 50 years) who underwent benign biliary strictures (between June 2003 and November 2005, in Department of Hepatobiliary Surgery, First Affiliated Hospital, Medical College, Xi'an Jiaotong University, Xi'an). The average time interval between the first surgery and the second surgery was 16 mo, and the average admission time was 22 d. The causes of benign biliary stricture were bile duct injury or anastomotic stricture after biliary reconstruction ( $n = 17$ ), hepatolithiasis ( $n = 3$ ) and recurrent cholangitis ( $n = 3$ ). The specimens were obtained from the cicatrices of bile duct. Fibrosis was seen from HE staining. Six normal specimens of bile duct were obtained from donators in liver transplantation. The study protocol was approved by the Ethics Committee of the First Affiliated Hospital, Medical College, Xi'an Jiaotong University.

### **Antibodies**

Antibodies to TGF- $\beta_1$  (Rabbit anti-human monoclonal antibody, Santa-dilution 1:400), T $\beta$ R I (Rabbit anti-human monoclonal antibody, Santa-dilution 1:400), T $\beta$ R II (Rabbit anti-human monoclonal antibody, Santa-dilution 1:300), Smad4 (Rabbit anti-human monoclonal antibody, Santa-dilution 1:400), Smad7 (Rabbit anti-human monoclonal antibody, Santa-dilution 1:400) and CTGF (Rabbit anti-human monoclonal antibody, Santa-dilution 1:300) were purchased from Wuhan Boster Biological Technology Co. Ltd.

### **Immunohistochemical analysis**

The expression of TGF- $\beta_1$ , T $\beta$ R I, T $\beta$ R II, Smad4, Smad7 and CTGF was detected by SABC immunohistochemical method. The test kit of SABC was the product of Wuhan Boster Biological Technology Co. Ltd. In the control group, the primary antibody was replaced with PBS or normal rabbit serum. All paraffin embedded sections were deparaffinized and rehydrated, and pretreated for 20 min at 75°C in a microwave oven. After being treated with 1 mL/L H<sub>2</sub>O<sub>2</sub> for 30 min to block the

endogenous peroxidase, the sections were incubated with 20 mL/L fetal calf serum for 30 min to reduce nonspecific binding. Then the primary TGF- $\beta_1$ , T $\beta$ R I, T $\beta$ R II, Smad4, Smad7 and CTGF antibodies were applied to the sections and incubated at 4°C overnight. The sections were subsequently incubated with goat anti rabbit IgG at 37°C for 30 min, followed by incubation with SABC at 37°C for 30 min, and stained with DAB-H<sub>2</sub>O<sub>2</sub> for 5-10 min and counterstained with hematoxylin.

### **In situ hybridization for CTGF mRNA**

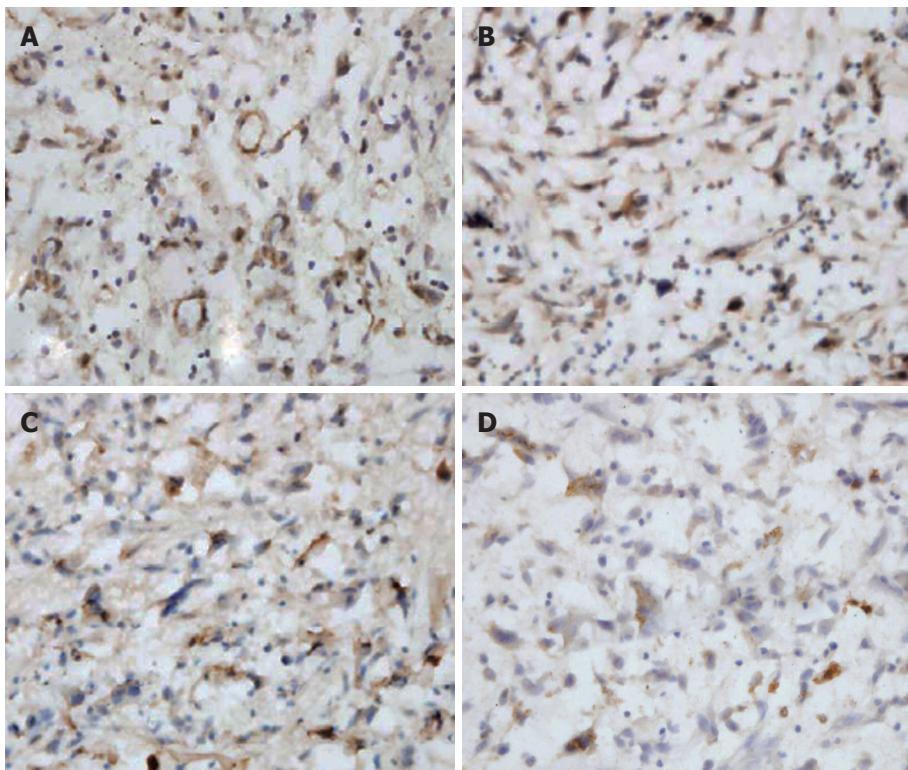

CTGF mRNA ISH detection kit and antisense oligonucleotide probe (digoxin-labeled) were purchased from Wuhan Boster Biological Technology Co. Ltd. A 30-mer sequence that is complementary to the region of CTGF mRNA was synthesized as follows: (1) 5'-CTG CTGCCCGTCTGCG CCAAGCAGCTGGG-3'; (2) 5'-CAACTGCCT GGTCAGACCACAGAGTGGAG-3'; (3) 5'-TGTACTACAGGAAGATGTACGGAGACATGG-3'. In brief, deparaffinized sections were incubated with 3% hydrogen peroxide for 30 min and then with 1 g/mL pepsin for 15 min. The prehybridization was performed at 37°C for 2 h, and the hybridization was conducted in a 42°C water bath for 18 h with each section covered with a soil coverslip. After thorough washing, tissue sections were preblocked for 20 min with blocking solution. Then, mouse anti-digoxin antibody was added for 60 min at 37°C. After washed in PBS, the sections were visualized according to the manufacturer's instructions. A negative control was prepared by using a hybridization solution without the probe.

### **Assessment of staining reactions**

A positive reaction was detected as plasmatic stain presenting in yellow or brown-yellow color. A modified Shimizu's method<sup>[14]</sup> was used to assess staining reactions. We selected 10 visual fields under HP microscope and counted 100 cells randomly. The following scoring system was used: (1) score 0, positively stained cytoplasm in less than 5% of cells; score 1, 5% - 35% positive; score 2, 36%-65% positive; and score 3, > 66% positive; (2) The staining intensity was estimated using a 4-grade scoring system (0, 1, 2, 3): very weak (1+ staining in some cells) (Score 0); weak (1+ staining in cells) (Score 1); moderate (2+ staining in cells) (Score 2); strong (3+ staining in cells) (Score 3). The examiners were blinded to patients' clinical and histological (HE staining) profile. Two investigators evaluated the staining levels independently, after which any discordant evaluations were adjusted by connected microscopes and scored jointly. The 1st and 2nd score were added together and divided 2, then the mean was made the final score; 0, 1, 1.5-2, 2.5-3 were recorded as (-), (+), (++) and (+++) respectively.

### **Statistical analysis**

The percentages of positive cells according to the final score of TGF- $\beta_1$ , T $\beta$ R I, T $\beta$ R II, Smad4,

**Figure 1** **A:** TGF- $\beta_1$  staining at stenotic bile duct (SABC,  $\times 400$ ); **B:** Smad4 staining at stenotic bile duct (SABC,  $\times 400$ ); **C:** CTGF staining at stenotic bile duct (SABC,  $\times 400$ ); **D:** CTGF mRNA staining at stenotic bile duct (INS,  $\times 400$ ).

**Table 1 Positive expression of various cytokines in TGF- $\beta_1$ /Smad/CTGF signaling pathway in benign biliary stricture group and normal control group**

Group	TGF- $\beta_1$	T $\beta$ R I	T $\beta$ R II	Smad4	Smad7	CTGF	CTGF mRNA
Benign biliary stricture (%)	91.3 <sup>a</sup>	82.6 <sup>a</sup>	87.0 <sup>a</sup>	78.3 <sup>a</sup>	70.0	82.6 <sup>a</sup>	65.2 <sup>a</sup>
Normal control (%)	33.3	16.7	50.0	33.3	50.0	50.0	16.7

<sup>a</sup> $P < 0.05$  vs control.

Smad7, CTGF and *CTGF* mRNA were calculated. Fisher's exact probability test was used to analyze the relationship between stricture group and normal control group. Spearman linear correlation analysis was used to analyze correlativity between TGF- $\beta_1$ , Smad4 and CTGF, respectively.  $P < 0.05$  was considered statistically significant in difference. Statistical analyses were performed with SPSS version 11.0 (SPSS Inc., Chicago, IL, USA).

## RESULTS

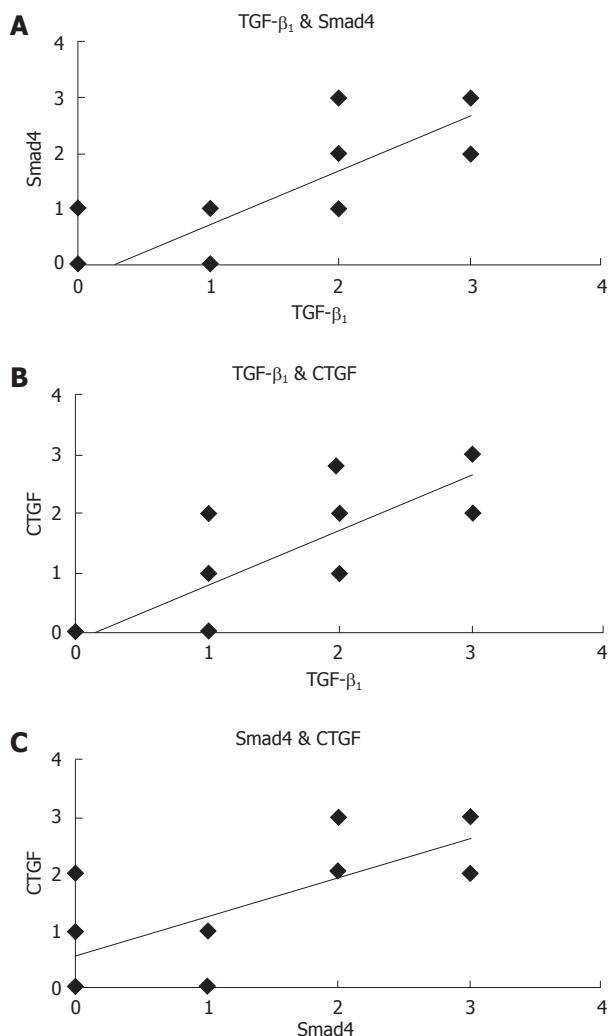

### Expression of TGF- $\beta_1$ , T $\beta$ R I, T $\beta$ R II, Smad4, Smad7, CTGF and CTGF mRNA in benign biliary stricture group and normal control group

TGF- $\beta_1$ /T $\beta$ R was expressed focally or diffusely in granulation tissue and cytoplasm of fibroblasts, macrophages, vascular endothelial cells, and inflammatory cells (Figure 1A). The expression of TGF- $\beta_1$  was weak in fibrous tissue of normal bile duct wall. The positive percentages of TGF- $\beta_1$ , T $\beta$ R I and T $\beta$ R II at benign biliary stricture group were 91.3% (21/23), 82.6% (19/23) and 87.0% (20/23), respectively. Smad4/Smad7 was mainly expressed in cytoplasm and nucleus of fibroblasts, and some was expressed

in fibrocytes (Figure 1B). The positive percentages of Smad4 and Smad7 at benign biliary stricture group were 78.3% (18/23) and 70.0% (16/23), respectively. Positive cells of CTGF were stained as yellow or brownish yellow granules in cytoplasm at immunohistochemical staining and *in situ* hybridization staining (Figure 1C and D). CTGF was expressed mainly in cytoplasm of fibroblasts in benign biliary stricture group, while it was scarcely expressed in fibrocytes in the wall of common bile duct of normal control group. The positive percentages of CTGF and *CTGF* mRNA of benign biliary stricture group were 82.6% (19/23) and 65.2% (15/23), respectively. The percentages of positive expression of various cytokines in TGF- $\beta_1$ /Smad/CTGF signaling pathway in benign biliary stricture group and normal control group are shown in Table 1.

### Linear correlation of TGF- $\beta$ /Smad/CTGF expression

By Spearman linear correlation analysis, expression of TGF- $\beta_1$  has positive correlation with expression of Smad4 ( $r = 0.848$ ,  $P = 0.000$ ) and CTGF ( $r = 0.848$ ,  $P = 0.000$ ); furthermore, Smad4 also has positive correlation with CTGF ( $r = 0.764$ ,  $P = 0.000$ ). Linear correlations of TGF- $\beta$ /Smad/CTGF expression are shown in Figure 2.

**Figure 2** A: Correlation between TGF- $\beta_1$  and Smad4; B: Correlation between TGF- $\beta_1$  and CTGF; C: Correlation between Smad4 and CTGF.

## DISCUSSION

In our previous study, we found that epithelial cells of the bile duct recovered poorly, chronic inflammation existed continuously, fibroblasts proliferated actively, collagens were over-deposited in submucosa, and reconstruction was poor after injury of bile duct. All these result in proliferation of cicatrix and high morbidity of stenosis of anastomosis<sup>[8]</sup>. Many studies have shown that TGF- $\beta_1$  is the most important cytokine in the pathogenesis of over proliferation of cicatrix<sup>[15-17]</sup>. High expression of TGF- $\beta_1$  and its receptors was found in keloid, and the expression of TGF- $\beta_1$  was significantly high in fibroblasts of hypertrophic scar tissues that were cultivated *in vitro*<sup>[18]</sup>. In the present study, we observed that the expression of TGF- $\beta_1$  in stenotic bile duct is significantly higher than that in normal bile duct, further confirming the outcome of our previous animal experiment<sup>[19]</sup>.

Biological effects of TGF- $\beta$  are regulated by specific signal transduction pathway. Smad family proteins have been identified as signal transducers for the TGF- $\beta$  superfamily<sup>[20-22]</sup>. Following activation of the TGF- $\beta$  receptor, intracellular signal transduction is mediated

by a variety of Smad proteins. TGF- $\beta_1$ /Smad signal transduction pathway can regulate itself by positive and negative feedback regulation loops<sup>[23,24]</sup>. Smad4/Smad7 are the important factors in the two circuit loops, respectively. In the T $\beta$ R I, T $\beta$ R II and Smad signaling pathway, TGF- $\beta_1$  can transfer and amplify signal, initiating its diverse cellular responses by binding to and activating specific cell surface receptors that have intrinsic serine/threonine kinase activity. These activated TGF- $\beta$  receptors stimulate the phosphorylation of receptor-regulated Smad proteins (PSmad), which in turn form complexes with Smad4 that accumulate in the nucleus, activate the promoter of TGF- $\beta_1$  and induce the expression of endogenous TGF- $\beta_1$  by itself; this forms the positive feedback regulation loop. Meanwhile, PSmad proteins also can activate the promoter of Smad7 that inhibits TGF- $\beta$ -induced transcriptional responses<sup>[25]</sup>. Psmad2 and Psmad3 may also affect its own promoter region, inhibiting transcription itself, and down-regulate the expression of R-Smad proteins, inhibiting signal transduction<sup>[26]</sup>. Accordingly, TGF- $\beta_1$  inhibits its signal transduction by negative feedback regulation loop made by activating Smad7 expression and down-regulating R-Smad expression.

This study indicates that T $\beta$ R I, T $\beta$ R II, Smad4 in tissue of stenotic bile duct also have high expression besides TGF- $\beta_1$ ; furthermore high expression of TGF- $\beta_1$  has positive correlation with Smad4 ( $r = 0.848$ ,  $P = 0.000$ ). We believe that this may be because high-expression of TGF- $\beta$  can promote the expression of itself and its receptor by a positive feedback regulation loop. This over-expression then could amplify bioactivity and constantly activate smads complexes, which accumulate in the nucleus and regulate the transcription of target genes, resulting in active proliferation of fibroblasts and excessive collagen deposition. So, we can presume that high-expression of R-Smad and Co-smad maybe an important mechanism in pathogenesis of benign biliary stricture. Lasting stimulus of TGF- $\beta_1$  that was constantly secreted in tissue of stenotic bile duct and high-sensitivity of the receptor to TGF- $\beta_1$  possibly result in the above consequences.

This study also has observed that the expression of Smad7 is higher in tissue of stenotic bile duct than that in normal bile duct, but there was no statistical significance between the two groups. We think that because of the tissue difference, Smad7, which is up-regulated in benign biliary cicatrix does not predominate in the competition with R-smad that was also activated and up-regulated, so Smad7 can't play a role in inhibitive function. R-smad, which predominates in the competition, is phosphorylated by T $\beta$ R I and further binds to Smad4; the complex transfers into nucleus and regulates the expression of target genes.

CTGF is considered a modulator and assisted mediated factor that mediates biologic function of other molecules, and promotes fission of fibroblasts and accumulation of collagen<sup>[27]</sup>. CTGF can promote the synthesis of ECM such as collagen I, collagen III and FN. Lasky *et al* observed that CTGF is over-expressed in

pathogenesis of fibrosis in skin, kidney, liver and heart<sup>[28]</sup>. Igarashi *et al*<sup>[29]</sup> thought that the expression of CTGF gene is directly regulated by TGF- $\beta_1$ . Grotendorst *et al*<sup>[30]</sup> also believed that CTGF, which promoted cell proliferation and deposition of ECM, was a downstream medium in the process in which TGF- $\beta_1$  produced a marked effect on connective tissue cell.

The results have shown that expression of CTGF in stenotic bile duct tissue is significantly higher than in normal bile duct specimens. This difference indicated that CTGF plays an important role in the pathogenesis of over proliferation of cicatrix and benign biliary stricture. The expression of TGF- $\beta_1$  has a positive correlation with that of CTGF ( $r = 0.848, P = 0.000$ ); this confirms that both of them play roles of superior and inferior grade in signal transduction pathway in the pathogenesis of benign biliary stricture, similar to other fibrotic disease, whereas the positive correlation between expression of Smad4 and CTGF ( $r = 0.764, P = 0.000$ ) indicates that the relationship between TGF- $\beta_1$  and CTGF is connected by Smads signaling pathway.

Taken together, the present study indicates that the mechanism of effect in TGF- $\beta_1$ /Smad/CTGF signaling pathway is as follows. The continuity of bile duct wall is destroyed after bile duct injury, which results in changes of adjacent intra-cellular metabolism. Then, TGF- $\beta$  is released and binded to the type II receptor at first; thus a binary complex is formed. Type I receptor then is recruited and phosphorylated in its GS domain by T $\beta$ R II, leading to activation of its kinase activity and subsequent formation of a signaling complex. R-Smads are phosphorylated by this signaling complex, and in turn can form heteromeric complexes with Smad4. These activated Smad complexes accumulate in the nucleus, where they directly or indirectly bind to specific promoter regions on target genes together with transcription factor (TF) and/or co-activators/repressors, and downstream mediator CTGF is activated. The activation of TGF- $\beta$ /Smad/CTGF signal transduction pathway can result in fibrosis in the interaction between cell and ECM, cause disorder of metabolism and regulation between inflammatory cell, repairing cell and collagen. Fibrocytes in submucosa are transformed into activated fibroblasts, which proliferate abundantly, and synthesize and secrete collagen fibers. Under the stimulus of bile and secondary infection, inflammation extends and the wound healing process disorders, chronic inflammation exists continuously, fibroblasts proliferate constantly, collagens are over-deposited in submucosa. All these result in a prolonged healing process of bile duct, proliferation of cicatrix and morbidity of benign biliary stricture.

## COMMENTS

### Background

Transforming growth factor beta 1 (TGF- $\beta_1$ ) has a key role either in the wound healing process or induction of fibrosis. The biological effects of TGF- $\beta_1$  are regulated by TGF- $\beta$ /Smad/connective tissue growth factor (CTGF) signaling pathway. The main manifestations of benign biliary stricture are scar contracture

and stenosis of bile duct. The exact role of TGF- $\beta$  signaling pathway in the pathogenesis of benign biliary stricture is still unknown.

### Research frontiers

In the last few years, many studies have shown that TGF- $\beta_1$  is the most important cytokine in the pathogenesis of over proliferation of cicatrix. Biological effects of TGF- $\beta$  are regulated by specific signal transduction pathway. Smad family proteins have been identified as signal transducers for the TGF- $\beta$  superfamily. The expression of CTGF gene is regulated directly by TGF- $\beta_1$ , CTGF, which promotes cell proliferation and deposition of extracellular matrix (ECM), is a downstream medium in the process in which TGF- $\beta_1$  produces a marked effect on connective tissue cell.

### Innovations and breakthroughs

The high expression of TGF- $\beta$ /Smad/CTGF signaling pathway plays an important role in the pathogenesis of benign biliary stricture. These results demonstrate a new view of TGF- $\beta$  signaling pathway involved in the benign biliary stricture.

### Applications

This study indicates that the mechanism of TGF- $\beta$ /Smad/CTGF signaling pathway in pathogenesis of benign biliary stricture. It may provide new targets for further understanding of the pathogenesis of benign biliary stricture and new therapeutic targets.

### Terminology

Smads are the only substrates for type I receptor kinases known to have a signalling function; they were first identified as the products of the Drosophila Mad and C. elegans Sma genes, which lie downstream of the BMP-analogous ligand-receptor systems in these organisms. Smad proteins transduce signals from TGF- $\beta$  superfamily ligands that regulate cell proliferation, differentiation and death through activation of receptor serine/threonine kinases.

### Peer review

The study is well designed and contains important information and novelties concerning TGF- $\beta_1$  signaling pathway in benign biliary stricture. The authors performed a great amount of experiments and a comprehensive statistical analysis of data.

solution containing 0.01 mmol/L egtazic acid (EGTA), genistein and resveratrol inhibited the first phasic contraction induced by acetylcholine (ACh), but did not affect the second contraction induced by CaCl<sub>2</sub>. In addition, genistein, resveratrol and 17β-estradiol also could reduce the contractile responses of ACh and KCl, and shift their cumulative concentration-response curves rightward.

**CONCLUSION:** Phytoestrogen genistein and resveratrol can directly inhibit the contractile activity of isolated gallbladder muscle both at rest and in response to stimulation. The mechanisms responsible for the inhibitory effects probably due mainly to inhibition of tyrosine kinase, Ca<sup>2+</sup> influx through potential-dependent calcium channels (PDCs) and Ca<sup>2+</sup> release from sarcoplasmic reticulum (SR), but were not related to the estrogen receptors.

Inhibitory effects of genistein and resveratrol on guinea pig gallbladder contractility *in vitro*. *World J Gastroenterol* 2008; 14(31): 4955-4960 Available from: URL: <http://www.wjgnet.com/1007-9327/14/4955.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.4955>

## Abstract

**AIM:** To observe and compare the effects of phytoestrogen genistein, resveratrol and 17β-estradiol on the tonic contraction and the phasic contraction of isolated gallbladder muscle strips and to study the underlying mechanisms.

**METHODS:** Isolated strips of gallbladder muscle from guinea pigs were suspended in organ baths containing Kreb's solution, and the contractilities of strips were measured before and after incubation with genistein, resveratrol and 17β-estradiol respectively.

**RESULTS:** Similar to 17β-estradiol, genistein and resveratrol could dose-dependently inhibit the phasic contractile activities, they decreased the mean contractile amplitude and the contractile frequencies of gallbladder muscle strips, and also produced a marked reduction in resting tone. The blocker of estrogen receptor ICI 182780 failed to alter the inhibitory effects induced by genistein and resveratrol, but potassium bisperoxo (1, 10 phenanthroline) oxovanadate bpV (phen), a potent protein tyrosine phosphatase inhibitor, markedly attenuated the inhibitory effects induced by genistein and resveratrol. In calcium-free Kreb's

## INTRODUCTION

Female sex hormones are known to affect cholesterol metabolism, gallbladder and sphincter of Oddi motility<sup>[1-4]</sup>. Phytoestrogens represent a wide group of compounds which are naturally found in many plants, and they are defined as plant substances that are structurally or functionally similar to estradiol<sup>[5,6]</sup>. These natural products possess a wide spectrum of physiological and pharmacological effects such as estrogenic effects<sup>[7,8]</sup>, anti-atherosclerosis<sup>[9]</sup>, anti-osteoporosis<sup>[10]</sup>, relieving menopausal symptoms<sup>[11]</sup> and the inhibitory effect of tyrosine kinases<sup>[12,13]</sup>. Recently, many papers indicate that phytoestrogen genistein and

resveratrol can inhibit vasocontractile responses and relax vascular smooth muscles by a  $\text{Ca}^{2+}$  antagonistic property which is very similar to estradiol<sup>[14,15]</sup>, and data from electrophysiological studies suggest genistein reversibly inhibits L-type calcium current in isolated guinea-pig ventricular myocytes in a concentration-dependent manner<sup>[16]</sup>. Therefore, the biological actions of genistein and resveratrol are very useful for medicine and nutrition, and they are proposed to have potential as natural substitutes of estrogen therapy. Despite the increasing interest in the effects of phytoestrogen in the cardiovascular system, little is known about the effect of genistein and resveratrol on gallbladder smooth muscle. The present study was designed to observe and compare the effects of phytoestrogen genistein, resveratrol and 17 $\beta$ -estradiol on the tonic contraction and the phasic contraction of isolated gallbladder muscle strips both at rest and in response to acetylcholine (ACh) and KCl and to study its underlying mechanisms.

## MATERIALS AND METHODS

### **Animal and tissue preparation**

The present work was conducted in conformity with the procedures described in the Guide for the Care and Use of Laboratory Animals of the National Institute of Health, and the procedures performed were in accordance with institutional guidelines. Adult male or non-pregnant female guinea pigs (weighing 387.8  $\pm$  7.5 g, provided by the experimental animal center of Lanzhou University) were utilized in this study. Preliminary studies indicated that no differences existed between the sexes with respect to either the contractile responsiveness to the agonists or to the sensitivities to genistein, resveratrol and 17 $\beta$ -estradiol. All animals were fasted overnight prior to being sacrificed by overdose injection of pentobarbitone and the whole gallbladders were quickly removed and placed in Kreb's solution containing the following compositions (mmol/L): NaCl 120, KCl 5.9,  $\text{NaH}_2\text{PO}_4$  1.2, MgCl<sub>2</sub> 1.2,  $\text{NaHCO}_3$  15.4, CaCl<sub>2</sub> 2.5, and glucose 11.5, buffered at pH 7.4. After removal of the mucosa by blunt dissection, muscle strips (5 mm  $\times$  10 mm) were prepared from the body of the gallbladder by cutting parallel to the long axis of the tissue, and then were mounted horizontally in separate 5-mL tissue chambers containing 37  $\pm$  0.5°C Kreb's solution, bubbled with 95% O<sub>2</sub> and 5% CO<sub>2</sub>. The muscle preparations were allowed to equilibrate for 2-3 h with a resting tension of 1.0 g and the solution was changed every 20 min. The isometric contractions were measured with force transducers and recorded with the BL-420E<sup>+</sup> experimental system of biological function (TME, China) by microcomputer.

### **Experimental protocols**

In order to observe the effects of genistein, resveratrol and 17 $\beta$ -estradiol on the basal contractile activities of gallbladder, the different concentration (1, 10, 20 or 40  $\mu\text{mol}/\text{L}$ ) of genistein, resveratrol and 17 $\beta$ -estradiol or the same dose of solvent (control) was added

respectively to the tissue chamber for 10 min. A specific antagonist of estrogen receptor ICI 182780 (10  $\mu\text{mol}/\text{L}$ ) or a potent protein tyrosine phosphatase inhibitor bpV (phen) (1  $\mu\text{mol}/\text{L}$ ) was added 10 min before administration of 10  $\mu\text{mol}/\text{L}$  genistein or resveratrol to investigate whether their actions were relevant with the estrogen receptors and tyrosine kinase inhibition in gallbladder smooth muscle.

To evaluate the possible effect of genistein, resveratrol and 17 $\beta$ -estradiol on ACh-induced calcium release and calcium influx through receptor-operated calcium channels (ROCs), gallbladder muscle strips were incubated in calcium-free Kreb's solution containing 0.01 mmol/L egtazic acid (EGTA) for 30 min, and then treated with ACh (10  $\mu\text{mol}/\text{L}$ ). When the contractile response had reached a plateau, CaCl<sub>2</sub> (10 mmol/L) was added into the organ chamber and a further contraction was obtained. Tissues were washed with  $\text{Ca}^{2+}$ -free Kreb's solution and left to return to baseline tone. The strips were then treated by ACh and CaCl<sub>2</sub> again after being incubated with genistein (20  $\mu\text{mol}/\text{L}$ ) and resveratrol (20  $\mu\text{mol}/\text{L}$ ) or the same dose of solvent for 6-8 min.

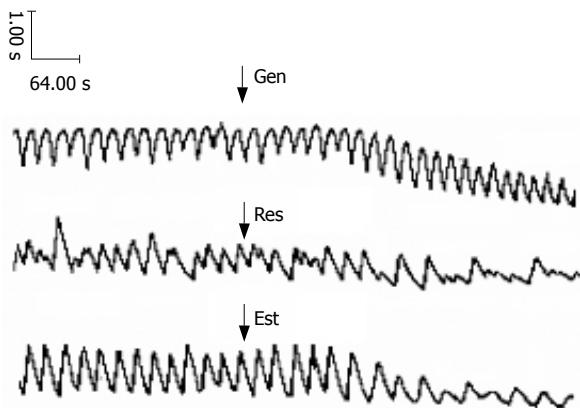

In some experiments, to determine the effect of genistein, resveratrol and 17 $\beta$ -estradiol on contractile response to ACh and potassium, the control contractile response curves to ACh ( $10^{-8}$ - $10^{-3}$  mol/L) and KCl (10-100 mmol/L) were obtained respectively, then the strips were washed repeatedly with Kreb's solution until the strips returned to the basal tension. The strips were then incubated with genistein (40  $\mu\text{mol}/\text{L}$ ), resveratrol (40  $\mu\text{mol}/\text{L}$ ) or 17 $\beta$ -estradiol (40  $\mu\text{mol}/\text{L}$ ) for 10 min respectively, and ACh or KCl concentration-dependent contraction curve was obtained again.

### **Drugs**

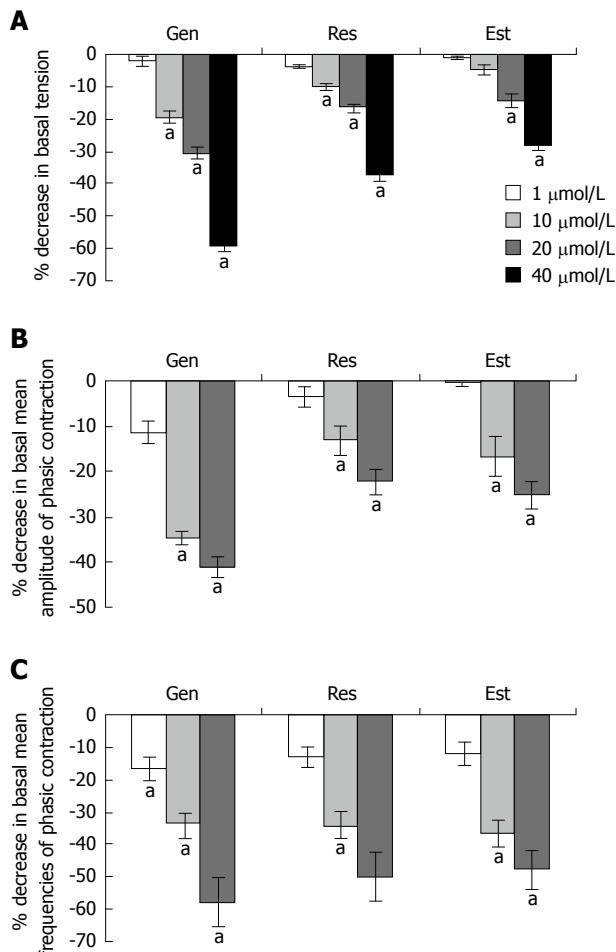

Genistein, resveratrol, 17 $\beta$ -estradiol (Sigma, Chemical Co, USA); ACh (the Second Pharmaceutical Factory of Beijing, China); ICI 182780 (Tocris Cookson Inc., Bristol, UK); potassium bisperoxo (1,10 phenanthroline)oxovanadate bpV (phen) (Alexis Biochemicals, San Diego, CA). ICI 182780, genistein, resveratrol and 17 $\beta$ -estradiol were dissolved with dimethyl sulphoxide (DMSO). The final concentration of DMSO in the bath in each case was always no more than 0.1% and had no effect on basal contraction.

### **Statistical analysis**

All results are expressed as mean  $\pm$  SE. "n" refers to the number of guinea pigs used in the study. Data were expressed as % decrease in the basal tension, mean amplitude and mean frequencies of phasic contraction. In experiments involving concentration-response curves, the results were expressed as percentage of control maximal contractile responses induced by  $10^{-3}$  mol/L ACh or 100 mmol/L KCl respectively. The EC<sub>50</sub> value of each strip was determined by the Scott Method, and was expressed as negative log molar (pD<sub>2</sub>) value. Statistical analysis was performed using the Student *t*-test and analysis of variance (ANOVA). Each group was compared with the solvent control. *P* < 0.05 was considered significant.

**Figure 1** Sample traces showing the basal contractile activity of the gallbladder before and after the administration of 20  $\mu\text{mol/L}$  genistein (Gen), resveratrol (Res) and 17 $\beta$ -estradiol (Est).

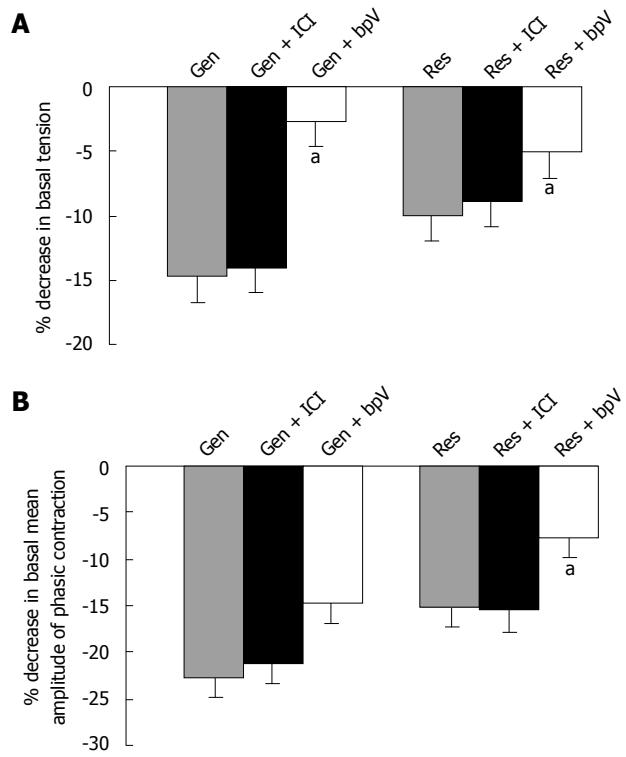

**Figure 2** Effects of genistein (Gen), resveratrol (Res) and 17 $\beta$ -estradiol (Est) on resting tension (A), mean contractile amplitude (B) and (C) mean frequencies of phasic contraction in isolated guinea pig gallbladder muscle strips ( $n = 10$ ).  $^aP < 0.05$  vs solvent control.

## RESULTS

### Effects of genistein, resveratrol and 17 $\beta$ -estradiol on basal activities of gallbladder muscle strips

The spontaneous contractile activities of isolated gallbladder smooth muscle were not very regular, and some strips had obvious spontaneous phasic

**Figure 3** Effects of genistein (Gen, 10  $\mu\text{mol/L}$ ) and resveratrol (Res, 10  $\mu\text{mol/L}$ ) on the basal tension (A) and mean amplitude (B) of phasic contraction in isolated guinea pig gallbladder muscle strips after preincubation with ICI 182780 (ICI) or bpV (phen) (bpV) ( $n = 5$ ).  $^aP < 0.05$  vs corresponding Gen or Res group.

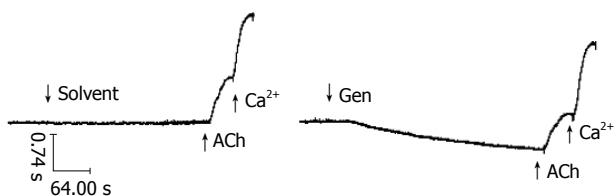

contractions with mean amplitude of  $0.49 \pm 0.06$  g and mean frequencies of  $2.80 \pm 0.25$  waves/min (Figure 1) while the others only possessed tonic contraction. In the strips with spontaneous phasic contractions, genistein, resveratrol and 17 $\beta$ -estradiol (1, 10, 20 or 40  $\mu\text{mol/L}$ ) could dose-dependently inhibit the phasic contractile activities, they decreased the mean contractile amplitude and the contractile frequencies and also produced a marked reduction in resting tone (Figures 1 and 2). Increasing the concentrations of the above three estrogens to 40  $\mu\text{mol/L}$ , the phasic contractile activities disappeared completely, the decreased percentages of the mean contractile amplitude and the contractile frequencies all reached 100%.

### Effects of genistein and resveratrol on basal activities of gallbladder in the presence of ICI 182780 and bpV (phen)

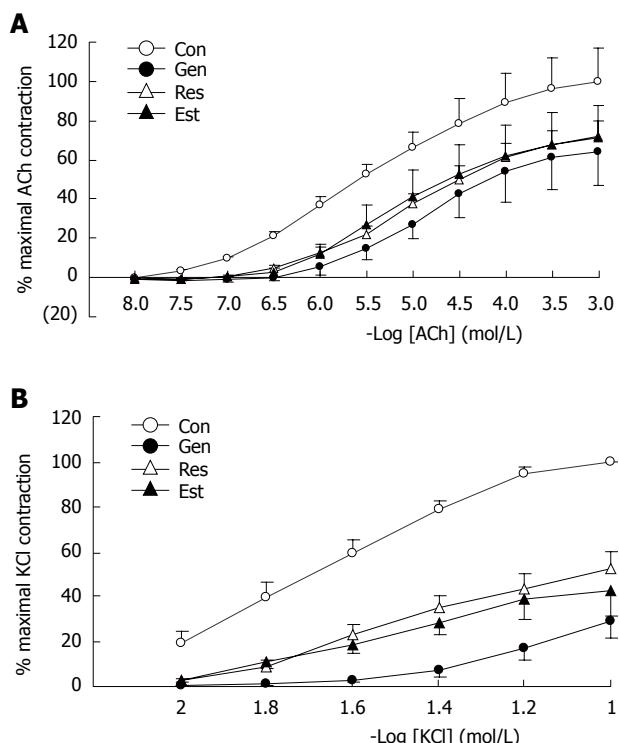

The inhibitory effects induced by genistein and resveratrol in gallbladder muscle strips had no obvious change in the presence of the specific estrogen receptor inhibitor ICI 182780 (10  $\mu\text{mol/L}$ ) (Figure 3), but after incubating the strips with the potent protein tyrosine phosphatase inhibitor bpV (phen) (1  $\mu\text{mol/L}$ ), the inhibitory effects induced by genistein and resveratrol markedly attenuated (Figure 3). ICI 182780 (10  $\mu\text{mol/L}$ ) and bpV (phen) (1  $\mu\text{mol/L}$ ) alone had no obvious effect on basal activity.

### Effects of genistein and resveratrol on biphasic contraction induced by ACh and CaCl<sub>2</sub>

In calcium-free (0.01 mmol/L EGTA) Kreb's solution,

**Figure 4** Traces of ACh and  $\text{CaCl}_2$ -induced contraction of gallbladder muscle strip in  $\text{Ca}^{2+}$ -free Kreb's solution in the absence and presence of genistein (Gen, 20  $\mu\text{mol/L}$ ).

**Figure 5** **A:** Line plots showing effects of genistein (Gen, 40  $\mu\text{mol/L}$ ), resveratrol (Res, 40  $\mu\text{mol/L}$ ) and 17 $\beta$ -estradiol (Est, 40  $\mu\text{mol/L}$ ) on ACh concentration-dependent contraction curves in isolated guinea pig gallbladder muscle strips ( $n = 6-7$ ). **B:** Effects of genistein (Gen, 40  $\mu\text{mol/L}$ ), resveratrol (Res, 40  $\mu\text{mol/L}$ ) and 17 $\beta$ -estradiol (Est, 40  $\mu\text{mol/L}$ ) on KCl concentration-dependent contraction curves in isolated guinea pig gallbladder muscle strips ( $n = 12$ ).

no spontaneous phasic contractions were observed, but ACh (10  $\mu\text{mol/L}$ ) could cause a transient contraction with the tensile increase of  $0.89 \pm 0.10$  g. As soon as such contraction reached a plateau,  $\text{CaCl}_2$  10 mmol/L was rapidly added into the bath and another higher contractile response occurred with the tensile increase of  $1.10 \pm 0.18$  g ( $n = 4$ ). Genistein (20  $\mu\text{mol/L}$ ; Figure 4) and resveratrol (20  $\mu\text{mol/L}$ ) reduced the first contraction induced by ACh from  $0.89 \pm 0.10$  g to  $0.50 \pm 0.18$  g and  $0.64 \pm 0.15$  g respectively (all  $P < 0.05$ ,  $n = 4$ ), but did not change the second contraction caused by  $\text{CaCl}_2$  ( $1.23 \pm 0.25$  in genistein groups and  $1.18 \pm 0.15$  in resveratrol groups  $\text{vs}$   $1.10 \pm 0.18$  g in control groups respectively, all  $P > 0.05$ ,  $n = 4$ ) in  $\text{Ca}^{2+}$ -free Kreb's solution.

#### Effects of genistein, resveratrol and 17 $\beta$ -estradiol on agonist-induced contractions

ACh ( $10^{-8}$ - $10^{-3}$  mol/L) and KCl (10-100 mmol/L)

elicited concentration-dependent contractile responses in isolated gallbladder muscle strips. However, genistein, resveratrol and 17 $\beta$ -estradiol significantly reduced the responses to ACh and KCl, and made their concentration-dependent contraction curves shift to the right (Figure 5). The pD<sub>2</sub> values of ACh in control and after incubation with 40  $\mu\text{mol/L}$  genistein, 40  $\mu\text{mol/L}$  resveratrol and 40  $\mu\text{mol/L}$  17 $\beta$ -estradiol were  $3.97 \pm 0.16$ ,  $3.38 \pm 0.17$  ( $P < 0.05$   $\text{vs}$  control,  $n = 6$ ),  $3.54 \pm 0.08$  ( $P < 0.05$   $\text{vs}$  control,  $n = 10$ ) and  $3.45 \pm 0.14$  ( $P < 0.05$   $\text{vs}$  control,  $n = 7$ ), respectively. The pD<sub>2</sub> values of KCl in control and after incubation with 40  $\mu\text{mol/L}$  genistein, 40  $\mu\text{mol/L}$  resveratrol and 40  $\mu\text{mol/L}$  17 $\beta$ -estradiol were  $1.61 \pm 0.30$ ,  $0.70 \pm 0.07$  ( $P < 0.05$   $\text{vs}$  control,  $n = 11$ ),  $1.12 \pm 0.03$  ( $P < 0.05$   $\text{vs}$  control,  $n = 14$ ) and  $1.10 \pm 0.05$  ( $P < 0.05$   $\text{vs}$  control,  $n = 7$ ).

## DISCUSSION

The gallbladder and gut should be viewed as hormonally responsive organs. The normal physiology of which may be altered by the sex hormones<sup>[1]</sup>. Also, it is well established that cholelithiasis is more frequent in women than in men. This difference is usually explained by the effects of estrogens and progesterone on the metabolism of bile acids, biliary cholesterol secretion and saturation, and gallbladder motility<sup>[3,4]</sup>. As we know, gallbladder motility has an important role in the regulation of bile flow, its function disturbances may prevent normal bile flow and thus enhance the probability of common bile duct stone formation. Sex steroid hormone have inhibitory effects on the contractility which may be mediated by the inhibition of the mobilization of intracellular calcium and calcium influx in gallbladder smooth muscles<sup>[4]</sup>.

Papers have shown that there are structural similarities between the steroid nucleus of 17 $\beta$ -estradiol and the rigid ring structure of phytoestrogen genistein, and because both of them are lipid-soluble compounds and their molecular weight are not large, they can easily enter cytoplasm through the cellular membrane to affect expression of some genes. The affinity of genistein to the classic estrogen  $\alpha$  receptor (ER $\alpha$ ) presented on reproductive organs is less than that of estrogen<sup>[17]</sup>, but it has a similar affinity as estrogen for the novel estrogen  $\beta$  receptor (ER $\beta$ ) in the vasculature<sup>[18]</sup>. As well as evidence that resveratrol exhibits variable degrees of estrogen receptor agonism in different test systems, and the similarity in structure between resveratrol and the synthetic estrogen diethylstilbestrol (DES; 4,4'-dihydroxy-trans- $\alpha$ ,  $\beta$ -diethylstilbene) prompted us to investigate whether resveratrol might exhibit estrogenic activity in gallbladder motility<sup>[19]</sup>. The present study has shown that the phytoestrogen genistein and resveratrol can induce significant inhibitory effects on isolated gallbladder contractility in a similar way as 17 $\beta$ -estradiol does, and the effects were dose-dependent. Gallbladder smooth muscle cells have been shown to express functional ERs<sup>[2]</sup>, so the effects of phytoestrogen genistein and resveratrol may be attributed to their combination with ERs, but our study demonstrates

that the inhibitory effects induced by genistein and resveratrol are unlikely to be mediated through the ER, as the actions of genistein and resveratrol had no obvious change in the presence of the pure and specific ER antagonist ICI 182780, although it can block not only the classical ER<sub>a</sub> but also the novel ER<sub>b</sub><sup>[20]</sup>. These results suggest that the acute inhibitory effects caused by genistein, resveratrol and 17-β estradiol are not mediated by the classical estrogen receptor and are independent of gene-mediated events.

It is well known that genistein and resveratrol are tyrosine kinase inhibitors<sup>[12,13]</sup> and tyrosine kinase activity has been demonstrated to play a role in smooth muscle contractility<sup>[4,21]</sup>. In the present experiment, a potent protein tyrosine phosphatase inhibitor bpV (phen), which can prevent the decrease of protein tyrosine phosphorylation, markedly attenuated the inhibitory effects of 10 μmol/L genistein and 10 μmol/L resveratrol on gallbladder smooth muscle contractile activities. Our results suggest that tyrosine kinase inhibition is probably responsible for the inhibitory effects induced by genistein and resveratrol in gallbladder smooth muscle contractility. These results are supported by the evidences that tyrosine kinase inhibition contributes to the decrease of Ca<sup>2+</sup> influx and Ca<sup>2+</sup> mobilization<sup>[21,22]</sup>.

The presence of cholinergic M receptors in guinea pig gallbladder smooth muscle cells has been reported<sup>[23]</sup>. ACh can activate receptor-operated calcium channels (ROCs) in the cellular membrane of gallbladder smooth muscle and increase calcium influx, while also activating G proteins and phospholipase C to produce inositol trisphosphate (IP<sub>3</sub>) which causes calcium release from endoplasmic reticulum<sup>[4,23]</sup>. As we know, the contractile response to ACh comprises two distinct components in Ca<sup>2+</sup>-free medium: an initial phasic component that results from IP<sub>3</sub>-mediated release of Ca<sup>2+</sup> from intracellular Ca<sup>2+</sup> stores followed by a tonic component that requires addition of Ca<sup>2+</sup> in the continuous presence of ACh, due to Ca<sup>2+</sup> influx. This is so-called biphasic contraction induced by ACh and Ca<sup>2+</sup>. In calcium-free Kreb's solution, genistein and resveratrol could significantly decrease ACh-induced contraction but they did not affect the latter CaCl<sub>2</sub>-induced contraction. In normal Kreb's solution, genistein, resveratrol and 17β-estradiol could also reduce the contractile responses of ACh and shift their cumulative concentration-response curves rightward in a parallel manner. Considering these observations, it seems reasonable to suggest that the inhibition of Ca<sup>2+</sup> release may involve in the inhibitory effects of genistein and resveratrol on gallbladder smooth muscle contractility.

Potential dependent calcium channels (PDCs) are activated by depolarization of the plasma membrane when the extracellular K<sup>+</sup> concentration is increased, and it has been reported that potassium-stimulated gallbladder contraction depends exclusively upon the influx of extracellular calcium<sup>[4]</sup>. In the present experiment, genistein, resveratrol or 17β-estradiol could shift the KCl concentration-dependent contraction

curves to the right in normal Kreb's solution and inhibited KCl concentration-dependent contractile responses in a noncompetitive manner. The results suggest that genistein and resveratrol may have Ca<sup>2+</sup> antagonistic properties which are consistent with the effect of 17β-estradiol, and inhibit extracellular Ca<sup>2+</sup> influx through PDC.

In summary, similar to 17β-estradiol, genistein and resveratrol have been shown to have a direct inhibitory effect on both the basal and agonist-stimulated contractile activity of guinea pig gallbladder *in vitro*.

## COMMENTS

### Background

Phytoestrogen genistein and resveratrol are structurally and functionally similar to estrogen and possess many physiological and pharmacological effects. Data indicate that genistein, resveratrol can inhibit vasocontractile responses and relax vascular smooth muscles by a Ca<sup>2+</sup> antagonistic property which is similar to estradiol, but little is known about the effect of genistein and resveratrol on gallbladder smooth muscle motility.

### Research frontiers

Gallbladder disease is more prevalent in women than men, and estrogen therapy has been associated with an increased incidence of gallbladder disease in both sexes, suggesting that hormones may play an important role in these conditions. Phytoestrogens such as genistein and resveratrol have estrogen agonistic/antagonistic effects, and are proposed to have potential as natural substitutes of estrogen therapy.

### Innovations and breakthroughs

This study aim is to compare the direct effects of genistein and resveratrol on isolated gallbladder smooth muscle motility with that of 17β-estradiol both at rest and in response to stimulation, and to elucidate the underlying mechanisms.

### Applications

The present results reflect the pharmacological actions of genistein and resveratrol and can provide the pharmacological guidance for the application of these compounds which are very valuable for medicine and nutrition.

### Peer review

This is an interesting report of effects of genistein and resveratrol on gallbladder contractility.

## Abstract

The management of Meckel diverticulum found unexpectedly during an abdominal operation remains controversial. Most published reports have included only patients undergoing diverticulectomy or bowel resection through laparotomy. We report a case of a carcinoid tumor in a Meckel's diverticulum which was incidentally detected and removed during laparoscopic inguinal hernia repair. Although there is no compelling evidence in the literature to recommend prophylactic diverticulectomy, laparoscopic stapled resection represents a viable and safe approach in healthy individuals undergoing elective surgery for other purposes.

## INTRODUCTION

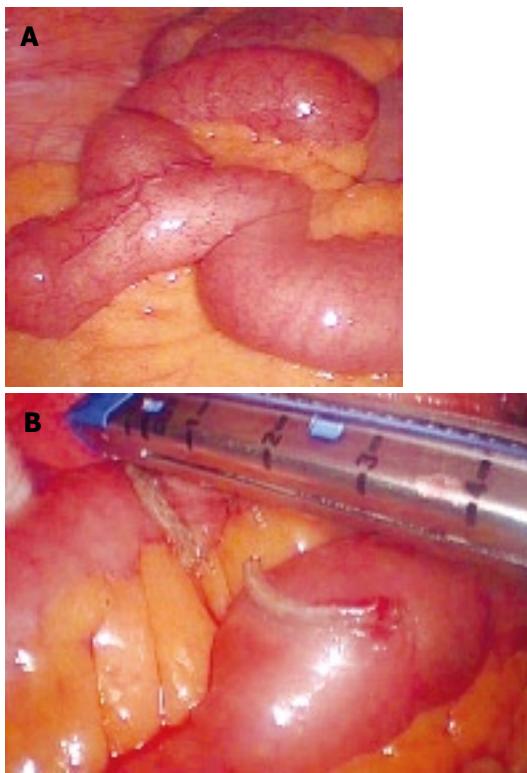

Meckel's diverticulum (MD) is one of the most common congenital abnormalities of the gastrointestinal tract, as it occurs in approximately 2% of the population. This true diverticulum results from an incomplete obliteration of the vitelline duct during the fifth week of gestation and arises from the antimesenteric border of the distal ileum, within 100 cm of the ileocecal valve in the adult. In the majority of cases, the MD is asymptomatic and the diagnosis is made during elective surgery for other intra-abdominal disorders. In some circumstances, the MD can be associated with heterogeneous clinical manifestations ranging from recurrent abdominal pain to life-threatening problems, such as gastrointestinal bleeding or acute bowel obstruction. The diverticulum may contain areas of ectopic mucosa, more commonly of gastric type, or malignant tumors such as carcinoids<sup>[1]</sup>.

The decision to perform diverticulectomy for MD incidentally detected during an abdominal operation is still controversial. Over the past two decades, laparoscopy has been extensively used in the diagnosis and treatment of various abdominal disorders. The opportunity provided by the laparoscopic approach to perform a complete abdominal exploration may increase the number of incidental findings, and this may again pose a dilemma to the surgeon who is more and more committed to the principles of evidence-based medicine for a better and more cost-effective patient care.

## CASE REPORT

A 66 year-old man was seen in the outpatient clinic because of the chronic complaint of pain on exertion and a bulge localized at his left groin. His medical history was unremarkable, except for a mild hypertension. The body mass index was 30. Physical examination showed a bilateral inguinal hernia. An abdominal ultrasonography was negative. Elective laparoscopic repair of the bilateral hernia was scheduled after the patient gave his informed consent.

Preoperative antibiotic prophylaxis (Cefazolin, 2 g i.v.) was administered. Under general anesthesia, pneumoperitoneum was established using a Veress needle. Three bladeless trocars were inserted along the transverse umbilical line, and a 30° angled scope was introduced through the umbilical port. Laparoscopic explora-

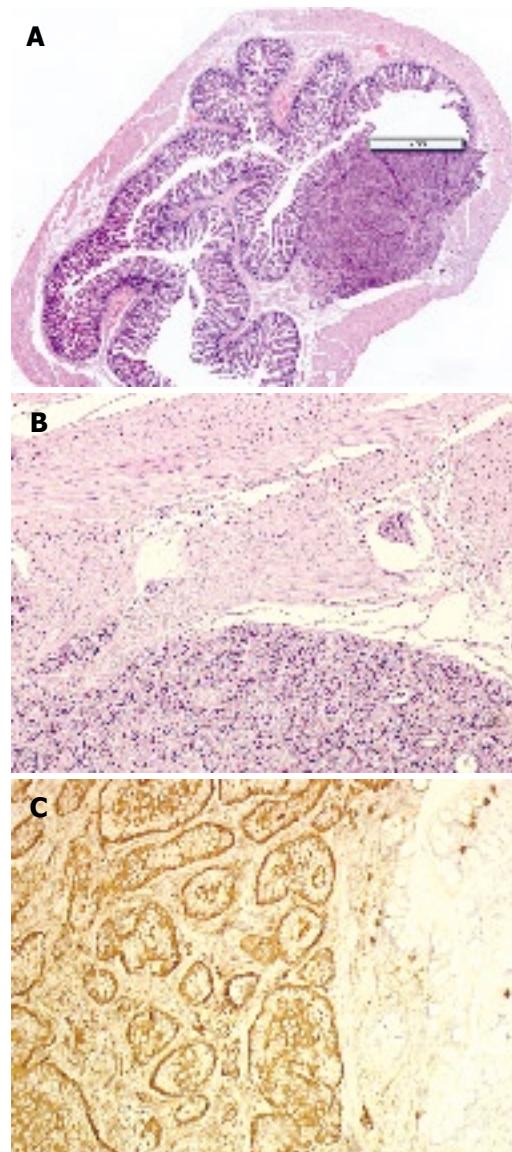

**Figure 1** Meckel diverticulum found unexpectedly during laparoscopic inguinal hernia repair (**A**) and resection of the diverticulum with an endoscopic linear stapler (**B**).

tion immediately revealed a 4 cm long MD arising from the distal ileum, about 70 cm proximal to the ileocecal valve (Figure 1). Priority was given to the inguinal hernia repair. Starting from the left groin, a curvilinear incision was made in the peritoneum beginning laterally and extending to the medial umbilical ligament. A peritoneal flap was created medially by blunt dissection to expose the Cooper's ligament. A preformed polypropylene mesh was placed within the pre-peritoneal pocket and secured with staples and fibrin glue. The peritoneal layer was closed with a running suture (PDS, Ethicon). The same procedure was repeated in the right groin. Upon completion of the hernia repair, the MD was held with an atraumatic grasper through the left port and an endoscopic linear stapler (EndoGIA II, 60 mm, Covidien) was tangentially applied across the base of the diverticulum and fired. The specimen was put into a plastic bag and removed through one of the ports. The patient had an uncomplicated recovery and was discharged home on postoperative day 2. Pathologic examination of the surgical specimen showed a normal ileal mucosa lining and a nodule, 1.5 cm in diameter, with a pattern indicative for a carcinoid tumor located in the proximity of the tip of the diverticulum (Figure 2).

## DISCUSSION

It has long been stated that the risk of developing complications following the incidental removal of MD can offset the potential benefits of this procedure<sup>[2]</sup>. Opponents to incidental diverticulectomy often cite Soltero

**Figure 2** Meckel diverticulum with a nodule 1.5 cm in size (HE, x 1.5) (**A**), superficial infiltration of the diverticulum wall (HE, x 10) (**B**), and immunohistochemical stain with chromogranin A showing a strongly positive reaction and normal intestinal mucosa with control stain of endocrine single cells on the right (x 10) (**C**).

and Bill<sup>[3]</sup> who, in 1976, estimated that the life-time risk of complications from an untreated MD was 4.2%, and that this risk decreased to zero with age. These authors recommended refraining from incidental diverticulectomy because there is only a small chance of MD-related complications in later life. In contrast, almost twenty years later, the results of a large population-based study in Olmsted County, Minnesota, provided data in support of prophylactic diverticulectomy<sup>[4]</sup>. This study reported a 6.4% cumulative rate of developing complications of MD that required surgery over a life-time, especially in male patients up to 80 years of age. Diverticulectomy for complicated MD carried an operative mortality and morbidity of 2% and 12%, and a cumulative risk of long-term complications of 7%. The corresponding rate for incidental diverticulectomy is 1%, 2% and 2%, respectively. Interestingly, in this latter subgroup of patients,

the mortality was related to the primary operation or the patient fitness but not to the diverticulectomy itself<sup>[4]</sup>. A subsequent report from the Mayo Clinic recommended MD resection only in male patients younger than 50 years of age, or when the diverticulum length is greater than 2 cm, or when abnormal features are detected within the diverticulum<sup>[1]</sup>. Of interest, a carcinoid tumor was found in 2.2% of the symptomatic patients and in 2.1% of the asymptomatic ones in this series<sup>[1]</sup>. More recently, however, a systematic review of the English literature has shown that there is no compelling evidence to support prophylactic resection<sup>[5]</sup>. In fact, resection of incidentally detected MD has a significantly higher early complication rate than leaving the diverticulum *in situ* (5.3% vs 1.3%,  $P < 0.0001$ )<sup>[4]</sup>.

It should be noted that most of the data upon which recommendations have been based so far originate from retrospective studies in patients who underwent incidental diverticulectomy or bowel resection through laparotomy<sup>[5]</sup>. The advent of laparoscopy may have changed this scenario. Laparoscopy allows a complete abdominal exploration in patients undergoing minimally invasive procedures and has the potential to reveal additional pathological findings. Moreover, laparoscopy has been used to diagnose and treat patients with MD complicated by small bowel obstruction or bleeding caused by occult heterotopic gastric mucosa<sup>[6,7]</sup>.

To our knowledge, this is the first reported case of carcinoid in MD which was incidentally found and removed during laparoscopy for inguinal hernia repair. Carcinoids are slow growing tumors with a malignant potential arising from the diffuse neuroendocrine system. The gastrointestinal tract is the largest neuroendocrine organ in the body and the site of origin for 90% of all carcinoids. The most common location of carcinoid is the appendix, where tumors are usually small and benign, followed by the ileum, where they are often multiple and characterized by a more aggressive biological behavior. More than 100 cases of carcinoids in MD have been reported in the literature, 72% of the tumors were located at the tip of the diverticulum, and distant metastases were

present in 24% of the patients at the time of diagnosis<sup>[8]</sup>. Immunohistochemical studies have shown that Meckel's carcinoids are closer to the ileal rather than to the appendiceal carcinoids<sup>[9]</sup>. Histopathological analysis in our patient demonstrated a R0 resection and the presence of limited superficial invasion of the diverticulum wall, confirming that diverticulectomy is adequate. Although there is no compelling evidence in the current literature to support prophylactic diverticulectomy for patients with MD, we believe that simple laparoscopic tangential resection with an endostapler is a viable and safe procedure during elective operations for healthy patients.

### INTRODUCTION

Small-cell carcinoma (SCC) is common malignancy of the lung and represents 20%-25% of all bronchogenic carcinomas<sup>[1]</sup>. It seldom originated from extrapulmonary sites (2.5%-4% of all SCC). The primary site of extrapulmonary SCC (EPSCC) can be in a variety of organs and the clinical course of these tumors has been found to be aggressive, with early dissemination and frequent recurrence. Primary SCC of the pancreas is rare, comprising about 1% of all pancreatic malignant tumors<sup>[2]</sup>. Because of its aggressiveness, most of patients with SCC of the pancreas are diagnosed at an advanced stage of disease. According to previous reports, survival of patients with SCC in the pancreas varies between 2 and 5 mo<sup>[3]</sup>. Here, we report a case of unusually long-term survival after curative surgery and combined chemotherapy for poorly differentiated SCC of the pancreas.

### CASE REPORT

A 62-year-old woman presented to our institute with a 3-wk history of anorexia, dyspepsia, epigastric pain. She had drunken extracts of Hovenia dulcis for 5 mo. There was no history of smoking and regular alcohol consumption. Her family history revealed no abnormalities. She had no relevant previous medical or surgical history. Physical examination was unremarkable except for epigastric tenderness.

Laboratory studies revealed increased total bilirubin (4.9 mg/dL) and direct bilirubin (3.5 mg/dL). Liver enzymes were raised, with serum alkaline phosphatase (1072 U/L), SGOT (233 U/L) and SGPT (101 U/L). The calcium was 9.9 mg/dL and phosphate was 4.0 mg/dL. Serum viral markers, including HIV, HBsAg, and HCV were nonreactive. Tumor markers included carbohydrate antigen 19-9 (CA 19.9, 291.6 U/mL), alpha-fetoprotein (AFP, 3.6 ng/mL), and carcino-embryonic antigen (CEA, 3.2 ng/mL). Serum neuron-specific enolase (NSE) was

### Abstract

Small cell carcinoma (SCC) of the pancreas is rare. It has similar histological features to pulmonary small cell carcinoma and is equally aggressive. Most patients with SCC in the pancreas reported in case studies died within 1 year after diagnosis. We present a case of unusually long-term survival after surgery and combined chemotherapy for SCC of the pancreas. A 62-year-old woman presented with epigastric pain and jaundice. Computed tomography revealed dilated common bile duct caused by external compression of the mass in the pancreatic head. Exploratory laparotomy and pancreaticoduodenectomy (PPPD) was performed with histopathological analysis confirming a primary small cell carcinoma of the pancreas. After an uneventful postoperative recovery, the patient was treated with 6 cycles of combined chemotherapy consisting of cisplatin and ectoposide. During the follow-up, there was no evidence of recurrence and the patient has remained in a good health condition for 36 mo since the diagnosis.

**Figure 1** **A:** Abdominal computed tomography in the arterial phase shows poorly demarcated mass compressing CBD (black arrow); **B:** In delayed phase, mass (white arrows) at the pancreatic head revealed with relatively well delineated margin.

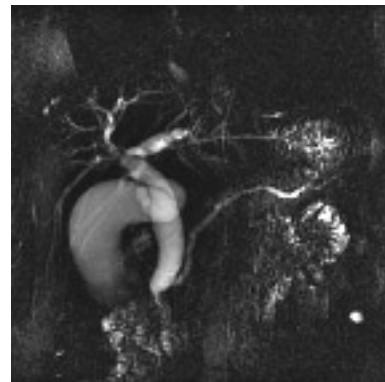

12.5 ng/mL (normal, 0.1-16.3 ng/mL).

A contrast-enhanced computed tomography (CT) of the abdomen showed dilatation of intrahepatic duct, common bile duct (CBD), and pancreatic duct. There was 1.3 cm sized mass at the head of pancreas compressing the distal CBD (Figure 1). There was no evidence of pancreatitis. Magnetic resonance cholangiopancreatography and endoscopic-retrograde cholangiopancreatography (ERCP) was performed and confirmed abrupt CBD narrowing due to extrinsic compression (Figure 2). During the ERCP, it was possible to obtain tissue from the CBD.

The histopathologic study revealed small uniform nuclei with inconspicuous nucleoli and scanty cytoplasm. The morphology of the cells was similar to that of small cell carcinoma of the lung. The immunohistochemical (IHC) stain results were positive for CD56 and thyroid transcription factor-1 (TTF-1) stain and negative for NSE. Typical microscopic features confirmed small cell carcinoma. Chest X-ray and bone scan were normal.

The tumor was localized in the head of the pancreas and no extension beyond the locoregional boundaries; we performed PPPD (Longmire III operation). During the operation, there was no peritoneal seeding or invasion to adjacent organs. Common hepatic artery (No 8) and para-aortic (No 16) lymph node were enlarged but they were found out to have no metastasis in frozen section biopsy. The patient recovered without any postoperative complications.

Examination of the surgical specimen showed an

**Figure 2** Magnetic resonance cholangiopancreatography (MRCP) shows abrupt narrowing of the distal common bile duct and mild dilatation of pancreatic duct.

**Figure 3** Gross appearance of the specimen shows a tumor nodule 2 cm in diameter at the head of the pancreas.

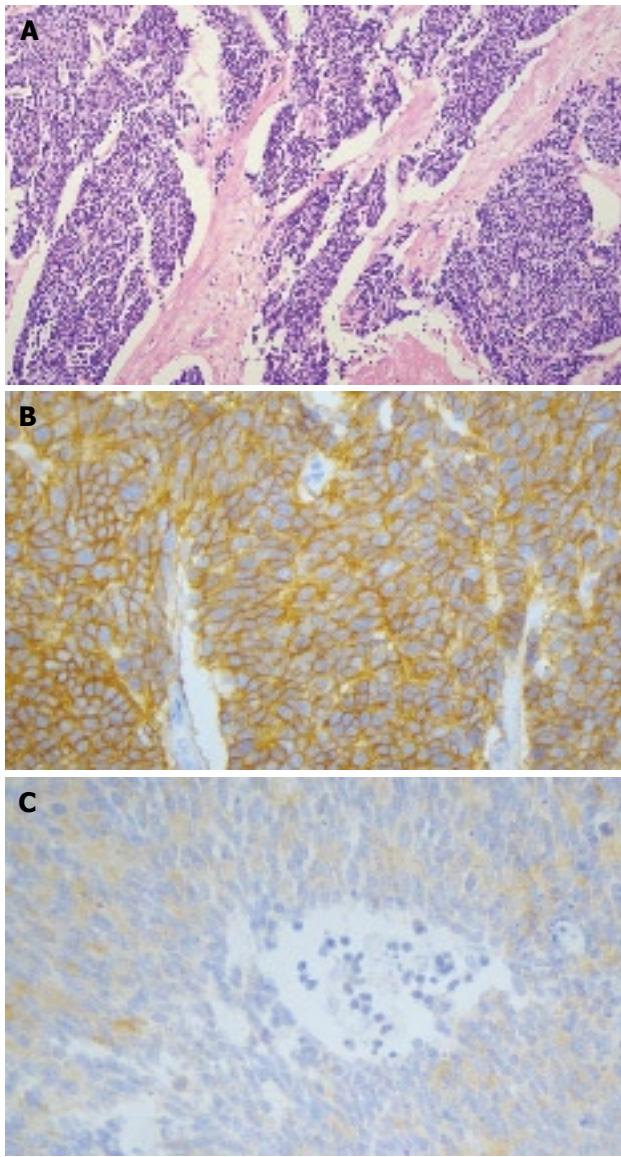

ill demarcated grayish white and firm mass measuring 2.0 cm × 1.2 cm in size in the head of the pancreas. 1 out of 16 lymph nodes showed tumor metastasis (Figure 3). There was lymphatic and perineural invasion. The tumor was composed of small monotonous and hyperchromatic poorly differentiated cells with higher nuclear to cytoplasmic ratio, and were positive for CD56, cytokeratin, chromogranin, TTF-1 and CEA, but negative for NSE, CD99 and equivocal for synaptophysin (Figure 4).

Four weeks after the operation, the patient received chemotherapy consisting of cisplatin (100 mg/m<sup>2</sup>) and ectoposide (60 mg/m<sup>2</sup>, day 1-3) for 4 wk intervals. After first cycle of chemotherapy CA 19-9 decreased to 19.0 U/mL. The chemotherapy was tolerated well and was continued for 6 cycles. During the follow-up there was no evidence of recurrence and the patient has remained in a good health condition for 36 mo since the diagnosis.

## DISCUSSION

Extrapulmonary small cell carcinomas (EPSCC) are rare with an incidence between 0.1%-0.4% of all cancers<sup>[1]</sup>. Approximately 2.5% of all SCC's arise in extrapulmonary sites such as head and neck region, esophagus, stomach, colon, rectum, gallbladder, uterine cervix, breast, urinary bladder, liver, and prostate<sup>[4-8]</sup>.

SCC of the pancreas is a rare entity. Since the earliest case report of pancreatic SCC with clinical

**Figure 4** A: The tumor consisted of small round or oval cells with hyperchromatic nuclei and scant cytoplasm; B and C: Immunohistochemical staining for CD56 (B) and synaptophysin (C) reveals a positive reaction.

and pathologic findings in 1973<sup>[9]</sup>, only a few reports have been published with fewer than 40 cases<sup>[3,10-12]</sup>. According to the previous studies, SCC of the pancreas is likely to occur in the head of pancreas in patients with average age of 60 and common clinical manifestations are abdominal pain, weight loss and jaundice. Many of the cases reported were diagnosed at autopsy, since most of patients with SCC of the pancreas are diagnosed at an advanced stage of disease and their survival varied between 2-5 mo<sup>[1,3]</sup>.

SCC is thought to originate from neuroendocrine cells, which are found in the epithelium of many mucosal surfaces. Despite evidence of neuroendocrine involvement, the origin of EPSCC is still unclear as development from undifferentiated airway epithelium has also been suggested along with the amine precursor uptake and decarboxylation (APUD) system hypothesis which proposes a common ancestral cell derived from the neural crest, migrating to various epithelial tissues

and sites within the body<sup>[13,14]</sup>. Since SCC cell has similar properties to the endocrine cells of APUD system, EPSCC may also secrete hormones. But in the case of SCC of the pancreas, there is only one report of ACTH-producing tumor by Corrin *et al* and one case associated with hypercalcemia<sup>[9,15]</sup>, which is different from frequent paraneoplastic syndromes in pulmonary SCC. There were no abnormal findings suggesting paraneoplastic hormone syndromes in the case of our patient. O'Connor *et al* reported NSE was clearly elevated in SCC of the pancreas. They suggested that serum NSE could be a tumor marker for SCC of the pancreas, but NSE was within the normal range in this case<sup>[16]</sup>.

EPSCC of the pancreas is histologically indistinguishable from metastatic pulmonary SCC. Therefore, exclusion of pulmonary small cell carcinoma is a prerequisite for the diagnosis of EPSCC. In our case, chest X-ray and PET-CT were negative for the lungs. Since the biopsy from the pancreas is difficult, most of the cases were diagnosed by biopsy from the liver metastasis or lymph node or autopsy and a few cases after surgical removal<sup>[3,11,17,18]</sup>. To evaluate dilated CBD, our patient received ERCP before surgery. During the procedure it was possible to obtain tissue from the narrowing portion of the CBD. We could confirm the tumor as EPSCC before the surgery.

On gross findings, SCC of the pancreas appears as a poorly demarcated white-gray mass with areas of necrosis and hemorrhage. It usually involves the head of the pancreas with a mean diameter of 4.2 cm<sup>[3]</sup>. The histopathologic appearance of the tumor consists of nest of small to medium sized round to oval shaped cells with a finely granular and hyperchromatic nucleus, inconspicuous nucleoli and scanty cytoplasm. Primary small cell carcinoma of the pancreas has a varied immunohistochemical profile.

Neuroendocrine markers such as CD56, chromogranin, TTF-1 and CEA were positive but NSE and synaptophysin was negative in current case.

Unfortunately clinical presentation of EPSCC is usually at an advanced stage due to the aggressive nature of the disease. Therapeutic modalities are determined by the location and extent of disease. Usually chemotherapy remains the treatment of choice and local modalities such as surgery and radiotherapy remain limited in localized disease<sup>[19]</sup>.

In our case, the tumor was localized in the pancreas with regional lymph node involvement. Since there was no extension beyond the locoregional boundaries (limited disease), we could perform curative surgery.

Because of the high incidence of metastasis, chemotherapy should be given after a successful resection of the tumor. Only one case was reported long survival after curative resection of SCC of the pancreas without adjuvant chemotherapy<sup>[18]</sup>. There are no definite chemotherapeutic regimens for SCC of the pancreas due to the small patient numbers. But the combination cisplatin and etoposide showed best result with response rates reaching 70% in an analysis of the

different patients of EPSCC with chemotherapeutic regimens. Doxorubicin-based regimens appear to be less effective<sup>[20]</sup>.

Complete response has been observed with cisplatin-etoposide based treatment in a patient with widespread metastatic disease<sup>[11]</sup>. The two patients reported by van der Gaast had extensive disease with a survival of 16 and 11 mo after combined chemotherapy with cyclophosphamide, doxorubicin and etoposide<sup>[21]</sup>. Another patient survived 14 mo with combined chemotherapy and the radiotherapy<sup>[22]</sup>. Our patient received chemotherapy consisting of cisplatin (100 mg/m<sup>2</sup>), etoposide (60 mg/m<sup>2</sup>, day 1-3) for 4 wk after the surgery. A CT scan of the abdomen after 6 cycles of chemotherapy showed no evidence of metastasis. The patient remains in good health 36 mo after the surgery. The reason for the good prognosis may be associated with an early detection of the tumor and the fact that the tumor was localized and showed no metastasis or dissemination.

Because of the unfavorable prognosis of EPSCC, multimodal therapy was used in most of reported cases with limited disease. In the case of resectable SCC of the pancreas, it is reasonable to perform the extensive surgery followed by chemotherapy. We report a case of primary SCC of the pancreas with unusually long-term survival after multimodal therapy.

### INTRODUCTION

Malignant melanoma occurs most frequently in skin but also in many organs and tissues of the body. However, primary hepatic malignant melanoma is exceedingly rare. Only 12 cases, including 8 cases from PubMed and 4 cases from Chinese literature<sup>[1-4]</sup>, have been reported. In PubMed, there are only 3 cases of definite primary melanoma<sup>[5-7]</sup>. Microscopically, it may be easily misdiagnosed because of morphological heterogeneity and hypomelanotic appearance. The present case represents the only case encountered in our department. In this report, we describe our pathological observations and review the literature in order to improve our understanding of the disease, avoid misdiagnosis and provide evidence for its clinical treatment and prognosis.

### Abstract

Primary malignant melanoma of the liver is an exceedingly rare tumor. Only 12 cases have been reported in the worldwide literature. We present a case of isolated malignant melanoma of the liver occurring in a 36-year-old Chinese male patient. Comprehensive dermatologic and ophthalmologic examinations revealed no evidence of a cutaneous or ocular primary lesion. Other lesions in brain, respiratory tract, lung, gastrointestinal tract and anus, were not demonstrated by serial positron emission tomography (PET). Microscopic examination of the resected specimen revealed a malignant melanoma, which was confirmed by immunohistochemical staining for HMB-45, S-100 protein, melanoma-pan and vimentin. Moreover, electron microscopy demonstrated melanosomes in tumor cell cytoplasm. Our case shows that primary malignant melanoma may occur in the liver and should be considered when the histopathological appearance is not typical for other hepatic neoplasm.

**Key words:** Primary malignant melanoma; Liver;  
Diagnosis; Histopathology; Immunohistochemistry

### CASE REPORT

A 36-year-old man was admitted to the Department of General Surgery, Tangdu Hospital, Fourth Military Medical University (Xi'an, Shaanxi Province, China) because a mass in his liver was found 4 d ago at a routine health check. He had no history of alcohol abuse or hepatitis. No record of hepatocellular carcinoma (HCC) or any hereditary disease was found in his family members. Routine clinical biochemistry showed normal levels of aspartate aminotransferase (AST), alanine aminotransferase (ALT), lactate dehydrogenase (LDH),  $\gamma$ -glutamyltransferase ( $\gamma$ -GTP),  $\alpha$ -fetoprotein (AFP) and plasma proteins. Laboratory tests failed to show any positive hepatitis B surface antigen (HBsAg) or anti-hepatitis C virus (HCV) antibody. Contrast-enhanced abdominal computerized tomography (CT) displayed a 10.1 cm  $\times$  12.8 cm well-defined hepatic mass in the right-posterior lobe of the liver without evidence for spread to neighboring lymph nodes or abdominal dropsy

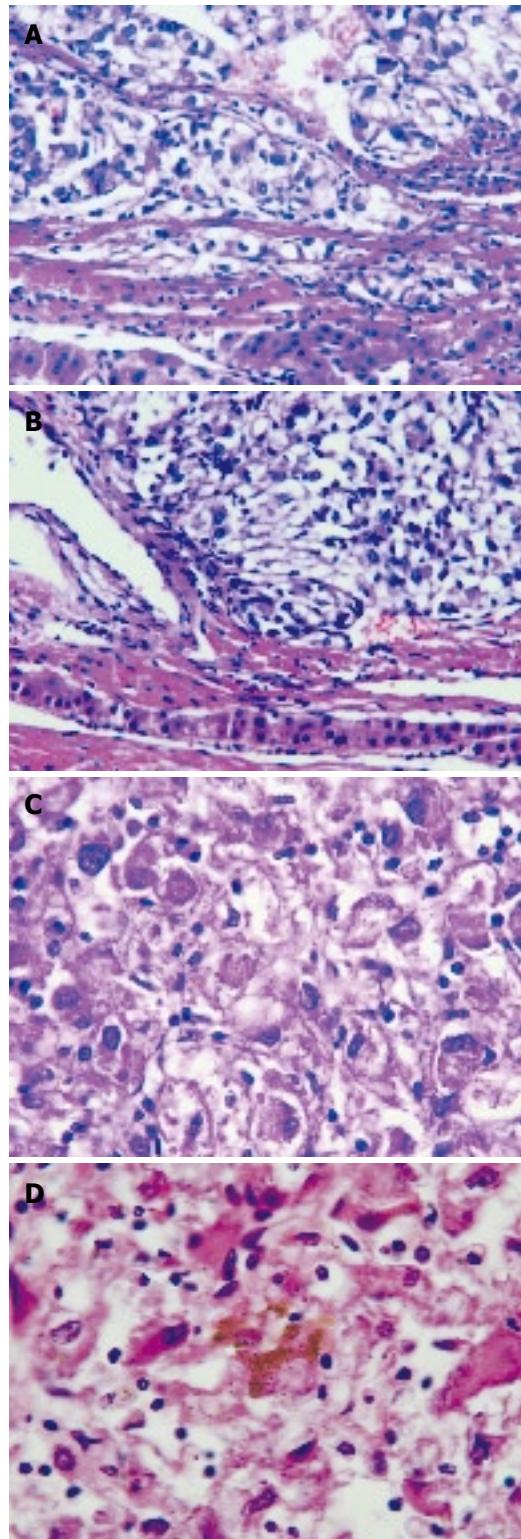

**Figure 1** Contrast-enhanced abdominal CT scan showing an oval, low-density, well-defined mass measuring 10.1 cm × 12.8 cm in the right posterior lobe of the liver.

**Figure 2** Gross appearance of the resected specimen showing the oval outline of tumor adjacent to normal liver tissue.

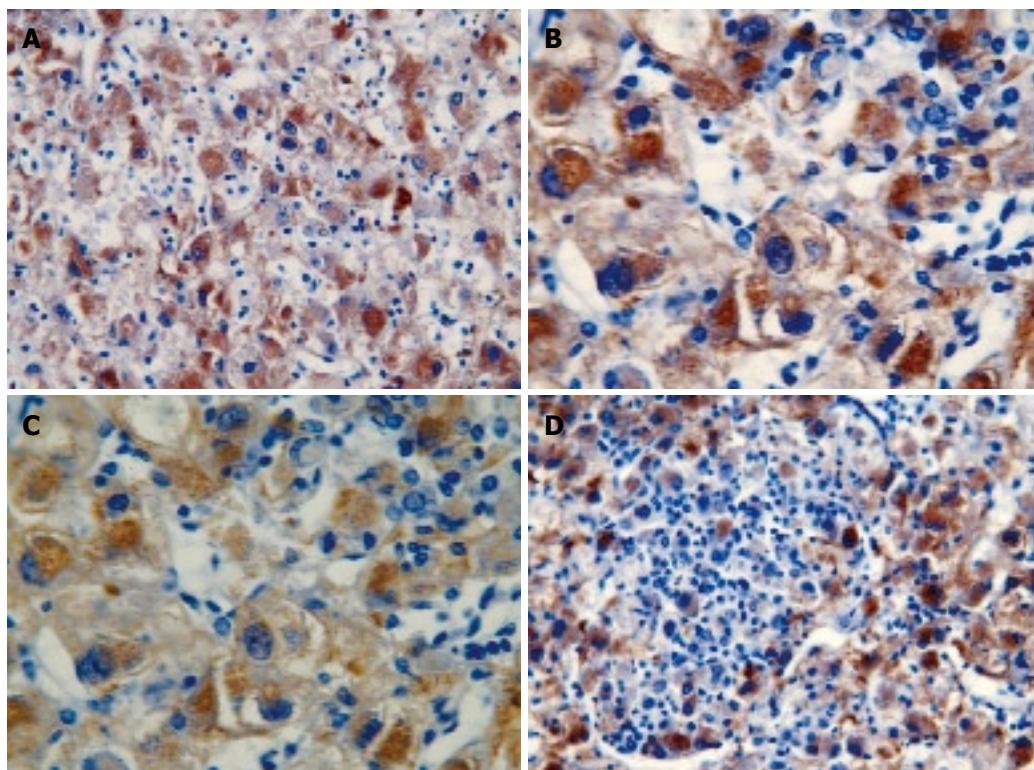

(Figure 1). The resected fresh tissue was fixed in 40 g/L formaldehyde solution, embedded in paraffin. Sections of 4 μm in thickness were prepared and stained with hematoxylin and eosin (HE). Immunostaining was carried out using a streptavidin-labeled peroxidase (S-P) kit (KIT9730) according to its manufacturer's instructions. Primary antibodies used in this study included those against HMB-45, melanoma-pan, epithelial membrane antigen (EMA), carcinoembryonic antigen (CEA), cytokeratins (18, 19, 7, 8), high-MW-CK, chromogranin A (CgA), synaptophysin (syn), sesmin, nerve specificity enolase (NSE), smooth muscle actin (SM-actin), vimentin, CD34, AFP, S-100 protein, CD117, human chorionic gonadotrophin (HCG), leucocyte common antigen (LCA), HBsAg, hepatitis B core antigen (HBcAg), as well as anti-HCV antibody. All of the reagents for immunostaining were supplied by Maxim Biotechnology Corporation Ltd, Fuzhou, China.

Grossly, the resected mass measured 12 cm × 11 cm × 6 cm (Figure 2). There was a clear differentiation between the mass and its surrounding normal tissue, and the cut surface of the tumor was grayish-yellow in color. Microscopically, the tumor cells showed a diffuse infiltration, and fibrous tissue could be observed between the lesion and normal hepatocytes. A few tumor cells breaking through the capsule infiltrated the adjacent liver tissue (Figure 3A and B). The tumor cells were

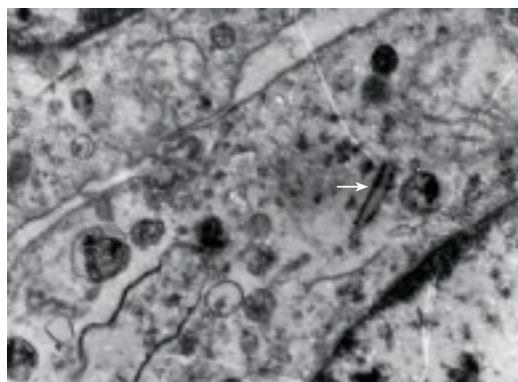

**Figure 3** Microscopy showing diffusely infiltrating tumor cells (A) and fibrous tissues (B) between the lesion and normal hepatocytes with a few broken tumor cells through the capsule infiltrating the adjacent liver tissue (x 200), pleomorphic tumor cells with round, spindle-shaped and irregular morphologies (x 400) (C), and some tumor cells containing melanin deposition (x 200) (D).

pleomorphic, with round, spindle-shaped and irregular morphologies. The tumor cell nuclei were round or oval, and the nucleoli were prominent, with both eosinophilic and basophilic varieties observed (Figure 3C). Some

**Figure 4** Immunohistochemistry revealing tumor cells positive for vimentin ( $\times 200$ ) (A), melanoma-pan ( $\times 400$ ) (B), HMB45 ( $\times 400$ ) (C) and S-100 protein ( $\times 200$ ) (D).

**Figure 5** Electron microscopy displaying occasional melanosomes in the cytoplasm (arrow).

tumor cells contained melanin deposition (Figure 3D). Immunohistochemically, the tumor cells were positive for vimentin (Figure 4A), melanoma-pan (Figure 4B), HMB-45 (Figure 4C) and S-100 protein (Figure 4D), but did not display AFP, high-MW-CK, CK18, CEA, CK19, CD34, CD117, NSE, LCA, CgA, HCG, EMA, desmin, SM-actin, SC-actin, myoglobin and immunoreactivity. Electron microscopy revealed occasional melanosomes in cytoplasm (Figure 5).

The complete absence of evidence for any cutaneous, ocular, mucosal lesions in all organs examined by serial position emission tomography (PET) supported the final diagnosis of primary melanoma.

After a wide local surgical resection, the patient received a 4-wk immunomodulatory therapy at a high dose of IV interferon alpha-2b, once a day. He then received a lower dose subcutaneous regimen, three times a week for a further 9 wk. This regimen was

well-tolerated. He was regularly followed up. Three months after operation, he had no recurrence of the disease. However, recurrent foci were found 5 mo after operation.

## DISCUSSION

Melanoma is a melanin-induced malignant tumor, most prevalent in patients over the age of 30 years. It mainly occurs in skin, but may be found in retina, anorectal canal, genital tract, gastrointestinal (GI) tract, accessory nasal cavity and parotid. Non-cutaneous primary melanomas carry a particularly high mortality because of their propensity for dissemination and invasion, often before they are clinically apparent.

Primary malignant melanoma of the liver is an extremely rare non-epithelial neoplasm, and few cases have been reported. We thus summarize, in this paper, the clinical characteristics and histopathologic manifestations of this unusual tumor.

Malignant melanomas of the skin originate from epidermal melanocytes or neural cells, both are derived from neural crest precursors<sup>[8]</sup>. Several factors, including race, heredity, tissue injury, stimulation, viral infection, sun-exposure and immunization, can lead to malignant transformation<sup>[9]</sup>. The origin of mucosal malignant melanoma is unclear. Most experts hold that malignant melanomas of non sun-exposed tissues are linked to stimulation by the blood-borne sunlight circulation factor, expressed in sun-exposed melanoblasts<sup>[10]</sup>. Based on the origin of primary melanomas of the esophagus and stomach, some authors believe that these alimentary tract neoplasms originate from migrating melanocytes invaginated by digestive tract epithelial cells during

embryogenesis<sup>[11,12]</sup>, which is supported by the distribution of melanocytes in other typically-occurring mucosal cells of the rectum<sup>[13]</sup>. However, the origin and pathogenesis of primary melanomas arising in parenchymal organs are still unclear.

It is difficult to show the clinical characteristics of primary hepatic malignant melanoma because case reports are available prior to the 1970s, except for 5 Chinese patients (2 males and 3 females, mean age 42.2 years, range 27-60 years). Previously reported patients had no readily identifiable risk factors when compared to patients with primary HCC.

Pathologically, hepatic malignant melanoma resembles that of the skin or mucosa, exhibiting morphologic variability within the tumor sample. Microscopically, the tumor mass is comprised of epithelioid cells arranged in nests, or spindle cells arranged in fascicles, with or without melanin pigment deposition. Mitotic figures are readily apparent. However, our case suggests that it may be difficult to identify malignant melanoma from a biopsy sample in some cases, because portions of the tumor may be amelanotic. In these cases, ancillary immunohistochemical staining may be extremely valuable<sup>[14]</sup>. In our case, when specimens of HCC, haemangioma, large-B cell lymphoma, smooth muscle tumor and rhabdomyosarcoma were all considered in the differential diagnosis, all of which were potentially consistent with the intact capsule, large size, and well-circumscribed boundaries. However, all the above tumors could be ultimately excluded based on their histopathologic characteristics and immunohistochemical staining. After reviewing a number of additional sections and detecting sporadic pigment granules in the tumor cytoplasm, we considered a diagnosis of malignant melanoma. The tumor cells expressed HMB45, S-100 protein, vimentin and melanoma-pan, all of which were consistent with hepatic melanoma. Our preliminary diagnosis was then confirmed by electron microscopy.

Once the pathologic diagnosis was established, whether the tumor was a primary or secondary lesion should be considered. An extensive investigation of potential primary sites demonstrated no evidence for hepatic melanoma, suggesting that the tumor is a primary melanoma of the liver.

Given the rarity of this tumor, the optimal therapeutic regimen is not known. In fact, the natural

history of these cases also remains unclear. Since surgical therapy is usually palliative, a more aggressive oncologic regimen consisting of chemotherapy, immunotherapy and radiotherapy may be required. With the natural history largely unknown, it is necessary to find treatment modalities for other deep primary melanomas,

## ACKNOWLEDGMENTS

The authors thank all the patients and their families for participating in this research.

### Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London, The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (*World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly open access peer-reviewed journal supported by an editorial board consisting of 1208 experts in gastroenterology and hepatology from 60 countries. The aim of the journal is to deliver the most clinically relevant original and commentary articles to readers, and to make the full text publicly available to all clinicians, scientists, patients and biomedical students on an unrestricted platform, so that they can access and learn about the most recent key advances in the field.

In addition to the open access nature, another key characteristic of *WJG* is its reading guidance for each article which includes background, research frontier, related reports, breakthroughs, applications, terminology, and comments of peer reviewers for the general readers.

*WJG* publishes articles on esophageal, gastrointestinal, hepatobiliary and pancreatic tumors, and other esophageal, gastrointestinal, hepatic-biliary and pancreatic diseases in relation to epidemiology, immunology, microbiology, motility & nerve-gut interaction, endocrinology, nutrition & obesity, endoscopy, imaging and advanced hi-technology.

The main goal of *WJG* is to publish high quality commentary articles contributed by leading experts in gastroenterology and hepatology and original articles that combine the clinical practice and advanced basic research, to provide an interactive platform for clinicians and researchers in internal medicine, surgery, infectious diseases, traditional Chinese medicine, oncology, integrated Chinese and Western medicine, imaging, endoscopy, interventional therapy, pathology and other basic medical specialties, and thus eventually improving the clinical practice and healthcare for patients.

The WJG Press

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

#### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://wjg.wjnet.com/wjg>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjnet.com/wjg/help/instructions.jsp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [submission@wjnet.com](mailto:submission@wjnet.com), or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was carried out; author contributions; disclosure of any financial support for the research; and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (remove all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s), and full family name.

**Author contributions:** The format of this section should be like this: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed research; Wang CL, Zou CC, Hong F and Wu XM performed research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed data; and Wang CL, Liang L and Fu JF wrote the paper.

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

#### Abstract

An informative, structured abstract of no more than 350 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipment, and the experimental procedures should be included. RESULTS: The observed and experimental results, including data, effects, outcome, etc. should be included. Authors should present *P* value where necessary, and also include any significant data. CONCLUSION: Accurate view and the value of the results should be included.

The format for structured abstracts can be found at: <http://www.wjnet.com/wjg/help/11.doc>.

#### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

#### Text

For articles of these sections, original articles, rapid communication

and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, should be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

### Illustrations

Figures should be numbered as 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...etc. It is our principle to publish high resolution-figures for the printed and E-versions.

### Tables

Three-line tables should be numbered 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P* < 0.05 and <sup>d</sup>*P* < 0.01 are used. A third series of *P* values can be expressed as <sup>e</sup>*P* < 0.05 and <sup>f</sup>*P* < 0.01. Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, □, ▲, △, etc., in a certain sequence.

### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

### PMID requirement

PMID roots in the abstract serial number indexed by PubMed (<http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed>). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information for journal citations is very important. Using the reference testing system, the authors and editor should check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in an ASP file so that the readers can immediately access the abstract of the citations online.

### DOI requirement

A CrossRef DOI® (Digital Object Identifier) name is a unique string created to identify a piece of scholarly content in the online environment. The author should supply the DOIs for journal citation(doi:10.3748/wjg.13.6458). This link (<http://www.crossref.org/SimpleTextQuery/>) allows you to retrieve Digital Object Identifiers (DOIs) for journal articles, books, and chapters by simply cutting and pasting the reference list into the box. You may use the form with any reference style, although the tool works most reliably if references are formatted in a standard style such as shown in this example: Assimakopoulos SF, Scopa CD, Vagianos CE. Pathophysiology of increased intestinal permeability in obstructive jaundice. *World J Gastroenterol* 2007; 13(48): 6458-6464

The accuracy of the information of journal citations is very important. We will interlink all references with DOI in ASP file so that readers can access the abstracts of cited articles online immediately.

### Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

### Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

*Patent (list all authors)*

- 16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

## Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those linked with a hyphen when the difference between the two numbers is greater than five. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered inappropriate references. Authors should not cite their own unrelated published articles.

## Statistical data

Write as mean  $\pm$  SD or mean  $\pm$  SE.

## Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as *v* (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

## Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5  $\mu$ g/L;  $\text{CO}_2$  volume fraction, 50 mL/L  $\text{CO}_2$ , not 5%  $\text{CO}_2$ ; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: <http://www.wjgnet.com/wjg/help/15.doc>.

## Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of

Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

## Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindII*, *BamHI*, *KhoI*, *KpnI*, etc.

Biology: *H pylori*, *E coli*, etc.

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

## Editorial Office

### World Journal of Gastroenterology

Editorial Department: Room 903

Ocean International Center, Building D

No. 62 Dongsihuan Zhonglu

Chaoyang District, Beijing 100025, China

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

Telephone: +86-10-59080039

Fax: +86-10-85381893

## Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

## Copyright assignment form

Please download a Copyright assignment form from <http://www.wjgnet.com/wjg/help/9.doc>.

## Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/wjg/help/10.doc>.

## Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

## Links to documents related to the manuscript

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

## Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

## Publication fee

Authors of accepted articles must pay a publication fee. EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

## Contents

<b>EDITORIAL</b>	4977 Update and actual trends on bacterial infections following liver transplantation <i>del Pozo JL</i>
	4984 Calcium signaling and T-type calcium channels in cancer cell cycling <i>Taylor JT, Zeng XB, Pottle JE, Lee K, Wang AR, Yi SG, Scruggs JAS, Sikka SS, Li M</i>
	4992 Diagnostic criteria for autoimmune pancreatitis in Japan <i>Kamisawa T, Okazaki K, Kawa S</i>
<b>REVIEW</b>	4995 Giant duodenal ulcers <i>Newton EB, Versland MR, Sepe TE</i>
<b>GASTRIC CANCER</b>	5000 Mechanism and pathobiologic implications of CHFR promoter methylation in gastric carcinoma <i>Gao YJ, Xin Y, Zhang JJ, Zhou J</i>
<b>LIVER CANCER</b>	5008 Positional and expressive alteration of prohibitin during the induced differentiation of human hepatocarcinoma SMMC-7721 cells <i>Xu DH, Tang J, Li QF, Shi SL, Chen XF, Liang Y</i>
<b>RAPID COMMUNICATION</b>	5015 Significance of scintigraphy for the localization of obscure gastrointestinal bleedings <i>Brünnler T, Klebl F, Mundorff S, Eilles C, Reng M, von Korn H, Schölmerich J, Langgartner J, Grüne S</i>
	5020 Probiotic effects on intestinal fermentation patterns in patients with irritable bowel syndrome <i>Barrett JS, Canale KEK, Gearry RB, Irving PM, Gibson PR</i>
	5025 Hepatocytes isolated from neoplastic liver-immunomagnetic purging as a new source for transplantation <i>Gunasegaram A, Akhter J, Yao P, Johnson LA, Riodan SM, Morris DL</i>
	5032 Differentiation of malignant and benign proximal bile duct strictures: The diagnostic dilemma <i>Kloek JJ, van Delden OM, Erdogan D, ten Kate FJ, Rauws EA, Busch OR, Gouma DJ, van Gulik TM</i>

**Contents**

**World Journal of Gastroenterology**  
**Volume 14 Number 32 August 28, 2008**

- 5039** Accuracy of *Helicobacter pylori* serology in two peptic ulcer populations and in healthy controls

*Lindsetmo RO, Johnsen R, Eide TJ, Gutteberg T, Husum HH, Revhaug A*

- 5046** Endoscopic findings in patients with upper gastrointestinal bleeding clinically classified into three risk groups prior to endoscopy

*Tammaro L, Di Paolo MC, Zullo A, Hassan C, Morini S, Caliendo S, Pallotta L*

- 5051** Colonoscopy evaluation after short-term anti-tuberculosis treatment in nonspecific ulcers on the ileocecal area

*Park YS, Jun DW, Kim SH, Lee HH, Jo YJ, Song MH, Kim NI, Lee JS*

- 5059** Cellular DNA repair cofactors affecting hepatitis B virus infection and replication

*Zhao F, Hou NB, Song T, He X, Zheng ZR, Ma QJ, Li L, Zhang YH, Zhong H*

- 5066** Treatment of polycystic liver disease with resection-fenestration and a new classification

*Li TJ, Zhang HB, Lu JH, Zhao J, Yang N, Yang GS*

- 5073** Treatment of upper gastrointestinal fistula and leakage with personal stage nutrition support

*Wang Q, Liu ZS, Qian Q, Sun Q, Pan DY, He YM*

- 5078** Polymorphisms of alcohol dehydrogenase 2 and aldehyde dehydrogenase 2 and colorectal cancer risk in Chinese males

*Gao CM, Takezaki T, Wu JZ, Zhang XM, Cao HX, Ding JH, Liu YT, Li SP, Cao J, Matsuo K, Hamajima N, Tajima K*

- 5084** Ivor Lewis subtotal esophagectomy with two-field lymphadenectomy for squamous cell carcinoma of the lower thoracic esophagus

*Wu J, Chai Y, Zhou XM, Chen QX, Yan FL*

- 5090** *Lactobacilli* inhibit interleukin-8 production induced by *Helicobacter pylori* lipopolysaccharide-activated Toll-like receptor 4

*Zhou C, Ma FZ, Deng XJ, Yuan H, Ma HS*

**CASE REPORT**

- 5096** Large solitary ovarian metastasis from colorectal cancer diagnosed by endoscopic ultrasound

*Moparty B, Gomez G, Bhutani MS*

## Abstract

Recent advances in effective antimicrobial prophylactic strategies have led to a decline in the incidence of opportunistic infections in liver transplant recipients. However, morbidity and mortality due to infectious diseases remain as major problems. Bacterial infections occurring early after transplant are mainly related to the technical aspects of the procedure. By contrast, after the first postoperative days and beyond, the nature and variety of infectious complications change. Opportunistic bacterial infections are uncommon after 6 mo in patients receiving stable and reduced maintenance doses of immunosuppression with good graft function and little is documented about these cases in the literature. Transplant recipients may be more susceptible to some pathogens, such as the *Nocardia* species, *Legionella* species, *Listeria monocytogenes*, *Mycoplasma* species, *Salmonella* species or *Rhodococcus equi*. Respiratory infections due to capsulated bacteria, such as *Streptococcus pneumoniae* and *Haemophilus influenzae*, can be life-threatening if not promptly treated in this population. These late bacterial infections may be very difficult to recognize and treat in this population. In this article, we review what has been described in the literature with regards to late bacterial infections following liver transplantation.

## INTRODUCTION

Since the first report in 1963, liver transplantation has become an established treatment for properly selected patients with end-stage liver disease, primary and some secondary hepatic malignancies and some rare metabolic liver-based disorders. During the past decade, survival rates after liver transplantation have steadily improved, with one-year survival exceeding 90% and approaching 70% at 8 years<sup>[1]</sup>. Increasingly, potent immunosuppressive agent use has dramatically reduced the incidence of rejection in the transplanted population, while increasing patient susceptibility to opportunistic infections and cancer<sup>[2]</sup>. However, recent advances in effective antimicrobial prophylactic strategies have led to a decline in the incidence of opportunistic infections in liver transplant recipients. Nevertheless, morbidity and mortality due to infectious complications remain as major problems in this selected population.

Infection and rejection remain major causes of morbidity after a liver transplant, accounting for up to 85% of deaths in some studies<sup>[3]</sup>. Infections were the most common cause of death after liver transplantation, and were present in 64% of a total of 321 cases in a study<sup>[4]</sup>. Two-thirds of all infections occurred during the first 100 d post transplantation in this study. Overall, the infections were bacterial in 48% of the cases, fungal in 22%, and viral in 12%<sup>[4]</sup>. The ratio of infectious to non-infectious causes of death did not change significantly during the 15-year study period, and the relative percentages of bacterial, fungal, and viral infections showed relatively little discrepancy on a year-to-year basis in this study<sup>[4]</sup>. In one other study, 83% of a liver transplant population had 1 or more episodes of infection and 67% had severe infections<sup>[5]</sup>. 70% of severe infections occurred within the first 2 mo after transplantation. The most frequent severe

infections occurred were abdominal abscesses, bacterial pneumonia, invasive candidiasis, *Pneumocystis jirovecii* pneumonia, and symptomatic cytomegalovirus infection<sup>[5]</sup>. In a 10-year Swiss single-centre study<sup>[6]</sup>, 80% of patients developed an infection following transplantation. Almost half of these were bacterial with an infection rate that peaked during the first month following transplantation. The temporal relation between graft rejection and the occurrence of infection showed that the incidences of both viral and bacterial infections were increased by immunosuppressive supplementation. The overall incidence of bacterial infections was much higher during the first month following transplantation than after 1 mo in this study; 188.2 vs 5.8 episodes per 1000 patient-days<sup>[6]</sup>.

Patterns of opportunistic bacterial infections after transplantation have been altered by routine antimicrobial prophylaxis for *Pneumocystis jirovecii* (trimethoprim-sulfamethoxazole prophylaxis for as little as 3 mo or for as long as a lifetime), and by infections due to organisms with antimicrobial resistance. Infections occur in a generally predictable pattern after solid-organ transplantation and most can be grouped into three major periods: the early period posttransplant (up to 6 wk), an intermediate period (1 to 6 mo); and a late period (more than 6 mo)<sup>[2]</sup>.

Infections occurring immediately post-transplantation are similar to those seen in post-operative immunocompetent hosts. Bacterial infections predominate; they usually have a nosocomial source, such as central vascular access sites, external drainage catheters or are related to foreign bodies, necrotic tissue, or prolonged endobronchial intubation. Abdominal abscesses and peritonitis, intrahepatic abscesses (often associated with hepatic artery thrombosis), cholangitis, wound infections, nosocomial pneumonias (in patients who require prolonged ventilation) are common during this time frame. Patients may become infected with nosocomial, antimicrobial-resistant bacteria, including methicillin-resistant *Staphylococcus aureus*, vancomycin-resistant *Enterococcus faecalis*, *Clostridium difficile*, and antimicrobial-resistant gram-negative bacteria.

During the intermediate period, the nature of common infections changes and patients are most at risk for the development of opportunistic infections due to the cumulative effect of relatively high-dose immunosuppression, although residual problems from the perioperative period can persist. Viral pathogens and allograft rejection are responsible for the majority of febrile episodes that occur during the period from 1 to 6 mo after transplantation<sup>[2]</sup>.

Opportunistic infections are uncommon after 6 mo in patients receiving stable and reduced maintenance doses of immunosuppression with good graft function, and little is documented about them in the literature. Potential etiologies of infection in these patients are diverse, including common, community-acquired bacterial infections seen in the general population, and uncommon opportunistic infections of clinical significance only in immunocompromised hosts. Respiratory infections due to capsulated pathogens,

such as *Streptococcus pneumoniae* and *Haemophilus influenzae*, can be life-threatening if not promptly treated in this population. In addition, transplant recipients may be more susceptible to certain bacterial pathogens, such as the *Nocardia* species, *Legionella* species, *Listeria monocytogenes*, *Mycoplasma* species, *Salmonella* species *Bartonella* species, or *Rhodococcus equi*. These late bacterial infections may be very difficult to recognize and treat in this population. Little information is available on the opportunistic late bacterial infections in liver transplant recipients. This review will focus on the risk, recognition and management of specific late bacterial infections, which are anticipated to occur more than 6 mo after liver transplantation.

## SPECIAL INFECTION CHARACTERISTICS OF THE LIVER TRANSPLANT PATIENT

In general, it is more difficult to recognize infection in transplant recipients than it is in patients with normal immune function. Inflammatory responses associated with infection may be impaired by immunosuppressive therapy, and signs and symptoms of infection may often be diminished. Furthermore, noninfectious causes of fever, such as allograft rejection, may develop in these patients. Because of the immunosuppressed state of this population, they are susceptible to a broad range of opportunistic infections, which frequently present with multi-organ system involvement and progress rapidly. In addition, altered anatomy following transplant surgery may alter the physical signs of infection.

Cytomegalovirus infection can be documented in more than half of patient populations after organ transplantation<sup>[7]</sup>; with viral replication persisting long term. It is known that cytomegalovirus can affect the capacity of the host to mount a defense against complicating infections. Cytomegalovirus infection was associated with a 2.45-fold higher incidence of major infections between day 30 and 180 after orthotopic liver transplantation in a study, with most of these infections caused by gram-positive cocci<sup>[8]</sup>.

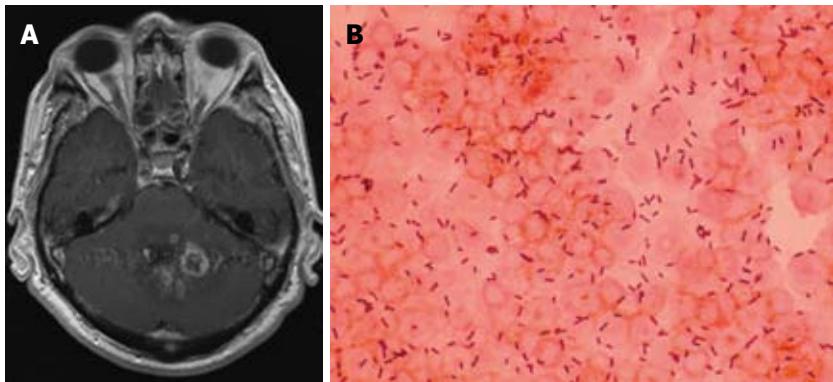

Serologic testing is not generally useful for diagnosis since seroconversion is often delayed in these patients (antigen-based tests or nucleic acid-based molecular assays are recommended for diagnosing in this population). In the same way, tissue biopsies with histopathology and microbiology are often needed to make an early and specific microbiologic diagnosis.

The choice of antimicrobial regimens is often more complex than in other patients due to increased antimicrobial resistance, urgency of therapy and the high frequency of drug related toxicities and interactions with immunosuppressant drugs.

## SPECIFIC LATE BACTERIAL INFECTIONS

### *Listeria monocytogenes* infection in the liver transplant patient

Listeriosis is a clinical condition occurring with an annual

**Figure 1** A: Gadolinium enhanced brain MRI demonstrating multiple ring-enhancing lesions, compatible with abscesses, located in the cerebellum; B: Gram stain of the spinal fluid of the same patient showing gram-positive rods. *Listeria monocytogenes* was isolated in spinal fluid culture.

incidence of 4.4/million individuals in the US and an associated mortality of approximately 20%<sup>[9]</sup>. *Listeria monocytogenes* has long been known as a pathogen of immunocompromised hosts (Figure 1). However, *Listeria* infections have only rarely been reported following orthotopic liver transplantation. The low incidence may be due, in part, to the prophylactic use of trimethoprim-sulfamethoxazole for *Pneumocystis jiroveci* pneumonia for up to 1 year following liver transplantation. Listeriosis occurs rarely after this 1 year period, so that further use of prophylactic antibiotics against this infection seems unjustified according to some authors<sup>[10]</sup>. The route of infection is usually through the intestinal tract following ingestion of contaminated food products, as well as from mother to child either transplacentally or during childbirth. The importance of dietary and other environmental exposures cannot be underestimated<sup>[11]</sup>. Most reported cases of listeriosis occurred months to years following liver transplantation, but it may also occur in the early postoperative period<sup>[12]</sup>. Its principal manifestations include bacteremia<sup>[10,13]</sup> and meningitis<sup>[14,15]</sup>, although endocarditis<sup>[16]</sup>, peritonitis<sup>[17]</sup>, hepatitis<sup>[18,19]</sup>, epididymitis or orchitis<sup>[20]</sup> have been reported. *Listeria* meningitis can be associated with profound changes in mental status or focal neurologic signs from involvement of the brain stem (rhombencephalitis) or even presence of a brain abscess<sup>[15]</sup>. Clinically, bacteremia is almost always present and is usually instrumental in getting the diagnosis. Treatment with antibiotics including ampicillin or trimethoprim-sulfamethoxazole with or without an aminoglycoside has proven successful in the majority of the cases.

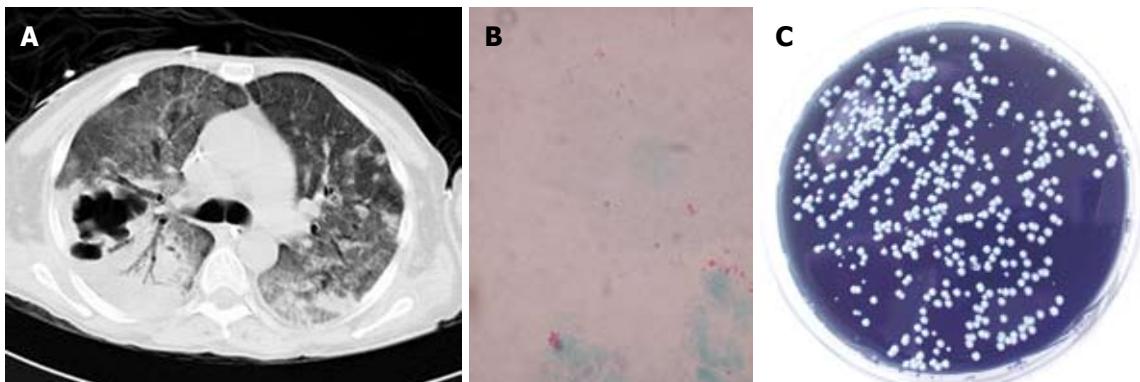

Five cases of listeriosis following liver transplantation have been reported<sup>[14]</sup>, four within 3 wk and one within 4 mo following transplantation. Rettally *et al*<sup>[10]</sup> reported a case of a patient presenting with *L. monocytogenes* bacteremia at 32 mo following orthotopic liver transplantation. The patient was successfully treated with 3 wk of intravenous treatment with ampicillin and vancomycin. In the case reported by Avery *et al*<sup>[16]</sup>, the patient was receiving trimethoprim-sulfamethoxazole prophylaxis for *P. jiroveci* pneumonia until 7 mo post-transplant, at which time aerosolized pentamidine was substituted because of the concern about possible drug hepatotoxicity. Three months later, the patient was diagnosed with a tricuspid valve *L. monocytogenes*

endocarditis. The patient was successfully treated with a total of 6 wk of ampicillin followed by penicillin therapy, with gentamicin administered for the first 4 wk of this course. Doses of her immunosuppressive medications were decreased. Bourgeois *et al*<sup>[18]</sup> reported the case of a liver transplant recipient who was diagnosed with *L. monocytogenes* acute hepatitis 8 mo after grafting. The patient made a full clinical recovery after therapy with ampicillin and gentamicin intravenously for 4 wk.

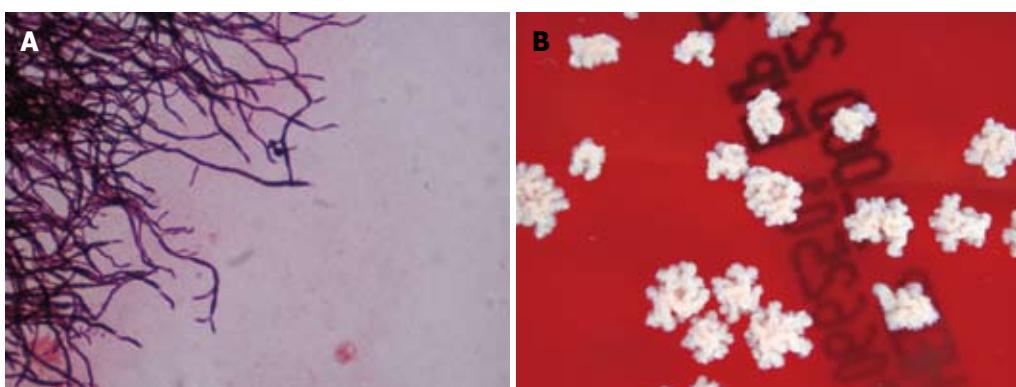

#### ***Legionella* species infection in the liver transplant patient**

*Legionella* species account for approximately 5% of cases of pneumonia in the general US population. Although more than 30 species have been described in the *Legionellae* family, 70% to 90% of infections are caused by *L. pneumophila*, particularly serogroups 1 and 6, followed by *L. micdadei*<sup>[21]</sup>. Aquatic habitats are considered the environmental reservoir for community and nosocomial acquired pneumonia<sup>[22]</sup>. Susceptible hosts include the elderly, cigarette smokers, individuals receiving immunosuppressive therapy, and organ transplant recipients<sup>[23]</sup>. Although community acquisition occurs, nosocomial *L. pneumonia* is more commonly reported in transplant patients (Figure 2). In solid organ recipients, infection often occurs early in the post-transplantation period or coincidentally with corticosteroid therapy for allograft rejection<sup>[22]</sup>. The radiographic findings of *L. pneumonia* in immunosuppressed patients can vary and include unilateral or bilateral dense, patchy, or nodular pulmonary infiltrates that can progress to cavitation.

The first case of infection with *Legionella* species in a liver transplant recipient was reported by Tokunaga *et al*<sup>[24]</sup> in 1992. *L. pneumophila*, serogroup 1, was identified by direct immunofluorescence in the lung and liver graft from a 2-mo-old infant who underwent orthotopic liver transplantation because of fulminant hepatic failure secondary to neonatal hepatitis. The patient died of respiratory failure due to this infection 22 d after transplantation despite treatment with erythromycin. Singh *et al*<sup>[25]</sup> described 3 adult liver transplant patients with evidence for Legionellosis acquired within 2 mo of surgical transplantation, including one case of *L. bozemanii* pneumonia, one case of *L. pneumophila* pericarditis, and one case of *L. pneumophila* pneumonia. In addition, the third case also had *L. micdadei* isolated from

**Figure 2** **A:** Chest CT scan showing multilobar pneumonic consolidation with cavitary lesions; **B:** Gimenez stain of a bronchoalveolar lavage specimen of the same patient showing small red coccobacilli; **C:** *Legionella pneumophila* was cultured on selective buffered charcoal yeast extract agar.

**Figure 3** **A:** Gram stained smear of a subcutaneous lesion aspirate demonstrating branching and beaded filamentous appearance gram-positive rods; **B:** *Nocardia asteroides* was isolated in culture.

pleural fluid. All three cases responded to a combination of erythromycin and ciprofloxacin. A *L. pneumonia* nosocomial outbreak after liver transplantation has been described<sup>[26]</sup>. Patients presented with fever, nonspecific constitutional symptoms, and either unilateral or bilateral infiltrates developing 3 wk to 12 wk after transplantation. Treatment with either erythromycin (four cases) or ciprofloxacin (one case) was successful in three of five patients. A hospital-acquired pneumonia due to *L. parisiensis* was reported by Presti *et al*<sup>[27]</sup> in 1997. The diagnosis was made on the basis of clinical and radiological signs of pneumopathy in a liver transplant patient and was confirmed by microbiological data. The patient was successfully treated with erythromycin for 3 wk, allowing resolution of the pneumonia. Ernst *et al*<sup>[28]</sup> reported a liver transplant recipient with community acquired *L. midiae* pneumonia 8 years after transplantation. The patient was successfully treated with a 3-wk course of ciprofloxacin. According to the authors, the predisposition in this case might in part be attributed to the need for a course of heightened immunosuppressive agents to treat an episode of acute organ rejection. Fraser *et al*<sup>[29]</sup> reported a liver transplant recipient who presented with cavitary pneumonia caused by *L. pneumophila* 7 years after transplantation. The patient required surgical resection and a 21-d course of therapy with levofloxacin for diagnosis and cure.

*Legionella* pneumonia is a rare complication of orthotopic liver transplantation in adults, and it remains a significant cause of morbidity and mortality in the susceptible host. Definitive diagnosis of *Legionella* pneumonia can be particularly elusive. As the urinary *Legionella* antigen is negative when other species or serogroups different than *L. pneumophila* serogroup 1 are implicated, examination of respiratory secretions in combination with immunofluorescent staining or specialized culture is required to establish the diagnosis. Erythromycin, rifampin, trimethoprim-sulfamethoxazole, doxycycline, clindamycin, and quinolones, alone or in combination, for 3 wk are effective treatments. Due to the risk of undesirable drug interaction of erythromycin with tacrolimus or cyclosporine, fluoroquinolone agents such as levofloxacin or ciprofloxacin may be the preferred treatment for legionellosis in transplant recipients.

#### ***Nocardia* species infection in the liver transplant patient**

*Nocardia* species are ubiquitous environmental saprophytes, living in soil, organic matter and water<sup>[30]</sup>. There are at least 12 species with *N. asteroides* complex (*N. asteroides* sensu strictu, *N. farcinica* and *N. nora*), with *N. brasiliensis*, *N. otitidiscavarium* and *N. transvaliensis*<sup>[30]</sup> being the most important ones. *Nocardia* species are Gram-positive, variably acid-fast, actinomycetes with branching rods (Figure 3). The frequency of nocardial

infections in solid organ transplant recipients varies between 0.7% and 3% and has mostly been reported in heart, kidney and liver transplant recipients, and less frequently in lung transplantation<sup>[31]</sup>. In a recent study involving 1840 liver transplant recipients, only 2 (0.1%) had a Nocardia infection and only 1 of them had a disseminated infection consisting of bacteremia<sup>[31]</sup>. Disseminated nocardiosis is more frequent in cellular immunocompromised patients, and it is often a potentially life-threatening infection. It is endogenous (i.e., secondary to bloodstream spread) from a primary pulmonary infection<sup>[30]</sup>. However, it may result very rarely from a primary nonpulmonary (e.g. cutaneous, gastrointestinal) infection. The brain is the most frequent nonpulmonary site involved in disseminated nocardiosis<sup>[32]</sup>. A *N. farrinica* disseminated (subcutaneous and neural) infection has been described in a liver transplant recipient<sup>[33]</sup>. The patient presented in postoperative mo 3 with fever and pain in the lower leg. Ten days after admission, the patient developed neurological symptoms and 3 brain abscesses were detected in an MRI.

A case of *N. asteroides* osteomyelitis of the tibia accompanied by brain abscesses in a liver transplant recipient was recently described<sup>[34]</sup>. The majority of bone cases are presumed to be due to direct extension from local soft tissue infection. Imaging of the brain should be performed in all cases of nocardiosis affecting a liver transplant recipient, since central nervous system involvement may be present even in the absence of neurological findings. Pulmonary involvement should also be excluded.

An optimal therapeutic approach has not been well established, especially in the disseminated forms. It is debated whether invasive resection or aspiration of the CNS lesions are necessary<sup>[2,35,36]</sup>. Some authors recommend an early biopsy of the lesions to achieve specific identification, even in cases where an extra-cranial focus of infection is found<sup>[37]</sup>. However, there are some reports that suggest that brain surgery is not always needed<sup>[35,36]</sup>. Sulfonamides are the drugs of choice for treatment of nocardiosis; however, there are an increasing number of reports of resistance to these agents<sup>[38]</sup>. The length of therapy in the treatment of nocardial infections in the transplant patient is debated. Some authors suggest extending it for 9 mo to 12 mo if there is CNS involvement<sup>[37]</sup>. The clinical use of other drugs should be supported by susceptibility testing. Linezolid is an oxazolidinone with activity against all of the clinically relevant species of Nocardia<sup>[39]</sup>, which has been shown to be an effective alternative for the treatment of nocardiosis, especially for the CNS forms<sup>[34]</sup>. Lewis *et al* described a case in which minocycline was used for 12 mo with a good response. Doxycycline and minocycline<sup>[34,40]</sup> may be attractive options as rescue therapy in those patients in which other treatments failed.

### Rhodococcus equi infection in the liver transplant patient

*Rhodococcus equi* is an intracellular gram-positive,

aerobic, nonmotile, non-spore-forming bacillus that is an increasingly important opportunistic respiratory pathogen in immunocompromised hosts. Impairment of cell-mediated immunity is the most important risk factor for infection with *R. equi* in humans<sup>[41]</sup>. Several cases have been described in patients with immunosuppression due to either human immunodeficiency infection, therapy for neoplastic disorders, or kidney and heart transplantation. 15 patients with a *R. equi* infection following solid-organ transplantation have been described in the literature<sup>[42-45]</sup>. In all patients, rhodococcal infection presented late after transplantation (median, 4 years). *R. equi* resides in the soil and humans acquire the infection through the respiratory tract. Exposure to farm animals was reported in only two cases; in four cases contact with contaminated soil or manure was considered a likely infectious source. Thirteen of 15 patients had pulmonary and/or pleural involvement. Soft-tissue infections were common in this population. Most patients received erythromycin and/or ciprofloxacin in combination therapy, which was generally associated with a successful outcome. Recurrent disease was observed after initial treatment with imipenem and tobramycin and in patients receiving monotherapy.

Sabater *et al*<sup>[43]</sup> reported the first case of *R. equi* infection in a liver transplant recipient. The patient was diagnosed with two subcutaneous abscesses on his left arm and an asymptomatic necrotizing bilateral pneumonia 28 mo following transplantation. The patient had been intensively immunosuppressed and working with calf manure. He was successfully treated with a combination of erythromycin, ciprofloxacin, and rifampicin. A case of vertebral osteomyelitis due to *R. equi* in a liver transplant recipient 7 mo after transplantation was reported by Fischer *et al*<sup>[42]</sup>. The patient was initially diagnosed with a recurrent pneumonia and a pleura-based lung abscess and subsequently developed osteomyelitis of the lower thoracic spine. Drainage of the paraspinal abscess and removal of the infected bone was performed while he was being treated with erythromycin and imipenem. Postoperatively, the patient received intravenous imipenem, vancomycin, and erythromycin for 14 d and then oral clarithromycin and rifabutin. Schilz *et al*<sup>[44]</sup> reported a case of a liver transplant patient with a pulmonary nodule caused by *R. equi* that followed a benign clinical course and resolved spontaneously.

Although solid-organ transplant recipients are rarely affected, *R. equi* must be included in the differential diagnosis of recurrent pneumonia or lung abscess in liver transplant recipients. Metastatic spread of infection is common, and diagnosis of pulmonary rhodococcal infection should prompt a search for additional involvement of extra-pulmonary sites. Monotherapy must be considered insufficient for transplant patients and surgery may be helpful in some cases.

### Other late bacterial infections in the liver transplant patient

*Bartonella benselae*, the etiologic agent of cat-scratch

disease, may cause a spectrum of illness in both immunocompetent and immunocompromised hosts. Disseminated infections caused by *Bartonella* species have been reported infrequently in solid organ transplant recipients. Humar *et al*<sup>[46]</sup> reported a case of a liver transplant recipient who presented 4 years later with fever of unknown origin, and was found to have a granulomatous hepatitis of the transplant allograft with a *Bartonella* species. Diagnosis was performed by serology (immunofluorescent antibody test). The patient completed a successful 4 wk course of azithromycin.

Apalsch *et al*<sup>[47]</sup> described a case of a disseminated cat-scratch disease in a 12-year-old liver transplant recipient with fever and lymphadenopathy. Granulomatous inflammation was shown in liver and lymph node biopsy specimens.

Because this organism may be difficult to grow in culture, serological and molecular tests are important for diagnosis. Antimicrobial therapy can result in prompt resolution of illness and usually consists of a macrolide or tetracycline derivative. However, the optimal antibiotic and duration of therapy for disseminated disease in immunocompromised patients is unknown.

Three cases of *Mycoplasma hominis* infections have been reported in the literature. Jacobs *et al*<sup>[48]</sup> reported the case of a recipient of liver transplantation with a postsurgical infection and Vogel *et al*<sup>[49]</sup> reported two patients with extragenital infections.

*Clostridium difficile* remains a significant complication in liver transplant recipients. In this patient population, *C. difficile* diarrhea may be more difficult to diagnose and may have a more complicated clinical course than in non-immunocompromised patients. Although the prevalence of *C. difficile* infection is usually the highest during the early post-transplant period, when immunosuppression is the highest, Albright *et al*<sup>[50]</sup> described 3 cases of late onset *C. difficile* infection (2, 3 and 5 years after transplantation). Nevertheless, the prognosis is good in most cases with timely diagnosis and treatment.

## CONCLUSION

In summary, late opportunistic bacterial infections following liver transplantation are rare. Trimethoprim-sulfamethoxazole taken daily or three times weekly in patients without an allergy to sulfonamides for the first 4 to 12 mo posttransplant primarily reduce the risk of *P. jiroveci* pneumonia and probably also helps to prevent infections with *L. monocytogenes*, *N. asteroides*, or *Toxoplasma gondii*. Early detection and treatment of these late bacterial infections is the key to obtaining a better prognosis in liver transplant patients.

### Abstract

Regulation of intracellular calcium is an important signaling mechanism for cell proliferation in both normal and cancerous cells. In normal epithelial cells, free calcium concentration is essential for cells to enter and accomplish the S phase and the M phase of the cell cycle. In contrast, cancerous cells can pass these phases of the cell cycle with much lower cytoplasmic free calcium concentrations, indicating an alternative mechanism has developed for fulfilling the intracellular calcium requirement for an increased rate of DNA synthesis and mitosis of fast replicating cancerous cells. The detailed mechanism underlying the altered calcium loading pathway remains unclear; however, there is a growing body of evidence that suggests the T-type  $\text{Ca}^{2+}$  channel is abnormally expressed in cancerous cells and that blockade of these channels may reduce cell proliferation in addition to inducing apoptosis. Recent studies also show that the expression of T-type  $\text{Ca}^{2+}$  channels in breast cancer cells is proliferation state dependent, i.e. the channels are expressed at higher levels during the fast-replication period, and once the cells are in a non-proliferation state, expression of this channel is

minimal. Therefore, selectively blocking calcium entry into cancerous cells may be a valuable approach for preventing tumor growth. Since T-type  $\text{Ca}^{2+}$  channels are not expressed in epithelial cells, selective T-type  $\text{Ca}^{2+}$  channel blockers may be useful in the treatment of certain types of cancers.

### INTRODUCTION

Calcium is an essential signal transduction element involved in the regulation of many eukaryotic cellular functions including cell cycle progression<sup>[1]</sup>. Control of intracellular  $\text{Ca}^{2+}$  ( $[\text{Ca}^{2+}]$ ) is crucial for the orderly progression of the cell cycle and plays a vital role in the regulation of cell proliferation and growth<sup>[2]</sup>; however, excessive calcium or loss of control in calcium signaling can lead to cell death<sup>[3]</sup>. Therefore, careful control of calcium signaling is required for cell survival. Upon stimulation, the intracellular calcium concentration can increase dramatically, often reaching micromolar amounts. This increase in cytoplasmic calcium can occur via release from intracellular stores or influx through a variety of plasma membrane ion channels. Voltage-gated and ligand-gated  $\text{Ca}^{2+}$  channels in the plasma membrane, along with ryanodine receptors (RyR) and inositol triphosphate receptors (IP3R) at the intracellular calcium stores, provide fluxes of  $\text{Ca}^{2+}$  to the cytoplasm.

The driving force for calcium entry is the result of an electrochemical gradient between the extracellular concentration ( $1.3 \times 10^{-3}$ - $2 \times 10^{-3}$  mol/L) of calcium and the intracellular concentration (<  $10^{-8}$  mol/L).

In general, non-excitable tissues, including the epithelium, do not express voltage gated  $\text{Ca}^{2+}$  channels. This is partly because the ranges of membrane potential changes in these cells are too small to activate these channels. However, recent studies show that T-type  $\text{Ca}^{2+}$  channels are expressed in cancerous cells, although their functional role has only begun to be investigated. Furthermore, there is a growing body of evidence suggesting that tumor cell proliferation can be halted by the use of ion channel blockers. T-type calcium channels are a class of calcium permeable low voltage activated (LVA) ion channels which open after small depolarizations of the membrane. Molecular biology has revealed the existence of three different T-type calcium channel subunits, the  $\alpha_{1G}$ ,  $\alpha_{1H}$  and  $\alpha_{1I}$ . The  $\alpha_1$  designation refers to the channels primary ion conducting protein, which consists of four domains each containing six transmembrane segments. There are other auxiliary calcium channel subunits; however, the LVA alpha1 subunits can function as stand alone complexes. The unique low voltage dependent activation/inactivation and slow deactivation of T-type  $\text{Ca}^{2+}$  channels indicate that these channels may play a physiological role in carrying depolarizing current at low membrane potentials. Therefore, these channels may play a direct role in regulating  $[\text{Ca}^{2+}]_i$ , especially in non-excitable tissues, including some cancerous cells. At low voltages, T-type  $\text{Ca}^{2+}$  channels are known to mediate a phenomenon known as "window current"<sup>[4-6]</sup>. The term "window" refers to the voltage overlap between the activation and steady state inactivation at low or resting membrane potentials. As a result, there is a sustained inward calcium current carried by a small portion of channels that are not completely inactivated. Window current allows T-type  $\text{Ca}^{2+}$  channels to regulate  $\text{Ca}^{2+}$  homeostasis under non-stimulated or resting membrane conditions<sup>[7]</sup>. The most direct evidence of T-type  $\text{Ca}^{2+}$  channel mediated  $\text{Ca}^{2+}$  window current is from a study conducted in HEK-293 cells expressing the T-type isoform  $\alpha_{1G}$ <sup>[8]</sup>, which demonstrated window current peaked at -48 mV. Membrane potentials around this voltage can occur in un-stimulated non-excitable cells.

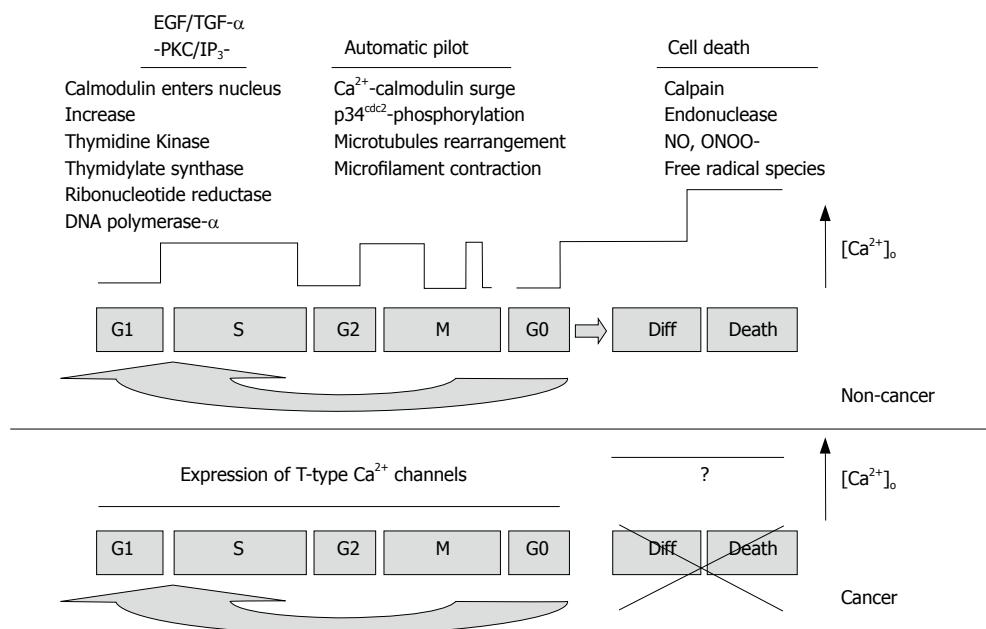

## CALCIUM SIGNALING AND CELL CYCLING

As shown in Figure 1, the cell cycle is divided into four stages: G1, S, G2 and M. DNA replication occurs in the S phase and mitosis occurs in the M phase. Cells must pass through a restriction point between the G1 and S phases before continuing proliferation; otherwise, they exit the cell cycle to G0 and differentiate or terminate. Another checkpoint in the cell cycle is between phases G2 and M. For cells to pass through these various points, one of the most prominent messengers is  $\text{Ca}^{2+}$ , as demonstrated by the induction of mitotic events by

injection of exogenous  $\text{Ca}^{2+}$  in a fertilized egg model<sup>[9]</sup>. Steinhardt *et al*<sup>[10]</sup> observed transient increases in cytosolic  $\text{Ca}^{2+}$  during late G1, prior to the initiation of the S phase and during G2 before entry into the M phase that were dependent upon external physiological  $\text{Ca}^{2+}$  concentration. In the transition from G1 to S phase, cells require external  $\text{Ca}^{2+}$  in addition to functional calcium channels in order to directly or indirectly trigger a myriad of critical downstream enzymes such as thymidine kinase, thymidylate synthase, ribonucleotide reductase and DNA polymerase and begin DNA replication. In the transition from G2 to M phase,  $\text{Ca}^{2+}$  flashes activate enzymes that are critical for microtubule rearrangement and microfilament contraction. In order to confirm the significant role that  $\text{Ca}^{2+}$  plays in the cell cycle, researchers have blocked the progression of the cell cycle *via* injection of  $\text{Ca}^{2+}$  chelators into the same fertilized eggs<sup>[11]</sup>. The influence of  $\text{Ca}^{2+}$  channels on cell growth is clearly demonstrated in pharmacological studies using  $\text{Ca}^{2+}$  channel antagonists. In a study by Zeitler *et al*<sup>[12]</sup>, various  $\text{Ca}^{2+}$  channel blockers, including verapamil, nifedipine, diltiazem and isradipine, caused G0/G1 cell-cycle arrest in growth factor induced human umbilical arterial endothelial cells (HUAEC) during proliferation. The  $\text{Ca}^{2+}$  signal has also been linked to activation of immediate early genes (e.g. *c-fos*) that are responsible for inducing resting cells in G0 to re-enter the cell cycle, an attribute most frequently up-regulated in rapidly proliferating cells<sup>[10]</sup>.

At the end of the cycle, cells can undergo suicide through a process known as apoptosis or active cell death, which is a genetic program specifically designed to shape organs during development and adjust cell population levels to appropriate values. The key players of apoptosis are a killer  $\text{Ca}^{2+}$  surge and the nuclear membrane  $\text{Ca}^{2+}$  activated endonuclease, which terminates the cell by cutting chromatin into fragments (Figure 1). Underlying mechanisms for  $\text{Ca}^{2+}$  mediated effects in cell proliferation may involve a wide variety of other intracellular signal transduction pathways such as G-proteins, protein kinase C (PKC), calmodulin, m-calpain, MAP kinase, phospholipase A2 and others<sup>[13,14]</sup>. Although the details of each pathway is beyond the scope of this discussion, there are several notable mechanisms that act to amplify  $[\text{Ca}^{2+}]_i$  for activation of gene transcription or cell migration. One mechanism is the hydrolysis of inositol lipids by the enzyme phospholipase C, the activation of which is itself dependent on an initial rise in  $[\text{Ca}^{2+}]_i$ , producing diacylglycerol (DAG) and InsP3. Resulting from the activation of G protein-linked or tyrosine-kinase linked receptors<sup>[15]</sup>, InsP3 thus causes a form of  $\text{Ca}^{2+}$  dependent  $\text{Ca}^{2+}$  release from intracellular stores. Described as "calcium puffs", which propagate into a local or global  $\text{Ca}^{2+}$  signal, this  $\text{Ca}^{2+}$  release is important for converting the cytoplasm into an excitable medium that can support repetitive  $\text{Ca}^{2+}$  oscillations<sup>[16]</sup>. The resulting amplification of  $[\text{Ca}^{2+}]_i$  contributes to the signal for mitosis and DNA synthesis.

In addition to InsP3, sensory proteins also play

**Figure 1**  $\text{Ca}^{2+}$  signaling pathways differ between cancerous and non-cancerous cells (adapted from <sup>[23]</sup>).

a role in maintaining the calcium signaling system. Calmodulin is a  $\text{Ca}^{2+}$  binding protein that acts as a  $\text{Ca}^{2+}$  sensor in the cell cycle. High expression of calmodulin has been observed during the S phase and mitosis, while inhibition of its activity by administration of calmodulin monoclonal antibodies is shown to block DNA synthesis<sup>[17]</sup>. Another sensory mechanism occurs through an extracellular calcium ion concentration sensing receptor (CaR) and calbindin, a high affinity  $\text{Ca}^{2+}$ -binding regulatory protein belonging to the same family as calmodulin. Parkash *et al* observed that CaR plays a role in sensing and responding to changes in extracellular  $\text{Ca}^{2+}$  ( $[\text{Ca}^{2+}]_o$ ). Upon activation by increased  $[\text{Ca}^{2+}]_o$ , CaR interacts with phospholipase C (PLC) via G proteins to produce DAG and InsP3<sup>[18]</sup>. The subsequent increase in  $[\text{Ca}^{2+}]_i$  is regulated by calbindin, which was previously found to bind to L-type HVA  $\text{Ca}^{2+}$  channels in pancreatic islets-cells<sup>[19]</sup>. It has also been shown that calbindin/CaR co-localization occurs in the estrogen receptor positive breast cancer cell line MCF-7<sup>[20]</sup>. Activated CaR also increases parathyroid hormone related protein (PTHrP), which appears to exacerbate cell metastasis in MCF-7 cells<sup>[21]</sup>. A study by Lewalle *et al*<sup>[22]</sup> shows that an increase in  $[\text{Ca}^{2+}]_i$  mediates tumor cell transendothelial migration *in vitro*. By associating the upregulation of these mechanisms in cancerous cells, increases in  $[\text{Ca}^{2+}]_i$  are shown to provide an important and pronounced signal for cell growth.

Calcium signaling in cancerous cells, however, uses an altered pathway during cell cycling<sup>[23]</sup>. Whitfield has shown that colon carcinomas undergoing carcinogenesis, which have lost their tumor-suppressing genes, have dramatically altered calcium signal mechanisms, and have ignored normal calcium-dependent restrictions by overproducing calcium-binding signal proteins (Figure 1)<sup>[18]</sup>. Attempts to terminate the mutant cells with  $\text{Ca}^{2+}$  signal

surges are futile, as the cells are no longer responsive to  $\text{Ca}^{2+}$  signals: instead, they produce and respond to their own renegade growth factors.  $\text{Ca}^{2+}$  and the signaling enzymes that are directly activated by  $\text{Ca}^{2+}$  or by  $\text{Ca}^{2+}$ -binding proteins play crucial roles in most cell signals and programs and must be understood and implemented in any future differentiation therapies. Since cancerous cells express T-type  $\text{Ca}^{2+}$  channels, it is possible that these channels provide an altered  $\text{Ca}^{2+}$  influx pathway in responding to the increasing demand of  $\text{Ca}^{2+}$  during rapid cell proliferation.

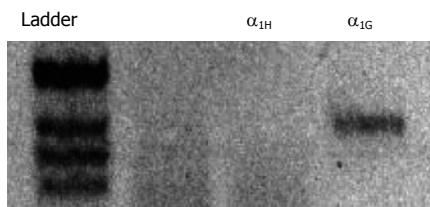

## T-TYPE CALCIUM CHANNELS IN CANCEROUS CELL PROLIFERATION

### *T-type $\text{Ca}^{2+}$ channels and non-cancerous cell cycling*

The function of regulating  $\text{Ca}^{2+}$  homeostasis may allow T-type  $\text{Ca}^{2+}$  channels to play an important role in controlling cell proliferation and differentiation in many tissues. In primary cultured rat aortic smooth muscle cells, a T-type  $\text{Ca}^{2+}$  current was found to be present in cells during the G1 and S phases but decreased or absent in all other phases of the cell cycle<sup>[24-26]</sup>. It was shown that cultured smooth muscle cells exhibited an increased T-type  $\text{Ca}^{2+}$  current during stages of proliferation and this current decreased as the cells became confluent or when they came into contact with one another<sup>[27]</sup>. T-type  $\text{Ca}^{2+}$  currents are also present in freshly dissociated or 1-2 d cultured neonatal rat ventricular myocytes when they are still able to proliferate, but are not observed in cells cultured greater than 3 d<sup>[28]</sup>. Likewise, older tissues under pathological conditions, such as cardiomyopathic hamster heart<sup>[29]</sup>, hypertrophied adult feline left ventricular myocytes<sup>[30]</sup>, and rat neointimal formation after vascular injury<sup>[31]</sup> have increased T-type  $\text{Ca}^{2+}$  current activity. These studies suggest that T-type calcium

channels may play a vital role in regulating proliferation under specialized conditions.

#### **T-type $\text{Ca}^{2+}$ channels are broadly expressed in tumor cells**

If these channels do participate in proliferation under abnormal conditions, cells must first maintain control of the expression of  $\alpha_{1G}$  T-type  $\text{Ca}^{2+}$  channel messenger RNA in order to prevent functional expression of the protein. Otherwise, loss of this control may lead to aberrant cell growth and tumor progression. A recent study revealed the presence of T-type calcium channel mRNA expressed in breast tumor tissue that was removed from human biopsies (Figure 2)<sup>[32]</sup>. In this case, the tumor was later diagnosed as malignant and estrogen receptor positive by pathological examination. Expression of these channels in tumor cells has been reported broadly, as shown in Table 1<sup>[1,33-49]</sup>. For example, MCF-7 cells, a cell line derived from a human breast adenocarcinoma that has been shown to express  $\alpha_{1G}$  and  $\alpha_{1H}$  T-type  $\text{Ca}^{2+}$  channel mRNA and current transiently (Table 2)<sup>[33]</sup>. T-type  $\text{Ca}^{2+}$  channels have also been suggested as a potential therapeutic target for intracranial tumor and prostate cancer. Mibepradil was found to inhibit human astrocytoma (U87-MG) and neuroblastoma (N1E-115) proliferation and that over-expression of T-type  $\text{Ca}^{2+}$  channel protein doubled the proliferation rate while antisense treatment reduced

**Table 2** Q-RT-PCR detected T-type  $\text{Ca}^{2+}$  channels expression in non-confluent cultures of breast cancer cell lines

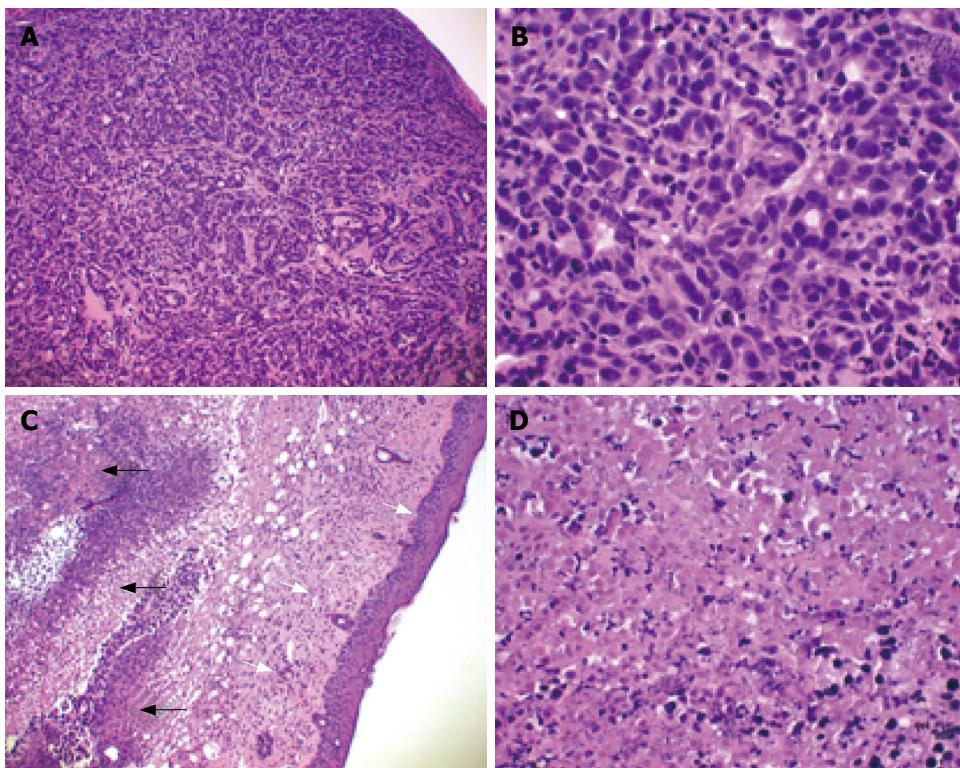

Cell types	T-channels	Non-confluent $\Delta\text{ct}$	Confluent $\Delta\text{ct}$

MCF-7	$\alpha_{1G}$	7.32 ± 0.3	NA, ct > 40

NA: Not applicable.

the proliferation rate of these cells<sup>[37]</sup>. Human prostate cancer epithelial cells (LNCap) have also been shown to express increased T-type  $\text{Ca}^{2+}$  channel ( $\alpha_{1H}$ ) current and mRNA. Similarly, increased T-type  $\text{Ca}^{2+}$  channel protein doubled proliferation while antisense treatment reduced the proliferation rate of these cells<sup>[1,43]</sup>. It was also shown that these channels were found to regulate intracellular calcium in LNCap cells. Another study examined the role of T-type  $\text{Ca}^{2+}$  channels in esophageal carcinoma cell proliferation; these data suggested that T-type  $\text{Ca}^{2+}$  channels may have a functional role in proliferation that can be reduced by inhibition of T-type  $\text{Ca}^{2+}$  channels<sup>[44]</sup>. Given the role that T-type calcium channels play in cell cycle progression and the relatively recent findings that show the functional expression of these channels in many different cancerous cell types, researchers have now been given the opportunity to investigate the potential of an entirely new target in the fight against cancer. Developing new compounds that target these proteins may hold the key to controlling certain types of cancer.

#### **EFFECT OF T-TYPE $\text{Ca}^{2+}$ CHANNEL BLOCKERS ON BREAST CANCER CELL PROLIFERATION**

The function of T-type  $\text{Ca}^{2+}$  channels with regards to

**Figure 3** Mibepradil destroys tumor cells implanted in a nude mouse. HE stain was applied to show the nuclei and cytoplasm of the cells (**A** and **C**,  $\times 100$ ; **B** and **D**,  $\times 400$ ).

tumor cell proliferation was also reviewed<sup>[50,51]</sup>. One study found the T-type  $\text{Ca}^{2+}$  channel to be particularly effective in controlling oscillations in intracellular  $\text{Ca}^{2+}$  as the result of the channels unique activation/inactivation properties. It was concluded that new selective antagonists may become helpful as a therapeutic approach against tumors in which proliferation depends on T-type  $\text{Ca}^{2+}$  channel expression<sup>[51]</sup>. A study performed in knockout animals found that selective inhibition of T-type  $\text{Ca}^{2+}$  channels may have impact upon the treatment of cancer<sup>[52]</sup>.

Studies have shown an inhibition in breast cancer proliferation by the channel blockers pimozide, thioridazine<sup>[53]</sup> and mibepradil<sup>[42]</sup>. The endogenous cannabinoid anandamide has also been shown to block T-type  $\text{Ca}^{2+}$  channels<sup>[54]</sup>, in addition to inhibition of breast cancer cell proliferation<sup>[55]</sup>, an effect that may be due to blockage of T-type  $\text{Ca}^{2+}$  channels.

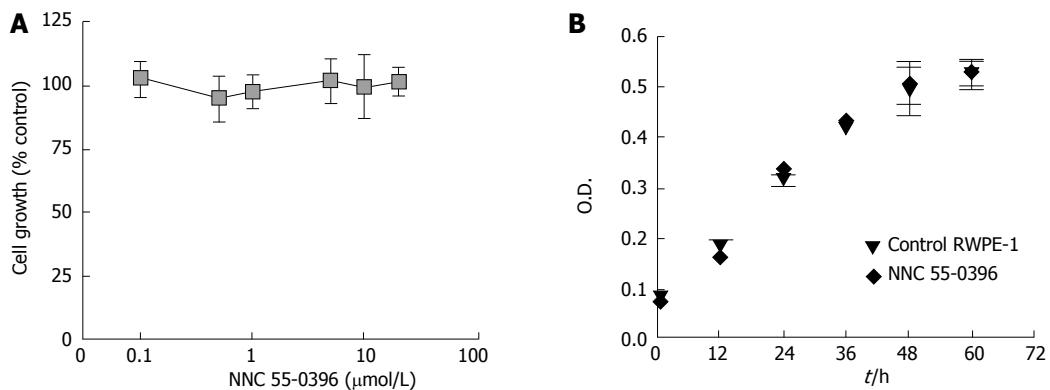

The anti-cancer effect of a T-type  $\text{Ca}^{2+}$  channel antagonists on tumor cells *in vivo* has been investigated<sup>[32]</sup>. MCF-7 cells were implanted into nude mice, athymic nude BSLB/c, and then either mibepradil (0.5 mg/100  $\mu\text{L}$ ) or saline (0.5 mg/100  $\mu\text{L}$ ) was injected locally at the tumor sites (s.c) twice a week. After 30 d of the treatment, mice were sacrificed and the tumors were removed for histochemistry examination.

As shown in Figure 3A and B, in the saline injected tissue the proliferation of the malignant tumor cells formed nodules in subcutis. The tumor cells were malignant as indicated by hyperchromatic nuclei with enlarged nuclei, irregular nuclear membrane, prominent nucleoli, and many mitotic features. No signs of degeneration and necrosis were detected. In contrast, the mibepradil injected tissue showed large areas of tumor degeneration and necrosis (Figure 3C and D). The

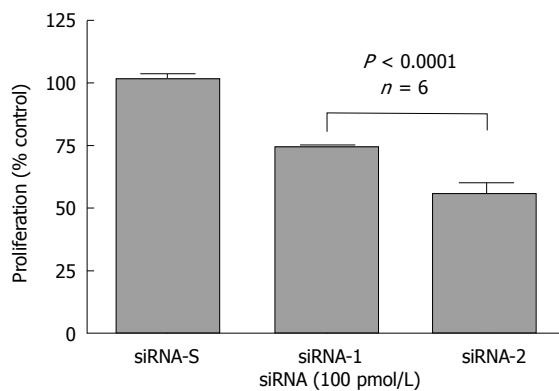

tumor necrosis was accompanied by prominent edema. Furthermore, as shown in Figure 3C, mibepradil more potently destroyed breast cancer cells (indicated by the black arrows) than non-cancerous cells at adjacent areas (indicated by the white arrows), including fibroblasts, endothelial cells and keratinocytes. These results indicate that a local injection of mibepradil induces necrosis of human breast carcinoma cells implanted into subcutaneous adipose tissue in mice.

More recently, the antiproliferative effect of the T-type calcium channel inhibitor NNC 55-0396<sup>[56]</sup> has been examined in cell lines derived from breast epithelial tissue, MCF-7, MDA-MB-231(ER- $\alpha$ ), and an adriamycin resistant cell line ADR. All three of these cell types express  $\alpha_{1G}$  and  $\alpha_{1H}$   $\text{Ca}^{2+}$  channel mRNA and their proliferation was suppressed by NNC 55-0396, with  $\text{IC}_{50}$  of about 1-2  $\mu\text{mol/L}$ <sup>[32,33]</sup>. The specificity of NNC 55-0396 antagonism on cancerous cell proliferation was investigated in a prostate epithelial cell line (RWPE-1) that does not express T-type  $\text{Ca}^{2+}$  channels<sup>[32]</sup>. As shown in Figure 4, NNC 55-0396 exhibited neither dose-dependent (up to 20  $\mu\text{mol/L}$  Figure 4A) nor time-dependent (up to 60 h, Figure 4B) inhibitory effects on RWPE-1 cell growth, suggesting that the anti-proliferation effect of NNC 55-0396 most likely resulted from blocking T-type  $\text{Ca}^{2+}$  channels of breast cancer cells. It also suggested that the general toxicity of NNC 55-0396 is minimal at the concentration that induces suppression of proliferation. T-type  $\text{Ca}^{2+}$  channel antisense treatment in these cells reduced the proliferation rate by 45% and antisense had no effect on proliferation on tumor cells not expressing T-type  $\text{Ca}^{2+}$  channels.

The role of T-type  $\text{Ca}^{2+}$  channels in cancerous cell proliferation has also been examined with specific siRNA

**Figure 4** Effect of NNC 55-0396 on RWPE-1 cell proliferation (Error bars represent SE;  $n = 3$ ).

**Figure 5** Effect of siRNAs on MCF-7 cell proliferation.

antagonism<sup>[33]</sup>. Specifically, MCF-7 cells were treated with siRNA targeting both  $\alpha_{1G}$  and  $\alpha_{1H}$  ( $\alpha_{1G/H}$ ). The cells were treated with scrambled (siRNA-S, 100 pmol/L),  $\alpha_{1G/H}$ -1 (siRNA-1) or  $\alpha_{1G/H}$ -2 (siRNA-2) for 48 h and subjected to MTT assay. The effects of siRNAs on cell proliferation were shown as percent (%) of vehicle control. As shown in Figure 5, scrambled siRNA was not significantly different than the control. However, both siRNA-1 and siRNA-2 treated cells had significantly lower proliferation rates compared to the scrambled and vehicle control siRNAs. These results strongly support the role of T-type  $\text{Ca}^{2+}$  channels in breast cancer cell proliferation and indicate that the effect of NNC 55-0396 on the breast cancer cell proliferation is due to the blockade of these channels.

## CONCERNs

Since T-type  $\text{Ca}^{2+}$  channels are normally expressed in the brain, heart and endocrine tissues of the human body, the potential side-effects of T-type  $\text{Ca}^{2+}$  channel blockers to these systems are of concern for therapeutic applications. Although T-type  $\text{Ca}^{2+}$  channel blockers have been used clinically for the treatment of neurological disorders (e.g. ethosuximide for absence seizures), the adverse effects of these drugs on the cardiovascular and central nervous systems are still unclear. Specifically, it is important to determine the possible arrhythmic and sedative effects of these drugs.

Human blood cells do not express T-type  $\text{Ca}^{2+}$

channels; therefore, it is advantageous to apply T-type  $\text{Ca}^{2+}$  channel blockers in the hemopoietic system, since current chemotherapeutic drugs have displayed severe side effects on this system. If we can locally deliver T-type  $\text{Ca}^{2+}$  channel blocker into the hemopoietic system, the compound should be very selective in eliminating the breast cancer cells in the blood stream. Thus, T-type  $\text{Ca}^{2+}$  channel blockers can be potential anti-metastasis drugs for adjuvant therapy of breast cancer.

## PERSPECTIVES

The function of T-type  $\text{Ca}^{2+}$  channels may not be restricted to cancerous cell proliferation. These channels may also play roles in cancerous cell colonization, invasion, secretion and angiogenesis. The growing number of proliferating cells need to attract blood vessels (angiogenesis) in order to receive nutrients,  $\text{O}_2$ , etc. to sustain themselves. The transformed cells are able to enter the blood stream and survive there, and colonize (metastasize) other tissues. Invasive growth or cell migration is a highly regulated process in which the migrating cells must secrete matrix proteases that disrupt the extracellular matrix (ECM) and permit easier transit through the surrounding environment. In addition, they must also profoundly reshape their structure, which involves massive cytoskeletal rearrangement. Precise regulation of intracellular calcium concentration is crucial for all of these processes. It is very possible that T-type  $\text{Ca}^{2+}$  channels also play significant roles in these processes<sup>[45]</sup>.

An expansion of the list of ion channels implicated in cancer development is expected, and the tools needed to investigate this issue are more readily available. As is the case with other protein families, it will be probably difficult to ascribe tumor development to the malfunction of a single ion channel. Rather, defects in T-type  $\text{Ca}^{2+}$  channels probably contribute to the neoplastic phenotype through complex interactions with other ion channels, most of which have not been properly identified. For instance, regulation of  $\text{K}^+$  channels can affect the membrane potential, which in turn regulates the window currents mediated by T-type  $\text{Ca}^{2+}$  channels. However, since in many cases there are already known pharmacological modulators (blockers

and activators) of ion channels, identification of a single defective ion channel in a particular cancer could provide a ready-to-go therapeutic approach.

## INTRODUCTION

Autoimmune pancreatitis (AIP) is a particular type of pancreatitis of presumed autoimmune etiology. Currently, AIP should be diagnosed based on combination of clinical, serological, morphological, and histopathological features. When diagnosing AIP, it is most important to differentiate it from pancreatic cancer. Diagnostic criteria for AIP, proposed by the Japan Pancreas Society in 2002 first in the world, were revised in 2006. The criteria are based on the minimum consensus of AIP and aim to avoid misdiagnosing pancreatic cancer as far as possible, but not for screening AIP. The criteria consist of the following radiological, serological, and histopathological items: (1) radiological imaging showing narrowing of the main pancreatic duct and enlargement of the pancreas, which are characteristic of the disease; (2) laboratory data showing abnormally elevated levels of serum  $\gamma$ -globulin, IgG or IgG4, or the presence of autoantibodies; (3) histopathological examination of the pancreas demonstrating marked fibrosis and prominent infiltration of lymphocytes and plasma cells, which is called lymphoplasmacytic sclerosing pancreatitis (LPSP). For a diagnosis of AIP, criterion 1 must be present, together with criterion 2 and/or criterion 3. However, it is necessary to exclude malignant diseases such as pancreatic or biliary cancer.

## Abstract

Autoimmune pancreatitis (AIP) is a particular type of pancreatitis of presumed autoimmune etiology. Currently, AIP should be diagnosed based on combination of clinical, serological, morphological, and histopathological features. When diagnosing AIP, it is most important to differentiate it from pancreatic cancer. Diagnostic criteria for AIP, proposed by the Japan Pancreas Society in 2002 first in the world, were revised in 2006. The criteria are based on the minimum consensus of AIP and aim to avoid misdiagnosing pancreatic cancer as far as possible, but not for screening AIP. The criteria consist of the following radiological, serological, and histopathological items: (1) radiological imaging showing narrowing of the main pancreatic duct and enlargement of the pancreas, which are characteristic of the disease; (2) laboratory data showing abnormally elevated levels of serum  $\gamma$ -globulin, IgG or IgG4, or the presence of autoantibodies; (3) histopathological examination of the pancreas demonstrating marked fibrosis and prominent infiltration of lymphocytes and plasma cells, which is called lymphoplasmacytic sclerosing pancreatitis (LPSP). For a diagnosis of AIP, criterion 1 must be present, together with criterion 2 and/or criterion 3. However, it is necessary to exclude malignant diseases such as pancreatic or biliary cancer.

## CLINICAL DIAGNOSTIC CRITERIA FOR AUTOIMMUNE PANCREATITIS 2006

The diagnostic criteria for AIP in Japan are based on the minimum consensus of AIP and aim to avoid

misdiagnosing pancreatic cancer as far as possible, but not for screening AIP. Therefore, the criteria emphasize the importance of imaging studies. In the 2002 criteria<sup>[3]</sup>, extent limitation on main pancreatic duct involvement (more than one-third the length of the entire pancreas) was required to diagnose only typical AIP cases and to avoid the possible inclusion of pancreatic cancer. However, with the accumulation of more AIP cases, it has become clear that, in several cases that are strongly suspected of having AIP, the degree of narrowing of the main pancreatic duct is less than one-third of the entire pancreas<sup>[5-7]</sup>. Furthermore, serum IgG4 levels are rather significantly and specifically elevated in AIP patients<sup>[8]</sup>. Thus, the 2006 criteria<sup>[4]</sup> delete the requirement that “more than one-third of the entire pancreas” is involved, allowing segmental AIP cases to be diagnosed. Furthermore, the 2006 criteria<sup>[4]</sup> include elevation of the serum IgG4 level as a diagnostic factor. Finally, the 2006 criteria<sup>[4]</sup> stress the need to exclude malignant diseases such as pancreatic or biliary cancer, before making the diagnosis of AIP (Table 1).

The preface of the criteria is described below<sup>[4]</sup>. It is suspected that the pathogenesis of autoimmune pancreatitis (AIP) involves autoimmune mechanisms. Currently, the main cases observed for characteristic findings of AIP are the diffuse enlargement of the pancreas and the narrowing of the pancreatic duct, which are associated with the findings that are suggestive of the involvement of autoimmune mechanisms such as increased levels of  $\gamma$ -globulin and IgG, the presence of autoantibodies, and the effective response to steroid therapy. In some cases, AIP shows extra-pancreatic manifestations such as sclerosing cholangitis, sclerosing sialadenitis, and retroperitoneal fibrosis, suggesting that AIP is a systemic disease. In Western countries, AIP is occasionally observed in association with ulcerative colitis and formation of tumors, suggesting that it is somewhat contrary to the definition and concept of the disease adopted in Japan.

Patients with AIP often show discomfort in the epigastrium, obstructive jaundice due to bile duct stricture, and diabetes mellitus. AIP is more common in middle-aged and elderly males. Although long-term prognosis of the disease is not clear, pancreatic stone formation has been found in some cases. When diagnosing AIP, it is important to differentiate it from neoplastic lesions such as pancreatic or biliary cancer, and to avoid facile therapeutic diagnosis by steroid administration. The present criteria, therefore, are based on the minimum consensus of AIP to avoid mis-diagnosing pancreas or biliary cancer as far as possible, but not for screening AIP.

Furthermore, description note of the criteria is reported as below<sup>[4]</sup>: (I) Imaging studies: (1) Diffuse or localized swelling of the pancreas. Abdominal ultrasonography (US), computed tomography (CT), and/or magnetic resonance imaging (MRI) show diffused or localized swelling of the pancreas. (A) The US feature of pancreatic swelling is usually hypoechoic, sometimes with scattered echogenic spots. (B) Contrast-enhanced CT generally shows delayed enhancement similar to normal pancreas with a sausage-like enlargement, and/or a capsular-like low density rim. (C) MRI shows diffuse or localized enlargement of the pancreas with a lower

**Table 1 Clinical diagnostic criteria for autoimmune pancreatitis 2006<sup>[4]</sup>**

**Clinical diagnostic criteria**

- 1 Diffuse or segmental narrowing of the main pancreatic duct with irregular wall and diffuse or localized enlargement of the pancreas by imaging studies, such as abdominal ultrasonography (US), computed tomography (CT) and magnetic resonance imaging (MRI)
- 2 High serum  $\gamma$ -globulin, IgG or IgG4, or the presence of autoantibodies, such as antinuclear antibodies and rheumatoid factor
- 3 Marked inter-lobular fibrosis and prominent infiltration of lymphocytes and plasma cells in the peri-ductal area, occasionally with lymphoid follicles in the pancreas

For diagnosis, criterion 1 must be present, together with criterion 2 and/or criterion 3. Diagnosis of autoimmune pancreatitis is established when criterion 1, together with criterion 2 and/or criterion 3, are fulfilled. However, it is necessary to exclude malignant diseases such as pancreatic or biliary cancers.

density in T1-weighted image and a higher density in T2-weighted image compared with each of the liver images. (2) Narrowing of the pancreatic duct. The main pancreatic duct shows diffuse or localized narrowing. (A) Unlike obstruction or stricture, narrowing of the pancreatic duct extends over a larger range where the duct is narrowed with irregular walls. In typical cases, more than one-third of the entire pancreatic duct is narrowed. Even in cases where the narrowing is segmental and extends to less than one-third, the upper stream of the main pancreatic duct rarely shows notable dilatation. (B) When the pancreatic images do show typical findings but laboratory data do not, there is a possibility of AIP. However, without histopathological examinations, it is difficult to distinguish AIP from pancreatic cancer. (C) To obtain the images of pancreatic duct, it is necessary to use endoscopic retrograde cholangiopancreatography (ERCP), and additionally the direct images taken during the operation or on specimens. Currently, the diagnosis is difficult to depend on magnetic resonance cholangiopancreatography (MRCP). (3) The pancreatic image findings described above may be observed retrospectively at the time of diagnosis. (II) Laboratory data: (1) In many cases, patients with AIP show increased levels of serum  $\gamma$ -globulin, IgG or IgG4. High serum IgG4, however, is not specific to AIP, since it is also observed in other disorders such as atopic dermatitis, pemphigus, or asthma. Currently, the significance of high serum IgG4 in the pathogenesis and the pathophysiology of AIP are unclear. (2) Although increased levels of serum  $\gamma$ -globulin ( $\geq 2.0$  g/dL), IgG ( $\geq 1800$  mg/dL), and IgG4 ( $\geq 135$  mg/dL) may be used as criteria for the diagnosis of AIP, further studies are necessary. Health insurance in Japan does not cover the cost of measuring serum IgG4 levels in AIP patients. (3) Autoantibodies, such as antinuclear antibody and rheumatoid factor, are often detected in patients with AIP. (III) Pathohistological findings of the pancreas: (1) Fibrotic changes associated with prominent infiltration of lymphocytes and plasma cells, occasionally with lymphoid follicles, are observed. In many cases, infiltration of IgG4-positive plasma cells is observed. (2) Lymphocytic infiltration is prominent

in the peri-ductal area, together with inter-lobular fibrosis, occasionally including intra-lobular fibrosis. (3) Inflammatory cell infiltration involving the ducts results in diffuse narrowing of the pancreatic duct with atrophy of acini. (4) Obliterative phlebitis is often observed. (5) Although fine needle biopsy under ultrasonic endoscope (EUS-FNA) is useful in differentiating AIP from malignant tumors, diagnosis may be difficult if the specimen is too small. (IV) Endocrine and exocrine function of the pancreas: Some patients with AIP show decline of exocrine pancreatic function and diabetes mellitus. In some cases, steroid therapy improves endocrine and exocrine pancreatic dysfunction.

AIP may be associated with sclerosing cholangitis and sialadenitis, or retroperitoneal fibrosis. Most of AIP patients with sclerosing sialadenitis are negative for both anti-SSA and anti-SSB antibodies, suggesting that AIP is different from Sjogren's syndrome. Sclerosing cholangitis-like lesions accompanying AIP and primary sclerosing cholangitis (PSC) respond differently to steroid therapy and follow different prognoses, suggesting that they are not the same disorder. Further studies are necessary to clarify the role of autoimmune mechanisms in AIP.

In the diagnostic criteria in Korea<sup>[5]</sup> and the United States (Mayo Clinic)<sup>[6]</sup>, "response to steroid" is included as one of the diagnostic items. When response to steroid therapy is added to the criteria, the diagnostic sensitivity is increased. Since relief of narrowing of the pancreatic duct can be seen as early as 2 wk after steroid therapy in AIP cases, it does not occur in pancreatic cancer cases. The Korean investigators advocate a short trial of steroid therapy to differentiate AIP from pancreatic cancer in cases that do not fulfill the Japanese criteria<sup>[5]</sup>. We also agree that a trial of steroid therapy can be used to assist in making the diagnosis when it is used appropriately. However, since general physicians who are not pancreatologists use the criteria, it is possible that the facile use of steroid trials will delay pancreatic cancer surgery, which could lead to cancer progression in some cases. Therefore, "response to steroid" is excluded in the diagnostic criteria in Japan<sup>[4,9,10]</sup>.

AIP with neutrophilic infiltration in the epithelium of the pancreatic duct (idiopathic duct-centric chronic pancreatitis: IDCP, or granulocyte epithelial lesion: GEL) has been reported by American<sup>[11]</sup> and Italian<sup>[12]</sup> pathologists. These patients showing different clinicopathological features from AIP are defined in Japan as follows: no predilection for elderly males, frequent association with inflammatory bowel disease, and weaker association with other sclerosing diseases. Histopathological finding of AIP in Japan is lymphoplasmacytic sclerosing pancreatitis (LPSP), and the above Western AIP cases have not been confirmed in Japan owing to the limited number of studies.

AIP patients usually have various extrapancreatic lesions such as sclerosing cholangitis and sialadenitis, and retroperitoneal fibrosis<sup>[13]</sup>. The histopathological findings of these extrapancreatic lesions are uniformly fibrosis with marked infiltration of IgG4-positive plasma cells and lymphocytes, which are similar to those in the

pancreas<sup>[14,15]</sup>. Therefore, the recent concept of AIP suggests that AIP is a pancreatic lesion of IgG4-related systemic disease<sup>[1,15,16]</sup>. In the future, criteria for AIP might develop into criteria for IgG4-related systemic disease.

### INTRODUCTION

The history of giant duodenal ulcers (GDUs) dates back to 1931 when Brdiczka first described these exceptionally large ulcers<sup>[1]</sup>. Initially, GDUs were notable for being difficult to diagnose with barium roentgenogram<sup>[2,3]</sup> and their high morbidity and mortality<sup>[4-6]</sup>. Prompt and correct diagnosis was often delayed, and for decades the only curative intervention was invasive, surgical procedures fraught with technical difficulties. Until the early 1980's, few cases were ever described within medical literature in which patients with GDUs were successfully treated with medical therapy. Since the late 1970's and early 80's, technological and pharmacological advancements have markedly changed the manner in which physicians diagnose, treat and manage patients with GDUs. The widespread use of endoscopy, the introduction of H-2 receptor blockers and proton pump inhibitors, and the improvement in surgical techniques have all contributed to this evolution. Despite this, we suggest that GDUs remain an under recognized entity, and are often assumed to be identical to standard sized ulcers. A careful review of the literature highlights the important differences when comparing GDUs to classical peptic ulcers and why they must be thought of differently than their more common counterpart.

### Abstract

Giant duodenal ulcers (GDUs) are a subset of duodenal ulcers that have historically resulted in greater morbidity than usual duodenal ulcers. Until recently, few cases had been successfully treated with medical therapy. However, the widespread use of endoscopy, the introduction of H-2 receptor blockers and proton pump inhibitors, and the improvement in surgical techniques all have revolutionized the diagnosis, treatment and outcome of this condition. Nevertheless, GDUs are still associated with high rates of morbidity, mortality and complications. Thus, surgical evaluation of a patient with a GDU should remain an integral part of patient care. These giant variants, while usually benign, can frequently harbor malignancy. A careful review of the literature highlights the important differences when comparing GDUs to classical peptic ulcers and why they must be thought of differently than their more common counterpart.

### HISTORY AND DEFINITION

Brdiczka is credited with being the first to describe GDUs and their radiographic appearance<sup>[1]</sup>. Most early case reports and small series emphasized the common problem of missed diagnosis on barium studies<sup>[7-10]</sup>. This was due to the fact that the ulcer crater was so large it would often be mistaken for a normal or slightly deformed duodenal cap. Kirsh and Brendel best illustrated this in their 1968 publication<sup>[4]</sup>. They examined 42 cases of GDU and found that only 24 were correctly diagnosed with a barium meal. They also established criteria for the diagnosis of GDUs. Their criteria included: an ulcerative crater greater than 2 cm, performance of the roentgen examination before surgical or pathological demonstration of ulcer, proof

that the lesion was benign and confirmation at surgery or post-mortem examination. Over the years, with the advent and technologic advancements of endoscopic evaluation, the criteria have unofficially evolved. Today, endoscopy has essentially replaced barium contrast studies for visualization of the upper gastrointestinal tract and there is little difficulty with the diagnosis of these lesions. GDUs are generally now defined simply as a benign, full thickness ulcer at least 2 cm in diameter, and usually involving a large portion of the duodenal bulb<sup>[11]</sup>.

## EPIDEMIOLOGY

Peptic ulcer disease remains a common medical problem worldwide, with the lifetime prevalence ranging from approximately 11% to 20% for men, and 8% to 11% for women<sup>[12]</sup>. Given this substantial lifetime prevalence, there are major economic loses and health care expenditures due to this problem. GDUs comprise approximately 1%-2% of all duodenal ulcers<sup>[13]</sup> and 5% of peptic ulcers requiring surgical intervention<sup>[14]</sup>. In most epidemiologic studies, the male to female ratio of standard sized ulcer disease is 2.3 to 1<sup>[15]</sup>, and the ratio in those with GDUs is approximately 3 to 1<sup>[11]</sup>.

The etiology of standard sized and GDUs has been associated with two major contributing causes: recent usage of nonsteroidal anti-inflammatory drugs (NSAIDs), and *Helicobacter pylori* (*H pylori*) infection. Worldwide, infection with *H pylori* continues to be widespread despite decreasing prevalence in select countries such as the United States. In addition, NSAID use has remained high, and the point prevalence of standard sized duodenal ulcers can reach 19% in chronic NSAID users<sup>[16]</sup>. Given these statistics, the clinician's awareness and familiarity with GDUs will be necessary, as patients will assuredly continue to develop these dangerous variants of peptic ulcer disease.

## PATHOPHYSIOLOGY

As stated above, GDUs have been most commonly associated with recent NSAID use and *H pylori* infection. The mechanism by which each of these factors causes duodenal ulcers is markedly different. Simply stated, *H pylori* infection has been shown to lead to a dysregulation of acid secretion, and an antral predominant gastritis. This leads to a high duodenal acid load and promotes gastric metaplasia within the duodenal bulb. This in turn favors *H pylori* colonization in the duodenum within these islands of gastric metaplasia. Through multiple different mechanisms, the bacteria cause inflammation within the duodenum, which is exacerbated by the increased acid load, and ultimately leads to the formation of an ulcer<sup>[17]</sup>. Meanwhile, NSAIDs lead to ulcer formation primarily through the inhibition of prostaglandins and direct mucosal injury<sup>[17]</sup>.

The true incidence of *H pylori* in standard sized duodenal ulcer formation is not known, but recent data suggests that it exceeds 85%<sup>[18,19]</sup>. However, two recent studies suggest that the percentage of GDUs caused by

*H pylori* is less than when compared to standard sized ulcers, and that NSAID use may play a more prominent role<sup>[20,21]</sup>. In 1999, Fischer *et al* reviewed 28 cases of GDU. In their study, only 39% of patients tested were found to have *H pylori* infection. In addition, Colleen *et al*<sup>[20]</sup> evaluated 184 patients with duodenal ulcers, and compared patients with standard sized ulcers to those with GDUs. They found that 53% of patients with GDUs had used daily NSAIDs in the month prior to presentation versus only 8% in the standard sized duodenal ulcer group. This same study also evaluated the basal acid output of patients with GDUs as compared to those with standard size ulcers; however, no significant difference existed<sup>[20]</sup>.

This collection of data suggests that daily NSAID use plays a more prominent role in the formation of GDUs than in standard sized duodenal ulcers. And while *H pylori* infection likely plays a role in the formation of GDUs, it is not as prevalent as it is with the formation of standard size duodenal ulcers.

Unfortunately, little data exists to explain the pathophysiologic differences that lead certain patients to develop these giant variants. Plausible explanations include genetic predisposition, dietary or environmental factors, microbial influence, variations in immunologic response or any combination of these factors<sup>[22,23]</sup>. Clearly, investigation and research are necessary to help provide further insight into these heretofore unexplained mechanisms.

## CLINICAL FEATURES

The presenting symptoms of most patients reflect the anatomical changes and the histopathology of the disease process. The most common of these symptoms is abdominal pain. Most patients describe the pain as involving the epigastric region, and some experience involvement of the right hypochondrium and/or radiation into the back. This requires the physician to include biliary and pancreatic pathology in their differential diagnosis. The pain of these ulcers has been described as more persistent than classically described with smaller duodenal ulcers. In addition, patients with GDUs are not provided relief from food or alkali<sup>[6,24]</sup>.

The majority of GDUs will present with hemorrhage<sup>[6,25]</sup>. This may manifest with melena, hematochezia, hematemesis, or any combination of the above. Anemia typically occurs in the setting of the bleeding ulcers. Surgical and endoscopic evaluation has often revealed the gastroduodenal artery within the ulcer bed. The size of the ulcer and the surrounding inflammation may cause gastric outlet obstruction. This often causes nausea and vomiting. Obstruction may be evident endoscopically by the presence of a large volume of gastric contents.

Additionally, the inflammatory mass can produce significant constitutional symptoms such as weight loss, cachexia, malnutrition and chronic abdominal pain. This constellation of symptoms can often mislead the clinician to suspect malignancy as the most likely

diagnosis.

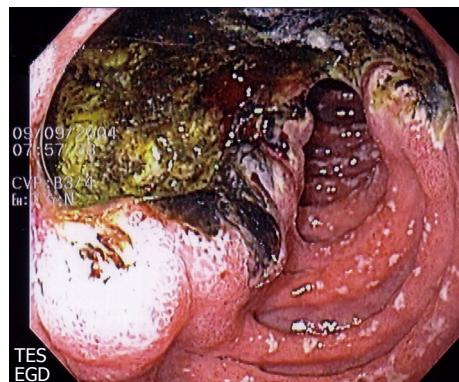

Other important historical features are the personal history of ulcer disease and the recent use of NSAIDs. Some case series note that over 40% of patients will have a prior history of a peptic ulcer<sup>[11]</sup>. In 1994, Colleen *et al*<sup>[20]</sup> revealed that patients with daily NSAID use greater than 1 mo prior to presentation had a markedly increased risk of forming GDUs.

It is well known that there is a high rate of complications with GDUs, and these complications directly lead to the high morbidity and mortality associated with this entity<sup>[5,6,25]</sup>. Common complications encountered with GDUs include bleeding and, on occasion, massive hemorrhage. One study showed that a GDU with adherent clot or a visible vessel on index EGD is a marker of an ulcer that is more likely to require surgical intervention<sup>[21]</sup>. Another feared complication is perforation. In previous case series, the perforation rate has varied between 0% and 7%<sup>[20,21,25,26]</sup>. Other complications include obstruction of the affected portion of the duodenum or proximal pylorus due to the massive inflammatory response, fistula formation, adhesions to or erosions into surrounding organs, and stricture formation in the biliary tree, pancreatic duct or the small bowel itself. These inflammatory changes are also one of the reasons that make a surgical approach fraught with technical difficulties<sup>[11,25,26]</sup>.

## DIAGNOSIS

As discussed above, the difficulty in diagnosis of GDUs has been one of the hallmarks of this disease entity since first described. Making the radiographic diagnosis by barium meal has been difficult<sup>[2,3]</sup>. The size of the ulcer often causes replacement of the duodenal bulb. As a result, GDUs may be altogether missed or misinterpreted as a deformed bulb, diverticulum or pseudodiverticulum during a barium study. The radiographic criteria to make the diagnosis of GDU were summarized by Klamer and Mahr in 1978<sup>[25]</sup>. Despite increased awareness of these criteria by clinicians, the successful diagnosis based solely on upper GI series remained unacceptably low. As a result, the entity of GDUs was likely under-diagnosed and frequently missed<sup>[4]</sup>.

The advent and widespread use of endoscopy has markedly improved clinician's ability to detect GDUs with greater accuracy<sup>[27]</sup>. Jaszewski *et al* highlighted this in 1983. In their series, seven cases of GDU were initially evaluated by upper GI barium meal. EGD then followed. GDUs were successfully diagnosed with roentgenography in only three of the seven cases. However, endoscopy confirmed the presence in all seven cases. This highlighted the importance of endoscopy in patients with symptoms suggestive of giant or regular duodenal ulcers. Subsequent case series have since used only endoscopy with measurements as diagnostic criteria<sup>[13,21]</sup>. Indeed, barium studies are now used far less frequently, typically when endoscopy is contraindicated or incapable of passing through a stricture. As a result, many clinicians may now encounter a GDU during an

**Figure 1** Endoscopic photograph of a Giant Duodenal Ulcer in a patient taking NSAIDs. The ulcer involves the proximal second portion of the duodenum. The ulcer seen is larger than 2 cm, and involves over fifty percent of the mucosal circumference.

endoscopy without the expectation of finding one, and may be inclined to misdiagnose a GDU as a simple peptic ulcer. Please see Figure 1 for an example of a GDU appearance during endoscopy.

The other obvious benefit of endoscopy is the ability to biopsy. This allows the clinician to exclude a neoplastic source as the cause of ulcer formation. While routine biopsy of standard sized duodenal ulcers is generally not recommended, this practice is worthwhile in the setting of GDUs, particularly those with nodularity at the edge. These giant variants, while usually benign, can frequently harbor malignancy. This was supported by a recent review of 52 cases of duodenal ulcers larger than 2 cm which were biopsied by Rathi *et al*. They found a malignancy rate of approximately 19% (primary duodenal carcinoma in 15%, lymphoma and tuberculosis in 2% each)<sup>[13]</sup>. Thus, we recommend multiple biopsies from the ulcer edges in all cases of GDUs.

## DIFFERENTIAL DIAGNOSIS

Prior to endoscopy, the differential diagnosis of benign GDUs had to include entities that mimicked its appearance on upper GI series. This included carcinoma of the duodenum, lymphosarcoma, duodenal diverticulum, pseudodiverticulum, regional enteritis, MALT lymphoma and tuberculosis. However, with the widespread use of endoscopy as detailed above, the differential diagnosis is somewhat narrowed. Frequently, the endoscopist cannot differentiate a benign giant ulcer from a malignant one macroscopically. As described above, patients may present with insidious symptoms such as weight loss, anorexia, and malnutrition raising concern for a malignant etiology. Therefore, again, biopsy and histopathologic examination is a necessity. Gastrinoma must also be included in the differential diagnosis, particularly in patients with evidence of acid hypersecretion, multiple ulcers extending beyond the second portion of the duodenum, diarrhea or a personal or family history of multiple endocrine neoplasia type 1 (MEN1).

## TREATMENT

Prior to the introduction of H<sub>2</sub> receptor blockers in the late 1970's, GDUs were managed primarily with surgery. This was reflected in the literature, as before 1982, there were very few cases published detailing successful medical management of GDUs<sup>[10-12]</sup>. Lumsden was able to document one patient who was a long-term (> 6 mo), asymptomatic survivor of a GDU after medical treatment only<sup>[6]</sup>.

Initially, the mortality rate associated with surgical management of GDUs was extremely high, reaching greater than 40% in early case series<sup>[24,25]</sup>. Those patients who had prompt and accurate pre-operative diagnosis had the lowest mortality. The inflammatory qualities of GDUs that make them distinct in size and nature from standard ulcers also make them more difficult to approach surgically<sup>[11]</sup>. Classically, the surgical technique most commonly recommended is truncal vagotomy and subtotal gastrectomy<sup>[21]</sup>. However, technical variations of the surgical approach have been debated. For example, management of the duodenal stump has been controversial<sup>[11,28]</sup>.

In subsequent decades, the mortality rate has fallen markedly due to numerous factors including improved radiographic technique, the advent of endoscopy and improved surgical and anesthetic techniques<sup>[11,21]</sup>. Most recently, since the 1970s, the advent of new acid suppression medication, the discovery of *H pylori* and its role in ulcer formation, and the importance of eradication therapy has led to the possibility of successful medical management of GDUs<sup>[21,27,29]</sup>.

In 1983, Jaszewski *et al*<sup>[27]</sup> reviewed 14 consecutive cases of GDUs between 1980 and 1982. Nine patients qualified for a trial of extended conservative medical treatment with close follow up. They were treated with cimetidine 1200 mg daily and antacids every 2 h while awake. Eight of the nine patients were successfully treated with the medical regimen and were asymptomatic for a mean of 14.9 mo. One patient failed medical treatment and had a perforation on day 23. This study suggested that medical treatment of uncomplicated GDUs could be accomplished with medical management, close observation and follow up with the assistance of endoscopic monitoring. In a Letter to the Editor responding to this article, Porro *et al* retrospectively reviewed 23 cases of GDUs, nine of which were eligible for similar treatment with cimetidine. Their letter agreed that H<sub>2</sub> receptor blockers could be used as short-term medical treatment of GDUs<sup>[30]</sup>.

Both of these reviews were performed before the release of proton pump inhibitors. In 1999, Fischer *et al*<sup>[21]</sup> published a prospective study of 28 patients with GDUs. One patient met criteria for immediate surgical referral, and the remaining 27 were placed on omeprazole 40 mg by mouth daily. Of these 27 patients, 7 required secondary surgical treatment for GDU complications or failure of medical therapy (4 emergent operations for re-bleeding, 3 elective operations for gastric outlet obstruction). Of these twenty remaining patients, fifteen of them had complete documented

healing on endoscopy. Of the eight patients requiring surgery, seven had a visible vessel or adherent clot on index EGD. Lastly, only 39% of patients had evidence of *H pylori* infection, and these patients were less likely to require surgery than those who were *H pylori* negative. The authors concluded that omeprazole appears to be a safe first-line treatment in stable patients, and should decrease the eventual need for operative intervention.

Several studies have confirmed the superiority of proton pump inhibitors (PPIs) versus H<sub>2</sub> receptor blockers in the treatment of standard sized gastric and duodenal ulcers<sup>[31-34]</sup>. Thus, attempts at medical treatment of GDUs should consist of proton pump inhibitors.

Despite the marked improvement delivered by the administration of proton pump inhibitors, GDUs are still associated with high rates of morbidity, mortality and complications. Thus, surgical evaluation of a patient with a GDU should remain an integral part of patient care. Indeed, there are indications for emergent and elective surgical intervention. The most common emergent indications include uncontrolled hemorrhage and perforation whereas unresolving obstruction, intractable or recurrent bleeding, and fistula formation are some of the elective indications<sup>[14]</sup>. Based on the data above, PPIs should be administered as a medical adjunct to the operation.

Lastly, discontinuation of NSAIDs and antimicrobial treatment of *H pylori* infection are recommended in the presence of these risk factors. Eradication of *H pylori* has been well documented to improve healing of peptic ulcers<sup>[29,35]</sup>.

## CONCLUSION

Historically, the two hallmark features of GDU disease were the difficulties in prompt diagnosis and the failures of medical management. A review of the literature suggests the changing nature of both of these features. The advent and widespread use of endoscopy has made a prompt diagnosis of GDU more accurate and easy to obtain. Once a diagnosis has been made, initiation of therapy can begin. Uncontrolled hemorrhage, perforation and unstable patients still should be cared for with immediate surgical evaluation and management. Recent data examining the use of H<sub>2</sub>-receptor blockers and proton pump inhibitors suggest that stable patients may be safely treated initially with medication, close observation and repeat endoscopic evaluation<sup>[21,27,30]</sup>. In addition, endoscopic biopsies allow a clinician to test for malignant etiologies of giant ulcers, which may be more common than suspected<sup>[13]</sup>. For this reason, we recommend that biopsies should be performed on all duodenal ulcers > 2 cm in diameter, particularly those with nodular appearing edges.

Due to evolving endoscopic and medical therapies, the management of GDUs has changed. What was once a disease that was difficult to diagnose, and managed solely with surgical intervention has become one easily diagnosed and potentially treated medically. It is of utmost importance that physicians recognize GDUs as

being different than their standard sized counterparts, and that we continue to further our understanding of this entity.

was significantly higher than that in well-differentiated GC samples ( $P = 0.014$ ). Moreover, the negative CHFR protein expression rate in paraffin-embedded GC samples was 55.07% (38/69), the positive rate in poorly differentiated GC samples was 36.73% (18/49), which was significantly lower than 65.00% (13/20) in well-differentiated GC samples ( $\chi^2 = 4.586, P = 0.032$ ).

**CONCLUSION:** Aberrant methylation of the *CHFR* gene may be involved in the carcinogenesis and development of GC, and is the predominant cause of down-regulation or loss of *CHFR* mRNA or protein expression. As aberrant methylation of CHFR promoter is correlated with tumor differentiation, it may help to predict the prognosis of GC and *CHFR* may become a novel target of gene therapy for GC in the future.

## Abstract

**AIM:** To investigate the aberrant methylation of CHFR promoter in human gastric cancer (GC) and its impact on the expression of *CHFR* mRNA and protein, as well as its correlation with clinical and histological features of human GC.

**METHODS:** Methylation-specific polymerase chain reaction (MSPCR) was used to detect the methylation status of CHFR promoter in 20 primary GC samples and paired normal gastric mucosa. The *CHFR* mRNA and protein expressions were investigated both by RT-PCR and by Western blotting. The CHFR protein expression in 69 GC samples was immunohistochemically examined.

**RESULTS:** The DNA methylation of the *CHFR* gene was found in 9 of the 20 GC samples (45%) and the down-regulation of *CHFR* mRNA and protein was significantly associated with the methylation status of the *CHFR* gene ( $P = 0.006$ ). In 20 samples of corresponding non-neoplastic mucosa, no DNA methylation of the *CHFR* gene was detected. The *CHFR* gene methylation in poorly differentiated GC samples

## INTRODUCTION

Gastric cancer (GC) is one of the most common malignancies worldwide<sup>[1]</sup>. As other malignant tumors, gastric carcinogenesis is a pathological process involving multiple genes and steps. The relevant genes are mainly oncogenes, tumor suppressor genes, and DNA mismatch repair genes. Tumor suppressor genes may lose their functions by gene mutation, loss of heterozygosity and methylation of promoters. Methylation is an epigenetic modification whereby the gene activity is controlled by adding methyl groups (CH<sub>3</sub>) to specific cytosines of the DNA. This control mechanism is important during mammalian embryonic development, and has received increasing attention in

carcinogenesis research<sup>[2]</sup>. Aberrant DNA methylation can change the chromosomal structure and DNA stability, cause abnormalities of gene expression, and affect proliferation and differentiation of tumors<sup>[3]</sup>. Hypermethylation in the promoter region, as a key factor for carcinogenesis, causes silencing of suppressor genes<sup>[4,5]</sup>. *CHFR* (checkpoint with FHA and RING finger) is a mitotic checkpoint gene that is localized at chromosome 12q24.33. *CHFR* encodes a protein with FHA and RING finger domains that governs transition from prophase to metaphase in the mitotic checkpoint pathway. In cellular response to mitotic stress by microtubule inhibitors, *CHFR* activation delays chromosome condensation during prophase and increases the cells' ability to survive the stress<sup>[6]</sup>. *CHFR* prevents errors in chromosome segregation that can lead to neoplasia. Recently, some studies showed that *CHFR* is an important tumor suppressor gene and its encoding product is a ubiquity ligase of Plk1<sup>[7-10]</sup>. Plk1 regulates both Wee1 kinase and Cdc25C phosphatase, which in turn control the Cdc2 kinase activity at the G2 to M transition. The *CHFR* gene can ubiquitinate and degenerate the Plk1, which prevents cells from entering prophase and metaphase. *CHFR* is ubiquitously expressed in normal human tissues while loss of *CHFR* expression has been observed in human tumors, in which it fails to prevent proliferation of abnormal cells from G2 to M phase, and abnormal differentiation and proliferation of cells occurs<sup>[11]</sup>. Moreover, CHFR protein, comprised of fork head-associated FHA and RING-finger (RF) domain, is frequently down-regulated in human colon cancer and GC (up to 50%). Loss of *CHFR* mRNA expression is a consequence of promoter methylation, suggesting that it plays a tumor suppressor role in gastrointestinal carcinogenesis. The checkpoint function of the FHA domain of *CHFR* is a core component of anti-proliferating properties against gastrointestinal carcinogenesis<sup>[12]</sup>. GC is the second most common cause of cancer-related death in Asia. Although surgery is the standard treatment for this disease, early detection and treatment are the only way to reduce its mortality<sup>[13]</sup>.

This study was performed to assess the methylation of CHFR promoter in Chinese GC tissue samples, its impact on gene expression, and its correlation with the clinical and pathobiological characteristics of GC.

## MATERIALS AND METHODS

### Tissue samples and DNA extraction

We studied GC samples and adjacent normal mucosa from 20 patients who underwent surgical resections at the Department of Surgery of Liaoning Tumor Hospital (Shenyang, China) from March to September 2007. None of these patients received chemotherapy or radiotherapy before surgery. Informed consent for use of the samples was obtained from each patient before surgery. All tissue samples were confirmed by histopathology. The samples were placed in liquid nitrogen immediately and then stored at -80°C until

analysis. For immunohistochemical analysis, we used archival formalin-fixed, paraffin-embedded tissues from 69 GC patients and paired normal gastric mucosa, which were obtained from the First Affiliated Hospital of China Medical University during December 2003 to May 2004. Age and sex of the patients, tumor size, differentiation degree, Borrman type, depth of tumor invasion and status of lymph node metastasis were obtained from the histopathological reports of these patients. We attributed highly or moderately differentiated adenocarcinoma to "well differentiated", and attributed adenocarcinoma, mucinous carcinoma and signet cell carcinoma to "poorly differentiated". High molecular weight genomic DNA was extracted using the TIANamp genomic blood/cell/tissue genomic DNA kit (TIANGEN Biotech, Beijing), according to the manufacturer's instructions.

### Bisulfite modification and methylation-specific polymerase chain reaction (MSPCR)

Sodium bisulfite treatment of DNA converted all unmethylated cytosines to uracils, but the level of methylated cytosines was unaffected. Briefly, 2 µg aliquots of genomic DNA was denatured by adding 6 µL freshly prepared 3 mol/L NaOH and incubating the solution at 37°C for 10 min. For complete denaturation, the samples were incubated at 95°C for 1 min and subsequently cooled on ice. Bisulphate solution was prepared by dissolving 8.1 g sodium bisulphite in 16 mL H<sub>2</sub>O, adding 30 µL 10 mmol/L hydroquinone solution and adjusting the pH to 5.0 with 520 µL 3 mol/L NaOH. Bisulphate solution (0.5 mL) was mixed with the denatured DNA, overlaid with mineral oil, and incubated at 50°C for 17.5 h in a water bath in the dark. DNA was recovered using the Wizard DNA clean-up system (Promega, Madison, WI, USA) and eluted in 100 µL H<sub>2</sub>O. Following this, 11 µL 3 mol/L NaOH was added and the sample was incubated for 15 min at 37°C. The solution was then neutralized by adding 110 µL 16 mol/L NH<sub>4</sub>OAC (pH 7.0). DNA was ethanol-precipitated, washed with 70% ethanol, dried and resuspended in 50 µL distilled H<sub>2</sub>O. Bisulphite-treated DNA, as a template for MSPCR, was used in each of the PCR assays. Amplification was carried out in a 25 µL reaction volume containing 2 µL 1 × PCR buffer, 2.0 mmol/L MgCl<sub>2</sub>, 2.5 mmol/L dNTPs, 50 mg/mL DMSO, 10 µmol/L each primer, 50 ng DNA template, 2 U hot start Taq polymerase (Finzymes OY, Finland). After heating at 95°C for 5 min, PCR was performed in a thermal cycler for 40 cycles of denaturation at 95°C for 45 s, annealing at 51°C (*CHFR*-UMS) or at 55°C (*CHFR*-MS) for 45 s and extension at 72°C for 45 s. Distilled water without DNA was used as a negative control. The PCR products were separated on 3.0% agarose gels. The following primer sets were used: *CHFR* M forward (5'-TTTT AATATAATATGGCGTCGATC-3'), a *CHFR* M reverse (5'-AACGACAACAAACGAAACCG-3') for methylated *CHFR* sequences, which could amplify a 141-base pair product. *CHFR* U forward (5'-GTTC

TAATATAATGGTGTGATT-3') and CHFR U reverse (5'-AAAACAACAACAAACAAA CCA-3') for unmethylated CHFR sequences, which could amplify a 144-base pair product as described previously<sup>[14]</sup>.

#### **Reverse transcription-PCR (RT-PCR)**

Expression of the *CHFR* gene was analyzed by RT-PCR. Total RNA was extracted with TRIzol reagent (Invitrogen, Carlsbad, CA, USA) according to the manufacturer's instructions. First-strand cDNA was generated using a first strand cDNA synthesis kit (Qiagen, German), then amplified by a primer set that is specific for the *CHFR* gene. The primer sequences are CHFR S (sense): 5'-TAAAGGAAGTGGTCCCTGTG-3' and CHFR AS (anti-sense): 5'-GGTTGGGCATTCTACGC-3', which resulted in a DNA product of 205 bp. The PCR amplification consisted of 1 cycle at 95°C for 5 min, 35 cycles at 95°C for 30 s, at 58°C for 45 s, and at 72°C for 1 min, and 1 cycle at 72°C for 6 min. The expression of β-actin was used as a control to confirm the success of RT-PCR using the following primer pair: 5'-AGTTGCGTTACACCC TTTCTTG-3' (forward) and 5'-TCACCTTCACCCTCCAGTT-3' (reverse). The PCR products were separated by 2% agarose gel electrophoresis, stained with ethidium bromide, and visualized under UV light. Electrophoresis strips were analyzed by BANDSCAN 5.0 software and the optical density ratio of target mRNA to β-actin served as an index for statistical analysis. If the relative optical density value of *CHFR* mRNA expression was decreased more than 50% compared with paired normal gastric mucosa, it was defined as down-regulation of expression. No expression was regarded as loss of mRNA expression.

#### **Western blotting**

Tumor and control tissue samples were homogenized for extract preparations in an ice-cold mild lysis buffer containing 10 mL/L nonidet P-40, 0.15 mol/L NaCl, 0.01 mol/L sodium phosphate (pH 7.2), 2 mmol/L EDTA, 50 mmol/L sodium fluoride, 0.2 mmol/L sodium vanadate, and 1 μg/mL aprotinin. The tissue homogenates were centrifuged at 20 000 r/min for 15 min and supernatants were collected. Protein density was determined by Coomassie brilliant blue, and then 12% SDS polyacrylamide gel electrophoresis was performed. Separated proteins were then transferred onto nitrocellulose membranes, which were blocked in 50 g/L nonfat milk in TBST (TBS buffer containing 1 g/L Tween 20) for 2 h at room temperature, incubated in primary antibodies specific for mouse CHFR (1:400 dilution) for 2 h, washed and probed with horseradish peroxidase-conjugated secondary antibody for 1 h at room temperature. Immunoreactive bands were visualized by enhanced chemiluminescence (Santa Cruz Biotechnology, Santa Cruz, CA, USA). The specific bands were quantified by BANDSCAN 5.0 software and the optical density ratio of target protein to β-tubulin served as an index for statistical analysis. If the relative optical density value of CHFR protein expression was

decreased more than 50% compared with paired normal gastric mucosa, it was defined as down-regulation of expression. No expression was regarded as loss of protein expression.

#### **Immunohistochemical staining**

Tissue chips of GC, precancerous lesions and normal gastric mucosa were immunohistochemically stained by the Envision method. Immuno-bridge kits, mouse anti-human CHFR monoclonal antibody (diluted at 1:75) were bought from Abnova Company. All steps were accomplished in accordance with the instructions. PBS (0.01 mol/L, pH 7.4) was used instead of specific antibodies for negative control. Immunohistochemical staining was graded as positive if the staining signals of CHFR protein were yellow brown granules and located in cytoplasm. For each sample, two representative high power fields were examined. The average positive rate was assessed by the percent of positive cells in the totally counted 100 cells from two representative high power fields. Positive cells ≤ 20% of the totally counted cells were defined as negative while positive cells > 20% of the totally counted cells as positive.

#### **Statistical analysis**

The data were processed by SPSS 13.0 statistical software. Quantitative data were expressed as mean ± SD. Data were analyzed by Fisher's exact test and chi square test, independent sample t-test and Spearman rank related test.  $P < 0.05$  was considered statistically significant.

## **RESULTS**

#### **Aberrant methylation of *CHFR* gene in GC tissue samples**

The representative results of MSPCR for the *CHFR* gene promoter in GC samples are shown in Figure 1 and Table 1. DNA methylation of the *CHFR* gene was detected in 9 (45%) of the 20 GC samples. By contrast, no methylation was detected in the corresponding normal gastric mucosa from these same patients. The difference in GC tissue and normal gastric mucosa samples was significant ( $P < 0.001$ ). A significant difference was observed in the tumor samples ( $P = 0.014$ ), indicating that poorly differentiated GC is more frequently methylated than well-differentiated GC. However, aberrant methylation of the *CHFR* gene in human GC was not significantly correlated with other clinicopathological factors such as gender, age, tumor size, Borrman type, depth of tumor invasion, and status of lymph node metastasis.

#### **Aberrant expression of *CHFR* mRNA in GC tissue samples**

As shown in Table 2, *CHFR* mRNA expression was down-regulated in GC tissue samples ( $0.2186 \pm 0.2113$ ) compared with normal gastric mucosa ( $0.7020 \pm 0.2163$ ) and the difference was significant ( $t = 7.148$ ,  $P < 0.0001$ ).

Among them, CHFR mRNA expression in 14 poorly differentiated GC tissue samples ( $0.1364 \pm 1.1772$ ) was significantly lower than that ( $0.4106 \pm 0.1574$ ) in 6 well-differentiated GC samples ( $t = 3.276$ ,  $P = 0.004$ ). The representative RT-PCR results for the CHFR mRNA expression in GC samples are shown in Figure 2.

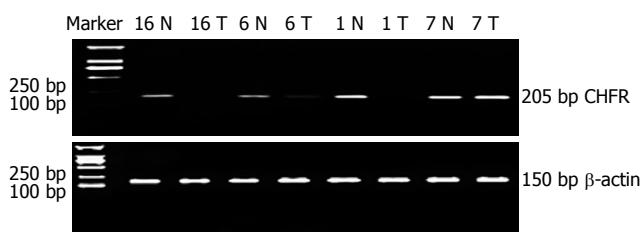

#### CHFR protein expression levels in GC tissue samples

Western blotting analysis showed that the down-regulation and loss rate of the CHFR gene-coded protein was 70.00% (14/20) in GC tissue samples. The

difference in relative optical density value between GC tissue and normal gastric mucosa samples was significant ( $0.2435 \pm 0.2620$  vs  $0.5955 \pm 0.2196$ ,  $t = 4.605$ ,  $P < 0.0001$ ). The level of CHFR protein expression in poorly differentiated GC tissue samples was significantly lower than that in well-differentiated GC tissue samples ( $t = 5.162$ ,  $P = 0.001$ ). The CHFR protein expression level was correlated with the other clinicopathological features of GC tissue samples and paired normal gastric mucosa samples (Table 2). The representative Western blotting results for the CHFR protein expression in GC samples

**Figure 1** Representative results of MSPCR in human GC tissue samples. Lanes U and M: Products derived from unmethylated and methylated alleles, respectively. Methylation of the *CHFR* gene was detected in 16 and 6 poorly-differentiated adenocarcinoma tissue samples and 1 mucinous adenocarcinoma tissue sample, while unmethylation of the *CHFR* gene was detected in 7 well-differentiated adenocarcinoma tissue samples. PUC18: Marker; N: Normal gastric mucosa corresponding to tumors; T: Gastric cancer.

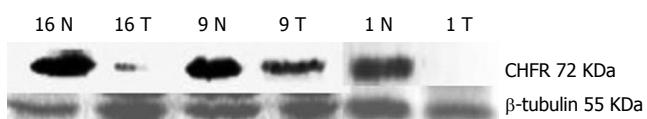

**Figure 2** Representative results of RT-PCR in human GC tissue samples.  $\beta$ -actin was used as an internal control. *CHFR* mRNA expression level in 16 and 6 poorly differentiated adenocarcinoma tissue samples and 1 mucinous adenocarcinoma tissue sample was significantly lower than that in paired normal gastric mucosa samples from the same patients, while no difference was found in 7 well-differentiated adenocarcinoma tissue samples. Marker, D2000: Marker; N: Normal gastric mucosa corresponding to tumors; T: Gastric cancer.

are shown in Figure 3.

In addition, the *CHFR* protein expression in 69 GC tissue samples was analyzed by immunohistochemical staining of paraffin-embedded sections. Negative staining was observed in 55.07% of GC tissue samples (38/69). Positive staining was observed in 36.73% of poorly differentiated GC tissue samples (18/49), which was significantly lower than 65.00% (13/20) of well-differentiated GC tissue samples ( $\chi^2 = 4.586$ ,  $P = 0.032$ ). However, the *CHFR* protein expression in human GC tissue samples was not correlated to the other clinicopathological factors such as gender, age, tumor size, Borrmann type, depth of tumor invasion and status of lymph node metastasis. The example of immunohistochemical staining is shown in Figure 4.

#### Correlation of aberrant *CHFR* methylation with mRNA and protein expression level

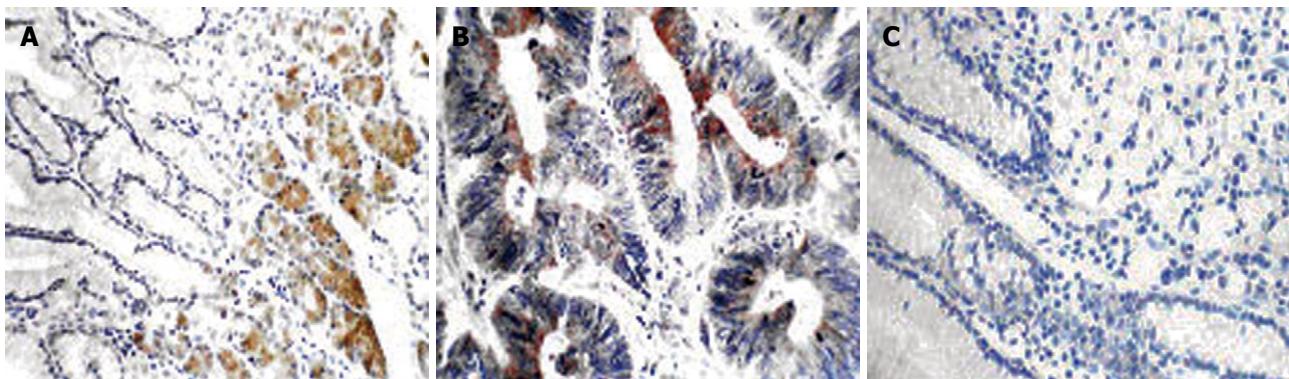

The level of *CHFR* mRNA and protein expression in 9 GC tissue samples with *CHFR* methylation was down-regulated or lost. The level of mRNA and protein expression was down-regulated only in 5 of the 11 GC tissue samples with an unmethylated *CHFR* gene. The *CHFR* mRNA and protein expression was inversely correlated with promoter methylation ( $r = 0.592$ ,  $P = 0.006$ ).

**Figure 3** Representative results of Western blot in human GC tissue samples.  $\beta$ -tubulin was used as an internal control. *CHFR* protein expression level in GS tissue samples was significantly lower than that in paired normal gastric mucosa samples. Aberrant methylation of *CHFR* and down-regulation or loss of *CHFR* mRNA expression were detected in 16 poorly differentiated adenocarcinoma tissue samples and 1 mucinous adenocarcinoma tissue sample, while positive protein expression of *CHFR* was detected in 9 moderately-differentiated adenocarcinoma tissue samples without *CHFR* methylation. N: Normal gastric mucosa corresponding to tumors; T: Gastric cancer.

It is well known that both carcinogenesis and tumor progression evolve from genetic and epigenetic alterations of several genes<sup>[15]</sup>. Epigenetic alteration refers to the heritable phenotypic alteration in the absence of DNA sequence changes, and DNA methylation is one of the extensively studied epigenetic alterations<sup>[16]</sup>. In human beings and other mammals, CpG island methylation is an important physiological mechanism. The inactivated X-chromosome in female silenced alleles of imprinted genes or inserted viral genes and repeat elements are inactivated through promoter methylation<sup>[17]</sup>. Aberrant CpG methylation is common in cancer development and may play an important role in the carcinogenic process<sup>[18-25]</sup>. Methylation changes occurring in cancer include global hypomethylation in genomic DNA and gene-specific promoter hypermethylation. Whereas global hypomethylation increases mutation rates and chromosomal instability, promoter hypermethylation usually results in transcriptional gene inactivation. Thus, promoter hypermethylation, by silencing anti-cell-proliferation genes, anti-apoptosis genes, anti-angiogenesis genes, DNA repair genes, and anti-metastasis genes, plays an important role in carcinogenesis<sup>[26,27]</sup>. Recent evidence indicates that epigenetic changes might "addict" cancer cells to altered signal-transduction pathways during the early stages of tumor development. Dependence on these pathways for cell proliferation or survival allows them to acquire genetic mutations in the same pathways, providing the cells with selective advantages that promote tumor progression<sup>[28]</sup>. Processes that regulate gene transcription are directly under the influence of genome organization. DNA methylation of CpGs constitutes an epigenetic mark generally correlated with transcriptionally silent condensed chromatin. Replication of methylation patterns by DNA methyltransferases maintains genome stability through cell division. Periodic, strand-specific methylation and demethylation occur during transcriptional cycling of the *pS2/TFF1* gene promoter activated by estrogens. DNA methyltransferases exhibit dual actions during these cycles and are involved in CpG methylation and active demethylation of 5mCpGs through deamination. Inhibition of this process precludes demethylation of the *pS2* gene promoter and its subsequent transcriptional activation. Cyclical changes in the methylation status of

## DISCUSSION

**Figure 4** Immunohistochemical staining for CHFR protein expression in GC tissue samples and normal gastric mucosa samples. Positive expression of CHFR in normal gastric mucosa tissue samples (A), in well-differentiated adenocarcinoma tissue samples (B), and in signet-ring cell carcinoma tissue samples (C).

promoter CpGs may thus represent a critical event in transcriptional achievement<sup>[29]</sup>.

However, aberrant methylation of CpGs is not a random event, but an event with gene-specific or tissue-specific differentiation. According to quantitative DNA methylation patterns at 4600 *Not I* sites and more than 150 differentially methylated regions in several C57BL/6J mouse tissue samples, comparative analysis between mice and human beings suggests that some, but not all, tissue-specific differentially methylated regions are conserved. A deeper understanding of cell-type-specific differences in DNA methylation might lead to a better illustration of the mechanisms behind tissue-specific differentiation in mammals<sup>[16]</sup>.

As a tumor suppresser gene, aberrant methylation of CHFR promoter region associated with gene silencing has been reported in several primary tumors as followsings<sup>[30-35]</sup>.

The aberrant hypermethylation rate of CHFR was 12.3% (2/14) in cervical adenocarcinoma samples<sup>[30]</sup>. Thirty-six percent of patient samples showed a low or negative CHFR protein expression or staining. In addition, lack of CHFR detection was associated with increased tumor size and weakly correlated with estrogen receptor-negative tumors, suggesting that decreased CHFR expression results in the acquisition of many phenotypes associated with malignant progression, including accelerated growth rates, higher mitotic index, enhanced invasiveness, increased motility, greater aneuploidy, and amplified colony formation in soft agar, further supporting the role of *CHFR* as a tumor suppressor in breast cancer<sup>[31]</sup>. An aberrant methylation of the *CHFR* gene was detected in 25 out of 98 (26%) primary colorectal cancers and no methylation was detected in the corresponding normal tissue specimens<sup>[32]</sup>. In 46 patients with GC, 24 (52%) had aberrant CHFR methylation. By contrast, aberrant methylation was detected in only 2 samples (4%) of normal gastric mucosa and CHFR methylation status did not correlate with gender, sex, and clinicopathological features, such as tumor size, histological type, and stage. In cell lines, aberrant CHFR methylation correlated with the loss of mRNA expression, and treatment with the methyltransferase inhibitor 5-aza-dC induced re-

expression of the gene, indicating that loss of CHFR expression due to aberrant methylation may be a cancer-specific event, which frequently occurs in primary GC<sup>[33]</sup>. CHFR staining was lost in 33% (57/174) of GC tissue samples, and there was a significant difference between staining in diffuse and intestinal histology. Loss of CHFR expression was found more commonly in the diffuse-type GC ( $P = 0.001$ ), but no correlation was observed with age, location or tumor stage<sup>[34]</sup>. The aberrant methylation rate of CHFR was 41.1% (23/56) in GC samples. The mean age of patients with CHFR methylation was significantly higher than that of patients without CHFR methylation ( $P = 0.040$ ). However, no significant correlation was observed with the other clinicopathologic factors<sup>[35]</sup>.

In this study, the methylation rate of *CHFR* genes in GC tissue samples was significantly higher than that in paired normal gastric mucosa, suggesting that aberrant methylation of *CHFR* gene may be involved in carcinogenesis and development of GC. In addition, a significant difference was observed in GC ( $P = 0.014$ ), indicating that poorly differentiated GC is more frequently methylated than well-differentiated GC and that aberrant methylation of the *CHFR* gene may participate in histological differentiation of GC and is associated with tumor malignant behavior. Its exact mechanism needs to be further studied. However, aberrant methylation of the *CHFR* gene in human GC was not significantly correlated with other clinicopathological factors such as gender, age, tumor size, Borrmann type, depth of tumor invasion and status of lymph node metastasis. Moreover, the *CHFR* mRNA or protein expression level in 9 GC tissue samples with CHFR methylation was down-regulated or lost, while the level of the mRNA or protein expression was down-regulated only in 5 of 11 GC tissue samples with an unmethylated *CHFR* gene. These findings show that aberrant methylation of CHFR promoter in GC tissue samples is the main cause of down-regulation or loss of its mRNA or coded protein expression. On the other hand, CHFR staining was lost in 55.07% (38/69) of GC tissue samples, and there was a significant difference between staining in poorly differentiated and well-differentiated GC tissue samples. Because such a loss

was found more commonly in GC tissue samples, CHFR probably acts as a tumor suppressor in development of GC.

In conclusion, aberrant methylation of the *CHFR* gene is a frequent event in human GC and the principle mechanism underlying gene silencing, down-regulation or loss of CHFR. Since aberrant methylation of *CHFR* gene is closely correlated with tumor pathobiological behavior, the detection of the *CHFR* gene may be helpful in predicting the prognosis of GC and *CHFR* may become a novel target of gene therapy for GC in the future.

## ACKNOWLEDGMENTS

The authors would like to thank Dr. Xi-Ming Yuan from Linköping University (Sweden) for his helpful suggestions and careful revision of the manuscript in English.

## COMMENTS

### Background

*CHFR* is a novel tumor suppressor gene and its encoding product is a ubiquitous ligase of Plk1. In cellular response to mitotic stress induced by microtubule inhibitors, CHFR activation delays chromosome condensation during prophase and increases the cells' ability to survive the stress. CHFR prevents errors in chromosome segregation that can lead to neoplasia. CHFR is ubiquitously expressed in normal human tissues while loss of CHFR expression due to aberrant methylation has been observed in human tumors, suggesting that it may be involved in carcinogenesis and development of gastric cancer. To date, few studies have addressed whether aberrant methylation of CHFR promoter is a common event in gastric cancer (GC).

### Research frontiers

The pathogenesis of GC is poorly understood. DNA methylation is an epigenetic modification. This control mechanism has received increasing attention in carcinogenesis research. As a tumor suppressor gene, aberrant methylation of CHFR promoter associated with gene silencing has been reported in several primary tumors including lung, esophageal, colorectal and hepatocellular cancers. In this study, we found that aberrant methylation of CHFR promoter played an important role in gastric carcinogenesis.

### Innovations and breakthroughs

Our study showed that aberrant methylation of CHFR promoter was a frequent event in Chinese GC tissue samples and the principle mechanism underlying gene silencing, down-regulation or loss of CHFR. Aberrant methylation of CHFR promoter was closely correlated with tumor pathobiological behavior. Results of the present study may further our understanding of the molecular mechanism of DNA methylation, which is an epigenetic modification.

### Applications

The data obtained from this study demonstrate that aberrant methylation of *CHFR* gene is a frequent event in human GC and the principle mechanism underlying gene silencing, down-regulation or loss of CHFR, suggesting that CHFR probably acts as a tumor suppressor in development of GC. Moreover, aberrant methylation of the *CHFR* gene was found to be closely correlated with tumor malignant behavior, indicating that detection of the *CHFR* gene may be helpful in predicting the prognosis of GC and CHFR may become a novel target of gene therapy for GC in the future.

### Peer review

In this study, the authors showed that methylation of CHFR promoter was significantly increased in GC tissue samples and was higher in poorly differentiated GC tissue samples than in well-differentiated GC tissue samples. Protein expression was found to be inversely correlated with promoter methylation. These findings suggest that aberrant methylation of the *CHFR* gene may be involved in the development of gastric carcinoma. This paper is original and informative.

## Abstract

**AIM:** To explore the existence and distribution of prohibitin (PHB) in nuclear matrix and its co-localization with products of some related genes during the differentiation of human hepatocarcinoma SMMC-7721 cells.

**METHODS:** The nuclear matrix of the SMMC-7721 cells cultured with or without  $5 \times 10^{-3}$  mmol/L hexamethylene bisacetamide (HMBA) was selectively extracted. Western blot was used to analyze the expression of PHB in nuclear matrix; immunofluorescence microscope observation was used to analyze the distribution of PHB in cell. LCSM was used to observe the co-localization of PHB with products of oncogenes and tumor suppressor genes.

**RESULTS:** Western blot analysis showed that PHB existed in the composition of nuclear matrix proteins and was down-regulated by HMBA treatment. Immunofluorescence observation revealed that PHB existed in the nuclear matrix, and its distribution regions and expression levels were altered after HMBA treatment. Laser scanning confocal microscopy revealed the co-localization between PHB and the

## INTRODUCTION

Prohibitin (PHB) is a tumor suppressor protein that is expressed in a variety of cell lines. It is not only localized to the inner membrane of mitochondria, where it acts as a chaperone protein, but is also present in the nucleus where it negatively regulates transcription. PHB plays important roles in the regulation of cell growth, proliferation, differentiation, aging and apoptosis. It is also involved in the genesis of tumor and some degenerative diseases<sup>[1-3]</sup>. In cell differentiation, some studies have found that the expression level of PHB was very low in rapidly proliferating cells, whereas it was much higher in cells undergoing differentiation. This indicates that PHB may promote cell differentiation and suppress cell proliferation<sup>[4]</sup>. Heretofore, over-expression of PHB has been found in various tumor cells. This seems to be conflictive with its tumor suppressive function. So far, the mechanism of its subcellular localization, nuclear transportation and regulation of cell proliferation and differentiation are

not well understood. Our previous studies revealed that PHB existed in nuclear matrix extractions of human adenocarcinoma MGc80-3 cells, and its expression level was altered during the differentiation induced by hexamethylene bisacetamide (HMBA)<sup>[5]</sup>. Furthermore, in the differentiation of human osteosarcoma MG-63 cells, we observed similar results<sup>[6]</sup>. This implies that PHB might be a common differentially expressed nuclear matrix protein in some tumor cells. In this study, we further studied the existence, localization, expression alteration of PHB in the nuclear matrix and the relationship between PHB and related products of oncogenes during the differentiation of human hepatocarcinoma SMMC-7721 cells induced by HMBA. This study provides scientific evidence for the function of PHB during cell differentiation and understanding of the mechanism of development of cancer and its reversion.

## MATERIALS AND METHODS

### Materials

Human hepatocarcinoma SMMC-7721 cells were obtained from China Center for Type Culture Collection (Wuhan University). RPMI-1640 was from Gibco Co., newborn calf serum was from Hangzhou Sijiqing Biological Engineering Materials Co., Ltd. HMBA was from Sigma Co. The antibodies used are listed in Table 1.

### Cell culture and inducement

Human hepatocarcinoma SMMC-7721 cells were cultured at 37°C in RPMI-1640 medium (pH 7.2) supplemented with 15% newborn calf serum, 100 U/mL penicillin, 100 U/mL streptomycin and 50 µg/mL kanamycin. Cells were passaged in log phase. Twenty-four hours after passaging the cells the experimental group was treated with culture media containing 5 mmol/L HMBA. Fresh culture media was added to the cells every 48-72 h. Cells were harvested at subconfluence.

### Cell selective extraction and sample preparation for light microscope

The cells were selectively extracted as described in our previous article<sup>[7]</sup>. The nuclear matrix-intermediate filament (NM-IF) samples on the cover slip strips after the selective extraction were prefixed in 2% glutaraldehyde at 4°C for 30 min, and rinsed in phosphate-buffered saline (PBS), pH 7.4. The samples were then stained with 0.2% Coomassie brilliant blue for 20 min, washed in distilled water, air dried, clarified by xylene, enveloped in the resin, and observed using an Olympus BH-2 microscope.

### Purification of nuclear matrix proteins

Nuclear matrix proteins of SMMC-7721 cells were purified by using a routine method with a few improvements<sup>[8]</sup>. The SMMC-7721 cells were washed with PBS and extracted with cytoskeleton buffer (CSK100) (10 mmol/L PIPES pH 6.8, 300 mmol/L sucrose, 100 mmol/L NaCl, 4 mmol/L CaCl<sub>2</sub>, 1.0 mmol/L PMSF, 0.5% Triton X-100) at 0°C for 10 min,

**Table 1 Antibodies used in the study**

Antibodies	Source	Antibodies	Source
Mouse anti-human PHB	NeoMarkers Co.	Goat anti-mouse IgG/HRP	Boster Co.
Goat anti-rabbit IgG-FITC	KPL Co.	Goat anti-rabbit IgG/HRP	Boster Co.
Goat anti-mouse IgG-TRITC	KPL Co.	Rabbit anti-p53	Boster Co.
Rabbit anti-human β-actin	Boster Co.	Rabbit anti-pRb	Boster Co.
Rabbit anti-c-Fos	Boster Co.	Rabbit anti-c-Myc	Boster Co.

and subjected to centrifugation for 5 min at 400 g. The pellet was washed twice with CSK50 (10 mmol/L PIPES pH 6.8, 300 mmol/L sucrose, 50 mmol/L NaCl, 4 mmol/L CaCl<sub>2</sub>, 1.0 mmol/L PMSF, 0.5% Triton X-100) and digested for 30 min at 25°C in the same buffer containing 300 U/mL DNase I. One mole per liter ammonium sulfate was added dropwise to a final concentration of 0.25 mmol/L. After incubation for 15 min, the nuclear matrix proteins were pelleted by centrifugation at 1000 r/min for 5 min, and washed once with the CSK50 buffer, then stored at -80°C.

### Western blot of PHB

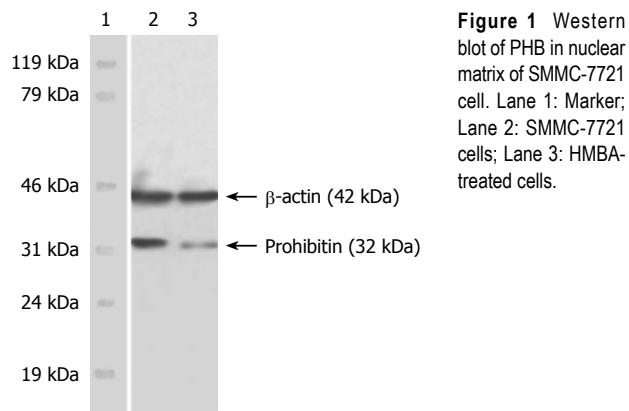

The nuclear matrix proteins were separated by SDS-PAGE and then transferred onto PVDF membranes. Nonspecific reactivity was blocked by incubation at room temperature for 1.5 h in 5% BSA buffer. The membrane was then incubated with PHB (1:2000) primary antibody at room temperature for 2 h. After washing, a horseradish peroxidase tagged secondary antibody was used to detect the primary antibody. Reactive protein was detected by the enhanced chemiluminescence (ECL) detection system (Pierce). As a negative control, the primary antibody was replaced by 5% BSA buffer. β-actin was also detected as an internal control.

### Sample preparation for fluorescence microscopy

The NM-IF samples on the cover slip were prefixed in 4% paraformaldehyde at 4°C for 10 min, rinsed in the TPBS (contain 0.5% Triton X-100) twice, 5 min each, blocked by 5% BSA at room temperature for 1 h, incubated with mouse anti-PHB monoclonal antibody (1:300) at room temperature for 30 min, and 4°C overnight, then washed 3 times with TPBS. Then, the cells were incubated with goat anti-mouse secondary antibody labeled with fluorescence dye TRITC, washed with water and dried by airing. Afterwards, 90% glycerol/PBS was applied and the cells observed using fluorescence microscopy. The entire process after incubation with secondary antibody was performed in the dark. The primary antibody was replaced by 5% BSA buffer as a negative control.

### Sample preparation for LSCM

Cells on the cover slips were rinsed in PBS, submerged in TBS (including 0.5% Triton X-100) for 30 min. After being washed with PBS, the cells were fixed in 4% paraformaldehyde for 10 min, blocked with 5%

BSA at room temperature for 1 h, and then incubated with dual primary antibodies at room temperature for 30 min and then 4°C overnight. The dual primary antibody sets comprised of PHB (1:1000)/c-Fos (1:200), PHB (1:1000)/c-Myc (1:200), PHB (1:1000)/p53 (1:200), PHB (1:1000)/pRb (1:200). After being washed with TTBS, the cells were incubated with different secondary antibody sets (goat anti rabbit or goat anti mouse) which were labeled with FITC and TRITC, respectively, at room temperature for 30 min and then 4°C overnight, washed with TPBS, enveloped with 90% glycerol/PBS after drying and then observed under LSCM (TCS- SP2 MP).

## RESULTS

### Detection of PHB in nuclear matrix by Western blot

Western blot results showed the dominant PHB band located at 32 kDa (PHB) and β-actin positioned at 42 kDa. The immunobead of PHB in the nuclear matrix of SMMC-7721 cells was obviously fuscous, while it was light and thin in HMBA-treated cells. The expression level of hnRNP A2/B1 was significantly decreased. The expression level of β-actin, which was referred to as endogenous control, had no obvious changes (Figure 1).

### Localization and expression of PHB in the NM-IF system of SMMC-7721 cells

Light microscopy observation revealed that the intermediate filaments in SMMC-7721 cells were sparse and arranged irregularly. In HMBA-treated MG-63 cells, the whole framework became more outspread, and the NM-IF system showed characteristics of uniform distribution. The intermediate filaments, which were uniformly stained, spread from the region around the nucleus to the cellular edge and formed a well-distributed and regular network throughout the cytoplasmic region. The nuclear matrix filaments were abundant and evenly distributed (Figure 2A and B).

The observation of immunofluorescence revealed the localization and expression of PHB. PHB was labeled with TRITC (red). The results showed PHB existed in the whole cell, but was weak in nuclei where it was scattered as little particles. It was relatively strong in regions near the nuclear membrane. The distribution of PHB was

uniform in the cytoplasmic region (Figure 2C). After treatment with HMBA, the distribution and expression of PHB in the NM-IF system was significantly altered. The holistic intensity of the fluorescence in nuclear matrix and nuclear lamina region dropped dramatically, while the fluorescence in the cytoplasmic region of HMBA-treated cells strengthened. It displayed a tendency of transferring from NM to lamina and cytoplasm of PHB (Figure 2D).

### Co-localization study of PHB with products of several predominant oncogenes and tumor suppressor genes

The localization of PHB and the opposite proteins including c-Fos, c-Myc, p53 and pRb were observed by LSCM. PHB was labeled with TRITC (red), other proteins were labeled with FITC (green). The co-localization fluorescence was yellow or orange when two different colors of fluorescence overlapped (Figure 3).

In SMMC-7721 cells, PHB mainly distributed in the nucleus, nuclear membrane, cytoplasm and the edge region of cells. In karyoplasm, the fluorescence was relatively weak and scattered unevenly. In SMMC-7721 cells treated with HMBA, PHB expression became decreased or even disappeared in the nuclear regions and was enhanced and scattered broadly in the cytoplasm.

### Co-localization of PHB with c-Fos in SMMC-7721 cells

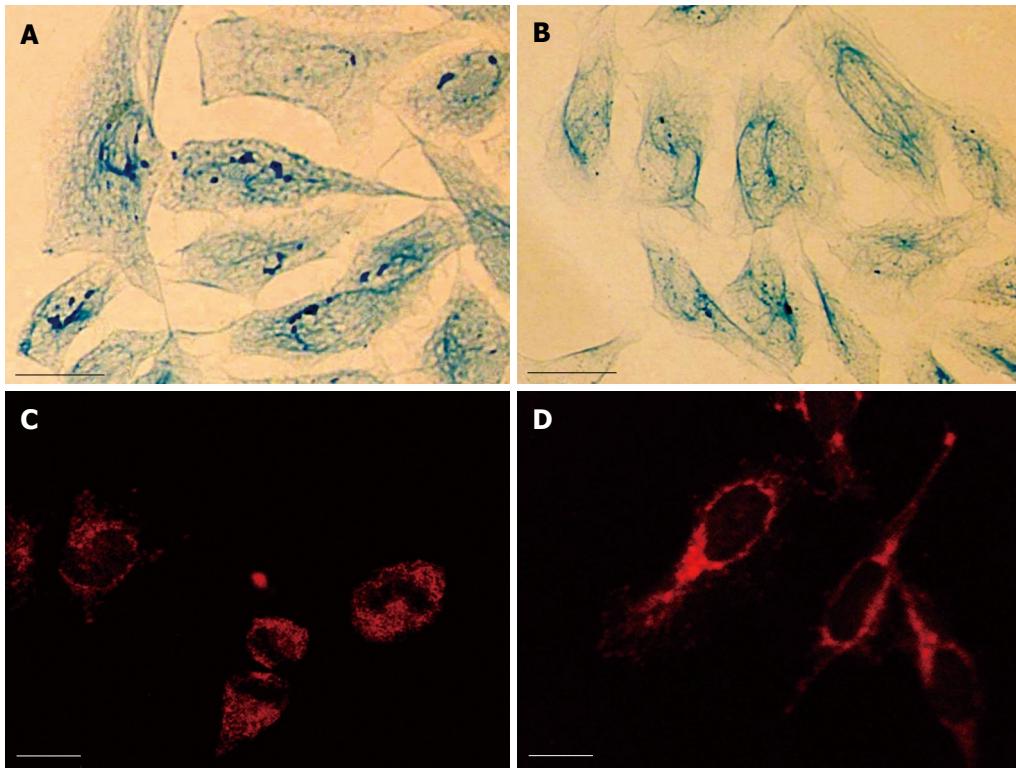

In SMMC-7721 cells, c-Fos was distributed mainly in the nucleolus region. The yellow overlapped fluorescence indicated co-localization between PHB and c-Fos existed mainly in the nucleolus region. In SMMC-7721 cells treated with HMBA, the holistic intensity of PHB and c-Fos fluorescence all weakened. The overlapped fluorescence indicated that the co-localization between PHB and c-Fos in the nucleolus weakened, but the co-localized fluorescence in karyotheca and cytoplasm was enhanced. It seemed that the co-localized region of both proteins transferred from the nucleolus region to karyotheca and cytoplasm (Figure 3A-F).

### Co-localization of PHB with c-Myc in SMMC-7721 cells

In SMMC-7721 cells, the highly-expressed c-Myc distributed mainly in the nucleolus and its peripheral regions. The overlapped fluorescence indicated they were co-localized in karyoplasms and karyotheca. In SMMC-7721 cells induced by HMBA, c-Myc dispersed in the whole cell, and its expression decreased. The overlapped fluorescence of PHB and c-Myc showed that the co-localization of two proteins strengthened in the karyotheca region, and clustered co-localization fluorescence could be seen in some special places. It indicated the tendency of transportation from karyoplasm to the nearby nuclear membrane (Figure 3G-L).

### Co-localization of PHB with p53 in SMMC-7721 cells

Due to the short half-life of wild-p53 in tumor cells (6 min), the p53 detected in this article was mostly its mutant counterpart namely mtp53. In SMMC-7721 cells, the highly-expressed mtp53 concentrated mainly

**Figure 2** **A:** LM observation of NM-IF system in SMMC-7721 cells, coomassie brilliant blue staining, bar = 10  $\mu\text{m}$ ; **B:** LM observation of NM-IF system in SMMC-7721 cells after HMBA treatment, Coomassie brilliant blue staining, bar = 10  $\mu\text{m}$ ; **C:** Immunofluorescence staining of PHB in the NMIF system of SMMC-7721 cells, bar = 10  $\mu\text{m}$ ; **D:** Immunofluorescence staining of PHB in the nuclear matrix-intermediate filament system of SMMC-7721 cells after HMBA treatment, bar = 10  $\mu\text{m}$ .

in the nucleolus and evenly distributed in other regions of the nucleus. The overlapped fluorescence indicated the co-localization distributed mainly in the region of karyoplasm and cytoplasm. In SMMC-7721 cells induced by HMBA, mtP53 decreased and its distribution was much more dispersive than that of untreated cells. The overlapped fluorescence showed the co-localization region of two proteins existed in the cytoplasm and lamina regions, and the co-localization fluorescence weakened remarkably after treatment (Figure 3M-R).

#### Co-localization of PHB with pRb in SMMC-7721 cells

In SMMC-7721 cells, Rb expression in the nucleolus was stronger than in other regions where it was relatively weak and distributed evenly. The overlapped fluorescence indicated they were co-localized in most regions of the nuclear membrane and cytoplasm. After treatment with HMBA, Rb increased remarkably and localized mainly at the nuclear membrane and nucleus regions after HMBA treatment. The overlapped fluorescence indicated the co-localization region of two proteins existed mainly in the nuclear membrane. It also showed their co-localization had a tendency of transferring from the cytoplasm to the nuclear membrane during the differentiation of SMMC-7721 cells (Figure 3S-X).

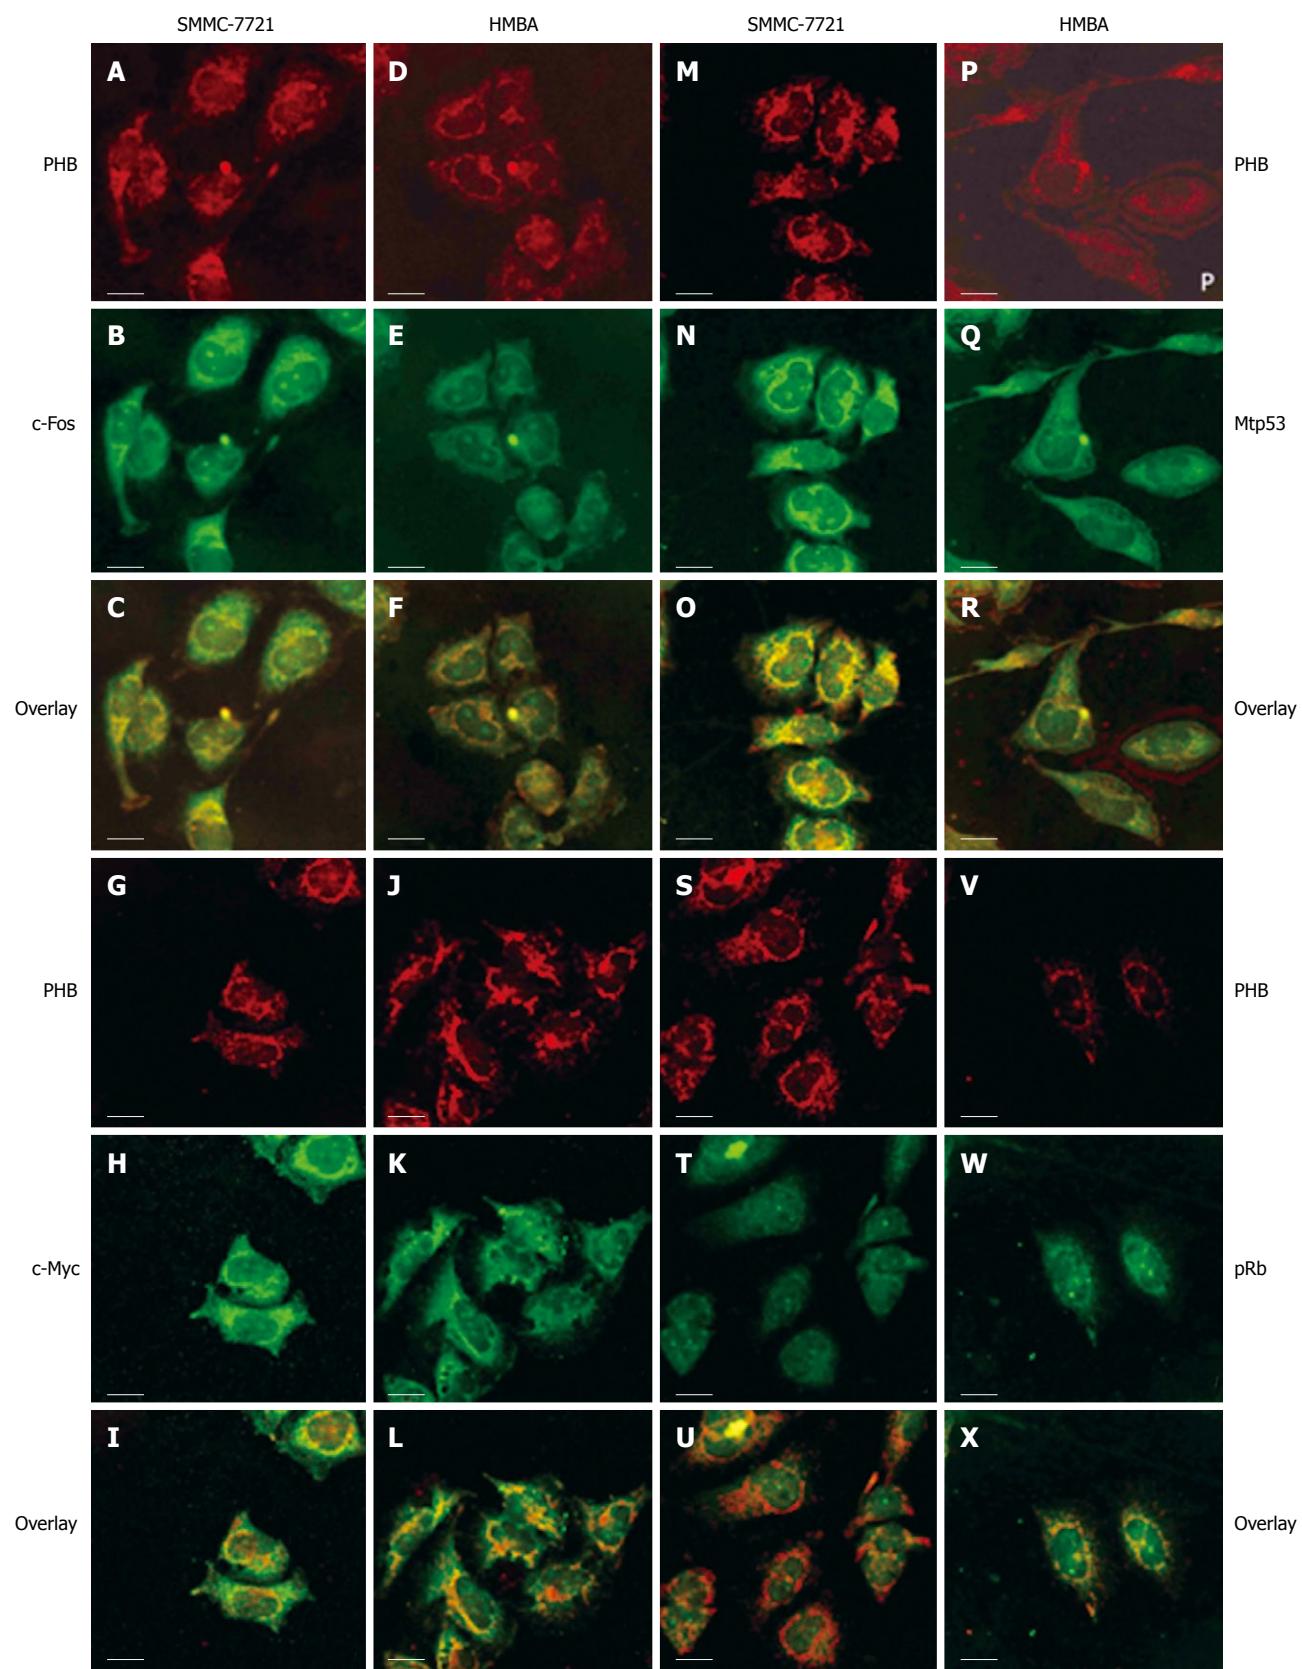

## DISCUSSION

### Changes of the expression and localization of PHB in the nuclear matrix

PHB is an important tumor suppressor protein. It not only mediates signaling of cell proliferation by acting as a membrane receptor, but is also involved in the maintenance of stability and function of

mitochondria. Previous studies have shown that PHB was mainly present in the mitochondria, and could be found in other subcellular organelles rarely<sup>[9,10]</sup>. So far, the localization of PHB in the nuclear matrix has not been reported. In this study, Western blot analysis confirmed that PHB was one of the components of the nuclear matrix and its expression in the nuclear matrix was down-regulated remarkably after treatment with HMBA. Immunofluorescence microscopy revealed that PHB was distributed mainly in the regions of the nuclear membrane and cytoplasm of SMMC-7721 cells. These results indicate that PHB exists not only in the cytoplasm, but also in the nuclear matrix of SMMC-7721 cells. Therefore, our laboratory, for the first time, has discovered the subcellular location of PHB in the nuclear matrix and showed it was a nuclear matrix protein.

PHB has great relevance to the development of cancer. Recent studies have shown that expression of PHB was abnormal in a variety of tumor cell lines<sup>[11-14]</sup>. In this study, using Western blot analysis, we found PHB is expressed highly in the nuclear matrix of SMMC-7721 cells, but in cells treated with HMBA, its expression was down-regulated. Immunofluorescent microscopy showed that the distribution of PHB in the nuclear matrix of SMMC-7721 cells was altered after HMBA treatment. PHB was mainly distributed in the karyoplasms and cytoplasm region, while in the HMBA-treated cells, PHB localized to the nuclear membrane and cytoplasm. PHB might have undergone translocation from nucleus to cytoplasm. Over expression of PHB has been reported in many kinds of tumor cells<sup>[15,16]</sup>. Our previous studies on the nuclear matrix proteins

**Figure 3** LSCM observation of the co-localization of PHB, bar = 10  $\mu$ m. **A-F:** With c-Fos in SMMC-7721 cells; **G-L:** With c-Myc in SMMC-7721 cells; **M-R:** With mtp53 in SMMC-7721 cells; **S-X:** With pRb in SMMC-7721 cells.

of human adenocarcinoma MGc80-3 and human osteosarcoma MG-63 cells showed that PHB existed as a component of the nuclear matrix, and expression

of PHB was down-regulated during differentiation. Therefore, our results further affirmed the alterations of PHB expression, and confirmed the involvement of

PHB in the regulation of tumor cell proliferation and differentiation.

### **Co-localization of PHB with products of related genes and its alteration during differentiation of SMMC-7721 cells**

The regulation of PHB in cell proliferation, senescence, apoptosis and differentiation involves complicated molecular mechanisms, including interaction between PHB and associated regulators in signaling and cell cycle, the subcellular localization of PHB in the cell, the phosphorylation level of PHB, and the connection between PHB and related oncogenes<sup>[17-19]</sup>. In this study, the results of laser scanning confocal microscopy revealed that there was a co-localizational relationship between PHB and the products of *c-fos*, *c-myc*, *p53* and *Rb* genes in SMMC-7721 cells, and the co-localization areas changed after HMBA treatment.

*c-fos* and *c-myc* are oncogenes whose expressions are up-regulated frequently in hepatocellular carcinomas (HCC). Our research indicated PHB colocalized with c-Fos, c-Myc in the nuclear region of SMMC-7721 cells. When SMMC-7721 cells were induced into differentiation, the co-localization relationship of PHB with c-Fos and c-Myc strengthened in the regions of lamina and karyotheca, but weakened in the karyoplasms. Other studies showed that PHB was a downstream target gene of *c-myc* and *c-myc* could bind to the promoter region of the *PHB* gene<sup>[20]</sup>. This indicated the close relation between PHB and c-Myc. The direct interaction of PHB and c-Fos has not yet been reported. Our research showed the co-localization between PHB and c-Myc, c-Fos in the region of the nucleus, and its alteration in SMMC-7721 cells after treatment with HMBA. It suggested that PHB might interact directly with the products of *c-myc* and *c-fos* genes. Our study discovered that PHB and p53 were co-localized at the nuclear membrane and karyoplasms region. The co-localization fluorescence transferred from nucleus to cytoplasm after HMBA treatment. This suggested that PHB might have direct connection with p53. Recently, some studies showed that PHB and p53 could cooperate with each other and participated in regulating downstream gene expression. Some studies found co-localization between PHB, p53 and E2F1 in the nucleus of breast cancer cells, and demonstrated PHB could activate transcription mediated by p53 and enhance binding of p53 with the promoter. It is also reported that p53-PHB complex translocated from nucleus to cytoplasm after stimulation by the signal of apoptosis<sup>[21-23]</sup>. Our results were consistent with former studies. It implies that PHB can directly interact with p53 and participate in the regulation of transcription mediated by p53. The co-transferring of p53 and PHB may be one of the mechanisms that mediate regulation of cell proliferation and differentiation. The studies about Rb and PHB showed that PHB could cooperate with products of Rb, a dominant tumor suppressor gene which regulates transcriptional activity of E2F. PHB could also form a triad with Rb and E2F in the nucleus, suppress activity

of E2F, and thereby inhibit cell proliferation<sup>[24,25]</sup>. The results of this study revealed that the co-localizational fluorescence in the region of the nuclear lamina was enhanced after HMBA treatment. It is obvious that the alteration is correlative with the state of proliferation and differentiation of SMMC-7721 cells. Nuclear lamina is the active site of DNA replication and transcription. Because of these, the alteration of PHB transferring and its enhanced combination with Rb in the lamina might repress the activity of E2F which promotes transcription of its downstream genes.

Taken together, these findings suggest that the subcellular localization and altered expression of PHB may have a potential role in the differentiation and phenotype reversion of SMMC-7721 cells by cooperating with products of oncogenes or tumor suppressor genes. Further investigation of the function of PHB in the nuclear matrix will help to clarify the mechanism of cell differentiation, cell cancer development and its reversion.

## **COMMENTS**

### **Background**

Previous studies showed that prohibitin (PHB) played important roles in the regulation of cell growth, proliferation, differentiation and tumorigenesis. However, the existence and expression of PHB in the nuclear matrix of tumor cells have not been well illustrated, and the functions of PHB in the induced differentiation of human hepatocarcinoma SMMC-7721 cells have also not been investigated in detail.

### **Research frontiers**

To identify differentially expressed nuclear matrix proteins and analyze their function in cancer cell differentiation is one of the most interesting hotspots in current studies of nuclear matrix.

### **Innovations and breakthroughs**

The authors revealed for the first time that PHB was a nuclear matrix protein in SMMC-7721 cells, and the distribution/expression of PHB and its relation with associated genes played a significant roles during the differentiation of SMMC-7721 cells.

### **Applications**

PHB can be used as a potential target in both diagnosis and treatment of tumors.

### **Terminology**

Nuclear matrix is the residual protein structure that remains after the nuclei are depleted of the nuclear membranes, histones, soluble nuclear proteins and nucleic acids. The structures that remain in matrix preparations are the nuclear lamina, the residual nucleolus and the fibrillar granular network.

### **Peer review**

The study is about the expression and distribution of proteins. Scientific content is interesting as several protein complexes are involved in cellular processes and identification of a role for PHB in carcinogenesis by association with other oncogenes is intriguing.

positive scintigraphy was independent of the age of the examined patient. A provocation test for bleeding with heparin resulted in an additional 46% of positive scintigraphies with a reliable localization in primary negative scintigraphies.

**CONCLUSION:** Our results show that scintigraphy and scintigraphy with heparin provocation tests are reliable procedures. They enable a reliable localization in about half of the obscure GI-bleeding cases. Scintigraphy is superior to angiography in locating a bleeding. It is shown that even in the age of video capsule endoscopy and double-balloon enteroscopy, scintigraphy provides a reliable and directed localization of GI bleeding and offers carefully targeted guidance for other procedures.

## Abstract

**AIM:** To determine the role of scintigraphy in patients with gastrointestinal (GI) bleeding of unknown localization.

**METHODS:** We performed retrospective analyses on 92 patients receiving scintigraphies from 1993 to 2000 in the University of Regensburg hospital, which were done for localization of GI bleeding as a diagnostic step after an unsuccessful endoscopy. In addition to the scintigraphies, further diagnostic steps such as endoscopy, angiography or operations were performed. In some of the scintigraphies with negative results, a provocation test for bleeding with heparinisation was carried out.

**RESULTS:** 73% of all scintigraphies showed a positive result. In 4.5% of the positive results, the source was located in the stomach, in 37% the source was the small bowel, in 25% the source was the right colon, in 4.5% the source was the left colon, and in 20% no clear localization was possible. Only 4% of all scintigraphies were false positive. A reliable

## INTRODUCTION

Gastrointestinal (GI) bleeding is a common GI disorder that requires an exact localization to guarantee adequate treatment. The clinical presentation ranges from asymptomatic or mild symptoms to a life threatening situation with mortality rates of up to 10%-14%<sup>[1-3]</sup>. Most deaths are associated with comorbidities and often occur in elderly patients<sup>[1,2]</sup>. Moreover the incidence of GI bleeding increases with age<sup>[3]</sup>.

GI bleeding is usually categorized by its localization as an upper GI bleeding (originating proximal to the Ligament of Treitz) or a lower GI bleeding (localized distal to the Ligament of Treitz), or must be classified as

obscure bleeding if not defined<sup>[4]</sup>. Dependent on local and on other factors, such as hemodynamic instability or age, different diagnostic steps, including endoscopic, radiological, or nuclear medical methods, must be performed. An example for such a diagnostic algorithm was published by Lee and Laberge 2004<sup>[5]</sup>.

Radionuclide imaging is one diagnostic possibility for the detection of GI bleeding. Its sensitivity as well as its specificity for bleeding localization seems to be high, with results of 93% to 95% at a rate of 0.04 mL/min for red blood cell (RBC) scans<sup>[6]</sup>. Its accuracy rises up from 41% to 97% when the results are verified by endoscopy, angiography or surgery<sup>[7]</sup>. This method offers advantages in being non-invasive, not requiring special preparations for the patient, and detecting both arterial and venous bleeding sites, whereas angiography only detects arterial bleedings. Moreover it offers the capability of imaging over a prolonged period of time. But, as a disadvantage, localization of bleeding sites is often not precise.

In our study we retrospectively evaluated the results of 92 patients requiring scintigraphy with <sup>99m</sup>Tc-labelled red blood cells with special focus on elderly patients, patients with scintigraphy after a provocation test with heparin, and comparison of the results with angiography.

## MATERIALS AND METHODS

### Patient recruitment and review of data

This is a retrospective study performed at a university hospital. By searching the internal medicine databases, 92 patients were identified with the diagnosis GI bleeding of unknown localization who underwent scintigraphy with <sup>99m</sup>Tc-marked red blood cells as a diagnostic procedure. If a patient required a second hospital stay, it was considered as a new case. Demographic (age, sex) and clinical data (length of hospital stay, underlying diseases if related to bleeding) as well as diagnostic and therapeutic approaches performed were collected by reviewing patient flow charts. Thereby we assessed the time of scintigraphy in relation to the time of first bleeding symptoms. Duration of not more than 7 d was classified as acute bleeding; a bleeding persisting for more than 7 d was classified as chronic bleeding. For laboratory values, we assessed the red blood cell count, and if patients required blood products we evaluated the number of red blood cell units and classified the patients as having received one unit, two units, three or more units.

For negative scintigraphies, a provocation test for bleeding with heparinisation was carried out. Comparative diagnostic or therapeutic procedures following scintigraphy, such as gastroscopy, colonoscopy, angiography, laparoscopy, and computed tomography (CT) scan, were assessed.

### Nuclear medicine procedures

For scintigraphy with <sup>99m</sup>Tc labeled red blood cells, a kit from Nycomed Amersham Sorin Italia, containing

24 mg DTPA, 3.6 mg SnCl<sub>2</sub> H<sub>2</sub>O, 22 mg Sodium-acetate and 9 mg Sodium-chloride, was used. The intravenous <sup>22m</sup>Tc pertechnetate activity was 1000 MBq. Imaging procedures were performed dynamically during the first hour (one picture every second during the influx period, then one picture per minute until 1 h) with a static image after exactly 1 h. If further images were needed they were performed up to 29 h after the initial application. For imaging procedures, a Siemens Company camera was used as well as an Icon Processing Work Station for reconstructions.

### Statistical analysis

Statistical analyses were performed with SPSS 12.0 statistical software (SPSS inc., Chicago, IL) and Microsoft Excel. Values are shown as total numbers, average or median with range, or as percentages where necessary. Kind support for statistical analyses was given by Metronomia Clinical Research GmbH (Munich, Germany).

## RESULTS

### Patient population

From our database, we identified 92 patients with GI bleeding who received scintigraphy as a diagnostic procedure and for whom complete data could be collected. Table 1 shows demographic characteristics, underlying diseases, fractions of acute and chronic bleeding, use of red blood cell units and the need of heparin induced provocation as a further diagnostic step for all 92 patients.

### Characteristics of scintigraphy

The details of performed scintigraphy in relation to a positive or negative result are shown in Table 2. In 25 patients (27%), there was no evidence of GI bleeding and no further examination or treatment was necessary in 19 patients. In 67 patients (73%), a positive result was found. Verification of the location was performed with further diagnostic procedures, such as gastroscopy, colonoscopy, angiography, computed tomography, and laparoscopy. 23 results were definitely correct and 7 were definitely false. A positive scintigraphy result was not confirmed by further diagnostic procedures in 37 patients (Figure 1).

Concerning reliable positive scintigraphies, no significant difference between age-groups was found (Figure 2).

### Scintigraphy after provocation with heparin

A provocation test with heparin was performed in 13 patients. Five of these patients had previously received a scintigraphy without heparinisation, which was negative in 2 patients, slightly positive in 2 patients, and positive without localization in one patient. The other 8 patients received a heparin-provoked scintigraphy initially in our hospital because they had a negative scintigraphy outside the university hospital. Six (46%) patients had a positive result with localization of the bleeding, 3 (23%)

patients showed a positive result without localization, and 4 (31%) patients showed a negative result.

### Comparison in patients receiving angiography

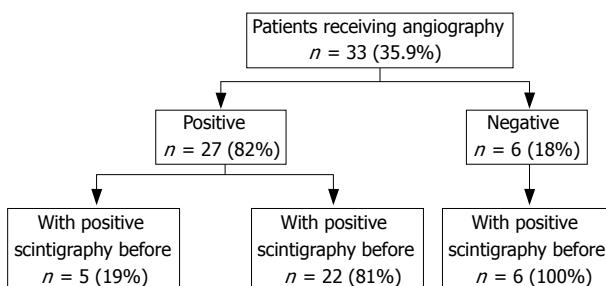

An angiogram was performed in 33 of our 92 patients. 6 patients were negative in both tests. Retrospectively, 1 of these 6 patients showed a false negative result in both of the examinations. Twenty two patients had a negative angiogram, however, 9 of these patients showed a positive scintigraphy result (correct localization in 8 patients and unclear localization in 1 patient). Thirteen patients showed a false positive scintigraphy result. Five

**Figure 1** Scintigraphy results.**Figure 2** Reliable positive scintigraphies by age.

patients showed a positive angiogram with positive scintigrams. The localization was correct in 2 patients, unclear in 2 patients and in 1 patient correct in the angiogram but false positive in the scintigram (Figure 3).

### Relevance of performed scintigraphy

Our results showed a sensitivity of 79% (23/29) for the presence of bleeding with scintigraphy, and a specificity of 30% (19/63). The negative predictive value was 76% (19/25), the positive predictive value 77%, including the patients with a positive scintigraphy result without confirmation 34% (23/67).

**Figure 3** Angiography.

### Outcome

Nine of 92 patients died. Death occurred due to underlying diseases, which was hemato-oncologic malignancy in 6 patients, sepsis by vasculitis and gangrenous leg in one patient, sepsis and cirrhosis of the liver in one patient, and terminal heart insufficiency due to ischemic cardiomyopathy in one patient.

No death was correlated to the performed scintigraphy, and there were no procedure-associated complications documented. In the subpopulation of patients receiving heparinisation, no patient died. Scintigraphy itself, even with heparin-induced provocation, seems to be a safe procedure.

## DISCUSSION

Scintigraphy with  $^{99m}\text{Tc}$  labelled red blood cells is a possible tool in the diagnosis of GI bleeding<sup>[8-13]</sup>. The reported success rates for identifying correct locations of bleeding range from 19% to 96% according to the literature<sup>[14-19]</sup>.

Different reasons may explain the wide range of sensitivities, specificities or accuracies of localizations. In some studies, results were not confirmed by further diagnostic procedures or were confirmed by diagnostic tests, such as barium contrast studies or simple clinical observation, which are not very effective procedures regarding localization of GI bleeding. Therefore, confirmation of scintigraphy results differs in the reported studies making comparisons of results difficult.

In previous studies, focus was on positive results rather than negative results, however, mortality and morbidity due to diagnostic and therapeutic procedures can be controlled by a cautious and well planned surgical approach. It has been shown in this context that a negative result is predictive of a good outcome, and may help in diagnostic risk stratification by avoiding unnecessary emergency care<sup>[20]</sup>. This fact may also be reflected in our population with 3 out of 25 patients dying in the subpopulation of patients with negative scintigraphy results but with no death correlated with the GI bleeding.

For imaging procedures, we used scintigraphy with  $^{99m}\text{Tc}$ -labelled red blood cells. Imaging protocols have recently been well described<sup>[21-23]</sup>. Active bleeding rates greater than 0.3 mL/min can be detected<sup>[24]</sup> and also some evidence exists that bleeding rates lower than 0.1 mL/min can be detected<sup>[25]</sup>. In contrast to the erythrocyte labelled method, there is also the possibility

of using  $^{99m}\text{Tc}$ -labelled sulfur colloid scintigraphy. This method, first described in 1977<sup>[26]</sup>, is also a successful tool for identification of bleeding sites, but may be problematic in the detection of bleeding in the stomach, proximal duodenum, or colonic flexures, due to intense radiotracer activity within the liver and the spleen. It has been shown that there is no practical advantage in the use of  $^{99m}\text{Tc}$ -Technetium labelled red blood cell scintigraphy over  $^{99m}\text{Tc}$ -labeled sulfur colloid scintigraphy<sup>[27]</sup>.

Our study has some limitations. One limitation is the study was retrospective within a single centre. Moreover, the patient cohort was mixed in terms of existing underlying diseases.

Our study shows that scintigraphies, as well as scintigraphies with heparin provocation tests, are safe procedures. They enable a reliable localization in about half of the GI bleeding cases. Scintigraphy is, in our setting, superior to angiography and there is evidence that it seems to be a helpful procedure especially for older patients who are restricted concerning invasive procedures. To our knowledge, no literature exists specifically for older patients receiving blood pool scintigraphy.

Even in the era of video capsule endoscopy and double-balloon enteroscopy, we showed that scintigraphy is a safe and helpful diagnostic tool, which allows for safe detection of GI bleeding sites and therefore carefully targeted use of further procedures.

## COMMENTS

### Background

In 30%-35% of all gastrointestinal (GI) bleedings no clear localization of the bleeding site through endoscopy is possible. For further diagnostic steps scintigraphy is a safe method to detect the possible localizations of a so far unknown bleeding.

### Research frontiers

Blood pool scintigraphy is an established method in the diagnostic of the obscure GI bleeding. Our data show that it is a safe procedure being non-invasive with low-examination-related risks. Further prospective evaluation and correlation with further diagnostic tests as i.e. capsule endoscopy and double-balloon enteroscopy scintigraphy is needed.

### Innovations and breakthroughs

It is shown that even in the time of video capsule endoscopy and double-balloon enteroscopy blood pool scintigraphy enables a reliable and directed localization of a GI bleeding and a carefully targeted use of further diagnostic procedures.

### Applications

These findings may help to optimize the diagnostic approach in patients with an obscure GI bleeding.

### Peer review

The study was a retrospective analysis of 92 patients for patients with unknown intestinal bleeds further leading to unsuccessful endoscopy. The significance of scintigraphy is under evaluation and this paper helps to bring focus on this issue particularly as there is presently a limited ability to detect GI bleeding.

### Abstract

**AIM:** To determine whether *Lactobacillus casei* strain Shirota (Yakult<sup>®</sup>) can alter small intestinal bacterial overgrowth (SIBO), as tested by the lactulose breath test, and whether this is associated with changes in symptoms in irritable bowel syndrome (IBS).

**METHODS:** 18 patients with IBS (Rome II criteria), who showed an early rise in breath hydrogen with lactulose (ERBHAL), consumed 65 mL of Yakult<sup>®</sup> daily for 6 wk. Lactulose breath test was repeated at the end of the treatment period. Symptoms were recorded daily using a 10 cm visual analogue scale.

**RESULTS:** 14 patients completed the study, 9 (64%) had reversal of ERBHAL, with the median time of first rise in breath hydrogen increasing from 45 to 75 min ( $P = 0.03$ ). There was no significant improvement in the symptom score with probiotic therapy, except for wind ( $P = 0.04$ ). Patients commencing with at least moderate symptoms and who no longer had ERBHAL at the end of treatment, showed improvement in the overall symptoms scores [median final score 5.3 (IQR 3.9-5.9), 55% reduction;  $n = 6$ ] to a greater extent than those who had had persisting ERBHAL [final score 6.9 (5.0-7.0), 12% reduction;  $n = 5$ ;  $P = 0.18$ ].

**CONCLUSION:** Yakult<sup>®</sup> is effective in altering fermentation patterns in the small bowel, consistent with reducing SIBO. The loss of ERBHAL was associated with reduced symptoms. The true interpretation of these findings awaits a randomised, controlled trial.

### INTRODUCTION

Irritable bowel syndrome (IBS) is the most common gastrointestinal disorder, thought to affect approximately 15% of the population<sup>[1]</sup>. Differences in gut microflora are evident between IBS sufferers and controls, with the former demonstrating significantly lower concentrations of bifidobacteria and lactobacilli, and higher concentrations of *Streptococcus*, *E. coli* and *Clostridia*<sup>[2,3]</sup>. Small intestinal bacterial overgrowth (SIBO) occurs in up to 78% patients with IBS, and may be directly related to the genesis of IBS symptoms<sup>[4,5]</sup>. The mechanism by which symptoms are generated from SIBO is most probably through fermentation, with rapid production of hydrogen, methane and carbon dioxide. This results in distention of the small intestine, leading to discomfort, sensation of bloating and secondary disturbances in motility.

SIBO is difficult to assess, but can be detected indirectly through the use of lactulose breath hydrogen or <sup>14</sup>C-xylose breath tests. In the case of the lactulose hydrogen breath test, a rise in breath hydrogen is expected approximately 90 min after the solution is consumed. An early rise in breath hydrogen after lactulose (ERBHAL) leads to one of two conclusions: either bacterial fermentation is occurring in the small intestine due to bacterial overgrowth, or there is rapid small intestinal transit<sup>[6]</sup>.

The role of SIBO in the genesis of IBS symptoms has been reviewed recently<sup>[7]</sup>. Several clinical trials have played

a key role in examining this association, in which antibiotic use has not only normalized lactulose breath hydrogen tests but has also led to an improvement in the symptoms of IBS<sup>[5,8-10]</sup>. It has also been suggested that malabsorption of fructose and lactose may result from SIBO, which, when corrected with antibiotics (as demonstrated by normalisation of the lactulose breath test), is associated with improved absorption of these sugars<sup>[5,8]</sup>.

Apart from antibiotics, other potential therapies have been suggested for the treatment of SIBO. Dietary restriction of fermentable carbohydrates is promising, as shown by the use of elemental diets<sup>[11]</sup>. However, an elemental diet is not a practical solution. Secondly, prokinetic agents, such as tegaserod, may play a role in promoting clearance of the lumen<sup>[12]</sup>. Finally, probiotics may influence bacterial populations in the small intestinal biofilm, manifesting as reduction in the total count or as a change in the activity, such that symptoms are not induced. It has been well documented that probiotics modify fermentation in the large intestine by increasing the absolute count of probiotic-type bacteria and reducing the *Streptococcus* counts<sup>[13]</sup>. It has also been shown that some probiotic strains improve symptoms of bloating, wind and pain in IBS patients<sup>[14,15]</sup>. However, the impact of probiotics specifically on SIBO in IBS patients has not been formally investigated.

The primary aim of the present study was to address the hypothesis that probiotics reverse SIBO, as defined by the breath hydrogen criteria. The secondary aim was to determine whether changes in the symptoms were associated with changes in breath test patterns. To examine this, an open label, pilot study was performed to assess the effect of *L. casei* strain Shirota (Yakult®) on ERBHAL in patients with IBS and ERBHAL.

## MATERIALS AND METHODS

### **Patients**

Patients referred for breath testing, who were found to have ERBHAL and fulfilled Rome II criteria for IBS, were invited to participate in the study. Patients were excluded if they were currently taking IBS medication, had previous specific dietary therapy, had taken probiotics for greater than 2 wk within the previous six months, or antibiotics in the previous 2 mo, were ingesting aspirin, non-steroidal anti-inflammatory drugs or alcohol in excess of 20 g/d, or had any clinically significant co-morbidity. Eighteen patients were recruited. The mean age (range) was 44 (20-70) years; five subjects were male. All patients fulfilled Rome II criteria for IBS, with 8 (44%) being constipation-predominant, 4 (22%) diarrhoea-predominant, and 6 (33%) having alternating bowel habits.

### **Experimental protocol**

Patients undertook a 1 to 2 wk run in period during which they completed a daily symptom diary. Daily recordings were made regarding symptom severity and, at the end of each week, the patients rated their symptoms overall, including the following specific

symptoms-abdominal pain/discomfort, bloating, satisfaction with stool consistency, passage of wind, tiredness, and nausea-using a 10 cm visual analogue scale (VAS). The symptoms were classified as "mild" if VAS was < 3 cm, "moderate" 3 to < 7 cm and "severe" ≥ 7 cm. The patients were then started on probiotic therapy, comprising of 65 mL (one bottle, 6.5 billion bacteria, 1 g lactose per dose) of *L. casei* strain Shirota in a solution containing sucrose, skim milk powder and dextrose (Yakult®, Yakult Ltd, Melbourne Australia), which was taken each morning prior to breakfast, for 6 wk. The same symptom diary and weekly questionnaire was completed throughout the treatment period. The patients were reviewed after 3 and 6 wk of treatment. During the last week of the study, the lactulose breath test was repeated.

Patients whose symptoms worsened significantly, terminated the study early and, if possible, the lactulose breath hydrogen test was performed prior to the cessation of the probiotic therapy. The symptom scores were considered valid if the patient had completed at least 3 wk of treatment.

### **Breath hydrogen test**

Prior to the breath hydrogen test, dietary restriction (minimising intake of fibre and poorly absorbed short-chain carbohydrates) was advised for 24 h and the subjects fasted overnight. The patients consumed 15 g lactulose, made up to a 100 mL solution with water. Breath hydrogen samples were collected at baseline and every 15 min for at least 2 h.

ERBHAL was defined as a rise of breath hydrogen of 10 ppm or greater above the baseline breath hydrogen on two consecutive 15-min samples before 90 min, following the ingestion of lactulose. The time of the first rise in breath hydrogen of 10 ppm or more was recorded.

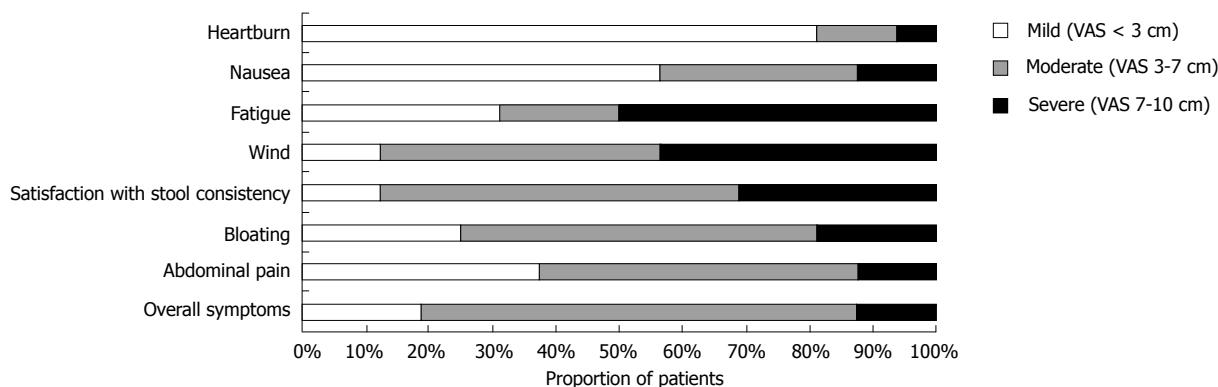

### **Statistical analysis**

Data were expressed as mean and standard error of the mean (SEM), or median and interquartile range (IQR) according to the distribution of the findings. Changes in the end-points were compared using a Wilcoxon matched pairs test. Univariate regression analyses were performed and Pearson's correlation coefficients were calculated. All statistical tests were performed using Microsoft Office® Excel 2003 and GraphPad Prism (version 3.00 for Windows, GraphPad Software, San Diego California USA).  $P \leq 0.05$  was considered statistically significant.

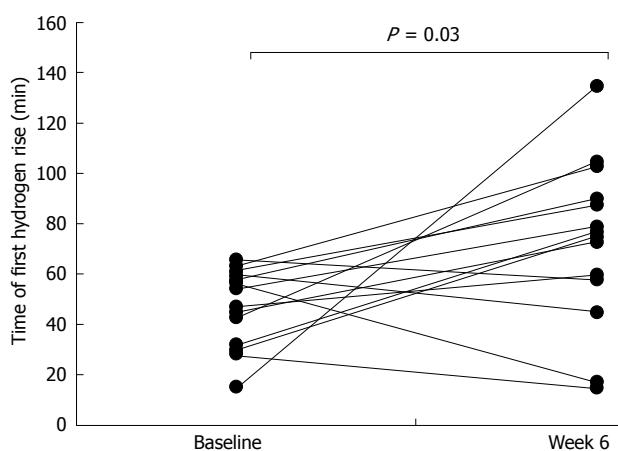

## RESULTS

### **Patient baseline symptom characteristics**

On the self-rated scales, the overall symptom severity varied across the patients, with three patients experiencing very mild symptoms, 11 moderate symptoms and two severe symptoms. However, all patients, rated at least one specific abdominal symptom as ≥ 3 cm, with the passage of wind and dissatisfaction with stool consistency being

**Figure 1** Individual and overall symptom scores at baseline, based on the visual analogue scale (VAS).

**Figure 2** The time of the first rise at or above 10 ppm in breath hydrogen after lactulose during the baseline period, and during treatment with *L. casei* strain Shirota. The time during the treatment period was significantly later compared to at baseline ( $P = 0.03$ , Wilcoxon matched pairs test).

the most frequently reported symptoms. The proportion of patients with mild, moderate or severe baseline symptoms is shown in Figure 1.

#### Adherence to protocol and treatment

Two patients terminated the study after taking Yakult® for < 2 wk due to intolerable symptoms (increasing nausea). They were excluded from the analysis as per protocol. An additional patient terminated after 3 wk, also because of increasing nausea but did not agree for a repeat hydrogen breath test. One patient commenced antibiotics for an unrelated illness after taking Yakult® for 3 wk and was withdrawn from the study due to the confounding influence of antibiotic therapy. Thus, breath test assessment was performed as per protocol in 14 patients and the effect of probiotics on symptoms was evaluable in 16 patients.

Adherence to the study treatment was > 95% in all the participants, as judged by the returned open and unused probiotic bottles.

#### Effect of Yakult® on end-points

Prior to treatment, the median time after ingestion of lactulose when breath hydrogen deviated by  $\geq 10$  ppm from the baseline was 45 min (IQR 30-60) (Figure 2).

During probiotic therapy, the median time for the first breath hydrogen rise increased to 75 min (IQR 60-90) ( $P = 0.03$ ) with 9 patients (64%) no longer demonstrating an ERBHAL, according to the entry criterion (Figure 2).

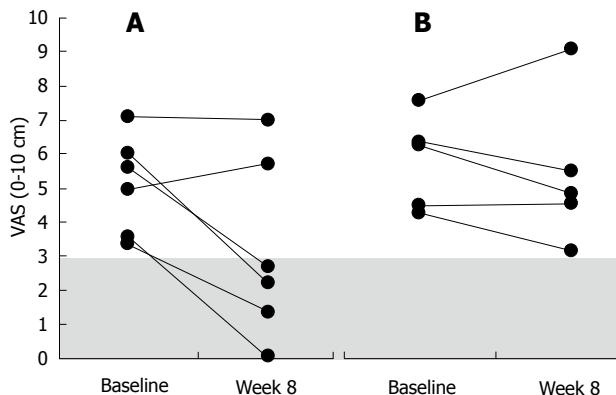

There was no significant difference in the VAS score for the overall abdominal symptoms from baseline ( $4.8 \pm 0.56$  cm) to the final week of treatment ( $4.2 \pm 0.68$  cm) ( $P = 0.33$ ). The effect of probiotic treatment was examined for each individual symptom. Only the VAS score for the passage of wind improved significantly with Yakult® ( $6.1 \pm 0.5$  cm to  $4.4 \pm 0.56$  cm;  $P = 0.04$ ), while none of the symptoms worsened significantly. There was no association of change in the symptoms with the subtype of IBS (data not shown).

#### Relationship between final ERBHAL status and change in symptoms

Patients were divided into two groups: those who no longer had ERBHAL at the end of 6 wk's therapy ("no-ERBHAL" group;  $n = 9$ ), and those with continuing ERBHAL ("ERBHAL" group;  $n = 5$ ). The change in VAS for the overall symptoms in the two groups is shown in Figure 3. Seven of the 9 patients in the no-ERBHAL group had moderate overall symptoms prior to treatment; 5 improved by at least 2 cm on the VAS, compared with none of 5 patients in the ERBHAL group ( $P = 0.06$ ; Fisher's exact test). The change in the overall symptom score in patients with at least moderate symptoms prior to treatment was greater in those who no longer had ERBHAL [median final score 5.3 (IQR 3.9-5.9), 55% reduction;  $n = 6$ ] compared to patients with continuing ERBHAL [final score 6.9 (5.0-7.0), 12% reduction;  $n = 5$ ;  $P = 0.18$ ; Mann Whitney *t*-test].

## DISCUSSION

This is the first study on the effect of a probiotic agent in patients with IBS and ERBHAL. The findings show that Yakult®-induced change in the fermentation pattern resulted in 64% patients no longer fulfilling the definition of ERBHAL at the end of the treatment period. While such a change may represent regression towards the mean due to the repetition of the breath test<sup>[16]</sup>, it more likely reflects a physiological change. This could conceivably be due to slower oro-caecal transit,

**Figure 3** The overall abdominal symptom score at baseline in patients with more than minimal symptoms (VAS < 3 cm), compared with scores at week 6 of treatment, with and without ERBHAL at the conclusion of the treatment. **A:** Without ERBHAL; **B:** With continuing ERBHAL. Shading indicates the minimal symptom score category. These changes were statistically not significant.

however, there are no reports of *L. casei* altering gastric emptying or small intestinal transit time. Alternatively, the effect may represent a more distal intestinal shift in the initial fermentation of lactulose. Formal radionuclide transit tests could address this issue in future studies, but the findings that ERBHAL represents SIBO in the majority of patients has been observed previously, along with the findings of reduction in functional gut symptoms, with the use of antibiotics and elemental diet<sup>[5,8,9,11]</sup>.

The criteria used for the diagnosis of SIBO by the lactulose breath test have varied with different investigators. Much of the earlier work used bacterial cultures of the proximal small bowel as the gold standard<sup>[6,17]</sup>. However, such methodology is not helpful in detecting an increase in bacterial biofilm, if it occurs in the distal small bowel. The presence of findings such as a double peak in hydrogen production after lactulose, or high basal breath hydrogen are not well validated in patients with IBS, and are no longer considered appropriate diagnostic features. Glucose breath hydrogen test is useful for the detection of proximal bacterial overgrowth, but since glucose is readily absorbed in the proximal small intestine, SIBO occurring more distally is not detected<sup>[18]</sup>. The most consistent and accepted measure is the time of the first significant rise (usually  $\geq 10$  ppm) in breath hydrogen after lactulose, which therefore was applied in the present study.

No consistent effect of treatment with Yakult® was observed on abdominal symptoms or fatigue; some patients worsened whereas others improved. Three patients terminated the study early because of increasing nausea. All three complained of nausea at baseline and only one had previously been tested for lactose intolerance (that person was not lactose intolerant). However, regardless of whether these patients were lactose intolerant, it is unlikely that the small amount of lactose in 1 bottle of Yakult® (1 g) was the cause of these symptoms, given that up to 7 g of lactose in one sitting is well tolerated even in true lactose intolerant patients<sup>[19]</sup>.

The loss of ERBHAL resulted in improvement in

the overall abdominal symptom VAS score by at least 2 cm in 71% of the patients with moderate to severe baseline symptoms compared to 0% who maintained the early rise. However, one patient who lost ERBHAL developed more severe symptoms compared to the baseline findings. It cannot be expected that all patients will improve with the correction of ERBHAL, since only 35% improved symptomatically when ERBHAL was corrected with the use of antibiotics<sup>[9]</sup>. Previous studies on IBS have identified a particular ability of probiotics to improve bloating and wind<sup>[20-22]</sup>. While bloating did not improve with Yakult®, a significant improvement was seen in the passage of wind. A pathogenic link between the passage of wind, bacterial overgrowth and fermentation can be postulated. The present study was not designed to specifically address the effect on symptoms. However, our findings raise the possibility that symptomatic benefit can be obtained when ERBHAL is corrected with the use of Yakult®.

In conclusion, the hypothesis that treatment with Yakult® alters the fermentation pattern, exhibited by hydrogen breath testing after lactulose was supported in this uncontrolled, proof-of-concept study. A small dose of *L. casei* strain Shirota led to a statistically significant shift in the time of early rise of breath hydrogen after lactulose, suggesting a reduction in SIBO. Furthermore, the overall abdominal symptoms tended to improve when ERBHAL was corrected. Our findings suggest that probiotics may have a beneficial effect, but further work is required to determine the dose effects and clinical relevance with well powered, double blind, placebo-controlled trials including the measurement of transit time to support the interpretation of ERBHAL.

## COMMENTS

### Background

Small intestinal bacterial overgrowth (SIBO) is a common feature of irritable bowel syndrome (IBS) and may be directly related to the genesis of IBS symptoms. An early rise in breath hydrogen after lactulose (ERBHAL) may indicate SIBO. The use of antibiotics and elemental diets has been shown to be effective in treating SIBO, but the efficacy of probiotics is untested.

### Research frontiers

This was a pilot study designed to determine the effect of *Lactobacillus casei* strain Shirota (Yakult®) on the intestinal fermentation pattern in IBS, using the lactulose breath test. The results indicate that Yakult alters the fermentation pattern suggesting a reduction in SIBO. ERBHAL may also indicate rapid transit and therefore, in order to confirm the effect of Yakult on SIBO, future studies should include monitoring of transit time in addition to a placebo control group.

### Innovations and breakthroughs

The most promising treatments to date for SIBO are antibiotics and elemental diets, the side effects and practicalities of which make them undesirable

options. This is the first study evaluating the effect of a probiotic on SIBO. The shift of the time of the first rise of hydrogen following lactulose indicating SIBO was no longer present at the end of 6 wk of treatment. These results offer a promising alternative treatment for SIBO in IBS. A placebo controlled trial is required to confirm these findings.

### Applications

The results indicate that Yakult® may be an effective treatment for SIBO in IBS. Our findings have important implications in the treatment of IBS if these results are supported by a placebo controlled trial.

### Peer review

The shift in fermentation patterns and the trend towards improvement of symptoms indicates the need for further work to examine the dose effects and clinical relevance with well powered, double blind, placebo controlled trials including the measurement of transit time to support the interpretation of ERBHAL. This is a well written paper with a nice literature review.

tumors in Balb/C nude mice. Co-transplantation of hepatocytes with tumor cells did not increase tumorigenesis of the tumor cells.

**CONCLUSION:** Immunomagnetic depletion appears to be an effective method of purging contaminating tumor cells to below threshold for likely tumorigenesis. Along with improved techniques for isolation of large numbers of viable hepatocytes, normal liver resected for neoplasia has potential as another clinically useful source of hepatocytes for transplantation.

Hepatocytes isolated from neoplastic liver-immunomagnetic purging as a new source for transplantation. *World J Gastroenterol* 2008; 14(32): 5025-5031 Available from: URL: <http://www.wjgnet.com/1007-9327/14/5025.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.5025>

## Abstract

**AIM:** To investigate whether hepatocytes isolated from macroscopically normal liver during hepatic resection for neoplasia could provide a novel source of healthy hepatocytes, including the development of reliable protocols for malignant cells removal from the hepatocyte preparation.

**METHODS:** Hepatocytes were procured from resected liver of 18 patients with liver tumors using optimised digestion and cell-enrichment protocols. Suspensions of various known quantities of the HT-29 tumor cell line and patient hepatocytes were treated or not with Ep-CAM-antibody-coated immunomagnetic beads in order to investigate the efficacy of tumor-purging by immunomagnetic depletion, using a semi-quantitative RT-PCR method developed to detect tumor cells. Immunomagnetic bead-treated or bead-untreated tumor cell-hepatocyte suspensions were transplanted intra-peritoneally in Balb/C nude mice to assess the rates of tumor development.

**RESULTS:** Mean viable hepatocyte yield was  $9.3 \times 10^6$  cells per gram of digested liver with mean viability of 70.5%. Immunomagnetic depletion removed tumor cells to below the RT-PCR detection-threshold of 1 tumor cell in  $10^6$  hepatocytes, representing a maximum tumor purging efficacy of greater than 400 000-fold. Transplanted, immunomagnetic bead-purged tumor cell-hepatocyte suspensions did not form peritoneal

## INTRODUCTION

While advances in supportive medical care have improved survival, liver failure in its most severe form continues to carry a high mortality rate unless orthotopic liver transplantation (OLT) is performed. Nonetheless, there is a limit to the number of patients that can be treated in this way. The rapidity with which the clinical syndrome often progresses and a worldwide shortage of donor organs are significant limiting factors and many patients listed for OLT die or develop contraindications to transplantation before a donor liver becomes available. Further, the presence of co-morbidities in a substantial number of patients often precludes listing for OLT altogether. Consequently, there is considerable ongoing interest in the provision of other means of liver support, including extracorporeal artificial or bioartificial devices and hepatocyte transplantation (HT).

The feasibility of HT as a therapeutic tool has been demonstrated in studies performed in animals with liver-

based metabolic defects such as analbuminaemic and Gunn rats, hypercholesterolaemic rabbits and dogs with impaired purine metabolism<sup>[1-3]</sup>. Experience with HT in experimental animals with liver failure due to chemically-induced hepatic necrosis, surgical models of hepatic ischaemia or resection has also been favourable, with evidence of improved survival even when small numbers of cells (0.5% to 3% of normal hepatocyte mass) are used<sup>[4-7]</sup>.

Transplantation of human hepatocytes has, to date, been performed in only a small number of paediatric and adult patients with liver failure<sup>[8-11]</sup>. Instances of mostly short-term improvement in encephalopathy and some metabolic parameters have been recorded both in OLT and non-OLT candidates. Potential advantages of HT over OLT include its minimal invasiveness, ease of treatment, substantially lower cost and the possibility of on-demand use following the establishment of a cell bank. Limited availability of primary human hepatocytes for transplantation however, represents a major limitation. Currently, the standard approach is to isolate hepatocytes from livers rejected for liver transplantation due to excessive steatosis, cirrhosis and prolonged ischemia. However, availability of hepatocytes from this source is in increasingly short supply and concerns with the functional capability of such cells have been raised<sup>[12]</sup>.

Our group recently reported the feasibility of harvesting tumor-free hepatocytes from macroscopically normal liver unavoidably removed during hepatic resection for malignancy<sup>[13]</sup>. Here we report further improvements in our hepatocyte isolation and tumor-purging techniques, resulting in the harvest of sufficiently large numbers of viable hepatocytes from resected liver specimens to offer the prospect of effective clinical support and a high degree of tumor-purging efficacy. Furthermore, we demonstrate the safety of transplantation of hepatocytes harvested in this way, in terms of lack of complicating tumor development in an athymic mouse model.

## MATERIALS AND METHODS

### *Hepatocyte isolation and cryopreservation*

The human isolation study was approved by the South East Sydney Area Health Service Ethics Committee (approval No. 01/123). Hepatocytes were harvested from liver resection specimens of consenting patients undergoing partial hepatectomy for neoplasia. Patients with hepatocellular carcinoma were excluded. Patient demographic and disease details are outlined (Table 1). The bulk of specimens (61%) arose from livers with colorectal metastases.

Following resection, the specimen was transferred to a sterile table where the diseased portion of the liver was dissected with a 1cm margin, leaving the remaining macroscopically normal liver for hepatocyte harvest. The tissue was placed immediately into a sterile cooling solution (< 4°C) and 2-4 of the largest vessels were cannulated. Warm ischemic time, defined as clamping time of hepatic inflow and/or outflow during resection

**Table 1 Patient demographic, clinical and operative details**

Parameters	n

plus specimen processing time before being cooled, was recorded. Cannulae ranging from 0.95 mm to 2 mm diameter were suture-ligated around the respective vessels and capped with one-way valved bungs to prevent backflow. Histoacryl® (Braun, Germany) was used to seal most of the remaining liver surface, in addition to the cannula entry points. This was done to prevent leakage of perfusate and to maximize perfusion of the microcirculation during isolation, having been previously shown to increase hepatocyte yield and viability<sup>[14,15]</sup>. The specimen was then flushed with 500-1000 mL of heparinized (5000 units per litre) Custodiol® histidine-tryptophan-ketoglutarate (HTK) solution (Kohler Chemie, Germany)<sup>[16]</sup> to prevent obstruction of the hepatic microcirculation by thrombus and facilitate organ preservation. The specimen was then transported under sterile conditions to the laboratory where it was re-warmed and digested by a modified version of Seglen's original 2-step technique<sup>[17]</sup>. Cold ischemic time, defined as time that the specimen had been on ice prior to re-warming, was recorded. Pre-warmed (37°C) buffers were perfused in the following order: (1) Wash buffer-HBSS without Ca<sup>2+</sup>/Mg<sup>2+</sup> (Gibco, Auckland, New Zealand) + 208.1 mg/L EDTA (Sigma, St Louis, MO, USA) + ascorbic acid 50 mg/L (Sigma, St Louis, MO, USA) + bovine serum albumin (BSA) (Sigma, St Louis, MO, USA) 0.5% w/v-10 min perfusion and then discarded. (2) EDTA washout-HBSS + BSA 0.5% w/v; 5 min perfusion and then discarded. (3) Digestion buffer-HBSS + 0.05% w/v Collagenase P (Roche, Germany) + 0.5% w/v BSA-re-circulated for 20-30 min.

Perfusion was carried out manually due to the varying size of the specimens (range, 55-690 g) at 20-40 mL/min per cannula depending on the weight of the specimen and cannula size. Digestion buffer was perfused until the specimen was soft and friable. A cell suspension was obtained by gentle mechanical dissociation of the digested specimen in 500 mL of ice-cold suspension buffer DMEM (Gibco, Auckland, New Zealand) + 10% (v/v) FCS (Gibco, Auckland, New Zealand) +

1% antibiotic-antimycotic Penicillin 10000 units/mL + streptomycin 25 µg/mL + amphotericin B as Fungizone® (Gibco, Auckland, New Zealand) and sequentially filtered through three sterile stainless steel filters of decreasing pore size (425 µm, 150 µm and 75 µm) (Endecotts, UK). The raw fraction was pelleted by centrifugation at 50 g for 3 min at 4°C and washed three times in the suspension buffer. Cells were counted in quadruplicate and viability assessed by Trypan blue exclusion, using a hemocytometer (Neubauer, Germany). Cells were cryopreserved in suspension medium containing 10% DMSO in 5-mL tubes by freezing to -80°C in 1°C decrements per minute and then transferred to liquid nitrogen after 24 h.

### **Hepatocyte spiking & purging**

*In vitro* and *in vivo* studies were performed using suspensions of isolated human hepatocytes spiked with various numbers of HT-29 human colorectal cell-line tumor cells and then treated or not with immunomagnetic beads (CELLlection® Epithelial Enrich; Dynal AS, Oslo, Norway), in the method described by Kielhorn *et al*<sup>[18]</sup> and Flatmark *et al*<sup>[19]</sup>. Specifically, we used 4.5 µm magnetic beads coated with mouse IgG1 Ber-EP4 antibody against Ep-CAM, an antigen highly expressed on colorectal cancer (CRC) cells (including HT-29 tumor cells), but not on mature hepatocytes<sup>[20]</sup>.

### ***In vitro* hepatocyte and HT-29 cell-line preparation**

Cryopreserved human hepatocytes were thawed in a 37°C water bath, diluted in suspension medium, pelleted by centrifuging at 50 g for 3 min at 4°C and re-suspended in suspension medium. Density gradient centrifugation was performed to purify the thawed hepatocytes. The suspension was then mixed with a Percoll® (Amersham Biosciences, Uppsala, Sweden) density gradient (25% final concentration) medium and centrifuged at 75 g for 5 min at 4°C to separate viable from dead hepatocytes. Pellets were re-suspended in PBS with 0.1% BSA and placed on ice. Cells were counted in quadruplicate, using a hemocytometer (Neubauer, Germany), and their viability assessed by Trypan blue exclusion. HT-29 cells grown in 75 cm<sup>2</sup> culture flasks (Greiner Bio-One, Germany) in 95% O<sub>2</sub> and 5% CO<sub>2</sub> at 37°C were trypsinised, washed in PBS (Invitrogen, Auckland, New Zealand), pelleted by centrifugation at 75 g for 5 min, re-suspended in PBS and counted as above.

### **Determination of RT-PCR sensitivity for tumor cell detection**

One, 10, 50, 100, 1000, 5000 or 10000 HT-29 cells were added to suspensions of 1 million human hepatocytes to establish the lower limit of detection of tumor cells by RT-PCR. Suspensions of 1 million HT-29 cells alone and 1 million hepatocytes alone served as positive and negative controls respectively.

Total RNA was extracted using TRIzol® reagent (15596026, Invitrogen) as per the manufacturer's instructions. Following DNase I treatment (18068-015,

Invitrogen), the total RNA concentration and quantity was assessed by spectrophotometry at 260 nm and the RNA stored at -80°C.

### **RT-PCR**

cDNA was synthesized from total RNA using One-Step SuperScript III® system (12574-026, Invitrogen) with target specific primers as per the manufacturer's instructions. EpCAM primers were as published by Sakaguchi *et al*<sup>[21]</sup> with actin housekeeping primers as follows; antisense 5'-GGAGCAATGATCTTGATCTT-3'; sense 5'-CTTCCTGGGCATGGAGTCCT-3'. The RT-PCR program was as follows; cycle one, 56°C, 30 min, 94°C for 3 min, followed by 40 cycles of 30 s at 94°C, 30 s at 60°C, 30 s at 72°C, with a final extension for 10 min at 72°C. The cDNA products were visualized on a 1% agarose gel, and sequenced to confirm product identity.

### **Immunomagnetic bead treatment of spiked hepatocytes**

Five mL suspensions of 1 × 10<sup>6</sup> hepatocytes spiked with 1000, 10 000 and 50 000 HT-29 cells per mL were prepared in duplicate. Immunomagnetic beads (CELLlection® Epithelial Enrich; Dynal AS; 4 × 10<sup>8</sup> beads/mL), were washed in PBS + 0.1% (w/v) BSA, and added to half the tubes in the ratio of 20 beads to 1 HT-29 cell. The remaining preparations constituted controls and contained no immunomagnetic beads. All tubes were placed in a rotator (15 r/min) at 4°C for 30 min, to allow maximal tumor cell-bead contact and capture. Treated tubes were placed in the magnetic particle concentrator provided by the manufacturer for 2 min, the supernatant transferred to new tubes and the process repeated. One mL from each sample was collected after treatment for RT-PCR analysis to assess the efficacy of immunomagnetic bead-mediated tumor-purging.

### ***In vivo* study**

Male Balb/C athymic nude mice (Animal Resource Centre, Perth, WA, Australia) were housed and fed under specific pathogen-free conditions according to study protocols approved by the Animal Care & Ethics Committee of UNSW (approval No. 02/103). The athymic mouse was chosen due to its minimal cellular immunity, so as to minimize risk of rejection of human hepatocytes and facilitate tumor engraftment. The main aims were to study (a) the tumor load required for tumorigenesis following intraperitoneal transplantation, (b) the effect of co-transplantation of human hepatocytes on tumorigenesis and (c) the effect of our immunomagnetic purging protocol on tumorigenesis. The experimental protocol is described below in Table 2.

Hepatocytes and HT-29 cells were prepared as per the *in vitro* arm, separately and in combination to produce suspensions containing the cell numbers required per mL PBS (cf Table 2). Two hundred µL samples, containing 20% of the cell number in each 1 mL inoculation, were collected for negative control,

**Table 2 Mice & cell transplantation details**

Treatment groups	Mouse group	IP injection	No. of mice
Negative control (Hepatocyte only)	1	$5 \times 10^6$ hepatocytes	3
Positive control 1 (HT-29 only)	2	5000 HT-29 cells	3
	3	100 000 HT-29 cells	3
	4	500 000 HT-29 cells	3
	5	2 million HT-29 cells	3
Positive control 2 (Hepatocytes + HT-29)	6	5 million hepatocytes + 5000 HT-29	3
	7	5 million hepatocytes + 100 000 HT-29	3
	8	5 million hepatocytes + 500 000 HT-29	3
	9	5 million hepatocytes + 2 million HT-29	3
Bead (Hepatocyte + HT-29)	10	5 million hepatocytes + 5000 HT-29	3
	11	5 million hepatocytes + 100 000 HT-29	3
	12	5 million hepatocytes + 500 000 HT-29	3
	13	5 million hepatocytes + 2 million HT-29	3

**Table 3 Tumor growth**

Treatment groups	IP injection	Mouse with tumour	Percentage expression (%)
Negative control (Hepatocyte only)	$5 \times 10^6$ hepatocytes	0/3	0
Positive control 1 (HT-29 only)	5000 HT-29 cells	0/3	0
	100 000 HT-29 cells	1/3 <sup>1</sup>	0 <sup>1</sup>
	500 000 HT-29 cells	2/3	67
	2 million HT-29 cells	3/3	100
Positive control 2 (Hepatocytes + HT-29)	5 million hepatocytes + 5000 HT-29	0/3	0
	5 million hepatocytes + 100 000 HT-29	0/3	0
	5 million hepatocytes + 500 000 HT-29	3/3	100
	5 million hepatocytes + 2 million HT-29	2/3	67
Bead (Hepatocyte + HT-29)	5 million hepatocytes + 5000 HT-29	0/3	0
	5 million hepatocytes + 100 000 HT-29	0/3	0
	5 million hepatocytes + 500 000 HT-29	0/3	0
	5 million hepatocytes + 2 million HT-29	0/3	0

<sup>1</sup>Injection-site tumor in skin only; In italics: Groups in which tumor was found; In standard form: Tumor-free.

positive control and immunomagnetic bead groups, before and after purging for RT-PCR analysis.

Mice were monitored for 28 d post-transplantation after which they were sacrificed with a lethal 6 mg dose of pentobarbital sodium. The abdomen, pelvis and thorax were examined visually for the presence of tumor.

## RESULTS

### Isolation of hepatocytes

The total viable hepatocyte yield averaged at  $9.3 \times 10^8$  cells per isolation (range  $2.0 \times 10^8$ - $36.3 \times 10^8$ ; mean  $\pm$  SD viable hepatocyte yield  $9.33 \times 10^8 \pm 6.0 \times 10^6$  cells/g digested liver tissue), with the five most recent isolations each yielding over  $1.0 \times 10^9$  cells. The mean viability of freshly isolated hepatocytes was  $70.5\% \pm 8.1\%$ . Mean warm ischemic time was  $31 \pm 19$  min (range, 25-60 min); mean cold ischemic time was  $1.5 \pm 0.6$  h (range, 0.5-16 h).

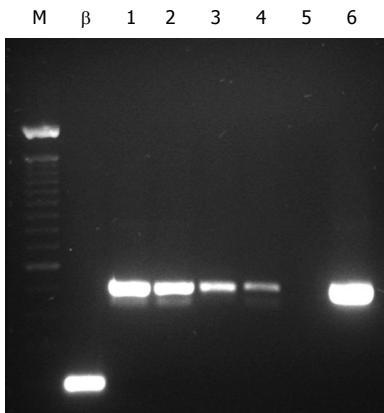

### Tumorigenesis of transplanted hepatocyte and tumor cell suspensions

RT-PCR analysis demonstrated clear single bands at the 515 bp position, indicating Ep-CAM detection, in representative samples of all hepatocyte/HT-29 cell suspensions transplanted into mice belonging to Positive

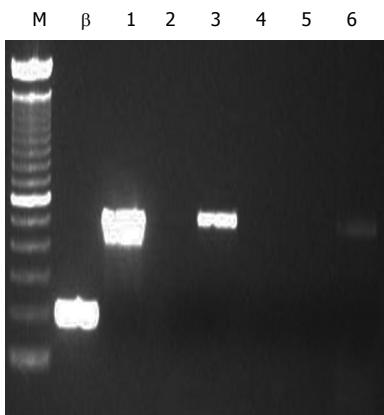

Control 2 and pre-treatment Bead groups. No detectable bands were seen in the samples transplanted into the Negative Control and post-treatment Bead groups (gel images not shown), indicating in the latter case the removal of Ep-CAM positive cells (including HT-29 cells) to below the detection limit of 1 tumor cell in 1 million hepatocytes (Figure 1) and thus, a maximum tumor purging efficacy of immunomagnetic bead treatment of at least 400 000 fold (Figure 2).

In the control groups, all mice injected with 100 000 HT-29 cells and below showed no tumor, except for one animal inoculated with 100 000 HT-29 cells only. The mouse developed a small (0.1 g) skin nodule at the injection site and had no evidence of intra-abdominal tumor on detailed examination. This is probably due to an inadvertent subcutaneous rather than intraperitoneal injection of cells, and could thus be excluded on the basis of technical error. All except two mice inoculated with at least 500 000 HT-29 cells (83%) developed tumor. There was no significant difference in tumor expression between mice injected with or without hepatocytes (Tables 2 and 3). These results would suggest that the minimum tumor load required for engraftment and growth was between 100 000 and 500 000.

There was a complete absence of tumor development in any mouse injected with HT-29 cell-spiked hepatocyte

**Figure 1** Detection sensitivity. RT-PCR detection of HT-29 cells in  $1 \times 10^6$  hepatocytes. suspensions treated with immunomagnetic beads. All mice survived until day 28 without any significant weight loss/gain or signs of malaise or distress. Where intraperitoneal tumors occurred, these were seen only intra-abdominally, expressed as distinct, scirrhouous, white nodules adherent to the parietal or visceral peritoneum, without evidence of metastasis.

## DISCUSSION

Our results show that clinically relevant numbers of hepatocytes can be recovered from macroscopically normal liver unavoidably removed during hepatic resection for neoplasia. Further, when isolated and subjected to an immunomagnetic cell separation technique, the resulting hepatocytes can be safely transplanted intra-peritoneally in athymic mice without increased risk of development of tumor. Only patients requiring anatomical resection were included in this study. Our technique may be less useful in the case of

patients undergoing small, non-anatomical resection; in this situation the viable hepatocyte yield would be less.

Our mean viable yield of  $9.33 \times 10^6$ /g is a significant improvement from our preliminary study<sup>[13]</sup> and marginally exceeds that reported by Richert *et al*<sup>[22]</sup>. To achieve this, the original isolation protocol was altered to include sealing of cannula points and cut surfaces prior to perfusion and ensure a cold ischemic time of less than 5 h; both of these changes have been independently identified to positively influence viable yield<sup>[22,23]</sup>.

The number of hepatocytes transplanted in clinical experiences to date has ranged between  $2 \times 10^8$  to  $4 \times 10^9$  cells<sup>[24]</sup>. Given a mean viable yield of  $9.3 \times 10^8$  cells per isolation, our technique offers the possibility of one hepatocyte transplant for every hepatocyte isolation. In the order of 80–100 liver resections are performed annually in our unit, of which approximately half will be suitable for hepatocyte isolation. Thus, a minimum of forty hepatocyte transplants could potentially be performed annually.

A comparison of viable hepatocytes yield from resection specimens versus cells obtained from explanted organs rejected for OLT shows that the resected specimens have a consistently higher viable yield<sup>[22]</sup>. Further, recovery from cryopreservation of hepatocytes derived from normal resected liver is significantly higher compared to that of cells obtained from organs rejected for liver transplantation<sup>[25]</sup>, thus improving the potential quality and quantity of bankable cells for use on-demand. Such factors, combined with the opportunity to utilize a hitherto untapped hepatocyte source, further enhance the potential application of hepatocyte transplantation as a clinically relevant treatment modality.

An important concern regarding the use of hepatocytes isolated from liver resections performed for malignancy has been the possibility of co-transplanting contaminating tumor cells. Although immunomagnetic cell separation has been widely utilized to enhance detection of tumor cells in different body compartments, purging has been mainly limited to *ex vivo* removal of tumor cells from autologous stem cell transplants<sup>[18,19,26,27]</sup>. To our knowledge, our centre is the first to propose immunomagnetic purging of any residual, contaminating tumor cells from isolated hepatocyte suspensions.

The Ep-CAM cell-surface antigen is consistently present on both HT-29 colorectal cancer cells and most colorectal metastases<sup>[28]</sup>, the pathology in the majority of our liver resection specimens in this study. The antigen is not expressed by mature hepatocytes<sup>[20]</sup> making differential separation of Ep-CAM-expressing tumor cells by immunomagnetic beads (coated with Ber-EP4) possible. Various other carcinomas, including all the types from our patient cohort, also express Ep-CAM<sup>[29]</sup>. As Ep-CAM has been shown consistently to be absent in hepatocellular carcinoma, patients with such tumors, along with other Ep-CAM-negative lesions, were excluded from our study to avoid undetectable tumor contamination. Whilst hepatocytes were harvested only from patients whose tumors expressed Ep-CAM in this

study, the targeting of additional molecular markers such as CK-20 and CEA enhanced detection of any potential tumour cells without an Ep-CAM phenotype<sup>[30,31]</sup>. Additional surface antigens are currently being studied to potentially increase the tumor-purging efficacy by multiplying the number of target molecules per cell.

In our study, immunomagnetic purging was shown to remove tumor cells by a factor greater than 400 000. This compares favorably with similar large-scale experiments involving breast cancer cells in blood stem cell harvests<sup>[32]</sup>. It also represents a substantial improvement on our preliminary experience<sup>[13]</sup>, attributable to optimization of the sample purging treatment and bead to cell ratio employed. The development of an RT-PCR detection assay, in addition to standard immunohistochemical methods, has enabled a more efficient and sensitive detection of tumor contamination (1 tumor cell per 1 million hepatocytes) enabling confidence that in a typical human hepatocyte transplant of 1 billion cells, a maximum tumor load of no more than 1000 cells could be present in the preparation. This is significantly below the 100 000-500 000 cell threshold for tumor engraftment and growth demonstrated in our athymic mouse model in this study. Further, no additional growth potential was conferred to tumor cells by the co-transplantation of hepatocytes, an important observation that indicates that the presence of hepatocytes does not magnify the risk of tumor cell engraftment.

We have demonstrated that with the use of an optimized cell-isolation protocol, liver resection specimens obtained from patients undergoing resection for neoplasia can offer sufficient viable hepatocytes to potentially provide clinically-relevant liver support. We have further shown both *in vitro* and in a suitable *in vivo* animal model that immunomagnetic purging can confer safety from the potential of tumor contamination of hepatocyte suspensions. We therefore propose that liver resection specimens, by a simple purging step, may provide a safe, alternative hepatocyte source for clinical transplantation.

## COMMENTS

### Background

With a world wide shortage of liver donor organs, adjunct treatment regimes to support patients to orthotopic liver transplantation (OLT) or to replace when OLT is contra-indicated are becoming increasingly important. Hepatocyte transplantation is one such, however, a major limitation to its clinical application is the availability of primary human hepatocytes. Hepatocytes isolated from macroscopically normal liver removed during hepatic resection for neoplasia could provide an additional source of hepatocytes, given the development of strategies to detect and remove residual malignant cells.

### Research frontiers

The liver margins of neoplasia patients, an increasingly common procedure, are normally discarded. The aim was to discover whether clinically relevant numbers of healthy hepatocytes could be recovered from these waste pieces and used for transplantation, thereby adding another source to the traditional sources of hepatocytes.

### Innovations and breakthroughs

It was found that clinically relevant numbers of hepatocytes can be recovered from macroscopically normal liver removed during neoplasia hepatic resection. A protocol based on current immunomagnetic bead technology was developed

to capture and remove cancerous cells from hepatocytes in concert with a novel RT-PCR assay for detection of the tumour cells.

### Applications

An additional source of hepatocytes for transplantation boosts both ongoing research into the efficacy of hepatocyte transplantation and clinically, increases the number of treatable patients. Additionally, hepatocytes prepared correctly can be stored until required, divided amongst multiple patients, or combined with hepatocytes from other donors, increasing further the number of patients that can be treated.

### Peer review

The authors evaluated the efficacy of Ep-CAM antibody-coated magnetic beads in tumor cell removal from hepatocyte suspensions. This is an interesting work that normal liver resected for neoplasia may be potential as another clinically useful source of hepatocytes for transplantation.

### Abstract

**AIM:** To identify the criteria for the differentiation of hilar cholangiocarcinoma (HCCA) from benign strictures.

**METHODS:** A total of 68 patients underwent resection of lesions suspicious for HCCA between 1998 and 2006. The results of laboratory investigations, imaging studies and brush cytology were collected. These findings were analyzed to obtain the final diagnosis.

**RESULTS:** Histological examination of the resected specimens confirmed HCCA in 58 patients (85%, group I) whereas 10 patients (15%, group II) were diagnosed to have benign strictures. The most common presenting symptom was obstructive jaundice in 77% patients (79% group I vs 60% group II,  $P = 0.23$ ). Laboratory findings showed greater elevation of transaminase levels in group I compared to group II. The various imaging modalities showed vascular involvement exclusively in the malignant group (36%,

$P < 0.05$ ). Brush cytology was positive for malignant cells in only 50% patients in group I whereas none in group II showed malignant cells.

**CONCLUSION:** Despite improvements in imaging techniques, 10 patients (15%) with a presumptive diagnosis of HCCA were ultimately found to have benign strictures. Except for vascular involvement which was associated significantly with malignancy, there were no conclusive features of malignancy on regular imaging modalities. This uncertainty should be taken into account when patients with a suspicious lesion at the liver hilum are considered for resection.

### INTRODUCTION

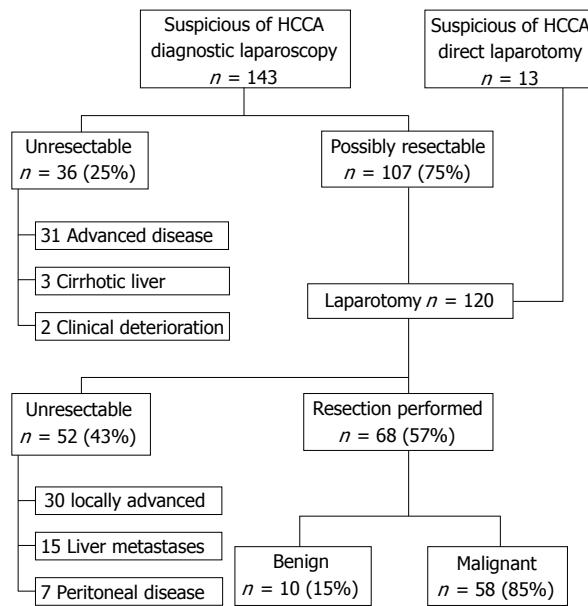

Hilar resection en bloc with liver resection is the only curative treatment option for patients with carcinoma at the hepatic duct confluence. Although mortality rates associated with partial hepatectomy have decreased markedly in the past decades, postoperative morbidity is considerable and can exceed 50 percent<sup>[1-4]</sup>. Undertaking partial hepatectomy for hilar cholangiocarcinoma (HCCA) becomes even more a subject of discussion when histopathology of the resected specimen shows benign disease. A variety of benign lesions at the liver hilum can mimic malignancy. In particular, inflammatory lesions may present with the same clinical and radiological features as a malignant tumor.

In the past decade, imaging techniques have improved and the diagnostic work-up of patients suspected of HCCA usually comprised of ultra-sonography (US), contrast enhanced multi-slice computed tomography (CT) and magnetic resonance cholangiography (MRC). In experienced hands, colour Doppler US is very useful in assessing proximal biliary extension of the tumor and vascular invasion, but has limited value in distinguishing HCCA from inflammatory lesions<sup>[5]</sup>. Contrast enhanced CT and MR imaging (MRI) provide important information regarding resectability and vascular involvement<sup>[6-8]</sup>. Furthermore, these cross-sectional imaging modalities are accurate in detecting a tumor mass and signs of lymphadenopathy, although both features may also be present in benign diseases. Cholangiography in combination with brush cytology has a low sensitivity, and although the specificity is higher, it is not 100% since longstanding stenting of the biliary duct may give rise to false positive cytology results<sup>[9]</sup>. Overall, an extensive work-up with multiple imaging techniques may improve the differentiation between malignant and benign proximal bile duct strictures.

Several studies have noted that approximately 14% to 25% of patients resected for presumed HCCA prove to have a benign lesion at histopathology<sup>[10-14]</sup>. A recent study attempted to identify potential criteria for distinguishing patients with HCCA from those with an alternative diagnosis<sup>[15]</sup>. However, the non-HCCA patients in this series comprised of benign and malignant diseases (for instance gallbladder cancer), which makes any conclusions difficult to interpret. In a previous series of 132 patients who had undergone surgical treatment for suspicious HCCA at our center from 1983 to 1998, 15% (20/132) of the patients had benign lesions<sup>[16]</sup>. In the present study, which covers a more recent period during which improved imaging techniques were used, the rate of mis-diagnosed benign lesions was re-examined and the diagnostic features of benign and malignant lesions was compared. The aim of the study was to identify criteria that can differentiate HCCA from benign proximal bile duct strictures.

## MATERIALS AND METHODS

Between January 1998 and December 2006, a total of 143 patients underwent a diagnostic laparoscopy for staging of HCCA, and 13 patients underwent laparotomy without diagnostic laparoscopy. Unresectable disease was found in 36 patients undergoing laparoscopy, and in the majority of these cases the diagnosis was confirmed by histology (Figure 1). Another 52 patients were found to have unresectable disease during subsequent laparotomy which was confirmed by histology. Finally, 68 consecutive patients underwent resection and are the subject of the present study (Figure 1). These patients had hilar resection with complete lymphadenectomy of the hepato-duodenal ligament usually en bloc with (extended) hemi-hepatectomy including resection of the caudate lobe and left or right portal vein<sup>[17]</sup>. Although in the majority of the patients included in the study,

**Figure 1** Flow chart of patients eligible for resection of hilar cholangiocarcinoma (HCCA) with final histopathological outcome in the period from January 1998 to December 2006.

the initial diagnostic evaluation was performed at the referring hospital, imaging studies such as US, CT and MRC were usually repeated in our center. The medical data of patients obtained from these hospitals and from our center included demographic features, relevant medical history, presenting symptoms, laboratory investigations, results of imaging studies (including cholangiography, CT, MRC, duplex US), radiological and endoscopic interventions including placement of a stent, brush cytology and intra-operative findings.

The results of biliary brush cytology obtained during antegrade percutaneous transhepatic cholangiography (PTC) or endoscopic retrograde cholangiopancreaticography (ERCP) were categorized as follows: highly suspicious for adenocarcinoma, atypical cells/inconclusive, and no malignant cells. Data from imaging studies were collected for staging purposes. The data recorded from these studies included: the presence of a mass lesion, proximal extent of the tumor within the biliary tree according to the Bismuth-Corlette classification system, vascular involvement (hepatic artery, portal vein), liver lobe atrophy, and lymphadenopathy. Ultrasonography, CT and MRI were used to detect a mass lesion, to determine the size of the lesion and the level of the biliary obstruction. Findings on PTC and/or ERCP showing an irregular and eccentric stenosis and/or a blunt end rather than a smooth tapering narrowing of the duct were considered more suggestive of a malignant lesion. Vascular invasion on colour Doppler US was defined as an increase in flow compatible with stenosis or absence of flow compatible with occlusion. Furthermore, on contrast enhanced CT, presence of vascular stenosis or occlusion of the portal vein and encasement of the artery were indicative of vascular involvement.

The final histological diagnosis was correlated with

the preoperative clinical and laboratory findings as well as with the radiological data in an effort to identify criteria which may be useful for the differentiation of HCCA (group I, 58 patients) from benign proximal bile duct stricture (group II, 10 patients). The resected specimens of the benign lesions were re-assessed by a single pathologist, specialized in hepatobiliary pathology (FJ. tK.). The results obtained are expressed as the mean (SEM). The differences between categorical variables were evaluated by chi-square analysis, while Student's *t* test was used for all comparisons among continuous variables. A two-tailed *P* value less than 0.05 was considered to indicate significant differences. All statistics were carried out using the SPSS Base 12.0 for Windows Statistical Package for Social Sciences (SPSS®, Chicago, IL).

## RESULTS

The demographic features, presenting symptoms, and preoperative laboratory findings are shown in Table 1. The mean age and male-female gender ratio were equal in the two study groups. Although 9 patients (groups combined) had a prior cholecystectomy, none of the patients had a complicated procedure with bile duct stricture. In the group with benign lesions, one patient had history of alcohol abuse and related chronic pancreatitis, and another patient had history of inflammatory bowel disease (ulcerative colitis). In the malignant group, one patient had history of alcohol abuse and one patient had Crohn's colitis with primary sclerosing cholangitis (PSC).

There were no statistically significant differences between the two groups with respect to the clinical presentation. Jaundice was present in 79% of the patients in group I and 60% of group II. Abdominal pain, usually located in the right upper abdomen or in the epigastric region was mostly vague and nonpersistent. Weight loss was observed in both groups with a median loss of 6.4 kg in group I (range 2-16) and 7.3 kg (range 2-10) in group II. No differences were observed in the results of the laboratory tests, except for serum transaminase levels which showed higher levels in group I compared to group II (*P* < 0.05, Table 1). Assessment of tumor markers, including carcinoembryonic antigen (CEA) and carbohydrate antigen 19-9 (CA 19-9) was not performed routinely.

The majority of patients underwent imaging studies, and interventions such as ERCP, PTC and diagnostic laparoscopy (Table 2). The mean number of imaging procedures was 3.3 per patient in both groups. CT scan was performed most frequently, with an overall rate of 96%. Sixty patients (88%) underwent colour Doppler US, while MRI was performed in 21 patients (31%). Cholangiography (either ERCP or PTC) was performed in 63 patients (93%). Forty-seven patients underwent ERCP and 15 patients underwent PTC with at least one bile duct stent or drainage tube inserted. Five patients underwent both ERCP and PTC to achieve biliary decompression. Examination of brush cytology, shown

in Table 2, showed malignant cells in 50% of patients in group I, whereas none in group II showed malignant cells (*P* < 0.05). Furthermore, brush cytology in 9 patients in the malignant group proved false negative. Atypical cells were found in 6 and 2 patients in group I and II, respectively.

The findings obtained with the imaging studies are shown in Table 3. A mass lesion at the hepatic duct confluence was seen in 56 patients (97%) in group I and 8 patients (80%) in group II. The presence and size of a mass could not distinguish between benign or malignant disease. The extent of bile duct involvement classified according to the Bismuth-Corlette system was similar in the two groups. Vascular involvement was

observed only in patients with malignant disease ( $P < 0.05$ ), although lobar atrophy was not more frequent in the malignant group. Lobar atrophy was present in one patient in the benign group, probably caused by segmental biliary obstruction. Moreover, the presence of enlarged lymph nodes ( $> 1$  cm, short axis diameter) could not differentiate the two groups. After taking into consideration the clinical presentation, laboratory findings, imaging studies, prior interventions and brush cytology, all 68 patients were diagnosed to have a lesion suspicious of HCCA.

During surgical exploration, frozen sections were obtained of suspicious lymph nodes, tissue suspicious of tumor infiltrating the vessel walls, and the resection margins to ensure radical resection in all patients except one (Table 3). The frozen section examination confirmed malignancy in 35% of the patients in group I, and no false positive results were obtained in group II ( $P < 0.05$ ). A palpable, suspicious hilar tumor was found in 5 patients (50%) in the benign group and in 51 patients (88%) in the malignant group. Eventually, 70% of all patients underwent hilar resection, in combination with partial liver resection; the prevalence of local bile duct excision was equally divided between the two groups. Histological analysis of the resected specimens showed a benign bile duct stricture in 10 patients, diagnosed as chronic fibrosing lesion, erosive inflammation, sclerosing cholangitis or autoimmune cholangitis (IgG4-related) (Table 4). In the remaining 58 resection specimens, histology confirmed HCCA.

## DISCUSSION

Cholangiocarcinoma and benign, inflammatory lesions of

the biliary tract may have a similar clinical presentation. Differentiating the two conditions is complex because on the one hand, HCCA is frequently associated with secondary inflammatory changes, and on the other hand, conditions such as PSC predispose to malignancy of the bile ducts (with a reported prevalence of 30%)<sup>[18]</sup>. A combination of different imaging modalities is usually employed in the diagnosis of hilar bile duct lesions<sup>[8]</sup>. However, to date, no single investigation has been found to reliably differentiate HCCA from benign proximal bile duct strictures.

In the present study, the rate of patients (15%) with benign lesions misdiagnosed as malignancy was similar to the rate (15%) observed in a previous study performed at our center a decade earlier (1983-1997)<sup>[16]</sup>. Despite considerable improvements in imaging techniques (contrast enhanced multi-slice CT and MRC), and an increase in the number of imaging procedures (a mean of 3 modalities in comparison to 2 in the previous study), patients still required unnecessary extensive resections, for achieving adequate biliary drainage. Case series from other groups worldwide, have noted comparable rates of benign lesions in resections performed for presumed HCCA (Table 5). Our observations confirm the findings of these studies and emphasize the difficulty in differentiating benign from malignant lesions at the liver hilum, despite use of state-of-the-art imaging modalities.

Clinical features alone cannot differentiate HCCA from benign proximal bile duct strictures. With regard to laboratory tests, plasma transaminase values were significantly elevated in the malignant group compared to patients with benign hilar lesions. Although raised transaminase values may occur in patients with benign proximal bile duct strictures (usually in conjunction with cholangitis), our results show that this is an uncommon finding. Other laboratory tests failed to identify patients with a malignancy. The diagnostic value of tumor markers such as CA 19-9 and CEA in biliary cancer has been extensively studied. One study showed 100% sensitivity using a combination of CA 19-9 and CEA<sup>[19]</sup>, but these results could not be confirmed by other workers<sup>[9,10]</sup>. Another, potentially useful test is serum IgG4. Recently, IgG4-related lymphoplasmacytic sclerosing disease was observed in patients with strictures of the pancreatic duct mimicking carcinoma<sup>[20]</sup>. In a study from our center, it was shown that IgG4-related sclerosing disease also occurs in patients with benign proximal bile duct strictures<sup>[21]</sup>. In the present series, two of the ten patients with benign proximal bile duct strictures showed infiltration by IgG4-plasma cells with histological features suggestive of an autoimmune disorder. Serum levels of IgG4 have potential to differentiate benign disease from HCCA, although the diagnostic value of this marker and the role of immunomodulatory drugs requires further investigation<sup>[22]</sup>.

The findings obtained with the different imaging studies revealed that only one feature, i.e. vascular involvement, was significantly different between the

benign and malignant groups. Even a mass lesion was not able to differentiate between the two groups. Furthermore, in contrast to the report by Are and co-workers<sup>[15]</sup>, we did not find any difference between the benign and malignant groups with respect to either the level of obstruction or the extent of lesion. Moreover, there was no difference in rate of liver lobe atrophy. Portal vein occlusion of one side of the liver typically gives rise to ipsilateral lobar atrophy and compensatory hypertrophy of the contralateral lobe. However, it is possible to develop lobar atrophy without portal vein occlusion. In benign disease, lobar atrophy can develop secondary to longstanding cholestasis. In a series of 162 patients with intrahepatic cholelithiasis, lobe atrophy was observed in 7% of the patients<sup>[23]</sup>. Overall, the finding of lobar atrophy is uncommon with benign disease and should be considered as a manifestation of vascular involvement and therefore of malignancy. Occlusion of the portal vein obviously suggests malignancy, however two cases have been reported of a benign inflammatory pseudotumor mimicking HCCA with vascular involvement<sup>[24,25]</sup>. Therefore, although uncommon, even vascular involvement may be seen in benign lesions at the liver hilum.

Brush cytology of a biliary stricture is often undertaken during ERCP or PTC. Unfortunately, the diagnostic yield is poor with sensitivity rates around 50%<sup>[9,26]</sup>. Moreover, the specificity is not 100% since longstanding stenting of the biliary duct induces chronic inflammation, which makes it difficult to differentiate benign from malignant cells, resulting in false positive results<sup>[9]</sup>. The present study showed similar rates which is consistent with previous studies. Fluorescence in situ hybridization (FISH) has been increasingly used to facilitate the identification of neoplastic cells in cytologic specimens<sup>[27]</sup>. In one study, 20% of patients with cholangiocarcinoma missed by conventional cytology were identified by FISH without affecting the specificity<sup>[28]</sup>. Several studies have evaluated the diagnostic yield of endoscopic US fine needle aspiration in patients with biliary strictures<sup>[29-32]</sup>. In one of the studies, the sensitivity and specificity of biopsy were 89% and 100%, respectively<sup>[30]</sup>. Moreover, the planned surgical approach was changed in 27 of 44 patients. Therefore, biopsy from either the mass or the surrounding malignant-appearing lymph nodes appears to have a higher sensitivity than ERCP or PTC with brush cytology. More recently, techniques such as intraductal ultrasound (IDUS) and cholangioscopy have been used to obtain direct biopsy specimens. IDUS with biopsy increased the accuracy of ERCP from 58%-60% to 83%-90% in distinguishing benign and malignant strictures<sup>[33]</sup>. These diagnostic modalities appear very promising in differentiating benign and malignant biliary lesions, although they are highly expert-dependent and are still not widely available.

In one-half of the patients diagnosed to have a benign lesion at the liver hilum, the intra-operative findings were consistent with a malignant tumor (i.e. positive frozen section diagnosis and/or evident palpable mass). Furthermore, 7 patients in the malignant group were not found to have a suspicious lesion during laparotomy. Thus, even at surgery it is difficult to determine the nature of a hilar lesion, and resection is the only way to rule out malignancy.

In conclusion, despite improvements in the quality and increase in the number of imaging studies, 10

out of 68 (15%) patients with presumed HCCA, were misdiagnosed. Vascular involvement showed a significant association with malignant lesions. However, there was no feature on imaging studies or laboratory tests that reliably distinguished HCCA from benign proximal bile duct lesions. Therefore, differentiation of benign from malignant lesions at the liver hilum remains difficult and this should be taken into account when considering resection in patients with suspicious hilar lesions.

## COMMENTS

### Background

The main etiology of proximal bile duct stricture is hilar cholangiocarcinoma (HCCA). However, the differentiation of benign and malignant strictures is difficult which has obvious important consequences for management. Extensive work-up including multi-slice computed tomography and magnetic resonance cholangiography may help improve the diagnostic dilemma.

### Research frontiers

The differentiation of benign and malignant lesions at the liver hilum remains a diagnostic dilemma despite improvements in the quality and increase in the number of imaging techniques. Novel diagnostic and imaging techniques are discussed, although none have shown a high rate of accuracy. The most promising diagnostic modality appears to be intraductal ultrasound in combination with cholangioscopic biopsy.

### Innovations and breakthroughs

The authors observed that vascular involvement had a significant association with malignant lesions. No other feature on imaging studies or laboratory tests was able to reliably distinguish HCCA from benign proximal bile duct lesions.

### Applications

Vascular involvement emerged as the most important diagnostic feature.

### Terminology

Vascular invasion on colour Doppler ultrasonography was defined as an increase in the portal and/or hepatic arterial flow compatible with stenosis, or absence of flow compatible with occlusion. Furthermore, on contrast enhanced computed tomography a vascular stenosis or occlusion was considered as vascular involvement.

### Peer review

This is a retrospective study of 68 patients with suspicion of cholangiocarcinoma. Fifteen percent of patients were found to have benign strictures after resection. The authors concluded that despite the use of sophisticated diagnostic tests and imaging studies, differentiation of malignant from benign hilar lesions remains a dilemma.

compared to the serology test. The sensitivity of the serology test was good, but the specificity was low (41%-71%). The association between *H pylori* IgG antibodies and scores of gastric mucosal inflammation and current or previous peptic ulcer were weak.

**CONCLUSION:** The accuracy of C14-UBT to diagnose *H pylori* infection was good, and the clinical utility of a negative *H pylori* serology test was substantial, while the gain in clinical information of a positive test was meagre. Positive *H pylori* titres could not distinguish between subjects with or those without active peptic ulceration.

Accuracy of *Helicobacter pylori* serology in two peptic ulcer populations and in healthy controls. *World J Gastroenterol* 2008; 14(32): 5039-5045 Available from: URL: <http://www.wjgnet.com/1007-9327/14/5039.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.5039>

### Abstract

**AIM:** To estimate the test characteristics of *Helicobacter pylori* (*H pylori*) serology and of C14-urea breath test (C14-UBT) in two different peptic ulcer populations and in community controls. Second, the aim was to explore the association between the level of *H pylori* IgG antibodies and severity of inflammation as to active peptic ulceration in the same populations.

**METHODS:** Vagotomized ( $n = 83$ ), medically treated peptic ulcer patients ( $n = 73$ ) and one reference group of community controls ( $n = 88$ ) were gastroscoped. *H pylori* status was determined by histology, bacterial growth, C14-UBT and serology. Based on the updated Sydney System, cumulative scores from biopsies from the prepylorous, incisura angularis, corpus and fundus were calculated.

**RESULTS:** The prevalence of *H pylori* infection varied from 70% to 79%. The C14-UBT had high accuracy

### INTRODUCTION

Serology and C14-urea breath test (C14-UBT) are the most commonly used non-invasive tests of *Helicobacter pylori* (*H pylori*) infection<sup>[1-3]</sup>. Knowledge about the diagnostic validity of particular serological tests is mandatory for inferring its test results<sup>[4]</sup>. In the diagnostics of *H pylori* infection, most commercially available serological tests are reported to have both a high sensitivity and a high specificity<sup>[5]</sup>. The diagnostic characteristics of the tests depend also on the prevalence of *H pylori* infection in the population tested<sup>[5-7]</sup>. Higher prevalence's would imply higher sensitivity and lower specificity<sup>[5-7]</sup>. There are reports suggesting that there is an association between the level of *H pylori* IgG antibodies and the severity of inflammation of the gastric mucosa and also

between antibody level and a current peptic ulcer<sup>[8-10]</sup>. If so, the level, not only positively or not, of *H pylori* IgG antibody tests might be of clinical importance.

The aim of this study was to estimate the test characteristics of *H pylori* serology compared to the urea breath test (C14-UBT) in two different peptic ulcer populations and in a randomly selected group of community controls without known peptic ulcer disease. Second, the aim was to explore the association between the level of *H pylori* IgG antibodies and severity of inflammation as to active peptic ulceration in the same populations.

## MATERIALS AND METHODS

Based upon a questionnaire survey<sup>[11]</sup>, three groups of subjects were invited to participate in an upper endoscopic investigation: one group of vagotomized peptic ulcer patients; one group of medically treated peptic ulcer patients and one reference group of community controls without known peptic ulcer disease.

### Vagotomized peptic ulcer patients

The medical records of all patients operated with a vagotomy for peptic ulcer disease from 1967 to 1990 at Tromsø University Hospital were reviewed, totally 1038 records. Seven hundred and twenty one were alive and received a postal questionnaire with 105 different questions on abdominal and dyspeptic complaints, medications, use of health services, health, life style, diet and social conditions. Two hundred and eighty two answered that they were interested in a gastroscopic examination if offered. By binomial distribution 106 of these 282 vagotomized patients were randomly selected and invited into the study. Sixteen patients were excluded because they had undergone gastric resections in addition to the vagotomy operation and seven due to interrupted endoscopic examination according to the patient's wishes. Accordingly, 83 patients in these groups completed the investigation protocol. Fifty nine had been electively vagotomized, whereas 24 had been vagotomized on emergency indications.

### Medically treated, non-operated, peptic ulcer patients

Two hundred and thirty one medically treated patients with radiographically (barium meal) or endoscopically verified peptic ulcer disease diagnosed in the period 1979 to 1986 received the same questionnaire as the vagotomized patients. One hundred and five were interested in an endoscopic examination if offered. All of these were invited. Seventy four finally accepted the invitation; one patient failed to swallow the endoscope. Accordingly, 73 patients fulfilled the investigation protocol.

### Community controls

For comparison a group of community controls was included. Seven hundred and sixty two inhabitants of the local municipality were randomly selected from the National Population Registry. They were all without

known peptic ulcer disease and were invited to participate in the same questionnaire survey as the peptic ulcer patients to serve as a community reference group in the comparison of abdominal and dyspeptic complaints. They were group-matched with the vagotomized patients regarding sex distribution and mean age. Two hundred and twenty five persons responded positively to the offered endoscopic examination. By binomial distribution, 105 subjects were randomly selected and invited to the endoscopic study. Ninety six finally accepted the invitation of which 7 were excluded due to interrupted endoscopic examination according to the patient's wishes, and one because of previous gastric surgery. Accordingly, 88 community subjects completed the investigation protocol.

The Regional Ethical Committee for Medical Sciences and the Norwegian Social Science Data Services approved the study design and the data security. There was no financial gain or hints of health benefits associated with participation in the study.

After an overnight fast, all subjects were pre-medicated with a topical anaesthetic spray (lidocaine hydrochloride, 10 mg/dose, Astra, Sweden). No additional sedation was used. The same endoscopist (ROL) examined all patients, and he was unaware of the subjects' peptic ulcer history, any previous treatment or current dyspeptic or abdominal complaints. All endoscopies were recorded by a Sony Hi-8 video-recorder using a Pentax gastroscope EG 2901.

None of the participants in the study received long term or continuous medical acid suppressive treatment prior to the endoscopic examination or any known treatment against *H pylori* infection.

### Detection of *H pylori*

The culture, PCR and the serology tests were performed in the laboratories at the Department of Microbiology, Tromsø University Hospital (accredited according to the ISO 45001 standard).

### Histology

The biopsy specimens for histological detection of *H pylori* infection was taken from the greater curvature of the duodenal bulb, from the greater curvature in the prepyloric antrum 2-3 cm from the pyloric channel, from the angulus (incisura angularis) of the lesser curvature, from the corpus of the greater curvature 10 cm from the cardia, and from the fundic top. Separate biopsy specimens were taken from all lesions. All biopsies were fixed in neutral-buffered 4% formaldehyde. Hematoxylin-eosin stains of paraffin-embedded biopsies were used for histological evaluation<sup>[12]</sup>. Histology was considered positive if *H pylori* like organisms were found in any of the four gastric biopsy sites, and negative if *H pylori* like organisms were not found in any of the biopsies. All histological specimens were evaluated by the same experienced pathologist (TJE) who was blinded for the subjects' medical history and other *H pylori* test results. The histological evaluations were performed according to the updated Sydney System recommendation<sup>[13]</sup>.

**Table 1** Sensitivity, specificity and likelihood ratio of positive test (LR+) of C14-UBT and IgG and IgA antibodies against *H pylori* at cut-off values 300 and 500 in vagotomized (vag) or medically (med) treated peptic ulcer patients (med) and in community controls (con)

	Sensitivity (95% CI)			Specificity (95% CI)			LR+ (95% CI)		
	vag	med	con	vag	med	con	vag	med	con
Method of detection									
C14-UBT	94 (85-99)	92 (81-98)	96 (87-100)	85 (62-97)	80 (56-94)	90 (73-98)	6.3 (2.4-31.5)	4.6 (1.7-17.6)	9.3 (3.0-46.6)
Serology IgG300	95 (86-99)	98 (90-100)	93 (83-98)	41 (21-64)	50 (28-72)	68 (49-83)	1.6 (0.9-3.2)	2.0 (1.0-4.2)	2.9 (1.5-6.4)
Serology IgG500	87 (76-94)	90 (79-97)	83 (70-91)	55 (32-76)	50 (28-72)	71 (52-86)	1.9 (1.0-4.2)	1.8 (0.9-3.9)	2.8 (1.4-6.6)
Serology IgG/IgA <sup>1</sup>	95 (86-99)	98 (90-100)	93 (83-98)	32 (14-55)	50 (28-72)	58 (39-76)	1.4 (0.8-2.7)	2.0 (1.0-4.2)	2.2 (1.2-4.4)

*H pylori* infection detected by a positive histology and/or by a positive culture was defined as reference standard. <sup>1</sup>Serology IgG/IgA: IgG ≥ 300 and/or IgA ≥ 500.

### Gastric inflammation score

Semi-quantitative descriptions of the updated Sydney System were transformed to exact numbers from 1-4 (1 = no/none/no *H pylori*, 2 = slight/mild/*H pylori* in 1-3 pits, 3 = moderate/*H pylori* in more than 3 pits, but not all, 4 = severe/*H pylori* in all pits). The score from the 4 local biopsy sites were added up and the total scores were grouped in order to describe the histologically evaluated gastric inflammation of the total gastric mucosa. The same semi-quantitative terms were used for the chronic gastritis score. A score of 4 denotes no chronic gastritis/no *H pylori*, 5-8 denotes mild chronic gastritis/few *H pylori*, 9-12 denotes moderate chronic gastritis/some *H pylori*, 13-16 denotes severe chronic gastritis/much *H pylori*. The inflammatory activity was described as 1 = no inflammatory activity, 2 = slight/moderate inflammatory activity, 3 = severe inflammatory activity. In the scoring of the inflammatory activity 4 denotes no inflammatory activity, 5-6 slight inflammatory activity, 7-8 moderate inflammatory activity, 9-12 severe inflammatory activity.

### *H pylori* culture growth

Two biopsies taken from the angulus of the lesser curvature were placed in a transport medium (Portagerm pylori, bioMérieux, Lyon, France) and immediately transported to the Department of Microbiology for culture and detection of the *H pylori* DNA by PCR. Culture was performed using selective (Oxoid SR 147E supplement) and nonselective columbia agar (Oxoid CM 331) with 7% lysed horse blood at 37°C. The plates were incubated under a microaerobic atmosphere (5% O<sub>2</sub>, 7% CO<sub>2</sub>, 8% H<sub>2</sub>, 80% N<sub>2</sub>) for at least 7 d. The culture was classified as positive when oxidase-, catalase- and urease positive colonies showed typical *H pylori* morphology on Gram staining.

### C14 urea breath test

Fifty milliliters of tap water with 2.5 µCi carbon-14 labelled urea was given orally to the overnight fasted patient. Double breath samples were taken immediately before and at 10, 20 and 30 min after the ingestion of the urea solution and analysed for <sup>14</sup>CO<sub>2</sub> in a Beta-counter as a measure of *H pylori* urease activity in the stomach. *H pylori* negative patients do not expire <sup>14</sup>C labelled CO<sub>2</sub>. A <sup>14</sup>C

urea breath test was positive when the accumulated <sup>14</sup>CO<sub>2</sub> in the breath samples adjusted for the patients' body-weight and the background radiation was more than 1.5% of the ingested <sup>14</sup>C dose<sup>[14]</sup>.

### Enzyme-linked immunoabsorbent assay (ELISA) detection of IgG and IgA *H pylori* antibodies

ELISA was used for detection of serum IgG and IgA antibodies according to the specifications of the manufacturer (Pyloriset EIA-G®, Orion Diagnostica, Finland). A titre ≥ 300 was interpreted as a positive IgG serology result.

### Reference standard

As reference tests were chosen the combination of histologically detected presence of *H pylori*-like organisms in any of the four biopsy sites<sup>[15]</sup> augmented by *H pylori* culture growth. A patient was considered as *H pylori* positive when having a positive test for *H pylori* by histological examination and/or by culture. The biopsies from the gastric mucosa were taken according to recommended biopsy sites and procedures<sup>[16]</sup>.

### Statistical analysis

The microcomputer software Confidence Interval analysis<sup>[17]</sup> estimated 95% confidence intervals for the various proportions and Epiinfo 6<sup>[18]</sup> was used to analyze dichotomous variables by the Mantel-Haenszel  $\chi^2$ -test with Yates correction.

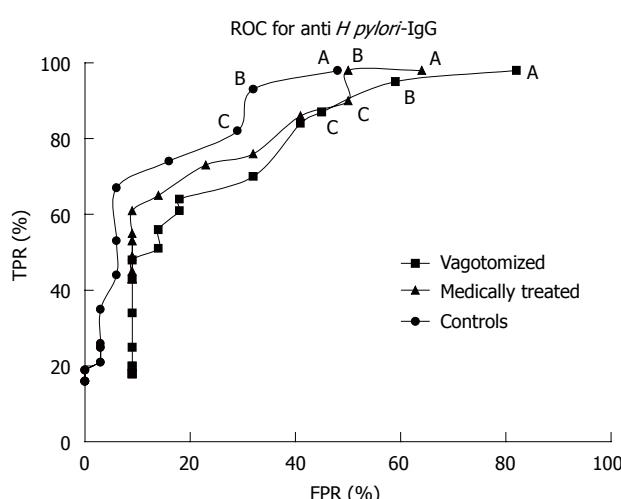

## RESULTS

The prevalence of *H pylori* positive individuals among the vagotomized peptic ulcer patients was 79% (95% CI: 69-88), 75% (95% CI: 63-85) among the medically treated peptic ulcer patients, and 70% (95% CI: 59-80) among the community controls.

Anti *H pylori* IgG at a cut-off value 300 had comparable properties to C14-UBT in detecting the true positive patients in all three groups with sensitivities around 95% (Table 1). When increasing the cut-off value to 500, the sensitivities decreased 8%-10% in all three groups. The combination of anti *H pylori* IgG at a cut-off value 300 and anti *H pylori* IgA at a cut-off value 500 did not improve the sensitivity or specificity of the test in any of

**Table 2** *H pylori* status by histology and inflammatory activity in the gastric angulus (anginflam) in different combinations with culture growth, related to level of IgG antibodies against *H pylori* in each category

	<i>n</i>	Range	Mean (95% CI)	Median
IgG when histology HP neg and growth neg	66	100-12800	700 (290-1120)	200
IgG when histology HP pos and growth neg	9	100-18000	4960 (530-9390)	4000
IgG when histology HP pos and growth pos	143	100-20000	3480 (2740-4220)	1600
IgG when histology HP neg and growth pos	12	200-7000	2660 (1270-4050)	2250
IgG when anginflam neg and growth neg	60	100-18000	690 (90-1290)	200
IgG when anginflam pos and growth neg	8	300-9000	3830 (1420-6240)	3750
IgG when anginflam pos and growth pos	126	100-20000	3500 (2700-4300)	1650
IgG when anginflam neg and growth pos	19	100-13000	2840 (960-4720)	1200

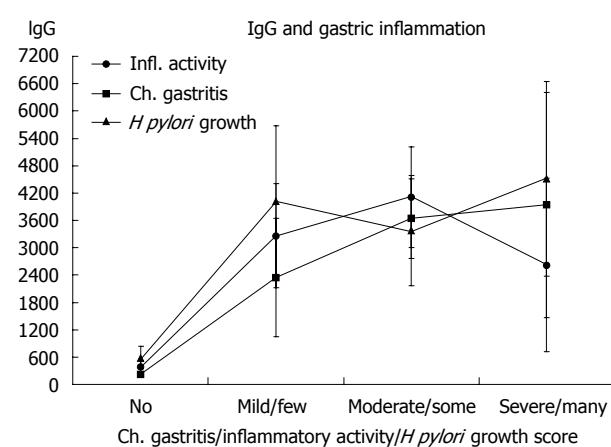

**Figure 1** Receiver operating characteristic (ROC) curve for different cut-off values for *H pylori* IgG antibodies in vagotomized or medically treated peptic ulcer patients and in community controls. Cut-off values were 200, 300, 500, 600 and at intervals of 300 for IgG values above 600 to 4800. TPR = True positive rate (sensitivity), FPR = False positive rate (1-specificity). A: Cut-off 200; B: Cut-off 300; C: Cut-off 500.

the groups. The specificity of anti *H pylori* IgG and IgA were between 32%-50% among the peptic ulcer patients and 58%-71% among the controls, and far lower than C14-UBT with a specificity ranging from 80%-90% in all three groups.

When combining the sensitivity and specificity expressed by the ROC (receiver operating characteristic) curve for anti *H pylori* IgG curves for each group, the area under the curve was largest in the control group (Figure 1).

Incomplete or missing biopsies for *H pylori* detection by both histology and culture growth occurred in 14 cases (*n* = 230, histology HP and growth, Table 2), whereas 215 biopsies were finally included to evaluate inflammation in the angulus. Two of these had missing culture growth biopsies (*n* = 213, anginflam and growth, Table 2).

Anti *H pylori* IgG had a median value of 200 when the reference standard (no *H pylori* like bacteria in any of the four biopsy sites and negative culture growth) was negative. Signs of *H pylori* either by histology or by bacterial growth, or by inflammation in the angulus were associated to elevate anti *H pylori* IgG levels (Table 2).

**Figure 2** Grade of inflammatory activity (no, mild, moderate, severe), grade of chronic gastritis (no, mild, moderate, severe) and semiquantitative numbers of *H pylori* (no, few = *H pylori* like organisms in 1-3 pits, some = *H pylori* like organisms in more than 3 pits but not all, many = *H pylori* like organisms in all pits) detected in gastric biopsies from 4 different biopsy sites (prepylorus, angulus, corpus and fundus) related to the mean value with 95% confidence intervals of IgG antibodies against *H pylori* in each category.

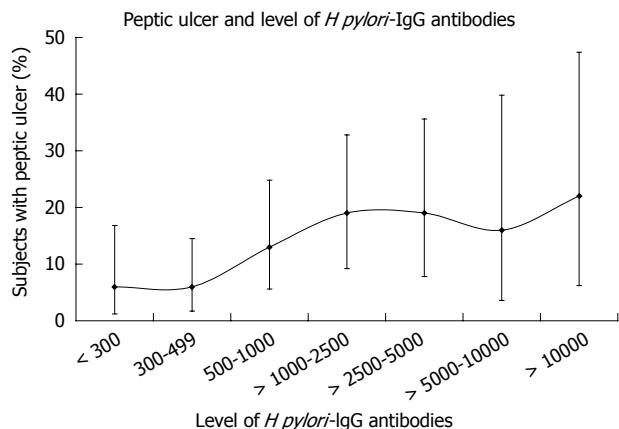

This association was dichotomous and independent of severity of active inflammation or quantitative histological evaluation of *H pylori* (Figure 2).

Increasing levels of *H pylori* IgG antibodies were associated with increasing frequency of subjects with active peptic ulcer (Figure 3). With levels of *H pylori* IgG antibodies above 1000, there was an increase in PU prevalence ( $P = 0.03$ ). Still, 80% of the subjects did not have PU.

## DISCUSSION

The prevalence of *H pylori* in the peptic ulcer patients was 75%-79%. This is somewhat lower than expected in peptic ulcer populations<sup>[19,20]</sup>. Among the vagotomized or medically treated patients are subjects with gastric ulcers that have a lower *H pylori* prevalence than duodenal ulcer patients have<sup>[19]</sup>. In addition, false negative *H pylori* tests or previous antibiotic treatment of other indications than *H pylori* infections might also decrease the prevalence of *H pylori* infection.

In populations with high prevalence of *H pylori* infection the test characteristics of C14-UBT are very good. While the sensitivity of the serology test is excellent too,

**Figure 3** Subjects with peptic ulcer related to level of *H pylori* IgG antibodies. Frequencies are shown with 95% CI.

the specificity is low. The validity varies with the prevalence of *H pylori* infection, illustrating the effects of spectrum bias<sup>[21]</sup>. The test characteristics are, at best, in the control group with the lowest prevalence of *H pylori* infection. Increasing the threshold of a positive test from 300 to 500 or higher did not improve the validity of the test.

The relative low specificity of the anti *H pylori* IgG and/or IgA test indicates a high antibody titre despite no actual presence of *H pylori* in the gastric mucosa. Previous *H pylori* infection or cross-reacting antibodies from closely related bacteria might explain a positive serology test despite no actual *H pylori* infection.

Likelihood ratio is a more clinically relevant method of reporting accuracy than only specificity and sensitivity of a test. The probability of having a disease after a positive or negative test can be calculated and reveals more understandable information in the clinical setting and could also be applied to the clinical problem of dyspepsia management<sup>[22]</sup>.

By comparing the true positive rate to the false positive rate, information about the probability of whether a positive test result is likely to be from a truly *H pylori* positive subject, compared to a similar result to be from a truly *H pylori* negative subject, can be obtained (positive likelihood ratio)<sup>[15]</sup>. By this method C14-UBT was about three times better than Hp serology. 13C-UBT is in full concordance with 14C-UBT and should be preferred because of its lack of radioactivity.

The low specificity reduces the clinical utility of a positive test rest result. When, among medically treated peptic ulcer group, applying the test results of a sensitivity of 98%, a specificity of 50%, and a pre-test probability of 75%, the post-test probability of a positive test barely increases to 85%, while the post-test probability of a negative test enlarges from 25% to 90%.

In 21 subjects, there were discrepancies between the results of histological identification of *H pylori* and growth of the bacteria. As culture growth is highly specific<sup>[2]</sup>, and since none of the 12 subjects with negative histology and positive culture is a false positive, the sensitivity of the histology could not be 100%<sup>[16]</sup>. If there is a misclassification of the reference standard applied

in this study, the direction is towards an overrating of *H pylori* positive subjects. Consequently, the test characteristics, mainly the sensitivities of serology could be somewhat underestimated.

Others have published sensitivity of 100% and specificity of 79% using the same serology Elisa-kit<sup>[23]</sup>. However, the population was on average about 10 years younger than in this study and the *H pylori* prevalence was 82%. The prevalence of *H pylori* is equivalent to our vagotomy group. While the sensitivity is comparable, the populations differ regarding the specificity of the test. The two populations could differ regarding number of case-mix, or people in North Norway might have more infections that could cross-react with *H pylori* serology kits.

An objection to this presentation is the lack of validation of the constructed cumulative scores of inflammatory activity, chronic gastritis and *H pylori* density, based on the histological Sydney System scores at the four different biopsy sites. The chronic gastritis and the subsequent atrophic changes in *H pylori* infected subjects are commonly described as antrum pre-dominant, corpus-predominant or both (pangastritis)<sup>[24]</sup>. However, the objective of this study was to detect any association between the global measurement of *H pylori* serology and the general inflammatory status of the gastric mucosa. Depending on the severity grading, according to the updated Sydney System, the antral predominant chronic gastritis would thus have a relatively high cumulative score, as the condition would be detected in the biopsies from both the pre-pylorus and from the incisura angularis. In addition to the corpus biopsy, the corpus-predominant chronic gastritis should also be reflected in the cumulative scoring system in the transition zone (incisura angularis) as much as the antrum-predominant chronic gastritis. Pangastritis would be reflected by even higher scores by summation from all four biopsy sites.

The percentage of subjects with peptic ulcers was not significantly different at various levels of *H pylori* IgG antibodies above the recommended cut-off titre value of 300. The same tests could neither differentiate between previous peptic ulcer patients and healthy community controls, nor in the severity score of gastric inflammation measured by inflammatory activity, chronic gastritis or histologically evaluated bacterial growth.

In this study, *H pylori* IgG antibodies could not be used to differentiate between previous peptic ulcer patients and healthy community controls, nor between patients with or those without active peptic ulcers.

No association was found between the level of positive IgG titres and the cumulative scores of inflammatory activity and *H pylori* density, according to the updated Sydney System, from the four different biopsy sites in the gastric mucosa. In the clinical setting, this means that the level of positive *H pylori* titres give no diagnostic information about the degree of inflammation in the gastric mucosa, nor cannot distinguish between subjects with or those without active peptic ulceration, nor between previous peptic ulcer patients and community controls. Others have also reported that *H pylori* serology is a poor marker of peptic ulcer disease<sup>[25-28]</sup>.

When using *H pylori* serology tests a negative result is of clinical importance at the recommended cut-off value of IgG titre 300, due to the high sensitivity of the test. A negative serology test result is also reported to almost rule out pre-malignant conditions in the gastric mucosa in screening situations<sup>[29]</sup>. A low specificity, however, reduces the clinical utility of a positive test result. Independent of previous peptic ulcer status among the tested subjects, *H pylori* serology and C14-UBT showed comparable sensitivity.

We could not find any association between gastric mucosal morphology and serology, in contrast to what is published by others<sup>[30]</sup>. However, in that study, a combination of serology tests were used, and a more dichotomous approach to the presence of *H pylori* infection and its morphological consequences were applied.

Uncritical use of *H pylori* serology will represent a considerable overestimation of *H pylori* prevalence in the population tested. *H pylori* serology is, on the other hand, very reliable to exclude *H pylori* infection and thereby useful in screening purposes.

## ACKNOWLEDGMENTS

The authors want to thank the staff in the Department for Clinical Investigation for their excellent service to the patients and their valuable contribution in the administration of the study. We also want to thank the Department of Microbiology and Department of Pathology for expedited and high quality service of all the biopsy specimens.

## COMMENTS

### Background

Serology and C14-urea breath test (C14-UBT) are the most commonly used non-invasive tests of *Helicobacter pylori* (*H pylori*) infection. Knowledge about the diagnostic validity of particular serological tests is mandatory for inferring its test results. In the diagnostics of *H pylori* infection, most commercially available serological tests are reported to have both a high sensitivity and a high specificity. The diagnostic characteristics of the tests depend also on the prevalence of *H pylori* infection in the population tested. Higher prevalences would imply higher sensitivity and lower specificity.

### Research frontiers

Application of test characteristics to illustrate limited value of a commonly used blood test (*H pylori* serology) for detection of *H pylori* gastric infection or peptic ulcer. However, a negative test result rule out *H pylori* infection with high certainty.

### Applications

General practice and gastroenterological specialist practice.

### Terminology

Sensitivity means a test ability to correctly identify a true positive subject with a positive test result (frequency of positive test or true positive rate). Specificity means a test ability to correctly identify a true negative subject with a negative test result (frequency of negative test or true negative rate).

### Peer review

This retrospective study has estimated the test characteristics of *H pylori* serology and of C14-UBT in 83 vagotomized patients, 73 medically treated peptic ulcer patients and 88 gastroscooped community controls in Norway. It is helpful to know the prevalence of the infection in the area of study.

## Abstract

**AIM:** To investigate in a prospective study whether a simplified clinical score prior to endoscopy in upper gastrointestinal bleeding (UGIB) patients was able to predict endoscopic findings at urgent endoscopy.

**METHODS:** All consecutive UGIB patients referred to a single endoscopic center during a 16 mo period were enrolled. Before endoscopy patients were stratified according to a simple clinical score (T-score), including T1 (high-risk), T2 (intermediate-risk) and T3 (low-risk). Endoscopy was performed in all cases within 2 h, and high-risk stigmata were considered for further analysis.

**RESULTS:** Out of the 436 patients included into the study, 126 (29%) resulted to be T1, 135 (31%) T2, and 175 (40%) T3. Overall, stigmata of recent haemorrhage (SRH) were detected in 118 cases (27%). SRH occurred more frequently in T1 patients than in T2/T3 cases (85% vs 3.2%;  $\chi^2 = 304.5309$ ,  $P < 0.001$ ). Older age ( $t = 3.311$ ;  $P < 0.01$ ) and presence of comorbidities ( $\chi^2 = 14.7458$ ;  $P < 0.01$ ) were more frequently detected in T1 than in T2/T3 patients.

**CONCLUSION:** Our simplified clinical score appeared to be associated with the detection of endoscopic findings which may deserve urgent endoscopy. A further,

randomised study is needed to assess its accuracy in safely scheduling endoscopy in UGIB patients.

## INTRODUCTION

Acute upper gastrointestinal bleeding (UGIB) is a very common condition, with an estimated incidence as high as 40-150 cases per 100 000 annually<sup>[1-3]</sup>. Undeniably, UGIB is a dramatic event resulting in a high mortality rate, ranging from 0.9% to 26.5%<sup>[1-4]</sup>. Moreover, it leads to 50-150 hospitalizations per 100 000 adults each year<sup>[5]</sup>. Upper gastrointestinal endoscopy plays a pivotal role in the diagnosis and therapy of these patients, reducing mortality, rebleeding, requirement for transfusion, hospital stay and health care costs<sup>[6-9]</sup>. Endoscopic haemostasis has been shown to be effective in most of the causes of UGIB, such as peptic ulcer, gastro-oesophageal varices and Mallory-Weiss lesions<sup>[8,10,11]</sup>. For this reason, urgent endoscopy is routinely provided by several hospitals both in Europe and United States. Moreover, the absence of stigmata of recent haemorrhage (SRH), such as an adherent clot or an arterial bleeding, may prompt an early discharge of the patients, resulting in substantial healthcare savings<sup>[12]</sup>. Furthermore, several scoring systems, based on clinical-

endoscopic features, have been extrapolated in order to predict the risk of rebleeding and mortality<sup>[13-17]</sup>. Specifically, haemoglobin level, hemodynamic instability, and the presence of comorbidities have been shown to be clinical variables associated with a poorer outcome. Regarding timing of urgent endoscopy, it is widely accepted that it should be performed within 24 h from the admission<sup>[18]</sup>. However, within this period of time, it is still unclear whether it should be performed either very early-i.e. within 2 h- or in a more delayed interval, such as after 6, 12 or 24 h. In particular, some retrospective series did not show a clear advantage for early versus delayed urgent endoscopy<sup>[19-22]</sup>. However, in clinical practice, the endoscopist may be expected to be called by the emergency department immediately after the hospital admission of the bleeding patient, making it his responsibility to proceed towards an immediate procedure or delaying it up to 12 or 24 h. Legal aspects are clearly entailed in this decisional process, so that, in the absence of clear data, endoscopists may be expected to rush in the endoscopic units, even in low-risk cases. This may be particularly troublesome in large hospitals in which the specialist may be repeatedly called during the night or on non-working days. Moreover, due to lack of clinical evidence, administrative parameters have been shown to be important predictors of the timing to endoscopy in UGIB, dangerously exposing similar patients to different outcomes according to the referral hospital. Therefore, optimal timing for urgent endoscopy in UGIB patients has not been yet established. The aim of this prospective study was to evaluate whether a simplified clinical score prior to endoscopy in UGIB patients was able to predict either active bleeding or SRH that may require an urgent (< 2 h) endoscopy.

## MATERIALS AND METHODS

All consecutive patients referred to a single Endoscopic Unit because of an episode of UGIB during a 16 mo period were enrolled. The Endoscopic Unit belongs to a large hospital in which the physicians are urged to contact the gastroenterologist on call when patients present with an UGIB. For the purpose of the study, urgent endoscopy was always performed within 2 h from the referral. Before the procedure, patients were stratified by the endoscopists according to 4 easily assessable clinical variables, already validated in the UGIB setting: (1) general conditions (poor, intermediate, good), (2) pulse (< 90 beats/min, 90-110 beats/min, > 110 beats/min), (3) systolic blood pressure (< 90 mmHg, 90-110 mmHg, > 110 mmHg), and haemoglobin level ( $\leq 8$  g/dL, 9-10 g/dL, > 10 g/dL)<sup>[13-15]</sup>. General conditions were intended as a measure of the risk of an impending shock or the presence of symptomatic comorbidities (cardiovascular, hepatic, nephropathic, diabetes, malignancy). In detail, “poor condition” included patients with impending shock or with  $\geq 3$  comorbidities, “good condition” included patients with no debilitation and without postural hypotension and  $\leq 1$  comorbidity, and “intermediate condition” those

**Table 1** Numerical values for each parameter of the clinical index adopted in the study

Clinical parameter	Score		
	1	2	3
General conditions	Poor	Intermediate	Good
Pulse (beats/min)	> 110	90-110	< 90
Systolic blood pressure (mmHg)	< 90	90-110	> 110
Haemoglobin levels (g/dL)	$\leq 8$	9-10	> 10

The T-score is the sum of the corresponding values for the 4 parameters. In detail, a sum  $\leq 6$  corresponds to T1 (high-risk), 7-9 to T2 (intermediate-risk), and a cumulative value  $\geq 10$  to T3 (low-risk).

patients with conditions in the middle. As shown in Table 1, a numerical score was created for each of these parameters, the sum of all the parameters resulting in the total score (T-score) for each patient who was thereafter classified according to arbitrarily defined T-score cut-off in 3 categories. In detail, a sum  $\leq 6$  corresponds to T1 (high-risk), a sum of 7-9 to T2 (intermediate-risk), and a cumulative value  $\geq 10$  to T3 (low-risk). Further clinical information were collected for data analysis. Validity of such a classification was tested according to the presence of SRH at endoscopy. In detail, SRH was defined as an adherent clot, a bleeding (oozing or spurting) or nonbleeding visible vessel<sup>[23]</sup>, or gastro-oesophageal varices with active or recent signs of bleeding, such as a fibrin clot. All patients gave their informed consent prior endoscopic examination.

## Statistical analysis

Data analysis was performed by using Chi-square and Student's *t*-test as appropriate, and *P* < 0.05 was considered statistically significant.

## RESULTS

Overall, 436 patients (270 males, 166 females; Mean age:  $65 \pm 13$  years) were included in the study. Regarding the setting, 126 (29%) patients were already hospitalized before the UGIB, whilst the remaining 310 (71%) had been admitted by the emergency department because of the UGIB. Major comorbidities were present in 157 patients (36%). In detail, a cardiac disease was present in 78 (18%) patients, a hepatic disease in 61 (14%) cases, a clotting impairment in 9 (2%) cases, whilst renal or neurological comorbidities were detected in the remaining 9 (2%) cases. The mean time between the request to the endoscopic unit and the performance of the urgent endoscopy was  $1.6 \pm 0.47$  h. No death occurred before or during the endoscopic procedure itself. The main endoscopic findings are provided in Table 2. In detail, SRH were detected in 118 cases (27%), prompting an immediate endoscopic haemostasis in 105 (89%) of these cases. When classifying patients according to T-score, 126 (29%) resulted to be T1, 135 (31%) T2, and 175 (40%) T3. A SRH was detected at endoscopy in 107 (85%) T1-cases. In detail, an active bleeding (oozing or spurting) was reported in 34 (32%) T1-patients, a nonbleeding visible vessel/adherent clot was described

**Table 2 Endoscopic findings and SRH detected in the study population**

	<b>Number of patients (%)</b>
Endoscopic finding	436 cases
Duodenal ulcer	144 (33)
Gastric ulcer	74 (17)
Gastro-oesophageal varices	52 (12)
Erosive esophagitis	44 (10)
Malignancy	35 (8)
Erosive gastritis/duodenitis	80 (18)
Mallory-Weiss syndrome	7 (2)
SRH	118 cases
Active bleeding	37 (31)
Nonbleeding visible vessel	16 (14)
Adherent clot	40 (34)
Gastro-oesophageal varices with active or recent signs of bleeding	25 (21)

in 50 (47%) cases, and gastro-oesophageal varices with active or recent signs of bleeding in 24 (22%) patients. As far as T2-patients are concerned, only in 7 (5%) cases a SRH was detected, being an active bleeding in 2 cases, a nonbleeding visible vessel/adherent clot in 4 cases, and gastro-oesophageal varices in 1. Regarding the 175 patients classified as T3, a SRH was found at endoscopy only in 3 (2%) cases, being a nonbleeding visible vessel/adherent clot in 2 patients and an oozing bleeding in 1 case. When comparing the rate of SRH in T1 patients (85%) with that identified in T2 (5%) and/or T3 (2%), a significant difference emerged ( $P < 0.001$ ). Comparison of further demographic and clinical variables is provided in Table 3. As shown, patients classified as T1 were older ( $69 \text{ vs } 63$  and  $64$  years;  $t = 3.311$  and  $3.443$ , respectively;  $P < 0.01$ ) and more frequently had comorbidities ( $49\% \text{ vs } 20\%$  and  $31\%$ ;  $\chi^2 = 14.7458$  and  $13.4355$ , respectively;  $P < 0.01$ ) than T2 and T3 patient groups.

## DISCUSSION

UGIB incidence may be expected to increase as the proportion of elderly people in the population rises, because of the higher prevalence of gastroduodenal diseases in this subgroup of people<sup>[24]</sup>, particularly those NSAID associated<sup>[1,25]</sup>. Indeed, NSAIDs are widely used in clinical practice and they are the most relevant cause of UGIB<sup>[1,2,26]</sup>, and recent data suggested that even selective COX-2 inhibitors are not risk free<sup>[27]</sup>. Undeniably, UGIB has a relevant economic impact<sup>[28]</sup>. Therefore, optimizing an urgent endoscopy setting is of a paramount importance. Indeed, upper endoscopy plays a pivotal role in UGIB diagnosis and treatment<sup>[29]</sup>. However, although it is widely accepted that urgent endoscopy should be performed within 24 h, the best timing is still unclear<sup>[18]</sup>. In the present study, we evaluated whether a simplified clinical score prior to endoscopy in UGIB patients was able to predict either active bleeding or SRH that may require an urgent (< 2 h) endoscopy. Our data found that within 24 h, different timing of urgent endoscopy for UGIB may

**Table 3 Demographical and clinical characteristics of the UGIB patients according to T-score classes**

<b>Variable</b>	<b>T1 (n = 126)</b>	<b>T2 (n = 135)</b>	<b>T3 (n = 175)</b>	<b>P</b>
Mean age ± SD (yr)	$69 \pm 13$	$63 \pm 16$	$64 \pm 12$	$< 0.01^1$
Male sex (%)	66	62	60	NS
Comorbidities (%)	49	20	31	$< 0.01^1$
Systolic blood pressure (mmHg)	$85 \pm 15$	$106 \pm 22$	$139 \pm 37$	$< 0.01^2$
Hemoglobin level (g/dL)	$7.2 \pm 1.3$	$9.7 \pm 2.3$	$13.8 \pm 3$	$< 0.01^2$

<sup>1</sup>T1 vs T2 or T3; <sup>2</sup>T1 vs T2 or T3 and T2 vs T3.

be proposed. In particular, urgent endoscopy may provide a therapeutic resource for most of the patients in severe clinical conditions (T1 score), whilst it does not appear to be necessary in those patients with more favourable conditions (T2/T3 score). Although there was no evidence of a better clinical outcome-i.e. rebleeding and mortality-after a very early endoscopy in some retrospective series<sup>[19-22]</sup>, our study shows that endoscopic therapy is necessary in most of the clinically severe cases. Since an effective endoscopic haemostasis has been associated with a better outcome for both variceal and non-variceal UGIB<sup>[8,9]</sup>, it may be conservatively advised to perform a very early endoscopy, at least in patients in more severe conditions. Moreover, endoscopy may be also useful to stratify these compromised patients, since endoscopic SRH have been shown to predict the UGIB-associated morbidity and mortality<sup>[13]</sup>. On the other hand, our prospective study clearly shows that urgent endoscopy is useless in the vast majority of those patients in intermediate or good clinical conditions, which account for more than two thirds of all UGIB patients, since only a very few of them really gain some benefit from the endoscopic procedure. Due to the relatively stable clinical conditions, it is foreseeable that even in those few patients with SHR, a delay in the urgent endoscopy to 12 h, sufficient to postpone the endoscopy procedure from the night to the immediate following day endoscopic routine list, would have not changed the overall outcome. Our study suggests that the use of a simple clinical score may predict endoscopic SRH in UGIB patients. In particular, to our knowledge, this is the first time that a simple clinical score has been associated with endoscopic findings at urgent endoscopy in a prospective series. This points out that clinical parameters are not only useful in selecting those who may need an urgent endoscopy from those who may not, but also in selecting, among those who need it, those who need a very early procedure. On the other hand, upper endoscopy in T2/T3 score patients may be delayed until the next routine endoscopic list, in which a more suitable setting, i.e. either a more skilled endoscopist or a prolonged pre-endoscopic proton pump inhibitor therapy may result in a better outcome<sup>[29,30]</sup>. Importantly, no death occurred before endoscopy and in the endoscopic setting, supporting the safety of a very early endoscopy even in severe patients, although previous series described

higher cardiovascular complications as compared to more delayed procedures<sup>[21]</sup>. Although urgent endoscopy is usually defined as a within 24 h-procedure<sup>[18]</sup>, legal aspects may be raised against the on-call physician who prefers a delayed approach, when severe complications or even mortality associated to the UGIB episode occur before endoscopy. For this reason, endoscopists generally prefer to anticipate more than to delay an emergency procedure. We feel that our study allows an immediate and user-friendly clinical stratification, allowing less severe patients to be postponed until the next morning. Some limitations are entailed in the present study. In particular, we did not assess the rebleeding rate and the associated mortality in the post-endoscopic period. Nevertheless, SRH's have been shown to be intimately related with these outcomes, and may therefore be regarded as valid intermediate surrogates. However, further studies specifically addressing these end-points, namely rebleeding rate and associated mortality, are needed before proposing the use of such a pre-endoscopic score in clinical practice. In particular, we cannot exclude that even severe UGIB episodes may be only of marginal clinical interest in patients affected by severe comorbidities, such as renal failure. Moreover, it would be important to further validate in future studies our score with others already available in the literature. Secondly, we did not apply different timings (very early *versus* delayed) in T2/T3 patients. However, after these findings, we feel clinically meaningful to plan a further study in which different timings will be tailored according to clinical conditions. Thirdly, we may not exclude that if the urgent endoscopy had been performed later than 2 h, but still within 24 h, the rate of SRH would have been different. However, it is unlikely that such a wide difference between T1, on one side, and T2 and T3, on the other, would have been significantly affected. Fourthly, we applied our score also to oesophageal variceal bleeding. However, as soon as these patients are correctly diagnosed with the underlying liver disease, they should have a prompt endoscopy, irrespective of the severity of the bleeding.

In conclusion, our study shows that timing of urgent endoscopy following an episode of UGIB could be differentiated according to a simple score purely reflecting the clinical conditions of the patients. This would allow most of the patients with SRH to be effectively treated, whilst delaying most of the purely diagnostic procedures in low risk clinical patients. A future, randomized study is required to validate this clinical score.

## COMMENTS

### Background

Acute upper gastrointestinal bleeding (UGIB) is a very common condition, with an incidence of 40-150 cases per 100 000, resulting in high hospitalization and mortality rates. Upper gastrointestinal endoscopy plays a major role in the diagnosis and therapy of these patients, reducing mortality, rebleeding, requirement for transfusion, hospital stay and health care costs. It is widely accepted that urgent endoscopy for UGIB should be performed within 24 h from the admission. However, within this period of time, it is still unclear whether

it should be performed either very early, i.e. within 2 h, or in a more delayed interval, such as after 6, 12 or 24 h. Therefore, optimal timing for urgent endoscopy in UGIB patients has not been yet established.

### Research frontiers

A simple clinical score prior to endoscopy, purely based on general conditions, pulse and haemoglobin level, was strongly associated with the detection of active bleeding or stigmata of recent hemorrhage. When classifying 436 patients according to this score (T-score), active bleeding or signs of recent hemorrhage was detected in 85% of T1 (most severe) patients and only in 5% and 2% of those T2/T3 (less severe), respectively.

### Innovations and breakthroughs

This study shows that timing of urgent endoscopy following an episode of UGIB may be differentiated according to a simple score purely reflecting the clinical conditions of the patients. This would allow most of the high-risk patients to be effectively treated, whilst delaying most of the purely diagnostic procedures in low risk clinical patients. A future, randomized study is required to validate this clinical score.

### Peer review

This is an interesting study that attempts to stratify the urgency for upper GI endoscopy in a patient presenting with acute bleeding. The choice of the "clinical" parameters and the cut-off values chosen are empiric.

"bowel disease group" were finally diagnosed as Crohn's disease or nonspecific colonic ulcers during long-term follow up.

**CONCLUSION:** Follow-up colonoscopy shows a healing stage ulcer or scarring change without an active ulcer with just 2 mo to 3 mo of medication in patients with tuberculous colitis. Colonoscopy follow-up after short term anti-tuberculosis trial in patients with nonspecific ulcers on the ileocecal area is valuable in making early differential diagnosis of tuberculous colitis.

### Abstract

**AIM:** To evaluate the efficacy of colonoscopy follow-up after short-term anti-tuberculosis treatment in patients with nonspecific ulcers on ileocecal areas being suspicious of tuberculous colitis.

**METHODS:** We prospectively analyzed the colonoscopic findings before and after short term anti-tuberculosis treatment in 18 patients with nonspecific ulcers on the ileocecal area and compared them with 7 patients of confirmed tuberculous colitis by acid-fast bacilli or caseating granuloma on colonic biopsy.

**RESULTS:** Mean duration for short-term follow-up was 107.3 d with combined chemotherapy containing isoniazid, rifampicin, ethambutol and pyrazinamide. Seven patients with tuberculous colitis showed complete healing of active ulcers after short-term medication. After short-term anti-tuberculosis treatment, follow-up colonoscopy findings divided 18 patients with nonspecific ulcers into two groups by ulcer state. One is the "suspicious tuberculous colitis group" showing healing of ulcers and erosions and another is the "suspicious inflammatory bowel disease group" showing active ulcers with or without aggravation of the lesion. Finally, all 9 of the "suspicious tuberculous colitis group" were diagnosed as tuberculous colitis showing no recurrence of ulcers after termination of 9 mo of anti-tuberculosis medication. Patients of the "suspicious inflammatory

### INTRODUCTION

Worldwide incidence of abdominal tuberculosis has been steadily increasing for the past 20 years<sup>[1-4]</sup>, and 2%-3% of reported patients with abdominal tuberculosis have isolated colonic involvement<sup>[5]</sup>. Particularly in Asia, pulmonary and extrapulmonary tuberculosis have been rare until now. Although both the incidence and prevalence rates of inflammatory bowel disease (IBD) are still relatively low compared to Europe and North America, they are increasing rapidly in many Asian countries, including Korea<sup>[6]</sup>.

Difficult colonoscopic differentiation between tuberculous colitis and Crohn's colitis is caused when both entities can present themselves with mucosal ulcerations and nodularity, aphthous ulcers, edematous mucosal folds, strictures, pseudopolyps and luminal narrowing on the ileocecal area<sup>[7]</sup>.

Although caseating granulomas and acid-fast bacilli

make it easy to differentiate the disease entity, many nonspecific ulcers on the ileocecal area in patients with chronic diarrhea and right lower quadrant pain do not provide confirmative diagnosis between tuberculous colitis and other inflammatory bowel diseases.

Therapeutic trial of anti-tuberculosis treatment has been accepted in the case of high clinical suspicion of tuberculosis, which should be continued if there is a good clinical response<sup>[8]</sup>. Sometimes clinical response is not correlated with disease itself. Generally 9 mo to 12 mo of anti-tuberculous medication is necessary for tuberculous colitis. In patients with IBD, disease will be more aggravated during that long-term therapeutic trial. The clinician needs a diagnostic tool confirming tuberculous colitis as early as possible. The precise colonoscopic features after 2 mo to 3 mo of short-term medication in patients with either tuberculous colitis or suspicious tuberculous colitis have not been documented. Thus, we prospectively evaluated the colonoscopic findings after short-term anti-tuberculosis treatment both in patients with nonspecific ulcers on the ileocecal area and in patients with confirmed tuberculous colitis.

## MATERIALS AND METHODS

### **Patients**

This prospective case-control study was conducted at the Medical Center of Eulji University, from March 2002 to October 2004. Eighteen patients (6 males and 12 females) with chronic diarrhea or right lower abdominal discomfort and showing nonspecific ulcers on the ileocecal area on initial colonoscopy were enrolled. The definition of nonspecific ulcer in this study is colonic ulcer with chronic active inflammation without caseating granuloma on biopsy. As a control, we evaluated colonoscopic features of 7 patients with tuberculous colitis who had either acid-fast bacilli or caseating granuloma on colonic biopsy combined with active pulmonary tuberculosis.

Patients with less than 3 wk of symptoms combined with perianal lesion or skip lesion on either the left side of the colon or proximal small bowel were excluded. Stool exam and culture studies were performed to exclude any parasites and bacterial infection. The anti-tuberculosis medication trial proceeded after full and informed consent was granted by each patient.

### **Methods**

One expert colonoscopist, with more than 10 years experience, performed the colonoscopies throughout this study. Colonoscopy was performed with videocolonoscopes (CF240L, Olympus, Japan) after 4 L polyethylene glycol preparation. The whole colon from rectum to cecal base and terminal ileum was photographed for comparison. Chest X-ray and small bowel double-contrast barium study were performed before medication for evaluation of small bowel lesion and pulmonary lesion. During anti-tuberculosis medication, liver function test results, clinical symptoms and follow-up chest X-ray were regularly evaluated.

To determine the patient's susceptibility to drug, we regularly evaluated the tolerance, upper GI symptoms and allergic symptoms relating to medication on outpatient care. "Very good" meant "no complaints during medication; no side effects", "good" meant "some complaints after taking medication", "poor" meant "difficulty in taking medication" due to GI trouble or side effects.

The regimen for tuberculosis was combined chemotherapy containing isoniazid, rifampicin, ethambutol and pyrazinamide.

### **Study design**

The follow-up colonoscopy was performed after 2-3 mo of anti-tuberculosis medication on all enrolled patients by the aforementioned colonoscopist, and some of the features evaluated were ulcer shape, number and location. Compared with colonoscopic features of patients with tuberculous colitis, we subdivided the patients with nonspecific ulcers into either a "suspicious tuberculous colitis group" or "suspicious inflammatory bowel disease (IBD) group". If there were healing of active ulcers similar to tuberculous colitis on follow-up colonoscopy findings, the patients were classified as "suspicious tuberculous colitis group", and if there were still active ulcers or extension of the lesion, classified as "suspicious IBD group". Finally, we confirmed tuberculous colitis by complete resolution of the whole lesion and clinical symptoms after 10 mo of anti-tuberculosis treatment in the "suspicious tuberculous colitis group". For the "suspicious IBD group", we stopped anti-tuberculosis treatment after a short-term trial and reevaluated.

The human subject committee of our hospital approved this study.

### **Statistical analysis**

Kruskal-Wallis tests (three groups) were used for intergroup comparison of continuous variables, whereas Fisher exact tests were used to compare the categorical variables. Continuous variables are summarized as median  $\pm$  SD, whereas categorical variables are summarized as counts or percentages. Statistical analysis was performed with SPSS 11.0 software.

## RESULTS

### **Clinical findings**

All enrolled patients were performed follow-up colonoscopy after short-term anti-tuberculosis treatment. The mean duration of the trial was 107.3 (62-120) d.

Clinical features for enrolled patients are summarized in Table 1. The median age of patients in the "suspicious IBD group" was younger than patients in the "tuberculous colitis group" or "suspicious tuberculous colitis group". Active lesion or old pulmonary lesion on chest X-ray was significant in helping the diagnosis of tuberculous colitis ( $P < 0.001$ ). On laboratory findings, there are no specific differences between groups.

NS: Not significant. <sup>1</sup>Significant at P < 0.05 by Fisher's exact test.

Serologic results of patients with nonspecific ulcers are not so helpful in diagnosis. On small bowel study, there are no significant differences between groups. All of the enrolled patients had no ano-rectal symptoms or any other Upper GI tract lesion.

### Colonoscopy findings

Initial Colonoscopy findings before anti-tuberculosis medication are summarized in Table 2. Ulcers were located at the ileocecal valve, cecum, proximal ascending colon and terminal ileum in both groups. There were no rectal and perianal lesion in enrolled patients initially. Ulcers showed geographic, irregular shape and sometimes-transverse array. Significantly, aphthous

NS: Not significant. <sup>1</sup>Significant at P < 0.05 by Fisher's exact test.

ulcers were common in the "suspicious IBD group" (P = 0.01). About 30% of patients in each group showed non-caseating granuloma on biopsy. Acid-fast bacilli were noted in only 3 patients of tuberculous colitis even though this is definite evidence of tuberculosis infection.

The follow-up colonoscopy features are summarized in Table 3. After short-term anti-tuberculosis medication, there are only scarring and inflammatory polyps remained in patients with tuberculous colitis (Figure 1).

Nine of 18 patients with nonspecific ulcers also showed dramatic response after short-term trial similar to patients with tuberculous colitis presenting no active ulcer or erosions, irrespective of initial lesion (Figure 2, P < 0.001). We regarded them as the "suspicious tuberculous colitis group" and maintained anti-tuberculosis treatment for 10 mo.

The extent of lesion and stenosis in "tuberculous colitis" and "suspicious" groups were also improved, except in one patient of the "suspicious tuberculous colitis group" who underwent ileocectomy due to obstruction during short-term anti-tuberculosis treatment.

Another 9 patients of nonspecific ulcers who showed active ulcers remaining and sometimes more aggravated after trial (P < 0.001) were regarded as the "suspicious IBD group".

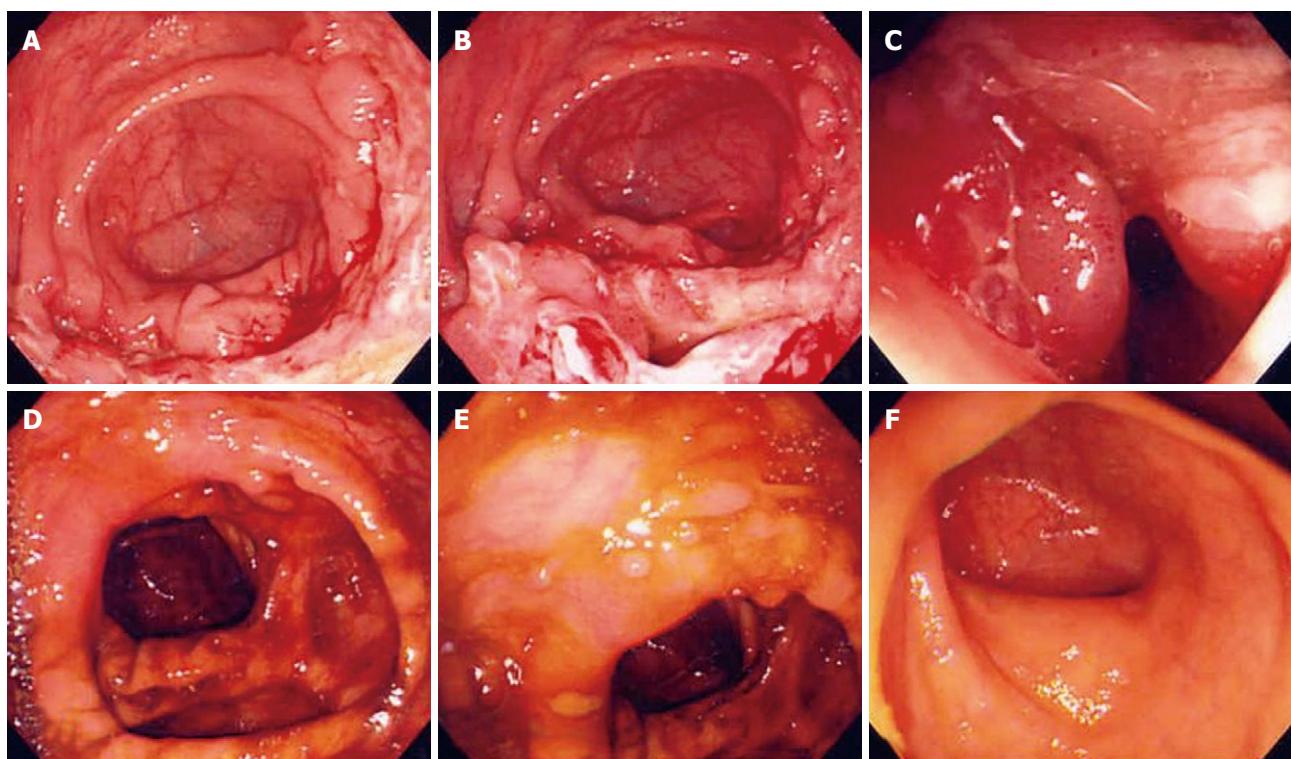

Some patients of the "suspicious IBD group" showed an expansion of the extent of involved colon with aggravation of stenosis (Figures 3 and 4).

### Feasibility of anti-tuberculosis treatment

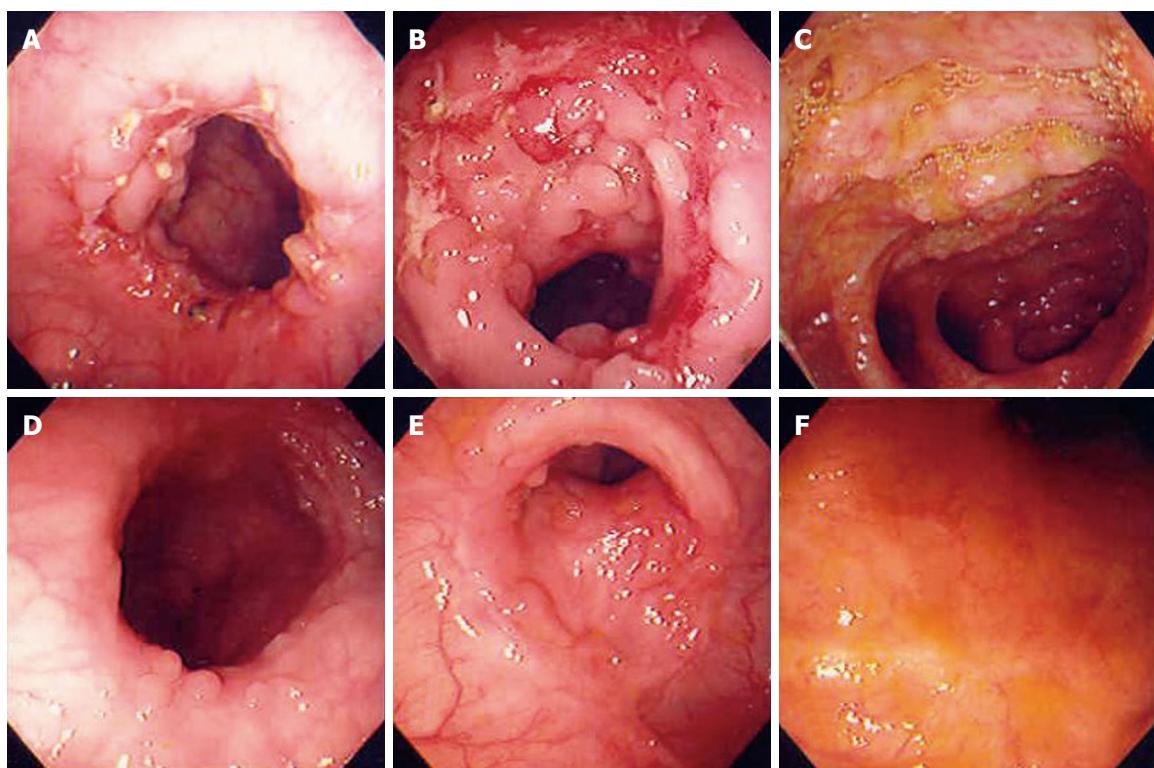

Most of the patients in the "suspicious tuberculous colitis group" showed good tolerance of anti-tuberculosis treatment during the trial, some of the patients in the "suspicious IBD group" showed poor tolerance of anti-tuberculosis treatment (P = 0.01, Table 3). But more than half of the "suspicious IBD group" also showed good toleration and mild symptomatic improvement in spite of aggravating colonoscopic findings.

### Clinical outcome

The 9 patients of the "suspicious tuberculous colitis

**Figure 1** Colonoscopy findings before (A-C) and after (D-F) anti-tuberculosis medication in a 30-year-old male patient with tuberculous colitis on the ileocecal valve which shows acid-fast bacilli on biopsy. After medication, scar and inflammatory polyps were noted.

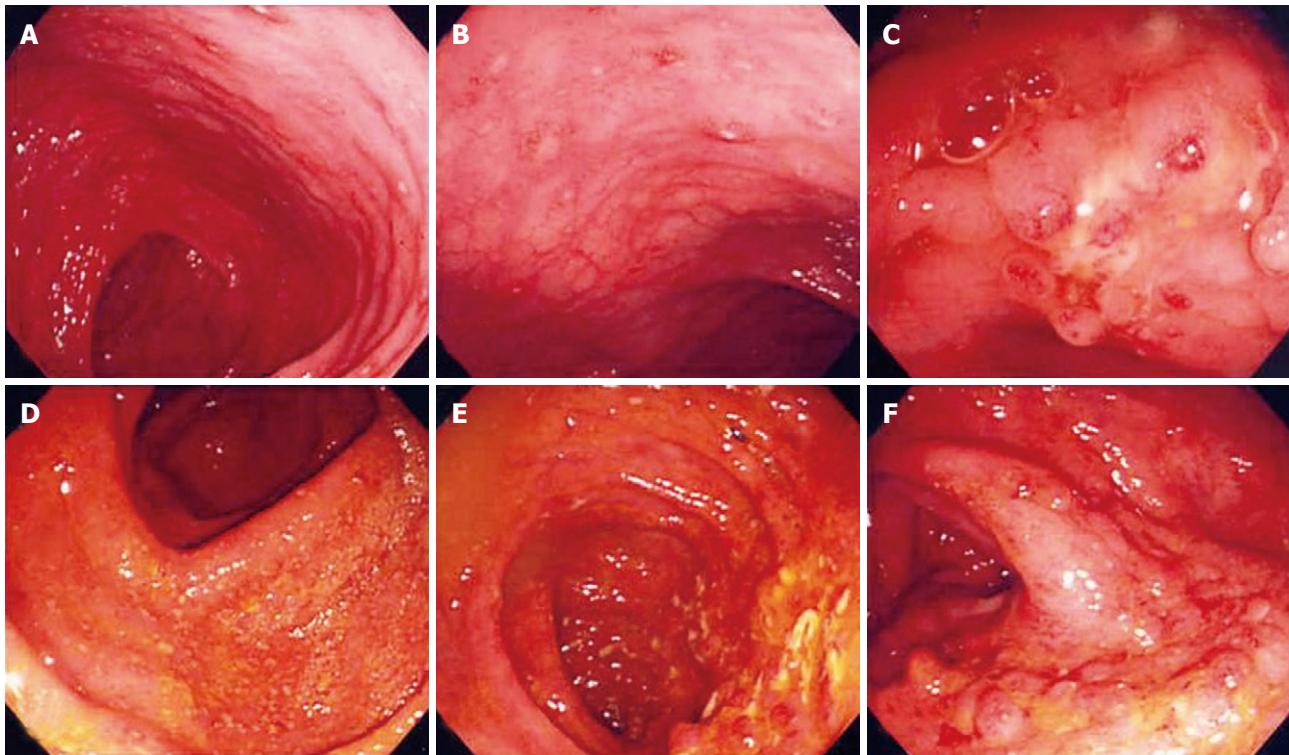

**Figure 2** Colonoscopy findings before (A-C) and after (D-F) anti-tuberculosis treatment in a 37-year-old female patient. It showed transverse arrayed geographic ulcers on ileocecal valve with granuloma on biopsy and presented nodularity on terminal ileum. After medication, only healing stage ulcers were left. We classified this case as "suspicious tuberculous colitis group".

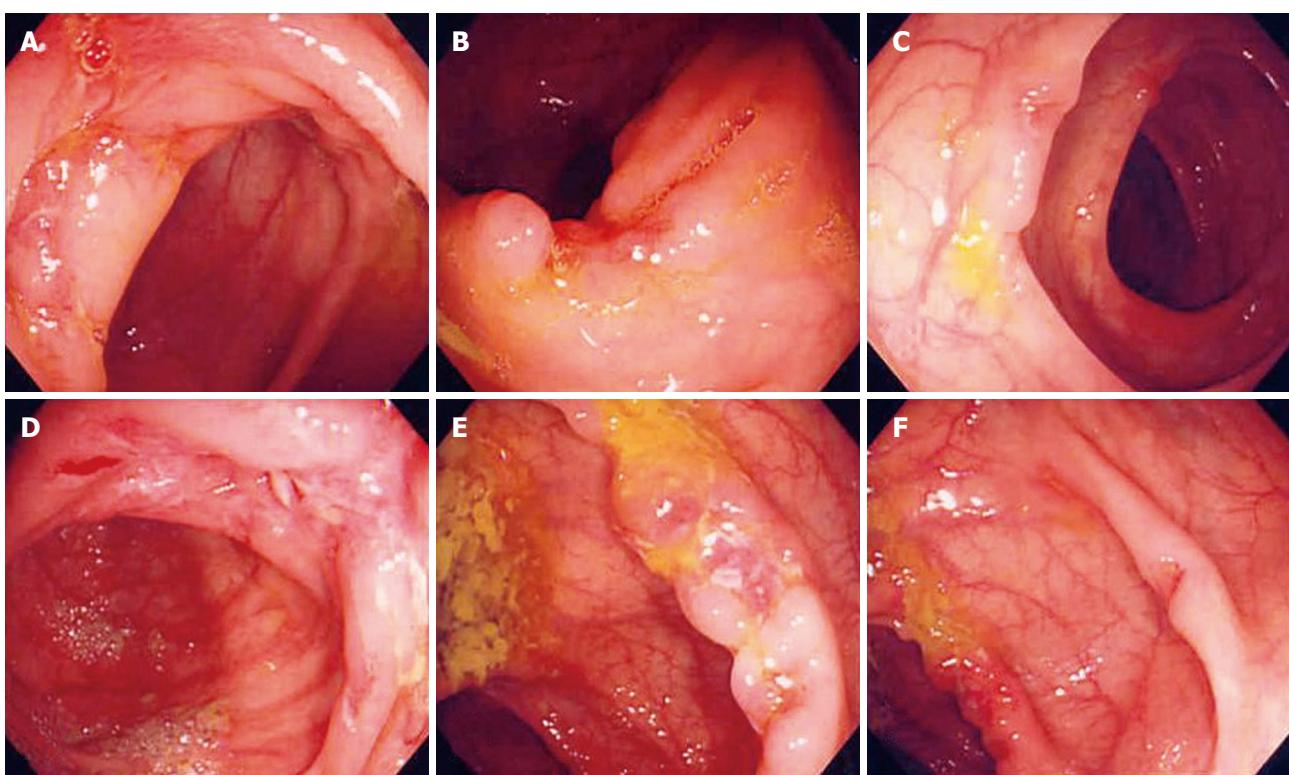

group" showed weight gain and general improvement in well being along with complete resolution of the whole lesion and GI symptoms after 10-mo of anti-

tuberculosis treatment. They were therefore finally confirmed as tuberculous colitis.

The 9 patients in the "suspicious IBD group" who had

**Figure 3** Colonoscopy findings before (A-C) and after (D-F) anti-tuberculosis treatment in a 23-year-old male patient with aphthous ulcers on the proximal ascending colon. After medication it shows aggravating active ulcers and extension of the lesion. We classified this case as the “suspicious IBD group”.

**Figure 4** Colonoscopy findings before (A-C) and after (D-F) anti-tuberculosis medication in a 39-year-old female patient with irregular ulcers on the ileocecal valve and proximal AC. After medication, it showed active ulcers and extension. We classified this case as “suspicious IBD group” and performed mesalazine trial. The patient showed no response to all the medical trials, so we confirmed this case as the “nonspecific colonic ulcers” by surgery.

active ulcers on follow-up colonoscopy were reevaluated; a second biopsy was performed and withdrawn from the anti-tuberculosis treatment trial. They were switched

to mesalazine and/or corticosteroid for inflammatory bowel disease. The new medication was well-tolerated and showed slow clinical improvement by 8 of the “suspicious

**Table 4** Final diagnosis of the patients of “suspicious inflammatory bowel disease group”

Patient	Response	Other manifestation during follow-up	Final Dx
#1 F/32	Response to mesalazine		CD
#2 F/15	Response to steroid	perianal abscess after 2 years	CD
#3 F/20	Response to mesalazine		CD
#4 F/39	No response to mesalazine, active ulcer and symptoms	hemicolectomy	Non-specific ulcers
#5 M/24	Response to mesalazine		CD
#6 M/42	Response to steroid		CD
#7 M/16	Response to mesalazine	Ileocectomy due to ileal perforation after 2 years	CD
#8 F/27	Response to mesalazine	perianal fistula after 2 years	CD
#9 M/26	Response to steroid	perianal abscess after 1 year	CD

IBD group”. However, 1 patient of the “suspicious IBD group” complained of sustained symptoms and weight loss and his 3rd colonoscopy showed more aggravation of lesions, chronic inflammation was found on repeated biopsy. After a 6-mo trial of mesalazine which did not show improvement, it was decided to perform a right hemicolectomy for confirmative diagnosis and treatment (Figure 4). The surgical specimen showed diffuse chronic ulcers on the ileocecal valve and ascending colon with neither granuloma nor any other malignant cells. After operation, the patient was observed for 2 years without further GI problems. During the 2 years of follow-up, 8 patients of the “suspicious IBD group” were improved in diarrhea, abdominal pain and colonic lesion, but 3 patients developed anal problems, and 1 patient underwent an operation due to ileal perforation. Finally 8 patients of the “suspicious IBD group” were diagnosed as Crohn’s disease, one patient as nonspecific simple colonic ulcers after a right hemicolectomy (Table 4).

## DISCUSSION

The Asian Pacific region was previously designated as a low incidence area of IBD, but this could be due to lack of solid population-based studies, low diagnostic awareness, and high incidence of intestinal infections. Current literature and recent information leave no doubt that a true increase of IBD is occurring throughout this region<sup>[9]</sup>. By contrast, the incidence of tuberculosis is rising, both in the United States of America as well as in the United Kingdom<sup>[3,10,11]</sup>. Following the resurgence of tuberculosis, two series of patients with abdominal tuberculosis were recently published in the United States<sup>[12,13]</sup>.

Thus, each side of the world is having to face the task of differentiating between the two diseases, Crohn’s disease and tuberculous colitis, which are similar in both clinical features and colonoscopy findings. In spite of similar clinical findings, the ultimate natural history of the two diseases is different. Appropriate anti-tuberculosis treatment leads in most cases of tuberculous ileocolitis to complete cure, whereas Crohn’s disease is a progressive relapsing illness unaffected by anti-tuberculosis treatment.

In tuberculous colitis, the cecum, Ileocecal valve and terminal ileum are commonly affected sites<sup>[14-17]</sup>, and are also the most common sites of Crohn’s disease. In all

areas of the world where Tuberculosis is endemic high-risk patients in developed countries need differentiation of the two diseases as early as possible.

Typical colonoscopy features described in patients with tuberculous colitis are transverse or linear ulcers, nodules, a deformed ileocecal valve and cecum, presence of inflammatory polyps, and multiple fibrous bands arranged in a haphazard fashion<sup>[14-16,18]</sup>. By contrast, typical Crohn’s disease shows segmental longitudinal ulcers with a cobble stone appearance, stricture, perianal lesion and pseudo polyps<sup>[19]</sup>. In clinical practice, however, nonspecific ulcers on ileocecal valve and cecum without typical features are often seen.

Biopsy during colonoscopy helps in the diagnosis of nonspecific ulcers in the ileocecal area. Caseating granulomas and/or acid-fast bacilli are present only in a small proportion of patients with tuberculous colitis<sup>[20]</sup>. Granulomas, with or without caseation, are usually seen in less than 50% of patients with tuberculous colitis<sup>[3,15,16]</sup>, while clusters of epithelioid cells without well formed granulomas have been reported to occur in 20%-30% of the biopsies obtained<sup>[15,16]</sup>. Our study shows non-caseating granuloma is not significant to the differential diagnosis of tuberculous colitis from Crohn’s colitis.

Acid-fast bacilli have been reported in 50%-100% of specimens from patients with tuberculous colitis<sup>[21-24]</sup>, but there are several reports where acid-fast bacilli could not be detected on histological examination of the biopsy material<sup>[14-16,18,25]</sup>. Acid-fast bacilli were seen in only 3 specimens (21.7%) in our cases. Thus, in a considerable number of tuberculous colitis the biopsies have features of chronic inflammation but no granulomas, caseation or clusters of epithelioid cells<sup>[15,16]</sup>. Culture of the biopsy material may increase the diagnostic yield<sup>[3]</sup>. However, disappointing results with 0% detection of acid-fast bacilli have also been reported<sup>[16]</sup>. Polymerase chain action analyses of biopsy specimens obtained endoscopically has been shown to be more sensitive than culture and acid-fast stains in diagnosing tuberculous colitis<sup>[26]</sup>. Other studies have suggested that an enzyme-linked immunosorbent assay using mycobacterial saline-extracted antigen may increase the yield of correct diagnosis of colonic tuberculosis<sup>[27]</sup>. The symptoms of tuberculous colitis such as chronic diarrhea, RLQ discomfort, and malaise are non-specific. But chest radiographs showing evidence of

active or healed pulmonary infection may be a clue to diagnosis<sup>[15,16,28]</sup>, in our cases, 70% of tuberculous colitis and 33% of suspicious tuberculous colitis cases showed active pulmonary tuberculosis and old scar in 22% of suspicious cases. By contrast, none of the patients of the “suspicious IBD group” showed abnormal chest radiographs ( $P < 0.001$ ).

In clinical practice, therefore, nonspecific ulcers on the ileocecal valve and cecum without any other clue for specific diagnosis are often seen. Efforts to exclude other infection including amoeboma, *Yersinia* infection, GI histoplasmosis, and periappendiceal abscess must be considered<sup>[3]</sup>. If the clinical and colonoscopy features are suggestive of tuberculous colitis and multiple target biopsies do not show evidence of any other disease, then a therapeutic trial of anti-tuberculosis treatment can safely be given to these patients<sup>[29]</sup>. Clinical response to the anti-tuberculosis treatment is usually dramatic and less than 1-year treatment is sufficient for patients with tuberculous colitis compared to life long treatment for inflammatory bowel disease.

The recommended regimen for pulmonary tuberculosis is combined chemotherapy containing isoniazid, rifampicin, ethambutol and pyrazinamide during 9 mo<sup>[30]</sup>. But the exact duration of anti-tuberculosis treatment for tuberculous colitis is not yet established due to difficulties in bacteriological diagnosis and the assessment of response to therapy. As a result, extra-pulmonary tuberculosis has been treated for 12 mo to 24 mo on the basis of warnings of disease recurrence without supportive data. Recent study has shown tuberculosis enterocolitis can be treated with 9 mo of chemotherapy without disease recurrence<sup>[29]</sup>. Our study showed that 10 mo of 4 regimens of chemotherapy were adequate for patients with tuberculous colitis combined with or without pulmonary tuberculosis.

How long a period will be adequate for an empirical trial of undetermined patients? Generally, 2 mo to 3 mo are accepted as adequate for trials based on clinical response. However, the colonoscopy findings are not reported after a 2-mo to 3-mo trial. As our study shows, active ulcers and erosions are completely healed after 2 mo to 3 mo of medication and only leave scarring and inflammatory polyps in all patients with tuberculous colitis and suspicious tuberculous colitis. That means a 2-mo to 3-mo trial of anti-tuberculosis treatment and colonoscopy follow-up are very useful for differential diagnosis of tuberculous colitis with other inflammatory bowel diseases. It is an exciting result that some patients with suspicious tuberculous colitis, who showed no active ulcer and significant resolution on follow-up colonoscopy without any other specific clue for tuberculosis, were also confirmed as tuberculous colitis after 10-mo medication. Likewise, every patient of the “suspicious IBD group” who showed no response to a short-term trial was ultimately confirmed as Crohn’s disease or non-specific ulcer. This study also showed that, in patients with suspicious inflammatory bowel disease, a 2-mo to 3-mo trial was sufficient to exclude tuberculous colitis and adequate medication for

inflammatory bowel disease could be started based on the trial.

Clinical response of symptoms and tolerance to anti-tuberculosis treatment was also important during the trial. In our study, most patients of the “suspicious tuberculous colitis group” tolerated medication well. About 45% of patients in the “suspicious IBD group” showed poor tolerance. But half also showed good tolerance to anti-tuberculosis treatment and mild clinical response during the trial too. Thus, during the anti-tuberculosis treatment trial, the physician’s concern for a patient’s tolerance to drug and clinical improvement is helpful but not definitive to decide maintaining anti-tuberculous treatment. We conclude that in cases of a therapeutic trial on nonspecific ulcers of the ileocecal area, 2 mo to 3 mo of anti-tuberculous medication and colonoscopy follow-up are valuable for making early confirmatory diagnosis.

## COMMENTS

### Background

Differentiation between tuberculous colitis and Crohn’s colitis can be difficult due to nonspecific GI symptoms and similar colonoscopic findings. In Asia, pulmonary and extrapulmonary tuberculosis are not rare until now. Also, the incidence and prevalence rates of inflammatory bowel disease (IBD) are increasing rapidly in many Asian countries, including Korea.

### Research frontiers

There are efforts to differentiate two disease entities through colonoscopic findings. But some of them still could not be confirmed by initial colonoscopic findings. Short-term trial of anti-tuberculosis treatment is necessary before confirmative diagnosis of Crohn’s colitis in the endemic area of tuberculosis.

### Innovations and breakthroughs

The precise colonoscopic features after short-term medication in patients with either tuberculous colitis or suspicious tuberculous colitis have not been documented. This study was performed prospectively and showed that active ulcers and erosions were completely healed after 2-mo to 3-mo of medication and only leave scarring and inflammatory polyps in all patients with tuberculous colitis and suspicious tuberculous colitis. This study showed that, in patients with suspicious inflammatory bowel disease, a 2-mo to 3-mo trial and colonoscopic evaluation would be sufficient to exclude tuberculous colitis and adequate medication for inflammatory bowel disease to be started.

### Applications

We conclude that in cases of therapeutic trial on nonspecific ulcers on the ileocecal area, especially the endemic area of tuberculosis, 2 mo to 3 mo of anti-tuberculous medication and colonoscopy follow-up are valuable for making early confirmatory diagnosis. Duration of the therapeutic trial will be shortened after further clinical trial.

### Peer review

This study provides colonoscopic features after short term anti-tuberculosis medication in patients with tuberculosis colitis and other chronic inflammatory bowel disease.

## Abstract

**AIM:** To investigate whether hepatitis B virus (HBV) infection activates DNA damage response and DNA repair cofactors inhibit HBV infection and replication.

**METHODS:** Human hepatocyte cell line HL7702 was studied. Immunoblotting was performed to test the expression of ataxia telangiectasia-mutated (ATM)-Rad3-related protein (ATR), p21 and the level of phosphorylation of Chk1, p53, H2AX, ATM in HBV-infected or non-infected-cells. Special short RNAi oligos was transfected to induce transient ATR knockdown in HL7702. ATR-ATM chemical inhibitors caffeine (CF) and theophylline (TP), or Chk1 inhibitor 7-hydroxystaurosporine (UCN01) was studied to determine whether they suppress cellular DNA damage response and MG132 inhibits proteasome.

**RESULTS:** The ATR checkpoint pathway, responding to single-strand breaks in DNA, was activated in response to HBV infection. ATR knockdown cells decreased the HBV DNA yields, implying that HBV infection and replication could activate and exploit the activated DNA damage response. CF/TP or UCN01 reduced the HBV DNA yield by 70% and 80%, respectively. HBV abrogated the ATR-dependent DNA damage signaling pathway by degrading p21, and introduction of the p21 protein before HBV infection reduced the HBV DNA yield. Consistent with this result, p21 accumulation after MG132 treatment also sharply decreased the HBV

DNA yield.

**CONCLUSION:** HBV infection can be treated with therapeutic approaches targeting host cell proteins by inhibiting a cellular gene required for HBV replication or by restoring a response abrogated by HBV, thus providing a potential approach to the prevention and treatment of HBV infection.

## INTRODUCTION

Eukaryotic cells employ multiple strategies of checkpoint signaling and DNA repair mechanisms to monitor and repair damaged DNA. There are two branches in the checkpoint response pathway: ataxia telangiectasia-mutated (ATM) branch and ATM-Rad3-related (ATR) branch<sup>[1,2]</sup>. Many viruses are now known to interact with DNA damage sensing and repair machinery. These viruses have evolved tactics to eliminate, circumvent, or exploit various aspects of the DNA damage response to the host cells. Strategies include activation of repair proteins or targeting of specific cellular factors for degradation or mislocalization<sup>[3-6]</sup>. It is necessary to examine the DNA damage pathway activated by viral replication for generation of antiviral drugs. In human immunodeficiency virus (HIV), it has been clearly determined that prevention of viral integration inhibits viral replication and promotes cellular apoptosis. The ATM-specific inhibitor ku55933 can inhibit HIV replication in primary T cells<sup>[7]</sup>.

Although a safe and efficient vaccine is available at present, chronic hepatitis B virus (HBV) infection

remains a major health problem worldwide. Interferon treatment is effective in only approximately one-third of the patients and produces considerable side effects. Long-term treatment with the second-generation of nucleoside analogue lamivudine (lam) efficiently inhibits HBV replication with frequent viral polymerase mutations. We found that HBV infection could trigger ATR-dependent DNA damage response, resulting in increased ATR and Chk1 phosphorylation levels. However, ATR checkpoint signaling is blocked downstream of the p53-dependent pathway to evade apoptosis by degrading p21. We designed a strategy to select new drug targets that inhibit a cellular gene required for HBV replication or restore a response stalled by HBV in the ATR DNA damage pathway.

The ATM and ATR kinases are targets of a known inhibitor, caffeine (CF), of DNA damage response. CF has shown to inhibit the activity of these kinases *in vitro* and the response to cellular DNA damage controlled by ATM and ATR. Theophylline (TP) is a product of CF metabolism *in vivo* and has been clinically used in treatment of asthma. It has also been demonstrated that TP exhibits CF-like effects on DNA damage response<sup>[8]</sup>.

Originally developed as a protein kinase C (PKC) inhibitor, 7-hydroxystaurosporine (UCN-01) has been subsequently shown to inhibit several other cell survival/cell cycle regulatory proteins, including Chk1 and 3-phosphoinositide-dependent protein kinase-1 (PDK1)/protein kinase B (Akt). By inhibiting Chk1, UCN-01 blocks the proteasome degradation of the cdc25C phosphatase, resulting in dephosphorylation (activation) of p34<sup>cdc2</sup>. In this way, UCN-01 functions as a checkpoint abrogator that potentiates the lethal effects of several DNA-damaging agents, including ara-C18 and camptothecin<sup>[9,10]</sup>.

Proteasome, a multicatalytic enzyme complex, controls the regulation (by means of degradation) of many proteins involved in cell cycle arrest and apoptosis. The proteasome inhibitor MG132 can restore wild-type (WT) p53 levels reduced by E6 and sensitize HPV-positive cervical cancer cell lines to apoptotic stimuli such as rhTRAIL. It was also reported that MG132 could inhibit HSV replication by preventing HSV-1-induced NF-κB activation<sup>[11,12]</sup>.

In this paper, we report that HBV infection activates and exploits DNA damage response to replication stress. We investigated whether inhibition of DNA damage response by CF, TP and UCN01 or restoration of p21 expression by p21 transfection or proteasome inhibition leads to suppression of HBV replication. We set up a chronic HBV infection model by culturing HL7702 liver cells with HBV-positive serum without washing off input virus as conventional. HBV DNA titers inside the infected cells represent the final viral amount including the infected DNA not degraded and the newly synthesized HBV DNA. In this way, we could study the efficacy of DNA damage response inhibitors on HBV infection and replication. In addition, since DNA damage response is an acute response occurring quickly after virus infection, we assume that early intervention

of the DNA damage pathway would function more efficiently, and thus can be used in clinical practice as a HBV infection therapy during its early infectious stage or fulminant HBV infection.

## MATERIALS AND METHODS

### Chemicals

CF, TP, UCN01 and MG132 were obtained from Sigma (St. Louis, MO). The stock concentration was 100 mmol/L. CF and UCN01 were dissolved in water, whereas TP was dissolved in 0.1 mol/L NaOH, and MG132 was dissolved in DMSO.

### Cell cultures, HBV strains, and infections

The human hepatocyte cell line HL7702, isolated from a HBV sera-negative individual, was obtained from Shanghai Biochemistry Institute. HL7702 cells were cultured in RPMI-1640 with 10% heat-inactivated fetal bovine serum (FBS). Serum samples from HBV carriers obtained for infection test were analyzed. The number of serum HBV viral particles was  $7 \times 10^9$  copies/mL, as quantified by FQ-PCR. The sera were stored at -80°C until use.

HBV infection was monitored by culturing  $10^5$  HL7702 cells in a 6-cm plate in 3 mL RPMI-1640 containing  $10^6$  HBV virus particles. Infected cells were simultaneously treated with different types of drugs (CF, TP and UCN01) at various concentrations. The cells were washed thoroughly 8 times to remove excessive viral inputs and drugs before harvesting. Serum from healthy individuals was used as a negative control. All procedures were performed under level P2 biosafety conditions to minimize the possibility of cross-contamination.

### RNA interference

siRNA duplex composed of 21-bp sense and antisense oligonucleotides of ATR was synthesized by Beijing AuGCT Biotechnology Co. Ltd (China). The sequence of siRNA oligos used in this study was (only the sense strand is shown) siATR: 5'-AACCUCCGUGAUGUUGCUGATT-3'. HL7702 cells were transfected with 50 nmol/L siRNA using lipofectamine 2000 (Promega Corp., Madison, WI, USA) according to the manufacturer's protocol. At 24 h after transfection, cells were subjected to HBV infection and then the HBV DNA load was tested at indicated time points post-infection.

### Detection of HBV DNA by FQ-PCR

For FQ-PCR analyses, virus DNA was extracted from the culture medium using an alkaline lysis method. Briefly, HBV DNA was measured using a FQ-PCR diagnostic kit from Da-An Gene Corporation. FQ-PCR was performed using a Lightcycler™ Roche FQ-PCR system with the following amplification cycle: an initial denaturation at 93°C for 2 min, followed by 40 cycles of annealing at 93°C for 5 s, at 57°C for 45 s, and a final extension at 37°C for 10 s.

### Immunoblotting assay

Cell extracts were lysed in ice-cold Tris buffer (50 mmol/L, pH 7.5) containing 5 mmol/L EDTA, 300 mmol/L NaCl, 0.1% Igepal, 0.5 mmol/L NaF, 0.5 mmol/L Na<sub>3</sub>VO<sub>4</sub>, 0.5 mmol/L PMSF, and antiprotease mixture (Roche Molecular Biochemicals) for 30 min and centrifuged at 13 000 × g for 10 min. The supernatant protein concentration was determined with the Bradford procedure (BioRad). The proteins were resolved on a 7%-15% SDS-PAGE gel and transferred onto nitrocellulose membranes. Blots were blocked in TBST containing 5% nonfat dried milk and incubated with the primary antibodies. Antibodies against p21, ATR (Santa Cruz) and tubulin (Sigma) were incubated at room temperature for 1 h, while antibodies against ATM phosphoserine 1981 (ATMp), Chk1 phosphoserine 345 (Chk1p), and p53 phosphoserine 15 (p53p) (cell signaling) were incubated at 4°C overnight. Secondary antibodies were from Jackson Laboratories. Horseradish peroxidase-based detection was performed using a chemiluminescence reagent (Amersham Biosciences), according to the manufacturer's instructions.

## RESULTS

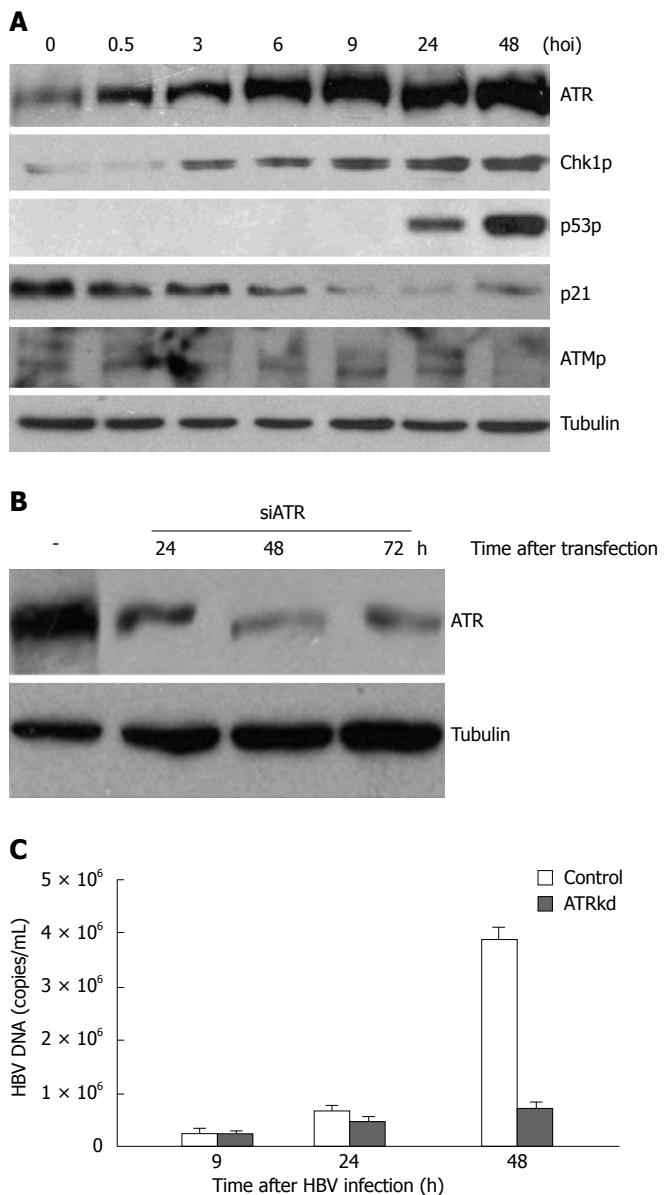

### HBV infection induced an ATR-dependent cellular DNA damage response

To identify whether a cellular DNA damage response was induced upon HBV infection, we set up a HBV infection and replication model by culturing normal HL7702 liver cells with HBV-positive serum<sup>[13]</sup>. A monolayer ( $10^5$ ) of the human HL7702 liver cells in 6-cm plates was infected with  $10^6$  HBV-DNA copies/mL serum at 37°C in an atmosphere containing 50 mL/L CO<sub>2</sub>. HBV infection induced an increase in the steady state levels of the ATR protein and in the phosphorylation levels of its downstream substrates Chk1 and p53 (Figure 1A). Chk1 phosphorylation at Ser-345 was evidently increased at the start of infection with a further increase from 6 to 48 h. p53 phosphorylation at Ser-15 was elevated beginning at 24 hpi and increased considerably at 48 hpi.

In contrast to ATR and its target, the phosphorylated form of ATM at Ser-1981 did not effectively increase upon infection. Furthermore, the phosphorylation of its downstream substrate Chk2 at Thr-68 began to decrease from 3 hpi (data not shown). p53 transcriptional target p21<sub>cip1/waf1</sub>, a cyclin-dependent kinase inhibitory protein, decreased substantially with time after infection, suggesting that p53-dependent downstream signaling can be blocked during HBV infection despite the appearance of phosphorylated p53. Taken together, these results indicate that HBV infection elicited activation of the ATR DNA damage checkpoint pathway that responds to replication stress rather than the ATM DNA damage checkpoint pathway.

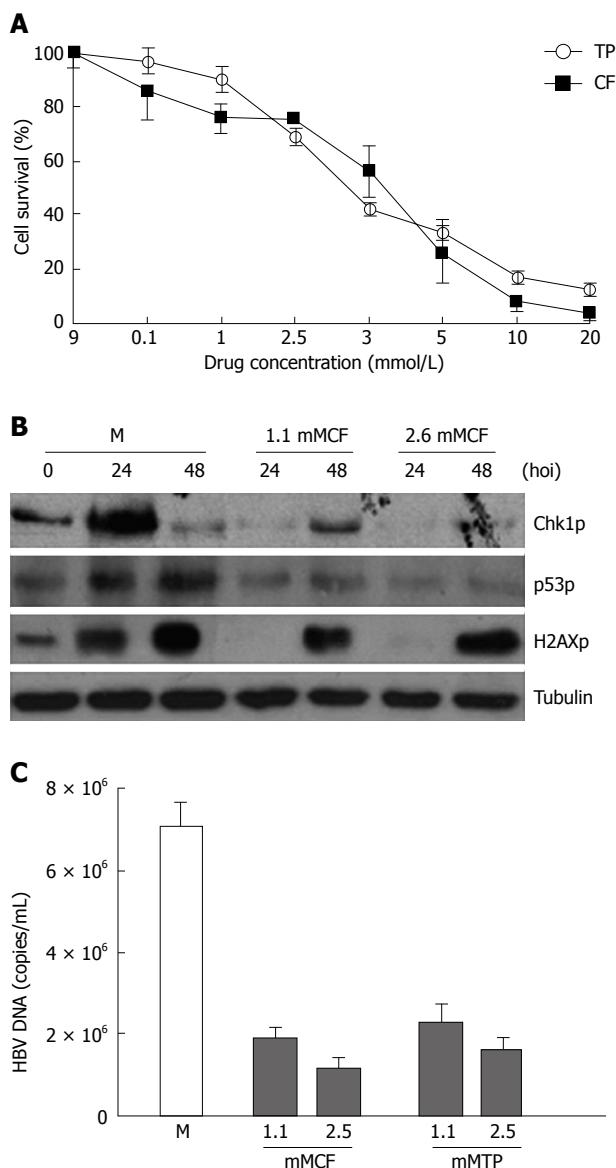

### HBV infection and replication exploited activated DNA damage response

To investigate the effect of the activated DNA damage response on HBV infection and replication, HBV

**Figure 1** An ATR-dependent cellular checkpoint response activated by HBV infection. **A:**  $10^5$  human HL7702 monolayer liver cells in a 6 cm plate were infected with  $10^6$  virus particles from HBV-positive patients at 37°C in an atmosphere containing 50 mL/L CO<sub>2</sub>. Normal serum from healthy individuals was used as non-infected control. Prior to cell harvesting, the cells were washed 8 times thoroughly to remove the excessive viral input. Whole cell lysates were prepared at various time points of infection (hours of infection, hoi) and subjected to immunoblotting assay using antibodies to the indicated proteins. Alpha-tubulin was used as the equal loading control; **B:** Specialized siRNA for ATR was transfected in HL7702 cells using lipofectamine 2000. At the indicated time points, cells were collected for Western blotting testing the ATR level; **C:** HBV-positive serum was added to ATR knockdown cells 24 h after transfection, cells were then harvested for FQ-PCR to test HBV DNA titers at the indicated time points post-infection.

infection was performed in ATR knockdown cells. ATR knockdown was conducted with short RNAi oligos transfection using lipofectamine 2000. RNAi technique diminished total ATR protein from 24 h to 72 h after RNA oligos transfection (Figure 1B). Based on this, HBV-positive serum was added to ATR knockdown cells 24 h after the transfection, cells were then harvested for HBV DNA titer assay at 9, 24 and 48 h, respectively, after infection. HBV DNA load in ATR knockdown

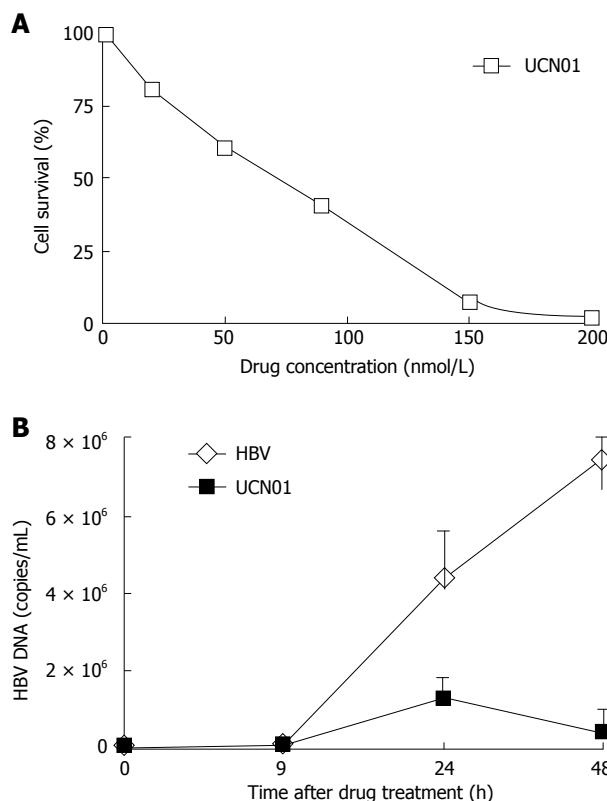

**Figure 2** HBV infection and replication suppressed by CF and TP. **A:** Cells were treated with CF or TP at different concentrations for 48 h, and survived cells were counted with trypan blue staining; **B:** Results of whole cell lysis, Western blotting of infected cells (M) or addition of CF-treated cells (1.1 mol/L CF, 2.5 mmol/L CF) and antibodies at the indicated time points; **C:** FQ-PCR analysis of HBV DNA from the infected cells (M) or addition of both HBV and CF (mMCF) or TP (mMTP).

cells was reduced to about 20% of control (Figure 1C), indicating that HBV replication is dependent on the presence of ATR protein.

#### ATM-ATR kinase inhibitor suppressed HBV infection and replication

To evaluate the influence of the ATR and ATM kinase inhibitor CF and its methylxanthines on HBV replication, the infected cells were simultaneously treated with different types of drugs (CF and TP) at various concentrations. Trypan blue staining was performed and viable cells were counted at different time points after drug addition. The percentage of cells survived was determined by the ratio of the number of treated cells divided by the number of untreated cells. The DNA

**Figure 3** HBV infection and replication suppressed by CF and TP. **A:** HL7702 cells were treated with the indicated concentrations of UCN01, and survived cells were counted 48 h post-treatment with trypan blue staining; **B:** FQ-PCR analysis of HBV DNA from the infected cells (HBV) or addition of both HBV and UCN01 (UCN01) at the indicated time points.

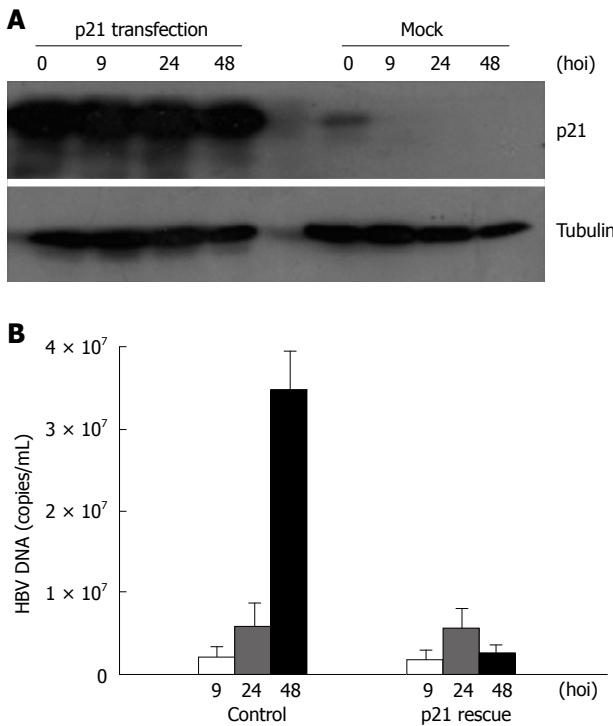

extracted from the infected cells was subjected to FQ-PCR analysis, and the degree of amplification of the viral genome over the time course of infection was determined. We observed a 70% decrease in HBV DNA yields in cells treated with 1.1 mmol/L CF at 48 h during HBV infection (Figure 2C). However, such a dose did not affect cell proliferation (Figure 2A) but abrogated the phosphorylation of target proteins with ATR kinase activity such as Chk1 at Ser-345, H2AX at Ser-139, and p53 at Ser-15 (Figure 2B).

#### Chk1 inhibitor suppressed HBV infection and replication

Chk1 phosphorylation was greatly increased during HBV infection. We therefore investigated whether Chk1 inhibitors would have an effect on HBV replication. Infected cells were simultaneously treated with various concentrations of UCN01. The percentage of survived cells was calculated as described above. The DNA extracted from infected cells was subjected to FQ-PCR analysis. We observed a 90% decrease in HBV DNA yields in cells treated with 50 nmol/L UCN01 (Figure 3B), which did not significantly affect the cell survival was not significantly affected in 48 h (Figure 3A).

#### p21 introduction suppressed HBV infection and replication

In contrast to increased levels of sustained ATR and Chk1 (ATR substrate) phosphorylation during HBV

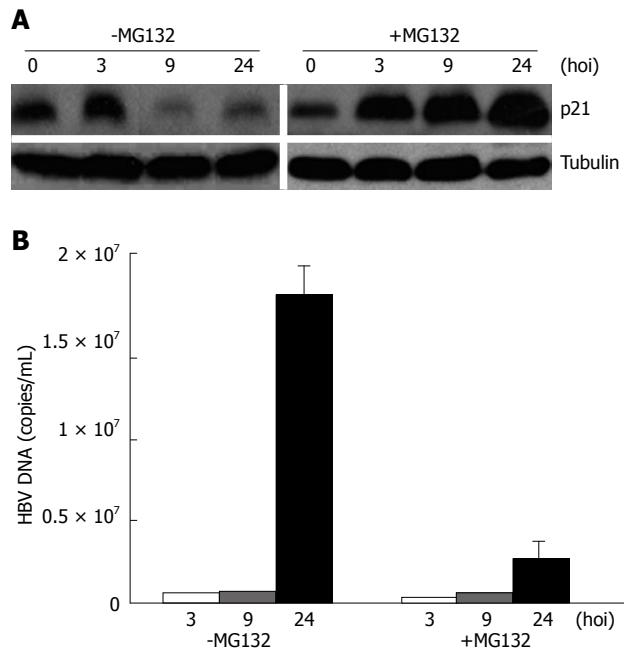

**Figure 4** HBV infection and replication suppressed by introduction of p21. **A:** Result of whole cell lysis, Western blotting of p21-transfected cells and control cells (Mock) at the indicated time points; **B:** FQ-PCR analysis of HBV DNA from the infected cells (control) or both HBV and p21-transfected cells (p21 rescue) at the indicated time points.

infection, HBV abrogated p53-dependent cell cycle checkpoint signaling by degrading p21 (Figure 1A). We thus introduced p21 into host cells to investigate its effect on HBV replication. WT p21 cDNA was transfected into HL7702 cells, which were infected with HBV-positive serum 24 h later, harvested at 9, 24 and 48 h respectively after HBV infection, and subjected to FQ-PCR and immunoblotting. p21 expression decreased with time after infection, and myc-tagged p21 expression was higher in the transfected host cells than in the mock-transfected cells (Figure 4A). We then investigated the effects of p21 transfection on HBV infection and replication. Figure 4B showed that the yield of HBV DNA in the p21-transfected cells was only approximately 8% of that in the cells infected only with HBV, indicating that recovery of p21 destroyed by HBV infection has a detrimental effect on replication of the virus.

#### MG132 inhibited HBV replication

Previous studies have established that HIV-1 infection can be enhanced by treatment of infected cells with proteasome chemical inhibitors<sup>[7,8]</sup>. It is likely that such inhibitors protect the viral core from degradation in target cells. We have proved that introduction of p21 into infected cells leads to decreased HBV replication. Therefore, we tested whether the proteasome inhibitor MG132 would have an effect on HBV replication in the presence of p21 accumulation. To determine p21 levels and the effect of proteasome inhibitors on cell susceptibility to HBV infection, we pretreated cultures

**Figure 5** HBV replication inhibited by MG132. **A:** Result of whole cell lysis, Western blotting of MG132-treated cells (+MG132) and control cells (-MG132) at the indicated time points; **B:** FQ-PCR analysis of HBV DNA from the infected cells (-MG132) or both HBV and MG132-treated cells (+MG132) at the indicated time points.

of HL7702 cells with MG132 (10 μM) for 2 h and then monitored HBV infection. HBV-infected cells were harvested at 0, 9, 24, 48 h after extensive washes 8 times with PBS, and then subjected to immunoblotting and FQ-PCR. The level of p21 expression decreased with time after infection, the addition of MG132 resulted in a substantial increase in the p21 expression levels (Figure 5A). To investigate whether treatment with MG132 can also effectively inhibit virus replication, we analyzed the effect of MG132 on HBV replication. The yield of HBV in the presence of proteasome inhibitors was only approximately 10% of that in control cells 48 h after HBV infection (Figure 5B), indicating that proteasome inhibitors can reduce HBV replication by up-regulating p21.

## DISCUSSION

Several viruses, including DNA virus herpes simplex virus (HSV)<sup>[14,15]</sup>, Kaposi's sarcoma-associated herpesvirus<sup>[16]</sup>, human cytomegalovirus (HCMV)<sup>[17]</sup>, Epstein-Barr virus (EBV)<sup>[18]</sup>, papillomavirus<sup>[19,20]</sup>, simian virus 40 (SV40)<sup>[21]</sup> and retrovirus HIV<sup>[22-24]</sup>, trigger cellular signaling cascades that are characteristic of a DNA damage response. Infection and replication of HBV have been achieved in human hepatoma cell lines and primary fetal human hepatocytes using transfected HBV genomes or HBV serum. In this study, HL7702 cells were inoculated with HBV serum consistently ( $10^6$  particles per  $10^5$  cells), mimicking the HBV infection process. Serum from healthy individuals was used as the non-infected control. By using FQ-PCR and southern blotting, we demonstrated that human hepatocytes

could maintain HBV infection *in vitro* and support the replication of HBV DNA (data not shown), suggesting that HBV infection activates the DNA damage response to replication stress accompanying increased ATR and Chk1 (ATR substrate) phosphorylation. Furthermore, HBV abrogated the checkpoint signaling by degrading p21. The results of this study show that the ATM and ATR inhibitor CF and its methylxanthine TP, the Chk1 inhibitor UCN01, the proteasome inhibitor MG132 and p21 up-regulation could suppress HBV replication. These findings suggest that some DNA damage responsive proteins are implicated in modulating HBV infections and therefore can be used in treatment of drug-resistant viral strains. In addition, targeting cellular proteins with a low mutation rate may not lead to the rapid emergence of HBV strains that are resistant to inhibitors of these proteins.

The effect of CF is mediated by inhibiting its cellular target, the ATR kinase involved in retroviral integration. The precise role of ATR in HBV replication is unclear. The integration of HBV DNA into chromosomes has been reported<sup>[13]</sup>. Interestingly, treatment with TP has an inhibitory effect on HBV replication even at a concentration as low as 0.1 mmol/L, which is too low to impact ATM/ATR kinase activity. Therefore, the antioxidant function of TP or CF may have a great inhibitory effect on HBV infection process, and further experiments should be done on this issue.

Chk1 is activated following HBV infection and the Chk1 inhibitor UCN01 can inhibit HBV replication; however, the precise mechanism underlying this inhibition remains to be determined. The resultant S-G2 phase-like cellular condition appears to favor replication of viral DNA.

In cervical carcinogenesis, the p53 suppressor pathway is disrupted by HPV E6-mediated proteasome degradation. MG132 could restore WT p53 levels and thus may sensitize papillomavirus (PV) positive human cervical cancer cells to apoptosis<sup>[11,25]</sup>. Several studies have recently demonstrated that proteasome is a suitable neoplastic target with a clinical potential<sup>[26-28]</sup>. We report here that MG132 can be used to suppress HBV replication by up-regulating p21. As a latency virus, HBV abrogates the checkpoint signaling controlled by ATR to prevent triggering of apoptotic signals. The mechanism underlying the regulation of apoptosis by HBV is *via* both p53-dependent pathways. The p53-dependent cell cycle checkpoint pathway involves p21-mediated inactivation of cdk2/cyclinE. HBV abrogates p53-dependent checkpoint activation by degrading p21. Our results demonstrate that MG132 could up-regulate p21 and thus suppress HBV replication, possibly due to the partial recovery of the p53-dependent checkpoint signaling pathway.

In summary, CF and its related methylxanthines can suppress replication of HIV as previously reported<sup>[8]</sup>. However, since DNA damage response is acute, DNA repair cofactors against HBV infection and replication should be used in early stage HBV infection. Further studies are necessary to determine the mechanism by

which DNA damage response inhibitors down-regulate HBV infection and replication.

## COMMENTS

### Background

Eukaryotic cells employ multiple strategies of checkpoint signaling and DNA repair mechanisms to monitor and repair damaged DNA. There are two branches in the checkpoint response pathway: ataxia telangiectasia-mutated (ATM) branch and ATM-Rad3-related (ATR) branch. Many viruses are now known to interact with DNA damage and repair machinery. These viruses have evolved tactics to eliminate, circumvent, or exploit various aspects of DNA damage response to the host cells. Strategies include activation of repair proteins or targeting of specific cellular factors for degradation or mislocalization.

### Research frontiers

In human immunodeficiency virus (HIV), prevention of viral integration inhibits viral replication and promotes cellular apoptosis. Thus, the ATM-specific inhibitor ku55933 can inhibit HIV replication in primary T cells.

### Innovations and breakthroughs

In this paper, we first report that (hepatitis B virus) HBV infection activates and exploits DNA damage response to replication stress. We investigated whether the inhibition of DNA damage response by CF, TP and UCN01 or the restoration of p21 expression by p21 transfection or proteasome inhibition would lead to suppression of HBV replication. We set up a chronic HBV infection model by culturing HL7702 liver cells with HBV-positive serum without washing off input virus as conventional. HBV DNA titers inside the infected cells represent the final viral amount including the infected DNA not degraded and the newly synthesized HBV DNA. In this way, we can study the efficacy of DNA damage response inhibitors on HBV infection and replication.

### Applications

Since DNA damage response is an acute response occurring quickly after virus infection, we assume that early intervention of the DNA damage pathway would function more efficiently and thus can be used in clinical practice as a HBV infection therapy during its early infectious stage or fulminant HBV infection.

### Peer review

This is an interesting article that reports data on the effect of DNA repair cofactors on HBV replication and infection. The study is well designed. The data or findings are reliable.

### Abstract

**AIM:** To evaluate outcomes in patients with autosomal dominant polycyst liver disease (APLD) treated by combined hepatic resection and fenestration. A new classification was recommended to presume postoperative complications and long outcome of patients.

**METHODS:** Twenty-one patients with APLD were treated by a combined hepatic resection and fenestration technique. All patients were reviewed retrospectively, and clinical symptoms, performance status and morbidity were recorded. A new classification of APLD is recommended here.

**RESULTS:** All patients were discharged when free of symptoms. The mean follow-up time was 55.7 mo and three patients had a recurrence of symptoms at 81, 68 and 43 mo after operation, respectively. The overall morbidity rate was 76.2%. Two patients with Type B-II and Type B-I developed biliary leakage. Four patients had severe ascites, including three with Type B-III and one with Type B-II. Nine patients had pleural effusion, including one with Type A-I; one with Type B-I; five with Type B-II; one with Type A-III and one with Type B-III. Three patients with Type B had recurrence of symptoms, while none with Type A had severe complications.

**CONCLUSION:** Combined hepatic resection and fenestration is an acceptable procedure for treatment of APLD. According to our classification, postoperative complications and long outcome can be predicted before surgery.

### INTRODUCTION

Autosomal dominant polycyst liver disease (APLD) is a genetic heterogeneous disorder characterized by progressive development of multiple fluid-filled, biliary epithelial liver cysts<sup>[1-5]</sup>, and is frequently associated with autosomal dominant polycystic kidney disease<sup>[5-7]</sup>. Most cases of APLD are asymptomatic and do not require surgical treatment. However, a number of patients with highly symptomatic cystic hepatomegaly or with a complicated presentation would benefit from surgical decompression of the hepatomegaly<sup>[8]</sup>. Currently, there is controversy over what is the most appropriate therapeutic approach for APLD. Transient improvement with non-surgical treatment such as sclerosing agents has been reported<sup>[9,10]</sup>. Surgical therapies include laparoscopic fenestration<sup>[11-14]</sup>, open fenestration<sup>[15-18]</sup>, liver resection and fenestration<sup>[19-22]</sup>, and liver transplantation<sup>[23-26]</sup>. In 1997, Giot *et al*<sup>[1]</sup> recommended a stratification scheme for the most appropriate surgical approach. In the present study, we evaluated outcomes in patients with APLD treated by combined hepatic resection and fenestration, and provided a new classification to presume the postoperative complications and long-term outcome of patients with APLD.

### MATERIALS AND METHODS

Between May 1995 and May 2007, 21 patients with APLD-associated severe symptoms were referred to Eastern Hepatobiliary Surgery Hospital of the Second Military Medical University in Shanghai. They were

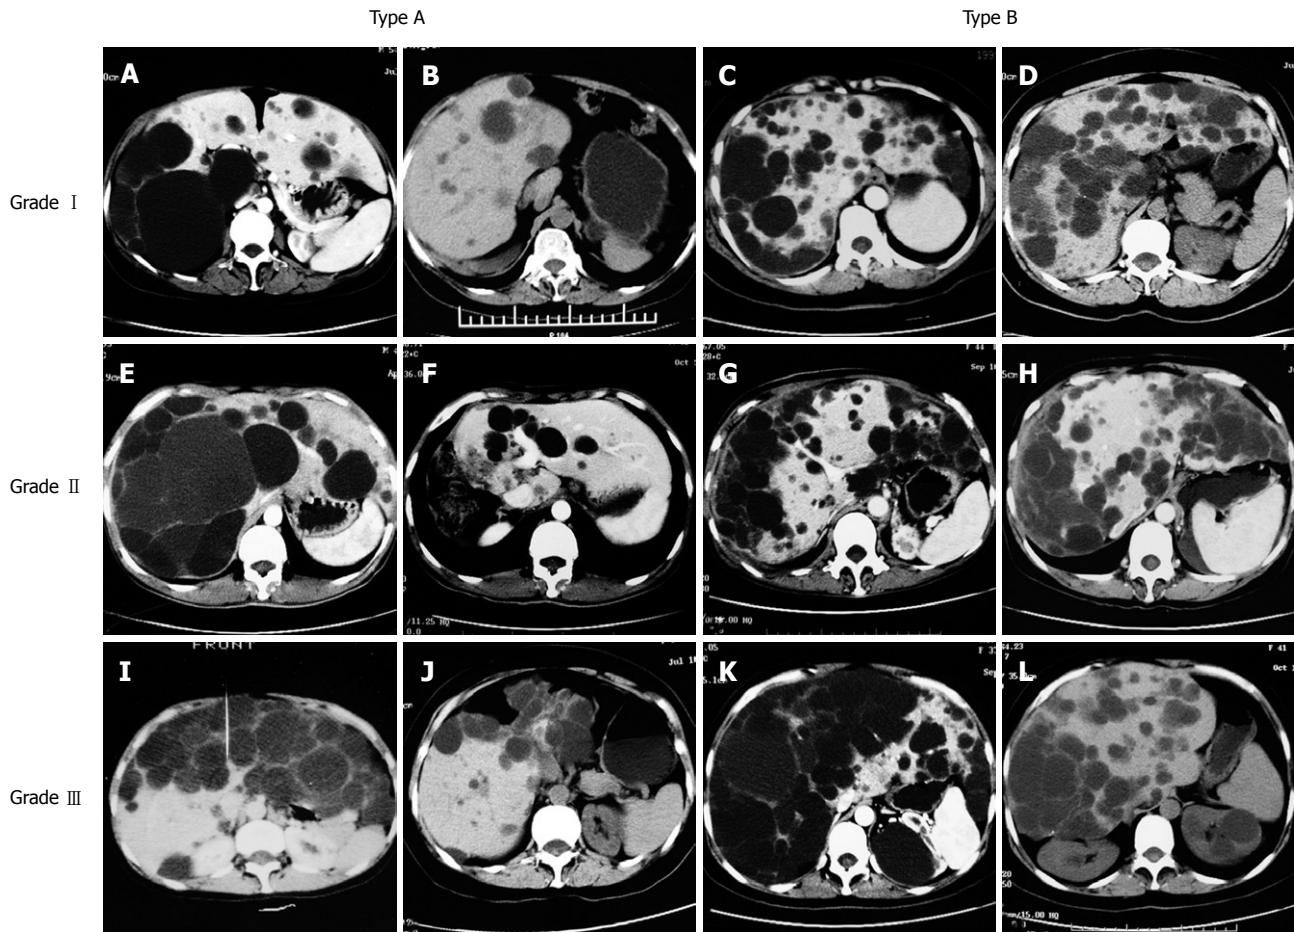

treated by a medical team headed by Dr. Yang *et al.*, using the combined hepatic resection and fenestration technique. The patients included 19 women and two men ranging in age from 34 years to 63 years with a mean of 44.7 (median, 43) years. Of the 21 patients, 12 patients (57.1%) had a familial history of polycystic liver disease (PLD), and 17 patients (81.1%) had associated autosomal dominant polycystic kidney disease. The mean time lag between the diagnosis of APLD and surgery was 65.3 mo (median, 60; range, 1-240 mo). The mean duration of symptoms was 30.6 mo (median, 24; range, 1-168 mo). Specific symptoms included massive abdominal distention (20/21, 95.2%), early satiety (11/21, 52.4%), chronic abdominal pain (9/21, 42.9%), hypertension (8/21, 38.1%), ascites (5/21, 23.8%), supine dyspnea (3/21, 14.3%), elevated temperature related to superinfected cysts (2/21, 9.5%), regurgitation (2/21, 9.5%) and pleural effusion (2/21, 9.5%). Abdominal examination revealed hepatomegaly in all patients. Eleven patients had received treatment previously, including percutaneous cyst aspiration with alcohol sclerotherapy in eight patients, laparoscopic fenestration in two patients, and laparoscopic fenestration in one patient. Liver function tests were essentially normal, except for mild elevation of serum alkaline phosphatase in two patients, glutamyltranspeptidase in five patients, hypoalbuminemia and hyperbilirubinemia in four patients. All patients underwent an abdominal computed tomography (CT) scan in order to delineate cyst distribution, assess portal vein patency, and provide baseline measurement for follow-up comparison in each patient. Since some of the patients in our series were not appropriate for Giot classification<sup>[1]</sup>, a new classification of APLD patients that is different from Giot classification was recommended. This new classification involved a preoperative evaluation of the number of deep cysts in the liver parenchyma that could not be treated during operation. Based on the preoperative evaluation, APLD patients were classified into two types: Type A, with a small number of cysts that could not be treated and left in the deep site of the liver parenchyma (usually  $\leq 15$ ), and Type B, with a large number of such cysts (usually  $\geq 15$ ). For each type, according to the location of cysts diffused in the liver, they were further classified into three grades: Grade I included patients with diffused cysts occupying less than one lobe of the liver; Grade III was a severe form of APLD with liver parenchyma involving fewer than 3 segments; and Grade II was the grade between Grade I and III, where liver parenchyma was limited in the right lobe or left lobe of the liver, or involving 3-4 segments, but not limited in one lobe of the liver (Figure 1).

Preoperative preparations of each patient included: electrocardiography (ECG), gastroscopy and pulmonary function, major medical contraindications for surgical resection were identified, and specific hepatic factors were evaluated. In 13 patients, prothrombin time (PT) was prolonged (within 3 s above the normal reference). Venous catheterization was also important with these

patients. The abdomen was explored through a bilateral subcostal incision. The hepatoduodenal ligament was explored to provide access to vascular clamping areas and to identify major vascular and biliary structures. The liver was mobilized by the division of hepatic peritoneal attachments, which was facilitated by sequential fenestration of accessible cysts according to the Lin technique<sup>[15]</sup>. Liver segments spared of cystic involvement were identified to define limits of resection. No anatomic segmental or lobar planes were removed even if cysts distorted the normal anatomy. Liver segments spared of cystic involvement were identified prior to parenchymal transaction to define limits of resection. Significant islands of functional liver parenchyma were preserved when possible. Two to five segments were resected during operation. After resection of the major cyst segments, extensive fenestration of the residual cysts in the parenchyma was addressed by excision of the cyst walls. Using cautery, the transection plane was developed further by division and excision of the inter-cystic septa<sup>[27]</sup>. Vascular and biliary radicals that coursed through the cyst septa were ligated as indicated. Finally, cyst cavities exposed to the peritoneum were fulgurated by argon beam coagulation (Bard Electromedical Systems, USA) in 15 patients in an attempt to ablate secretory epithelium and reduce postoperative peritoneal fluid losses<sup>[28]</sup>. The portal vein, hepatic vein and small bile duct were identified and carefully protected in order to avoid hemorrhage and bile leakage. Cholecystectomy was performed in seven patients. The hepatic resection beds were drained by two large closed suction drains. Eighteen patients were monitored in the intensive care unit. Both colloid and crystalloid fluids were used for volume replacement to compensate for expected postoperative fluid losses and excessive peritoneal drainage. Fluid maintenance and hemodynamic balance were aided by central venous pressure. Postoperative blood gas analysis was examined in all patients. All patients were followed-up through either telephone calls or at clinical visits. Special data included CT scan and current hepatic and renal function test. SPSS 10.0 was used for statistical analysis.

## RESULTS

No patient died during the operation. All 21 patients were discharged from the hospital free of the preoperative symptoms. The mean postoperative hospital stay was 15.5 d (median, 13; range, 6-60 d). The mean operation time was 247.6 min (median, 225 min; range, 150-435 min). Component transfusion was given intraoperatively and during hospitalization in 16 patients. The median transfusion of packed red blood cells was 4.5 units (range, 1-20 units). The median transfusion of blood plasma was 1400 mL (range, 200-4600 mL). Fifteen patients had ascites. The mean duration of drainage was 8.29 d (median, 5 d; range, 2-57 d). Needle aspiration was attempted to prevent ascites from infection. Seven patients received continuous needle aspiration to relieve ascites, with a

**Figure 1** CT examinations of our classification of APLD. **A** and **B**: Type A-I, preoperative and postoperative CT examinations; **C** and **D**: Type B-I, preoperative and postoperative CT examinations; **E** and **F**: Type A-II, preoperative and postoperative CT examinations; **G** and **H**: Type B-II, preoperative and postoperative CT examinations; **I** and **J**: Type A-III, preoperative and postoperative CT examinations; **K** and **L**: Type B-III, preoperative and postoperative CT examinations.

mean duration of 7.54 d (median, 4 d; range, 3-24 d). Eight patients were successfully managed with diuretics and drainage was achieved within one week. Nine patients had pleural effusion, of which 6 patients needed thoracentesis due to chest distress. Bile leakage occurred in two patients. Postoperative hemorrhage occurred in one patient. The overall morbidity rate was 76.2%. There was a morbidity rate of 38.1% for complications that required special treatment. These included severe ascites, bile leakage, hemorrhage, and pleural effusion. The mean follow-up duration was 60.7 mo (median, 59; range, 10-155 mo). Two patients died of renal failure due to polycystic kidney disease at 137 and 85 mo after operation. Three patients had recurrence of the symptoms at 81, 68 and 43 mo after operation with a recurrence rate of (3/21) 14.3%. Total bilirubin was slightly elevated in two patients. The symptoms (occasional abdominal swelling and abdominal pain) of three patients were not severe, therefore they received outpatient treatment.

Follow-up CT data were available in 19 patients, and lost in the remaining two patients who died. Six patients were classified as Type A, including three with Grade I, one with Grade II and two with Grade III. Thirteen patients were classified as Type B APLD, including one with Grade I, eight with Grade II and four with

Grade III. The mean age, mode of presentation, duration of symptoms, mean operation time, intraoperative component transfusion and hospital stay were not significantly different between the two types.

Of the six patients with Type A in our series, three had mild ascites and one had pleural effusion after operation. None of the patients with Type A had severe complications. In patients with Type B in our series, one with Grade II who received laparoscopic treatment 4 years earlier had massive hemorrhage after operation. Biliary complications occurred in two patients, including one with Grade II and one with Grade III. Severe ascites occurred in three patients with Grade III and one patient with Grade II. Eight patients had pleural effusion, including one with Grade I, six with Grade II, and one with Grade III. Eleven patients had mild ascites, including two with Grade I, seven with Grade II, and two with Grade III. Symptoms reoccurred in three patients with Type B, including one with Grade I, and two patients with Grade II. The follow-up ranged from 12 mo to 155 mo with a mean of 61.2 mo for Type A patients, and from 10 mo to 141 mo with a mean of 58.2 mo for Type B patients. There was no significant difference in follow-up duration between the two types. Postoperative complications and symptom recurrence based on our APLD classification are presented in Table 1.

**Table 1** Postoperative complications and symptom recurrence based on our APLD classification

Classification	<i>n</i>	Severe ascites	Pleural effusion	Bile leakage	Mild ascites	Hemorrhage	Recurrence
Type A	I	3	-	1	-	1	-
	II	1	-	-	-	1	-

## DISCUSSION

APLD is a rare disorder usually associated with autosomal dominant kidney disease<sup>[7,29]</sup>. An increasing prevalence is associated with age and female sex<sup>[30]</sup>. Symptoms usually arise from liver enlargement and compression of adjacent organs. Most symptomatic patients complained of an increasing abdominal girth and chronic abdominal dull pain. Liver enlargement may cause early satiety, respiration compromise, and physical disability. Complications such as portal hypertension, pleural effusion, esophageal varices, obstructive jaundice, hepatic failure and malignant degeneration are rare<sup>[31-33]</sup>. In patients with APLD, the optimal treatment is still under dispute. Percutaneous aspiration with alcohol sclerotherapy seems valuable for solitary cysts but not for patients with APLD because cyst collapse may not be sufficient<sup>[9,10]</sup>. In 1968, Lin *et al*<sup>[15]</sup> reported the use of a more extensive cyst fenestration procedure in three patients in whom successively deeper cysts were unroofed and drained through more superficial ones, resulting in a long-term favorable outcome. Kabbej *et al*<sup>[13]</sup> reported in a recent study that 13 patients with APLD underwent laparoscopic fenestration, with a symptom recurrence rate of 72% during a mean follow-up of 26 mo. In patients with the majority of cysts in segments VI, VII, VIII, and in patients with deeply seated cysts that are difficult to visualize and fenestrate with laparoscopy, the postoperative recurrence rate is usually high due to inadequate fenestration of all cysts<sup>[12,14,34]</sup>. Armitage *et al*<sup>[27]</sup> described a patient with APLD who was treated by partial hepatic resection and cyst fenestration in 1984. This procedure allowed for excision of most prominent cysts with minimal resection of the liver tissue, and the liver parenchyma was preserved as much

as possible. Other reports have shown the feasibility of such an approach<sup>[11,18-20,35,36]</sup>(Table 2).

We have already reported seven patients with APLD who were treated by hepatic resection and cyst fenestration during a follow-up of 20.4 mo<sup>[22]</sup>. All patients were relieved of the symptoms after operation. Mild symptoms recurred in three patients, and symptoms were relieved after treatment in the ambulatory clinic at 6-mo intervals. The long-term benefit of combined hepatic resection and fenestration depends on whether there is a progressive increase in size of deep residual untreated liver cysts rather than new cyst development<sup>[1]</sup>. Our experience with the treatment of Type B patients also supports this conclusion. Current data of the natural history of autosomal dominant polycystic kidney disease (APKD) and APLD suggest that progression of cystic disease is slow, affording the possibility of prolonged benefit. Our experience with combined hepatic resection and fenestration shows that some patients with massive polycystic liver benefit markedly from this procedure. No patients with polycystic kidney disease had kidney failure during operation. Two patients in our series died of renal failure during the follow-up period due to polycystic kidney disease. Whether this operation technique affects renal function is still unknown.

According to our classification of APLD patients with Type A seemed less likely to have severe complications after operation. None in Type A had severe ascites or bile leakage in our studies. Patients in every grade with Type A, had more cysts to be resected than cysts to be fenestrated during operation. In addition, their cysts in the liver parenchyma were relatively superficial, and could be treated easily. After fenestration there was little difference in cyst epithelium areas exposed to the abdominal cavity in each grade of patients with Type

A, so their ascites and pleural effusion occurrence rates were seemly no different after operation. Some Type A patients had small bile leakage or hemorrhage during the operation, but these were found easily during operation. In different grades, operative technical difficulties to repair these leakages and hemorrhages were different. Patients in Grade III had large numbers of cysts to be resected or fenestrated, and vascular and biliary radicals coursing through the cyst septa were more difficult to recognize than those of patients in Grade II or Grade I. Operative risk factors increased with increasing grades. Vascular and biliary radicals should be recognized and protected during operation to avoid injury, especially for patients in Grade III.

In Type B patients, a proportion of cysts needed resection, but most cysts in the liver parenchyma could not be resected in order to preserve liver parenchyma as much as possible. Therefore, Type B patients had more cysts requiring fenestration, and cyst epithelium areas that were exposed to the abdominal cavity were also larger. Since cystic epithelium functions in secretion<sup>[37]</sup>, severe ascites occur more in Type B. Severe ascites was found in four patients in Type B, including three with Grade III and one with Grade II. Patients with Grade III had more cysts to be fenestrated than patients with Grade II, and patients with Grade II more than patients with Grade I during operation. Patients with Grade III also had larger cyst epithelium areas exposed to the abdominal cavity than Grade II, and patients with Grade II more than patients with Grade I after operation. We presume that patients with Grade III are more likely to develop ascites than patients with Grade II, and patients with Grade II are more likely to develop ascites than patients with Grade I. Bile leakage occurred in two patients in our series with Type B, including one with Grade III and one with Grade II. Patients with Type B had more cysts in the deep liver parenchyma. We attempted to fenestrate the cysts when possible, though it was dangerous to fenestrate deep interseptal cysts without sufficient exposure. Two risk factors may contribute to biliary complications. One is the possible injury to small biliary radicals on the surface of the cyst lining, when the cyst lining was fulgurated by argon beam coagulation to ablate secretory epithelium. The other is that biliary ducts distorted in polycystic liver anatomy are usually difficult to identify, and likely to be injured within cystic septa during a fenestration procedure especially of deep cysts<sup>[1]</sup>. These two patients with peritoneal closed suction drainage had spontaneous resolution 27 d and 56 d after operation as identified by subsequent radiologic examination. Therefore we recommend a clearly routine examination on the wound surface to avoid missing the biliary ducts and veins which are possibly injured by the end of the operation.

Our classification of APLD applied the postoperative course which was uncomplicated in six patients with Type A, including three patients with mild ascites and one patient with pleural effusion. No patient in Type A had symptom recurrence in the follow-up period. In Type B, two patients had bile leakage, four had severe ascites,

seven had pleural effusion, and three had symptom recurrence. Type A APLD patients may have good immediate and long-term outcomes, so we recommend a combined hepatic resection and fenestration. Symptom recurrence was related to a progressive increase in size of deep residual untreated liver cysts. Patients in Grade I and in Grade II with Type B had more cysts in deep sites within the liver parenchyma, which could not be treated during operation, therefore those patients had a high rate of symptom recurrence. Cysts in Grade III patients can be resected or fenestrated effectively during operation, leading to less symptom recurrence. So we recommend a new classification to predict the postoperative complications and long-term outcome of patients with APLD. This classification still needs to be validated in the future.

We had two patients who received laparoscopic fenestration and one patient received laparoscopic fenestration previously. They had symptom reoccurrence 99, 67 and 53 mo after operation, and received combined liver resection and fenestration. They are living well asymptotically. But in these patients, more intense intra-abdominal adhesions posed technical difficulties<sup>[28]</sup>. Their complications were severe after operation, including one that had abdominal hemorrhage, and one that had severe ascites and bile leakage. The patient who underwent laparoscopic fenestration previously had an abdominal hemorrhage in the right lobe, due to tight adhesion of the cyst wall with the diaphragm, where a small artery was not ligated after stripping. Hemorrhage occurred when blood pressure was returned to normal after operation. For these patients, combined fenestration with resection still can be considered as the choice of treatment, but their operation should be performed by experienced surgical teams due to their severe postoperative complications. Liver transplantation as a treatment for APLD may be another good way to treat APLD, but it has a limited role due to the shortage of liver donors and severe postoperative complications. Two large studies reported by Lang *et al*<sup>[24]</sup> and Pirenne *et al*<sup>[25]</sup> reported the outcomes of liver transplantation in 17 and 16 patients respectively. The former reported 5 deaths (29%) and the latter reported 2 deaths (12.5%). The mortality they reported is higher than that in patients who received combined fenestration procedures. Patients with APLD who receive liver transplantation are placed on immune suppression therapy, and therefore do not have a "normal immune system." Immune suppressants have many side effects on patients with liver transplantation, and after operation they still need much attention to sustain the state of immune suppression to avoid graft rejection. Starzl and his colleagues described the "syndrome of lethal exhaustion" as the major indication to consider when offering transplantation to these patients<sup>[38]</sup>. We fully agree that liver transplantation should be used for patients with cachexia, weight loss, portal hypertension, refractory ascites, liver insufficiency or associated with severe kidney disease<sup>[24,25,39,40]</sup>. Liver resection and fenestration of the remnant liver are more effective than

fenestration and less invasive than liver transplantation, combined liver resection and fenestration should be considered as the choice for treatment for APLD.

## COMMENTS

### Background

Autosomal dominant polycystic liver disease (APLD) is a rare disorder usually associated with autosomal dominant kidney disease with an increasing prevalence associated with age and female sex. Symptoms usually arise from liver enlargement and compression of adjacent organs. Surgical therapies include laparoscopic fenestration, open fenestration, liver resection and fenestration, and liver transplantation, what is the optimal treatment is still under dispute.

### Research frontiers

The study analyzed and summarized the author's clinical experiences in recent 12 years in the treatment of APLD and in an attempt to propose some practicable guidelines, and suggested a new classification to presume postoperative complications and long outcome of each patient.

### Innovations and breakthroughs

Combined hepatic resection-fenestration is a good choice for the treatment of highly symptomatic adult polycystic liver disease. According to the author's classification, postoperative complications and long outcome of each patient can be predicted before surgery.

### Applications

The study provides some practicable guidelines for the treatment of APLD, and according to the author's classification, postoperative complications and long outcome of each patient can be predicted before surgery.

### Peer review

The paper analyzed and summarized some practicable experience for the treatment of APLD and recommended a new classification. It is valuable to see the actual results from various therapies and the new classification by the authors over the last 12 years.

Treatment of upper gastrointestinal fistula and leakage with personal stage nutrition support. *World J Gastroenterol* 2008; 14(32): 5073-5077 Available from: URL: <http://www.wjgnet.com/1007-9327/14/5073.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.5073>

## Abstract

**AIM:** To investigate the feasibility of treatment for upper gastrointestinal fistula and leakage with personal stage nutrition support.

**METHODS:** Forty-three patients with upper gastrointestinal fistula and leakage were randomly divided into two groups. Patients in group A were treated with personal stage nutrition support and patients in group B were treated with total parenteral nutrition (TPN) in combination with operation. Nutritional states of the candidates were evaluated by detecting albumin (Alb) and pre-Alb. The balance between nutrition and hepatic function was evaluated by measurement of aspartate aminotransferase (AST), alanine aminotransferase (ALT) and total bilirubin (Tbill) before and after operation. At the same time their complications and hospitalized time were surveyed.

**RESULTS:** Personal stage nutrition support improved upper gastrointestinal fistula and leakage. The nutrition state and hepatic function were better in patients who received personal stage nutrition support than in those who did not receive TPN. There was no significant difference in the complication and hospitalized time in the two groups of patients.

**CONCLUSION:** Upper gastrointestinal fistula and leakage can be treated with personal stage nutrition support which is more beneficial for the post-operation recovery and more economic than surgical operation.

## INTRODUCTION

The primary causes of death secondary to gastrointestinal fistulæ and leakage include malnutrition, electrolyte imbalance, and sepsis. Without help of an experienced nutrition team, patients with gastrointestinal fistulæ and leakage may not tolerate nutrition support and would have more severe pain due to the doctor's negligence. Nutritional support can improve wound healing<sup>[1]</sup> and gastrointestinal permeability<sup>[2]</sup>, decrease catabolic response to injury<sup>[3]</sup> and bacterial translocation<sup>[4]</sup>, and achieve better clinical outcomes, including a decrease in complications and hospital stay time and cost saving<sup>[5-8]</sup>. It is necessary to find a perfect treatment for gastrointestinal fistulas. More studies have been done on the gastrointestinal fistula, especially on upper gastrointestinal fistula and leakage. Absolute diet has been recognized as a routine diet during treatment of digestive fistula and leakage, and total parenteral nutrition (TPN) has been accepted by many doctors. We have successfully treated acute pancreatitis with "personal stage nutrition support" in the past 10 years. On this basis, we wonder if we can develop a new way of "personal stage nutrition support" for upper gastrointestinal fistula and leakage.

## MATERIALS AND METHODS

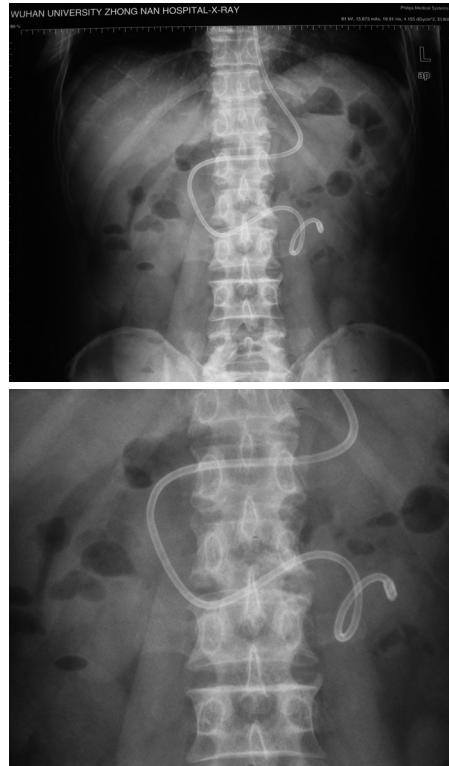

### Patients

Forty-three patients (27 males and 16 females) with upper gastrointestinal fistula and leakage were selected

from Zhongnan Hospital Wuhan University from January 2005 to November 2007. Their age was 20 to 72 years with a mean age of  $51.3 \pm 2.6$  years. The occurrence of upper gastrointestinal fistula was due to emergency of trauma in 6 patients, post-operation for gastric ulcer in 13 patients, excision of duodenum ulcer in 8 patients. Sixteen patients had leakage after gastric perforation neoplasty. Patients with malnutrition or liver dysfunction induced by cancer, tuberculosis, severe anemia, malabsorption, hepatitis, hepatic cirrhosis and other severe cardiovascular disease were excluded. Endoscopy revealed the position of the fistula and leakage above the Vater ampulla. All patients had no severe abdominal cavity infection before surgery and were divided into group A and group B. Group A, that received personal stage nutritional support, served as an experimental group. Group B that received TPN served as a control group. Those who did not finish the treatment plan were excluded. All patients were numbered randomly. During the treatment, all data including electrolyte, liver function, renal function, blood analysis and complications were submitted to professor Yue-Ming He to decide whether it was necessary for the patients to quit from or receive the treatment plan.

### Treatment intervention

Nutrition support for group A was carried out in three steps: TPN stage, parental nutrition (PN) + enteral nutrition (EN) stage, and total enteral nutrition (TEN) stage. (1) TPN stage lasted 4-10 d (mean  $7.8 \pm 2.2$  d). All the patients were asked to take absolute diet and supplied with 10-20 g/d albumin (Alb) and somatostatin. (2) PN + EN stage lasted 8-15 d (mean  $11.6 \pm 3.0$  d). When the function of stomach and intestine recovered with the signal of outgas or defecation, EN was performed. In brief, one spiral nasojejunal feeding tube (Nutricia Company, Holland) was placed in the intestine below Treitz ligament (Figure 1) with the help of intestine enterokinesia after removal of the spiral coil guide wire. The distance from the tip of the tube to the orificium fistula was greater than 30 cm. The position of the nasojejunal tube should be confirmed by X-ray after 8-12 h since auscultation and pH aspiration techniques are inconclusive<sup>[9]</sup>. Nutrient substance was injected into jejunum through the spiral nasojejunal feeding tube. At the same time, we provided the patients with part parental nutrition as supplements. Chinese folk foods such as rice-water, fruit juice, vegetable soup, gravy soup, bean juice, as well as milk and peptison, could be used as nutrient substances and must be discontinued as soon as complications including stomachache, abdominal distension or diarrhea occurred. After we changed the speed and quantity of injection, all patients finished the stage. During this stage, somatotropin was also used. (3) TEN stage lasted 6-8 d (mean  $7.5 \pm 1.2$  d). After completion of the PN + EN stage, we started the third stage, namely TEN stage which was started with closure of the fistula by endoscopic examination. After 35 d, the patients were asked to drink fresh water and take food. Gastrointestinal

**Figure 1** Placement of a spiral nasojejunal feeding tube in the intestine below Treitz ligament, 48 h after X-ray examination.

decompression and drain were performed through the spiral nasojejunal feeding tube in the first stage. At the same time, water and electrolyte disturbances must be prevented by changing ingredient and quantity of nutrient substances. Antibiotics (ceftriaxone sodium) and gastric acid secretion inhibitors (omeprazole) were given by intravenous drip in the first stage.

Patients in group B were given TPN through a central venous catheter which was inserted into the superior vena cava via one of the subclavian veins and advanced into the superior vena cava before and after operation. Basic heat energy was calculated depending on Harris-Benedict's formula, the mean heat energy was 10460kJ (2000-2500 kcal) per day. Nutritional liquids containing glucose and amino acids were supplied with 8368 kJ (2000 kcal). Amino acids (9.4-14.1 g) were provided every day and 500-1000 mL of 10% intralipid was given to meet the need of fat. No hyperlipidemia occurred in our patients. Gastrointestinal decompression and drain were carried out for 7 d. Antibiotics (ceftriaxone sodium) and gastric acid secretion inhibitors (omeprazole) were given by intravenous drip for 7 d.

The electrolyte, liver and renal function, and blood analysis were monitored for preventing electrolyte disturbances and infection. Fluid needs could usually be met by giving 30-35 mL/kg body weight although allowance must be made for excessive losses from drains and fistulae, etc. The feeds contain adequate electrolytes to meet the daily requirement of sodium, potassium, calcium, magnesium and phosphate, although specific requirements may vary greatly.

**Table 1** Levels of Alb, TSF and pre-Alb at different time points in the two groups (mean  $\pm$  SD)

Time	Alb (g/L)			TSF (g/L)			Pre-Alb (mg/L)		
	A	B	P	A	B	P	A	B	P
1 d before treatment	40 $\pm$ 2.1	39 $\pm$ 3.2	0.11	3.51 $\pm$ 0.17	3.49 $\pm$ 0.14	0.78	340 $\pm$ 51	341 $\pm$ 28	0.64
1 d after treatment	39 $\pm$ 3.6	37 $\pm$ 2.5	0.06	3.27 $\pm$ 0.26	3.18 $\pm$ 0.21	0.26	327 $\pm$ 43	308 $\pm$ 19	0.15
15 d after treatment	37 $\pm$ 2.7	35 $\pm$ 3.5	0.05	3.20 $\pm$ 0.33	2.98 $\pm$ 0.25	0.45	321 $\pm$ 37	271 $\pm$ 21	0.001
30 d after treatment	38 $\pm$ 3.8	33 $\pm$ 3.2	0.001	3.28 $\pm$ 0.35	2.77 $\pm$ 0.22	0.001	325 $\pm$ 24	236 $\pm$ 17	0.001

**Table 2** Nitrogen balance between the two groups at different time points (mean  $\pm$  SD)

Time	Nitrogen balance (g)		
	A	B	P
1 d before treatment	-10 $\pm$ 3.6	-8 $\pm$ 4.1	0.17
1 d after treatment	-11 $\pm$ 2.1	-9 $\pm$ 4.5	0.81
15 d after treatment	2 $\pm$ 2.9	2 $\pm$ 3.1	0.95
30 d after treatment	6 $\pm$ 4.2	5 $\pm$ 4.8	0.51

### Plasma protein measurement and liver function evaluation

Five hundred microliter serum segregated from peripheral blood was analyzed by chromatometry to measure the levels of Alb, TSF and pre-Alb. Liver function analysis was completed by Department of Laboratory, Zhongnan Hospital, Wuhan University

### Examination of nitrogen balance

Twenty four-hour urine was collected to determine the level of nitrogen output as previously described<sup>[10]</sup> 1 d before operation and 1, 15 and 30 d after operation, respectively. Total nitrogen was calculated with the following formula: total nitrogen = nitrogen input-(nitrogen output + 3).

### Comparison between complications, hospitalized time and expenditure

The complications, hospitalize time and expenditure were compared after recovery and discharge of the patients.

### Statistical analysis

Data were analyzed with unpaired *t* test using SPSS 13.0. *P* < 0.05 was considered statistically significant.

## RESULTS

Two patients were excluded from our study because they had to accept abdominal cavity drainage for severe abdominal cavity infection. As one of them could not tolerate nasojejunal feeding tube, his data were not included in our statistical analysis. The remaining 40 patients were divided into group A and group B, 20 in each group. Patients in group A received personal stage nutrition support, patients in group B underwent operation and received TPN. We found that there was no significant difference in the levels of Alb, TSF and pre-Alb between the two groups of patients before and after operation. The levels of Alb (g/L), TSF (g/L) and

pre-Alb (mg/L) in patients of group B were lower than those in patients of group A (Table 1). No significant difference in nitrogen balance was found between the two groups (Table 2). Thirty days after operation, the levels of aspartate aminotransferase (AST, U/L), alanine aminotransferase (ALT, U/L) and total bilirubin (Tbill, mol/L) were much higher in group B than in group A (Table 3), indicating that personal stage nutrition support can alleviate the impairment of liver function caused by extended TPN. The complications and the mean hospital stay time of the patients in group A were less than those of the patients in group B (Table 4). The mean cost for the patients in group A was lower than that for the patients in group B.

## DISCUSSION

The traditional treatment of gastrointestinal fistula is surgical operation in combination with prolonged nutrition support. So it is very important to find the best way to support patients with enough nutrition which may achieve good results. Gastrointestinal fistula, especially upper gastrointestinal fistula and leakage are hard to recover. TPN has been widely used in treatment of gastrointestinal fistula. Priorities of the management of gastrointestinal fistulas include restoration of blood volume and correction of fluid, electrolyte and acid-base imbalance, control of infection and sepsis with appropriate antibiotics and drainage of abscesses, as well as TPN and TEN<sup>[11]</sup>.

TPN has many advantages. For example, it is accepted by patients more easily, the supplement of water and electrolyte are more convenient, nutrient substances are infused through veins, etc<sup>[12]</sup>. TPN is a form of nutritional support most suitable to patients with gut failure<sup>[13]</sup>. On the other hand, TPN provides sufficient heat and nutrient substances to meet the need of metabolism. Glyconeogenesis can be inhibited, thus keeping a positive nitrogen balance. In our research, there was no significant difference in nitrogen balance between the two groups. All the patients were switched from negative nitrogen balance to positive nitrogen balance. At the same time many disadvantages were discovered such as metabolic disturbance, catheter septicemia alteration in liver function and cholestasis<sup>[14]</sup>, especially when patients received prolonged TPN, which is consistent with our findings. The levels of AST, ALT and Tbill were much higher in group B than in group A 30 d after TPN. In the stress condition, proper nutritional support may provide necessary nutrients, reduce clinical complications

**Table 3** Liver function of patients in the two groups at different time points (mean  $\pm$  SD)

Time	AST (U/L)			ALT (U/L)			T bill (mol/L)		
	A	B	P	A	B	P	A	B	P
1 d before treatment	26 $\pm$ 2.2	27 $\pm$ 1.9	0.27	27 $\pm$ 1.9	26 $\pm$ 1.6	0.85	15 $\pm$ 1.6	14 $\pm$ 1.8	0.68

Average stay (d)	40 $\pm$ 2.6	50 $\pm$ 3.7	0.001
Average expenditure(10 thousand yuan)	2.3 $\pm$ 0.5	3.9 $\pm$ 0.8	0.001

and promote patients' recovery from illness<sup>[12]</sup>. TPN provides significant benefits to patients<sup>[15]</sup>. In the stress stage, all of our patients were given TPN. When the stress condition of patients improved, they should be supported with EN followed by TEN. Gramlich *et al*<sup>[16]</sup> reported that EN could significantly decrease the incidence of infectious complications and may cost less, and they believe that EN should be the first choice of nutritional support. Goonetilleke<sup>[17]</sup> holds that all patients should accept EN after operation. Zaloga<sup>[18]</sup> and Marik<sup>[19]</sup> believe that the gastrointestinal tract is the preferred route for nutritional support in hospitalized patients. Patients with a functioning gastrointestinal tract should be fed enterally. Patients with upper gastrointestinal fistula and leakage have a functioning intestine and can receive EN through a spiral nasogastric feeding tube which can arrive at the upper jejunum enterokinesia. In our study, patients with upper gastrointestinal fistula could accept EN after the stress condition was over. EN has many advantages. For instance, it can relieve the burden on the liver and protect the liver against damage and infection and maintain the balance of visceral blood flow compared with TPN. Enteral nutrition after stress can maintain immunocompetence and gut barrier integrity, and promote wound healing and reduce septic complications<sup>[20]</sup>. Early enteral feeding can prevent enterogenic infection in severely burned patients<sup>[21]</sup>. However, EN also has many disadvantages leading to abdominal distension, diarrhea, nausea and vomiting, etc, which are consistent with the findings in our study. It was reported that TPN can substantially improve the prognosis of gastrointestinal fistula patients by increasing the rate of spontaneous closure and improving the nutritional status of patients requiring repeat operations<sup>[11]</sup>. In the stress stage, EN is not suggested because a lot of digestive fluid is secreted in the gastrointestinal tract and pancreas which may destroy gastrointestinal fistula. Therefore, TPN was

used in all of our patients in the first stage. However, the length of stress stage, nutrition state and recovery speed were all different in each patient. This is why we established the "personal stage nutrition support". As soon as the stress stage was over, we could give the patients EN together with PN in the PN + EN stage. Satinsky<sup>[22]</sup> reported that all patients should be supported with PN + EN after operation. We suggest that even surgical patients could be provided with personal stage nutrition support including PN + EN. We should provide nutrition support in the three stages for patients with upper gastrointestinal fistula and leakage. Since TPN and EN have their advantages and disadvantages, we should make use of their advantages as much as we possibly can. Significant differences were found in complications, hospitalized time and cost between the two groups. When EN and PN are applied, strategies should be adopted to optimize their benefits and minimize their potential harms. This is why we used personal stage nutrition support but not operation in treatment of patients with upper gastrointestinal fistula. We believe that it is feasible to cure upper gastrointestinal fistula with personal stage nutrition support.

## COMMENTS

### Background

Much research work has been done on gastrointestinal fistula, especially on upper gastrointestinal fistula and leakage, but there are many discussions about how to provide nutrition for patients. Absolute diet has been accepted as a routine diet in the treatment of digestive fistula and leakage, and total parenteral nutrition (TPN) is widely used by many doctors. We tried to find a better treatment modality for upper gastrointestinal fistula and leakage in this study.

### Research frontiers

Many randomized controlled clinical trials as well as meta-analysis and systematic reviews have been performed to compare enteral nutrition (EN) with parenteral nutrition (PN). However, no definite conclusion is available. Some people considered that EN with PN should be employed according to the state and development of disease.

### Innovations and breakthroughs

In the present study, we, for the first time, put forward the concept of personal stage nutrition support and applied it in the treatment of upper gastrointestinal fistula and leakage in combination with operation.

### Applications

We have successfully treated acute pancreatitis with "personal stage nutrition support" in the last 10 years. On this basis, we wonder if we can develop a new treatment modality with "personal stage nutrition support" for patients with upper gastrointestinal fistula. A spiral nasojejunal feeding tube has been used for provision of enteral nutrition for several years outside of China.

### Peer review

The research provides a new treatment modality for upper gastrointestinal fistula and leakage with personal stage nutrition support. The new concept is interesting and informative. The paper is well organized except for correction of some errors in writing and punctuation.

genotypes were identified by PCR and denaturing high-performance liquid chromatography (DHPLC). Information on smoking and drinking was collected and odds ratio (OR) was estimated.

**RESULTS:** The *ADH2* A/A and *ALDH2* G/G genotypes showed moderately increased CRC risk. The age- and smoking-adjusted OR for *ADH2* A/A relative to G/A and G/G was 1.60 (95% CI=1.08-2.36), and the adjusted OR for *ALDH2* G/G relative to G/A and A/A was 1.79 (95% CI=1.19-2.69). Significant interactions between *ADH2*, *ALDH2* and drinking were observed. As compared to the subjects with *ADH2* G and *ALDH2* A alleles, those with *ADH2* A/A and *ALDH2* G/G genotypes had a significantly increased OR (3.05, 95% CI= 1.67-5.57). The OR for CRC among drinkers with the *ADH2* A/A genotype was increased to 3.44 (95% CI= 1.84-6.42) compared with non-drinkers with the *ADH2* G allele. The OR for CRC among drinkers with the *ALDH2* G/G genotype was also increased to 2.70 (95% CI= 1.57-4.66) compared with non-drinkers with the *ALDH2* A allele.

**CONCLUSION:** Polymorphisms of the *ADH2* and *ALDH2* genes are significantly associated with CRC risk. There are also significant gene-gene and gene-environment interactions between drinking and *ADH2* and *ALDH2* polymorphisms regarding CRC risk in Chinese males.

### Abstract

**AIM:** To evaluate the relationship between drinking and polymorphisms of alcohol dehydrogenase 2 (*ADH2*) and/or aldehyde dehydrogenase 2 (*ALDH2*) for risk of colorectal cancer (CRC) in Chinese males.

**METHODS:** A case-control study was conducted in 190 cases and 223 population-based controls. *ADH2* Arg47His (G-A) and *ALDH2* Glu487Lys (G-A)

## INTRODUCTION

There is epidemiological evidence that alcohol intake is associated with increased colorectal cancer risk<sup>[1]</sup>. The oxidative metabolites of ethanol, acetaldehyde, is recognized to be carcinogenic in animals and suspected to have similar effects on human beings<sup>[2]</sup>. Since acetaldehyde accumulates in the blood causing uncomfortable symptoms of facial flushing, palpitation and headache, even when a small amount of alcohol is consumed, greater alcohol consumption is often limited in sensitive individuals.

Ethanol is oxidized to acetaldehyde and then to acetate by alcohol dehydrogenase (*ADH*) and aldehyde dehydrogenase (*ALDH*) in the liver. Most of the acetaldehyde generated during alcohol metabolism *in vivo* is promptly eliminated by *ALDH2*, a low-K<sub>m</sub> mitochondrial *ALDH*<sup>[3]</sup>. The gene for the homotetrameric enzyme *ALDH2* has a polymorphism and its mutant *ALDH2*\*2 allele (Glu487Lys, Lys or A allele) encodes a catalytically inactive subunit<sup>[4]</sup>. *ADH2* is also polymorphic and its mutant *ADH2*\*2 allele (Arg47His) encodes a superactive subunit of *ADH2*<sup>[3,4]</sup>. The *ALDH2* Glu487Lys and *ADH2* His47Arg polymorphisms thus have a strong impact on alcohol metabolism. Inactive *ALDH2* and superactive *ADH2* are considered to contribute to alcohol flushing and prevent people from developing alcoholism<sup>[5-7]</sup>.

Our previous studies have shown that males with a habit of drinking are at a significantly higher risk for colorectal cancer<sup>[8,9]</sup>. In this study, we attempted to define the role of *ADH2* and *ALDH2* polymorphisms and drinking habit in the development of colorectal cancer.

## MATERIALS AND METHODS

### Study subjects

We recruited colorectal cancer patients from the Cancer Registries in Huian and Jintan Cities of Jiangsu Province of China, and also recruited patients who visited Jiangsu Provincial Cancer Hospital from August 2000 to September 2002. All patients were histopathologically diagnosed as having a primary colorectal cancer. Physicians at the hospital asked eligible patients to participate in our study, and doctors or nurses interviewed the subjects and collected blood samples from a peripheral vein after obtaining informed consent. Population-based controls were selected from healthy residents in eight villages or towns of Huian and Jintan Cities. Doctors of the public health centers randomly selected one or two controls for each patient, after matching for ethnicity, sex and age within 2 years using the records of residents at the local governmental office, and then asked eligible residents for their participation. Interviews and blood collection were performed as for the cancer patients. A few patients and residents refused to participate in our study, but the response rate was 97% for patients and 93% for controls, respectively. The Ethics Committee of Jiangsu Provincial Institute of Cancer Research

approved this study. Associations could not be assessed in women because of sparse drinking habits.

### Environmental factors

Smoking and drinking habits were covered in our questionnaire. Each subject was asked whether he had ever smoked at least one cigarette per day for six months or longer. If he answered yes, he was further asked about the age at which he started to smoke cigarettes regularly, the average number of cigarettes smoked per day, and the number of years he had smoked. If the subject had quit smoking at least one year ago, the age at which he stopped smoking was recorded. Each subject was asked whether he had ever drunk alcoholic beverages at least once a month for one year or longer. If his answer was yes, he was asked to provide the age at which he started to drink regularly, frequency and usual amount of hot wine, beer and grape wine consumed separately every time. If the subject had quit his drinking habit at least one year ago, the age at which he stopped drinking was recorded. Consumption of ethanol every month was calculated according to 25 g/100 g of hot wine, 3.5 g/100 g of beer and 12 g/100 g of grape wine. In the present study, smoking status was categorized as never and ever-smokers (including both current and former smokers) and alcohol consumption as drinkers/non-drinkers (the latter including individuals whose alcohol intake was less than 30 g/mo).

### DNA extraction and genotyping

Whole blood was collected into EDTA-coated tubes and centrifuged for 15 min. The buffy coat layer was isolated. Genomic DNA was extracted from 200 μL of buffy coat using a Qiagen QIAamp DNA blood mini kit (QIAGEN Inc., Valencia, CA).

Genotyping of *ADH2* and *ALDH2* was determined by polymerase chain reaction (PCR) and denaturing high-performance liquid chromatography (DHPLC). The sequences of primers used in this study are F: 5'-GGCTTAGACTGAATAACCTTGG-3' and R: 5'-AGGGAAAGAGGAAACTCCTGAA-3' for *ADH2* Arg47His, and F: 5'-TGCTATGATGTGTTGGAGCC-3' and R: 5'-GGCTCCGAGGCCACCA-3' for *ALDH2* Glu487Lys. Reactions were carried out in a total volume of 25 μL containing 20 pmol of each primer, 0.25 mmol/L each dNTPs, 2.0 mmol/L MgCl<sub>2</sub>, 2.5 μL 10 × buffer, 1 IU hotTag polymerase and 0.5 μL genomic DNA. PCR conditions were as follows: denaturation at 95°C for 7 min, followed by 35 cycles at 95°C for 30 s, at 62°C for 30 s, at 72°C for 30 s, and a final extension at 72°C for 5 min. The products were denatured at 94°C for 4 min, and their temperature was declined to 25°C step by step according to 0.1°C/s.

Transgenomic WAVE DNA fragment analysis system (WAVE-300, Transgenomic, USA) and associated WAVEMAKER software were used for genotyping. An aliquot (5 μL) of the PCR products was directly injected into a DNAsep column. The column mobile phase for sample elution consisted of a mixture of buffer A

[0.1 mol/L triethylammonium acetate (TEAA)] and buffer B (0.1 mol/L TEAA with 25% acetonitrile). Samples were eluted at a linear gradient of buffer B over a 4.5-min period at a constant flow rate of 0.9 mL/min. For each DNA region, DHPLC conditions were established by a titration analysis at 1–3°C above and below the mean melting temperature predicted by software simulation. There were three genotypes: namely G/G, G/A, and A/A, for *ADH2* Arg47His and *ALDH2* Glu487Lys, respectively.

### Statistical analysis

Associations between the *ADH2* and *ALDH2* polymorphisms and colorectal cancer risk were estimated by OR, using the unconditional logistic regression model. The procedure LOGISTIC from the statistical package SAS was employed for the calculations. The probability of Hardy-Weinberg equilibrium was assessed by the  $\chi^2$  test.

## RESULTS

The numbers of 190 patients with colorectal cancer and 222 controls are listed in Table 1. The proportional distributions of age and smoking did not significantly differ in patients and controls, but the proportional distributions of alcohol drinkers (including current and former drinkers) were significantly higher in colorectal cancer patients than in controls.

The frequencies of *ALDH2* G/G, G/A and A/A genotypes were 68.95%, 28.42% and 2.63% in patients and 55.41%, 40.54% and 4.05% in controls, respectively (Table 2). The distribution of *ALDH2* genotypes was significantly different in controls and patients ( $\chi^2=7.938$ ,  $P = 0.019$ ). The frequencies of *ADH2* A/A, A/G and G/G genotypes were 53.68%, 38.42% and 7.89% in patients and 41.89%, 49.10% and 9.01% in controls, with no significant difference ( $\chi^2=5.786$ ,  $P = 0.055$ ). The allelic distribution of *ADH2* and *ALDH2* polymorphisms in controls was in the Hardy-Weinberg equilibrium ( $P > 0.05$ ). Therefore, the controls from the general population could be considered as a representative.

The *ADH2* A/A and *ALDH2* G/G genotypes showed a moderately increased risk for colorectal cancer. The age- and smoking-adjusted OR relative to G/A and G/G was 1.60 (95% CI=1.08–2.36), and the adjusted OR for *ALDH2* G/G relative to G/A and A/A was 1.79 (95% CI=1.19–2.69).

The ORs and 95% CIs for association of alcohol drinking with colorectal cancer risk are shown in Table 3. Compared with non-drinkers, the age-adjusted and smoking-adjusted OR for colorectal cancer among alcohol drinkers was 2.04 (95% CI=1.36–3.08). Furthermore, a significant increase trend in the risk of colorectal cancer with amount of alcohol intake was also observed ( $P = 0.0001$ ).

The results of multivariate analysis of smoking, alcohol drinking, *ALDH2* and *ADH2* genotypes and risk of colorectal cancer are shown in Table 4. After

*ALDH2* G/G genotype was markedly increased to 2.70 (95% CI=1.57-4.66) compared to non-drinkers with *ALDH2* A allele (Table 6).

## DISCUSSION

Our previous studies showed that drinking is associated with increased colorectal cancer risk<sup>[8-10]</sup>. We also found that a polymorphism of cytochrome P450 2E1 (*CYP2E1*), an alcohol metabolizing enzyme, could influence susceptibility to colorectal cancer and *CYP2E1* C2/C2 genotype and alcohol drinking have a coordinated effect on the development of colorectal cancer<sup>[9]</sup>. In the present study, polymorphisms of the *ADH2* and *ALDH2* genes were significantly associated with the risk of colorectal cancer in Chinese males. Significant gene-gene and gene-environment interactions were also found between alcohol drinking and *ADH2* and *ALDH2* polymorphisms.

Colorectal carcinogenesis, as with other cancers, is complex and due to the coordinated effects of environmental and genetic factors. Thus, the exposure dosage to chemical carcinogens could vary with enzyme activity. In theory, when *ADH2* activity is increased or *ALDH2* activity is decreased, the blood acetaldehyde level also increases in drinkers, thus increasing the risk of developing colorectal cancer. However, inconsistent results have been reported in many studies on the relation between *ADH2* and *ALDH2* gene polymorphisms and cancer susceptibility<sup>[11-18]</sup>. Yokoyama et al<sup>[11]</sup> found *ALDH2* G/A genotype encoding inactive

<sup>1</sup>OR was adjusted for age and smoking status.

*ALDH2* and *ADH2* G/G genotype encoding the low-activity form of *ADH2* can enhance the risk of esophageal cancer in Japanese alcoholics. For those individuals with both *ALDH2* G/A and *ADH2* G/G genotypes, the risk of esophageal cancer is increased in a multiplicative fashion. It was reported that after adjustment for age, daily alcohol consumption and amount of cigarette smoking, the risk of developing oropharyngolaryngeal, esophageal, stomach, colon, lung and multiple primary cancers is significantly increased in the presence of *ALDH2* A allele<sup>[12]</sup>. In a study on the association between genetic polymorphisms of tobacco- and alcohol-related metabolizing enzymes and esophageal squamous cell carcinoma susceptibility, Hori et al<sup>[13]</sup> showed that there is a significant difference in the distribution of *ADH2* and *ALDH2* genotypes between healthy controls and esophageal cancer patients, and that *ADH2* G/G and *ALDH2* G/A genotypes are significantly higher in esophageal cancer patients than in healthy controls. Furthermore, persons with combined genotypes of *ADH2* G/G and *ALDH2* G/A are at a high risk of developing esophageal squamous cell carcinoma. Chao et al<sup>[14]</sup> reported that Chinese alcoholic patients with *ADH2* G and *ALDH2* A alleles are more susceptible to esophageal cancer. However, Ohhira et al<sup>[15]</sup> showed that 10 patients with hepatocellular carcinoma (HCC) associated with pure alcoholic liver disease all have *ALDH2* G/G genotype. Takeshita et al<sup>[16]</sup> also examined associations between *ADH2* and *ALDH2* polymorphisms, alcohol drinking and HCC development in Japanese, and showed that a greater cumulative amount of alcohol consumption is significantly associated with HCC development but

not with *ADH2* and *ALDH2* genotypes, indicating that ethanol is directly involved in the development of HCC rather than acetaldehyde. The latest evaluation in 2007 by the International Agency for Research on Cancer (IARC) confirmed that alcoholic beverages are carcinogenic to human beings (Group 1), thus increasing the occurrence of cancer in many sites, such as oral cavity, pharynx, larynx esophagus, liver, colorectum and female breast<sup>[17,18]</sup>.

Our previous study showed that *ADH2* and *ALDH2* polymorphisms are not significantly associated with the risk of developing liver, stomach and esophageal cancer<sup>[19-21]</sup>. However, those with *ALDH2* G allele drinking a greater amount of alcohol significantly elevates the risk of developing HCC and those with *ALDH2* G/G genotype drinking a larger amount of alcohol are at a significantly increased risk of developing gastric cancer. Matsuo *et al*<sup>[22]</sup> evaluated the relationship between genetic polymorphisms of *ADH2* His47Arg and *ALDH2* Glu487Lys and occurrence of colorectal cancer in Japan, and showed that *ADH2* Arg allele is associated with an increased risk of CRC. However, no significant association was found with the *ALDH2* polymorphism itself, a significant interaction between *ALDH2* and *ADH2* polymorphisms was observed in their study.

In the present study, *ADH2* A/A and *ALDH2* G/G genotypes moderately increased the risk of developing colorectal cancer in Chinese males. Significant gene-gene and gene-environment interactions were also observed between alcohol drinking and *ADH2* and *ALDH2* polymorphisms regarding colorectal cancer risk. However, further study is needed to confirm our results with a large sample size.

## ACKNOWLEDGMENTS

The authors would like to thank the medical staff of Huai'an Municipal Hospital and the staff of the Public Health Centers of Huai'an and Jintan Cities for their assistance in data collection.

## COMMENTS

### Background

Colorectal cancer (CRC) is the fifth most common cancer in China. There is epidemiological evidence that alcohol intake is associated with an increased CRC risk. Alcohol dehydrogenase 2 (*ADH2*) and aldehyde dehydrogenase 2 (*ALDH2*) have a strong impact on alcohol metabolism. To evaluate the relationship between habitual drinking and genetic polymorphisms of *ADH2* and *ALDH2* with reference to the risk of CRC in Chinese males, we conducted a population based case-control study of CRC in Jiangsu Province of China.

### Research frontiers

Susceptibility to cancer is generally thought to be the sum of complex interactions between environmental and genetic factors. Therefore, interaction between environmental and genetic factors is a hotspot of cancer epidemiology. We studied interactions between *ADH2* and/or *ALDH2* and habitual alcohol drinking in CRC development.

### Innovations and breakthroughs

The present study showed that *ADH2* A/A and *ALDH2* G/G genotypes were correlated with the increased risk of CRC. Furthermore, a significant cooperative role of *ADH2* A/A and/or *ALDH2* G/G genotypes and alcohol

consumption was also observed in the development of CRC.

### Applications

This research showed the genetic risk factors and the role of gene environment interactions in identifying individuals at risk of CRC, which have certain theoretical and application values for studying the etiology of CRC and its prevention.

### Peer review

The correlation between habitual drinking and genetic polymorphisms of *ADH2* and *ALDH2* was studied with reference to the risk of CRC in Chinese males. Furthermore, significant gene-gene and gene-environment interactions between alcohol drinking and *ADH2* and *ALDH2* polymorphisms were also found regarding the CRC risk. The experiments contained appropriate controls and data about the age, smoking status and alcohol consumption. This research also reported the genetic risk factors and the role of gene-environment interactions in identifying patients at risk of developing colorectal cancer in Chinese males.

## Abstract

**AIM:** To evaluate the clinical outcome of Ivor Lewis subtotal esophagectomy with two-field lymphadenectomy for patients with squamous cell carcinoma of the lower thoracic esophagus.

**METHODS:** From January 1998 to December 2001, 73 patients with lower thoracic esophageal carcinoma underwent Ivor-Lewis subtotal esophagectomy with two-field lymphadenectomy. Clinicopathological information, postoperative complications, mortality and long term survival of all these patients were analyzed retrospectively.

**RESULTS:** The operative morbidity and mortality was 15.1% and the mortality was 2.7%. Lymph node metastases were found in 52 patients (71.2%). Nodal metastases to the upper, middle, lower mediastini and upper abdomen were found in 13 (17.8%), 15 (20.5%), 30 (41.1%), and 25 (34.2%) patients, respectively. Postoperative staging was as follows: stage I in 5 patients, stage II in 34 patients, stage III in 32 patients, and stage IV in 2 patients, respectively. The overall 5-year survival rate was 23.3%. For N0 and N1 patients, the 5-year survival rate was 38.1% and 17.3%, respectively ( $\chi^2 = 22.65, P < 0.01$ ). The 5-year survival rate for patients in stages IIa, IIb and III was 31.2%, 27.8% and 12.5%, respectively ( $\chi^2 = 29.18, P < 0.01$ ).

**CONCLUSION:** Ivor Lewis subtotal esophagectomy

## INTRODUCTION

Radical esophagectomy with lymphadenectomy remains the mainstay of curative therapy for esophageal carcinoma. Complete resection of esophagus and regional lymph node ( $R_0$  resection) are essential to improve long-term survival<sup>[1-3]</sup>. For carcinomas of the lower thoracic esophagus, different tumor characteristics between the Western and Eastern countries cause various attitudes on their surgical management<sup>[4]</sup>. Depending on the attending surgeon's philosophy, surgical approaches to carcinomas of the lower thoracic esophagus vary from the conventional left thoraco-abdominal approach<sup>[5,6]</sup> to the transhiatal approach without thoracotomy<sup>[7-9]</sup>, Ivor Lewis approach<sup>[10-12]</sup>, and recently reported thoracoscopic approach<sup>[13-15]</sup>. On the other hand, controversy continues over the optimal extent of lymphadenectomy to be performed with esophagectomy. Some authors do not favor lymphadenectomy considering lymph node involvement as systemic disease with no hope for cure, and the primary goal of surgical intervention is palliative, with a low surgical morbidity and mortality<sup>[8]</sup>. However, some authors prefer two-field lymphadenectomy and regard it as a standard surgical procedure<sup>[10,12,16]</sup>. What is more, other authors, mainly from Japan, advocate three-field lymphadenectomy in order to obtain accurate staging,

control locoregional recurrence and improve long-term survival<sup>[17-20]</sup>.

At our hospital, the main surgical approach to lower thoracic esophageal carcinoma is the Ivor Lewis approach, instead of left thoraco-abdominal approach that is widely adopted in China, because Ivor Lewis approach provides a wider extent of lymphadenectomy than left thoraco-abdominal approach, and the chance of obtaining R<sub>0</sub> resection is greater. The aim of this study was to retrospectively assess our results of Ivor Lewis subtotal esophagectomy with two-field lymphadenectomy for patients with squamous cell carcinoma of the lower thoracic esophagus.

## MATERIALS AND METHODS

### **Patients**

From January 1998 to December 2001, 73 patients with squamous cell carcinoma of the lower thoracic esophagus underwent Ivor Lewis subtotal esophagectomy with two-field lymph node dissection at Zhejiang Cancer Hospital, Hangzhou, China. There were 65 men and 8 women. Median age was 57 years (range, 39 to 78 years). Preoperative evaluation was performed for all patients with a barium swallow examination, endoscopy with biopsy, ultrasonography of the neck and upper abdominal compartment. Cardiac and pulmonary functions were also routinely performed for these patients to determine their ability to withstand the planned surgical procedure. Before treatment, diagnosis of all patients was established histologically. No patient received chemotherapy or radiotherapy before operation. Postoperative staging was based on the 2002 UICC-TNM classification<sup>[21]</sup>.

Duration of surgery, operative blood loss, and the number of lymph nodes were recorded. Postoperative complications were also recorded. Operative mortality was defined as any death during the first 30 d after operation or during the same hospital stay.

### **Surgical technique**

All patients underwent Ivor Lewis subtotal esophagectomy with two-field lymphadenectomy. In brief, all resections were carried out by initial abdominal exploration through an upper midline laparotomy. The stomach was mobilized on the right gastric and gastroepiploic arteries. The left gastric artery was divided at its origin, and all lymph nodes along the celiac axis and its three branches along the left aspect of the portal vein, in front of the inferior vena cava, along the diaphragmatic pillars, and in front of the left adrenal gland were *en bloc* resected. A pyloromyotomy was performed routinely for all the patients. No drainage procedure was done. After the abdominal stage, a right posterolateral thoracotomy was performed. The thoracic dissection included removal of azygous arch with its associated lymph nodes, thoracic duct, and the low paratracheal, subcarinal, paraesophageal, and parahiatal nodes in continuity with the resected esophagus. In addition, upper mediastinal, paratracheal lymphatic tissue

**Table 1 Postoperative pathological staging in 73 patients with esophageal carcinoma**

Stage	TNM	Patients, n (%)
I (n = 5)	T1N0M0	5 (6.8)
II a (n = 16)	T2N0M0	7 (9.6)
	T3N0M0	9 (12.3)
II b (n = 19)	T1N1M0	3 (4.1)
	T2N1M0	15 (20.5)
III (n = 32)	T3N1M0	29 (39.7)
	T4N1M0	3 (4.1)
IV (n = 2)	T3N1M1	2 (2.7)

including lymph nodes of the left and right recurrent laryngeal nerves were also removed. Denudation of the lesser curvature was usually performed in the pleural cavity. After resection of the specimen, an anastomosis was constructed between the stomach and esophagus. The anastomosis was located in the apex of the chest in all patients.

After surgery, all patients returned to the intensive care unit for 2 d on average. On day 5 after surgery, patients underwent contrast X-ray study for assessment of esophagogastric anastomosis and then received enteral feeding.

### **Follow-up**

Postoperative data were collected at the outpatient clinic. Follow-up data were obtained by telephone. The follow-up time ranged 0-88 mo (median 47 mo). Survival time was defined as the period from the date of surgery until death or the most recent follow-up investigation (September 2005), with none lost to follow-up.

### **Statistical analysis**

Survival analysis was carried out with the Kaplan-Meier method, and the log-rank test was used for comparisons. Estimates and 95% confidence intervals (CI<sub>95</sub>) were given for 5 years. Fisher's exact two-tailed test was used to compare categorical data. P < 0.05 was considered statistically significant.

## RESULTS

### **Pathological findings**

All the 73 patients acquired complete resection (R<sub>0</sub> resection). The postoperative stage and TNM classification are shown in Table 1. Of the 8 patients with pathological T1 tumors, 2 had muscularis mucosae tumors and 6 had submucosal tumors. Nodal involvement was found in 3 of the 6 patients with submucosal tumors. Of the 3 patients with pathological T4 tumors, 2 had liver involvement and 1 had lung involvement. Combined resections were performed for the 3 patients. Metastases were found in celiac nodes of 2 patients with M1 disease.

### **Operative outcomes**

The operation time was 243 ± 40 min. The operative blood loss was 365 ± 230 mL. The number of lymph

**Table 2 Postoperative complications in 73 patients with esophageal carcinoma n (%)**

Complications	Patients	Patients died
Pneumonia	4 (5.5)	1 (1.4)
Vocal cord palsy	3 (4.1)	0 (0)
Arrhythmia	3 (4.1)	0 (0)
Anastomotic leakage	2 (2.7)	1 (1.4)
Postoperative bleeding	1 (1.4)	0 (0)
Wound infection	1 (1.4)	0 (0)

**Table 3 Relation between depth of tumor infiltration (T) and lymph node metastasis (N)**

T	N0	N1	Prevalence of nodal metastases (%)
T1 (n = 8)	5	3	37.5
T2 (n = 22)	7	15	68.2
T3 (n = 40)	9	31	77.5
T4 (n = 3)	0	3	100

P = 0.888.

nodes resected was  $31 \pm 11$  (median, 27). Postoperative complications are listed in Table 2. Complications occurred in 11 patients (15.1%, CI<sub>95</sub> 6.9%-23.3%). Of the 73 patients, 2 (2.7%, CI<sub>95</sub> 0%-6.5%) died due to pneumonia and anastomotic leakage, respectively, within 30 d of the operation.

### Tumor depth and lymph node metastases

Lymph node metastases were found in 52 patients and the prevalence of nodal metastasis was 71.2% (CI<sub>95</sub> 60.8%-81.6%). As shown in Table 3, the prevalence of nodal metastases increased with increasing tumor depth, but the difference was not statistically significant. The prevalence of nodal metastases was 37.5% in T1 stage patients, 77.5% in T3 stage patients, which was statistically significant ( $\chi^2 = 5.06$ , P = 0.025). Other differences in the two stages were not statistically significant (T1 vs T2, T1 vs T4, T2 vs T3, T2 vs T4, T3 vs T4).

### Distribution of metastatic lymph node

The frequencies of nodal metastases in different anatomical regions are shown in Table 4, which were statistically significant (P = 0.004). The frequency in lower mediastinum (41.1%) was higher than that in upper (17.8%,  $\chi^2 = 9.53$ , P = 0.007), and middle mediastini (20.5%,  $\chi^2 = 7.23$ , P = 0.007). The frequency in upper abdomen (34.2%) was higher than that in upper mediastinum (17.8%) ( $\chi^2 = 5.12$ , P = 0.024). Other differences in frequencies between the two regions were not statistically significant. Among the 52 patients with lymph node involvement, 13 (25.0%, CI<sub>95</sub> 13.3%-36.7%) had skip nodal metastases without invasion of peritumoral nodes. Isolated lymph node involvement was observed in the upper mediastinum of 6 patients (4 with positive left recurrent laryngeal nerve nodes, 2 positive right left laryngeal nerve nodes) and in the upper abdomen of 7 patients with positive left gastric arterial nodes, respectively. These patients (17.8%, CI<sub>95</sub>

**Table 4 Distribution of lymph node metastatic locations**

Metastatic location	Patients with negative lymph node (n)	Patients with positive lymph node (n)	Frequency of nodal metastases (%)
Upper mediastinum	60	13	17.8
Middle mediastinum	58	15	20.5
Lower mediastinum	43	30	41.1
Upper abdomen	48	25	34.2

P = 0.004.

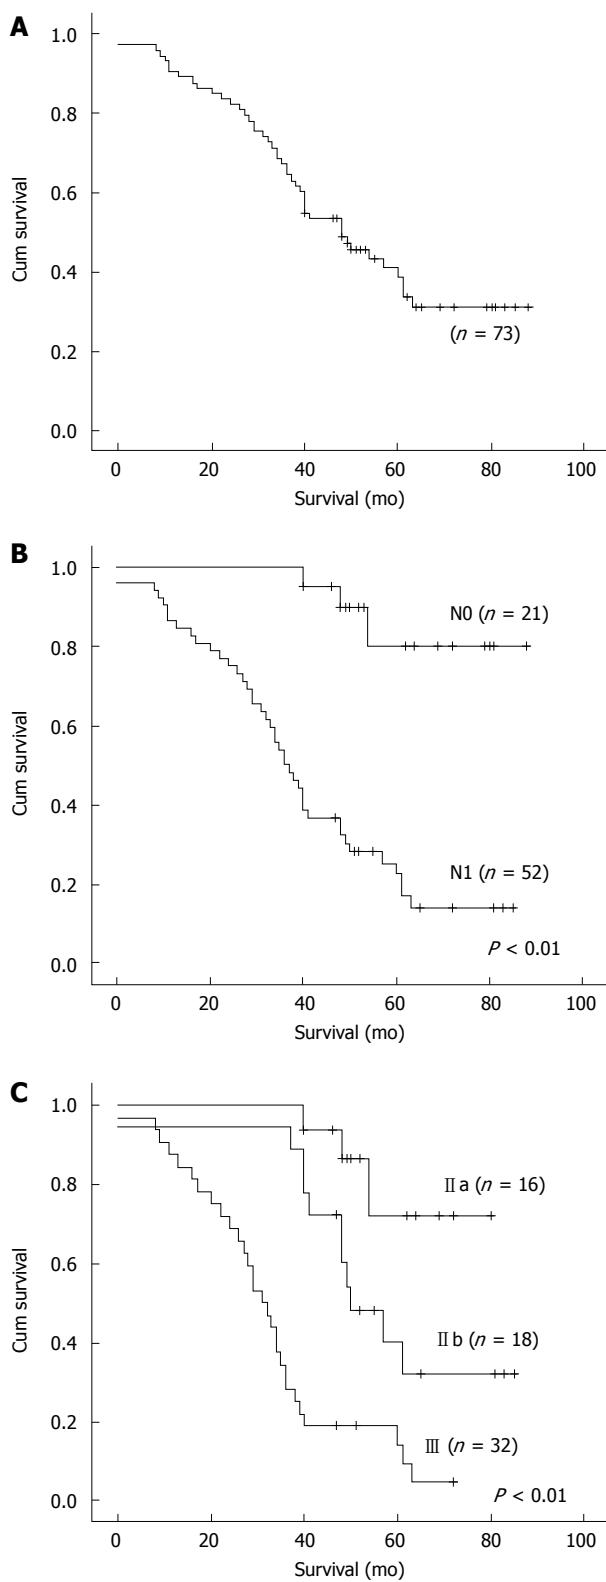

9.0%-26.6%) did not undergo two-field lymphadenectomy but received incomplete resections (R<sub>1</sub> resection of microscopically residual tumors or R<sub>2</sub> resection of macroscopically residual tumors). Had upper mediastinal lymphadenectomy not been performed, six patients (8.2%, CI<sub>95</sub> 1.9%-15.5%) would not have undergone upper mediastinal lymphadenectomy but received inaccurate staging.

### Survival rate

The 5-year survival rate was 23.3% (CI<sub>95</sub> 13.5%-32.9%) for all patients (Figure 1A). The 5-year survival rate was 38.1% (CI<sub>95</sub> 17.4%-58.8%) and 17.3% (CI<sub>95</sub> 7.0%-27.6%) for N0 and N1 patients, respectively ( $\chi^2 = 22.65$ , P < 0.01, Figure 1B). The 5-year survival rate for patients in stages II a, II b, and III was 31.2% (CI<sub>95</sub> 8.9%-53.5%), 27.8% (CI<sub>95</sub> 7.1%-48.5%) and 12.5% (CI<sub>95</sub> 1.0%-24.0%), respectively ( $\chi^2 = 29.18$ , P < 0.01, Figure 1C).

## DISCUSSION

Studies demonstrated that extensive submucosal lymphatic drainage to the esophageal wall causes a unique pattern of nodal metastases<sup>[1,2,4]</sup>. It was reported that the prevalence of nodal metastases of lower thoracic esophageal carcinoma is up to 70%<sup>[1-3]</sup>. Lymphatic dissemination is an early event of esophageal carcinoma, and involved nodes are found in 30%-40% of submucosal tumors<sup>[2,3]</sup>. These data are consistent with our results (71.2% and 50%, respectively). It has been documented that the likelihood of nodal metastases of esophageal carcinoma depends on the depth of tumor invasion of the esophageal wall<sup>[2,3]</sup>. The prevalence of nodal metastases increased with the increasing tumor invasion depth in this study. The prevalence of nodal metastases had no difference between the two groups according to their T status, suggesting that it may be related to the small sample size. Unlike squamous cell carcinoma of the upper thoracic esophagus, which shows lymphatic flow is mainly in the upward direction along the esophageal wall, squamous cell carcinoma of the lower thoracic esophagus, which shows lymphatic spread is mainly in the downward direction along the esophageal wall<sup>[2,4]</sup>, which is consistent with our findings. Although to some degree, the frequencies of lower mediastinal and upper abdominal metastases were higher than those of upper and middle mediastinal metastases, the frequency of upper mediastinal metastases (17.8%) was still not as low as that of middle mediastinal

**Figure 1** Survival curves for the 73 patients with squamous cell carcinoma of the lower thoracic esophagus (A), according to the N status (B), and the TNM stage (C).

metastases (20.5%) in the patients with lower thoracic esophageal carcinoma. An even higher frequency of upper and/or middle mediastinal metastases (30%-40%) has been reported<sup>[2,4]</sup>. In our study, skip nodal metastases were found in 25% of nodal positive patients. Of the 52 patients, 6 (11.5%) and 7 (13.5%) had positive nodes in

the upper mediastinum and abdomen, respectively. Hosch *et al*<sup>[22]</sup> reported that skip metastases nodal positive patients and a frequent event in esophageal cancer. Based on these nodal metastatic features, in order to obtain R<sub>0</sub> resection, lymphadenectomy with upper mediastinal dissection should be performed for squamous cell carcinoma of the lower esophagus.

The greater the number of lymph nodes is removed, the greater the chance of obtaining a R<sub>0</sub> resection, and the more precisely the disease can be staged<sup>[1-3,11]</sup>. The extent of lymphadenectomy for a cancer in the thoracic esophagus has been classified by the Consensus Conference of the International Society for Diseases of the Esophagus (ISDE) as a standard, extended, total, or three-field lymphadenectomy<sup>[23]</sup>. The optimal lymphadenectomy for squamous cell carcinoma of the lower thoracic esophagus is still debatable. Of the 4 types of lymphadenectomy, three-field lymphadenectomy can, most likely, achieve a R<sub>0</sub> resection and accurate staging. The question is whether it definitely improves the long-term survival of patients. However, most data are available from nonrandomized retrospective historical studies in Japan. Igaki *et al*<sup>[4]</sup> reported that three-field lymphadenectomy could prolong the survival time of patients with squamous cell carcinoma of the lower thoracic esophagus compared to 2-field lymphadenectomy for nodal metastases present in the upper and/or middle mediastinum. Fujita *et al*<sup>[24]</sup> reported that there is no difference in survival rate for patients with lower thoracic esophageal cancer between the two procedures of lymphadenectomy. Three-field lymphadenectomy has its obvious advantages and disadvantages<sup>[16,18]</sup>. Hence, two field lymphadenectomy seems to be a more reasonable choice of treatment for squamous cell carcinoma of the lower thoracic esophagus. This viewpoint is far out weighed by the fact that the emphasis on three-field lymphadenectomy has shifted to lymphadenectomy along the recurrent laryngeal nerve chains, where lymph nodes could be dissected through two-field lymphadenectomy<sup>[16]</sup>. Among the other three types of lymphadenectomy, total (mediastinal) lymphadenectomy which was applied in this study, provides more chances to obtain a R<sub>0</sub> resection and accurate staging than the other two types of lymphadenectomy. As our data show, if a standard lymphadenectomy was performed, positive nodes would be left intact, thus only R<sub>1</sub> or R<sub>2</sub> resection could be achieved, leading to stage migration from N0 to N1 in 6 patients (8.2%). If an extended lymphadenectomy was performed, stage migration from N0 to N1 would occur in 4 patients (5.5%), which can be explained by the fact that the extent of standard lymphadenectomy does not cover the upper and left upper mediastini. Total (mediastinal) lymphadenectomy is therefore an alternative for squamous cell carcinoma of the lower thoracic esophagus. Then, which surgical approach could satisfy the demand for total lymphadenectomy? Transhiatal approach without thoracotomy is unlikely to be chosen. In the left thoraco-abdominal approach we used previously, upper mediastinal lymph nodes are

not available. In the McKeown approach (anterolateral right thoracotomy), a radical lymphadenectomy is more difficult to achieve than the Ivor Lewis approach<sup>[5,12]</sup>. Thoracoscopic approach to esophageal carcinoma remains to be investigated and no systemic data are available to support its advantages over the minimally invasive approach to esophagectomy<sup>[25]</sup>. Ivor Lewis approach which allows complete visualization of mediastinum, especially upper mediastinum, seems to be most appropriate for squamous cell carcinoma of the lower thoracic esophagus.

Morbidity increases with the extent of lymphadenectomy but does not lead to a higher mortality<sup>[11]</sup>. Pneumonia was the most common complication in this study, which is consistent with previous reports<sup>[10-12]</sup>. Vocal cord palsy caused by lymphadenectomy around recurrent laryngeal nerves also occurs occasionally. Functional mediastinal lymphadenectomy can preserve the bronchial artery and bronchial branches of the vagus nerve, thus reducing the respiratory complications<sup>[20,26]</sup>. To prevent vocal cord palsy, electrocautery close to the recurrent laryngeal nerve and drawing the nerve with a vessel tape should be avoided during lymphadenectomy<sup>[19]</sup>.

The overall 5-year survival rate of our patients was only 23.3%, which may be due to the small sample size in our study. On the other hand, the survival of patients was ascertained in September 2005 when 15 patients were alive at the most recent follow-up. Accordingly, this overall survival rate could not completely explain the effect of treatment since we did not make comparisons with others. However, there was a significant difference in the survival rate between the two groups of patients with different N status and different stages. This series were proved to be more homogenous with regard to the clinical variables, such as tumor site and pathological type. The surgical procedure performed in this series revealed more R<sub>0</sub> resection and staging information than other surgical procedures (except three-field lymphadenectomy). Compared to other surgical procedures, Ivor Lewis esophagectomy with two-field (total mediastinal) lymphadenectomy could achieve better results in patients with squamous cell carcinoma of the lower thoracic esophagus. Because of the small sample size used in this study, further studies are needed to confirm our results.

In conclusion, Ivor Lewis subtotal esophagectomy with two-field (total mediastinal) lymphadenectomy is a safe and appropriate surgical procedure for squamous cell carcinoma of the lower esophagus.

## COMMENTS

### Background

Radical esophagectomy with lymphadenectomy is still the mainstay of curative therapy for esophageal carcinoma. This study retrospectively analyzed the clinical outcome of Ivor Lewis subtotal esophagectomy with two-field lymphadenectomy for squamous cell carcinoma of the lower thoracic esophagus.

### Research frontiers

Adenocarcinoma of the lower thoracic esophagus is a common pathological type in Western countries, while squamous cell carcinoma is the main type in Eastern countries. The attitudes to the surgical approach and the extent of the lymphadenectomy for the lower thoracic esophageal carcinoma are different in

Western and Eastern countries. Western general thoracic surgeons prefer the transhiatal approach and limited extent of lymphadenectomy, whereas Eastern general thoracic surgeons prefer the transthoracic approach and 2-field or 3-field lymphadenectomy.

### Innovations and breakthroughs

In China, the left thoracoabdominal approach and standard 2-field lymphadenectomy are widely performed for lower thoracic esophageal carcinoma. In our clinical practice, however, they are widely performed as upper mediastinal lymphadenectomy. Furthermore, the prevalence of upper mediastinal nodal involvement is not low. 3-field lymphadenectomy is still controversial. This type of lymphadenectomy is not routinely performed in our institution. We prefer the Ivor Lewis approach with total mediastinal 2-field lymphadenectomy in the treatment of this disease.

### Applications

Ivor Lewis subtotal esophagectomy with 2-field lymphadenectomy is a safe surgical procedure for squamous cell carcinoma of the lower thoracic esophagus.

### Terminology

Ivor Lewis subtotal esophagectomy is a laparotomy followed by a right thoracotomy. Two-field total mediastinal lymphadenectomy involves resection of bilateral upper mediastinum in addition to a standard lymphadenectomy.

### Peer review

The paper is scientific, innovative and readable, showing the advanced level of clinical research in gastroenterology both at home and abroad.

### **Abstract**

**AIM:** To investigate the effect of *Lactobacillus bulgaricus* (LBG) on the Toll-like receptor 4 (TLR4) pathway and interleukin-8 (IL-8) production in SGC-7901 cells treated with *Helicobacter pylori*Sydney strain 1 lipopolysaccharide (*H pylori*SS1-LPS).

**METHODS:** SGC-7901 cells were treated with *H pylori*SS1-LPS in the presence or absence of pretreatment for 1 h with viable LBG or supernatant recovered from LBG culture MRS broth (LBG-s). Cellular lysates were prepared for Western blot with anti-TLR4, anti-transforming growth factor  $\beta$ -activated kinase 1 (TAK1), anti-phospho-TAK1, anti-nuclear factor  $\kappa$ B (NF- $\kappa$ B), anti-p38 mitogen-activated protein kinase (p38MAPK), and anti-phospho-p38MAPK antibodies. The amount of IL-8 in cell culture medium was measured by ELISA.

**RESULTS:** *H pylori*SS1-LPS up-regulated the expression of TLR4, stimulated the phosphorylation of TAK1, subsequently enhanced the activation of NF- $\kappa$ B and the phosphorylation of p38MAPK in a time-dependent manner, leading to augmentation of IL-8 production in SGC-7901 cells. Viable LBG or LBG-s pretreatment attenuated the expression of TLR4, inhibited the phosphorylation of TAK1 and p38MAPK, prevented the activation of NF- $\kappa$ B, and consequently blocked IL-8 production.

### **INTRODUCTION**

Infection with the human gastric pathogen *Helicobacter pylori* (*H pylori*) can develop into chronic gastritis, peptic ulcer and gastric cancer. Some studies<sup>[1-5]</sup> demonstrated that *H pylori* can stimulate interleukin-8 (IL-8) production in gastric mucosal epithelia, which induces accumulation of neutrophilic granulocytes in mucosa. Chemotactic response initiates inflammatory damage to gastric mucosa, which plays a crucial role in the pathogenesis of *H pylori*. However, signal transduction through which *H pylori* modulates IL-8 production from gastric epithelia is not fully understood.

The product of particular significance for the virulent action of *H pylori* is its cell wall lipopolysaccharide (LPS). The effects of *H pylori* lipopolysaccharide (*H pylori*-LPS) have been manifested by the marked increase of nitric oxide and proinflammatory cytokines including IL-8 in gastric mucosa<sup>[6,7]</sup>, abrogation of proliferation and induction of apoptosis in gastric epithelia<sup>[8]</sup>. Mammalian Toll-like receptors trigger the signaling pathways involved in innate immune responses to microbial challenge after recognizing pathogen-associated molecular patterns.

*H pylori*-LPS is the natural ligand for Toll-like receptor 4 (TLR4) in gastric epithelia. It has been proposed that *H pylori*-LPS induces IL-8 production in gastric epithelia through activating the TLR4 signaling pathway<sup>[7,9]</sup>.

Probiotics are living microorganisms with no or low pathogenicity, which exert beneficial effects on the host. *Lactobacillus bulgaricus* (LBG), a bacterium used in the production of yogurt, is one of the best-studied probiotics. There is increasing evidence<sup>[10,11]</sup> that LBG has therapeutic effects on *H pylori*-related diseases, including enhanced eradication of *H pylori*, amelioration of resistance to antibiotics, down-regulated side effects of antibiotic-based therapy, decreased recurrence of *H pylori* infection, and inhibition of *H pylori*-induced apoptosis. The mechanisms underlying these effects include inhibition of *H pylori* growth and attachment to epithelial cells, inactivation of virulent factors such as urease, and decrease in production of *H pylori*-induced proinflammatory cytokines<sup>[12-16]</sup>. However, the signaling pathways which are modulated by LBG in gastric epithelia have not been well elucidated.

In this experiment, we demonstrated that viable LBG inhibited the activation of the TLR4 signaling pathway and IL-8 production induced by *H pylori*Sydney strain 1 lipopolysaccharide (*H pylori*SS1-LPS) in SGC-7901 cells. Furthermore, supernatant recovered from the LBG culture MRS broth (LBG-s) also exerted these effects on SGC-7901 cells treated with *H pylori*SS1-LPS. These observations provide the novel insight into the rationale for LBG as a potential treatment for *H pylori*-related diseases.

## MATERIALS AND METHODS

### *H pylori*SS1 culture and *H pylori*SS1-LPS preparation

*H pylori*SS1 was kindly offered by Professor Qian Yu (School of Public Health, Sichuan University). *H pylori*SS1 was incubated in Brucella broth (bioMérieux Corporate, La Balme-Les Grottes, France) supplemented with 10% fetal calf serum (FCS; Invitrogen GIBCO, Carlsbad, California, USA), 10 mg/L vancomycin, 10 mg/L amphotericin and 2500 U/L polymyxin B in a shaking incubator (100 r/min) at 37°C in an atmosphere containing 50 mL/L O<sub>2</sub>, 100 mL/L CO<sub>2</sub> and 850 mL/L N<sub>2</sub> for 48 h. *H pylori*SS1 was precipitated from Brucella broth by centrifuging at 10 000 r/min for 10 min at 4°C and washed twice with PBS. Then the concentration of *H pylori*SS1 in PBS was adjusted to 10<sup>8</sup> colony forming units (CFU)/mL with optical density determined as 1 at  $\lambda_{660}$ . The *H pylori*SS1-containing PBS was used to prepare *H pylori*SS1-LPS with the LPS extraction kit (bioMérieux) following guidelines from its manufacturer. *H pylori*SS1-LPS concentrations were determined with the kinetic Limulus amebocyte lysate assay kit (Cambrex, Walkersville, Maryland, USA) according to the manufacturer's instructions.

### LBG culture and LBG-s preparation

LBG, kindly offered by Professor Qian Yu (School of

Public Health, Sichuan University), was incubated in MRS broth (bioMérieux) in a candle jar at 37°C for 24–48 h, precipitated from MRS broth by centrifuging at 5000 r/min for 10 min and washed twice with PBS. Then the concentration of LBG in PBS was adjusted to 10<sup>7</sup> CFU/mL with optical density determined as 0.5 at  $\lambda_{660}$ . LBG was precipitated from PBS by centrifuging at 5000 r/min for 10 min and resuspended with an equivalent volume of RPMI 1640 medium (Invitrogen GIBCO) for pretreatment of SGC-7901 cells.

LBG-s was generated by centrifuging at 1000 × g for 15 min and filtering (0.2 µm) LBG culture MRS broth, then the filtrate was concentrated using Centricon Plus-20 (5-100 kDa; Millipore, Bedford, Massachusetts, USA) by centrifugation at 4000 × g for 1 h following guidelines from the manufacturer. Protein concentrations were determined with the Pierce protein assay kit (Pierce, Rockford, Illinois, USA) using MRS broth as the control.

### Cell culture

SGC-7901 cell line was established from human gastric adenocarcinoma cells. Though the characteristics of cell apoptosis and proliferation are different from the cell line derived from normal gastric epithelia, SGC-7901 cells have been widely used as models for investigations on *H pylori*-induced gastric epithelial inflammatory responses because their inflammatory responsibility is similar to normal gastric epithelia. Therefore, SGC-7901 cells were used in our experiment. They were grown in RPMI 1640 medium supplemented with 10% FCS, 100 U/mL penicillin and 100 µg/mL streptomycin at 37°C in an atmosphere containing 50 mL/L CO<sub>2</sub>. After 3–4 times of passage, SGC-7901 cells were seeded to generate 1 × 10<sup>6</sup> cells per 6 cm culture dish and incubated in RPMI 1640 medium containing 10% FCS, 100 U/mL penicillin and 100 µg/mL streptomycin at 37°C in an atmosphere containing 50 mL/L CO<sub>2</sub> for 24 h. Then all cells were serum-starved (0.5% FCS) for 24 h before experimentation.

### Treatment of cell line

SGC-7901 cells were treated with 25 endotoxin units (EU)/mL *H pylori*SS1-LPS for 0, 30, 60 min or 120 min in the absence or presence of pretreatment for 1 h with 10<sup>7</sup> CFU/mL viable LBG or 10<sup>-2</sup> mg/mL LBG-s. At the end of each time point, cells were collected for Western blot, and RPMI 1640 medium was collected for ELISA. Each experiment was in triplicate.

### Preparation of cellular lysates and Western blot analysis

Nuclear and cytoplasmic extraction from SGC-7901 cells was performed using the nuclear-cytosol extraction kit (Cell Signaling Technology, Danvers, Massachusetts, USA) following guidelines from the manufacturer. Protein concentrations of all extracts were determined with the Pierce protein assay kit. Each extract was mixed with an equal amount of 2 × loading buffer and heated at 100°C for 5 min. Thirty micrograms of protein was loaded in each lane, resolved in sodium dodecyl

sulphate-polyacrylamide gels and electrotransferred to polyvinylidene difluoride membrane ( $1.2 \text{ mA/cm}^2$ , 1 h). After blocked with 5% fat-free dried milk in Tris-buffered saline containing 0.1% Tween-20 (TBST) for 1 h, the membrane was incubated overnight at 4°C with the following primary antibodies: anti-TLR4, anti-transforming growth factor  $\beta$ -activated kinase 1 (TAK1), anti-phospho-TAK1 (p-TAK1), anti-nuclear factor  $\kappa$ B (NF- $\kappa$ B), anti-p38 mitogen-activated protein kinase (p38MAPK), anti-phospho-p38MAPK (p-p38MAPK; all at the dilution of 1:1000, Cell Signaling Technology). Anti- $\beta$ -actin and anti-lamin B1 (both at the dilution of 1:1000, Santa Cruz Biotechnology, Santa Cruz, California, USA) were used for the control of equal protein loading. After washed three times in TBST, the membrane was incubated with horseradish peroxidase-conjugated IgG (1:5000, Santa Cruz Biotechnology) as the secondary antibody at room temperature for 1 h. The photographic film was exposed to bands visualized with the Supersignal West Pico chemiluminescent substrate kit (Pierce). The integrated optical density (IA) of each band was quantified using Quantity One software 4.5.0 (Bio-Rad Laboratories, Hercules, California, USA). Each value for TLR4 band was normalized as the ratio of IA of TLR4 band to that of  $\beta$ -actin band. Each value for p-TAK1 band was normalized as the ratio of IA of p-TAK1 band to that of TAK1 band. Each value for p-p38MAPK band was normalized as the ratio of IA of p-p38MAPK band to that of p38MAPK band. Each value for NF- $\kappa$ B band was normalized as the ratio of IA of NF- $\kappa$ B band to that of lamin B1 band. Each Western blot analysis of extract samples was performed in triplicate.

#### Detection of IL-8 production

The concentration of IL-8 in RPMI 1640 medium was determined with a commercially available ELISA kit (R&D Systems, Minneapolis, Minnesota, USA) following guidelines from the manufacturer. Each sample was detected thrice.

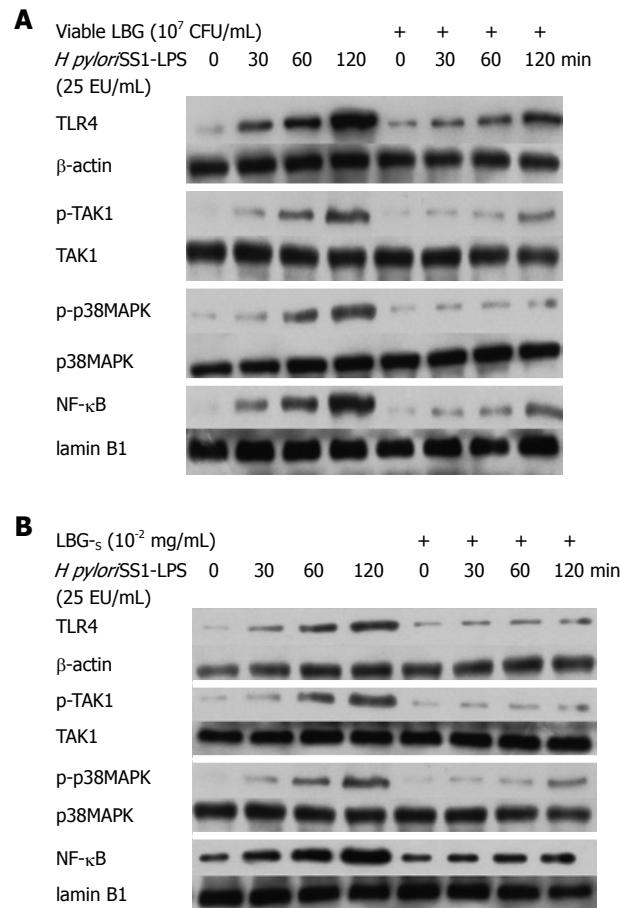

#### Statistical analysis

The data were expressed as mean  $\pm$  SD, and analyzed by SPSS13.0 software (SPSS, Chicago, Illinois, USA) for One-Way ANOVA test.  $P < 0.05$  was considered statistically significant.

## RESULTS

#### Viable LBG or LBG-s inhibited *H pylori*SS1-LPS-induced activation of TLR4 signaling pathway

Twenty-five EU/mL *H pylori*SS1-LPS up-regulated the expression of TLR4, enhanced the phosphorylation of TAK1 and p38MAPK, and induced the translocation of NF- $\kappa$ B into nuclei in a time-dependent manner (Figure 1A and B, Table 1). These results demonstrate that *H pylori*SS1-LPS could activate the TLR4 signaling pathway. Pretreatment for 1 h with  $10^7$  CFU/mL viable

**Figure 1** Expression of TLR4 and activation of TAK1, p38MAPK and NF- $\kappa$ B in SGC-7901 cells treated with *H pylori*SS1-LPS in the absence or presence of pretreatment with viable LBG (A) and LBG-s (B).

LBG (Figure 1A) or  $10^2$  mg/mL LBG-s (Figure 1B) significantly inhibited these effects of *H pylori*SS1-LPS on the TLR4 pathway in SGC-7901 cells to a great extent (Table 1).

#### Viable LBG or LBG-s inhibited *H pylori*SS1-LPS-induced IL-8 production

The production of IL-8 in SGC-7901 cells treated with 25 EU/mL *H pylori*SS1-LPS for 0, 30 or 60 min in the absence or presence of pretreatment for 1 h with  $10^7$  CFU/mL viable LBG or  $10^2$  mg/mL LBG-s was almost undetectable (Table 2). No significant difference in these data was possibly attributed to their extremely small value. Thirty or 60 min of treatment with *H pylori*SS1-LPS might be too short for SGC-7901 cells to produce enough IL-8 for ELISA, because cytokine production usually is posterior to the process of corresponding signal transduction. If we detected IL-8 mRNA in SGC-7901 cells using the retro-transcriptional polymerase chain reaction, results at 30 min or 60 min should have been significantly higher than those at 0 min. Only 120 min of treatment with 25 EU/mL *H pylori*SS1-LPS augmented IL-8 production in SGC-7901 cells (Table 2), which was, however, down-regulated by pretreatment for 1 h with  $10^7$  CFU/mL viable LBG or  $10^2$  mg/mL LBG-s (Table 2).

## DISCUSSION

*H pylori* have recently been considered an indigenous biota of human stomach and a dominant niche in gastric microecology including *Lactobacilli* and *Sacharomyces* with the capability of cross-species communication<sup>[17-19]</sup>. There is evidence that Helicobacter species are ancient inhabitants of human stomachs for at least 60000 years which have co-evolved with the host and developed their excellent adaption to humans<sup>[20,21]</sup>. Though the vast majority of people in developing countries carry *H pylori*, most of them have no clinical manifestations at all<sup>[22]</sup>. More and more observations are consistent with the hypothesis that *H pylori* have both pathogenetic and symbiotic features, thus relatively balance their cost and benefit<sup>[23,24]</sup>. Changes in life style and sanitation conditions cause a probable disturbance of gastric microecology, which plays a more important role in the pathogenetic mechanism of *H pylori* in the modern era<sup>[25,26]</sup>. Therefore, eradication of *H pylori* does not seem justified for all individuals, especially children. These findings lead to the speculation that we are supposed to domesticate *H pylori* through restoring the homeostasis

of the gastric microecosystem. It was reported that administration of exogenous *Lactobacilli* has therapeutic effects on *H pylori*-associated diseases by interfering with the pathogenetic progress of *H pylori*<sup>[27-30]</sup>. Inhibition of *H pylori*-induced proinflammatory factor production by *Lactobacilli* is a very important aspect. It has been demonstrated that *Lactobacilli* abrogate *H pylori*-mediated IL-8 release *in vitro* and *in vivo*<sup>[31,32]</sup>. A large body of evidence has shown that *H pylori*-LPS-induced inflammation in gastric mucosa has nearly the same pathological characteristics as the mucosal inflammation initiated by *H pylori* infection<sup>[6,7]</sup>. Bhattacharyya *et al*<sup>[33]</sup> reported that pretreatment with LPS inhibitor greatly attenuated *H pylori* extract-mediated gastric mucosal inflammation, suggesting that *H pylori*-LPS may be a major virulent factor for *H pylori*-associated mucosal inflammation, which urged us to research the effect of *Lactobacilli* on *H pylori*-LPS-induced IL-8 production. It has been documented that *H pylori*-LPS induces mucosal inflammation including IL-8 production via TLR4 signaling. In brief, *H pylori*-LPS is recognized by TLR4 of the gastric epithelium, and then activates interleukin-1 receptor-associated kinase, tumor necrosis factor receptor-associated factor-6, TAK1 and TAK1-binding protein 1/2, p38MAPK and NF- $\kappa$ B at last in a cascade mechanism<sup>[7,9]</sup>. However, whether *Lactobacilli* have the capability of inhibiting *H pylori*-LPS-activated TLR4 pathway through interacting with gastric epithelia directly has not been extensively researched. Our findings demonstrate that viable LBG and LBG<sub>s</sub> can prevent TLR4 signaling activation and IL-8 production mediated by *H pylori*SS1-LPS in SGC-7901 cells, which strongly supports the hypothesis that some soluble proteins secreted by LBG and (or) somatic constituents of LBG exert inhibitory effects on the TLR4 pathways in SGC-7901 cells treated with *H pylori*SS1-LPS. Yan *et al*<sup>[34]</sup> reported that *Lactobacillus rhamnosus* GG (LGG) or supernatant recovered from LGG culture MRS

broth (LGG-s) ameliorated apoptosis of young adult mouse colon cells treated with tumor necrosis factor  $\alpha$  (TNF- $\alpha$ ), interferon- $\gamma$  or interleukin-1 $\alpha$  through blocking p38MAPK and stress-activated protein kinase/c-Jun amino-terminal kinase pathway. In addition, they have identified two proteins in LGG-s with molecular sizes of 80 and 42 kDa, which may be possible substantial effectors in LGG-s<sup>[34]</sup>. In a recent study, they purified the two proteins from LGG-s again, ultimately determined their molecular weight as 75 and 40 kDa, and named them p75 and p40 respectively<sup>[35]</sup>. Their results demonstrate that both p75 and p40 can inhibit TNF- $\alpha$ -induced apoptosis of intestinal epithelia and promote cell growth through activating Akt<sup>[35]</sup>. LBG-s in our experiment probably contained the similar or even same proteins, which could intervene in *H pylori* SS1-LPS-activated TLR4 signaling through modulating other pathways in SGC-7901 cells. Further study is needed to evaluate the hypothesis. In the purification and characterization of the aforementioned potential soluble proteins secreted by LBG, we also detected the effect of heat-killed LBG (hk-LBG) on *H pylori* SS1-LPS-activated TLR4 signaling for evaluating the presumption that some somatic constituents of LBG may inhibit the effect of *H pylori* SS1-LPS. The incomplete data indicate that hk-LBG could also disrupt the *H pylori* SS1-LPS-activated TLR4 pathway. Nevertheless, the effect of hk-LBG was obviously smaller than that of viable LBG at the same concentration.

In conclusion, our evaluation of LBG as a model probiotic organism reveals an important and novel relationship between *H pylori*-LPS-activated TLR4 signaling and selective microflora, and further our understanding of the signal pathways in gastric epithelia involved in inflammatory responses that are regulated by probiotics and pathogenic bacteria composing the gastric microecosystem.

## ACKNOWLEDGMENTS

The authors thank Professor Qian Yu (School of Public Health, Sichuan University) for her kind donation of *H pylori* Sydney strain 1 and *Lactobacillus bulgaricus* as well as Drs. Xiang Liu, Ming-Jiang Bie and Jian Wang (Laboratory of Medical Laboratory Sciences, School of Public Health, Sichuan University) for their assistance in performing the experiments.

## COMMENTS

### Background

Some studies have demonstrated that *Helicobacter pylori* (*H pylori*) can stimulate the release of interleukin-8 (IL-8) from gastric epithelia, which initiates inflammatory damage to gastric mucosa and plays a crucial role in the pathogenesis of *H pylori* infection. *H pylori* lipopolysaccharide (*H pylori*-LPS) is a major virulent factor for *H pylori*-associated mucosal inflammation, which induces IL-8 production via activation of the Toll-like receptor 4 (TLR4) signaling pathway in gastric epithelia. Since *H pylori* is an indigenous biota in gastric microflora including *Lactobacilli* and disturbance of the gastric microecosystem plays a more important role in pathogenetic mechanisms of *H pylori*, eradication of *H pylori* in all individuals does not seem justifiable. The gastric microecosystem was restored after treatment with exogenous *Lactobacilli*.

However, whether *Lactobacilli* inhibit *H pylori*-LPS-induced IL-8 production through blocking *H pylori*-LPS-activated TLR4 pathway needs further study.

### Research frontiers

Though there is more and more evidence that *Lactobacilli* have beneficial effects on gastrointestinal diseases, the molecular mechanisms are not well understood, especially in *H pylori*-associated diseases. Whether certain soluble proteins secreted by *Lactobacillus bulgaricus* (LBG) and somatic constituents of LBG directly interact with some signaling pathways in gastric epithelia has not been clearly demonstrated. Our study indicated that *Lactobacillus rhamnosus* GG secreted p75 and p40, two proteins with a molecular size of 75 and 40 kDa respectively, could ameliorate apoptosis of intestinal epithelia treated with tumor necrosis factor  $\alpha$ , interferon- $\gamma$  or interleukin-1 $\alpha$  and promote cell growth through activating Akt, blocking p38 mitogen-activated protein kinase and stress-activated protein kinase/c-Jun amino-terminal kinase signaling. The supernatant recovered from LBG culture MRS broth (LBG-s) in our experiment may contain the similar or even same proteins, which could intervene in *H pylori* Sydney strain 1 lipopolysaccharide (*H pylori* SS1-LPS)-activated TLR4 signaling through modulating other pathways in SGC-7901 cells, suggesting that probiotic bacterial components may be useful in preventing *H pylori*-associated diseases.

### Innovations and breakthroughs

Viable LBG or LBG-s blocked the *H pylori* SS1-LPS-activated TLR4 pathway in SGC-7901 cells, leading to their inhibitory effects on IL-8 production induced by *H pylori* SS1-LPS.

### Applications

This study implied that certain soluble proteins secreted by *Lactobacilli* could directly interact with some signaling pathways in gastric epithelia and partly block the noxious effects of *H pylori*. This may benefit the exploration of new drugs for the treatment of *H pylori*-associated diseases.

### Peer review

The results of this study indicate that *H pylori* SS1-LPS could increase IL-8 production through TLR4 signaling in gastric epithelia and probiotic bacteria attenuate IL-8 production via inhibition of the TLR4 pathway. The manuscript contains some interesting data, viable probiotics and their extracts against *H pylori*-LPS cytotoxicity.

### INTRODUCTION

Approximately 148 000 new cases of colorectal cancer are detected yearly in the USA<sup>[1]</sup>. Ovarian metastasis has been reported in various studies to occur in 3%-14% of patients<sup>[2-5]</sup>. Endoscopic ultrasound (EUS) has been shown to have high accuracy in staging rectal cancer<sup>[6]</sup>. The use of EUS for detecting ovarian metastasis from colorectal cancer has not been established. We describe a case of a patient with ovarian metastasis from a rectal cancer that was not detected on computer tomography (CT) scan but detected as a peri-rectal mass on preoperative EUS.

### CASE REPORT

#### Abstract

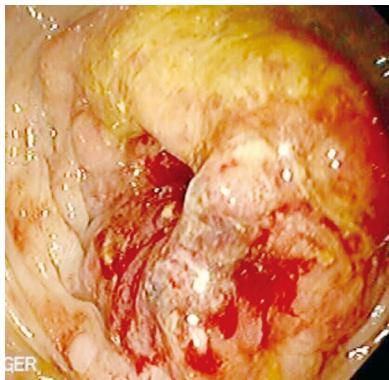

A case is presented of rectal carcinoma in which during staging by endoscopic ultrasound (EUS) a second large extrarectal mass was seen not otherwise visualized on computer tomography (CT) that was a solitary ovarian metastasis. The surgeon was alerted to the EUS finding prior to the planned laparoscopic colectomy. On retrospective review of the CT pelvis after surgery, the radiologist could still not diagnose the ovarian lesion separated from the primary rectal tumor due to their close proximity. However, on EUS we were able to clearly see on real-time imaging that there was a distinct peri-rectal mass apart from the primary rectal tumor.

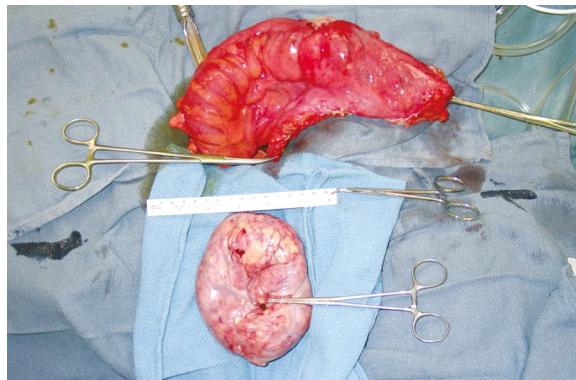

**Figure 1** Colonoscopic view of an obstructing rectal cancer.

**Figure 2** Radial EUS. A: Cancer in Figure 1 demonstrating it to be a T3 lesion; B: Revealing an extra-rectal hypoechoic round mass (between the calipers) measuring 5 cm in size, inferior to and clearly distinct from the primary rectal mass shown in Figures 1 and 2A.

## DISCUSSION

Colorectal cancer with ovarian metastasis has been reported in multiple studies<sup>[2-5]</sup>. Patients generally present with vague symptoms<sup>[7]</sup>. Colonoscopy or barium enema can help identify an intrinsic colonic lesion. If a rectal cancer is detected, EUS is performed to stage the cancer by assessing the extent of infiltration, and the presence/absence of lymph nodes<sup>[6]</sup>. EUS also allows for visualization of adjacent organs such as bladder or prostate. CT abdomen/pelvis is generally performed to evaluate metastasis of the colorectal cancer to the liver and other organs. It may be difficult at times to assess on CT, concomitant adjacent pelvic organ metastasis due to the close proximity to the bowel or to be able to differentiate the origin of a pelvic mass, whether

**Figure 3** Gross pathologic findings at surgery showing the resected rectal carcinoma and the solitary ovarian metastases correlating with the findings in Figure 2.

colorectal or perirectal.

Our case demonstrates the utility of EUS in detecting peri-rectal lesion, which in our patient was difficult to detect even on retrospective review of the CT. Combining information from imaging modalities such as CT and EUS may be even more important when minimally invasive surgical techniques are employed for cancer surgery to provide the surgeon with the maximal amount of pre-operative information. If a solitary ovarian lesion is noted, oophorectomy is generally performed. There has been debate on whether routine bilateral oophorectomy should be performed routinely in those undergoing surgery for colorectal cancer<sup>[8]</sup>. Some recommend discussing this option with the patient prior to surgery since reports suggest that ovarian metastasis occurs in 3%-14%<sup>[2-5]</sup>.

In conclusion, for patients who present with a pelvic mass, and are found to have a colorectal cancer, EUS may be performed preoperatively to detect adjacent perirectal masses such as ovarian metastatic lesions.

intestinal uptake of dietary and biliary cholesterol. It was approved by the FDA in 2002 for hypercholesterolemia alone or associated with statins. Since then, the use of ezetimibe has increased, especially in the United States<sup>[1]</sup>. Some guidelines suggest that ezetimibe may become the first choice for patients who do not tolerate statins<sup>[2]</sup>. Randomized clinical trials showed that ezetimibe caused significant liver function abnormalities in 1% of the treatment group. These changes were asymptomatic and entirely reversible. We report a case of serious hepatitis secondary to ezetimibe.

### CASE REPORT

A 56-year-old woman was admitted because of painless jaundice and pruritus. Her past medical history revealed essential hypertension, uterine myoma and a hiatal hernia. She never consumed more than 1 alcoholic drink per day. In the last three years, her medication was unchanged and consisted of bisoprolol 10 mg/d and omeprazol 20 mg/d. Because of persistent hypercholesterolemia, her family doctor prescribed ezetimibe 10 mg/d for 4 mo before admission. She was referred to our unit because of apparition of jaundice, a progressive scratching and liver test abnormalities.

At physical exam, there was intense jaundice and some scraping lesions. Her liver was not palpable and there were no further abnormalities. Laboratory investigation showed the following results: aspartate transaminase, 16.64 kat/L (normal, < 0.5 µkat/L); alanine transaminase, 26.26 µkat/L (normal, < 0.56 µkat/L); γ-glutamyl transferase, 1.15 µkat/L (normal, < 0.43 µkat/L); alkaline phosphatase, 1.9 µkat/L (normal, < 1.5 µkat/L); total bilirubin, 602 µmol/L (normal, < 18 µmol/L). Blood count, prothrombin time and kidney function test were normal. Viral serology tests were negative (hepatitis A, B, C, Epstein-Barr virus, Herpes virus, HIV and cytomegalovirus). Autoimmune serology (antinuclear, antimitochondrial, anti-liver-kidney microsomal and anti-smooth muscle) was all negative. At ultrasoundography, the liver showed no abnormality and biliary obstruction was disclosed.

Ezetimibe was stopped. Jaundice and pruritus improved slowly as well as laboratory results. Four weeks later a laboratory exam was completely normal.

### Abstract

Ezetimibe is the first member of a new family of lipid-lowering drugs that inhibits uptake of dietary and biliary cholesterol. It was approved by the FDA in 2002 for hypercholesterolemia alone or in combination with statins. Its use has been spreading over the last years. Ezetimibe was considered a safe drug. We report a case of a woman who developed a serious hepatocellular drug-induced liver disease after 4 mo therapy with 10 mg daily of ezetimibe. After withdrawal of the drug, the patient recovered slowly. Ezetimibe may produce serious toxic hepatitis and prompt withdrawal is mandatory in case of a significant abnormality in liver testing after beginning or during treatment with ezetimibe.

### INTRODUCTION

Ezetimibe is the first lipid-lowering drug that inhibits

### DISCUSSION

The temporal association, the improvement after

cessation of the drug and the exclusion of alternative possible causes permit us to diagnose ezetimibe-induced hepatotoxicity with confidence. Although rechallenge with the same drug could give us a definitive diagnosis, the clinical severity of the hepatitis made us exclude this possibility. Liver biopsy can suggest hepatotoxicity or exclude alternative diagnoses but it was not performed in this case.

Ezetimibe does not affect the cytochrome P450 system; it undergoes extensive glucuronidation in the wall of the small intestine and liver to form the active metabolite ezetimibe glucuronide. Ezetimibe does not induce or inhibit enzyme systems in the liver but undergoes enterohepatic circulation and is exposed to the liver and bile.

Statins rarely cause clinically significant liver injury, although asymptomatic elevations in aminotransferases are common. It has been suggested that this laboratory abnormality may result from muscle damage and not by hepatic injury<sup>[3]</sup>. Ezetimibe does not interfere with plasma levels of HMG-coA reductase inhibitors such as atorvastatin and simvastatin. Association of ezetimibe and statins does not lead to an apparent increase of hepatic side effects. Ezetimibe was expected to be even less hepatotoxic than statins and has been considered a safe drug. Nevertheless, it should be kept in mind that in a newly marketed drug, finding hepatotoxicity with an incidence of 1:10000 (the approximate incidence of most idiosyncratic reactions) would require 30 000 patients treated with this drug<sup>[4]</sup>.

The pattern of drug-related liver injury can be classified in hepatocellular, cholestatic or mixed according to laboratory data<sup>[5]</sup>. Until now, four cases of significant drug-induced liver injury associated with ezetimibe have been reported<sup>[6-8]</sup>, three of them associated with atorvastatin. One case was a cholestatic type, another one was hepatocellular and the last two were drug-induced acute autoimmune hepatitis. Our patient presented as serious hepatocellular hepatitis<sup>[9]</sup>. Patients with acute toxic hepatocellular damage are at high risk of acute liver failure. Mortality, or its surrogate marker, liver transplantation, is superior to 10%; this is known as "Hy's rule".

Although causes of ezetimibe toxicity are unclear,

apart from an idiosyncratic drug reaction, it could be hypothesized that a conjugation defect leads to accumulation of toxic levels of ezetimibe or their metabolites. As hepatotoxicity by ezetimibe has been reported in different types according to laboratory data, several mechanisms may be implied.

The current recommendation to monitor liver function after beginning therapy with statins is controversial with some experts calling for its re-examination. Ezetimibe, alone or associated to statins, may produce serious toxic hepatitis. Caution should be taken and the necessity of analytical follow-up after beginning or during the treatment with ezetimibe is unknown. A prompt withdrawal of the drug is mandatory in case of a significant abnormality in liver tests.

## ACKNOWLEDGMENTS

# Acknowledgments to Reviewers of *World Journal of Gastroenterology*

Many reviewers have contributed their expertise and time to the peer review, a critical process to ensure the quality of *World Journal of Gastroenterology*. The editors and authors of the articles submitted to the journal are grateful to the following reviewers for evaluating the articles (including those published in this issue and those rejected for this issue) during the last editing time period.

### Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London, The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (*World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly open access peer-reviewed journal supported by an editorial board consisting of 1208 experts in gastroenterology and hepatology from 60 countries. The aim of the journal is to deliver the most clinically relevant original and commentary articles to readers, and to make the full text publicly available to all clinicians, scientists, patients and biomedical students on an unrestricted platform, so that they can access and learn about the most recent key advances in the field.

In addition to the open access nature, another key characteristic of *WJG* is its reading guidance for each article which includes background, research frontier, related reports, breakthroughs, applications, terminology, and comments of peer reviewers for the general readers.

*WJG* publishes articles on esophageal, gastrointestinal, hepatobiliary and pancreatic tumors, and other esophageal, gastrointestinal, hepatic-biliary and pancreatic diseases in relation to epidemiology, immunology, microbiology, motility & nerve-gut interaction, endocrinology, nutrition & obesity, endoscopy, imaging and advanced hi-technology.

The main goal of *WJG* is to publish high quality commentary articles contributed by leading experts in gastroenterology and hepatology and original articles that combine the clinical practice and advanced basic research, to provide an interactive platform for clinicians and researchers in internal medicine, surgery, infectious diseases, traditional Chinese medicine, oncology, integrated Chinese and Western medicine, imaging, endoscopy, interventional therapy, pathology and other basic medical specialties, and thus eventually improving the clinical practice and healthcare for patients.

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

#### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://wjg.wjnet.com/wjg>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjnet.com/wjg/help/instructions.jsp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [submission@wjnet.com](mailto:submission@wjnet.com), or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was carried out; author contributions; disclosure of any financial support for the research; and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (remove all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s), and full family name.

**Author contributions:** The format of this section should be like this: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed research; Wang CL, Zou CC, Hong F and Wu XM performed research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed data; and Wang CL, Liang L and Fu JF wrote the paper.

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

#### Abstract

An informative, structured abstract of no more than 350 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipment, and the experimental procedures should be included. RESULTS: The observed and experimental results, including data, effects, outcome, etc. should be included. Authors should present *P* value where necessary, and also include any significant data. CONCLUSION: Accurate view and the value of the results should be included.

The format for structured abstracts can be found at: <http://www.wjnet.com/wjg/help/11.doc>.

#### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

#### Text

For articles of these sections, original articles, rapid communication

and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, should be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

### Illustrations

Figures should be numbered as 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...etc. It is our principle to publish high resolution-figures for the printed and E-versions.

### Tables

Three-line tables should be numbered 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P* < 0.05 and <sup>d</sup>*P* < 0.01 are used. A third series of *P* values can be expressed as <sup>e</sup>*P* < 0.05 and <sup>f</sup>*P* < 0.01. Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, □, ▲, △, etc., in a certain sequence.

### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

### PMID requirement

PMID roots in the abstract serial number indexed by PubMed (<http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed>). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information for journal citations is very important. Using the reference testing system, the authors and editor should check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in an ASP file so that the readers can immediately access the abstract of the citations online.

### DOI requirement

A CrossRef DOI® (Digital Object Identifier) name is a unique string created to identify a piece of scholarly content in the online environment. The author should supply the DOIs for journal citation(doi:10.3748/wjg.13.6458). This link (<http://www.crossref.org/SimpleTextQuery/>) allows you to retrieve Digital Object Identifiers (DOIs) for journal articles, books, and chapters by simply cutting and pasting the reference list into the box. You may use the form with any reference style, although the tool works most reliably if references are formatted in a standard style such as shown in this example: Assimakopoulos SF, Scopa CD, Vagianos CE. Pathophysiology of increased intestinal permeability in obstructive jaundice. *World J Gastroenterol* 2007; 13(48): 6458-6464

The accuracy of the information of journal citations is very important. We will interlink all references with DOI in ASP file so that readers can access the abstracts of cited articles online immediately.

### Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

### Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

*Patent (list all authors)*

- 16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

## Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those linked with a hyphen when the difference between the two numbers is greater than five. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered inappropriate references. Authors should not cite their own unrelated published articles.

## Statistical data

Write as mean  $\pm$  SD or mean  $\pm$  SE.

## Statistical expression

Express  $t$  test as  $t$  (in italics),  $F$  test as  $F$  (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as  $r$  (in italics), degree of freedom as  $v$  (in Greek), sample number as  $n$  (in italics), and probability as  $P$  (in italics).

## Units

Use SI units. For example: body mass,  $m$  (B) = 78 kg; blood pressure,  $p$  (B) = 16.2/12.3 kPa; incubation time,  $t$  (incubation) = 96 h, blood glucose concentration,  $c$  (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA mass concentration,  $p$  (CEA) = 8.6 24.5  $\mu$ g/L;  $CO_2$  volume fraction, 50 mL/L  $CO_2$ , not 5%  $CO_2$ ; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: <http://www.wjgnet.com/wjg/help/15.doc>.

## Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of

Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

## Italics

Quantities:  $t$  time or temperature,  $c$  concentration,  $A$  area,  $l$  length,  $m$  mass,  $V$  volume.

Genotypes:  $gyrA$ ,  $arg\ 1$ ,  $c\ myc$ ,  $c\ fos$ , etc.

Restriction enzymes:  $EcoRI$ ,  $HindII$ ,  $BamHI$ ,  $KhoI$ ,  $KpnI$ , etc.

Biology:  $H\ pylori$ ,  $E\ coli$ , etc.

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

## Editorial Office

### World Journal of Gastroenterology

Editorial Department: Room 903  
Ocean International Center, Building D  
No. 62 Dongsihuan Zhonglu  
Chaoyang District, Beijing 100025, China  
E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)  
<http://www.wjgnet.com>  
Telephone: +86-10-59080039  
Fax: +86-10-85381893

## Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

## Copyright assignment form

Please download a Copyright assignment form from <http://www.wjgnet.com/wjg/help/9.doc>.

## Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/wjg/help/10.doc>.

## Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

## Links to documents related to the manuscript

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

## Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

## Publication fee

Authors of accepted articles must pay a publication fee. EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.
